Data were collected over five days as visitors interacted with the simulation. Data sources include audio recordings and screencasts of each participant's screen, and observational notes made by a researcher in the back of the room. For this study, we narrowed down the data to recordings and screencasts of 6 groups' experiences. These groups were selected because they engaged with the simulation for at least 9 minutes, included at least three participants, talked with each other consistently throughout, and represented a diversity of age distributions. Audio recordings for each group were transcribed in entirety. Screenshots of key moments were included in transcripts.

Data analysis

All transcripts for the selected 6 groups were reviewed and analyzed for knowledge resources, social resources, and ideological resources drawn on by learners at different moments. This process was guided by principles of microgenetic learning analysis (Parnafes & diSessa, 2013), as well as prior work using similar theoretical lenses (e.g. Philip, 2011). Analysis specifically focused on moments of visible decision-making, evidenced through verbalizations about uncertainties of what to do next within the simulation. We chose to focus analysis on such moments, as decisions represented times in which learners were likely to draw on a variety of cognitive, social, and ideological resources (Aikenhead, 1985); analysis of these moments could shape learning theory related to SSIs and decisions around them. Additionally, understanding resources drawn on in decisions could possibly provide insight into socio-scientific decisions with which people are confronted in their lives.

We bounded moments of decisions in transcripts by identifying discourse markers that indicated the initial surfacing of uncertainty or the need to decide a specific action, as well as discourse markers that indicated the decision had been made. If conversation ever returned to that specific decision, for example several minutes later as participants reviewed the actions taken during the round, such conversation was included in analysis. Guided by extant research in KA and IA (e.g. Brown et al., 2016; Hall & Stevens, 2016; Parnafes & diSessa, 2013; Philip, 2011), we analyzed moment-to-moment processes within these instances of decisions, identifying knowledge, social, and ideological resources made salient.

Findings

RQ1: What knowledge, social, and ideological resources do learners draw on?

Across groups, participants drew on a variety of knowledge, social, and ideological resources, and that often these resources were intermixed in moment-to-moment processes. However, each group also tended to exhibit their own patterns and reliance on certain sets of resources. We will now describe key themes that came from analysis, although given the brevity of this proposal, this is not a comprehensive summary.

Knowledge resources related to mechanism relationships among energy, climate, and ecosystems

Participants across all 6 groups drew on resources related to mechanistic knowledge of relations among fossil fuel combustion, climate, the built environment, and local ecosystems. In some groups, these knowledge resources of mechanisms, or cause-and-effect relationships, were drawn on frequently within decision-making. Typically, these knowledge resources emerged in moments of decision about whether to build a particular energy source, such as a coal-fired power plant or solar panels. For example, after one round of a game in which the group did

not meet their energy goals, a participant said "We need more energy and more food." In response, a few turns later, another participant posed the question to the group "Should I do a coal power plant?". In response, group members shouted "No!", with one calling such a move "bad for the climate." Even without a full mechanistic explanation, such moments indicate participants drawing on various pieces of a knowledge system in which coal-fired energy contributes to climate change, likely through exacerbation of the Earth's natural greenhouse effect.

Social positioning resources and moment-to-moment identity work

Social resources emerging through interaction were often drawn on in decision-making. Typically, these resources relied on social positioning among group members with certain identities—identities that were both relevant to the simulation and those that were more global. Often, identities local to the simulation were identities related to leadership. In many groups, particularly in family groups with young siblings, one participant would position themselves as leader, as indicated by discourse in which that person directed others what to do, or attempted to shape the group's direction by using the first-person plural to phrase directives (e.g. "we should…"). Moments in which the group's progress toward energy, food, fun, and climate goals tended to make salient this position.

Another local identity that emerged through interaction in two groups was an identity of subversion. Such positioning often started early in the game, with a participant audibly positioning themselves as counter to the aims of the whole group. Typically, over the course of the game, they would act in accordance with such an identity, often choosing moves that increased climate change or interfered with others' goals. When others noticed this interference, they would typically respond with anger and further social positioning of the subversive actor into such an identity. An example comes with a family group that played for approximately 40 minutes. The family included 5 children and 2 adults, with the adults supporting from behind and occasionally rotating into play. Within the first minute of starting the game, the following scene unfolded (Transcript 1):

Transcript 1

Line	Speaker	Speech
1	Matt	Okay, we're supposed to all work together for good...good climate.
2		No more climate change!
3	Dad	Okay
4	Eli	Rounds left to make your choices now.
5	Matt	I know where the...
6	Anna	I want to make the coal power plant.
7	Matt	No we go to the garbage
8		Am I the only one that is trying to save the environment?!
9	Bryce	No I am
10	Matt	Are you trying to destroy it? Anna's destroying the environment!
11		Wait don't have a coal power plant. Wait smog vacuum.
12		I'm getting a smog vacuum.

Immediately here, Matt, who positioned himself as a leader throughout the game, verbalized the group's aims, with "we're supposed to all work together for good…good climate" (Line 1). While Eli and Dad responded in relatively neutral ways to Matt's orienting of the group towards reducing climate change, Anna declared that she wanted to build a coal plant (Line 6). Throughout the 40-minute dataset, there is much evidence that Anna understood very well the mechanistic relationship between coal combustion and climate change. And here, she seems to be drawing on this knowledge resource to counter Matt's declared aims for the group and, thereby, position herself as subversive. This attempt at subversion is evidenced further throughout the transcript—she cheered at the end of a round when climate change went up, shouting "Yay climate change!". At one point, she stealthily tapped Bryce's screen while he was not looking to choose to build a coal plant on his behalf. Furthermore, the others took up this positioning of Anna and reinforced it through their social positioning of her as subversive. In the first few moments of the game, in response to Anna's move to build a coal plant, Matt said "Am I the only one that is trying to save the environment?!" and two lines later "Anna's destroying the environment!" (Lines 8, 10). This social positioning of Anna parallels her own positioning of herself throughout the game as a counter-operative. For example, when Anna selected a natural gas plant about 20 minutes into the game, Bryce shouted "Anna, no! Don't place a gas power plant!". This was followed by Matt saying "Anna is literally trying to sabotage it", and Bella following up with "Anna is trying to be the bad guy". This identity of Anna as subversive was made salient at decision-making time, particularly when it was known to the group that Anna had the option to select a carbon intensive energy source, such as coal or natural gas.

Ideological resources

All groups showed evidence of use ideological resources to make decisions. For some groups, ideological resources tended to emerge and be drawn on within decision-making more frequently than knowledge resources, while in others they were less common. In some cases, these resources emerged through assumptions about what was "good for the environment" and what was "bad for the environment", thereby framing many decisions as a binary choice, easily made by consulting with the group. In other cases, participants made material ideological resources that bore assumptions about relationships between people and land. For instance, in one group, a participant repeatedly expressed a "need" to build something in an undeveloped piece of land because "there [was] literally nothing there". This comment made material ideology about hierarchies of humans in the natural world, expressing an assumption that the natural world exists to be developed by people. Similar tacit understandings about relationships among humans, landscapes, and animals were expressed by many participants across groups.

RQ2: What patterns exist among resources drawn on?

Often resources were intermixed in moment-to-moment processes of sensemaking. Some patterns of this intermixing were identifiable across all groups, while some were unique to specific groups.

Pattern #1: Social positions intersected with ideological resources

One identified pattern was the intersection of social positions with ideological resources. For example, in Transcript 1, Matt said "Am I the only one that is trying to save the environment?!" In doing this, he positions himself with an identity as defender of the environment while also drawing on ideological resources about the environment—namely, that it both is something distinct from the human world and that it needs and/or merits saving by people (Line 1). Similarly, the social positioning of Anna intersected and overlapped with the emergence of ideological resources. She positioned herself and was positioned as subversive. To do this positioning, she and the others drew on ideological resources about what was "good" and "bad" for the environment, often opting to do whatever was deemed "bad" to further her position as subversive.

Pattern #2: Ideological resources intersected with mechanistic knowledge resources

Another pattern was the intersection of ideological resources with mechanistic knowledge resources. Often, participants made comments that both reflected an implicit understanding of causal relationships, for example between fossil fuel combustion and climate change, and made material various ideological resources. One example comes with the group described above, evidenced in a short exchange (Transcript 2):

Transcript 2

Line	Speaker	Speech
1	Matt	—Oh, I'm going to do a natural gas plant!
2		Is that good?
3	Bella	Uh no. You could tap on the [inaudible].
4		State park.
5		Do state park.
6	Matt	I'm going to put my state park here in the very corner because there's not that many animals.
7	Bella	That. It's—there. Okay, put it down there.
8		Okay, nice.
9	Matt	We are the climate warriors.
10	Anna	I hate climate.

Here, after Matt declared that he was going to build a natural gas plant (Line 1), he conferred with the group about the move, asking "Is that good?" (Line 2). In asking this question, Matt brought tacit assumptions about the meaning of "good" and "bad" to categorize different energy sources, presumably a categorization that relies on carbon impact to the atmosphere of the given energy source—a knowledge resource part of a larger knowledge system about causal relationships related to climate change. Bella then replied with "no," meaning that a natural gas plant is not good and instead suggested building a state park, which, by the group's tacit definition is "good", in that it does not directly contribute to increasing atmospheric CO_2. Yet, in making this comment, Bella also made material ideology about the relationship among people and land, possibly an assumption that land is to be used by people, even via measures traditional viewed as conservation, such as a state park.

Also evident within this interaction are other resources. Matt declared that he would build his state park in an area where "there's not that many animals" (Line 6), evidencing a knowledge resource regarding the

mechanistic relationship between building a feature and the consequent decline of animal species. He then made material ideological resources by saying "We are the climate warriors" (Line 9), surfacing implicit ideological assumptions about the relationship between people and climate change—that is, that climate change is something that needs to be fought or battled—an assumption that positions humans in a combative role but that also elides human responsibility in climate change. And again, positioning herself as the contrarian of the group, Anna said that she "hate[s] climate", likely indicating here that she hates the idea of doing things on behalf of climate change and/or that she wants to pursue *further* climate change in her local identity as destroyer of the environment.

Discussion & conclusion

While previous work has examined learning outcomes of SSI instruction, little has investigated moment-to-moment learning processes around SSIs. This paper advances the field by integrating multiple theoretical approaches to generate initial ideas about the learning processes unfolding around engagement with an SSI in a digital climate simulation in an informal science center.

First, and perhaps obviously, this study shows that knowledge resources were drawn on by learners. Specifically, we point to the many knowledge resources regarding scientific mechanistic knowledge about climate change drawn on by learners over the course of engagement with the scenario. In particular, specific contexts of the simulation appeared to make salient these resources. Often those contexts were moments of decision-making, and often when that decision-making was encountered socially, as a group. Given that prior work has demonstrated the significance of mechanistic knowledge in navigating climate change in scientifically accurate ways (Author et al., 2021; Stevenson et al., 2014), we see this finding as an important one to highlight, as it speaks to the promise of leveraging digital simulations for climate science learning. Yet, at the same time, this study also demonstrates the multitude of ways in which scientific knowledge resources intersected with both social positioning resources and ideological resources to influence the learning process in, at times, surprising ways.

Of the complexity of knowledge and interactional resources involved in SSI learning, we suggest that the intersection of social and ideological resources could be particularly influential, as in this study we observed how moment-to-moment identity work done by participants contributed to the association of various social and ideological resources for particular participants, such as Anna, with her subversive, counter-operative efforts to "destroy the environment". With this finding in mind, we use this study as a call for further research examining moment-to-moment identity processes and integrating multiple theoretical approaches to study the learning process around characteristically modern SSIs.

International Society of the Learning Sciences

Shifting from "broadening" to "empowering": One community's perspective on changing the learning sciences

Jeremy Roschelle, Digital Promise, jroschelle@digitalpromise.org
Wendy Martin, Education Development Center, wmartin@edc.org

Abstract: The ISLS theme addresses "global perspectives on equity and justice that promote the empowerment of educational innovation for all." We report on a large virtual convening (n=310), where learning scientists, computer scientists, and educators in one country considered how research should change to address equity and justice. We report on the output of working group strategy sessions and a culminating discussion that elicited "bold steps" for change. Our analysis of bold steps submitted by eleven teams led to re-grouping by the actors involved: (1) researchers, (2) partnerships, (3) technology design, and (4) community values should each change. For each group, we report key themes. We note limitations and broader implications (e.g., what a shift to language about "empowering" implies). Conducting similar meetings in other regions and reporting complementary outcomes could be powerful.

Introduction

The 2022 ISLS conference theme focuses on a wave of change in the learning sciences that is bigger than any one research project, theory, design, or finding: our society seeks to spur transformation of our work to value diversity and drive toward equity and justice. What does this transformation entail? In an unsatisfactory view, it could mean highlighting aspects of what we already do that relate to equity and justice, without much change in how learning scientists are prepared, how they form research teams, how their values translate into action, or in their design focus. Or it could mean that every individual researcher and team must figure out what the desired transformation means in their own unique work—with a community or society role only in providing a forum to report insights and findings. We find transformation only as individuals or in isolation to be untenably hard and ultimately insufficient. Our work is situated within larger systems that reinforce specific ways of doing things. For real change to occur, change also must occur at the system level (as well as at more local levels).

Through our role in a research hub that hosts a national convening of researchers who do learning sciences and innovation work, we sought to organize a two-day virtual convening that would elicit a community-wide prioritization of how our work should change. While our convening was necessarily localized to our context, we hope to make two contributions by reporting on its process and outcomes: (1) to share a virtual community-wide process that others could enact in their regional communities and (2) to share tangible recommendations for change that may contribute to discussion about a society-wide course of action.

Background

In the United States, as in many other countries and regions, government funders of learning sciences research make awards that create a portfolio of related projects. Later, they often host convenings across the portfolio of projects to bring together the teams and to cross-fertilize findings. At convenings, teams discuss their work, identify synergies, and discuss next steps. The authors have been leaders in a nonprofit collective that organizes and hosts such convenings on behalf of the government funders; we have run convenings for one particular portfolio of learning sciences research for about a decade. The portfolio focuses on the "future of learning" and requires computer scientists and learning scientists to collaborate in exploratory research. Over the decade, we observed a shift in the focus of the research community that attends these convenings. The focus of conversation shifted from mostly technical discussions of research about future learning environments to a broad interest in equity and then to a sense of a "call to action"—that we should more directly focus research to address equity (Roschelle et al., 2017). In preparing for our 2021 convening, we organized a program committee of stakeholders in our regional research community and asked them what the central theme of the convening should be. They strongly recommended a thematic focus on the *how* and not just the *why* of promoting equity and justice in our research. We developed a program for the convening to emphasize this theme and to produce collective recommendations for *how* we should change. Approximately 350 individuals registered for our convening and 310 attended. The convening was held virtually for eight hours spread across two days. We report further details on how we organized the program and collected outcomes and other data next.

Before continuing, we acknowledge other important forums where similar ideas are being discussed. Our society now has an Equity and Justice Committee, for instance. Our publications include seminal equity-focused papers (e.g., Gutierrez & Jurow, 2016; Jurow & Shea, 2015; Muller, 2004). Other regions of the world have their

 © ISLS

own forums to organize researchers around equity and justice. We are aware that we offer just one perspective, grounded in a particular set of circumstances, and that we report on just one relatively short event. By sharing what we learned, we hope to learn about and combine with complementary and contrasting perspectives from other places.

We also acknowledge upfront that our process did not converge on one outcome, nor did we converge on one definition of equity. We have observed different foci for equity in our research community, including students with disabilities, students in poverty, students in rural areas, and—of great importance in the United States—students who have experienced racism. We believe it takes more than a single virtual convening to get an agreement on a definition of equity among such a large group of projects, each of which tackles different aspects of the challenge. We chose not to try to wordsmith definitions during our convening, but to focus on prioritization of bold steps and other recommendations our program committee believed we could accomplish in the time available. (A further limitation of which we are acutely aware is that there is scholarly precedent for almost every point raised during our convening, but we could not possibly systematically cite all the relevant prior work and stay within the 8-page limit).

Methods

The convening that we describe in this paper had the theme of exploring how a research community can have a broader impact by reassessing fundamental aspects of its work. With an internal hosting team and an external program committee, we designed a program that had a storyline: we would get to know each other as a community (leaders from different projects often do not have strong relationships), work together to educate ourselves about the theme, and then develop prioritized bold steps for how we could change our work. Overall, our community process follows the method of "forming, norming, storming, and performing." (Tuckman, 1965) Due to the nature of the event as serving a national funding agency, we also allocated time for necessary announcements and informational updates about new funding opportunities and for roundtable sessions and poster sessions where participants could give updates on their work. To launch the theme, we invited two keynote speakers who addressed issues of equity and power in computer science, artificial intelligence (AI), and educational technology. Nicki Washington (2020) discussed how the culture of computing often marginalizes Black and Latinx students, and how we need to explicitly help students in computer science programs create a sense of identity and belonging in that community. In Figure 1, we show a graphic illustration that was created "live" as the first keynote speaker spoke. In keynote 2. Craig Watkins (2018, 2019) discussed his work with Black and Latino students and young professions in STEM and technology, and the nature of specific opportunities and supports that enable their growth and success. These keynotes offered sharp contrasts between meaningfully addressing equity and just evoking it at a surface level, giving participants food for thought. We engaged with a graphic illustrator throughout the meeting to capture and share what was being said and to spur further deliberation and reflection.

Figure 1. Graphic illustration of Nicki Washington's keynote address

In other sessions, such as "expertise connection" sessions and talks on specific research projects, we asked presenters to orient their presentations around the idea of rethinking how we include, reach, and support diverse communities in our work. Near the end of the convening, we asked participants to work in small groups to draw on what they learned and heard over the course of the convening to come up with strategies for thinking about new ways for our work to have a broad impact. The small groups focused on different aspects of our community's research and development work. Some examples of groups included:

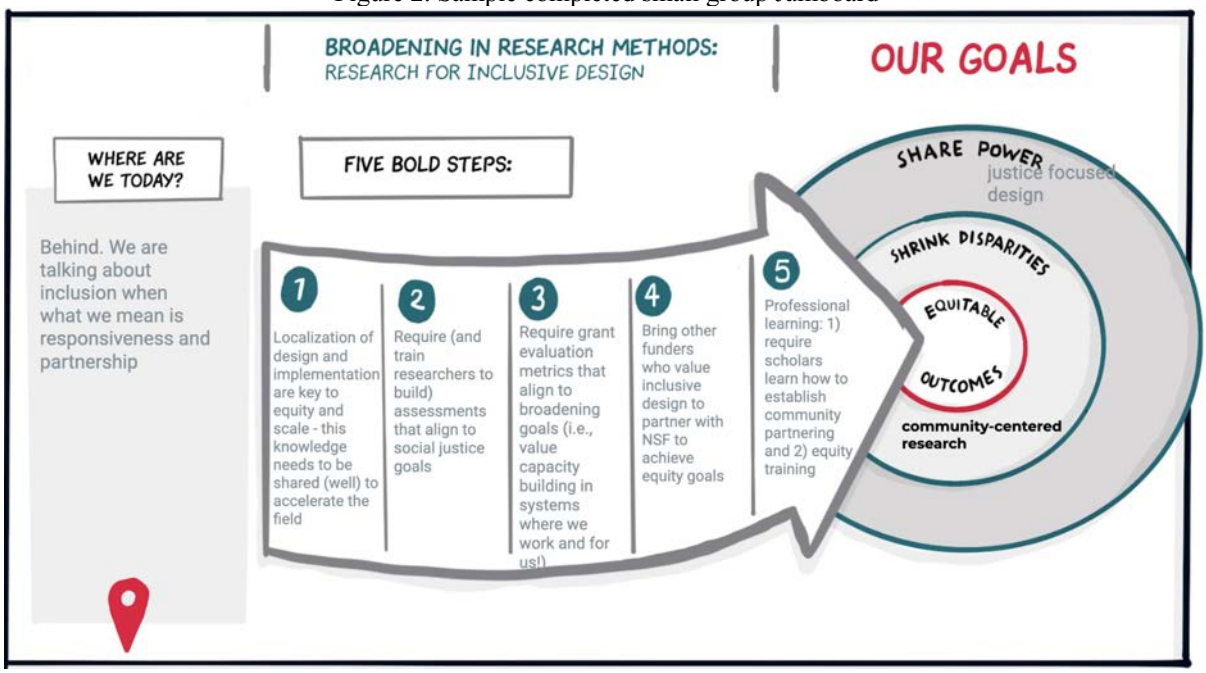
- Research for inclusive design
- New human-technology interactions
- Learning analytics
- AI in education policy
- Communication and dissemination

The groups were asked to discuss where the community is *now* in terms of having a broad impact in relation to their topic and what our *goals* are, and then come up with five *strategies* for getting the community to where we want to be. They made their recommendations on Jamboards. Then we had a "town hall" session to report out with the graphic illustrator. As groups each reported a first idea from their group in a round-robin format, the illustrator captured the emerging recommendations of the collective. A panel commented on these ideas and asked follow-up questions. The effect was of a voice-only panel whose ideas were appearing in an illustration in real time, which was captivating to watch and participate in. Over time, the conversation was opened to everyone present, and they were invited to add ideas via chat.

Data collection

Ideas from the small groups were documented in two ways. Initial brainstorming was recorded on post-it notes on a Jamboard under the headings "Where are we now?" "Bold steps" and "Goals." The groups then had to prioritize and consolidate their ideas so that they could be put into a second Jamboard that had a graphic illustration as its background. (See Figure 2.)

Figure 2. Sample completed small group Jamboard



In addition, we also conducted an evaluation survey that was distributed via email after the convening to get feedback on the event as a whole as well as on the different sessions.

 © ISLS

Data analysis

Members of the convening organization team analyzed the data from both Jamboards from all eleven of the small groups. The analysis used a grounded theory approach (Strauss & Corbin, 1990), in which we read through all of the post-it notes on the brainstorming boards as well as the finalized ideas presented by the groups on the graphic boards and identified key themes that emerged from the data. A draft of these themes was created in which the community's ideas were categorized according to the various ways the work of the community could change for broader and more meaningful impact to be realized. The categories that arose were:

- Changing how researchers are prepared
- Improving community partnerships: valuing assets and knowledge
- Changing our technology design focus
- Rethinking broader impacts across the research community

These categories, along with the supporting descriptive data, were shared with the entire research team, who then reviewed the Jamboards and contributed clarifications and refined the analysis. Evaluation surveys were analyzed using descriptive statistics. There was a response rate of 25% for the survey (79 respondents out of a population of 310).

Findings

The analysis of the evaluation survey showed that 85% of the respondents agreed that they gained a new perspective on how to reassess what we mean by "broadening impact" from the meeting. The analysis of the Jamboard data revealed that our research community had many ideas for strategies to change the way we think about research and development. They recognized that we need to reflect on our practices and norms at multiple levels if we are going to transform how we conceive of broadening impact in our work.

How researchers are prepared

Community members across most of the groups pointed out that we need to examine how we ourselves are prepared to conduct research and how we prepare the next generation of researchers. We are the first agents of change in this larger process of transforming the community's values and practices. Small group participants acknowledged that they were under-prepared for the work that comes into view once we center equity and "remaking broadening." Our analysis identified a set of key ideas about what researchers in this field wanted to change (see Figure 3).

Selecting research opportunities in Pasteur's Quadrant

The community is concerned that researchers may be inclined to select research problems or opportunities that value theoretical or technological novelty over the potential to make a difference in the real world. Consequently, our exploratory research may learn a lot about technologies that have no realistic chance of making large-scale contributions to an equitable society. A revised definition of "innovative" would consider the possibility for highly valuable change in a large community of practice. Likewise, training may overemphasize collecting one's own data over leveraging larger scale data sets that already exist. To define problems for investigation that are "fundamental" in one's discipline yet "powerful" in a community requires researchers to ask what the community's most pressing questions are. This is not currently a typical starting place.

Frameworks for setting goals, assessing learning, evaluating approaches

The community does not want to focus on technology itself nor only on contributions to research journals that follow well-trodden paths. Calls to action use a variety of terms that include justice-centered, human-centered, responsible AI, fairness+accountability+transparency+equity (FATE), inclusive innovation, and value-sensitive design. Researchers need to grow in their ability to understand how to go from the broad call of action to the design of a specific exploratory research project, which includes not only the vision for the project but also how student or teacher learning would be assessed within it, and how the promise of the focal technology design can be evaluated. Although frameworks exist, learning how to engage these frameworks while doing specific research is more aspirational than everyday practice. As one community member wrote, we need to "identify new learner outcomes of interest (which include equity) and instruments that measure these outcomes."

Multidisciplinary refinement of key equity concepts

Participants recognized that within computer science and AI, concepts like bias, fairness, and transparency are still in their early stages. Although the scholarly discourse in education and in learning sciences on these topics may be somewhat longer standing, there is still a lot of room for growth in how learning scientists are trained to work with similar concepts like bias, cultural responsiveness, and including student voice—especially as these concepts are invoked while exploring new designs for learning technologies. A multidisciplinary approach to tackling any of these problems is still very novel and almost everyone in the field must learn to do it well.

Preparing to be a good partner

The community recognizes that partnering with others is challenging and many researchers are under-prepared. This includes the challenge for computer scientists of partnering with learning scientists (and vice versa) as well as challenges of partnering with communities that would use or be affected by new technologies. Foci for learning for researchers before they engage in partnerships could include communication practices, listening practices, understanding and mitigating power differences, and practices that develop empathy and cultural competence. Our community is responsible for developing the next generation of scholars and has the responsibility to make sure that the ethic of inclusion of diverse stakeholders in research and collaboration with peers and practitioners is clearly communicated and expected in dissertation research, valued in job applications, and used in early career evaluations. More discussion on partnerships will come up in the next section.

Figure 3: This illustration (one of several) highlights proposed changes in how researchers are prepared.

Improving community partnerships: Valuing assets and knowledge

In a shift to the social activism model (empowering) from the technology transfer model (broadening), there was a strong call across most strategy sessions about involving communities of teachers and learners early in the research process, listening to them, and yielding more power to their voices while making decisions about what technology designs merit exploratory research and which questions about the novel technologies deserve priority. Researchers' view of who to partner with was very broad—students, teachers, parents, policymakers, school leaders, community center leaders, museum staff, and other stakeholders might all be important partners.

Committing to early, mutual, lasting partnerships

Community members observed that we need to form mutually beneficial, long-term partnerships to ensure our work has a meaningful impact. Getting feedback from teachers on instructional materials or research instruments is not a partnership. That is asking participants to provide a service to the researcher with little to no benefit for the participant. A research partnership requires that the researcher start by learning about and understanding the needs and interests of the partner organization or participants and commit to exploring those together.

Listening to transform

Researchers at the meeting reflected on their own experiences where listening to student voices, working closely with teachers, or connecting with leaders and policymakers completely changed their view of the problem they were trying to solve. They realize they may extrapolate from their own experiences of teaching and learning in ways that do not fit what today's teachers and learners want—and this may block progress towards broad equity goals. Conversely, they reported excitement and challenges resulting from deeply listening to partners for ideas that could transform their intended exploratory research.

Value what communities are already doing

Some of the most important work in building capacity for local communities to achieve self-identified goals is already happening by stakeholders in those communities. The community may have the greatest impact by putting our skills in the service of those stakeholders. Our community can benefit as much from learning about what these communities are doing as we can from disseminating information about our own work.

Valuing capacity building

Researchers in this space recognize that when they work with partners, they have to focus on giving something valuable to the community they work with. Because their exploratory prototypes may not be ready for prime-time even at the end of their project, the work they do to build capacity in communities of practice to solve problems that the community cares about has to count as a valued outcome of doing partnership work. One outcome of valuing capacity building could be the emergence of regional hubs or networks that work over long periods of time with researchers on issues related to emerging technology. Another outcome can be to help partners lead dissemination efforts and outreach to policymakers.

Changing our technology design focus

This research community called for centering the voice of partners in choosing the focus of a research-based technology design project, as discussed above. This is fundamental and is elaborated across points below.

Insisting on accessibility

Accessibility guidelines are well established but too many exploratory research projects do not address them. Accessibility needs to be addressed from a project's conception and viewed as a necessary component rather than an optional "nice-to-have."

Realistic usability and multilevel explorations

Researchers worry that too much of exploratory research is devoted to expensive or "clunky" gear. Obviously, there is a tension here, because technologies that will be commonplace in ten years may be expensive now. The community sees value in a pattern of exploratory research that might look at an overall concept in several different renderings—some which have less fidelity to the vision yet are more usable today and others which have greater fidelity but are more cumbersome or expensive. Although the expensive version may have more fidelity in one way, what we learn about the concept may be broader if stakeholders can use it more easily and often. So, there could be a benefit to exploring the same concept at different "entry points."

Exploring with platforms and infrastructure

There is a limit in how far we can get when each project tries to design its own complete experience. Community members suggested focusing more attention on how innovative explorations could occur within platforms or with infrastructures that are broadly supported in the world.

Rethinking broader impacts at the research community level

The attendees were also cognizant that the research community is structured in fairly set ways, and that they need to consider how community-level roles and processes must be addressed as we "remake broadening." This can include what we value in peer review of proposals, what we consider publishable in journals or presentable at conferences, what we see as the community's outputs or products and how we structure research projects.

From "moonshots" to focused substantial advances in practice

A challenge for researchers in our community is that exploratory research projects often last for only a few years and are funded at relatively low levels, making broad impact difficult. Progress can be made not by sweeping this challenge under the rug but by greater clarity about the kind of impact an exploratory project can have. Taking a

risk to make a substantive or radical change in practice for one school/group/organization rather than reaching a large number of people might be a more appropriate outcome for an exploratory project. Designing processes so that students, teachers, and other stakeholders can contribute to deliberations about the future of learning with technology can count as a meaningful impact. Finding ways to elaborate a concept like "bias" so that computer science, learning sciences, and educator views are all respected can be seen as a broad impact. Creating tools and methods so that partners can look at the transparency of an algorithm could count. Depth of transformation can be changes in the researchers' own practices. Having the community commit to reviewing proposals and their peers' work with this definition of impact in mind would itself lead to transformation in the field.

Values around ethics and risks

Norms and values typically are developed by communities and reside at a community level. Our research community recognizes that "high-risk" research should be valued as we explore technologies that are ten years out, but we also need to be mindful that those who might be harmed must be consulted before we can determine what an appropriate risk is. Similarly, the use of big data or AI in learning technology projects carries risks to privacy, security, and more. When technologies are tested in partnerships that use them with teachers and learners, there are ethical considerations. Our community should insist that, from the onset of a project, researchers must involve local stakeholders in discussions around risks.

Sharing tools and processes for co-design, co-analysis, and partnership

Some members in our community have been engaging in co-design and collaborative analysis of data with local partners for a long time and have learned many lessons about how to do it effectively. The tools and procedures for doing this kind of work should be shared within our community and with our partners so that they can be used more broadly and improved through regular, iterative use. The same emphasis that the research community has given to assessments and data collection instruments should be given to protocols to support effective co-design, co-analysis, and productive partnerships.

Reconceptualizing dissemination

This community repeatedly expressed the need to disseminate research findings to communities of practitioners, local stakeholders, and policymakers rather than the typical academic communities that are primarily valued by funders and tenure review boards. With limited resources in terms of funding and time, expecting researchers to do this kind of outreach in addition to what is already expected is unrealistic. Our community needs to be part of the effort to change incentives around what is shared, how, and where. Members of our community are not only researchers, we are also the people who review proposals and articles, hire new faculty, serve on tenure review boards, and create dissemination plans. It is this community's responsibility to place a higher value on reaching practitioners, local stakeholders, and policymakers than traditional academic audiences. We also need to encourage our partners to engage in dissemination and ensure that the materials that we produce are available to teachers, learners, and communities long after research is completed.

Implications

The analysis of our research community's discussions illuminated the specific directions we want to take. Regardless of whether the small groups were talking about AI, inclusive design, or communication and dissemination, larger themes bubbled up, in part no doubt because of the community's values but also possibly because of the calls to action made during two provocative keynote addresses. A willingness to look at our community critically was a strength of the small group conversations. There was a clear interest in generating practical ideas for moving forward and getting to work. Many of the specific strategies are elaborated above. We intend to plan further activity to move these strategies into action.

From broadening impact to redistributing power

Given that the convening was designed to reassess what we mean by "broad impact," it is perhaps fitting that our final sessions led us to realize that maybe having a broad impact should not be the goal at all, but rather we should be striving to empower others to make their own impact. Time and again community members stated that we need to value capacity building as a key outcome of our research. Even more important, we need to step back and honor the capacity that already exists in the communities we work with and see our role as collaboratively designing the research strategy that will support that community's efforts to achieve the goals they already have. Coming up with an innovative application of emerging technologies to address a problem that we ourselves identify and then sharing that innovation with other academic researchers has up to now been how we conceive our work. The

contributions of our community members indicate that we need to rethink many of these assumptions about who identifies the problem, how we design the innovation, and what kind of sharing is most meaningful and effective.

Aligning exploratory research to the scale and context of disparities

The systemic problems in education and the larger society that the convening keynote speakers and our community member discussions surfaced are not going to be solved by any one research project or even our collective projects. However, the kind of exploratory research that our community engages in has the potential to take bold steps that are necessary to make meaningful changes in the communities where we work. Smaller-scale, high-risk projects can test innovative approaches to integrating technology into learning environments that larger-scale projects might not be able to. We as a community need to realign our expectations of exploratory research so that we can make the most of what it is most suited for.

Strengthening our own accountability to equity and ethics goals

Researchers have a great deal of experience creating data collection instruments to measure how effective our interventions are at achieving certain outcomes such as learning disciplinary knowledge or changing attitudes and interests. We need to use those same skills to ensure that our interventions and our own practices reflect the ethics and values of equity and justice for those involved in our research. We as a community need to support each other in this effort by co-creating and sharing tools to gather this kind of data and preparing both experienced and emerging researchers to do this work and hold each other accountable for living up to these principles. The systemic change that we hope to see requires a mutually supportive and accountable set of expectations for how we do our work.

By sharing our process and findings, we hope to inspire others to orchestrate convenings in their regions to arrive at a community-level agreement on bold steps, and to share their bold steps so that as an international community, we can converge on practices, values and goals that reflect what we hope to achieve.

Using Problem (Re)framing and Teachers' Pedagogical Responsibility to Facilitate Teacher Learning Opportunities

Samantha A. Marshall, North Carolina State University, smarsha3@ncsu.edu

Abstract: Although for decades there has been a strong coalition of teachers working for social justice, we still know little about how teachers' learning to do this work can be supported. In this paper, I use interaction analysis to investigate a teachers' learning opportunities, finding that the teacher's learning opportunities were facilitated by coaching strategies including: (1) a co-inquiry approach, (2) deliberate and persistent problem (re)framing, (3) grounding interpretations in student sensemaking, and (4) building on the teacher's pedagogical responsibility. These findings contribute to theory of teachers' learning, suggesting some of the ways in which such learning can be supported in a video-based coaching model.

In mathematics, a movement to teach content in connection with sociopolitical contexts and applications has resonated with many teachers and researchers (Bartell, 2013; Frankenstein, 1983; Gutstein, 2007). However, authentically situating mathematics in real-world, sociopolitical contexts is a complex, demanding endeavor (Leonard et al., 2010) and we know little about how teachers' learning to do this work can be supported. Designing and investigating supports for teachers' learning to do this work is, then, an important research topic for the field (Bartell, 2013).

In this paper, I report an investigation of one teacher's learning to integrate mathematics and social justice, utilizing a video-based coaching model. Through interaction analysis (Jordan & Henderson, 1995) of a *critical case* (Flyvbjerg, 2006) of strategic importance to this challenge, I show how learning opportunities for the teacher arose in coaching conversations. Additionally, I share implications for design of learning environments for teachers, especially as it relates to supporting teachers' learning of justice-oriented pedagogies. Because of growing pressure for teachers to integrate content and social justice topics, a pressing challenge for the field is understanding how to support teachers' learning in this realm. This study begins to illuminate potential mechanisms of teachers' learning through coaching and provides important considerations for future design.

Study context

This study is situated in a four-year research-practice partnership, in which we developed a video-based coaching model. In this research, we partnered with a professional development organization, working with experienced mathematics teachers to support their development of ambitious and equitable pedagogies (Horn & Garner, 2022).

Conceptualizing teachers' learning through video-based coaching

To support teachers' learning in and from practice, we sought a novel form of coaching that would be built around teachers' own personal goals for their learning and that could respond to challenges that arise in teachers' ongoing instruction (Horn, 2020). To this end, we designed our model as "co-inquiry," where teachers and their coaches collaboratively investigate elements of teachers' practice, honoring the teachers' own learning goals and disrupting traditional hierarchies in coaching. In most cases, the focal teacher – whose classroom was filmed – was joined by a colleague (a "partner teacher") for collaborative engagement in the video-based coaching model; this partner teacher worked at the same school and was also part of the professional development organization.

In our model, teachers first identify a question for co-inquiry, then we film in-class instruction to capture phenomena of interest using a two-camera, multi-microphone recording system that captures both the teacher's point of view (Sherin et al., 2008) and a view of the entire classroom with simultaneous tracks of audio from student groups. After filming, members of the research team review the video, selecting clips to share with the teacher based on her inquiry question(s). We then debrief the lesson, using episodes of interest from the classroom video (Horn & Garner, 2022).

Theoretical perspective

To investigate teachers' learning opportunities, I take a situative perspective. This perspective offers useful analytic tools for studying teachers' learning (Greeno, 1998; Peressini et al., 2004), allowing a focus on teachers' contextualized negotiation of meaning (Nolen & Ward, 2008). Situative perspectives focus on "joint interactional accomplishments of individuals in relation to broader communities, processes, and structures" (Hand, 2010), such as how a teacher makes sense of deeply local problems of practice, while keeping broader systems such as the

school and sociopolitical climate that also have a bearing on this meaning-making in sight (Nasir & McKinney de Royston, 2013).

Problem-based learning

Our video-based coaching design was inspired by models of problem-based learning (PBL) for teachers (e.g., Horn, 2013), intentionally building learning experiences around real-life decision making (Horn, 2020). By centering active inquiry around authentic problems, we conjectured that PBL can support teachers' learning in ways that may more easily translate to complex, dynamic classroom life. PBL has most often been studied in K-12 classroom settings (e.g., Malmia et al., 2019), but Horn (2013) argues that teaching consists of copious problem-solving and that many rich learning opportunities occur when teachers engage in problem-solving around their work. Thus, using video, our model capitalizes on naturally-occuring problems in teachers' daily practice, using challenges that are identified by teachers themselves and that occur in their complex classroom ecologies.

Learning opportunities

To understand how teachers' learning can be supported through video-based coaching, I drew on Greeno and Gresalfi's (2008) characterization of learning opportunities as "*affordances* for changing participation and practice" (p. 172). These can include new ways of positioning teachers toward their practice (Horn, 2010); resources available in the activity system that might support different forms of understanding, participation, or practice (Greeno & Gresalfi, 2008; Horn, 2007); or patterns of interaction that afford or constrain different participatory identities (Greeno & Gresalfi, 2008; Holland et al., 1998).

Problem formulation and framing

To understand how learning opportunities arise in problem-based learning, I pay special attention to problem formulation. Problem formulation is a collaborative process that involves teachers' views about their work (Horn, 2013) and can occur through framing (Bannister, 2015; Goffman, 1974). *Framing* refers to the ways that problems, and possible solutions for them, are conceptualized (Horn, 2013). Frames can profoundly shape teachers' learning opportunities; they may orient teachers toward productive solutions or "render a problem insoluble and therefore encourage the abandonment of such a pursuit" (Horn, 2010, p. 230).

Rich representations of practice

Horn (2005, 2010, 2013) found that representations of practice were crucial resources in teachers' collaborative learning (see also Little, 2003). Because problems of practice often occur during the fast-moving work of teaching, "[s]tabilizing these moments to create a common object of inquiry (Bransford et al., 2000) requires means for representing it" (Horn, 2013, p. 134). In this vein, she refers to *rich representations of practice* in the form of video-records of classroom interaction (Horn, 2020) in which we captured the teacher's point of view as well as the whole class and four tracks of student audio. Horn argues that such rich representations of teaching practice can be key sensemaking resources for teachers.

Focal case: Bridgette

In this paper, I focus on one teacher's learning opportunities in one particular debrief from our video-based coaching model. I chose to zero in on this critical case (Flybjerg, 2006) because it highlights important affordances of video-based coaching for supporting teachers' learning, particularly as it relates to justice-oriented pedagogies such as social justice mathematics.

Bridgette and her colleague, Elaine (all names are pseudonyms), were accomplished high school mathematics teachers who had worked together for the majority of their careers. They had a close working relationship and seemed socially open with one another – they often expressed joy and frustration about how both their personal and professional lives were going. Both worked at Katherine Johnson High School, a large community school that hosted three smaller schools on campus. Bridgette and Elaine deliberately chose to work at this school because of deep commitments to supporting students whom the system has given up on and to social justice.

Although Bridgette was passionate about social justice, the lesson debrief analyzed in this paper reflects one of her first attempts to integrate mathematics and social justice in the classroom. On the day our team video-recorded Bridgette's classroom, she taught a lesson about the foundational concept of *functions.* Functions are a concept used to model the world and allow us to make predictions about phenomena. Aiming to show how functions can model sociopolitical realities, Bridgette used the criminal (in)justice system(1) to illustrate the concept. She drew on examples of sentencing for various crimes committed, providing scenarios describing legal infractions and their consequences. Most of the student discourse centered around a situation describing two

different rape charges that resulted in two starkly different sentences. Bridgette asked students to discuss whether the situations described were "predictable" and thus modeling a functional relationship.

Bridgette and Elaine were joined at this debrief by three members of the research team including the author. One member of the research team, Claire, had taken the lead in reviewing Bridgette's video and served as the primary "coach" for this debrief, although the others also occasionally contributed to conversation.

Methods

This analysis was guided by the question, *How can video-based coaching support teachers' learning to integrate mathematics and social justice?* To understand teachers' learning opportunities, our team used ethnographic methods of data collection (Emerson et al., 2011) as participant observers (Spradley, 1980) throughout the 4-year study. This larger ethnographic corpus, including a video-elicited member check interview (Leander, 2004) serves to contextualize and allow triangulation (Denzin, 2009) against the in-depth interaction analysis of one video-recorded debrief.

I use discourse and interaction analysis methods (Gee, 2014; Jordan & Henderson, 1995) to identify interactional, conversational, and design features that afford or constrain Bridgette's learning opportunities. During and after data collection, I wrote reflective and analytic memos about salient moments and emergent questions and hunches that I had (Hatch, 2002). I followed Ochs' (1979) transcription conventions, slightly modified (Table 1).

Table 1

Summary of Transcription Conventions Used in Data Excerpts

Convention	Description
text—	self-interruption
italics	speaker emphasis
(.)	brief pause (less than one second)
:	elongated syllable (each ":" represents one beat)
//text]	overlapping speech
?	rising intonation
…	some of the transcript omitted for brevity
((*text*))	gesture
=	latched speech

Data analysis

To analyze the learning opportunities afforded to Bridgette through video-based coaching, I followed Horn's (2005) method of breaking the debrief transcript into *episodes of pedagogical reasoning* (EPRs). EPRs are "moments in teachers' interaction in which they describe issues or raise questions about teaching practice that are accompanied by some elaboration of reasons, explanations, or justifications" (Horn, 2007, p. 46). EPRs "can be individual, single-turn utterances… or multiparty co-constructions over many turns of talk" (Horn, 2010, p. 237), depending on the boundaries of topical shifts in conversation. Importantly, this unit of analysis allowed me to identify learning opportunities within the interaction contexts in which they arise (Horn & Little, 2010).

After coding for learning opportunities, I looked for sensemaking resources in the coaching interactions that seemed to shape Bridgette's learning opportunities about what it means to integrate mathematics and social justice in her instruction (Horn, 2013). Sensemaking resources that emerged during the coding process included *anecdotes of student thinking* provided by the rich representations of practice as well as ideas related to Bridgette's *pedagogical responsibility* (Horn, 2020) such as *ethical stances, moral precepts,* and *teaching principles*. *Pedagogical responsibility* refers to "whom or what teachers feel beholden to, and often – although not always explicitly – underlies teachers' pedagogical reasoning about their pedagogical actions" (Chen et al., 2020, p. 3). *Ethical stances* refer to teachers' positions about what is right or worthwhile to do (Ricoeur, 1992). These can be outright declarations or implicit in teachers' pedagogical reasoning. I defined *moral precepts* as guiding principles, often taken to be shared general rules about what is good. These were often contained in *teaching principles* – that is, propositions or claims about teaching (Horn, 2013). I then coded for coaching strategies, to understand how the coaches' participation may have supported or constrained Bridgette's learning opportunities.

Findings

Overall, the sensemaking resources that supported Bridgette's learning opportunities included: (1) ethical stances, (2) moral precepts, and (3) anecdotes of student thinking that came from the rich representations of practice. Her

learning opportunities were facilitated by four key coaching strategies: (1) our co-inquiry approach, (2) deliberate and persistent problem (re)framing (Bannister, 2015; Horn, 2010), (3) grounding interpretations in student sensemaking, and (4) building on the teacher's pedagogical responsibility. In the following section, I describe the arc of the debrief by summarizing the seven EPRs analyzed. Next, I present analysis of two focal EPRs that exemplify how learning opportunities arose for Bridgette. Through this analysis, I highlight how Bridgette's learning opportunities were supported through sensemaking resources and the video-based coaching process.

The arc of the debrief

I closely analyzed seven EPRs which contributed substantially to Bridgette's learning opportunities, but for the sake of space, I focus here on three. First, I present in broad strokes a summary of the seven focal EPRs to show the flow of the debrief conversation and to situate the focal EPRs in the larger context. Next, I present a fuller analysis of three focal EPRs.

Because this was Bridgette's first video-based coaching session ever, she was unsure what type of co-inquiry question to pose, so in the first EPR, she and the coaches spent some time discussing what she would like to see and think about. The coaches, Claire and Kyndal, began to formulate a problem by elaborating the complexity of the topic and highlighting different students' interpretations of the term *predictable*. Claire grounded this problem in specific student quotes from the video and began to crystalize the initial problem: that students had varying understandings of the idea of predictability, and this was hampering their ability to draw strong conclusions about the mathematics and the task.

In EPR 2, Bridgette responded to the first clip viewed by sharing more about her sense of pedagogical responsibility, clarifying that part of her purpose in teaching this mathematical topic using the analog of the (in)justice system was that she wanted students "to be very aware of what's happening" and to support them to "*think* more" even when they leave class. In this episode, Elaine asserted the moral precept that "[students] should have their own thoughts about [sociopolitical issues]," and Bridgette responded with an important ethical stance: *I should not foist my own commitments onto students*.

In EPR 3, the coaches responded by building upon the pedagogical responsibility that Bridgette had just expressed, highlighting some specific areas of student discomfort that might need to be addressed. They leveraged Bridgette's expressed pedagogical responsibility to continue reframing the problem, highlighting the teaching principle that *wrapping up such discussions about social issues may be an important piece of this kind of lesson*, especially because students were left with problematic issues having been raised, but with no opportunity for resolution. They acknowledged Bridgette's ethical stances but gently reframed her pedagogical responsibility. Instead of worrying about *telling* "students what to think" (Bridgette's words), Claire asked, "what does it mean to have these types of conversations [in a way] that does feel safe and inclusive for students?" Claire did not dismiss the ethical stance that teachers should not brainwash students, but she layered on a new framing that another important part of teachers' pedagogical responsibility is *fostering a safe and inclusive learning environment*. This reframing was critical; it both affirmed Bridgette's concern about telling students what to think and opened a new way of thinking about her pedagogical responsibilities.

Claire's problem reframing from EPR 3 sparked, in EPR 4, an extended turn by Bridgette in which she named multiple ethical stances and moral precepts that she saw as part of her pedagogical responsibility. First, she took the stance that *simply raising awareness that these issues exist is not enough*. However, in the next breath, she clarified that *raising awareness was important*, a key part of why she taught these topics in a mathematics class ("And like I want them to be aware of them because some of them are like, 'Oh, I didn't know about *any* of that'"; turn 384). She then further elaborated that *raising awareness is insufficient if students are not empowered or motivated to make change* but contrasted this with another ethical stance: *teachers should not foist their own commitments onto students* ("Then, I also don't want to (.) like *brainwash* them [into] what I think"; turn 384). This turn culminated with two more clear ethical stances: *teachers should prepare students to challenge systems of oppression* and *teachers should prepare students to navigate their oppressive world*. As she concluded, Bridgette landed on the pedagogical dilemma of *how to support students to navigate an oppressive world* – a problem framing that arose directly from her expressed pedagogical responsibility.

Focal EPR (5): Coach introduces a new problem frame using rich representation of practice

In EPR 5, Claire again drew on the rich representations of practice – video clips of students' sensemaking – to frame a new dilemma (Table 3).

Line number	Speaker	Transcript
385	Claire:	I wonder too, you've mentioned using these contexts as a way into the math. Amena said something at the very beginning about the video. Sh— they— When you gave them time to process how they felt about the video, that group mostly talked about, like 'it's really scary,' 'it's really sad,' 'it's really depressing' and Amena said, 'Does this have to do with math?' And the other students were like, 'I don't know, does it?' And she's like, 'Well, if this is math, I don't want to do math because it's scary.'
386	Bridgette:	Mm::::: ((*looks up, smiles tightly, then looks down placing hands on cup*))
387	Kyndal:	Someone here said that too.
388	Claire:	So that makes me wonder a little bit about the connection.
399	Bridgette:	Yeah.
400	Claire:	And like what are— how are students thinking about the relationship between the context that you're using and the math? I don't have more to say than that.
401	Bridgette:	If this is math, this is scary.

In turn 385, Claire built on one of Bridgette's articulated ethical stances, that *social justice topics should bridge students' interests and mathematics*; Claire contrasted this aim with students' reactions as heard in the video clips – they viewed the topic as scary and depressing. Bridgette's response in turn 386 was a drawn out "mm" and was accompanied by a shift in her posture: she looked up sharply, gave a tight smile, then looked down, resting her hands on her coffee cup. Her body language, tone, and utterances suggest that these student perspectives gave her pause. Her repeat of a student's phrase in turn 391, "If this is math, this is scary" also signals that she continued to engage this problem frame and seemed to be bothered by students' emotional response.

Focal EPR (6): Coach builds on teacher's pedagogical responsibility for new problem framing

In EPR 6, Kyndal built on the teacher's pedagogical responsibility and the problem frame offered by Claire in EPR 5 that students may have emotional responses to these topics. She offered an implicit moral precept that *education should not skirt topics simply because they are uncomfortable*, highlighting that as students discussed the case of the two rape convictions, they expressed highly problematic ideas about consent. She then reframed Bridgette's pedagogical responsibility, using language from her own ethical stance (Table 4).

Table 4

Transcript Excerpt from EPR 6

Line number	Speaker	Transcript
394	Kyndal:	I would be okay with brainwashing them about that.
395	Bridgette:	((*laughs loudly*))
396	Kyndal:	//If we're going to brainwash] them about something.
397	Claire:	//there are some things]
398	Bridgette:	Yeah.

Although she used Bridgette's language, Kyndal inverted the pedagogical responsibility as she reframed the problem; Bridgette had earlier expressed reluctance to foist her own commitments onto students, stating that she did *not* want to brainwash them. Kyndal instead asserted a new moral precept that *on some issues, students should be told what to think.* Again using anecdotes of student thinking, Kyndal framed a problem that *students' understanding about social issues was partial and problematic.* Both coaches used quotes they heard from students to vividly illustrate the complexity of the sociopolitical topics, and the partial understandings that students held about them.

Focal EPR (7): Coach builds on teacher's pedagogical responsibility for prognostic framing

In the final EPR analyzed here, the problem framing in EPR 6 was followed by an extended turn by Bridgette in which she reasoned in detail again about her pedagogical responsibility. In Bridgette's opening sentence, she revealed one part of her pedagogical responsibility; she seems to see her work as satisfactory if *conversations about social issues are happening* ("Okay I guess I'm okay then now that those conversations are happening"; turn 403). In her view, if she could support her students to have meaningful discourse about tricky social issues,

this was a step toward empowerment. She concluded "Okay, that's what I want. I want them to be able to speak up and have conversations and be okay with that" (turn 403).

In the next turn, Claire gently extended Bridgette's pedagogical responsibility, as though she was completing Bridgette's sentence. She said:

> I think in a way that also feels good for the people listening. I think this was Mariana, she was doing a lot of hedging when she was making inferences about the Stanford player probably being white and the Vanderbilt player probably— She kept saying, "I'm not racist but, I'm not racist but." I wonder in a situation like that, she's trying to be careful, she's also drawing on patterns and correlations that we know exist in the world. I wonder if a student like her, if she had a little more support around, how to communicate her idea— She clearly has no problem saying what she thinks but if she had a little more support around how to do that, I wonder if she would feel more comfortable and not do as much hedging and not have to worry that she's accidentally offending other people. (turn 404)

In her first utterance, Claire drew on a new moral precept to add to Bridgette's pedagogical responsibility — the idea that *students should not feel too uncomfortable in the classroom*. In the next breath, she illustrated the need for this element of pedagogical responsibility, directly quoting a student to show that more support in having conversations around race and social injustices might be needed. By reframing the problem as one of student discomfort, she set the stage for a new prognostic frame: that *scaffolding students to have conversations about sensitive topics might be an important part of social justice mathematics pedagogy*.

Discussion

The way Bridgette grappled with her pedagogical responsibility in this debrief is not uncommon when teachers begin the work of integrating mathematics and social justice. Bartell (2013) found that teachers centered their goals for social justice mathematics "on student awareness more than on specific understanding of and action toward confronting injustice. In doing so, teachers perhaps avoided grappling with sociopolitical issues in the complex ways that their lesson warranted" (p. 145). In Bridgette's case, video-based coaching provided opportunities for her to confront such avoidance, giving her time and space to process some of what may be beneficial or harmful about this lesson and to workshop ideas for the future.

The sensemaking resources that contributed to learning opportunities for Bridgette included anecdotes of student thinking (provided by the rich representations of practice), as well as ethical stances and moral precepts found in Bridgette's articulated pedagogical responsibility (Horn, 2020). Her learning opportunities were facilitated by coaching strategies including: (1) a co-inquiry approach, (2) deliberate and persistent problem (re)framing, (3) grounding interpretations in student sensemaking, and (4) building on the teacher's pedagogical responsibility. Because teaching mathematics for social justice is such a complex endeavor, the co-inquiry approach was well-suited to supporting learning opportunities, enabling the coaches to capitalize on the challenges Bridgette faced in her specific context and allowing problems of practice relevant to her work to drive discussion. By persistently reframing problems, the coaches repeatedly pressed on Bridgette's sensemaking and surfaced numerous problems of practice within the one-hour debrief, highlighting multiple angles of her pedagogy that may have been invisible without this problem reframing. Finally, by building on the teacher's pedagogical responsibility throughout, the coaches kept problems of practice close to issues of importance to her, and helped highlight areas of potential disconnect between her sense of pedagogical responsibility and her pedagogical actions, supporting robust pedagogical reasoning; these are conditions Horn (2020) describes as ripe for developing pedagogical judgment.

Because of the short duration of this debrief, it is difficult to make claims about Bridgette's learning, thus I focused primarily on the *opportunities* afforded by this video-based coaching model, bolstered by the in-depth grappling with these problems of practice that she and the coaches did during the debrief. In this debrief, analysis showed that Bridgette had learning opportunities about multiple dimensions of her social justice pedagogy, including the complexity and partiality of students' understanding, what it means to support students in conversations that feel safe and inclusive, what the purposes of teaching mathematics and social justice topics should be, how to prepare students for navigating an oppressive world, how to scaffold students to have conversations about sensitive topics, and more. However, I conducted a video-elicited interview with Bridgette two and a half years after this debrief, during which she confirmed several ideas that she has developed as a result of this debrief conversation, including *what it means to support students in conversations that feel safe and inclusive* and *addressing the complexity and partiality of students' understanding*.

Conclusion

Although mathematics teachers hear increasing calls to integrate mathematics and social justice and to learn social justice pedagogies, there remains little support available to them (Bartell, 2013). Those who want to begin such efforts are often on their own to find or develop curricula, and have few mechanisms for feedback or reflection to improve such practice, even though social justice pedagogies are far from straightforward (Kokka, 2017). Because the video-based coaching design relies on teachers' own inquiry questions and rich video-records of classroom interactions for discussion, it positions "participants to think about themselves, their circumstances, and their future actions in ways that are deeply contextualized" (Gutiérrez & Jurow, 2016, p. 4).

This analysis shows some of the ways in which video-based coaching may be a promising tool for supporting teachers' learning to integrate mathematics and social justice—in part by offering teachers a glimpse into students' sensemaking, emotional reactions, and other elements of their experiences of this kind of mathematics. These insights, which were not otherwise available to Bridgette, supported her pedagogical sensemaking about her own students, their experiences in mathematics, and her practice. This model may be fruitful for supporting teachers' learning of other justice-oriented pedagogies. After an extensive database search and literature review (Marshall & Buenrostro, 2021), I concluded that this is the first study to investigate this potential. Self (2016) cautions that "culturally responsive teachers must become vigilant to the possibilities that exist, both positive and negative, for the approach they have chosen" (p. 67). The video-based coaching process afforded opportunities for Bridgette to become vigilant to such possibilities.

Endnotes

(1) The system commonly referred to as the criminal "justice" system is, in fact, wildly unjust. Therefore, I follow Golembeski and Fullilove (2005) in calling it the criminal (in)justice system.

Lessons from Manoomin: Toward Acknowledging the Sovereignty of Indigenous Making and Sharing

Megan Hamilton, Christina Morgan
megan.hamilton@usu.edu, christina.morgan@usu.edu
Utah State University

Abstract: While multiple systematic reviews on constructionist learning activities have been conducted over the past decade, very few acknowledge the unique contributions of Indigenous learners and their communities as part of the maker movement. The purpose of this paper is to provide a review of existing literature on Indigenous approaches to making and sharing with a goal of identifying common technologies utilized when designing learning-by-making experiences for Indigenous youth. We summarize current findings and categorize them in alignment with principles of Indigenous making and sharing practices. These findings promote a comprehensive perspective on ways to enact Indigenous making and sharing approaches while working with Indigenous young learners and their communities. We conclude with recommendations for furthering current understandings of Indigenous making and sharing skills and pedagogical practices as well as weaving in lessons we have learned from manoomin.

Introduction

Throughout wild rice camp, or manoominike, we ate what our ancestors had eaten. We shared stories that our ancestors had passed down. We renewed our relationships just like our ancestors had before us. And we did this all to fulfill our responsibilities to ourselves and our Anishinaabeg community. To this day, this experience remains by far the most enriching and profoundly transformative making activity I have ever experienced during my lifetime. As a result, I wonder how rich learning experiences, like manoominike, are being represented across the current scholarship of making and makerspaces. --Author 1

Wild rice, or *manoomin* (pronounced Ma-nō-min), is hand-harvested each fall by the Anishinaabeg across the Great Lakes region. Manoomin (*Zizania palustris*) is a type of grass that grows on the lakes, and it is one of the only grains native to North America. The Anishinaabe people's companionship with manoomin goes back centuries (e.g., Vennum, 1988). Often referred to as the "seed of life," manoomin is culturally vital and sacred to the Anishinaabeg. The Anishinaabeg believe we owe our lives to manoomin since it provides nourishment throughout each season for human and more-than-human relatives alike, especially when food is not always plentiful. For generations, wild rice camps like these have engaged Indigenous youth, families, and cultural leaders alike in the sharing of traditional teachings and creation stories, demonstrating companionship with wild rice and other more-than-human relatives, and constructing their own rice tools for harvest (e.g., Vennum, 1988).

As a scholar of Anishinaabe (Ojibwe) and European descent, Author 1 was struck by how deeply engaging and transformative her manoominike experience was. Especially in how it embodied the "traditional forms of making as a living legacy of Indigenous scientific and technological activity" (Barajas-López & Bang, 2018, p. 18). Moreover, having participated in the design and research of multiple learning-by-making experiences, the authors were further perplexed as to why Indigenous making and sharing is not more widely represented across the maker movement and maker spaces. The dissonance between such a rich "maker" activity and the limited representation of such knowledge in the maker movement scholarship prompted us to take a deeper look at what we can learn from Indigenous making and sharing. While the scholarship is still largely rooted in western ways of knowing and being, we also encountered rich cultural experiences that enacted principles of Indigenous making and sharing and (re)centered Indigenous ways of knowing and being (Barajas-López & Bang, 2018). In this paper, we look across this work on Indigenous making and sharing with youth to offer expanded understandings through a systematic review woven together with lessons we learned from sacred manoomin.

Overview of Indigenous Making & Sharing Principles

The principles of Indigenous making and sharing have been enacted in Indigenous communities since time immemorial. The Anishinaabeg, for example, have stewarded manoomin ever since it was gifted to them by the Creator (*Gitche Manitou)* for generations prior to settler colonial expansion. While conducting a summer Science, Technology, Engineering, Art, Mathematics (STEAM) camp with Indigenous youth, Barajas-López and Bang (2018, p. 17) observed the principles of Indigenous making and sharing practices to include: (1) Enacts and

communicates stories in a multiplicity of forms in and across temporalities. Knowing, being, and doing are simultaneously unfolding and are essential/defining elements in the practice of material storytelling; (2) Reflects the patterns and processes that cultivate life and draw on deeply interrelated socioecological phenomena requiring interdisciplinary forms of sense-making; (3) Enacts relationships with animate materials that have life courses toward the fulfillment of communal responsibilities; and (4) Enables continual renewal of family and community to assert contemporary presences and living Indigenous nature-culture relations.

Similarly, Author 1 observed Indigenous making and sharing principles during her family's wild rice camp experiences that unfolded near the waters of Little Elbow Lake on Gaa-waabaabiganikaag (White Earth Nation). In our findings, we further discuss Author 1's observations of these principles being enacted at wild rice camp as well as the lessons from manoomin we have learned over the course of this literature review.

Need for Literature Review

Over the past decade, multiple systematic reviews have been conducted on constructionist learning activities (Papavlasopoulou et al., 2017; Timotheou & Ioannou, 2019). While findings from these literature reviews help us further our understanding of making, few acknowledge the unique contributions of Indigenous learners and their communities as part of the maker movement. As a result, they do little to address tensions surrounding equity and pedagogical practices of the broader maker movement (Vossoughi & Bevan, 2014). Therefore, in this paper, we examined studies incorporating Indigenous notions of making and sharing while maintaining and acknowledging Indigenous ways of knowing and being. We focused solely on studies that described any kind of learning-by-making experience with Indigenous youth.

The purpose of this review was to examine the current state of scholarship in the maker movement and how it intersects with Indigenous making and sharing practices. For this systematic review, we examined empirical studies grounded in Indigenous epistemologies that attempt further exploration of the making practices specific to Indigenous communities. Guided by Barajas-López's and Bang's (2018) definition of Indigenous making and sharing, we address the following research question: How does scholarship on Indigenous making and sharing define and enact making and sharing principles?

Procedures & Methodology/Methods Literature Search

We conducted a systematic literature review (Gough et al., 2012) by examining scholarship related to Indigenous making and sharing with youth. We explored article databases in the fields of learning sciences and Indigenous education including Education Source, PsycINFO, and JSTOR as well as journal databases such as Association of Computing Machinery (ACM) and the Journal of American Indian Education (JAIE). Keywords used to search the databases included the following and similar terms: "Indigenous", "making", "youth", "science", and "technology". We found a total of 333 articles.

Inclusions Criteria

We included empirical articles and conference proceedings published in the last twenty years and applied the following criteria:(1) peer reviewed article, (2) full text available, (3) written and/or available in the English language, (4) having Indigenous or Aboriginal young learners in their participant population, and (5) published in an academic journal or conference proceedings. First, we evaluated the titles and abstracts of each article according to the inclusion/exclusion criteria, which resulted in 99 articles. Next, we screened for inclusion/exclusion based upon whether each article was related to learning experiences where Indigenous learners are engaging in learning-by-making as a result. This resulted in 20 articles included in this review.

Classification Criteria

We modified and collapsed principles of Indigenous making and sharing identified by Barajas-López and Bang (2018, p. 17) to classify the articles in our literature search. Specifically, we classified literature based on these four major categories: (1) enacts and communicates storytelling (2) walking and reflections of sense-making and interrelated socioecological phenomena (3) enacts making (including both forms of Indigenous and/or western forms of making) and (4) demonstrates renewal of family and community relations. Category classifications were not mutually exclusive.

First, we identified the types of technologies used to create learning artifacts across each of the 20 studies. We classified the articles into learning experiences that utilized original technologies (e.g., making of moccasins, claywork, building of canoes, etc.) versus digital technologies (e.g., digital storytelling, software, etc.). Similar to Barajas-López and Bang (2018), we refer to Indigenous technologies as "original technologies" in order to reclaim old and new Indigenous making and sharing practices and acknowledge them as more than just "artistic expressions" (pp. 9-10), but rather legitimate productions of the knowledge-making process. Next, we classified

studies based on what categories of Indigenous making and sharing they utilized (Barajas-López & Bang, 2018). To be classified in the "enacts and communicates storytelling" category, youth had to engage in either oral storytelling or digital storytelling practices as a means to "communicate meaning, feelings, and ways of being" (Barajas-López & Bang, 2018, p. 9). For many of the studies, oral narratives were shared through some form of digital media. Therefore, we utilized the following definition of digital storytelling: "Digital storytelling combines the art of telling stories with a mixture of digital media, including text, pictures, recorded audio narration, music and video" (Robin, 2016) to inform our categories. And lastly, we examined studies that specified the renewal of family and community relations. Studies that utilized this principle had to demonstrate some form of collaboration with Indigenous community members in order to be assigned to this category.

Findings

We use principles of Indigenous making and sharing (Barajas-López & Bang, 2018) to frame our findings. We first provide a summary of findings. Then for each principle we provide (1) definitional grounding, (2) discuss related findings from our review, and (3) reflect upon lessons we have learned from manoomin as they relate to each principle.

Summary of Findings

This review focuses on current research in learning-by-making experiences designed for Indigenous youth. Studies noted a range of learning environments that included informal after-school settings, summer camps, in-school spaces, and libraries. Many of the learning-by-making experiences described in sections below utilized Indigenous making and sharing practices. Of the examined studies, we found three studies (Barajas-López & Bang, 2018; Carlson et al., 2011; Searle et al., 2017) that utilized all four Indigenous making and sharing categories in their learning experiences. Also, we found four studies that enacted a single Indigenous making and sharing category in their experiences (e.g., Eglash et al., 2013; Webb et al., 2012). Because these studies demonstrated a single category of "enacted making," it is a matter of debate as to whether Indigenous making and sharing was truly demonstrated across such studies. We highlight these areas throughout the findings as critical needs for further research. Table 1 below provides a summary of setting, assigned category, technology used, and learning artifact(s) created to serve as guide for the remainder of the findings section.

Enacts & Communicates Storytelling

Storytelling is a key pedagogical practice and learning tool valued by many Indigenous cultures for centuries (Kawagley, 2006; Marin & Bang, 2015). Central to Indigenous ways of learning and research, the practice of storytelling "sustains communities and validates the experiences and epistemologies of Indigenous peoples" (Iseke, 2013, p. 559). Through storytelling, community members can impart cultural and traditional Indigenous knowledge to young learners (Davis, 2014; Iseke, 2013). Learning scientists are starting to examine storytelling practices in their research with Indigenous learners (e.g., Barajas-López & Bang, 2018; Searle et al., 2017; Tzou et al., 2019). For example, Barajas-López and Bang (2018) youths' participation in storytelling was not only found to allow for Indigenous young people to practice their own forms of storytelling, but it also allowed for them to participate in relationship-building activities with members from their Indigenous communities.

Throughout our review, we found storytelling to take on various digital and original forms. Of the studies we found to utilize storytelling (n = 11), nine studies incorporated digital tools (e.g., film, robotics, video games, digital stories) to assist young learners in their story creation process while two studies used oral technologies (e.g., oral traditions) as part of their learning experience. As an example, Carlson and colleagues (2011) illustrated storytelling practices when they asked Elders to teach part of their science curriculum and share Indigenous perspectives of science with Native students. As part of their study, Elders engaged in ceremonial practices with their students prior to harvesting materials to build heritage crafts (e.g., snowshoes).

The practice of storytelling also emerged as a framework for centering "family-making" practices where family members share stories and memories while creating and learning intergenerationally. As an example, Tzou and colleagues (2019) designed a family-based robotics program, called TechTales, grounded in storytelling that was implemented over the course of multiple weekly workshops. Two Indigenous families used both personal and traditional stories to inform the design of dioramas they co-created using robotics as well as other technologies. Tzou and colleagues (2019) argued that engaging in family-making and storytelling helped the families to deepen their own personal and cultural identities while also participating in acts of "renewal and resurgence" of Indigenous ways of knowing (Tzou et al., p. 324).

Teaching 1 from Manoomin

Prior to the official start of camp, our cultural leader spoke in Anishinaabemowin and offered his blessings for the harvest. He explained how our ancestors were given spiritual instruction to travel to the place where food grows on water and how the thunder beings own manoomin. He also described how manoominike represents a (re)creation of the creation story when the seed falls into the water. --Author 1

In Author 1's narrative, the sharing of creation stories and enactment of ceremonial practices allowed for her to make sense of manoominike through Anishinaabeg ways of knowing. Historically, many Indigenous peoples have demonstrated learning through experiences and the passing down of oral histories from one generation to the next (e.g., Kawagley, 1995). Indigenous oral narratives often include stories of origination, shared life-experiences among community members, and other ancient teachings (e.g., Davis, 2014). Manoomin also reminds us of the significance of storytelling practices as "the accumulation of thousands of years of making that are based on storytelling and apprenticeship relationships" (Barajas-López & Bang, 2018, p. 14).

Walking & Sense-Making with Interrelated Socioecological Phenomena

For many Indigenous peoples, knowledge and culture are heavily influenced by relationships with the land (Brayboy, 2005; Barajas-López & Bang, 2018b). Land-based pedagogies (e.g., Benton, 2017) are commonly used approaches for cultivating environmental awareness among Indigenous learners. Land-based and place-based pedagogies (Feld & Basso, 1996) are similar learning practices due to how deeply situated within the concepts of time and space. Land-based pedagogies also incorporate Indigenous ways of knowing by including Traditional Knowledge perspectives (Tuck et al., 2014). As an example, Barajas-López & Bang (2018) utilized the principle of "walking and sense-making" with youth as they participated an I-STEAM program where learners were encouraged to walk while engaging in storytelling involving their surrounding local ecosystems.

Youth engaging in sense-making with socioecological phenomena occurred in less than half of the studies we examined (n = 6). There were a variety of land-based and space-based pedagogies utilized among the studies examined. For instance, Searle and colleagues (2017) employed space-based pedagogies with Native youth during visits to community sites. The sites youth visited then became incorporated into the designs of their games for future visitors to play. Other land-based pedagogies invited youth to manipulate aspects of their physical world. As an example, Carlson and colleagues (2011) provided Ojibwe students direct interactions with physical space by teaching them to harvest maple syrup. This experience encouraged young learners to engage in their people's ancient traditions while also gaining knowledge in key features of their local food sources. Given the deep connections between many Indigenous peoples and their traditional land and ecologies (e.g., Barnhardt &

Kawagley, 2005), it is concerning that this way of being is not more represented in current work with Indigenous youth around making and sharing.

Teaching 2 from Manoomin

On one side of camp, campers placed moccasins on their feet to jig the rice in a bucket (which allows the rice to loosen its hulls) while the camp cultural leader sang and played a one-sided drum. The camp organizer held a birch bark basket, repeatedly tossing manoomin into the wind and catching it again in the basket. She explained how this process (called "winnowing") causes the hulls to be separated from the rice, leaving only rice kernels behind. Meanwhile, other participants engaged in land-based pedagogies of hunting, fishing, and harvesting only to return in the evenings before dinner preparation. --Author 1

In this narrative, Author 1 witnessed how youth engaged in sense-making with socioecoloogical phenomena, particularly through the jigging and winnowing of manoomin. Similarly, Marin and Bang (2018) investigated land-based pedagogies through their examination of how a Native American family engages in intergenerational conversations and sense-making practices while walking together through nature. Throughout this process, family members participated in the methodologies of "walking, reading, and storying the land" as they engaged in the "coordination of attention and observation between humans and more-than-human others to identify and name living and natural kinds, finding evidence, and generating explanations to create a story about the perceptual field" (p. 90). Their study as well as Author 1's manoominike experience demonstrate the importance of engaging Indigenous learners by connecting learning to their local land-based systems.

Enacts Making

Learning through the process of making has taken place for generations of Indigenous learners. In his study of Yupiaq culture, Kawagley (1995) describes how members of his tribe have long engaged in scientific and technological practices while being guided by the "knowledge of their ancestors" (p. 56). For example, he describes the science and technology incorporated into the design of Yupiaq's local fish camps. Each Yupiaq family owns a fish camp, which serves as a space for living, fish preparation, and storage during the fishing season. While taking a Yupiaq worldview, Kawagley (1995) proposed an educational program to teach Indigenous youth about scientific phenomena including weather patterns and local fauna and flora. The program also teaches how to use solar energy while creating culturally centered products such as a fish rack for their fish camp. His proposed educational program illustrates the making of culturally related artifacts (e.g., fish racks) that could help create authentic learning experiences for students from traditional societies.

All studies we examined (n = 20) enacted making throughout a prescribed learning experience (including forms of both digital and original technologies). We observed original technologies (e.g., making of moccasins, claywork, building of birch bark canoes) to reflect Indigenous forms of making versus digital technologies (e.g., digital storytelling, software, etc.) that reflected more western instantiations of making. We classified only nine studies as including forms of original technologies, while 15 studies utilized contemporary western digital technologies. Three studies utilized both types of technologies and were classified in both categories. For example, Searle and Kafai (2015b) used e-textile construction kits combined with traditional sewing practices for their learning experience with American Indian boys. The medium uniquely pulled in a "strong-community based craft tradition linked to heritage cultural practices and Indigenous Knowledge Systems" (Searle & Kafai, 2015b, p. 31).

The nine studies including original technologies showcased technologies used for developing land restoration practices (e.g., Bang et al., 2013), claymaking (e.g., Barajas-López & Bang, 2018), making moccasins, harvesting maple syrup, building birch bark canoes (e.g., Carlson et al., 2011) and designing fish racks for drying salmon (e.g., Rickard, 2005). Digital technologies, though, were the most common technologies used in current Indigenous making and sharing experiences with Indigenous youth. Of the 20 studies, we classified 15 learning-by-making experiences that utilized some form of digital and/or digital fabrication technologies. This included technologies for digital storytelling (e.g., Beltrán & Begun, 2014; Coenraad, 2019; Iseke & Moore, 2011; Mills et al., 2015; Riecken et al., 2006; Searle et al., 2017; Weston & Biin, 2015; Wexler et al., 2013), game design and development (e.g., Lameman et al., 2010; Webb et al., 2012), and heritage craft design and development (e.g., Eglash et al., 2013; Kafai et al., 2014; Searle & Kafai, 2015a; Searle & Kafai, 2015b). The majority (n = 8) of the learning experiences included digital technologies that specifically supported digital storytelling. The types of digital storytelling media ranged from film or video production to augmented reality and interactive storytelling platforms. In sum, there is currently an overrepresentation of western technologies in the learning-by-making workshops with Indigenous youth.

Teaching 3 from Manoomin

We walked around camp admiring the learning that was going on around us. Children of all ages sat under the canopy of trees, teasing each other, and constructing rick knockers made of cedar and dolls made of corn husks. Occasionally each child made their way over to an Elder and showed off their creations with pride. --Author 1

From this narrative, Author 1 witnessed how youth engage in learning-by-making activities through the constructing of wild rice tools and corn husk dolls. This enabled youth to utilize original technologies of the Anishinaabeg. Many wild rice camp participants engaged in the pedagogies of walking and material storytelling, and constructed rice tools that enabled them to utilize their "own technologies and practices of making" (Barajas-López & Bang, 2018, p. 9). Therefore, manoomin also teaches us the importance of encouraging youth to engage in learning-by-making experiences using original technologies.

Demonstrates Renewal of Family and Community Relations

Including family and community members in the design and implementation of learning experiences is a distinguishing feature of Indigenous knowledge systems (e.g., Barnhardt & Kawagley, 2005) and Indigenous making and sharing practices (Barajas-López & Bang, 2018). Members of Indigenous committees can also serve as cultural practitioners, so-called "cultural gatekeepers," who have critical insights into the cultural practices of Indigenous peoples (Bequette, 2007). Throughout the various forms of these storytelling processes, we reviewed a range from within-family interactions (e.g., Tzou et al., 2019) to larger across community interactions (e.g., Iseke & Moore, 2011). Many of the studies engaged community members as cultural experts. For example, Riecken and colleagues (2006) conducted a participatory research project where Indigenous youth developed their research questions and conducted interviews with members of their family and community to create a video that they would share with their community.

The renewal of family and community relations involves both living and more-than-human relatives (Barajas-López & Bang, 2018). From the perspectives of Barajas-López and Bang (2018), Indigenous making and sharing allow participants to employ their own agency while engaging in the histories and technologies of their ancestors and subsequently maintaining such practices for future generations. One of the participants of their I-STEAM project, Miguel, describes his first-time experience in the use of claywork by stating that he "was able to connect with those that came before me" throughout the experience (Barajas-López & Bang, 2018, p. 7). However, this was the only examined review that demonstrated the renewal of family and community relationships with more-than-human relatives.

To date, many studies that demonstrate aspects of Indigenous making and sharing also involve different forms of community engagement. Of the 20 studies reviewed, 13 studies showed the renewal of family and community relationships in some form during the learning-by-making process. Demonstration of renewal of family and community relationships varied across experiences, but a common thread among the studies was that community members were utilized as cultural experts at some point in time during the making process. Sometimes this took place on a broader scale across communities or in a smaller family setting. Researchers like Tzou and colleagues (2019) conducted their intergenerational, robotics-based storytelling intervention with two Native American families. Other scholars like Wexler and colleagues (2013), who implemented multiple digital storytelling workshops across Alaska, took place across multiple communities. Seven articles did not mention any form of family or community involvement. Further, while the studies we reviewed included aspects of family and community engagement, the extent to which families and communities were engaged throughout the entirety of the learning experience, beyond cultural experts, was limited.

Teaching 4 from Manoomin

The botanist in charge of our plant walk explained that the plants she was showing us had been revealed to her during dream time. She directed us down a gravel road and then down a path sheltered by trees. She showed us the characteristics to look for in wild strawberries, plantain, dandelion greens, and wild ginger. We collected types of each plant, making sure not to take too much and leave some behind for our relatives, especially as the drought had not left many berries. We spent over an hour foraging, cleaning, and preparing food for our communal feast afterward. --Author 1

In this example, Author 1 describes how she engaged in communal responsibilities of foraging and preparing food for other camp participants. Ultimately, many are worried that manoomin and the Anishinaabeg's spiritual connection to the land and each other will disappear as a result of the intensifying climate crisis: "We are defined by manoomin. It is the whole reason we were sent here by Creator...So, when the rice is destroyed, it is modern-day genocide. When the rice is gone, we cease to be who we have been for thousands of years" (Stone, 2021). Consequently, the principles of Indigenous making and sharing enacted by the Anishinaabeg when they

hand-harvest and steward manoomin are also at risk if settler colonial pursuits persist. Therefore, the fourth teaching of manoomin encourages us to engage young learners in maintaining our nature-culture relations.

Discussion, Implications, and Limitations

Our analysis helped us to identify ways Indigenous making and sharing approaches have been enacted while working with Indigenous young learners and their communities. In the following discussion, we discuss the limitations of our review as well as turn to ways in which manoomin has taught us and continues to teach us.

This review seeks to acknowledge the unique contributions of Indigenous peoples to the field of maker education and by further revealing non-normative instantiations of learning-by-making experiences. The major limitation of our review is that our extensive search yielded only 20 articles. While the amount of scholarship on the maker movement is increasing, there remain few projects that further the principles of Indigenous making and sharing. We found limited literature addressing walking & sense-making with interrelated socioecological phenomena (n = 6) as well as literature demonstrating renewal of family and community relations (n = 13). Even more, of the 20 articles included in this review, four studies only include a single category of Indigenous making and sharing principles, specifically "enacting making," in their work with Indigenous youth. Taking this together with the fact that most studies also solely utilized western digital technologies, there is great need for deeper integration of Indigenous and western making and sharing, especially when working with Indigenous youth and their communities. To this knowledge, as we further explore such integrations, scholars like Barajas-López and Bang (2018) warn us to not "fit or impose Indigenous knowledge systems into Western conceptions of knowledge means maintaining asymmetrical power relations and reproducing inequities and dominance" (p. 20). After all, Indigenous knowledge systems and practices are not assets to be appropriated nor exploited but rather embraced.

Throughout our search, we did not identify any guidelines for conducting Indigenous making and sharing principles with Indigenous families and communities. As such, as we continue such scholarship, we must begin to acknowledge our responsibilities toward protecting Indigenous making and sharing from appropriation and exploitation. Sovereignty and stewardship of these practices require the highest levels of protection as we work to provide and sustain reciprocal relations (e.g., Kimmerer, 2015). Like manoomin, wild rice camp and other forms of Indigenous making and sharing are spiritual entities with their own agencies that require reciprocal relations. Therefore, as we reflect upon the lessons that manoomin provides us, we also question how and to what extent we as scholars should move to protect the sovereignty of Indigenous making and sharing as its own entity.

Examining the instructional norms that support student participation and engagement in whole class science discussions

Jarod Kawasaki, California State University, Dominguez Hills, jakawasaki@csudh.edu

Abstract: The latest reform efforts in science education emphasize the centrality of productive classroom discourse to learning science with an emphasis on students' learning to explain and argue. These instructional demands require that teachers master instructional norms and routines that support these discursive practices. Novice teachers have difficulty learning to notice and respond to student thinking, a crucial element to promoting productive classroom talk. This paper examines a whole class discussion in one novice science teacher's classroom to document the teacher moves that promote and manage productive discourse and the instructional norms that support them. Structuring learning experiences around these instructional routines and norms in university teacher education programs can help teachers learn to facilitate these types of productive whole class discussions.

Introduction

Science instruction that meets the demands of the Next Generation Science Standards (NGSS Lead States, 2013) emphasizes the idea that students must learn to explain and argue around everyday science phenomena. Designing this type of instruction asks teachers to create opportunities for students to interact regularly with each other's ideas and explanations (Windschitl et al., 2012). For these student-to-student interactions to be meaningful, students need to be positioned as constructors and critiques of scientific claims (Ford, 2008) taking ownership and responsibility for the aims, processes, and standards of scientific knowledge production (Elgin, 2013). Positioning students in this way empowers them as epistemic agents (Stroupe, 2014) where students are participants in the knowledge production process. This epistemic agency is fundamentally dialogic and demands that teachers re-orient their teaching around promoting and managing whole class discussions among students (Kelly, 2014; Mercer, 2009).

Promoting and managing productive classroom discourse require teachers learn to notice, elicit, and respond to student thinking (Barnhart & van Es, 2015). Noticing and responding to student thinking is a complex task that requires that teachers having a clear sense of specific responses and ideas they are looking for in the context of a particular science lesson or idea that is being discussed and the practices that will make students' ideas visible (Luna, 2018). Given this complexity, teachers need to implement instructional norms and routines that support these discursive interactions. Exemplary teachers establish discursive norms using effective questioning techniques (McNeil & Knight, 2013), talk moves (see Michaels & O'Conner, 2012), appropriate responses to student questions and ideas to promote elaboration and student to student discourse (Colley & Windschitl, 2016; Kazemi & Cunard, 2016), and noticing moments of interaction that can be leveraged for student learning (van Es, 2011). Yet, novice teachers have difficulty effectively using these practices and establishing consistent norms for student-to-student talk (Kang & Anderson, 2015; van Es & Sherin, 2008). In this study, I examine a whole class discussion facilitated by a novice teacher where students were productively engaged in science discourse with both the teacher and each other. In this whole class discussion, I identify the instructional norms that are evidenced by student responses to teacher questions and probes.

I draw upon the work of Michaels, O'Conner, and Resnick (2008) who describe a set of practices and norms for academically productive talk in the classroom (i.e., Accountable Talk). Accountable Talk was conceived to promote equitable student participation in rigorous academic settings and encompasses three dimensions of practice for promoting productive student talk (i.e., accountability to the community, acceptable standards for reason, and knowledge). I used the Accountable Talk framework to document the ways that students responded to one another and the teacher during whole class science discussions. I used these interactions as evidence for the instructional norms in place. Although there are many participation structures where students interact with each other, I have chosen to focus on whole class discussions because the facilitation role that the teacher plays, provides insight into the ways that the teacher notices and responds to student thinking during the interaction and it reveals the extent to which instructional norms are adopted by students during their interactions with the teacher and each other.

Methods and study context

This study asks, how do pre-service teachers enact instructional norms intended to promote productive student discourse? In answering this question, I aimed to document the instructional norms that created a learning

 © ISLS

environment conducive to whole class discussions. Documenting these instructional norms can provide teacher educators and pre-service teachers concrete examples to support teacher learning around the practices that encourage productive student participation and engagement in whole class discussions.

This study takes place in a teacher preparation program in a large university in metropolitan southwest United States. The program has an explicit focus on preparing social justice educators to work in schools serving working class communities of color. The program's conception of social justice and equity centers on the idea that students' histories, experiences, knowledge, and dispositions are assets that support them to engage and learn in the classroom (i.e., humanizing pedagogy). To define asset-based teaching, Yosso (2005) uses Critical Race Theory to conceptualize cultural wealth of marginalized groups that may go unnoticed by teachers. It is vital for social justice teachers to use the knowledge of students, families, and their communities to inform their classroom teaching (Yosso, 2005). Humanizing pedagogy calls teachers to debunk notions of deficit thinking around the academic achievement of students who have been historically marginalized (Bartolome, 1994). In the program, teachers are prepared to design science units and lessons using a humanizing approach. Teachers are also asked to dive deeply into what it means to be a social justice educator by reflecting on their multiple identities in relation to privilege and power. By understanding their positionality, teachers form a deeper understanding around why practices that value student voice are necessary for enacting humanizing pedagogy (Takacs, 2003). Teachers come to realize that to meet the needs of their students, critical theories and pedagogies must shape the way they approach science teaching.

The faculty in the program have developed and piloted a classroom observation framework that operationalizes science teaching from a justice and equity perspective (Nava et al., 2019). The second dimension in this framework focuses on promoting content discourse in the science classroom. The framework guides all the courses that teachers take in the program, and thus promoting content discourse was a major emphasis throughout pre-service teachers' preparation program. The cohort understudy included 24 secondary pre-service science teachers participating in a yearlong science methods course. In the methods course, teachers have multiple opportunities to video record their teaching during their clinical experiences as part of a series of feedback and reflection cycles to prepare them for their performance task at the end of the program (i.e., EdTPA).

In total, I collected 31 video recorded lessons (~10 min each) for a little over 5 hours of video. I used interaction analysis (Jordan & Henderson, 1995) to examine the opportunities teachers provided for students to interact with each other. Interaction analysis involves identifying episodes of analytic interest and the iterative viewing and analysis of such episodes to identify patterns in interaction. When useful, particular events or sequences of events within episodes were transcribed to explore in fine-grained detail how talk is organized in the moment. My analysis involved viewing episodes of interest, generating potential descriptions and explanations of events, and testing those against the rest of the corpus, through progressive and recursive analytic induction (Erickson, 1998). During my analysis, I focused on student responses in relation to teacher talk as well as any student-to-student discourse. For this paper, I focused on videos that contained whole class discussions because I was interested in how instructional norms were evidenced in this setting. Of the 31 video recordings, 16 included a whole class discussion. Of those 16, most of the whole class discussions resembled elicitation discussions (Michaels & O'Conner, 2012) where the teacher's questions to students intended to draw out the "correct" answer, with little attention to student thinking and rare effort to juxtapose students' ideas. Elicitation discussions are important for making student thinking visible but are not the types of discussions that foster productive science learning. One video was an exception. The whole class discussion in Margret's (a pseudonym) class stood out because of several moves she made that fostered the types of students' sensemaking that take place during productive discussions in science classrooms (e.g., juxtaposing students' ideas, promoting student to student discourse). Given this one video, I sought out to determine the conditions that allowed for this whole class discussion to take place. I used interaction analysis to create a detailed account of teacher and student moves during the whole class discussion and used this account to identify the instructional norms that were present during Margaret's whole class discussion.

Findings

To illustrate my findings, I describe Margaret's 10-minute whole class discussion that followed a week-long experiment. In the experiment, students identified two locations within their school to collect and document insect biodiversity. Each group of students selected two locations for their data collection, a large space covered with dirt, and another covered by grass, flowers, and other shrubs. The goal of the lab was to document the number of different insect species that collected in a sticky cup with a sugar solution throughout the week. The disciplinary core idea understudy is *Interdependent Relationships in Ecosystems (LS2:A)*. I share excerpts from a transcript of the discussion to depict how Margaret promoted and managed the conversation as it unfolded over the 10 minutes and call attention to the different instructional norms present in the discussion.

Provide reasoning that connects the evidence to a claim

The first example of an instructional norm that Margaret installed into her class was the expectation that students needed to provide some reasoning that connected their claim and evidence. In this example, students shared the areas that they found the most biodiversity.

Turn	Speaker	Utterance
1	T:	Why was that location more biodiverse though?
2	S1(B):	It had more species.
3	T:	Ok, it had more species, but why did it have more species, what was in that environment.
4	S (many):	It had more dirt
5	T:	It had more dirt, so why is dirt important?
6		So, it can hide
7	T:	So, the insects can hide, ok, excellent work, S2(G), you had a question or
8	S2(G):	I wanted to help her.
9	T:	Ok, did you want to agree or disagree? She said that location 1 had more biodiversity.
10	S2(G):	I disagree with S1(B) because I found more biodiverse in location 2, I think it happened because it had grass and water and they are there at the same time, not just dirt.
11	T:	Ok that is an excellent reason. Why are those important again?
12	S2(G):	That is what insects live off of, grass.

In line 5, Margaret asked students to tell her why dirt was important for the insects. This move acted as an ask for students to make a connecting statement between their claim and evidence. In the excerpt above, S1 claims that location one was more biodiverse because it had dirt. Dirt was important because it allowed insects to hide from, presumably, predators. Margaret repeated this ask for justification in line 11, where a student disputed the claim that the dirt area had the most biodiversity and instead claimed that she found that the grass had more biodiversity. Margaret asked the student to explain why grass was important and the student responded with a justifying statement, "that the insects live off (i.e., sustain themselves) of the grass". Later in the transcript (see line 25 in the next excerpt below) Margaret once again asked a student to offer a reason that connected their claim and evidence, and the student responded with appropriate reasoning that connected their claim and evidence. It seemed that students were accustomed to responding to this type of request from Margaret. On all three occasions, multiple students responded to her question of why something was important. I can infer, then, that using reasoning to connect claims and evidence was a norm that Margaret consistently reinforced during these types of discussions. This instructional norm aligns with the *accountable to the standards of reason* dimension in the Accountable Talk framework. Using evidence and reasoning to support a claim is a foundational epistemic practice of the scientific community and, here, Margaret holds her students accountable to this standard.

Students are competent contributors to class discussions

Another instructional norm that Margaret instituted within her classroom was around positioning students as competent contributors to constructing and critiquing science claims (Ford, 2008). This excerpt is a continuation of the conversation above.

Turn	Speaker	Utterance
13	T:	Ok, great, excellent, who agrees or disagrees with S2(G)? S3(B), say I agree because…
14	S3(B):	I agree because we found four species in location 2, it's more, more culturally diverse.
15	T:	Culturally diverse? *(students laugh),* we don't know the insect life, we can't say if insects have culture, but what kind of diversity?
16	S3(B):	uh
17	T:	Do you need help?
18	S3(B):	It's like genes or genetic.
19	T:	Not genetic
20	S4(G)	Can I help?
21	T:	Yes

 © ISLS

22	S4(G):	Species biodiverse
23	T:	Yes, S3(B) helped that species have biodiversity, S4(G) helped us out to show that we have more species biodiversity, it helps all species help survive in these locations and so we have a few people who have agreed on location 2 being more biodiverse and only 1 that agrees that location 1 is more biodiverse. Anyone else want to agree or disagree or add on, I haven't heard from team 2, team 1 or 4. Do you want to agree or disagree. Accept or reject? Yes, no? S5(B)?
24	S5(B):	I agree with S2(G), section 2 was more biodiverse. Instead of more plants there was more water and dirt in location 1.
25	T:	That is important because…
26	S5(B)	Well, the plants were taller so they could blend in from the public
27	T:	So, they could remain hidden, so that is like S1(B) reasons for the dirt, so that is an interesting idea. I love it! Ok, so it is interesting that we have some agree and some disagree with where we found more biodiversity, yes no?

In this excerpt, students discussed their experimental data, trying to determine which specific location in their experiment was most biodiverse. In the first turn, Margaret followed up a student claim with a talk move asking other students whether they agreed or disagreed with their classmate. In the same turn, she used a sentence starter to help S2 respond to S1 (i.e., 'Say I agree…'). Margaret's moves were an attempt to get students to respond to each other's ideas, a move that she scaffolded with the sentence starter. In the next three turns, Margaret sought clarification from S2 on a response he gave. When S2, struggle, S3 offered him help. In this case, building on one another's answers included helping fellow students. After S3's assistance, Margaret revoiced all of the responses and explicitly juxtaposed students' responses with one another. This move to juxtapose students' ideas makes the disagreement explicit for students that may not have noticed the disparate ideas. Then finally, she asked the tables that had not responded whether they wanted to agree or disagree or add on to the existing responses. Having students respond to the ideas of others and juxtaposing conflicting accounts during this whole class discussion acted as an effort to support consensus building within the classroom community, an important feature of scientific discourse. This discourse extends beyond eliciting students' ideas and positions ideas in relationship to one another to figure out the most suitable explanation. The instructional norm that students are competent contributors aligns with the *accountable to knowledge* dimension in the Accountable Talk framework. Students shared their ideas and knowledge and that knowledge had to hold up against the critique and expertise of the other students in the classroom.

Maintain a safe and positive science learning environment

Participating in a whole class discussion can make students vulnerable to ridicule from their peers, evaluation from the teacher, and self-doubt about their linguistic and content knowledge, especially in schools that serve working class communities of color. Yet, classroom discourse is a key aspect of learning and engaging in science. Thus, teachers that use whole class discussions need to have norms and routines in place that create a safe and positive learning environment so that students are willing to participate without fear of these vulnerabilities. In this excerpt, we see how Margaret maintained a safe and positive learning environment when two students had a negative interaction after one of the students volunteered that he had tried this experiment at home and wanted to share his findings with the class.

Turn	Speaker	Utterance
28	T:	So, none of you are wrong. We can't know for sure which is more biodiverse from this experiment. This is what real scientists do and when they come to conclusions that are conflicting and they have to figure out how to make them better. So, what could we have done to make our experiment better or would we keep it the same? We could have changed our materials, added more juice to the cups, or was it good. We waited a week to collect, we put it in the Wednesday before or maybe our data table was bad, and we wanted to look at more factors.
29	S (many):	More time, more time
30	T:	So, if you have ideas, just volunteer, S6.
31	S6(B)	Materials, I did something creative, I put honey and lettuce into the cup and let it sit out for the week.
32	S7(B):	If the bugs hit the honey, they are going to stick

33	S6(B):	That is the whole purpose to count the bugs, dummy
34	T:	Hey, hey, positivity! Do not talk to another classmate like that S6.
35	S6(B):	That is the whole purpose is to count the bugs. Mr. S7?
36	T:	We did count them on a sticky pad. So, he is right. We did want to catch them, maybe our materials didn't collect enough insects because we didn't have enough to attract them to the location. So, we didn't get an accurate measure. So, what are you thinking S8(G)?
37	S8(G)	um I think, I agree with Shaun, but I think you guys should have had sticky cups and honey to attract them
38	T:	So, S8(B) is saying that we needed honey to attract. S8(G) is saying that we needed both to get an accurate measure. What are you thinking back there? Is that a hand raise?

This is tricky situation for teachers to navigate. In that moment, Margaret must either stop the entire conversation to address the name calling, why it is inappropriate to say that a person with a wrong or incorrect answer is a "dummy", or take quick and affirming, yet holding students accountable type action, and keep the conversation moving. In this instance, she quickly intervened, and the student restated his claim using the appropriate address to the student who was contesting his idea, "that is the whole purpose is to count the bugs, Mr. S7". In the video, the tone from S6 was somewhat sarcastic, but nonetheless, S6 responded appropriately to Margaret's ask for positivity simply continuing with his argument for why he did his own experiment, even addressing S7 in a collegial way. It is plausibly more common in moments such as these that the science discourse ceases altogether, and the conversation moves to intervening around the insult. In this case, Margaret's intervention and the student's subsequent response indicated that there were instructional norms in place around maintaining a safe and positive learning environment. Instructional norms around maintaining a safe and positive learning environment align with the *accountable to the learning community* dimension in the Accountable Talk framework. The learning environment must be conducive to student participation where students intently listen to their peers' ideas and ask clarifying questions on areas that are unclear. This is the initial stage to building consensus within the classroom community.

It is also noteworthy that Margaret started this conversation saying that none of the students were wrong and that competing findings often occur in science. Furthermore, she stated that competing claims and evidence were a necessary step in coming up with the most accurate findings for an experiment. Margaret's move helped students understand the nature of science as tentative and uncertain, affirming that students' inaccuracies and mistakes were necessary steps in their scientific investigation.

Position science in the context of local and community issues

There is one final excerpt that does not align with the Accountable Talk framework, but also revealed an instructional norm within Margaret's classroom. The instructional norm was that students should think about the connection of science to their everyday lives. This excerpt takes place at the end of the 10-minute discussion and Margaret attempted to connect the experiment to a broader issue that was facing the community, the building of a new football stadium.

Turn	Speaker	Utterance
39	T:	I am going to mention this quickly, the new NFL stadium is being built about six miles from here, it is being built over the park and race track. So, how many species and individual bugs did we see in this little location? I just want you to think about how this relates to biodiversity here. What happens if the NFL stadium is built over the park?
40	S9 (B):	They are gone, the bugs are gone.
41	S10 (B):	They will build houses.
42	S11(G):	Rent will go up.
43	T:	So, you are thinking more human implications. Rent will go up, maybe a little bit more tourism. But what about the environment? If we don't have this place for the insects to come and live and built over it…
44	S12(G):	They are going to die.
45	S13(B):	They are going to lose their homes
46	T:	They are going to lose their homes, so knowing what we know about how important insects are to life, like bees that we will lose 1/3 of our food if we lose bees, so just think

	about the implications of this stadium for biodiversity in our city and what can happen to it.

Students' responses to this community issue were rather typical and mundane, possibly because Margaret asked known answer questions rather than open questions that with multiple answers. Yet, responses from S10 and S11 indicated that these two students were thinking about some causal effects for themselves or people they know that live close by the stadium (i.e., human implications). Responses from S12 and S13 indicated that these two students were considering the consequences of the new stadium and how it might displace wildlife that were native to that area.

Discussion and implications

This study sought to understand the instructional norms that supported student participation and engagement in whole class discussions. To do this, I analyzed the interactions between a teacher and her students during a whole class discussion around a student-centered science experiment where they investigated insect biodiversity at their school site. My analysis revealed that students responded to the teacher and each other in ways that demonstrated that there were specific instructional norms in place that allowed for meaningful and productive participation in the whole class discussion. For example, Margaret asked students on three separate occasions the question, and why is that important? Each time, students responded with some reasoning that connected the evidence that they were presenting to the claim they were making. Margaret's move of asking for reasoning in a way that made sense to students (i.e., why is that important?) supported student participation and engaged them in the scientific discursive practice of using reasoning to connect a claim to its supporting evidence (c.f. McNeil & Krajcik, 2011). Anecdotally, it seems that practitioners use of the claim-evidence-reasoning framework often strays far away from the discursive practice from which it originated and is largely used as a summative assessment that students submit at the end of a science unit. Using the idea of providing reasoning to connect evidence to a claim as a discursive norm engages students in a knowledge building practice of the scientific community (Manz, 2015).

While the instructional norm of using reasoning to connect evidence to a claim is specific to the discipline of science, the other instructional norms evidenced in Margaret's class were more generally aimed at building a classroom learning environment conducive to classroom discourse. The teacher education program that prepared Margaret uses a science teaching and learning framework that includes dimensions that are science specific and those that are more general (e.g., classroom ecology/learning environment dimension) (Nava et al., 2019). As mentioned previously, this framework also has a dimension around promoting content discourse. Margaret's effort to engage her students in rigorous science tasks (i.e., designing and conducting their own experiment on biodiversity), lead students through whole class discussions, and build a positive classroom ecology and learning environment are all evidence of her adoption of these practices from her teacher preparation program. Yet, my review of the video recorded lessons from her cohort revealed that this type of learning was more of an anomaly rather than the norm suggesting that these instructional norms are difficult for novice teachers to adopt and incorporate into their classrooms. Documenting the instructional norms present in Margaret's class highlights the ways that the Accountable Talk framework manifests itself in the classroom, yet additional work is needed in teacher preparation to ensure that more teachers can incorporate these practices and norms into their science classrooms, so that students have opportunities to engage in productive conversations around science ideas.

I draw two conclusions from these findings with implications for teacher educators and teacher preparation programs. First, is that teacher preparation programs need to find ways to support teacher development around teaching practices that helps them to incorporate instructional norms for managing and promoting student discourse into their classrooms. Encouraging productive classroom discourse is a pedagogical indicator of classrooms that promote greater equity and access to sciences instruction (Lee, Miller, & Januszyk, 2014). Yet, productively promoting and managing student discourse, especially whole class discussions, is difficult for novice teachers. Research suggests that specific practices in teacher preparation can support teachers' learning of productive instructional norms and routines, including rehearsals and field-based methods courses (Kazemi & Waege, 2015; Lampert et al., 2013). In addition, having pre-service teachers analyze and reflect on video recorded teaching episodes, both exemplars and recordings of their own teaching, can support teachers to recognize areas for improvement around making student thinking visible and promoting student talk (van Es et al., 2017). Giving pre-service teachers multiple opportunities in their teacher preparation program to observe these instructional norms in classroom teaching as well as opportunities for them to incorporate these into their student teaching placements is needed so that they can include classroom discourse and whole class discussions into their unit and lesson plans. Documenting the instructional norms in Margaret's class during this whole class discussion provides some concrete examples of what these norms look like in practice and evidence for their productiveness in supporting student participation and engagement in classroom discourse.

Second, I recognize that Margaret's discursive segment followed traditional notions of scientific discourse and epistemology. Margaret was prepared in a justice and equity focused teacher preparation program, yet I did not necessarily see her engage with her students with issues around power and race that were emphasized in the program. Nor do I see students' histories and identities affirmed within this discussion. It is not to say that Margaret or any of the other science teachers in her cohort do not take up these types of issues, just that they were not evidenced in the video recorded lessons that were analyzed for this paper. Agarwal and Sengupta-Irving (2019) take up this issue to broaden how and in what ways minoritized students of color meaningfully participate in classroom discussions drawing on their identities and histories as students of color and providing epistemic diversity in the perspectives that are valued and shared about whose and what knowledge counts in a science classroom. Supporting teachers to develop the instructional norms and practices that support student participation and engagement in whole class discussions can both support students to learn science and provide opportunities for students to share and affirm their ideas, histories, knowledge, and identities in ways that contribute to learning within the classroom community.

Applying Sequence Mining to Explore Students' Problem-solving Practices Using an Interactive Simulation-based Task

Karen D. Wang[1], Carl E. Wieman[1,2]
kdwang@stanford.edu, cwieman@stanford.edu
[1]Graduate School of Education, [2]Department of Physics, Stanford University

Abstract: Extensive research has been done to capture and understand human problem solving across different research methods and traditions. This study examines how interaction data generated in an open-ended, interactive task could be used to identify patterns of effective and ineffective practices for solving problems in science and engineering domains. We collected data from 80 undergraduate students on their solutions and problem-solving processes as interaction data logged in the task environment. The log data was parsed to reveal the sequence of test trials conducted by individual participants when solving the problem as well as the pauses in-between test trials. Results of the clustering analysis showed that distinct trial sequence patterns were associated with different levels of performance and provided evidence for specific problem-solving practices. These results have implications for how to assess a complex construct like problem solving and how real-time feedback could be provided to improve students' problem-solving practices.

Introduction

Problem-solving situations arise as scientists investigate and build models and theories about the phenomena in the natural world and engineers design and build systems (NGSS, 2013). Authentic problems like these need to be incorporated into science and engineering classrooms to help students develop expertise in systematic practices of scientific inquiry and problem solving (Krajcik, 2015). One efficient and cost-effective way of engaging students in authentic problem solving is through technology-based, open-ended learning environments, such as interactive simulations. In this paper, we employ an interactive task embedded in a physics simulation to elicit undergraduate students' problem-solving performance. Furthermore, we explore how different patterns of students' interactions in the task environment as recorded by the log data are associated with effective and ineffective problem-solving practices.

Background

Student-centered, open-ended learning environments (OELEs) provide opportunities for students to engage in authentic scientific inquiry and problem solving (Hannafin et al., 1994; Land & Jonassen, 2012). In contrast to traditional end-of-chapter exercises in science textbooks, interactive tasks embedded in OELEs can be designed to better mimic authentic problems by situating the task in an engaging, real-world context and providing minimal data upfront. One example of OELEs is educational simulation, where students explore scientific phenomena and solve problems in an authentic, safe, and cost-effective manner (Wieman, Adams, & Perkins, 2008). The interactive task environments uniquely allow students to decide what information they need to solve the problem, how to collect that information, and what conclusions they can draw from it. These decisions are integral parts of the practices adopted by scientists and engineers to solve problems encountered in their work (Price et al., 2021).

In the process of students working on the problem embedded in OELEs, large volumes of log data are generated in the backend of the task environments. How to analyze the log data and extract insights about students' cognitive and metacognitive processes is an evolving area of inquiry, especially in the fields of learning analytics and educational data mining (Fischer et al., 2020). Approaches and techniques adopted to process and model log data in previous research include directly hand coding log data to create a training set for classifying students' inquiry skills (Gobert et al., 2013), engineering features based on raw data and using them to identify patterns of productive actions in a circuit simulation (Fratamico et al., 2017), and conducting sequential pattern mining analysis to group students based on their behavior sequences (Eichmann et al., 2020). One promising approach for feature extraction is to incorporate human knowledge gained through domain expertise or direct observation of students solving the task into log data processing, creating a set of semantically meaningful features. These features can then be used as inputs to either supervised machine learning algorithms to predict performance, or to unsupervised algorithms to identify differentiating patterns among students. In this paper, we applied such approach to analyze the log data generated in an interactive problem-solving task in a physics simulation. Our goal is to identify patterns of students' actions that reflect specific problem-solving practices and understand how these patterns are associated with different levels of problem-solving performance.

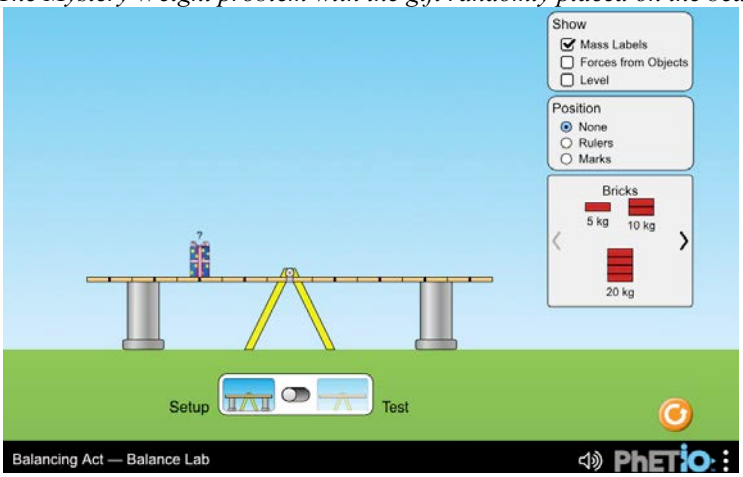
Methods

The Mystery Weight problem embedded in the PhET Balancing Act simulation was used in this study (phet.colorado.edu/en/simulations/balancing-act). Students were first introduced to a scenario of needing to measure the weight of a gift to be mailed without access to a weighing scale. They were then presented with the task of figuring out the weight of the gift using a seesaw and a few bricks of known weights in the Balancing Act simulation. Figure 1 presents the user interface of the task. Students can place bricks and the gift at various marked locations on the beam in the "Setup" mode and observe the outcome of the trial (i.e., how the beam would rotate or stay balanced) in the "Test" mode. The simulation does not allow bricks to be stacked on top of each other, which makes the problem less intuitive and more difficult. Furthermore, the weight of the gift was deliberately chosen to be unsolvable using a single brick. Balancing the beam thus requires a combination of different weights placed at different locations.

Figure 1

The Mystery Weight problem with the gift randomly placed on the beam



80 undergraduate students in STEM majors across the US (47.5% female) were recruited via an online research crowdsourcing platform, Prolific (www.prolific.co). Students received $4 for participating in the 30-min online study and up to $4 additional bonus for correctly solving the problems. During the study, participants first worked on a Mystery Weight problem and were then randomly selected to view one of the two versions of worked examples demonstrating how to solve the problem. Participants worked on a second Mystery Weight problem afterwards. In this paper, we focus our analysis on participants' performance in the first problem prior to any interventions.

Data collected to capture participants' problem-solving performance include 1) their solutions for the mystery weight (the gift's weight in kg); 2) their responses to a post-task question probing whether the torque formula was used when solving the problem; 3) log data recording participants' actions within the task environment in JavaScript Object Notation (JSON) files as they worked on the problem. The log data was parsed using a Python script to reveal a sequence of test trials conducted by individual participants and the pause time after each test trial. The TraMineR R package (Gabadinho et al., 2011) was used to visualize and analyze the sequential data. In the following section, we first discuss participants' overall problem-solving outcomes as measured by their solutions to the problem. We then present the features extracted from the log data and results of a cluster analysis on the sequential features.

Results

Problem-solving outcome

Participants' problem-solving outcomes were determined by their solutions for the weight of the gift. We coded the correct solution and near-correct solutions (17-19kg) both as "correct" and solutions outside the range (< 17kg or > 19kg) as "incorrect." Four participants were excluded from data analysis due to extremely low time-on-task (< 1 min). Among the remaining 76 participants, 45% reached a correct or near-correct solution while 55% did not.

Number of test trials conducted

In the mystery weight simulation, users can place objects on and remove them from the beam in the "Setup" mode. Once they set up a trial, they can toggle to "Test" mode to observe how the beam might tilt based on the weights and positions of the objects. A test trial is thus characterized by the number and type of objects used (both the gift with unknown weight and bricks with known weights) as well as their positions on the beam. Guided by qualitative observation of students solving the problem in a pilot study, we focused on the test trials instead of discrete actions and abstracted sequences of low-level actions into test trials conducted by individual participants, along with timestamps recording when the trials took place during their problem-solving processes.

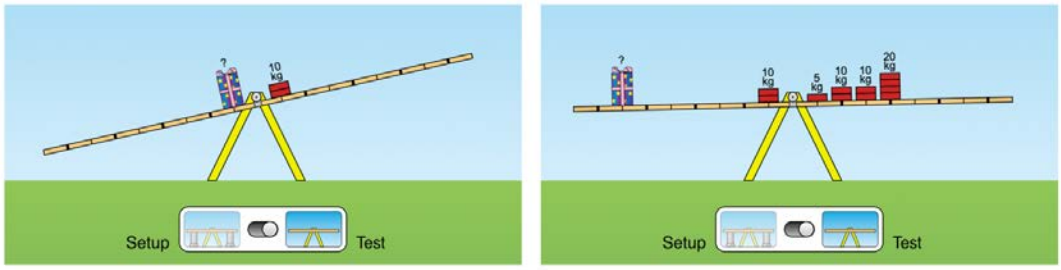
Participants were instructed to solve the mystery weight in 15 test trials or less and stop working after reaching 15 trials. However, the log data revealed that 41% of the participants (n = 31) continued working on the problem after Trial 15, indicating deep engagement with the task. One exceptional participant conducted 106 test trials in 26 minutes. The mean number of trials conducted excluding this participant was 17, with a minimum of 4 trials and a maximum of 46 trials.

Number of weights used in a test trial

The test trials conducted represent participants' efforts to collect the data needed to solve the weight of the mystery gift. Figure 2 shows two sample test trials: the left one features a simple set-up using two weights (the gift and one brick) while the right one features an overly complex set-up using six weights (the gift and five bricks) at different locations on the beam. The optimal number of weights required to solve the problem is three (one gift and two bricks). Across all trials conducted by all participants, the mean number of weights used in a test trial was 3.4 (sd = 1.3), with a minimum of 1 and a maximum of 13 weights used.

Figure 2

Two sample test trials conducted when solving the mystery weight problem; the left trial used two weights and the right trial used six weights



Pause after a test trial

While the number and nature of test trials conducted represent how participants actively went about solving the problem, the pause times, or periods of inactivity in the simulation after each test trial, potentially constitute an important signal on how participants managed their problem-solving processes. Based on our previous research (Wang et al., 2021), we define a meaningful pause as one where the time between the action of toggling to "Test" and the next action recorded in the simulation being longer than 10 seconds. This definition allows us to differentiate between longer, meaningful pauses indicative of underlying cognitive processes and shorter, mechanical pauses that are approximately the time required to view the outcome (i.e., how the beam will tilt) of the test trial. A few extremely long pauses (> 2 mins) were excluded from the analysis as they were likely incurred due to off-task behaviors. Among all participants, six did not have any meaningful pauses throughout the problem-solving process. The number of meaningful pauses range from one to eleven for the remaining 70 participants.

Qualitative interviews of students' working through the mystery weight problem in our previous research revealed that the underlying cognitive processes during a meaningful pause may include 1) pause to understand the nature of the problem and devise a solution plan; 2) pause to record and interpret the data observed from the trial using relevant physics knowledge; and 3) pause to evaluate and revise their strategies after unsuccessful attempts to solve the problem.

The sequences of test trials conducted by individual participants

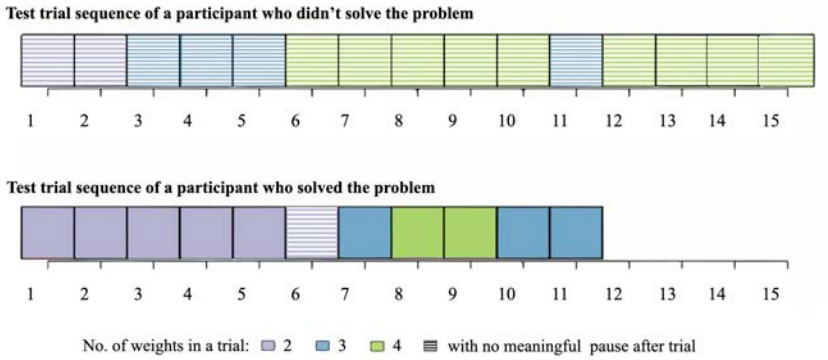
We plotted the sequence of test trials conducted and whether each trial was followed by a meaningful pause for individual participants. Figure 3 illustrates the test trial sequence of a participant who did not solve the problem (top) and one who reached the correct solution (bottom). A qualitative examination suggests that there were differences between the two sequences, notably around the frequency of meaningful pauses. We applied cluster

 © ISLS

analysis to further investigate whether there exist differentiating interaction patterns among participants and how these patterns are connected to problem-solving performance.

Figure 3

Test trial sequences of individual participants. The length of the sequence reflects the no. of test trials conducted. The colors reflect the no. of weights used in each test trial. Solid colors indicate that the trial was followed by a meaningful pause.



Clusters of participants' test trial sequences

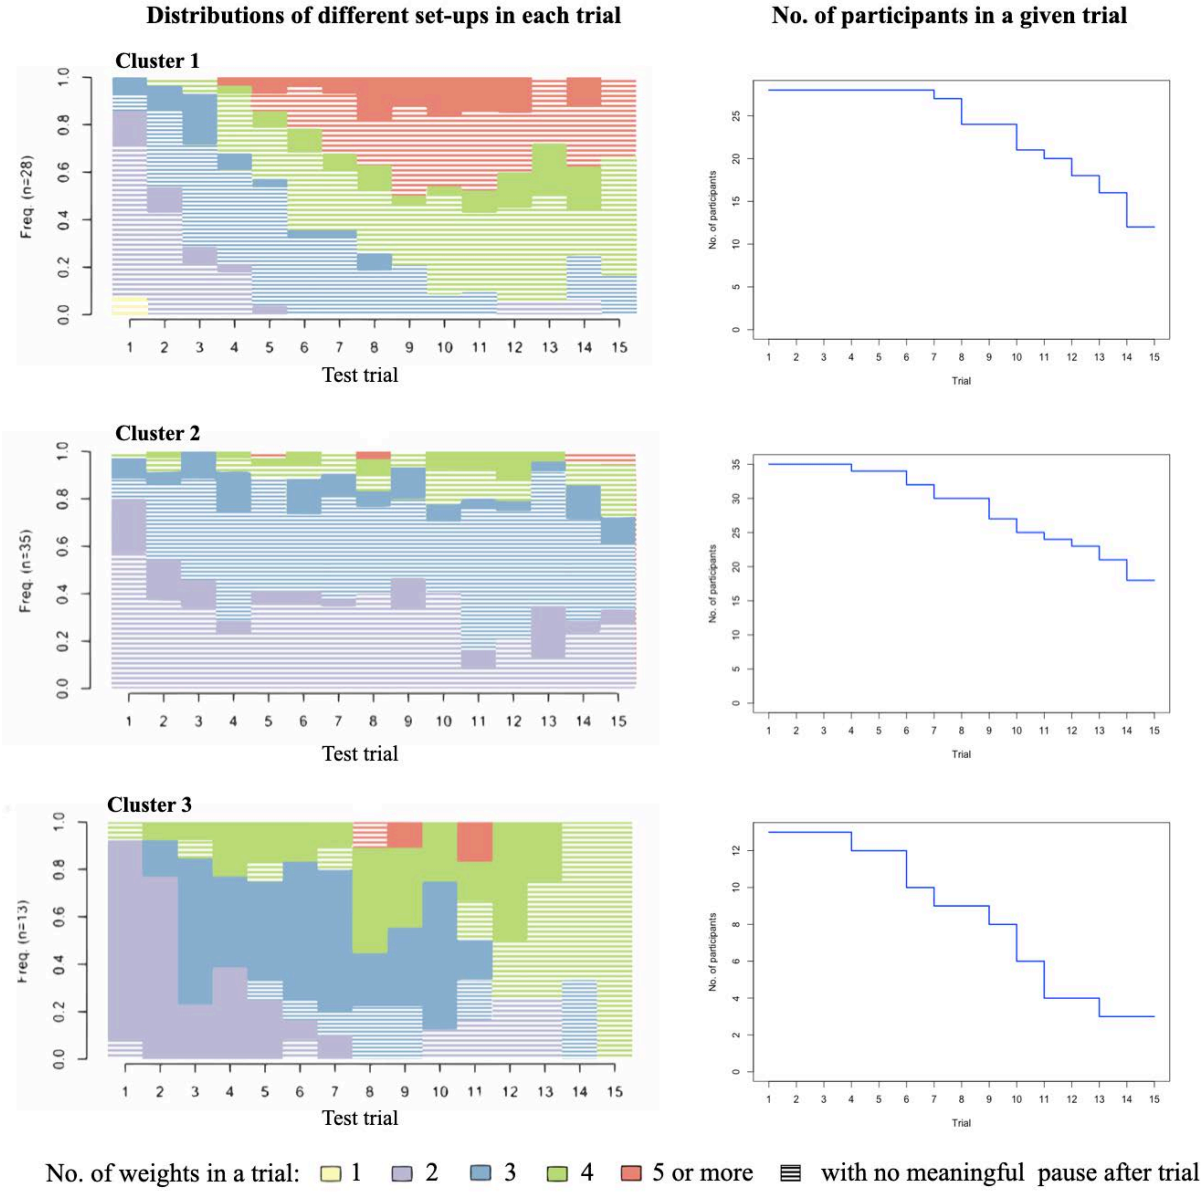
As shown in Figure 3, a test trial sequence is characterized by its length (no. of trials conducted), simplicity (no. of weights used in each trial), and pace (whether the trial was followed by a meaningful pause). Given the large variance in the number of trials conducted by individual participants, we truncated the sequences of all participants to the first 15 test trials to be used as inputs to cluster analysis. This decision ensures that the sequence length will not be the dominant factor for clustering and allows us to explore how we might be able to efficiently identify different problem-solving profiles with only a portion of students' interaction data.

A matrix of pairwise distance between individual participants' test trial sequences was computed using an Optimal Matching algorithm. The Ward hierarchical clustering method was then applied to cluster the sequences into distinct groups based on the distance matrix (Murtagh & Legendre, 2014). The average silhouette width was used to select the appropriate number of clusters (Rousseeuw, 1987). Figure 4 shows the resulting three cluster groups: the horizontal bar plots on the left show the distribution of different trial set-ups (i.e., no. of weights used at each trial); the line plots on the right show the number of participants remaining at the *n*th trial ($1 \leq n \leq 15$). For example, in Cluster 2, around 60% of the first trial conducted by participants used two weights on the beam with no pause afterwards and there were 18 participants remaining at Trial 15. In contrast, in Cluster 3, around 80% of the first trial conducted by participants used two weights and included a meaningful pause afterwards. There were only three participants remaining in Cluster 3 at Trial 15, as most solved the problem within 15 trials. In the following, we will describe the three clusters in detail and discuss how different problem-solving practices were reflected in these clusters.

Figure 4

Distribution of different types of trial set-ups (left) and no. of participants remaining at each trial (right) in the three clusters. The x-axis denotes the no. of trials conducted by participants. The left y-axis denotes the frequency of different trial set-ups, and the right y-axis denotes the no. of participants remaining at specific trials through the problem-solving trajectory.

 © ISLS



Cluster 1. Participants in this cluster (n = 28) quickly increased the number of weights used in subsequent test trials from two to five or more and rarely paused after conducting a trial. These sequences of test trials represent participants' attempts to counter the direction of the tilting and get the beam balanced by adding more weights to different positions on the beam. The lack of meaningful pauses indicates that there were minimal efforts to make sense of a test trial and use it to estimate the weight of the gift, or to evaluate whether their strategy was an effective one. 39% of the participants in this cluster self-reported using torque when solving the problem and 32% recorded some form of notes using a table provided in the task environment. In the end, 36% of the participants in this cluster reached a correct or near-correct solution. We label the problem-solving practices observed in this cluster as *ineffective data collection using overly complex set-ups and non-reflective*.

Cluster 2. Participants in this cluster (n = 35) generally kept the set-up of test trials simple with two or three weights on the beam yet paused minimally after test trials. Like participants in Cluster 1, they made minimal efforts to pause and interpret a test trial. Only 23% of the participants self-reported applying the torque formula when solving the problem. Their actions of moving the weights around different positions on the beam were largely driven simply by the reaction to counter the tilting of the beam. 23% of the participants in this cluster took notes and 37% reached a correct or near-correct solution. We label the problem-solving practices observed in this cluster as *collecting data using simple set-ups yet non-reflective*.

Cluster 3. Participants in this cluster (n = 13) kept their trial set-ups simple in the first ten trials and mostly paused after conducting a trial. As shown by the last plot on the right, the majority of the participants in this cluster solved the problem by Trial 11, and so the last four trials, with few participants remaining, were not representative of the general pattern of the cluster. Cluster 3 participants were systematic and deliberate in their problem-solving approaches: first putting the gift on one side of the beam and a brick on the other side to narrow down the range of the gift's weight, followed by adding a second brick to balance the beam after they discovered that the weight of the gift could not be solved by a single brick. Participants also paused after test trials to interpret and record the data collected in the trials and plan for the next ones. 85% of participants in this cluster reported applying the torque formula when solving the problem and 92% took notes using the table provided in the task environment. In the end, 85% of the cluster reached a correct or near-correct solution. We label the problem-solving practices found in this cluster as *effective data collection using simple set-ups and reflective.*

In summary, the cluster analysis of test trial sequences revealed that we could derive semantically interpretable clusters of participants who adopted similar problem-solving practices. For example, one cluster primarily consisted of effective problem solvers who set up easy-to-interpret trials and frequently paused to record and make sense of the data collected in each trial. Another cluster contained problem solvers who set up increasingly complex trials by piling on many objects on the beam and did not pause meaningfully throughout the problem-solving process. We checked the external validity of the clusters with participants' solution correctness and found a significant relationship between cluster membership and obtaining the correct solution, $X^2(2, N = 76) = 10.10$, $p < 0.01$. Furthermore, we found significant relationships between cluster membership and applying torque to solve the problem, X^2 $(2, N = 76) = 15.13$, $p < 0.001$, and between cluster membership and taking notes during the problem-solving process, X^2 $(2, N = 76) = 20.01$, $p < 0.001$.

Discussion & Conclusion

Despite the recognition that students need to learn science and engineering practices useful for solving authentic problems, valid and efficient assessments of these practices remain scarce (Quellmalz et al., 2013). Researchers in the learning analytics and educational data mining communities have explored how to model student abilities and knowledge states using large volumes of interaction data generated in open-ended learning environments. In this study, we extend the research efforts and seek to understand how the log data of students solving a problem in a physics simulation could be used to capture and evaluate specific problem-solving practices of college students in science and engineering domains.

The results indicate that there exist distinct patterns of test trials conducted by effective and ineffective problem solvers. Effective problem solvers set up simple trials and paused frequently after conducting a trial, while ineffective problem solvers either switched to increasingly complex trials by using more and more weights or kept the trial set-up simple yet quickly moved the weights around many different positions. There were minimal pauses in-between test trials among both clusters of ineffective problem solvers. These differentiated interaction patterns were closely related to how well participants adopted specific problem-solving practices, including collecting data, recording data, interpreting data using domain knowledge, and reflecting on their progress towards a solution. Specifically, the difference in pause patterns provided microscopic behavioral evidence for how effective and ineffective problem solvers differed in their monitoring and management of problem-solving processes as noted in Schoenfeld (1981). While effective problem solvers were deliberate in considering and accommodating new information gained from each test trial, ineffective problem solvers largely resorted to unstructured exploration.

The finding that the absence of meaningful pauses during problem solving is associated with poor performance is consistent with previous research that used OELE-based tasks to study students' higher order thinking skills. For example, Amerish and Conati (2009) found that low-performing students paused significantly shorter on average than high-performing students when interacting with an OELE presenting artificial intelligence algorithms. Perez et al. (2017) reported that a strategic use of pauses during an inquiry activity in a circuit simulation is associated with productive learning outcomes. Wang et al. (2021) found that the occurrence of meaningful pauses can predict problem-solving performance above and beyond students' domain knowledge. Instances of pause during students' work process may foreground key cognitive and metacognitive processes involved in problem solving and inquiry and should be explored more fully in future research.

This study has important implications for how we assess students' proficiency in science and engineering practices, as well as for how to provide real-time feedback to help students improve their problem-solving practices in simulation-based tasks. As shown by the results of the cluster analysis, differentiating patterns already emerged in the first few minutes of students working on the task. Understanding which pattern a student's sequence of operation falls into would allow us to support and guide them with targeted feedback, potentially in real-time in the task environment. This would afford students the opportunity to iteratively adjust their problem-

solving approaches and acquire expert-like thinking and practices. In future studies, we will also explore whether students' problem-solving practices as captured by the brief simulation-based task are connected to their broader academic performance.

Hiroshima university, Japan

Abstract: The activities learners do in making summaries facilitate them to think more carefully than only reading. Although summary writing can be helpful both for fostering and assessing performance in reading, it remains a challenge for most learners, especially in languages learners are not familiar with. Moreover, summary writing can be a problem for students to master because some learners have difficulties identifying the main ideas from detailed information in the text. This study focuses on the issue of improving the performance of English as a foreign language (EFL) learners' summary writing skills by utilizing the kit-build concept map tool and text structure strategy. A web-based system has been developed, and an online cross-experiment has been conducted, with 75 Indonesian students at the intermediate level of language proficiency involved. Students' written summaries were collected and evaluated based on two indicators. The result indicates the effect of system use on improving the quality of summary is positive. It supports learners by helping them clarify important ideas and write summaries with organized information.

1 Introduction

Summary writing is a bridge that connects writing and reading. The writing of a summary plays a dual role in reading comprehension. It can both boost and measure reading comprehension: when learners are involved in writing a summary of a reading text, they need to attend more closely to what they are reading to communicate the text in their own words; on the other hand, they are supposed to demonstrate how they comprehend the given source text through writing (Mokeddem & Houcine, 2016). Ferris and Hedgcock claimed that learners summarizing what they are reading get involved in the process of reproduction which includes: (a) thorough comprehension of the source; (b) selection of the text's most salient information; (c) deletion of less-than-essential information; (d) comprehension and integration of the selected information; and (e) arrangement of selected material in a way that reflects the rhetorical structure of the original. When they start to write a summary, there are two main tasks. One is to sift through material, extracting the main ideas. The other is to integrate those important ideas or information, weaving them into a consistent expression of words. They are supposed to review the source text during this process, weighing each piece of information presented. Such activities mean that making summaries while reading will think more carefully than only reading. Therefore, summary writing is a conducive way to better performance in reading. By doing this, readers are required to concentrate on the overall comprehension of the source text compared to those who just focus on following the idea at the word or sentence level.

2 Problem and research goal

Although summary writing can be useful for fostering and assessing performance in reading, it remains a challenge for most learners. The situation could be even worse when it comes to a language that they are not quite familiar with, such as English as a foreign language (EFL) learner. Previous studies shed light on this issue. Researchers claimed that summary writing appears to be the most difficult to master (Lin & Maarof, 2013). It is "a highly complex, recursive reading-writing activity involving constraints that can impose an overwhelming cognitive load on students. (Kirkland & Saunders, 1991)" Othman (2009) stated that the result of her study based on the reports of 60 secondary school teachers revealed that learners have difficulties in differentiating between main ideas and supporting details from source texts. As mentioned before, the process of summarization can be mainly divided into two parts. Whether learners can properly pick the main ideas should be given great weight, and these choices significantly affect their summarization performances. Learners can never make a good summary if they cannot decide what kind of ideas should be given more weight. However, problems are far more than this. In light of other studies, students generally follow a strategy of copying sentences from the source text; have difficulty writing summaries with their own words (Kirkland & Saunders, 1991)(Othman, 2009).

Hutchins (1987) has claimed that summarization involves the understanding of texts. Kintsch and Van Dijk (1978)(1983) that discourse comprehension necessarily involves recognizing text structures and the ability to summarize. When it comes to the structure of a text, two notions should be made clear: the microstructure and

 © ISLS

the macro-structure. There is a basic distinction between these two terms. The micro-structure represents the relation between the sequence of sentences in the actual text. The macro-structure represents relations between blocks of sentences and the global organization of texts. These relations, at both levels, may be thematic and semantic. Thematic relations include anaphora, backward and forward reference, and topicalization. Semantic relations include cause-effect, time, and logical relations (Hutchins, 1987). Hutchins (1987) also stated that there is no unique summary for a text because summaries are expressions of the macro-structure of the source as interpreted by an individual in the light of background knowledge.

This study aims to try to tackle one or some of the problems discussed above to help EFL learners reach better performance in summary writing. The criteria applied to evaluate a summary focus on two perspectives. In terms of the content, whether learners' summaries contain main ideas (important information) from the original text as many as possible and to what extent the redundancy is. On the other hand, from the perspective of the organization of information, whether they can arrange their ideas in an organized way or whether their ideas are logically connected/integrated to follow the macro-structure of the source.

3 Method

The structure strategy teaches readers to identify the overall top-level structure of the expository text and to use that structure to organize their reading comprehension. Comprehension is defined as the synthesis of new ideas with existing memory structures using the framework of the structure strategy (Meyer & Wijekumar, 2007). Generally speaking, the top-level structure has five patterns: cause and effect, problem and solution, sequence, description, and comparison. The power of teaching students the structure strategy includes helping them follow the logical structure of text to understand how an author organized and emphasized ideas" and "help learners organize their writing such as written summaries" (Meyer & Ray, 2011). The structure strategy's main idea patterns give them even more help in identifying and strategically using the organization of the text." (Wijekumar et al., 2012) A concept map or conceptual diagram is a diagram that depicts suggested relationships between concepts (Hager & Corbin, 1997). Tajeddin and Tabatabaei (2016) also have stated the advantages of using concept mapping include: "allowing students to think deeply about concepts and to store information more effectively in their memory" and "helping students organize different concepts and visualize the relationships between the main concepts in a meaningful way." Chin et al. (2010) state the effectiveness of interactive feedback and automated assessment of concept maps. Kit-build concept map (Hirashima et al., 2015) is a digital tool derived from the common concept map and supports a concept map strategy (Pailai et al., 2017). The ability of Kit-build concept map includes a construction tool where users can construct concept maps and an automatic concept map assessment where the system can report diagnosis reports.

4. Function design

Dealing with summary writing as a whole would be a challenge for learners. Summary writing requires learners to have the ability to understand what is important and how the important ideas should be logically organized or related. To address this issue, an alternate is to decompose the task into certain sub-tasks. Based on this, learning activities carried by the system can be defined as follows:

1) **Kit-building on paragraph level**: In this step, learners can construct concept maps from given kits for each paragraph and get diagnosis feedback.
2) **Clarification of important information:** following the instruction of structure strategy. In this step, learners can pick up propositions, choose a structure for the proposition and clarify the roles of concepts. Feedback is also available.
3) **Integration of information:** identifying as a structure. In this step, learners can merge/integrate concepts. They can also split merged nodes in case of mistaken operation.

4.1 Kit-building on the paragraph level

To reach a summary with good quality, one premise is that learners need to understand each paragraph of the original text. By utilizing the kit-build concept map, learners can check the reflection of their understandings and see the difference between their comprehension and the instructor's comprehension. They can choose to modify their maps according to the feedback they get. Figure 1 shows an example of a kit decomposed from a concept map made by a teacher. In Kit-building, learners make propositions with the provided nodes and links for making a concept map of the reading text. This phase aims to make the same concept map as the teacher to understand what is written in the text correctly. The system provides feedback to learners on the difference between the learner's and the teacher's concept map, as shown in Fig.2. The solid arrows represent that the learner's link is

the same as the teacher's one, and the dotted arrows represent that the learner's one is not the same as the teacher's one.

Figure 1
An example of a kit for kit-building of a concept map.

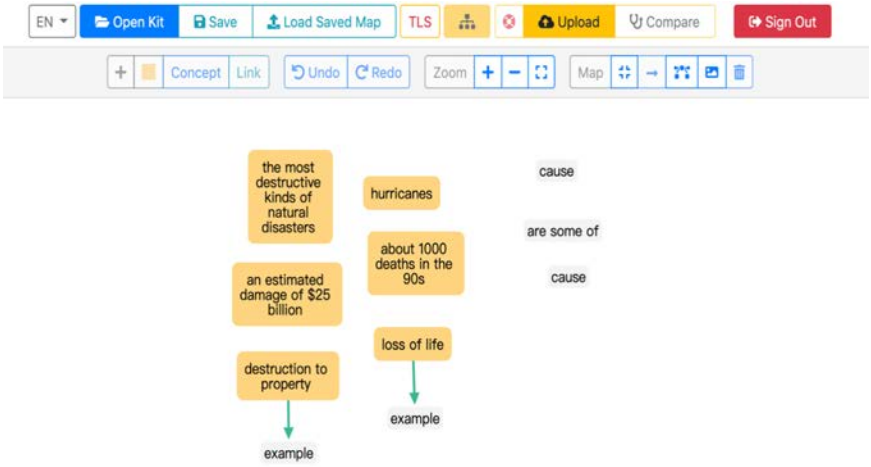

Figure 2
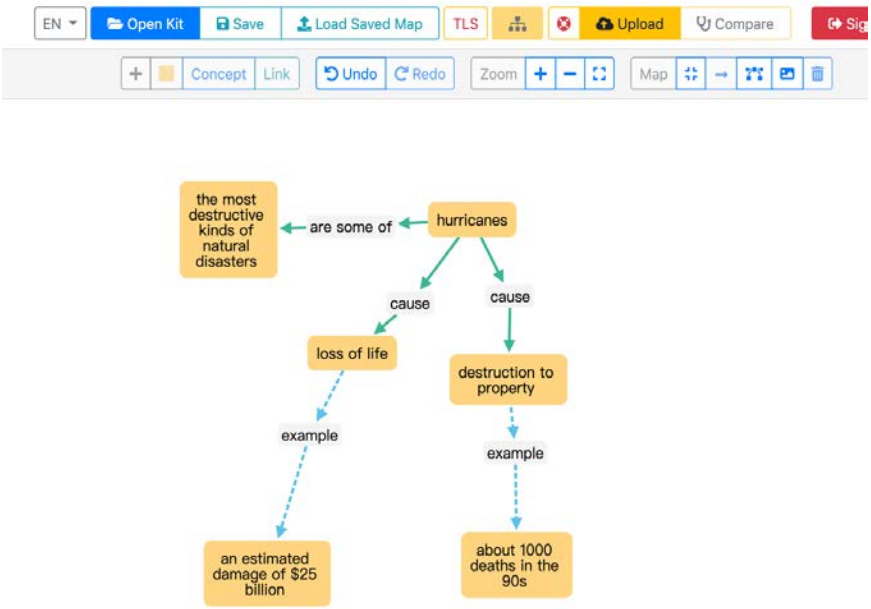
Feedback from the system.



4.2 Clarification of important information

Structure strategy focus on information that describes the relationship generalized into five patterns (or structures): problem/solution, cause/effect, sequence/time order, description, and contrast. That is, information that describes one of the five relationships mentioned above should be viewed as important information (This study only focuses on two structures which are problem/solution and cause/effect). In this phase, learners should identify whether the idea presented fits one certain structure. In the system, learners pick up important information by choosing important propositions from the concept maps they have made for each paragraph in the previous phase. Figure 3 shows the scene in which the system provides the list of propositions made in the concept map made in the previous phase. With this interface, learners put structure patterns on important propositions. For example, in Fig. 3, the learner identifies the second proposition from the top as an important proposition and puts a cause/effect structure on it. This means that "hurricanes" cause the *effect* of "distraction to property."

4.3 Integration of information

In the last step, learners comprise the text's main ideas by connecting important propositions picked up from each paragraph in the previous phase. To achieve a coherent summary, it is necessary to integrate the ideas. The structure strategy's main idea patterns can help them identify and strategically use the text's organization. In this phase, the propositions picked up by learners in the previous step are shown with the structural roles in Fig. 4. The task in this phase is that learners unify nodes and make a structure in which all the picked-up propositions are connected. Figure 5 is an example of a structured summary. The learner unified "hurricanes" linked with "distraction to property" and "loss of life." He also unified "loss of life" and "lives being lost" even though the labels differed. Like this, learners can unify nodes with different labels on their decision.

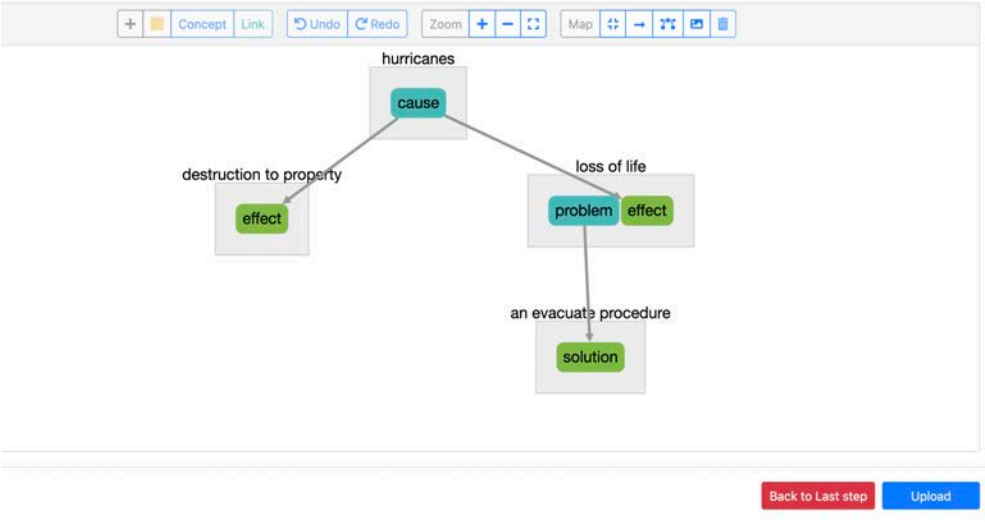
The structured summary (Top-level structure).



5 Experimental results

5.1 Experiment

An experiment was implemented involving 75 Indonesian college students (2 classes, class A: n = 38, class B: n = 37). Before the experiment, they all practiced with the system for 1 hour. The flow of the experiment is shown in Fig. 6. This experiment is designed and implemented to answer the following research questions:
1) Does the use of the system positively affect the quality of learners' summaries?
2) What aspect of quality of summary writing can be improved by the system?

Figure 6
The flow of the experiment.

5.2 Results

As shown in table 1 and table 2, there is a significant difference between results without and using the system. Parameter Main Points denotes the number of main ideas a learner mentioned in his/her summary. It evaluates their ability to clarify important ideas from the source. Redundancy refers to the number of information that is less essential. Integrated ideas show the number of pairs of ideas from different positions or paragraphs a leaner integrated into his/her summary. These tables show that their scores of main points and integrated ideas increased while their redundancy decreased with the use of the system. An increase in scores of main points means that students' summaries focus more on the important information. A decreasing redundancy indicates the conciseness of their summaries has been improved. With the use of the system, learners' ability to identify what kind of information is salient and the ability to get rid of less-useful information has been improved. An increase in integrated ideas implies that learners can better see global connections among ideas by using the system. Global connections point to the global organization of the text. It is a sign of a better arrangement of information.

Then we checked the average map scores and top-level structure (TLS) map scores and the qualities of their summaries between the classes. We can tell from Tables 3 and 5 that there are significant correlations between the TLS map score and the number of pairs of information integrated. For Global Warming, only a marginally significant difference between the TLS map score and the number of main ideas. At the same time, there is a significant correlation between them in Poaching. However, there seems to be no strong correlation between the KB map score and other parameters used to evaluate the summary's quality. Based on this result, table 4 and table 6 imply a significant positive linear relationship between TLS map scores and the number of integrated information. Therefore, they will have a good performance in the combination of ideas. Good use of a TLS map can help them see the connection between ideas and thus lead to a good arrangement or organization of these ideas. As for the relationship between the TLS map score and main ideas, table 6 shows no significant relationship between these two.

Table 1
Result of nonparametric test on summary writing performance (Global Warming)

	Median		p value
	Without system use	With system use	
Main points	3.000	4.000	0.007**
Redundancy	3.000	0.500	<0.001**
Integrated ideas	0.000	1.000	0.001**

Independent variable	Dependent variable		
TLS map score	Main points	0.059	0.147
TLS map score	Integrated ideas	0.201	0.005**

Table 7 and Table 8 show another parameter: structural organization. This parameter denotes whether information within a summary follows a structural organization. Following a structural organization means information in such summaries is well-arranged and is logically connected. By contrast, not following a structural organization means information in summaries is simply listed, and the logical relationship between information has been omitted. The result of binary logistic regression shows a positive relationship between the TLS map score and the possibility of following a structural organization. This result means the better the TLS map a learner makes, the higher possibility his/her summary could have followed a good structure.

Table 7
Parameter estimates (binary logistic regression) for Global Warming

Parameters		Coeff	Std. Err	p value	OR
Independent variable	Dependent variable				
TLS map score	Structural organization	0.030	0.012	0.013	1.030

Table 8
Parameter estimates (binary logistic regression) for Poaching

Parameters		Coeff	Std. Err	p value	OR
Independent variable	Dependent variable				
TLS map score	Structural organization	0.034	0.015	0.029	1.034

There is a gap between the two classes' AVG TOEIC scores (426 versus 501). Table 9 and Table 10 show that the correlation between TOEIC scores and learners' performance in summary writing is weak.

Table 9
Result of correlation test between-group AVG TOEIC score and other parameters (class A)

		Main points(GW)	Redundancy(GW)	Main points(P)	Redundancy(P)
group AVG TOEIC score	coefficient	0.161	-0.188	-0.013	-0.132
	p value	0.404	0.328	0.949	0.495

Table 10
Result of correlation test between-group AVG TOEIC score and other parameters (class B)

		Main points(GW)	Redundancy(GW)	Main points(P)	Redundancy(P)
group AVG TOEIC score	coefficient	0.068	-0.028	0.162	-0.283
	p value	0.671	0.858	0.304	0.070

6 Concluding Remarks

According to the results, we can now answer two research questions remained. First, the use of the system has a significant positive effect on the quality of learners' summaries. With the support of the system, the content of learners' summaries contains more important ideas and is more concise than those without using the system. On the other hand, students tend to easily see connections between ideas. The way they arrange information within their summaries has also been improved with the support of the system. The three learning activities integrated into the system each contribute to each step of summary writing. The use of kit-build concept mapping and its instant feedback positively affects learners' summary writing. The application of structure strategy helps learners clarify essential information; TLS mapping is conducive to seeing the connections between ideas and organizing ideas.

Acknowledgments

The authors would like to thank Dr. A. Pinandito for his technical assistance in developing the system. We also thank Ms. Nurmaya for the opportunity to conduct the experience at a university in Indonesia.

Indian Institute of Technology Bombay, Mumbai, India

Abstract: Participant retention in online learning has often been discussed as a challenge in educational research. During 2020-2021, the existing challenges were burdened by the COVID-19 pandemic. This study explores certain engagement techniques with participants through an online project-based learning mode provided as a part of a nationwide robotics competition during the pandemic. 54 teams (176 participants) from 42 institutions participated in the competition to build a sophisticated Field Programmable Gate Array (FPGA) architecture. The study aims to understand participant engagement, the effect due to COVID-19 pandemic and lockdown, personal development due to competition, and the effect of scaffoldings and guided efforts. Despite the challenges due to the pandemic, additional scaffolding and guided efforts lead to approximately 24% of teams successfully building the architecture. This is similar to an average of 26% in pre-pandemic editions of the competition without these additional scaffolds. These efforts and mode of learning are thus found to successfully engage participants during pandemic.

Introduction

With technological advancements, online learning gained popularity (Hung & Chou, 2015; Peltier et al., 2007) and provided opportunities to learn from renowned faculty and universities in a distance mode (Phatak, 2015). However, participation, satisfaction, and retention in online learning has been a challenge that is continuously researched by the educational community (Alqurashi, 2018; Panigrahi et al., 2018). COVID-19 followed by lockdown forced educational institutions across the globe to adapt to online learning in 2020 (Patricia Aguilera-Hermida, 2020). The pandemic and lockdown led to several new challenges for online learning. It tested the readiness of teachers to adapt to online learning (Scherer et al., 2021), student's preparedness for the same (Alshurafat et al., 2021), and innovativeness in the educational systems (Pokhrel & Chhetri, 2021) to face the new challenges in changing times. The closure of universities for the physical presence of students and teachers forced researchers to explore new ways of engagement, especially for implementing pedagogies such as project-based learning in an online mode (Charania et al., 2021). Thus, participant retention and providing an apt learning experience became even more challenging. Adequately planned and designed instructions are needed for online education in such crises to achieve learning goals (Adedoyin & Soykan, 2020).

Due to pandemic situations, learning has also been affected due to lifestyle changes (Lee et al., 2021), fear in the community due to pandemic (Hall et al., 2008) causing increased stress and anxiety (Hasan & Bao, 2020; Rehman et al., 2021), etc. Attempts are being made continuously to provide as much engaging learning experience as possible in the online mode. These attempts are not only to make the learning experience similar to the in-person mode of learning but also to support and motivate students through conversations and collaborations (Yates et al., 2020). These conversations are found to foster knowledge construction among participants, especially through discussion forums leading to collaborative learning (Sun et al., 2018). This collaboration among peers and with instructors is also found to influence learner retention by keeping participants engaged (Hone & el Said, 2016; Peltier et al., 2007). To further keep participants engaged, a well-orchestrated learner-centric course that understands and addresses learner needs and enables them to learn by doing also results in better engagement (Murthy et al., 2018). Apart from engagement, the learning experience design also plays a crucial role in learner retention. Studies have found course design as an important factor in guiding learner retention as well as in achieving learning goals (de Freitas et al., 2015; Lai & Bower, 2020; Rayyan et al., 2016).

Thus, various factors affect learner engagement in online learning. However, the existing literature does not discuss the effect of these factors in pandemic situations in massive project-based learning conducted in an online mode. This paper explores the effect of various scaffolding and guided efforts on participant's experience in such a learning experience. We study the experience of participants in the e-Yantra Robotics Competition (eYRC). eYRC is a massive online robotics competition with typically 10000+ participant conducted in a distance mode. This competition is conducted annually during September to March by e-Yantra (a project funded by the Ministry of Education, Govt. of India) at the Indian Institute of Technology Bombay since 2012. In eYRC,

 © ISLS

students from undergraduate engineering, polytechnic, and science colleges participate as a team of four. These teams are allotted a problem statement called a "theme" which is an abstraction of a real-world problem. Each theme requires teams to learn and implement complex robotics and embedded systems tasks to win the competition. Participants learn these skills at a distance in a project-based learning mode (Krithivasan et al., 2015). The competition is conducted in two stages wherein the first stage provides all the participants with the basic knowledge and trains them in the skills required for solving the theme. Typically, 25% of the top-performing teams in the first stage are qualified for the second stage of the competition. In the second stage, teams are given all the necessary hardware to implement the learnings to solve the theme problem. They are provided with more resources, tips, guidance, and doubt clearing through discussion forums and online sessions to build a robot for solving the theme problem statement. They are provided with a document called "Rulebook" that describes this problem statement and the evaluation criteria in detail. The overall problem is divided into three sub-problems. These sub-problems are given as tasks.

In this study, we attempt to answer the following research questions pertaining to the second stage of a theme called "SankatMochan Bot" in the competition conducted during COVID-19 lockdown (December 2020 to March 2021):

(RQ 1): What was the level of engagement of participants as they complete the competition?
(RQ 2): What are the self-rated effects of COVID-19 and lockdown on the performance of participants?
(RQ 3): How do participants report the impact of competition on personal development?
(RQ 4): How do participants perceive scaffolding and guided efforts?

SankatMochan Bot

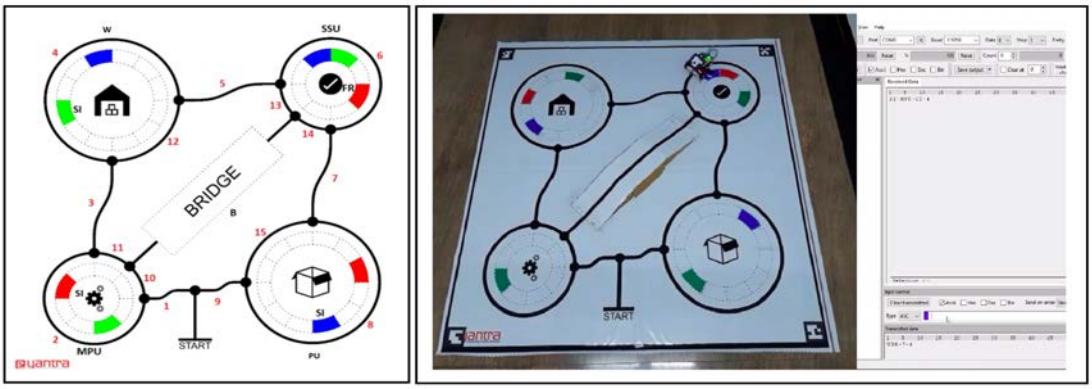
Theme Play: Problem

"SankatMochan" is an Indian word in Hindi language that can be split into *sankat (danger)* and *mochan (saviour)* to resemble someone who saves a person in danger. "SankatMochan Bot" is an abstraction of an Industry 4.0 problem where teams build a robot to identify potential dangers/threats and act before any crisis. Figure 1 (a). shows a 6ft x 6ft arena that represents the various units of an industrial plant. These units are called Warehouse (W), Main Processing Unit (MPU), Packaging Unit (PU), Safety Services Unit (SSU). On the arena, the units are represented as circles, and are connected by a black-lined path for the robot to navigate. The path is divided into sections identified by numbers as shown in the figure. There is an elevated path called "BRIDGE" that connects MPU and SSU directly. Colored patches are placed in W, MPU, and PU on the arena to indicate industrial faults. For example, fire, chemical spill, and circuit trip are indicated by red, blue, and green color patches. Their remedies are the same color patches present in the SSU. The teams had to build an autonomous robot that begins at the "START" and navigates through PU, MPU, and W checking the safety status at each unit using a color sensor. As soon as the robot identifies a fault, it indicates the same by glowing a corresponding color on the Red-Green-Blue (RGB) LED and communicating to a computer system through wireless communication. It then reports to SSU, identifies remedies for the faults found, and turns OFF the corresponding LED. Finally, it wirelessly communicates the fault resolution to the computer system.

Theme Play: Tasks

Participating teams were guided through three tasks to solve the theme problem statement in the final task. The first task had two parts which were printing the arena on the flex sheet and testing the hardware. The teams received all the major hardware along with their datasheets and manuals to build the robot. Some of the major components included a Field Programmable Gate Array (FPGA) board, color sensor, line following sensor, ZigBee module, motors, motor drivers, wheels, battery, etc. All these components were tested by the participants as per the instructions provided in the first task. In the second task, participants had to build a robot using the provided components to autonomously follow the line and encircle one of the units on the arena. The robot also had to identify a color patch and establish wireless communication with the computer system. In the third task, participants had to make the robot traverse autonomously through two units. The robot was required to use the bridge and identify the faults as it encountered them and communicate wirelessly to the computer system. In this task, teams integrated all the modules which they had developed in previous tasks. This task was a mini version of the final problem statement and aimed to prepare participants for the final task. In the final task, participants were given a configuration (placement of color patches, a combination of unavailable paths, etc.) of the problem statement to be solved. Figure 1 (b). provides a snapshot of the theme run of one of the teams showing the robot traversing the arena and the messages displayed on the computer system.

Figure 1
Arena and theme run on arena



(a) (b)

Scaffolding and guided efforts

We aimed to keep the participants engaged in the competition and to ensure that maximum teams complete and submit the final task. For this, teams were provided with various scaffolds and were guided through various activities during the tasks. One of the scaffolds was the structuring and problematization of the final problem. In the literature, these are found to be effective scaffolds to change the task so that it helps learners accomplish it, which otherwise would be out of the learner's reach (Reiser, 2004). The competition was structured and the entire implementation for the final problem statement was broken into different tasks. Some major technical challenges were to design a robot with FPGA (acting as a brain), wireless communication, sensor interfacing, path planning, bridge traversal & algorithm design using concurrent programming. These challenges were divided into different tasks as described earlier.

A thorough understanding of the problem statement in the first place is necessary to solve the problem. This problem statement with rules and scoring formula was described in the rulebook provided to the teams. A quiz was provided to the participants that gave them an opportunity to test their understanding of rules through taking this quiz enabling them to learn by doing (Murthy et al., 2018). In this quiz, they were provided necessary hints and were directed to relevant sections of the rulebook for incorrect answers. They could attempt the quiz multiple times until they have thoroughly understood the problem statement and rules.

Apart from scaffolding, instructor-student engagement plays a significant role in ensuring continuous participation and apt learning experience in online learning mode (Hone & el Said, 2016; Peltier et al., 2007; Petronzi et al., 2016). We used Piazza (https://piazza.com/) to facilitate interaction among students and instructors. This platform was available for students to clear their doubts 24x7. Piazza also provided an opportunity for peer-to-peer interaction where other participants can help to clear the query. Being a competition, they were instructed to help each other but not to publish or share the solution. Apart from query resolution, each week on Monday and Thursday, instructors posted hints and tips called Monday Mantras and Thursday Tips. These posts aimed to help participants get different perspectives on the problem and develop various approaches to test and debug solutions and guide them to be informed designers (Crismond & Adams, 2012). To further assist teams, instructors conducted three online doubt clearing sessions through video conferencing during the competition. These sessions were intended to resolve doubts and queries that were difficult to be addressed on the discussion forum. Furthermore, one-to-one interaction was also conducted where instructors guided teams on their approach to solving the problem, clarified their doubts, and motivated them to complete the competition.

Method

Participant Details

In the second stage of the competition, 54 teams (176 students) had participated. These participants were undergraduate engineering students from 42 institutions and various engineering streams. This included 146 participants from Electrical, Electronics or Electronics & Communication Engineering, 15 participants from Computer Science and Information Technology and 15 participants from other streams such as Mechanical (8), Mechatronics (4), and Robotics and Automation (3). Among the 176 participants, 56 were in the final year of their engineering, 95 in the third year, and 25 participants in the second year of engineering. There were 120 male participants and 56 female participants.

Data Collection

Online feedback was taken after submission of the final task to understand the experience of participants through a questionnaire. These questions were based on various aspects of online learning and pandemic situations found in literature, as discussed earlier. Participants were asked to rate theme design, competition structure, doubt clearing through the discussion forum, live interaction, rulebook quiz, weekly tips, hints, etc., and the perceived impact of lockdown. They were also asked if they had COVID-19 cases at their home which affected their participation. Informed consent was taken from participants to use their feedback and demographic details for research purposes. Total 143 participants filled the feedback which is considered in this study.

Results

Participant engagement as competition continues (RQ 1)

To understand participant engagement, we first consider the trends of submission and completion of tasks. Table 1 provides participant engagement statistics regarding submission and completion trends and discussion forum activity. A score of 40% or more in a task is treated as task completion. We see an average 37.56% drop in submission at each task. A drop of 59.13% was observed till task 3 in the number of teams completing the tasks. We also observe that all the teams that submitted the final task also completed it. Four teams that could not complete task 3 were also found to complete the final task.

In terms of activity on the discussion forum, although the number of posts increased, the number of active participants significantly dropped in task 2. The participants were again active in task 3.

Table 1
Participant engagement in competition

	Count of	Task 1	Task 2	Task 3	Final Task
Submission and completion statistics	Submitting teams	54	30	19	13
	Completing teams	54	21	9	13
Discussion forum activity	Posts	277	339	265	230
	Active participants	60	26	44	31

Instructors also conducted 90-120 minutes of online doubt clearing sessions during task 2 and task 3 and a one-to-one session with teams during the final task. Total 36, 31, and 24 teams attended the doubt clearing session for task 2, task 3, and one-to-one session respectively.

Impact of COVID-19 and lockdown (RQ 2)

To understand the effect of pandemic and lockdown, questions pertaining to COVID-19 situations were asked in the feedback. In the feedback received from 143 participants, 86 mentioned no COVID-19 cases at their home, 21 mentioned having COVID-19 cases at home but it did not affect their participation, while 36 mentioned having COVID-19 cases at home which affected the participation. Due to lockdown, team members were not necessarily in the same locality and the required hardware was sent only to one member of the team. Feedback was collected from the participants to understand the impact of the availability of hardware. 43 participants reported not having access to hardware, 33 reported that they were able to visit their college and work in a group, 47 participants reported working together on hardware at other team members place and 20 participants reported having access to hardware at their own home. Table 2 provides the final task completion-wise statistics of COVID-19 impact and hardware access.

Table 2
Impact of COVID-19 and hardware access on completion of final task

	Impact	Final task complete	Final task not complete
COVID-19	No case – not affected	20	66
	COVID-19 case – not affected	4	17
	COVID-19 case - affected	4	32
Access to hardware	Yes	47	53
	No	3	40

Participants were also asked to provide their perceived experience if the competition had been in non-COVID-19 situations. The participant response collected on a 5-point Likert scale (5-Strongly Agree, 1-Strongly Disagree) is presented in Table 3. We see the participation of the teams is affected by COVID-19 situations and access to hardware due to lockdown. Also, the teams perceived better performance, learning, increased focus, less stress, and better time and work management in non-COVID-19 situations.

Table 3
Perceived experience in non-COVID-19 situations

Question	Subquestion	Rating	
		Mean	SD
If the same competition were conducted during a non-COVID-19 situation, you would have had	Better performance	3.94	1.13
	Better learning	3.78	1.25
	Increased focus	3.82	1.22
	Less stressed	3.64	1.35
	Better Time and Work Management	3.72	1.36

Impact on personal development (RQ 3)

To understand the impact of competition on personal development, feedback was collected through a rating on a 5-point Likert scale (5-Strongly Agree, 1-Strongly Disagree). Table 4 provides the participant response. We find despite the impact due to COVID-19 and lockdown, participants have reported the competition to have helped in personal development.

Table 4
Personal development due to competition

Question	Rating	
	Mean	SD
I would prefer an individual format rather than team	2.72	1.47
My hands-on learning skills have improved	4.62	0.49
I have become a better Team Player after competition	4.52	0.5
I have become more confident in taking up challenges	4.54	0.5
My "peer-learning abilities" (ability to understand concepts, information, etc. from teammates and peers) have improved	4.54	0.5

Effect of scaffolding and guided efforts (RQ 4)

Table 5 provides the response of participants pertaining to various scaffolding and guided efforts on a 5-point Likert scale (5-Strongly Agree, 1-Strongly Disagree). We observe that participants appreciated the scaffolding and guided efforts to have helped them keep engaged in the competition.

Table 5
Feedback on scaffolding and guided efforts

Question	Subquestion	Rating	
		Mean	SD
There was a gradual increment in task difficulty		4.08	0.97
Discussion forum was effective in doubt-clearing		4.24	0.66
Following was helpful and encouraging to continue participation	Doubt Clearing Session	4.34	0.77
	Motivation by mentor on Piazza	4.26	0.75
	One-to-one interaction	4.44	0.61
	Thursday Tips and Monday Mantras	4.02	0.8
	Rulebook Quiz	4.18	0.63

To further understand the impact of these scaffolds, we consider the completion rate of past year's competition. Table 6 provides the percentage of teams completing Stage 2 in the previous four years (pre-pandemic) (e-Yantra, 2021). In these years, participants worked on similar problems with similar technologies having the same level of difficulty and complexity. The competition format (participation as a team, breaking problems into tasks, use of discussion forum, providing hardware, etc.) was also similar. However, the scaffolding and guided efforts such as more engagement through weekly posts, online doubt clearing sessions, one-to-one

interactions, and rulebook quiz were introduced in this edition to keep participants engaged. As we see, the average completion rate is 24.07% for the current year compared to 26.15% for the previous four years. Although the completion rate has not improved, but it is similar to that in pre-pandemic years. Thus, the effect of these efforts is evident in keeping participants engaged.

Table 6
Comparing the completion rate with pre-pandemic editions

Year	% teams completing the competition in Stage 2
2020-21	24.07
2019-20	34.44
2018-19	26.67
2017-18	19.47
2016-17	24.03

Discussion

The competition discussed in this paper is conducted annually since 2013 and has received an immense response from students (Sabanwar & Arya, 2019). However, during 2020-2021, in a pandemic situation, many factors were different. The team members were not necessarily at the same place. This hindered the participants from effective meetings and discussions necessary for collaborative learning (Kolodner et al., 2009). This effect could be implied from the gradual decrease in the submission rate in the tasks. As the tasks become difficult, more collaboration and brainstorming among participants becomes necessary. Although participants had various online modes of collaboration such as video conferencing, hardware availability became another obstruction in participant retention. The hardware kit to solve the theme problem was available to only one team member. As a result, only the team member having access to hardware could undertake robot building, testing, and all other tasks which also leads to increased load, resulting in dropout (Bawa, 2016). Thus, among the participants completing the final task, we see the majority of the team members had access to hardware (47 of 50).

Studies have found the pandemic situation impacting learner engagement due to changes in lifestyle, increased stress, and anxiety (Hasan & Bao, 2020; Lee et al., 2021). This paper also shows a similar impact. Almost 50% of the participants that did not complete the final task reported their participation was affected due to COVID-19 cases in their home during competition. Participants also reported COVID-19 situations to influence their experience. Their feedback on perceived experience in non-COVID-19 situations highlights the aspects of non-course or learning-related factors influencing learner retention (Henderikx et al., 2018).

Understanding the challenges due to COVID-19 situations, various efforts were taken for participant retention. These efforts are found to help participants in continued participation. These findings are in line with previous studies to engage learners in online mode (de Freitas et al., 2015; Hone & el Said, 2016; Peltier et al., 2007). Studies have reported the pandemic situation to negatively affect learner engagement, satisfaction, and retention (Wang et al., 2021; Wester et al., 2021). However, the extra efforts to scaffold the learning and motivate participants in this edition of the competition resulted in continuous participation and similar retention rates as during pre-pandemic editions of the competition.

Participants reported a positive impact of competition on their personal skills. Although all members did not get the opportunity of working on hardware, the collaborative activity helped them contribute at their own level leading to learning (Alibali & Nathan, 2018; Lave & Wenger, 1991). Despite the issues in collaboration due to online mode, participants preferred to work in teams rather than individually. Thus, even in these challenges, the competition achieved various project-based learning goals (Krajcik & Blumenfeld, 2005).

Conclusion

This study discussed various efforts for participant retention in a massive online robotics competition conducted during COVID-19 lockdown. Our study shows that the pandemic situation has impacted the participants performance. Apart from the impact on performance, pandemic also impacted their learning and focus leading to increased stress. Scaffolds such as a gradual increase in task difficulty, doubt clearing, and continuous engagement through the discussion forum and online interactions through video conferencing helped in keeping participants engaged in the competition. As a result of these efforts, despite the pandemic, the completion rate was 24% which is similar to that in the pre-pandemic situation. The study is based on participant feedback through an online self-reported survey. This limits the generalization of findings in this scope. Further studies with more ways of data

collection and application of the scaffolding efforts in other domains (other than engineering education) can confirm the findings discussed to be generally applicable.

"It's good because he said so" — The Effects of Pre-Service Teachers' Passive vs. Constructive Engagement on Technology Acceptance

Tugce Özbek, Christina Wekerle & Ingo Kollar
tugce.oezbek@uni-a.de, christina.wekerle@uni-a.de, ingo.kollar@uni-a.de
Augsburg University, Germany

Abstract: Pre-service teachers' rather suboptimal use of technology in teaching may be explained by low levels of technology acceptance. We assumed that encouraging pre-service teachers to constructively engage with information about technology rather than passively reading information about tools should increase their perceived usefulness (PU), perceived ease of use (PEU) and intention to use (ITU). *N*=53 pre-service teachers were either asked to read a blog post about the potential of a mind mapping tool (passive condition) or to work on small tasks that covered the same informational aspects as the blog post (constructive condition). Contrary to our assumptions, reading a blog post significantly contributed to pre-service teachers' PEU and PU (in tendency) compared to working constructively on open-ended tasks. The results also suggest that it may be necessary to differentiate between the learning activity that is prompted and the activity that is performed. Possible explanations for these effects will be discussed.

Introduction

Digital technology is attributed great potential to facilitate student learning in the classroom. For example, quiz apps can help to incorporate activities that are associated with higher levels of engagement and knowledge change processes of the learners (Sung et al., 2016). However, teachers only partially make use of technology affordances to engage students in high-level learning activities (Sailer et al., 2021).

In the past two decades, a number of researchers have sought to determine what may prevent teachers from an effective use of digital technology in the classroom (e.g., Eickelmann & Vennemann, 2017; Ertmer & Ottenbreit-Leftwich, 2010). For example, low technological pedagogical content knowledge can lead to teachers not using digital technology in a way that is beneficial for learning (Pamuk, 2012; Joo et al., 2018). Also, a possible lack of technology acceptance might be a potential factor of maladaptive use of digital technology, and prior research seems to support this concern (Backfisch et al., 2021). In addition, German teachers in particular show less positive attitudes than teachers from other countries regarding the results of learning with digital technology (Fraillon et al., 2019).

Therefore, since intervention studies that target pre-service teachers' technology acceptance are rare (Kale, 2018), the objective of this study is to determine how pre-service teachers' technology acceptance may be promoted when engaging with information about a particular digital tool. More precisely, the aim is to investigate whether having pre-service teachers engage in different kinds of learning activities (passive vs. constructive; see Chi & Wylie, 2014) while interacting with information on a particular digital tool has differential effects on their technology acceptance.

The technology acceptance model (TAM)

The design of appropriate learning opportunities may be informed by the Technology Acceptance Model, originally developed by Davis (1986). It points to users' perceived usefulness (PU) and perceived ease of use (PEU) of a technology as relevant factors that influence both the intention to use a certain digital technology and its actual use, with the perceived ease of use having a direct influence on perceived usefulness (see Fig. 1).

Davis defined perceived usefulness (PU) as the degree to which a person believes that using a particular technology would enhance her/his job performance. In the case of teachers, Scherer et al. (2015) showed that teachers found those tools useful that promoted learners' interest and learning outcomes. In contrast, perceived ease of use is defined as the degree to which the person believes that using the particular technology would be free of effort (Davis, 1986), for example, whether a teacher finds the user interface of a tool easy to understand. Both beliefs were hypothesized to be directly influenced by external variables (Venkatesh & Davis, 2000), such as system features or user training (Chuttur, 2009; Venkatesh & Davis, 1996).

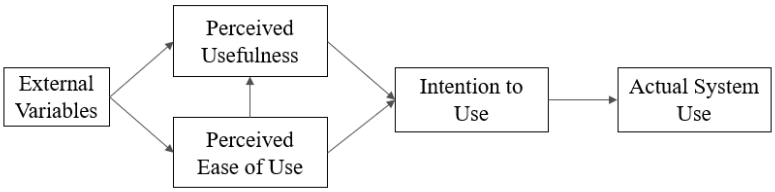
Figure 1
Technology Acceptance Model (Venkatesh & Davis, 1996)



Existing research indicates that pre-service teachers' perception of the usefulness and ease of use of particular tools predicts their intention to incorporate them in their future teaching (e.g., Joo et al., 2018; Scherer & Teo, 2019). An extended form of the TAM with PU, PEU and subjective norm (i.e., perceived social pressure to perform certain behavior; Teo, 2010) explained about 43% of the variance for intention to use among Swedish pre-service teachers (Ma et al., 2005). Similarly, in a study by Teo (2009) in Singapore and Malaysia, TAM (PU, PEU and attitude towards computers) was able to explain 27% of the variance in pre-service teachers' ITU (Teo, 2009). Scherer et al. (2019) also found in a meta-analysis that TAM is applicable to both pre- and in-service teachers. For example, Sadaf et al. (2016) investigated predictors of student teachers' intention and actual use of Web 2.0 applications in a two-phase, sequential explanatory design with surveys (N = 189) and interviews (N = 12). They found that PU was one of the strongest predictors of intention to use and actual use of Web 2.0 applications. In addition, there was a significant positive relationship between intention and subsequent behavior of pre-service teachers (Sadaf et al., 2016). In a study by Yuen and Ma (2008), however, PEU was the only determinant to predict ITU.

Taken together, these results point to the importance of technology acceptance of digital tools for their actual use in the classroom. So far, however, research on how to positively influence the perceived usefulness and perceived ease of use of the technology, especially among pre-service teachers, is scarce (Kale, 2018).

Fostering pre-service teachers' technology acceptance with constructive learning activities

When teachers encounter digital tools that might support their teaching, they often do so on the Internet. For instance, there are websites and blogs that contain texts or videos that provide arguments for the effectiveness and usability of a given digital tool to be used in the classroom, such as "www.edutopia.org". In terms of TAM, such websites typically are designed in a way that is intended to facilitate the perceived ease of use and the perceived usefulness of the tool under scrutiny, for example by sharing the experiences of other teachers that report on their positive experiences with the tool.

From an instructional perspective, it however is questionable whether reading about the alleged advantages of a certain tool will be enough to positively influence the perceived usefulness and perceived ease of use on the side of a potential user of that tool. For example, based on the ICAP framework by Chi and Wylie (2014), it might be expected that having learners passively receive information about digital tools would probably be less effective than engaging them to productively interact with that information, for example by having them sort and weigh information about the tool in terms of its usefulness and ease of use.

More specifically, the ICAP framework defines cognitive engagement activities based on students' overt behaviors. It proposes that engagement behaviors can be categorized and differentiated into one of four modes: passive, active, constructive, and interactive (Chi & Wylie, 2014). The so-called ICAP hypothesis states that as students become more engaged with the learning materials, i.e., the more they move from an engagement in passive towards an engagement in interactive activities, the more their learning will increase, because each mode corresponds to a different set of underlying knowledge-change processes and a deeper understanding of the learning material. Thus, reading a website or a blog post would correspond to a *passive* learning activity. In this case, learners simply read a text or watch a video about a digital tool without doing anything else. This way, the received information is stored in an isolated fashion and not well integrated with existing prior knowledge (Chi & Wylie, 2014). In an *active* mode of engagement, learners manipulate the material, for example, by marking passages in the text. In this manner, prior knowledge is activated, and existing schemata may be completed. The new knowledge can then be applied in similar contexts, and there is a superficial understanding (Chi & Wylie, 2014). When learners engage in *constructive* learning activities, they create content that goes beyond the existing materials. This applies, for example, when learners draw concept-maps, take notes in their own words, or explain concepts. As a result, constructive activities are assumed to induce inference processes, whereby new information is integrated with prior knowledge. This way, a deeper understanding and transfer of the learning material can

take place (Chi & Wylie, 2014). Finally, being *interactive* requires that learners refer to other learners' ideas, for example by arguing in dyads or small groups about a digital tool. This enables learners to generate new knowledge together through interaction and the opportunities for sharing feedback or ideas that come with it. According to the model, this activity has the potential for an in-depth understanding of the learning material and the greatest possibilities for developing new ideas together.

A study by Menekse et al. (2013) confirmed the ICAP hypothesis in a study with engineering students. They investigated the effects of all four modes of engagement on learning outcomes in a learning unit on atomic bonds and crystal structures. With respect to the comparison we intend to investigate in our study, the results showed that students' knowledge significantly increased in the constructive condition in which students were instructed to interpret a diagram that contained information from a text compared to the passive condition (in which students only read the text) from pre- to posttest. However, a few studies also suggest that under some circumstances, passive learning may be more beneficial for learning success. For example, MacDonald and Frank (2016) showed that learners perform better in sequences in which they first passively and then actively engage with the learning material than vice versa. For this reason, it is questionable whether higher-order learning activities as defined by the ICAP model are generally associated with higher learning success than passive learning activities. Even though the ICAP model does not focus on the effects of student engagement in these different kinds of activities on attitude change, but rather on knowledge acquisition, it is conceivable that a more comprehensive knowledge about the tool, such as its potential or application scenarios, might be positively related to technology acceptance. Therefore, student engagement in constructive activities should be beneficial for reaching higher levels of PU, PEU, and ITU. However, this has not yet been investigated in previous research. Thus, the aim of this study is to compare the effects of passive and constructive learning activities on the technology acceptance of pre-service teachers.

Research questions and hypotheses

In this quasi-experimental study, we provided pre-service teachers with information about a specific digital tool that might be used in the classroom to support student learning. We then created two experimental conditions: In one condition, students just read a blog post about the tool (passive condition), while in the other, students were instructed to perform six constructive tasks covering the same aspects as the blog post.

Consequently, our research question was: To which degree does an engagement in constructive learning activities while learning about the potentials of a certain digital tool (compared to an engagement in passive activities) have a positive effect on pre-service teachers' (1) PU and (2) PEU and (3) ITU of technology?

Based on ICAP, we assumed that because an engagement in constructive activities should result in deeper processing of information about the tool than an engagement in passive activities, student engagement in constructive compared to passive learning activities should contribute to higher perceived usefulness (H1), higher perceived ease of use (H2), and an increased intention to use the tool (H3).

Method

Participants and design

A total of 53 pre-service teachers participated, who were on average 22 years old (MAge = 21.42, SDAge = 4.18). The majority of our participants were in their second semester (MSem = 1.94, SD = .99) and mostly female (approximately 69.8%). They took part in an online experiment that was embedded in a psychology lecture, which was compulsory for all students. They received course credit for participation. Establishing a 1x2 between-subjects design, students were randomly assigned to a passive or a constructive condition (Npassive = 25, Nconstructive = 28). According to their allocation, participants in each condition had to carry out one passive or several constructive tasks related to a specific digital classroom tool (see below).

Procedure

After completing a survey that asked for demographic data, participants received basic information about an online collaborative mind mapping tool, called Coggle (https://coggle.it/). The user interface of the tool and an example for a mind map were shown. As a short description of its features, it was stated that Coggle can be used to generate collaborative mind maps in real time. This way, participants should get a rough idea of the tool, even if they were not familiar with it yet. After that, they were asked to rate its PU, PEU and ITU.

In a next step, all participants read a one-page text about the ICAP framework to help them understand the subsequently presented learning-related potentials of the tool. Then, participants in the *passive* condition were asked to read a blog entry of a fictitious teacher who described his personal experiences handling the tool and who addressed its usefulness by referencing the ICAP framework. In the *constructive* condition, participants

worked on six, mostly open-ended exercises covering the same informational aspects as the blog entry. For example, in the first task of the constructive group as well as in the blog post, there was a labelled illustration of the user interface of the tool. Participants in the constructive condition were instructed to inspect the illustration and to describe the illustrated functions of the tool in a text field in their own words. In the blog post of the passive group, the functions are described in sentences by the teacher. Furthermore, in a second task, a diagram from an article by Menekse et al. (2013) about learning success in a knowledge test after performing different learning activities was presented. The constructive group was instructed to interpret the graph in their own words in the light of the ICAP model. The same graph was also included in the blog post. There, the teacher talked about the results of the study and described the graph. In addition, for example, participants in the constructive condition were instructed in another task to develop usage scenarios of the tool based on the ICAP model, whereas participants in the passive condition could read about the usage scenarios of the fictitious teacher in the blog post. In the posttest, participants rated their PU, PEU and ITU again.

Variables

The scales used to measure PU, PEU and ITU were adapted from Hu et al. (2003), Teo (2011) and Venkatesh et al. (2003) and were reformulated to fit the tool "Coggle". Before and after the intervention, participants were asked to rate its PU (5 items, e.g., „Using Coggle would enhance my job performance", Cronbach's α=.90) and PEU (5 items, e.g., „I find it easy to get Coggle to do what I want it to do", Cronbach's α=.75) and ITU (4 items, e.g., „I intend to use Coggle in my lessons in the future", Cronbach's α=.84) on a Likert scale from (1) do not agree to (4) totally agree.

Statistical analyses

To examine our research question, we performed three separate mixed ANOVAs. The condition represented the between-subjects factor (passive vs. constructive), whereas the within-subjects factor was time (pre- vs. posttest). The alpha level of all analyses was set to 5%.

Results

Effects of engagement in passive vs. constructive activities on PU, PEU, and ITU

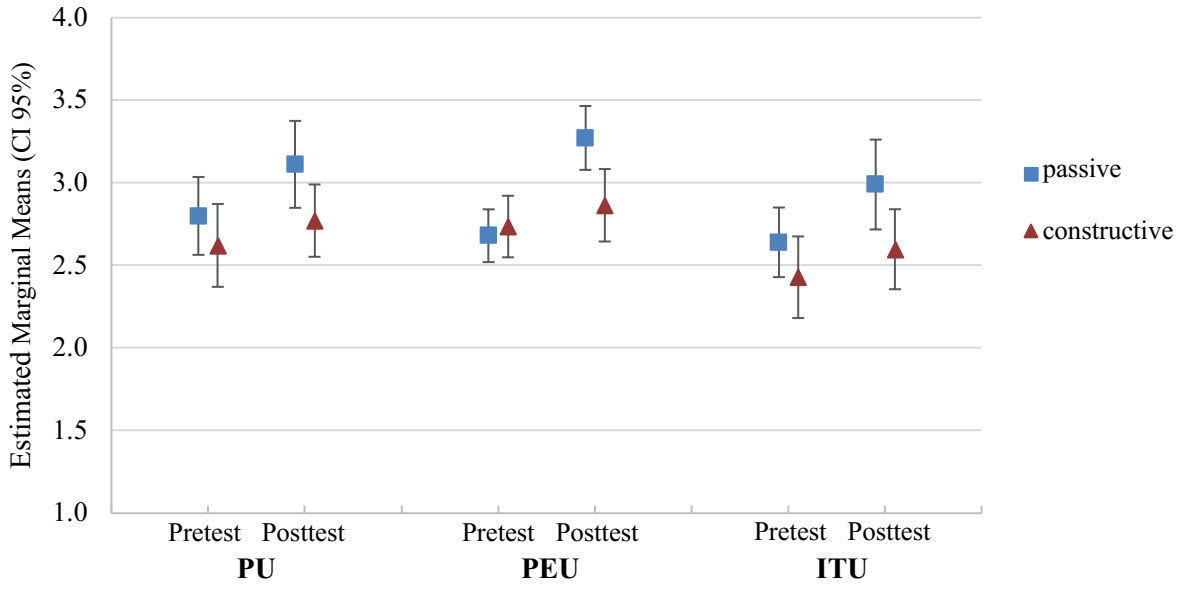
Concerning H1, figure 2 illustrates the descriptive statistics for PU for both groups. Descriptively, the means of both groups were higher in the posttest than in the pretest, and learners from the passive condition generally (i.e., both in pre- and posttest) displayed higher values of PU than learners from the constructive condition.

A mixed ANOVA with condition (passive vs. constructive) as between- and time as within-subject factor did not result in a significant interaction for PU, $F(1,51) = 1.15$, $p = .29$, partial $\eta^2 = .02$. A main effect of group was only significant by tendency in favor of participants in the passive condition, $F(1, 51) = 3.04$, $p = .087$, partial $\eta^2 = .06$. However, the increase of PU over time for both conditions was significant, $F(1, 51) = 9.38$, $p = .004$, partial $\eta^2 = .16$.

Regarding H2, figure 2 illustrates that PEU increased over time for both conditions, with a more pronounced increase from pre- to posttest in the passive condition. Subsequently, a mixed ANOVA with condition as between-subjects factor and time as within-subjects factor and PEU as dependent variable showed a significant interaction effect, $F(1,51) = 8.88$, $p = .004$, partial $\eta^2 = .15$, albeit in an unexpected direction. The simple main effect of condition was significant in the posttest, partial $\eta^2 = .14$ $p = .006$. The simple main effect of time was significant in the passive condition, $F(1, 24) = 44.95$, $p < .001$, partial $\eta^2 = .65$, but not in the constructive condition, $F(1, 27) = 1.08$, partial $\eta^2 = .04$, $p = .31$.

With respect to H3, figure 2 shows that ITU increased over time in both conditions. For ITU, an analogous mixed ANOVA with condition as between-subjects factor and time as within-subjects factor and ITU as dependent variable did not result in a significant interaction ($F(1, 51) = 1.15$, $p = .25$, partial $\eta^2 = .03$). However, the main effect of condition was significant, $F(1, 51) = 4.05$, $p = .05$, partial $\eta^2 = .07$, with students in the passive condition displaying a higher level of ITU than students in the constructive condition. There was a significant increase of ITU over time for both conditions ($F(1, 51) = 11.45$, $p = .001$, partial $\eta^2 = .18$).

Figure 2
Means and 95%-confidence intervals of PU, PEU and ITU by mode of engagement



Further analyses

Based on the hypotheses, these results were rather unexpected. Therefore, we wondered to what extent participants in the constructive condition actually engaged in constructive activities (N = 28). For this reason, we looked at how extensively the tasks in the constructive condition were actually carried out. As a first indicator, we found that the number of words in the first task significantly and positively predicted the change in PEU between pretest and posttest, $F(1, 26) = 5.98$, $\beta = .48$, $p = .02$, indicating that the more constructive students were, the more positive they rated the PEU of the tool. However, the prediction of the change in PU was not significant, $F(1, 26) = .94$, $\beta = -.39$, $p = .34$.

Discussion

The present study was designed to determine the effects of prompting pre-service teachers to engage in passive and constructive learning activities on their acceptance of a particular kind of technology. The literature on technology acceptance provides very little information on the question of how technology acceptance can be influenced (Kale, 2018). Based on the ICAP framework by Chi and Wylie (2014), we assumed that a constructive engagement with learning material about the digital tool would result in a higher technology acceptance than an engagement in passive activities when being confronted with the tool. Yet, at least at first sight, our results do not provide much evidence for this assumption.

Regarding hypothesis 1, no significant interaction between time and group on PU was found. Nevertheless, the significant effect of time on PU suggests that participants' PU improved significantly regardless of condition. Thus, on the basis of this result, an engagement in constructive activities does not seem to have larger effects on PU than an engagement in passive activities. Obviously, reading about a fictitious teacher's positive experiences regarding the usefulness of digital tools may already suffice to boost PU in the intended direction.

Concerning hypothesis 2, we found a significant interaction effect for PEU. Contrary to our expectations, however, reading a blog entry passively seemed to have a stronger positive effect on PEU compared to working constructively on open-ended exercises. Moreover, this effect can be considered large (Cohen, 1988). Interestingly, the examination of the simple main effect of time also shows that only passively reading the blog post resulted in a significant improvement in PEU, but not performing the constructive tasks.

Finally, with respect to hypothesis 3 for ITU, the results show no interaction effect. Yet, a significant effect of time and group could be observed. The effect of time again suggests that participants' ITU improved regardless of their condition. In other words, both passive and constructive learning activities thus might be related to an improvement in ITU. Moreover, this effect can again be regarded as large (Cohen, 1988). Presumably, this

 © ISLS

can be interpreted as a result of the fact that PU and PEU were supposed to predict ITU and that similar effects were observed in the previous analyses (e.g. Joo et al., 2018; Ma et al., 2005; Teo, 2009).

Consequently, contrary to expectations, for none of the factors PU, PEU or ITU did the constructive tasks have a larger effect than reading the blog post. The only interaction effect indicates that reading a blog entry passively seemed to have (at least partially) contributed to pre-service teachers' more positive technology acceptance as compared to working constructively on open-ended exercises, having a significant effect on a more positive PEU. Also, the effect of reading the blog post on PU tended to be almost significant.

However, these initially surprising results could be explained in several ways related to the assumptions of the ICAP model: First, there may be differences between (a) the activities that learners are instructed to perform and (b) the activities that they actually carry out (Vogel et al., 2017). For example, learners may have been instructed to constructively summarise the functions of the tool, but then might simply have copied the information. This in turn would mean that they did not work constructively, but rather actively. This might also be concluded on the basis of the preliminary analysis on word count. The opposite scenario is also conceivable: Even if the learners were instructed to merely read the text information, it is possible that they thought more deeply about the content, such as explaining it to themselves. This in turn would mean that they elaborated on the content more than the ICAP model would assume (Chi & Wylie, 2014). For this reason, it is possible that the participants in the constructive condition showed a lower level of engagement or in the passive group a higher level of engagement than actually assumed. Ultimately, the ICAP model only ever refers to a probability that certain visible activities are related to the corresponding (possibly more profound) learning processes. Chi and Wylie (2014) recommend that the outputs generated by the learners should be analysed in order to arrive at an indication of which activity was actually carried out. It is possible that further analysis of learner responses could be helpful in uncovering such discrepancies. Beyond that, it is likewise conceivable that in this case a certain sequence of learning activities, beginning with passive learning activities, are better suited to promoting technology acceptance, similarly as in terms of learning success (MacDonald & Frank, 2016).

Yet, there are further possible explanations for our findings: For example, it might be that the constructive condition imposed high cognitive load on students, with the effect that they might not have had sufficient opportunity to invest effort in elaborating the information about the tool, as following the task instructions might have been too strenuous to follow. Indeed, research shows that working on complex tasks without further instructional guidance is particularly ineffective when learners have little prior knowledge (Kalyuga et al., 2001; van Gog, et al., 2008), which might have been the case for our sample of (beginning) pre-service teachers. In this sense, the tasks of the constructive condition might be seen as complex tasks in which the learners have not received any additional support. In contrast, the elaborated blog post of a teacher about the potentials and the use of the tool might be considered as a worked example to the constructive tasks, in which participants in the constructive condition had to generate the corresponding knowledge themselves. In view of the present sample of students in the second semester with a supposedly low level of prior knowledge, a so-called worked example effect might have occurred in the passive condition (Renkl, 2014).

The low level of prior knowledge is accompanied by another challenge: students with little prior domain-specific knowledge tend to overestimate their competences (Dunning et al., 2003). If students only superficially engage in a topic, they may mistakenly think that they have already grasped the learning content, although this is not always the case (Renkl, 2014). It is possible that reading the blog post and the teacher's explanations gave the students the impression that they had already comprehended the affordances of the tool. For this reason, the passive learners might underestimate the challenges occurring when using the tool and overestimate the PU or PEU of the tool accordingly. Consequently, future studies should control for learners' prior knowledge and assess their cognitive load. In light of this reasoning, it would then also be thinkable that the actual use in the classroom differs in a similar way and is, for example, associated with greater difficulties.

Limitations and conclusions

Of course, this study is not without limitations. Besides our rather small sample size, it is important to note that we exclusively used subjective data. Thus, we do not know whether students who indicated a high ITU would actually use the tool in their classrooms more often than students with lower levels of ITU. Second, applying ICAP (which actually focuses on learning processes and outcomes) on the build-up and change of attitudes might be an inappropriate theoretical stretch. Perhaps, taking more specific theories into account that may explain attitude change (such as Elaboration-Likelihood-Model, Petty & Cacioppo, 1986) might be more fruitful for the design of effective interventions.

Furthermore, it must be taken into account that we did not include a control condition without treatment. Also, follow-up studies are needed to test the sustainability of the effects. In addition, it must be examined whether the higher intention to use actually results in more frequent use in the classroom in the long term. Moreover, the

small sample size increases the likelihood of a type II error. Future studies should therefore be conducted with larger samples and a subsequent investigation should assess actual use of the tool.

Despite these limitations, our study suggests that technology acceptance can be promoted by engaging with information about a digital tool. If an experienced teacher's accounts, as in the form of the blog post, are particularly conducive to technology acceptance, a possible approach would be for in-service teachers to share their personal experiences of digital tools and their use in the classroom. In this way, pre-service teachers' technology acceptance might potentially be promoted in a very economical way. Thus, the present study provides important insights on how the technology acceptance of pre-service teachers could be further investigated and promoted.

"I'm still learning": Experienced Mathematics Teachers' Development of Adaptive Expertise Amidst the COVID-19 Pandemic

Katherine Schneeberger McGugan, Elizabeth Metts
k.schneeberger.mcgugan@vanderbilt.edu, elizabeth.c.metts@vanderbilt.edu
Vanderbilt University

Abstract: In 2020, the global COVID-19 pandemic disrupted education across the country, requiring a re-organization of instruction on a large scale. This study examines the experiences of highly-committed secondary mathematics teachers in a large urban U.S. public school district as they shifted their instruction online for an entire year. Using the framework of *adaptive expertise* – processes and dispositions that can enable teachers to extend their knowledge to novel situations – this paper contrasts the cases of three teachers' development of adaptive practices over time. Drawing on data gathered from semi-structured interviews, participant observation, and content analysis, we discuss how teachers' engagement in the processes of *identification* and *negotiation* contributed to their adaptive orientations. By documenting how highly-reflective educators adjusted their instruction to respond to unprecedented teaching demands, this study contributes to the field's understanding of adaptive expertise in mathematics teaching.

In March 2020, school districts across the country spontaneously moved all instruction online as the COVID-19 pandemic spiked. Teachers who had spent years honing their craft in the classroom were forced to learn a different job. As a field, we know little about the processes through which experienced teachers continue to learn to adapt their existing knowledge to new and novel situations. This study explores the ways that secondary mathematics teachers developed adaptive expertise to meet the demands of their various novel teaching contexts. To do so, this paper builds on an existing four-year partnership with a highly-selective professional development organization for mathematics teachers, most of whom teach in a large urban school district in the Western United States. These teachers demonstrate strong commitments to their own and their students' learning and occupy resource-rich professional networks. By working closely with mathematics teachers and documenting their responses to teaching in the midst of the pandemic, this study contributes to educational practice and research. Practically, this study offers examples of the different ways teachers developed adaptive expertise in their unique learning environments. Theoretically, this is a case study of adaptive expertise as a process of mathematics teacher learning, contributing to the field's understanding of how teacher learning environments can be designed to support the development of experienced teachers' adaptive expertise in post-pandemic learning contexts. Specifically, this study examines the question: How are well-resourced, experienced secondary mathematics teachers in a large urban school district transforming their teaching during the COVID-19 pandemic?

Theoretical Framework and Prior Work

Adaptive expertise

We take a situative view of teacher learning, a subset of sociocultural theories rooted in Vygotsky's (1978) early work (Lave & Wenger, 1991). Because of its attention to learners-in-context, it is possible to leverage this perspective to investigate teachers' transformations and adaptations, in the context of the COVID-19 pandemic. Teachers were thrust into mandated online teaching, bringing about entirely new demands that required them to move beyond the application of existing knowledge. Faced with a novel situation, teachers had to make a situational adjustment (Becker, 1964) – rather than completely reinventing their practice, teachers made adjustments, changes, and choices between situationally feasible alternatives, choosing actions that best meet their professional demands and expectations as well as align with their professional, ethical, and personal commitments. This kind of problem solving supports the construction of knowledge, making this context a compelling place to study teacher learning.

The unique context of pandemic teaching lends itself to specifically examining teachers' development of adaptive expertise. Drawing on ideas about adaptive expertise in teaching (Crawford et al., 2005), adaptive expertise can be described as flexible and innovative and marked by the ability to extend current understandings to meet the demands of novel problems or atypical contexts. This stands in contrast to what has been described as routine expertise (Hatano & Inagaki, 1984), marked by speed, efficiency, and automaticity but does not necessitate flexibility or adaptability to new situations. Adaptive expertise is a *stance* on knowledge and practice: adaptive

 © ISLS

experts approach new situations flexibly and learn throughout their lifetimes (Bransford et al., 2000). Furthermore, adaptive expertise is not only a way to describe how teachers have changed their practice, but it also motivates their own learning, as they recognize when rules and principles do not apply to situations, seeking instead to develop new practices (Gott et al., 1992).

Crawford et al. (2005) describe several necessary dispositions and skills that teachers must possess in order to develop adaptive expertise, adaptive practices – an instructional practice that is evolving in order to meet the demands of a novel situation – and to be considered adaptive experts. Particularly relevant to this study is an inclination to acknowledge and even push the limits of one's ability while also assessing the adequacy of current knowledge or practices for meeting the needs of particular problems. Cognitively, adaptive experts look for evidence to inform their plans, seek causality as well as feedback, monitor the results of their decisions and their own learning, and assess their own and the field's knowledge for addressing the situations at hand. These dispositional and cognitive tendencies support a balance between efficiency and innovation in teaching. On the one hand, by having and relying on developed routines, adaptive experts can move through predictable aspects of their work smoothly. On the other hand, by sensitizing themselves to the feedback that things are not going as expected, they can seek new forms of practice rooted in well-understood principles. This conception of teacher learning implies that knowledge is flexible and contextual and that teachers' ongoing learning is responsive to a changing context and dynamic community instead of being a set of skills or static knowledge.

Adaptive expertise in teaching and learning has been studied in a multitude of contexts: exploring different conceptions of mathematics student understanding (Hatano & Inagaki, 1984); characterizing reasoning and problem solving processes that enable adaptive experts to continue to learn in adult professional settings (Bransford et al., 2000; Feltovich et al., 1997; Gott et al., 1992); and describing the epistemic/dispositional aspects of adaptiveness and the habits of mind involved in science teacher professional development (Crawford et al., 2005). This body of work has evolved over time to recognize that the content or characteristics of learners in any context are not static over the course of teachers' careers. However, this research fails to discuss how adaptive expertise is developed.

Identification and Negotiation

In keeping with the goal of understanding teachers' developing adaptive expertise from a situative perspective, we draw on Horn et al.'s (2008) conceptions of identification and negotiation in their discussion of preservice teacher learning. Specifically, this paper is in alignment with their view of identity:

> Identity, as an analytic construct, provided access to both individuals' dispositions and the environments they encountered. Because accounts of identity necessarily provide for the description of individuals, it helps us see the people we are trying to understand. At the same time, identities are constructed through culturally available descriptors, narratives, and archetypes, embedding and linking the individuals in the contexts around them. (p. 62)

Viewing identity as both individual and contextual provides insight into the ways teachers' pre-pandemic, in-person teaching identities evolved during mandated online teaching as they adapted their existing knowledge through processes of identification and negotiation. *Identification* is the process through which teachers integrate new understandings into their existing identities while *negotiation* is when teachers modify their existing identities based on new understandings. Together with adaptive expertise, the processes of identification and negotiation serve as a rich theoretical basis through which to investigate experienced teachers' transformation during the COVID-19 pandemic.

The ideas of identification and negotiation are similar to the cognitive, adaptive processes of assimilation and accommodation (Piaget, 1970). In their discussion of identification and negotiation, Horn and colleagues (2008) extend Piaget's ideas in their work with pre-service teachers. Liking identity to Piaget's concept of cognitive structures, they consider the ways preservice teachers maintain or transform their identities in the face of external elements. This work has since been taken up by many scholars – primarily the idea that teacher identity formation involves the interweaving of the individual and the social (eg. Beltman et al., 2015; Stenberg et al., 2014). Together with adaptive expertise, the processes of identification and negotiation serve as a rich theoretical basis through which to investigate experienced teachers' transformation during the COVID-19 pandemic; this analysis seeks to connect teacher identity – namely identification and negotiation – with the ideas on adaptive expertise to gain understanding on how adaptive expertise can be developed.

Methods

This study extended a four-year ethnographic study of secondary mathematics teachers in urban public schools, conducted in partnership with a professional development organization (PDO). Teachers were recruited from the PDO, resulting in a convenience sample of 8 teachers (Gerson & Damaske, 2020).

Research Context

In mid-march 2020, the first documented COVID-19 cases appeared in the United States, including the city in which the PDO teachers work. Several days later, district leaders emailed teachers that schools would close for two weeks, initially with no mandated online learning. In the midst of this initial closure, teachers in this study were notified that the closure was extended through the end of the 2019-2020 school year and that continued online learning was mandated. In July 2020, all teachers in the district were notified that the 2020-2021 academic year would remain virtual indefinitely. The effects of COVID-19 on schools have had a global reach – internationally, teachers found themselves in similar positions as teachers in the US and in our study. Unique to this study, some of the burden regarding safety as well as untenable working conditions in the shift to online teaching was eased by the strong local teachers union as well as effective district leadership. One teacher, Amber (1), who was the union representative at her school described the extensive time the union spent negotiating over the summer for continued online instruction in the 2020-2021 school year with school administrators and district leadership: "I think we didn't get everything that we asked for, but we never will. I think we ended in a place that was doable for what we were about to start" (Interview 2, August 2020) – indicating the strength, influence, and support of the union. Furthermore, district leadership prioritized teacher and student safety throughout the pandemic. The teachers in this study did not experience some of the same uncertainties that others across the country have, such as having access to vaccines to go back to school in person or not having access to adequate professional development to learn new technologies (Cornish, 2021). The specific sources of uncertainty that remained – like how to be a good online math teacher – presented opportunities to study the development of adaptive expertise. For example, one of the focal teachers, Linda, explained "the fact that [reopening during the 2020-2021 school year] hasn't been a part of the narrative- it hasn't been a huge piece of the conversation has made everybody else feel better and feel like they could focus more" (Interview 4, March 2021). This supportive local context freed up emotional stress and physical time for teachers in this study to focus on transforming their teaching, making it an ideal location for the study of adaptive expertise. Further, this particular study context is compelling in the way that everyone felt like an amateur, or outsider. In interviews, experienced teachers discussed feeling like first year teachers all over again due to the overwhelming novelty of mandated online teaching. This dynamic provided a space ripe for exploration as traditional boundaries of expert-novices in research were blurred.

Participants

The participants for this study were determined through theoretical sampling and convenience sampling (Gerson & Damaske, 2020). First, participants were strategically recruited from the PDO. According to an external evaluator's report, PDO teachers typically experience higher satisfaction with professional learning, greater retention, and stronger student survey and test results than a matched control group. PDO teachers are passionate about and committed to their work, collaborate regularly, reflect on their instruction, and are seen as leaders in their schools. Recruiting exclusively from this PDO ensured that the teacher participants would be experienced and well-resourced.

In May 2020, teachers from the PDO were given the option to volunteer to participate in the study. Of the 80 teachers in the PDO, 8 elected to continue to participate. Due to this participant selection, we conceptualize this study as a best case study (Yin, 2017) for several reasons. First, the eight teachers in this study were all experienced teachers with 15 years or more teaching experience. They were seen as leaders in their schools or departments and were highly-reflective, continually seeking out opportunities to learn. Second, these teachers had a strong community of support through the professional development organization. They all reported collaborating regularly with both school-based teacher teams and colleagues in the organization. Lastly, the teachers in this sample were members of a strong teachers union and feel supported by a data-driven district superintendent. By conceptualizing this sample as a best case sample, the findings from this study can be extended to consider the contextual circumstances that enabled participating teachers to develop adaptive expertise.

Data Collection

Data for this study included interview transcripts from all 8 participating teachers, fieldnotes from participant observations of 3 of the 8 teachers' department meetings, and content analysis of relevant announcements from the district and national media coverage of education during COVID-19 (Altheide & Schneider, 2012). In this semi-structured interview study, we conducted iterative cycles of data collection and

analysis, starting with Interview 1 in May 2020 (Emerson et al., 2011). While the study concluded with a final interview in June 2021, the data for this paper are drawn from four interviews across 8 participating teachers from May 2020 to March 2021, as well as content analysis (Altheide & Schneider, 2012) and participant observation (Emerson et al., 2011). In between interviews, data from previous interviews, content analyses, and participant observations were analyzed and used to inform subsequent interview protocols.

Data analysis

Across-teacher learning analysis

Aligned with our ethnographic approach (Emerson et al., 2011), data analysis centered participants' own meanings. After each round of interviews, we identified teachers' sensemaking via open coding, consolidating themes across the interviews (Charmaz, 2008). For instance, a common (and novel) dilemma emerged around engaging kids in synchronous online lessons: should teachers require that students' cameras stay on? On one hand, cameras leave students vulnerable, since peers see into their living spaces or screengrab awkward moments to post on social media; yet without students' faces, teachers struggle to gauge engagement. Discussing such dilemmas provided insight into developing adaptive expertise as teachers deliberated on what made the most sense for different teaching situations. Cross-case comparisons enabled me to identify clusters of responses (e.g., choosing primarily cameras off) and to extrapolate conditions in which different instructional responses make sense.

Within-teacher learning analysis

Alongside group-level analysis, we analyzed individual teacher interview data and fieldnotes from participant observations of department meetings to understand how each teachers' local, school-based contexts supported the development of adaptive expertise over time. We hypothesized that different teachers' constraints and affordances make identification or negotiation more sensible, thus shaping their learning. For each teacher, we coded for statements that provided insight into their pre-pandemic teaching identities. For example, when describing his reliance on humor during in-person teaching, Ezio described "I'll toss out a corny math joke and I'll laugh at my own joke, and then the kids will laugh… so that's how my classes normally are" (Interview 2, August 2020). When we coded for identification, we looked for evidence that teachers were integrating new understandings gained from mandated online teaching into their existing, or pre-pandemic, teaching identities. When coding for negotiation, we looked for evidence that teachers had shifted or modified their pre-pandemic teaching identities based on new understandings.

Comparative Case Analysis

Throughout the data collection and analysis process, we looked at the data across all 8 participants. For this paper, we focus on three of the teachers – Linda, Brad, and Ezio – because we found that they all adapted differently. By looking across these three cases, we can get a sense of how adaptive expertise is developed. Specifically, we will discuss how Linda limited her development of adaptive expertise by not engaging in meaningful identification or negotiation, how Brad developed adaptive expertise primarily through identification, and how Ezio developed adaptive expertise through negotiation.

Findings

To explore the ways experienced teachers developed adaptive expertise, we investigated the ways that teachers responded to the dynamic and novel context of online teaching during the COVID-19 pandemic, illustrated in the following three cases. In this study, we found that the teachers' learning and development of adaptive expertise was contextual and dynamic. Specifically, some teachers were able to develop adaptive expertise by engaging in identity identification or negotiation while others teachers' development of adaptive expertise was limited. For each case, we will describe the teachers' pre-pandemic, or in-person, teaching identity. We will then describe the teachers' engagement with identification or negotiation in their attempt to adapt their current understandings. We will conclude with a description of the ways each teacher developed adaptive expertise or was limited in their development.

Case 1: Linda, Limited Development of Adaptive Expertise

During the study, Linda did not engage in identification or negotiation because of discordance between elements of her pre-pandemic teaching identity and the demands of online teaching. In interviews, Linda often discussed how the physical space of her classroom contributed to her pre-pandemic identity: "I have built a very intentional learning space that has particular things on the walls. It has particular arrangement of the tables" (Interview 3, November 2020). She often referenced the importance of physical materials in her teaching – "I teach very driven

 © ISLS

by the stuff on the table kind of thing" (Interview 2, August 2020), referencing yardsticks, string, scissors, and other physical materials she typically had available on student desks. Her reliance on the physical resources in her classroom was rooted in her pedagogical commitment to learning being physical, embodied, and experiential. Being unable to access these resources during online teaching left Linda at a loss for how to negotiate the demands of online teaching.

In interview transcripts, we found no evidence that Linda engaged in identification by integrating new understandings into her existing pre-pandemic identity. Because the physical space and materials were no longer available to her in virtual teaching, she couldn't integrate new understandings into this element of her existing identity. This was evidenced when she said "I'm realizing how much they're not learning because they're not marinating in the environment" (Interview 3, November 2020), or when she discussed not knowing how to teach trigonometry:

> I am absolutely at a loss for what the heck I'm going to do. Really, really confused because for the last four or five years, we start trig by actually building a trig table on the board and they don't know that's what they're doing. But then, at their tables, they're given a bunch of index cards with different angle degrees marked on it, and they're going to mark that angle and then they build a right triangle. And they measure, and we just record all of these ratios and build this giant thing by hand up on the board and then start analyzing it. And it's like, I can't get kids to draw stuff because I don't know what equipment they have. They have no protractors. They have no rulers. (*Interview 3, November 2020)*

Linda described confusion about how to teach trigonometry because she didn't have the physical materials of protractors and rulers available to them.

When looking for data that supports negotiation, we looked for evidence that Linda modified her existing identity based on new understandings. However, Linda often framed negotiation as not worthwhile. For example, she expressed a lack of desire to invest time in learning new technologies: "I just don't care that much about it to invest umpteen oodles and oodles in learning like every new widget, whatever" (Interview 3, November 2020). Further complicating her dilemma, "the idea of having this co-constructed, giant thing that we do in person, right? … I don't want to let go of it entirely because trig is confusing" (Interview 3, November 2020). Her pre-pandemic identity was rooted in the physical materials in her classroom and tied to her conception of being a good math teacher. At the same time, it was incompatible with her online teaching practices. Therefore, Linda was unable to reconcile her pre-pandemic identity with the demands of online teaching by engaging in identification or negotiation, ultimately resulting in limited development of her adaptive expertise. She recognized this limitation when she explicitly described how unsuccessful she felt teaching online:

> I feel now that I know this is not me at my best, I know this is not- the Linda in the little box is not as good as Linda in person… I've never felt so incredibly inadequate and I don't, I don't know that I would go so far as to say a fraud but certainly so far from who I want to be as a teacher. (*Interview 3, November 2020)*

Case 2: Brad, Developing Adaptive Expertise through Identification

Before the pandemic, facilitating whole class discussions was a significant facet of Brad's identity. He valued conducting whole class discussions driven by students' current understandings, motivating his monitoring of student work and intentionality in guiding students' discussions. He was still able to act on this part of his identity during online teaching: "Kids… still feel like they still have a teacher in front of them, and still allow[s] the teacher to do teacher moves in terms of looking at their responses, filtering the ones that we can have a discussion about, pausing them, and then we're going to discuss it" (Interview 1, April 2020). While he was successful in incorporating new practices and adapting his discussion practices through identification, Brad did not engage in negotiation – he was able to adapt to online teaching without negotiating his pre-pandemic teaching identity.

To investigate the ways in which Brad engaged in identification, we looked for evidence that he had integrated new understandings into his existing identity of building and eliciting student understandings in whole class discussions. We found that Brad continually developed new understandings of a technology platform, Desmos, and integrated those new understandings to *maintain* his existing identity. Desmos is a free technology that hosts digital classroom activities designed for students to "explore [math] concepts more deeply, collaborate with their peers on problem-solving, and apply knowledge creatively as mathematicians" (Desmos.com). Teachers can also develop their own classroom activities catered to their specific students and content while utilizing the tools built into Desmos for student exploration and collaboration.

Brad's incorporation of Desmos during online teaching was notably different from his pre-pandemic teaching. In person, Brad reported only using Desmos for specific lessons that were few and far between. In interviews, Brad described the new ways he utilized Desmos to meet the demands of online teaching including enabling certain features like non-math check-ins and modifying the in-person curriculum to make it more accessible to students at home, spending 10-16 hours a week converting in-person lessons to desmos. For example, he said:

> What does it look like lesson planning is basically thinking from what my lesson would look like in class and they can get into Desmos and enabling features that I think would make it easier for students, cutting out questions that I think would only be able to be done with same manipulatives or say if they were in a group setting where I could be supporting them a little more or things like that. (*Interview 1, April 2020*)

He continued to explain the ways that Desmos connected his in-person teaching identity with the novel context of pandemic teaching: "that's been my mindset, is how can I keep my lessons engaging, make [the students] learn while also figuring out the best ways to allow me to still make it feel like a classroom" (Interview 1, April 2020). Brad's pre-pandemic teaching identity involved teacher moves like looking for, listening to, and discussing students' thoughts and understandings, and transforming all of his lessons into Desmos and learning how to utilize more features enabled him to preserve this existing identity.

Brad's engagement in identification contributed to the development of his adaptive expertise – he extended his knowledge to meet the demands of online learning. Namely, he spent time incorporating new understandings of the applications of Desmos to make it possible – even easier – to facilitate the type of discussion he valued in person:

> It's like when you're hovering around a class- Desmos is actually easier to facilitate discussion than when you have a clipboard and you're like, "Ooh. James, number two you said something really cool, that's really creative." I'll call on James for question number two. I can see it right in front of me at all times, all the things kids are not understanding and things that kids are understanding and things that kids are solving in unique and creative ways. That's why I think it's worth it.(*Interview 3, October 2020*)

Importantly, Brad developed adaptive expertise through identification but not negotiation. While he adapted his teaching practice, he did so in ways that left his existing identity intact. Supported by Desmos as a mediating tool, Brad was able to adapt his practice to meet the demands of online teaching in ways that aligned with his identity rooted in eliciting and giving feedback on student understanding.

Case 3: Ezio, Developing Adaptive Expertise through Negotiation

In our final case, we found that Ezio attempted to engage in identification and developed adaptive expertise through negotiation. Prior to mandated online teaching, Ezio deeply valued discovery-based learning. At the same time, his teaching identity included not being a technology person. He reiterated this many times in interviews, saying things like "technology is not my thing" (Interview 1, May 2020). For example, in Interview 3, Ezio says "I was never the tech person. I was the old school- I had no problem- give me a chalkboard, I feel perfectly comfortable with a chalkboard and chalk" (Interview 3, November 2020). Ezio was settled in who he was as a teacher, and salient to him, this did not include incorporating technology.

Initially, Ezio attempted to engage in identification by recording in-person style lectures and resisting incorporating new technology: "This virtual world is new to me, so it was just safer. Just stick with what you do. Go ahead, lecture the whole time, lecture the whole hour" (Interview 3, November 2020). However, he came to recognize that maintaining this aspect of his identity ultimately limited his ability to adapt to online learning in a way that made him feel successful:

> And even though it wasn't effective, I guess as the days or weeks wore on, then it started getting to me. Okay, this isn't working. You're not doing your job, you're just lying to yourself when you're doing that. (*Interview 3, November 2020*)

Ezio felt particularly unsuccessful in the ways online teaching did not meet his expectations rooted in his value of discovery-based learning – he did not feel like he was meeting the needs of his students or demands of online teaching.

In response to these feelings of dissatisfaction, Ezio engaged in negotiation, modifying his existing identity based on new understandings. He described taking an entire weekend to learn Desmos. He felt so successful that he has taken up the identity of being the 'tech pioneer' of his school. When asked how he felt being considered the 'tech pioneer' of his school, he explained "It feels good… on the one hand, I feel bad for our situation in general for our teachers, but on the other hand, I'm happy. I wanted to learn more for my own class" (Interview 3, November 2020). This shift in identity to becoming the technology resource in his school was also evidenced in a department meeting with colleagues. During an observed virtual department meeting, Ezio taught his 8th grade math team members a new feature of Desmos:

> Ezio's screen is still shared, and he now goes to the Desmos website and walks the teachers through an annotation ("sketch") feature. Ms. Guo says that she would like to come to Ezio's class (virtually) during her conference (planning) period to observe him so she can "come and learn from you." Mr. Iweala says that he would like to join Friday too as he pulls up his schedule. Ezio agrees they can observe, and Ms. Guo says "thank you so much for opening your classroom so we can learn from you." (*Fieldnotes, February 2021*)

After attempting to maintain his pre-pandemic identity of not being a technology person, Ezio gained new understandings of the demands of online teaching and *modified* his identity to meet those demands. Namely, he extended his knowledge to include new technology in response to his realizing that online teaching was making him feel unproductive. For example, he said "I'm using Desmos a lot more in my classroom… I just feel more productive now. I have something to build from. Not that I'm doing everything perfect in Desmos, but I'm learning as I go along" (Interview 3, November 2020). Initially, Ezio identified as "not a tech person" and attempted to engage in *identification* to adjust his practices in line with this identity. However, he then *negotiated* this aspect of his identity to become the "tech pioneer" of his school, further adapting and transforming his practice to meet the demands of online teaching.

Discussion

This study provides insights into how the field can better understand experienced teacher learning through the concept of adaptive expertise. Theoretically, this paper contributes to a richer understanding of adaptive expertise by examining its development through the lens of identification and negotiation. Practically, this study highlights the ways that supportive district leadership, strong union presence, and resources for collaboration provide a context for experienced teachers to reflect and adapt to new and novel situations. While we certainly hope that the findings are not used to inform teacher learning during a future international pandemic, we conceptualize this study as an extreme case (Yin, 2017) for understanding how teacher learning environments can be designed to support the development of adaptive expertise in less extreme, post-pandemic learning contexts. In this spirit, the findings contribute to the fields' understanding of teacher learning processes by investigating the different ways that Linda, Brad, and Ezio engaged in identification or negotiation in response to the dynamic and novel context of online teaching. Aligned with our situative view of teacher learning, each case highlighted the contextual and flexible nature of teachers' knowledge. Specifically, we have described how Brad and Ezio developed adaptive expertise by engaging in identification and negotiation while Linda's development of adaptive expertise was limited.

We found that all teachers in this study were supported to attempt adaptations to online teaching by the insulated support of district leadership as well as the influence and presence of the teachers union. By removing many external uncertainties, teachers were able to devote their focus on their teaching practice. This kind of support can be valuable in creating learning environments ripe for ongoing teacher learning; whether in a global pandemic or not, teachers negotiate countless institutional and local demands. We show that experienced teachers' sensemaking and learning can be better supported by alleviating these stresses.

There is also a lot to be learned from our focal teachers. Brad and Ezio both developed adaptive expertise in different ways as they incorporated Desmos into their online teaching practice. Although Desmos aligned with Brad's existing identity, supporting his identification, Desmos did not align with Ezio's existing identity. His attempts to integrate online teaching practices into his existing identity made him feel unsuccessful, motivating him to seek out something different and engage in negotiation. Similarly, Linda too felt unsuccessful in engaging in identification. Her lack of engagement in the process of negotiation indicated that this was a place in which she may have benefitted from additional support.

Taken together, our three focal cases illustrate how teacher learning can be studied and supported through the lenses of identification and negotiation and underscore the centrality of identity. On the one hand, when teachers' identities are thoughtfully considered, teachers can be supported by resources that align with their

identities to foster identification. On the other hand, teachers may also need to be supported to negotiate aspects of their identity that are incompatible or unproductive with their particular teaching context. It is important to note that the pre-pandemic identities described in this paper are not the teachers' only identities. Our conception of identity as socially and contextually constructed (Horn et al., 2008) suggests that the identities of these teachers are multifaceted and dynamic. Indeed, the teachers in our study both developed adaptive expertise and were limited in this development with respect to the identities described here, but they also exhibited entirely different adaptive practices with respect to other facets of their teaching identities. Further research is needed to explore the interplay of the multiple elements of experienced teacher identities and how they contribute to ongoing teacher learning.

A Learning Experience Design Approach: Investigating the Mediating Roles of Situational Interest and Mind-Wandering in Children's Online Engagement

Joseph Wong, Edward Chen, Natalie Au-Yeung, Bella Lerner, Lindsey Richland
joseph.wong@uci.edu, cheneh1@uci.edu, natalie.auyeung@uci.edu, lerneri@uci.edu, l.richland@uci.edu
University of California, Irvine

Abstract: Historically, learning for young students has occurred in formal, in-person classroom environments, but the distance learning context has opened a myriad of learning modalities. To this end, we aim to better understand how deploying learning experience design (LXD) approach supports or hinders children's engagement while participating in an online, video-based math course. This study operationalized LXD through the integration of evidence-based pedagogical instructional design and human-centered user experience (UX) design. Findings suggest that students' situational interest and mind-wandering significantly mediate the relationship between user experiences and online engagement. These results provide practical implications for how researchers, designers, and instructors can intentionally iterate the learning experience to reduce mind-wandering and sustain children's online engagement with learning theories as we consider the future of online teaching and learning modalities.

Introduction

The field of teaching and learning has rapidly undergone a major shift over the last two years of distance learning through the COVID-19 pandemic. The pandemic abruptly caused shifts in workflows across many sectors, and education specifically was required to fundamentally modify course delivery infrastructures. COVID-19 necessitated a systematic change in course delivery due to the nationwide orders of social distancing to mitigate spread, resulting in the suspension of in-person instruction (Ferrel & Ryan, 2020). For many educational institutions, transplanting the same in-person teaching through synchronous Zoom meetings may have been sufficient. However, it was always intended to be a short-term emergency solution that while facilitated the continuance of teaching and learning, is still distinctly different to online learning experiences grounded with evidenced-based pedagogical learning design.

Zoom certainly facilitated teaching and learning, but it also brought concerns of student disengagement, lack of interest, and validity from both the instructors and the student perspectives (Son et al., 2020; Unger & Meiran, 2020). At the same time, students described issues related to technical difficulties, increased distractions, and decreased motivation, with emergency remote distance learning through Zoom—all of which are critical contributors affecting the student learning experience (Agarwal & Kaushik, 2020; Fawaz & Samaha, 2021). As a result, this study documents the efforts to shift from synchronous Zoom courses to design, deploy, and document the impacts of an online math course grounded in the learning experience design (LXD) framework to examine children's frequency to mind-wandering and online engagement.

Learning experience design (LXD) refers to the creation of learning situations that extend beyond the formal classroom learning environment and which often utilize online and virtual technological formats (Ahn, 2019). LXD is the process of developing effective learning experiences that enable learners to reach a specified learning outcome in a human-centered goal-oriented method (Floor, 2018). Weigel (2015) further defines LXD as an interdisciplinary synthesis of instructional design, teaching pedagogy, cognitive science, learning sciences, and user experience design. As such, LXD broadens our definitions of what is to be considered a learning experience, affording instructors, designers, and researchers the opportunity to empathize with learners and develop experiences that expand our learning design toolbox (Ahn et al., 2019; Weigel, 2015).

In the context of our study, we operationalized LXD by grounding our online course in learning design frameworks and ensuring quality user experience design. We also explored the connection between students' situational interest and students' mind-wandering as a result of our LX designs within a learning environment, supporting or hindering students' online engagement. Courses designed with the LXD paradigm are relatively new, and this study provides insight into evidenced-based asynchronous online learning environments grounded in LXD as a feasible learning modality for children learning math. To this end, we aim to better understand how our design efforts foster children's' engagement while participating in an online grounded in the LXD paradigm.

Theoretical approach towards learning experience design

 © ISLS

The following sections provide an overview of the literature on engagement, mind-wandering, situational interest, and user experience examined, which ultimately serves to theoretically ground our analytic model. Situational interest was identified as a potential source of mind-wandering that may positively or negatively mediate the relationship of students' online engagement. Further, a critical factor influencing students' levels of situational interest is the medium of learning and the quality user experience that medium evokes. Limited studies have examined the interrelation of such specific constructs, even less so during a crisis learning context, warranting analysis. Reviewing these key bodies of literature thereby informs the basis of our hypothesized model to characterize the student learning experience by examining the effects of students' situational interest and mind-wandering mediating the relationship between students' user experience influencing their online engagement.

In education, student engagement is defined as the amount of student effort or active participation needed to complete a learning task (Richardson & Newby, 2006). In an online course, engagement can be further described as the attention, curiosity, interactivity, and interests students exhibit during an instructional unit, which further extends to the level of motivational traits students may have during the learning process (Pellas, 2014). Research in online learning attributes increased student engagement to quality instructional design (Pappas, 2015), student user experience with the interface (Hu, 2008), and student motivational factors (e.g., interest, self-efficacy) that can emerge as a result of the learning environment (Sun et al., 2012). When learning interfaces are difficult to navigate, uninteresting, or unengaging, studies have shown that this will likely lead to negative learning experiences such as increased mind-wandering, or the direction of attention away from a primary task (Desideri et al., 2019). Thus, we focus our design efforts onto ensuring quality instructional design to foster students' interests and strong user experience in order to maximize students' participation and degree of interactivity.

Mind-wandering or the colloquial term "zoning out," is defined as the shift of an individual's attention away from a primary task at hand and towards other internalized information (Smallwood & Schooler, 2006). Another way to describe mind-wandering is the human experience of drifting into thoughts away from the "here and now" (Smallwood & Schooler, 2006). Unlike being in a state of focus, mind-wandering is considered an off-task processing state such that the individual experiences an attentional lapse (Danckert, 2018). Mind-wandering is more likely to occur during monotonous environments (Eastwood et al., 2012) or long cognitively undemanding tasks (Smallwood & Schooler, 2015). Conrad and Newman (2020) conducted a mind-wandering study on students during the COVID-19 pandemic and found that students with greater instances of mind-wandering during long continuous Zoom class sessions had lower achievement scores. Considering that "Zoom" classes typically represent a low cognitively demanding task, often plagued by boredom, frustration, and lack of engagement (Katz & Kedem-Yemini, 2021) identifying potential detrimental factors that contribute to mind-wandering may be essential to better support students' learning (Randall, 2015; Smallwood & Schooler, 2006).

Since mind-wandering indicates a fault in information processing, where external task-related information shifts towards processing internal task-unrelated information (Smallwood & Schooler, 2009), this attentional shift is theorized to be a decoupling process between the task (external information) and the existing mental model (self-generated thoughts) of the individual (Mills et al., 2013; Smallwood et al., 2007). The Current Concerns Hypothesis suggests that mind-wandering occurs when intrinsic or extrinsic reinforcement where thinking about other personal goals outweighs the reinforcement for processing primary task goals (Klinger, 2009). Taking this into account, students' personal values in a teaching and learning context might be assessed by considering students' situational interests while engaged in a learning experience.

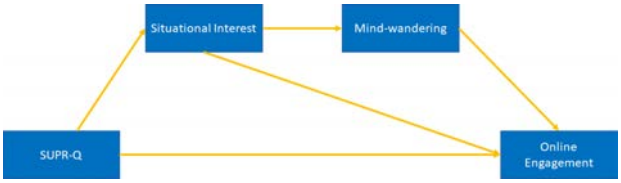
Situational interest (SI) refers "to the interest activated by the immediate learning environment" or the interest given the novelty aspect of a learning task (Schraw & Lehman, 2001). Past research indicates that situational interest is a powerful motivator in areas of math, reading, and history, when learner participation and interaction throughout the entire learning process is sustained (Chen et al, 2001). While situational interest and student engagement have been widely evaluated in the context of traditional in-person learning activities (Sun et al, 2012), less is understood about how to facilitate situational interest for young students in online learning environments while also reducing the onset of students' mind-wandering. We hypothesized that operationalizing the LXD learning design paradigm may aid in our juncture of supporting elementary students adopting an asynchronous online learning modality.

As SI refers to the interest activated by the learning environment, user experience can be seen as a measure linking the learner's experience of a specific learning interface and their interest in learning as a result of this utilizing this medium. Broadly defined, user experience (UX) is "the extent to which a product can be utilized by specified users to achieve specific goals with effectiveness, efficiency, and satisfaction in a specified context of use" (ISO 9241-11, 1998). In an online course, UX refers to the effectiveness of the learning interface and whether or not a student can successfully interact with the course platform to accomplish an intended task. Learning environments with strong UX redirect students' efforts towards the learning task, rather than learning how to access the content. This shifts the researcher and instructor's perspective from only focusing on instruction,

to also considering the deep understandings of learners, what they need, what they value, their abilities, and the limitations of the learning interface. As such, UX aims to create a positive student learning experience through content accessibility, interest, and design —all of which are significant predictors of student engagement in online learning environments (Thomson & Lynch, 2003).

The Situated Cognition Theory (SCT) instructional design framework was chosen to facilitate students' interests (Ghefaili, 2003) and inform the design of effective e-learning experiences while young students acclimate to distance learning. Centered around the notion that "learning" is inseparable from "doing," we adopted this framework so that learners could grasp the concepts and skills that are taught in the context in which they will be utilized (Brown et al., 1989). In practice, SCT emphasizes immersive learning environments, where new information is taught to learners in a way that simulates real-life settings. We operationalized this by using pre-recorded videos of a real-world math lesson taught by a teacher to students in a real classroom, and embedding interactive opportunities for modeling, coaching, scaffolding, articulation, reflection, and exploration (Pappas, 2015). Through this learning framework, students watched bite-sized video segments of real classroom interactions between a teacher and students, immediately practiced what they have learned through scaffolded problem scenarios, and provided written reflections on how they solved each math problem. As such, we implemented the SCT e-learning design framework to foster a deeply situated learning environment for students to actively develop interests, reduce instances of mind-wandering, and engage contextually within the online learning environment.

Figure 1. Hypothesized model for SUPR-Q (user experience), situational interest, mind-wandering, and online engagement.



Current study

Young students over the past two years have adapted to using a myriad of "edtech tools" to facilitate teaching and learning, in some cases adopting completely new modes of learning, facing new unforeseen learning challenges with the change in learning modalities (Agarwal & Kaushik, 2020). Building off the beta iteration of this online course deployed previously at the height of the pandemic (Wong et al., 2021), we gleaned the affordances and constraints identified by student commentaries to inform the design improvements of this current study to support children's online learning experience. One salient theme identified from our previous study was the notion of sustained engagement and mind-wandering while learning online (Wong et al., 2021). In this study, we employ evidence-based pedagogical LXD as a lever to support students' situational interest (SI) and ensure human-centered user experience (UX) design to alleviate technical worries related to distance learning. We then further explored the combination of situational interest and user experience predicting students' engagement, while considering the impacts of our design as a potential mechanism to reduce students' frequency to mind-wander in an online course grounded with learning experience design. This study is guided by the following research questions: (RQ 1) *To what extent do students' user experience, situational interest, and mind-wandering directly affect students' online math engagement?* (RQ 2) *To what extent do students' mind-wandering and situational interest mediate the relationship between students' user experience and students' perceived online math engagement?* (RQ 3) *To what extent does situational interest and mind-wandering sequentially mediate the path from students' user experience to online math engagement?*

Methodology

Course design context

We first worked with teachers to align with their existing Common Core State Standards (CCSS) math lesson plans. After understanding how we could best support teachers in the classroom, we then proceeded to co-develop the video lesson. Teachers, researchers, and course designers worked collaboratively to develop a script introducing ratio and proportions. Then, the instructional videos were recorded as a live, semi-scripted lesson on proportional reasoning taught by a teacher in a diverse class of fifth- and sixth-grade students. Utilizing multi-camera video production, one camera focused on the teacher, the second camera captured the teacher and the whiteboards, and the third camera captured only the students. These camera angles allowed for post-production

manipulations, directing students' attention to specific camera angles for increased engagement. During the editing process, we employed a reform-based instructional model in which the teacher first asks the students to solve a challenging proportional reasoning problem on their own, prior to receiving explicit instruction (Schwartz et al., 2011). Next, the teacher strategically chose students using the target solution strategies to describe their strategy to the class. Following each student, the teacher-led a discussion on the procedures and higher-level conceptual overview of each respective target strategy: the equivalent fraction strategy and the unit ratio strategy.

Cognizant of the research behind effective user experience (UX) and instructional design (ID) in self-paced courses, these online modules were designed to be flexible and learner-paced, enabling students to start on their own time and work through the course at their own speed (Richardson et al., 2016). In addition, intentional design choices were made to maximize digital interactivity, reduce mind-wandering, and learner engagement. More specifically, an hour-long video lesson was segmented into ten parts instead of one long continuous stream to reduce fatigue, cognitive load, and opportunities for students to mind-wander (Mayer, 2019). Scaffolded problem sets (worked examples) were specifically placed in between video segments for students to practice problems immediately after learning. These types of problems scaffold novice learners by drawing attention to the structural similarities in the lesson to ensure students attend to the key ideas, concepts, and relationships in practice (Begolli & Richland, 2016). For example, students were first asked to recall strategies they observed from watching the videos. Next, students plugged in the procedural steps to solve the math question. Then, students were asked to compare their procedural steps with model example strategy solutions. Video animations that displayed the sequential ordering of mathematical procedures called "worked examples" were added to enhance the visual representations and conceptual comparisons across solution types. This allowed students the option to review and crystallize the different solution strategies prior to moving on to the next problem. After making comparisons across problem types and strategies, students would solve the math problem by assessing their conceptual understanding. Lastly, solution reflections were embedded within each problem scaffold for students to explain, in their own words, how they solved each math problem with their chosen solution strategies. This design choice enabled students to actively engage in their own productive metacognitive judgments and reflect on "how and why" they arrived at their solutions, which has been found to foster learner responsibility, increased test preparation, and review and practice (Tullis & Benjamin, 2011).

Careful considerations were made to ensure that the course interface facilitated quality user experience design. For example, course roadmaps, course goals, and navigational instructions were clearly "highlighted" and "boxed in" to promote learner ease of use and findability within the online learning environment. Additionally, standardized vector icons were utilized before every instructional type, allowing students to differentiate between interface instructions as opposed to lesson specific instructions. A table of contents and progression bar was added to let learners know their progression within the course. Each video also had instructions clearly stating how to pause, play, and re-watch. These UX design choices were made to mitigate visual complexities, technical difficulties, and allow users to focus on the content most relevant for the task at hand. The ability to click backwards in the course was activated for students to freely navigate the course space with more autonomy. This design change was incorporated to account for students potentially making mistakes or clicking through the online course too quickly. Another recommended addition to the course was to include explicit breaks from the math problem sets by asking fun and engaging pop-up questions with GIFs that students could freely respond to. Since our math lesson was immersed within the theme of cooking recipes, these GIFs and accompanying questions asked students about what they might be baking or cooking at home and how these proportional reasoning concepts might be applied in their everyday lives. While maintaining the theme of our lesson, this presented break opportunities for students to share what they were doing during shelter in place and express how these math concepts might be applied in a non-academic context. Through these iterations, an array of design decisions grounded in LXD principles were implemented to co-develop this online-video math course, with the goal of integrating elements of a real classroom and interactive features of an online learning environment in order to maximize students' online engagement while reducing the frequency of students' mind-wandering through the rapid co-design of an online math course.

Data collection and analysis

We recruited 5th and 6th grade teachers from two school districts in the Orange County area. A total of three 5th grade teachers, six 6th grade teachers, and one 5th/6th grade combination class teacher agreed to be a part of the study. There was a total of 12 classes and each classroom had between 26-33 students. Of the (N = 303) students who participated, 56.1% of the participants identified as female and 42.6% identified as male. Student ages ranged from 10 to 12 years old, with a large majority of students being age 10 (42.6%) and 11 (55.7%). This sample consisted of children from a variety of racial/ethnic backgrounds (22.6% White, 3.8% Black, 1.1% Native American, 17.7.1% Asian, 1.1% Native Hawaiian, 21.0% Latinx/ Latino, 27.19% other, 4.8% Mixed).

We administered five questionnaires during Part 2 of the study. This included the Situational Interest Scale (Chen et al., 2001), which measured students' levels of interest in the specific online mathematics lesson we distributed, the Standardized User Experience Percentile Rank Questionnaire (SUPR-Q) (Sauro, 2015), which examined students' experiences with the online platform, and the perceived online engagement scale which measured students' engagement within the online learning experience (Rossing et al., 2012). These three measures were 5-point Likert Scales ranging from 1 (*strongly disagree*) to 5 (*strongly agree*). Lastly, students' mind-wandering was measured using the Mind-wandering Questionnaire (Mrazek et al., 2013) designated on a 6-point Likert scale, 1 (almost never) to 6 (almost always).

Data were analyzed using SPSS to conduct scale reliabilities, descriptive statistics, missing data analysis, correlations, and AMOS 26 for structural equation modeling. Scale reliability checks were conducted to verify the Cronbach's alpha coefficients for all of the validated instruments used in this study. Cronbach's alpha coefficients greater than $\alpha = 0.70$ were considered acceptable levels of reliability (Nunnally, 1994). Measured variables were analyzed by first recoding the Likert questions followed by computing descriptive statistics of the items associated with each instrument. Full information maximum likelihood (FIML) was utilized as the missing data estimation approach to account for data missing at random, maximizing the case-wise likelihood of the observed data (Carter, 2006). Preliminary analysis tested assumptions of sample size, multivariate normality, linearity, and multicollinearity of the variables of interest. Bivariate correlation analysis evaluated the linear relationships between the different study variables. Lastly, AMOS was used to conduct a path analysis using the maximum likelihood estimation (MLE) in order to analyze the hypothesized research model (See Figure 1). More specifically, we conducted a covariance-based path analysis, a subset of structural equation modeling (SEM), to examine a simple mediation and sequential mediation within the same model to investigate our research questions with measured variables (Lleras, 2005). Fit indices such as the goodness of fit test conformity (Chi-square statistic), the goodness of fit index (GFI), comparative fit index (CFI), normed fit index (NFI), and the root mean square error of approximation (RMSEA) were calculated (Kline, 2012). Lastly, unique direct and indirect effects were analyzed to examine the factors influencing students' mind-wandering and online engagement.

Findings

Descriptive statistics and correlations for the measured data (Perceived Learning Engagement, Situational Interest, Mind-wandering, and SUPR-Q scores) are provided in Table 1. In addition, the reliability estimates (Cronbach's alpha) of all the adapted scales are shown in Table 1. All of the measures were reliable based on the widely accepted recommendation of a Cronbach's alpha of .70 (Nunnally, 1978).

Table 1: Descriptive Statistics and Correlations for Study Variables (N = 303) **. Correlation is significant at the 0.01 level (2-tailed).*. Correlation is significant at the 0.05 level (2-tailed).

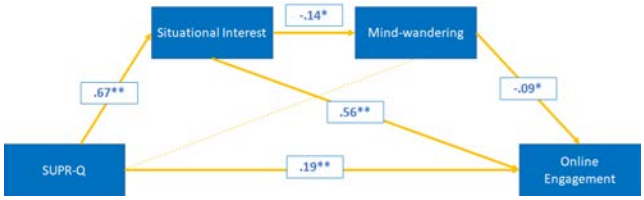
In the initial examination of the path analysis, we tested a fully saturated hypothesized model, analyzing the conformity indices and direct effects of user experience, situational interest, and mind-wandering influencing students' online engagement. The $\chi 2$ conformity index of the model was significant $\chi 2$ (1, N = 303) = 4.419, p = 0.036. A non-significant p-value is typically required to prove a high level of conformance; however, this is highly sensitive to large sample sizes (Hoyle, 1995). As such, the Root Mean Square of Approximation (RMSEA) was calculated to accommodate for the slightly significant chi-square statistic due to the large sample size. In this initial model, the RMSEA was 0.061 where values of < 0.08 indicate a good fit, with values closer to 0 representing a perfect fit (Kline, 2015). To determine the square root of the difference between the residuals of

the sample covariance matrix and the hypothesized model (Kline, 2005), the SRMR was calculated to be 0.028, with the recommended cut-off value of less than 0.08. Lastly, the GFI, CFI, TLI, and NFI was calculated to be 0.992, 0.992, 0.950, and 0.989, respectively. Index values of 0.95 or greater represent acceptable conformity (Schumacker & Lomax, 2004). Estimating the structural β coefficients of the model provided the statistically significant pathways on all variables measured. As such, a model re-specification was not necessary, and the hypothesized model was selected as the final model.

Figure 2. Standardized structural regression model for SUPR-Q (quality of user experience on website), situational interest, mind-wandering, and online engagement for sample (n=303). *Note*. **.Correlation is significant at the 0.01 level (2-tailed), *. Correlation is significant at the 0.05 level (2-tailed). Dotted lines represent non-significant path.



After determining the model conformity indices, the standardized beta coefficients of the direct effects were further examined. A summary of the effects can be found in Figure 2. The standardized coefficients can be interpreted as a change in units of standard deviations. For example, a 1 unit change in SUPR-Q is related to 0.193 increase in standard deviations for online engagement. Consistent with our predictions, we found that both students' SUPR-Q (user experience) ($\beta = 0.193$, $p < 0.01$) and students' situational interest ($\beta = 0.558$, $p < 0.01$) had significant positive direct effect on students' online engagement. Furthermore, students' mind-wandering ($\beta = -0.088$, $p < 0.05$) had a significant negative direct effect on students' online engagement. Altogether, students' user experience, situational interest, and mind-wandering together accounted for 51.7% of the explained variance in students' online engagement ($R^2 = 0.517$). We also found that students' situational interest ($\beta =- 0.136$, $p < 0.01$) had a significant negative direct effect on students' mind-wandering, accounting for 1.9% of the explained variance in students' mind-wandering ($R^2 = 0.019$). Lastly, we found that students' SUPR-Q ($\beta = 0.674$, $p < 0.01$) had a significant positive direct effect on students' situational interest with it accounting for 45.5% of the explained variance ($R^2 = 0.455$)

As the aforementioned direct effects were significant, the simple and sequential mediating effects of students' situational interest and mind-wandering were examined. To evaluate these mediation effects, we first examined the significance of the simple (mediated) indirect effects of students' situational interest on (1) students' SUPR-Q and students' mind-wandering and (2) students' SUPR-Q and students' online engagement. Next, we examined the significance of the indirect effects of students' mind-wandering on students' situational interest and students' online engagement. The standardized indirect (mediated) effect of students' SUPR-Q on students' mind-wandering was ($\beta = -0.092$, $p < 0.05$). In addition, the standardized indirect effect of SUPRQ mediated by situational interest on students' online engagement was ($\beta = 0.384$, $p < 0.01$). Next, we evaluated the significance of the simple mediation effect of mind-wandering on situational interest and students' online engagement. The standardized indirect (mediated) effect of situational interest on online engagement was ($\beta = 0.012$, $p < 0.05$). Lastly, we examined the cascading relationship of students' user experience indirectly related to students' online engagement through the sequential mediating effects of situational interest and mind-wandering. The standardized direct effect of students' SUPR-Q on SI ($\beta = 0.674$, $p < 0.05$), SI on MW ($\beta = -0.136$, $p < 0.05$), and MW on Engagement ($\beta = -0.088$, $p < 0.05$) were all significant. As a result, the standardized indirect (mediated) effect of students' SUPR-Q on students' online engagement was ($\beta = 0.008$, $p < 0.05$). The standardized total effect of SUPR-Q on SI was ($\beta = 0.674$). The standardized total effect of SI on MW was ($\beta = -0.136$). The standardized total (direct and indirect) effect of MW on PLE was ($\beta = -0.088$). The standardized total effect of SI on PLE was ($\beta = 0.570$). The standardized total (direct and indirect) effect of SUPR-Q on MW was ($\beta = -0.092$). The standardized total effect of SUPR-Q on PLE was ($\beta = 0.577$). These results suggest the partial mediation of the association between students' user experience and online engagement through situational interest and students' frequency to mind-wander.

Conclusion, implications, and limitations

During this unprecedented time, LX designers have the challenge to not only develop learning environments that increase conceptual understanding by drawing on theories of learning sciences, but also create experiences that

are interesting, engaging, and human-centered to support a broad range of learners given the disruptions to teaching and learning. This affords a unique opportunity to deploy online courses that are grounded in evidence-based pedagogies to further validate the utility and efficacy of online learning as an effective mode of learning in its own right that may have been plagued by Zoom teaching methods. As LX designers, educators, and researchers, we must be conscientious of students' dynamic learning contexts and the impacts of their surrounding environment to empathize with young students' needs while developing educational interventions (Seymour, 2020). Thus, by collaborating with teachers directly, codesigning the online video lessons to fit the classroom curricula and assessing the needs of teachers and their students while distance learning, we co-developed a video-based online math course to explore how best to support students' engagement through LXD.

More specifically, this study operationalized LXD through the combination of instructional design as a lever for promoting students' situational interest (SI), emphasis on human-centered design to support students' user experience (UX), and the combination of situational interest and user experience to reduce students' mind-wandering and foster student engagement in an online learning environment. Interestingly, our analyses suggest that students' situational interest and user experience while interacting with the online learning interface were significant predictors of students' online engagement. The results also reveal that situational interest and mind-wandering were significantly corelated to students' online engagement. Thus, when analyzing the indirect pathways, we confirmed our hypotheses that students' mind-wandering and situational interest as significant mediators explaining the relationship between students' user experience in the course and their online engagement. Furthermore, we identified sequential mediating effects of students' user experience to engagement through situational interest and mind-wandering.

These findings illuminate our understandings of the application of LXD, suggesting a potential underlying mechanism explaining our LX design impacts on learners' course experience and course engagement. On average, we documented that students who experience high user experience within the learning environment, show greater situational interest within the math course, and ultimately show greater instances of course engagement. The results also suggest that students' situational interest positively effects their level of engagement, when factoring in how much students' mind-wander. By preserving the ecological validity of the classroom environment in the instructional videos, students were able to follow along with the teacher and immediately practice the math concepts. This may be one factor in the course design that increases students' situational interest and reduces students' mind-wandering, as it provides a similar in-person learning context of the classroom while also utilizing the key affordances of asynchronous online learning (Begolli & Richland, 2018). Careful attention to the course usability aimed to promote quality user experience design by facilitating ease of use, findability, and navigability (Simunich et al., 2015). Additionally, to maximize opportunities for engagement, knowledge checks, scaffolded problem sets, math animations (worked examples), and math reflections were embedded within each math problem to guide students through sustained participation and interactivity. These user experience design decisions afforded students the opportunity to recognize their initial understandings of the math concepts and allow students to review and practice by navigating backwards or replaying a video. As such, students were able to actively take control of their learning pace and adapt their learning behaviors to mind-wander less and stay engaged in the course content. Thus, quality user experience and the degree of interaction between learners and the online learning environment are consequential to supporting students' engagement in an online learning environment. These findings suggest that the LXD paradigm of combining evidenced-based pedagogical learning design and human-centered user experience design as a feasible approach to generate interest, reduce the onset of mind-wandering, and increase engagement in asynchronous teaching and learning with children.

While the results of this study are correlational which serves as a limitation, there are important theoretical underpinnings and practical implications that support children's motivational, cognitive, and behavioral factors that can be applied to online teaching and learning immediately. As referenced earlier, emergency remote online learning is fundamentally different from online courses designed with evidence-based theory and practice. However, this presents a unique opportunity to further research and identify how instructors can better support their student's learning experience, as the remote learning context has paved the way for alternative learning modalities. Based on our study findings, we have learned that students' engagement is, in part, explained by their user experience with the learning platform, and mediated by situational interests and mind-wandering. These results are important as it affords instructors to consider the LXD paradigm to better attend to factors that positively impact students' mind-wandering and online engagement. Thus, our study makes an important contribution to building and clarifying learning theories with educational technologies, as it suggests design factors contributing to students' user experience and situational interest together with mind-wandering mediates students' online engagement. Moreover, these results add to our understandings of students' learning experience during emergency remote distance learning, which will serve as a foundation for future experimental research iterations to implement online LX design principles. As the landscape of teaching and learning continues

to evolve with expanded learning options, this research provides insights into LXD as a feasible pedagogical model and suggests design facets that may be implemented in-person and through hybrid modalities in the future.

Epistemic Games with Emergent Systems Microworlds

Sugat Dabholkar, Uri Wilensky
sugat@u.northwestern.edu; uri@northwestern.edu
Northwestern University

Abstract: This paper is about designing learning environments that support students' epistemically agentic participation in a science classroom. We use Collins and Ferguson's idea of *epistemic games* to investigate students' participation and learning with an Emergent Systems Microworld (ESM)-based learning environment. ESMs are computational models that are designed using agent-based representations and constructionist design principles. Qualitative analysis of student responses to embedded curricular questions reveals different epistemic games they engaged in using the ESM. An in-depth analysis of an epistemic game demonstrates how agent-based representations supported student investigations of a phenomenon related to natural selection. The findings illustrate how ESM-based learning environments can support students' agentic participation in epistemic games to make sense of emergent phenomena.

Introduction

Science educators, science education researchers, and designers of learning environments have argued that student participation in science classrooms should go beyond 'knowing about' disciplinary ideas in science and the practices of scientists and include authentic participation in scientific inquiry practices to 'make sense of the world' (Chinn & Malhotra, 2002; Miller et al., 2018; Scardamalia & Bereiter, 1991; Schwarz et al., 2017). To design for such authentic and epistemically agentic participation, we build on two design theoretical frameworks, constructionism (Papert, 1980) and agent-based models to investigate and learn about emergent systems phenomena (Wilensky, 2001; Wilensky & Rand, 2015).

We use 'epistemic games' as a theoretical construct in this paper to analyze students' participation in the learning environment that we designed. The notion of epistemic games is inspired by Collins and Ferguson's conceptualization of epistemic games (Collins & Ferguson, 1993). Another commonly used conceptualization of epistemic games in the field of Learning Sciences is Shaffer's framework of epistemic frames and games (Shaffer, 2006). Though there are similarities between these conceptualizations at the fundamental level - both are about strategies related to knowledge construction - their operationalizations differ. Collins and Fergusson define epistemic games as strategies and rules that practitioners of science use for constructing knowledge about natural phenomena whereas Shaffer's work is about educational role-playing games which are framed as epistemic games (Arastoopour & Shaffer, 2013; Collins & Ferguson, 1993). In our work, we use Collin and Fergusson's definition in the context of science education. We frame students' epistemic games as strategies that they use to investigate and construct knowledge about natural phenomena in a learning environment designed for this purpose.

In this paper, we study students' epistemic games in a type of learning environments, which we call *Emergent Systems Microworlds (ESM)-based learning environments* (Dabholkar et al., 2018). These learning environments use ESMs which are agent-based computational models that are designed as interactive constructionist microworlds (Edwards, 1995; Papert, 1980). We use the term ESM-based learning environment to include an ESM, curricular activities, and pedagogical practices. We investigate how students engaged in different epistemic games and how that engagement supported their learning of disciplinary ideas. We also investigate how agent-based representations used in the ESM supported learning of an emergent phenomenon modeled in the ESM. We first discuss theoretical and design frameworks that informed this work, which we see as our contributions to approaches for designing learning environments. Then we present our findings and discuss how they demonstrate the effectiveness of our design approach for supporting students' agentic learning.

Theoretical Frameworks

Epistemic Forms and Games

The theoretical framework used in our analysis is inspired by Collins and Ferguson's notion of epistemic forms and games (Collins & Ferguson, 1993). Epistemic forms are the target structures that guide a scientific inquiry, and epistemic games are the rules and strategies that researchers use to generate epistemic forms. A metaphor that Collins & Ferguson (1993) use is the game tic-tac-toe. The nine squares form a target structure to be filled and thus determine the epistemic form. The rules that players follow and the strategies they use to place crosses and noughts (Xs and Os) are part of the epistemic game. Epistemic forms are generative frameworks with slots and

 © ISLS

constraints regarding filling those slots. The desired result of an epistemic game is to complete a target structure that corresponds to a particular epistemic form. For example, making a list of invasive species in a particular habitat is an epistemic game and the target epistemic form is *the list* itself. In this paper, we use these notions in a novel approach to inform the design of learning environments and analyze student learning with those curricula.

Agent-based restructurations

Another theoretical framework that is used for the design of the ESM-based learning environment is called the theory of restructurations (Wilensky, 2020; Wilensky & Papert, 2010). The theory of restructurations is about investigating how new representational forms reformulate knowledge in various disciplines often with dramatic effects. Agent-based modeling of emergent systems is an example of restructuration and consequently one of the central design features of an ESM. Dynamic computational agent-based representations are restructurations of emergent phenomena. While these are typically taught with differential equations or static models (Wilensky & Papert, 2010), the power (the analytical power to express and investigate an emergent phenomenon) and learnability (cognitive, social, affective, and diversity) properties of agent-based representations make them effective for investigating and learning about emergent phenomena.

Design Framework

Emergent Systems Microworlds

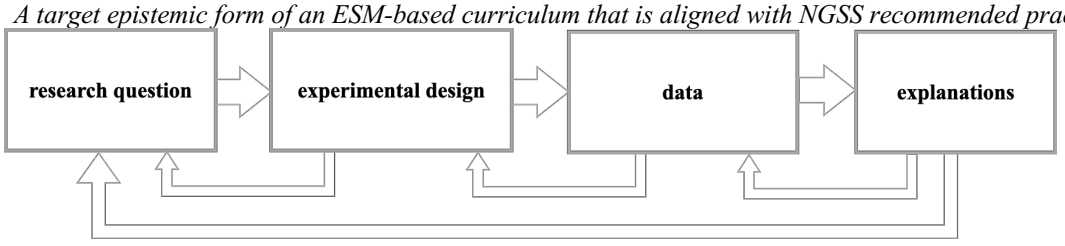
The ESM design framework combines agent-based modeling and constructionism and is inspired by similar prior work (for example, see Wilkerson-Jerde & Wilensky, 2010) and a related design framework called Emergent Systems Sandboxed (ESS) (Brady et al., 2015). The framework for design of ESMs and ESM-based curricula draws its theoretical foundations from Wilensky and Papert's theory of restructurations (Wilensky, 2020; Wilensky & Papert, 2010). In addition to using agent-based restructurations, ESMs are designed as interactive microworlds for students to explore and investigate phenomena (Dabholkar et al., 2018). A microworld, which is a constructionist design concept, is an encapsulated open-ended computational exploratory environment in which a set of ideas can be investigated that lead to knowledge construction (Edwards, 1995; Papert, 1980).

Epistemic form and epistemic games with an ESM

We use the Epistemic Forms and Games theoretical framework to analyze an ESM-based learning environment designed for students to engage in epistemic games to generate a desired epistemic form (Collins & Ferguson, 1993). The Next Generation Science Standards (NGSS) pushes for the learning of practices in disciplinary contexts, which can take various epistemic forms (NGSS Lead States, 2013). We developed one such form for pedagogical purposes, which we have used to design an ESM-based curriculum (Figure 1).

Figure 1

A target epistemic form of an ESM-based curriculum that is aligned with NGSS recommended practices.



This target structure in an ESM-based curriculum often takes the form of what Collins and Fergusson refer to as process analysis (Collins & Ferguson, 1993). Process analyses attempt to characterize behaviors of dynamical systems. ESMs are models of a dynamic complex system that provide easy access to visualization and investigation of emergent patterns that arise from agent interactions. Users have visual access to agent-level interactions and system-level emergent patterns. As evidenced in the data that we present later in this paper, when students use an ESM to engage in this epistemic form (Figure 1), their explanations about emergent properties of a system (such as a change in a population because of natural selection) are often based on the mechanistic details of agent integrations in the system (such as inheritance, predation, reproduction).

Research Context

Participants and setting

Evolution of Populations is a ten-day ESM-based biology unit designed by the lead author in consultation with high school biology teachers. Ms. Lydia (pseudonym), a biology teacher in a large Midwestern city's public

school, taught this unit in 2018 to freshman students in four classes (n = 88). 100% of the participating students were on a free lunch program (an indicator of belonging to an underserved population). Students were predominantly of Hispanic or Latino (75%) and African American (11%) ethnicity.

ESM-based Curriculum

The ESM-based curriculum was designed to introduce students to population dynamics, prey-predator relationships in an ecosystem, and natural selection. Activities were delivered through an online curriculum portal (https://ct-stem.northwestern.edu/curriculum/preview/681/) and were split into lessons. Each lesson consisted of 3-4 pages. Typically, on each page, students read a prompt with a description of a computational model and suggestions for exploration. Then, students answered 2-5 embedded assessment questions on each page. The ESMs in the unit are built using NetLogo (Wilensky, 1999), an agent-based modeling platform that is intentionally designed to foreground emergent systems modeling for educational and research purposes.

An ESM in this unit was designed as a computational experimental system for students to investigate phenomena related to population dynamics, population genetics, and natural selection. The design of the ESM was inspired by a short film designed by Howard Hughes Medical Institute (HHMI)[1] about natural selection and adaptation in populations of rock pocket mice. The HHMI film gives a geological history of the American Southwest and discusses the research about changes in populations of rock pocket mice. Rock pocket mice belong to a species of mice *Chaetodipus intermedius*, which are mainly found in rocky outcrops in the deserts of the southwestern United States and Mexico. Mice that camouflage well with the surroundings have a higher chance of surviving predation by avian predators. The mice that are found in sandy areas typically have a light fur-coat, whereas the ones found in rocky areas have a dark-colored fur-coat. Evolutionary biologists and molecular geneticists who have studied these populations in New Mexico have attributed this adaptive variation in the color of fur coat primarily to mutations in a gene called the melanocortin-1-receptor gene, *Mc1r* (Nachman et al., 2003).

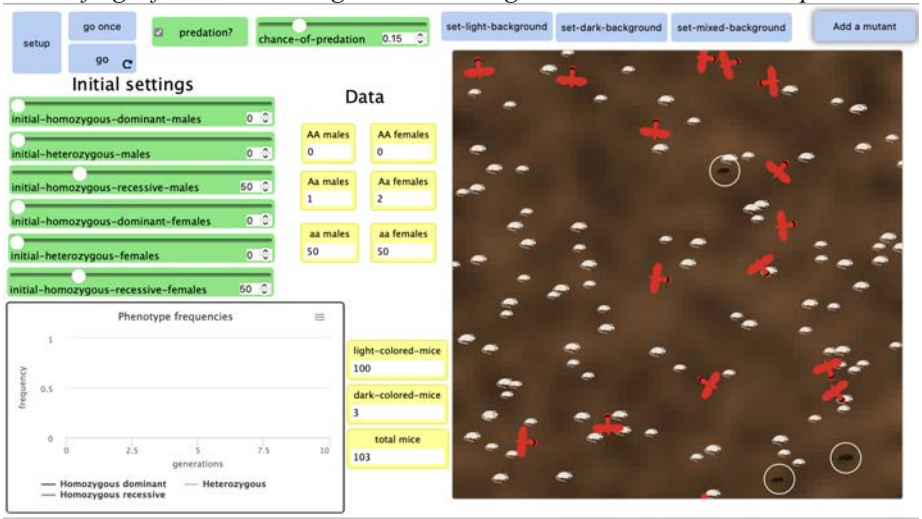
We designed the curricular activities to scaffold students' use of the ESM to design and conduct investigations using the ESM (Figure 2). The curricular activities included - (a) students watching the HHMI video and deciding research questions they want to investigate about rock pocket mice, (b) students' open-ended explorations of the ESM, (c) refinement of the research questions such they can be answered using the ESM, (d) scaffolded activities to understand specific aspects of the ESM such as inheritance or predation, (e) final refinement of research questions, self-driven experimental investigations of those research questions.

Possible Epistemic games with the ESM

The Rock Pocket Mice ESM was designed for students to investigate how populations of different initial compositions change in response to different environmental conditions. Students could choose different settings to investigate different aspects of the phenomenon (see Figure 2 and Table 1).

Figure 2

Rock Pocket Mice ESM in which users can engage in many different epistemic games by deciding initial population composition, predation rate, background colors, and whether to introduce mutant or not. In this figure, a user has introduced three mutants (heterozygous dark-furred mice) into a population of light furred mice living in a dark background environment with a predation rate of 15%.



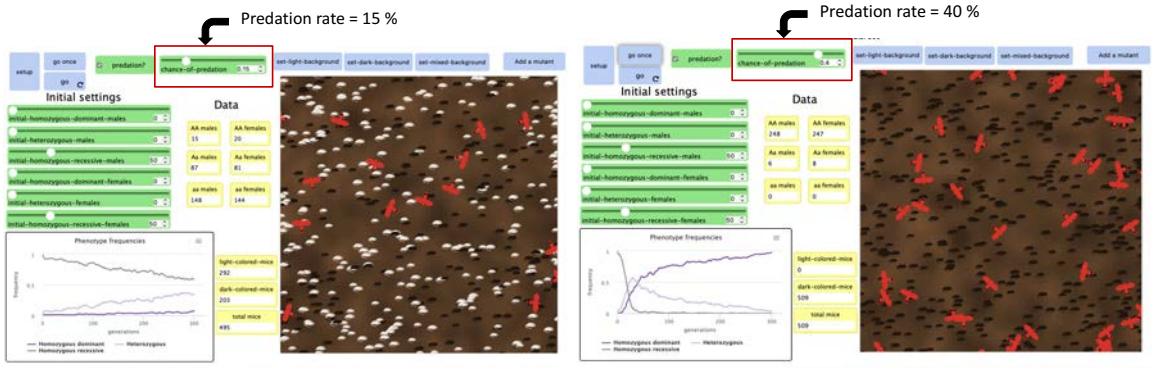
[1] https://www.biointeractive.org/classroom-resources/making-fittest-natural-selection-and-adaptation

For example, one of the students in the class wrote her final research question as follows:
If we have a population of mice with light fur coats only living in a dark background, and we add 3 mutant mice, how will the population change after 300 generations with a 0.15 chance of predation?
For this research question, the experimental setup would look like what is shown in Figure 2. Students could use this ESM to set up their experiments by changing one or more of the four conditions – initial population, background color, predation, and introduction of mutants (See Table 1). Combinations of these experimental conditions allowed students to investigate various aspects regarding how populations change because of natural selection such as the effect of camouflage for survival, predatory pressure, etc.

Table 1
Different experimental settings in the ESM that users can decide to design computational experiments for investigating their research questions

Initial population composition	**Background**	**Introduction of mutant/s**	**Predation**
Light (homozygous recessive), dark (homozygous dominant, or heterozygous), or mixed	Light, Dark or mixed	Yes, or no	Low, high or no predation

Depending on how experimental conditions were set, students saw different experimental outcomes. For example, with a 15% of predation rate, which was mentioned in the research question, three hundred generations are not enough for the dark fur phenotype to become predominant in the population, whereas predation rate of 40% causes elimination of light fur phenotype in the population after 300 generations (See Figure 3).
Figure 3
Experimental outcomes after 300 generations with different predation rates



In the first part of our analysis, we investigate different kinds of epistemic games that students played using the ESM. In the second part, we present in detail an epistemic game of a student and discuss student engagement in an epistemic game to help us investigate their learning with the ESM. Our research questions are:

1. What were the different kinds of epistemic games that students played using the rock pocket mice ESM?
2. How did agent-based representations support learning of an emergent phenomenon as students participated in epistemic games?

Methods

We performed a qualitative analysis of student responses to the questions in the ESM-based curriculum to investigate their epistemic games (Miles et al., 2014). Student responses to the following question were coded to identify their epistemic games:
Come up with a question about natural selection in the case of the pocket mice, which can be answered using this model. One example of a question that could be answered using the model: If we introduce a mutant (with a dark-fur-coat) in a population of mice with light-fur-coats that are living in a mixed background environment, how will to population change after 500 generations?

Note that this question in the curriculum provides students with an example question, which is likely to have guided framing of student responses. Nevertheless, as seen in the data presented in the findings section, students designed several different kinds of epistemic games. Based on the conditions that students could vary in the ESM to investigate their research questions, we created the following codebook to code students' epistemic games.

 © ISLS

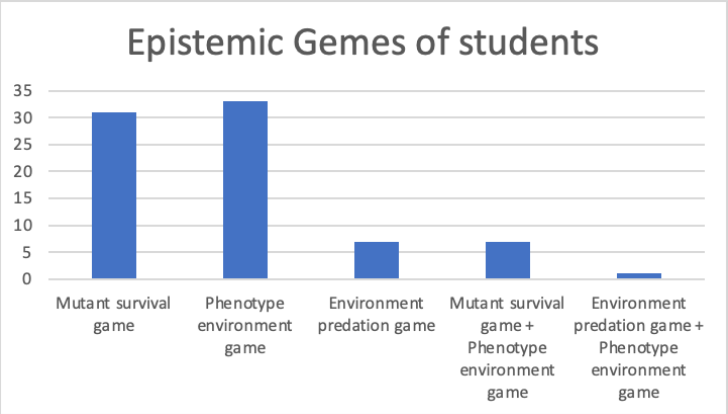
Table 2
Codebook used to code for students' epistemic games

Epistemic Game Code	Explanation	Example
Mutant survival game	An epistemic game of investigating how mutant mice survive in a population of specific composition living in specific environmental conditions.	*If we have a population of mice with light fur coats only living in a dark background, and add 3 mutant mice, how will the population change after 300 generations with a 0.15 chance of predation?*
Phenotype environment game	An epistemic game of investigating how specific phenotypes survive in specific environmental conditions	*If we have a few with light fur coats in a population of homozygous dominant (dark fur coat) mice that are moving in a mixed background environment, how will the population change after 200 generations?*
Environment predation game	An epistemic game of investigating how different predation rates affect survival	*If we have a normal amount of heterozygous mice on different backgrounds how will they react to a high and low predatory rate?*
Mutant survival game + Phenotype environment game	An epistemic game of investigating the survival of specific phenotypes and mice with the mutant phenotype in specific environmental conditions	If we decrease the population of dominant dark-colored mice to 30 and increase the population of light-colored mice to 150 that are living in a mixed background but add about 10 mutants, how will the population of dark-colored mice look over 300 generations?
Environment predation game + Phenotype environment game	An epistemic game of investigating how the predation rate affects survival of mice with specific phenotypes living in specific environmental conditions	If we change the predation percentage to .15 in a population of mice with both light and dark fur colors (heterozygous) that are living in a dark environment, how will the population change after 250 generations?

Findings

The ESM supported designing and conducting experiments to engage in various kinds of epistemic games. Students participated in five kinds of epistemic games. The majority of students participated in mutant survival (n= 31) and phenotype environment (n = 33) games (See Figure 4). The mutant survival game is the same as the one mentioned in the example research question provided to the students. This game involves introducing mutant mice in a specified environment and studying their survival. A phenotype survival game is about investigating the survival of mice of a specific phenotype (dark fur or light fur) in a specific environment (dark/light/mixed background, predators present/absent). Environment predation game is a more sophisticated game, which 7 students participated in. This game involved investigating the effects of predation rates on the survival of mice. 8 students played combinations of games – 7 played mutant survival + phenotype environment game and 1 played environment predation and phenotype environment game.

Figure 4
Frequencies of students participating in different epistemic games



Each type of students' epistemic game attempted to investigate different kinds of research questions. For example, in the *mutant survival* games, the research questions were about introducing specific kinds of mutants in a specific kind of environment and investigating their survival (See an example question in Table 2). In each epistemic game the specific details of the investigations – the experimental conditions, data collection and analysis strategies – were different. These differences show how they exercised their epistemic agency in performing scientific investigations. In the next part, demonstrate this further by performing an in-depth analysis of an epistemic game of a student.

Emma's epistemic game

In the second part of the analysis, we discuss the epistemic game of a student, Emma (pseudonym). We argue how agent-based restructurations in the ESM facilitated Emma's investigations of the emergent phenomenon related to the change in the population of rock pocket mice because of natural selection. Emma participated in the ESM-based curriculum as a part of a group of five students. That is the reason why in Emma's responses she uses 'we' instead of 'I'. Emma's group participated in the mutant survival game. Their game involved introducing mutant agents in populations of specific agent characteristics (homozygous recessive) and observing system-level changes in the population after 400 generations (see Figure 5). Emma's responses about their hypothesis and the experiment design help us understand their epistemic game better. They added 10 mutant mice with dark-colored fur to the population of homozygous recessive mice (light-colored fur), in a light background with a predation rate of 35%. Their hypothesis was about the survival of dark-colored mice. They hypothesized that the population of dark-colored mice will be less and less. In their experimental design, they system-level settings related to the environment - predation rate and background color and agent-level properties of the population of mice and how they would change the initial population composition by adding 10 mutants.

Figure 5

Emma's research question, hypothesis, and experimental design

Research Question -

If we introduce 10 mutants in a population of homozygous recessive mice that are living in a light background environment, how will the population change after 400 generations?

Hypothesis -

If we add the 10 mutants with dark colored fur to the population of homozygous recessive mice that are living in a light background environment then the population of the dark colored mice will be less and less because [because] they will be the ones standing out in the light enviroment [environment] not being able to camoflauge [camouflage].

Experimental design -

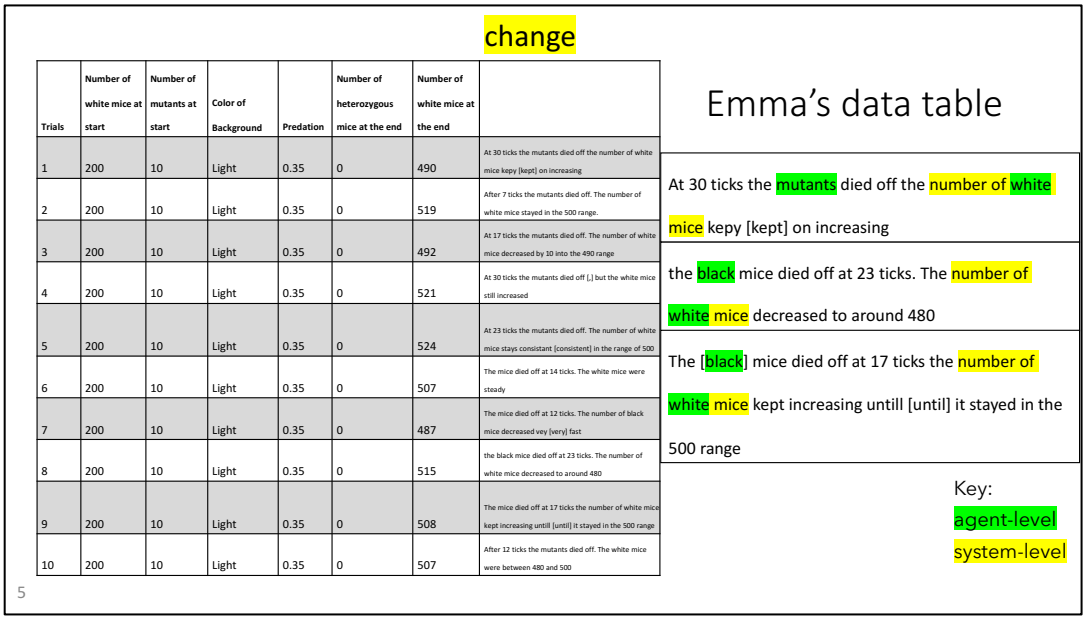
we kept the predation on at 0.35	Environment - predation
we set the background environment color to light	Environment - background
we set all the other sliders to zero except for homozygous recessive males and homozygous recessive females.	Genotype/phenotype
we set the homozygous recessive males and homozygous recessive females sliders to 100	Genotype/phenotype
we then would add 10 mutants	change
we would keep the number of mutants the same in each experiment.	Multiple trials

Key:
agent-level
system-level

Emma's response to a question about data collection (See Figure 6) shows the experimental settings and outcomes that they recorded in each of the ten trials conducted. They also wrote their observations at the end of each of the trials. We have enlarged three observations in the data table to show how the students noted agent properties and system-level changes at the end of each trial.

Figure 6

Emma's data and observations: Emma conducted 10 trials and noted number of *white mice at start, number of mutant at start, color of background, predation, number of heterozygous mice at the end, number of white mice at end* and qualitative observations at the end of each trial. three observations are enlarged as examples.



change

Trials	Number of white mice at start	Number of mutants at start	Color of Background	Predation	Number of heterozygous mice at the end	Number of white mice at the end	
1	200	10	Light	0.35	0	490	At 30 ticks the mutants died off the number of white mice kepy [kept] on increasing
2	200	10	Light	0.35	0	519	After 7 ticks the mutants died off. The number of white mice stayed in the 500 range.
3	200	10	Light	0.35	0	492	At 17 ticks the mutants died off. The number of white mice decreased by 10 into the 490 range
4	200	10	Light	0.35	0	521	At 30 ticks the mutants died off [,] but the white mice still increased
5	200	10	Light	0.35	0	524	At 23 ticks the mutants died off. The number of white mice stays consistant [consistent] in the range of 500
6	200	10	Light	0.35	0	507	The mice died off at 14 ticks. The white mice were steady
7	200	10	Light	0.35	0	487	The mice died off at 12 ticks. The number of black mice decreased vey [very] fast
8	200	10	Light	0.35	0	515	the black mice died off at 23 ticks. The number of white mice decreased to around 480
9	200	10	Light	0.35	0	508	The mice died off at 17 ticks the number of white mice kept increasing untill [until] it stayed in the 500 range
10	200	10	Light	0.35	0	507	After 12 ticks the mutants died off. The white mice were between 480 and 500

Emma's data table

At 30 ticks the mutants died off the number of white mice kepy [kept] on increasing

the black mice died off at 23 ticks. The number of white mice decreased to around 480

The [black] mice died off at 17 ticks the number of white mice kept increasing untill [until] it stayed in the 500 range

Key:
agent-level
system-level

5

Finally, Emma wrote her conclusion as follows:

In conclusion or [our] hypothesis was correct. We asked about how adding 10 mutants to the population of mice would chnage [change] it . We thought that the black furred mice would decrease in population because they would be the ones tanding [standing] out in the light environment. We were right becuase [because] in all of our trials the black furred mice ended up dieing [dying] off after a couple of generations. The mutants did not affect the population of light furred mice because [because] probably predators would eat them before they got a chnace [chance] to reproduce and produce mixed offspring.

Emma's response in her conclusion shows how she and her group considered agent properties and agent behaviors to explain a system-level change in the population. They also discussed that the dark-furred mice could not survive beyond a few generations because they did not camouflage and got predated before they could breed with the light-furred mice to produce mixed offspring.

Discussion

The findings of our study demonstrate how the ESM-based learning environment supported student engagement in different kinds of epistemic games, which helped them learn about disciplinary ideas by engaging in science practices in epistemically agentic ways. Characterization of students' epistemic games revelated that they played five different kinds of epistemic games using the ESM. Each type of game is helpful to study different aspects of the natural phenomenon being investigated and develop mechanistic explanations regarding the phenomenon. The epistemic games that students played were not assigned to them or even pre-decided in the curriculum. These games were identified and characterized based on students' research questions. The ESM served as an experimental system or a playground for students to devise and play their epistemic games to investigate those research questions. These findings demonstrate that the ESM design and ESM-based curriculum supported investigations of different aspects of a phenomenon by encouraging self-driven agentic learning.

The qualitative analysis of Emma's case demonstrates how agent-based representations and constructionist design features of the ESM supported her participation in her epistemic game. Emma's experimental design was aligned with her research question. It involved manipulation of the composition of the initial population by specifying agent properties and system-level environmental conductions. Her experiment was meticulously designed, which included ten trials. The data analysis helped her develop mechanical explanations regarding natural selection. Her answer shows how she considered the effect of agent properties and system-level environmental conditions in determining their survival and reproduction, which would in turn affect the passing of traits in the next generation and survival of those traits in the population. This analysis demonstrates how Emma's epistemic game using the ESM for creating the epistemic form (Figure 1) helped her learn about some of the fundamental ideas regarding natural selection.

In the future, we want to focus on how student groups in an ESM-based learning environment can learn from the epistemic games that other student groups in the class play. In this study presented in this paper, sharing across student groups did not happen as much as we wanted. The teacher asked students to share their research questions, however, student groups were not asked to share their claims and evidence that they used to verify their

claims. Our future work will involve designing specific scaffolds in the curricula that will facilitate sharing across groups so that students learn different kinds of epistemic games that can be played to learn about a phenomenon (practices) and conclusions from those games (disciplinary ideas).

Mediating elementary students' mechanistic reasoning in collective embodied modeling activities

Mengxi Zhou, Morgan Vickery, Joshua Danish
Indiana University Bloomington
mz13@iu.edu, moravick@iu.edu, jdanish@indiana.edu

Abstract: This paper explores elementary students' mechanistic reasoning about states of matter during a series of collective embodied modeling activities. Recognizing students' mechanistic reasoning in a collective embodied space can be challenging since students' reasoning is often deeply - yet implicitly - embedded in their interactions. In this paper, we use Russ et al.'s (2008) mechanistic reasoning framework as a guide to identify moments of mechanistic salience for students and draw upon the learning in embodied activity framework (Danish et al., 2020) to map the mediators within the environment that contribute to the production of such mechanistically rich moments.

Introduction

Mechanistic reasoning is a reasoning ability about the causal process that underlie natural phenomena (Russ et al., 2008). Prior studies have explored the potential of embodiment as a way to explore and understand mechanisms (Danish et al., 2017; Dickes et al., 2016; Mathayas et al., 2019). In the present study, we seek to elaborate the potential connections between mechanistic reasoning and embodiment by examining elementary students' embodied sense-making around mechanism in collective embodied modeling activities using the Science through Technology Enhanced Play (STEP; Danish et al., 2015; 2020) mixed reality (MR) environment.

Students who are participating in a collective embodied model are often moving continuously. Thus, while teachers and experts may recognize mechanisms embedded in those actions and movements, those embedded mechanisms are not always attended to by students who shift their attention and movements from moment to moment. For example, students may move slowly to represent a liquid state of matter without intentionally aiming for an intermediate distance between their enacted particles, nor noticing this as relevant to producing that state of matter. As such, the present analysis focuses on moments when mechanisms are visible in students' interactions to understand how students' attention to those mechanism is mediated by their interactions. We then ask: how do mediators in a collective embodied modeling activity affect students' understanding of mechanism within states of matter?

Theoretical framework

Mechanistic reasoning

Mechanistic reasoning, particularly its use to account for dynamics within the natural world, is foundational to the development of students' scientific inquiry skills (Koslowski, 1996; Russ et al., 2008). In such contexts, mechanistic reasoning is conceptualized by Russ et al. (2008) as the development of ontological and causal descriptions of underlying structures based on prior knowledge, expertise in a domain (diSessa, 1993), and everyday experiences (Keil et al., 1999). While scholarship has proven the value of creating explanations for how a cause brings about an effect (Schauble, 1996), Kuhn (1997) expands on this conception, drawing attention to understanding the 'broad cause' of a phenomenon. This framing encompasses not only the association between agents and sequential effects but also the underlying processes of that association thus enabling students to make predictions (Russ et al., 2008). Furthermore, mechanistic reasoning integrates students' explanations of how unobservable structures and components at the micro-level of a system account with observable changes at the macro-level (Schauble, 1996). Although mechanistic reasoning is considered a high-level reasoning ability, prior studies have demonstrated that young children can be scaffolded to construct and explain the mechanism of natural phenomena in different domains, such as biology (Danish et al., 2017) and ecology (Dickes et al., 2016).

Mediated collective embodied activity

This study is guided by the Learning in Embodied Activity Framework (LEAF; Danish et al., 2020) which expands upon Cultural Historical Activity Theory (CHAT; Engeström, 1999) for embodied learning contexts. LEAF synthesizes individual and sociocultural theories of learning and highlights the role of the body as a

 © ISLS

valuable learning resource; within LEAF, each mediator in Engeström's CHAT framework (subject, object, division of labor, community, rules, and tools) is analyzed for its role in transforming embodied learning at both individual and collective levels. To privilege the body as a sensemaking resource, LEAF draws on situated simulation theories (Alibali & Nathan, 2012) and body cueing (Lindgren, 2015) at the individual level, merging them into sociocultural context to understand students' engagement in a joint embodied activity. Individual students' embodiment needs to be understood through alignment with others. The present study design was heavily guided by these principles, situating the various elements present as *mediators* of the activity.

Vygotsky (1978) defines mediators as material and/or ideal cultural tools that transform the relationship between a subject (participant) and the object (goal) of their activity. These mediational means are socioculturally situated and have associated constraints and affordances. In our analysis, we view students' experiences in STEP through the lens of *mediated action* (Wertsch, 1981) where students engage in meaningful action and may as a result appreciate the value of the cultural mediators for their action and apply them in later activity. Our goal is to explore what mediators are present in moments when students identify aspects of mechanism and how these mediators contribute to students' mechanistic reasoning. In the present study, an individual student (subject) embodies a water particle (rules) in a space that is tracked and visualized by a simulation (tool) to inquire particle behaviors (rules) through modeling different states of matter (object) with other "particle" students (community). Some students (community) observe their peers' embodied modeling and make inferences (a division of labor) about the impacts of embodiment on the state of matter based on the simulation feedback. Facilitators (community) scaffold students' embodied modeling and regulate students' classroom behaviors.

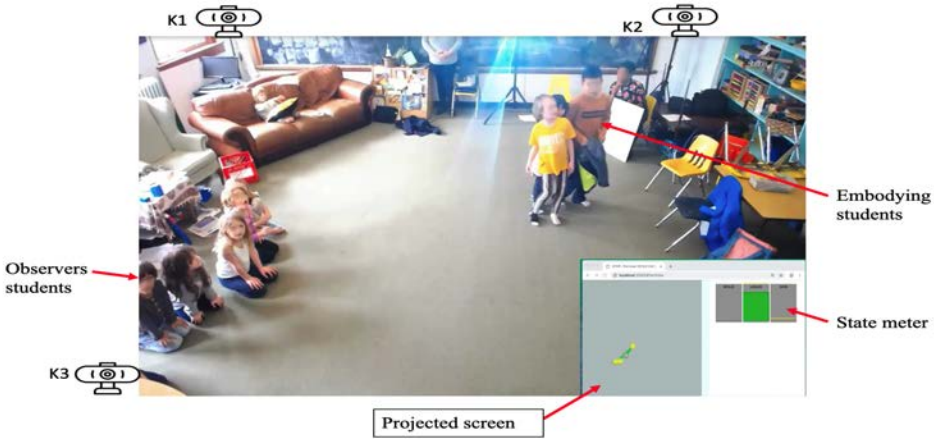
Methods

Design

The present modeling activities occurred using the STEP system, a MR environment for students to explore complex science phenomena (Danish et al., 2015). This curriculum featured 22 first and second-grade students from the Midwest engaging in seven thirty-minute class sessions to explore particles' behavior in three states of matter (Danish et al., 2020). As illustrated in Figure 1, there were three Kinect cameras (labeled K1, K2, and K3) tracking students' movements and projecting them as digital water particles on a projected screen. As students move and interact with each other as particles, their movement and interactions are simulated into different states of matter and displayed through the state meter on the screen.

Figure 1

Students in the STEP MR environment



Data source

This analysis focuses on how mediators in a collective embodied modeling activity contribute to students' collective mechanistic reasoning. We reviewed and contented logged video data across the seven days of the implementation. Next, we identified days three and six as offering the clearest contrast in how students explored mechanisms in exploratory versus more structured activities. During day three, students attended the state meters to indicate how their behavior and collective configurations produced different states of matter. During day six, facilitators asked students to demonstrate their understanding of mechanism by acting out the behavior of particles within predetermined environments as made visible on the projection (pond, ice world, and dessert).

 © ISLS

These two class sessions offer us insight into how students engage with mechanistic aspects of states of matter through embodied representations.

Applying Russ et al. (2008) mechanistic reasoning framework to STEP: Particles

In the present study, we draw Russ et al. 's (2008) mechanistic reasoning framework to understand students' reasoning on mechanisms in the context of the state of matter. Russ et al.'s (2008) framework arranges aspects of students' reasoning in a hierarchy based on logical connections and scientific sophistication. These components include (1) description of the target phenomenon, (2) identification of setup conditions, (3) entities, (4) entity activities, (5) entity properties, and (6) the organization of entities that followed mechanistic processes such as (7) chaining, (8) use of analogies, and (9) the use of animated models. We use this framework to characterize students' engagement in mechanistic reasoning through collective embodiment.

In the case of states of matter, we view *the target phenomenon* as the particle behavior that led to the three states of matter (solid, liquid, and gas) in the context of water. An example would be students' commenting on the appearance of a particular state of matter (i.e., "there is a solid") during the embodied activities. We coded *setup conditions* as the moments where students identified the necessary conditions in the environment to produce the phenomenon. For example, students might note that the environment needed to be hot to achieve a 'gas' state. *An entity* in this context was an individual water particle. Students' representations of *properties of entities* included identification of the different speed and attraction strengths of particles in different states. We coded *identifying the organization of entities* when students attended to the difference in distances between particles. *Activities* were coded as an acknowledgement of the various things that an entity engages in; and when students commented on particles' actions (i.e., the use of phrases such as "do," "go," or "move"); for example, when a student commented "let's go into a circle." We coded students' reasoning about changes in a phenomenon as a result of other events elsewhere/at a different scale as *chaining.* An example of (backward) chaining would be students' reasoning that "to make gas, we should move fast."

Data analysis

Two authors collaboratively and iteratively watched video data of the two class sessions through the lens of Russ et al. 's, (2008) framework to identify episodes where aspects of mechanistic reasoning were most salient in students' interactions. Two seven-minute episodes of video data were then selected because they depicted in-depth discussion of mechanism. These were then analyzed to explore how the activity design mediated those discussions. To accomplish this, each video was first segmented into 10-second segments. Authors then jointly coded all of the segments using Russ et al.'s mechanistic reasoning framework as a coding scheme. Next, the first author transcribed the moments with the highest number of mechanistic codes applied into multimodal transcripts. Finally, all authors used interaction analysis (Jordan & Henderson, 1995) to identify how mechanism was being represented through students' interactions, the mediators that contributed to this mechanistic reasoning, and other emergent patterns through iterations of collaborative data sessions.

Findings

The following three cases represent episodes during days three and six of the states of matter unit in which students collectively engaged in mechanistic reasoning about how particles produce states of matter using their bodies. We argue that as mediated action is situated in a particular time and space, that the mediational means present in the classroom function differently in different moments as demonstrated by the ways students do and do not appropriate them. Case one illustrates an episode early in the implementation in which students explored how their bodies could be used to represent particles of a state of matter. Here, verbal and visual cues functioned to productively constrain students' efforts; students realized that appropriate embodiment required attending to particular mechanistic properties of particles. Case two depicts an episode in which students' embodiment did not produce the intended state of matter; facilitators' verbal cues functioned to remediate the activity by shifting students' attention towards why their movements were not working and how to correct them. In case three, we focus on how the STEP system, as a mediator, functions (a) as an instructional organization tool and (b) to simultaneously orient students toward multiple aspects of mechanism at the microscopic and macroscopic level.

Case 1: Early explorations of state

The following episode was taken from a day three activity in which students are introduced to the concept of particles as related to the state of matter. The activity is exploratory and open-ended; students were not explicitly told that their movement were being mapped onto those of particles; however, through the use of simulation feedback (visual mediation), students came to the conclusion that (a) they were particles and (b) that

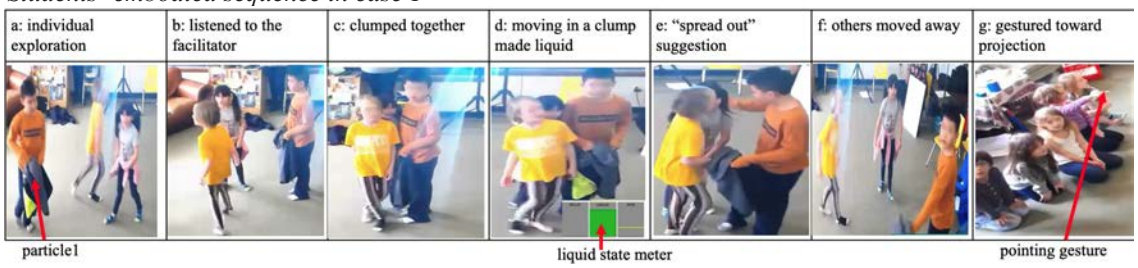
 © ISLS

their proximity to each other was integral to which state of matter was being produced. Table 1 and Figure 2 illustrate this episode.

Table 1
Case 1 transcript

	Actor	Talk	Embodiment
1	Particles		(Fig 2a) Students wander around individually.
2	Facilitator	What happens when you move together, try to notice something?	(Fig 2b) Three students stop, look at the facilitator, and listen.
3	Particle 1	OK	(Fig 2c) Particle 1 pull other particles together into a tight clump.
4	Facilitator	Instead of running around crazily.	(Fig 2d) All particles move in a tight clump.
5	Observer	Oh, it makes more liquid, the particles go closer together	
6	Facilitator	What happens when they are closer?	
7	Observer	Liquid, more liquid	
8	Particle 1	((hard to hear))	(Fig 2e) Particle 1 points to a farther place and gently pushes the other two students back.
9	Observer	Are they particles?	(Fig 2g) An observer points to the simulation.
10	Observers	They are particles!	All students look at the simulation.
11	Facilitator	Nice, Observer!	

Figure 2
Students' embodied sequence in case 1



Line 1 and Figure 2a shows how students moved around the embodied space individually with few observable indications that they recognized the importance of their movement relative to their peers. The facilitator offered a suggestion (Lines 2 &4) which students accepted as evidenced by how they moved closer together (Lines 3 & 4 and Figures 2c & 2d). This acceptance of the facilitator's suggestion signals that students' conceptions of 'moving together' was heavily related to proximity (speed has been a side-effect). The projected simulation responded to this change in movement by increasing the 'liquid meter' on the graph (Figure 2d) and the observing students shared their realization that this change in movement produced liquid (Line 5 &7). One of the embodying students (labeled 'Particle 1') attended to entity proximity (coded as *the organization of entities*) (Line 8 and Figure 2e) by suggesting that the other embodying students spread out; this suggestion was also accepted as evidenced by their peers moving away (Figure 2f). An observing student inferred that their peers were embodying particles (Lines 9 & 10 and Figure 2g) by gesturing towards the projection of the particle avatars. The rest of the observing students shifted their gaze towards the projection (Figure 2g), exclaimed in agreement (Line 10), and the facilitator expressed approval (Line 11).

This episode demonstrates how facilitators' verbal input and simulation feedback honed students' attention towards mechanistic aspects of the states of matter phenomenon. The combination of facilitator prompts, embodying students' movement as response to the prompt, and real-time projected simulation feedback increases the salience of these mechanistic aspects for students. First, this episode illustrates how students realized that their movements as particles (microscopic *entities*) are connected to which state of matter (the *target phenomenon*) is present. Furthermore, students acknowledged how the phenomenon was determined by the group's collective embodiment rather than individual movement; in this episode, collective embodiment was interpreted as particles distance from one another (*entity organization*).

Case 2: Acting as particles to produce target states of matter

This excerpt portrays a moment from day six (near the end of the unit) where students were tasked with embodying particles at a microscopic scale based on a visualization of the environment at a macroscopic level. A newly introduced mediator - the toggling of a background depicting an icy, pond, or desert environment (Figure 3h) – was disregarded by embodying students despite the target state of matter being continuously mediated by facilitators' questions (Lines 2 through 8). Observing students responded to the failure to embody the target phenomenon by offering a series of recommendations (Line 9). Here, we shift our perspective towards the observing students; we frame embodying students' movement as mediating observing students' engagement with aspects of mechanism such as speed (as a *property* of particles) and distance (*organization of entities*). We offer the following transcript (Table 2) and video sequence (Figure 3) to exemplify the use of students' embodied performances as a mediator for observing students' learning.

Table 2

Case 2 transcript

	Actor	Talk	Embodiment
1	Facilitator	I am going to take particles and transform them into a space, to a setting. And their job is to act like the particles in that setting.	
2	Facilitator	So, what should you guys be?	(Fig 3a & 3b) Particle 1 shows a shivering gesture. Particle 2 holds hands with Particle 1 and Particle 3. Particle 4 wanders in a circle.
3	Particle 2	Uh let's be...solid	
4	Facilitator	So, where are you? Can someone tell me where you are	
5	Facilitator	One of the particles where do you think you are looking at the screen?	(Fig 3c) Particle 4 accepts an invitation to hold hands from Particle 2 & 3.
6	Facilitator	So, Particle 2 said you're going to be solid, why?	(Fig 3d) Particles look at the screen. Particles 1 & 3 walk to the circle center.
7	Particle 2	Uh, we just wanted to be solid	(Fig 3e) Particle 3 leads a "circle dance."
8	Facilitator	You just want to be solid? What setting are you in right now?	(Fig 3f) All particles gaze towards the projection.
9	Observers	You need to be slow and close together	
10	Particle 2	We need to be slow and close together	(Fig 3g) Particles move slowly and closer to each other, accepting Observers' suggestion.
11	Facilitator	How are they doing observers are they making solid? When they are slow and close together?	
12	Observer	Yes, for a second	(Fig 3h)

Figure 3

Students' embodied sequence in case 2

 © ISLS

This episode opens with facilitators' attempts to direct embodying students' attention towards the background of the projected simulation (an icy environment as the new *setup condition*) in order to clarify the target state of matter (solid) to the larger group (Line1). Although an embodying student answered (Line 3) with the correct state of matter, it becomes clear that there is a disconnect between why students should be embodying solid water particles; there is no student response to the facilitators several probing questions regarding 'where' the particles are. We interpret this instance (Lines 1 through 8) as embodying students' failure to connect the behaviors of microscopic *entities* (particle movement) to the larger macroscopic *phenomenon* (state of matter): the core causal relationship (coded as *chaining*) within the states of matter content area (as discussed more in Tu et al., 2022). While this failure is indicative of a gap in embodying students' understanding, it functions as a mediational cue for observing students' learning. An observing student proceeded to instruct their embodying peers to be "slow" (a *property* of solid particles) and "close together" (in reference to the *organization of entities*). The embodying students echoed this instruction (Line 10) as an indication that they would accept the suggestion, and the observing students confirmed that a solid was produced (Figure 3h). Here, we see how students' talk and embodiment function as bi-directional mediators for each other's learning. Whereas embodying students' failure to recognize the connection between the simulation's projected background and particle behaviors led to observing students articulating insights regarding the target particle behaviors, observers' verbal scaffolds had a re-mediating effect on embodying students' actions.

Case 3: Embodying the mechanisms linking movement and state

Embodying students continued to explore and began noticing the link between their movement and the simulation's depiction of state. This continued into case three in which students were challenged to quickly adopt the movements of and iterate on their embodied representations to model solid, liquid, and gas states as determined by the background currently visible in the projected simulation (Figure 4). Unlike case two in which embodying students struggled to understand the causal (coded as *chaining*) relationship between microscopic particle behaviors and macroscopic states of matter, case three demonstrates students understanding of not only the relationships between microscopic behaviors and macroscopic states, but the importance of drawing on a multidimensional understanding of particle movement to appropriately represent the target phenomenon.

Table 3
Case 3 transcript

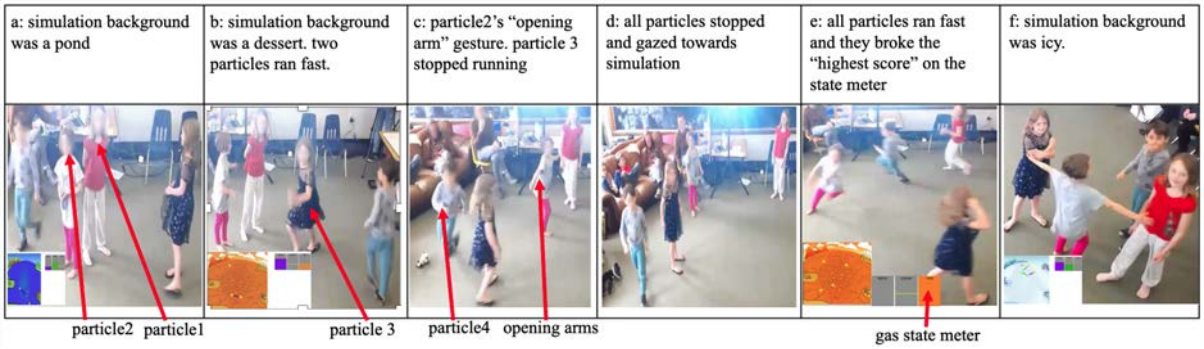
	Actor	Talk	Embodiment
1	Facilitator	I am going to transform you to one more place.	(Fig 4a)
2	Observers	Oh!	(Fig 4b&4c) Two particles begin running fast. Particle 2 suggests "spread out" with an opening arms gesture
3	Particle 2	No, no, no. Spread out	(Fig 4c) Particle 3 stops running and accepts Particle 2's embodied suggestion. Three particles spread out. Particle 4 runs fast.
4	Observers	Run fast!	(Fig 4d) Particle 4 stops running. All particles gaze towards the projected simulation.
5	Observers	Go to gas! Make it go!	(Fig 4e) All particles run fast.
6	Observers	They break the high score ((State meter reached to the top))	(Fig 4e)
7	Particle 2	Wait, let's try to go in a circle ((the facilitator changed the environment back to be icy))	(Fig 4f) All particles stop moving. Particle 3 hugs her arms. Particle 2 organizes students to go back into a circle.

This activity is split into two phases as differentiated by which environment (*setup condition*) was being projected as the simulation background and thus which macroscopic state (*target phenomenon*) students should have been emulating. During the first phase, a group of students embodied particles as the projected background of the simulation changed from a pond (indicating the target state to be 'liquid') to a desert (where the target state is 'gas') (Line 1). Immediately, students responded to this change, however there was a disagreement in which aspects of particle movement were currently relevant; two students started to run to indicate an attention to speed (a *property*) (Figure 4b) whereas another student made a gesture (Figure 4c) to indicate that the group should spread out (*organization of entities*). While both interpretations are appropriate

for the desert setting and gas state, the simulation's state meter did not indicate successful representation of gas particles. This failure prompted the embodying students to pause their activity and look towards the state meter (Figure 4d). An observing student suggested that the embodying students all "run fast." The group accepted this suggestion as indicated by their movement, and the state meter indicated the successful representation of gas (Lines 4 -6 and Figure 4e). While the observer's suggestion to "run fast" initially seemed to require that some students compromise on their idea to spread out (attend to distance) in lieu of their peers' idea (to move fast), the outcome of this interaction involved the integrated recognition of multiple aspects of mechanism. In accepting the suggestion and adopting a 'fast' speed, they demonstrated how the embodiment of gas requires that particles both move fast (*property*) and be far apart (*organization of entities*).

Figure 4

Students' embodied sequence in case 3



The next phase of the activity started immediately afterwards and was indicated to the class by a change to the background environment (to icy Figure 4f). As with the prior phase, students immediately acknowledged the change in environment (the *setup condition*) and recognized that they should be embodying solid particles (the *target phenomenon*) by adopting a new set of movements. They stopped running (to represent slow movement as a *property* of solid particles) and decreased their distance from one another (to represent solid particles as being *organized* closely together) (Line 7 and Figure 4f). The alternating environment (the simulation's background) mediated the activity by functioning as an instructional organization tool; it prompted the entire group to reconsider the requirements of the environment and thus their individual and collective movements. Observers' suggestions scaffolded embodying students' activity by directing attention towards an aspect of particle movement which was currently missing from the embodiment. Here, mediation functions to organize activity based on the macroscopic conditions and make students aware of the multiple intersecting aspects of the phenomenon and particle behavior to successfully represent the target state.

Discussion

This paper explores students' mechanistic reasoning related to states of matter in three collective embodied activities. Mediating students' exploration of different mechanistic properties is an essential part of how classroom teachers and activity systems support this complex reasoning. We notice how mediational means function differently across three different cases; in case one, we see the use of visual and verbal cues to productively constrain students' exploratory movements toward a common objective. Case two illustrates how observing students' talk can be used to scaffold their peers' embodiment as they articulate connections that may not be visible to those 'in' the simulation in a sort of bi-directional mediation. Case three exemplifies how mediation in the form of peer observation and real-time simulation feedback can support students in making connections between mechanistic aspects at both microscopic and macroscopic levels.

We have demonstrated that mediation of collective embodied sense-making to represent scientific phenomena affords students opportunities to engage with aspects of mechanism at both the macroscopic and microscopic levels. Our analysis also indicates the importance of teasing out moments where mechanism is being enacted versus where mechanism is understood. From a teachers' perspective, we suggest that attending closely to students' actions and offering real-time feedback as informed by students' actions can lead to the productive constraining of students' attention towards aspects of the mechanism. From an activity design perspective, we recommend organizing activities to allow for students' embodiment of the target phenomenon in addition to activity observation. This will enable students to articulate the patterns they are noticing in their peers' embodied modeling while their embodied peers leverage this observational talk as verbal mediation. The above cases demonstrate how as students are confronted with various aspects of mechanisms through embodied

modeling, mechanistic aspects are compounded and thus simultaneously engaged with during more conceptually difficult activities. Once aware of these multiple aspects, students can more explicitly and maturely attend to the causal relationships and processes that underlie phenomena.

Abstract: This paper presents a case study of a student's participation in an expansively-framed unplugged computer science (CS) instructional unit that leverages activities and materials not typically associated with CS: playing an "unplugged" tabletop board game and designing a paper prototype of a new game level. We use the practice-linked identity framework as a lens to characterize resources available in our instructional design and how they afforded or hindered the student's participation across the instructional activities. Our findings highlight the importance of relational resources in influencing participation, both positively and negatively, and provide implications for the design of future CS learning environments.

Introduction

One approach to making computer science (CS) instruction more accessible to those who are historically underrepresented in the field is to change the materiality through which CS ideas are encountered. This is an approach that has been used to some degree of success with craft materials, such as electronic textiles (Searle & Kafai, 2015) and paper circuitry (Lee & Recker, 2018). Presumably, this also is part of the appeal of "unplugged" approaches to CS instruction that do not involve an actual computer in order to enact. By moving CS away from the screen, it seems possible that the standard pathways for participation can be disrupted. New participants can gain entry when the barriers associated with traditional media are removed.

Taking seriously the idea that encountering CS through different media has promise in changing who can participate in and become proficient with computing, we have been engaging in iterative design-based research that introduces CS through an unplugged medium but, in lieu of stopping once those ideas are initially encountered, attempts to facilitate transfer to the more canonical computing medium (e.g., a screen-based programming environment) (Lee et al., 2020). The specific form of unplugged computing from which we begin is the computing involved in board game play (Berland & Lee, 2011). Students then transition to using Scratch to play the same game and program new game levels.

The present study examines, by way of case study, the student experience of participating in this unit. We sought to understand if and how this strategy of beginning with unplugged materials and then shifting to plugged materials enabled participation and identification with CS over the course of the unit. To do this, we strategically identified a specific student success case from one iteration of the designed and enacted unit and then reviewed all video records of that student's participation. We found, and describe in this paper, that materiality contributed to this youth's self-reported positive identification with CS. However, the case was more complex than simply concluding that new materials increased access. There were also important social interactions that we identified as being likely contributors to the case student's positive identification with CS. Through iterative review and coding, we found that viewing this case study as the product of a combination of material, relational, and ideational resource availability yielded the most insight for us. This case study was formed around the question of, *how do material, relational, and ideational resources combine in cultivating a positive identification with computer science in the context of an unplugged-to-plugged unit?*

Theoretical framing

The focal case in this study is a fifth-grade student, Ella, who showed a positive change in her identification with CS after participating in a research-designed unplugged-to-plugged unit. Because the change we observed in Ella was connected to participation in an activity and involved developing positive identification with CS, we chose a theoretical lens that explains identity construction through activity, specifically practice-linked identity resources.

Practice-linked identity resources refer to supports that were made available and accessed during participation in social activities. Through a study of how positive identities were constructed through participation in a track and field team, Nasir and Cooks (2009) identified three practice-linked resources found in learning settings: material resources, ideational resources, and relational resources. Material resources are physical artifacts in the settings and "the way in which the physical environment, its organization, and the artifacts in it support one's sense of connection to the practice" (Nasir & Cooks, 2009, p.47). Second, "relational resources refer to the

 © ISLS

positive relationships with others in the context that can increase connection to the practice" (Nasir & Cooks, 2009, p.47). Finally, "ideational resources refer to the ideas about oneself and one's relationship to and place in the practice and the world, as well as ideas about what is valued or good" (Nasir & Cooks, 2009, p.47). While Nasir and Cooks originated this theory from naturalistic study of intact social practices, we believe that it has potential for looking at researcher-designed activities, such as a curriculum. Indeed, through its use, we noticed some unintended but influential relational resources that were provided to our case student by members of our research team. While these were not intentionally designed as part of the curricular unit as resources, they appeared to counteract some other interactions that restricted resource access for the case study student. Before describing how that transpired, we first turn to a description of the designed unit.

The designed elementary computer science unit

With the potential of alternative media for providing different forms of access to CS in mind, we developed our unit based off of a commercial paper-based board game. Board games have been both studied and designed as computationally rich environments; a number of computational ideas can be instantiated through game play, whether or not the players are aware that what they are doing is computational. Some board games where this had been explored include one on disease spread simulation and another that represented a wolf-sheep predation model (Horn et al., 2012). However, there are now board games that explicitly present their game play as computing and their value to players as supporting learning of CS (Poole et al., 2021). These games vary in structure but can instantiate CS in the form of actions presented as written code, algorithmic sequences represented as player moves, and or solutions as being derived through application of Boolean logic.

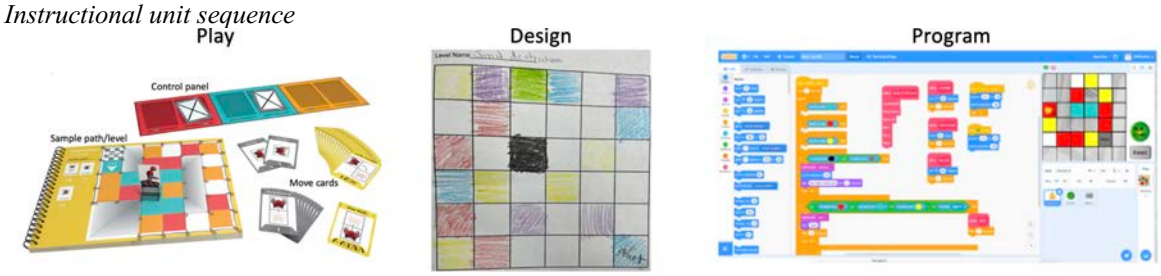
After review of several options, we created our designed unit with the commercial board game, *//Code: On the Brink,* published by ThinkFun, as the initial unplugged entry point. The board game is comprised of levels, or puzzles for players to solve. Each level has a path within a grid through which a player needs to 'program' an agent (a robot token) to move from a 'Start' square to 'Finish' square. The Start and Finish are separated by colored spaces. Landing on a colored space means executing the commands associated with that color. Players need to figure out the procedures for each color such that the robot token can execute the commands from the colored starting space and then whichever colored spaces it lands on so that it will eventually, without any changes to the player-specified procedures, land on the 'Finish.'

Players use move cards ('Move Forward', 'Turn Right', 'Do Nothing' etc.) that they place on a control panel to make procedures for each color (see Figure 1). For example, if a player puts a 'Turn Right' in the first spot and 'Move Forward' in the second spot of the control panel for blue, each time the robot lands on a blue it will rotate right and then move forward one square.

The designed unit consists of seven weekly lessons that span the classroom and school library. This was done because the partnering schools were exploring the school library as a setting for implementing CS instruction. Our unit design was an effort to support both the classroom teachers and school librarians in providing CS instruction. In separate work, we found that the use of the board game and the unplugged-to-plugged structure served as a support for the teachers and school librarian to learn new ideas about CS (Stephens et al., 2021).

Figure 1

Instructional unit sequence



The general lesson structure involved a portion that began in the classroom (for up to 20 minutes) and was led by the classroom teacher. Then students went to their scheduled weekly library time and, for the next 30 minutes had CS instruction. At the library, the school librarian introduced and then helped facilitate student work in pairs to: ***play*** the physical board game; play a Scratch version of the same game; ***design*** their own level of the game on paper using colored paper pieces and then colored pencils; and then ***program*** their level in Scratch for their classmates to try. As this was a research endeavor, research team members were present to set up cameras and microphones. However, they provided assistance as needed with the unit, helping to distribute materials or answer questions as needed. As we will show later, this proved consequential for our case student's participation and identification with CS over the course of the unit.

Methods and data

This project was conducted with a rural elementary school in the western United States. Seventy-four fifth graders (girls = 35) across three classrooms participated in this iteration of the project. Ten of those students were randomly selected (girls = 5) to be focal students. While all students completed pre-post surveys, the focal students were interviewed before and after the unit. They were also videotaped throughout the unit.

As we were interested in understanding if and how the unit worked as intended, we identified the focal student who started the unit with low affect and knowledge in programming, yet showed the largest growth, based on the pre-post surveys. This student was Ella (a pseudonym). We then reviewed all video records we had collected with Ella featured in them. This occasionally included full class activity in the classroom, but very minimally. The bulk of our analysis leveraged a total of two hours of video footage of her and her partner, Astor, in the library. This footage included the pair: playing the game, designing a level, and programming their level in Scratch. Analysis consisted of a combination of open and In Vivo coding. We coded interactions around her use of materials across the different activities and identified themes around how the activities shaped her access to identity resources. We then collapsed them into two contrasting categories of support/access/affordances and constraints/limitations/barriers. We focus our analytic findings on how the constraints and affordances shaped her participation. Table 1 shows examples of the identity resources that were available to Ella across activities.

Table 1

Identity resources afforded by the unit

Identity resource	Examples of resource use
Material resources	In the play activity, material resources consisted of the board game components: move cards, control panel, and a robot marker (see Figure 1). In the design activity, resources were paper, color pencils, and the robot marker (see Figure 3). In the programming activity, resources were a Chromebook, a computer mouse, Scratch, and their paper design.
Relational resources	Relational resources consisted of the interactions: Ella's interactions with her partner, other students in the classroom, and researchers in form of asking questions, providing feedback, and negotiating access to materials.
Ideational resources	Examples of this resource include instances when Ella showed her understanding of a concept, took ownership of her work, or showed excitement related to the activity.

Findings

As discussed earlier, our expectation was that the choice of materials can positively shape one's participation in learning activities. Through analysis based on practice-linked identity resources, we found that the use of materials, one's relationship to others, and one's view of self were indeed all linked and shaped Ella's participation in the unit and identification with CS. However, we found that these interacted in ways that both constrained or afforded participation. We describe these constraints and affordances below.

Constraints to participation

In this section, we offer examples of the constraints that hindered Ella's participation in the instructional unit. We found that constraints were often related to relational resources such as negotiating access to materials, negotiating decisions around materials, or seeking information from peers.

Negotiating access to materials

In terms of negotiating access to materials, whether the activity was *unplugged* or *plugged* further shaped how Ella and her partner participated. As partners, Ella and Astor shared control of materials between them. Since students were working in pairs, a student could assume one of two roles: a driver or a navigator. The driver controlled the materials, whereas the navigator gave instructions to the driver. Students were encouraged to switch roles between them but the switching was not enforced. During the board game play, the driver physically controlled the movement of the robot on the puzzle. In the design activity, the driver moved the colored paper pieces on the grid to design their puzzle. In the Scratch programming, the driver controlled the computer mouse and keyboard to make changes in Scratch (see Figure 2). Ella had more control of the materials in proportion to Astor during the *unplugged* activities (game play and design) than in the *plugged* (computer-based) activities (see Table 2). During the plugged activity they continually fought for control of the mouse and keyboard. During one fight for control, Ella was using the computer mouse to work on the digital version of the game board in Scratch. Astor wanted to do something else, so he tried to get control by moving his finger on the touch pad of the laptop. Astor said in a loud voice, "why don't you let me do anything?" Hearing this, the librarian walked over to them.

Astor told the librarian, "… she won't let me do anything…" The librarian told Ella to "take turns" and that she does not "get to just do it all" as she walked away. This example illustrates how Astor's fight for the materials constrained Ella's participation during the plugged activity. However, Ella remained engaged in programming and continued to negotiate for control of the materials. Ella's control of the materials and fewer instances of conflict during the unplugged activities show that the sequence of activities in the unit afforded her participation.

Table 2
Counts of Ella's and Astor's control of the materials

Instance type	Number of instances coded in data					
	Board game play		Design		Computer activity	
	Ella	Astor	Ella	Astor	Ella	Astor
User in control of the materials	40	31	37	21	28	33
Refused to give up control	2	3	5	3	11	4

Figure 2
Examples of Ella and Astor controlling the materials in the three activities.

Negotiating decisions around the materials

In terms of decisions around the materials, Ella had to negotiate decisions with Astor in all settings (playing, designing, and programming). When they were not able to reach agreement, Ella often got out of her seat and asked a researcher for help.

In the following excerpt, Ella and Astor had just started designing their game on paper. They started their board with a blue square. Students had the option to use up to 3 individual movements for each color. She asked Astor "what should blue do" three times and he did not answer. Ella decided to make the first movement 'move forward three.'

E: "So let's do… Move… Three.." (She said it while she wrote on the paper)
A: "No, you can only do.. move forward once."
E: "She said we should make some up."
E: "So… One two three" (She moved the robot three steps on their paper game board)
A: "That's not what she meant."
E: "Ok, I'm gonna [unintelligible]" (She got up from her seat and walked up to a researcher, and talked to her, their conversation was inaudible, she then returned to her seat)
E: "Yea we can, we can move.." (She sat down and took the robot out of Astor's hand)
E: "Ok, so.. one, two, three" (She put the robot on the blue square and moved it forward three squares)

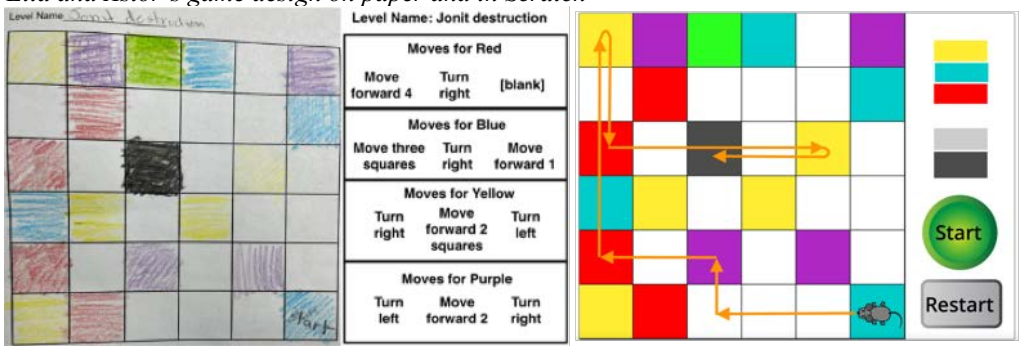
As shown in the example above, Astor challenged Ella's decision so Ella accessed a relational resource, a researcher, to get feedback. We saw other instances of Ella seeking feedback from researchers while students were learning how to play the game, while designing their game on paper, and while programming it in Scratch. Ella may have interpreted being questioned by Astor as him undermining her expertise and a potential barrier to her participation. She sought recognition from a more knowledgeable other in moments of conflict with Astor. By seeking help from the researchers Ella confirmed her decision and received recognition. Accessing a relational resource in this example led to her practicing her creative choice and personalizing the design of their boardgame.

However, Ella did not always seek help and sometimes conceded to Astor. For example, after they completed the design of their game on paper and wrote their procedures for landing on Red, Blue, Yellow, and Purple squares (see Figure 3), Ella decided to color some of the blank squares as distractors to make their board more challenging. This strategy makes it harder to identify the pattern or correct path when looking at the board. Astor insisted on coloring one of the squares green, even though they didn't use green in their game. A disagreement ensued because as Ella told him that they did not have any instruction set for green so people would

know it was not part of the path: “No, because then they can tell, there are no greens” (she gestured to their sheet indicating the red, blue, yellow, and purple squares). After a few minutes of Astor begging, she finally relented and let him color a green square on their board. By conceding and letting Astor put a random green square that served no game purpose on the board, Ella was also conceding to participation on Astor’s terms. According to Nasir and Cooks (2009), material resources are artifacts in the environment that support one’s sense of connection to practice. For Astor, adding the green square may have created a personal connection for him, because according to him it was “the color of his favorite transformer”, but its purpose undermined Ella’s connection to the practice of designing the board. Ella’s actions of coloring in squares as distractors and her concern that “they can tell” suggest that she wanted to express her ideas in their design and wanted to make their game challenging.

Figure 3

Ella and Astor’s game design on paper and in Scratch



Requesting feedback from peers

Students were given the ability to develop their own procedures for moves. Ella’s decision to ‘move forward three’ for the first step of blue was an example of her making up a procedure. When programming their game in Scratch, two nearby boys, Cody and Brian, had been trying to create a procedure they called “shimmy” in which the robot moved and rotated. When they finally got their procedure to work, they cheered and caught Ella’s attention:

Ella: “You made it do it?”
Brian: “What? Yea we got it! [unintelligible]”
Ella: “Wait how did you get that?”
(Ella stood up and started walking towards their computer to take a closer look at their code)
Brian: “We’re not gonna give you the code”
Ella stopped, turned and went back to her seat.
Astor stood up and leaned forward and looked at Brian and Cody’s computer screen.
Ella: “I know. How did you make it shimmy like?” (She moved her body possibly mimicking the shimmy)
Astor: “Uh. It’s just moves”
Cody: “Yea it’s moves”
Astor: “Move something. Move right or move left”
Cody: “Yea, you can also do move back”

In this example, we see how her peers and partner constrained Ella’s participation. By refusing to show their code to Ella but showing Astor, her peers undermined her place and participation in learning. These examples around constraints illustrate ways Ella’s relationship to place, practice, and CS was challenged. Relational resources are a way for people to connect to practice (Nasir & Cooks, 2009). While Ella was able to make connections to the researchers and seek help and confirmation of her CS knowledge, her partner and boy peers often functioned as barriers to her participation. Relational resources can often function as a source of motivation for participation and learning (Nasir & Cooks, 2009). By hindering her relational resources, i.e., interpersonal connections, her peers were deciding who could participate and how.

Affordances to participation

Participation in the unit involved students working in pairs, thus it is not surprising that relational resources shaped Ella’s participation in many ways. As we saw in the previous section, her interactions with her partner and peers often created constraints and barriers to participation. In this section, we focus on her interactions with researchers

that shaped her participation and connection to practice in positive ways. In particular, we focus on the interactions that happened during the unplugged activity of designing their board game level. The structure of this activity led to researchers walking around the room and asking students about their design and their procedures. As we saw in Table 2, Ella had more control of the materials than Astor during this activity and seemed engaged in the design. At one point, Ella and Astor were working on their board when a researcher looked at their moves:

R: "Move forward four and turn right?" (Referring to the procedure for red, see Figure 3)
Ella nodded her head.
R: "Oh man, you got some crazy blocks"
E : "Yeah, I do!" (She said excitedly with a big grin)

This excerpt shows how Ella took ownership of her design and recognized her place in the practice. She showed excitement upon someone else noticing the complexity of their design, recognizing what others value, which is a type of ideational resource.

When Ella was done with the board and coloring in the distractor squares, a researcher walked up to her:

R: "Look at that beautiful board. Wow"
E: "Yea it's.. a hard board "
R: "Is it?"
E: "Very hard [laughs]"
(Later in the conversation)
R: "Oh, do you think this is gonna work?"
E: "Yea, we tried it many times"

In this example, Ella once again took pride in her ability to create a complex design. She also showed confidence in her knowledge of the activity when she said "Yea, we tried it many times" when questioned by the researcher on whether it was going to work or not.

These examples show that when someone took notice of Ella and Astor's game's design, Ella was the first one to respond. She showed excitement about others noticing their design and took pride in it. In the interactions Ella had with her peers, they did not recognize her competence. In her interactions with researchers, however, she received recognition for it. In other words, Ella was accessing her ideational resources during her interactions with the researchers. Her interactions with the researchers appeared to make her feel good about her design. Her agreeing that her blocks were "crazy" and adding that her board was "hard" showed she knew what was valued and good in terms of the practice of designing the game level. This also could explain why she resisted Astor's efforts to add a green block to their board because it took away from what was valued (e.g., being hard).

We found that Ella's participation in the unit changed her ideas around what programming was and what participating in it meant. In the post-interview, she told us that:

> "[this project]...got me more interested in programming. Because at first, when I thought about it, I thought this was gonna be the most boring project ever. Now I really want to do computer programming."

Changing the materials and activities in Ella's computing class changed how she participated. The activities afforded different identity resources which further shaped her participation. When asked about how this project compared to what she typically did in her computer class, she said: "You weren't just sitting on your computer the entire time; you were actually designing your game." A common stereotype that can negatively affect girls' interest in programming is that it involves sitting at a computer all day (Pantic et al, 2018). Ella's preference for the unplugged activity of game design illustrates the importance of changing the activities and materials associated with programming and or CS in order to broaden participation.

It is important to note that Ella had a positive experience despite the barriers to participation she experienced. Another student in Ella's shoes may not have persisted. While we can design curricula that empowers participation for individuals, like in the case of Ella, we need to also ensure the classroom culture and environment enables all students to participate. Without making any causal claims about Ella, we assert that the design of media is not sufficient for enabling participation of everyone. Ella needed 'others' in the setting to access her practice-linked identity resources. In case of Ella, she sought recognition of her ability to create a complex design. She did not find this recognition from her peers, but she did find it from the researchers present in the room. We assert

that in order to further the goal of broadening participation in CS, more effort needs to be put in engendering values in learning settings that help students feel supported and recognized by others.

Discussion and conclusion

The study explored how one student, Ella, participated in a CS unit that was specifically designed around activities and materials not typically associated with CS: playing board games and designing a game level on paper. Using Nasir and Cooks' practice-linked identity resources framework as a lens, we discussed how the design of the unit influenced student participation. Our findings showed how others in the setting afforded as well as constrained Ella's participation in the unit.

Relational resources are one's relationship to others in the environment. Our findings showed how Ella's partner and her peers constrained her participation and restricted her access to material resources. The findings also showed how this lack of support mediated access to ideational resources. Ideational resources constitute one's relationship to the place, practice, and the world and one's ideas about themselves (Nasir & Cooks, 2009). In one example, we saw how Ella's peers refused to share their 'shimmy' code with her, but shared it with her (boy) partner. By excluding Ella, her peers undermined her place and participation in the learning setting. Challenging someone's place can also have an effect on their ideas about themselves and who they consider themselves to be. Research has shown that subtle cues that suggest students don't belong can weaken motivation to participate and that women leave STEM because the social climate undermined their motivation (Cheryan et al, 2009). On the other hand, receiving public recognition for one's competence from more knowledgeable others can lead girls to identify themselves as expert coders (Hughes et al., 2021). Our findings revealed that Ella actively sought recognition from more knowledgeable others, e.g., researchers, on multiple occasions. In one example, she sought feedback from a researcher to resolve a conflict with Astor when he challenged Ella on creating a new move for a blue square. Ella also sought recognition for her ability to create a complex design. She was elated when a researcher commented on her "crazy blocks". In another example, a researcher commented on how beautiful their board (board game design) was. Ella's response was "Yea it's a hard board," indicating that she was seeking recognition despite the lack of recognition from her peers. The recognition Ella received from the researchers helped her view herself as a competent coder. Ella's persistence in learning and taking part in activities as an equal participant is also evidenced by her refusal to give up control of the materials in the plugged activity. Despite the barriers she faced in the form of a lack of recognition from and restrictions from accessing material resources by her peers, Ella persisted. However, it is important to note that not all students will.

Implications

Our findings have implications for researchers, designers, and instructors of CS curricula. The first implication relates to the design of the CS unit. We assert that in order to appeal to a broader set of participants, the media used for learning should be designed to afford participation from a variety of learners. Consider the example during the plugged (computer-based) programming activity in which Ella asked her peers (boys) to teach her how they had programmed their sprite to do a shimmy and they refused. Similarly, Ella and Astor continued to fight for the control of computer mouse and keyboard. One possible explanation for Ella's tension with them can be explained by the prevailing gendered cultures in CS education. Studies have shown that boys are less likely to share control of the resources during coding activities (Gray & Leith, 2004), while girls are likely to have a lower sense of belonging in computing activities than boys owing to perceived stereotypes (Master et al., 2016). In contrast to plugged activities, unplugged activities of playing the board game and designing the new game levels provided students with tangible materials. Ella was much more in control of the materials during the unplugged activities, while she struggled to keep control of the materials in the plugged tasks. We also argue that the sequencing of our activities encouraged Ella's participation. In our unit, CS concepts were introduced in unplugged media and then revisited in the plugged media. Ella appeared to have a high level of engagement during the unplugged activities. Her participation changed during the plugged tasks owing to Astor seizing more control of materials. In spite of that, Ella sustained a high level of engagement and persisted to keep control of the materials. We thus see how the use of unplugged materials to introduce CS concepts, before transitioning to the use of plugged materials may have helped Ella to assert herself during the computing tasks, and to go against the stereotypes embedded in the discipline of CS (Master et al., 2016).

The second set of implications of this study relates to the role of others present in a learning setting. Studies suggest that girls perceive CS as a stereotypically male discipline (Master et al., 2016). Thus, in order to engage girls in CS learning, the 'others' in the learning setting should recognize expertise of girls. Recognition of one's expertise can transform one's view of the field (Keune et al., 2019) and help girls become more confident in their abilities to code (Hughes et al., 2021). As we saw in Ella's example, 'others' meant researchers in the

room, her partner, as well as other students in the classroom. In a more naturalistic classroom, the class teacher should play a similar role as the researchers did for Ella.

We thus highlight that educator should be aware of the role their recognition can play in encouraging girls to participate in CS classrooms. The second part of our assertion relates to creating environments where girls are also recognized by their peers for their expertise. Even though Ella received recognition she sought from the researchers, we saw examples in which Ella lacked support from her partner and her peers. In their study of three girls in a code camp, Hughes et al. (2021) found out that public recognition of girls by their teachers in a CS classroom can lead other students to perceive the girls that receive recognition as expert coders. In our study, however, Ella did not receive recognition from her peers. In sum, CS curriculum design should foreground how activity structures and materials shape who participates and how they participate. Further, the design of learning settings should include strategies that help a broader array of students feel supported as well as recognized by others.

A comparison of refutational and rhetorical aspects in science arguments by grade level

Veronica L. Cavera, veronica.cavera@rutgers.edu, Hebbah El-Moslimany, hebbah.el-moslimany@rutgers.edu, Ravit Golan Duncan, Ravit.Duncan@gse.rutgers.edu, Clark Chinn, Clark.Chinn@gse.rutgers.edu, Rutgers University

Abstract: Engaging students in the process of argumentation supports student understanding of scientific knowledge. We present a comparison of arguments from 7th and 11th grade biology students from modeling tasks using an argumentation framework to investigate differences in student approaches during two comparative tasks. While students at both grade levels constructed arguments that contained multiple reasons and epistemic ideals, we identified differences in rhetorical statements and refutational strategies by grade level. High school students attended to the underlying model-evidence relationship to explore differences between competing models and to make comparisons and refute the competing model at higher instances than middle schoolers. Refutational strategies by high schoolers connected multiple pieces of evidence, or made connections between provided models and evidence, while middle schoolers made use of epistemic ideals to refute a competing model. These differences are discussed in conjunction with implications for design.

Argumentation engages students with constructing and critiquing claims about phenomena using appropriate and sufficient evidence (e.g., McNeill & Krajcik, 2011). Students can leverage evidence in arguments in multiple ways to make sense of phenomena and to articulate evidentiary relationships of the natural world (e.g., Nussbaum, 2021). Sometimes to increase the challenge of the task, students are presented with models in lieu of claims. These models include mechanisms and serve to explain some phenomena. Students can be tasked with constructing, evaluating, or revising such explanatory models (e.g., Passmore et al., 2009). Scientific argumentation plays a central role in evaluating competing models based on evidence, or identifying the best model or explanation (e.g., Krajcik & McNeill, 2012; Nussbaum et al., 2019). Research on student argumentation relies on argumentation frameworks to provide insight about how students evaluate and use evidence to articulate claims and revise their own and others' claims.

These argumentation frameworks tend to focus on argumentation structure with less focus given to the role of epistemic knowledge about what qualifies as a good argument, a good model, good evidence, or the relationship and interaction of models with evidence. Some of these frameworks focus on a specific aspect or aspects of arguments in order to conceptualize student understanding. Paying specific attention to these structural aspects is critical but tends to hide other aspects such as the rhetorical nature of arguments. To better bridge this gap we use the *Integrative Argumentation Framework (IAF)* which examines arguments as a series of argument moves (Cavera et al., 2018a). This framework attends to structural aspects of arguments (e.g., capturing the claims made, supporting or refuting statements), appeals to epistemic criteria of model quality, and rhetorical nature of arguments as argument *moves*. These moves serve to capture how students convince a reader of a standpoint as they move through the pieces of their argument.

Scaffolding and task structure play a major role in the kinds of arguments that students can construct and critique (e.g., McNeill & Krajcik, 2012). These arguments tend to contain increasingly robust aspects of arguments (e.g., a refutation, more reasons) when explicit scaffolds help students attend to those features of arguments. While we know that students tend to construct increasingly robust arguments as they move through different grade bands particularly with scaffolding (e.g., Kuhn & Udell, 2003; Nussbaum et al., 2019) we know less about the nuance between those differences. This paper intends to address the impact of scaffolding on student argumentation and evaluate the kinds of complexity and nuance that students develop at two grade levels (middle school and high school) using the same argumentation framework, *IAF*.

Theoretical Framework

Argumentation is the process of using data to defend or refute a standpoint (Toulmin, 1958; 2003), and is a critical knowledge-building process that appears in science classrooms as a way to support student understanding of science concepts (e.g., Driver et al., 2000). Students can be presented with claims that describe scientific phenomena or scientific models that include an underlying mechanism, but students find evaluating competing mechanistic models to be cognitively demanding (e.g., Krist et al., 2019; McNeill & Krajcik, 2012). Scientists

 © ISLS

make these kinds of evaluations about complex arguments of phenomena (Popper, 2014). Students can critique and argue about why one argument is better supported by evidence oftentimes by demonstrating that more evidence supports evidence over another. This kind of weighing strategy has been described before (e.g., Nussbaum et al., 2019) as a way of either counting the amount of supporting evidence in support of a chosen model or by integrating evidence into the argument or by integrating evidence into the model and showing how that evidence relates to the chosen model, either as warrant or backing for a chosen model (Cavera et al., 2018a).

However, we know that students find difficulty in constructing and critiquing competing claims and models of competing phenomena, often developing supporting statements of their chosen claim without discussing a competing idea. This idea of discussing the opposing side, or refuting competing claims, evidence, or discussing the contra argument, is often considered one of the more difficult aspects for students to attend to in argumentation. This process of identifying differences between competing ideas is central to the argumentation process. Osborne and colleagues (2016) discuss arguments that include a *counter claim with justification* as one in which a student can explain why the competing claim is wrong by leveraging a warranted comparative argument. This kind of sophisticated reasoning pattern is a difficult move for students to tackle and appears at the highest level of their argumentation learning progression. McNeill & Krajcik (2012) discuss scaffolding students' rebuttals last in class as part of their claims, evidence, reasoning, and rebuttal (CERR) framework in order to reduce cognitive load. Successfully navigating and discussing their own argument as well as the counterargument in both of these instances is seen as an achievement. Often the idea *rebuttal* and *refutation* are used interchangeably in the literature but are distinct ideas. Toulmin (1958) defined rebuttal as "conditions of the exception", whereas refutation is a contradictory idea to the chosen claim (van Eemeren & Grootendorst, 2001). When students identify juxtaposing ideas between comparative models, they are refuting such as in the case, *I believe in model 1. It is better supported by the evidence unlike model 2 which is supported by less, low quality evidence.* A rebuttal could be posed as, *model A is always right except when it is supported by less evidence.*

We know that students struggle to form refutations and without sufficient scaffolding struggle to form refutations on their own. For example, Nussbaum and colleagues encouraged students to juxtapose competing arguments as part of a scaffold known as the argument vee diagram (AVD) at the middle school and college level which supports students to make comparisons to integrate competing arguments (Nussbaum, 2021; Nussbaum et al., 2019). This kind of comparative strategy allowed students the planning space to identify flaws in the counterargument. Essentially, refutation in this case was defined as the identification that the conclusion of the counterargument is false or that the premises of the competing argument is flawed. By allowing students the space to build an integrative solution, or a *design claim*, students can identify flaws and explore both an argument and counterargument using the AVD scaffold.

These and other approaches attempt to capture the nuance and complexity of student argumentation at the middle or high school level (e.g., Grooms et al., 2018; Nussbaum, 2021; Nussbaum et al., 2019) though these often focus on analyzing *how* students construct and critique arguments and the kinds of structural and epistemic ideas that students have about a topic. In this, we focus on argumentation moves across two grades (7th and 11th grade) in order to understand more about the differences in argumentation across middle and high school. We apply the Integrated Argumentation Framework (*IAF*) which focuses on an analysis of nuance of arguments through the lenses of structural, epistemic, and rhetorical perspectives of arguments (Cavera et al., 2018a). These moves aim to capture how students articulate their standpoint by capturing three lenses of argumentation: structural aspects (e.g., supporting claims, refuting claims), appeals to epistemic criteria, and rhetorical features. We applied *IAF* to student arguments to identify the kinds of arguments that students develop in middle and high school. We developed similar assessments about a topic in biology that aimed to evaluate students' competencies and reasoning with models, and the construction of evidence-based arguments about core science topics. Our research questions are: What are the kinds of arguments that students develop at the middle school and high school levels? What are the types of refutational and rhetorical features identified in student arguments?

Methods

Study Context

The study took place in two suburban schools in the United States—a middle school (7th grade) and a high school (11th grade) in which students were learning biology topics in the same school district. The schools were considered academically average in mathematics, language arts, and science performance. The district served 79% White, 9% Hispanic, 6% Black, 1% Asian, and the remaining students identify as mixed race. Approximately 34% of the students were classified as economically disadvantaged, with 27% of students qualifying for free or reduced lunch in the middle school while 34% qualified in the high school.

 © ISLS

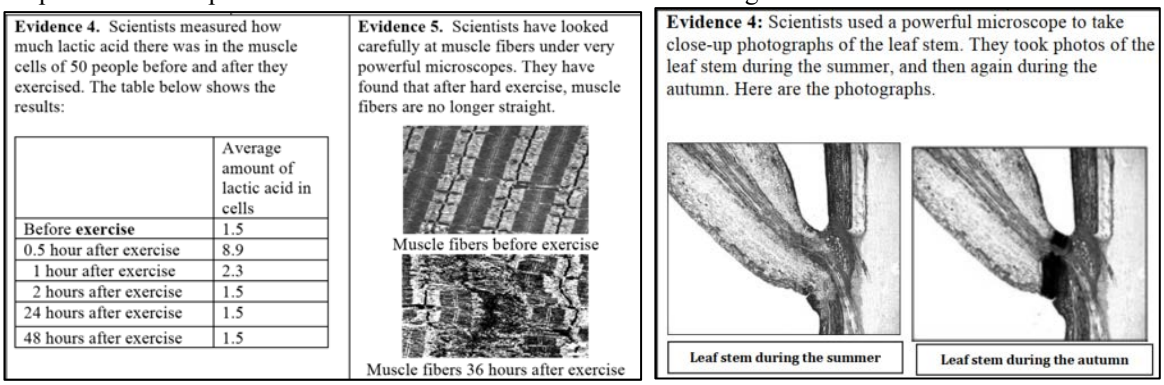
In both grades, students participated in a modeling-based biology curriculum which engaged students in the development, evaluation, and revision of models of scientific phenomena, and provided students with multiple opportunities to develop evidence-based arguments in support of a chosen model (from 2-3 competing alternative models and multiple pieces of evidence that varied in quality). In both high school and middle school levels, students were assigned either a task called Falling Leaves (*FL*) or Muscle Pain (*MP*) at the close of instruction.

Instrument Design & Data Collection

Students were provided with 60 minutes to complete the task. The assessment tasks included five pieces of evidence that varied in quality and two competing explanatory models, and students were asked to build an argument in support of the explanatory model they thought best explained a phenomenon they had not studied in class around the topics of muscle pain (e.g., Why do you think muscle pain occurs after heavy exercise?) or leaves falling off trees (e.g., Why do you think leaves fall off trees in the fall?). We will be discussing posttest arguments written by students at both grade levels. The evidence provided to students were either of high quality (e.g., scientific studies), provided information on the phenomenon (e.g., description of the phenomenon), or was an anecdotal account.

Figure 1

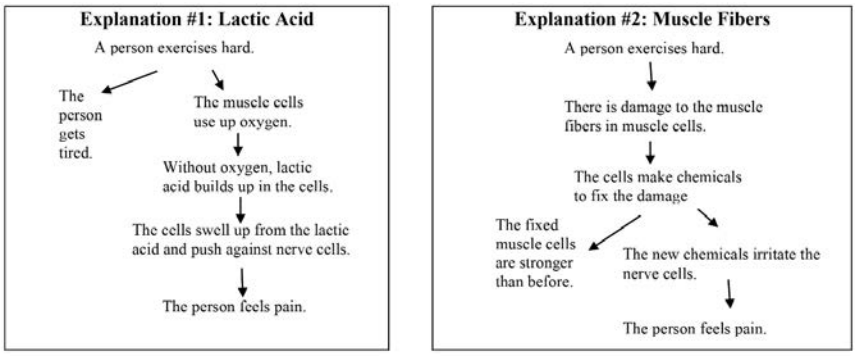
Example of evidence provided to students in the Muscle Pain and Falling Leaves assessments



For space purposes, we provide two sample evidences from the Muscle Pain (MP) assessment, and one from the Falling Leaves (FL) assessment (Figure 1). Evidence 4 (left) describes that right after exercising lactic acid levels rise but that approximately two hour later, levels drop to their initial level. Evidence 5 (right) shows the damage to muscle cells that comes from exercising but does not show the mechanism. These evidences are designed to support or contradict one or both of the models. Evidence 4 from FL shows photographs of leaf stems.

Figure 2

Explanatory models presented in the Muscle Pain assessment

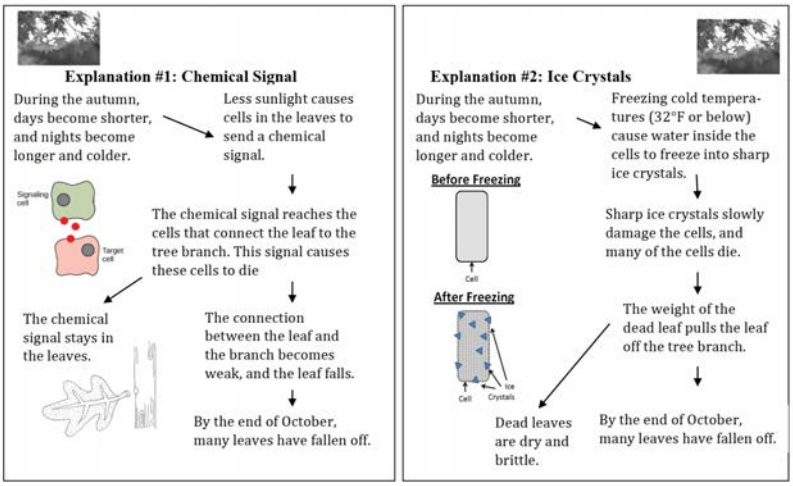


In the MP task, students were presented with two competing explanatory models about the mechanism of muscle pain (Figure 2). One explanation suggested that when a person works hard oxygen is used up causing a buildup of lactic acid in cells causing cells to swell and push against nerve cells causing pain (which is incorrect based on the provided evidence). The other explanation hypothesizes that the cells are damaged during exercise

leading to fiber damage which causes cells to fix the damage. These chemicals cause irritation which causes pain. The key distinction here is the underlying damage causing irritation to the nerve cells as opposed to the buildup of lactic acid. This idea is not supported by the provided evidence. Once students were presented with all five pieces of evidence and the two explanatory models, they were asked to write an argument that explored which model best explored why muscles hurt 24 to 72 hours after exercise, the *lactic acid explanation* or the *muscle fibers explanation*? They are asked to provide reasons and to write to someone may disagree with you, but who has not seen the evidence.

Similarly, in the FL assessment, students were provided with five pieces of evidence and two competing mechanistic models. One explanation suggested that in autumn shorter days resulted in less sunlight and the release of a chemical from leaf cells, which in turn causes the connection between the leaf and the branch, making the leaf fall. The competing model suggested that the shorter days resulted in cold temperatures which resulted in the production of ice crystals inside the leaf cells and causing damage and increasing the overall weight of the leaf cells. The key distinction is the impetus for the underlying mechanism—shorter days resulting in the release of a chemical or colder temperatures causing ice crystal to build up in the cells. The first hypothesis, shorter days resulting in the release of a chemical is correct based on the provided evidence.

Figure 3
Explanatory models presented in the Falling Leaves assessment



We report data from students who completed the argument in the MP task (n = 92 at the middle school level, n = 119 at the high school level) and the FL task (n =107 at the middle school level, n = 112 at the high school level). Each was given to students at the end of instruction which was approximately 20 weeks for middle school and 10 weeks for high school. Any students who did not complete the argument (e.g., blank essays) were removed from data analysis.

Data Analysis

We analyzed student arguments using the *Integrative Argumentative Framework (IAF)* (Cavera, 2018a). This argumentation framework analyzes student arguments by segmenting student arguments into coherent propositions or *argument moves*. These moves are categorized into three major perspectives: *structural*, which captures the presence of a *Claim statement* (e.g., *I believe model A is best*.) which can either open or close the argument, and *Support* and *Refute* statements which provide credence (e.g., *I think the model is correct because evidence 1 and 2 support it.*) or demonstrates how the competing model is false (e.g., *The only evidence that supports model B is evidence 4 and that isn't a good quality piece of evidence*.). *Epistemic* moves are those in which a student appeals to epistemic ideals to satisfy an epistemic aim (e.g., *The model has good pictures. It shows a step-by-step process.*). *Rhetorical* moves include the *Setting the Stage* moves, which are those that provide a strategic organization of the argument. We identified two major types of *Rhetorical* moves: (a) Overview moves where students identify differences between models (e.g., *Model B talks about damaged cells which Model A doesn't even mention.)* and (b) Preview where they provide a summary or layout their argument (e.g., *I think [the] lactic acid [model] is better. There are more evidence in support of it and it's clearer organized*.).

We took this framework and expanded the *Refute* move category based on a prior coding scheme (Cavera, 2018a) in order to capture the kinds of refutational strategies that students applied during their arguments. We

identified three major refutational strategies: (a) refutation based on congruence with existing theories, (b) refutation based on evidence credibility, or (c) refutation by evaluating the quantity of evidence that supported each model in conjunction with (a) or (b). Three independent coders coded 22% of the middle school data and 38% of the high school data. Interrater reliability was 86% and 91%, MS, HS respectively. All disagreements were discussed.

Results

We begin our analysis by discussing the kinds of argumentation moves those students displayed at each grade level, then discuss the refutational moves and rhetorical moves more specifically by grade level. By starting with discussing the arguments more generally and then moving to examples we explore the trends displayed by each group and then can explore what these argumentation moves look like in practice.

Composition of student arguments at the middle school and high school levels

When comparing each of the groups of arguments (Table 1), students at the middle school level on average wrote shorter arguments than students at the high school level across assessments. This was captured both by the average number of words as well as the average number of argumentation moves. While students at both grade levels selected the model supported by evidence (Explanation B: the muscle fibers model in MP and Explanation A: Chemical Signal in FL) at approximately the same rate, we note differences in the amount of *Support, Refute, Epistemic*, and both types of *Setting the Stage* moves. We also note that a percentage of students at the middle school level did not select between the two provided explanatory models in their claim statement while all of the students at the high school level chose between the two models. We also note that students in both grades did not provide rhetorical set ups in the FL task.

Table 1: *A comparison of arguments at the middle school and high school levels*

	Middle School-MP	High School-MP	Middle School-FL	High School-FL
Model Selection	Explanation A: 47% Explanation B*: 51%	Explanation A: 46% Explanation B*: 54%	Explanation A**: 49% Explanation B: 46%	Explanation A**: 55% Explanation B: 45%
Avg. moves	3	4	4	4
Avg. word count	70±15	177±12	79±8	144±11
Support Moves	44%	34%	53%	47%
Refute moves	9%	14%	7%	12%
Epistemic moves	21%	16%	23%	17%
Setting the Stage moves	Overview: 3% Preview: 4%	Overview: 9% Preview: 5%	Overview: 1% Preview: 1%	Overview: 2% Preview: 1%

*Model B is better supported by the evidence provided in MP
**Model A is better supported by the evidence provided in FL

Rhetorical Strategies & Appeals to Epistemic Quality

Rhetorical and epistemic strategies were evaluated at both grade levels in terms of the identification of our *Setting the Stage* and *Epistemic* moves (Table 1). An example MP middle schooler provided both a preview of their argument, *It is supported by more, higher quality evidence than explanation A is*, as well as an overview of their argument by juxtaposing the evidences in conjunction with each of the models. This student wrote, *evidence 2 supports model B because it mentions the nerve cells. Evidence 3 supports model B because it explains how the muscles get swollen which is in model B not A.* MP high school students alerted readers of important features in their argument, for example, *One reason why I think model B is better is because out of the 5 evidences, [the] majority of them support model B.* The student guides the reader through how the majority of the evidences support their model instead of the competing model and provides a 'roadmap' to follow and be aware of aspects the student deemed important. Towards the end of their argument the example high school MP student states, *Overall, we can see that model 1 has more evidence contradicting it than supporting it than model 2. Model 2 has the best pieces of evidence supporting it and more evidence supporting it than model 1 does. Comparing the models directly, they are constructed in an identical fashion, so they both meet the same model criteria. Thus, model 2 is the better explanation.* By attuning the reader to this rhetorical strategy—discussing each evidence and its relation to each of the models, the student is then able to then juxtapose the models again once they have evaluated each

of the evidences. The high school example sets up and relies on the relationship between the quantity and quality of supporting evidence for their selected model throughout the entirety of the argument. This student also addresses states that there are differences between the two provided models, addressing the epistemic appeals of the model criteria and relying solely on the relationship between model and evidence to make a decision between the models.

In the FL task, middle school students focused on sense-making epistemic features like: *it* [model B] *makes more sense because when it gets colder, the leaf freezes, and forms ice crystals.* High schoolers similarly described the quality of evidence provided and connected it to the provided models in such cases as, *The best explanation is explanation 2. This is because it has the strongest piece to go with it which is evidence 5. 5 is the best because it shows you a detailed graph of exactly how much of the leafs [SIC] are left other then that there's a blurry picture and some common knowledge about trees. So the best explanation with the best form of evidence will obviously be the best.* Overall, in the FL task regardless of grade level students attended to the rhetorical aspects of arguments at a lower level than students completing the MP task. Some students provided an overview of their argument like this high school student, *I believe explanation 1 is the best explanation of why leaves fall from trees because the act of a chemical signal being sent to the leaf and causing the leaf stem to weaken from the branch makes more sense. Explanation 2 makes no sense because cells in the leaves are full of water and get frozen and ice crystals form and the weight of the leaf pulls it off the tree right? Then how do they become dry and brittle instantly before falling if there frozen and autumn leaves are already dry as is on the tree?* This rhetorical set up is a great opener to help set the reader up to juxtapose the content of the two explanatory models.

General trends were noted in both assessments, some students also discussed the epistemic qualities of the evidence and models as a way of determining their model selection. Middle school students tended to favor explicitly pointing out how their chosen model connects to common class criteria lists for good models (e.g., the model describes the phenomenon, the model is good, clarity of the model, etc.,). High school students did this as well, though more often pointing out the communicative features (e.g., clarity, large sample size) and the role of the evidence in supporting each of the models.

Refutational approaches at the high school and middle school grade levels

Discussing the competing model is a difficult task for all students and like others, students in both groups could produce refutations at a rate of 9% and 14%, and 7% and 12% (middle school, high school, MP to FL, resp.). Parsing the kinds of refutations that students attended to in their arguments (Table 2) students at the middle school level focused on the credibility of the competing evidence as a means of refuting the competing model. Students employed this strategy 36% of the time on its own and all but one student used it in conjunction with the *quantity of evidence model that supported each model* strategy. When high school students refuted, they often combined strategies in conjunction with the *quantity of evidence that supported each model* with more students focusing on the *credibility of evidence* than *congruence with existing theories*.

Table 2: *Refutational strategies by grade level*

	Middle School-MP	High School-MP	Middle School-FL	High School-FL
Credibility of evidence strategy	39%	28%	45%	31%
Congruence with existing theories strategy	23%	24%	18%	22%
Quantity of evidence that supported each model strategy	38%[α]	48%[α]	37%[α]	47%[α]

[α] Represents all students who chose this refutational strategy with either the credibility of evidence strategy and congruence with existing theories strategy.

In practice, students who refuted heavily favored the *quantity of evidence that supported each model strategy* combined with one of the other strategies or the *credibility of evidence strategy* alone to refute the competing model as compared to the *congruence with existing theories strategy*. Middle schoolers were more likely to focus on the credibility of evidence. For example, a middle school student completing the MP task organizes their argument by discussing how several evidences support their chosen explanatory model (Model A, the lactic acid model). Throughout their argument, the student demonstrates that several evidences (evidences 2,

3, and 4) all provide support only for their model and not the competing model by describing how specific statements only appear in the text of one model, *model A is supported by evidence 4 because it mentions lactic acid which is obviously only in model A, the main idea of model A [it's] even in the title.* This, tied with their credibility of the evidence that supports their chosen model, such as in the case: *model A is better because it has a chart explaining before and after exercise meanwhile model B only has pictures that to me don't help the reader*.

High school students tended to have a different approach. For example, a high school student completing the FL task stated that their model is supported by more, high quality evidence, such as evidence 4 and 5. They state that the picture (evidence 4) contradicts model 2 because *ice would be throughout the leaf to support the model*, *but model 1 shows that the damage is in just the stem. So this supports model 1 and contradicts model 2.* Evidence 5, a graph that depicts the number of nights below freezing and the percentage of leaves still on trees fully disproves model 2 because *there were no below freezing nights until December but the trees are bare!*

Discussion

Prior to students completing the post argument assessment, which was examined in this study, students were provided with scaffolds that were embedded into the curriculum. Due to students' use of these scaffolds, we have found that students developed extended arguments that contain rhetorically complex ideas and refutations. Not only do students generate these kinds of arguments at each grade level they attend to different kinds of strategies to refute the competing model. Students at both grade levels are also able to attend to the rhetorical nature of arguments and appeal to epistemic qualities of evidence and models.

Refutational strategies and complexity

Appeals to epistemic ideals, rhetorical ideas, and refutations are evident, identified here as argumentation moves, both middle school and high school students developed arguments that contained features but did so in different manners. Previous researchers have identified that with scaffolding students can take the tactic of refuting a competing argument by evaluating the amount of supporting evidence for competing arguments (Nussbaum, 2021; Nussbaum et al., 2019). This approach is similar to the strategy discussed here though many of our students additionally combined this approach with an additional appeal to epistemic quality. Middle school students who refute tend to focus on the epistemic qualities and features of the evidence in order to refute the competing model. High school students tend to focus on the relationship between the models and evidence, attacking the connection as compared to middle schoolers who attack *qualities* of the model and evidence. In each instance students are refuting; however middle schoolers tend to focus on their model quality criteria list and describing how each of the evidence support their own model and not the competing model based on the provided scaffold. This demonstrates the difference in what is important to tackle and differentiate between—the model evidence connection or the epistemic qualities of the evidence. Students can evaluate the quality of the evidence that support their own model or claim or the quality of the connection between the model and evidence.

Arguments written by high schoolers contained more variation in argument moves and were more likely to contain both types of *Setting the Stage* move in the MP task. These rhetorical moves were noted at a much lesser degree in the competing FL task. High school arguments were, on the whole, longer than the arguments written by middle schoolers which lends themselves to the increased level of nuance. However, at both grade levels students could include a *Setting the Stage* move, often cueing the reader of how their argument was organized or of what features they would discuss throughout the argument. This idea of setting up the argument is an important rhetorical strategy that alerts the reader of important features of the competing argument but also tied into a refutation it demonstrates a powerful approach to argumentation.

The role of scaffolding on argument complexity

A major contributing factor to the development to the nature of the arguments that students developed was a feature of the task design. During instruction, students were provided with the Model-Evidence Link (MEL) matrix scaffold and expected to discuss the competing models and relationship between the models and evidence. For the assessment the scaffold was removed, and we found that at both grade levels students struggled to discuss the competing models, a finding consistent with previous work (Cavera et al., 2018a; 2018b).

This work further supports the idea that students can argue in robust ways with respect to rhetorical and refutational aspects of argumentation. Previous researchers have demonstrated that taking students to make comparisons between competing claims is difficult, challenging students with competing multistep models increases the difficulty—even with sufficient scaffolding. This work contributes to the body of work that has shown that students at both the middle and high school levels can form refutations; this work demonstrates that students at each of the grade levels go about the process in different ways dependent on task and grade level. We also find task dependent differences with respect to rhetorical approaches. We hypothesize that students responded

to each task differently because this assisted in how they made sense of each task. As these tasks were completed by student populations that seen the phenomenon of leaves falling off trees before this, coupled with the provided evidence may not have required the set up for the underlying mechanism. Comparatively, the complexity of muscle pain (a phenomenon students have experienced but cannot physically see) may have required more mental effort to unpack and explain lending itself to more rhetorical maneuvering.

Students at both grade levels can argue rather complexly especially when it comes to refuting. They just need to be provided complex tasks that ask them to develop extended evidence-based arguments. The refutations attended to are powerful but the strategies at each level were different with more attention at the high school level paid to the connection between the model-evidence connection while middle schoolers paid more attention to the qualities of the evidence that support their own model. These approaches differ from what Anderson and colleagues (2001) and Nussbaum and colleagues (2019) have previously found. We also know from previous work and others in the field that discussing the communicative features of arguments (e.g., pictures, titles, etc.) are what students' value *before* instruction (e.g., Pluta et al., 2011; Cavera et al., 2018b). Even with scaffolding students at the middle school level rely on these communicative features to refute the competing model and its evidence. Students at the high school level begin to tackle that relationship between the model and evidence noting the strength of the model is only as good as the evidence that supports it.

Towards a "Slowed Down" Pedagogy: An Emergent Youth-Led Practice of Politicized Care

Melissa Perez, Angela Calabrese Barton, Chandler Turner, Day Greenberg, Devon Riter
[perezme, angiecb, chanturn, daygr, driter] @umich.edu
University of Michigan

Abstract: We discuss how youth "slowed down" an online STEAM makerspace during the COVID-19 pandemic, opening up new ways of being and doing together. The practices youth enacted in slowing down arose from their politicized care for one another. Adult mentors, through moments of slowing down, were given an opportunity to rethink how to listen to youth's desired ways of doing STEAM. To discuss the implications of slowing down, this article features two instances in which Black youth "slowed down" in sessions to demonstrate their desired ways of being together/doing together within the STEAM context. Highlighting youths' moves has implications for how educators think about co-designing programs with youth and how to enact politicized care in the face of rapid social, environmental, and political change.

Introduction

The typical pandemic Green Club (GC) meeting began with the images of the adult mentors huddled on a computer screen in individual tiles on a black background, chatting and waiting for youth to file into the Zoom room. The regulars usually joined before the allotted after-school time: Lulu and Shadow (sister and brother), Finn, and May appeared in their tiles one by one, though their rectangles typically featured their screen names instead of their faces. One of them, without fail, started us off with their usual question: 'Can I show you guys something I drew?' This question always elicited positive responses to the tune of "YEEEEESSSSS" and "please do!" in the chat from the mentors and the other youth. The youth who were regulars during the in-person STEM-Rich program integrated their recent art during each virtual Wednesday session with updates on what they had been drawing in their free time.

This ritual that developed is just one example of how youth "slowed down" (Shahjahan, 2015) our engagements in the virtual space of GC. Sharing artwork was eventually institutionalized in the agendas mentors created, allowing for more time to appreciate each other's work that had taken place when we were not together. In this example of youth-led practice, youth show that "being with" (Villenas, 2019) each other is not precluded by being physically apart. Rather, there are ways to "be with" one another that center relationships, processes, and expressing critical discourses of the "multi-pandemic" (Calabrese Barton & Greenberg, 2021) that can emerge when youth have space to enact it.

We therefore discuss how youth helped adult mentors make space for their desired ways of engaging with each other and STEAM through slowing down in the virtual club. Slowed down pedagogy emerged during the peak of physical distancing practices and uncertainty of the future of the pandemic, when vaccines could not come fast enough and terms like "Zoom fatigue" (Schroeder, 2021) and "learning loss" (Merrill, 2021; Calabrese Barton & Greenberg, 2021) proliferated throughout educational discourses in the U.S.. We therefore emphasize the relational nature of the learning that took place in this year of GC. We argue that slowed down pedagogy has relevance to multiple educational contexts wherein educators are invested in being responsive to the ways that youth can reshape normative engagements/discourses. To support this argument, we explore how Black youth sought to reorganize practice in the remote STEAM makerspace, the "Green Club" (GC), by collaboratively engaging in a practice of *slowed down pedagogy* (Shahjahan, 2015) that built over the COVID-19 multi-pandemic. We position this slowing down as stemming from GC members' *politicized care* (McKinney de Royston et al., 2017) for one another. We answer the questions: **How and why did youth "slow down" the learning environment through their discourses and practices? What impact did youths' relationship building have on their opportunities to learn and become in STEAM?** In answering these questions, we begin to illustrate what "slowing down" can look like, and how it can be responded to by adult educators in order to transform learning environments towards equity.

Background

We start from the premise that youth are constantly developing, demonstrating, and sharing expertise in many different subjects, with STEAM being one of those, and that STEAM-rich making in a community oriented youth makerspace is a site for this sort of learning to occur (Calabrese Barton & Tan, 2018). Foregrounding youths' moves to "be with" (Villenas, 2019) each-other in the online format, we build on work that views STEAM learning

 © ISLS

as a constellation of relationships, practices, and discourses that ultimately position them as knowledgeable and creative STEAM makers. We also position it within work that aims to reimagine why we teach STEAM in the first place. Instead of centering labor and the projects of STEAM, we aim to center the relationships and alternative discourses that can take place within these contexts (Sengupta-Irving & Vossoughi, 2019). This is what we refer to as the "relational" aspects of learning; how youth and adults came together to co-create the experience of GC.

Much effort was required from families to reorganize time, priorities, and resources due to the pandemic (Jalongo, 2021). Our remote program took place during larger "community infrastructuring" efforts (Greenberg et al., 2020) which focused on "build[ing] capacity for disrupting injustice and supporting each other during the COVID-19 crisis" (Greenberg et al., 2020, pg 1). GC continuing into a socially distanced program held online was part of this move towards infrastructuring, in that it served as a space for youth to come together to create work and discuss the pandemic as it unfolded. The youth discussions and practices that are highlighted in this paper are part of "disrupting injustice and supporting each other" in the context of learning more about STEAM.

Theoretical frameworks: Slowing Down & Politicized Care

It was essential that the space of GC reflect caring relationships which recognized the multiple pressures on families and youth during the height of social distancing (Thompson et al., 2021). Slowed down pedagogy emerges from the nexus of politicized care and slowing down. This particular mixture creates a lens through which we can understand youths' projects, relationships, and interactions that does not center the end products of their work.

Politicized care encompasses the ways that adults of color care for youth of color, bringing attention to the politicized dimensions of their needs (McKinney de Royston et al., 2017). We build on the concept of politicized care to show not only how teachers or adult facilitators enact politicized care for their students, but how, in a setting where youth are co-constructors of the program, youth enact politicized care for each other. Politicized care can be seen in the relations between members of the learning community, such as when they affirm/build on/push on critical discussions about their lives that are often politicized (such as climate change or police brutality), or when they uplift each other as knowers and doers of STEAM who also carry vital community knowledge and ways of knowing.

Often, youth enacted moments of politicized care for one another, ***slowed down*** the GC agenda, often times to a point where it was changed entirely. We refer to 'slowing down,' initially conceptualized by Shahjahan (2015), as practices/moves that focus on the embodied nature of learning and "being with" (Villenas, 2019) each other, placing an emphasis on the bodily, emotionally, and socially shaped dimensions of youths' learning experiences. 'Slowing down' was one way that youth invited all participants to put aside learning expectations and norms that had developed over time in previous years as a way to care for each other. Occassionally, this meant that preexisting agendas would be thrown out in favor of youths' needs in the moment. We claim that 1) these efforts to slow down the STEAM program were led by youth, through discourses and practices that affirmed each other, and 2) this process of slowing down made space for critical and political discourses on substantive concerns about the world we live in, while also re-orienting their maker program/experiences/projects in ways that more explicitly reflected these forms of caring.

Methods

Context

GC has been a fixture for over a decade, in-person, at a local Great Lakes City, Midwest youth center. During the 2020-21 academic year, GC went virtual due to COVID-19 physical distancing guidelines. The virtual sessions were held on Zoom and lasted approximately one hour at least twice a week. The purposes of these meetings varied: one meeting (Monday) was dedicated to adult and youth researchers co-designing the topics, goals, and timelines of projects and sessions, while the other meeting (Wednesday) focused on making and working through the focal project for the semester. We had two semester-long projects (the "focal projects") where youth collaboratively planned, designed, and created projects that engaged both STEAM and their community, both widely construed. These were "2020 stories," where youth told their stories of the multi-pandemic using a broad array of materials, including anything from their homes and materials that could be distributed from the makerspace. Youth were encouraged to be imaginative and open-minded when thinking about what they could use to tell their stories, leading to a variety of project mediums such as paint on canvas, a written story, a coding project, and videos. The winter project was a podcast where youth talked about their collective interests and learned how to use audio editing software. Each week youth ideated on new topics to discuss with each other and recorded it. They also broke into groups to work on other necessary projects for the podcast, such as creating the cover art and deciding how to edit.

Participants

The youth in this program are predominantly Black middle schoolers of various gender identities who live in GLC. Throughout the year, participation ebbed and flowed, but there was a core group of 5-7 youth that would consistently join in on the Monday and Wednesday meetings, though there could be anywhere from 2-10 youth in the session on a given day. There were 5 adult mentors, 2 of whom were White women, 1 Black woman, 1 Latinx woman, and 1 White man. Of this group, 3 of the adults are from or have lived for a while in the GLC community, and taught for many years in this program. All of these mentors are authors of this paper.

Data Generation

We engaged in data co-generation through critical ethnographic methods, which included writing field notes, video-recording sessions, saving Zoom meeting chat logs, collecting artifacts from sessions, and facilitating participatory, long-form interviews with youth twice throughout the school year. Data were analyzed as analytic memos of moments that stood out to adult researchers. In a second round of analysis, researchers debated-towards-consensus what types of "slowing down" were happening in different identified moments. Finally, we organized these types into analytic claims, mapping them to empirical evidence of how our shared youth-adult engagement forms shifted and transformed, and what that shifting/transforming revealed to us about slowed-down pedagogy in our program. All names mentioned here are pseudonyms chosen by the participants.

Findings

We return to our original research questions to structure the findings. First, how and why did youth "slow down" the learning environment through their discourses and practices? We zoom into moments where they enact politicized care for one another by slowing down. In the introduction, we shared an example of youth creating a ritual that made space for sharing work and affirming one another. This ritual was one of an arrangement of practices that youth engaged in that showed politicized care for one another in a way that was developmentally appropriate and emphasized the importance of the quality of attention that we allow for the youth to enact.

Second, we answer the question: what impact did youths' relationship building have on their opportunities to learn and become in STEAM? During the COVID-19 pandemic, youth's relational learning took center stage in their work. We privilege this relational work while also drawing attention to the STEAM learning that they demonstrate through their practices. These enactments of politicized care productively slowed down GC and opened up new spaces for engaging in STEAM. Making explicit how youths' relational development mattered in the space is important not only for understanding this in the context of the pandemic, but for designing future learning environments in which relational learning is valued. The two vignettes support our view of the importance of relational learning. In the first, we see how one of the youth calls attention to silence and uses it to spark critical discussion. In the second, we see how leaving space open for redirection can still lead to substantive learning while honoring the ways in which youth want to engage.

Negotiating the initial slowing down through calling attention to silence

Finn, a Black non-binary youth, has found a video relevant to what GC members would be interested in, and wants to share it. We show how Finn's action of calling attention to "silence" and using it to make space for critical political discourse about both the environment and their futures is one way youth sought to slow down and re-orient their program around new directions and relationalities. In this first example, we describe a moment where an adult educator negotiates the activity with youth to slow down and support youths' relationship building in STEAM.

In the moment, Luz, a Latinx femme adult mentor, is trying to engage the youth in their chosen project, creating a podcast. At the start of the session, during the time when youth shared updates about their work, Finn asked if they could share a video they saw online. Luz tried to keep the group on a schedule for the podcast, and asked if they could save it for later. She then started sharing platforms for editing a podcast to ask youth which one they would want to use. Between her explanations and sharing of websites, there were a handful of times where no one was talking or responding. During a particularly long pause, Finn called attention to it, saying "Question." Luz invited them to ask, though it was hard to hear through the glitching of Finn's audio.

"Why is it so quiet?" Finn asked, laughing. "I'm like, 'uh oh, what happened?' [...] it seems like we, kind of, don't have anything else to talk about…" They said this slowly, knowing they were about to offer a subject change back to the video. Here, Finn does not reject the project, but puts forth a new idea for the group to think about. None of the youth outright rejected the idea of working on the podcast at that time, yet they were trying to tell the adults something through their inaction/non-response. In this moment, Finn 'broke' a silence that came out of working on a project that they and the other youth were not engaging in at the moment. The silence

created a space for taking a different direction than working on the podcast. Silence was a necessary first step as part of "slowing down," which youth created and Finn stewarded.

In response to Finn trying to change the subject, Luz then asked the group if they should try to record something before listening to the video. Finn responded that it would be fine, but then proceeded to talk about "Dear 2045," (SugarDaisy, 2020), which is "about all the stuff that happened last year [...] Technically, it's about the pollution and all that stuff, and about how Donald Trump did all those [inaudible] things." While they were explaining, Luz started sharing her screen, in an attempt to draw attention back to the podcast. During this time, Finn's audio cut out, and Luz asked them if they could paste a link to it in the chat. She attempted for a few more minutes to engage the youth in the podcast. Luz's audio went out for a minute, and Finn asked if they could share their screen. At this point, Luz recognized that this is important to Finn, and that the other youth are interested in what they have to share, so she stops pressing the project.

However, this was not without some collaborative efforts by the youth. For example, in moments when Finn's audio would cut out, other youth would let them know in the chat they cannot hear Finn, with short messages like "I can't hear you." This was in tension with Luz's moves to focus on the project, which used those moments when Finn's audio would cut out as opportunities for redirecting back to the "main" project, such as sharing her screen when Finn was talking then asking them to paste it in the chat. When the other youth would actively support Finn's idea of sharing the video through keeping their attention on them, Luz recognized their quality of attention for the podcast was and would not be good without first hearing Finn out. Recognizing and leaning into the quality of learners' attention on a project was crucial for "slowing down," and was a way that youth could show how they wanted to engage with each other and STEAM.

After Finn shared the music video for "Dear 2045" (with some technical hiccups), they told the group "exactly why [they] wanted to share it": they thought it was a "great description of what's happening in the real world" and they "love how these people, like, care about what's going on." Finn pointed out that people "think [climate change]'s a joke," and sometimes "bully" people for caring about the environment. Finn said that this song might help people realize that climate change is a serious issue and that they should support people who care about it instead of bullying them. This song "inspires [Finn] to be more careful about what is going on around everybody else." Finn shares why it is an important message for others to hear, remarking on the video's ability to reach people in an emotional and "real" way. This demonstrates political clarity, which is an important aspect of politicized care, and was a necessary precursor for Finn to want to share with the group to begin with.

Negotiating the initial slowing down through calling attention to silence

We show how youth take up slowing down to collaborate and demonstrate their relationships with one another and continue to express critical discourse of the environmental crisis. This example takes place a few weeks after Finn shared the Dear 2045 video, during our updates time in the Wednesday session. Finn shared that they have been learning to sing the song "Snowman" by SIA. We all, youth and adults, encouraged them to sing it. After some technical issues, they sang it and it was beautiful. Lulu, another youth, was inspired to sing the same song. The session, similarly to the Dear 2045 session, was meant to be for working on our collective project. However, the youth wanted to sing and write music. This time, instead of trying to divert the youth to the plan, the adult mentors responded by supporting the writing of a "rap." However, even though Lulu and Finn had shared out loud, writing the rap was quiet. The majority of the work took place in the chat. Any verbal contributions were to either support what was being said in the chat or to ask questions about the project to check in if they wanted to work on it.

Below, the final rap was edited in format to show the contributions between youth and adults. In the passage below, the adult contributions, primarily from Maria and Starr, are completely left aligned. Every other line has a different number of tabs which differentiates each youth: Lousie, Finn, Tris, and Lulu. This format is meant to give an idea of who contributed what, how, and when, while also emphasizing the artistic nature of the work the group engaged in.

Green Club investigators…. We like snakes and alligators!
	i am a dog, you see this tree? it is a log
		le bark bark.
I'm dog, but I like me fish.
		I eat food in my dog dish.
			i have a pet fish, her name is miss she lives in a dish.
			i ate her she delish.
	My dog has a wish,
		to eat YOUR fish!

 © ISLS

Wait that's too violent, tisk tisk!
When green club tries something, we never miss!
Normally when I count time, I rhyme, not only that but I count dimes
These things keep our earth alive, most things we need to survive
like plants and water, like food and shelter
I like dirt,
the sun's our ice melter!
When they see us they say hi but when we is mad they run and hide
I water Kiri, he turns into a shark, when I go near Kachan he goes Bark Bark
we all have superpowers, we just need to use them…angel
I live in Space, I eat some grapes, and when I get tested I always Ace
we don't stand down, we empower
till my guinea pig bit. he devour.
I feel betrayed. I've been attacked.
i can only type with one finger and a half.
---gets holy bible and shouts S t a y b a c k!
should i put hand sanitizer on the bite?
it might burn but that is OK
not finna become todoroki due to a sanitizer…
we'll share more next time, so please stay!
And
help fight for the earth
so it doesn't go away

At the end of the 30 minutes it took to write, the rap was performed by Tris, Lulu, and Shadow individually. During this time, they hyped each other up to sing it and when someone would stop midway, they would encourage each other to keep going. These practices are part of what they did to enact politicized care; they demonstrated communal bonds by being encouraging and writing together as a group. It was also a developmentally appropriate way for them to demonstrate their knowledge of STEAM while also expressing their views over the future of the environment.

We also see that the slowed down work extended over time and brought up ways for youth to engage with one another. The GC raps session happened because youth wanted to share their ability to sing/rap, which is something that has been done in different forms in the past but was brought back in an organic way. This rap was collaboratively produced in a way that was mostly quiet. For example lines such as "till my guinea pig bit. he devour. // I feel betrayed. I've been attacked. // i can only type with one finger and a half" were developed as youth talked about Lousie's guinea pig. We see how youth centered silence/listening in the creation of the rap because of how the chat influenced this. In the audio, we hear mostly the GC members saying positive things to each other and laughing along as we write. Youth/adults invite each other to share their thoughts by asking open questions or calling on each other for responses, recognizing when other people want to be able to speak so they listen and support them.

Learning across the examples

To discuss learning across these examples, we emphasize how youth learning took the form of relational work that supported how they engaged with STEAM. For instance, they demonstrate their knowledge production around the environment in both examples, both through their discussions of the future in the Dear 2045 example or through their invocations of needing to protect the earth. Youth share a powerful video about climate change, and illustrate the points where politicized care and slowed down pedagogy appear in their moves to make space for STEAM engagement by and for the other youth. This brings in critical political discourses about the world, their futures, and the environment.

Discussion

The featured vignettes are examples of how youth "slowed down" STEAM making through their politicized care for one another. Finn's experience as a youth and a long-time member of the group allowed them to enact politicized care for their peers in a way that Luz did not recognize at first. Finn's moves to "slow down" were oriented around sharing the "Dear 2045" video, which opened up a conversation on the role of STEAM in society and how youth play a role—displaying political clarity. Luz, recognizing how silence and youths' quality of attention were shaping the session, stepped back for Finn to take an active role in the moment. This points to the

need for creating spaces for youth to slow-down as a way to support them in naming and enacting their desires for their program and their lives.

The whole group vignette where the youth co-wrote a rap together showed how from making space for slowing down there can be productive disruptions that take a different path to get where we want to go. Though the rap was not part of the plan, it was still part of what we envision as participating in STEAM. We were able to do this because we let go of the agenda and went with what youth showed us how to do in the moment. This points to how it is possible to find a balance between participating in STEAM in "traditional" ways while being responsive to youth. The implications of these points have reach in how we think about co-designing programs with youth and how we consider learning in general.

Implications for co-design with youth

We posit that slowing down can be a form of in the moment co-design with youth that seeks to maintain an overall vision of the learning that the space is designed for, while being attentive to the ways that youth want or need to interact with one another. While our Monday sessions featured explicit co-design time, where youth and adults came together to plan our projects and the overall timelines, in the moment co-design was equally as important for the overall implementation. Being able to negotiate the plan in the moment via slowing down is crucial to recognizing how youths' relational work is playing into STEAM learning.

Implications for learning

We situate this form of learning within the narratives of "learning loss" that pervade pandemic educational discourse. We argue that youth are showing us in this space that they are actually learning much about subjects that are not often emphasized in schools. Youths' work in this case sits at the margins of "learning loss" discourse, because what they are doing matters in profound ways yet is not recognized or valued. However, relational work is more important than ever in this time of isolation and social distancing. Further, the effects of the pandemic on entire generations of learners has yet to be seen. Research in the area of relational learning will continue to be important, and slowing down afforded a space to see this youth work.

Conclusion

This paper presents examples of how slowed down youth-led pedagogy, stemming from their politicized care for one another, contributed to youth's STEAM learning and presented adult mentors an opportunity to rethink how they listen to youth. We share two vignettes, one featuring Finn, a Black youth in an informal STEAM program, who "slowed down" a session, and in doing so was able to share a powerful video about climate change and insights on the power of youth. We also shared an example of how a group of youth embodied this by collaborating on a rap that was written entirely in a chat on our online platform.

These examples show us that slowed down pedagogy allows for a shift in how we approach STEAM making so that it is less tied to neoliberal logics of production, innovation, and competition in favor of developing relationships, exploring new processes, and collaboration. Throughout this paper, we have illustrated the points where politicized care and slowed down pedagogy take precedence in youth's moves. This lens offers us implications for both how we think about co-designing programs with youth, and how we work to de-center normative engagements with STEAM learning.

Abstract: A core aspect of scientific inquiry is developing and revising models. This practice is supported by shared epistemic criteria to evaluate the "goodness" of models (and other epistemic products). A prominent criterion used by scientists is evidential fit. The use of epistemic criteria is gaining traction in science education; however, there is a gap in the research about the extent to which students view evidential fit as a central epistemic criterion of scientific models and what sense they make of the role of evidence in modeling. Using the *Grasp of Evidence* framework, we examined how students reasoned about evidential fit and its relationship to model goodness. We found that students understood that evidential fit confers accuracy and considered nuances of evidential reasoning, such as relevance and sufficiency. We discuss educational implications of these findings for advancing students' evidential reasoning with scientific models.

Introduction

Recent reforms in science education in the US have emphasized engaging students in knowledge production practices (NGSS, 2013; NRC, 2012). Knowledge production practices, such as modeling, have therefore increasingly been a focal point in science curricula. Giere (2004) defined models as, "…idealizations that scientists use to represent aspects of the world for specified purposes" (p. 742). Examples of models include the Copernican and Ptolemaic models of the solar system (Frigg et al., 2020) and Darwin's model of natural selection (Passmore & Stewart, 2002). The practice of modeling involves creating, evaluating, and refining models to explain and predict phenomena (Ke & Schwarz, 2020; Kenyan et al., 2008; Schwarz et al., 2009).

Scientific models are created and evaluated based on shared epistemic criteria for what counts as good models in science (Kuhn, 1977; Longino, 2002). Examples of epistemic criteria are fit with empirical evidence, explanatory power, fit with other established theories, conceptual consistency and coherence, and parsimony (Kuhn, 1977; Longino, 2002). Fit with evidence is considered as a central, perhaps the most important, criterion (Longino, 1996). Scientists create, evaluate and revise models in light of new evidence and even discard them if the model fails to fit a growing body of evidence. Fit with evidence is important because models with good evidence fit are more likely to resemble the world in desired respects (Bonjour, 2009; Strevens, 2020). In this study we used the term *accuracy* to mean how closely the model resembles reality in the desired respects.

Although evidential fit is a central criterion for making and evaluating scientific models, scientists often need to make tradeoffs among criteria (Kuhn, 1977). For example, a complex model that fits the evidence might not be parsimonious. A simpler model might offer greater explanatory power but not fit the available evidence as well as a more complex model (Longino, 1996). Scientists consider the tradeoffs between evidential fit and other criteria such as explanatory power, complexity, and conceptual coherence in pursuit of an aim. For example, models that will be shared for use by the public might need to be parsimonious; however, models that will be shared with scientists who have expert domain knowledge can be complex. Therefore, a complex model that fits all available evidence might be altered to fit the most relevant evidence and still be understandable.

Although scientists grasp the connection between evidential fit and accuracy, there has been little research on how science students understand the relationship between these ideas. Prior research has not yet investigated how students view the connection between evidential fit and accuracy; whether students see evidential fit, and accuracy as connected, and further, whether students see evidential fit as conferring accuracy. We also do not know how students prioritize criteria in instances when criteria need to be weighed against each other; for example, whether models should fit the evidence and be complex or whether they should fit less available evidence but be simple and easy to understand.

Prior research has shown that fifth-grade students were able to develop normative criteria for scientific models as a class community (Murphy et al., 2021). These included the criteria that models should be

 © ISLS

understandable and that they should be supported by relevant evidence. Students are also able to prioritize criteria and provide justifications for why criteria are important including meta epistemic justifications about criteria importance in relation to each other (Murphy et al., 2021). Av-Shalom et al., (2018) found that all class criteria lists that were developed during the intervention included some form of fit with evidence, which shows that students are aware of the importance of the criterion fit with evidence (Av-Shalom et al., 2018). Further, Av-Shalom et al., (2018) found that students are able to reason that scientific models should fit most of the evidence and it is preferable that there be no counterevidence. Ryu and Sandoval (2012) found that upper elementary students were able to construct and evaluate arguments according to evidential criteria; however, Sandoval and Millwood (2005) found that although students stated that fit with evidence was important, 73% of students did not provide sufficient data to support a claim and failed to explain how data supported claims.

Although prior research has shown that students prioritize evidential criteria, less is known about what fit with evidence means to students, how fit with evidence relates to other criteria, and how students would reason about tradeoffs between different criteria (in instances when criteria compete). To address these issues, we conducted an interview study with fifth graders following a five-week inquiry project in which students frequently used and discussed criteria for good models. Our specific research questions were as follows:

1. How do students conceptualize the relationship between evidence fit and accuracy?
2. How do students navigate the tension between potentially competing criteria? (e.g., when more understandable models are simpler but don't fit the evidence)?

Theoretical framework: Grasp of evidence

To guide our thinking and analysis, we used the *Grasp of Evidence* framework (Duncan et al., 2018). To *grasp* evidence means to understand how experts construct, evaluate, and use evidence and how lay people can adequately use evidence themselves. Part of being able to engage with evidence involves meta-awareness of how evidence is constructed and how to adequately critique evidence which can be guided by ideals (epistemic criteria). Therefore, understanding how epistemic criteria guide evidence construction and critique can help to develop sophisticated evidentiary reasoning. The Grasp of Evidence framework unpacks five dimensions of expert and lay evidentiary reasoning: evidence analysis, evidence evaluation, evidence interpretation, evidence integration, and laypeople's use of evidence. The first four dimensions capture *experts' evidentiary practices*, which are the processes that scientists engage in when using evidence to further scientific knowledge. The fifth dimension, *lay peoples' evidentiary practices,* captures the ways that laypeople can reason about evidence themselves. Although experts and lay peoples' evidentiary practices differ, it is helpful for laypeople to understand scientists' evidentiary practices so they can understand how scientific knowledge is produced. Gaining exposure to experts' evidentiary reasoning skills can enable laypeople to better assess the science they encounter in their everyday lives by giving them insight into appropriate methods and validity of conclusions. Further, laypeople can develop an understanding of the cognitive division of labor as they see that scientific knowledge is produced by many highly specialized credible experts which might engender trust in science.

We were interested in how students conceptualize evidence in relation to scientific models therefore the dimension of the GoE framework that helped to guide analysis was dimension four, *evidence interpretation* which looks at how evidence gains significance in relation to a claim, argument, or theory. Before we explain this dimension more fully, it is useful to consider how we define evidence. We lean on Walton et al's., (2008) definition: data becomes evidence when it is used in support of a claim. Looking at evidence in relation to models considers how evidence is explained by a model and how well the evidence supports the model. The aim of evidence interpretation is seeking strong evidence to determine model validity. Ideals (criteria) guide attainment of the aim; in this case, seeking strong evidence to determine model validity. Laypeople can assess whether evidence is strong by considering the following ideals: *relevance*: how relevant the evidence is to the model; *core support or refutation*: whether the evidence supports core (versus peripheral); parts of the model; *diagnosticity*: precise fit with the model; *comprehensiveness*: the extent to which the evidence addresses multiple components of the model; and *directness*: how direct is the chain of reasoning. Engaging in an assessment of the aims and ideals when interpreting evidence means that students can understand how scientists interpret evidence which should help guide them to interpret evidence in relation to models and decide between competing models.

Therefore, in this study we considered how students interpreted evidence in relation to scientific models by analyzing how students saw evidence as supporting models in terms of conferring accuracy. We were also curious how students would reason about the interplay between evidential fit for scientific models in terms of how much evidence is deemed sufficient to support a model and how contradictory evidence would impact model accuracy. We also wondered whether students saw evidential fit as the eminent criteria or, like scientists, they would make tradeoffs between other criteria depending on the aim. We will explore these questions in the results.

Methodology

Context and participants

Data from this study came from an implementation of a five-week model-based inquiry unit in a public charter school in the Northeast of the United States. Two fifth-grade classes (termed 5A and 5B) participated, with a total of 50 students. The demographics of the school were 60% White, 22% Asian, 9% African American, 7% Latinx, and 2% other; 5% of students were eligible for free and reduced lunch. The school performs above average on standardized state tests on Mathematics, Language Arts and Science.

In the unit, students developed models to explain the phenomenon of eutrophication, which is the process by which an excess of nutrients causes an increase in plant growth which depletes the oxygen supply and causes fish to die by suffocation. Students built an understanding of eutrophication through analyzing reports of empirical studies and interacting with a simulation. Based on these two types of evidence, students created models in a new modeling software called [MEME] (Danish et al., 2019) to explain why fish were dying in a local pond. The models consisted of components (parts) that were linked by mechanisms (processes) to create a causal account of why the fish were dying. The evidence was stored in [redacted], and students could link the evidence to the parts of the model to support the components and mechanisms.

The evidence consisted of reports of empirical research and NetLogo simulations. Students sought to account for both types of evidence as they developed their models of eutrophication. Examples of reports given to students were an autopsy report explaining why the fish died, graphs showing the amount of sunlight and nutrients in the pond, and a fertilizer label to show the chemical ingredients accompanied with reports of how fertilizer increased plant growth in a pond ecosystem. The agent based NetLogo simulations (Tisue & Wilensky, 2004) showed how the variables sunlight, fertilizer, and oxygen impacted fish death on a micro and a macro scale.

Model creation and evaluation were guided by a list of epistemic criteria that was developed by each class. The class criteria list was made by analyzing pairs of models about scientific processes, such as fossilization and life cycle of the frog, and coming up with a list of agreed and shared upon criteria. Half-way through the unit the students revised their class criteria lists based on observations and critiques to their models during a gallery walk. The final class criteria list featured normative criteria such as models should make sense; each component (part) and mechanism (process) should have a clear explanation supported by reasons and evidence; be organized, clear, and explain what is happening; and models should include relevant evidence (Murphy et al, 2021).

Data collection and analysis

At the end of the unit, seventeen students were interviewed in dyads. The data for this study was taken from interviews with all nine dyads from class 5A. The data from this study specifically focused on a task that assessed students' conceptions of model evidence fit. In the task, students were asked a series of questions that probed students' conceptions about the relation between evidence and models.

In the first part of the interview task students were asked the following questions to probe the relationship between evidential fit and accuracy: *1) What does it mean for a model to be accurate? 2) What is more important, accuracy or fitting the evidence?3) Can a model be accurate but not fit the evidence 4) Can a model fit the evidence but not be accurate? 5) Does a model need to fit all the evidence? 6) Can a model that does not fit all the evidence be right? 7) What if there is evidence that contradicts the model?* The results from these questions will be explored in the results section under research question one.

In the second part of the interview task, students were asked questions to probe their understanding of the tension between scientific models that fit the evidence and are complex versus scientific models that are understandable but do not fit the evidence: *1) Which is more important for a good model, that it is understandable or that it fits the evidence? 2) Suppose scientists wanted to build a model to explain why mosquito bites itch. Suppose that one scientist comes up with a clear, easy to understand model, but it doesn't fit the evidence and another scientist comes up with a model that is complex and harder to understand, but it fits all the evidence. Which model would be better?* The results will be explored in the results section under research question two.

The interviews were videotaped, and audio recorded, and later transcribed. The transcripts were then reviewed in two rounds of analysis. First, the transcript of each dyad was analyzed to build an understanding of individual students' concepts relating to model evidence fit across the interview task. Second, the transcripts were analyzed by comparing the responses of the dyads in a cross-comparison method (Glaser, 1965) to build an understanding of students' evidentiary concepts across students. The rounds of analysis helped us see patterns within students, such as whether students saw evidential fit as conferring accuracy, and across students, such as why students thought that models did (or did not) need to fit all available evidence and how students saw contradictory evidence as impacting models (Duncan et al., 2018). Any issues that arose were resolved by presenting the data to the larger research team, reviewing the data, and discussing interpretations until we reached

consensus. The data is presented in terms of numbers of students who gave responses (instead of number of dyads) because every student did not respond to every question (sometimes one student in the dyad spoke but not the other) and sometimes students in a dyad disagreed. Therefore, the totals do not always add up to eighteen students for every question. The findings from the data analysis are presented in the next section.

Results

Research question 1: How do students conceptualize the relationship between evidence fit and accuracy?

These analyses examined students' responses to the seven questions in the first part of the interview (see above). The responses to the question, "*What does it mean for a model to be accurate?"* provide us with insights regarding what students meant by "accuracy." Seven students responded that a model is accurate if it has "true information," "true evidence," or "matches real life." Students did not explain what they meant by true information and true evidence, but we assumed they are different ways of saying the same thing: a model is accurate if the evidence or information that informs the model is also accurate. We think this because, throughout the unit, teachers and students often referred to evidence as "true information". These seven students therefore held a definition of accuracy that approximates scientists' definition of accuracy. The following excerpt from Rochelle and Iona show their reasoning that models are accurate if they match real life:

> Rochelle: What it means to be accurate is like if say it's a simulation or something like we did in class… if we do like the exact same things that we did in the simulations in real life it will turn out the same and that's like accurate.
> Iona: And then the simulation would be accurate because it's similar to real life.

Eight students said that a model is accurate if it has true information or true evidence, but they also added in at least one other criteria: makes sense, on topic, has all the criteria (on the class criteria list), is in order, neat, and complete. These students therefore saw a wider range of criteria as conferring evidence. Three students explained that a model is accurate if it is on topic, makes sense, and is relevant, without any reference to evidence or true information.

We also found that students were able to reason about how evidential fit impacts model accuracy. In response to the question, "*What is more important, accuracy or fitting the evidence?"* Thirteen students stated that accuracy was more important because if the evidence is wrong then the model will be wrong. The following quote from Maggie illustrates this understanding:

> Maggie: I think that it's more important to be accurate because the evidence could be not true so it (the model) will fit it (the evidence) and still be not true.

Two students responded that fit with evidence was better because it means the model will be accurate; further, if the evidence is true, then the model will provide a better understanding. Therefore, all fifteen students that prioritized either accuracy or evidential fit did so based on the same understanding: fit with evidence confers accuracy. Finally, two students explicitly stated that both accuracy and fit with evidence was needed because accurate evidence makes the model accurate and incorrect evidence makes the model incorrect, showing that fifteen students understood that incorrect evidence would impact model accuracy.

When asked "*Can a model be accurate but not fit the evidence?"* nine students responded that a model cannot be accurate without fitting the evidence because the evidence must be accurate for the model to be accurate; again, showing that students see incorrect evidence impacting model accuracy. However, another common response (from nine students) was that a model can be accurate without fitting the evidence if the evidence is off topic, therefore showing that they have considered how irrelevant evidence (an aspect of evidence interpretation of GoE) could impact model accuracy (Duncan et al., 2018). We saw the same kind of evidentiary reasoning to the question "*Can a model fit the evidence but not be accurate?"* Twelve students responded that a model could fit the evidence but not be accurate because the evidence is inaccurate. Three students asserted that it is not possible for a model to fit the evidence but not be accurate because if the model was accurate then it will fit the evidence, therefore showing understanding that evidence fit confers accuracy. Two students responded that a model could fit the evidence but not be accurate because the evidence is irrelevant to the model. Thus, ten students used the idea of evidence-model relevance to account for instances when models can fit the evidence and not be accurate, as well as instances in which models can be accurate without fitting the evidence (Duncan et al., 2018).

When asked "*Does a model need to fit all the evidence?"* students considered how much evidence was sufficient for a good model-evidence fit. Six students said that a model should fit most of the evidence, five students said that a model should fit some but not all the evidence, and one student said a model should fit all the evidence. The justifications students provided for why models do not need to support all evidence showed that they thought about how much evidence was sufficient for scientific models in terms of relevance and comprehensiveness, which are ideals in the GoE framework (Duncan et al., 2018). Two students explained that a model does not need to fit all the evidence but that including the most relevant evidence was better. Another student claimed that it was sufficient to explain part of the model, therefore going against the ideal of comprehensiveness in the GoE framework (Duncan et al., 2018).

In response to whether models needed to fit all the evidence, two students (from the same dyad) questioned whether fit with all evidence was even attainable. First, the dyad thought about the evidence they had encountered in the unit. A few studies showed the chemical makeup of fertilizer and how fertilizer increased plant growth in ecosystems. The dyad reflected on this study and stated that the scientist might not know enough about the exact chemicals in the fertilizer that caused eutrophication, therefore the scientist might not have enough domain knowledge to know if the evidence adequately fits. Second, the dyad also reflected on when they built their own model in the unit and how they used the most relevant evidence to support the model. Some studies were ruled out as the unit progressed, so students did not link every piece of evidence to their final model. Due to these reasons, the dyad wondered whether fit with *all* evidence was even attainable.

Students were able to reason about whether all the evidence needs to be right that supports a model. In response to the question, "*Can a model that does not fit all the evidence be right?"* Nine students responded that it was possible for a model to be right and not fit all the evidence. Eight of these students responded by thinking about either the evidence or the model in parts. Four students responded that a model that does not fit all the evidence can be right because part of the model will not be supported but the other parts will be supported, therefore going against the comprehensiveness ideal in the GoE framework (Duncan et al., 2018); whereas four students responded that a model can still be right because part of the evidence does not fit, either because it is irrelevant (one student), inaccurate (one student), or does not make sense (two students). Two students reasoned about evidence relevance by considering how a model can fit only the relevant evidence and still be right; a model does not need to fit irrelevant evidence. Three students responded that the model would not be right because it would not be accurate. Thus, students' responses showed that they specified conditions under which models might be accurate even though they did not fit all the evidence (cf. Duncan et al., 2018).

Table 1

Reasons for Why Contradictory Evidence Makes a Model Stronger or Weaker

Reasons Why Contradictory Evidence Makes Models Stronger (frequency count)	Reasons Why Contradictory Evidence Makes Models Weaker (frequency count)
- Provide a counterclaim to show a weakness in the model so the scientist can revise the model and make it stronger **5** - Can make the model stronger because you can acknowledge both sides **2** - Contradictory evidence that is weak is still good because it will show that this side is better **1** - Just because there is evidence that goes against it, doesn't mean the evidence is accurate or correct **1**	- It wouldn't be good if evidence went against the model because it might prove the model wrong **2** - A model can't be good if there is evidence that goes against it (no justification given) **1** - A model that has contradictory evidence would prove it's not on that side **1**

Students were also able to reason about how contradictory evidence would impact models (see Table 1). Nine students responded that contradictory evidence would make the model stronger. This is somewhat surprising and counterintuitive. However, students provided reasons for this assertion. The most common reason (five students) was that if there was contradictory evidence, it would provide a counterclaim, which would show a weakness in the model. The scientist can then revise the model and thus make the model stronger. Another reason (two students) was that it is best for a model to represent both sides. It was curious to us why students thought a model should represent both sides and we were unsure that they meant. However, we know that students were also using the CER framework (McNeill & Krajcik, 2011) in science and English Language instruction and thus were likely used to teacher requesting them to provide counterclaims as a means to strengthen an argument and that better arguments address both sides (rather than ignoring counter claims or contradictory evidence). It is possible that students transferred these norms to their understanding of models, which would explain their reasoning here. In contrast to those arguing that contradictory evidence would make the model better, some

students (four) reasoned that contradictory evidence would make the model weaker. The most common response for why contradictory evidence makes the model weaker (two students) was that contradictory evidence would prove the model wrong—thus indicating that poor evidential fit reduces model accuracy. One student said a model would not be good if there was counterevidence because the model would prove it is not on that side and one student did not provide a justification.

Research question 2: How do students navigate the tension between potentially competing criteria? (e.g., when more understandable models are simpler but don't fit the evidence)?

In this section we will explore students' concepts about the relationship between models that fit the evidence but are complex and hard to understand, and models that do not fit the evidence but are simple and understandable. We chose this contrast because in class discussions, some students expressed a preference for simpler models that were easier to understand. But which model should be preferred when simpler and easier-to-understand models do not account for the evidence? How do students think about the trade-offs between these criteria?

In this section of the interview, we found that students' responses shifted from the first to the second question. The questions were: *1) Which is more important for a good model, that it is understandable or fits the evidence? 2) Suppose scientists wanted to build a model to explain why mosquito bites itch. Suppose that one scientist comes up with a clear, easy to understand model, but it doesn't fit the evidence and another scientist comes up with a model that is complex and harder to understand, but it fits all the evidence. Which model would be better?* In response to the first, general question about which was better- understandability or evidential fit, more than half of students (ten out of eighteen) prioritized understandability because then they know they have the right evidence. These ten students therefore conflated understandability with evidence fit. The following transcript excerpt shows how Iris conflated understandability and evidence fit:

> Iris: Ummm, understandable. Because if you understand (the model) most likely it will have the right evidence.
> Int: Okay
> Iris: Because you can't understand a model if the evidence is not correct… but if the model's accurate then the evidence will make sense.

In response to the second question, nine students thought that it was important for models to be both understandable and fit the evidence. This time, students did not conflate understandability with evidential fit. Instead, students saw the criteria as separate and viewed them both as important. Four students explicitly stated that the more complex model was better because it meant the model was accurate; however, they emphasized that a model should both fit the evidence and be understandable. All nine students explained how a complex model could be understandable: the scientist can explain the model to the audience, the audience can look up the words in the dictionary, the scientist can show where the model starts, the scientist can make an easy one that is understandable, and complex models are also understandable. The following excerpt from Axel highlights that both understandability and complexity were needed because complex models can still be understandable:

> Axel: Well, I pick the one that you can understand, but it's hard (to choose) because if it's just simple, easy, and it doesn't fit the evidence (the simple model) then you don't actually figure out the answer... And even if it's hard (the complex model) and not easy to understand, you can still understand some of it and figure out how they… and make an easy one, and one that has good, that has good evidence. You can combine the two.

A smaller number of students, five, responded that the complex model that fit the evidence was more important than the model that was simple and easy to understand. These students prioritized the complex, hard to understand model *over* the simple, easy to understand model, because it fit the evidence and would be accurate.

Discussion

Overall, the findings showed that most fifth-grade students in the intervention understood evidence as conferring accuracy and that incorrect evidence would make the model incorrect. Students' understanding of fit with evidence therefore somewhat parallels scientists' understanding of the importance of the criterion evidential fit for scientific models. Students also showed nuance in their evidentiary reasoning by thinking about how irrelevant

evidence would not impact model accuracy and how much evidence was sufficient by thinking about whether evidence could fit parts of the model or whether part of the evidence was enough.

Students reasoned about the interplay of competing criteria by considering whether a more complex model that fit the evidence but was not understandable was preferable to a simple and clear model that was understandable but did not fit the evidence. Initially, more than half of students conflated understandability and fit with evidence (they stated that understandable models will fit the evidence and vice versa); however, in response to a second, more concrete scenario, students shifted their explanation to view understandability and evidence fit as separate and important criteria for scientific models. The way students were able to reason about competing criteria of scientific models again mirrors the tradeoffs scientists make between criteria in pursuit of an aim. Scientists hold empirical consistency as a key criterion of scientific models (Longino, 1996); however, they recognize that this criterion cannot always be stringently applied (Hogan and Maglienti, 2001).

The findings contribute to research by showing how students reasoned about evidence in relation to scientific models, that students understood evidence as conferring accuracy, and that students can prioritize seemingly competing criteria. The results support previous research that showed students understand the importance of fit with evidence as a criterion (Av-Shalom et al., 2018; Murphy et al., 2021); however, they also extend prior research by showing that students in this study did not think models need to fit all available evidence and by reasoning about how counter evidence can make a model stronger (not weaker) by providing a counterclaim against which the scientist can strengthen the model. The findings also extend previous research by Ryu and Sandoval (2010) by showing that students have the capabilities to understand that evidential criteria for scientific products, such as models, are important for conferring accuracy, and the research by Sandoval and Millwood (2005) by determining not only that evidential fit is important but why, and how much evidence is sufficient to support models. Overall, students showed more nuanced and complex reasoning about evidential fit as a criterion for scientific models than previously shown by exhibiting reasoning at the metacognitive level about standards for model accuracy and what they deem to be sufficient standards of evidence for model accuracy.

Implications

The results of the intervention show that engaging students in collective negotiations about how evidence supports a model, adapting a model to evidence, and discussing criteria utility and value, supports students' metaepistemic scientific reasoning about the nuances in the relation between evidential fit and scientific models. The findings therefore point to suggestions for science education. Students can be engaged in fruitful discussions, specifically about how relevant, and irrelevant evidence impacts model accuracy, how much evidence is sufficient for a model to be accurate, and how contradictory evidence impacts model accuracy. It will be helpful for students to understand which criteria confer accuracy (evidence, true information, reasons etc.) and which criteria are important but do not impact accuracy, such as understandability.

Students can also be engaged in discussions that weigh criteria against each other in pursuit of an aim. For example, whether models should fit all available evidence and thus be complex and harder to understand or whether models should be simpler and easier to understand but fit less evidence. When students are discussing tradeoffs, teachers can point out that they are talking about the relevance of two or more criteria on their class criteria lists and this is what scientists do, thus developing students lay understanding of experts' reasoning about scientific models. The recommendations will assist students in developing a grasp of evidence (Duncan et al., 2018) and a grasp of practice (Ford, 2008) as students deepen both scientific practice and metacognitive understanding of the criterion evidential fit in relation to models.

Abstract: Socially shared regulation of learning (SSRL) is essential for the success of collaborative learning, yet learners often neglect needed regulation while facing challenges. In order to provide targeted support when needed, it is critical to identify the precise events that trigger regulation. Multimodal collaborative learning data may offer opportunities for this. This study aims to lay such a foundation by exploring the potential for using machine-learned models trained on multimodal data, including electrodermal activities (EDA), speech, and video, to detect the presence of SSRL-relevant process-level indicators in successful and less successful groups. The study involves thirty groups of secondary students (N=94) working collaboratively in five physics lessons. Considering the demonstrated positive results of machine-learned models, the advantages and limitations of the technical approach are discussed, and further development directions are suggested.

Introduction

Self-regulated learning theory describes the phases and processes through which learners navigate towards achieving learning goals in the face of challenges posed across situations. Collaborative learning has advanced self-regulated learning theory contextualized within collaborative contexts under the distinct headings of co-regulation and socially shared regulation (Hadwin et al., 2018). While self-regulated learning is important for individual academic achievements, previous studies have shown that processes identified as socially shared regulation of learning (SSRL) enhance group performance and produce better learning outcomes during collaborative learning (Isohätälä et al., 2017; Järvelä, Järvenoja, et al., 2019). Nevertheless, self-regulated learning is often difficult and not always conducted by the learners while confronting learning challenges. Regulation of learning is even more difficult in collaborative learning when the individual processes must be coordinated and communicated between learners within a group. Accordingly, it is suggested that collaborative learning interventions should aim to promote SSRL.

However, it is difficult to provide just-in-time support for SSRL since the cognitive and affective processes at its core are unobservable by learners and, thus, they are not always aware enough in order to regulate them (Azevedo & Gašević, 2019; Järvenoja et al., 2018). Research in self-regulated learning has highlighted the methodological challenges in capturing the dynamic and cyclical nature of regulation. Although extensive research has been published examining self-regulated learning and its influence on learning success, a systematic understanding of how SSRL evolves in collaborative learning is nascent. While self-regulation of learning is difficult to capture at the individual level, it is even more difficult to detect and support SSRL in the face of the dynamic interactions and influences among learners in collaborative learning settings. If there would be an efficient and effective approach to capturing regulation in collaborative learning, it could significantly progress research on SSRL.

Recently, initial methodological progress towards establishing a means to make SSRL observable has been published (Hadwin, 2021; Järvelä, Järvenoja, et al., 2019). In particular, Dindar et al. (2020) has utilized electrodermal activity (EDA) data to investigate the interplay of temporal changes in self-regulated learning processes connected with behavior, cognition, motivation, and emotion in computer-supported collaborative learning. The relative importance of multimodal data analysis on SSRL research has also been subject to considerable discussion. However, despite the potential to advance domain knowledge and offer innovative learning support, recent studies have recognized issues and challenges that still need to be addressed using multimodal and multichannel data regarding self-regulated learning (Azevedo & Gašević, 2019). One of the most frequently stated problems relates to integrating the plethora of theoretical models and frameworks from multiple disciplines including educational and computational sciences. Consensus built from consideration of recent studies calls for design and application of theoretically based and empirically derived approaches for collecting, measuring, and modeling multimodal and multichannel data to elucidate the complexity and temporality of underlying processes to address learners' self-regulatory needs (Azevedo & Gašević, 2019; Hadwin, 2021). Considering recent methodological progress and related data for SSRL, advanced technologies under the headings

 © ISLS

of Artificial Intelligence (AI) and machine learning could be further harnessed in order to push forward the nascent science to this end.

In this paper, we present an interdisciplinary study attempting to address these methodological challenges and issues in utilizing advanced technologies on multimodal and multichannel data to study self-regulated learning. This study aims to explore different types of interactions for learning regulation between successful and less successful groups in collaborative learning. We focus more specifically on designing a machine learning model with multimodal data to automatically detect these regulatory interactions. Our study addresses the following research questions:

1) How do interactions for learning regulation differ between successful and less successful groups in collaborative learning?
2) How can machine learning architectures and multimodal data representations be designed for the successful detection of regulatory interactions for both successful and less successful groups in collaborative learning?

This study offers some important insights into the application of advanced technologies in examining regulation in collaborative learning. The experimental work presented here provides one of the first investigations into how multimodal AI deep learning could be used to exploit SSRL with the fusion of features gathered from multiple data modalities and channels. Although the study does not yet examine the direct effects of SSRL on learning performance or specifically offer a prediction of the level of success for collaborative groups, it does present a compelling novel approach and meaningful evaluation of challenges and limitations to inform future work in this area within this research community. Furthermore, this study will contribute towards methodological progress to build a foundation for future theoretical investigation of SSRL and for the development of SSRL interventions.

Theoretical Approach – Regulation of Learning in Collaborative Learning

Our theoretical approach to the study is grounded in self-regulated learning (SRL) and socially shared regulated learning theory suggesting that regulation of learning is not solely a learning process at the individual level but also involves social and contextual processes (Hadwin et al., 2018).

Self-regulation of cognition, emotion, and behavior has been a critical aspect of learning and successful academic performance (Winne, 2019). Self-regulation refers to the process in which a learner goes through goal-setting, self-monitoring, self-instruction, and self-reflecting to understand and manage their own learning (Zimmerman & Schunk, 2011). Research on self-regulation has progressed over decades with several theoretical perspectives and models proposed to describe and provision regulation in learning (Panadero, 2017). As the field has evolved, recent attempts have been made to investigate the phenomenon of regulation in a complex and dynamic collaborative learning environment. Going beyond self-regulation of an individual learner, co-regulation and socially shared regulation presented other social forms of regulation operating in collaborative learning. While co-regulated learning (CoRL) generally explains the learners' regulation with support from team members through social interactions, socially shared regulation of learning (SSRL) addresses the complementary perspective relating to a group's deliberate, strategic, and transactive planning, task performance, and reflection in learning (Järvelä, Järvenoja, et al., 2019). Although considerable effort has been made to understand the complex process of regulation of cognition, motivation, and emotion (Winne, 2019), the mechanisms that underpin regulation in collaborative learning are not yet fully understood.

Regulation of learning in collaborative settings is a complex and cyclical process in which the learners regulate themselves and each other (Järvelä, Järvenoja, et al., 2019). In the best cases, learners conduct all three forms of regulation together while confronting learning challenges progressing towards desired learning outcomes. These three forms of regulation in collaborative learning often occur alongside interactions aimed towards regulation (Isohätälä et al., 2017). Group interaction processes play a critical role in regulation promoting group success in collaborative learning. This study focuses on different types of interactions for regulation in collaborative learning. Previous studies have recognized a variety of specific challenges in capturing regulation in collaborative learning due to the complexity, "unobservability, temporality, multifaceted and situated nature of learning regulation" (Azevedo & Gašević, 2019; Hadwin, 2021; Järvelä, Järvenoja, et al., 2019). The methodological progress we report herein capturing regulation could offer a solid foundation for extending understanding regulation of learning, developing relevant theories, and designing support for promoting regulation of learning hence improving learning.

Methodological Approach – Multimodal Data and Machine Learning for Understanding Regulation of Learning

Recent progress in learning regulation research has increased the demands for innovative and robust methods in examining social aspects of learning regulation (Järvelä, Järvenoja, et al., 2019; Winne, 2019). Recently, research on learning analytics and educational data mining has exploited cutting-edge data collection and analytic technologies to reveal new insights into learning and learning processes with the goal of advancing learning sciences theories (Nguyen et al., 2020, 2017; Noroozi et al., 2019). Developments in sensor technologies have provided accessibility to different data channels such as physiological data. Collecting and analyzing data from multiple modalities and channels has provided exposure to signals thought to be related to regulatory processes treated previously as unobservable when the primary method for studying these processes was through self-report instruments such as questionnaires or interviews (Azevedo & Gašević, 2019; Järvelä & Bannert, 2019; Noroozi et al., 2019).

Previous studies have utilized multimodal data to provide and triangulate evidence of temporal and adaptive processes of learning regulation (Järvelä, Järvenoja, et al., 2019). Although the recent pioneers in using multimodal data for examining learning regulation have contributed to better understanding the complex nature of (S)SRL (See Järvelä & Bannert, 2019; Noroozi et al., 2019), they have encountered several issues related to synchronizing data from different sources (Azevedo & Gašević, 2019; Hadwin, 2021). Nevertheless, prior studies analyzing and triangulating multimodal data have provided valuable insights and progressed regulation concepts that provide the foundation for this work. The current study builds on and extends this foundation through the development of technological advances that enable effective integration of the synergistic features from multimodal data for better understanding and supporting learning regulation.

Advanced Artificial Intelligence (AI) technologies, specifically what is currently known as deep learning, have offered the capabilities to not only automatically detect cognitive and emotional activities in real-time but also objectively measure and classify relevant learning behaviors. For instance, the application of deep learning across different media has been applied to the problem of detecting human emotions including micro-expressions (Tzirakis et al., 2017; Zhao et al., 2011). Furthermore, AI deep learning methods potentially allow the fusion of features obtained from multiple data modalities to enhance the accuracy of recognizing and classifying human cognitive and emotional activities (Tzirakis et al., 2017). As cognitive and emotional activities are at the core of learning and learning regulation, the use of multimodal AI deep learning methods offers the potential for gaining novel understandings of the phenomenon and providing effective support to promote SSRL. Despite the potential of advanced technologies such as AI deep learning in examining SSRL, there are only a few studies that have empirically investigated the phenomenon. Indeed, apart from the study proposed by Nguyen et al. (2021), our search of the literature failed to find any prior studies utilizing multimodal AI deep learning to examine interactions for regulation in collaborative learning. We thus argue that the contribution of the current study is in affording the potential to establish methodological foundations to push (S)SRL research forward.

Research Methods

Participants and Procedures

The participants of this study included secondary school students (N = 94) working collaboratively in groups of three or four during five physics lessons. They were divided into 30 groups and the group assignment was based on the grades they earned in previous science courses. Students and their processes of learning and collaboration were monitored and documented with video recordings and through individual-level physiological measures.

Data collected from different modalities and channels may allow for uncovering the complex interactions of both the visible actions and the invisible mental and metacognitive processes in collaborative learning (Azevedo & Gašević, 2019). Following this line of research, our study attempted to collect the multimodal data from several channels to reveal the interactions for regulation in groups. Particularly, we capture students' physiological activities through the measurement of Electrodermal Activity (EDA) by using Shimmer3 GSR + devices. These data reflect the physiological reactions that occurred during a learning situation, such as students' physiological activation related to emotion and cognition. In addition, we used Insta360 Pro video cameras and microphones to capture the visual and acoustic data reflecting engagement in learning activities in the classrooms' natural setting.

Qualitative Coding and Quantitative Data analysis

Qualitative coding through a multi-step analysis schema was conducted to label types of interactions for regulation. First, the videos and audio were divided into thirty-second segments. Previous research suggested that the time-based segmentation of videos for observing collaborative learning would benefit the analysis by enabling time series modeling of a progression over time and providing a consistent unit of analysis (Sinha et al., 2015). The types of interactions for regulation were classified using four separate labels: 1) metacognitive interaction, 2) socio-emotional interaction, 3) task execution and 4) other interactions. The identification of these types of social

interactions would lead to the recognition of SSRL when it emerged as SSRL is socially situated and achieved through social interactions (Isohätälä et al., 2017). By examining the four types of social interactions for regulations, we could better understand how SSRL could be effectively developed to enhance group performance through different social interactions. The coding scheme is shown in Table 1. To ensure the reliability of the labels, we validate the coding by conducting interrater reliability testing on the initial set of coded data. This initial set of data are coded for ten videos randomly selected from the dataset. The result shows a substantial agreement among the results with Cohen's Kappa values above 0.7.

Table 1: Qualitative Coding Schemes for Preparing Interaction Data

Type of Interactions for Regulation	Description of behavior	Examples
Socio-emotional interaction Socio-emotional interaction was coded when group members expressed clear indicators of positive/negative affect or made a positively/negatively charged comment. Emotional expressions included verbal or other clear indicators of positive or negative affect and negatively or positively charged interaction.	Verbal indicators, e.g.: - positive/negative content - positive/negative tone of voice - sarcasm - laughing, singing, groaning, whining Bodily indicators, e.g.: - smiling - dancing - sighing - facepalm Emotionally charged interaction, e.g.: - Joking, praising - Arguing, criticizing	*"This [shimmer] gets stuck everywhere. I hate these. I wish this would be over already."* *"You sound like a hamster!"* **laughter** *"How are you able to draw such straight lines without a ruler? Look! She didn't even use a ruler to draw this line!"* *"Can he be quiet? The mic doesn't like it when he does that all the time"*
Cognitive interaction Metacognitive interaction was coded when group members' discussion targeted their cognitive processes.	Discussion regarding: - Task goals - Task understanding (e.g. checking task demands) - Prior knowledge - Resources (e.g. procedures, strategies) needed to solve the problem - Progress with the task (e.g. checking/evaluating progress) - Selecting strategies (e.g. help-seeking) - Quality of task solution (e.g. evaluation of the correctness of the answer) and overall performance	*"Okay, what are our goals?"* *"Isn't this the first task? About volume?"* *"No, it is this way, we did this yesterday in math."* *"I don't think that we have time to do that. [The teacher] is already writing down the homework"* *"Jane, is this [answer] good?"*
Task execution Concrete work towards task completion. No interaction required.	- Reading or discussing task material or content - Executing task-related measurement or calculation - Otherwise physically executing task experiment - Writing down calculations or answer	*"[Exercise] 2. d) How long does it take sunlight to reach the Earth?"* *"What was the answer to exercise 3?"*
Other interaction Non-task-related interaction	Discussion regarding: - Other school-related issues - Free-time activities - Research setting	*"Maybe [the teacher] was talking about who will be in our group during home economics class"*

Before conducting machine learning modeling for automatic detection of regulatory interactions, we investigated whether the interactions for regulation differed among successful and less successful groups. We conducted a Pearson Chi-square analysis of homogeneity of proportions to examine the differences in regulatory interaction frequencies. We hypothesized that the proportion of the types of regulatory interactions is different between successful and less successful groups. This offers empirical evidence that detection of this four-way distinction will provide leverage towards our future work automatically detecting the level of success that groups are likely to achieve as they are working, and using that detection to prompt needed interventions.

AI Deep Learning Modelling and Evaluation

The multimodal deep learning modeling approach is adopted for developing the predictive model to detect interactions for regulation. Different AI deep learning frameworks will be used to extract features from each data modality and the extracted features will be then fused using a multi-layer perception. In particular, the pre-trained 18-Layer Residual Network (ResNet-18) (He et al., 2015) was applied to encode the video stream into a sequence of features, referred to as a vectorized representation. The same method is utilized to encode the audio data into a vectorized form. Besides, the electrodermal activity (EDA) processing approach follows prior work in which EDA is also used in a deep learning framework designed for emotion classification (Ganapathy et al., 2020). EDA data were decomposed into the tonic component or skin conductive level (SCL) and the phasic component or skin conductance response (SCR). EDA features were encoded and vectorized using a convolutional neural network (CNN). A dense layer using a multi-layer perceptron with a binary cross-entropy loss function was applied to perform deep learning to identify patterns within the transformed feature encoding related to the prediction labels. We train three AI deep learning models using multimodal data from: 1) successful groups; 2) less successful groups, and 3) all groups. Figure 1 demonstrated our prototype design for AI deep learning for (S)SRL.

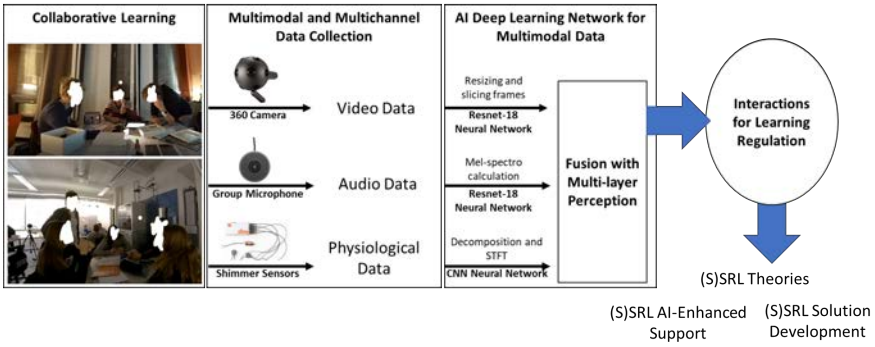

Figure 1: AI Multimodal Deep Learning for (S)SRL

For each AI deep learning model, we followed the typical machine learning experimental methodology to conduct training, validation, and evaluation. In particular, each multimodal dataset was randomly split into three subsets consisting of a training set, a validation, and a test set with a ratio of 8:1:1. The model is trained on the training set, where parameters are tuned to maximize performance on the validation set. The tuned model is then tested on the test set for evaluation. The common values of F1-score, mean Average Precision (mAP), and Accuracy score were obtained for the evaluation on the validation test and test set. The Area Under the Curve of Receiver Operating Characteristics (AUC-ROC or AUROC) is also computed for the evaluation of each model.

Results

We first address the question of the value of the four-way distinction used to code data segments to separate successful and unsuccessful groups, under the expectation that observations related to engagement in SSRL processes are included among the factors that separate these groups. The results of the Pearson Chi-Square test showed significance in the relationship between the observed distribution of types of interactions for regulation and group performance ($\chi_2 = 56.76$, $df = 3$, $p < 0.01$). In other words, the distribution of counts of different types of regulatory-relevant interactions is not independent of the success of the group. Next, we address the capability of the technical approach to automatically assign the four-way distinction to data segments. Table 2 demonstrated the results for AI deep learning evaluation for models on successful groups, less successful groups, and all groups.

Table 2: Evaluation Results for the AI Deep Learning Evaluation

	Successful Groups	Less Successful Groups	All Groups
Evaluation on the validation set			
F1-score	0.63	0.67	0.73
mAP	0.67	0.72	0.79
Accuracy	0.69	0.81	0.79
Evaluation on the test set			
F1-score	0.65	0.61	0.63
mAP	0.67	0.74	0.70
Accuracy	0.68	0.72	0.73

 © ISLS

Overall, our results illustrate that using AI deep learning on multimodal data has the potential to automatically detect interactions for regulation in collaborative learning. In the evaluation on the validation set, we found that the predictive accuracy on detecting the regulatory interactions for successful groups (F1-score = 0.63, mAP = 0.67, and Accuracy = 0.69) is lower than for less successful groups (F1-score = 0.65, mAP = 0.67, and Accuracy = 0.68). The evaluation on the test set also confirmed that the deep learning model for successful groups (F1-score = 0.65, mAP = 0.67, and Accuracy = 0.68) is not as accurate as for less successful groups (F1-score = 0.61, mAP = 0.74, and Accuracy = 0.72). Nevertheless, the evaluation on both the validation set (F1-score = 0.73, mAP = 0.79, and Accuracy = 0.79) and evaluation set (F1-score = 0.63, mAP = 0.70, and Accuracy = 0.73) for the inclusive AI deep learning model using multimodal data from all groups has the capability to predict interactions for regulation at a reasonable level. Thus, we believe we have a proof of concept to drive forward research, but note that in future research particular attention should be paid to performance specifically on

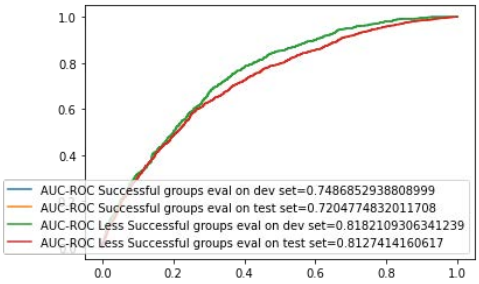

Figure 2: The Area Under the Curve of Receiver Operating Characteristics (AUC-ROC or unsuccessful groups.

Figure 2 showed the results for the Area Under the Curve of Receiver Operating Characteristics (AUC-ROC or AUROC) for both models on the successful and less successful groups. The results show that both models could reasonably predict the interactions for regulation in collaborative learning (AUC-ROC > 0.72). The lower predictive power in the successful groups (AUC-ROC=0.74 and 0.72 for evaluation on the validation and dataset) could be explained by a higher complexity in interactions for regulations than the less successful groups (AUC-ROC=0.82 and 0.81 respectively). Future work could be conducted to examine this difference further. Nevertheless, the results have validated the feasibility of our model to recognize interactions for learning regulation in both conditions.

Discussion and Implications

The development of sensor-based technologies and machine learning techniques together presents a unique opportunity to leverage data collected from different modalities in the context of collaborative learning. Prior work has reported that multimodal data have shown promise for advancing our understanding of learning regulation (Noroozi et al., 2019), yet so far very little attention has been paid to how machine learning techniques could be implemented to examine the multiple facets and processes of learning regulation. This study explored the use of the AI deep learning approach on multimodal data to detect regulatory interactions for successful and less successful groups in collaborative learning.

First, we investigated whether the types of interactions for regulation are related to group performance. The results support our hypothesis that the proportion of types of regulatory interactions differs between successful and less successful groups. Previous research demonstrated that SSRL emerged from different types of interactions and contributed to the success of collaborative learning (Isohätälä et al., 2017). Therefore, the capabilities to capture regulatory interactions could establish a solid foundation for identifying triggers for regulation and providing support to promote SSRL, hence enhancing learning performance (Nguyen et al., 2021). This study extends the understanding of learning regulation by providing evidence for the difference in the proportion of types of regulatory interactions between the successful and less successful groups in collaborative learning. Accordingly, our results showed a significance for the difference in regulatory interactions and provisioned the importance of capturing different types interactions for regulation in collaborative learning.

The development and evaluation of AI deep learning models using multimodal data in this study demonstrated the feasibility of this approach to capture the regulation of learning in collaborative settings. Previous research has already recognized the potential of utilizing multimodal data for SSRL (Engelmann & Bannert, 2021; Järvelä, Malmberg, et al., 2019), but the field has struggled with an analysis of multimodal and multichannel data, even recognizing that the data allows for examining the interplay of different facets and processes of learning regulation (Hadwin, 2021). For instance, while Engelmann and Bannert (2021) analyses the

screen recordings and verbal protocols to assess cognition and metacognition processes of regulation, Järvelä, Malmberg, et al. (2019) showed the use of facial expression extracted from video interactions and physiological data including heart rate and electrodermal activity (EDA) data to examine the SSRL facet of emotions. These studies provided evidence for the use of the multimodal approach for understanding the situated nature and temporality of regulation. Nevertheless, the synchronization of multiple data modalities across multiple data channels is complex and faces several challenges (Azevedo & Gašević, 2019; Järvelä & Bannert, 2019). Triangulating data from multiple channels could examine the interplay of multiple facets and processes of learning regulation and comprehend findings from each of the data sources (Järvelä, Malmberg, et al., 2019). While multimodal and multichannel data triangulation has provided valuable insights to extend our understanding of learning regulation, the cohesive multimodal analysis with potential synergistic effects for research on learning regulation has received scant attention in the literature. Since different data modalities from different channels reflected different facets and processes of learning regulation, utilizing synergistic features from multimodal and multichannel data could further address the temporality of regulation. However, the complexity and dynamics of synergizing features from multiple data modalities raised several methodological challenges. Therefore, this study demonstrated the opportunities offered by advanced technologies, specifically AI deep learning, for analyzing multimodal data in research on learning regulation.

This study has some limitations. First, the approach for qualitative coding and segmentation into thirty-second blocks is theory-grounded and supported by several published studies in the domain (e.g. Järvenoja et al., 2018; Sinha et al., 2015), yet other approaches should be examined and compared for improving performance. Second, while immersive video data hold valuable features for studying learners' behavior and learning, we noted that the current machine learning methods for video and image processing for this type of video data are still limited. Furthermore, the pre-trained models for analyzing video data are mostly trained with open databases in which the data are often retrieved from video scenes. The complexity and dynamics of authentic learning environments could influence the predicting performance of the pre-trained models. Thus, this study presented a unique contribution to the field with the model trained from a large dataset captured from real-life situations. And it could lead to a fruitful area for further work on SSRL theoretical investigation and multimodal methodological development.

Conclusion and Future Directions

In recent years, advanced technologies have brought opportunities for transformation across societal sectors, including education. Among these advanced technologies, Artificial Intelligence (AI) has been one of the most influential technologies and has been widely utilized in online education. However, there has been much less attention paid to the application of AI in face-to-face classroom settings. Although face-to-face learning has not been responsible for the bulk of available data from educational settings, the advancement of sensor technology and multimodal data collection methods has enabled the possibility of applying AI in the face-to-face classroom context. Despite the significant potential of AI in education, there remains a paucity of evidence on how AI could be applied to extend our understanding of learning in the classroom. This study demonstrated the implementation of an AI deep learning approach to address the methodological and theoretical challenges in the domain of self-regulated learning and collaborative learning. In particular, we designed and validated how the AI deep learning approach could reveal the previously "unobservable" processes of regulation by using multimodal data to automatically detect interactions for regulation. Future research could attempt to examine different AI approaches to offer novel methods to collecting and analyzing educational data, hence extending the methodological and theoretical boundaries in learning sciences. The results of this study also shed a light on the development of real-time support for regulation in collaborative learning. We look forward to future work building on and extending these findings in the design and creation of AI-enhanced solutions for promoting the regulation of learning.

A Tale of Two Teacher Trajectories: Analysing Change in Teachers' Beliefs on Technology Integration during the COVID-19 Pandemic

P. A. Nandan and Murthy Sahana
nandan.p.a@iitb.ac.in, sahanamurthy@iitb.ac.in
Indian Institute of Technology Bombay

Abstract: Existing research on teachers' beliefs remains majorly focused on cognitive aspects, while lesser attention has been paid to affect and context. In the present study, we use the lens of the cognitive-affective model of conceptual change, to understand how teachers' beliefs about technology integration changed when they were compelled to move to online teaching as a result of the COVID-19 pandemic. We present findings from a multiple-case study of two secondary school teachers in Kerala, India. Contrary to expectations, the teacher who had low training and low self-efficacy showed stronger belief change towards effective integration of technology, compared to a teacher who was skilled in using technology for physical classroom activities. Motivation, context and situational resources played a crucial role in understanding the difference. The findings have implications for learning sciences researchers working on effective integration of technology-focused solutions in the classroom and in designing TPD programs.

Introduction

Aligned to global trends, India is striving to transform the nation into a digitally empowered society and knowledge economy. It is envisioned that technology will play an important role in achieving this goal by improving educational processes and outcomes (NEP, 2020). However, even when policies favour the integration of technology in education, its effectiveness depends on teachers' beliefs about teaching, learning and technology, and how they include it in their actual practice (Ertmer, 2005). Even if first-order barriers to technology integration such as access, training, and support were removed, teachers would not automatically use technology effectively unless their beliefs aligned with a constructivist pedagogy (Ertmer, 1999), thus the consequences of belief congruence or incongruence become important. When teachers are required to implement practices that are different from the beliefs they hold about teaching and learning, it may adversely affect their satisfaction and well-being and they may implement the practices in an ineffective manner (Buehl & Beck, 2015).

Research on how and when teachers change their beliefs is vast and diverse (Pajares, 1992; Ertmer, 2005; Park & Ertmer, 2007; Taimalu & Luik, 2019). While research has largely focused on the cognitive aspects of teacher belief change, (Fives & Buehl, 2012), recent studies have recognised the role that affective (Watt & Richardson, 2014; Gill & Hardin, 2014) and contextual factors (Tschannen-Moran et al., 2014) play in teachers' beliefs. The affective factors include motivation, emotion, goal orientation etc. and contextual factors include social, cultural, political, historical and school contexts teachers experience during their careers and have been reported to be inseparable from the teachers' beliefs and actions (Levin, 2015). One contextual factor that may play an important role in influencing a change in teachers' beliefs is an emergency situation such as the COVID-19 pandemic.

In the Indian context, there are a few studies that give evidence for the relationship between affective and contextual factors on teachers' beliefs about technology integration (Bandyopadhyay, 2013; Chand, et al., 2020; Sharma & Srivastava, 2020; Kundu, et al., 2020). However in-depth studies exploring the role of affective and contextual factors in the process of change in teachers' beliefs about technology integration are lacking. The present study aims to address this research gap and contribute to further expanding the belief change model. We chose the educational context of the state of Kerala in India to understand how teachers' beliefs about technology integration changed when they were compelled to move to online teaching as a result of the COVID-19 pandemic, and the role played by affective and contextual factors. Our research question for this study is "How do teachers' beliefs about technology integration change and what role do affective and contextual factors play?"

Theoretical framework

Teachers' beliefs about technology integration

According to Park & Ertmer (2007), teachers' beliefs about technology integration comprise three components: pedagogical beliefs about teaching and learning, self-efficacy beliefs for using technology, and beliefs about the

value of the use of technology. These three components were found to be the main predictors of teachers' use of technology for pedagogical purposes (Taimalu & Luik, 2019).

Ertmer (2005) considered pedagogical beliefs as the teachers' educational beliefs about teaching and learning. Teachers with more traditional beliefs tend to implement more teacher-centred uses of technology and do not see technology as important and useful for teaching and learning, whereas teachers with more constructivist beliefs tend to implement more student-centred uses of technology and are seen as innovators (Taimalu & Luik, 2019; Ertmer et al., 2015). Bandura (1997) defined perceived self-efficacy as "beliefs about one's capabilities to organise and execute the courses of action required to produce given attainments". Self-efficacy is formed based on four major sources of information: enactive mastery experiences, vicarious experiences of observing others succeed through their efforts, verbal persuasion and physiological and affective states (Bandura, 1997). Teachers' perception of the value of using technology for teaching and learning is an important predictor of their future use of technology in their class. Researchers found that teachers will use technology only when they see value in using technology for specific educational purposes (Ertmer, 2005).

Cognitive-affective model of conceptual change (CAMCC)

Although conceptual change models are developed primarily to explain knowledge acquisition, they could be effective in studying changes in beliefs as well (Gill et al., 2004; Posner et al., 1982). Consequently, we adopted the Cognitive-Affective Model of Conceptual Change (CAMCC) as a potentially appropriate model for our analysis, which integrates cognitive frameworks of belief change with motivational and affective factors (Gill, 2003). The CAMCC model proposes two routes of belief change resulting in either assimilation or accommodation and identifies systematic processing as the mediator of conceptual change. The belief change process begins with the presentation of *a reform message* to the teacher. If the message causes dissonance to the existing beliefs of teachers (*Implicate self? Yes*), they appraise the situation as stressful (*Stress appraisal*). It is important to note here that teachers' appraisal of the reform message happens automatically before characteristics of the message (*intelligibility, plausibility, fruitfulness*) are seriously considered.

Even though dissonance is a prerequisite, belief change is unlikely to occur unless the teachers perceive sufficient motivation and ability. Kubanyiova (2012) in their integrated model of Language Teacher Conceptual Change (LTCC), which is a modified version of CAMCC, proposed to combine motivation and ability components into a single component called '*Reality check appraisal*'. During the reality check appraisal, if a teacher feels that his or her internal and/or external resources are sufficient, may appraise the situation as challenging (*Challenge appraisal*) and adopt an immediate goal to approach the reform message (*Approach intention*), which eventually leads to its '*systematic processing*'. The CAMCC proposes that only this systematic route can lead to a teacher's belief change. However, systematic processing does not guarantee a change unless the teacher yields to the message (*Yielding?*).

On the other hand, if a teacher does not see him or herself implicated by the reform message *(Implicate self? No*), will therefore not experience stress, discomfort or dissatisfaction. This may be either because he or she believes that they are already using technology in their classroom effectively (*Positive appraisal*) or because he or she sees the reform message as neutral and therefore dismisses the reform input as irrelevant (*Benign appraisal*). The CAMCC proposes that those who make such appraisals will lead to a '*heuristic processing'* rather than systematic processing. Heuristic processing further leads to a decision choice (Yielding?). If the teachers yielded or accepted the message, he or she will lead to a state of *Assimilation or Superficial belief change.* Similarly, even if the teacher may have entered the systematic route of belief change (*Implicates self? Yes*; and experienced dissonance emotions), there is a chance that he or she may revert to a '*heuristic processing*'. During the '*Reality check appraisal*', if the teacher feels his or her internal and/or external resources are insufficient, the teacher will perceive the message as a threat (*Threat appraisal*) and adopt an immediate goal of avoiding the threat (*Avoidance intention*). From this point, the teacher follows the same path discussed in the heuristic processing.

Educational context

The present study is conducted in the state of Kerala in southwest India, which is known for its high literacy rate. Kerala has implemented various innovative programmes to support teaching and learning through technology such as VICTERS (Versatile ICT Enabled Resource for Students) and Samagra eResource Portal. VICTERS allows students and teachers to access quality education from experts through its TV and YouTube channels. Samagra eResource Portal is a repository of digital resources on various subjects from grades 1 to 12. These initiatives have strong support from the government but are driven primarily by teachers, who contribute learning resources such as videos, animations, audios, stimulations and interactive content which can be accessed by students. Teachers also contribute unit plans for various topics in addition to micro-planning that can be accessed

by any other teacher for preparing their instruction. The Samagra portal has active discussion forums, in which teachers can communicate with each other and clarify their doubts.

After the closure of schools due to the pandemic in March 2020, the Kerala government decided to continue school education through online media. The General Education Department initiated an interim arrangement for regular classes for students of grades 1-12, called 'First Bell'. The classes under the First Bell programme were streamed live through VICTERS educational channel. The unaided private schools mainly utilised tools like Google Meet for delivering classes. All schools extensively used the WhatsApp tool for communicating with students and teachers, sharing materials and providing feedback.

Methods

Participants and data collection

Our broader study has been designed for 15 teacher participants from different types of schools (government, government aided-private, and unaided-private) in Kerala. This study began in mid-2020, a few months after the pandemic and lockdown in India. The Institutional Review Board (IRB) approval was obtained from our institution. Teachers from schools near the home district of the first author of this study were contacted. Data collection includes interviews, observations of online teaching and teacher reflections. The study is ongoing and so far we have interviewed 6 teachers.

The present study used a multiple-case design and followed a theoretical replication logic (Yin, 2018). As per the 'maximum heterogeneity sampling' strategy (Patton, 2015), we purposefully selected two teachers, who showed clear evidence of the role of affective and contextual factors in the process of belief change.

The researcher conducted semi-structured interviews with the participants. The interview protocol was designed in such a way to elicit the changes in teacher beliefs about technology integration (i.e. pedagogical beliefs, self-efficacy beliefs for using technology, and beliefs about the value of the use of technology) and the cognitive, affective and contextual factors influencing this change. We also tried to understand teachers' perceptions about the use of instructional technology in future. Interviews were conducted over the mobile phone in the native language Malayalam and took approximately 1 hour. Follow up clarifications were sought via text and audio messages. All interviews were audiotaped for further analysis purposes. Personally identifiable data were anonymized immediately after data collection. Sample interview questions included:

- On a typical day, how do you utilize technology in your classroom? Briefly describe any two such instances from your classroom one year before and the present day.
- How competent do you perceive yourself to select and use various technologies to support teaching and learning?
- What might be your response if I had asked you the same question one year before? Provide some instances for supporting your statement. What might be the reason for this change?

Data analysis

The recorded interviews were transcribed into Malayalam text. The transcribed text is translated into English for further analysis. The CAMCC framework is used as a 'coding frame' for structuring transcribed data (Schreier, 2012). We have used a concept-driven way (deductively) and tried to find evidence from the data that corresponds to the related aspects of the framework.

Additionally, some of the constructs were operationalized as follows. 'Reality check appraisal' encompasses self-efficacy beliefs as well as other aspects, such as actual cognitive ability, subject-matter knowledge, educational context, supportive colleagues, students' expectations, resources and time. 'Yielding' to the reform message is influenced by a variety of factors, such as whether the processing was biased, teachers' existing conceptions, and characteristics of how the message is perceived (Gill, 2003).

Findings

Case 1: Teacher Ms. D

Ms. D is a higher secondary (Grades 11-12) school teacher in an unaided private school. She teaches Accountancy and Business. She is on a contract and her job is not permanent. Her school is situated in rural areas of the Thrissur district of Kerala. At the beginning of the lockdown, she had two years of teaching experience at the school level and four years of teaching experience at the college level prior to that. She has MPhil and BEd and is qualified State Eligibility Test (SET). She has not received any training on ICT and her exposure to educational technology before the COVID-19 pandemic was limited to WhatsApp for social networking.

Ms. D and her colleagues were not prepared for the sudden change to online teaching due to the lockdown. Ms. D and her colleagues started using the Google Meet platform to conduct online classes. It was the first time Ms. D and most of the other teachers in her school were using this platform. Teachers sat together in the school and learned the features of the platform from each other using trial and error methods. They conducted mock classes among themself to understand the possible challenges and errors that may arise during the live classes. They also used WhatsApp groups to share new ideas and information about the technology, and practices for online classes. In addition, teachers used Google classroom for sharing materials and worksheets for formative assessment. The ICT teacher in the school helped Ms. D to install the Google classroom app on her mobile phone and taught her basic features of the platform. Ms. D also took help from her husband and children to understand how to write content and upload it on the platform.

Ms. D used WhatsApp groups for communication, sharing educational materials, off-the-class discussion space for students to clarify their doubts, conducting formative assessments using quizzes and thought-provoking questions, and conducting summative assessments in which question papers and answer sheets are communicated. WhatsApp is also used as a way to encourage students by putting students' artefacts as WhatsApp status. In addition, Ms. D used WhatsApp to communicate with her students' families also.

Analysing Ms. D's change in beliefs about technology integration

The compelling situation when Ms. D's school instructed all the teachers to seek various digital alternatives for their classes can be considered as the reform message, i.e. 'rearranging the teaching-learning process by utilising available digital resources to help students to continue their education during the difficult time of COVID-19 pandemic' (see Figure 1). The message of this reform is strong because of multiple reasons. Ms. D's ability to implement this message had consequences for her continuing to keep her job. Also, she was aware of the need for students to continue their education even during the lockdown.

> *"When the school was closed……. students were anxious about their future career. Because the secondary level is the stage they need to make a career choice. As teachers we are also concerned about our students and their better career. I think these online classes can reduce these anxieties."*

However, implementing this reform message was a difficult process for Ms. D because she had no exposure to teaching online and the message challenges her conventional instructional practices. Ms. D considered this message as a dissonance to her existing beliefs about the teaching-learning process and her self is at stake (*implicates self*).

> *"We can understand things by looking at the faces of children in a normal class..further explanation is required or not. But there are limits to such things in online classes."*
>
> *"Studious children will learn in all mediums. Normal classroom learning is a must if you want to bring children who are backward in education to a forefront of the class."*

Hence she is likely to appraise the situation as stressful, (*Stress Appraisal)* and feel corresponding anxiety at first. Those who make such a stress appraisal will show the necessary motivation to process the reform message systematically. Here *motivation* will be decided by the characteristics of the person such as *Knowledge* and *Self-efficacy beliefs for using technology*. Despite Ms. D's six years of teaching experience and strong command of subject knowledge, her self-efficacy beliefs for using technology were low initially. She had not received any training in integrating technology into the teaching process. She expressed this unfamiliarity and lack of opportunity multiple times.

> *"I am not fully confident. I have not studied computers yet. I use my family's help to manage technology. I am still at an LKG [lower kindergarten] level in technology."*

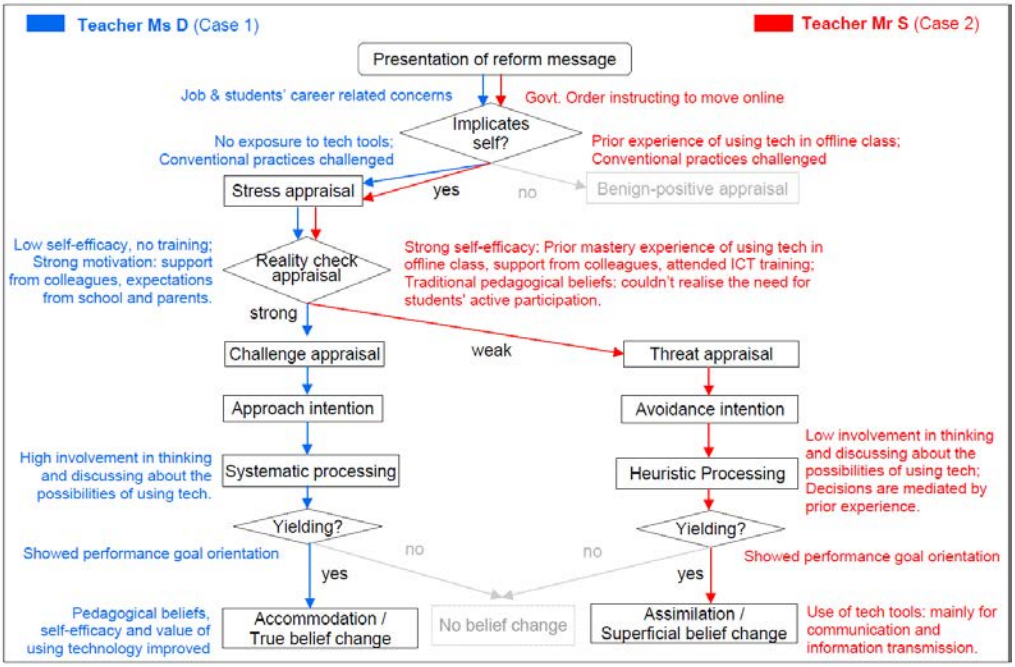
In Ms. D's case, contextual factors played an important role to affect her motivation. She shared that her colleagues and friends helped her a lot in preparing to shift to an online medium and learn new technologies to facilitate the online teaching process. There was also a high expectation from the side of school administrators, parents and students to continue schooling using digital technologies. Thus, Ms. D was motivated to approach the reform message, despite her weak self-efficacy and ability. This strong *Motivation* made her perceive the reform message as a challenge (*Challenge Appraisal*) and *processes the message systematically*. She had spent a considerable amount of time discussing with colleagues, friends and family members the possibility of moving into an online teaching-learning process. She took their help in learning the affordances of new tools required for conducting online classes and preparing materials. She made efforts to prepare students for online learning. In the case of Ms. D, since her school was a private unaided school and her posting is on a contractual basis, she had to prove that she is capable of teaching in an online medium. Otherwise, it may affect her job also. All these compelling situations created a performance goal orientation in her. Since she has strong beliefs about the value of the use of technology and goal orientation that supports the reform message, she *Yields to*, or accepts, the reform message.

Before the lockdown, Ms. D had no experience teaching with technology, and hence no specific pedagogical beliefs about technology integration. A year after teaching online, Ms. D recognised the affordances of technology, used it to foster deeper learning, and reflected upon the impact it made on her students (*true conceptual change)*.

> *'Usually, we utilize the imagination while teaching a concept. It is very difficult to pass on the imagination in our minds to children. We do not know what each child's thinking. But when we visualize with technology, we can bring everyone's thinking together to the same point."*

Figure 1

Visual model of two teachers' belief change as per the CAMCC model



Case 2: Teacher Mr. S

Mr. S is a high school Physical Science teacher. His school is a government-aided private institution located in the rural areas in the Malappuram district of Kerala. Malayalam is the medium of instruction in this school. Mr. S has eight years of teaching experience and has a BSc degree in Physics and a BEd degree in Physical Science. He has also qualified for the Kerala Teacher Eligibility Test (KTET), a state-wide teacher certification program. He has attended an induction programme for training teachers to integrate educational technology in their classrooms. In this programme, he was introduced to the pedagogical use of educational technology. He has learned to use various digital content and resources, such as those from Samagra eResource Portal and PhET simulations and completed various activities using these platforms to get a firsthand experience. Before lockdown, he had utilised Samagra eResource portal for showing educational videos to his students in a face-to-face classroom. He was also familiar with WhatsApp and used it mainly for social networking.

During the lockdown, classes were streamed through VICTERS TV and YouTube channels which are of lecture or demonstration type with thought-provoking questions to students. At the end of each class, resource teachers in the VICTERS classes gave common activities and assignments to the entire students of a particular grade in the state and asked the students to submit their answers to their concerned class teacher. Mr. S utilised WhatsApp groups for coordinating this process of collecting students' responses and giving feedback to them. Mr. S and students mainly used the texting and audio messaging features of WhatsApp for their communication. He also conducted online meetings using Google meet app weekly to clarify students' doubts and provide extra information and materials related to the topic. Mr. S used the lecture method for teaching and a blackboard for drawing diagrams and demonstrating problem-solving activities during the online class. Worksheets were created by a group of high school Physical Science teachers in the Tirur Education District. The same worksheet was given to the students in that entire educational district. The team members change every week. Every day, after the class on the VICTERS channel, the team used to meet online and prepared the worksheet. Teachers used

WhatsApp and Google Meet to coordinate this process. Students' responses to these worksheets were evaluated together in a term and these grades were considered for students to pass to the next class.

Analysing Mr. S's change in beliefs about technology integration

The reform message reached Mr. S as a government order (Department G. E., 2020) to 'rearrange the teaching-learning process by utilising VICTERS channel and available digital resources to help students to continue their education during the difficult time of COVID-19 pandemic' (see Figure 1). The order also mandated Mr. S to communicate with students before and after each class on the VICTERS channel by using social media or mobile or any other medium or face-to-face, for motivating students to actively participate in the classes and to take remedial measures to clear doubts raised by students. Even though Mr. S has some experience in using educational technology in his face-to-face class, moving completely to an online medium challenged Mr. S's conventional instructional beliefs. For example, he mentioned that:

> *"We never get satisfaction in Online mode like we get in a face-to-face classroom." "We can not get students' responses directly in online mediums and this lack of immediate feedback makes it difficult for us to improve our instructional practices."*

Mr. S acknowledged that the reform message requires something different from what he was doing in his classroom (*Implicates self? Yes*). Thus he appraised the situation as stressful and considered the message as a stake to himself (*Stress appraisal*). This is the first step on the path that eventually can lead to belief change. Mr. S has some prior mastery experiences of using educational technology in his face-to-face classes and observed that it helped students to learn the concepts much more easily. He had received practical training to integrate educational technology into the teaching and learning process. These experiences acted as a source of his strong *self-efficacy beliefs for using technology*. The *ability* (time, knowledge, resources) to implement the reform message is also an important factor. In this case, time, supportive colleagues and subject matter knowledge will determine whether Mr. S will approach or avoid the reform message. In Mr. S's case, the school was closed in the month of March 2020 and decided to start online learning in June 2020. So the decision to completely move to online learning was quick and he didn't get much time to prepare. However, he had received training to integrate technology in the teaching-learning process before the lockdown and that exposure probably gave him confidence. Similarly, colleagues, friends and family supported him to learn and use the online learning platforms.

Mr. S had reported constructivist pedagogical beliefs about teaching in face-to-face environments before the lockdown. For example, he shared an instance from his previous face-to-face class where he conducted a group activity on the topic of light dispersion, the process of converting sunlight into seven colours using a prism.

> *"We can either use sunlight or white light from a torch. The light from the torch will spread further as it passes through the prism. So we preferred sunlight for the experiment. The classroom was on the second floor of the school building. My period was after the interval. During the interval time the children fixed a mirror on the handle of a bike that was parked outside the classroom. The mirror arrangement was such that the sunlight reflected from it would fall on the prism placed in the class. The children were very excited when the rainbow was created like this."*

During this activity, he facilitated students to conduct the activity by fixing and adjusting the angle of the mirror properly to reflect the sunlight into the prism. He also stated his views about promoting the active participation of students.

> *"Discipline is not affected when children are part of the activity. I give instructions to the children before the activity begins. I explained to them about what they will to do in the class. For example, after doing this experiment, you should write down what you observed in your notebook, find out what is the reason. Then children do the activity and each group representative reads their findings in front of the class."*

However, Mr. S held more traditional pedagogical beliefs while integrating technology into his teaching. Even though he used videos and animations, his intention was mainly for information transmission and making students aware of science concepts. He could not realise the need for students' active participation in the learning process. Mr. S has failed to understand the pedagogical affordances of the simulation software and the role it could play as a facilitator of knowledge construction for students. Even though he had experience in using Samagra videos, he was reluctant to utilise those videos for online learning. He argued that students' active participation in online learning was not practical and teachers could not conduct any group activities in online classes. Because of these pedagogical beliefs, Mr. S experienced the reform message as a threat (*Threat appraisal*), despite strong self-efficacy and sufficient ability. This approach took him to *heuristic processing* of reform messages and led to a decision choice, *Yielding?* A variety of factors, such as the quality of existing beliefs about pedagogy and value of technology, and characteristics of how the message is perceived, decide whether the person will make any conceptual change finally.

When analysing Mr. S's beliefs about the value of the use of technology, we can see that he has shown utility value for the reform message.

> *"Showing the 3D versions of the atom model through digital technology can be very helpful. Children can understand and easily visualise the size of an atom and see how the heat is generated."*

At the same time, he has shown a cost value (the effort the task may take to implement online learning).

> *"There are a lot of difficulties in the online classes. There will be delays in seeing and getting feedback… more time is required for teaching a topic in online class than in face to face classes."*
>
> *"There are physical discomforts when you have to use technology for four or five hours straight."*

Mr. S has shown a performance goal orientation. His reason for considering the reform message is that he compared himself with other teachers who were going to implement this message. All high school teachers in the state were going to use technology and hence he has to consider this reform message. Similarly, Mr. S considered the reform message initially as plausible because he thought that using technology was the only way to continue education in this lockdown situation. When considering the influence of all these variables we can conclude that Mr. S has yielded to the message and ended up in *assimilation or superficial belief change*.

Discussion

The study conducted among secondary school teachers in the state of Kerala, India has shown a different range of changes in teacher beliefs about technology integration. We have found that teachers have undergone different path of beliefs changes in accordance with CAMCC. These changes can be attributed to a number of contextual and motivational factors of teachers.

In the case of Ms. D, the self-efficacy beliefs for using technology and ability were found to be very low. In spite of the weak and insufficient characteristics of the teacher, Ms. D processed the reform message systematically. The situational resource (supportive others) is found to be a crucial factor in the process. Ms. D and colleagues formed WhatsApp groups to discuss their concerns and problems faced during technology integration, share their experience of successfully using technology tools, and deepen their knowledge and expertise in both content and technology use. The idea behind this communication through WhatsApp was with a hope that everyone will benefit from their issues and expertise. Since the teachers used WhatsApp groups as their primary mode of interaction, they can also be considered virtual communities of practice (Wenger, 2008; Dubé et al., 2005). One more factor is Ms. D's empathy toward her students. She was very concerned about students' lack of digital resources. She was available to students even during weekends, through WhatApp and mobile calls for solving doubts and sharing their concerns. She was aware of the role online learning played during the pandemic in shaping students' education and their future careers. For Ms. D, technology was more than a transactional medium. She used it in a broader way by involving other stakeholders in her students' learning process and building community.

Mr. S had strong self-efficacy beliefs for using technology and sufficient ability. In some contexts, his beliefs as well as his practices were aligned and strongly supported student-centred learning. For example, he was successful in implementing active learning in face to face classes. However, his pedagogical beliefs on technology integration were found to be traditional, so he used technology mostly for communication and operational tasks. He did not show any instance of using technology for learner participation. Nor did he make the effort to exploit the affordances of the new technology medium. While he had good training and experience using technology and support from the school in terms of access to digital resources, he was unable to integrate student-centric learning practices into the new medium. In fact, despite repeated probing, he showed an inability and unwillingness to conceptualize student-centred practices in the online medium.

This case study highlights the importance of factors influencing effective technology integration, going beyond training on how to use technology. We found that factors such as support from colleagues and concern for students' future and a sense of community played a major role. At the same time, our findings may seem counterintuitive, where the trained teacher did not change his beliefs as much as the teacher who had low training for technology use due to the presence of the affective and contextual factors. However, the training prior to the pandemic did not provide for the unique situation we are in now. Hence, the training may have made Teacher 2 more rigid in their use of technology. The findings from this study contribute to expanding the understanding about the belief change process. Specifically, this study illustrates the importance of favourable contextual factors in the effective integration of technology. The findings have implications to learning sciences researchers working on effective integration of technology-focused solutions in the classroom and in designing TPD programs.

Even though we have valuable findings from the study, one limitation is that we do not have measurements of teachers' beliefs prior to the pandemic, except via retrospective reflections of teachers. We have not yet measured teachers' actual practice in the digital medium and it will be a part of future work.

Extending "othered" bodies into learning environments: Queer reorientations, virtual reality, and learning about gender and sexuality

Dylan Paré, University of Calgary, dylan.pare@ucalgary.ca

Abstract: In this paper, I illustrate how interacting with an immersive, virtual reality (VR) experience designed with queer phenomenological approaches can deepen understandings of gender and sexuality. I show how extending the queer phenomenological concept of *reorientations* (Ahmed, 2006) with complementary theories of ideological stance-taking (Philip et al., 2017) and emotional configurations (Vea, 2020) can highlight moments of emotional-ideological sense-making practices where learners become *reoriented* by reflexively negotiating between themselves and "othered" objects and people. I present an interactive, branching narrative told in immersive VR, in which the player uncovers the narrator's memories of gender and sexuality-based marginalizations in STEM learning environments. I then present illustrative cases from an ongoing design study. Analysis of the VR interactions reveals how participants used the narrative and virtual objects to recognize normative orientations to STEM and *reorient* toward counter-hegemonic actions and marginalized people.

Introduction

In this paper, I illustrate how interacting with an immersive, virtual reality experience designed with queer phenomenological approaches can deepen understanding of gender and sexuality and intersecting identities as complex experiences with individual and systemic dimensions. As reviewed by Paré et al. (2019), empirical research has shown that embodied interactions in virtual worlds can support learners to take on perspectives that would otherwise be difficult for them to adopt, across topics ranging from physics and chemistry to animal rights, racism, and ageism. I show how extending the queer phenomenological concept of reorientations (Ahmed, 2006) with complementary theories of ideological stance-taking (Philip et al., 2017) and emotional configurations (Vea, 2020) can highlight moments of emotional-ideological sense-making practices where learners reflexively negotiate between 1) their stances, 2) the "othered" people and objects they interact with, and 3) the socio-political contexts that coordinate individual and systemic conditions for marginalized people. This extended analysis of reorientations further supports identifying solidarity as an interactional phenomenon of reorienting one's emotional and ideological sense-making toward actions in solidarity with marginalized people.

Learning Sciences scholars have repeatedly called for the field to reorient itself in solidarity with marginalized people so that our research remains relevant (The Politics of Writing Collective, 2017; Curnow & Jurow, 2021), attends to issues of equity and justice (Bang & Voussoughi, 2016; Philip et al., 2018; Philip & Gupta, 2020; Philip & Sengupta, 2021), and better understands the political in learning (McKinney de Royston & Sengupta-Irving, 2019). However, despite recognition by many of the authors of these calls to include LGBTQ+ people and queer contexts in the Learning Sciences, this scholarship remains at the margins of the field (Curnow & Jurow, 2021). Nevertheless, Learning Sciences scholars have offered novel approaches to applying queer theory to illustrate how learners resist normativity (Lizárraga & Cortez, 2019; Paré et al., 2019; 2020; Takeuchi & Dadkhahfard, 2019; Takeuchi & Aquino Ishihara, 2021). In addition, Learning Sciences scholars working with LGBTQ+ identified learners have argued for greater attention to the emotional and political dimensions of learning in queer(ed) learning environments across digital and physical spaces (McWilliams, 2016; McWilliams & Penuel, 2017; Schrodes, 2021; Uttamchandani, 2021).

To this end, I present Mementorium, an interactive, branching narrative told in immersive, virtual reality, in which the player uncovers the narrator's memories of gender and sexuality-based marginalizations in STEM learning environments, moving from childhood to early adulthood, by interacting with meaningful objects in the narrator's bedroom. Analysis of the VR interactions and interviews reveals that participants drew upon the narrative and virtual objects of the VR game to recognize normative orientations in STEM learning environments. Furthermore, they *reoriented* toward counter-hegemonic and nonnormative actions and people in their narrative choices and reflection upon their lives.

 © ISLS

Theoretical background: Queer reorientations

My theoretical framework expands Ahmed's (2006) queer phenomenological concept of *reorientations* by bringing it into conversation with complementary theories of ideological stance-taking (Philip et al., 2017) and emotional configurations (Vea, 2020).

Scholarship on ideological sense-making as an interactional practice of stance-taking (Philip et al., 2017) offers a way to highlight the moment-to-moment processes of ideological reasoning in interaction with objects and others. Drawing upon Du Bois's (2007) dialogic framework of stance, Philip et al. (2017) showed in their analysis of classroom interactions how stance "is a matter of simultaneously evaluating an object and positioning oneself in relation to others" such that "every stance exists in a triangular relationship among the stance taker, the object that is being evaluated, and other subjects" (p. 196). The theory of ideological stance-taking aligns well with Ahmed's queer phenomenological approach that frames compulsory heterosexuality as an embodied experience of being oriented to normative ways of life in interaction with others and objects. Ahmed (2016) shows how "compulsory heterosexuality diminishes the very capacity of bodies to reach what is off the straight line" (Ahmed, 2006, p. 67) and, further, how, for BIPOC (Black, Indigenous, People of Colour), "that are not extended by the skin of the social, bodily movement is not so easy. Such bodies are stopped, where the stopping is an action that creates its own impressions. Who are you? Why are you here? What are you doing?" (p. 115). How we are oriented by others and objects affects how certain bodies can or cannot extend into learning environments. These moments of being stopped (Ahmed, 2006) and confronted with "the skin of the social" and "compulsory heterosexuality" become moments of embodied, ideological learning for marginalized QTBIPOC people (Queer, Trans, Black, Indigenous, People of Colour). This ideological learning occurs for those who are stopped, whose bodily movement is constrained by societal marginalization. A marginalized identity becomes the reason one is stopped, thus making these identities salient, while privileged identities are treated as already belonging, allowing them to go unnoticed by the privileged person. This scenario is not a simple binary in practice as people hold multiple identities, privileged and marginalized, that create unique intersecting oppressions (Crenshaw, 1990).

The reorientation of learners toward marginalized "others" and "objects" can be further understood through the lens of emotional configurations, where the emotions that emerge within social interactions shape ideological sense-making (Vea, 2020). Bringing together emotional configurations and ideological-political analyses is further supported by Curnow and Vea's (2020) work demonstrating how emotion is a key factor in understanding sense-making when learning about politics, power, and privilege. For example, Vea's (2020) analysis of animal rights activists showed that social movement learning in these spaces centered on the emotional configurations that organized social relations of "feeling, sense-making, and practice" in relation to other activists and nonhuman animals (Vea, 2020, p. 328). Specifically, Vea (2020) showed how animal rights activists intentionally organized emotional experiences, making emotion a target for learning that would then shape activist-participants' ideological sense-making by challenging human-animal relationships with nonhuman animals ("the other") and meat ("the other-as-object"). Thus, through a process of emotional configuration in collective action, animals were reconceptualized from being objects without needs or desires to being recognized as "othered" beings worthy of empathy and equitable consideration (Vea, 2020). Similarly, a queer phenomenological *reorientation* to the design of learning environments can create an intentional emotional configuration of learners from a normative alignment with the cisheterosexual "straight line" toward a counter-hegemonic reconceptualization of marginalized queer and trans people.

I propose a queer phenomenology of *reorientation* as a lens to support the design and analysis of learning environments that attend to learners' experiences of recognizing and resisting normative enforcements of docility and that reorient learners toward counter-hegemonic and nonnormative actions and people. Attending to reorienting acts highlights how learners make sense of inequities experienced by marginalized people and offers a lens to deepen our understanding of how to reorient learning and learners toward more equitable, counter-hegemonic ways of being and knowing. Extending queer phenomenological theories of *reorientation* through complimentary Learning Sciences theories of ideological and emotional learning offers an analytic lens to investigate queer(ed) learning environments that support reasoning about gender and sexuality and intersecting identities as embodied, complex experiences with individual and systemic dimensions. Further, my conceptualization of *reorientations* highlights moments of emotional-ideological sense-making practices where learners reflexively negotiate between their stances, the people and objects they interact with, and the socio-political contexts that coordinate individual and systemic conditions for marginalized people. *Reorientations* further supports identifying solidarity as an interactional phenomenon of reorienting one's emotional and ideological sense-making toward "othered" people and objects. This takes solidarity beyond an individual and internal state of being and into the realm of action, where we can leverage moments of counter-hegemonic affinity and design for reorienting learners toward solidarity-in-action.

Research questions

In this study, I ask the following two research questions:
RQ1: How can interacting with an immersive, virtual reality experience designed with a queer phenomenological lens deepen understandings of gender and sexuality and intersecting identities as complex experiences with individual and systemic dimensions?
RQ2: How do learners use emotional-ideological sense-making practices to reflexively negotiate between their stances in relation to virtual "othered" people and objects and the socio-political contexts that coordinate individual and systemic conditions for marginalized people.

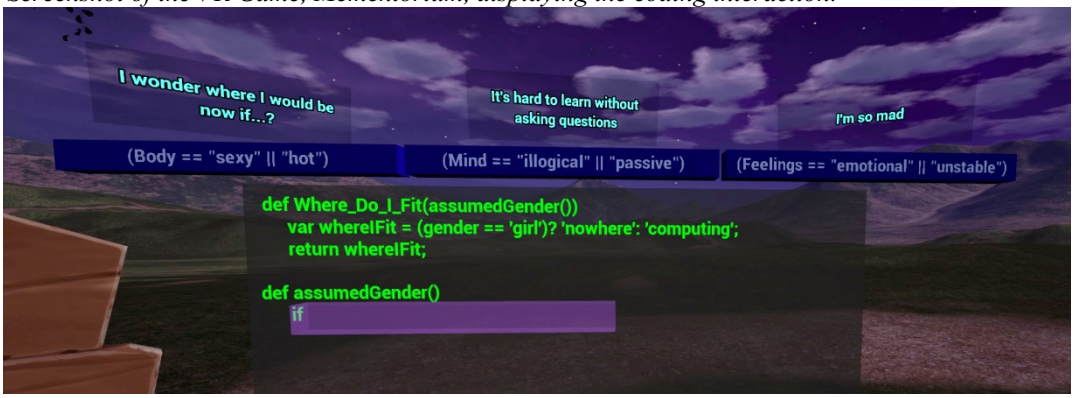
The research objectives are two-fold: 1) to deepen connections between the Learning Sciences scholarship on ideological and emotional sense-making in learning with phenomenological scholarship on gender and sexuality, and b) to extend the Learning Sciences literature on the design and analysis of queer(ed) learning environments and immersive technologies that attend to learners' experiences of recognizing and resisting normative enforcements of docility and that reorient learners toward counter-hegemonic and nonnormative actions and people.

The virtual reality game: Mementorium

To this end, I present Mementorium, an interactive, branching narrative told in immersive VR, designed by the author and collaborators. VR is experienced using a head-mounted display that players wear to enter the virtual world, hear sounds spatialized to match the source of the sound within the virtual environment, move within the virtual environment using VR controllers, and interact with virtual objects by, for example, picking up and touching objects.

To play the game, the player uncovers the narrator's memories of gender and sexuality-based marginalizations in STEM learning environments by interacting with meaningful objects in the narrator's childhood bedroom. Each of the memories that the player uncovers has three branching points in the narrative. First, the player uncovers the memory, revealing the harm caused by marginalization. Next, the player chooses their reaction to the situation that reorient the player to the narrator's experiences. Paré et al.'s (2020) work on queering simulation design found that designing interactions to encourage people to reorient their attention and emotions toward marginalized experiences supports deep reflection and learning. Finally, the player chooses a future-oriented response to direct the narrator's actions, offering choices for individual or group-oriented action or action on a larger scale of social change. The interaction design uncovers story branches that reorient players toward queer and trans imaginaries by queering science and technology objects and environments otherwise seen as politically neutral (Paré, 2021). For instance, in one interaction, the player is introduced to the narrator's experiences of a high school coding classroom. Next, the player is presented with a block-based coding interaction where the blocks they choose to complete the code also reflect their branching story choices. As the code is entered, the player is constructing Python-based code poetry that reflects experiences of gender, sexuality, and belonging in coding learning environments (see Figure 1).

Figure 1
Screenshot of the VR Game, Mementorium, displaying the coding interaction.



Each interaction with a story object transports the player to an outdoor, prairie-like environment where their bedroom furniture still exists as it did in the bedroom but is situated among flowers and trees. In the outdoor environment, each interactive object from the bedroom has been "transformed" into a fantastical or metaphorical version of itself that could not exist in reality. The game is structured around five branching narratives, occurring

at various times in the narrator's life (elementary, middle/junior high, high school, entering postsecondary, and early adulthood). Gameplay typically takes approximately 30 minutes to complete when not extended by conversations with the researcher.

Methods

As part of an ongoing design study, I have interviewed seven participants thus far as they interacted with the VR game. Interviewing people who already use VR was necessary for the study because people who are new to the technology can become distracted by the novelty of VR. The study setting is over Zoom videoconferencing, in which participants were provided access to the VR application and played the game while screen sharing their gameplay screen over Zoom. Participants included people of various genders and sexualities, ranging from their early 20s to mid-50s, and geographic locations including Canada, the United States, Australia, and Switzerland. Each participant was connected to virtual reality through interest or career -- some were interested in VR for research, others for design and application development, many were also hobbyists and players, and some were teachers interested in bringing VR into K-12 schooling. The study involved a single session, approximately 2 hours, including a pre-interview, the interaction with the VR game, and a post-interview. The pre-interview was conducted to learn about each participant's prior virtual reality experiences, knowledge of and learning experiences related to gender and sexuality, and experiences of gender and sexuality in the context of technology. During participant interactions with the VR game, I asked participants questions to understand how participants were making sense of their interactions and how they related or did not relate to the game.

Analysis and data collection were intertwined throughout the time that interviews were being conducted. Videos were transcribed, and codes were developed iteratively as data gathering continued. Videos, alongside their transcriptions, were coded line-by-line to inductively find emerging themes for focal analysis (Emerson, Fretz, & Shaw, 2011). Emergent themes were refined through my theoretical focus on identifying occurrences — i.e., turns of conversations between a participant and the game narrator or game object, or between a participant and the facilitator — that involved reasoning about gender and sexuality through stance-taking and emotional configurations. In each of these occurrences, I was specifically interested in how the participant was reasoning in relation to the game's narrative and objects — i.e., sharing personal stories related to the narration or explaining their reasoning for choosing a narrative branch or game object.

My presentation here includes Nate (he/him) — a self-identified cisgender man, primarily heterosexual, early-30s, high school computer science teacher in Alberta, Canada — and Meeran, who self-identified as a masculine-aligned homosexual assigned male at birth and still identifies as male. Meeran is in his early twenties, lives in the Southeastern United States, and is college-educated. Neither participant self-described their race. Nate appeared to be white. Meeran interviewed from within VR and presented in an anthropomorphized animal avatar. I chose to focus the analysis of this paper on these participants because their experiences of gender and sexuality differed from the VR game's narrator, thus offering distinct insights into reasoning about the "other."

Findings

Case 1: Nate reasoning about bringing gender and sexuality into his high school computer science classroom

In the pre-interview, Nate explained that he is progressively minded and relatively knowledgeable about different genders and sexualities. Nate has had discussions with his learning leader about encouraging more girls to be involved in STEAM courses. His school department decided to ask students for their preferred names and pronouns. Nate also includes some representation of gender and sexual diversity in his computer science classes through a brief history of computer science, including Ada Lovelace, Alan Turing, and Judith Love Cohen. He is also aware of industry problems such as the general male-dominated environment of computer science and issues with sexual harassment, specifically in the case of the gaming company Activision Blizzard. However, in his pre-interview, Nate explained that he finds few opportunities to include gender and sexual diversity as topics for learning in a computer science classroom.

> **Turn 1** Nate: it's just like it's it's it's hard to include gender and identity in there when it's we're literally just talking about, you know, multiplying numbers. ... it's not like there's an LGBTQ+ line of software development that we could study either.

As the VR game progresses to the fourth of five story branches, Nate begins to anticipate the narrator's experiences of exclusion before they are revealed.

> **Turn 1** The narrator tells story about being at a postsecondary open house and expressing interest in a computer science program.
>
> **Turn 2** Nate: [talking alongside the narrator and anticipating the outcome] Let me guess. He's going to ignore you. [expressed in an annoyed tone].
>
> **Turn 3** The narrator is given a cold response by the male representative that, "You have to be good at Math," and then being ignored.
>
> **Turn 4** Nate: Of course, he did [expressed in an annoyed tone].
>
> **Turn 5** Nate: [explaining to researcher] so what I was thinking about through all that was that I should definitely do a lesson on gatekeeping in computer science because computer science classes, they're not just about the coding, right? They're about the whole kit and caboodle of it. So. So maybe just even as a reminder or something that if you had any resources on that specifically, like any good ways to set up a lesson, feel free to email me those after this. And because at this point, I'm like hopping mad. I want to like on Monday, I almost want to walk in there and, you know, first 15 minutes of class, just do a lesson on that. And so like, the way I'm thinking about it is is. I mean, you know, the direct way would just be like, look around the room, what can you tell me about the people sitting here? And I'm sure someone would say it like I can think of like one or two students who probably are observant enough or it would get that of what I'm talking about to bring it up. But of course, like going about it in a more roundabout way, I'm sure, as you know, is probably more effective. So again, if you got any resources on that, you think I might be able to use for that, then feel free to send them to me.

In turns 2 and 4, Nate's anticipation of the narrator's experience and expression of annoyance demonstrate his emotional configuration toward the marginalized narrator. Then, in Turn 5, Nate's deepening emotional configuration, being "hopping mad," provokes an ideological stance that reorients his earlier stance toward computer science. Nate turns from a normative orientation to computer science during the pre-interview - seeing it as just "multiplying numbers" - to later challenging this idea, stating, "computer science classes, they're not just about the coding, right? They're about the whole kit and caboodle of it." He then quickly imagines a possible lesson design to address the problem in his next class and asks the researcher for resources to integrate more content about the political issues (gatekeeping) prevalent in computer sciences. Imagining lesson designs and asking for resources demonstrates a reorienting toward counter-hegemonic and nonnormative action in solidarity with marginalized people. Next, after the fourth story branch concludes, the researcher and Nate return to discussing industry issues as an example of gatekeeping.

> **Turn 1** Researcher: And so like I wonder like how do you? How do you bring up the relevance of these industries and their problems as students are learning computer science and thinking about their future paths? Do you see those kinds of conversations as relevant because you're obviously very aware of some of the problems, especially in terms of like some of the gaming companies?
>
> **Turn 2** Nate: I'm thinking now about like, OK, how can I do lessons on that as well? And it's. Like from the computer science curriculum, it doesn't really talk specifically about like that, the culture within the industries, which, you know, of course, now I'm going to be writing my MLA [provincial government representative]. Not that, you know, that UCP guy [Conservative party representative] will listen to me or anything. But just saying that, you know, that is something that should be included in the curriculum.

From this interaction, we can see that Nate is committed to addressing the issues raised in the narrative. He has decided that he needs to incorporate more lesson plans to address the matter and suggests contacting his government representative to argue for curriculum change. Although Nate was already knowledgeable and believed in supporting equity issues, implementing these into a computer science classroom was not a clear path given the overwhelmingly cisheteronormative orientation of the computer sciences discipline and curriculum (Paré, 2021). Lastly, Nate explains how the VR game solidified his commitments to equity and supported him in thinking through how to incorporate issues he was aware of but was not sure how to include into a lesson.

> **Turn 3** Nate: like around, like the culture within, within the companies, for example, you know, it's like, it's always been there in my brain, but. But, you know, it gave me the idea, oh, well, I should, I should address this. Like, that is relevant to my classes.

When prompted by the narrative, Nate recognized and resisted the normative orientations to computer science. Additionally, he reoriented toward counter-hegemonic and nonnormative actions by thinking about how he could teach his students to identify inequities in the classroom and challenge gatekeeping in computer science.

Case 2: Meeran reasoning about gender-neutral pronouns.

This case focuses on the interaction between Meeran and the fifth and final branch of the game narrative. Meeran demonstrates shifting stance-taking as he reasons about pronouns and gendered language.

> **Turn 1** The narrator tells a story about struggling to fit into a women's coding group that misgenders them, saying "hey, ladies" and assuming the narrator's pronouns.
>
> **Turn 2** Meeran: [heavy sigh outward] And unfortunately, I still say, hey, guys, a lot. Or you guys. I just, I don't feel like there's a standardized, gender-neutral system within the English lexicon. So, I hear from a lot of people who are transgender or gender-neutral. Usually, "you guys" or "hey, guys" like saying guys in general is OK, but I still wish there would be like an inclusive, like gender-neutral terminology. I, before I even knew, I just, I was thinking to myself, What's the gender-neutral term for sir or ma'am? There isn't really one. But I shouldn't assume.

Meeran's sigh after hearing the narrator's story expresses his emotional alignment with the narrator. Then, this sigh is followed by his sense-making of how his everyday practices perpetuate the same exclusions. As is a common initial ideological stance when people are reasoning about gender-neutral language, Meeran identifies the source of the problem as the English language. This move locates the problem in a structure ("the Lexicon") and suggests a linear system where the language structures dictate individual practices, where "you guys" exists because of the lack of "gender-neutral terminology." Next, Meeran begins reflecting on the choice for the following narrative branch about what the narrator should do about being misgendered.

> **Turn 1** Three narrative choices appear in order from left to right, floating as boxes above three chairs. The player must seat the bear in the chair of the choice: "Just ignore it," "Teach people how to include you," and "Set boundaries to be respected."
>
> **Turn 2** Meeran: You can't just ignore it. [referring to story choice 1 of 3] You have to be who you are. "Teach people how to include you" [reading story choice 2 of 3]. And I personally, I'm a masculine man. I. I look the part as well. Um. I've actually never been misgendered in my life at all. I'm.. I actually don't, unfortunately, have the experience of it, but I respect everybody's spaces. I call them whatever pronouns that they set themselves as. So, it doesn't hurt me. It doesn't hurt them. It doesn't hurt anybody. So. [looks at story choice 3 of 3: "Teach people how to include you"] I'm glad whenever people tell me their pronouns, but because I look and sound the part in how I express myself online. Plus, also just how I look in real life, I don't, I don't usually tell people my pronouns because people always assume it's masculine. And I'm OK with it. But I had a couple of people ask me what my pronouns were in VR, so I didn't think anything of it, and I just said "he/him". But people should get into the habit of asking for pronouns a little bit more often. So, "Set boundaries to be respected" [this story choice becomes Meeran's first choice] and also "Teach people how to include you." I want to choose both of these. This would be like one [pointing to story choice 2], two [pointing to story choice 3], three [pointing to story choice 1], but again, you can't just ignore it [referring to story choice 1]. [Meeran chooses, "Set boundaries to be respected."

Meeran states his ideological stance that the narrator cannot ignore misgendering because "you have to be who you are," showing an ideological orientation toward individual freedom of expression. He then relates to his own experiences with being correctly gendered by others' assumptions and identifies his lack of marginalized experience as a deficit to fully understanding the narrator's perspective. His emotional configuration toward the narrator supports extending his perspective beyond his own. By recognizing the limits of his perspective, Meeran reorients to the narrator as an expert of their life. During this reorientation, he reasons with the story object, "Teach people to include you," and notes that he appreciates when people tell him their pronouns. However, he recognizes

that his privilege means that he does not have to tell others his pronouns. His reasoning with the story object elicits the ideological stance that he likes when people tell him their pronouns, but his earlier emotional configuration supports him to recognize that his perspective is limited. He concludes that people should ask for others' pronouns more often. Meeran reorients his stance from his initial perspective toward a perspective more aligned with "the other." He chooses the story object "Set boundaries to be respected," reasoning that this is most aligned with the marginalized narrator's perspective. Merran then listens to the narrator explain similar reasoning that the burden of asking and providing pronouns should not always fall to marginalized people.

> **Turn 1** The narrator explains that the burden should not be on marginalized people to pre-empt others' assumptions of them by offering pronouns first when they are already at a disadvantage as a marginalized person.
>
> **Turn 2** Meeran: But I feel like saying hi, everybody or addressing everybody as well, everybody would work. It's just not used that often because again, everybody just likes saying, Hey gals or Hey guys.

In Turn 2, Meeran counters his initial stance that the English language does not offer gender-neutral options for addressing people and, instead, reasons that "hi, everybody" is a possible solution to the gendered language problem. He further identifies that the barriers to using gender-neutral language have less to do with the formal English language structure and more to do with the gendered social conventions that people reproduce as they tread familiar paths that orient them to the "straight line."

Summary and Discussion

Overall, my work offers insights into designing VR experiences and learning environments in general that extend "othered" bodies and their ways of knowing and being into the learning environments. The design, development, and investigation of Mementorium supports developing understandings of how to use new technologies (VR) and pedagogies (immersive, interactive narratives) to create learning environments that can address inequities in education (LGBTQ+ learners' marginalization).

Pedagogically, this work advances understanding of designing activities that encourage reasoning about socio-political issues of gender and sexual identity that encourage learners to reorient their perspectives toward marginalized people. This shifts the design of learning interventions that address LGBTQ+ inclusion away from conceptual approaches based on definitional work ("what is a trans person?") toward a more meaningful, phenomenological approach grounded in more profound forms of experience. Teaching gender and sexuality-based issues is often challenging work for marginalized people because it puts them at risk for harmful interactions when learners become defensive or resistant. Defensive learners often engage in microaggressions that deny marginalized people's ways of knowing their experience, leading to epistemic injustice (Fricker, 2007; Kidd, Medina, & Pohlhaus, 2017). However, people who do not experience marginalization but aim to act in solidarity (often called allies) lack valuable lived expertise (and sometimes also formal training) to lead the work. As a result, allies can fail to reorient themselves to the marginalized perspective in the ways necessary to act in solidarity (McKinnon, 2017). The design of Mementorium begins to address these problems by removing marginalized people from direct harm without losing the expertise of lived experiences and formalized expert knowledges that are present in the form of the immersive, interactive narrative game design.

Theoretically, this work extends queer phenomenological *reorientations* as a lens to support the design and analysis of learning environments through a complimentary combination with theories of ideological stance-taking (Philip et al., 2017) and emotional configurations (Vea, 2020). Further, I show how a theory of *reorientation* can attend to learners' experiences of recognizing and resisting normative enforcements and support reorienting learners toward counter-hegemonic and nonnormative actions and people. This takes solidarity beyond a notion or expression — "I am in solidarity with such and such marginalized group" — and into the realm of solidarity-in-action, where researchers can leverage moments of counter-hegemonic affinity (reorienting to emotional configurations in alignment with marginalized people) and design for reorienting learners toward ideological stances and proposed actions in alignment with the needs of marginalized people.

Elevating the Ways in Which Latina Mothers Perceive, Do, and Envision Early STEM learning

Leiny Garcia, Wendy Roldan, Vanessa Bermudez, Andres Bustamante, June Ahn
leinyg@uci.edu, wr4@uw.edu, vnbermud@uci.edu, asbustam@uci.edu, junea@uci.edu
University of California, Irvine

Abstract: Early STEM learning opportunities aligned with families' funds of knowledge can produce meaningful learning experiences for children. We investigated Latina mothers' perceptions and values of STEM learning, STEM-related activities with their children, and the early STEM learning experiences mothers designed for community spaces. In a research-practice partnership, we conducted seven virtual co-design sessions with 32 caregivers and individual interviews with a subset of 10 mothers. A thematic analysis revealed that Latina mothers' STEM perceptions were primarily informed by school-based notions, yet they also integrated STEM in everyday, family practices such as cultural games. Mothers valued experiences promoting family unity, intergenerational learning, heritage, active citizenship, and *ganas.* Finally, Latina mothers' values and practices informed their vision and design of early STEM learning artifacts in the community. Thus, diverse parents' contributions in design efforts can serve as a mechanism through which stakeholders connect and enhance children's learning experiences across contexts.

Introduction

Education researchers and learning designers recognize the critical role of caregivers in facilitating learning outside of school with their children. One ongoing effort is to create Playful Learning Landscapes (PLL), environments that combine science, technology, engineering and math (STEM) experiences, with play and family-interactions in everyday spaces (e.g., bus stops, grocery stores; Bustamante et al., 2019). Despite efforts to include diverse perspectives on STEM learning experiences (Garibay & Teasdale, 2019), much of the research on STEM learning activities may not accurately represent the diverse practices of families who are multilingual, from a lower socioeconomic status, and from underrepresented cultural groups. To promote STEM learning outside of school, it is critical to ground the design of learning experiences to support daily parent-child practices by recognizing and leveraging the ways caregivers already encourage STEM learning with their children. In this work, we unpack the current ways Latina mothers perceive STEM learning, how they naturally engage in STEM learning with their children, and the ideas they have for future experiences for their children. Our guiding research questions are:

RQ1: What are Latina mothers' perceptions and values for their children's STEM learning?

RQ2: What are the activities at home and in their community that Latina mothers engage in with their children that support STEM learning?

RQ3: How do Latina mothers' perceptions, values, and activities relate to the kinds of STEM learning experiences they design for the community?

To examine these research questions, we analyzed a research-practice partnership (RPP) with leaders and mothers of a community organization, and a university in Southern California focused on designing PLLs in community spaces. We analyzed seven virtual participatory design sessions where we engaged 32 caregivers to design STEM learning experiences. Our data set also included interviews with a subset of 10 mothers to gain an in-depth understanding of their experiences with STEM learning at home and in the community. We used theoretical frameworks from funds of knowledge (Moll et al., 1992) and speculative futures (Lukens & DiSalvo, 2011) to guide our analysis and research questions. We offer design implications for STEM learning experiences that honor the ways Latina mothers conceptualize STEM learning, are grounded in the concrete ways they already facilitate STEM learning, and are informed by their ideas for STEM learning futures.

Theoretical Framework

Funds of knowledge

Funds of Knowledge (FoK) refers to families' strategic and cultural "bodies of knowledge and skills" accumulated over time and with their communities that are "essential for household or individual functioning and well being"

 © ISLS

(Moll et al., 1992, p. 133). The framework counters deficit thinking of linguistically, economically, and culturally diverse students and instead leverages the FoKs within diverse families and communities that are assets in supporting students' learning (Llopart & Esteban-Guitart, 2018). Across content domains, researchers have adopted FoK to align programs to families' values and practices and create more meaningful experiences for students (e.g., Olmedo, 1997; Riojas-Cortez & Bustos Flores, 2009). In K-12th grade STEM education, most recent studies using FoK have focused on curriculum development, improvement of teaching practices, and community-school connections (Denton & Borrego, 2021). Such approaches are crucial to address the systemic disadvantages underrepresented students undergo in the pursuit of STEM careers (Whitcomb & Sign, 2021). We aim to create community-home connections through designs that align with families' FoK and promote early STEM learning in out-of-school community spaces. We use FoK to identify the perceptions and values of Latina mothers and their family activities that support children's STEM learning.

Speculative futures

In the human-computer interaction literature, scholars describe the ways in which the act of creating design artifacts and envisioning those artifacts in an intended context is meaningful research of a speculative and desired future (Zimmerman & Forlizzi, 2014). Utilizing design as a reflective practice, the manner that a problem space is interpreted and framed by participants provides insight as to what the world can progress towards (Rittel & Webber, 1973; Schön, 1983). Lukens and Disalvo (2012) propose key characteristics of speculative design approaches which include projects that are future oriented, cross-disciplinary, and integrative. We build on a speculative future design framework to analyze the artifacts mothers created which not only focused on STEM learning principles but also the ecosystem within which these design ideas would be implemented in their neighborhoods. We intersect this lens with FoK to unveil the underlying perceptions, values, and assets that inform the design of playful learning landscapes.

Methods

Research-practice partnership

This project is part of a larger multi-year study to design playful learning landscapes with and for local community members using a research practice partnership (RPP) approach. The RPP involves partners from the university, the city, and nonprofit organizations. Our leading partner was a cross-sector community organization of caregivers, educators, and community leaders committed to enhancing early learning opportunities and outcomes for children in the local community. The local school district serves children who are predominantly Latine (80%), of low-income households (about 87%), and from families who speak Spanish at home (79%).

Participants

Participants were recruited with the help of the directors of the community organization. Participants were 32 caregivers of children enrolled in kindergarten through 12th grade and members of the organization. Latina mothers composed almost all of our participants (N= 31) and one participant was a Latino father. Our sample is primarily representative of Latina mothers' viewpoints and therefore we represent our findings as such. Participants were predominantly of immigrant backgrounds, mainly of Mexican descent, and Spanish-speaking.

Procedure

Between November 2020 and May 2021, we conducted seven monthly 2-hour codesign sessions over a video conferencing platform due to the COVID-19 pandemic. The virtual sessions consisted of whole group discussions and six breakout groups of 4-7 parents. Participants' attendance per session ranged from 72% to 97%, with most parents (81%) attending six or seven sessions. We also conducted 1-hour individual interviews with a subset of 10 mothers who volunteered. The design sessions and interviews were all facilitated in Spanish to allow for more comfortable and genuine discussions, with a translator present for non-Spanish speaking researchers. We compensated participants $50 for attendance to every 2-hour session and $25 for interviews.

Each codesign session was structured to facilitate three types of activities. The first two types were conducted in breakout groups and facilitated by Spanish speakers who were instructed on the activity goals prior to the session. The first was a reflective activity focused on eliciting prior experience and knowledge of the topic. For example, we used storytelling to learn about families' everyday experiences and practices centered on science and math learning across contexts. We asked questions such as, "*What are everyday science things you do as a family?*" and *"Tell us a story about grocery shopping with your family when you were little and now with your children."* The second type of activity was design-based where we asked mothers to use arts and crafts to create

low-fidelity mock-ups of the type of installations they would like to see in their community spaces that bridged their backgrounds and values with general learning principles (e.g., active, meaningful, joyful; Hirsh-Pasek et al., 2020) and practices and cross-cutting concepts that support STEM learning (e.g., making observations, asking questions, cause and effect; National Research Council, 2012). Finally, we concluded the sessions by sharing key themes from our small group discussions as a community.

The second codesign session focused on eliciting core values mothers wanted the installations to perpetuate for their community. First, mothers engaged in a reflective activity in breakout groups, where they shared photos of their community and gave stories of those spaces, described the characteristics of people or things in that space, the feelings evoked, and what they valued about those spaces. In those same groups, we then asked mothers to complete a mad-lib design activity that completes a statement on principles. The purpose of the task was to convert values into community design principles to serve as a foundation for future designs emerging from our partnership. The mad-lib was presented in Spanish and read:

> I would like for us to create something _ (a descriptive word)_ while upholding _ (value)__while making sure people who are __(characteristics)__ feel welcomed, and feel _(feeling)__while interacting with the playful learning landscape.

In the individual interviews, we aimed to gain a deeper understanding of families' STEM activities, and their perceptions and values on STEM learning. We asked questions on math and science such as, *"What themes or concepts do you relate to learning science,"* and *"What feelings do you associate with science and its learning?"* Furthermore, we inquired about science and math activities at home with questions like *"What type of activities do you and your family engage in at home related to science and math learning?*"

Data analysis

We video recorded, transcribed, and translated all sessions and interviews using software programs and Spanish speaking members of our team for reliability. We obtained a total of 47 recorded codesign sessions (~ 42 hours total) composed of whole group and breakout room discussions. For this study, we analyzed 24 codesign video sessions and all 10 interviews. The analyzed codesign sessions included at least two breakout videos of each of the seven sessions, with a focus on the first two sessions due to the emphasis on family practices. We analyzed the data in Spanish using two phases. First, four researchers approached the data with inductive thematic analysis (Guest et al., 2012). At this stage, four progressions of a codebook included codes of *Described Parental Roles*, *General Learning Values*, and *Doing STEM with Children*. In the second phase, three researchers reviewed the codebook in conversation with existing literature, a deductive process (Azungah, 2018) that primarily informed subcodes such as *Activity Transfer Across Settings* and *Cultural Artifacts* for the root code of *Doing STEM*.

Findings

We divide our findings into three parts. First, we describe how Latina mothers perceive STEM learning and its relation to values they want to instill in their children. Second, we illustrate the ways Latina mothers currently enact STEM learning experiences in the home. Third, we provide an overview of the imagined futures mothers wanted for STEM learning experiences for the children in their community through the designs they developed.

Latina Mothers' STEM perceptions and values

Perceptions

The mothers' perceptions of STEM learning were informed by school-based learning experiences: STEM learning experiences in their youth and their child's learning journey at school. When asked what math and science meant, mothers defined the "doing" of math and science under the academic lens of school, with math associated with skills such as recalling numbers and conducting operations while science was often associated with hands-on school experiments and projects. One mother stated, "*For example, for the kids to learn numbers. I would really like for designs to have numbers, and to have those [geometric] shapes. And for them to say on their own that 1+1 is 2.*" While mothers saw the importance of math and science as disciplines that are "*necessary for any career because in reality… in a job it is what is needed*", many admitted to a negative sentiment towards the field due to its difficulty or lack of experience in applying the disciplines beyond everyday practices. As one mother noted, "*Mathematics, it is a very important subject to which I have panicked about,*" despite describing the use of math when managing money everyday.

Yet mothers acknowledged that school-based or formal ways of learning were not the only way, nor the best, to learn these disciplines, "*I think that it would be very, very rewarding ... for children in these times to not see something repetitive in science, something boring ... They are very intelligent so if they do it in a more fun way they can obtain more... like deeper into something*." Furthermore, mothers envisioned STEM learning as a process to promote agency, intergenerational interactions, and fun in their child's learning experience; one mother mentioned, "*I would like us to create something fun… to promote learning and family bonding*."

Values

We observed five core values mothers defined and abided by when tasked to design STEM learning spaces: family unity, intergenerational learning, heritage, active citizenship, and *ganas* or a will to succeed. Family unity or a sense of togetherness through activities echoed the concept of *familismo* that represents interdependence, loyalty, and cooperation in Latine households and that places family at the core (Espinoza, 2010). Mothers extended *familismo* to a learning value of intergenerational learning, which they defined as experiences that promoted family learning regardless of age, such as between grandparents and grandchildren. Mothers wanted installations to represent their heritage, and allow for the opportunity to teach children about their culture, the history of their city, and for a majority of mothers, their homeland of Mexico.

Mothers voiced the value of active citizenship or giving back to the community under the premise of *respeto* and *bien educado*. These values consisted of cultivating positive relationships and acting "appropriately" to others (Espinoza, 2010). While this premise is often associated with the concept of "good behavior" (Valdés, 1996), the mothers oriented this concept of *respeto* and *bien educado* to active citizenship and defined ways they wanted their children to conduct positive actions for the benefit of their community and beyond their immediate family household. Additionally, most of our mothers model active citizenship to their children by being involved in grass-roots initiatives such as park reconstruction. One mother expressed:

> I am doing it for my children, I am doing it for the children, I am doing it for, wanting to leave a better future for them... At first I began to want to give my children values, even if it was to participate in church. Then at school and then at the community level.

Finally as mothers described what they wanted children to take away from these playful learning landscapes, they referred to the notion of *ganas*, that evokes the motivation and the will to overcome challenges. *Ganas* is often used to instill perseverance and confidence in order to believe one can succeed and be able to take actions toward success (Barrios Gutierrez, 2010). As one mother mentioned: "*Having two girls here in [city anonymized] has given me the opportunity to get involved in many [educational] programs so that they see that I am interested in their progression ... they are in a place where 'Si se puede' and 'Echarle ganas' [Give it all]."*

Mother-Child STEM activities

As mothers reflected on family activities associated with STEM learning, many described structured activities that entailed a prescribed approach or a clear end-goal as opposed to a discovery approach. Cultural game-based activities were the most prominent way that mothers facilitated STEM learning opportunities, such as *loteria* or *pirinola* games. Mothers described how actions required to play the game can develop and reinforce math skills such as recalling numbers or math operations like summation. For example, one mother stated:

> We try to find table games… that I used to play with my mother, my sisters. Like Juego de la Oca [Game of the Goose], Lotería [Bingo], Serpientes y Escaleras [Snakes and Ladders]. I would explain how to play them.... There is a game that I love; it has always fascinated me since I was little, the Basta one… I like it because we are learning, even if we think we are not. We put in a little bit of math, counting squares, counting the dots in the dice, and adding.

The quote above emphasizes how games are a cultural socialization practice that Latina mothers transmit to their children and are valuable due to the memories, enjoyment and connection between family members, and learning they facilitate. To further support their children's learning, mothers also demonstrated high agency in looking to community video platforms like Youtube and TikTok, afterschool programs, and school activities for inspiration to expand learning in the home. Mothers noticed the benefits of these platforms, "*My daughter, the little one, has a lot of that [behavior] of going to YouTube and doing many things*" and utilized the learning affordances that technology provides in scientific practice (Yip et al., 2014). Mothers reported how these resources promoted structured STEM learning activities at home like making slime, volcanoes, or crystals.

Despite the prominence of structured activities, mothers also viewed everyday practices as opportunities for STEM learning. Mothers actively connected math and science ideas to their daily actions like running and measurement of speed, daily practices like counting money or cooking, and utilized daily surroundings such as learning about ecosystems and plants at the park. Without using the specific terminology, mothers alluded to the teaching of various science *crosscutting concepts* and *practices* (as specified in the Next Generation Science Standards; National Research Council, 2012) as they conducted activities and catered discussions with their children. Cooking is a prominent family activity that supports the learning of practices like making observations of food texture or taste, and crosscutting concepts such as quantity, proportion, and numbers. One mother said, "*On the example of cooking, if you want to make cookies, you are going to use a certain amount of sugar and if you want twenty cookies, you are going to double the amount of sugar. Like the idea of proportion, but in this concept of science.*" Cooking at home which requires experimenting with recipes represent open-ended explorations as opposed to the prescribed nature of formal learning environments.

As mothers described their learning practices at home, they simultaneously revealed their approach to facilitate these learning opportunities by taking on co-learner roles and child-centered teaching. Despite having revealed negative sentiments or fear of not knowing enough about STEM, mothers often placed themselves as co-learners with their child and expressed a willingness to learn alongside their children. As a parent mentioned, "*Well, when they have any questions related to any of these [science or math] topics, I try to help them the best I can. If I don't have the answer, I go to Google and we look for it together and I learn at the same time.*" Mothers still viewed their participation in their child's learning as essential to teach kids how to navigate learning more so than teaching content "*because we ourselves are the teachers in which we are teaching them how to participate.*" Furthermore, mothers noticed that young children were naturally curious and were filled with questions about their world. Thus, they embraced this natural curiosity to promote child-centered ways of learning where the child was encouraged to think through a problem with the scaffolding and guidance of the parent. They did so by giving responsibilities to their children that required the use of STEM skills, such as collecting the right number of food items when cooking at home or shopping at a grocery store.

Imagined STEM learning experiences

Overall, in our design sessions caregivers came up with ideas that echo their values, existing practices, and perceptions of learning. In this section, we provide two illustrative examples that highlight key themes caregivers emphasized throughout our design sessions toward their imagined futures ideas for playful learning landscapes that promote STEM learning: sustainability and games.

Sustainability vignette

The third co-design session had mothers design an installation for their community with three constraints. Mothers were randomly assigned an object or place, a value, and a science practice (e.g. making observations, making predictions) or crosscutting concepts (e.g. patterns, cause and effect) to guide ideation. Mothers were provided with crafting materials, paper, and markers to create a visual representation of their idea at home.

One group was assigned the design constraints of a street as the place, intergenerational learning as their value, and scale/proportions as their science focus. Their design idea was centered around a community trash awareness activity that helped people learn about scale, proportion, and quantity. When sharing their idea, the mothers noted that the inspiration for their design was their observation of community members constantly throwing their trash on the streets and the desire for more civic responsibility among them, especially their children. The mothers explained that if the community were more conscious about the impact of waste habits, trash would be disposed of and placed in the appropriate waste bins. One caregiver noted, *"like a community we could come together or as families…we could come together as one to maintain our streets clean and we can teach our kids how to properly dispose of their trash."*

Despite the focus on the intergenerational value where they designed an opportunity to teach their children about wasteful habits, this idea also echoes the value of active citizenship where mothers want their children to be positive members of their community. The group resorted to varied math measurement systems to measure waste in a way that would encourage comparing trash weights across streets, including a height or measurement feature across the bins. Thus we note that they viewed mathematics as a mediator for community action and promotion of active citizenship. Mothers explained that the design would motivate children to separate the trash into recyclable, non-recyclable, organic, and inorganic trash to teach children how to differentiate between the trash contents. Related to the community value of intergenerational learning, this design idea shows how it would be meaningful to the community to improve the neighborhood as a collective activity that includes people from all ages, and through an active manner that involves collecting, separating based on observations of the characteristics of items, and measuring.

Gaming Vignette

Just as game-based activities were a primary mechanism to learn STEM in the household, mothers designed a plethora of ideas for games that could promote STEM learning with their children in their community. In another case, we saw how mothers' prior experiences in STEM learning and perceptions of what counts as STEM played a key role in the majority of brainstormed activities. These games included competitive and active versions of card games, puzzles, memory games, and physical challenges that would test or familiarize children to fundamental skills or content. Among these game-based ideas, Hopscotch was prominent throughout the codesign sessions as mothers shared that they played Hopscotch to actively learn colors, shapes, and numbers.

> Juego de avión [Hopscotch] is what we call it in Mexico and I think the children are playing it here [United States]. They are having fun and they are also learning mathematics because they are jumping … to number ten and … you can also ask what number you stayed at.

Mothers redesigned Hopscotch to include prompts or questions that would reinforce children's math and science skills, including jumping to a shape of a certain color or size or integrating math questions. While these ideas were grounded in mothers' experiences, they used their values as a guide to modify those experiences towards a specific learning goal. In this example, intergenerational learning informed the manner in which parents modified Hopscotch in order to share a piece of their past with their children. Family unity was also a prominent value as mothers proposed to infuse hopscotch into everyday, family spaces such as integrating this activity into the sidewalks that families use to walk children to school.

Discussion

Our findings reveal how mothers approach and conduct early STEM learning as informed by cultural values and evolving perceptions of what counts as STEM. The FoK lens unveiled existing practices and knowledge that mothers contributed to early STEM learning. Mothers largely refer to school-based content for the "what" of STEM such as math operations, and utilize child-centered approaches for impactful learning. We saw mothers encourage the transfer of activities from school or online platforms into the home to support their child's natural curiosities and take on co-learner approaches despite their lack of confidence in the topic. Additionally, mothers leveraged everyday practices such as cooking or grocery shopping to incorporate STEM concepts relevant to a child's daily life. This is essential for youth to become full participants in the field (Yip et al., 2012) and mothers are a clear resource to promote relevance. As such, their cultural values represent the deeper lessons and morals they want to instill in their children, thus viewing STEM learning as an opportunity to promote family unity, intergenerational learning, heritage, active citizenship, and *ganas*. Instilling these values in the design of future STEM learning experiences symbolizes the desired or speculative future mothers wish for their children.

Implications

Our analysis of mother's perceptions shed light on research studies of Latine parent perceptions in early STEM. Most research on Latine parents' perceptions and involvement have focused on general education (Valdes, 1996; Tinkler, 2002) and those focused on STEM subjects have yet to explore current family practices for young age groups (Deleon, 2018; Hernandez et al., 2016). We build on this past work through an FoK and speculative futures lens to show how mothers immediately resorted to school-based notions of what counts as science and math, however, through further prompting and designing for speculative futures in community, they revealed the need for and practice of informal, everyday approaches that instill values in their children. This aligns with Latine families' notion of education, where academic goals and morality are seen as interconnected and not mutually exclusive learning experiences (Halgunseth et al., 2006).

FoK is a lens that reveals opportunities for designers to actively design for inclusion that is built on families' values and the ways that diverse parents support children's learning. Understanding the cultural knowledge of underrepresented families when designing for spaces that are not historically inclusive of diverse practices is an important step towards validating and leveraging their forms of learning (Aschbacher et al., 2010). For example, *familismo* is critical in the development of STEM identities of Latine students, as they often rely on friends and family as a source of aspirational capital (Matos, 2021). Yet such value contradicts values upheld by academic institutions which embrace the US culture of independence and self sufficiency (Espinoza, 2010; Rodriguez, 2021). In the context of designing playful learning landscapes, the focus on FoK and cultural assets allowed us to reimagine ways that STEM learning can embrace community values explicitly using math and science learning opportunities. Through the lens of speculative futures, this awareness resulted in design ideas

such as an activity that focuses on environmental sustainability through the measurement of community waste. The idea was meant to take advantage of moments of family unity and togetherness, such as walking around the community or waiting for a bus stop, to encourage active citizenship through math.

Involving caregivers in the design of STEM learning installations in their community ensures that ideas are grounded in the lived experience of families who will use them. Designing from an approach that builds on families' experiences and incorporates parents in the design process can result in greater usability of artifacts, more rich learning experiences for children facilitated by family members, and families feeling greater ownership of the artifacts resulting in their long-term sustainability. In this paper, we have shown that Latine mothers' values and practices are reflected in their design ideas, and as such the contributions of diverse parents in design efforts can serve as a mechanism through which researchers and practitioners connect and enhance children's learning experiences across home, school, and other community spaces. This contributes to ongoing research on the development of meaningful STEM experiences that is inclusive of different cultural communities through community-based informal learning (Clegg et al., 2014; Santo et al., 2019). We extend this body of research with the perspective of Latina mothers' practices for early STEM education through play.

Limitations and Further Research

One limitation to our research are the missing perspectives of Latino fathers in the design of STEM learning artifacts. Prior research suggests that mothers and fathers in Latine families do not always socialize their children in the same ways and that children's responses to a specific practice sometimes vary depending on which parent it involves (e.g., Kuhns & Cabrera, 2020). Thus, future research in STEM learning should include fathers and potentially extended family members (e.g., grandparents, aunts or uncles, godparents) that might have an additional contribution to the learning experiences of underrepresented young children. Another limitation in our study is that our team is currently working on the final designs of playful learning landscapes and as such we have not yet examined the extent to which families' cultural knowledge is maintained and incorporated in the final artifacts resulting from the elaboration process between community members and the research team in RPP work. Our next steps are to evaluate the alignment between families' cultural assets and learning principles in the final artifacts and whether installing those artifacts in community spaces result in greater opportunities for families to engage in STEM learning interactions.

The sensitive nature of feedback as a sequential phenomenon

Oskar Lindwall, University of Gothenburg, oskar.lindwall@gu.se
Gustav Lymer, Stockholm University, gustav.lymer@edu.su.se
Jonas Ivarsson, University of Gothenburg, jonas.ivarsson@gu.se

Abstract: Social actions such as advice and feedback are sensitive actions, often triggering emotional and defensive reactions. Moreover, just how to understand and describe such actions – for instance, as "constructive advice", "complaints", or even "insults" – is a potential point of contention and dispute for participants in interaction. Based on a corpus of video data from higher education, our research aims to develop a conceptual and empirically grounded understanding of the social organization of feedback. This study investigates how students and teachers orient towards the sensitive nature of feedback in critique sessions in architectural education. With a few examples from the data set, the study focuses on three issues: a) the sequential organization of feedback; b) the grounds for two (conflicting) orientations to the feedback; and c) the ongoing instructional work to make the students hear the feedback in the "right" way.

Introduction

Numerous studies and meta-studies show the massive presence, relevance, and diversity of feedback in higher education – from formative assessments of completed course work to responsive instructions produced during the performance of tasks (e.g., Evans, 2013; Hattie & Timperley, 2007). Feedback is used to point out mistakes or misconceptions, provide advice on how an assignment could be further improved or differently approached, and strengthen the students' ability to monitor their own performance. While the central role of feedback is agreed upon, not all feedback is equally effective in terms of learning. In a review of research on feedback, Hattie and Timperley (2007) maintain that praise is ineffective "because it contains such little learning related information" (p 86). They further argue that feedback seems to be "more effective when there are perceived low rather than high levels of threat to self-esteem, presumably because low-threat conditions allow attention to be paid to the feedback" (ibid.).

Although claims by Hattie and Timperley could be problematized on both empirical and conceptual grounds, they highlight a persistent challenge for university teachers: how to point out mistakes and deliver advice that is beneficial to student learning in ways that pose little 'threat' to students. Students and teachers tend to report different perspectives on what feedback is or should consist of (see Carless, 2006; Henderson et al., 2019). It is often possible to understand feedback, advice, or critical remarks in different ways. What the teachers perceive to be constructive feedback, the students might hear simply as complaints. This tension is not limited to higher education: feedback, advice, and similar social actions are delicate matters in mundane and institutional settings (Sutton et al., 2012).

When locating feedback as a critical activity within many educational settings, we see a need to enrich the view on what this notion might encompass. This study, therefore, takes an interest in the delicate, ambiguous, and potentially contentious nature of critical feedback and how this delicacy is constituted and handled in interaction. We have examined a larger corpus of recordings of critique sessions in architecture education with an analytical starting point in ethnomethodology and conversation analysis (Garfinkel & Sacks, 1970). To develop our line of argument, we will address a) the sensitive nature of feedback as a *sequential* phenomenon; b) the grounds for two potentially conflicting *orientations* to feedback; and c) the ongoing *instructional work* designed to make students hear and understand feedback in the "proper" way.

Background

Before turning to the empirical part of the study, we outline some prior research tied to the interactional phenomena and context of the study. The first section summarizes some findings on the social organization of feedback, advice, and critique, and more specifically, studies that investigate the sensitive and potentially problematic aspects of this type of interaction. The second section concerns the context of the study, and briefly discusses prior research on 'critique sessions' in architecture education. As the term critique session implies, and the existing literature demonstrates, such educational arrangements are useful settings for investigating *critical* feedback and how teachers and students orient to its sensitive nature.

 © ISLS

The interactional organization of feedback and advice

The problematic and ambiguous character of critical feedback is reflected in the English language (as well as other languages). As a verb, 'critique' could mean to "evaluate (a theory or practice) in a detailed and analytical way", but also to "indicate the faults of (someone or something) in a disapproving way" (Oxford Dictionary of English). Delivering 'constructive criticism' might have positive connotations, but 'being criticised' seldom does; and although 'complaining' is regularly understood to be essentially different from 'giving advice,' it is often hard to determine whether an utterance removed from its natural context is advising, critiquing, complaining, or something else. Whether an utterance is understood to be offering advice or making a complaint is tied to particular occasions, and its sense might be perceived differently by speakers and recipients (Heritage & Sefi, 1992).

Actions are also reflexively tied to activities and membership categories (Sacks, 1992). A remark on the speed of a driver that is uncontroversial during a driving lesson, has the potential of becoming provocative when it is said by a fellow passenger. During a driving lesson, the remarks, directives, and advice from the traffic instructor are relevantly understood in terms of teaching and learning. When fellow passengers comment on the speed or proximity to the roadside, this might be heard as a negative remark on the driving. As noted by Heinemann and Traverso (2008), speakers seldom characterize what they are doing as complaining, but instead use "less negatively valenced labels such as 'criticizing,' 'troubles-telling' or even 'factually reporting'" (p. 2381). Nevertheless, the insurance that the passenger is 'just telling' does not necessarily lead the driver to hear anything but a 'complaint' from a 'back-seat driver.' As Edwards (2005) surmises, "'complaining' [and we might add, 'critique' and 'feedback'] is a defeasible vernacular category with normative oriented-to properties and consequences" (p. 7)

In educational settings, where feedback and critical advice from teachers are expected features of educational exchanges, one might think that the sensitive aspect of feedback would be absent. As observed in previous research on feedback in higher education (Vevhiläinen, 2009), however, the educational context per se does not remove the sensitive nature of feedback. When a teacher suggests that something could be done in a different way – for instance, that the introduction of a manuscript could be differently organized – it could potentially be heard by the student as saying that the introduction is not good enough, or that the student has failed to live up to the relevant standards. It is therefore common that teachers orient towards feedback that potentially involves negative assessment as socially problematic (Skovholt, 2018). As testified by the literature on architectural critiques, moreover, students sometimes experience that feedback is more closely tied to power and authority than to learning and development.

Critique sessions in architecture education

All over the world, students of architecture traditionally spend much of their time working with models, sketches, and plans in different kind of design-projects – sometimes alone, at other times collaborating in small groups (Schön, 1983). At the end of a course, students and their projects are regularly assessed and evaluated. Reflecting the project-based structure of the education, as well as the complexity and multifaceted nature of the domain, assessments such as written tests are commonly put back in flavor of what is variously called *design reviews*, *juries, dialogues, critiques*, or *crits*. Design reviews typically begin with students presenting their projects to an audience of staff members, professional architects, and peers (e.g., Lymer, Ivarsson & Lindwall, 2009; Lymer, Lindwall & Ivarsson, 2011; Webster, 2005, 2007). After the presentation, staff members and invited professionals criticize, comment on, and discuss the students' work, elaborating on the strengths as well as the weaknesses of the presented projects.

When asked, students and staff members often highlight that design reviews provide students opportunities to display their work and to articulate their ideas, to receive formative feedback from teachers and peers, and to critically reflect central issues, and to improve and progress in their work (Smith 2021). Even if the strengths of design reviews are brought forward, however, students as well as staff frequently display mixed feelings about these events. As noted by Webster (2007), for instance, it is not uncommon for "students to describe the purpose of design juries as an occasion for both individual learning and the collective celebration of student achievements while at the same time recalling their own experiences of design juries as profoundly de-motivating and competitive." (p. 287). Other students express more reproving attitudes towards the design reviews, describing them "as an ordeal devised by tutors to leave them feeling as though they have been 'undressed in public'" (Doidge, Sara & Pamell, 2000, s. vii).

With titles such as "Design juries on trial" (Anthony, 1991), "Judging juries" (Anthony, 1989), "Reviewing the review" (Wilkin, 2000), and "Critiquing 'Critiques'" (Dannels & Norris Martin, 2008) several studies of design reviews critically assess and evaluate the educational format. Reporting on a one-year ethnographic study at a British school of education, for instance, Webster maintains that the design reviews mainly

are events where "staff uses their power to coerce students into reproducing staff-centered constructions of architectural habitus" (2005, p. 265). She further argues that the practice of critique itself is replete with structural features working against student learning. In light of this argument, "the continuing use of the architectural review is questioned" (ibid.). In a later study based on the same material, Webster (2007) draws on Foucault to discuss "the analytics of power" and the "startling schism between the official, or declared, intentions of the critics and their actions" (p. 24). From this analysis, Webster concludes that the design review should be "replaced by a new set of pedagogic events that are carefully constructed to support student learning" (p. 21). Other researchers, while acknowledging the problems with the design reviews, take a less radical approach and point to the need of "feedback literacy" among students and teachers (Smith, 2021).

Theory and methods

In this study, and in contrast to some of the research outlined in the previous section, we are less interested in evaluating or critiquing the educational format, as in explicating the local and situated organizations that occasions the sensitive or contentious features of feedback. Prior studies that have investigated these features have drawn on existing models and theories from sociology and social psychology, and conceptualizing the sensitive nature of feedback in terms of face-work (Goffman, 1955), politeness (Brown & Levinson, 1987), and motivation (Swann, 1990). With an analytical starting point in ethnomethodology and conversation analysis (Garfinkel & Sacks, 1970), our interest is instead directed to the endogenous organization of social actions, and how members continually display their understanding of and orientation to prior actions as a constitutive part of this organization.

As repeatedly demonstrated in conversation analytic studies, social actions have a sequential organization; this means that each turn-at-talk displays an 'analysis' of the previous, which may then be either ratified or 'repaired' in subsequent contributions. This, in turn, provides us as researchers the material for our 'second-order' analysis – if the members sequentially display their understanding to each other, they do so for us as professional analysts as well (Lindwall, Lymer, & Greiffenhangen, 2015; Sacks, Schegloff and Jefferson; 1974). This sequentially based interactional conception of participant orientations provides a powerful analytic tool to ground claims that participants in a particular activity can be described as, for instance, orienting towards aspects of feedback as 'delicate' or 'sensitive'. Likewise, an analysis of resistance and/or dispute in relation to feedback interactions can be grounded in the sequential, turn-by-turn achievement of shared, contested or negotiated understandings.

In conversation analysis, the notion of "sequence organization" refers to the organization of meaningful courses of action enacted through turns-at-talk and embodied practices such as head nods, gestures, and shifts in posture (Schegloff, 2007). In order to follow and to be part of a meaningful interactional exchange, members need to monitor and analyze talk and embodied practices so as to understand what other members are doing and in order to respond in appropriate and coherent ways. The most basic sequential organization is the adjacency pair, which is a unit consisting of two actions produced by different speakers, and where one of the actions initiate the exchange, whereas the next action responds to the first. Typical examples of adjacency pairs include greetings ("Hello", "Hi") and question-answers ("what time is it?", "five a clock?"). In feedback interactions, more complex sequences emerge. Just as with adjacency pairs, however, analytic attention is devoted to examining actions and their responses, along with the ensuing sequences.

The study is part of a larger project where we investigate the sensitive nature of feedback across different settings, including text supervision in social science and 'debriefings' in martime and medical education. The examples presented in this study is drawn from a corpus of 70 hours of video material of critique sessions in architecture education. The recordings were made during a period of four months at a Swedish school of architecture. In total, 159 critique sessions have been video recorded, ranging in length from 10 minutes up to one hour. In the present paper, a highly selective approach is taken, presenting two extracts of interaction as illustrative examples of the issues under discussion. The episodes have been transcribed following the conventions developed in conversation analysis (e.g., Jefferson, 1984). In the transcripts, pauses are represented as numbers of seconds within brackets, with (.) indicating micro pauses. Co-occurring talk is horizontally aligned, with square brackets marking the onset of overlap. Extended vowel sounds are marked with colons, as in e:::h; >talk< indicates that it was delivered more rapidly than the surrounding talk, and <talk> that it was delivered more slowly. The original material is in Swedish, but given the limited space, only the English translations are offered here. For the same reason, actions such as gestures, head nods, and posture are excluded from the transcripts.

Results

Feedback and sequence organization

By examining the video recorded material, and returning to the notion of sequence organization, it is clear that feedback is not constituted by one specific type of initiating action with its corresponding next; feedback sequences do not constitute a particular form of adjacency pairs. The feedback provided by instructors and professional architects in the critique sessions take many forms and shapes; among the common variants, we find assessments ("this is a beautiful solution"), suggestions ("perhaps you could have used marble as the base"), questions ("what was the main concept with this floor plan?"), and directives ("do not read the presentation, but speak freely instead").

A first issue for students is whether they should explicitly respond to the feedback or not. This issue turns on the shifting and ambiguous addressivity of critic's talk – and its 'split audience design'. On the one hand, the critique is addressed to the group of students responsible for the design. Also present, however, are the students' peers from the same class. In an important sense then, the feedback is at the same time produced to be heard by a larger audience of students. During the course of a session, the relative emphasis put on addressing the particular group, or addressing the audience as a whole tends to vary. The critic might move from asking the responsible students a series of questions about the design, to elaborating on more general concerns. Even when doing the latter, however, the particular design proposal is often explicitly used as an example. This generates an interactionally difficult situation for students, in terms of the relevance of responding to feedback.

If a first issue for students is when to respond, a second issue is how responses should be designed. Since conversational exchanges are produced sequentially through a 'paired' structure, which includes expansions to the 'base-pair', the students need to produce a next action that fits the first for the interaction to be coherent. A request can both be met with acceptance and rejection, but if someone responds with a greeting it could potentially signal some trouble of hearing or understanding. In the design reviews, students typically respond to initiating actions with "type-conforming" (Raymond, 2003) nexts; i.e., questions are responded to by answers or accounts, suggestions with acceptance or rejection, and assessments with acknowledgement or perhaps second assessments.

Going back to the introduction, however, feedback in its various forms have the potential to be understood in different ways. Regardless of the form of the criticism – whether it is produced as questions, reminders, or assessments – it could be heard as doing 'complaining' rather than 'constructive advice'. Given that interaction is sequentially ordered, moreover, these understandings are displayed in and through the students' responses. When advice is is met by "I am sorry I made these mistakes", moreover, the response is not only doing an excuse, it also shows that the student heard a complaint in the previous utterance. In our data, such ascriptions are treated as problematic by instructors and invited professionals, and they typically engage in attempts to 'repair' the students displayed understanding of feedback as complaints.

'Counter complaints' is another next action produced by students which turns the interaction away from issues of learning and constructive advice towards issues of guilt and blame for having done something wrong. Excerpt 1 is a case in point. Before the episode, the students had presented a design proposal which include a hotel and a restaurant. One of the things that the instructor raises in relation to this proposal is the size of the ventilation shaft. When the episode in Excerpt 1 begins, the critic has already told the students that the ventilation shaft needs to be much larger, and he concludes by summarizing this point in the first three lines of the transcript.

Excerpt 1

```
01 KENT: what one has to show when making hotel and restaurant in this way (.) you have to
02       think like something goes up and something also goes down (.) we recycle air (.) and
03       things like that=
04 Per:  =it had been good if you had told these things us when we asked you
05       [during the process]
06 KENT: [yea but you have  ] to arrive at that point in the drawings (.) we can't
07       tell you everything from day one you know cause then (.) you'll (.)
08       collapse in-=
09 Dan:  =but [we   ] have had            [just] that discussion with you actually
10 KENT:      [yeah ]                     [yeah]
11 Dan:  =if one should be strict (.) and we didn't get any measurements,
12 KENT: yeah
13 Dan:  it's very hard when you say (.) that yea it demands very much  [space]
14 KENT:                                                                [yeah ]
15       but [then I say that now         ]
16 Dan:      [yea and then it's like that ] aha then we asked like this y'know
```

 © ISLS

In the beginning of the episode, the critic turns from looking at the plans to the audience of peer students when saying that "one has to show" (line 01 and Figure 1). The gaze and the posture, together with the use of a generic one (sv. *man*), marks the utterance as addressed to all the students rather than just those responsible for the project. When shifting from "one" to "you" (sv. *ni*) in "so you have to think like" (403), the critic is still looking at the audience, and the utterance can therefore be relevantly heard as still addressing a generic recipient rather than pointing out those who had produced the design proposal. Understood in this way, the comment is not just about this specific project, but something that all aspiring architects have to think about. This kind of hearing would also constitute a case of 'formative' assessment, where the comments grounded in the current example occasions larger issues and contexts not yet encountered. It is something to be heeded by all participants, not just the group under scrutiny.

The discussion that ensues, however, makes evident that the presenting students hear the critic differently. The comment about missing air ducts is treated as a 'summative' assessment of the presented design and not just a relevant consideration for anyone designing a hotel or restaurant. The missing feature is thereby understood as a flaw in the design. While hearing the critics remark in this way, the students are unwilling to take the full blame. By topicalizing a prior discussion about ventilation when the critic was acting as teacher, Per and Dan jointly formulate a counter-complaint targeting the lack of prior advice. The organization of this interchange is more complex than the examples of adjacency pairs initially offered in this section. For the purposes here, however, the most relevant thing is that the students, through their response, treat the feedback as a complaint about the design and by implication their performance. Heard as such, the critic's comments are relevantly countered based on what happened during the process.

In his response to the students' counter complaint, the critic addresses both the grounds of the counter-complaint and dismissing the relevancy of it in the current situation: he talks about the conditions of giving feedback – that it is impossible to provide all the relevant information at once – and that he frames the feedback as advice that is offered "now" (line 15), thereby accentuating the forward-looking aspect of the design reviews. The comments are thereby framed as lessons to be learned from the design review rather than evaluations of previous performance.

Two orientations

Design reviews have both *summative* and *formative* functions. On the one hand, the activities provide evaluations and gradings on students and their projects. On the other hand, they are instructional activities, aimed at furnishing and scaffolding the learning and development of disciplinary skills – for the students responsible for the project, but also for the peers acting as an audience to the critique. In Excerpt 1, like in many other episodes in our material, there is a tension between how the students and the critics approach the design review. In this example, the students orient towards the summative rather than the formative aspects of the critics' comments – it is about *their* design and what *they* should have done. The manifest orientation of the critic is different: he uses the students' design proposal to make general and instructive comments to the audience of students in the room, not just the ones that presented their project. The core issue is what the design proposal in front of him can teach all students present in the room.

From the latter orientation, the students 'misunderstand' the remarks by responding to them as primarily having a summative and retrospective character. Although he initially addresses the issue of the 'missing advice', and the rationale for why he did not do what the students wanted him to do, he then turns to the ways in which the comments should be heard – that it is the lesson that is important, not when this lesson is learned. For students and critics alike, however, the situation is inherently unstable. The students are sometimes expected to provide accounts and explain their choices, whereas at other times, such explanations are treated as interferences. This means that from one situation to a next, the activity could turn from an assessment of a particular project to a 'lecture' where the work of the students is merely used as an example of some more general issue.

The two orientations can partly be understood with reference to the members' different relation to the design proposal. The students have spent several weeks, working hard to produce a strong design proposal that is now to be assessed and discussed by a professional architect. They are there to present and to some extent defend their proposal, and it might therefore be hard to switch to a hearing where the proposal is just being used as an example. For the critic, in contrast, the proposal is just one of several proposals that are being discussed that day, and the point is not just to give feedback to the students who produced the proposal but also to use the occasion to lecture about general issues central to architectural practice.

In other design reviews, the issue of 'fairness' is raised by students: 'how come that the critic raised a problem with our design proposal and not with the subsequent proposal which had the same manifest problem?' From the point of giving advice to the whole group of attending students, however, the very fact that they have already dealt with the issue is a reason for not dealing with it again. There are countless issues that could

potentially be raised during the design review and time is limited so there might be plenty of reasons to not bring the same issue up again. Still, the design review is also an occasion for assessment, and as such, it is understandable that the students orient to quality – the strengths and weaknesses of design proposals – in relative terms.

Continuous interactional work

A central point in Mehan's (1979) classic study "learning lessons" is that pupils in the lower grades are not just learning the content of the lessons – they are learning 'lessons' in the sense of learning the endogenous organization of the lesson, how to appropriately take the turn, respond to a question, hear and understand what an appropriate question sounds like et cetera (see also Macbeth, 2003). In a parallel way, the students (and in a different way, the critics) taking part of the design review are learning how to hear and understand the critique. Although there are separate occasions where the format of the design reviews is discussed, including how one gives and receives critique, the instruction on how the critique should be heard is ongoing throughout the actual critique sessions. As already pointed out, the situation is in a sense inherently unstable where the students sometimes are expected to give accounts for their decisions and at other times they are just supposed to listen.

In Excerpt 1, this could be seen in how the critic attempts to end the issue of 'who's to blame', and the associated retrospective orientation, by pointing out that the main thing is what is said here and now. During this sequence, moreover, the critic breaks in with (10, 14, 16) minimal responses in overlap, thereby signaling a move towards a closing of the sequence. This orientation towards the ways in which the comments are heard and responded to is also displayed through bodily means. The critic might for instance give a thumbs up, showing a positive stance towards the effort that the students have put in their work, at the same time as he looks down (Figure 1, left) or turn towards their design proposal, thereby signaling a readiness to move on to the next thing; or use a gesture to the effect that an account is not necessary (Figure 1, right).

Figure 1. To the left, the critic gives a thumbs up while looking away and then turning to the poster. To the right, the critic makes a gesture to the effect that further explanations are not necessary.

On some occasions the purpose of the critique, and how the critique should be heard and understood are formulated explicitly. Excerpt 2 takes place approximately a minute after Excerpt 1, and during this time, the issue has centered on what was done in the design studio, and what teachers could or could not be expected to do – especially whether and to what extent the teachers should or could provide answers to the students' detailed questions about their projects. At this point, the critic breaks in by formulating the activity of critique, which is heard and treated as closing this particular issue, and a move to the next.

```
Excerpt 2
01 KENT:  but take don't take it like the correct answer don't take critique in that way.
02        like we have taken apartments but but (.) bring with you the knowledge y'know
03        instead tha- better (.) uhm it's only that you can do this (.) you can think like
04        that when you redesign the house.
```

In Excerpt 2, the critic is explicitly correcting the students' responses to the critique and previous comments and proposes how they should understand the critique instead. According to this proposal, it is not so much about the mistakes made – that the students "have taken apartments" – but that they should bring with them "a knowledge." This formulation of the activity provides a clarification of how critique should be understood: that they should listen to critique as suggestions on what they "can do" and "can think," rather than about the things that actually have or have not been done.

Discussion

A central aim of the project is to use the empirical results to discuss, problematize, and expand the theoretical literature on feedback. Schegloff (1996, p. 164) has argued that the disciplined study of particular actions is missing in much of the social scientific discourse. He adds that sometimes "they appear to be virtually epiphenomenal expressions of 'underlying' factors, processes, and variables – norms, rationality, conformity, power, system functions, and the like, but important largely as the public face, the accessible display and indicator, of those underlying forces." This characterization is also applicable to theories that set out to investigate the sensitive nature of feedback. Although theories of facework, politeness, and self-enhancement have some explanatory value, our video recorded material suggest that such matters are secondary to more manifest and pedagogically relevant concerns. The point of the infamous 'sandwhich model of feedback', where constructive or critical feedback are embedded in positive comments delivered before and after the critique, might not be to act or come across as nice or polite, as often is claimed; but to make the student hear, understand, and respond to the comments as educationally relevant feedback and not compliants. We therefore believe that a reconceptualization of feedback, grounded in the in vivo orientations of the participants and sequential organization of the interaction, would be a significant conceptual expansion of and a potential alternative to current theories and models.

A prominent strand in educational research on feedback is a 'remedial' agenda, embodied both in the efforts to develop optimal ways of delivering feedback, and in the fostering of student and teacher competencies to relevantly understand the significance of instructional feedback. Although there are many mertis to such appcoaches, it is also important to understand how the ambiguous nature of critique is not limited to educational situations and that the very *possibility* of hearing an advice in a negative way might be without remedy. At the same time, it is important to understand that that an emotional and defensive reaction to critique cannot be discarded simply as a 'misunderstanding'. The possibility of emotional and defensive responses are to no small degree provided by the interactional nature of feedback activities; "hearing it the wrong way" is one in a range of accountably rational ways in which any instantiation of feedback can be heard. There are of course strong reasons why we should aim for a better 'climate' in educational setting and there are clearly benefits of fostering different forms of 'feedback literacies'. Nevertheless there are also reasons to closely investigate the 'endogenous pedagogies' of settings where critical feedback is a constituve part, and to connect our understanding of feedback with our understanding of how critique is produced and received in other mundane and institutional settings.

It might be possible to read Hattie and Timperley's (2007) conclusions regarding "low levels of threat" through an interactional lens, as saying that feedback should ideally be produced and heard as e.g., 'constructive criticism', rather than 'complaints'. As Edwards (2005) notes, however, these lables are defeasible vernacular categories "with normative, oriented-to properties and consequences" (p. 7). The defeasibility of categorizations point to the fact that "the same stretch of talk might […] be glossed as criticism or accusation, troubles-telling, or merely story-telling or factual reportage, which are potentially relevant alternatives for speakers when characterizing their activities" (ibid). This means that what levels of perceived threat might be ascribed to a particular instance of feedback cannot be located solely in the production features of the feedback turns. As our analyses illustrate,moreover, orientations to 'threat' is a sequential phenomenon, developed incrementally through student responses as much as the design of the feedback itself. In some cases, something akin to 'perceived threat to self-esteem' is even explicitly addressed in critics' remarks regarding 'how to take critique'. Excerpt 2 can be read as an exhortation to pay attention to the feedback, instead of responding to its summative elements. The important thing is, again, that these are sequential phenomena with an inherent openness to them.

Although the problem of how critique is heard or understood is inherently interactional, it is also connected to whatever resources one has to make sense of the critique. In this respect we could observe that students became accustomed to feedback as something prospective and formative as they progressed through their education. This form of hearing is thus itself a lesson to be learned where one adjusts to the professional expectations at work. Nevertheless, there is still room for instructions in the communication. Whenever there are shifts between retrospective assessments and prospective lecturing these shifts can be more or less clearly communicated. The mitigation of what is perceived as threatening to students could reasonably be managed by critics overtly describing what they aim to accomplish with specific comments. We certainly see that this is happening in our materials (and it is partly present in the example as well). For the future however, this topic is worth further treatment.

Abstract: Assessing individual students' learning progress is a key task in teachers' everyday life, which allows them to infer students' zone of proximal development and offer adaptive support. Because of the complexity of the diagnosing in classroom settings, training pre-service teachers using standardized settings with adaptive support seems desirable. However, to design effective learning environments and offer adaptive support, a deep understanding of the diagnostic process is necessary. Thus, the present study investigates the diagnostic process of pre-service teachers in a video-based simulation by examining the occurrence of diagnostic activities and their relation to relevant learner prerequisites and learners' diagnostic outcome. Findings suggest that describing and evaluating simulated students' learning process is sufficient for an accurate diagnosis. However, only students with higher professional knowledge made further-reaching pedagogical decisions. Moreover, we identified three profiles representing pre-service teachers' distinct engagement in diagnostic activities and suggest the implantation of different types of scaffolding.

Introduction

Assessing individual students' learning progress is a key task in teachers' everyday life. For instance, teachers gather information about students' current understanding of a concept or method, about students' learning prerequisites in general, or about their current learning processes. This information enables teachers to infer students' learning status and their zone of proximal development (Vygotsky, 1980), which in turn allows them to make adaptive pedagogical decisions, for instance, by adapting the conduct of a lesson, by scaffolding individual students' learning processes (Reiser & Tabak, 2014; Wood et al., 1976), or by giving individual recommendations for further training (e.g., Südkamp et al., 2012; Urhahne & Wijnia, 2021). Thus, teachers' ability to accurately diagnose students' learning progress is vital for teaching quality and has been shown to positively impact student learning (e.g., Brunner et al., 2013; van de Pol et al., 2013). Yet, prior research has also shown that teachers in general and novice teachers in particular, often struggle when diagnosing (e.g., Urhahne & Wijnia, 2021).

Based on novice teachers' struggles and their so-called practice shock, there has been a call for a 'practice turn' in teacher education. Consequently, researchers as well as practitioners have emphasized the need to implement authentic learning opportunities, often called approximations of practice (Grossman et al., 2009), for pre-service teachers in higher education. Simulations have been proposed as one such means, as they allow to offer a balance between cognitive demand and authenticity (Codreanu et al., 2020). The general idea of simulations is that learners can engage in authentic situations that represent real world demands and by that develop complex skills, which are based on and at the same time exceed their prior knowledge acquired during their studies. Moreover, such simulations allow to adapt the complexity and course of the simulation based on learners' individual learner prerequisites and processes. Thus, simulations allow for individualizing learning processes and for implementing adaptive learner support, which allows increased learning effects (Chernikova, Heitzmann, Stadler, et al., 2020; Radkowitsch et al., 2021). Although adaptivity as a core feature of learning environments is not a new concept (see Plass & Pawar, 2020) and contingency as a key aspect of scaffolding is based on adaptivity, implementing adaptive support in scalable learning environments such as simulations requires a deep understanding of i) participants' learner prerequisites (e.g., Kramer et al., 2021) and ii) participants' cognitive processes within such learning environments (Stadler et al., 2019). With respect to diagnosing, most research has focused on outcomes of a diagnostic process (mostly diagnostic accuracy) (Urhahne & Wijnia, 2021) and the influence of various covariates such as content knowledge (CK) or pedagogical content knowledge (PCK) (e.g., Brunner et al., 2013; Kramer et al., 2021). However, participants' diagnostic process in such simulations, differences between their individual diagnostic process as well as the relation to various prerequisites are not yet well understood.

 © ISLS

To address this gap in prior research, this paper examines a video-based simulation for diagnostic skills for mathematics teacher education and investigates i) how pre-service teachers' diagnostic activities within the simulation are interrelated and how they relate to their ability to diagnose accurately as well as to learner prerequisites, ii) if there are systematic differences between pre-service teachers' diagnostic activities that can be interpreted as different profiles, and iii) if these profiles differ systematically regarding their learner prerequisites and the diagnostic accuracy. Results not only give novel insights into pre-service teachers' diagnostic process within simulations, but also provide essential information for adapting such simulations to learners' needs, for example by implementing contingent scaffolding (see further Plass & Pawar, 2020).

Diagnostic skills and diagnostic process

Educational assessment is a core task for teachers and is seen as an essential prerequisite for individual support and adaptive teaching (Reuker et al., 2021). Although different terms are used to describe educational assessment and corresponding skills (e.g., diagnostic competence (Heitzmann et al., 2019; Herppich et al., 2018), assessment literacy (Xu & Brown, 2016)), conceptions agree that diagnosing involves gathering and integrating information in a goal-directed way in order to reduce uncertainty with respect to a professional decision (Heitzmann et al., 2019). The central indicator for teachers' diagnostic skills has long been the accuracy of the diagnosis, operationalized as the extent to which a teacher's judgement matches a (more or less) objective measure (e.g., by using standardized tests or expert ratings) of a student's true performance (Südkamp et al., 2012).

Lately, research has shifted the focus on the diagnostic process (e.g., Herppich et al., 2018) as its understanding generally is an important requirement for the implementation of instructional support (Engelmann & Bannert, 2021). There are different frameworks describing the diagnostic process and different activities therein. For example, the diagnostic process was described based on frameworks for teachers' professional vision (Goodwin, 1994; Seidel & Stürmer, 2014), in which important cues of a specific diagnostic situation are first noticed and then processed internally to arrive at a diagnosis and an educational decision (Loibl et al., 2020). The professional vision paradigm assumes that for the deep processing of the noticed cues, teachers need to describe the specific information, explain the described information by linking it to professional concepts and finally predict students' learning by drawing conclusions (Seidel & Stürmer, 2014). Similar activities were described by Blömeke et al. (2015) for the conceptualization of their so-called situation-specific skills and for the conceptualization of scientific reasoning by Fischer et al. (2014). In an attempt to unite these frameworks in the context of diagnosing, Codreanu et al. (2021) proposed four observable diagnostic activities: *describing* (verbalize noticed cues or information), *evaluating* (inferring a general pattern of behavior of the student), *explaining* (linking the respective information to professional concepts), and *decision-making* (drawing conclusions about educational actions). Despite these numerous, mostly overlapping conceptualizations of the diagnostic process, little is known about teachers' engagement in different activities during diagnosing, about individual or situation-specific factors determining the engagement in specific activities, or about the relation between these diagnostic activities as process measures and outcome measures such as diagnostic accuracy.

Learning with simulations

Simulations are representations of real-world situations that allow learners to engage in relevant activities for the specific situation (Gegenfurtner et al., 2014). Thus, simulations allow learners to apply knowledge to realistic cases in standardized settings and by that to acquire practice-oriented knowledge (Kolodner, 1992). Additionally, simulations allow learners to focus on specific professional skills and to learn in a risk-free environment. A crucial point is that simulations reduce complexity of a specific task for training, but at the same time approximate practice (Codreanu et al., 2020; Grossman et al., 2009).

There is a vast amount of research showing the general effectiveness of simulations for learning but also a large amount of unexplained variance (e.g., Chernikova, Heitzmann, Stadler, et al., 2020; Gegenfurtner et al., 2014). For example, Chernikova, Heitzmann, Stadler, et al. (2020) found positive effects of simulations on learning of complex skills such as diagnostic skills in their meta-analysis. Effects of simulations were higher if learners received additional instructional support during learning, yet the type of instructional support interacted with learners' prior knowledge. Thus, adapting instructional support to learners' prerequisites and/or learning process seems beneficial (Plass & Pawar, 2020; Radkowitsch et al., 2021). This, however, requires a deep understanding of the cognitive processes and of learner prerequisites that might influence the cognitive process.

Beside their general positive effect on learning, simulations (and especially digital simulations) additionally allow to document cognitive processes in detail, for instance, based on logfiles or notes. The documentation of learning processes allows researchers to infer on and analyze cognitive processes that are involved during solving the task (Greiff et al., 2015), which is important for gaining a better understanding of the concept under research, e.g., diagnostic skills. Moreover, simulations allow to standardize the simulated situation

in a way that reduces the possible influence of confounding variables (Herborn et al., 2018). This seems particularly important in situations in which interaction between persons is simulated (e.g., interaction between a teacher and a student) and which are as "messy" as teaching situations in regular classrooms. For instance, the motivational or affective state of an unstandardized student could affect a teacher's judgement of the students' learning processes. Keeping constant the motivational or affective state of students during a training session in a simulation might thus help pre-service teachers with little experience to focus on the relevant aspects of the diagnosis.

Influence of relevant learner prerequisites

Learner prerequisites are likely to influence diagnostic processes as well as outcomes within a simulation (e.g., Heitzmann et al., 2019; Kramer et al., 2021). Therefore, investigating how learner prerequisites affect the diagnostic process as well as and outcomes seems important when investigating diagnostic skills. So far, research on teacher education has largely focused on the role of professional knowledge. Particularly, CK, that is subject knowledge about facts, concepts, and methods, and PCK, that is knowledge about how to teach a specific content, taking into account subject-specific (mis-)conceptions and instructional strategies (Shulman, 1986) seems to be predictive of teaching quality and learning of students (Baumert & Kunter, 2013). Less evidence exists for the role of professional knowledge for diagnosing (see Förtsch et al., 2018). Kramer et al. (2021) investigated the influence of professional knowledge on the diagnostic process and the diagnostic outcome in a simulation and found that PCK enhances both, diagnostic process and the diagnostic outcome, but CK does not.

Besides professional knowledge, Heitzmann et al. (2019) suggest a number of other factors possibly influencing the diagnostic process and outcome such as interest (e.g., Rotgans & Schmidt, 2014), self-efficacy (e.g., Klug et al., 2016), or motivation (e.g., Wigfield & Eccles, 2000), which may be especially important in simulations as learning environments. As evidence of the impact of these learner prerequisites on the diagnostic process and outcomes is sparse and relevant learner prerequisites might be target of specific interventions, identifying prerequisites that affect how pre-service teachers engage in diagnostic activities seems relevant.

Research questions

Based on the prior research presented above, the present study investigates diagnostic skills of pre-service teachers in a video-based simulation by examining the occurrence of diagnostic activities and their relation to relevant learner prerequisites and diagnostic outcome. More precisely, the following research questions are addressed: (1) To what extent are pre-service teachers' diagnostic activities interrelated and related to their diagnostic outcome as well as their learner prerequisites? (2) Do pre-service teachers systematically differ in the extent to which they engage in different diagnostic activities? (3) To what extent do pre-service teachers with distinct profiles differ with respect to their diagnostic outcome and learner prerequisites?

Method

Sample and procedure

We used data from two studies (N_{Study1} = 60, N_{Study2} = 84) that investigated pre-service mathematics teachers' diagnosing. Data of 26 participants was excluded since the data coding process of Study 2 was not yet finalized. The included sample consisted of 118 pre-service mathematics teachers (N_{female} = 76) from five German universities. Their age ranged from 18 to 43 years (M_{age} = 23.32, SD_{age} = 3.59). In both studies, all participants first completed a questionnaire and test assessing their cognitive and motivational-affective learner prerequisites. Afterwards, participants diagnosed two simulated students' mathematical argumentation and proof skills using the video-based simulation.

Video-based simulation

In the simulation, participants acted as intern who was asked to diagnose two students with respect to their mathematical argumentation skills in the context of a geometry proof. For that, pre-service teachers watched short, staged video clips about one-on-one teacher-student interactions in which the teacher prompted the student to share their thoughts about the task. Meanwhile, participants were asked to take notes relevant for the given diagnostic task. All notes were used to examine participants' diagnostic activities. After each clip, participants could decide on whether they wanted to further observe the respective student by watching another video clip. Participants could watch up to 10 videos. Once participants had decided to stop observing the teacher-student interaction, they were asked to rate students' mathematical content knowledge, methodological knowledge, and problem-solving strategies. For more information about the simulation, see Codreanu et al. (2021).

 © ISLS

Instruments

In both studies, we assessed participants' diagnostic activities and diagnostic accuracy based on notes and ratings generated during the interaction with the simulation. Moreover, we used a self-generated test to assess CK and PCK as well as a questionnaire to assess interest for diagnosing, for geometry, and for mathematics education, their self-efficacy as well as their motivation focusing on the perceived task value and their expectancy to succeed.

The *diagnostic activities* were assessed based on the notes taken by the participants during watching the videos. Notes were segmented content wise into sense units. We coded whether each segment contained one or more of the diagnostic activities describing, evaluating, explaining, and decision-making based on Codreanu et al. (2021). *Describing* was coded when participants described observations of actions (e.g., "She used the characteristics of angles in parallel lines without being able to name them explicitly"). *Evaluating* was coded when participants inferred levels of knowledge or patterns of behavior (e.g., "He has very big problems with mathematical terms and concepts"). *Explaining* was coded when participants named reasons for the students' actions or their level of knowledge (e.g., "Her methodological knowledge is already quite good since she tries to use the angles to establish a proof."). *Decision-making* was coded when participants made recommendations for further pedagogical actions (e.g., "In order to improve the understanding, the basic characteristics of the congruence theorems and quadrangles must be deepened."). For each simulated student, counts for each activity were summed up for all notes taken during the simulation. We calculated the mean across both simulated students.

We used the final ratings of the simulated students' mathematical content knowledge, methodological knowledge, and problem-solving strategies as indicator for participants' *diagnostic accuracy*. For each content dimension, participants rated two to three items on a 4-point Likert scale with a total of 8 items per simulated student. Ratings were compared to an expert solution. If participants matched the expert rating, they received 1 point. Participants' diagnostic accuracy ranged from 0 to 16 points. Scores were rescaled to lie between 0 and 1.

CK and *PCK* were each assessed using 8 items that were developed to fit the content of the video-based simulation. Participants' *interest* was measured using 9 items (3 for each aspect) adapted from Rotgans and Schmidt (2014), which were rated on a 5-point Likert scale. *Self-efficacy* was measured using six items adapted from Kunter et al. (2002), which were rated on a 5-point Likert scale. We assessed *task value* with four items that were rated on a 5-point Likert scale from Wigfield (1994). *Expectancy to succeed* was assessed with four items on a seven-point Likert scale adapted from Rheinberg et al. (2001). Cronbach's alpha for all scales and tests reported above were acceptable (between .55 and .90). For all scales, scores were rescaled to lie between 0 and 1.

Data Analysis

We used R version 4.1.2 for all analyses. To answer the first research question, we computed Pearson correlations between all diagnostic activities as well as the diagnostic accuracy, and learner prerequisites using the *Hmisc* R package. To answer the second and third research questions, we conducted a latent profile analysis (LPA) with the diagnostic activities as indicators. All indicators were *z*-standardized to increase the probability of convergence. We then estimated model fit for models with one to six profiles using the *tidyLPA* R package. The best fitting model was chosen based on relevant fit indices (AIC, corrected AIC, BIC, Entropy, and BLRT *p*-values) as well as content related interpretability. For AIC, corrected AIC, and BIC, smaller values indicate better model fit. Entropy values should be close to 1. Next, we assigned participants to the most likely profile. Finally, we compared profiles with respect to relevant learner prerequisites and diagnostic accuracy.

Results

For the descriptive results, means and standard deviations for all diagnostic activities as well as for pre-service teachers' diagnostic accuracy and their individual prerequisites are displayed in Table 1. For example, pre-service teachers on average wrote down 1.82 descriptions per simulated student throughout all videos watched from that student. For all variables except for the diagnostic activities, possible values range between 0 and 1.

Concerning RQ 1, we identified a sign. moderate correlation between the diagnostic activities evaluating and describing (see Table 1). Evaluating and describing also correlated significantly with diagnostic accuracy. No other diagnostic activity was sign. related with diagnostic accuracy. CK and PCK were both sign. related to the diagnostic activity decision-making. However, only PCK was related sign. to diagnostic accuracy.

For the RQ 2, we conducted LPA with 1 to 6 profiles. Statistical fit indices for all models are listed in Table 2. Based on the fit indices (particularly cAIC, BIC) the three- and five-profile models seemed best fitting. Upon inspection, the five-profile model merely reflected the four distinct diagnostic activities included into the analyses and a fifth group that has low values for all activities. Thus, due to theoretical considerations and to address the need for parsimony, the three-profile model was considered as the best fitting model. The profiles and their specification regarding the four diagnostic activities are depicted in Figure 1.

Table 1
Pearson Correlations Between Diagnostic Activities, Diagnostic Accuracy, and Learner Prerequisites.

	M	*SD*	1	2	3	4	5	6	7	8	9

** $p < .01$, * $p < .05$; D-M: Decision-Making; S-E: Self-efficacy; Mot: Motivation

Pre-service teachers in the first profile engaged in all diagnostic activities on an above average level. Especially for the diagnostic activity decision-making, participants showed much higher numbers in their notes compared to the other profiles. Therefore, we named this profile *decisive profile*. On average, participants in this profile showed 2.13 descriptions, 3.13 evaluations, 0.52 explanations, and 1.37 decisions in their notes per simulated student. In total, 23 participants (19.5% of the sample) were assigned to this profile.

Pre-service teachers in the second profile engaged above average in the diagnostic activities describing, explaining, and in particular in evaluating. We named this profile *evaluating* profile, as they showed most engagement in evaluating. On average, participants in this profile showed 2.65 descriptions, 5.35 evaluations, 0.58 explanations, and 0.15 decisions in their notes per simulated student. In total, 20 participants (16.9% of the sample) were assigned to this profile.

Pre-service teachers in the third profile demonstrated below average diagnostic activities in general. Thus, we named this profile the *restrained* profile. On average, participants in this profile showed 1.51 descriptions, 2.08 evaluations, 0.21 explanations, and 0.14 decisions in their notes per simulated student. In total, 75 participants (63.6% of the sample) were assigned to this profile.

Table 2
Statistical Fit Indices for Different Profile Solutions.

Number of profiles	AIC	corrected AIC	BIC	Entropy	BLRT *p*-values
1	1329.56	1359.73	1351.73	1	-
2	1310.48	1359.50	1346.50	.77	.01
3	**1280.18**	**1348.05**	**1330.05**	**.82**	**.01**
4	1268.78	1355.51	1332.51	.88	.01
5	1248.94	1354.52	1326.52	.90	.01
6	1258.95	1383.38	1350.38	.69	1

To answer RQ 3, we analyzed whether the profiles identified for RQ 2 differed systematically with respect to relevant learner prerequisites and diagnostic outcome. We found descriptive differences (see Table 3) between most variables showing that the restrained profile was less accurate, had lower prior knowledge, and was less interested compared to both other profiles. Participants associated to the decisive profile had descriptively higher prior knowledge. The evaluating profile showed the descriptively lowest self-efficacy.

Discussion

As an overarching finding, our results demonstrate that assessing the diagnostic activities in a simulation based on pre-service teachers' notes is generally feasible and results in theoretically meaningful differentiations between activities and participants. Based on pre-service teachers' notes, we identified three distinct profiles that differ with respect to the amount to which they engage in the different diagnostic activities. These profiles allow for the implementation of specific scaffolding that addresses pre-service teachers' needs and takes their actual cognitive processes into account (Engelmann & Bannert, 2021; Plass & Pawar, 2020). Compared to a "one scaffolding fits all" strategy, this should lead to better learning outcomes (Chernikova, Heitzmann, Fink, et al., 2020).

On a more specific level, our results show that pre-service teachers mostly describe and evaluate when diagnosing a simulated student. Higher order activities such as explaining or decision-making occur only rarely and mostly in a subgroup of pre-service teachers. On a first look, this is unproblematic, as only describing and evaluating are significantly positively related to diagnostic accuracy. Explaining and decision-making do not seem necessary for making an accurate judgment about the students' learning process. Although this might be a

Figure 1
The Profiles Based on the Engagement in Diagnostic Activities

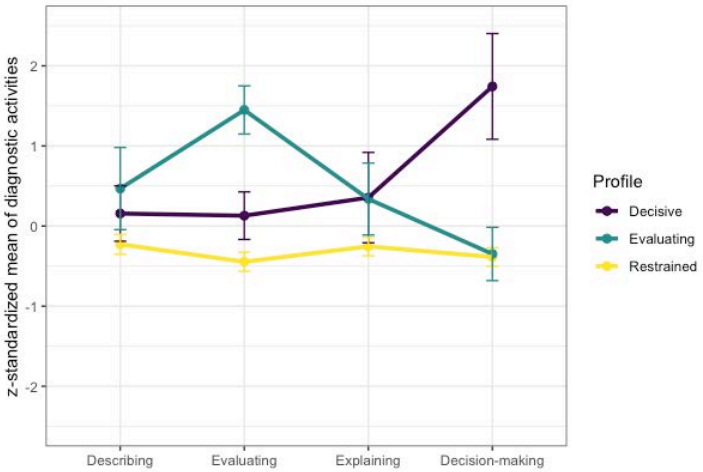

Table 3
Differences in Learner Characteristics between Profiles

Learner Prerequisites	Decisive profile		Restrained profile		Evaluating profile		Overall	
	M	*SD*	*M*	*SD*	*M*	*SD*	*M*	*SD*
Diagnostic accuracy	0.50	0.25	0.46	0.21	0.50	0.17	0.47	0.21
CK	0.74	0.14	0.60	0.17	0.64	0.19	0.64	0.17
PCK	0.71	0.09	0.65	0.10	0.68	0.11	0.67	0.10
Interest	0.77	0.14	0.73	0.17	0.77	0.13	0.74	0.16
Self-efficacy	0.63	0.20	0.61	0.16	0.58	0.18	0.61	0.17
Motivation	0.74	0.11	0.71	0.11	0.71	0.12	0.72	0.11

statistical artefact since explaining and decision-making rarely occurred, it seems conceptually plausible that describing and evaluating a specific aspect of a students' learning progress is more important for an accurate judgement than theoretically explaining it or deciding on future pedagogical interventions. However, from a practical perspective, this is problematic because going beyond the mere diagnosis by inferring pedagogical actions from the diagnosis is *the* key challenge for adaptive teaching and individual scaffolding of students (Reuker et al., 2021). Our results allow for some conclusions about how those pre-service teachers who make decisions differ to those who do not: decision-making seems to be mainly related to pre-service teachers' professional knowledge (see Table 1), which is also reflected in the finding that pre-service teachers associated to the decisive profile seem to have more professional knowledge than participants associated to both other subgroups. Although results are only provided on a descriptive level, particularly the difference between profiles in their CK is interesting. These findings partially disagree with findings from Kramer et al. (2021) who found no relation between CK and diagnostic activities on an aggregated level. Yet, our findings suggest that CK and PCK are not equally important for all diagnostic activities, which could explain their null finding. Our findings related to CK, thus, suggest that pre-service teachers with low professional knowledge need to be scaffolded to make pedagogical decisions. For instance, knowledge prompts could be a suitable means to support pre-service teachers in their higher order diagnostic activities. Moreover, the difference between the predictivity of the diagnostic activities for judgement accuracy (describing, evaluating) vs. for adaptive teaching (explaining, decision-making) suggests that future research should not only focus on diagnostic accuracy (e.g., Südkamp et al., 2012), but understand diagnostic skills in a broader sense to include decisions based on the diagnosis and investigate how different diagnostic activities are related to this broader conception.

Interestingly, we identified only small differences between the three profiles beyond the differences in professional knowledge. Even the restrained profile, which engaged little in all diagnostic activities, was not much less accurate than both other profiles and was also not less motivated or self-effective. It is unclear, what exactly leads to the differences between participants' engagement and motivational interventions appear only little suited. Future research should examine their partially smaller values on interest. It might be that they are not as much interested in the topic of diagnosing and that an intervention addressing their interest could enhance their general engagement. However, the restrained profile captured more than half of all pre-service teachers who participated in the study and it could be that the group is rather heterogeneous. Further qualitative analyses of the restrained

group might enhance our understanding of how participants in this group could be scaffolded beyond knowledge prompts to also engage in higher order diagnostic activities.

As always, this work is not without limitations. Firstly, the diagnostic activities were captured based on notes learners generated during the diagnostic process. Hence, conclusions of our work are limited to observable diagnostic activities represented within these notes. Pre-service teachers might differ systematically in the extent to which they noted down their observations and thoughts and even might not be able to access all relevant cognitive processes themselves since reasoning processes often happen unconsciously (e.g., Loibl et al., 2020). Yet, our analyses resulted in meaningful profiles which should be extended by further qualitative analyses as mentioned above. Secondly, we group participants to the profiles based on the most probable profile membership. We did not (yet) consider that participants could have similar membership probabilities for the profiles. Future research should address this issue by comparing different methods for class membership (e.g., BGH method).

In all, our study provides valuable insights into pre-service teachers' diagnostic process and suggests more and less relevant starting points for adaptive scaffolding. Yet, more research is needed with respect to their ability to make inferences about pedagogical actions and how different diagnostic activities are related to this ability. Besides, studies implementing the suggested scaffolds and longitudinal investigations focusing on how pre-service teachers learn to diagnose in the long term are necessary. Altogether, we showed that pre-service teachers' diagnostic process in simulations differ inter-individually and that their diagnostic activities are related to professional knowledge and to the diagnostic accuracy and we emphasized the importance of taking the diagnostic process into account when facilitating pre-service teachers' learning of diagnosing.

Constructing relations between STEM researchers and publics: A case study of empathy in action

Tanner Vea, Pennsylvania State University, tvea@psu.edu
Brandon Reynante, Stanford University, reynante@stanford.edu
Shelley Goldman, Stanford University, sgoldman@stanford.edu

Abstract: How academic researchers engage with non-researchers is critical to supporting the public's understanding of complex socio-scientific and sociotechnical challenges. In this paper, we examine the learning of one scientist, Murphy, in the STEM Liaison Program (SLP), a project that trained university STEM researchers to design public engagement events. Focusing on the ways "empathy" was represented in trainings and enacted by Murphy as a kind of emotional configuration (Vea, 2020), we track accompanying shifts in how Murphy saw youth in a residential treatment facility and his own role in conducting public engagement efforts with them. We argue that tracing the co-constitution of emotional configurations with "relationship schemas" (Polletta, 2020), cognitive and cultural representations of the nature of relationships and what obligations they entail, can expand the learning sciences' understandings of relationships as a learning outcome with important societal implications.

Public understanding of scientific and social scientific phenomena is crucial for addressing massive public crises like climate change and pandemic diseases. How academic researchers engage with non-researchers is important to supporting people's learning of these complex and collective problems. People are radically dependent on the actions of each other in approaching these problems. They require cooperative behavior and ways of seeing our dependent relations that support us to take action. How we learn to be in relationship is a critical question, and survival depends on how we collectively respond.

In this paper, we present a case study of the pathway one scientist traveled with incarcerated youth towards realizing the capabilities members of the public have for engaging with complex science. The scientist was a participant in the STEM Liaison Program (SLP), a project that trained and supported university STEM researchers to design public engagement events for groups underserved by informal STEM opportunities and institutions such as those who are incarcerated, people with disabilities, or seniors in constrained living situations. The program combined training in science communication methods with practices from human-centered design. In a human-centered design approach, designers engage in empathy-focused practices such as observation and interviewing to gain understanding of the perspectives and needs of those for whom they are designing (Goldman & Zielezinski, 2021; Hasso Plattner Institute of Design, 2013). With the incorporation of these empathetic practices, the program provided a novel approach to building relationships between STEM researchers and public groups around science exposure and understanding. Through the case study, we explore how a physical anthropologist named Murphy conceived of and shifted his relationships with non-scientists as he tried to bridge the gap between science and the public. We ask:

1. How does the STEM researcher come to enact and represent "empathy" in the design of his public engagement activities?
2. What kinds of social relationships are cultivated through the design processes as he practiced them?

In the following sections, we provide background on empathy and navigating it within STEM professional contexts, describe our approach to understanding emotion and the construction of relationships using sociocultural learning theory, articulate our methods in relation to SLP, and present findings from the case study of Murphy and his learning as a scientist doing outreach. Finally, we present implications from the case for the learning sciences and public engagement efforts in STEM, and we discuss future directions for this research.

Navigating empathy in STEM

The word "empathy" has multiple meanings, but it generally indicates a complex of feeling and knowing (Verducci, 2000). It involves a form of intentionality directed at the experiences of another (Stein, 1989). Empathy has been considered to have two major roles, one epistemological and the other social and relational (de Vignemont & Singer, 2006; Song, 2015; Verducci, 2000). Epistemologically, empathy provides a basis for intersubjective understanding of the experiences and subjective point of view of another person. This understanding aligns with an interpretivist epistemology in which knowledge is constructed by people in relationship with each other. In its relational and social role, empathy can be seen as a form of sharing of another

 © ISLS

person's "inner experience," fostering a sense of connection with the other. Empathy in this sense facilitates effective social communication and motivates cooperative and prosocial behavior.

The study of STEM disciplines is a social system itself (Latour & Woolgar, 1986). It is governed by norms that are socially and interactionally achieved, and that develop and change through their enactment. They are also powered and determine who gets to be where in relation to science and STEM (McDermott, 2013; Medin & Bang, 2014). Part of the norms of Western science is what forms of emotion are considered appropriate (Davidson et al., 2020). In the dominant, Western white ways in which STEM is instantiated in university departments, empathy is seen as running counter to its practices and epistemologies. Hegemonic STEM epistemologies are positivist, holding that all true knowledge can be scientifically verified (empiricism) or is capable of logical proof (rationalism) (Reynante et al., 2020). A discipline's underlying epistemology or theory of knowledge has significant ramifications for how the discipline determines what counts as legitimate knowledge. We see this problematic as a central challenge both of SLP in its preparation of STEM researchers for public engagement and for the larger question of relational development between STEM researchers and publics in approaching global sociotechnical and socio-scientific challenges. Learning sciences researchers have previously examined how learners in STEM can come to navigate across multiple epistemological systems (Bang & Medin, 2010; Rosebery et al., 2010). In this paper, we aim to build on this and similar work by focusing on the relational and emotional dynamics that are central to researchers' navigation of empathy and STEM in SLP.

Conceptual resources: Empathy as relational and emotional configuration

Sociocultural theories of learning have long supported a softening of individual autonomy, figuring the individual within social relationships that support learning (Lave & Wenger, 1991; Vygotsky, 1978) and adopting units of analysis that extend beyond the individual learner (Engeström, 1999; Wertsch, 1998). An ongoing line of research examines how relations develop between actors in learning settings as a kind of learning outcome (Nasir & Hand, 2006). For example, DiGiacomo and Gutiérrez (2016) argued that relational equity, marked by more symmetric relations between teachers and learners, should be considered as "both a tool and an outcome of designed learning activities" (p. 141).

There is an opportunity to further explore the interplay of cognition and emotion in the achievement of relation as a learning outcome. In social movement studies, Polletta (2020) explored how "relationship schemas," cultural and cognitive patterns that shape our expectations and norms for interacting with one another, shape what kinds of participation are possible. She describes the formation of relationships as a process of "relationship work" (p. 11)—a matter of "craft" and "invention" (p. 9). A relationship schema is a constructed understanding of the ties between self and other that also carries with it implications for who we can be and how we can act together. In light of these bodies of work, we attend in our analyses to the ways being together and cultural materials support people's developing understandings of how they are in relation to one another.

Due to the specific focus on empathy in SLP, we also place analytical focus on the role of emotion in these developing understandings. While many models of emotion in affective science assume that emotion is an internal and individual phenomenon, a sociocultural and social constructivist view of emotion is gaining traction (Clore & Ortony, 2013; Mesquita & Boiger, 2014). In this view, emotions emerge from social interactions and relationships, which they in turn constitute, shape, and change. They are also situated—embodied, enacted, and experienced in particular situations which give them particular definition and meaning. Therefore, while "empathy" has particular meanings in psychological research, we defer specialist definitions in favor of seeking how empathy is emotionally configured (Vea, 2020) within the specific cultural settings and practices of SLP.

Just as relationship schemas point to the importance of attending to the relationship work that people do as they make sense of their commitments to one another, the notion of emotional configurations directs attention to the ways emotion becomes meaningful in the conduct of social activity. The ways humans configure emotion, such as how a concept like "empathy" becomes enacted in social practices and interactions, have implications for what is possible to achieve together. In this sense, both relation and emotion are processes and outcomes of learning. Furthermore, emotion and relation are co-constituting. How we see our relationships helps determine how we feel toward one another, and how we come to feel for one another helps determine how we relate (Dewey, 1975; Jasper, 2011). As a result, the form that scientists' designs for public engagement take emerge in part from the interplay of emotional configurations and relationship schemas that participants in social activity construct.

Methods

Research context

We conducted research in SLP, an initiative that facilitated a multi-faceted engagement model for STEM researchers working with communities and people in the public who have historically lacked access to STEM

research and STEM researchers. The goals of SLP included helping STEM researchers gain new understandings of public groups, supporting public learning in STEM, and connecting public groups with STEM fields and researchers in new ways. In other words, SLP involved refiguring the social relationships between scientists and the public. The SLP was innovating a combination of three engagement models: a model of science communication informed by learning research, an outreach mentorship structure to support researchers as they engaged in the planning and execution of public engagement, and practices and principles from human-centered design. The human-centered design components of SLP provided a structure, a set of practices, and ways of thinking that supported the construction of a different kind of social arrangement between researchers and public groups. Human-centered design's "empathy" focus encourages designers to see beyond their own expertise and understand what the situation looks like from someone else's perspective. These insights can then help the designer develop interventions (in this case, public engagement programming) that meet their needs. Human-centered design also entails taking a different emotional and relational stance compared to Western science.

Each year, the SLP invited a cohort of university STEM researchers to participate in training and subsequent supports that covered aspects of the three models. Two of the three authors of this paper, along with other members of our research team, developed and led workshops on the use of human-centered design for developing public engagement in STEM. This training included understanding the empathy basis of human-centered design and how making sense of empathy can lead to more effective design outcomes than processes that center on designer expertise alone. The training began with a focus question: "How might we design engaging and effective science outreach events for non-traditional outreach participants, about whose life experiences, interests, and concerns we know very little?" This question emphasized that public engagement in STEM is "for" the public and should serve their interests and needs. Yet it also emphasized that most STEM researchers were starting from a position of incomplete understanding about the public, and that building a better understanding was key to designing successful public engagement.

Here we explore "empathy" as a kind of emotional configuration that brought together ways of feeling about members of the public with particular ways of making sense of their needs and the goals of public engagement. This configuration also included sets of practices aimed at understanding the other, distilling what was learned, and acting on that understanding through design. "Empathy" was explained as a way to understand the situation of public engagement from the public's point of view. Enacting empathy in this context required "lingering in ambiguity," immersing oneself in the problem space of trying to understand the needs of the public *before* jumping to design solutions. The training included opportunities to practice developing and enacting empathy with people for whom the STEM researchers would be designing public engagement programs, first through a prerecorded video interview and then with in-person interviews that the STEM researchers themselves conducted. In attending to other people's perspectives through these exercises, the researchers were encouraged to "Listen carefully," "Ask questions about the person's ideas and experiences," and "Never judge the person even if you do not agree." In this way, the enactment of empathy included interactional practices and habits of thinking in regard to those for whom the STEM researchers were designing. Collecting information was only half the picture. After taking notes and accounting for what they had heard, the STEM researchers were trained in strategies for sense-making around the information they gathered. This process involved reflecting on what they learned and trying to distill synthetic statements about what the members of the public they heard from might need to accomplish through engaging with STEM. These needs might be very different from the STEM researchers' own goals for public engagement. Finally, the STEM researchers were explicitly encouraged to think beyond the lecture-and-Q&A format of public engagement and to develop ways of relating to public groups that were more equitable and multi-directional in the flow of expertise and knowledge.

Data sources

We report on research that examined the experience of the STEM researchers who participated during the SLP's first two years. This analysis takes an in-depth case study approach aimed at examining the pathways and experiences of one researcher. A case study is an empirical inquiry that investigates a contemporary phenomenon within its real-life context by drawing upon multiple sources of evidence (Yin, 2013). The emphasis in performing case studies is primarily on interpreting the data (Stake, 1995). In this paper, we take a descriptive and exploratory approach, describing the data as they were generated in context and developing explanatory propositions for further inquiry (Yin, 2013). The goal was to deeply understand the experience of a STEM researcher in the program. Case studies are generalizable to theoretical propositions, but not to populations of cases (Yin, 2013). The goal of a case study is not usually generalization but rather particularization—emphasizing its uniqueness (Stake, 1995). We use the case of Murphy to help reveal the analytic contours of what is possible in shifting STEM researchers' relationships with the public, revealing theoretic propositions for further study.

In this paper, we focus on qualitative data and use an interpretive approach. In the larger study, we collected data for a subset of 16 SLP participants. Each case study subject was interviewed in a 20-40-minute interview prior to SLP training. They completed pre-program surveys, including open-ended written responses, that were administered to the entire cohorts. They were observed during the training, and observational field notes were written for each outreach event they completed. We recorded their initial meetings with program staff in which each answered a question about their commitments to public engagement. Evaluation feedback was collected from the public participants at their engagements, and the SLP researchers were asked to complete a reflection survey within 24 hours of completing an engagement event. Each SLP researcher also participated in an end-of-program personal interview and a post-program survey.

Analytical approach

All interviews were audio-recorded and transcribed verbatim. We developed a preliminary list of codes conducting an open-coding process (Emerson et al., 2011; Strauss & Corbin, 1994) and a grounded approach to data analysis and theory building. To ensure reliability, we co-coded data, checked for any discrepancies, and resolved disagreements through discussion. Of particular interest in this paper were codes and data sources that tracked the STEM researchers' developing practices and representations of empathy in the preparation for, execution of, and reflections about their public engagement activities. We paid close attention to constructions in language that documented the ongoing sense-making that STEM researchers were accomplishing about the role of empathy in developing relationships with public groups, how representations of empathy were related to the work of STEM research, and how researchers' constructions of STEM research itself shifted through the relational work of designing public engagements. In tracking how the emotional configuration of empathy was taken up, we also attend to the ways its enactment was associated with shifts in relationship schemas, the cognitive and cultural representations of the relationship between the STEM researchers and the public.

We present the case of one participant, Murphy, because it is indicative of growth in understanding and change in thinking about what people in the public know about science and how to approach engaging them. Rather than arguing that Murphy's experience in the program was representative of all SLP participants, we make the case that his experiences illustrate processes of shifting relations in ways that can be helpful for theory building and future design work.

Findings: Murphy and the public

Murphy was a graduate student in physical anthropology, studying the connection between genes and variation in the structure of brains of both humans and non-human primates. Based on prior experiences, Murphy had the idea that the general public has a very poor understanding of science, influenced by both his previous long career as a lawyer working with juries and his graduate studies in physical anthropology. During the pre-program interview, Murphy revealed a view of the general public as having poor understanding of science: "Because I came to science late in life, after another career… what I learned was—is that, um, people on juries—the level of their science knowledge is somewhat shockingly low." Also before the SLP, Murphy participated in a science outreach program at a local museum where his experiences might have reinforced that thinking. Murphy surmised that the attendees of his public talk at the museum were not very engaged because the adults did not ask many questions and they seemed to want to be entertained instead of to engage deeply with the science. When asked what he would think if the public at an engagement event had a great experience and were excited but left with inaccurate scientific understandings, Murphy shook his head back and forth: "Again, I suppose it accomplishes something, it puts a human face on scientists, but I think that there's… yeah, that's not good. Inaccurate information is not good. I think that that ought to be fundamental. Everything else ought to flow from that." In the interview, Murphy said it was important to bridge the gap in public science knowledge:

> What's happening in science today, especially in broadly speaking the field of genetics is astounding—it's changing people's lives. And will do much more so in the future, over the next ten or 15 years. But really the gap between the regular person who's not in science and what's happening is becoming broader and broader and broader.

Speaking of his previous STEM engagement experiences, Murphy said describing complex science to people who "don't know what cells are" made the talks ineffective. "People said, 'Wow, that's amazing,' which I guess is somewhat flattering, but I don't know how much it accomplished."

Murphy's enactments and representations of empathy

Murphy's thinking about the potential for the "public" to become engaged and think deeply about science shifted during his participation in the SLP. During his SLP participation, Murphy held engagements in two residential centers for youth. One was a medium security juvenile justice center that aimed to prepare youth to rejoin the wider community. The second was a residential treatment center for girls 12 to 17 years old where girls enter based on referrals from the juvenile justice system or Child and Family Services.

Murphy's most prominent enactments of empathy occurred during his first SLP engagement event, when he learned about the teenagers and their interests. He reported a change in opinion and increased empathy about what teenagers knew and how to approach science with them after the visit. Murphy started by mentioning that he was an anthropology student. Almost immediately, a girl asked, "What is anthropology?" which led to an explanation of the branches of anthropology and their differences. Murphy went on to show the youth a picture from the science lab where he worked, displaying the equipment and explaining what it does. After moving to explain how DNA sampling works, more questions started coming. Surprising Murphy, the teenagers backtracked to asking about how being a "PhD student works." They expressed interest in Murphy's previous career as a lawyer, and they wanted to know how the move from that profession to being an anthropology student happened.

Murphy then moved into asking the youth questions: "What is a gene? Do you know what an MRI is? Have you had one?" Murphy explained brain structures and asked them how brains recover from trauma. The youths' responses showed quite a bit of brain knowledge. This line of questions sparked a girl to ask about how brain changes can "make a person act differently, be more susceptible to drug or alcohol addiction." The youth also raised questions about Zika virus and microcephaly and how viruses can affect the brain and brain development. These questions and tangents had the participants involved. After Murphy answered them, he forged ahead to describe a set of topics more closely related to his personal work: different brain structures, the functions of neurons, risk and reward, different reactions of mice to stimuli, optogenetics, and algae. In each case, Murphy presented information, asked questions, and was asked questions. Finally, Murphy showed a demo of a chance and risk game that a few students got to play. All told, Murphy covered at least twelve sub-topics. The youth raised another six or seven topics. They asked a steady stream of questions that Murphy answered even when the questions were related to connections the youth were making instead of those that Murphy had planned to present. This experience was surprising for Murphy. Speaking of it in his post-SLP interview he said, "They asked questions constantly throughout the whole thing, a few of them did. If anything, it was... I would have guessed I would have been asked three or four questions. I was probably asked 30 or 40."

On the post-engagement survey regarding the first event Murphy wrote about what he learned about the youth in the facility and how he would apply his new empathic understanding in his future public engagements:

> I addressed some topics that I thought would be a big hit and I was wrong, but I'll learn from it all. These are young people that respond well when the subject matter is made directly applicable to their lives and their futures. I would be better prepared to address their career in science-related questions, and I would make more explicit the connections between different aspects of the presentation. The highlights were each of the several occasions when a significant portion of the students were amazed by the subject matter I was addressing.

In the way Murphy spoke and wrote about his experience in this event, we can see him enacting the emotional configuration of "empathy" presented in the SLP training in particular ways. Though he did not attempt to meet and learn about the teenagers before his first engagement event, he made note of his surprise at the questions they asked and how they wanted the science to be "made directly applicable to their lives and their futures." In the statements he made about what he "would be better prepared to address" in a future event, we see evidence of his sense-making about these young people and what it meant for productive public engagement.

Murphy's shifting relations with the public

Murphy treated this first SLP engagement as a prototype to learn from and to help him redesign the next engagement at the second youth facility, with 15 girls in attendance. We examine the second engagement event and Murphy's discussion of it to understand how his relations with youth in residential facilities were shifting.

In this session Murphy brought physical models of the brain and showed them to the youth, passing them around so they could feel them. Murphy started by explaining the career change from law to studying anthropology. Next, Murphy showed a slide on "what is anthropology," explaining what the word means then outlining the different branches of the discipline. Finally, when he got to biological anthropology, Murphy talked about the components of the brain, DNA, and genes. A girl asked a question about genetic traits, and Murphy talked about

eye color and height. Murphy showed an MRI image, compared it to a physical model of the brain, and passed around a cast of a homo habilis skull. During this time, Murphy fielded questions. Murphy then moved to discuss the specific gene of interest to his research and showed videos of mice activity. The students asked questions about the use of mice in research. Murphy showed them how to take a DNA swab from the cheek. The participants offered explanations and asked questions through the talk and demonstration. Murphy concluded again with a game about chance and risk.

Murphy left this second event feeling like the girls were engaged, even though not everyone understood every piece of the material. From the event itself and from Murphy's discussion of it, we analyze several ways in which the relations between himself as a science communicator and the girls in the facility were shifting. In his post-program interview, Murphy described how he had learned from the previous engagement event to plan differently for the second one:

> After the first one, I had a lot of ideas myself. Now at least I had some experience to know what worked and what didn't. The addition of these things that I passed around I think was important. I focused more on things people could relate to. Just that your brain weighs about three pounds and it's kind of a flimsy thing if you tried to hold it in your hand and it would leak through your fingers. Just things to make it more real.

In the first event, the girls had asked about brain changes that might make people more susceptible to addiction, and Murphy saw these questions as evidence that the girls were trying to understand what studying the brain could tell them about their own experiences. The model brain he brought to the second event was another thing he thought "people could relate to." Having learned that adolescents had some grounding questions at the beginning of the first engagement, Murphy also began the second one with those very questions: What is anthropology? What does it mean to be a Ph.D. student? Murphy's design for the second event further involved a different relation to the girls in the way he positioned his own goals. In the post-program interview, we asked: *Could you talk just a little bit in general about how you found a balance between your goals and your interests, what you wanted to communicate, and the needs and interests of the youth who were there?* He responded:

> I hope I abandoned my goals on the second one. I think that that's one of the wonderful things about this. I don't have a curriculum. I don't have to make sure I'm leaving no student behind or any of this or that they're going to do well on standardized testing. This is a tremendous advantage. You can go there, try to stay flexible, and be responsive to tell people what they're interested in. […] You also respond to questions and listening to the question carefully will take you a long way… I tried to be more responsive and to improvise more.

We take Murphy's words as evidence of a shift in his relationship with the public. He began to differentiate his relationship to the public in the SLP from the relationship between instructors and students. While Murphy kept key science messages in mind, he emphasized that adapting to the participants' particular questions and interests was the heart of his approach for the second and future engagements. His new relationship carried distinct expectations for his actions. His evolving relationship with the public required him to listen "carefully" to what people say and to be willing "to improvise more" rather than follow a unidirectional lesson plan. Relating to the public required that Murphy position his knowledge and practice more humbly.

Murphy also mentioned in the post-program interview that going into these events he did not much "like" teenagers. We see evidence that Murphy improved his regard for the youth at the first engagement, which then became consequential in the second engagement. On the post-engagement survey for the second engagement, Murphy wrote that he saw the girls as "engaged and attentive, mostly" and that they expressed "their appreciation at the end." At the same time, he saw how "the [girls'] participation can be encouraged by asking questions, answering questions even if off-topic and altering the presentation outline as participant areas of interest emerge." Murphy's perception of the girls as "engaged and attentive" contrasts with his earlier dislike of teenagers. His remarks also indicate a recognition that the qualities of the girls' participation were not innate to them, but rather at least partially a result of the way he related with them. Murphy sees his own role in fostering an engaged and interactive atmosphere, including altering the plan as participants' interests changed during the event. Murphy came to see the adolescents as engaged, curious, and insightful learners who thought scientifically and critically about the content at hand. Through interacting with them, Murphy learned about their knowledge, interests, and identities and seemed to have come away with a new appreciation for adolescents in terms of who they are and their capabilities. He recalled their "stunningly insightful" questions about genotype heritability, genes' effects on risky behavior, and the role of nature versus nurture. He said these questions "really illustrated a kind of

scientific thinking in my mind, and these are people who had gotten it and were trying to move a step ahead." He also saw them as "better questions, by the way, than I got when I did my four […] presentations up at the museum."

One of the goals of the SLP training was to emphasize the role that empathy could play in STEM communication (e.g., learner-centered activities, understanding the needs and interests of the public, and finding points of personal connection with non-scientists), and Murphy's experience seems to have provided an opportunity for growth in empathy. Responding to the question about the SLP's human-centered design training on empathy, Murphy said, "It helped me focus on the needs and desires of the participants, rather than on what I may think is important."

Discussion and conclusions

Murphy's case illustrates what may be possible in shifting STEM researcher's relations with the public. He came into the SLP thinking that members of the public had poor scientific understandings and that the most important thing in science communication was to deliver accurate information. In his first public engagement event in the SLP, Murphy's experience went off-course from his plans. He was surprised by the youths' interest in his personal trajectory and the overall sophistication of their questions. He worked to derive insights from his empathy experience in that first event and apply them in the design of the second event, in which he focused much more on grounding the presentation in aspects he thought the youth would relate to. He also tried to relate in ways that were more responsive to emergent interest and to be improvisational. The experience ultimately shifted how Murphy regarded the youth in the residential facilities as scientific, intelligent, and engaged.

From this case, we highlight several areas of significance for the learning sciences. First, while empathy has particular technical definitions in psychological and affective research, the case shows the importance of attending to how empathy takes shape as an emotional configuration, socially achieved through the framing enacted in the SLP training and in Murphy's uptake and enactment of empathy's practices and ways of thinking about the other in his public engagement events. We see evidence of Murphy's attunement over time to how the youth he encountered, despite being in a residential treatment facility, were engaged scientific thinkers who were interested in what biological anthropology might have to say about their life experiences and futures. We argue that the emotional configuration of empathy in the SLP provided structures for Murphy's thinking and practice that enabled him to improve his regard for these youth and for members of the public more generally. This case is also instructive as an example of how emotional configurations can be instructive outside the strongly politicized social movement context in which the theory was initially developed (Vea, 2020).

Second, building more generous interpretations of the youth and other members of the public was associated in this analysis with shifting ways for Murphy of seeing himself in relation the public. In his early interviews and surveys, he emphasized the central importance of providing correct scientific facts to uninformed publics. He saw himself as the holder of knowledge that should be transmitted to passive audiences. In contrast, by the end of the SLP, Murphy was articulating a revised relationship schema of public engagement. In his new understanding, he saw his role as connecting with what people see as meaningful to their lives—something that could not occur in a unidirectional transmission of his expertise to the public. Rather, this new relationship required Murphy to take up new ways of practicing in relation to the public. He saw the need to let go of his own agenda, be responsive to emergent interests, and improvise. If relationship schemas involve expectations and norms for how people should interact together (Polletta, 2020), the emotional configuration of empathy in the SLP helped Murphy shift his expectations for his own behavior as a STEM communicator. We see these shifts as productive for societal needs. Meeting collective sociotechnical and socio-scientific challenges will require STEM researchers to relate with public groups in new ways, and focusing public engagement work on what members of the public see as relevant to their lives and futures can help all of us work together toward collective solutions.

We see the potential for future work in the learning sciences to continue to analyze the relationship between emotional configurations and relationship schemas to understand how they co-constitute one another over the course of social interaction and unfolding activity. Interaction analytical approaches (Jordan & Henderson, 2011) may be especially useful for building on the work presented here by illuminating the moment-to-moment ways that people work together to shift their understandings of each other and their obligations to one another's wellbeing.

Possibility, Perspectives, Personal Investment, and Process: How K–12 Teachers Support Programming Projects Through Assessment

Paulina Haduong, Karen Brennan
haduong@g.harvard.edu, karen_brennan@gse.harvard.edu
Harvard University

Abstract: Creating personally authentic projects can support student engagement and motivation in learning to program. Assessment can play a role in supporting student learning, but it can be challenging for teachers to employ assessment practices that benefit students and their programming projects. In this interview study conducted with 80 U.S. K–12 computing teachers, we explored how teachers supported students' programming projects through their assessment practices. Teachers navigated tensions between their pedagogical aspirations (e.g., supporting creative possibilities) and practical considerations (e.g., logistical constraints) as they supported students projects by (1) encouraging possibility through rubrics; (2) inviting multiple perspectives through feedback; (3) increasing personal investment through self-assessment and resubmission; and (4) surfacing process through documentation and conversation. Findings from this work support understandings of how assessments can support or constrain learning through creating programming projects.

Introduction

Learning to program through the creation of personally authentic projects can be an inclusive and equitable pathway into computing, supporting learner motivation through experiences that are "personally or culturally meaningful in the mind of the learner" (National Academies of Sciences, Engineering, and Medicine, 2021, p. 30). In elementary school teacher Oscar's classroom, students created Scratch projects about their favorite locations in their neighborhoods, and in middle school teacher Tara's classroom, students designed 3D models of objects for their family members. Assessment is a critical component of supporting student learning through creating projects (Earl, 2012), but programming projects can be challenging to assess (Brennan & Resnick, 2012; Shute et al., 2017). Without clearer understandings of how to support students' programming projects through assessment practices, teachers may be deterred from designing opportunities for students to learn through the creation of programming projects altogether (Brennan, 2015). In this study, we investigated: *How do K–12 computing teachers support students' programming projects through their assessment practices?*

Background

When students engage in creating projects, well-designed and ongoing assessment is critical for supporting student learning (Barron & Darling-Hammond, 2010). It can be difficult to design effective assessments, however, because assessing and understanding student projects can be a complex process (Brinkerhoff & Glazewski, 2004; Pedersen & Hobye, 2020). Because students' projects and project processes necessarily diverge from one another, teachers often draw on pedagogical content knowledge (Jones & Moreland, 2005) and assessment literacy (Lew & Nelson, 2016) to effectively support many students simultaneously. A lack of time—not only for students to make projects but also for teachers to assess those projects—is a common challenge (Kleinert et al., 1999; Lumadi, 2013). Moreover, assessment practices themselves run the risk of stifling student motivation and interest (Earl, 2012). As Barnes et al. (2015) write, "assessment practices hold power that can enhance learning and democratic practice or can be used to punish and control learners, teachers, and schools" (p. 298).

In the context of teaching and learning computer programming, teachers may face unique challenges when supporting students in engaging in projects. While students' programming projects are easily visible, student learning may be harder to understand and support (Brennan & Resnick, 2012). In computing education, manual checking of student code is a customary and time-consuming form of assessment (Grover, 2017), though some researchers and educators have developed automated assessment tools (Blikstein et al., 2014; Douce et al., 2005; Ihantola et al., 2010). Even with automated tools, teachers need a high degree of pedagogical content knowledge to assess student learning through programming projects, particularly when students have been encouraged to take their projects in directions that feel personally authentic to them. Students' programming projects can vary, even when they incorporate the same or similar computational concept (Capraro & Slough, 2013). Students might engage with different computational concepts, practices, and/or perspectives by attempting projects in different

 © ISLS

ways (Brennan & Resnick, 2012). In the U.S., although there has been increased demand for and investment in computing education for students, there has been a lack of commensurate support for teachers' professional learning (Blikstein, 2018). Limited access to professional learning can stifle computing teachers' development of pedagogical content knowledge and assessment literacy, leading to difficulties in knowing what to teach and how to assess (Bower et al., 2017; Yadav & Berges, 2019). Without the requisite assessment literacy, computing teachers sometimes forego the assessment of projects altogether, relying on separate, more "traditional" assessments (i.e., handwritten exams) as ways of understanding student learning. These exams typically focus on student acontextual conceptual knowledge, and a lack of assessment around students' projects can unintentionally minimize how much students value their own projects (Yadav et al., 2015).

Method

In this study, we investigated the assessment practices that teachers implemented in their classrooms. We explored how teachers' aspirations for supporting students' programming projects informed their assessment practices, as well as how teachers negotiated challenges in employing these assessment practices.

Teacher participants and interview design

Eighty U.S. K–12 computing teachers were recruited via social networks (e.g., Twitter) and email listservs (e.g., Computer Science Teachers Association). Half of participating teachers worked with grades 9–12 and half worked with grades K–8. 20 teachers taught at least one Advanced Placement (AP) course. While some had prior CS experience, most participants taught other subjects (e.g., math, science, or the arts) and had begun teaching computing because of personal interest or school demands. They taught in rural, suburban, and urban districts in 27 states. School contexts varied, with two-thirds of teachers working at public schools. Some K–5 teachers taught all subjects, including computing, to their own class of students, while others taught computing to all students in the school in their roles as librarians/computer lab teachers.

Individual members of the research team conducted interviews with pairs of teachers about assessing programming projects in computing classrooms. Asking teachers to share and discuss two assessments they used in the classroom enabled us to ground interviews in student work and teacher-generated assessments. The pair design offered opportunities for peer learning and richer data (Haduong & Brennan, 2020). Interviews were virtual, over video chat, and teachers were paired randomly by scheduling availability. Interviews were structured as a three-part turn-based protocol: after the research team member asked a question, each participant responded to the same question. First, we asked participants to define key terms (e.g., "assessment") and how these constructs manifested in their classrooms. Then, participants shared their assessments (e.g., rubrics and student reflective writing), describing how and why these assessments were developed. Finally, we asked participants to share advice or questions they had for other teachers. Interviews averaged 75 minutes, and they were audio-recorded and transcribed. All teachers were assigned pseudonyms, which is how they are referenced in this article. After the interview, each participant received an Amazon gift card ($100).

Data analysis and limitations

Interviews were analyzed through a collaborative and iterative process of thematic analysis (Braun & Clarke, 2012). In the initial rounds of open coding, the first author and another research team member focused on assessment practices (e.g., "feedback"), coding together to develop a preliminary codebook in NVivo, then piloting the codebook by individually coding the same interviews and meeting weekly. Once the assessment practices had been established, the team then focused on developing codes related to each practice's underlying rationale (i.e., aspiration for supporting programming projects), as well as the challenges related to each practice. After a codebook was established, they engaged in split coding, discussing discrepancies and concerns weekly with the second author to arrive at consensus (Cornish et al., 2013). Through reflective memos and regular discussions, the research team worked together to reorganize codes and understand the relationships between aspirations for students' projects, assessment practices, and practice-related challenges. In the final phase, we looked for "discrepant evidence" that was at odds with the existing codebook (Maxwell, 2010) and revised accordingly (see Table 1).

There are several limitations to our approach. In this study, we recruited teachers interested in supporting and assessing student creative programming projects; this call may have excluded teachers who were implementing programming projects in the classroom but didn't feel that their work was "creative." As an interview study conducted remotely, we were not able to observe participants in their classrooms, though we triangulated participant responses with submitted assessment examples. We sampled a broad and diverse group of teachers working in K–12 computing education across the U.S. and found that key practices spanned contexts.

Table 1
Assessment Practice Codes by Teacher (n=80)

Aspiration	Practice	Example	Teachers
Possibility	Rubrics	"I want four sprites, but I don't specifically say what the four sprites are, and that gives them creativity within my constraints."	70
Perspectives	Feedback	"Bringing another person into the conversation helps them push their thinking along because they're testing their ideas out on an actual user … it's really great to get feedback from a peer, and it's great to watch someone play your game."	65
Personal investment	Self-assessment	"Did you do more than you ever thought you could do? And do you keep wanting to do it? That's when [you] can self-assess and say, "I'm starting to get there.'"	53
	Resubmission	"They can keep resubmitting, [and] manage and design their own test loop … they can iterate very quickly."	21
Process	Documentation	"It's like they're walking around with a tape recorder … And they're showing me all of the process that was involved, and then the product ends up only being a small part of it."	29
	Talking to students	"I walk around and they run [their programs] for me, and then I may ask them some questions about, "What did you do? How did this work? Show me what you did here."	68

Findings

In learning environments where students were engaging in programming projects, teachers aspired to encourage expansive possibilities, invite multiple perspectives on student work, increase students' personal investment in their projects, and surface students' process. One way these aspirations informed how teachers designed opportunities for creating programming projects was through their assessment practices, which enabled teachers to differentiate project support based on students' varied needs, skills, and lived experiences. At the same time, teachers negotiated external accountability demands, expectations of what learning and assessment "should" look like, and the time constraints of K–12 class schedules. Participating teachers described supporting programming projects through four assessment practices: (1) encouraging possibility through rubrics; (2) inviting multiple perspectives through feedback; (3) increasing personal investment through self-assessment and resubmission; and (4) surfacing process through documentation and conversation.

Encouraging possibility through rubrics

Having a sense of what is possible facilitates the ability to create personally authentic programming projects. Teachers described how students, unused to opportunities to engage in this type of open-ended project work, struggled to make sense of what they were "supposed" to create. In response to this challenge, most participating teachers (n=70) used rubrics (or scoring guides) when facilitating programming projects, which helped students imagine expansive creative possibilities while understanding expectations for project requirements. Defining expectations helped teachers justify grades. But teachers also felt that too many expectations could limit student freedom. More than half of teachers (n=48) asked students to make projects that included specific computational concepts (e.g., loops or variables) while leaving the type of project and specific implementation up to them, striving to support a diversity of outcomes. A few teachers (n=4) designed rubrics that were purposefully minimal and open-ended (e.g., "Creativity: Student explored and expressed multiple ideas in a unique way") while others (n=12) strove to make them as specific as possible (e.g., "Creativity: Student selected a stage, sprite, and action commands that create an engaging dance performance for the viewers"). Joshua, an elementary school teacher, described how the rubric–as–checklist helped students decide how much challenge they wanted to take on in their projects, while also helping students see what else they might do in their projects.

Several high school teachers noted that they used rubrics despite their limitations, particularly around student motivation. Derek said, "Many students see the rubric as the maximum" while others "see it as the minimum," and Shannon expressed a concern that using rubrics "really lowers the level of creativity and engagement in a project." Teachers also differed in *when* they shared rubrics with students in the project process. Some teachers (n=13) gave rubrics to students at the beginning of the process to help students imagine what was possible. Kayla, a high school teacher, said, "I do give [students] that base rubric so they have a starting point. I find that if I don't, they feel very lost." Some teachers (n=14) used the rubric as a checklist throughout the project

process, though others felt strongly about sharing the rubric only at the end. Damien said, "I don't want them going into checklist mode" in the beginning, because he wanted students to be "exploring and figuring out and not limiting themselves based on the rubric yet." Even though the use of rubrics was a common practice, several teachers raised questions about how rubrics could better support opportunities for students to understand what they might explore within their programming projects.

Inviting multiple perspectives through feedback

Programming projects can benefit from students' access to multiple perspectives, which can spark new ideas and support students when they get stuck. Assessment in support of learning is most effective when delivered in a timely manner (Brookhart, 2008), but teachers noted that, particularly with large classes, assessing student programming work could be burdensome. Erin's biggest problem was "timeliness in getting them feedback … I can't be a bottleneck for anything; kids have to know where they are as soon as they can." Throughout projects, many teachers (n=65) created opportunities for timely and individualized feedback by inviting multiple perspectives on students' projects. Erin, a high school teacher, incorporated peer feedback through "round robin presentations," splitting her class in half and asking each student to present individually to another student for ten minutes before rotating, so that every student was able to share and receive feedback multiple times. Teachers also reported that students valued peer feedback more than teacher feedback; Tracy, a middle school teacher, said, "the most meaningful thing [for kids] is the feedback they get from their peers."

Practicing assessing others' work can inform students' awareness of other solutions and scaffold their ability to assess their own programming projects (Smith et al., 2012). Having other people test their projects was often helpful for students' progress, and Leslie, a K–5 teacher noted that students were "really quick about finding mistakes" in others' work. Peer feedback, however, can take *more*, instead of less, time. Anita, an elementary school teacher, reported that written peer feedback resulted in more work because "it takes a long time for me to read all [the feedback] for the students." Students may also need to learn how to give each other feedback (Beach & Friedrich, 2006). Quentin, a high school teacher, printed and displayed students' code on large sheets of paper, so students could "appreciate other people's code and look at a variety of directions that students took to solve a problem." He then gave students sticky notes and discussed how to provide feedback. To his students, he said, "If I came to your desk and told you that your code was good or bad and didn't say anything else, you'd hate me, right? I'd be a bad teacher. So, be a good peer and provide constructive but respectful feedback."

Feedback could also come from other authentic audiences. In Jill's AP CS A classroom, industry volunteers offered technical expertise that she did not have. Jill, a novice programmer, described how having less content knowledge slowed down her ability to support student work. Because she was not able to understand students' code by reading it, she often had "to test it out because we don't know all the ways the kids' minds work … they're all over the place." A few teachers (n=8) also facilitated opportunities for students to receive feedback from audiences beyond their classroom, such as asking family members, friends, or industry volunteers to play the games they had designed. For students, receiving feedback from others at multiple points during their projects helped them refine their ideas and iterate on their projects.

Increasing personal investment through self-assessment and resubmission

When students are working on personally authentic projects, they are more likely to be invested in their creations. Personal investment can support persistence in the face of challenges, possibly leading to future participation in computing. Assessments can support personal investment, but assessments are often thought of as something done *to* students, instead of *with* students (Earl, 2012). Many teachers (n=60) spoke about tensions between how they wanted assessments to support student learning and the expectations that students, parents, and/or administrators brought to assessments. Teachers wanted to prioritize formative assessments, but the formal structures in which they were operating often demanded summative assessments that felt antithetical to learning goals. Teachers (n=35) also noted uneasy relationships between assessment, motivation, and teacher feedback. In class, high school teacher Lorena tried to encourage students working on projects to "forget about the grade, forget about what I want from you, because you're not doing this for me." But students would push back, expecting "traditional assessments," such as multiple-choice quizzes. Other teachers spoke about students' tendency to focus on grades, rather than reading and incorporating feedback. Ashley, a high school teacher, said, "Most kids honestly just look at the grade, and that's all they want to see," specifying that even though she wanted to give specific feedback, students "really just want to say, 'All right. Did she give me a B? What am I getting here?'"

To more closely connect student motivation to assessment processes, teachers (n=53) described the ways in which they helped students self-assess and resubmit their programming projects until they were satisfied with their work, as well as the teacher's assessment of their work. Evan spoke about how teaching kids to self-assess helped them "monitor their own progress," and Betsy felt that self-assessment involved students as "participants

in the process." Typically, teachers were asking students to give themselves a grade and offer a justification of why they deserved that grade. A high school teacher, Jesse also scaffolded students towards self-assessing their final project by using a consistent rubric across multiple projects before giving students a blank template and asking them to define their final project's minimum requirements, saying, "What I'm looking for from them is to not only decide what they want to make, but also to decide how they want me to assess it." This process of self-assessment helped teachers gain a better sense of whether students felt that they had met their own goals, and how students' understanding of their own learning was connected to their teachers' assessments. Students were fairly accurate, or even too harsh, in their self-assessments. Natalie, a high school teacher, said, "Usually, when students grade themselves, they're either right at where I graded them, or they're within one grade. When I give them back my rubric with the feedback on it, they can see … what they would need to do to change it if they wanted to."

Some teachers (n=21) encouraged regular resubmission of work for full credit if students were dissatisfied with their grade and wanted to resubmit. However, resubmission sometimes worked against students—Justin, a high school teacher, pointed out that students could introduce new bugs, saying, "Sometimes, when they fix one thing, they break something else." Resubmission offered opportunities for students to demonstrate what they knew, rather than what they were able to do in any particular moment. Rhonda noted, "Anytime they don't do as well as they can, I give them a chance to retake … It's not a test of, 'Did they do it right the first time?'" In creating opportunities for students to be more involved with the assessment process, teachers were helping students deepen their personal investment in their programming projects.

Surfacing process through documentation and conversation

When teachers have greater understandings of students' project creation process, they are better able to support students' current and future learning. Across grade levels, teachers experienced difficulties in understanding individual students' learning solely by examining students' work product. Several teachers (n=12) noted that students could copy and paste code into their projects without understanding how the code worked. Others (n=35) raised that seeing a student use a concept in a particular project did not indicate whether they understood the concept and could transfer that knowledge elsewhere. Many teachers (n=38) designed programming projects to be collaborative, but it was difficult to understand individual contributions. Natalie, a high school teacher, described how students with greater expertise could easily dominate in group projects. When looking at students' code, teachers (n=49) had difficulties seeing what students cared about and how much effort they invested, what their "individual gains and personal bests" were (Richards, 2010, p. 193). Even with recent increased access to computing in K–12, teachers (n=36) described how some students had many years of prior computing experience, while other students were new to the subject. Brooke, a middle school teacher, described this differentiation challenge as one of equality, of "how to assess [students] equally based on their skill level, because they're all at such varying levels when they come in." In contrast, Janet, a K–12 technology integration specialist, aimed to differentiate her assessments, saying, "If I'm looking at the work of one student, and then a different student's work, I have to remember where this person started from." Without understanding learners' process, it could be challenging for teachers to celebrate students' successes and highlight areas of future learning.

Sawyer (2021) notes that "ideas do not originate from internal thoughts during solitary meditation; rather, they emerge from a visible and embodied process of engaging with the work" (p. 17). Most teachers (n=74) found ways to attend to students' process as well as product, asking students to articulate their ideas through written documentation or in-class conversations. A third of teachers (n=29) asked students to document their process as a way of making their thinking and learning visible. Documentation helped teachers gain insight into whether and how much students understand the code in their projects. Students wrote in-line comments in their code, pasted screenshots of their projects into separate reflection documents, or recorded summative video reflections. Adrienne, a middle school teacher, said, "You could copy code quite easily … which has been an issue … that's why I use the design process of creating documentation. You're able to talk about what you've been doing. You can explain how you got the information you got."

Documentation practices also helped students develop insight into what they had learned. In Evan's inclusive classroom, students did not always finish their projects. He noted, "I hate for students, especially [those] who have struggled or who have IEPs[1] that really presented challenges in their learning to think the project was a wash." Writing a final reflection helped students realize, "Hey, there are times where I hit a challenge … and I grew." However, several teachers noted that documenting process could take time away from the product, particularly when there was emphasis on written reflections for English language learners or students with disabilities. Shannon, a high school inclusion teacher, said that documentation could be "way, way too oppressive, and then they can't be creative because they're so busy writing [things] down. It's a fine line." Lindsay, a middle school teacher, said that working "with the population of learners who struggle with reading and writing, I can't say I'm surprised that they're not putting comments in between their lines of code to express their thinking."

Many teachers (n=68) described a desire to assess process by talking to students about their work, which helped to develop shared understandings of what was new or exciting. But this could be time-consuming. Damien, a high school teacher, wanted to have conversations with every student but said, "I don't ever do that.… I don't know how to make it happen." Robin, an elementary school teacher who saw every class every week, said, "I'd love to [meet with students], but I have 800 students." Stacy, a middle school teacher, shared a story about the challenges of not being able to see what students had learned through working on their projects.

> Several years ago, I had this student. This girl, who was just really fun and a very creative girl, and she turned in this game that was a cute game. I wrote, "This is a cute game. You did this well, and you did that well and it … meets expectations." I got this seething email from her father that has really stayed with me. He said, "You know what? My daughter wanted to be a computer programmer until this moment, and now she never wants to do it." I thought, *Oh, my God. What have I done?* "She spent so long on this one feature, and you did not notice this feature."

Because of this experience, Stacy changed her assessment practices to focus on deepening her understanding of her students and their process, telling them,

> Please tell me what you're really proud of in this. Please tell me what I might not notice. I want to know what you were up against, and what battle you won. And if you didn't win the battle, but you were fighting it, I want to know that too. Please just tell me what to pay attention to.

When teachers were able to learn more about their students' process, they were better able to support students in making progress on their programming projects. Teachers (n=68) relied on their direct experiences with students to determine what they had learned. Jill, a high school teacher, emphasized the importance of classroom observation: "I observe my students interacting with each other's projects acutely, because that says so much that I could never [understand] otherwise."

Discussion and conclusion

Creating programming projects can offer opportunities for students to engage in personally authentic computing experiences, which can support sustained participation in computing. Across contexts, we saw K–12 computing teachers aspire to support students' programming projects by encouraging possibilities, inviting multiple perspectives, increasing students' personal investment, and surfacing students' process. The process of learning to program by creating projects, however, is seldom predictable or linear, and students' diversity of interests often led to a diversity of learning outcomes. We saw teachers grapple with these complexities as they used various assessment practices. Their assessment practices were typically formative, helping teachers assess what students had learned thus far while supporting their future learning. Through *rubrics*, teachers were describing to students what they might try in their projects. Giving and receiving *feedback* helped students develop judgment of their own and others' work. *Self-assessments* helped students set their own goals and decide what they wanted to learn. And by *documenting and talking about their work*, students stepped back and articulated their thinking, which could advance their learning. Teachers rarely relied on a single assessment practice—different practices were used at different moments during students' project processes. When used together, assessment practices supported teachers in developing better understandings of their students as thinkers, creators, and learners.

However, teachers' desired assessment practices could be hard to implement, given the time constraints of K–12 schools. Teachers offered opportunities for students to resubmit work, but that could take time away from the next project. Some teachers said that there was insufficient time for peer assessment, and others pointed out that students needed time to learn how to give feedback. Notably, many of the elementary school teachers, who often saw more students for shorter class periods, cited time as a limiting factor. Teachers' assessment practices were also striving to address this particular moment in U.S. computing education. Because of computing education's uneven implementation across K–12, the ability to offer learning experiences that meet the needs of all students can feel daunting, and almost half of participating teachers (n=36) described challenges they faced in offering differentiated teaching and assessment. Teachers are often working in inclusive classrooms, where students may have a range of learning needs, and students are entering classrooms with a range of prior programming experience. Some students may not have access to technology at home, reducing the amount of time that students can work on their projects. Building relationships helped teachers gain a better sense of students' prior experiences with computing and how much effort students were investing in their projects, but this could be a time-intensive process.

In addition, a desire to understand student learning can have unintended consequences on the design of opportunities to create personally authentic programming projects. Because it can be challenging to surface what students have learned through examining their projects, there may be an impulse to assess what is easily visible, focusing on accuracy in usage of programming concepts and/or easily-checked solutions to programming puzzles. Sometimes, this can mean divorcing the assessment of learning from the project process, or this can mean constraining student agency in their projects, such that students undertake similar project creation activities. When we limit ourselves to what is easily assessed, we risk artificially constraining learning opportunities in ways that benefit teachers and researchers, and not the students themselves. And when we limit student agency in their projects, we risk limiting opportunities for students to engage in expansive learning when learning to program (Wilson, 2021). As computing education becomes more widespread, there is increased need to consider not only whether students have access to computing education, but also what *kinds* of computing education opportunities are accessible. What are students being asked to do as they learn to program? And how might assessment practices support, rather than constrain, student learning?

Assessment practices can unintentionally undermine student confidence and their progress. But as teachers demonstrated, assessment practices can also encourage possibility, invite additional perspectives, increase personal investment, and surface creative process. Teachers' practices pushed back against traditional forms of assessment and encouraged understandings of assessment as an integral component of the project creation process. We hope that these teachers' assessment practices inspire researchers and teachers to expand access to opportunities for students to pursue personally authentic programming projects, which can enable students to express their ideas with code and see themselves as computational creators.

Queer Orientations as Resources for Mathematics Learning

Sarah C. Radke, Arundhati Velamur
scr274@nyu.edu, aav268@nyu.edu
New York University

Abstract: This paper investigates how queer orientations shaped mathematical meaning-making in an afterschool documentary filmmaking program. We focus on queerness as both a lived/experienced phenomenon *and* a lens for thinking about learning, following scholars who have examined mathematics learning from racialized and gendered lenses (E.g., Gholson & Martin, 2019; Rubel, 2016). To do so, this paper explores how the performance of and negotiations with queer identities are co-constructed and emerge with meaning making around mathematical concepts. Findings call for centering these stories as productive, critical aspects of learning such that youths' queer positionalities and identities in and across contexts are seen as an essential aspect to advancing equity in mathematics teaching and learning.

Purpose

It is late afternoon when four members of an after-school documentary filmmaking program we call Digital Studio (DS) – Zeena, Xane, Lucas, and Cai - huddle around a computer in a school's library. They are working on compiling research for their documentary on "The LGBTQ (1) Youth Experience in Schools in 2017." The Youth Producers (YPs) are creating a voiceover script for the documentary they will write, film, edit, and showcase within the course of one school semester. In small groups, they have spent the last few days looking for statistical information that describes the LGBTQ community. This afternoon they record informational statistics found online about the relative sizes of LGBTQ populations in different U.S. cities. As they gather the information for the voiceover, their discussions weave in and out of mathematics, such as notation, mathematical operations, and proportional relationships, and affective responses to the numbers. Amongst the note taking and calculations, ponderings emerge; how a statistic prompted one youth to reconsider a familial relationship, and another to hope for a desired future. A traditional lens on learning might isolate the explicitly mathematical parts of the conversation, finding a largely uncontested discussion of concepts and notation. Such an approach might further relegate the personal to an uninterrogated background, dismissing with it entire histories, identities, and relationships through which collective mathematical meaning emerges. In the analysis presented in this paper, we adopt a queer perspective and turn intentionally to this forgotten background to reclaim the more relational and subjective dimension of learning. Turning in this way allows us to bring into sharp relief how participant stories are implicated in the construction of a statistic for their documentary film.

In the past few decades, out of school settings have occupied a place of some prominence in mathematics education research (Carraher, et al., 1985; Ma, 2016; Nasir, 2002; Saxe, 1991). Collectively, these studies have examined the social and cultural practice of mathematics in everyday, non-school life. Yet, only a small subset of this literature has decentered school mathematics in informal settings, interrogating how mathematics learning and identity development are mutually constitutive of each other (e.g., Hull & Greeno, 2006; Nasir & Cooks, 2009; Radke, 2021). Such an approach has made it possible to understand how mathematics, as a practice, is the effect of interplay between subjects, artifact, and the environment. In particular, studies like Ma's (2017) of whole-body mathematics, Nasir's (2002) into domino and basketball activity, and Saxe's (1991) of gameplay have offered perspectives on how mathematics and mathematical activity are produced in interaction and within particular settings. We draw on this latter scholarship and extend its ideas by considering affect as another element of meaning-making in mathematics (Leander & Ehret, 2019).

This paper investigates how participants' queer orientations, discerned through a queer analytic lens, shaped mathematical meaning-making in an afterschool documentary filmmaking program. We begin by positioning ourselves as researchers from a post-colonial feminist perspective with an interest in surfacing erased stories of learning and practice in mathematics education. The Black/feminist scholar Kristie Dotson (2014) argues that stories often go untold due to our "inclination to understand oppression as we experience it and to extend our analysis of it beyond what we ourselves can see from our particular vantage point" (p. 57). She urges us to interrogate the places from which we see and conduct research to unpack the stories that might be obscured by our particular "socioepistemic orientations" (p. 45). Ahmed (2006) writes similarly about orientations:

 © ISLS

> Some things are relegated to the background in order to sustain a certain direction; in other words, in order to keep attention on what is faced. Perception involves such acts of relegation that are forgotten in the very preoccupation with what it is that is faced. (p. 31)

In other words, our orientation to a scene relegates some aspects of it to the background while foregrounding others. The orientation of our gaze, therefore, affects what we see and the stories we tell; the background, forgotten, holds some of the stories we may have lost along the way. The purpose of this paper is to search for these lost stories by critically attending to the forgotten background. We contend that by telling these lost stories, we are positioned to better understand learning as it takes place in the margins

An emerging field within educational and learning sciences literature engages marginalization as an intersectional phenomenon, and examines the ways in which race, class, gender, and other social subjectivities interweave to mediate experiences of learning. Gholson and Martin (2014; 2019) focus on Black girlhood as a unique social location from which Black girls experience the mathematics classroom. They point out that the social networks of Black girls at school form at the intersection of their Blackness and their girlness, so that any examination of their experiences of learning must necessarily recognize both race and gender. Similarly, by simultaneously interrogating institutions (such as schooling and STEM education) and structures (such as race, U.S. imperialism, and neoliberalism) across time and space, Sengupta-Irving (2021) and Sengupta-Irving & Vossoughi (2019) sought to give voice to the subjective experiences of Brown girls in contemporary western education. Taking a similar approach to studying embodied mathematical learning, Takeuchi & Ishihara (2021) followed the mathematical sensemaking of a collective of migrant women activists by attending to their social and political histories of migration and labor, as well as the violence their bodies had been subjected to. Taken together, these studies share a commitment to seeing social processes—and therefore learning—as at once emplaced, embodied, racialized, gendered, and classed. We share this commitment and offer (queer) orientations to surface socially, geographically, and politically entangled processes of learning.

While racialized (McGee, 2015; Leyva, 2016; Martin, 2012) and gendered (Ceci & Williams, 2011; Legewie & DiPrete, 2014) identities have been examined in mathematics education research, few scholars have centered the mathematical experiences of students with marginalized sexual identities with notable exceptions (e.g., Esmonde, 2011; Rubel, 2016). Thus, we focus on queerness as both a lens for thinking about learning and lived/experienced phenomenon. This paper is guided by the following questions: *What orientations are brought to the fore when interactions are viewed through a queer lens? And how did these orientations shape mathematical participation?* Analysis revealed that youth's reasoning followed personal trajectories into the past and future as part of their reasoning practices and that queerness was entangled (Philip & Sengupta, 2020) with their mathematical reasoning. Findings call for centering these trajectories as productive, critical aspects of learning such that youths' queer orientations in and across contexts are an essential aspect to advancing equity in mathematics teaching and learning.

Theoretical framework

This paper is centrally interested in meaning-making—and therefore learning—as culturally, spatially, and temporally mediated. We explore this interest by bringing together sociocultural and queer theories to episodes under analysis. Guided by sociocultural theory, we take up the conceptualization of *learning as movement* (Gutiérrez, 2008), developed across settings (Jackson, 2011) and through shifts in participation in activities (Lave & Wenger, 1991). We look to queer perspectives (Ahmed, 2006; Butler, 1990) to highlight the power relations that shape identity performances and learning. Butler reminds us that all identities are composed of self-making acts, composed through "corporeal signs and other discursive means," (Butler, 1990, p.333), through which people become socially intelligible. From this perspective, identity is not an expression of what one is, rather it is something that one does. Critical to Butler's theory of identity as performative is the understanding of performativity as contextual and structured by powered relations. Thus, identities are not only dynamic, but contextually situated, non-neutral social constructions, and understanding positioning thus requires analytic attention to both the in-the-moment efforts to perform and to the context in which these performances occur.

A queer phenomenology involves facing the back (p. 29), allowing the researcher to make sense of a scene by deliberately attending to the background, or, in other words, the systems and labor that sustain what comes to be foregrounded. Calling for a re-orientation to the back or background necessitates that something or things occupy the fore from which we deliberately turn. Ahmed specifically calls for this move as an explicit resistance of white, cis-, and heteronormative narratives. Like Butler, Ahmed (2006) conceives of gender and race as "effects of the kinds of work that bodies do" (p. 60). In turn, the raced and gendered labor of bodies frames the kind of work it becomes possible for those bodies to engage in. Historically othered bodies, having arrived in places that refuse them, regularly resist dominant imperatives by occupying space (literally and figuratively) in

new and unprecedented ways. Such resistances are a result of "different orientations, different ways of directing one's desires" (p. 68). Occupying a space with new desires has the potential to extend it in new ways, making possible new ways of doing, being, and thinking. We view the resistance of the othered body as a performance of queerness and seek to understand how queer orientations shape collective and individual sense- making. By conceptualizing meaning-making as a process that extends across space-times (Nespor, 2004) the analysis examined queer orientations as part of mathematical and interpersonal sense-making by attending to the social practices of both the collection and analysis of data to meet activity-related goals, the phenomena described by the statistic itself, and the sociocultural and/or political concerns made relevant to sense-making by the participants themselves. In the empirical examples that follow, these theories supported understanding the ways interactants' subjective experiences of queerness were part of whole-group statistical meaning-making.

Data and methods

Data comes from a larger study of mathematical learning pathways (Ma & Kelton, 2017) at Digital Studio (DS), an afterschool documentary filmmaking program that engaged underserved youth in documentary film production and civic engagement. In one school semester, Youth Producers (YPs) and an adult facilitator worked together to produce a documentary that addressed a student-selected social issue. Data included field notes, audio and video recordings, interviews, and material artifacts. Analysis occurred iteratively at two interrelated levels, the ethnographic (Spradley, 1980) and microethnographic (Streeck & Mehus, 2005). Analyses of episodes identified as "hot spots" (Jordan & Henderson, 1995) iterated between microanalytic methods of interaction analysis (Jordan & Henderson, 1995), and methods borrowed from the construction of grounded theory (Charmaz, 2006). Ethnographic analysis of the full data corpus through thematic memo writing (Schatzman & Strauss, 1973) supported microanalysis of episodes, focusing on how the desires of different bodies occupied with a shared task collaboratively shaped reasoning practices. Finally, analysis traced chronotopic laminations (Bhaktin, 1981) to attend to participants' social relations and histories of arrival (Ahmed, 2006) that were made relevant in interaction. Attending to how spacetimes were brought together over the course of talk and interaction (e.g., Leander, 2002) illuminated how participants continuously co-constructed stories about themselves and others across time and space, influencing their social positioning. Analysis traced how queer orientations, as one such cross-spacetime resource, emerged as part of ongoing individual and collective sense-making.

Analysis

In the following episodes, four youth worked at a shared computer to compile research for their film about LGBTQ youth's experiences in schools (see Figure 1). They had spent the last few days looking for statistical information that describes the LGBTQ community, what their facilitator described as, "hard numbers - quantitative supporting evidence," (Fieldnote, 11.16.2017).

Figure 12
(From left to right) Zeena, Xane, Lucas, and Cai sit around a computer searching online for statistics for their documentary, "The LGBTQ Youth Experience in Schools in 2017."

Zeena, not feeling well that day, sat silently through the episodes. She was an old-timer in relation to the other three YPs, and she openly identified to her peers as "not straight," but she had not come out to her family. Lucas,

a self-identified queer ally, was leading the online search. He paused on one website and began to read aloud, "Gates estimates that approximately 3.5% of Americans identify as lesbian, gay, or bisexual while 0.3% are transgender." Xane, who identified as straight and "previously anti-LGBTQ", reflected in a remorseful tone, "Wow, that's a lot." After some quick mental calculations Lucas offered Xane and Cai, an openly gay youth, an estimation that 3.5% represented "about, still 10 million" Americans.

[1.1] Xane: Yeah, that's a lot. I'm saying… Now I feel bad
[1.2] Lucas: Uh, it's also - you have to keep in mind that not everyone is comfortable to s-
like - [1.3] Xane: To say what th[ey are
[1.4] Cai: [there's probably more than that,[just like=
[1.5] Lucas: [yeah =they just aren't
comfortable with sharing the information
[1.6] Xane: Yeah I understand
...(15 seconds of silence)..
[1.7] Cai: Nine million people and not one for me ((Laughs))

Xane and Cai accepted Lucas's estimation. Xane affirmed the estimation represents "a lot" of LGBTQ people [1.1] and after the youth discussed the reality of estimation through cascading utterances, Xane reconfirmed his understanding [1.2]. An analysis of mathematical activity that attended only to the talk and action that was explicitly mathematical, in a schooled or disciplinary sense, might interpret the students' lack of discussion as evidence that the youth had come to a taken as shared understanding (Yackel & Cobb, 1996). However, by attending for and with queerness we see that they continued to reason with the statistic, recruiting memories and future imaginings. Xane's personal experiences as the brother of a gay sibling and his actions in a spacetime outside of DS emerged as intertwined resources for sense making. This included both his mathematical interpretation of 3.5% as representative of a large number of people and his personal reflection of "feeling bad" [1.1] Although there is no verbal evidence in this clip as to what Xane was referring to in his utterance, Xane had shared in previous whole-group discussions that he had a gay brother whom he has not treated kindly in the past, actions about which he was remorseful. Then they built an argument questioning the accuracy of that same percentage.

Beginning with Lucas, then Xane, then Cai, and finally book-ended by Lucas, their cascading utterances co-operatively (Goodwin, 2017) built to produce an agreement that the percentage was most likely not a complete representation because of the social stigmas attached to being categorized as LGBTQ. Xane deployed agreement utterances shifting his footing from regretful and guilty to in alignment with Lucas and Cai. He built on Lucas's use of safety by legitimizing people's right to "say what they are," [1.3] and then confirmed his understanding of the argument they collectively produced [1.6]. Finally, Cai's sense about the percentage was embedded in his future imagination of finding a partner. Unlike Xane's earlier interpretation as a large number of people [1.1], Cai determined 3.5%, when converted to an approximate number, as too *small* for him to have hope in his search for romance [1.7]. Cai's queer orientations to the statistic, which were shaped by his romantic desires, further orientated the group to the data. Analytically, one might cast Cai's comment as a comedic aside as it did not get an immediate response from anyone. But, as their work continued, Cai's queerness and future hopes became key resources in the joint mathematical reasoning.

Xane and Cai's contrasting interpretations of the largeness of the same statistic highlights how orientations towards data are aligned with sexual orientations. Xane's encounter with the statistic invited and challenged memories of his interactions with his gay brother; interpreting the population as large appears to have shifted his understanding of the marginalized experiences of the LGBTQ community. On the other hand, Cai oriented to the statistic through desires for a queer future with a partner; to him, nine million seemed like too small a number of people to make this imagined future a real possibility. Minutes later Lucas typed, "What percent of LGBT in [This City (2)]" into the search engine. He copied the results in the group's research packet and placed the packet on Cai's desk. When Cai returned from break, he read what Lucas wrote, leaned over, and read from the screen, and asked, "What does that mean?"

[2.1] Lucas: There's more - there's a better ratio.
[2.2] Xane: Maybe that's cuz it just [there's - there's more people here
[2.3] Cai: [Ohhh, so like San Francisco has - is
mostly - [2.4] Lucas: Uh:: It's because This City has more [people
[2.5] Xane: [more [people, yeah so
[2.6] Cai: [more people, yeah, yeah
[2.7] Lucas: And San Francisco has more LGBT people to the uh:[to the=

[2.8] Cai: [But they have-
[2.9] Xane: =To the population, yeah.

Lucas began by describing the phenomenon as due to "a better ratio," which Xane added to as being about a city having "more people." Together they reasoned that "a better ratio," [2.1] had to do with the part-whole relationship between the number of people who identify as LGBTQ (the part) and total population of people in a city (the whole). At this point the youth had co-operatively produced an answer that satisfied Cai's initial sense-making question. Here, Cai's musings about his future and finding a romantic partner extended their talk.

[2.10] Cai: Yeah. (3 seconds) That's cool. Better move to San Francisco ((laughs)).
[2.11] Lucas: It's not that much higher. It's like, I think -
[2.12] Xane: So
[2.13] Lucas: ((Scrolling through the article)) I think, it's like - a 2.2% difference
[2.14] Cai: Oh.
[2.15] Lucas: And you're gonna be dealing with a bigger gay community.

The group's mathematical understandings about how the statistic was constructed and Cai's identity as a gay youth were recruited as resources for discussing how Cai's imagined future might unfold. Cai initiated this when he verbalized an intention to move to the city with the highest percentage of LGBTQ members [2.10]. In laminating a future spacetime as part of their discussion in the present spacetime of DS, Cai re-framed the meaning-making about the percentage as big or small as interwoven with his option to move to another city. That is, 2.2% being a large or small difference could influence his decisions about where he might live in the future. In fact, a year later, one semester into college, he expressed the desire to move. He doesn't cite this conversation but does mention the "larger gay community." Cai's desires for a queer future thus occupied the space of statistical meaning-making in the episodes, shaping an understanding of the statistics the group encountered.

In terms of a queer phenomenology, Cai reaches for the data in non-normative ways (Ahmed, 2006), so that how the data are perceived becomes inextricably linked with how they were reached for, which in turn is a consequence of Cai's queer desires being present in the traditional discipline of statistical thought. Such an analysis also shows how meaning-making, or "coming to know," is necessarily affective: we draw here from Leander and Ehret (2019), who argued that while engaged in literacy-gathering activities such as data interpretation or data collection, subjects affectively interpret and collect meanings with and in relation to other subjects. Cai, Lucas, and Xane extend the space of statistics through their own subjective orientations to the data and to each other, collapsing time so that "present-past-futures of reading, imaging and researching come into contact, where here-and-nows are visited by there-and-then's or imagined-there's-and-could-be's" (p.144). A queer telling of the episodes thus illuminates more than queer stories. By invoking participants' histories and relationships, it draws out shifts in their reading, interpretation, and use of the data. For instance, Xane's affective response to the Lucas' estimation of the LGBTQ population in the U.S. only emerges when one attends to the histories Xane (who identifies as straight and cis) brings into DS. Lucas (who identifies as straight and a queer ally) joined Cai in his narration of this imagined future spacetime when he added the percentage difference as a possible deterrent to Cai's hypothetical plan to move [2.13]. Attending to Cai's queer identity as the grounds for their continued discussion makes visible how Cai's individual experiences and desires shaped the group's reasoning in the moment. 2.2% as a large or small difference was entangled with and mediated by Cai's lived experience to date. Cai initially interpreted it as large and San Francisco as a place where he might have better odds at finding a partner. When Lucas challenged Cai's interpretation [2.11;2.15], he merged his (Lucas's) percentage calculation about the percent difference with their collaboratively constructed understanding of the mathematical difference between percent and total population. Understanding the difference between percentage and total population and interpreting the statistical difference of 2.2% as large or small had implications for the group, and Cai specifically, which stretched beyond the spatial- temporal boundaries of the interaction.

Discussion

In the analysis of these episodes, we have detailed processes of learning, illuminating how youth bring their experiences and positionalities as resources for mathematical reasoning, and how their knowledge of mathematical concepts interplay with their reflections on past experiences and future possibilities. By combining queer phenomenology with microanalytic methods of interaction analysis we have shown that students' orientations to, of, and with queerness were woven into their math reasoning, as they continually worked to draw connections across their lifeworlds to "make sense of one's own identity in the broad context of time," (Gutiérrez & Jurow, 2016, p.567). These efforts shaped individual and collective learning, and the practice of statistics in a

way that was relevant to the filmmaking task before them. Additionally, mathematical understandings youth co-operatively developed were used as tools for finding and interpreting statistics for their film and as part of traveling on multi-sited, person-centered trajectories into the past and future in relation to queerness. The past and future spacetimes Xane and Cai laminated were legitimate parts of the group's mathematical reasoning and youth's individual reflections about their queer positionalities and/or identities. Xane's sense-making about the statistic, and Lucas's estimation that followed, was entangled with a past spacetime in which he had engaged in homophobic actions. Cai's sense-making about the second statistic and ratio relationship was embedded in his future imagination of finding a partner. Additionally, the personal relevance of the statistics to Cai's imagined future became a resource for extending the whole-group mathematical investigation. In these ways the youth queered (Mendick, 2006) their mathematical reasoning through their knowledge and use of mathematical concepts and their past and future experiences.

These findings extend empirical and theoretical understandings of the interrelationships between identity and mathematics learning beyond practice-related conceptions by suggesting that mathematics content itself can be a context for identity work (Radke, 2021); that is, embedded in relationships, memories, and desires rather than abstract skill that is enacted identically across different settings. What made these findings possible was our deliberate attention to the non-mathematical aspects of participant conversation, such as Xane's comments about "feeling bad" and Cai's stray remarks about finding a partner. This intentional turn toward what is often categorized as background information, if it is attended to at all, was critical to our emerging understanding of mathematical meaning-making as situated, historical, relational, and affective. We accomplished this turn through a queer phenomenology, by facing the back to examine how it sustains learning (Ahmed, 2006). To make visible the intimate nature of all learning—here mathematical learning—we sought to queer our own orientation as researchers. A queer turn in research thus has the potential to paint more nuanced pictures of learning as intricately tangled up with memory, history, desire, and hope.

Significance

Equity-focused research has long argued for supporting students in recognizing mathematics as valuable to their own lives (Kilpatrick, et al., 2001), seeing themselves in the mathematics (Gutstein, 2007), and having their family/home knowledges valued in schooling spaces (González, et al. 2005). The findings of this paper move beyond explaining marginalized youths' struggles by illuminating how students' construction and use of mathematical knowledge was shaped by their social, personal, and political stories. Recognizing the personally relevant ways youth took up and reasoned about content as part of learning illuminated one way to move towards epistemological shifts in our understandings of math meaning-making, driven by change-making desires (Takeuchi, et al., 2020). Implications call for research and pedagogical efforts to center these past and future stories as productive, critical aspects of learning so that youths' queer orientations are seen as essential to advancing equity in mathematics teaching and learning. We must prioritize how youth make math content relevant to their lives in the moment and follow youth as they recruit experiences and knowledge across spacetimes to ask new questions, reflect on their pasts, and set future goals.

The various approaches that fall under queer theory are committed in their refusal of fixed identities and are invested in apprehending and disrupting the binaries that emerge in discourse (Mendick, 2014). This refusal feels especially relevant to the task of telling humanizing stories of mathematics education, where mathematical knowledge continues to be conceived of as objective, neutral, and fixed, although these ideas have seen a challenge in recent years (Gutiérrez, 2013; Martin, Gholson, & Leonard, 2010). In the episodes analyzed above, a queer research orientation surfaced the ways in which the same statistic drew different affective interpretations from participants, thereby disturbing the very premise of a singular mathematics. A statistic is never *objectively* large or small, it depends (for instance) on how it is recruited into personal relationships, memories, and hopes. A queer lens on research into mathematical learning emphasizes a relational view of the discipline so that what mathematics is becomes inseparable from who reached for it, how they reached for it, and with whom (Ahmed, 2006). Implicit in this view is a conception of mathematics as many things, as plural and not fixed (Gutiérrez, 2013). It positions us to retrieve the stories of learning we may have lost to the dangerous myth of an apolitical mathematics (Martin, Gholson, & Leonard, 2010).

Endnotes

(1) A note about language; we use the acronym LBGTQ to broadly refer to students who do not identify as heterosexual or cisgender. The acronym serves as a tool to synthesize the many different queer identities, and we also recognize that there are differences and fluidity among these identities.

(2) Lucas named the city where the study took place. The transcript has been amended to anonymize the data.

Examining How Cognitively Guided Instruction (CGI) Professional Development Influences Struggling Students' Mathematical Problem Solving

Hua Ran, Department of Teaching and Learning, University of Miami, hxr240@miami.edu
Walter G. Secada, Department of Teaching and Learning, University of Miami, wsecada@miami.edu

Abstract: When students solve complex mathematical problems by themselves, many will experience and encounter difficulties, struggles, and tensions. Existing research provides little guidance on how teachers might productively respond to students' various struggles. Using the video data from the second year of *Cognitively Guided Instruction* (CGI, a professional development program) and comparison classrooms, this study examines the effects of CGI on struggling students' problem solving and investigates the mediation effects of enacted instructional practices on students' problem solving. Struggling students in the CGI classroom had higher problem-solving scores than their counterparts in the comparison classrooms. The mediation analyses showed that the two instructional practices (for student agency support and for extending student thinking) had a positive and significant impact on struggling students' problem solving. While the other two instructional practices showed a negative and non-significant impact.

Keywords: Struggling students; problem-solving in mathematics; enacted instructional practices

Introduction

Primary grade students often make errors and get mired in struggles during problem-solving processes. Struggle in problem-solving has not always been seen positively. Some early researchers saw struggle as a sign that students had failed the mathematical tasks, and they perceived struggle as something that needed to be overcome and to be avoided (Brown & VanLehn, 1982; Radatz, 1980). Hiebert and Grouws (2007) argued that struggle does not mean that students are undergoing needless frustration or extreme levels of challenges caused by nonsensical or overly difficult problems; instead, they argued that certain kinds of struggle indicate that students are expending intellectual efforts to make sense of mathematics and to figure out something that is not immediately overt. Their interpretation of struggle reconfirmed the importance of struggle in mathematical problem solving; that is, the process of struggle is essential for constructing deep mathematical understanding. Moreover, students engaged in productive struggle with meaningful mathematics are experiencing math as more than procedures and correct answers (SanGiovanni et al., 2020).

The significance of struggle has been recognized since the time of Dewey, who dedicated much attention to the importance of struggle. Deep subject knowledge is "the fruit of the undertakings that transform a problematic situation into a resolved one" (Dewey, 1926, p. 242-243). In developing deep knowledge, students inevitably encounter "some perplexity, confusion, or doubt" (Dewey, 1910, p.12). Struggle provides instructional opportunities through which students can delve more deeply into the mathematical structure of problems and the relationships among multiple mathematical ideas and concepts (Baker et al., 2020; NCTM, 2014). Though the importance of struggle in problem solving has been investigated, the specifics of how teachers might more effectively respond to students' struggles and support students' productive mathematical learning remain less well understood. Even less is known about the kinds of professional development programs that could increase teachers' awareness of their students' struggles and help teachers capitalize on those struggles in their mathematical teaching.

This study is embedded in the CGI setting, a professional development (PD) program based on the research of students' mathematical thinking. Teachers who have taken the CGI PD use their students' thinking to inform and to guide their instruction (Carpenter et al., 1989; Carpenter et al., 1996). The purposes of this study are to look at the influence of CGI on struggling students' problem solving and to investigate paths and mechanisms for how interventions on teacher PD would promote students' engagement in problem-solving. By focusing on teachers' enacted instructional practices in classrooms, this study addresses the important and complex link between teacher learning from PD and students' learning outcomes. The guiding research questions were the following three:

1. What are the effects of the CGI on struggling students' problem-solving? To what extent are CGI's effects on struggling students' problem-solving moderated by students' gender, grade, and struggle levels?

 © ISLS

2. What mediation effects of CGI on struggling students' problem solving through teachers' interactional time and enacted instructional practices emerge after controlling students' gender, grade, and struggling levels?

3. How did the teacher-student interactions look like in the CGI classrooms, when teachers often used the enacted instructional practices but did not result well in students' problem solving?

Method

Data sources and participants

The teacher and student samples for the current study were extracted from a large random controlled trial (RCT) study that explored how CGI influenced teachers' beliefs and knowledge and further impacted students' mathematical learning (Schoen et al., 2017; 2020). Twenty-two elementary schools from two Florida school districts were randomly selected as the participating schools. Eleven schools were randomly assigned to receive CGI PD, and 11 schools provided their usual PD and served as the comparison schools. Over two years, volunteer teachers in the CGI schools participated in extensive CGI PD workshops. In the first year, 157 teachers from the CGI schools received a total of eight days of CGI workshops; and 171 teachers from the comparison schools followed the district's PD plans. In the second-year stage, 156 teachers were assigned to the CGI group and 172 teachers to the comparison group. This study targeted the year-2 sample in order to investigate teachers' support for struggling students who may have been more sophisticated in implementing CGI.

All 47 teachers in the year-2 sample were videotaped for one lesson based on teacher consent and students' parental permission. First-grade teachers accounted for 57.45%, and second-grade teachers accounted for 42.55%. All the teachers were females. White teachers across each condition accounted for 91.67% in the CGI condition vs. 91.30% in the comparison condition.

Data analysis

The use of video data has become widespread practice within education research studying teachers' behaviors or social interaction in classrooms (Knoblauch et al., 2006). In this study, video constituted the main data corpus; hence, the preliminary analysis step was to analyze classroom videos.

Identifying mathematical struggle

A mathematical struggle episode was coded when students showed difficulties, confusion, or uncertainty while they endeavored to solve a problem. Multiple signs and sources were used for identifying a mathematical struggle episode. A clear indicator is students' spoken words, such as "I do not know what to do", "It is so hard", "I do not know how to do the problem", or "I need help". Other sources included students' written work, gestures, facial expressions, body movements, long pauses, and modal particles.

The coding of struggle types followed the three categorizations from Warshauer (2014): Struggle to start, struggle to carry a process, and struggle to explain and sense-make. His fourth type of struggle (expression of misconceptions and errors) was not considered since it could occur at any of three previous stages, and sometimes, the misconceptions are the reasons for students' struggles. Thus, the categorizations of student struggles came from one of the following: (1) confused (consciously or unconsciously) about what the task is asking and did not know how to begin and initiate the task, which was coded as struggle to start (level 2), (2) encountered difficulty or impasse in carrying out a process, using an algorithm to do the computation, or transferring information among representations, which was coded as struggle to carry out a process (level 3), (3) unable to and/or had difficulty in justifying their work, explaining their solving processes, giving reasons for their choice of strategies or solutions, which is coded as struggle to express and explain (level 4). Level 1 of struggle is more than one type. The assigning of levels to struggle types is based on the closeness to the success of problem solving.

Developing codes of instructional practices

The development of a coding manual for teacher instructional practices for struggling students was a combination of deductive and inductive approaches (Guest et al., 2011). First, a prior coding scheme of teachers' instructional practices for mathematics struggles was developed based on a wide range of perspectives in the literature concerning teachers' pedagogical behaviors. Meanwhile, a grounded-theory method was adopted to identify all the other potential instructional practices that were not found in the literature. This inductive-deductive cycle allowed for building a more systematic and complete framework of teacher instructional practices for struggling students. In the end, four groups of instructional practices were identified (see Table 1). To establish inter-rater reliability of video coding, at least 17% of lessons were separately coded by three coders who have a background in and knowledge of CGI. The post-discussion interrater reliability for coding struggle types is 97%, and 90% for the coding of the instructional practices.

Table 1
The coding framework of teachers' instructional practices for struggling students

Dimensions of instructional practices	Sub codes
Supportive strategies that direct to resolve the struggles	1. Support the use of home language 2. Suggest the use of cubes, manipulatives, or other tools 3. Simulate problem situations through embodied actions 4. Remind students to use another strategy 5. Ask open-ended/close-ended questions as scaffolding 6. Give hints/cues
Encourage perseverance and/or agency	1. Tell students it is okay to make mistakes/stuck 2. Praise students' efforts or specific aspects of mathematics work 3. Encourage students to persevere on mathematics tasks 4. Allow students to use any strategies that they prefer 5. Ask students' opinions about the using strategies/solutions 6. Encourage them to think independently
Encourage learning through others	1. Remind struggling students to listen to how someone else solves the problem 2. Ask students to diagnose/resolve struggling students' errors or misconceptions 3. Invite other students' explanation or interpretation
Extending students' thinking	1. Pursues further clarification/elaboration/justification, 2. Ask students to write/revise the symbolic notations, 3. Connect strategies with mathematics concepts, 4. Connect/compare multiple strategies/representations, 5. Direct students to multiple strategies.

Scoring of students' problem-solving

The instrument for scoring students' problem-solving performance was based on Gojak's (2013) rubric. For adapting this rubric to assess students' problem-solving performance in a CGI learning environment, two new dimensions—representation and explanation/communication, were added. Those two aspects were also highlighted in other problem-solving rubrics, for instance, Lopez's (2008) holistic scales. The dimensions for scoring struggling students' problem solving include:

Task understanding assesses whether students show a complete understanding of the task and can use and translate all the important information in the task.

Use of strategies assesses whether students can generate an efficient and appropriate strategy by themselves and whether the using strategies would lead to a complete solution.

Mathematics accuracy assesses whether students execute the computations correctly and reach an accurate solution/answer. When computation was not required, the scoring focused exclusively on whether the student got an accurate solution/answer.

Representations assess whether students use models, drawings, tools, and/or symbols to represent the task, strategies, and/or solving processes.

Explanation and communication assess whether students can clearly and coherently use mathematics language and/or notations to explain their solving strategies, thinking process, and/or answers.

Inter-rater reliability for problem-solving scoring was checked. Seventeen percent of lessons were scored by three raters for each dimension. There was substantial agreement in all the scoring dimensions; Krippendorff's alpha value was greater than 0.75 across all dimensions (Krippendorff, 2004).

Analysis methods

Overall, this study takes a sequential explanatory mixed-methods approach (Creswell et al., 2003), with initial quantitative methods to examine the effects of CGI on students' problem solving, then followed by an explanatory qualitative method to further explain the previous quantitative results.

To answer RQ1, a series of linear regression models were run on students' problem-solving scores as the outcome after adjusting their grade, gender, and struggling levels. To address RQ2, a two-way mediated path analysis was conducted by using interactional time and the four types of instructional practices as the potential mediators. Interactional time is transformed from the length of the struggle episode, which is the amount of time

that teachers interact with the struggling students to help their problem solving. Path a_x was to investigate the CGI effects on the mediators, and path b_x was to investigate the direct effect of mediators on struggling students' problem-solving after adjusting for students' gender, grade, and struggle levels. The specific indirect effect of CGI on struggling students' performance through interactional time was $a_1 \times b_1$, whereas the specific indirect effect through four instructional practices was $a_2 \times b_2$, $a_3 \times b_3$, $a_4 \times b_4$, $a_5 \times b_5$, respectively. In RQ3, a macro and in-depth interactional analysis (Jordan & Henderson, 1995) was used to explore the teacher-student interaction during students' problem-solving struggles within the CGI classrooms. Interactions involving struggling students with low problem-solving scores but receiving a lot of the selected instructional practices were chosen for this analysis. The conversations between students and teachers, as well as their actions, gestures, body movement, and eye gaze, were transcribed. Talk turns, especially in the whole class setting, were coded to examine the teachers' attention distributions among the initial struggling students and their peers.

Results

RQ1: The effects of CGI on struggling students' problem-solving

The treated effect estimates from the two models (without and with controlling for other covariates, Table 2) both showed a positive, large, and statistically significant impact of CGI on struggling students' problem solving (β = 6.30, SE = 0.50, $p < .001$; β = 6.06, SE = 0.51, $p < .001$, respectively). In addition, struggle levels were positively and significantly associated with struggling students' problem solving (β = 0.63, SE = 0.27, p = .02), showing that students with higher levels of struggle had higher scores in problem-solving. With one level increase in students' struggle, their problem-solving scores would increase by 0.63 points. There are no grade differences (grade 1 vs. grade 2) or gender differences (female vs. male) in students' problem-solving performance.

Table 2
Model estimates for the treated effects of CGI on struggling students' problem-solving

	Main effect model (Baseline model)		Model controlling for other covariates	
	Estimate	*SE*	Estimate	*SE*
CGI	6.30	0.50***	6.06	0.51***
Grade2	--	--	0.54	0.52
Female	--	--	0.04	0.49
Struggle level	--	--	0.63	0.27*

Note: *** p <0.001, **p<0.01, *p<0.05, ~p<0.10 (marginally significant). The reference group for condition is the comparison group, grade 1 is the reference group for grade, male is the reference group for gender.

After estimating the main treatment effects, three moderator models were run separately to test whether the effects of CGI on struggling students' problem solving get differentiated by their grade, gender, and struggle levels (Table 3). However, no significant moderator effects were found based on the three tested moderators in this study. On the other hand, the treated CGI effects were repeatedly found across the three moderator models. It showed that even adding other moderators in the model, a robust and consistent effect of CGI on struggling students' problem solving was still found. The highest estimates were found in the grade moderator model with a coefficient of 6.22.

Table 3
Model estimates for three moderator (grade, gender, and struggle level) effects on struggling students' problem solving

Moderators	Estimate	*SE*
Grade moderator		
CGI	6.22	0.64***
CGI*Grade2	-0.44	1.05
Gender moderator		
CGI	5.93	0.69**
CGI*Female	0.29	1.00
Struggle level moderator		

CGI	4.53	1.56**
CGI*Struggle level	0.58	0.56

Note. *** p <0.001, **p<0.01, *p<0.05, ~p<0.10 (marginally significant).

RQ2: Mediation effects of CGI on struggling students' problem-solving

Since significant CGI effects were found on all four instructional practices, they were all used as mediators to probe the mediating effects of CGI on struggling students' problem-solving outcomes. As shown in Table 4, the direct effects of interactional time, instructional practices related to student agency support, practices related to extending student thinking are found to be statistically significant and positive on struggling students' problem solving (β = 0.009, SE = 0.004, p <. 05; β = 0.98, SE = 0.26, p <.001; β = 1.35, SE = 0.23, p < .001, respectively).

Table 4

Direct and indirect effect of CGI treatment on struggling students' problem solving

Mediators	Direct effects of mediators on outcomes (Paths b_x)				Indirect effects of CGI on outcomes (a_x * b_x)			
	Estimate	*SE*	95% *CI*		Estimate	*SE*	95% *CI*	
			Lower	Upper			Lower	Upper
Interactional time	0.009*	0.004	0.001	0.01	0.93*	0.44	0.09	1.86
Supportive strategies	-0.12	0.12	-0.38	0.12	-0.16	0.18	-0.58	0.15
Agency support	0.98***	0.26	0.50	1.56	0.70**	0.22	0.33	1.20
Learning through others	-0.36	0.26	-0.85	0.18	-0.15	0.11	-0.40	0.06
Extending thinking	1.35***	0.23	0.93	1.83	1.79***	0.33	1.19	2.47
CGI	2.91***	0.59	1.73	4.04				

Note. *** p <0.001, **p<0.01, *p<0.05, ~p<0.10 (marginally significant).

In the full mediation model, the PD effects of CGI on struggling students' problem solving were significantly mediated by teachers' interactional time with a positive indirect effect of 0.93 (SE = 0.44 p < .05). Among the four types of instructional practices, the treatment effects on struggling students' problem solving were only mediated by the instructional practices related to agency support and extending student thinking with positive and significant effects of 0.70 (SE = 0.22, p < .01) and of 1.79 (SE = 0.33, p < .001), respectively. The magnitude of estimated effects for extending student thinking, both direct and indirect, was larger than the estimates for the other mediators. However, the direct and indirect estimated effects for instructional practices related to supportive strategies and of learning through others were negative though not statistically significant.

In sum, the total effect of CGI on struggling students' problem solving, without taking any indirect effects into account, was statistically significant and positive, with an estimate of 6.19 (p <.001). After adding the indirect effects of mediators, the effects of CGI were still found to be statistically significant and positive with a smaller estimate (β = 2.91, SE = 0.59, p < .001).

These findings support the conclusion that providing teachers with CGI-based PD is an important lever for improving students' mathematical performance when they encounter problems that elicit struggles. The path by which these effects are felt to be through increased instructional time and implementation of some instructional practices (i.e., supporting students' agency development and extending student thinking), Some instructional practices, such as supportive strategies that directly resolve students' struggles and encouraging their learning through others, did not support students' problem solving. An in-depth analysis of teacher-student interaction was used to investigate what actually happened between teachers and students and to better interpret this result.

RQ3: Teacher-student interaction patterns

Due to the page limitation, we only presented the interactional analyses when teachers frequently encouraged struggling students to learn through others. This instructional practice often happens in a small group or whole class setting, urging struggling students to learn from other students' problem-solving demonstrations and sharing, discussion of alternative strategies, and mathematical explanations. By examining the talk-turn distribution among struggling students and other peers in a big group, we could know how teachers assign their attention to students. It was found that some teachers unequally distributed their attention to students in the whole-class interaction and marginalized the original struggling students from participation in class discussion. On the other hand, using this practice might have the benefits of creating a collaborative learning environment where all students have the chance to participate in the co-construction process of the struggling students' problem solving.

The danger of marginalizing students who are struggling

The case of Nicklaus was selected as his teacher (Lara) frequently invited others to resolve and discuss his problem solving. At five minutes of Nicklaus's struggling episode in a whole-class setting, Lara had implemented the practice of "encouraging students to learn through others" five times. Four students joined the whole class discussion. Table 5 summarizes the key participation metrics for all the students in this episode.

Table 5
Participation metrics by persons in the struggling episode for Nicklaus (the struggling student)

	Talk turn		Words spoken		Word per turn	By teacher's call		By students themselves	
Teacher (Lara)	35	44.30%	384	58.81%	10.97				
Nicklaus	11	13.92%	50	7.66%	4.55	10	90.9%	1	9.1%
Jian	10	12.66%	58	8.88%	5.80			10	100%
Nishan	10	12.66%	48	7.35%	4.80	3	30%	7	70%
Stena	7	8.86%	73	11.18%	10.43	2	28.57%	5	71.43%
Janiya	2	2.53%	26	3.98%	13.00	1	50%	1	50%
Class	4	5.06%	14	2.14%	3.50				
Total	79	100%	653	100%	8.27				

These metrics allow us to examine Nicklaus' participation distribution as compared to other students' contributions in resolving his mathematical struggle. Each student' s talk turn and the word spoken are presented. The teacher spoke the most, took the most talk turns, and spoke the most words. Nicklaus took a similar amount of talk turns (13.92%, 11 turns) as Jian (12.66%, 10 turns) and Nishan (12.66%, 10 turns); but he spoke fewer words (7.66%, 50 words) than Jian (8.88%, 58 words) and Stena (11.18%, 73 words). Nicklaus also had shorter talk turns (avg. 4.55 word/turn) than Jian (avg. 5.8 word/turn), Stena (avg. 10.43 word/turn), and Janiya (avg.13 word/turn). Nicklaus' spoken chances were mainly reflected in elaborating and clarifying his own problem-solving process and strategies. Most of the time, Nicklaus was called by the teacher (90.9%); he seldom volunteered to speak in the group. Jian is the most active student; He initiatively suggested alternative problem-solving strategies and consistently made comments on Nicklaus's work.

Co-construction of struggling students' problem-solving

By inviting other students into the conversation, a collaborative learning environment can be created where more students are involved in the co-discovery and co-constructive process of struggling students' problem solving. The previous case of Nicklaus was still presented to show how students join and navigate each other in struggling students' problem solving.

Nicklaus' teacher selected his work for discussion is because of the uniqueness of his problem-solving approach and strategies (using addition to do a subtraction problem and utilizing an open number line). Interestingly, his teacher did not directly point out Nicklaus' mistakes, but rather, she allowed other students to discover them. In the beginning, the teacher led Nishan (another student) to figure out the answer based on the number line model. "How are you going to figure out what goes here? Do not tell him", this open-probed question left enough space and time for him to think about it. Nishan's first response is very blurry ("he used 28 to add up"). The teacher followed up with a series of probing questions for Nishan' s elaboration on how to add the number together to get 28. Importantly, the teacher did not say any comment that the computation was wrong. Instead, she asked another student—Janiya—if there was an alternative way to add those numbers quickly. This task did not seem easy because many previous demonstrations had shown that 28 is the correct answer. Therefore, Janiya got the right answer by adding one by one, but at the same time, she was very uncertain about this solution and consistently changed it ("Wait, 14 plus 8 is 22. 22 plus 8 is 30…". "Wait, is 28 (deep sign), wait"). Janiya is the first student who realized something was wrong with Nicklaus' problem solving, but she was not that sure. Nicklaus's mistakes were then affirmed by another volunteer student—Jian ("He messed up. It is not 6"; "He missed something"). Instead of rushing to give correct or wrong feedback in this whole process, the teacher left students with enough time to find out by themselves.

Discussion

The debate regarding which instructional approaches (student-centered vs. teacher-led) are more effective for students' mathematical learning continues to be intense among educators and researchers. This study, using the data from CGI PD, indirectly sheds some light on that debate since it investigated teachers' instruction of students who were engaged in mathematics struggles within a problem solving and student-centered learning environment.

It is important to note that not all students from this study are struggling students in the sense that the term is generally understood in the literature. Some students in this study could have been high performing, but they were engaged in mathematics struggles involved in very specific problems that they found difficult.

Although this study did not compare the two types of instructional approaches, results showed that the instructional practices that were more student-centered learning, such as allowing students to use strategies that they preferred, encouraging students' independent thinking, and directing students to use multiple strategies, etc. were positively related to students' high performance in their problem solving. On the other hand, the instructional practices that were more on the side of teacher-explicit instruction, including suggesting alternative strategies, giving hints/cues, and suggesting representations and tools, did not support students' performance as they struggled with problems.

The findings discussed above have important implications for both the design of CGI professional development and classroom instruction. First, the findings of this study offer exciting news as well as some insightful suggestions for improving the CGI program. Results from this study suggested that participation in the CGI program did benefit engaging students in struggles. Those benefits include increased interactional time and teachers' use of practices that help students successfully solve the mathematical tasks, even though some of the practices are not the specific focus of the CGI workshops. This might suggest that CGI focusing on building a conceptual model of students' mathematics thinking has the potential for teachers to develop equitable practices in real classrooms. This indication was also confirmed by Moscardini's (2009; 2010; 2014) year attempts to transplant the CGI program to the Scottish context, especially for students with special needs (i.e., students with learning disabilities and low-performing students). His observation studies demonstrated that special-needs learners have the capacity to make sense of mathematics and show engagement in classroom learning activities if the teachers adopt a CGI-approach instruction. Second, the results from this study help teachers recognize that struggle is a valuable part of learning with understanding. Students' various struggles are not something that should be avoided; instead, they offer teachers instructional chances to engage students in productive mathematical learning (i.e., collective discussions of unresolved problems, devising alternative problem-solving strategies).

Acknowledgments

The research reported here was supported by the Institute for Education Sciences, U.S. Department of Education, through grants R305A120781 (Replicating the CGI experiment in Diverse Environments) and R305A180429 (Follow-up to the Replicating the CGI Experiment in Diverse Environment Study) to Florida State University. We would like to acknowledge the contribution of Uma Gadge, who gave insightful suggestions to improve this work. We also would like to thank Maria Kolovou and Changzhao Wang, who helped check the reliability of video coding and scoring. Critical Biomaking: Socioscientific Issues as Contexts for Life Science Maker Education

Justice T. Walker, Alan Barrera, Rocio Sepulveda, Maria Perez-Piza

The University of Texas at El Paso

Advancements in life science education technologies have expanded contemporary perspectives on making—to now include biomaking where organisms can be altered to produce personalizable and useful products. These innovations have brought with them concerns about the consequences of material production, including impacts on society. It also raises questions about learning environment designs to support engagement with these issues in both life science and traditional maker contexts. In this exploratory study, we examine a group of six adult participant perspectives and artifacts in a biomaking workshop that uses socioscientific issues (SSIs) to frame learning. Our analysis suggests that biomaker activities provide a viable access point to engage complex SSIs. We also observed that participants took up making to solve personal and societal problems, they also critically posed problems about material production and its impact. We discuss how these implications might advance what we know about maker affordances in STEM teaching and learning.

Introduction

The maker movement has undoubtedly made significant inroads in science, technology, engineering, arts, and mathematics (STEAM) teaching and learning (Blikstein, 2018; Dougherty, 2012; Papavlasopoulou et al., 2017). This progress is reflected in the growing body of literature that examines making in relation to such areas as access, learning, and equity (Halverson & Sheridan, 2014; Russo et al., 2021). Despite progress maker perspectives have had on how the learning science community understands learning environments, processes, outcomes, and scales (Cohen et al., 2017; Peppler et al., 2016; Searle et al., 2019)—we know far less about how makers themselves contemplate and grapple with the accompanying social or cultural tensions that sometimes surround their productions (sometimes referred to as socioscientific issues or SSIs) (Zeidler, 2014). Examples include computer programs whose algorithms place end users at security risk, or maker products and practices that reify participation exclusion or stereotypes (Ames, 2018; Vossoughi et al., 2016). Thus, many of the SSI-based insights we have about making involve activities where objects are used to draw attention to social issues (e.g., the democratization of technology) rather than stances that highlight how objects themselves might create them (e.g., critical making) (Chou, 2018; Deibert, 2014; Greenberg et al., 2020; Lachney, 2017; Ratto, 2011). This raises questions about public awareness and literacy surrounding material production (Walker, 2021) and how, if at all, making attends to this educational priority. These concerns thus underscore an important need to examine how makers engage more critically with SSIs associated with production in the maker sphere.

A challenge in addressing this need is that most maker activities in education involve inanimate objects whose life cycle reaches an apparent stop once productions are no longer in use—and are out of sight and out of mind. This issue is reflected in learning science and education research where there are fewer perspectives on learning experience and design to support engagement with the complex social and cultural ramifications associated with maker productions or material artifacts long after they have been produced (Shaw et al., 2019). Synthetic biology—where organisms can be genetically modified for practical uses (e.g., art, food, sensing, etc.)—provides a unique frame within which to examine how makers contend with the relationship between their productions and society. This is, in part, because the lifespan of biological materials continues long after use—these material artifacts can proliferate into the environment.

To explore these issues, we use a biomaker themed workshop (Lui et al., 2019; Kafai et al., 2017; Kafai & Walker, 2020; Walker, et al., 2018) as a frame to investigate the ways a group of six adult participants grapple with the potential impacts synthetic biology products have on their local communities. Set in an informal learning environment located in a western borderland region of the United States, this exploratory research uses workshop artifacts and interview data to qualitatively examine what happens when biomaking is the access point for participants to critically consider SSIs associated with production. This study is guided by two research questions: (1) what do participants have to say about SSIs surrounding synthetic biology products and (2) what do workshop artifacts reveal about how participants view synthetic biology production and utility. We highlight two case examples drawn from our workshop and discuss the affordances and constraints biomaking has as a lens to critically engage SSIs associated with synthetic biology. We also address implications for other areas of making.

Background

Maker education

While there are a number of conceptualizations for making—many of which are distinguished by context and practice—central characteristics of this movement include material construction, interest-driven pursuits, and social engagement as learners build, design and share their productions (Dougherty, 2012; Papavlasopoulou et al., 2017). Maker approaches to K-12 STEM education have illuminated important insights about the nature of material artifacts and their role of mediating important learning processes and outcomes (Ames, 2018; Valente & Blikstein, 2019). Research along this trajectory includes examination of the various affordances making has in promoting STEM learning and is especially prominent in engineering and computer science education (Peppler et al., 2016)—areas where many efforts have sought to address learning outcomes as well as persistent issues related to domain access and participation parity (Calabrese Barton & Tan, 2018). From using Lego blocks, wood cutters, and 3D printers to design and construct robots, to sewing conductive thread in LEDs and microcontrollers to fabricate electronic textiles, making has shown to be a promising context for designing and examining learning in STEM domains. This includes research on how making encourages and sustains learner interests, knowledge acquisition, skill development and mindset shifts (Chou, 2018; Lin et al., 2020).

A growing area of research has examined making beyond digital and computational areas of STEM and into life sciences (Kafai, et al., 2017; Lui et al., 2019; Viñas et al., 2020). Momentum in this area of STEM learning science and science education research is the result of enabling biotechnologies (e.g., bioengineering, synthetic biology, biodesign, etc.) that have recently made use of these tools less costly, portable and thus accessible for educational purposes. Examples include tools that enable the genetic modification of bacteria or yeast to produce fruit or wintergreen scents, vitamins, or color pigments for use in food products or art (Kuldell et al., 2015). Learning science research in this area has emphasized learning design affordances and constraints of this approach to K-12 life science education. There is also a growing corpus of literature that examines ways to support material construction consistent with maker perspectives (Lui et al., 2019) in this genre of making with life science often referred to as biomaking. Biomaking has now made it possible for non-expert audiences to participate in biology-based material productions not ordinarily found in nature. Synthetic biology is distinct from other forms of biotechnology in that it borrows perspectives from computing to frame cells as programmable units that can be designed to generate novel outcomes (Kuldell et al., 2015). This technology is responsible for next generation innovations in medicine, manufacturing, and agriculture. Biomaking extends this perspective by leveraging synthetic biology for teaching and emphasizing materials, rather than genes or DNA exclusively, where learners can make art, bake, or produce other materials of personal interest. These developments raise questions that far less research has addressed—about how learners consider or grapple with the impact production and objects have on the community and society overall. For instance, plastic consumption and computer programs are rife with thorny SSIs around who has access to maker products, where those products end up in their life cycle, and how those products (and especially in their digital form) manifest and shape the world around us—after all computer programs can take on a life of their own after reaching global networks where they can be modified by others. Biomaking, synthetic biology for maker-style teaching and learning, makes these issues more apparent due, in part, to the fact that biological materials require special handling to mitigate the potential impact they might have on society and the environment. Thus, biomaking provides a unique vantage point to begin examination of maker production in the context of teaching and learning, including around areas of how we might begin to support upfront and critical engagement with material production in STEM maker education and the accompanying SSIs associated with those objects.

Socioscientific issues

Socioscientific issues (SSIs) are controversial science topics that require complex considerations often grounded in cultural, ethical, and/or moral values (Zeidler, 2014). Examples include topics related to climate change and its impact on society and the planet, or the risks associated with digital technologies and privacy. In STEM education and research, SSIs are frequently used to support literacy practices such as data analysis, argumentation and decision-making where learners reason through the often complicated social and cultural issues associated with these topics (Presley et al., 2013). Significant research in the learning science and science education literature has revealed a number of affordances of using SSIs as a frame for teaching and learning STEM (Dauer & Forbes, 2016) including opportunities for learners to make meaningful connections between science topics and their everyday lives. This line of research is especially prominent in life science education, where burgeoning biotechnologies have, for decades, drawn attention for the ethical and moral dilemmas they present. Examples

include issues associated with consuming genetically modified food products, the implications of consuming genetically cloning livestock, the risks associated with gene therapies to treat inborn disease, or the use of HeLa human cell lines that were taken, grown, and exploited for science discovery (Leiden, 2000; Savadori et al., 2004; Skloot, 2017; Solter, 1998).

Despite the influence maker education has had in STEM education, there is a dearth in the literature on topics at the intersection of making and SSIs (Shaw et al., 2019)—this is despite the fact that scholars have mostly examined related topics like how learners use digital productions to critique or disrupt complex and often thorny social and cultural issues related to STEAM and its impact on society. This gap in the literature also exists at the intersection of SSIs, making and the life sciences. This is due in part to the fact that the latter two areas—making in life science—have only recently been possible. Areas like biomaking therefore present a whole new wave of SSIs, and accompanying public attitudes (Walker, 2021), where material production and considerations span beyond scaled medical and agricultural applications, and into an era where genetic modification has proliferated locally. These developments create an early opportunity to examine life science maker learning in relation to socioscientific issues in a shift from discussing largely hypothetical scenarios or biotechnologies that have existed for decades, toward engagements that involve actual material products with real world implications. This research seeks to examine this context in order to shed early light on how biomaking affords, constrains, or extends what we know about SSIs in the context of production in life science education.

Methods

Context

This study took place as a workshop in a fabrication lab (FabLab), a not-for-profit organization that provides community access to fabrication tools and used for skill development, workforce training, creative collaboration, prototype development, and product manufacturing. The site is located in the western region of the United States near the Mexican border. The study consisted of a workshop that incorporated synthetic biology lab activities. The workshop ocurred over a period of five days for about four to six hours each day. The workshop included tasks: cell-line genetic modifications, design application prototyping, socioscientific issue discussions, and speculative design presentations (shown left to right in Figure 1a-d). These tasks are summarized in the next section.

Figure 1a-d. Biomaker Workshop Tasks in Genetics, Design Application, Discussion, and Presentation. (left to right) Participants: (a) Genetically modifying E. *coli* bacteria to produce color pigments, green, purple. (b) Use their genetically modified bacterial cells to make bioart designs. (c) Use case studies to discuss the impact of microbial-based synthetic biology applications on the environment. (d) Participants present on synthetic biology-based applications to manufacture solutions for flash floods.

Workshop design, participants, and data sources

The BioMaker workshop was structured along four main tasks. Participants, first, carried out genetic modifications (shown in Figure 1a) developed by the BioBuilder Educational Foundation (BioBuilder Educational Foundation, 2021). In this process participants produced bacteria that emitted wintergreen or banana smells, green, purple, and black pigments, as well as vitamin A. The second task (shown in Figure 1b) involved design prototyping where participants used genetically modified cell lines in a design application of their own designed applications for their synthetic biology lab products. This included such applications as making bioart and baked products infused with yeast they genetically modified. The third task (shown in Figure 1c) involved a series of SSI-based case study discussions about biomaker and synthetic biology-based applications and the impact those applications could have on society and the planet. Here participants had the opportunity in a think-pair-share

format to develop and express their opinions about biomaking used to genetically modify organisms (as they had done). In the last task (shown in Figure 1d), participants put together and presented speculative applications for future biomaker projects. In these presentations, they highlighted the benefits and potential harms of using biomaker projects in the community.

The biomaker workshop included six participants (ages ranging from 25-52)—four of whom self-identified as female and two of whom did as men. All self-identified as Latinx. Participants ranged in professional background that included a: high-school biotechnology teacher, homeschool teacher-mom, trained professional designer, elementary grade teacher, a Fab-Lab employee and adjunct social science instructor, and a mechanical engineer. While participants had diverse reasons for taking up the workshop, they all coalesced around a desire to learn and access Fab Lab activities, which offer ways for adults to do so informally and affordably.

Primary study data sources were workshop artifacts including: worksheets participants completed during SSI-based case study discussion (see Figure 1c) and presentation slides (see Figure 1d) participants used to present their own biomaker speculative design application. Secondary data sources included semi-structured interviews (conducted by authors two, three and four) and surveys (administered using an online survey instrument) where participants shared their opinions about biomaking and genetic modification in general. These secondary data sources were used to corroborate insights gleaned from workshop artifacts.

Analysis

Data sources were analyzed using a qualitative approach. First, workshop artifacts (e.g., worksheets and presentation slides) were digitally scanned and/or uploaded to an encrypted electronic cloud drive shared by authors. Workshop artifacts were then analyzed and coded by two researchers (authors two and three) using an inductive approach (Ravitch & Carl, 2019) wherein researchers identified themes related to what participants wrote about real world biomaker or synthetic biology-based products. In this process, authors two and three identified code categories (e.g., application type, context, and consideration type) based on what participants wrote in response to prompts about biomaking in relation to its impact on themselves, their community, and/or the planet as a whole. Those codes were discussed and developed iteratively in collaboration with authors one and four. A final codebook was then developed and applied to artifacts independently a second time by authors two and three. Code application disagreements were discussed and deliberated with all authors until 100% consensus was reached. Authors two and three then generated frequency charts and pie graphs (not shown in this paper) to visualize data and patterns. Those observations were then used to develop illustrative case study accounts. Interview data were used as secondary sources to triangulate ideas represented in workshop artifacts. This included participant comments about biomaking and its myriad uses.

Findings

Biomaking provides entry point for SSI discussions about production in life science

When analyzing written responses during biomaker SSI workshop activities, we observed that participants collectively considered a wide range of factors in relation to synthetic biology-based products and the potential impact they could have in society. Those considerations varied across application type (e.g., which organism to which synthetic biology was being applied), context (e.g., the purpose of the synthetic biology product), and values (e.g., moral/ethical consideration, risk/benefit assessments, etc.). We present two case examples of written perspectives to illustrate what participants had to say about these applications—including what they expressed about the various tensions associated with synthetic biology and the myriad impacts their products pose to the environment and society as a whole.

Alexis Padilla, a department chair in the biology department in a local high school, and Alejandra Garcia, a fashion designer trained at a school of design in a city located in the northeastern region of the United States, both joined the biomaker workshop for professional reasons. Alex had an interest in finding ways to innovate and expand curricular offerings at the school where she teaches. Having had significant training in fashion on the use of novel and biologically-produced textiles, Alejandra joined the workshop in hopes to continue, at a low cost, her explorations and experiences with materials. After reading an advertisement for the biomaker workshop in an email distribution list associated with the local Fab Lab—both registered as a way to support these personal goals. During the workshop, there were opportunities to learn and carry out synthetic biology, which involved genetically modifying cells and then using them in maker-like ways such as to design, personalize and fabricate products (e.g., baked products and bioart). In between these activities participants had opportunities to reflect and discuss their thoughts about synthetic biology overall through case studies and prompts provided by a worksheet. When presented with applications involving the use of synthetic biology in plants (to produce vitamin infused rice for

human consumption) or microbial (to spider silk for shoes) applications, both participants had a lot to write about regarding the issues these applications raise (shown in Figures 2a-d.). Alexis addresses (Figure 2a.) the potential social and environmental impacts these areas of production could have as she wrote, "of course if it works to the positive, the individual is fine as is society, but if it goes bad, the risk has a trickle-down effect. These researchers need to think long term not if it can be done" (Think-Pair-Share Argumentation Worksheet, Workshop Day 1). In another instance, Alexis weighed such concerns as the consequences that could result if an application is not used, and in relation to the potential risk to an individual person as she explained, "If I have limited or no access to fresh food, I probably don't have access to health care so something that cannot only provide nutrient but [also] create health benefit as well would be something I could use" (Think-Pair-Share Argumentation Worksheet, Workshop Day 3). These instances reflect how, for Alex, production using these biotechnologies creates competing perspectives and potential consequences, in broad terms for the environment all the way down to single individuals. In addition to environmental factors, Alejandra grappled (Figure 2c) with additional factors as she described, "it's a privilege to be healthy in this highly industrial world so if we can create a democratic solution to provide healthy options for everyone we should" (Think-Pair-Share Argumentation Worksheet, Workshop 3). Alejandra grounds her viewpoint around a geopolitical landscape—taking a stance beyond her personal benefit and in relation to society overall. Alejandra, like others, took similar positions about children who "can't make [decisions] themselves" and other species that "have been on this planet" and whose "disappearance could cost our eco-system" (Think-Pair-Share Argumentation Worksheet, Workshop 3). Participant considerations (shown in Figure 2a-d.) were expansive as they contemplated the impact these life science productions could have at the intersection of SSIs with consequential implications (e.g., personal, environmental, socioeconomic, geopolitical, etc.).

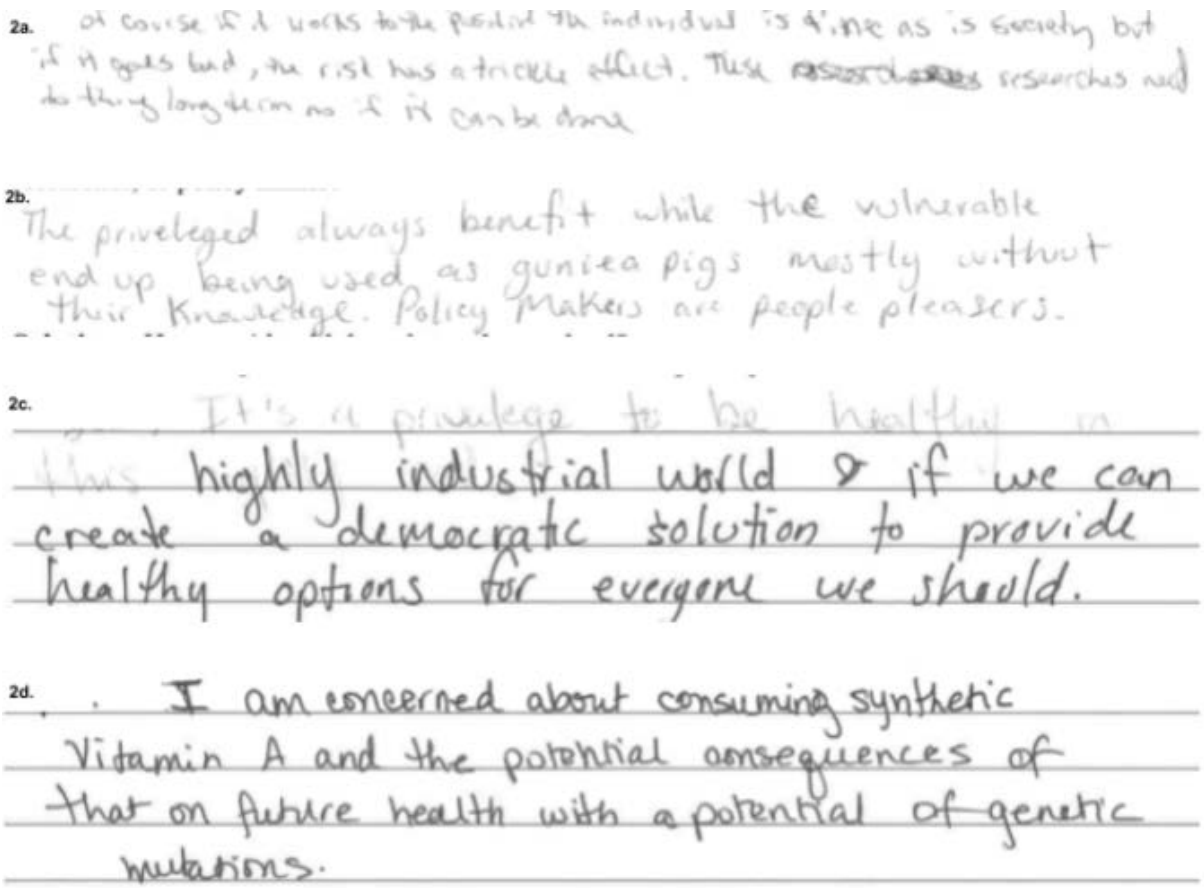

Figure 2a-d. Biomaker Participants Consider a Variety of SSIs Regarding Synthetic Biology.

Participants use biomaker projects to address personal and social issues

Examination of participant biomaker presentations involved synthetic biology applications that cut across a variety of personal and social issues related to interests (e.g, making products for pets), community infrastructure (e.g., creating ways to mitigate monsoon-driven floods), and the environment (e.g., undoing harm to endangered

wildlife). We present projects from case examples to illustrate participant views about synthetic biology utility in relation to themselves and their community. Alexis Padilla presented about how synthetic biology could be used to fabricate synthetic and animal friendly essential oils scents that could be used for household pet cats. Alexis argued that cats have important personal and household value (e.g., rodent control, companionship, longevity, etc.) that could be enhanced through the use of calming essential oils. She went on to point out that these products pose harm risks because they contain an ingredient (e.g., glucuronidation protein) that is not metabolized by cats, leaving them "vulnerable to organ failure" (Final Presentation, slide 3, Workshop Day 5). Alex speculated that synthetic biology could be used to synthesize essential oils without the protein deleterious to cats. During the workshop, Alexis shared her fondness for cats and expressed how she cared for her own—pets that meant a lot to her personally. Taken together, this evidence showed that to Alexis synthetic biology could be used as a tool to address an issue endemic to household feline pets. In a different instance, Alejandra considered using synthetic biology in a markedly different way—raising concerns about the environmental impact of the U.S./Mexico border wall on native species in the region. She argued that the binational barrier was primarily a "human problem" that "threatens the lives of over 90 endangered species" in the region (Final Presentation, slide 2, Workshop Day 5) shown in Figure 3a-c below. Alexis speculated the possibility of using synthetic biology approaches to isolate a gene found in a steel metabolizing bacteria (*H. Titanicae*) discovered on the sunken Titanic that could then be inserted in a native Ocotillo plant species (*F. splendens*) native to the Chihuahuan desert region. She argued that this plant, with its barbed branches, would create a structurally feasible human barrier that over time—using *H. Titanicae*-derived metabolic processes—decomposes the existing border wall while simultaneously allowing native species to pass unobstructedly throughout the region. In conversation with Alejandra we learned that her idea was consistent with her ideological concerns about the border wall in addition to concerns for the environment.

Figure 3a-c. Participant Biomaker Project Uses Synthetic Biology to Problematize Local SSIs
(left to right) Participant: (a) Presents a case example and background research of how the border wall in a binational region has an impact on endangered species, (b) Identifies microbes and native plants that would be suitable starting points for using synthetic biology to solve border wall ecological impact (c), Provides explanation for how steel metabolism would word in decomposing the existing border wall.

Implications

Socioscientific issues and maker education

Maker education, with its paradigmatically distinct focus on design and material production has had an undeniable impact on active approaches to STEM education and research. In this study we build on traditions that engage making to draw attention to social issues in participation (Greenberg et al., 2018; Searle, Tofel-Grehl, & Breitenstein, 2019), learning (Russo et al., 2021), and practice (Vossoughi, Hooper, & Escude, 2016) by also examining maker activities that address social issues that are the result of material production. Our biomaker activities, framed in the context of SSIs, revealed that biomaking—powered and enabled by biotechnologies like synthetic biology—is rife with complex issues that include both discipline-specific considerations (e.g., those related specifically to life science and its impact) and those that span across fields (e.g., those connected moral values or ideological orientations). This is reflected in the well-developed opinions participants had about synthetic biology and its various uses. We also observed in our workshop that these opinions reflect sentiments typical of SSI views about biotechnology (Solter, 1998; Savadori et al., 2004; Leiden, 2000; Shaw, Walker & Kafai, 2019), and included a myriad other considerations (e.g., personal, societal, socioeconomic, geopolitical, etc.). We consider this a reflection of the fact that the synthetic biology field brings with it a whole new set of possibilities (e.g., manufacturing pigments, food ingredients, etc.) that expand the corpus of SSI cases to engage.

This could also be because maker perspectives often involve broadly encompassing and interdisciplinary fields and practices that connect well with a variety of issues. These connecting points also highlight the affordances making has as a context to have productive discussions around production and SSIs topics that have been shown to be successful in promoting STEM literacy (Presley et al., 2013). Future research along this trajectory might consider how making with electronics and computational artifacts might also extend traditions (Zeidler, 2014) about how learners critically discuss, argue, and develop literacies around SSIs in innovation and production.

Critical biomaking: A context to solve and pose problems

Our examination of final presentations suggests that participants fundamentally viewed synthetic biology utility in two ways—as a tool to either solve or pose problems. Alejandra's presentation, distinct from Alexis who pursued a personal interest, showed a synthetic biology application designed and used as a provocation—around a complex geopolitical landscape rife with socioscientific implications. Rather than the typical frame of being a service *to* the community, both cases framed synthetic biology's utility as an instrument in service *of* the community, its interests, and politics. This critical biomaking approach is consistent with views in critical making (Deiber, 2014; Vossoughi, Hooper & Escudé, 2016) where participation enables both problem solving and the problematizations of practice. In a genre of making that continues to flourish as a field and method for enhancing STEM education, future research should examine critical biomaker focused learning designs that might be leveraged to support learning outcomes and reevaluate perspectives about making and its utility in the practice of modern science teaching and learning.

Translanguaging as a Tool to (Re)Connect: Co-designing Land-Based Learning Environments with Refugee Children

Sophia Thraya, Miwa A. Takeuchi
sophia.thraya@ucalgary.ca, miwa.takeuchi@ucalgary.ca
University of Calgary

Abstract: For many racialized and linguistically minoritized refugee youth and children, schooling can be experienced as a space of being assimilated into the dominant norms including the detachment from their home languages and community practices. In this paper, we examine how the participating school-aged refugee youth and children in our co-designed land-based program, Soil Camp have contributed to co-creating spaces to challenge dominant norms imposed upon them, together with facilitators (who were mostly racialized multilingual teachers). Our paper is centered around the question: How did the participants co-construct agency to shift away from dominant monolingual norms in their interactions during the land-based Soil Camp? Based on video-based interaction analyses, our findings illustrate how the co-constructed translanguaging interactions contributed to redefining geopolitics surrounding the participating refugee youth in moment-to-moment interactions. Our findings also show how translanguaging interactions can extend to creating connections between more-than-human lives and these youth and children.

Introduction

During the COVID-19 pandemic, community gardens and urban farms served as one of the few places people could safely gather and socialize, yet access to green space has not been equally distributed. In collaboration with community partners, we tried to address this inequity through the co-designed land-based learning pedagogy, *Soil Camp* (Takeuchi et al, 2021). With many Yazidi and Syrian refugees coming from agricultural backgrounds (Takeuchi et al., 2021), Soil Camp can help refugee children learn about the soil, plants, and animals along with key concepts in Science, Technology, Engineering and Mathematics (STEM), while being part of community and reconnecting with their family members' wisdom on sustainable farming. Our co-designed pedagogy respect and learn from land stewardship and land-based embodied knowledge of Indigenous communities (Simpson, 2014; Marin & Bang, 2018). We acknowledge the colonial history of lands and aim to work with Indigenous communities toward the revitalization of Indigenous food systems and knowledge of food and environment.

Through our community-based research, we worked closely with refugee children, youth, and families who experience oppressions of racism, classism, and gender-based violence as well as trauma from war and genocide. Within the last 10 years, Canada has had 302,890 persons making claims for refugee status (Government of Canada, n.d.). For many racialized and linguistically minoritized refugee youth and children, schooling can be often experienced as a space of being assimilated into the dominant norms including the detachment from their home languages and community practices. In this paper, we examine how the participating children were co-creating spaces to challenge dominant norms imposed upon them, together with facilitators (who were mostly racialized multilinguals). Our paper is centered around the question: How did the participants co-construct agency to shift away from dominant monolingual norms in their interactions during the land-based learning program?

Theoretical Framework

Learning happens as people move across multiple contexts and borders that bring forth the heterogeneous histories and power relations (Vossoughi & Gutiérrez, 2014). In the midst of movement and as learners imagine new mobilities in the places salient to them, learners actively make places, reconnect with lost relationships, and build new relationships (Marin et al., 2020). Engaging with the land and places for Indigenous communities is an act of resurgence where Indigenous youth reconnect with their ancestors' relationship to the land and Indigenous ways of knowing the land (Marin & Bang, 2018). Considering many Yazidi refugees who participated in Soil Camp are considered Indigenous in their countries of origin, reconnecting with the land is the act of *presencing* (Nxumalo, 2019) their intergenerational wisdoms in the predominantly white farmland landscape. Focusing on the gathering power of places, we pay attention to resistance, agency, and transformation in the everyday acts of Othered bodies by making their presence visible through occupying, gathering, and renewing the place (Takeuchi & Aquino Ishihara, 2021).

Learning is never politically neutral and reflexive of societal hierarchy and imperialism (Philip & Sengupta, 2021). Our design centered hybridity in the third space (Gutiérrez et al., 1999) by de-normalizing

 © ISLS

English imperialism and monolingualism in pedagogical spaces. In light of the criticality and activism that teachers of color have pushed forward (Pham & Philip, 2021; Strong et al., 2016), we highlight interactional co-construction of linguistic fluidity and anti-colonialism in relational spaces situated on the land. Central to our analysis is the notion of translanguaging. García and Wei's (2014) definition of translanguaging is an extension of the term coined by Cen Williams in their work on the pedagogical approach of bilingual language use in receptive and productive literacy contexts. The term translanguaging has evolved to encompass the fluid and dynamic practices of bilingual individuals' language use (García & Wei, 2014). Translanguaging challenges colonial monolinguistic norms and dominant deficit discourses on language minoritized individuals and communities by recentering the speaker and their unique lived bilingual language experience and repertoire (García et al., 2017; Suárez, 2020). By challenging the monolingual norms, we are also challenging the colonial matrix of power imposed by English imperialism (Takeuchi, 2021). Translanguaging also refers to the pedagogical approaches employed for leveraging such language use and practices (García et al., 2017). These pedagogical approaches allow for the streamlining and designing of learning environments that are reflective of the "actual languaging practices" of students and their lived experiences (García et al., 2017, p. 2). Additionally, this noted tool positions the bilingual identities and the individual's unitary linguistic system as working in conjunction with their lived experience for learning and knowledge sharing. The term, translanguaging stance, as described by García et al., (2017) refers to "the belief that bilingual students' different language practices need to be leveraged together and performed collaboratively with others" (p. 184). The *translanguaging stance* allows for the employment of features of language that best foster understanding and connection. The notion of translanguaging shifts away from the traditional bilingualism conceptualization of language, which sees languages as independent named autonomous systems that one employs as deemed appropriate by dominant listeners in the contextual climate (García & Wei, 2014). This limiting perspective demobilizes the rich unified linguistic resources that language minoritized individuals and communities hold and the potential for the co-creation of "new social realities" (García & Leiva, 2014, p. 204).

Extending this definition, we propose the reframing and extension of translanguaging as a pedagogical tool for (re)connection with each other, intergenerational knowledge, and more-than-humans. Thus far, the conceptualization of translanguaging has been anthropocentric, focusing on human communications. Marin (2020) reminds us that those who research STEM education should develop systems of analysis and ways of seeing and listening that allow us to "re-member (Grande & McCarty, 2018; Wa Thiong'o, 2009 as cited in Marin, 2020) relationships between land, humans, and more-than-human relatives" (p. 31). As children engage closely with more-than-human lives on lands (Marin & Bang, 2018), they could engage in translanguaging practices that go beyond human-to-human communications. In this paper, we aim to explore the possibility of extending the notion of translanguaging to include our communications with more-than-humans. This theoretical push is particularly important considering the influx of displaced refugee families who embody agricultural experiences being stripped from their generation connection to more-than-humans in the resettlement process.

Methodology

We draw from participatory social design research methodology (Gutiérrez & Jurow, 2016) that centers historicity, diversity, equity, and ecological resilience as design principles and aims to co-design just practices and futures in partnership with a range of communities. We are also guided by Indigenous ways of knowing and decolonizing methodology that acknowledge colonial relationships reinforced by research and honour and carefully listen to the voices of Indigenous people (Smith, 2001; Marin, 2020). Our co-design aims to foster collective actions for food justice and environmental restoration through Soil Camp (as discussed in Takeuchi et al., 2021). This co-design process started in January 2021 and our collaboration is ongoing.

In total, 65 youth and children (aged from 5 years old to 15 years old) and over 20 families joined our program in 2021. All attendees were refugees from Syria, Northern Iraq, Kurdistan, New Guinea, Pakistan, South Sudan, Ethiopia, and Eritrea who had resettled in Canada within the last five years. Thirteen teachers and teacher candidates (who are mainly racialized multilinguals) joined as facilitators of Soil Camp.

Data

A team of researchers collected the following datasets from two weeks of Soil Camp in July 2021: 1) video data collected using three different cameras (Go-Pro cameras worn by both the participants and by the researchers, Handycam video cameras held by the researchers, and still cameras with video functions taken by both the participants and the researchers). A total of 31.43 hours of video data was collected and analyzed by the team. In addition, each member of the research team has taken fieldnotes right after each activity. On-site interviews with the participants were conducted to elicit the participants' backgrounds in farming, their sensory experiences on the land (what they see, feel, smell, and hear), and their developing sense of soil and the land.

Analysis

We draw from critical and decolonial interaction analysis (Philip & Gupta, 2020; Marin, 2020) to bring forth the interactional phenomenon of translanguaging. As we analyzed the interactions, we closely attended to the power dynamics surrounding the participants, colonial histories (between humans and between humans and non-humans), and linguistic norms reproduced or challenged in particular interactions. As a first step, we content logged all the video data and revisited our fieldnotes. From there, we coded segments of data where the participants were bringing in non-dominant (and often censored) languages in institutionalized schooling spaces. We transcribed key segments of data as compelling enactment of translanguaging initiated by the participating youth and children.

Sophia Thraya (Author 1) is a current graduate student and a trained and certified teacher in Alberta, specializing in Elementary English as an Additional Language education. I (Thraya) am a second-generation Canadian of the Lebanese diaspora and self-identifies as bilingual, holding both English and Arabic in her linguistic repertoire and dear to her heart. To the field of the learning sciences, I bring in prior research experiences and engagement in sociology with both the resettled Syrian and Yazidi populations centering on the lived educational experiences of school-aged Yazidi refugee children. During the planning stages, I was an active collaborator and held the roles of program facilitator and researcher during the Soil Camp. My associations and position with and within the community(s) have shaped the ways in which she has approached her research, community engagement, and educational practice. I draw from these lived experiences as a guide for analysis. Collective viewing of data and collective analysis were followed to bring multiple voices into video data analysis.

Findings

In this paper, we highlight two episodes that depict themes that emerged from our analyses: co-creation of translanguaging interactions toward a renegotiation of relationships with each other and with more-than-human lives. As seen in these episodes, the participants collectively challenged the dominant discourses in education through the shift away from deficit casting gazes on linguistically minoritized learners. These episodes present evident inward listener reflection and co-created reenvisioning of the resettled refugee youth and children's linguistic and educational potential. Overlapping themes of both episodes include the active presence of racialized bilingual facilitators who modelled the strength in multilingual identities and language use. These facilitators followed the dynamic flow of participant connections, curiosity, and agentic understanding through translanguaging, which in turn allowed them to contribute to the co-construction of a hybrid third space (Gutiérrez et al., 1999). These episodes also exhibit the rich relationships fostered through the tool of translanguaging and the translanguaging stance between anti-colonial land-based pedagogy, participants, and more-than-humans.

Episode 1: Walking together and fostering relationships through a translanguaging stance

Figure 1

Facilitators and Children Walking Together

This segment of interaction begins during a transitional period where participants were moving from an activity in the plot area to the tipi that was built by a local Indigenous community. The tipi was situated roughly one hundred meters away at the start of this interaction. The group of participants independently walked across the land and during this time an interaction between Sophia (Author 1 and a teacher facilitator) and a girl-identified Yazidi participant, referred to as Viyan (pseudonym), was recorded on a wearable Go-Pro camera. This participant had previously been observed to be quite reserved and quiet in whole group settings. When Sophia approached her, she was walking alongside a same-aged peer with whom she developed a close bond. Sophia began the interaction by asking the girls whether they were going to come to see the tipi—due to the flexible design of programming that honored participants' choice, they had the agency and autonomy to choose whether to join. Both girls responded with a nodding motion showing that they were coming and joining the teaching inside the

tipi. Their use of physical response rather than verbal was in fact not "abnormal." Rather than continuing to walk and leaving the girls, Thraya chose to continue the interaction and walk alongside the girls. It became apparent that without such an effort for connection on Sophia's end, this could have been the end of this engagement. Thraya followed up with additional questions and Viyan began to engage in conversation with Thraya, employing her linguistic repertoire—Kurdish, English, gestures, and movement—as she saw fit.

After approximately one minute of personal interaction and conversation, Viyan asked Sophia a question that was quite pivotal in the conversation (see Table 1).

Table 1
Episode 1 Interaction 1

1	11:05:54-9	Viyan	You speak Kurdish and Arabic (posed as a question but intonation indicated statement).
2	11:05:56-4	Sophia	I can speak some Arabic, yeah ↑!
3	11:05:57-1	Sophia	I would love to learn Kurdish though.
4	11:05:59-6	Viyan	I speak little bit of English and Kurdish.

Above, there is a clear and observable foraging of connection (see Table 1). Viyan is communicating and showing Sophia the parallel between Sophia and herself, as she has "some" Arabic in her linguistic repertoire and Viyan has "a little bit of English" within her own. The evident use of quantifiers can be due to the ideal of "linguistic perfection" imposed by the dominant society and monolingual normativity. Within the translanguaging framework, such semantic micro politics (as seen in the case of such quantifiers in utterances 2 and 4) cease. Policing of language proficiency and mastery sentiments relating to national language agendas were not present in this interaction. Rather, experiences with and within the bilingual communities of each were validated in the above excerpt; regardless of being deemed fluent within them.

Viyan observed Sophia communicate in earlier interactions with Arabic-speaking peers. Knowing that Sophia holds a bilingual/multilingual identity, Viyan spoke up and asked Sophia what features and modes of language she uses. Viyan, without prompting, shared her own language identity. Sophia then proceeded to acknowledge the value in her repertoire and how she would love to learn Kurdish (see Table 2). She then shared with Sophia some features including the phrase 'how are you' (Chawa yee) and 'good' (ez bashem).

Table 2
Episode 1 Interaction 2

1	11:06:04-1	Sophia	That is awesome!
2	11:06:07-8	Sophia	I would love to learn some Kurdish; would you like to teach me some Kurdish?
3	11:06:13-7	Viyan	Yeah, like if someone says Chawa yee, you say Ez bashem
4	11:06:17-9	Sophia	[Chawa yee, yes, ez bashem]
5	11:06:20-2	Sophia	Is that hello ↑?
6	11:06:21-7	Viyan	Yeah, it says how are you, you say good.
7	11:06:21-7	Sophia	Ez bashem is good, okay. So, to say how are you, I say?
8	11:06:38-0	Viyan	Chawa yee.
9	11:06:43-3	Sophia	Perfect, I am going to practice!

The connection made between Sophia and Viyan is one that was built upon the shared sense of commonality regardless of the modes of language in their individual unitary repertoire. Both acknowledged and celebrated the rich value of holding bilingual identities and confidently employed their linguistic resources as they felt comfortable. Sophia and Viyan together transformed the space from one of silencing to one of rich connection—and co-constructed interactions that affirm translanguaging space to validate each other's full repertoires of language practices. This interaction ended with smiles and the emergence of a non-hierarchical teacher-student relationship stemming from their shared language experiences.

Episode 2: Cocreating the multilingual ecology—translanguaging through music with one another and more-than-humans

Figure 4

Children Listening to the Voice of the Lemon Plant

Episode 2 showcases a whole group interaction during an activity titled Listening to the Voice of Plants. This activity was led by Anita, another multilingual and racialized preservice teacher, and one of the community partners. This group comprised of multilingual participants from Kurmanji (a dialect of Kurdish), Arabic, and French-speaking communities. A majority of these participants were Yazidi children. This activity involved introducing an instrument to the children that converted plant biorhythms to synthesized musical notes. Electrodes were placed on the leaves of a lemon plant and the device began translating the electromagnetic waves from the leaves into musical notes. The children were quite astonished by this, many vocalized their learning, identifying patterns, emotional expression, and potential meaning behind the music. Many were curious as to how this technology could allow us (humans) to hear what the plant was vocalizing. After the explanations on the mechanisms behind this technology and plant systems, Anita introduced the next segment of the activity—interacting with the plant by singing to it.

Figure 5

The Group Singing to the Plant

Anita began this part of the activity by drawing on the children's knowledge of songs. One child suggested Twinkle Twinkle Little Star and Anita counted them in, and the group began singing. Once they finished the song, they all listened to the plant's response. Anita then asked the children if there was any difference in the sound of the music after they sang to it and they collectively agreed that there was a noticeable change. Following this, many disciplinary questions arose related to plant communication and cognition. This episode shows multilingual children's connection and communication that transcended language borders and boundaries between species. Anita then led them to sing another song, this time a child suggested another children's song Baa Baa Black Sheep in English. This song was a little more challenging as some of the participants were not familiar with the lyrics. The plant sounded quite somber, and this is when Anita asked the children if they could sing a song from their language communities (see Table 3).

Table 3

Episode 2 Interaction 1

1	00:14:40-1	Laylan (Yazidi Participant)	I speak Kurdish, almost everyone [here] speaks Kurdish

 © ISLS

2	00:14:45-8	Anita	Do you guys know any Kurdish songs?
3	00:14:59-1	Laylan	سنة حلوة /begins singing Happy Birthday in Arabic to the plant/
4	00:15:03-9	Nali (Yazidi Participant)	/Joins in/ That's Arabic!!
5	00:15:05-4	Mahmoud (Arabic-speaking youth volunteer)	That's Happy Birthday!
6	00:15:07-6	Laylan	But I wanna sing Happy Birthday so bad. سنة حلوة يا جميل /Continues to sing Happy Birthday in Arabic again/
7	00:15:14-8	Anita	Okay, let's sing Happy Birthday. Do you guys know how to sing Happy Birthday [in Arabic]?
8	00:15:17-1	Laylan	[He can sing with me] /pointing at Mahmoud/
9	00:15:18-5	Anita	In Arabic?
10	00:15:18-5	Salima (Arabic-speaking participant)	Yeah!
11	00:15:18-8	Mahmoud	Okay, سنة حلوة يا جميل سنة حلوة يا جميلسنة حلوةسنة حلوة سنة حلوة يا جميل /All join in/
12	00:15:31-5		Note: *All Yazidi participants, Arabic speaking participants, half of the youth leaders as well as Anita joined in and began singing Happy Birthday in Arabic.*
13	00:15:37-2	Laylan	Happy Birthday to Mr. Lemon

It is observable that the teacher facilitator Anita and the children together established a translanguaging space. Anita followed the flow of these bilingual children's lead, democratically letting the children be the experts which then allowed for a space for the exchange of knowledge. This series of interactions also allowed for connection across linguistic, social, ethnic, and geopolitical boundaries. Laylan employed the Arabic Happy Birthday song from her repertoire as a means of connecting with fellow participants, including those of her ethnoreligious community, even though it was not the language of her community.

This episode is particularly significant as Arabic was the national language of the dominant majority in their country of origin and the oppressive powers that unjustly subjected their community to violence and genocide. The very language of the oppressor, a language that older generations of Yazidis who resettled in Canada deny knowing and communicating in—due to the associated trauma—was repurposed by this young girl and sung in a playful manner. It is unbeknownst to the researchers as to where these children learned the Arabic version of this song, but an overwhelming majority of the Yazidi participants sang along without hesitation.

As showcased in these interactions, these land-based translanguaging interactions contributed to a space for renegotiating past experiences and geopolitics and redefining historically imposed relations among ethnic groups. These children engaged in a cross-linguistic exchange between one another; the children, junior leaders, facilitators, and more-than-human life cocreated a translanguaging environment to connect and reconnect. Even though Anita did not share the same linguistic backgrounds as the participants, as a teacher, she modelled a translanguaging stance—embracing fluid and agentic linguistic repertoires to maximize communication potential. She employed translanguaging within the activity design and was unafraid to follow the flow of what García et al. (2016) describe as the translanguaging *corriente*—current.

An additional noteworthy interaction occurred following this rich moment of interaction. After Happy Birthday was sung in Arabic, Anita asked if anyone could sing Happy Birthday in Kurmanji. Much back and forth between the Yazidi girls occurred in Kurmanji, but there appeared to be some confusion and some shyness when it came to sharing. This group did not end up singing Happy Birthday in Kurmanji, but Anita did not pressure and then leveraged other language identities within the space. Anita knew that a youth volunteer member spoke French and as such, she asked him if he could sing a song. A young French-speaking girl referred to as Esme immediately looked up and visually lit up. It was as if she was waiting for this moment for her linguistic identity to be acknowledged. At that moment a child from the back of the space asks if the group could sing Happy Birthday in French. Before anyone could say a word Esme looked back for a second and began to independently sing Joyeux Anniversaire. This was a powerful and validating moment: when such an opportunity arose to take on the expert role, she took it on proudly without hesitation or invitation. She was met with acceptance and support from all members of this activity shown through loud hand-clapping and high-fives—including the lemon plant which played a bright and melodic tune.

Discussion

The design that embraces translanguaging practice and stance creates learning spaces where traditional educational hierarchies can be challenged. For language minoritized children like our participants who have experienced situations that have demobilized their whole linguistic repertoire, being in translanguaging spaces can be transformational as it affirms their active role in co-constructing learning environments. The land-based translanguaging interactions could lead to a re-imagination of colonial institutionalized school learning. Reframing the dominant, deficit-oriented perspective imposed upon bilingual speakers is long overdue. As evident in the aforementioned findings, translanguaging can serve as a transformational tool for deconstructing the colonial views of what it means to learn in educational spaces and with what languages.

Taking full consideration of affordances of land-based pedagogy (Simpson, 2016; Marin & Bang, 2018), we offer a theoretical shift to include translanguaging as a tool for connecting with more-than-human life. As shown in our findings, facilitators, youth and children mobilized technology as a tool to translanguage with more-than-human lives. In this process, the more-than-human life came to teach the children the beauty of language and its communicative power beyond human-to-human communications. This shift away from an anthropocentric view of language could allow humans to better learn with and through land and more-than-human living things. In Episode 2, we can see children's desire for connection with the lemon plant. This theoretical push is significant, especially within resettlement work with refugee populations where families are renegotiating relations with land after their experiences of being stripped from the lands which they had intimate connection with. Our co-design could allow for remembering and reconnecting with traditional knowledge and ways of life through land-based experiences.

Multilingual educators of color were integral and central in establishing the Soil Camp's translanguaging spaces. Within the field of the learning sciences, teacher-child interactions have been rigorously analyzed and seen as a significant element of the learning experience, yet the significance of teacher identity has just begun (as seen in the works of Pham & Philip, 2021). Collectively, educators and facilitators that were racialized multilingual women of color challenged the dominant representation in education (where the majority of teachers are white English monolinguals in the local context) and modelled the strength in multilingual identities and language use in teaching and learning. We will further our inquiry into the experience for both the preservice and in-service teachers who had yet to see such an environment that empowered their own multilingualism and acknowledged their positionality.

Although there is little to no literature pertaining to the translanguaging stance on the so-called "silent period" phenomena (Dulay & Burt, 1974), we argue that linguistically minoritized individuals, especially those of refugee and immigrant backgrounds, are not *going through* a silent period when acquiring new linguistic features of their host countries, but rather are oppressively *silenced.* This is especially present in our educational settings, where it is widely accepted that newly resettled children will *go through* such a period, and in that time, they will follow along but not verbally engage. As we discussed in our findings, for children like Viyan, expectations in dominant society are such that the options of accepted communication are English or silence. Therefore, if the individual has yet to learn enough linguistic features of the society to communicate monolingually, their only option is to remain silent. Due to experiences in English-only environments, children like Viyan could have been silenced. The common view of the silence period can position bilingual children in a deficit perspective, as it categorizes individuals adding to their linguistic repertoire as infant-like, even though these individuals have rich linguistic repertoires to draw from, but it is not in the "desired" language. We take a stance that this phenomenon/hypothesis is nested in colonial logic of linguistic superiority and goals of assimilation. English-only spaces disregard bilingual children's full repertoires and can have damaging socio-emotional effects, including retraumatization, internalized cultural and linguistic stigma, and disconnection from traditional ways of knowing.

Reflecting upon our research question, it is evident that the participants co-constructed environments that were affirming to their multilingual identities and empowered agency within the teaching and learning spaces. There was a significant shift away from monolingual norms that can be seen in traditional schooling and dominant societal settings. Our study demonstrates the transformational power of bringing forth fluid and agentive translanguaging practices—to carefully listen to historically silenced voices and the voices of more-than-human beings.

Consequential Agency in Chemical Engineering Laboratory Experiments

Madalyn Wilson-Fetrow, Vanessa Svihla, Catherine Hubka, & Eva Chi
University of New Mexico
mefetrow144@unm.edu, vsvihla@gmail.com, chubka@unm.edu, evachi@unm.edu

Abstract: Despite being at the center of undergraduate engineering education, laboratory experiments have remained unchanged for decades, resulting in assignments lacking in opportunities for students to learn and grow. We used a survey to measure students' sense of agency in prototypical design and laboratory courses at research universities. We found students in laboratory courses at both levels experienced significantly lower framing agency than their peers in senior design, and that even those engaged in authentic course-based research did not perceive the experiments as more agentive or authentic. We infer students drew upon abundant low-agency experiences in laboratory experiments; maximizing learning in laboratory courses may hinge on clearer communication about authentic experiments or systematic redesign of earlier courses.

Purpose

While understandings of theory and ability to solve complex engineering problems on paper take up much of students' time, their time in laboratory courses and design projects offers the opportunity to test these ideas firsthand and direct their own investigations and problem framing and solving processes. Laboratory experiments in particular vary in offering students opportunities to make decisions about what question to pose, how to design an experiment, how to collect and analyze data, and how and with whom to share results. Upper division engineering laboratory experiments are typically more complex—and sometimes more authentic, involving students in aspects of faculty research—than those encountered in their supporting, introductory science classes, which tend to be cookbook in nature (Hauwiller et al., 2019). Yet, those foundational experiences may shape students' perceptions of the laboratory courses as being an opportunity to demonstrate their capacity to deliver the known answer, rather than participating in a discovery process (Chen et al., 2016).

We sought to understand how students perceived their agency in upper division chemical engineering laboratory courses. Specifically, we investigated students' agency in two domains: (1) experiment and analysis and (2) communication of their work. We compare this to students' framing agency—their capacity to make decisions consequential to the framing of design problems—to evaluate their perceptions of consequentiality within laboratory experiments. Making all such experiments high-agency is not feasible due to the high enrollment of these courses, as well as the specialized equipment and potentially hazardous nature of experiments. Understanding more about how students perceive their agency could provide insight about comparatively simple changes that encourage students to take more agentive roles. We sought to answer three research questions:

1. To what extent are students' perceptions of their agency similar across classical engineering design and experimental design contexts?
2. To what extent do students view their experiments as authentic to chemical engineering practice?
3. To what extent do students' perceptions of their agency differ across the two domains of (a) design of experimentation and analysis and (b) communication of results and across more and less authentic laboratory experiment contexts?

Theoretical framework

We frame our study by considering research on student agency across the learning contexts of prototypical design, experimental design, and communication. Across these, we consider the influence of authenticity, defined as having a "primary purpose and source [that is] a need, a practice, a task, a quest and a thirst existing in a context outside of schooling" (Strobel et al., 2013, p. 151).

What is framing agency?

Design problems are ill-structured, meaning these problems have more than one solution and path to solution, as opposed to a single answer (Jonassen, 2000). Designers direct the process of framing and reframing problems (Runco & Nemiro, 1994). This ability is consequential as the framing determines the ultimate choices and outcomes a designer can make. The empowerment to make such decisions is a specialized form of agency, termed framing agency (Svihla et al., 2019, 2021). The bounds on agency can be thought of as set by the opportunity

 © ISLS

structure (Narayan & Petesch, 2007), which shapes not only which and if decisions can be made, but the consequentiality of those decisions. For instance, traditional, well-structured classroom problems that have a single right answer limit the opportunity structure and students make few or no consequential decisions. In contrast, design problems, especially authentic problems sourced outside of school contexts, offer significant opportunity structure, allowing students to decide how to frame problems and proceed in their work. Designers make decisions about what they need to know, which in turn leads to learning, such as from consulting stakeholders (Basadur et al., 1982).

How does framing agency relate to laboratory experiments?

Laboratory experiments vary from authentic experiments conducted as part of research to cookbook-style experiences that are highly prescriptive, with a limited opportunity structure (Mohrig, 2004). As students advance in their programs of study, labs become more complex, meaning the number of variables and the relationships between variable increases (Jonassen, 2000). While this opens the opportunity structure somewhat as students make choices about which variables to control or vary, the problems typically remain well-structured, with the answer known ahead of time. In contrast, ill-structured experiments that engage students in discovery can support learning about the relationships between variables and the design of experiments (Flora & Cooper, 2005). Such problems may even be part of authentic research process, such as when faculty bring their research into the classroom through course-based undergraduate research experiences (Chase et al., 2016). More authentic problems should support greater agency. However, the preponderance of experience with well-structured problems could sabotage the sense of authenticity for students.

Making experiments fully authentic – meaning, based in problems that exist externally (Strobel et al., 2013) – is unrealistic in terms of time, cost, and capacity, including the acknowledgment that ill-structured problems are difficult to propose, implement, support, and evaluate, evidenced by the limited uptake of such approaches. And, more authentic tasks can also limit participation, as students may report low agency if they perceive the requisite decisions as beyond their reach (Hagvall Svensson et al., 2021). Thus, there is a need for investigations into ways to enhance agency in ways that is impactful for student learning and development yet feasible for faculty to manage.

How does framing agency relate to communication?

Writing tasks, encountered in both laboratory and design courses, also fall on a continuum from well- to ill-structured. The lab report is a quintessential form that narrows the opportunity structure, sometimes down to the sentence (Hicks & Bevsek, 2012). These reports can reinforce the idea that work is judged for accuracy, rather than authentically communicating new knowledge to an audience (Abidin et al., 2013). Yet, authentic technical communication, even when fit into genre and journal expectations, can be an ill-structured, iterative process much like design (Howell, 2015), in that authors define stakeholders (audience), purpose, and make decisions to reach those goals (Sharples, 1998). While more authentic forms of communication may enhance the consequentiality of students' agency, their expectations about lab reports may reduce the opportunity structure.

Methodology

We conducted comparative analysis of agency in design versus laboratory courses in engineering. This involved analysis of post-instructional surveys completed by students. We additionally had insight into course instruction via participant observation of the courses (Atkinson & Hammersley, 1994).

Participants and setting

We collected data in senior design courses (n=109) and in two laboratory courses (n=31 in the junior course; n=31 in the senior course). The senior design courses partially met the definition of authenticity, in that students selected projects that had originally been sourced in the world, but that had been reformulated as instructional projects (they included a client but were narrowed in scope by the instructor, or they lacked a client but were based in a prior authentic project).

The junior laboratory experiment asked students to evaluate and then calculate the friction and corresponding pressure drop of water flowing through pipes with different fittings and bends during turbulent flow. Students measured the pressure of water at the beginning and end of two (out of ten) different pipes of different lengths, and—combining their information with that of four other groups to form a complete data set—calculated information about how the bends, length, and fittings of the pipes differently affected the pressure drop and the relative friction. They were scaffolded on how to conduct analysis with an Excel worksheet and on how to communicate their results with a presentation outline. Each group created a 20-minute presentation detailing their findings.

The senior laboratory experiment focused on selective hydrogenization of acetylene into ethylene while minimizing the conversion of ethylene into ethane to be used later to create the plastic polyethylene. The catalysts used by each group was one of several catalysts synthesized in a research laboratory at the university and are part of a larger research study attempting to develop new catalysts to maximize the ability to create polyethylene. Students ran optimization experiments on their unique catalysts by determining the selectivity of converting acetylene to ethylene without converting ethylene to ethane by varying the proportions of starting gases, the flow rate, and the temperature. Students then calculated the kinetics of each reaction and evaluated the effectiveness of their own catalysts. Students worked in groups of five. They individually wrote a short technical report on their findings modeled after a short technical journal article. After peer review, the students in each group combined their individual reports into a single report.

Data collection and analysis

We used two versions of the framing agency survey (Table 1), a survey which has previously undergone validation procedures. In the design course, we used the original framing agency survey, which includes 18 items covering six factors—individual consequentiality; shared consequentiality; learning as consequentiality; constrainedness; shared tentativeness/ill-structuredness; and individual tentativeness / ill-structuredness (Svihla et al., 2020). We adapted questions to the context of experimental design and laboratory decision making within the original factors (Table 1). In addition, we added two questions about authenticity, in which students reported the likelihood their results would be used to inform future research or be shared with others outside the course, in a research lab, a publication, or similar.

We calculated descriptive statistics and used independent samples t-tests with effect sizes to selectively make comparisons between the two laboratory courses, and between design and laboratory courses. We used repeated measures two-way ANOVA to evaluate differences between the laboratory courses and domains (experimental design versus communication).

Table 1

Framing agency survey. All questions on a 7-point bipolar scale, with poles named in question stem.

Factor: Individual Consequentiality. [contextualized to design / contextualized to experimental design]
How responsible or not responsible did you feel for the outcomes of the [*design project/experiment*]?
Considering the (individual) decision you described, how important or unimportant was the decision?
Considering the (individual) decision you described, how important or unimportant was the impact of that decision on your [*design process / experimental design and interpretation of results; final presentation/report*]?
How responsible or not responsible did you feel for making decisions personally?
How responsible or not responsible did you feel for coming up with your own ways to make progress on the [*design project / experimental design and interpretation of results; the preparation of the presentation/report*]?
Factor: Shared Consequentiality
Considering the (team) decision you described, how important or unimportant was the impact of that decision on your [*design process / experimental design and interpretation of results; final presentation/report*]?
Considering the (team) decision you described, how important or unimportant was the decision?
Factor: Learning as Consequentiality
How much or little did you learn as a result of decisions about the [*design problem / experimental design and interpretation of results; presentation/report preparation*] a teammate made?
How much or little did you learn as a result of decisions about the [*design problem / experimental design and interpretation of results; presentation/report preparation*] you personally made?
Factor: Constrainedness
Considering these constraints, how free or restricted did your teammates seem when making decisions?
Considering these constraints, how free or restricted did you feel when making decisions yourself?
How free or limiting did the [*design problem / experiment*] seem to be?

Factor: Shared tentativeness / Ill-structuredness
How certain or uncertain do you feel that you have to [*solve the problem / carry out the experiment*] as given to you?*
How certain or uncertain do you feel that [*your design project has a single right solution / there is a single right way to conduct the experimental design and interpretation of results*]?*
How certain or uncertain do you feel that you have to just [*develop what was asked of you / collect data as you were asked to*]?*
How certain or uncertain do you feel that you know the optimal [*solution / experimental design and interpretation of results*]?*
Factor: Individual tentativeness / ill-structuredness
How certain or uncertain do you feel that you understand the [*design problem / experimental design*]?
Considering your [*design project / the experiment*], did you have many or few opportunities to make decisions as a team related to your [*design project / experimental design and interpretation of results*]?

*Reverse scored items

Results

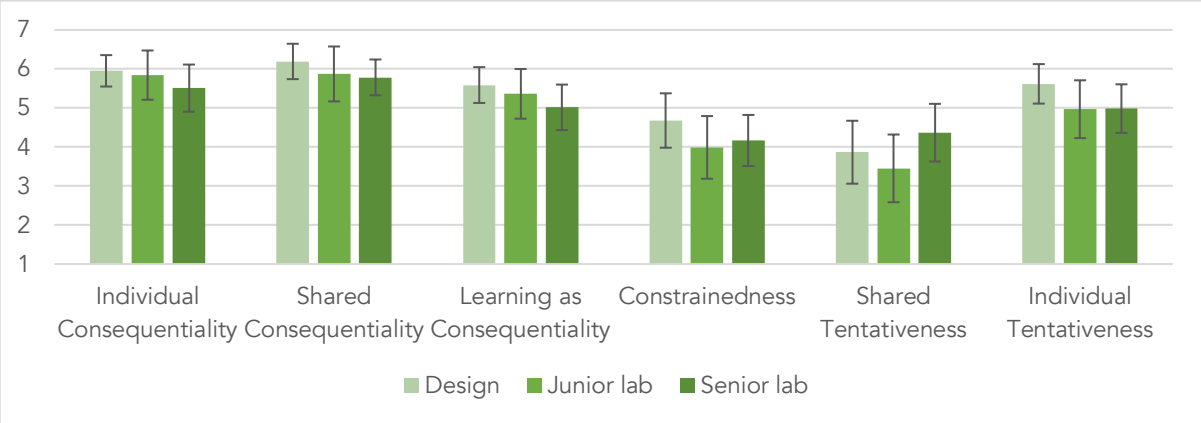
We organize the results by research question.

To what extent are students' perceptions of their agency similar across classical engineering design and experimental design contexts?

Overall, we found design students experienced higher levels of agency across all factors (Figure 1, Table 2). One exception was the senior lab which reported higher shared tentativeness on average. Responses range from 1, which is the lowest or most negative, to seven, which is highest or most positive). Scales differ by question.

Figure 1

Average scores by course on each factor. Refer to table 1 for definitions of Likert scales, as items are bipolar and construct-specific, and poles are named within the question stem.



Students enrolled in design courses reported significantly higher learning consequentiality than those in laboratory classes, $t(169) = 2.40$, $p = 0.017$, $g = 0.38$, a medium effect size. This suggests the kinds of decisions made in the former resulted in more learning opportunities about framing problems. Students enrolled in design courses reported significantly higher individual tentativeness than those in laboratory classes, $t(169) = 3.50$, $p < 0.001$, $g = 0.56$, a medium effect size. This suggests students in the design courses tended to believe there was not a single correct answer to the problem. Students enrolled in design courses reported significantly lower constrainedness than those in laboratory classes, $t(169) = 2.66$, $p = 0.009$, $g = .42$, a medium effect size. This indicates students in laboratory courses felt more limited by the structure of the problem than in design courses. These results indicate that students in laboratory courses experienced less agency than their peers in design courses.

Table 2

 © ISLS

Descriptive statistics. All measures on a 7-point scale

Factor	Design courses (n=109) Mean (SD)	Junior Lab (n=31) Mean (SD)	Senior Lab (n=31) Mean (SD)
Individual Consequentiality	5.95 (0.81)	5.84 (1.26)	5.51 (1.21)
Shared Consequentiality	6.19 (0.91)	5.87 (1.41)	5.78 (0.92)
Learning as Consequentiality	5.59 (0.92)	5.36 (1.27)	5.02 (1.16)
Constrainedness	4.68 (1.39)	3.99 (1.61)	4.17 (1.31)
Shared tentativeness / Ill-structuredness	3.87 (1.61)	3.45 (1.74)	4.37 (1.48)
Individual tentativeness / ill-structuredness	5.62 (1.01)	4.97 (1.48)	4.98 (1.24)

To what extent do students view their experiments as authentic to chemical engineering practice?

The second research question compared the inauthentic junior experiment to the senior experiment, which was part of faculty research. Overall, students reported relatively low authenticity. Students in the junior course reported somewhat lower authenticity ($M = 3.06$; $SD = 1.87$) than seniors ($M = 3.67$; $SD = 1.65$), but this difference was not significant, $t(78) = -1.33$, $p > 0.1$, $g = .34$, a medium size effect. This indicates that even experiments designed to be authentic do not necessarily translate to perceived authenticity.

To what extent do students' perceptions of their agency differ across the two domains of (a) design of experimentation and analysis and (b) communication of results and across more and less authentic laboratory experiment contexts?

We found no significant interaction effect and no difference between courses. This corresponds to students' reported sense of authenticity. Students reported significantly higher agency in the domain of communication than in experimental design, $t(62) = 2.82$, $p = .0064$, $g = .36$ for a medium effect size, indicating perceptions of agency vary across domains (Table 3).

Table 3

Repeated measures ANOVA of agency in two domains (experimental design and communication) between junior and senior courses

Source of variance	*df*	*Sum of Squares*	*Mean Square*	*F*	*p*

Discussion

Framing agency in laboratory and design courses

Students in capstone design report greater agency overall. This is unsurprising as students in design must make decisions about elements such as the scope of the problem and where to source information, which is consistent with greater opportunity structure (Narayan & Petesch, 2007). While the laboratory courses varied in the number of available consequential decisions, constraints like procedure and time limited the students' abilities to frame the problems for themselves. Because of these limitations, students do not have as much space to reframe the problems win whichever ways they see fit, making the problem more well-structured than design problems (Jonassen, 2000). We can also see that the option to make decisions doesn't necessarily translate to empowerment

to make decisions, which is the key component of framing agency (Svihla et al., 2019, 2021). Students in junior and senior labs have completed many well-structured experiments previously in their coursework, and this may have shaped their expectations about these labs.

Framing agency in experimental design

While the intended opportunity structure of the junior and senior labs differed, we found no significant difference between junior and senior students' overall perceptions of their agency. Even though the senior students had many more consequential choices (particularly when it came to design of experiments), this did not translate into sense of consequential agency. We consider the contextual factors that may have contributed to this.

First, felt time constraints meant that students in both the junior and senior courses had limited opportunity to reframe the problem presented to them or even to revise their method of solving it. However, students in the senior course did revise the parameters they used for data collection in response to unsuccessful results or additional information. Students had to frame the ways in which they interpreted their data and used it to make decisions moving forward by balancing variables and deciding their relevant importance. This is the type of framing through making decisions about importance and outcomes we would expect to be demonstrated in students' reports of their agency.

Second, we found that students perceived both the junior and senior laboratory experiments as inauthentic. Research suggests that taking part in authentic research can be sufficient to bring greater impacts to students (Chase et al., 2016). However, our findings indicate that the mere presence of authenticity was sufficient to convince students of their own agency. Students struggle to view assignments in their class as part of authentic research, given the many experiments they have done where the answer has been known for decades (Mohrig, 2004).

Framing agency in communications

Previous experience with lab reports as a genre may limit students' perceptions about the types of choices they may make (Hicks & Bevsek, 2012), with an emphasis on making the "correct" choices in their communication rather than communicating to an audience. In both the junior and senior laboratory courses, instructors emphasized that students needed to consider audience expectations. Students in both courses were asked to evaluate the specific target of their communication as well as choices that they should make to better meet the needs of that audience. While the communication was not authentic, meaning, students did not actually communicate their results to an audience outside the classroom, students still made genre considerations and framed the ways they wanted to present their results with the audience in mind (Sharples, 1998).

Students reported greater consequentiality in the communications of their results over the experimental design itself. It is much more feasible for instructors to support students to make decisions in their communications where there are no concerns about things like resources or safety. In addition, the line between decisions students make in the communication and the impact on the final product is much clearer, leading students to better understand the ways that their decisions are consequential.

Fostering framing agency to support professional identity formation

Having opportunities to make consequential decisions appears to support the development of engineering identity (Du & Naji, 2021; Godwin et al., 2013, 2016; Morelock, 2017). Indeed, engineering practices that depend on such decisions—analyzing data and designing—contribute to students' identities as engineers (Choe et al., 2019; Meyers et al., 2012). This is in part because, fundamentally, professionals have the capacity to make consequential decisions, and displays of doing so position one as belonging (Holland et al., 1998; Tonso, 2014). From this perspective, engineering identity is also double-sided, meaning the individual positions themself as an engineer, and they are recognized by others as belonging in engineering. Opportunities that foster consequential agency in line with what professionals do simulates professional practice, and this is one of the few forms of interventions shown to enhance professional identity formation (Morelock, 2017). In contrast, a preponderance of experiences with low-agency tasks can signal to students that engineers are skilled technical problem solvers who possess little agency (Chua & Cagle, 2017; Kirn & Benson, 2018). Thus, framing agency may shed light onto learning experiences that offer the kind opportunity structure needed to develop professional identity. While instructors may intend to offer ill-structure, students may not perceive this as consequential, instead treating it as just another chance to demonstrate the accuracy of their knowledge.

Conclusions

We found students in design courses reported greater framing agency, compared to laboratory courses. This highlights the importance such courses have in students' preparation. We contrasted laboratory experiments with high or low authenticity. We found no differences between perceived authenticity or agency. This contrasts with research suggesting course-based research experiences seem more valuable to students (Auchincloss et al., 2014). We interpret this finding as revealing the challenge of overcoming students' expectations about such experiences. In future, we plan to investigate ways to make the authenticity more apparent to students. Students in both laboratory courses reported higher agency related to communication, compared to experimental design. Future studies will investigate ways to enhance agency related to experimental design, while retaining the feasibility.

Limitations and implications

The study comes with limitations, including a relatively small sample size and relying on self-reported data. The methods did not include a means to control or randomize participants, and all data from laboratory courses comes from a single institution. Further steps include collecting data from additional laboratory courses, including at institutions with different contexts.

Our findings suggest that more needs to be done to support students' perceptions of their agency beyond simply providing them with opportunities to frame problems. However, the endeavor of supporting students' agency and interaction with realistic complex problems is vitally important to their understanding both of what engineers do and how they develop identities as engineers. Writing can be a potential avenue to feasibly enhance agency.

Our results more broadly inform the ways that agency and perceptions of agency are related in students. Perceptions of agency can be informed by the problems at hand but can also be influenced by other external factors like prior experiences and time pressure. Ideas about authenticity and ill-structuredness can inform each other, with students viewing their task with less agency, but also less belief about the authenticity (even when the problem is very authentic).

Abstract: The integration of computational modeling into instruction in science classrooms is complex in that it requires the synergistic application of students' developing science and computational thinking knowledge. This is not only difficult for students, but teachers often find it hard to parse the science content from the computational constructs to guide students when they have difficulties. Leveraging past literature that highlights the beneficial impact instructors can have when they immerse themselves in group problem-solving discussions, this paper examines the instructors' role in facilitating students' construction of and problem solving with computational models. We utilize a case study approach to analyze instructor-facilitated, synchronous group discussions during applications of synergistic learning processes to understand how instructors may elicit students' knowledge, misunderstanding, and difficulties to help guide, prompt, and engage groups in this complex task for more productive integration in K-12 science classrooms. We hope that this will lead to better scaffolding of students' learning, and better support for teachers when they use such curricula in classrooms.

Introduction

Computational modeling has received increased attention as a vehicle for integrating computational thinking (CT) in existing K-12 science classrooms (Wilensky & Reisman, 2006; Hutchins et al., 2020). This constructivist approach has been shown to be effective in helping students learn STEM and CT concepts (e.g., Sengupta et al., 2013), and develop problem-solving skills (Hutchins et al., 2020). In addition, it provides environments for encouraging productive, socially-shared collaborative problem-solving skills development (Emara et al., 2021). However, integration of STEM and CT in K-12 science classrooms comes with its own set of challenges for both students (Basu et al., 2016; Hutchins et al., 2020) and instructors (Wilkerson-Jerde et al., 2015). In this paper, we target two key challenges: (1) limited understanding of how instructors can engage in students' integrated learning of science and CT during computational modeling (Wilkerson-Jerde et al., 2015), and (2) student difficulties in communicating about applying complex, synergistic learning processes, such as initializing and updating variables during computational model building, and leveraging data tools and debugging processes to generate correct models (Snyder et al., 2019). To do so, we examine instructor engagement in student thinking and knowledge construction during computational modeling through instructor-facilitated, small group discourse, a pedagogical tactic that has shown to support problem-solving skill development (Fung et al., 2016).

While student discussions during learning and problem solving have been shown to be beneficial to student learning (Chi & Wylie, 2014), group discussions are not always effective (Dillenbourg et al., 1996). These difficulties can be exacerbated during scientific modeling due to the open-ended nature of the problem-solving task, as students collectively manage the complex integration of STEM and CT concepts and practices (Snyder et al., 2019), limiting applicability of common collaborative interventions. In this context, interventions must consider students' STEM and CT prior knowledge and their ability to (1) apply complex synergistic processes, such as translating prior knowledge into computational forms, and (2) communicate these processes to group members. This may provide a unique opportunity for instructors to engage in students' STEM and CT knowledge construction and problem-solving processes to support and to facilitate STEM+CT classroom integration.

This paper examines the research question: *how can instructor-facilitated small group discussions support our understanding of students' learning and problem solving during scientific computational modeling?* To answer this question, we define a framework that captures the roles instructors play in classroom instruction and group discussion. We adapt this framework to evaluate the instructor-facilitated, small group discourse during scientific computational modeling tasks. Our analyses revolve around two case studies examining how instructors guided small-group discussions linked to their students' computational modeling tasks. We study how instructors prompted students to elicit their knowledge in CT and the target science domain, exposed misunderstandings, and helped students develop complex, synergistic learning processes to support their

 © ISLS

learning tasks. We hypothesize that targeted instructor-facilitated discourse may support a deeper understanding of students' STEM and CT knowledge that may be difficult to assess through traditional summative assessment approaches. We illustrate how instructors, through explanation prompting, encourage discussions on translating conceptual knowledge to the computational form and support the groups' knowledge co-construction processes.

Integrating the C2STEM learning environment

C2STEM is designed to support the synergistic learning of physics and CT through the building, testing, debugging, and use of computational models to solve physics problems (Hutchins et al., 2020). The learning environment includes a block-based programming environment, an extension of Snap! (snap.berkeley.edu), equipped with a physics *domain-specific modeling language* to allow students to focus on constructing computational models of physics processes. The system includes *data tools* that provide students a means for checking and evaluating their physics models as they build them. In the curriculum students build increasingly complex models and complete a series of formative and summative assessments to help students and instructors monitor their evolving STEM and CT knowledge. The curriculum for this study was divided into three modules: (1) 1-D motion, where students build a model of a truck speeding up from rest to a specified speed limit, cruising at that speed, and then slowing down (decelerating) to come to rest at a stop sign; (2) a drone task where students build a computational model of a flying drone dropping a package onto a target; and (3) a second drone task where students model a flying drone dropping two packages in succession on two different spots on the ground.

For C2STEM implementations, we have developed instructor material to support modeling tasks based on prior classroom experience. Teachers also have access to the correct computational models. We have collected frequently-observed difficulties students face in building computational models. Difficulties include errors in domain-specific concepts and practices (e.g., setting an object's y-velocity to the gravitational constant, and errors in initializing and updating variables in CT). For example, Figure 1 shows a student's incorrect code for updating the *x*-position of an object. In this illustrated code, the *x*-position is set to '*x velocity in m/s * Δt in s*' but the student should have used the change *x*-position block. This demonstrates a potential misunderstanding about the difference between setting and changing variable values. We recommend instructors should prompt students to explain the behavior of the object by running the simulation and walking through the execution to let the student gain an understanding of how the simulation model executes and identify potential errors in their model. Another instructor move may involve prompting students to use the data tools to evaluate the position values and discuss how this information compares against their intuitions and knowledge of the physics phenomena.

Figure 1
Example student CT difficulty in a student's computational model code

Analyzing instructor facilitation during an C2STEM implementation

The impact of instructors during group discussions has been shown to help students' problem-solving processes as they think about the salient features of the problem and develop their problem-solving strategies (Webb et al., 2009). Research has identified strategies for facilitating online discussion that includes developing a social presence and emphasizing student-to-student interactions (Rovai, 2007). Our research is primarily focused on asynchronous online discussions and their effects on students' learning. In this research, we analyze facilitation strategies for synchronous discussions that are supported by our instructor material to improve our understanding of instructor engagement and to facilitate computational modeling of scientific processes.

Figure 1 shows the analysis framework used in our research. This approach is inspired by Berge's (1995) four instructor roles for online learning: (1) pedagogical, (2) managerial, (3) technical, and (4) social. Students may face multiple difficulties in understanding, applying, and integrating science and CT concepts in practices when building computational models (Basu et al., 2016). Instructors can mitigate these difficulties, once identified, to help students overcome these difficulties. In other words, *pedagogical support* is essential to helping students progress in their computational modeling tasks. Previous work has demonstrated that students need help in developing and applying productive synergistic learning strategies to help them translate their knowledge and understanding into successful computational structures for model building (Hutchins et al., 2020). In the form of *managerial support*, the instructor may guide the students discourse or model construction towards applying a

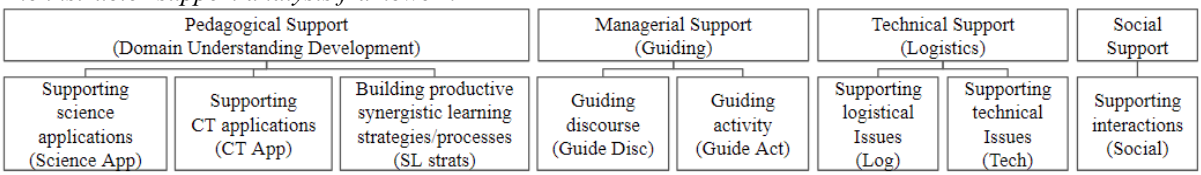
strategy by identifying relevant goals or guiding students to think about how they translated their knowledge in a previous task. The difficulties students face can be compounded by an unfamiliarity with the environment which can be mitigated with *technical support*. Instructors may also facilitate the discussion via *social support* by prompting and encouraging students to state viewpoints and discuss them with each other.

In C2STEM, *pedagogical support* manifests as (1) *supporting CT* applications, such as how to correctly implement the updating of a variable necessary in the physical phenomenon; (2) *developing physics knowledge*, such as the relationship between velocity and acceleration to ensure correct object motion; and (3) *building synergistic learning strategies,* such as translating conditional behavior changes to the right form of conditional statements, initializing and updating variables, debugging, and using data tools to construct or problem solve. *Managerial support* encourages students to reflect and plan, such as guiding students to remember how something was implemented in a previous task or suggesting a modeling-in-parts approach to develop more complex models. The complexity of the C2STEM modeling environment (e.g., the large variety and number of blocks) necessitates *technical support* to help students navigate an unfamiliar environment. Finally, the complex nature of tasks creates an opportunity for collaboration between students, which can benefit from *social support* from instructors.

Previous work has revealed unproductive collaboration in terms of difficulties students face in applying STEM and CT constructs, as evidenced by inability to co-construct knowledge, and inability to interpret and explain model behaviors (e.g., Emara et al., 2021). Facilitating discourse is considered to be an important task and responsibility of a synchronous instructor. These instructor facilitations are often delivered in the form of instructional statements, group participation encouragement and prompting questions. Instructor's question prompting may help students clarify confusions when explaining model behavior (Grover et al., 2019), identify and understand errors during debugging (Hutchins et al., 2020), justify their problem-solving strategies, and correct their misconceptions and suboptimal use of strategies (Kinnebrew et al., 2017; Webb et al., 2009). Moreover, instructors could use various guiding support as means to make the students' interaction more thought-provoking with the aim of translating STEM concepts and practices into computational form (Kinnebrew et al., 2017; van Vondel et al. 2017). For this analysis, we coded discourse based on the lowest level of Figure 2.

Figure 2

The instructor support analysis framework



Study description and data analysis methods

This study was implemented in the Southeastern United States with 22 high school students and 5 researchers who played the role of instructors for the study. The intervention included synchronous, small group computational modeling tasks, which were completed individually and asynchronously. They targeted students' abilities to apply what they learned during their small group work. Students worked in groups of 3 or 4 and the groups did not change through the course of the study. The synchronous, small group work occurred once a week for five weeks over Zoom, necessitated by COVID19 protocols. During these sessions, students had 10-15 minutes of instruction and 15-20 minutes of group discussion in a Zoom breakout room facilitated by the same instructor every week, except for week 3 when a full 30 minutes was used for instruction. Prior to the study, the instructors met for one hour to discuss the curriculum and review the instructor material discussed above. Following each synchronous session, instructors met for 15-30 minutes to review student progress and discuss their experiences.

Data collected for this study included students' pre- and post-assessment results, final computational model project files (scored using a predefined rubric from Snyder et al. (2019)), and the recorded Zoom sessions. When student groups collaborated, the student responsible for constructing the model (e.g., connecting the blocks, running the simulation, etc.) shared their screen on the Zoom session. For this analysis, we focus on two groups that had the same instructor in order to systematically compare differences in (1) the instructor's evidence-based responses to different group combinations and (2) each group's responses to the instructor's feedback.

We use a descriptive case study approach to analyze how instructor-facilitated small group discussion can support our understanding of students' learning and problem solving during scientific computational modeling. Specifically, we identify how instructors *identify* and *address* student misunderstandings and knowledge gaps through instructor-facilitated discussions of students' model construction steps. We examine the instructor-facilitated group discussion dialogue segments by coding the instructor utterances using the scheme in

 © ISLS

Table 1. Note that due to the overlap between support, we combine the two types of guiding into one code label. Two coders coded the utterances with very good agreement ($\kappa = 0.89$). We analyze students' individual computational model scores and prior knowledge, measured through pretest scores. The two groups selected for analysis had the same instructor and a mixture of prior knowledge, measured through a pretest, in both STEM and CT. The physics portion of the test had a total score of 17 points, with a student median of 12 points ($\sigma = 2.35$). The CT portion of the test had a total score of 16 points, with a median of 9.25 points ($\sigma = 2.81$). We categorized students as high or low prior knowledge based on their scores relative to the median. In the two groups we analyze in this work, the CT scores ranged from 13 to 6 points and physics scores ranged from 14 to 9 points.

Table 1
Coding scheme for implementing the instructor support analysis framework

Code	Description	Example(s)
Log & Tech	Helping the students log on, open projects, other technical or logistical issues, etc.	"S3 could you be the navigator and open the form today?"; "The block is in that section"
Guide Disc & Guide Act	Stating goals, guiding students to look at something	"Your goal for the next six minutes is to build and answer this question as a group."
Science App	Utterances focused on physics concepts	"What causes velocity to change?"
CT App	Utterances focused on CT concepts	"So, the simulation step repeats every time"
SL Strat	Utterances referring to synergistic learning processes or strategies	"That's an interesting way to debug"; "Definitely use the data tools to help you here'"
Social	Encouragement of social interactions	"Hi everyone", "S4, are you there?"

Results

The case studies presented target instructor-facilitated, small group discourse, of two groups, focused on key synergistic learning processes - initializing and updating variables, debugging, and using data to debug models. The first group (G1) has four students: two students, S1 and S2, with high prior knowledge in physics and CT, and two students, S3 and S4, with low prior knowledge in both domains. S1 and S2 contributed the most during the three discussion sessions (30% and 25% respectively) while S3 and S4 contributed 3% and 13% of the total utterances. The instructor contributed 28% of total utterances. The second group (G2) has three students: S5 who has low prior knowledge in both domains, S6 who has high physics prior knowledge and low CT prior knowledge, and S7 who has low prior knowledge in physics but high prior knowledge in CT. Unlike G1, the instructor contributed most to the group discussions with 39% of the total utterances over the three days. S5 and S6 contributed 31% and 21% respectively while S7 contributed the least with 9%. As seen in previous work (Snyder et al., 2019), students with low prior knowledge, S3, S4, S5 and S7, particularly improved over the course of the study. We hypothesize this may be due to the effectiveness of the group discussions facilitated by the instructors. In the following analysis, we explore the different ways the instructor facilitated these discussions in each group.

Instructor facilitation

We analyze the instructor-facilitated discussions utilizing the framework described above. Although facilitated by the same instructor, the role the instructor played is very different across the two groups. The role of the instructor in G1 discussions was primarily in the form of *technical support*: 38% of the utterances dealt with logistical and technical issues, 32% of utterances were *managerial support*, 26% *pedagogical support* and 4% *social support*. The role of the instructor in the G2 discussions was primarily *pedagogical support*: 46% of the utterances were classified as applications of physics, CT or synergistic learning process, 33% *technical support*, 11% *managerial suppor*t and 5% *social suppor*t. We hypothesize this difference in the support focus is due to the distribution of prior knowledge in each group. While the instructor was not aware of the prior knowledge of the students at the time of the discussions, the instructor's focus was impacted through the students' misconceptions and knowledge gaps that became apparent through their explanation prompting efforts, illustrated below.

Explanation prompting episodes

The three vignettes shown in Tables 2-3 illustrate how our instructor facilitated successful group discussions during the computational modeling of physics phenomena. To support successful model construction and integration of STEM and CT concepts, the instructor utilized explanation prompting to identify key misunderstandings and knowledge gaps; and group management prompting to encourage students to share knowledge learned to support group computational model construction. We illustrate a common CT misunderstanding students have between the use of the set and change blocks in Table 2 over the course of two

days. On Day 1, the instructor prompts S1 to check if they understand which block is appropriate for initializing variables. On Day 2, the student has an error in their model (Figure 3(a)) that is causing the truck to go from 0 m/s to 15 m/s instantaneously, instead of starting from rest and speeding up to 15 m/s.

Figure 3

Computational models prior to instructor engagement for G1 (a) and G2 (b).

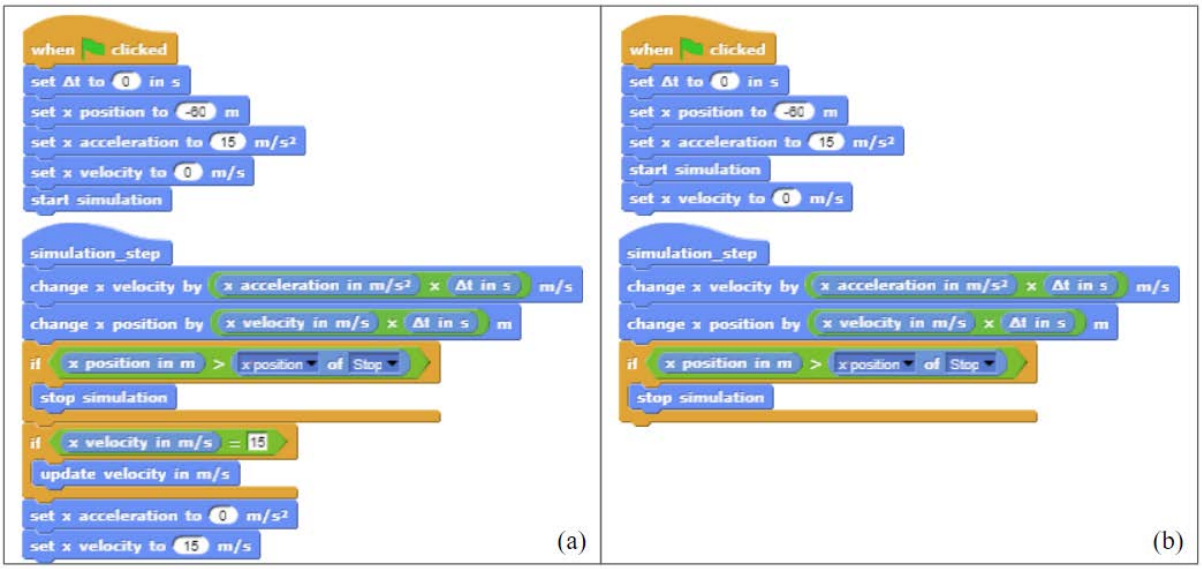


Table 2

G1 truck discussion across two days

Utterance	Description
Day 1: *G1 is initializing needed variables for the truck stop task.*	
Instructor: What do you think...should you set or change the position in order to start at -15m*?*	**CT application**: The instructor is prompting the student to select the relevant block(s) for initializing the position of the truck.
S1: Set I think, I think it's set. I don't know, let me try.	*S1 correctly identifies and utilizes the appropriate block.*
Day 2: *S1 has already determined what behavior in the model does not follow physics principles.*	
Instructor: Why do you think the velocity stays at 15?	**Guiding**: The instructor guides the student, through questioning prompts, to identifying the CT error.
S1: I think because of this, this update velocity because I try to put if velocity equals meters per second goes 15. I tried to put these ones in there instead of the update last one. But it didn't do anything	*S1 correctly identifies that the update velocity block is incorrect and explains their debugging process implemented in the conditional. S1 is showing a lack of understanding in which block is used to update velocity and what the set block does.*
Instructor: I can see.... So one thing to remember is the set and the change. So under the green flag, you have that you're setting that initial value. And then for the simulation step, that's where you update the behavior. So that repeats every time (step), so at the end of your simulation block you have a set	**CT application**: After identifying the lack of knowledge, the instructor is explaining how the *set x velocity position* block, the last block in the simulation step, is going to set velocity to 15 m/s every step of the program.
S1: So I should make it change velocity	*S1 tries to confirm the way to debug their model.*
Instructor: You have it correct at the top though. But you just have some extra blocks. If that makes sense.	**CT application**: The instructor helps the student understand that they are correctly updating velocity with the *change x velocity* block but then are incorrectly setting velocity to 15 m/s. This setting of the velocity effectively overwrites the updating process. The instructor refers back to S2's model which was shown and discussed previously.
S1: I think so…	
Instructor: So you set the velocity after you change it. That what's happening	
S1: So set it and then change it.	

 © ISLS

Instructor: If you remember with S2's code, and you'll want to set acceleration to zero but not the velocity because you're already doing everything right You're changing the velocity. Yeah.	
S1: So I set this back.	*S1 confirms that they are understanding correctly*.

In the first episode (Table 2), the instructor first prompts the student in G1 about how they should implement the initialization of variables on Day 1. While S1 correctly identifies the block to use, they express uncertainty, which underscores a lack of knowledge about the differences in initializing variables versus updating variables as the simulation advances in time. This is elicited, through explanation prompting, by the instructor during the group discussion on Day 2. Due to the S1's further explanation of what is causing the issue with their model, the instructor can identify that the student does not have a physics misunderstanding but has a CT knowledge gap about the correct blocks to implement the updating of velocity.. It is interesting to note that while the group demonstrated success on the CT pretest, the instructor's prompting provided additional insight into students' understanding of the difficult CT concept (i.e., student difficulties in translating conceptual understanding of variables from the pretest to the construction of their computational model).

The second episode (Table 3) shows an excerpt from one of G2's discussions. This instructor-facilitated discussion begins with the introduction of a synergistic learning strategy, the use of data tools, and is followed by a discussion that switches between the application of physics and CT concepts. S5 has incorrectly modeled the speeding up of the truck to 15 m/s as seen in Figure 3(b).

Table 3
G2 truck discussion

Utterance	Description
S1: And then, for the speed limit, I just changed set x acceleration. Instead of four, I changed it to 15. And that caused it to go 15 miles per second squared, and stop at the stop sign. And that's it.	S1 is describing how they tried to model the truck speeding up to 15 m/s. They have incorrectly initialized the acceleration value to 15 m/s^2.
Instructor: So click on the x position, there's a box right next to it, there's a checkbox. And then the x velocity below... Now try running your model...what do you guys see? What happened with the velocity?	**SL strategies:** By encouraging S1 to check the box next to x velocity, the instructor is helping the students monitor how the variable is updated in their computational model by using an inspection window that outputs the value. The instructor is encouraging the synergistic learning use of data tools to identify the error.
S5: Did it change?	*S5 runs the model and points out the changing velocity*
Instructor: So yeah, so when you have acceleration at 15, that's changing the velocity by 15 every time you repeat it.	**Physics application:** The instructor is explaining to the student that the velocity value is changing by 15 m/s at each time step, it is not being set to 15 m/s.
Instructor: If you...one thing I might switch here is… I'd just switch the x acceleration to... What was it...4? **S1:** Yeah. So change it back to 4?	**Guiding:** The instructor is encouraging the student to initialize the acceleration value back to the given value of 4 m/s^2 after explaining that setting acceleration to 15 m/s does not make the truck speed up to 15 m/s.
Instructor: Yep. Okay. And then one other quick thing that we just never taught you guys, as if you can move the set x velocity up above the start simulation.	**Guiding:** The instructor is addressing another error in the model (initializing velocity to 0 m/s after the simulation step block).
Instructor: A computer is like a baby, it's just gonna go line by line and you did it right in that it is under the green flag. But what the computer does is it's calling the start simulation and then it's doing the velocity, and you just want it to do that one before the start.	**CT application**: The instructor is pointing out that the student is right to initialize velocity under the green flag however, through an explanation of how the model is going to be executed by the computer, is emphasizing it should happen before the *start simulation step* block. The student may use this to perform line by line debugging.
Instructor: Perfect. That's perfect. So now try, so you'll see and then stop.	**Guiding**: The instructor is encouraging S5 to see the behavior of the model by running it now that the two errors have been identified and fixed.

 © ISLS

Instructor: Um, so you can see that it keeps going up and…. right about there is where you want to stop accelerating, right?	**Physics application**: Moving onto the next component of the task, slowing down the truck, the instructor is helping the students understand what the behavior of the model should be, according to physics principles.
Instructor: How would you guys do that?	**Guiding:** The instructor is encouraging the other two students in the group to contribute to the discussion.
Instructor: S7 or S6, you there?	**Social:** The instructor checks in with the other two students in the group who have been quiet.
S6: I'm a little bit lost because I thought that list is...like the initial one was right so I'm a little bit confused about what the changes we made are doing. I'm just trying to keep up the best as possible. Could you try and re-explain it for me, please?	*S6 expresses confusion about the identification of an error in the model and asks for clarification*.
Instructor: So actually S5, do you want to describe how you found what was wrong? Because you were, you're right with what was wrong with that first model?	**Guiding**: Instead of answering the question, the instructor encourages S5 to explain to S6. The discussion continues with S6 explaining the error to S5.

In the second episode (Table 3), the instructor is helping the students debug their model using the data tools. After walking G2 through how to view the values of the variables as the simulation runs, the instructor then prompts the students to explain what they are seeing. There are two errors in the model: a physics-focused misunderstanding of the relationship between velocity and acceleration and a CT-focused misunderstanding of how the ordering of blocks affects the updating of variables. The instructor emphasizes how acceleration and velocity relate, as well as explaining how the computational model runs to promote CT understanding. In this discussion, the instructor integrates physics and CT, using a strategy of switching between CT and physics concepts. It has been shown that this switching between domains leads to more successful modeling processes (Snyder et al., 2019). We can also see the instructor use prompting to encourage better collaboration.

Discussion

In the two episodes above, we illustrate how instructors support students' synergistic learning of STEM and CT concepts and practices. We look at how instructors *identify* and *address* students' misunderstandings and knowledge gaps. The instructor often utilizes the strategy of explanation prompting to identify student difficulties and gain additional insight into the students' knowledge that a pretest may not provide. This is illustrated in G1, where S1 is stronger in CT than physics according to their pretest scores but they require more CT support in the group discussions as seen in the first episode. We may assume that more of S1's difficulties will be physics-focused when looking at his/her pretest scores, however, our analysis shows that even students with high prior knowledge may face difficulties in translating that knowledge to the computational form (Basu et al., 2016).

In addition to identifying student difficulties, the above episodes illustrate the strategies used by the instructor to address student issues. In the second episode, we can see the instructor uses explanation prompting to point the students towards the error in their model, followed by guiding instructional statements that both explain the physics and CT errors in more detail and guide the students towards correcting the issues with the model. When another student expresses confusion over the instruction, instead of repeating the explanation, the instructor guides S5 to explain what was discussed. This prompting strategy allows the instructor to assess the impact of previous instruction on S5's knowledge gaps, and it encourages discussion between group members. In the continuing discussion, S5 correctly explains the CT issue but doesn't address the physics misunderstanding which leads the instructor to emphasize how velocity is incorporated into the model. We also see the instructor consistently assessing a possible student difficulty in the first episode. The instructor's revisiting of the difference between set and change blocks during the truck task leads to successful knowledge understanding by S1, as seen in their following drone tasks where they correctly implement initializing and updating variables.

Conclusions and future directions

Students often have issues translating science concepts and relations into executable computational structures, and this could be because they have difficulty in mapping the science concepts to the scenario they are modeling or a problem in understanding the basic computational structures. While we can identify the domain where students may have difficulties by analyzing their pretest results, these assessments often have difficulty predicting

students' difficulties in building their computational models. In this work, we see how *explanation prompting* can identify knowledge gaps and misunderstandings that traditional assessments, such as pretests, may not. Instructor-facilitated group discussions, utilizing strategies such as explanation prompting, create an opportunity where misunderstandings and knowledge gaps can be identified and addressed on an individual level.

While these supporting strategies help students in their model building tasks, future work will analyze the impact of different types of instructor support on students' knowledge construction processes. Other literature, e.g., Webb et al. (2009), showed instructor explanation prompting varied as they used it to identify and address student knowledge gaps while encouraging group participation. While the instructors did provide some of this social support, it was minimal compared to their domain focused explanation prompting. In future work, we will expand the social support students receive from instructors and study the impact. Limitations of our analysis include the small sample size. In the future, we aim to expand our analysis with multiple instructors of differing educational backgrounds and experience with CT and computational modeling and more diverse student groups, with an emphasis on better understanding the impact of the socio-cultural context of the research.

Institute for Geoinformatics Münster

Abstract: Researchers emphasize the need for a deeper understanding of children's navigational map reading and an emerging interest in digital geogames for educational purposes. However, there are only a few related studies. We conducted a navigational map reading study with children aged 6 to 13. The children were asked to navigate to a destination within a virtual environment by using a map and to explain their procedures thinking aloud. Some children described how they recognized the destination from its nearer environment, whereas others described their route and stopover locations towards the destination. Based on the children's statements, we formulated educational implications for geogame features with the potential to represent successful navigational map reading strategies for training purposes.

Introduction

Navigational map reading (NMR), map-aided navigation between locations in the environment (Lobben, 2007), is highly relevant in geoscience education (Hemmer et al., 2008; Ishikawa & Kastens, 2005). Children differ in their success in using maps for navigation. One reason for these individual differences is the amount of experience children have in reading a map which underlines the importance of NMR trainings (Hemmer et al., 2013).

The literature mentions several "abilities" and "skills" related to NMR, e.g. being able to locate oneself on a map, to navigate to a certain destination, to recognize objects on the way by locating them on the map, as well as to know the direction towards destination and start location (Arthurs et al., 2021; Hemmer et al., 2013; Lobben, 2007). High NMR performance is defined by short routes to the destination and correct turns as well as by little hesitations or spins around the own axis (Hergan & Umek, 2017; Hemmer et al., 2013; Lobben, 2007).

Despite its relevance, research on children's NMR strategies and processes is quite rare (Arthurs et al., 2021). Geoinformation technologies such as geogames are promising tools for spatial learning, but research on the effectiveness of these tools and its features in educational contexts is sparse (Laato et al., 2019; Baker et al., 2015). This paper aims to fill the research gap by investigating children's NMR strategies and suggesting geogame features with the potential to address these strategies within NMR trainings.

Educational geogames

Geogames are location-based games working on mobile and geoinformation technologies (Bartoschek et al., 2018) with a game activity that "evolves according to players' location" (Avouris & Yiannoutsou, 2012). Numerous location-based games with educational and non-educational purposes exist. They were associated with positive learning outcomes in the context of navigation (Laato et al., 2019). This contrasts with studies that demonstrated negative short- and long-term effects of geoinformation technologies on spatial learning which is explained by the user's passivity when using the technologies (Ishikawa, 2019; Field et al., 2011; Münzer et al., 2011). However, the technologies investigated in these studies were not designed for learning purposes. Therefore, we want to focus on geogames that were created with an educational intention. One example is *Biparcours* (Actionbound) which allows its users to create map-based rallies for a chosen location on different educational topics. It includes two types of navigation tasks (navigation following an arrow and navigation via a map) and a street map that is fixed to north and can be panned and zoomed. Navigation is supported by displaying the location, the destination, and a compass. Feedback can be turned on or off and shows the accuracy of the player's task solution as well as the correct answer. With its game idea as well as its limited customizability and availability of features, Biparcours represents one of several educational geogames that are currently available on the market. Since geogames are adjustable to their application, research on educational geogames should focus on the variety of possible *features* and their potential in addressing NMR strategies for training purposes.

Navigational map reading strategies

Lobben (2004, p. 272) defines *map reading strategy* as a "specific method or tactic employed by a map user to complete navigational map-reading tasks". With a short review of related studies, Lobben highlights that researchers often make use of think-aloud methods to investigate people's strategies in reading a map.

 © ISLS

Adamina and Erzinger (2017) interviewed third to sixth graders on their procedures in map-related tasks and identified different strategies used. In map-based navigation tasks many children used a kind of *matching strategy*: they tried to find already known representations based on their spatial experiences and used these for orientation. Moreover, many children made use of a *landmark strategy* (i.e. orientation to prominent landmarks such as school buildings or playgrounds) and/or a *route strategy* (i.e. use of route knowledge, directions, and connections in space such as right, left, straight ahead) when solving tasks involving mental mapping, describing routes, or direction pointing or when explaining how to orientate in an unknown environment. Other children solved these tasks with an *overview strategy* (i.e. imagining being above the ground and looking down on it by changing the own perspective).

The scientific and educational interest in children's NMR strategies is high, but research in that field is still in its early stages and remains underrepresented (Arthurs et al., 2021). This paper answers to this gap by exploring children's strategies via think-aloud method. Additionally, it makes suggestions for geogame features that have the potential to address *successful* NMR strategies in educational trainings.

Method

We conducted a study in forms of a digital map-based game that was played by children in a virtual environment. Participants had to solve NMR tasks by navigating through the virtual world and interacting with the digital map. We chose a virtual setting for conducting this study, since virtual reality is proven to offer realistic simulations for spatial cognition research and full experimental control (Hardiess et al., 2015). As a *sub-aspect* of this overarching study, we investigated the children's procedures and strategies in NMR via think-aloud method which is the basis for this paper.

Participants and materials

This study is a sub-study of an NMR study with 110 boys and girls (balanced) aged 6 to 13. For answering the question of this paper, we reduced the data to 37 datasets as explained in the Data analysis section. With regard to its socio demographic information, the sub-dataset represents the total population. The participants were locally recruited via advertisement. They participated one after another and were rewarded with certificates of participation and science toys. The study took place during the schools' summer holidays in our institute in Münster, Germany, in conformance with the local Covid-19 regulations.

Experimental design und procedure

The NMR tasks were implemented in the location-based geogame *GeoGami* installed on a 10.2" tablet. The virtual environment was shown via a projector on a large screen. The participants were sitting on a chair in front of the screen with the tablet on a stand next to them and a controller in their hands (see Figure 1).

Figure 1
Experimental design: navigational map reading in a virtual environment.

GeoGami presented the different NMR tasks in text and audio format as well as a map of the virtual environment. Participants had to solve the NMR tasks by navigating through the virtual environment using the game controller or by interacting with the map on the tablet. The game lasted 30 to 60 minutes and included eight

 © ISLS

navigation-to-a-flag tasks as well as eight self-location tasks. In the navigation-to-a-flag tasks, the children were asked to navigate to a flag marked on the map. In the self-location tasks, the children were asked to locate themselves by tapping on the map. The map was fixed to north and the children were not allowed to rotate the device, but free to zoom and pan the map. The virtual environment represented a park area with several paths and crossings, grass, trees, flowers, benches, trash cans, bridges, a river, and lakes as well as three unique landmarks (a playground with two swings, telephone booths, and a snack bar). The start location of the total game was the playground located in the south of the map.

In the first step, the participants took part in a tutorial that explained the game, the tasks, the map symbols, as well as the controller usage. They have been given around 10 or 15 minutes to practice. The game did not start until the participants felt confident in the controlling and tablet handling. During the game, after two specific tasks —a navigation-to-a-flag and a self-location task—we asked the children to explain their solution to the experimenter in forms of retrospective think-aloud statements. This procedure does not influence the task solution itself and is still representative because of its temporal proximity to the task. Already at the beginning of the experiment, we informed the children on that procedure and explained them that we would like to learn how they read and use maps for navigation. Directly after a participant solved one of these tasks, we asked: *"How did you solve/do that?"* or—if this question was unclear—*"How did you know you had to go here?"* or *"How did you know you were in/tapped on the right place?"* The experimenter transcribed the children's answers directly in the experimental situation including notes on gestures if a child was pointing at objects in the virtual environment.

In the following, we will focus on the statements of the navigation-to-a-flag task since it represents the *navigational* aspect of NMR which we aim to investigate. In this task, the children were initially informed on their start location by presenting them a location marker on the map next to the telephone booths (see Figure 2). They started this task with the view direction fixed eastwards. Afterwards, the location marker disappeared and a destination flag was presented. The flag was located at a three-paths-crossing with a trash can and a tree. The children were asked to move to the flag in the virtual world and to press an OK-button on the tablet when they thought they have reached the destination. They had to move in southern direction with a map aligned to the north. In the virtual world, there were also other similar locations: some with same objects but a different arrangement and some with the same arrangement of these objects. This design of the virtual environment ensured that children could not find the destination just by randomly searching for it. In order to solve the task, the children had to think spatially by using the objects, paths, and landmarks around.

Data analysis

In the first step, we identified participants who fully completed the game and who solved the navigation-to-a-flag task correctly. This way, the "successful" NMR procedures and strategies were accessed. They were of major interest for this sub-study since our implications for GeoGame implementations focus on the training of children in *successful NMR strategies*. The think-aloud statements were filtered for explanations with details on the procedure. Generic or general comments such as "I walked on the paths" or "I looked for benches and bridges" were ignored since they were not useful to understand the children's learning.

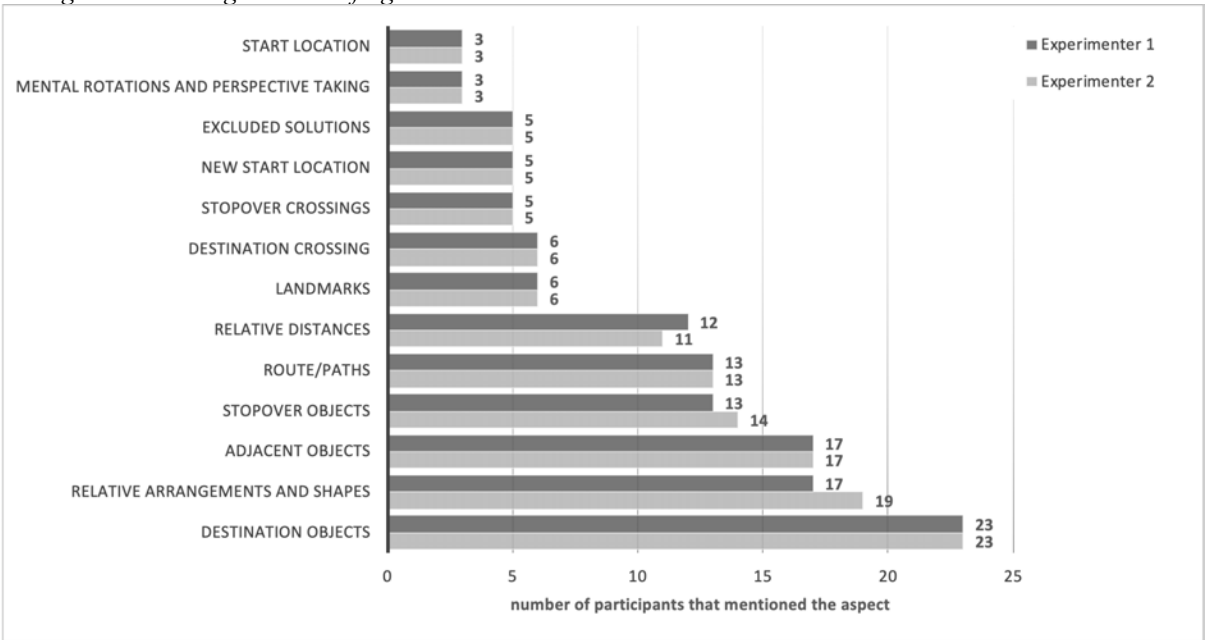
With the remaining 37 think-aloud statements, a content analysis was done by identifying and coding *aspects describing* the children's *procedures or strategies* in solving the navigation-to-a-flag task. The statements were coded by two experimenters with the software MAXQDA. In line with the literature, the focus of the analysis was on routes, crossings, objects, and landmarks as well as on mental rotation or perspective taking processes. Based on the children's statements, these categories were refined as described in the Results section. After comparing the first analysis' results among the experimenters, the codes were redefined to become clearer and more distinctive. Both experimenters rechecked their coding with regard to these definitions and overlooked aspects. Finally, the intercoder matching as well as the number of participants assigned to each code-category were determined with the use of MAXQDA. In order to learn more about possible strategies behind the children's statements, the aspects included in each statement were visualized with colors.

Results

By analyzing the think-aloud statements, we found 13 different aspects that were mentioned by the children in order to describe their NMR procedures or strategies in the navigation-to-a-flag task (see Figure 3). The intercoder matching (agreement) with regard to the existence of these aspects within the statements is 96.95 %.

Figure 3

Aspects mentioned by the participants to describe their navigational map reading (NMR) procedures or strategies in the navigation-to-a-flag task.



We distinguished between objects and crossings representing the start location, the destination, as well as "stopover" locations (i.e. objects and crossings that were visited while navigating to the destination). Additionally, we coded the snack bar and the playground as "landmarks" since they were unique in the whole environment (instead, the telephone booths were coded as "start location"). However, some children mentioned that they used the playground as an orientation point from where they restarted the navigation to the flag. We coded this procedure with "new start location". Objects that were near to the destination and mentioned for explaining the solution, but not explicitly described as stopover locations, were coded as "adjacent objects".

Most children (23 of 37) used the destination objects "tree" and/or "trash can" for their explanation (1), 6 children mentioned the destination crossing. 13 to 14 participants listed stopover objects like flowers, bridges,

trees, and benches and 5 used stopover crossings ("I have oriented myself a bit on the *crossings*"). Adjacent objects like flowers, bridges, trees, and benches were mentioned by 17 and the landmark "playground" or "swing" was included in the statement of 6 children. 5 children described that they restarted orientation from the playground ("I went to the *swing* first, from there it was *easier*"). This way, they changed the view and movement direction from south to north which simplified the original task. Only 3 children mentioned the start location when describing their procedure.

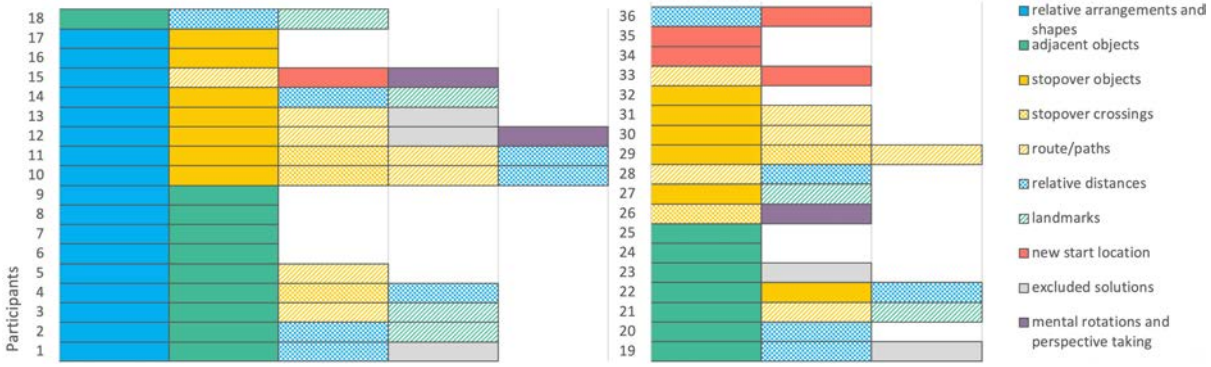
13 children described how they followed paths and route sections towards the destination ("Then I looked at *how I would have to run through the curves*"). Some children described the relative arrangements and shapes as well as relative distances of objects and paths to each other: 17 to 19 children mentioned how objects, paths, and stopover locations were arranged with words like "left", "right", "behind", and "between" as well as with terms describing shapes like "branching" or "edge". 11 to 12 participants also mentioned the relative distance of objects to each other or to themselves with terms like "near" and "far" ("I had to go to the trash can and it was the only one *near* the bridge").

5 children explained that they excluded routes or locations ("Then, I saw that there was a bench on the bridge, so *I didn't have to cross that bridge*."). 3 children were able to describe how he or she mentally rotated the map ("[I] turned it in the head to my perspective") or changed the own perspective ("If I were in there").

The color-visualization (see Figure 4) gives insight in the combination of aspects within the statements. Individual colors and pattern were chosen for each aspect. The visualization shows no distinct groups in the way aspects were combined. Rather, the results show combinations that were highly individual. However, two main tendencies can be observed in the data. A first group (14 children) described their procedure in a *dynamic way* by mentioning stopover objects, crossings, and/or the routes they took without explaining how the destination is located with regard to adjacent objects or landmarks. The 3 children that were able to explain how they mentally rotated or changed their perspective belong to this dynamic group. A second group (12 children) explained their solution in a *static way* by describing objects and landmarks that are adjacent to the destination. However, also explanations combining these two ways were observed. What additionally can be seen is that 3 of the 5 children that used the playground as their new start location mentioned neither the dynamic, nor the static way. One further child of these 5 children mentioned the travelled route (dynamic way) only very vague: "I then go to the playground, then I know where I am, because the game started there. I first looked from the playground, there were *paths* there, and with these *paths* I could see exactly where I had to go."

Figure 4

Combinations of aspects mentioned by the participants (unconsidered aspects: start location, destination objects, and crossings; coding: experimenter 1).



Discussion and suggestion for the design of a geogame

Children's navigational map reading strategies

Children differ in their procedure or strategy in how they solve navigation-to-a-flag tasks. In the specific task of this study, the children started at a landmark (telephone booths) and had to move in the southern direction to the destination. The destination was surrounded by objects that appeared also in many further places on the map. The nearest landmark was a playground which was several crossings away from the destination. Since it was no unique location, it was not possible for the children to find the destination just by accidently stumbling upon it. Therefore, we assume that the children's statements on the correctly solved task inform us on *successful* procedures or strategies in navigating with a map towards a destination. However, we suppose that the statements represent elaborated and less elaborated ways in doing so.

For each procedure or strategy aspect, we determined the number of participants mentioning it. The number gives us an idea on how aware a child was about the individual aspect as a part of his or her procedure. However, we cannot deduce from the statements whether the individual child did not consult further aspects. The number does not tell us how often children made use of individual aspects or if they were able to do so. Moreover, it is also conceivable that children noticed some aspects only afterwards, i.e. in retrospect. For future work, we suggest to ask for explanations also directly *in* the situation in order to prevent that children forget or add aspects in retrospective. This *concurrent* think-aloud method could also clarify which aspects are relevant to children at different decision points. However, it is possible that this method induces strategic procedures that would not have arisen with a retrospective think-aloud method.

The results show that children's successful NMR strategies incorporated the consideration of destination objects as well as adjacent objects and landmarks. The children included shapes, relative arrangements, and distances (closeness and farness) in their spatial analysis of the destination as well as the route towards it. Although the destination was distinguishable from other locations in the way the destination objects "tree" and "trash can" were arranged in relation to each other, the children did not explicitly mention this arrangement. The children's statements rather give the impression that the existence of and relative distance to other objects as well as their own way towards the destination played a greater role in their decision-making process: whereas some children predominantly analyzed the destination on site (static way) by mentioning adjacent objects and landmarks, others remembered how they planned and repeatedly checked the route towards the destination (dynamic way). Some children described that they mentally rotated the map or mentally changed their own perspective to support their route planning. Other children mentioned that they crossed decision points on which they decided on or excluded routes. These decisions were based on the existence, arrangement, and shape of objects, landmarks, and paths. It would be interesting to investigate if the "static" group took longer routes towards the destination (and therefore was less efficient in solving the task) than the "dynamic" group: could it be that the "static" group scanned the area in a trial-and-error way until they recognized the destination objects "tree" and "trash can" and verified their assumption with adjacent objects? Future work could also focus on self-locations tasks that are created to be solved *on site*: do children solve such tasks predominantly by focusing on adjacent objects or do some of them make use of their knowledge about their route towards the destination?

In addition to the so far mentioned procedures and strategies, there was another successful way in solving the navigation-to-a-flag task: some children looked for another, already known orientation point at the bottom of the map to prevent a non-alignment of view direction and map. They reorientated from the playground which was the start location of the total game. Although the children were successful in solving the task (and may have reduced their error probability this way), such a procedure causes significantly longer routes and is therefore less efficient than other strategies. As shown above, it occurred mainly isolated from the other procedures. Future work with a focus on children's statements on incorrectly solved tasks could possibly further illuminate such inefficient strategies.

Suggestions for the design and conception of a geogame

Based on our empirical findings described above, we developed a new concept for a geogame design. The focus is on geogame features that have the potential to represent or address successful procedures and strategies in NMR. Developing successful learning methods demands to understand the thinking of successful learners. The geogame as one possible methodic tool in geoscience education offer the potential to be adjusted to these educational needs.

Educational geogames are often map-based games using classical street maps that are fixed to north and can be *panned* and *zoomed*. Panning and zooming are useful in NMR situations because they allow the user to get an overview of the environment as well as to plan the route based on start location, destination, and possible stop-over locations. A north-oriented map activates the spatial thinking of the map reader when navigation is orientated to west, east, or south. But what is often missing in geogames is a customizability of the map in forms of a choice between automatic, manual, and no panning, zooming, and rotation. *Automatically or manually rotating maps* instead of fixed maps, for example, are helpful to address mental rotation and perspective taking or to facilitate the spatial perception of object arrangements (see Figure 5a). As an alternative to map rotations, *view direction markers* – either presented initially or during the whole NMR process – can visualize mental rotations, perspectives, and spatial arrangements without changing the map view (see Figure 5b).

Several educational geogames visualize the user's location and view direction. What is missing are customizable map marker settings. Location markers (see Figure 5c) can visualize start locations, destinations, and routes towards the destination. The absence of a marker activates the map reader in his or her spatial thinking. *Initial* location marker can support in the initial self-location and can then handover this process back to the map reader by disappearing during navigation. *Tracks* in forms of lines marking the route walked (see Figure 5d) or

highlighted streets representing the approximate location of the map reader (see Figure 5e) are further features with the potential to address route planning and self-location during navigation.

Point, line, or polygon markers are useful features to emphasize objects, landmarks, routes, start locations, and destinations, as well as the shape of landmarks for orientation (see Figure 5f). A *draw functionality* (see Figure 5g) allowing the map reader to mark objects, structures, and routes during the navigation process on his or her own is a helpful feature for making use of map details that are relevant to the individual map reader. In order to draw attention to relative distances and arrangements between objects or objects and map reader, a *buffer* (see Figure 5h) can be used that draws a circle around a certain location with a given diameter. All these features are no technical innovations, but missing in most educational location-based games.

Figure 5

Geogame features for representing and addressing successful NMR strategies: (a) map rotation, (b) view direction marker, (c) location marker, (d) track, (e) highlighted streets, (f) point, line, and polygon marker, (g) draw function, (h) buffer, (i) satellite picture and swipe function, (j) 3D map, (k) feedback on distance deviation, (l) feedback on task solution (GeoGami, map visualization based on OpenStreetMap and Mapbox).

Several educational geogames do not offer the option to change the map layer, but satellite pictures (see Figure 5i) and 3D maps (see Figure 5j) can help the map reader to recognize objects and special shapes of landmarks as well as to understand map visualizations. A *swipe* functionality (see Figure 5i) allowing the map reader to successively change the street map into a satellite picture and back is a further supportive feature for this kind of applications.

Already existing geogames give rather simple feedback on task solutions, but location-based technologies offer the possibility to give detailed feedback on task solution by highlighting deviation distances and angles (see Figure 5k), marking correct locations, view directions, and objects on the map (see Figure 5l) or giving custom messages on pre-defined errors. This is also missing in most educational geogames.

Although a huge variety of educational geogames exist, the customizability and availability of features like markers and layers, feedback, and map draw functionalities is very uncommon. Therefore, we are currently

 © ISLS

equipping our location-based geogame GeoGami with the above-mentioned features: some features are already implemented, others under development. Being interested in geoinformation technologies for school education requires rethinking these tools from an educational perspective. NMR training studies must consider tools that are adjusted for its special use. In this paper, we suggested enhancements for such tools based on an analysis of children's successful NMR strategies.

University of Toronto

Abstract: Transformative learning requires students to actively identify issues, question the narratives that surround them, and develop strategies for change (Freire, 1978). However, for such learning to be truly impactful it must be contextual and culturally relevant to learners. In this paper, we report on the design, implementation and outcomes of a performative learning workshop organized at a secondary school in Bengaluru, India. We highlight the importance of the co-design process and its influence on joint inquiry and increased community engagement. Data from student interactions, discourse and artifacts was analyzed to understand how a culturally relevant arts-based activity can engage students in critical action, collaboration, and embodied learning about local issues. The findings suggest that knowledge and action are both deeply embedded in and influenced by cultural experiences as represented in the students' collective creations. We discuss the implications of this research in the broader context of the learning sciences.

Introduction

This paper reports on a co-designed, culturally responsive learning experience that engaged students in arts-based critical action within a secondary school in Bengaluru, India. The activity took the form of a *Rangoli Utsav* (or Rangoli festival), as part of the school's Diwali celebrations. Rangoli is a traditional Indian art form that consists of multicolored drawings (typically circular patterns) designed on the floor using materials such as colored sand, powdered limestone, flower petals, etc. Over the past year, we have established a professional learning community for teachers in Southern India, comprising three workshops that focused on topics of critical action and culturally responsive pedagogies. This paper studies one of the curriculum activities produced by teachers, in which the *Utsav* provided a context for a performative learning workshop. Students were invited to use Rangolis to express their personal and cultural identities or address socio-environmental problems that concern them, as an exercise of critical action. This project is situated within a broader program of research and critical action called CALE: The Critical Action Learning Exchange (Carvalho et al., 2021). This research responds to a growing need in the learning sciences to nurture culturally responsive pedagogies in which students develop their own sense of local purpose (Enyedy et al., 2011, Paris & Alim, 2017) situated in authentic cultural contexts and belief systems (Hod et al., 2018).

The following research question guided our work: How can critical action pedagogy support students in developing understanding and expression about global issues within their local cultural context?

Theoretical Framework - Critical Action and Arts-based Pedagogy

In Freire's words, "Only beings who can reflect upon the fact that they are determined are capable of freeing themselves. Their reflectiveness results in the exercise of a profoundly transforming action upon the determining reality. Consciousness of and action upon reality are, therefore, inseparable constituents of the transforming act by which men become beings of relation." Critical action is here understood as the behavioural component in the Freirean concept of *conscientização*, which is the process of acquisition or development of critical consciousness. Critical consciousness is composed of three mutually reinforcing elements, namely critical reflection, critical motivation, and critical action (Diemer et al., 2015; Watts & Hipolito-Delgado, 2015). Critical reflection refers to the process of learning to distinguish culture from nature, or in other words, of acquiring a perspective that allows for social constructs and structures to be perceived as questionable and malleable, instead of being regarded as inescapable, naturally imposed realities. Critical motivation is an individual's perceived capability and commitment to contribute to social advancement through the reinvention of social structures that enable unjust, oppressive, harmful, or unhealthy conditions. Finally, critical action refers to the engagement in action dedicated to producing socio-political changes perceived as conducive to more just and healthy conditions (Freire, 1978; Watts et al., 2011; Jemal & Bussey, 2018). *Conscientização*, thus, can be understood in the words of Paulo Freire as the process of "learning to perceive social, political, and economic contradictions, and to take action against the oppressive elements of reality" (2000, p. 35)

 © ISLS

Culturally Responsive Teaching with Art

One form of critical action is art-making, given its capacity of encompassing the conceptual components of critical consciousness. Art is a powerful way to address global issues across cultural contexts. Teachers play a crucial role in this endeavour, enabling students to connect their lived experience to issues and ideas, culture and community. According to Stephen K. Levine:

> By creating an alternative world of the imagination, the artwork shows possibilities that are absent or dormant within our everyday awareness. Moreover, the work takes us away from this everyday world within which we experience ourselves as unable to act; we could say that it "decenters" us from this world. In so doing it frees us up for new possibilities that were not apparent within our limited horizon of understanding. […] Artmaking is itself a sensory-affective experience that gives participants an experience of their own capacities for action. Because it affects us through the body and the emotions, artmaking can provide experiences that restore us to a feeling of being fully alive. And in making the work, by acting within the limited frame of the materials and the time and space available, we recover our capacity to be effective in the world, something that we have lost in the helpless situation in which we find ourselves. (2011, p. 28)

In this sense, the process of artmaking awakens our "dormant" ability for critical reflection, triggers our critical motivation by helping us to perceive ourselves as "able to act", and "recovers our capacity" for critical action. There is a long history of using art education to confront issues of race, cultural discrimination or various forms of othering. According to Ladson-Billings' (1995) framework, arts-based pedagogy should respond to students' cultural knowledge, prior experiences, frame of references, and diverse performance styles (Lai, 2012; Lee, 2012). The present study addresses cultural responsiveness through designing learning activities in what Lai describes as culturally familiar and creative ways (Lai, 2012) Moreover, the arts have repeatedly demonstrated a capacity of catalyzing social change. Art has the power to raise our consciousness, empower, advocate, and provoke (Estrella, 2011, p. 42).

Communities of Learners

A final theoretical element for this work is that of learning communities, which can support collaboration and progressive discourse (Brown & Campione, 1994) a deep focus on ideas (Scardamalia & Bereiter, 2005), and collective forms of inquiry in which the community creates a knowledge base that serves as a resource for individuals and small groups (Slotta, Quintana & Moher, 2018). Critical action that occurs within the context of a community of one's peers can add meaning and purpose to the community, democratize learning, and support individual members as they develop an identity within the community context.

This study was conducted in the context of a particular professional learning community called the Critical Action Learning Exchange (CALE), which helps teachers develop curriculum lessons that empower students in the face of social, economic and political issues in a rapidly changing world (Carvalho et al., 2021). CALE supports teachers in the design of culturally responsive learning activities that encourage students to connect to global issues through their own personal and cultural lens moving from knowledge to action as explained in Figure 1.

Methods

Co-design is a participatory approach that brings together researcher's knowledge and lived experiences of the participants (Roschelle & Penuel, 2006). Our workshop was designed in partnership with a teacher-leader from the school, five classroom teachers and administrators. Identified priorities and indicators of success of the workshop were negotiated and tailored to the needs of the school in their local, temporal context. The timing of the workshop around the Hindu festival of Diwali was important to the school, since the festival itself represents the victory of good over bad, light over darkness and the need to act against the evils of society. Indian teachers chose the traditional art form of Rangoli for its familiarity to students and cultural appropriateness. The school had previously organized similar Rangoli festivals (see Figure 2), celebrating a folk-art rooted in 5000 years of tradition. But it had never been done as a source of critical action.

Figure 2
Rangolis drawn by students in the school in previous years

As a CALE curriculum, the Rangoli activity was designed to link to the six components of the framework shown in Figure 1. Students set out to investigate social issues by participating in a school-wide brainstorming activity during the weekly assembly and continued building knowledge around these issues (Knowledge). They then came together as groups, bringing in their individual ideas and visions for change, and reflecting on their positioning. They also investigated the forces that impact their chosen issue (Criticality). Working together, they determined what should be depicted within the Rangoli and how it would hopefully affect an audience of the wider school community (Action). Each student was given the opportunity to bring in their unique competencies and artistic skills (Individual), engaging in peer exchanges of ideas within their group. A learning community approach was adapted to move students from a competitive mindset to a collaborative one (Community). Finally, the Rangolis were on display for the school and shared with the research group in Canada. Pictures of the Rangolis serve as discussion artifacts showcased on social media with the goal of increasing the engagement of educators, researchers and students around the world (Globe).

Participants

Six teachers (including one teacher-leader who coordinates teacher professional development) from a secondary school in Bengaluru, India were engaged in the design of this curriculum, along with six members of the CALE research team in Canada. Participation in the *Rangoli Utsav* was open to all students in Grades 6-10. Interested students submitted their names and themes of interest, individually, or in pairs to their respective teacher coordinators. A total of 82 students, 63 of whom identified as girls and 19 as boys, signed up to participate in the workshop. These participants were surveyed verbally on whether they have engaged in critical action-oriented activities or Rangoli art before. While 72% of participants indicated some experience with Rangoli, none of the participants indicated any previous participation in critical action-oriented activities. The teachers then collectively deliberated on group formations based on student requests, interests, experience, synergy and motivations. 12 groups were formed of 6-7 students each; 4 students excused themselves from the groups and opted to be community helpers through the planning and execution of the workshop.

Procedure and Data Sources

While the brainstorming for the issues of significance to the community took place as a collective whole-school activity, interested participants gathered in their small groups to share their ideas on specific themes of interest.

Each group shared their top choices with other groups a few days prior to the workshops. Collectively, with some mediation from the teacher-leader, themes for each design were confirmed and adjusted to suit the group's interest and the community's collective voice. Students worked in their small groups on design ideas over a weekend, sharing their hand drawings, topic research, artistic ideas, design recommendations and individual motivations with each other on Monday. They also finalized some images, symbols, materials or any other visual elements that could be included in their Rangolis. Three examples of their progressive visualization of the issues can be seen in the drawings in Figure 2. Finally, they created group artist statements that discussed the social or environmental issue their rangoli addressed and highlighted important information around the issue they wanted to share with their community.

Figure 2
Students' iterative visualizations of their Rangoli themes

On the day of the workshop, students gathered in their groups in a large auditorium and worked collaboratively alongside other groups for a little over 2 hours. Some pictures and videos of their group discourse were captured by the community helpers. These helpers also played music, fetched supplies and proved to be an idea-soundboard to the teams. The completed Rangolis (Figure 3) were on display to the whole school community for the day. Upon requests from parents and teachers from neighbouring schools, the Rangolis were kept on display for an additional day to enable students from the other school to visit.

Analysis and Findings

To understand the ways in which our critical action workshop supported students in expressing their understandings of global issues that mattered to them, we performed an interpretive analysis (Sgier, 2012) on the data collected through artist statements, student artifacts, teacher and student discourse, workshop pictures and videos. Throughout the analysis, we sought to identify patterns of coherence, as well as anomalies to these patterns. Trustworthiness (Shenton, 2004) was established through a debriefing with the participants, iterative questioning, member checks, peer-scrutiny and thick descriptions.

Co-design Analysis

The co-design method had many benefits, including grounding our workshop in the local context of the school community, and enabling enthusiastic participation. As the teacher-leader noted, in her reflection, *"…they (the participants) have been so enthusiastic about the whole event …. they were so engrossed in doing it and immersed in the experience they didn't even want to have a break"*. In this project, co-design of the activities with teachers at the school achieved informal-mutual learning through (i) sharing past practices of community activities (ii) building common understanding around critical action; (iii) construction of shared meanings on arts-based pedagogy; and (iv) idea-generation.

Critical Visual Analysis of Artifacts

Instead of looking at the formal artistic elements such as line, value, shapes, forms, spaces, colour and texture, we analyze students' artistic creation using a Critical Visual Analysis (Aiello, 2006) in which the primary concern is students' perception of the critical issues, the ideology behind their creations, the iconographies students employed, and the use of social semiotics in illustrating the problems and solutions. Students' creations show a range of evidence of their perception of global issues: five rangolis included a representation of the globe; four

included a representation of a Hindu deity, demonstrating that students are employing icons from their traditional culture; eight out of 12 groups also expresses students' ideologies through the implementation of texts, such as "Her tears will not correct this imbalance, actions will save the girl child". Among the 12 pieces, the *Woman Empowerment* (see Figure 3) is a good example of students creating meaning through redefining the social semiotics of an Indian goddess as a determined woman. Students' embodied, collective Rangoli art populated their physical space with critical messages that connected global issues with their local culture.

Figure 3
Students' completed rangolis

Learning Community Analysis

Working together as a learning community required learners to work cooperatively and collaboratively to actively engage in a variety of interactions and intercommunications (Slotta et al., 2018). The embodied nature (walking a large floor to see a physically distributed set of these) was also understood as an important aspect. All teachers and researchers commented that the community-oriented nature of this design was instrumental to its success: students from the whole school created a large, spatial, cultural and conceptual artform, which then became the focus of a community event. Students worked collectively to define themes, then broke into teams of mixed grade levels to create a community product. Table 1 presents a view of the major activities, in terms of the community elements (individual, group or whole school), and the interactions they supported.

Table 1
Analysis of activities before, during and after the workshop

Activity name	Community elements *(# participants)*	Interactions
Brainstorm	School Community *(418)*	Real-life examples of issues contributed by every student who wished to, Idea build-ons
Sign up	Individual/Pairs. *(82)*	Identify themes of interest, generalize, contribute new ideas
Group formation	School Community (12 groups)	Teachers' facilitation of group-forming process
Theme selection	Group (12 groups)	Argumentation, negotiation, collaborative discourse
Rangoli design - ideation	Individual (78)	Exploration of issues, visualization
Rangoli design - iterations	Group (12 groups)	Visualization, collective exploration, new knowledge sharing, problem-solving, idea improvement
Material sourcing	Individual (78)	Critical thinking, negotiations, reflection
Rangoli - creation	Group (12 groups)	Embodied, tangible, problem-solving, deliberations, group idea cohesion
Artist Statements	Group (12 groups)	
Peer feedback	Individual/Group	Self-reflexivity, explanation, interpretation
Gallery walk - online	Globe (5)	Self-reflexivity, explanation, interpretation
Gallery walk – F2F	Local Community (600+)	Self-reflexivity, explanation, interpretation
Online Social Media Display	Ongoing	Interpretation, critical reflection

Several important outcomes can be identified within Table 1 relating to the impact of the learning community. First, a knowledge base was constructed, in the initial brainstorming of possible issues, which led to a balanced set of issues distributed amongst the design teams. Students in any working group were all able to see this overall spread of ideas and understand their own product and creative activities within that wider context. Second, reflection was supported by activities such as brainstorming, theme selection, and the actual Rangoli creation process. Third, the definition of groups was an outcome of the brainstorming and student voice, supported by a group of teachers. Fourth, creative resources and products emerged from the community. And finally, there was a powerful source of feedback and reflection from the community gallery walks.

Teachers interviewed at the end of the workshop suggested that the performative learning experience was helpful in supporting students' knowledge building around critical issues. They were surprised by the variety of curriculum concepts (such as greenhouse gases, malnutrition, epidemiological methods etc) that were depicted in the student artist statements. One teacher observed: "*...even different (curriculum) concepts should be taught through art. That way they don't feel the pinch or the burden of learning, and learning is more joyous than just-you know - through textbooks or lecture*". When reflecting on the lack of formal assessment of learning, another teacher said, "*I'm pretty sure if we ask them a question in the next assessment about this (their issue), they can write a lot because of this Rangoli...*"

Connections to the CALE framework

To determine how the critical action components of the CALE framework (the vertical axis in Figure 1) were addressed by this workshop, a content analysis was performed on the artist statements and student interviews, with a particular focus on student reflections during the process of Rangoli creation. Table 2 presents a summary of these findings. The main finding that emerged was that all groups (n = 12) appeared to understand what their issue was, the challenges of addressing the same, and the types of knowledge needed to effectively address them. Six of the 12 groups included short text descriptions within their Rangolis, to help the user interpret the issues. Also, four out of the 12 groups used their content knowledge to improve their artist statement and explain "their action". Interestingly, all four of those groups (Covid Warriors, Save Water, Save the Trees, One Planet One Chance) addressed the issues through a scientific lens. The "Good over evil" Rangoli, which showed an evil mythological villain with multiple heads, was unique in that, while it artistically portrayed a range of the issues, calling for action, there was no treatment of how these issues might be addressed. Individual interpretations of the

issue varied and were deeply rooted in students' own personal contexts. For example, while one student working on the "Remove your Obstacles" Rangoli (which addressed the issues around mental wellbeing) reflected on the symbolism of the elephant (big ears so we can listen more, big belly to laugh etc.), another student visualized the elephant as "path makers in a forest that lead the way", and another interpreted the same from a religious viewpoint, "you pray to Ganesh…". Groups also built on each other's calls to action, "education is the way to bring people out of slums and out of poverty". The most common theme that was found in the analysis of their artist statements and reflection was a call to the collective, "We Indians need to…", "it is necessary for every person in the country." etc. Finally, while the actions called for were not always critical in nature, they informed the community of its role in tackling these issues.

Table 2
Analysis of Rangolis

Rangoli	Theme	Actions	Community Connections
1.One Planet, One Chance	Global Warming, Personal lifestyle, Carbon footprint	Plant more trees, reduce carbon emissions	Global warming recognized as a "world problem". Questioning role of cities
2. Save the trees	Sustainable lifestyle, Forestry, Cultural sustainability	Respect and pray to nature (tulsi pooja), don't cut trees, participate in social national movements	Chipko (national) movement, Worship trees as a family
3. Women Empowerment	Gender equity, social issues,	Need to respect women. Help our mom and other women every day. Big goals for careers (girls)	Durga (goddess of courage) reimagined. Government policy connections
4. Remove your obstacles	Whole person, Mental wellness, Positive thinking	Self-assertion is important, "you can, you will, you do"	Lockdowns hard on us (Bengaluru). Be a path maker
5. Pandemic Warriors	Social movement, Public health, Social health	Respect frontline workers, get your vaccine, encourage others to get their vaccine shot.	Recognition of 'warriors'. Role of media (portraying India on world stage)
6. Yoga for Health	Whole person, Health, Personal Lifestyle	Practice yoga every day. Include it as part of school day	Recognition of yoga as an ancient practice, leaf arms
7. Save Water	Climate change, Personal lifestyle, Water footprint,	Critical thinking, negotiations, reflection	Embodiment of water
8. Farmers are our Future	Food sources, Food waste, Food justice, Environmental justice, Social justice	Embodied, tangible, problem-solving, deliberations, group idea cohesion	Support local farmers that involved social movement
9. Save the Girl Child	Gender Equity, Gender justice, Social movement	Change the social view toward gender equity, Stop abortion	Make an awareness in the society
10. Gender Equality	Gender equity, Social issues, Equal Participation	Make an equal situation for all men and women in all areas	Bring equality needs efforts of the whole community
11. Good over Evil	Various socio-political issues	Awareness of various critical issues	Representation of Diwali, victory of Lord Ram
12. Population Explosion	Climate change, Food justice, Social equity, Personal lifestyle, Sustainable future, poverty	Control population, Increase the quantity of the food, Save more water	Over populations make various issues for the whole community that required the collective action

Discussion

The CALE framework encouraged students to bring criticality and voice to their artistic designs through knowledge sharing. This was evident in the significant divergence of the Rangoli activities that occurred during this year's Diwali festival from those of years past. The framework provided pedagogical support for increasing both the scope and depth of students' critical inquiry. It helped them expand the range of their ideas, building

connections beyond the individual level, to include their broader community (e.g., farmers, health care professionals, teachers, the police) and the whole world (e.g., global warming). It also supported students in going progressively deeper in their ideas, helping them build knowledge about their local issues, engaging them in critical reflection, and engaging in critical action through art making. Thus, arts-based critical making enhanced students' expression of their ideas. Through collective inquiry on critical issues, connected to local cultural contexts, students perceived a sense of relevance, participation, and empowerment during this process. This experiential learning activity became a practice of meaning-making by designing, implementing, and sharing with others in their own community.

Conclusion

During the ICLS 2020 symposium on "Reconceptualizing Learning: A Critical Task for Knowledge-Building and Teaching" (de Royston et al., 2020) highlighted the importance of understanding participation in cultural practices as being fundamental to the study of learning, calling upon the community to engage in and with such "foundational work" at this critical time. The present research demonstrates some of the challenges and opportunities of situating learning in and within the cultural practices of students in India. Yet this is just the start. More work is still needed on how to extend our learnings to other contexts and develop guidelines for culturally responsive curriculum designs that go beyond the traditional definitions of learning by supporting student agency, knowledge building and growth as empowered citizens.

The instructional legacy of COVID-19: Teacher adaptation in response to the pandemic

Connolly, H., Teachers College, Columbia University, NWEA, hc2808@tc.columbia.edu
Abowd, N., Teachers College, Columbia University, nv2371@tc.columbia.edu
Chase, C. C., Teachers College, Columbia University, cc3663@tc.columbia.edu

Abstract: While being adaptive is a key characteristic of effective teaching, teachers can be resistant to change. In Spring of 2020, American teachers transitioned suddenly to distance learning because of the COVID-19 pandemic. This presented an opportunity to investigate teacher adaptations to extreme changes in teaching conditions. A survey study of 71 K-8 teachers conducted in Spring of 2020 found that teachers engaged in three of the core practices of adaptive experts. Moreover, most teachers planned to transfer what they learned to adapt future in-person teaching, and 30% of teachers planned to adopt transformative teaching practices. One positive outcome of the pandemic is that it promoted teacher adaptation and may have even prompted some teachers to develop lasting new practices.

Introduction

At the height of the COVID-19 pandemic in Spring of 2020, most K-12 schools in the United States closed, and teachers and students were suddenly forced into distance learning. Almost overnight, teachers were expected to shift from teaching in-person to teaching remotely under drastically new conditions. Many K-12 teachers had never taught virtually prior to this pandemic, and as such were required to adapt to these new conditions with very little prior experience or familiarity with digital tools and technologies (Herold, 2020; Mupinga, 2005). While these changes produced several challenges for teachers and students, they also presented a unique opportunity to study teacher adaptation to very novel conditions.

Teacher adaptation

When teachers adapt, they *change their teaching practices in response to new student needs, situations, or challenges*. For example, to support a new student who is an English language learner, a teacher might adapt his lessons to include visual instructions. To implement a new inquiry-based curriculum, a teacher might adapt her pedagogical style to include more questioning and challenging of student thinking. This kind of adaptivity has been lauded as a key characteristic of effective teachers (Borko & Livingston 1989; Corno, 2008; Darling-Hammond & Bransford, 2005; Fairbanks et al., 2010). Furthermore, research suggests that adaptive teaching can boost student achievement (Collie & Martin, 2017; Gambrell et al., 2011; Hattie, 2009). However, adapting teaching practices is difficult. For example, in observing 51 elementary literacy teachers over a 9-year period, Hoffman & Duffy (2016) found that teachers seldom adapted their instruction significantly, often sticking to preset scripts. Other studies have shown that teachers struggle to adapt in response to new curricula (Duffy & Roebler, 1986), technology (Cuban, 2001), educational reforms (Hiebert & Stigler, 2000) and professional development (Ketelhut et al., 2020; Hamilton, 2018).

Adaptive expertise and adaptive practices

Teacher adaptation has been associated with many overlapping constructs such as adaptability (Collie & Martin, 2017), improvisation (Borko & Livingston, 1989), thoughtful teaching (Fairbanks et al., 2010), teaching adaptively (Corno, 2008), and teachers' adaptive expertise (De Arment et al., 2013; Lin, Schwartz, & Hatano, 2005; Schwartz, Bransford, & Sears, 2005). In this paper, we view teachers' adaptations through the framework of adaptive expertise, which was proposed by Hatano and Inagaki (1986) to describe expertise in many domains.

Adaptive expertise is often defined in contrast to routine expertise. Routine experts are highly efficient and accurate when performing under conditions that do not change. In contrast, adaptive experts are able to adapt to the demands of a novel situation. They can invent new procedures when situational demands call for it, let go of old ways that are suboptimal, and seek to continually learn and grow. For example, a routine expert teacher might deliver lessons that are highly effective under typical conditions. However, when conditions change - a new curriculum, new standards, new assessments, new kinds of students - this teacher would falter. On the other hand, a more adaptive teacher would nimbly adjust and modify lessons appropriately for each new context.

 © ISLS

In this paper, we do not study expert teachers per se, but we use the framework of adaptive expertise to identify *adaptive practices* that teachers might adopt when thrown into the novel conditions of distance learning. Adaptive experts engage in three core adaptive practices. In this study, we looked for self-reported evidence of each of these three adaptive practices in K-8 teachers. First, adaptive experts can perceive new needs or *challenges* that call for adaptation (Lin et al., 2005). Without perception of a new need or challenge, there is no motivation to change. To assess this, we asked teachers to describe the key challenges they faced in designing instruction for distance learning. Second, adaptive experts modify or adjust current practices in response to new needs and challenges (Martin & Schwartz, 2009). We call these *reactive adaptations* because they occur in response to a perceived challenge. To assess this practice, we asked teachers to explain how they had changed their teaching during distance learning. Third, adaptive experts engage in *prospective adaptations* which are motivated by a desire to continually learn and improve their performance in the long-run, rather than in response to an immediate need (Martin & Schwartz, 2009). To assess prospective adaptations, we asked teachers what they planned to change about their teaching upon return to the in-person classroom.

How did teachers adapt to distance learning during COVID-related school closures?

A small body of emerging literature explores how teachers adapted their instruction during COVID-related school closures. We focus our review of this literature on evidence related to the three core practices of adaptive experts discussed above.

There is research suggesting that teachers faced several *challenges* during the transition to distance learning. Chief amongst them is lack of access to technology and/or internet connections (Francom, Lee & Pinkney, 2021; Simmons, 2020) and low familiarity with online learning tools and technology for both students and teachers (Anderson & Hira, 2020; Blagg & Luetmer, 2020; Doiron & Marsigliano, 2020; Herold, 2020; Mupinga, 2005; Saad & Sankaran, 2020). Studies also report high rates of absenteeism among students during the pandemic, particularly in less advantaged rural and urban populations (Anderson, 2020; Bintliff, 2020; Leech et al., 2020). One survey study suggested that teachers met with instructional challenges, such that 55% of teachers said that their lessons hadn't translated well to distance learning (Leech et al., 2020).

Most of the research documenting *reactive teacher adaptations* in response to COVID-related distance learning focuses on the adoption of new technological tools and their use. It is not surprising that teachers began using new technological tools, such as video conferencing platforms like Zoom and learning management systems such as Google Classroom to enable online mediums for previously in-person activities and functions. Teachers also adopted technologies for communication with parents, such as ClassDojo (Francom, Lee & Pinkney, 2021; Lieberman, 2020; Leech et al. 2020). There is also evidence that teachers engaged in new practices, such as pre-recording their lectures for students to watch on their own time (Pilkington & Hanif, 2021) or organizing virtual social gatherings to provide social and emotional support to students (Chamberlain et al., 2020).

Little research examines *prospective teacher adaptations* or planned future changes to teaching after the pandemic. One study found that teachers planned to continue using many of the technological tools discussed above to record their lectures, communicate with students more frequently, or even take students on virtual field trips, which suggests a positive outcome of COVID-19 (Francom et al., 2021). However, this study focused on technology adoption, not teacher practices.

A few patterns emerged from this literature review. The majority of the research on teacher adaptation during the pandemic was conducted in the context of higher education, used case study methods, or focused on technology. In contrast, our work examines K-8 teachers, uses survey methods, and focuses more broadly on teacher practices. Moreover, most research describes what teaching looked like during the pandemic, but very little work has explored how the pandemic could spur long-term changes to teacher practice upon a return to in-person instruction. Finally, we have not come across other papers that use the adaptive expertise framework to examine pandemic-related teacher change. We aim to fill these gaps with the current study.

The Current Study

In this study, we investigate teacher adaptation during the pandemic by surveying K-8 teachers about use of three adaptive teacher practices: (1) perception of **challenges** associated with distance learning, (2) **reactive adaptations** during distance learning (or adaptations made in response to new needs or challenges), (3) planned **prospective adaptations** for future in-person learning (or changes intended to be long-term improvements). This led us to examine the following research questions:

1. To what extent did teachers perceive challenges of distance learning, engage in reactive adaptations in response to the new conditions of distance learning, and plan to make prospective adaptations upon return to in-person learning?

2. What kinds of COVID-related challenges, reactive adaptations, and prospective adaptations did teachers experience?
3. To what extent did teachers plan to make prospective adaptations that were transformative to their teaching? What kinds of planned prospective adaptations were transformative in nature, signaling possible long-term changes in K-8 education?

During the sudden shift to distance learning, we expected that teachers would perceive many new challenges to teaching and respond by reactively adapting their teaching practices to meet at least some of these new challenges. Given the extremely novel conditions posed by distance learning, one could argue that teachers were essentially required to adapt their teaching to some extent, and we found some evidence of teacher adaptation during COVID-19 from our literature review. However, a more open question for us was whether the pandemic would spur teachers to plan prospective adaptations when they returned to in-person learning. While we found evidence that teachers may use newly learned technology after the pandemic (Francom et al., 2021), we were interested in better understanding the extent and types of planned changes to future teaching practices. In other words, would this experience of distance learning cause lasting changes to teachers' practices? Or would teachers simply go back to their old, routine ways of teaching once the pandemic ended?

Methods

Sample

In May and June of 2020, 71 K-8 school teachers completed the survey study. Teachers hailed from 8 public and 4 charter schools throughout New York and Connecticut. Overall, the sample contained teachers associated with a variety of different grades, subjects, experience levels, school types, and student SES levels. Our team contacted 103 principals across two states for whom contact information was publically available, inviting their school to participate in the study. About 23% of teachers who received the survey completed it.

Survey

While the survey included several demographic questions, this paper focuses on three open-ended survey questions about teaching both during and after the pandemic:

1. What key challenges have you faced in designing instruction for distance learning? Give one or two examples.
2. In which ways have you had to change your teaching practices to meet your students' needs during distance learning?
3. Is there anything you have learned from your experience with distance learning that will change how you teach once you are back in the classroom? If so, please describe.

Measures and Coding

Responses to questions 1-3 were coded for *types* of challenges, reactive adaptations, and prospective adaptations, respectively. Additionally, responses to the third question were coded for prospective adaptations that were *transformative*. We conducted primarily bottom-up, emergent coding of the types of challenges and adaptations, with some top-down coding based on our definition of adaptation (Chi, 1997). Each response was coded by two coders and acceptable interrater reliability was achieved ($\kappa > .7$).

Types of challenges & adaptations (reactive and prospective)

Nine types of challenges and adaptations emerged from the data. We coded for these in all three questions. Coding categories were not mutually exclusive. These categories were: (1) lessons and instructional design (*how* teaching happens), (2) curriculum, goals and expectations (*what* is taught), (3) engagement and motivation, (4) technology access and learning (as it relates both to teachers and students), (5) differentiation, (6) non-instructional teacher responsibilities (such as providing technology support to families), (7) assessment and feedback, (8) student autonomy, and (9) communication (with students and families).

Identifying prospective adaptations that transform the classroom

We looked more deeply into the prospective adaptations category to identify prospective adaptations that had the potential to transform a teacher's practice. We noticed that some prospective adaptations were improvements or variations on existing practices. Yet other prospective adaptations were more significant -- they represented a new teaching practice or a big change relative to the teacher's practice before the pandemic.

We call these **transformative adaptations**. For example, using a virtual platform to provide engaging visuals during a lesson is an improvement to an existing practice, as the tool enhances the lesson, but it does not create a significant change in the classroom. However, a new type of instructional design, such as a flipped classroom model, constituted a significantly new practice, potentially transforming the way students learn.

Results

Extent of reported challenges and adaptations

All teachers, save one, perceived challenges during distance learning (Table 1). Similarly, the vast majority of teachers (96%) reported reactively adapting their practices in some way during the pandemic to meet their students' needs. This was not surprising, given that distance learning created drastically new conditions requiring some level of adaptation. More surprisingly, 89% of teachers planned prospective adaptations to in-person teaching practices. The surprisingly high percent of teachers planning to change future practices suggests that post-pandemic classrooms may look different. These outcomes did not vary by teachers' characteristics, such as years of experience, subjects taught and grade.

Table 1
Percent of teachers who describe at least one challenge, reactive adaptation, and prospective adaptation.

Adaptive Practices	% Teachers
Challenges	99%
Reactive Adaptations	96%
Prospective Adaptations	89%

Types of challenges, reactive adaptations, and prospective adaptations

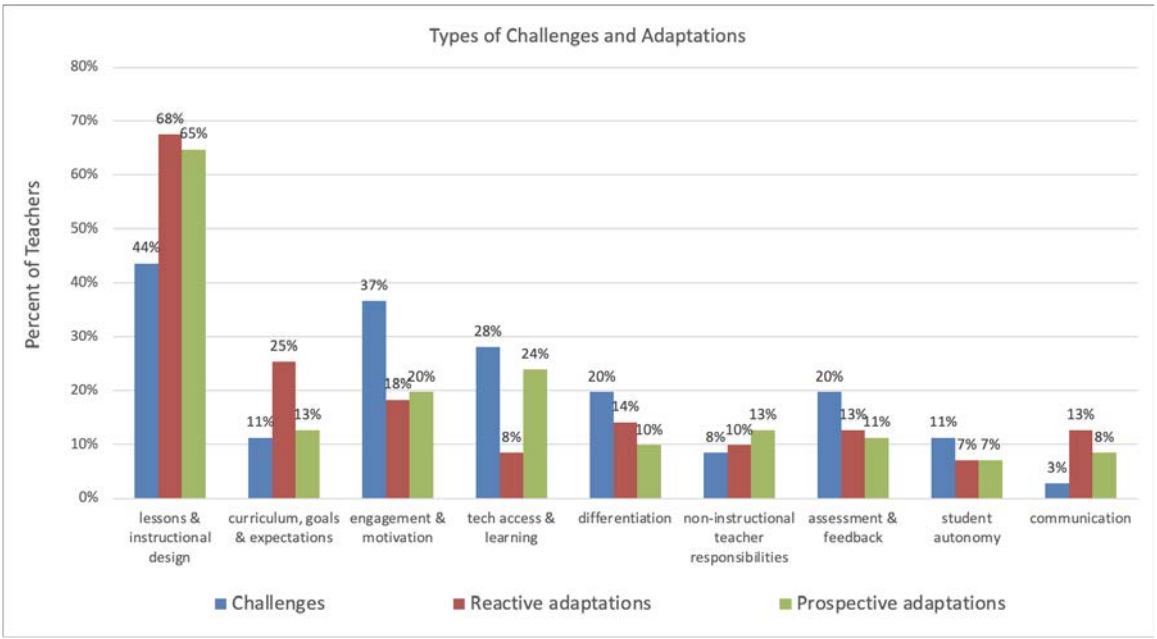
Figure 1 summarizes the prevalence of each type of challenge and reactive adaptation teachers experienced during distance learning, as well as planned prospective adaptations to future classroom practices. Bars represent the percent of teachers who mentioned each type of challenge, reactive adaptation, or prospective adaptation. Our description of these results will highlight the three most prevalent categories of each measure.

Challenges teachers perceived in Spring, 2020

The challenges teachers reported (Figure 1, blue bars) were broadly distributed across many categories, suggesting teachers perceived a range of challenges. The most frequently mentioned challenge was lessons and instructional design, mentioned by 44% of teachers, who often cited limitations in the modes of instruction and inability to incorporate hands-on materials, such as math manipulatives. Student engagement and motivation was the second largest category of challenges (37%), and included challenges related to poor participation, and difficulty keeping students motivated to learn. Technology was the third largest category (28%), with teachers reporting lack of student access and difficulty learning new technology.

Figure 1
Prevalence and types of reported challenges, reactive adaptations, and prospective adaptations

 © ISLS



Reactive adaptations implemented in Spring, 2020

The majority of reactive adaptations (68%) were to lessons and instructional design (red bars in Figure 1). These included incorporating new technology, use of tutorial videos, shortening lessons and assignments, higher levels of direct instruction, reduction of discussion and group activities, use of drawing and visualizations in the absence of manipulatives, and use of culturally authentic resources, such as dialogues, videos, posters and flyers. Adaptations to curriculum, goals and expectations comprised the next largest category of adaptations (25%), and included reduction or re-prioritization of content, and reduced goals and expectations. Finally, adaptations aimed at engaging and motivating students were the third largest category (18%). Examples include giving short, simple tasks to increase engagement and showing greater patience with work completion and outside student challenges.

Prospective adaptations to future in-person instruction

65% of teachers planned to adapt in-person lessons and instructional design based on what they learned during the pandemic (green bars Figure 1). This includes providing clearer and more concise directions, creating more effective visual aids, reducing speaking time by focusing on key ideas, and allowing more time for student practice. 24% of teachers reported they would make changes involving technology access and learning, by incorporating newly learned technology into the classroom. 20% of teachers planned to improve student engagement in the future, by utilizing culturally relevant resources, allowing students to respond to teacher feedback using digital tools, and promoting online student-to-student discourse. In comparison to adaptations during distance learning, fewer teachers reported future changes to curriculum, goals and expectations, suggesting these types of changes may have been short-term responses to reduced instructional time during the pandemic.

Prospective adaptations that transform the classroom

30% of teachers reported planning to implement a practice that would transform their classroom after the pandemic. Four themes emerged in the types of significantly new practices teachers reported: expanding the learning environment, new instructional approaches, expanding the learning community, and a new focus on student needs. Examples of these transformative adaptations are provided in Table 2. These new practices can provide insight into the types of changes we might expect to see in post-pandemic classrooms.

Table 2
Emergent themes and examples of transformative adaptations

Theme	Examples of transformative adaptations
Expanding the learning environment (n = 12)	• Creating resources that students can review at home • Creating digital resources students can use to make up for absences • Pre-teaching concepts digitally before teaching them in class
New instructional approaches (n = 9)	• Providing online resources for students to use at their own pace in class • Implementing a flipped classroom model
Expanding the teaching community (n = 5)	• Sharing resources to help parents identify signs of learning loss • Providing families and other teachers visibility into tools such as Google Classroom to enable better support of students • Giving students and parents access to learning materials at home • Weekly family newsletters
New focus on student needs (n = 5)	• Intentionally creating moments for students to feel connected and happy • Designing opportunities for students to develop social relationships • A new focus on praising for effort • Advocating for more resources for students with disabilities

Discussion

During the COVID-19 pandemic, teachers were suddenly forced to teach remotely. This may have had the hidden benefit of provoking teacher adaptation. In fact, we found evidence that teachers engaged in three of the core practices of adaptive experts during the pandemic. First, all of the teachers we surveyed (save one) perceived key challenges that motivate the need for adaptation. Teachers faced challenges in adapting their in-person lessons to an online format, motivating and engaging their students, and supporting technology learning and access. Second, almost all teachers reactively adapted their practices in response to the new challenges. They modified instruction for an online format, re-prioritized content due to limited instructional time, and simplified or shortened tasks. While challenges were broadly distributed across categories, teachers most often reported adapting lessons and instructional design in response to those challenges. One possible explanation is that teachers have significant control over lessons and instructional design, and are most comfortable enacting changes in that area. Third, most teachers in our study planned to prospectively change future classroom practices by applying what they learned during the pandemic to future in-person teaching. Overall, our evidence suggests that the pandemic acted as a catalyst for teacher adaptation.

Even more promising is the finding that 30% of teachers planned to adapt their future practices in ways that could transform their classrooms. Teachers learned a great deal from the experience of remote teaching which may have motivated them to adopt entirely new practices. Given the many examples of failed uptake of reforms by teachers (Cuban, 2009; Duffy & Roebler, 1986; Hiebert & Stigler, 2000), we find this to be a particularly encouraging result. The instructional legacy of the pandemic may be that it provoked some teachers to make major changes to their practice.

Why was the experience of remote teaching during the pandemic so successful at promoting teacher adaptation? We did not collect data on this directly, so we can only speculate. However, we see a parallel between the conditions of remote teaching during the pandemic and learning activities that promote the development of adaptive expertise. One way to develop adaptive expertise is to provide learners with exploratory, inventive learning experiences (Kapur, 2008; Schwartz & Martin, 2004). The pandemic may have provided a similar sort of learning experience for teachers, where they freely experimented with new teaching methods under novel constraints. This is different from typical models for affecting teacher change, such as traditional professional development. Therefore, our work may carry implications for the design of teacher education. Future research should investigate whether professional development which allows teachers to explore the design of instruction under novel conditions might spur teacher adaptation and the development of teachers' adaptive expertise.

The emergent themes in teachers' transformative changes offer a possible silver lining of the pandemic. If the learning environment can be extended, students can access learning materials outside of the classroom and during absences. This may mitigate some of the negative effects of absences on academic performance

(Gottfried, 2011). Similarly, expanding the teaching community may allow greater family involvement in education which is important for academic performance (Weiss, Bouffard, Bridglall & Gordon, 2009). Specifically, keeping families informed and providing access to educational resources can facilitate out-of-school learning and support. New instructional approaches might allow for increasingly personalized learning, or other teaching models that offer benefits to students (Pane, Steiner, Baird & Hamilton, 2015). Finally, by focusing on student needs, teachers become more attuned to the challenges their students face, which may prepare teachers to better adapt to the needs of their students in the future. Additionally, the increased focus on social-emotional needs may motivate educators to adopt social-emotional learning interventions in the classroom, which can offer benefits for childrens' mental health and academic performance (Zins, 2004).

One limitation of this study is that the data are obtained from self-reports. Future research should aim to obtain additional evidence of teachers' adaptive teaching practices during the pandemic. Additionally, while we collected data on planned adaptations, we do not know which of these were subsequently implemented in the classroom. We are currently analyzing data from a follow-up interview study to investigate which types of adaptations are actually implemented and which conditions make those changes possible.

International Society of the Learning Sciences

Combining Participatory Research with Responsible Research and Innovation to Develop Emerging Educational Technologies

Leah M. Friedman, University of Pittsburgh, leahf@pitt.edu
Alison Kenner, Drexel University, ali.kenner@gmail.com
Erin Walker, University of Pittsburgh, eawalker@pitt.edu

Abstract: The learning sciences have strong established practices of participatory research that encourage projects to be more relevant to today's educational issues. However, societal and personal considerations may also influence the relevance and impact of research. We propose using a Responsible Research and Innovation framework to build on participatory methods in the learning sciences and formalize a process for considering a project's broader context. Through a case study on neuroadaptive technologies for teaching and learning, we demonstrate a methodology for Responsible Research and Innovation that can support participatory methods by encouraging reflexivity from researchers and anticipation of a project's future use cases.

Introduction

The learning sciences have strong traditions of community-engaged participatory research. These research methods take the design of learning systems into real-world settings, centering stakeholder voices during the research process (DiSalvo & DiSalvo, 2014). Participatory methods range from contributory, where members of the public contribute data to a project designed by scientists, to collaborative projects with more public input into design, analysis, or research dissemination, to projects entirely co-created by scientists and community members (Bonney et al., 2009). Methods like Participatory Design and Participatory Action Research tend towards a co-created model, bringing communities into research as collaborators to define key issues and develop plans of action (Jacobs et al 2016). Other methods like co-design are more scientist-led but still engage deeply with members of the public in developing and evaluating solutions to educational needs (Roschelle et al. 2006). Participatory methods in the learning sciences often bring in students, teachers, and parents to create research that is more relevant and ideally provides benefits to the stakeholders involved in that research (Jacobs et al 2016).

However, societal and personal considerations beyond participation are necessary for the development of more responsible and relevant research agendas. A recent article by Selwyn (2021) brought to question the future of educational technology amidst a global landscape of recent disasters, including the COVID-19 pandemic. Selwyn argues that, while the field has made significant progress to improve learning and teaching, it has overlooked the potential of major disruptions and failed to anticipate the kinds of adaptations required by something like a global pandemic. Unintended consequences may also arise outside of global disasters, for instance out of a dominant trend in human-computer interaction to assume that race does not affect technological interactions. As Rankin & Henderson (2021) demonstrate, the common practice of ignoring race has led to erasing certain racial groups from the discussion, tokenizing Black children in participatory research, and a suite of other consequences. Following this line of thinking, public participation alone is not enough to anticipate major shifts and consequences in education; participation must be paired with an orientation to anticipate future societal contexts and with reflexivity from researchers to challenge their own biases and assumptions.

We propose that Responsible Research and Innovation (RRI) can extend the tradition of community-engaged research in the learning sciences to consider additional societal and personal factors. In other words, RRI is novel in contributing a broader iterative framework for responsible societal development of educational technologies. RRI ties the social and scientific together by emphasizing the need for **anticipation, inclusion, reflexivity,** and **responsiveness** (defined later in this article) in research and innovation approaches (Stilgoe et al., 2013; Stilgoe & Guston, 2017). Like Participatory Design and Participatory Action Research, RRI emphasizes researcher responsiveness to public input. However, RRI takes participatory methods a step further by highlighting the importance of researchers considering their pre-existing assumptions (reflexivity) and anticipating future technological landscapes. RRI can apply to future research landscapes globally or can pare down the scale to think about the future of a very specific technology (as we use it in this article).

Responsible Research and Innovation

Responsible Research and Innovation stems from the field of Science and Technology Studies, which acknowledges that science and culture are co-created and thus governance, innovation, and research must assess the socio-cultural systems that influence science and technology (van Atteveldt et al., 2019). There are multiple definitions of RRI but one of the most resonant from Stilgoe et al. (2013) defines RRI as a "means of taking care

 © ISLS

of the future through collective stewardship of science and innovation in the present." RRI contains four key components that call for (1) early **anticipation** of research consequences through (2) **reflexivity** (i.e., self-reflection and reassessment of pre-existing assumptions), (3) **inclusion** of the public in technological or research development, and (4) **responsiveness** of researchers and tech designers to components 1-3 (Stilgoe & Guston, 2017). One of the hallmarks of RRI is its reach to various sites of innovation; this means that RRI acknowledges that research projects alone are not charged with democratizing research and that every type of research stakeholder, including governments and funders, must consider the broader landscape of their work. The case study presented in this article decreases the scope of RRI to demonstrate how the framework can function on a researcher and single-stakeholder level that could then be integrated into a more system-level view.

In a review of RRI methodologies, Schuijiff & Dijkstra (2020) found that an RRI approach has been used most in the fields of nanotechnology and information communication technologies, with a few examples from other fields like synthetic biology. Schuijiff & Dijkstra (2020) found that researchers who incorporate RRI frameworks tend to focus on one of four methods in RRI: (1) Opening to stakeholders, (2) stimulating reflection from researchers and innovators, (3) anticipating ethical, legal, and socio-economic aspects, and (4) institutional-level responsibility. These RRI methods also include sub-methodologies. Opening to the public in RRI may involve creating narratives with multiple stakeholders, holding workshops, or other public engagement modes. Meanwhile, stimulating reflection can occur at different stages of research through facilitated workshops.

This project attempts to incorporate each component of Responsible Research and Innovation into the development of emerging educational technologies, specifically neuroadaptive learning tools. We primarily focus on methods to open up to stakeholders, encourage reflection, and anticipate context, excluding methods to encourage institutionalizing responsibility. Our case study incorporates each element of RRI into interviews with teachers and a workshop with researchers of a neuroadaptive learning technology project (see Table 1).

Table 1

Elements of Responsible Research and Innovation, their definition, and how they appear our case study

RRI Element	Definition	Implementation in Study
Anticipation	Exploring desired futures, alongside intended and unintended consequences of technologies before they are broadly disseminated	Teachers consider what their needs are in the classroom by discussing what superpowers they would like and reflect on the use of how neuroadaptive tools. Researchers consider how their project may be implemented in later stages of its development.
Reflexivity	Considering motivations, assumptions, biases, and worldviews driving innovation activities	Teachers reflect on choosing classroom technology, their views of tech in education, and their tech literacy. Researchers asked to explicitly state the assumptions they hold about the impact and use cases of their project.
Inclusion	Advancing deliberation amongst stakeholders to include perspectives on and knowledge of innovation	Teachers give feedback on the neuroadaptive learning tool and share cognitive states they'd find useful to know about their students. Researchers asked to think about how each part of the interviews can feed back into the project
Responsiveness	Translating the above practices into action as opportunities are identified	Researchers asked to define concrete steps to respond to teacher feedback.

Neuroadaptive Learning Technologies

In this paper, we extend the call for RRI to the development of emerging educational technologies, specifically neuroadaptive learning tools. Developments in portable brain imaging and machine learning have led to an increased interest in developing neuroadaptive technology and brain-computer interfaces (BCIs) for education that could assess a learner's cognitive state (e.g., frustrated, inattentive, etc.) and adapt in some way to that state (Wegemer et al. 2019; Liu et al., 2021). Our case study addressed an NSF-funded project that combines behavioral

data with non-invasive brain sensors from functional Near Infrared Spectroscopy (fNIRS) to capture a learner's cognitive state and adjust the learning experience appropriately in an Intelligent Tutoring System (ITS).

Neurotechnology research currently lacks a breadth of participatory research methods and would benefit from both a learning sciences perspective on participation and an RRI framing to contextualize research. Beyond a lack of participatory methods, research on neuroadaptive learning technologies seems misaligned with a broader educational context, potentially driven by technological novelty rather than social or educational issues. However, a lack of attending to social or educational issues does not mean that neuroadaptive learning technologies will not come to fruition. In a critical review of developments in educational neurotechnology, Williamson (2019) brings up emerging concerns such as invasion of student privacy and over-rewarding of specific cognitive skills. The review points out that studies of neuroimaging for education have led to inferences about quantifiable differences in brain function, for example differences resulting from socio-economic status, that could lead to tangible policy decisions. Even with some scientific skepticism about the accuracy of novel brain imaging devices, Williamson demonstrates that political support is emerging for commercial educational neurotech. The policy and social implications of such studies require that they be approached with attention to assumptions that are baked into the design and analysis of brain imaging, and with care for how findings are publicized.

In applying Responsible Research and Innovation to neuroadaptive educational technology, we aim to show how RRI can help reorient an exploratory educational technology to appropriate use cases that don't solely rely on technological novelty and consider potential downfalls. To the best of our knowledge, only one project to date has used an RRI framework in Mind, Brain, and Education research. van Atteveldt et al., (2019) conducted semi-structured interviews and focus groups with stakeholders to modify a neurofeedback intervention that aimed to improve learners' agency. They conclude that societal stakeholders are capable of deliberating on technical, social, and political constructs of innovation and that their viewpoints are necessary complements to researcher perspectives in the process of responsible research.

Building on the work of van Atteveldt et al., (2019) we are adding to evidence supporting the feasibility of RRI for emerging educational technologies, specifically brain-sensing learning tools. Actors in the educational neurotechnology space include researchers, educators, educational administrators, funders (private and public), companies, and policymakers (from local to federal), however, for the sake of feasibility in the case study, this research narrows in on the application of RRI between university researchers and teachers. We first gathered teacher feedback on the fNIRS project then conducted a workshop with the NSF project team to respond to feedback (as described further in the case study). By extending a Responsible Research and Innovation Framework to neuroadaptive educational technology research, we aim to:

1: Demonstrate a methodology for, and the merits of, integrating a Responsible Research and Innovation framework and participatory methods into emerging educational technology research.

2: Synthesize educator views on emerging educational neurotechnology and researcher responses to educator feedback. This synthesis is meant to inform and refine both the specific neuroadaptive tool in question (fNIRS for ITS) and future projects that aim to develop BCIs for education.

Case Study

We outline a case study that explored the feasibility of applying a Responsible Research and Innovation framework to neuroadaptive educational technology projects. We report on the project in question, then describe two initial pilot interviews, semi-structured interviews with teachers, and a workshop with the project team.

Project and Project Team

The NSF-funded educational neurotechnology project, initiated in 2018 with pilot research beginning 2-3 years earlier, aims to develop methods for using brain data in real-world educational environments by understanding changes in cognitive states during learning and broadly improving the design of an ITS. The project itself is focused on developmental math learning in college settings and singles out specific cognitive processes to study through brain sensing and behavior. The project examines frontal lobe activity using fNIRS during use of the e-learning system ASSISTments (Heffernan & Heffernan, 2014). The project team is composed of three co-PIs with expertise areas spanning fNIRS, human-computer interaction, machine learning, ITS, learning sciences, and cognitive neuroscience. The team also includes 3-4 PhD students, several undergraduates, and 2 teachers. Beyond participating in the workshop, the project team described here was not involved in designing, facilitating, or analyzing the case study in this article. Friedman had been an undergraduate research assistant on the project before beginning work on this case study, Kenner advised on all components of this case study, and Walker is a co-PI on the NSF project who advised on the framing and broader impacts of this case study after its completion. We acknowledge that two of the three authors on this article were very closely familiar with the NSF project.

Pilot Interviews

Methods

Pilot interviews were conducted prior to the beginning of the grant in early 2018 with two out of three co-PI's from the neuroadaptive learning project (one of whom was Walker prior to her involvement in this case study). These interviews asked the researchers about their backgrounds, the projects they're involved in, how they decide on collaborators in those projects, implementation or long-term goals for projects, and the funding landscape for educational and/or neurotechnology. Analysis of the pilot interviews then informed interviews with teachers.

Results

The primary finding from pilot interviews that influenced teacher interviews was that the two co-PI's were not clear on how they imagined the end use cases of the neuroadaptive technology project. When answering questions about end users, researchers instantly referenced use of brain-sensing devices in formal learning environments and then proceeded to question their assumption of formal learning applications. One researcher stated "we always talk about formal learning… [I] don't know why that's the case." On the other hand, both researchers talked about neurotechnology entering the market via gaming or self-directed learning. One researcher said it's possible that the technology could be used as a tool to teach students about technology without them ever actually using it.

Teacher Interviews

Teacher Recruitment and Demographics

Teachers were recruited for interviews through various venues including an NSF-funded Research Experience for Teachers (RET) at a northeastern university, a university research center, and personal connections. The RET program invites community college and/or high school teachers to spend three months working in a computing lab. Teachers received emails describing the interviews and asking if they knew others who may be interested in participating. Criteria for participation was simply that interviewees must be educators or teachers in high school/community college settings, could teach any discipline, and be in any phase of their career.

Teachers ranged widely in age (23-68) and number of years working as a teacher (ranging from one student teacher to 31 years of teaching). All the people interviewed taught STEM + Computing courses (computer science, chemistry, physics, digital media arts, biology, environmental science, math, astronomy, and makerspace directing) to grades 7-12, and 6 out of 11 teachers taught in private schools. The high proportion of private schools represented in our sample of teachers is a limitation in our study for the inclusion aspect of responsible research and innovation, however the demographics do not affect the ability to demonstrate an RRI methodology.

Teacher Recruitment and Demographics

Interviews with teachers were conducted in person and virtually from 2018-2019. Interviews aimed to understand teachers' experiences, gather feedback on the brain-sensing ITS, and fill in gaps that were identified in the pilot interviews. Questions were structured in five sections, two of which were tied to the anticipation and inclusion components of Responsible Research and Innovation:

1. *Teacher background:* inquired about current job, age groups taught, previous positions, teaching interests, and academic background.
2. *Information on technology use in the classroom (tied to reflexivity in RRI):* asked teachers to list the tools they use in the classroom daily or occasionally and probed about comfort with classroom technologies
3. *Speculation about future technology (tied to reflexivity and anticipation of future needs in RRI)*: teachers speculated about their current and future needs in the classroom by describing the superpowers they would like to have to help them do their job. This speculation was modelled after a study conducted by Holstein et al. (2017) that aimed to explore teacher's needs for real time analytics from Intelligent Tutors. In their study, the team used superpowers as a probe to investigate challenges that teachers face in the classroom. The question posed was "If you could have any superpowers you wanted, to help you do your job, what would they be?". The intention was to elicit classroom needs without technological limitations.
4. *Feedback on the neuroadaptive learning technology (tied to inclusion of public opinion in RRI)*: presented the neuroadaptive educational technology project to get feedback, asked about possible contexts of use (formal/informal learning, subject area), cognitive states of interest to teachers, and hesitations about using the technology.
5. *School technology policies:* Inquired about school policies that support or hinder implementation of new educational technologies. This interview section is not addressed in this case study.

Interviews were audio recorded and key quotes were later transcribed. Each interview was analyzed by a single researcher and commonalities were pulled out into a findings document to be presented to the research team. The focus of analyzing these interviews was to efficiently translate feedback and integrate it with the neuroadaptive educational project, therefore rigorous coding methodology was less of a concern.

Interview Results

Based on the background information collected in interviews, teachers' major goals in the classroom fell into three categories: (1) building community and collaborative learning experiences, (2) building critical skills and thought patterns, and (3) encouraging active learning. When it came to building critical skills, teachers emphasized general skills like self-confidence and communication. In addition to non-technological approaches, teachers described technologies that they use to address their classroom goals, including online visualization and lab tools, collaborative technologies that assist in individual learning, and technologies that easily transfer to homework (e.g., collaborative coding software or flipped classroom models where content is taught through homework).

In the section on reflexivity/speculation, teachers shared a series of superpowers that they would like to have to help them do their job. Teachers mentioned 9 superpowers, the top 4 of which are listed in Table 2.

Table 2

Describes the top superpowers that teachers mentioned when asked what would help them do their job.

Superpower	# Of Responses	Relevant Quotes
Knowing how to fashion material	4	*"To be able to perfectly come up with the… explanation that tunes into where they are with THEIR life and their understanding of things so that they get what I'm trying to explain to them"*
Give students perspective: situate them in an overview	3	*"A lot of students, they're young, they're in class, they've never known anything but school and how do you get them to stay engaged and move beyond the 'well I have to get through this step to get to that step'"- "[I want to] show them possible futures in a really concrete way"*
Confidence imbuer: show students their own superpower	3	*"Kids are smart in so many ways and … for lots of different reasons. Kids have ideas about what they can and can't do, and getting through that is a really huge part of the job."* *"It's easier to be creatively curious when you know that you have strengths that you bring in..."*
Teachers' time expander	3	

In providing feedback on the neurotechnology, teachers liked (1) the potential to individualize digital instruction to diverse learners, including helping students discover themselves, and (2) the possibility to help educators better understand their student's learning patterns at home. Teachers also shared a series of cognitive states they were most interested in knowing about their students (see Table 3). In parallel, teachers' primary concerns about brain-sensing learning tools included the possibility for automation to over-optimize or over-emphasize one learning style and leave little room for unstructured learning. There were also concerns about invasion of student personal information including the potential for student embarrassment, parental privacy concerns, and data privacy concerns.

Table 3

Top cognitive states teachers were interested in knowing about their students if given the chance

State	# Of Responses
Creatively Curious/Flow State	7
WHY not WHEN Zoning Out	3
Stress/Test Anxiety	3
Bored	2
Frustrated	2

Researcher Workshop

Workshop Methods

In the second phase of the project, thematic findings from interviews were discussed in a workshop with the neuroadaptive learning team. There were 6 attendees at the workshop including the 3 co-PIs, 2 PhD students, and one masters student. Prior to the workshop, synthesized de-identified interview findings were sent to the project team. Throughout the workshop, researchers worked from a packet of questions to document their thoughts and shared the most important highlights on a whiteboard and with sticky notes. This workshop was conducted as part of a PI meeting at the start of the NSF grant period and included three phases:

1. *Thinking reflexively about self and project:* Speculation about superpowers for teachers, personal and team goals within the project, development of the project in the short and long term, discovering which parts of the projects are or are not amenable to feedback
2. *Presentation and step through findings:* Presentation of interview findings during which the team was asked to consider which feedback would apply to the project, to what degree feedback could be incorporated, and how many years into the project the feedback would apply.
3. *Finding actionable items:* A discussion about notable feedback, which feedback can feasibly be incorporated into the project, and at what point in the project

Workshop Results

In the reflexive thinking portion of the workshop, researchers aligned on individual goals and goals within the timeline of the project. Individually, each researcher was motivated to partake in the project to learn more about the other disciplines (i.e., psychology, human-computer interaction, learning sciences). On a project level, the team agreed on three goals: The 1-year goal was to align cognitive constructs between controlled psychological tasks to the Intelligent Tutoring System ASSISTments; the 3-year goals were to collect brain data with the fNIRS device and to work on automatic classification of cognitive states based on that data; the 5-10 year goal was to begin prototyping learning systems to create meaningful learning interventions. One of the research team's key takeaways from a reflexivity perspective was the necessity of spending more time aligning goals between each project team member and learning about each other's disciplines. Aligning goals in the beginning of the workshop also helped to assess teacher feedback to understand where it could be incorporated in the timeline of the project.

While stepping through the findings, researchers decided that the project's most clear use case was as a homework assistant tool; the team also realized that supporting in-class collaboration was a major point of interest but was not necessarily suitable for this project. The team also landed on three ways that findings from the interviews could have an impact on the project and when in the project timeline these could have an impact:

1. Writing broader impacts sections – immediate implications for the project (0+ years)
2. Thinking critically about the cognitive and learning constructs being studied in this and future grants – immediate (0+ years) and short-term (1-3 years) implications for the project
3. Measuring not only learning but also self-efficacy in learning – immediate (0+ years), short-term (1-3 years), and long-term (3+ years) implications for the project

While stepping through interview data, the project team became interested in reconsidering which cognitive states the project should assess and better mapping those states to goals in the current experiment. The project was initiated with an interest in assessing changes in attention, rule-learning, and proactive/reactive control. In hearing about the cognitive constructs that teachers were interested in, researchers had a rich discussion about how those constructs appear in psychology, HCI, and the learning sciences. For instance, the top cognitive state of interest for teachers (flow state) was discussed as potentially measurable through deep learning in the learning sciences and the ideas of proactive vs. reactive control in psychology. Proactive control, which is defined as more goal-driven behavior, is closely mapped with specific brain states and was discussed in the workshop as potentially related to more active learning. Other immediate implications for the project arose from teachers' thoughts about

brain-sensing as a tool to provide feedback to students on their own learning styles to help develop learning self-efficacy. In considering the possibility of a self-efficacy application, the research team concretely considered integrating self-report prompts into experiments with the fNIRS device to assess self-awareness in conjunction with the cognitive state of interest. Integrating self-report would be a very concrete way to adjust the project to address possible use cases early in the research of emerging technologies.

Discussion and Conclusion

One of the strengths of our approach to RRI is that each of the four dimensions were tied together across the entirety of the case study. In their review of methodological RRI papers, Schuijiff & Dijkstra (2020) concluded that most methods focus almost exclusively on one dimension of the framework. They speculate that focusing equally on all of the dimensions could overburden the research process. However, the case study described in this article demonstrates the possibility of integrating each element in a single RRI process.

The clearest benefits of using RRI in the neuroadaptive learning project were in the dimensions of reflexivity and anticipation. In the speculative portion of the interviews, asking teachers about which superpowers they would like instead of what technological support they need (as per the methods described by Holstein et al., 2017) helped move beyond the concept of what is or is not technologically possible. Asking teachers about their desired superpowers *prior* to getting feedback on the neurotechnology helped ensure that teachers, especially those who were skeptical of the tool, provided useful feedback. During the workshop, discussing teachers' needs in terms of superpowers also helped paint a fuller picture of what teachers struggle with in the classroom.

Despite being useful in their own way, the speculative questions in the interviews did not directly lead to anticipation in the workshop. Instead, anticipation of project use cases was enabled by exercises in reflexivity in the beginning of the workshop, which helped researchers keep personal and project goals in mind while reflecting on teacher feedback. One of the teachers' top classroom goals involved building collaborative communities, which led the research team to realize that facilitating collaboration was also a shared interest of theirs but was not a suitable goal for the grant's scope and for the type of brain sensing. Instead, the team decided that the best framing for the neuroadaptive tool was as a homework assistant tool. This decision was in direct response to teachers' feedback on the neuroadaptive tool, seeing it as most useful during solo work to provide personalized feedback to students on their learning and feedback to teachers on their assignments. The anticipatory component of RRI was made more concrete by starting with goal setting at 1, 3, and 5-10 years away and continuously revisiting that timeline to situate feedback in certain points of the project. Future work could involve analyzing policy and school contexts to weave that information into the reflexivity and anticipatory aspects of the case study. Our approach to reflexivity could also benefit from investigation into the pre-existing biases of the research team to draw attention to value systems at play in the design of emerging educational technologies.

The responsiveness and inclusion dimensions of RRI were baked into the methodology of the project through consideration of teacher interviews during the workshop. The study demonstrated the feasibility and usefulness of extending participatory methods into the development of emerging technology not yet feasible for use in educational settings. However, the inclusion dimension would be strengthened by direct exchanges between researchers and teachers, as well as input from additional stakeholders like parents and students. Furthermore, beyond the workshop, there was minimal uptake of results into the project. The responsiveness dimension of RRI would have benefited from revisiting and more deeply integrating feedback throughout the project lifecycle. In this way, RRI might pull in participatory methods from the learning sciences, aiming for participation that is not just contributory as in our case study and instead co-creates a project with members of the public through methods like Participatory Action Research, Participatory Design, and Co-Design (Bonney et al., 2009; Roschelle et al., 2006; DiSalvo & DiSalvo, 2014; Jacobs et al 2016). This may help ensure that the inclusion component of RRI benefits teachers, students, and parents, by directly addressing their needs in the classroom.

This research was done without value alignments within the practices of Responsible Research and Innovation. One substantive contention with RRI is an underlying assumption that "good" research practices will lead to "good" outcomes. In fact, the same might be said of participatory research methods (i.e., research is inherently better if it is participatory). We also acknowledge that RRI does not necessarily account for secondary factors that make inclusion more equitable, such as appropriate compensation and community agreements. For our own future work and other practitioners looking to integrate RRI, Foley et al. (2016) suggest combining RRI with other aspirations such as sustainability, social justice, gender/racial equity, etc. Researchers in the learning sciences have already begun approaching participatory methods with specific value systems; Participatory Action Research has been imbued with ideas from feminist inquiry that call for an examination of power relations in the research process (Jacobs, 2016), while lenses of racial identity and Black feminist epistemology have been applied to participatory design methods for creating conversational agents with Black youth (Rankin & Henderson, 2021). Combining value-based participatory approaches with anticipatory and reflexive practices from RRI may help

formalize a process and definition for responsible research, ensuring that all stakeholders are on the same page about what is responsible.

In this work, we propose expanding on typical participatory methodologies in the learning sciences by contextualizing them in a responsible research and innovation framework and applying this framework to emerging educational technologies, specifically neuroadaptive learning tools. We conclude that participatory methods and Responsible Research and Innovation complement each other in conducting relevant, responsible, and inclusive research. RRI contributes contextual, anticipatory, and reflexive thinking to creating educational technology, especially tools that are still emerging. Meanwhile, participatory methods in the learning sciences, especially those that consider certain values, strengthen the responsiveness and inclusion dimensions of RRI. Connecting researcher and educator perspectives through a lens of Responsible Research and Innovation can clarify immediate and long-term goals of a project, contextualize a project in a specific use case, and help define how emerging technologies may ultimately be relevant for education and not simply technologically novel.

"A Tangled Moment": Unpacking Conflicting Frames by Examining Pedagogical Judgment

Elizabeth Metts, Vanderbilt University, elizabeth.c.metts@vanderbilt.edu

Abstract: Ambitious and equitable pedagogies have been widely accepted as a way to address systemic inequities. Current research and professional development efforts overemphasize practice and fall short in unpacking the complexities of supporting teachers' uptake of reform-oriented instruction. These practice-based efforts often fail to adequately address dominant discourses in mathematics classrooms – of particular interest to this analysis is a *culture of exclusion*. This paper describes how exclusionary and inclusionary frames were evidenced in instructional practice and how those frames surfaced and shifted during sustained reflection on instruction. Attention to pedagogical judgment in the analysis lays bare taken-for-granted conceptions of ambitious mathematics instruction. This case is conceptualized as extreme, demonstrating the ease of invoking exclusionary frames, despite the teacher's commitment to broadening access to mathematics and supportive professional network. Findings illustrate how attending to the components of pedagogical judgment can support teacher sensemaking around navigating the intricacies of ambitious and equitable instruction.

This study explores a common and important contradiction in mathematics teaching by looking at one teacher, who I call Julie Woodman (all teacher and student names are pseudonyms). Julie was an experienced teacher, committed to her professional growth and to building positive relationships and mathematical experiences for her students. Even though she was deeply committed to ambitious and equitable math teaching and to broadening access to rich mathematical engagement, there were still ways that exclusion came out in classroom activity. To understand why that might be, I studied two different sites of teacher sensemaking — during a lesson and a video-based coaching debrief afterwards. My analysis of her sensemaking was guided by the three components of pedagogical judgment – action, responsibility, and reasoning – to describe (1) how inclusionary and exclusionary frames of mathematical activity and ability were evidenced in instructional practice and (2) how Julie was supported to surface and shift these frames. I see this as an extreme case (Yin, 2009) of a common phenomenon that occurs (namely, exclusionary experiences in mathematics classrooms), even with an experienced and committed teacher.

Ambitious and equitable mathematics pedagogies have been widely accepted as a way to address systemic inequities (Boaler, 2002; Sztajn et al., 2017). Ambitious teaching works to support students' conceptual and procedural understanding through meaningful mathematics engagement (Cobb et al., 2020) while equitable teaching serves to support *all* students' learning. These pedagogies aim to position students with mathematical authority and agency by redefining competence in more expansive ways, opening up participation structures to allow for and foster more diverse ways of being, belonging, and knowing (Cohen et al., 1999; Esmonde, 2012; Gresalfi et al., 2009). However, classrooms do not exist in a vacuum – they are situated within broader discourses and power dynamics that are (re)produced through classroom activity and interaction. A great deal of professional development efforts have been made to support such reform-oriented instructional practices, and despite the ubiquity of these ideas, there is dearth of research regarding the necessary resources to support teachers and their learning in enacting reform-oriented teaching (Horn & Garner, 2022; Louie, 2017a).

Theoretical Framework

To understand the complexity of inclusionary instructional practice and teacher sensemaking, I draw on three theories: the culture of exclusion (Louie, 2017b), frame analysis (Goffman, 1974), and pedagogical judgment (Horn, 2019). Broader power dynamics play out in classroom interactions in the stories or broad narratives that serve as resources for participants to interpret and organize activity (Hand et al., 2012). Of particular interest to this analysis is how exclusion is fostered in the mathematics classroom. Louie (2017b) has described a *culture of exclusion*. Traditionally narrow conceptions around mathematical activity and ability occur in tandem with the (re)production of marginalization (Chen & Horn, 2020) resulting in a dominant one-size-fits-few discourse that is persistent and invasive in mathematics classrooms (Louie, 2017b). Exclusion manifests in two ways: "(a) exclusion from meaningful engagement with disciplinary ideas and practices through narrow definitions of mathematical activity

 © ISLS

and (b) exclusion from positive identities as learners and doers of mathematics through narrow and hierarchical definitions of mathematical ability" (Louie, 2017b, p. 490). One way that exclusion is made salient is in how mathematical activity and ability are framed (summarized in Table 1). Frame analysis (Goffman, 1974) therefore lends itself as a framework in order to describe and make sense of classroom interactions and the lesson debrief.

Table 1
Exclusionary and Inclusionary Frames (Louie, 2017b)

Exclusionary Frames	Inclusionary Frames
Rote Practice Activity Frame ● Valorizes correctness ● Routine tasks ● Closed questions ● Discussion centers on answer-getting	**Sensemaking Activity Frame** ● Valorizes meaning-making and connections ● Open-ended, non-routine tasks **Multi-Dimensional Activity Frame** ● Valorizes collaboration, experimentation, argumentation ● Open-ended, non-routine tasks
Hierarchical Ability Frame ● Ability is unequally distributed ● Valorizes speed and correctness ● Positions some students as helpers or in need of help	**Multi-Dimensional Ability Frame** ● Everyone has both strengths and areas for growth ● Valorizes skills not traditionally considered mathematical ● Positions students as resources

I also build on previous work around teacher learning. Work in teacher education is dominated by practice-based approaches, focused on the practical applications of teaching (pedagogical action). This has led to a predominance of "ideal types" (Horn, 2019), presented as tidy, one-size-fits-all solutions that do not account for the inevitable challenges that arise for teachers as they enact these practices in their individual contexts. Horn's pedagogical judgment provides a framework to describe the interplay between a teacher's pedagogical action, responsibility, and reasoning. I draw on this framework as a way to ensure that my analysis addresses the complex and interconnectedness of Julie's classroom practice that is rooted in her commitments, obligations, and sensemaking. Analyzing one of Julie's lessons provides evidence of her pedagogical action, while the subsequent debrief provides an opportunity to explore her reasoning and responsibility Teacher conversations centered on problems of practice make possible opportunities for rich interactional professional learning and reflection (Horn & Little, 2010), and sustained conversations and reflections focused on problems of practice reveal teachers' pedagogical judgment (Horn, 2019). This makes the lesson debrief an appropriate place to explore her reasoning and responsibility. Furthermore, the pedagogical judgment framework makes it possible to bridge the classroom and teacher learning contexts in my analysis.

Methods and Data

This analysis comes from a larger ethnographic study, connecting research and practice to understand and support urban mathematics teachers' development and enactment of ambitious instruction (Horn & Garner, 2022). The research team developed a Video-based Formative Feedback (VFF) cycle to support and create opportunities for co-inquiry into practice. The VFF cycle consisted of five steps: (1) the focal teacher identified a question or goal of interest; (2) on the day of the lesson, the teacher selected four focal student groups (blue, purple, green, and orange groups) to audio record; (3) the class was documented using a whole-class tablet camera mounted on a Swivl tripod, audio recorders for the four student groups, and a GoPro point-of-view camera attached to the teacher; (4) the research team reviews and analyzes the video and audio and identifies clips that support co-inquiry; (5) the research team meets with the teacher and their school-based colleagues within two days of filming to view and discuss the clips in light of the teacher's question. The VFF debrief (step 5) is filmed with a wide angle view of the participants. I have analyzed two data sources in this analysis: the classroom and the debrief. The classroom video data includes a whole class video and audio recordings of four focal groups. The primary participants of the debrief were the focal

teacher, and two researchers who facilitated the session (Brette and Lani). There was another researcher present, taking fieldnotes and a partner teacher at the school, however their interactions during the debrief were relatively minimal. The focal teacher, Julie Woodman, was a high school teacher with over five years of experience. She was supported by a selective and well-resourced PD organization, and Julie was deeply committed to broadening access to mathematics. In interviews, Julie expressed a desire to foster students' understanding through mathematical discourse and prioritizing building relationships in her classroom.

Focal lesson

Julie's AP Statistics lesson introduced hypothesis testing through a card game. Julie called on student volunteers to draw a card: if they drew a black, they got an extra credit point, if they drew a red, they had to sweep the classroom. Six students drew cards with replacement, and all six drew the same color card. The underlying question at play was *If the deck is fair, how likely is it to get 6 red cards in a row?* Following the game, students worked in groups during three episodes of groupwork, each followed by a whole class discussion.

Data analysis

For the post-lesson debrief data, I applied methods of flexible coding (Deterding & Waters, 2021) – initially indexing the entire debrief and utilizing analytic memos to derive the "main stories" (p. 725). My unit of analysis was episodes of pedagogical reasoning (Horn, 2005). I partitioned the conversation into EPRs based on the central topic of the conversation, and using open, concept-driven coding, I coded for aspects of pedagogical judgment and inclusive and exclusionary framing. To code for pedagogical judgment, I attended to Julie's pedagogical actions (when she talked specifically about what she did during the lesson), pedagogical reasoning (when she described her thinking, e.g., "I was intending…" or shared other contextual details to describe her thinking), and responsibility (when she expressed a sense of commitment, e.g., "I go really freaking fast because I have to"). When coding for inclusionary and exclusionary frames, I attended to what or who Julie and the facilitators discussed and used the framework described by Louie (2017, p. 496). I also looked for challenges or resistance to a particular framing. I confirmed interpretations with fieldnotes, interviews from the broader study, and with the researcher facilitators.

For the classroom data, I created a side-by-side transcript for each focal group within each episode of groupwork and the following whole class episodes. The groupwork episodes served as my unit of analysis, coded according to the culture of exclusion framework to describe students' conversations and mathematical activity that followed from Julie's initial framings. Specifically, I attended to how much students were talking, what kind of mathematical activity came up, evidence for sensemaking, and how connected the conversations were (i.e., did students engage with one another's' ideas, taking them up and building off each others' thinking?).

Findings

I will describe how frames of mathematical activity and ability were co-constructed in the classroom video by describing Julie's verbal directives and the resulting student conversations. Turning to the debrief, I will explore how Julie made sense of the classroom activity and describe how the exclusion that came out in the classroom activity contradicted with her inclusionary commitments to teaching.

Conflicting Frames in Pedagogical Action

Groupwork episode 1: What could be going on here?

Julie launched the first episode by telling groups "I need you to talk to each other about two possible explanations for how [drawing six red cards in a row] happened." Julie's direction to students was open-ended and nonroutine. Furthermore, her launch elicited focused math talk (Manz, 2012) and rich sensemaking in students' conversations. The groups generated the following possible explanations: 1) all the cards are red; 2) students drew cards from the same location in the deck; 3) the cards weren't shuffled; and 4) six students drew red cards by chance or bad luck. Although the groups' resulting conversations were driven by answering Julie's question, students freely contributed multiple ideas.

For example, the purple group began their discussion declaring that all the cards must be red, eliciting laughter from the group. Chris then posed a question about the probability: "They were all red? Or there's a 50-50 chance though right?" The group took up Chris's question and engaged for several turns of talk. Alyssa confirmed

 © ISLS

his probability: “It should be if it's a standard deck of cards and she didn't rig them” and elaborated that cards were drawn with replacement, making the chances the same. She then proposed another explanation that could affect the probability – students were picking from the same place in the deck. Bethany disagreed until Chris suggested that Julie could have been making students pick the same card. He expressed doubt with this suggestion, but Bethany added on “Oh like if it was on the top or something?” The group’s dynamic was overall affirming of one another’s ideas, both in utterances to show agreeance as well as in the way they took up one another’s ideas and questions, giving them value and merit in the conversation. Chris’s question was especially compelling – despite no explicit mention of probability during the game, it came up in *all* of the focal groups’ conversations, intuitively and organically describing the probabilistic nature of the activity without any focus on calculations or procedures. Further evidencing this pattern, Danny, a member of another group, made a connection to statistical significance:

> Of course they're all red, uhh, so in regards to how we got it, it could have just been that she took all the black cards out of it, or…she reduced the amount significantly to the point where it would be statistically…it's uh statistically impossible for us to actually get a black card.

The openness of Julie’s launch invited varied participation, and students were not limited by procedures or formulas, making it possible for students to make connections to other mathematical ideas. Students’ discussions were indeed mathematical in nature as students made sense of Julie’s question and their symmetric experience in the card game. Taken together, her question and the resulting conversations invoked the *sensemaking frame of mathematical activity.* Furthermore, the episode described here points to a discourse of inclusion, in terms of who had access to meaningful mathematical activity and ways in which students could be perceived as competent.

Groupwork episode 2: What is the probability?

After settling on the two explanations, students are unlucky or the deck is not standard, Julie told students, “Assume I'm telling the truth. If I'm telling the truth, I need you to calculate a probability of actually drawing six red cards.” This was perhaps a shift away from sensemaking, evidenced by directing students to find “*the* probability.” Indeed, students’ talk centered on recalling the procedure to determine the probability. Unlike Julie’s previous question, students did not contribute as freely, nor did they take up one another's ideas. To illustrate, the blue group was only concerned with trying to calculate the probability. Although multiple students offered possible solutions, no one’s idea took root in their conversation:

Isabel:	Six divided by…
George:	No it’s one out of 52...to the sixth power.
Jacob:	One times [...] It’s a one in 64 chance I think. One in 64.
George:	How you know?
Jacob:	It’s a one in 64 …

George made a bid to engage with Jacob’s solution, however Jacob only repeated his answer instead of discussing it with his groupmates. Further constraining students’ sensemaking, many groups did not have enough time to reach a consensus, leaving students’ contributions and ideas disconnected and unresolved – valorizing speed and correctness. For example, the green group did not arrive at calculating a probability because they were trying to determine the number of cards in a deck:

Farah:	How many are red and how many are black?
Danny:	So we already know it's independent you know what I mean?
Elijah:	How many cards are in a deck? 32?
Danny:	50? 72? So like, fifty two cards? Four times 13 is what, 52? And two jokers. 54.
Farah:	But there’s still red and black.

The majority of turns of talk turns were trying to make sense of the composition of a deck of cards. The group surfaced everything they needed to reach an answer – the number of cards, the color composition of the cards, and identifying that the card draws were independent. The group was moving towards finding a probability; however their individual ideas did not come together. Overall, the focal groups’ conversations were answer-focused with little

to no sensemaking, explanation, or co-constructing of ideas. Considering the nature of students' conversations that Julie's prompt elicited coupled with the time constraint suggested that this episode invoked the *rote practice activity frame and the hierarchical ability frame*. Importantly, Julie's framing on the activity alone is not necessarily enough to be considered rote practice. This move will be further unpacked in a later section of this paper, but it could be conceptualized as sensemaking *if* students' conversations suggested this kind of mathematical activity. However, her framing of the question and the time constraint she imposed led to a shift in students' participation and the nature of their mathematical engagement towards routine, rote practice motivated by a singular correct answer. Students did not participate as inclusively as they had in the first episode, as some students were excluded from mathematical sensemaking and opportunities for competence if they did not draw on an algorithm or work quickly enough.

Groupwork episode 3: Is Ms. Woodman lying?

In the subsequent whole class discussion, a student shared how to calculate the probability: "It's like one half probability of getting a red. That times the sixth power. [...] One over…64" or 1.65%. Julie then prompted groups to discuss, "I want someone to use that 1.5% in a sentence to answer the question of whether you think Ms. Woodman is lying to you or not." Along the same lines as the second episode, this question alone doesn't necessarily point to a particular frame. However, students took up her question as a cue of using 'statistical significance' as students worked to recall a particular scripted answer: "Um:: we have like do you remember the 5% thing?" again suggesting basic recall rather than sensemaking." Students in the focal groups were focused on coming up with a specific explanation or conclusion in a noticeably different way than in the first episode. In this episode, students' conversations centered on trying to come up with a *correct* answer that filtered their sensemaking:

> Myles: I feel like she is lying because isn't it like a very small chance-
> Liam: -I thought statistically significant - it's less than 2.5%
> Nina: No it's less than 5%.

Myles made a bid that could have prompted the group towards sensemaking, however the following turns of talk immediately went to "the 5% thing." Illustrated by these examples, students engaged in closed and routine mathematical activity that centered correctness – pointing to the *rote practice activity frame*.

Considering all three episodes together, students took up Julie's directives in ways that undermined inclusionary discourse brought out in the initial episode. As the nature of students' conversations changed, the mathematical activity with which they engaged shifted from rich sensemaking to narrow answer-getting as students worked to recall algorithms and scripted answers. Importantly, in the second two episodes, students were excluded from mathematical activity and did not have a chance to show mathematical competence – what students needed to participate (and to feel successful in doing so) was speed and correctness. Julie and her students co-constructed frames of mathematical activity and ability that brought exclusion to the surface of classroom activity. It is important to note that I would not say that this exclusion cancels out or undoes the inclusionary discourse in the initial episode, nor does it necessarily work against the inclusionary culture that might exist in the classroom outside of this singular activity. What this suggests, however, is that the culture of exclusion makes these frames sensible choices in interaction, making exclusionary experiences a common phenomenon in mathematics classrooms. What is compelling about this lesson is that Julie's pedagogical judgment is rooted in inclusionary commitments, as I will unpack in the next sections of this paper.

Inclusionary pedagogical responsibilities

Before recording the classroom video, Julie asked the researchers to pay attention to student dynamics and selected the focal groups because she suspected they had "status issues":

> There's some really confident, super high math kids that have gone through AP computer science and AP calc BC [...] They have all the math badges and this is the last one to hit. Then I also have a large group of students that are coming from regular Algebra II and this is their first time feeling an honors math class. They've gone through this process of failing a lot of times, but improving, improving, improving, but those other kids have been acing every test. I'm just wondering how that dynamic looks like in a group.

Throughout the debrief, Julie elucidated two primary responsibilities that motivated her lesson design and instructional choices – one of them being to attend to issues of status. Julie described how she designed lessons with status in mind, saying "I try to take a lot of the theoretical math out of it, like the formula-based stuff, and I try to make it something graspable." Then, connecting to the card game task, "there was no math involved there. Maybe a little bit at the end, but every one of them could have contributed to that conversation." Julie's reflections made clear that her intentions were rooted in her pedagogical responsibility to status. The task was open-ended, something that "every one of them could have contributed to" and, indeed, students did not need to rely on routines or algorithms but their intuition and experience instead. Her planning and design of the task, grounded in this responsibility, invoked the *multidimensional frames of mathematical ability and activity*.

Julie also spoke of a second responsibility – one to the AP curriculum. She described an obligation to support students to make connections between important mathematical ideas. For example, she interpreted her second prompt as a connecting to another mathematical idea: "I thought it was kind of cool that you're finding a p-value using prior knowledge, which I thought was kind of a cool way to introduce it." As she narrated her rationale, grounded in this responsibility, Julie drew on the *sensemaking frame of mathematical activity*.

Rooting out exclusionary frames in pedagogical reasoning

As Julie reflected on the lesson and responded to the video record of the focal groups, she elaborated on her pedagogical reasoning, surfacing assumptions about what she thought students should be able to do. The first two clips highlighted two groups answering Julie's first prompt (groupwork episode 1). Clip 1 featured Jacob's correct probability with no reasoning or explanation, Julie diagnosed as an issue of conceptual understanding: "This concept, the multiplication rule for independent events, which we've already taught in regular stats, we go over that so many times. It's one of the hardest things for kids to just remember." Brette presented a second clip of the green group who didn't have time to come to a consensus about the probability. Julie was surprised that the group spent time discussing the number of cards, and she expressed that she expected that calculation to be very quick. Brette used this clip to challenge Julie's diagnosis and presented two potential barriers to students: a pacing issue and the contextual underpinning of the card game impacted students' sensemaking.

In this conversation, Julie connected her pedagogical reasoning to her actions. *Because* Julie had expected students to answer her question quickly, she did not provide enough time for students to reach an answer. Brette and Lani continued to challenge Julie's assumptions:

Brette:	Not all kids have that knowledge super ingrained. It seems like-
Julie:	-We play with cards **a lot**. I give them cards for seating charts every unit. And it's on the table, like it's half and half. You know what I mean? I guess I didn't think that was going to be something they needed to think about.
Lani:	Right. We were talking about yesterday, when we were thinking about all of the math of this, we were thinking about how cards on the one hand you can make up suits and think about colors. The color is just 50-50, but you have to have sort of an abstract understanding to see-
Julie:	-And we do in the probability unit. I let them look at a deck of cards and we come up with a summary. There's 13 of each suit. There's four of each number card. There's four of each face card.
Lani:	They did 13 times four really quick.
Julie:	They knew the numbers. That's interesting. I would never have thought that was something that group struggled with.

Julie added, "It wasn't about the calculation. It was about the percent being low I guess. I got the answer and then was like 1.5% and let's talk about that." As she shared her evolving reasoning around what happened, Julie expressed a conflict between her pedagogical action and the original intention and the framing of the activity – classroom activity was focused on the calculation, not conceptual development of hypothesis testing and sensemaking, and this surfaced exclusion. Brette explained, "It seemed to create a pattern where the higher status kids are getting the right answers and the lower status kids didn't have a chance to get there." Although Julie's intentions were grounded in her inclusionary reasoning and responsibility, as the lesson played out, her subsequent actions (the wording of her directive to the group and the lesson pacing) undermined her intentions and invited

exclusionary frames of mathematical activity and ability as the students took up and responded to her moves. Contemplating the facilitators' claims, Julie shared with the team:

> I think I wasn't expecting to use the 1.5 before the lesson so I think I was just kind of going past where I wanted to go with that. [...] That moment was so unplanned because what I said, the goal wasn't even for them to get, like going into the lesson, that 1.5% was not something I was going to go for at all. [...] Then I was like in the moment like this will look good. They know how to calculate this probability already. They can just do it real quick. It's less than five percent. They don't even need the whole normal curve thing.

Julie provided important context behind her move to have students calculate the probability – it was an unplanned, in-the-moment decision. In fact, Julie explained that she noticed a student calculating the probability and saw this as an opportunity for students to move towards hypothesis testing by connecting to their understanding of probability. In this narrativization, Julie interpreted her move to be inclusionary, drawing on the sensemaking activity frame. Julie was supported to consider a different interpretation of her pedagogical actions – that the activity was actually exclusionary, drawing on the rote practiced ability frame and rote practice activity frame – by confronting the video record and the facilitators' moves to press against her assumptions. Lani described these conflicting frames as a "tangled moment," sympathizing with the tension Julie had uncovered in the debrief. Julie went on to explain how she now understood the conflicting frames in the activity:

> The deck of cards was a great way for them to develop those two competing hypotheses without realizing it, but then when I went to finish it off and do the math and stuff like that, that was completely unplanned. I wasn't mentally prepared for how to wrap that up and transition.

As Julie engaged in sustained reflection, she laid bare her pedagogical reasoning, surfacing assumptions she had made during the lesson. The researchers challenged these assumptions, and using the video record, illustrated how students' conversations during the second two questions exacerbated status issues. In response, Julie articulated a conflict between her pedagogical actions and her pedagogical responsibilities: the actions she took that were rooted in her responsibility to the AP curriculum undermined and conflicted with her responsibility to status and equity.

Discussion

The theoretical contribution of this paper stems from drawing connections across the classroom and teacher conversation settings. It has been pointed out that current literature on teacher learning rarely draws empirical connections between multiple contexts (Lefstein et al., 2020). By attending to Julie's sensemaking in multiple contexts, I was able to describe not only how exclusion came out during classroom activity, but also how she understood her actions, both in the moment during the lesson and later in reflection during the debrief. To only consider what played out during the lesson would be to tell a story of how mathematical ability and activity frames can contribute to inclusionary and exclusionary practices. In fact, current research and related professional development efforts do not adequately address the complexities of classroom activity and teachers' sensemaking of ambitious and equitable mathematics instruction (Horn, 2019; Horn & Garner, 2022). An overemphasis on Julie's pedagogical actions furthers a dichotomous view of teaching (that is, a good versus bad binary).

Turning to the debrief as a context to study teacher learning, the debrief was designed to support her inquiry and to avoid evaluation and "best practices." In preparation, Brette and Lani wanted to draw Julie's attention to how status issues were exacerbated and students were excluded from meaningful mathematics engagement. However, the debrief was not facilitated to provide Julie with simplistic fixes like "ask more open questions" and "give students more time." Rather, the facilitators unearthed Julie's assumptions and used the video record to support Julie in connecting her pedagogical actions and reasoning to students' mathematical activity and engagement. Furthermore, the debrief provided Julie an opportunity for sustained reflection and a chance to revisit her lesson which illuminated a conflict between her pedagogical responsibilities. Evidenced in the literature, reformed oriented pedagogies and similar frameworks are presented as tidy solutions (Horn & Kane, 2019), however, this analysis suggests that this is not the case. Classroom activity is deeply complex that is not dictated solely by teachers' intentions and actions and requires time and careful attention to understand. For teachers to grow in their practice, it is necessary to support them with feedback that centers on their pedagogical judgment and space to explore and reflect on their teaching.

Meta-Theoretic Competence Demonstrated by Students in the Patterns Class

Hillary Swanson, Utah State University, hillary.swanson@usu.edu

Abstract: Engaging students in theory building practices is an important focus of science education. This study aims to identify students' resources for engaging in scientific theory building. More specifically, it examines the resources 8th grade students brought to their engagement in theory building in a science elective course called the Patterns class. The Patterns class engaged students in a simplified version of theory building, which involved iterative cycles of articulation, evaluation, and refinement of pattern theories. Pattern theories were written descriptions of general patterns in behavior that could be found in examples across domains, such as threshold and equilibration. Approaching video data and student work through a microanalytic lens, resources were identified belonging to the articulation, evaluation, and refinement of pattern theories across dimensions of deeper structure, generality, domain of application, and causal relationships. In identifying theory building resources, the study introduces a new category of knowledge: meta-theoretic competence.

Introduction

In recent years, science education has shifted from teaching students the content and skills of science separately, to helping students learn both content and skills in an integrated way, through participation in science practices (Ford & Fordham, 2006). The construction of scientific theory is a central activity of science. Students should therefore have opportunities to engage in theory building in the science classroom and develop skills for participating in theory building practices. In alignment with this perspective, the U.S. Next Generation Science Standards include theory building practices such as modeling and explanation in their learning objectives for K-12 science education (NRC, 2012). Many research programs have investigated the impact of explanation- and model-based instruction on student science learning (Manz, 2012; Passmore & Stewart, 2002). A number of approaches have used explanation or modeling activities as a way of eliciting and building on students' ideas, in alignment with constructivist ideals (diSessa, 1995; Wilensky & Reisman, 2006). Studies to date have primarily focused on developing students' understanding of science concepts by refining their thinking through theory building activities. The present research is complementary to this work, having a long-term goal of designing theory building activities that engage and refine students' resources for theory building. A first step toward this goal is beginning to identify such resources.

There is a rich tradition of research examining the continuities that connect novices and experts, rather than the differences that divide them (Warren et al., 2001). Work within this paradigm has urged education researchers to take an anti-deficit perspective of learners and view them as bringing rich intuitive and culturally-learned funds of knowledge to their learning in and out of school (Adiredja, 2019; Moll, et al., 1992). Leaders in the field have challenged educators to find ways of honoring and leveraging the resources children bring to their learning, particularly with respect to children from non-dominant backgrounds, whose ways of knowing and making sense of the world have historically been marginalized by classroom instruction (Bang, et al., 2012). Research within this tradition has uncovered resources for understanding science topics from the elementary to the undergraduate level, as well as resources for productive engagement in scientific discourse (Hammer, 2000; Hudicourt-Barnes, 2003; Rosebery et al., 2010). The present work aims to make a contribution to this tradition of research by identifying resources students have for scientific theory building. In achieving this goal, it presents a new category of knowledge: meta-theoretic competence.

Theoretical Foundations

This work is motivated by an epistemological perspective called knowledge in pieces (KiP; diSessa, 1993). KiP grew out of Piagetian constructivism and shares with it a focus on the role of prior knowledge in learning. In addition to constructivism, KiP has roots in cognitive modeling, sharing with it the goal of building a theoretical framework for modeling knowledge and learning. With its attention to technical precision, KiP offers a detailed account of the conjecture that new knowledge is constructed by the learner through engaging their prior knowledge. KiP models an individual's knowledge as a complex system of a diverse array of knowledge elements. The knowledge system of the novice is characterized by loosely connected networks of elements. This means that networks of knowledge drawn on by the novice to explain a phenomenon shift from context to context, responding

 © ISLS

to context-specific features of the phenomenon. For example, a physics novice may draw on one set of knowledge elements to explain the orbit of the moon around the Earth and a different set to explain the arc of a tossed ball. The expert, by contrast, would draw on the same network of knowledge to explain both trajectories. KiP models the transition from novice to expert, or learning in general, as a process of reorganization and refinement of the knowledge system.

With this picture of learning, KiP views prior knowledge elements as resources for learning, rather than misconceptions that need to be replaced (McClosky, 1982). Instruction is therefore designed to help students engage and refine their existing ways of thinking and making sense of the world. Researchers working within the KiP paradigm have identified a number of resources that may be seeds for more sophisticated knowledge, practices, and epistemologies. The identification of productive ideas, moves, and perspectives demonstrated by students in both lab and classroom settings has led to the development of a number of new theoretical categories of knowledge.

For example, *phenomenological primitives* (p-prims) are intuitive knowledge elements that guide a learner's intuitive sense of mechanism (diSessa, 1993). *Coordination classes* are larger knowledge structures used in extracting information (like velocity or force) from observable data in the world (diSessa & Sherin, 1998). These categories of knowledge include resources for the development of conceptual understanding in science. Other categories of knowledge include resources for the development of skills for participation in scientific practices. For example, *meta-representational competence* (MRC) includes resources for constructing, critiquing, and making sense of representations (diSessa, 2004). Yet other categories of knowledge include resources for understanding the nature of science. For example, *epistemological resources* include resources for understanding the nature of knowledge and its origins, epistemological activities, and positions one might take towards knowledge (Hammer & Elby, 2002).

The present work uses meta-representational competence as a reference model for organizing resources for scientific theory building. To make the link to this model explicit, I call this category of knowledge *meta-theoretic competence* (MTC). Meta-representational competence features knowledge that transcends the production and use of representations (diSessa, 2004). It includes skills for the invention of new representations, for their critique, and for their explanation. Resources for representation invention include the ability to draw, and sensitivity to representational possibilities of visual elements (e.g., color, length, width). Resources for the critique of representations include criteria such as completeness, precision and parsimony. The resources belonging to MRC are assumed to be "gradually developed through cultural practices in and out of school" (diSessa, 2004, p.294). In the next section, I describe the empirical context for my work and my approach to analyzing data, which led to my development of meta-theoretic competence as a category of knowledge resources.

Methods

This work is situated in the context of a larger research project, which was aimed at the design of a middle school course on topics in the domain of dynamical systems theory. DST is a highly mathematical science, which uses differential and difference equations to model systems that change over time. The course guided students' development of descriptions of general patterns of change, which could be found in phenomena across domains. Such patterns include threshold, equilibration, exponential growth, and oscillation. Threshold, for example, can be seen in the tipping point of a tower of blocks and the limit of a person's patience. Many of the descriptions of these patterns, which the students wrote, were essentially conceptual versions of the mathematical equations DST uses to model phenomena. Our research team called students' written descriptions *pattern theories* and engaged students in an iterative process of pattern theory building and refinement. We called the course the Patterns class, because of its focus on exploring and describing patterns. The goal of the present work is to understand the productive resources students brought to their engagement in theory building in the context of the Patterns class.

The Patterns class was taught in a public middle school in an economically depressed neighborhood of a large city on the West coast of the United States. The school was selected based on the willingness of the 8th grade science teacher to share her elective period with the research team. She had traditionally used the elective as a science enrichment course for students who were proficient on tests of basic skills in English and math. The author taught the course, having been a high school science teacher for six years before transitioning to research. The class met on Monday, Tuesday, and Thursday mornings for 40 minutes, totaling 52 hours over the school year. Twenty-one 8th grade students (11 girls and 10 boys) participated in the course. Eighteen of the students had immigrated to the U.S. from Mexico and Central America. Two students identified as African American and one as Bosnian American. The majority of students attending the school were designated as English Language Learners and from low-income households. The students were selected on the basis of their availability and willingness to participate in the experimental curriculum.

Patterns class design

The course was designed to engage students in a simplified version of scientific theory building through an iterative process of theory articulation, evaluation, and refinement. Through this process, students constructed and refined theories for patterns including threshold, equilibration, exponential growth, and oscillation. Each unit opened with the exploration of two pattern examples, followed by students' articulation of their first draft pattern theories. The students then evaluated their theories against a third example and revised their thinking, producing second draft pattern theories. They generated additional examples and evaluated their theories against those, producing third and final draft pattern theories. In addition to mirroring a simplified scientific theory building process, the sequence was meant to help students articulate and iteratively refine their thinking and their theories. Below, I briefly unpack the first two pattern units, to give the reader a sense for the Patterns class and to provide a basic chronological reference for the narratives I provide to illustrate the elements of meta-theoretic competence.

Threshold unit

The threshold unit was designed with a pattern benchmark in mind. The threshold benchmark consisted of a *pre-phase*, *limit*, and *post-phase*. During the pre-phase, a system parameter is varied until it reaches a limit. When the parameter exceeds the limit, the system transitions to a post-phase, which is markedly different from the pre-phase.

The threshold unit began with the exploration of two examples: the addition of coins to a cup hung over a spaghetti bridge until the bridge broke, and the addition of drops of water to a coin until the water flowed onto the table. The students explored these examples in the context of small group team challenges, which were each allocated a single class period. Following their exploration of these examples, the students individually wrote their first draft pattern theories. Their theory building was guided by a prompt, which focused them on describing the pattern in behavior common to both examples: "Tell the story of both behaviors so that someone listening to your story would agree that you are talking about either one of the behaviors, but they wouldn't know for sure which one you were talking about." This activity was allocated about half a class period.

The students then evaluated their pattern theories against a third example: adding salt to a cup of water until a submerged egg floated to the surface. They explored this example in small groups in the context of an investigation, which was allocated a single class period. Students were asked to compare the egg example with the spaghetti bridge and drops-on-a-coin examples and record their thoughts in writing. The teacher collected their responses and presented the class with a representative sample of both their example comparisons and written pattern theories, facilitating a whole-class reflection during which students compared pattern theories with each other and with examples. The reflection discussion was given a single class period. The students were then invited to revise their pattern theories and write second drafts. This activity was allocated about 10 minutes and took place following the reflection discussion.

The students were then invited to generate examples from their own lives, which followed the pattern. Students worked alone to generate initial lists and then in small groups to create posters showcasing their favorite examples. They hung their posters around the classroom and participated in a gallery walk, considering their classmates' work. During the walk, they applied sticky notes to posters to identify examples they agreed with, disagreed with, or didn't understand. The teacher selected two contentious examples to feature in a whole-class debate (e.g., "bothering someone until they burst" and "getting a haircut"). Before the debate, she gave the students time both individually and in small groups to prepare arguments for why these examples did or did not follow the pattern. She then asked students to consider one example at a time, offering points to support or challenge the example. The students were invited to revise their pattern theories a final time and write third drafts. This activity was allocated about 10 minutes and took place following the debate.

Equilibration unit

The equilibration unit was designed with a pattern benchmark in mind. The equilibration benchmark was a pattern of *difference drives rate*. An equilibrating entity moves towards equilibrium at a rate proportional to the difference between its current state and its equilibrium state. A pattern of *difference drives rate* can be seen in both thermal equilibration and the calming of emotions over time.

The equilibration unit began with the exploration of two examples of thermal equilibration: the warming of cold milk to room temperature and the cooling of hot tea to room temperature. The students explored these examples in the context of small group investigations. The investigations took the form of traditional science labs and were each allocated a single class period. They were each preceded by activities in which the students created and presented hypotheses of how the temperature would change over time. They were each followed by activities guiding data interpretation and activities focused on the generation and discussion of potential causes for the fast-

then-slow temperature change. Following their exploration of these examples, the students were given half a class period to write their first draft pattern theories.

The students then evaluated their pattern theories against a third example: the diffusion of beans through a semi-partitioned box as they shook the box back and forth. They explored this example in small groups in the context of an investigation, which was allocated a single class period. They were asked to compare the bean example with the warming and cooling examples and record their thoughts in writing. The teacher collected their responses and presented the class with a representative sample of both their example comparisons and written pattern theories, facilitating a whole-class reflection during which students compared pattern theories and examples. The reflection discussion was given a single class period. The last 10 minutes of the period were reserved for the students to revise their pattern theories and write second drafts.

As in the threshold unit, the students were invited to generate examples from their own lives, which followed the pattern. They worked alone to generate ideas and then in small groups to create posters showcasing their examples. They hung the posters around the classroom and participated in a gallery walk, using sticky notes as they had in the threshold unit. The teacher selected a contentious example to feature in a whole-class debate (emotions calming). She gave the students time to prepare their thoughts on the example. During the debate, she asked students to either offer points in support of *emotions calming* as an example of the pattern, or points to challenge it. Following the debate, the students were invited to revise their pattern theories and write third and final drafts.

Data collection

Data were collected in the form of video footage, student work, and teacher reflections. Each class period was videotaped using two cameras. One camera was positioned at the front of the classroom and captured the students sitting at their tables in groups of 4. The other camera was positioned at the back of the classroom and captured the activity at the front board when the teacher or student presenters were speaking. When the class engaged in small group or individual work, this camera was repositioned to capture the work of one group. Student work was collected at the end of each class period. The work was scanned and returned to the students the next day to keep in their course portfolios. As the teacher, I recorded reflections at the end of each lesson, documenting things I had noticed in terms of student thinking and engagement, with respect to the course design.

Data analysis

The broader goal of the present study was to understand the nature of student theory building in the Patterns Class. I approached this goal through a KiP lens, expecting to find evidence of students' productive engagement in theory building. I analyzed student work using a microanalytic approach characteristic of knowledge analysis (diSessa, Sherin, & Levin, 2016). I examined students' written theory drafts for theory-like characteristics, and their notes from activities for evidence of their thinking between theory drafts. I reviewed the written teaching reflections, looking for class or small group discussions related to students' articulation and refinement of pattern theories. The teaching reflections helped me identify video footage to review, transcribe, and analyze. While watching the video footage, I noted on the transcript where I saw evidence of productive engagement in theory building, naming and briefly characterizing what looked like ideas, moves, and aesthetics that seemed productive with respect to students' theory building. I collected the elements I had named in a separate list.

It became apparent that the list of elements were student resources for theory building and the focus of my inquiry narrowed to identifying the productive resources students brought to their theory building in the Patterns class. The list was analogous to a collection of resources for engaging in another set of scientific practices, which already existed as a category of knowledge in the KiP literature. This category of knowledge was meta-representational competence (MRC; diSessa, 2004). My collection of resources for theory building was parallel to the collection of resources belonging to MRC, in several ways. Both are capacities for engaging in multiple dimensions of a realm of scientific practice (including generation and critique of scientific artifacts), and both include capacities gained from interactions with others in and out of school. Because of this analogy, I decided to use MRC as a reference model and named my category of resources *meta-theoretic competence* (MTC).

I reviewed the list, which I had thus far compiled, and combined resources that seemed similar and clarified distinctions between resources that seemed similar but were different in important ways. In sum, I engaged in an epistemic game of "list making" (Collins & Ferguson, 1993). I moved back and forth between my list and the data, refining the list so that it more accurately captured the productive things students were doing with respect to theory building. When I arrived at a final list, I described each resource and connected it with a particular example from the data. In working out the organization of the items on the list, it became apparent that there were two dimensions according to which the items on the list should be organized. These dimensions were stages of theory building (e.g., articulating, evaluating, and refining theories) and pattern-theory-specific elements

(e.g., deeper structure, generality, domain of application, and causal relationships). Because items on the list were connected with elements from both dimensions, I transferred my epistemic form from a list to a cross product or table (Collins & Ferguson, 1993).

Findings

My analysis of student engagement in the Patterns class produced a table of resources for meta-theoretic competence. The table outlines resources for three stages of theory building (articulating, evaluating, and refining pattern theories) across four characteristics of pattern theories (deeper structure, generality, domain of application, and causal relationships). Table 1, below, is meant to give the reader a sense for the larger ontology of meta-theoretic competence. Due to space limitations, I list only one resource per cell.

Table 1. Theory building resources demonstrated by students in the Patterns class

Stages/Pattern Characteristics	Deeper Structure	Generality	Domain of Application	Causal Relationships
Articulating	Articulating the pattern in behavior instantiated by examples	Using general language to describe a pattern in behavior	Generating examples from physical and psychosocial domains	Articulating intuitions about causal relationships underlying behavior
Evaluating	Comparing examples based on similarities and differences	Questioning the generality of the language used	Challenging and defending the fit between examples and pattern theories	Challenging and defending the logic of intuitions
Refining	Removing surface features from the pattern theory	Removing context-specific features to make the pattern theory applicable to more examples	*There was no opportunity in the course for students to demonstrate resources for this category	Responding to challenges by unpacking or modifying ideas

I unpack the list below, illustrating each category of resource with narrative from the class, drawing on either video transcript or student work. In the narrative, I highlight the particular resource using italics.

Deeper structure

An ability to look beyond a phenomenon's surface features and articulate its deeper structure is a hallmark of expertise in science and fundamental to the construction of scientific theories (Chi, Feltovich, & Glaser, 1981). Deeper structure can take different forms, from a mathematical relationship between system variables, to a mechanism driving system behavior. In the Patterns class, a theory attended to deeper structure if it described the *pattern in behavior* common to multiple examples, rather than their common surface features.

Articulating deeper structure

In the threshold unit, students were asked to individually write their first draft pattern theory after exploring two examples: adding coins to a spaghetti bridge until it snapped and adding drops of water to the surface of a coin until the water overflowed. Their theory building was guided by a prompt, which focused them on describing the *pattern in behavior* common to both examples: "*Tell the story of both behaviors* so that someone listening to your story would agree that you are talking about either one of the behaviors, but they wouldn't know for sure which one you were talking about." Some students produced pattern theories that focused on common surface features, for example: "Both involved household items, needed techniques in order to do both of these experiments, both took patience." Many of the students, however, *articulated patterns in behavior* common to both examples, for example: "Both of these patterns involve adding things to objects until they can't hold those objects anymore."

Evaluating deeper structure

Students were asked to evaluate their first draft pattern theory against a third example: adding salt to a cup of water until a submerged egg floated to its surface. Two examples of threshold were observed in this example by the students: the floating of the egg in response to the addition of salt, and the saturation of the water with salt. This led to two different conceptualizations of the pattern: one of threshold as *tipping point*, and one of threshold as *maximum capacity*. Following their exploration of the example, the students individually responded to prompts asking them to compare the new example with the initial two examples. Comparing the saturation of the water with the spaghetti bridge, Patricia *identified a similarity in behavior*, writing: "We had to see how many drops an object would hold." Another student, Selena, compared the floating egg with the spaghetti bridge. She *identified a similarity in behavior*, writing: "You added more objects in it." She also *identified a difference in behavior*, writing: "We were seeing if it floats and in the spaghetti bridge we were seeing how many pennies you could put before it breaks."

Refining deeper structure

Following the egg investigation, the teacher led the students in a discussion where they compared the examples they had thus far explored as well as their first theory drafts. The students were then invited to revise their thinking and write second draft pattern theories. Patricia's initial theory of the pattern had focused on the common material and social features of the spaghetti bridge and drops-on-a-coin examples: "Both used pennies, had to have a special technique." Her second theory draft characterized the pattern as: "They all involve adding something to get a *reaction* out of it. It mostly resulted in something overfilling up other objects." Notably, she refined her theory by *removing surface features* and focusing instead on the deeper pattern in behavior underlying examples.

Generality

The power of a scientific theory, in part, depends on its range of applicability, and therefore its level of generality (Atkins, 2010). In the Patterns class, a theory was considered general if it *used language that did not tie it to any particular example*.

Articulating a general theory

The students practiced tuning their theory's level of generality during each pattern unit when they responded to the prompt by telling "the story of both behaviors so that someone listening to your story would agree that you are *talking about either one of the behaviors, but they wouldn't know for sure which one you were talking about*." Students' pattern theories were considered general when they were written in language that did not tie them to a particular example. Their initial drafts in the threshold unit included theories that described the pattern in context of specific examples, for example: "We used pennies, we put the pennies in a container, we counted, we did it again." The students' later drafts tended to be context-free, *using general language to describe the pattern in behavior*, for example: "Adding something to something until it changes."

Evaluating the generality of a theory

Students were shown their peers' theory drafts before revising their theories. The teacher projected anonymous examples of students' work and asked the class to compare their theories. During this discussion, Alvaro problematized the name one group had given the pattern – "The Break" – saying: "Actually, not everything had to do with something breaking. Because you know the one where we squirted the drop of water onto the pennies? It didn't break, it spilled…" Alvaro pointed out the inadequacy of the word break, on the grounds that it didn't apply to all examples. In doing this, he demonstrated a resource for evaluating a theory's generality, specifically by *questioning the generality of the language used*.

Refining the generality of a theory

Students refined their pattern theories' level of generality. For example, in the threshold unit, one student's initial theory read: "We used pennies and with those pennies only a certain amount of weight had to be held before it interrupted the experiment." The pattern is described in the context of the spaghetti bridge investigation and is therefore not general. For their second draft of the pattern theory, the same student wrote: "You need to add something on an object until it breaks or you can't fit any more." The student *removed context-specific features* from their theory, making it applicable to a broad range of phenomena.

Domain of application

A scientific theory is applicable to a bounded regime (Suppe, 1972). In the Patterns class, students specified their theory's domain of application by *listing examples* that followed the pattern.

Articulating the domain of application

Once students had written their second draft pattern theories, they were invited to generate a list of their own examples. For the threshold unit, students *generated psychosocial examples* such as "adding more sadness until you cry," and "bothering someone until they burst." They *generated physical examples* such as "filling up a water balloon," "pulling gum until it snaps," and "getting a haircut."

Evaluating the domain of application

From the examples the students generated, the teacher identified two to feature in a whole-class debate: "bothering someone until they burst," and "getting a haircut." During the debate, students *challenged the fit between examples and theories* by attending to mappings between the two. For example, Martin challenged the example of bothering someone until they burst, saying: "There's not really a maximum, like you could keep annoying them... 'cause after they get burst you could still keep annoying them, it isn't, it won't, it's not going to get fulled up on anything." Martin viewed the pattern as maximum capacity, and for him, there was no maximum limit to bothering someone.

Causal relationships

A chief application of scientific theory is the explanation of observed phenomena (Hempel & Oppenheim, 1948). In the Patterns class, a theory was seen as articulating causal relationships if it moved beyond describing the pattern in behavior to *include a causal explanation* for it.

Articulating causal relationships

The students were encouraged to think about the causal driver underlying a pattern in the second unit of the course, which focused on equilibration. They participated in a whole-class discussion with the aim of developing a causal explanation for an example where a glass of cold milk warmed to room temperature fast-then-slow. Before the discussion, the teacher asked the students to write down their initial explanations. She then seeded the discussion by reading the students' explanations aloud, leaving them anonymous. The explanations included ideas about the milk slowing down to reach room temperature, the physical apparatus used to conduct the experiment, and the milk adjusting to room temperature. In generating these causal explanations, students demonstrated resources for articulating causal explanations in the form of *intuitions about causal relationships*.

Evaluating causal relationships

Having read all of the ideas, the teacher focused the students on one idea in particular: "Because it was getting to room temperature at the end, so it was slowing down. It's like a race, when you're getting to the destination you start to slow down." The students debated the idea, demonstrating resources for challenging and defending its logic.

> Leo: Why would you slow down when you're about to finish a race? It doesn't make sense.
>
> Alvaro: Say there's a wall. Are you going to run straight into it, Leo?
>
> Leo: Well, I'm not gonna go slower though, because then I'll lose.
>
> Alvaro: Like no-no-no-no-no! Like, say you're winning 'cause you're going as fast as you can, then when you're gonna reach the wall, don't you start to like kinda? [stomps feet on ground slowly]

Leo *challenged the explanation on the grounds of its logic*: who slows down at the end of a race? Alvaro *defended the explanation by modifying the race analogy* to make it logical, turning the general scenario of a race into a race that specifically ended at a wall, which he subsequently identified with room temperature.

Refining causal relationships

Through their discussion, the students refined a combination of several ideas to produce an explanation that was conceptually similar to Newton's law of heating: "That it has lots to cover so it just does it fast and then it starts slowing down because it needs to reach, it's almost reaching its max." The explanation was developed through students' modification of ideas in response to problems pointed out by their peers. In this way, students demonstrated resources for refining causal explanations, such as *addressing challenges by modifying ideas*.

Discussion

This paper presented a collection of resources for theory building, which were demonstrated by the 8th grade students who participated in the Patterns class. The collection of resources is only preliminary. It is assumed that other students participating in the same course would demonstrate different resources, and that different kinds of theory-building activities (e.g., computational modeling) would elicit different resources. Despite its limited scope, the list of resources for theory building makes an empirical contribution to literature concerned with identifying the productive knowledge students bring to their learning, responding to the call to education researchers to view students from an asset-based perspective. More broadly, the category of knowledge to which the theory-building resources belong is a theoretical contribution to the KiP research program, as an ontological innovation.

Restorying Toward Justice and Anti-Racism in ELA Classrooms

Kristina M. Stamatis, University of Nebraska Omaha, kstamatis@unomaha.edu

Abstract: Storytelling has been used as a vehicle to center diverse perspectives in classrooms; however, in the U.S., the most prevalent stories in schools continue to be those that reflect narratives of white supremacist systems. As educators search new ways to implement culturally sustaining pedagogies, storytelling can become a vehicle to allow students to voice their own funds of knowledge and act as experts on their own experiences. This participatory-design study examined ways that storytelling in 9th grade ELA classrooms supported students in restorying their classrooms and communities. Using jazz as a set of methodological tools, this study was codesigned with a U.S. mountain-west English teacher and her students as a digital storytelling project to disrupt dominant narratives in a rural school. Findings demonstrate the potential for historically marginalized youth to identify as agents of change when offered opportunities to restorying in historically white spaces.

Introduction

Sociocultural perspectives in education have long suggested that learning is deeply intertwined with the lived experiences that contribute to individual and collective identities and the practices and tools found in communities (e.g., Holland et al., 1998; Wertsch, 1991). For decades, the research community has agreed that there should be more space for learners to bring their identities and cultures—their stories—into learning environments (e.g., Dutro, 2009; González, Moll, & Amanti, 2005; Thomas & Stornaiuolo, 2016). However, recommendations for how educators can include learners' home practices, tools, and knowledges vary greatly. While critical scholars argue that learners, educators, and researchers should treat stories as legitimate forms of knowledge, understandings of how to design spaces that account for learner stories, and the success or failure of communities in enacting liberatory pedagogies around stories, continue to be needed (e.g., González et al., 2005; Kumashiro, 2000).

This participatory-design study used jazz tools (e.g., improvisation, trading fours, and harmonic substitution) to examine ways that storytelling in 9th grade English Language Arts (ELA) classrooms supported students in a process of disrupting dominant narratives by (re)storying (Stornaiuolo & Thomas, 2018) and critically reinventing (Morel et al., 2019) their classrooms and communities. The study took place in collaboration with Elizabeth Murray (all names are pseudonyms) and her 9th grade students during the 2018-2019 school year in a rural, mostly white community. Elizabeth and I co-designed and implemented a year-long curriculum based upon the *Throughlines* digital storytelling project (www.thethroughlinesproject.com) to support her 9th grade ELA students in understanding the ways their personal narratives intersected with or were missing from the dominant narratives of their communities. In this study, we sought to acknowledge the ways that whiteness has shaped institutional spaces and examine the ways that privilege might be leveraged and disrupted to shift educational spaces. While this study included students from a number of backgrounds, in this paper, I focus on the ways that students who self-identified as coming from historically marginalized backgrounds—for example, as people of color, LGBTQIIA+, neurodivergent, differently abled, and/or from lower socioeconomic classes—in order to explore the ways that these students described their experiences of restorying in a predominantly white space. Given the ongoing violence perpetuated against historically marginalized communities by white supremacist systems, there continues to be need for youth from these communities to have opportunities to see themselves as powerful and agentic historical actors (Gutierrez et al., 2019).

While jazz has previously been used as a metaphor for education, this study explored the ways that jazz tools can support researchers in better understanding the classroom as a dialogic third space (Gutiérrez, 2008). As a discipline, jazz has a rich history of disrupting white supremacy to restory the ways musicians and audiences interpret music. By drawing from these tools as part of my conceptual framework, I follow calls for engaging with new tools in learning sciences research to re-envision how researchers and teachers might work together to better understand how whiteness shapes classrooms, and what we can do to disrupt those systems and create space for students as epistemic agents. To do this, I explored the following questions: 1) How do storytelling projects in classrooms support students to practice restorying in their ELA classrooms? and 2) How can jazz tools support the ways researchers observe and understand students' and teachers moves toward restorying in classrooms?

Background

Jazz as Conceptual Framework

Jazz music bridges Western harmonies with African rhythms. Like the interactions in classrooms, the music moves between structure and improvisation, which has long been associated with storytelling. Jazz offers a rich history and tools through which to make sense of the complexity of learning and identity building that can take place when young people are given opportunities to examine their own stories. For example, as musicians improvise to come up with new melodies to compliment a composed song, they simultaneously recall the ideas put forth by the players who have come before and recreate the genre by engaging with new ideas from the world around them (Berliner, 1994). Miles Davis (1962), the jazz trumpet player, said that every time he played he had something to say, but it was up to the audience to be listening. Classroom interactions hold similar improvisations (e.g., Philip, 2019; Sawyer, 2004). Schooling, like jazz music, is steeped in structures defined by whiteness and connected to the oppression of historically marginalized people. However, amidst these structures exists a wealth of counterstories that allow us to speculate toward future worlds.

Jazz could be a tenuous framework for a study that takes place in a mostly white, rural school by white researchers and teachers. However, as a discipline, jazz is built upon a rich history of disrupting interactions, educational spaces, and practices that were historically defined or usurped by whiteness. As a learning scientist, I see jazz as an essential blending of cultural tools and practices to reimagine the world (Solis, 2009). Jazz in the U.S. was initially created by Black musicians as an assertion of agency, dismantling the chordal patterns and melodic phrasing of Western classical music (for an example of early 20th century jazz, hear Armstrong's (1962) "Mack the Knife"). The discipline, and its musicians, have continued to dismantle structures of whiteness in music by continuing to posit reconceptualizations of harmony and rhythm, playing within a group, and improvising outside the confines of traditional song structure (Gioia, 2011).

As a musician, I see jazz as an entry point into new ways of disrupting white supremacy in myself and in my work. North American jazz music grew out of acts of restorying, melding multiple cultures in the decades after slavery was abolished. Drawing from African call-and-response, improvisation, and polyrhythm, as well as Western harmonies and dance-based compositions, the music carries multiple stories to diverse audiences simultaneously (Gioia, 2011). Jazz offers us a set of tools for analyzing the ways that cultural stories are leveraged, engaged, and restoried in classrooms and a way to think about students and teachers as improvisers within the constraints of traditional schooling. In Elizabeth's classroom, jazz emerged as a set of tools through which I could better understand students' interactions. As I listened to Elizabeth's students assert their stories, I was reminded of the ways that jazz musicians trade themes, improvise new ideas and perspectives, and reimagine the world.

Restorying

Restorying has deep roots in traditions of storytelling, particularly as a practice of counter-storying through which individuals with historically marginalized identities can speak back to systems and structures of power. In education, counter-stories can serve to question the deficit perspectives and assumptions of what counts as knowledge found in traditional classrooms (Thomas & Stornaiuolo, 2016). Recent scholarship on "(re)storying" has emerged as a digital storytelling practice. "[A] process by which young people reshape narratives to reflect perspectives and experiences that have been routinely marginalized or silenced" (Stornaiuolo & Thomas, 2018, p. 346). Stornaiuolo and Thomas (2018) theorized restorying as "a way young people use digital tools to write themselves into existence, first narrating and analyzing their lived experiences and then synthesizing and recontextualizing those stories to represent a diversity of perspectives and reshape dominant narratives." These authors have pointed to the potential of restorying with youth to "reconfigure school spaces" (p. 346). They suggested that when youth are offered opportunities to "re-author themselves and the institutional spaces they encounter," they are also supported in historicizing the self, particularly with regard to "intersectional forms of systemic inequity and oppression" (p. 346). This form of restorying with students becomes a practice of supporting students in "selfmaking" and suggests that restorying with students holds potential as a rich practice to shift toward justice-oriented pedagogies and perspectives within classrooms.

Jazz as Tools for Restorying

Jazz as a dialogic music (Santi & Zorzi, 2016) offers a means through which to understand dialogue in education as part of the inherent structure of learning to communicate together (Bakhtin, 1981). Scroggins (2019) and Philip (2019) have each written about the potential of critical improvisation to inform teacher's justice-oriented practices. Though they draw primarily from improvisatory theatre, these scholars add critical lenses to jazz-oriented perspectives that improvisation within teaching leads to more creative support of students by attending to the positionality of the classroom participants (Solis, 2009). In improvisation, each participants' ideas hold possibility; the history and structure of the artform dictates how these ideas either act productively or antithetically within the collaborative whole. Structures can be changed, but must be done so with purpose (Berliner, 1994). As

Philip (2019) acknowledges, in education, improvisation must be "purposefully oriented toward justice" to "renegotiate power" toward more humanizing perspectives (p. 4-5).

In classrooms, youth often draw on improvisatory moves—trading and extending each other's ideas through theme and variation—to establish third spaces (Gutiérrez, 2008) that honor their own funds of knowledge and agency as historical actors (Gutiérrez et al., 2019). The multivoicedness of these educational environments can be theorized as forms of polyphony and polyrhythm, what Kuby and Christ (2018) describe as "the ways that a number of ideas and perspectives compose, harmonize, and play simultaneously without loss" (p. 294). In this paper, I take up these tools from jazz to better understand the process that young people engage in when they assert ideas about themselves and their communities with one another, using dialogue to build shared knowledge (Kinloch & San Pedro, 2014). As Gutiérrez et al. (2019) describe, this dialogic process is incomplete without engaging in acts of historicizing that support young people in seeing themselves as historical actors whose actions and interactions are part of a broader historical landscape. Building on a foundation of historicizing, Thomas and Stornaiuolo (2016) examined the ways that young people can "write themselves into existence" (p. 346) through acts of restorying that offer opportunities to reimagine how their stories are inscribed in communities. In this study, restorying appeared as an act of resistance for young people from historically marginalized communities as they engaged with the world around them and reasserted their own perspectives into dominant narratives.

Methods

This study took place at Williams High, a high school in the mountain west United States, over the course of the 2018-2019 school year across three 9th grade English language arts classrooms. Elizabeth Murray, who identified as white and female, had been teaching for 14 years at the beginning of our study. Williams High served nearly 1,500 students, 20% of whom identified as people of color and 30% of whom were identified as qualifying for free and reduced lunch. The 58 students who participated in this study resembled the demographics of the school. This study was surrounded by violent political rhetoric leading up to the 2020 U.S. presidential election. More than once, I entered the building to hear small groups of students discussing the benefits of a border wall. In the years after Trump was elected, Elizabeth reported responding to increased bullying and worried about how to offer her students a safe school environment.

Elizabeth and I drew from participatory design research and feminist ethnography because of their explicit attention to power, caring, and emotionality. Elizabeth and I designed curriculum and also shared meals, folded laundry, and weeded her garden. I see these interactions as part of our improvisations together as we designed our study. In her classroom, Elizabeth led students to engage with a number of writing experiences that we called the *Throughlines* project. Students read excerpts from Freire and other critical scholars, engaged with their own choice texts, analyzed social and news media pieces developed in their community, and wrote about their own experiences and the experiences of their communities. Throughout these experiences we asked students to consider "what stories are missing from the narratives you see every day in your school and community?" Students were then tasked with developing digital narratives that would begin to fill the gaps they noted in the stories they encountered every day.

Using ethnographic methods of data collection and analysis, we looked for patterns in her classroom. I collected classroom and design artifacts, 67.5 hours of observation recordings, fieldnotes, reflective memos, and at least two interviews with a sample of 22 students and Elizabeth. Following jazz as method, I also wrote short pieces of fiction as part of my analysis. I treated these pieces as improvisations, giving myself room to understand my data without immediately pinning my analysis to the people within this study. After this improvisatory exercise, I returned to the data and looked for counterpoints to deepen my understanding of the students' and Elizabeth's experiences.

I began my data analysis in concert with examining jazz as an emerging framework. I reviewed weekly audio recordings and fieldnotes, looking for examples of jazz tools being used by students in the classroom. This process began by analyzing student interactions that resembled *trading*, a dialogic practice of improvisation that constrains musicians to developing new ideas in a limited time frame. Discussions with Elizabeth about the ways her students' "off-topic" conversations might instead be framed as improvisatory moves shifted the ways that we designed daily lessons. Other tools such as *theme and variation*, *polyphony and polyrhythm*, and *swing* became codes that both emerged inductively that I applied deductively to guide me to jazz and restorying as a framework. Together, Elizabeth and I worked to hear the stories students told and the ways their restorying resembled jazz.

Findings and Discussion

The students included in this paper are examples of the ways that many of the students with identities that had been "shattered by persistent structural inequality" (Stornaiuolo & Thomas, 2018, p. 352) restoried themselves as powerful agents able to disrupt injustice. The following focuses on the experiences of three students who identified

as having non-dominant identities and whose individual experiences both represent the ways we used jazz tools to understand the actions and engagements of students in classrooms and the ways that students restoried the dominant narratives to see themselves represented.

Theme and Variation: Playing until you find what to say

Players restory in jazz by identifying musical motifs within a composition and then using improvisation to play variations on those themes. Elizabeth's students also restoried around themes throughout the year. While identifying thematic ideas is a practice of ELA, in Elizabeth's classroom, we not only asked students to identify themes they read in literature, but how they might take up those themes and shift them for their own purposes. Students identified themes as they read and wrote, and then worked together to create variations on those themes, some of which included stories of trauma, creativity, family, and justice.

Leaf, a student who identified as Transgender (capitalized in accordance with Leaf's preferences) and part of the LGBTQIIA+ community, drew upon his gender identity and the bullying he had faced as the theme around which he improvised across his projects. This began with a profile he wrote about himself at the beginning of the year, where he described a "complicated' relationship with his father, which he explained was because his father "struggled to accept me." In his profile, Leaf also discussed his respect for Justin Blake, the Transgender YouTube star who had spoken out about his own mental health and coping with bullying when he was in school. "I respect Justin Blake a lot. He's gotten so much crap and gotten discriminated against, but he still continues to put out so much positivity. That's really hard to do." In a reflection on his first project, Leaf wrote, "I want to raise awareness about Bullying. Yeah, there's signs saying no bullying or whatever but when it happens no one does anything. I hate that because I know how it feels and words hurt when they build up."

In his narrative project, Leaf again drew from his own experiences being bullied because of his gender identity. He wrote an essay entitled "Mental Health Awareness," in which he described interviewing his friends to ask, "Is mental health talked about enough?" Leaf reported his findings expertly, weaving quotes from interviews into his prose, offering examples of his own experiences, and calling for increased awareness in the community. However, he also chose to have his story password protected, explaining "I only want those I give the password to see it." Although Leaf repeatedly wrote in reflections about the importance of creating awareness about the connections between mental health, identity, and bullying, he was not yet ready to present that message to his peers beyond a small group he selected. In an interview he explained, "I kind of have a support network, you could say, but not really, my family doesn't really understand me…I don't really have anybody now, I guess you could say." Leaf explained that he felt isolated because "there aren't really people like me here." He also emphasized how important it was to him to feel like he was giving to others and noted, "Bonding with new people feels amazing" and that he really wanted to find ways to talk to people about the bullying he had experienced.

Throughout the year, we observed that as Leaf shared his narratives with small groups of peers, he appeared to grow more confident. When Leaf began a new project in which students were prompted to identify "what it means to be human," he also began to vary his theme of mental health to include perspectives on diversity as a benefit to society. In this iteration of his theme and variation, he also began to articulate excitement about being able to create a message that he could present "especially to teachers and counselors here [at Williams and at Dover Middle School], I think they really need to know more about diversity." In a shift from previous projects, Leaf actively sought feedback on his messaging from his teacher and new groups of peers. As he refined his presentation, he began naming gender identity as part of the diversity that defined humanity. He created a digital presentation to use as a resource for his classmates and the school's counselors.

While he was creating his presentation, protests against a Drag Queen Story Hour at the local library began. While Elizabeth and I were concerned about the ways Leaf might feel his story was being placed in public view, in a final interview he acknowledged the protests and then explained that he knew people "were closed minded" but focused on the fact that nearly 300 people had also joined the counterprotest. In his final project, Leaf affirmed his own identities, acknowledging that his feelings of difference and diversity were exactly what made him valuable and necessary. In it he wrote, "Being different is a way to spread that difference. Transfer your experiences with others so that they can learn and maybe feel more valid and accepted." By improvising around themes of identity, mental health, and diversity, he found a variation in messaging that allowed him to restory himself into the narratives in his community.

Stornaiuolo and Thomas (2018) "theorized restorying as a way young people use digital tools to write themselves into existence, first narrating and analyzing their lived experiences and then synthesizing and recontextualizing those stories to represent a diversity of perspectives and restory dominant narratives." They also explore the ways acts of restorying can "reconfigure school spaces" (p. 346). For Leaf, this reconfiguring took place over the year as he examined and improvised to find the ways that his own identities could be part of the dominant narratives he heard each day in Dover. Leaf shifted from explaining the importance of talking about

diversity and mental health to just a few of his trusted peers, to speaking about his own experiences and advocating for others like him by sharing his experiences and stories. In an interview at the end of the year, I asked how he decided to speak about his own diversity and identity. He said,

> [This year] I started changing and understanding myself better. It's kind of like, well, I've been in that spot before, depression and everything, and so I'll do everything I can, no matter if it's a person I hate, I don't want anybody to go through that because it's a lot to go through. Not a lot of people pay attention…it's just really important to me.

For Leaf, talking about his identities became a form of activism, a way to help others by restorying the narratives around him to acknowledge differences and be more inclusive. Like a jazz musician, exploring variations on a theme, it took Leaf time to recognize his own story and then to find the ways that he would feel empowered to share that story and assert his own humanity.

Polyphony & Polyrhythm: Centering family as counterstory

In jazz, polyphony and polyrhythm refer to many sounds and rhythms simultaneously. Jazz theorists often use these terms to describe the layering of instruments that creates unique textures and voicings within a piece of music (Berliner, 1994). Together, these layered sounds allow for dialogue between musicians, a kind of musical heteroglossia (Bakhtin, 1981; Wertsch, 1991), where multiple voices emerge using different discourses over different time frames. In Elizabeth's classroom, polyphony and polyrhythm acted as tools to observe the multiple discourses and timeframes that young people used as they added to narratives in their communities.

For example, some students restoried through a number of separate counterstories across the year to disrupt dominant narratives in her family, school, and community. Jazmine (who identified as Latina), for example, appeared to restory slowly and differently across each project, writing her way into the perspectives she wanted to share. On the other hand, Truc (who identified as South Asian and male) appeared to know immediately what kind of story was missing from the community. Truc seemed a popular student, friendly with nearly everyone in Elizabeth's second hour classroom. Although he was quiet in class, he articulated his ideas clearly; on a survey that he saw himself as capable, even if he "didn't always like English." When Elizabeth and I presented the narrative project, most students had questions about what it meant to identify the dominant narratives they engaged with each day. Truc, however, immediately began to write, sitting in the back of the classroom, ignoring most of the interactions of his peers. In my fieldnotes, I recorded a moment in the middle of the project where I was concerned that Truc was lost because he had been so quiet. I approached him and asked how it was going. "Good." He said, staring at his screen. Not wanting to disrupt him, I walked behind him, expecting to see a game many of the peers he sat with had downloaded. Truc had pages of writing and images already chosen for his webpage.

Truc's story was about his family, a memory that he described in his reflection as "ordinary," though he acknowledged that it was "really different than anything that would happen here." In his story, Truc described visiting Chicago's Chinatown with his parents and members of his extended family. His writing was extremely descriptive, with "streaks of shallow brightness" and "doors clanging continuously," as well as the smells of "perfume and plastic," "black coffee and green tea" making his experience "even more nostalgic." Truc described his disappointment with what he had ordered, writing, "I requested whatever my mom had, so I was given a bowl of rice, no more than two handfuls, and a piece of bread on the side." He described his disgust at the bread, alluding to how much he had wished to have tried some of the other foods that made this "one of the most saturated memories I have." Elizabeth and I both celebrated Truc's writing. In his audio reflection, he explained that he told this story because although his family made him move to Dover from a larger city, "family is of course important. Family is one of the main factors in molding the person you are." For Truc, this story seemed to be a way to assert his heritage and one of his identities as a person who really valued his family.

He later reflected that he missed the diversity of the city, and that diversity was something he was trying to portray with his story. Similarly, in his interview at the end of the year, Truc continued to elaborate, explaining,

> I really liked the story project. I could write about it and keep going as long as I wanted…I chose this moment because I just remembered it really well. I moved to [this state] because there were better jobs for my family, but Dover is just really different from there. Just how people talk, the attitude of people. I don't know how to explain it, there's less diversity, it's fine, I guess, I just feel like I wrote it for myself.

 © ISLS

Truc's immediate engagement in the project, and his acknowledgement that he missed the kind of diversity that had been present in the bigger city from which he had moved, suggested that he wanted to add a narrative to Dover that allowed for the small moments in his family to feel like they fit into his community.
At the end of the year, Elizabeth and I talked about how much easier it seemed to be for her students to add new narratives when they had lived somewhere other than Dover. Truc was able to quickly add a narrative to those he observed because he had so many experiences of what it felt like to live in a place with more diversity. Unlike many of his peers, who needed to craft their restorying across the year, Truc was immediately able to identify the difference in his story and know that, though it might disrupt the dominant narratives in Dover, it was fully accepted as part of the fabric of the culture in other places and in his family. Like a musician who draws on personal and ancestral histories to invoke polyrhythmic polyphony, Truc drew from his past and his family to add his story to the largely white narratives that emphasized different values and experiences from his own in Dover. In doing so, he also recognized himself as the most important audience for his restorying.

Improvising and Extending: Restorying as choice

As jazz performers grow in expertise, they also build new ways to extend improvisations, sometimes even playing outside of the written chord changes to reimagine a composed piece into something entirely new (Gioia, 2011). For Stornaiuolo and Thomas (2018), this kind of creative innovation is central to restorying, particularly with historically marginalized youth. In Elizabeth's classroom, we saw several students make moves to question the dominant narratives they were observing by improvising around the structures we offered for telling their stories throughout the year. In some instances, these improvisations became full of extensions of the projects. For example, Levi and Brandon (who both identified as white and male), shifted their project on the second amendment to hosting gun safety classes when they realized the correlation between accidental death and gun ownership. While these actions were still aligned with the project goals, they went much farther than Elizabeth had required and created meaningful possibilities for learning.

Bailey was another student who took up the projects that Elizabeth presented and adapted them, restorying her English class assignment by assignment to meet her own aims. Bailey (who identified as white, female, and physically disabled) was an extremely quiet student who spent the entire year in Elizabeth's fourth period class. She had been born with a congenital limb difference and in my fieldnotes, I noted that she carried the same denim coat nearly every day and would pull the jacket over her right arm if other students glanced in her direction. While I never recorded bullying, Bailey emerged as someone I paid attention to, first to ensure her safety, and then as I noted the ways she had reframed the projects to fit her own ideas throughout the year.

In her survey at the beginning of the year, Bailey noted that she had "never been in an English class before." However, this seemed to refer to "high school English class," as she had attended middle school with a number of the other students in her class. She also identified herself as "very creative" and "a writer," and noted that she felt she "mattered a tremendous amount" and "completely belonged" in Elizabeth's classroom. Throughout much of the year, she sat at the front of the classroom, often with two other students who also identified as white, female, and neurodivergent. Throughout the projects, Bailey voiced her commitment to being creative and adapted nearly every assignment to work on fantasy and fan-fiction narratives in which she reimagined the world as a place of "magic and adventure" as well as "sometimes a really bad place." Although Bailey's writing did not, at first glance, critique the structures of society, her commitment to writing what she wanted seemed to be a way of restorying her ELA class and each of the stories she constructed focused on a character who had a physical difference from their peers and families. For example, in "Pies," these differences were punished until the character discovered a way to escape or change the situation in which they found themselves. (In this story, the main character is locked in a basement because of her ability to do magic, escaping only when she learns to use her powers.) In others, such as the fan-fiction piece she wrote entitled "The Legend of Zelda Day and Night," the main character's differences are mentioned in the opening, but do not seem to impact the character as they move throughout the story. Although Bailey did not reference these characteristics in her analyses of her writing, she did explain that she felt it was important to "have a lot of people represented."

When asked in an interview how she had approached the class, Bailey answered, "I was creative…I wrote what I wanted to write." As she evaluated her work using the standards Elizabeth had asked her students to meet, Bailey also explained that she thought she could meet all of them through her fiction, so she had chosen to work in that genre. For Bailey, restorying was an act of questioning the ways that English language arts class was set up and then refusing that structure to engage in the kinds of writing that would further her own goals.

Jazz moves forward and expands because of the innovations of musicians who improvise outside of the boundaries and traditions of the music; however, this only occurs when they know the rules they're breaking. Like jazz musicians in their genre, Bailey was still working within the genre of ELA, she reframed the boundaries of Elizabeth's assignments and projects, adding her own "sound" and to get what she wanted from the class. As she

explained, "The most important thing to me is creativity. Being original. Like, making your own things and sometimes they can be inspired by other people, their creativity can inspire your creativity." While Bailey's stories did not directly critique the structures of schooling as did the stories of some of her peers, I saw her commitment to her own development as a writer as an act of restorying because she asserted a different set of values into a school system that had defined learning as a pursuit of the standards. Thomas and Stornaiuolo (2016) described restorying as "a participatory textual practice" (p. 313) that becomes a dialogue between two ways of being. For Bailey, restorying ELA participation meant disrupting power structures of the classroom to define her experience.

Across Elizabeth's classes, students like Leaf, Truc, and Bailey "write themselves into existence" (Stornaiuolo & Thomas, 2018, p. 345) by restorying the narratives that they were allowed to claim within their families, classrooms, and communities. For students like Leaf, restorying took place over the course of the entire year, as he solidified the ways he wanted to claim his own stories and then decided upon the variations that would most honor his identities. Other students knew the stories they wanted to add to their community almost immediately. Students like Truc restoried quickly, adding his own stories to Dover's narratives to assert that families like his deserved representation, even outside of the "big city." Then there were students like Bailey, who not only decided to write fanfiction to make her own story visible in her favorite games, but also decided that the entire ELA classroom needed to be restoried in order to meet her needs.

Significance

Jazz is deeply intertwined with justice. It has been the soundtrack of protests and the continuing fight for civil rights. As a music, its very existence is dependent on the restorying of white supremacist narratives to illustrate the multiplicity of stories and voices that have existed throughout the United States' history. As these narratives are perpetuated insidiously in this country, jazz too continues to evolve, its artists extending the music into new forms, adding new variations to compositions and playing outside the changes, catching their audience off-guard while pushing the music forward. In Elizabeth's classroom, the students we observed restorying were mostly those whose identities had been historically marginalized, whether in terms of race, culture, socioeconomic status, gender identity, or ability. Restorying for these students was an act of justice, claiming their right to tell their stories told in the spaces where they lived. As these students became more confident in the themes of their stories and the variations they wanted to tell, they also began to push the boundaries of their classroom, taking up new ways of interacting and producing content in order to honor their own ways of knowing. As Elizabeth said at the end of the year, isn't that what we want for our students?

As Elizabeth's students were supported to tell their stories, we also saw them make moves toward epistemic agency. I think of epistemic agency as the power to map one's stories onto the learning that takes place in school. In the push for inclusive and culturally sustaining schooling, *teachers* have often been tasked with determining how to include students' cultural knowledge in the classroom. However, in this study, we aimed to support students in determining how their own cultural knowledge could shift classroom learning. When students are supported with justice-oriented practices, they have the potential to reconsider the world and the ways that they move through it. For students from historically marginalized backgrounds this is often an act of restorying. For students from dominant backgrounds, it is often an act of questioning, beginning to discuss the histories of their privilege in order to shift perspectives. In an era characterized by a constant questioning of truth, it is more pivotal than ever that English teachers work to support their students in developing the skills to read the world and see themselves as powerful with potential to assert more humanizing forms of knowledge.

Jazz as Methodological Toolkit

Design research results not only in empirical findings, but also in the development of methods and theory. By structuring this study around jazz, I found that jazz became not only a metaphor, but a set of methodological tools through which I could make sense of the moves that students and Elizabeth made. Questions of structure and agency are enduring in education and anthropology; jazz as a tool kit provides a way to look at these questions from new perspectives in relation to human learning. For me, jazz is about joy. White supremacy lands heavily on all of us, even those of us whom it offers privilege. Music is ultimately about joy, and jazz is a direct expression of Black joy in the United States. Even in a mostly white, rural setting, and perhaps specifically because of this context, tools that speak to creativity and joy and triumph are exactly the counterpoint necessary to reimagine what learning can look like in these spaces. As we continue to encounter violence against Black people, while allowing education in highly segregated spaces, then we will continue to see white supremacy proliferate. Students need support to question their own histories and narratives. In our current reality—where police killings of Black men and boys perpetuate, where the COVID-19 pandemic continues to take the lives of people of color and people living in poverty at alarming rates, and where systemic oppression means that many people in the U.S. do not have enough to eat—helping students to reflect on their stories to disrupt inequity carries specific urgency.

Taking up new ideologies and ways of knowing in education has the potential to disrupt this cycle. Especially when we draw from tools that have successfully disrupted these perspectives in other genres and disciplines. Jazz tools offer a means of observing classrooms as holistic ecologies where every move has ramifications and improvisations can be traced. These tools also offer a way toward refusal (Tuck & Yang, 2014)— a means of reframing the world and refusing the framework of white supremacy. These tools offer researchers and educators new possibilities for "world making" (Solis, 2009), not only as a set of analytic tools, but also in the future as a toolkit for design, a way to listen deeply to the stories of our participants as we build new kinds of learning environments. In studies that claim criticality, making space for these new worlds based on the stories of teachers and students should be our top priority.

Perspectives on the Process of Design from Education and the Design Fields: Toward Transformative Design

Douglas B. Clark, David Scott, and Joshua DiPasquale
Werklund School of Education at University of Calgary

Abstract: This synthetic review explores traditional approaches to educational design that have predominated education for the past century, considers the limitations of these approaches for fostering transformative second-order changes in schools in ways that can counter normative hegemonic arrangements, and contemplates the possibilities of approaches to design from design fields and research on participatory design. The review closes with an exploration of potential approaches for educational design going forward to pursue changes that introduce new goals, structures, and roles to transform education in service of more equitable futures.

Introduction

A significant body of research suggests that the cultural configurations of schools, including their governance structures, organization, and teachers' approaches to curriculum and instruction, have not substantially changed in North America over the last century (Cuban, 1988, 2020; Tyack & Cuban, 1995; Hess, 2011; Payne, 2008). Acclaimed historian Cuban (1988) ascribes this reification to a traditional focus in education on first-order, as opposed to second-order changes. As Cuban (1988) explains, "first-order changes try to make what already exists more efficient and more effective, without disturbing the basic organizational features, without substantially altering the ways in which adults and children perform their roles" while "second-order changes seek to alter the fundamental ways in which organizations are put together" (p. 72). The ongoing COVID-19 pandemic, intensification of the global climate crisis, growing economic inequality, proliferation of fake news, increased global migration, calls for justice from minoritized groups, and demands for reconciliation and decolonization from Indigenous peoples have highlighted the need for new approaches to education involving second-order changes that can address issues central to larger shifting patterns of privilege and marginalization. There is a need in this regard to think creatively and explicitly about the assumptions and preconceptions of how we think about and enact education, not just at the macro level of how schools are organized, but at the everyday level of how teachers teach, how they organize activities for their students, and how students engage in these activities.

Questions remain, however, around how, and the extent to which, prominent and still emerging ways to conceptualize and carry out educational design can work to foster the kinds of second-order changes that might address the immense challenges and inequity present in the world today. Seeking to lend insight into this question, this review examines the limitations and affordances of various approaches to educational design for fostering second-order changes in schools that might advance more preferable educational futures.

We begin by defining what we mean by design processes and distinguishing between design processes and the more typical focus on design principles. Next, we review the traditional approach to design processes that persistently informs design in pre-service teacher programs, school districts/jurisdiction, and learning environments. We then discuss two alternative perspectives on educational design and research that are increasingly gaining traction in the field of education: (a) perspectives on design thinking arising out of design fields and (b) perspectives on participatory design. Each of these perspectives, we argue, offers opportunities for transformative design of learning environments through fostering second-order changes beyond what is usually possible through the traditional design processes. We conclude the review with a discussion outlining possible fusions and intersections of these various design perspectives that could better serve all students and address issues residing within the complex and diverse social and cultural worlds in which we live.

Defining Design Process: Design Processes Versus Design Principles

Before discussing design processes in education, it is important to first distinguish between what we mean by *design processes* in comparison to the more typical focus on *design principles*. In defining the nature of design principles, Kali (2006) explains that design fields commonly "gather and abstract designers' experiences and research by creating collections of design principles or design patterns that synthesize design knowledge and can be used to guide new designs" (p. 188). This dynamic can be seen in the field of education where researchers commonly articulate the implications of their work in the form of abstracted design principles (whether or not the researchers use this specific term) to highlight the design characteristics of productive learning environments.

By comparison, a focus on *design processes* defines characteristics of the processes through which desirable learning environments might be designed rather than defining the characteristics of the learning

 © ISLS

environments themselves. Specifically, by the term design process we mean both the articulation of the process of design as well as articulation of the mindsets that contribute to and support productive design. In so doing, we purposefully combine what McKenny et al. (2015) refer to as "technical" and "phenomenological" perspectives in terms of the activity flow of the design process as well as the productive mindsets of designers that facilitate the design process.

Certainly, designers might focus on design process as well as design principles, but in education much research is focused on design principles with less explicit articulation, particularly in the scholarly literature, of the design processes themselves. While design principles can serve as powerful heuristics to guide design of educational environments, without also attending explicitly to the processes by which educators design, educators miss a powerful opportunity to more fully realize transformative second-order changes because design principles tend to already assume or dictate a frame for the design rather than supporting or prioritizing consideration and exploration of new frames, which is an explicit goal of newer design thinking and participatory design processes. By frames, we refer here to the differing vantage points, perspective, and conceptual lenses by which "we name the things to which we will attend and frame the context in which we will attend to them" (Schön, 1984, p. 40).

Traditional Industrial Perspectives on Design Process in Education

While attending to the design process offers possibilities for transformative second-order changes, traditional design processes in education have historically focused on technical rational ways of thinking rooted in the "backward design" method first developed by Bobbitt (1918) and then fully articulated and popularized by Tyler (1949) three decades later. This design tradition continued in education with design processes and procedures associated with task analysis as articulated by Gagné (1965). Borrowing heavily from behaviourism, these process-based frameworks start with a learning objective and then work backward to plan for instruction. Within Gagne's proposed design process, for example, task analysis is conducted to decompose higher order skills and goals into subordinate constituent elements. Instructional design then focuses on sequential instruction of subordinate elements. The most popular approach to design taught in almost all teacher education programs in North America today, Understanding by Design (Wiggins & McTighe, 2005), continues to reflect this backward design process focussing on a sequence of (a) identifying the targeted outcomes in terms of big ideas and skills, (b) determining how those outcomes will be assessed, and (c) choosing learning activities that will support the targeted outcomes as measured by the assessments.

The ongoing prominence of these traditional approaches for conceptualizing design processes in the field of education may explain, at least in part, why education as practiced in K-12 classrooms has changed so little in North America over the last century (Cuban, 2020; Payne, 2008). These approaches to design are emblematic of a focus on first-order changes in educational environments, as opposed to second-order changes that seek to fundamentally alter the ways education is understood and organized (Tyack & Cuban, 1995). The reason for this focus on first-order changes can be largely attributed to the ways these processes reflect a technical rational stance towards design. By "technical rational," we refer to perspectives and approaches that view "practitioners as 'instrumental problem solvers' applying well-defined solutions to well-defined problems" (Anderson & Coleman, 2015, p. 270). Through these lenses, educational design is framed as an act of instrumental problem solving emphasizing correct solutions proceeding from a pre-set goal or aim, with little or no emphasis placed on deeply exploring the nature of the problem or the ends to be achieved (e.g., Schön, 1983; Strong et al. 2016). If designers seek to advance more equitable futures in our schools and society, attention needs to consider not only the discrete learning outcomes found in subject specific programmes of study but also the nature of educational problems and the frame within the designer might work (Clark, 2021).

One example of the importance of attending to the frame of design is highlighted by Dwayne Donald (2010) in relation to low graduation rates and academic success among Indigenous students in Canada. As Donald explains, much discussion around this issue tends to be framed in terms of how to raise graduation rates and academic outcomes of Indigenous students in ways that imply a cultural deficit wherein culture becomes a code word for race and problematic difference. Donald clarifies that such a framing fails to consider the ways the lack of success seen in Indigenous students is directly connected to the historic and current state of the relationship among Indigenous and settler populations in Canada. Donald discusses a more productive frame that focuses on the relationship itself as an educational priority, not just for Indigenous students but for all students and society writ large, equal to what we are talking about in terms of Indigenous student success. These insights highlight the importance, as we discuss below, of approaching the design process more in line with design fields that focus on problem finding and the lived experiences and perspectives of stakeholders to reframe educational challenges.

Perspectives on Design Thinking from the Design Fields

The linear, instrumental, and technical rational tradition of design in education stands in contrast to the ways

design is conceptualized and understood in design fields. While design fields focused heavily on the proposition that design could be a highly rational and scientific process through the middle and late middle portions of the 20th century (e.g., Simon, 1969), the field underwent significant paradigmatic shifts starting in the 1970s when design began to be understood more holistically in terms of the complexity and "wicked" nature of important design challenges that preclude, defy, and negate such technical rational approaches to problem solving (e.g., Buchanan, 1995; Norman, 1998; Rittel & Webber, 1973; Schön, 1984). This more human-centered approach to design — often termed a designerly stance towards design — includes: (a) deeply exploring the perspectives, experiences, needs, and goals of stakeholders in relation to wicked problems, (b) "reframing" design challenges by stepping back and reconsidering the vantage points, perspectives, and metaphors being used to define the actual nature of the challenges, and (c) engaging in ongoing cycles of ideation and iteration of possible responses through multiple rounds of feedback from stakeholders (Buchanan, 1992; Dorst, 2011; Norman, 2013; Schön, 1984).

Particularly over the last decade, there have been increased calls to integrate these more human-centered perspectives on design into education (e.g., Kirschner, 2015; Koh, Chai, Wong, & Hong, 2015; Razzouk & Shute, 2012). The most prominent approach to human-centered design in education, and across many other fields as well, involves the notion of design thinking as articulated and promoted by IDEO and the Stanford Design School (e.g., Brown, 2008; IDEO, 2012). Design thinking so conceptualized articulates stages of the design process that are referred to with various names but generally involve four key moments: (a) *discovery* (where the designer or team comes to understand the nature of the challenge, does background research, and often works to develop empathy with stakeholders), (b) *interpretation* (where the designer or team works to synthesize what is been learned in a way to frame or reframe the opportunities for design and the specific question that the design process seeks to address), (c) *ideation* (where the designer or team generates and refines a range of possible ideas to pursue to address the design question identified in the interpretation phase), and (d) *experimentation* (where the designer or team begins iteratively prototyping, gathering feedback, and refining the approach) (e.g., IDEO, 2012). The IDEO/Stanford perspectives on design also heavily emphasize that design thinking mindsets, such as embracing ambiguity, as well as the need for empathy and radical collaboration, are also central to the design process.

In terms of the affordances of design thinking for fostering second-order changes as compared to traditional backward design, there is an emphasis on the importance of: (a) divergent thinking in addition to the primarily convergent thinking of the backward design approaches; (b) coming to understand the needs and perspectives of stakeholders; (c) exploring the problem before framing or reframing the specific articulation of the design question to be explored rather than jumping in with assumptions of the questions to be design for as foregone conclusions; and (d) collecting feedback throughout the design process rather than completing the design process before seeking out feedback. This structuring thus has substantial affordances compared to traditional backward design approaches in terms of moving beyond "first-order changes [that] try to make what already exists more efficient and more effective, without disturbing the basic organizational features, without substantially altering the ways in which adults and children perform their roles" (Cuban, 1988, p. 72). By creating an opening to rethink the opportunities and questions to explore, design thinking can create the possibility of exploring "second-order changes [that] introduce new goals, structures and roles that transform familiar ways of doing things into new ways of solving persistent problems" (Cuban, 1988, p. 72).

Other research from design fields suggest, however, that design thinking thus conceptualized does not fully constitute a designerly stance that focuses on second-order changes in service of transforming the cultural configurations within schools. While basic design thinking approaches create openings to rethink educational challenges, issues, and problems related to equity, diversity, and inclusion that might foster second-order changes, research in design fields emphasize the importance of focusing the design process on what are known as "wicked problems" (Rittel & Webber, 1973; Buchanan, 1992). Wicked problems are problems that are difficult or impossible to solve, have multiple possible explanations depending on the worldview and perspective of the observer, are often symptoms of deeper structural problems, have no single solution, involve complex interactions of stakeholders with differing needs and values, and resist easy solutions because of complex interdependencies that result in or reveal new challenges when the problem is explored (Rittel & Webber, 1973; Buchanan, 1992). While research has explicitly focused on wicked or ill-formed problems in the context of design thinking with both preservice teachers (O'Byrne et al., 2018; Harth & Panke, 2019) and in-service teachers (Hubbard & Datnow, 2020; Marin et al., 2013; Retna, 2016; Sheehan et al., 2018), the IDEO and the Stanford Design School (Brown, 2008; IDEO, 2012) models of design thinking do not explicitly foreground or frame design challenges in terms of wicked problems. For example, the IDEO (2012) design thinking models encourage designers to frame problems in terms of 'How might we…' (HMW) questions, which can foster a tendency to place clear boundaries and constraints around problems whereby problems are viewed as relatively "tame," rather than dynamic, complex, ill-defined, and confusing (i.e., wicked) (Buchanon, 1992, p. 15).

Notably the implementations in education of IDEO and the Stanford design thinking models, paralleling

the situation in the field of business management, often don't engage with, or reference, other literature in design fields (Johansson-Sköldberg et al., 2013; Sosa, 2015). Reflective of this disconnect, design thinking as taken up in educational practice often does not deeply consider key elements inherent to a designerly stance towards inquiry such as the notion of "reframing" or "positioning" a design problem (Buchanan, 1992; Dorst, 2011; Gulari, 2015; Schon, 1984). While educators employing a technical rational stance towards design would be largely unconscious of how they are framing a problematic situation, those adopting a more designerly stance would work to reframe or reposition a problem by stepping back and considering it through differing vantage points, perspectives, and metaphors (Dorst, 2011). Working against the tendency of interpreting issues or challenges in education through traditional discourses, a designerly stance to framing challenges educators to view problems through non-dominant and often overlooked discourses in education (e.g., feminist, ecological, critical). Through this process, educators would then be able to reframe a challenge in ways that might better advance second-order changes that can counter status quo hegemonic arrangements in education.

The limitations of how human-centered design is most often taken up in educational contexts can also be seen in how stakeholders are positioned in the design process. While IDEO (2012), for example, emphasizes the ways design thinking is a "deeply human approach," it also asserts that it "relies on your ability to be intuitive, to interpret what you observe and to develop ideas that are emotionally meaningful to those you are designing for" (p. 14). Theorists in design fields, including Sanders and Stappers (2008), have criticized this designer-centered stance for the ways it promotes an "expert mindset" built on "hierarchy and control" (p. 9) that assumes the designer can determine what is best for those implicated in a problem. Additionally, while perspectives on design as promoted by IDEO and the Stanford Design School heavily emphasize that the process is not linear, and that there will be substantial iteration and recursion back and forth between stages of the process, the design thinking process is articulated from a procedural perspective. Reflective of a procedural stance towards design, there is often a focus in the educational literature on the relatively straightforward implementation of IDEO/Stanford conceptions of design thinking for preservice teachers (e.g., Henriksen et al., 2020; Shively & Palilonis, 2018) or inservice teachers (e.g., Spoon et al., 2020; Hennessey and Mueller, 2020; Scheer et al., 2012).

Recent research in the field of education, however, is moving beyond IDEO/Stanford conceptualization of design thinking, by incorporating expanded perspectives from design fields to address wicked problems (e.g., Norman, 2013; Schön, 1984) while working with both preservice teachers (e.g., Jordan, 2016) and in-service teachers (e.g., Goldman et al., 2020; Svihla & Reeve, 2016; Svihla et al., 2016; Koh, Chai, Benjamin, & Hong, 2015; Jordan et al., 2014). Within this body of literature, there is a particular focus on framing and reframing design challenges in terms of larger complex structural, social, cultural, historical, and political systems that are implicated in learning environments and students' opportunities to learn. While the IDEO/Stanford conceptualization certainly brings strengths in terms of how concrete and accessible it is to new designers, the broadening of conceptualizations of design thinking that are beginning to enter the field of education create many more opportunities for deep consideration of the framing and reframing process whereby challenges might be reconsidered from novel perspectives that have the possibility of generating second-order changes that account for greater equity in our schools and society.

Perspectives on Participatory Design in Education

Echoing the concerns discussed above, other researchers propose that the approaches to design thinking outlined in the previous section have substantial potential to sustain and extend neoliberal perspectives furthering the loss of already marginalized identities, perspectives, cultures, and value systems (Gram, 2019; CBC, 2019; Taboada et al., 2020). Essentially, while many design thinking approaches emphasize understanding stakeholder needs, gathering feedback from stakeholders, and even a focus on radical collaboration to include multiple perspectives on the design team, most perspectives on design thinking still envision the designer or the design team as designing "for" stakeholders rather than designing "with" stakeholders, which runs the risk of recreating or perpetuating inequitable power structures and barriers. This dynamic can be seen, for example, in the ways people with differing abilities can be seen as recipients design rather than participants in the design process itself. Liz Jackson, a disability advocate and design strategist, outlines how this designer-centric perspective can lead to "disability dongles" involving an "elegant and well-intended, but ultimately useless solution to a problem people with disabilities never knew they had" (CBC Radio, 2019, para. 2). Reflective of insights like this, approaches to participatory design (Björgvinsson, Ehn, & Hillgren, 2012; Ehn, 1988; Luck, 2018) and decolonial design (Taboada et al., 2020) have evolved in design fields resulting in approaches to collaborative design that are more just, equitable, and counter-hegemonic.

Building on these ideas, similar approaches to participatory design have been explored in education (e.g., Gutiérrez & Jurow, 2016; Bang et al., 2012; Penuel & Gallagher, 2009). In this section, we outline some of the major currents of participatory design in educational research and conceptualize them according to their potential

to enact second-order changes in schools by designing with, instead of for, stakeholders. That is to say, we seek to demonstrate how several recent participatory approaches to design in education may provide avenues to "introduce new goals, structures and roles that transform familiar ways of doing things into new ways of solving persistent problems" (Cuban, 1988, p. 72) in educational settings. In particular, the following paragraphs consider Participatory Design Research (PDR), Design Based Implementation Research (DBIR), and Cultural Historical Activity Theory (CHAT) approaches to participatory design.

Participatory Design Research. PDR can be defined as a form of inquiry designed to "create more culturally-relevant and reusable learning artifacts *for, with and by those* who will use them" (Chew et al., 2021, p. 541, italicized in original). Notably, as Jurow et al. (2016) explain, PDR "allows for the inclusion of diverse perspectives on what kind of learning matters, why, when, where, and for whom" and also "requires careful consideration and ongoing negotiation about what participation means and how it can be best enacted throughout the processes of design and research" (p. 219). PDR differs from traditional approaches to educational design and research in that it challenges assumptions about "normative hierarchically powered decision-making structures" (Bang & Vossoughi, 2016, p. 174). As a consequence, there are a number of putative advantages to PDR approaches over traditionally hierarchical educational research methods that may lend themselves to realizing second-order change in schools. For instance, PDR methods can function as a means of what Booker et al. (2016) regard as 'systematic repair' that supports "three related components of repair work: visibility, agency, and power" (p. 232) by promoting claims of *epistemic authority* among participants, which they describe as "exercising the right or the power to know" (p. 223). According to Booker and colleagues, such systematic repair can be enacted through PDR by (a) maintaining open conversations about phenomenon to be studied, (b) re-mediating the roles of all stakeholders, including the researchers, as both learners and as authorities in the process of knowing, (c) enacting multiple rounds of collaborative data analysis and design that can expand what counts as data (i.e., the collaborative and methodological processes themselves), and (d) eschewing deficit-based conceptions of the problem that can serve "to diminish participation" (p. 234). Ultimately, PDR, through its commitments to co-design, encourages researchers and educational designers to ask "who does the design and why" (Engeström, 2011, p. 600) and to also pay "attention to the positionality of researchers or their social identities in the unfolding of work" (Bang & Vossoughi, 2016, p. 174).

Design-Based Implementation Research. DBIR can be broadly defined as a collaborative mode of educational design and research that features elements of design thinking (Penuel et al., 2011). The main objective of DBIR is "to facilitate the design of educational interventions that are effective, sustainable, and scalable" (Fishman et al., 2013, p. 136). DBIR projects build upon four core principles as outlined by Penuel and colleagues (2011): (a) a focus on persistent problems of practice from multiple stakeholders' perspectives; (b) a commitment to iterative, collaborative design; (c) a concern with developing theory related to both classroom learning and implementation through systematic inquiry; (d) and an emphasis on developing capacity for sustaining change in systems (p. 332). DBIR explicitly emphasizes second-order changes by focusing on what Fishman and Penuel (2013) term infrastructuring, which is the "process of creating and sustaining new cultural practices and supportive technological mechanisms" (p. 393). Fishman and Penuel (2018) explain that DBIR's emphasis on how educational innovations are designed expands upon traditional educational research methods that often narrowly focus only on the potentially fleeting efficacy of educational innovations. Accordingly, DBIR is seen as an extension of educational design research that can assist researchers in creating "improvements to educational systems that last" (Penuel, 2018, p. 659).

Cultural-Historical Activity Theory Approaches. CHAT approaches to educational design vary in scope and name (e.g., Cole & Packer, 2016; Gutiérrez & Jurow, 2016; Sannino et al., 2016). Nevertheless, these approaches, when taken as a whole, focus on participatory design perspectives that "emphasize the cultural and institutional organization of human action in various forms, in a wide variety of social settings ranging from classrooms in schools to community settings and workplaces" (Penuel et al., 2016, p. 490). Of particular interest, CHAT research has articulated a particular approach to participatory design known as "Change Laboratories" (Engeström et al., 1996). The Change lab approach focuses on second-order change as a goal, which CHAT researchers articulate in terms of "expansive learning" (Engeström & Sannino, 2010). Essentially, a Change Lab brings together working practitioners and managers of a unit or group (which might be located in a school or other workplace) along with a small number of facilitators, interventionists, and/or researchers to support the group in their processes. Clients, students, and other stakeholders may also be represented in the group. The group conducts a series of five to ten Change Lab sessions. Sometimes these Change Labs are also conducted as boundary crossing laboratories with representatives from two or more groups engaged in collaboration or partnership. The Change Lab sessions are based on a "double stimulus" approach (Vygotsky, 1987, 1997). The first stimulus involves critical incidents, troubles, or problems from the workplace as recorded at the workplace that motivate the group to consider alternative approaches to their practice and organization. The group analyzes these first stimulus

events through the lens of a second stimulus that takes the form of conceptual tools (such as the iconic triangular models of the CHAT approach). These second stimulus models are often replaced or combined with mediating conceptualizations or models formulated by the participants through their work. Essentially, the participants explore second-order change by leveraging the mediating second stimulus in the design of a new concept for the activity they are trying to transform (Engeström & Sannino, 2010; Sannino, Engeström, & Lemos, 2016) through an *expansive learning* process (e.g., Engeström, 2015) that is "a creative type of learning in which learners join their forces to literally create something novel, essentially learning something that does not yet exist" (Sannino et al., 2016, p. 603).

Potential for Synthesis and Refinement Across Perspectives on Design

Rather than incommensurable, these perspectives on design offer opportunities for synergistic integration in support of second-order changes to create more equitable learning opportunities for all students and a more equitable world. Each perspective brings affordances and limitations. Traditional backward design perspectives, for example, emphasize integration, coherence, and alignment with end goals throughout the design process, but backward design perspectives are limited by their lack of emphasis on (a) reconsidering and exploring deeply the actual challenges and framings to focus upon and (b) the actual experiences, goals, strengths, needs, and perspectives of the stakeholders. Essentially, traditional backward design perspectives highlight convergent thinking but place less emphasis on articulating divergent thinking and stakeholder centrality. Design principle similarly can focus on first-order changes by already assuming or dictating a goal for the design. For example, within the UDL framework (Rose 2000; Hall et al., 2006), the curricular content and discrete learning outcomes that students are meant to learn is taken as a given. Design thinking perspectives, on the other hand, emphasize the cycles of divergent and convergent thinking much more explicitly, and in some cases focus deeply on the role of framing and reframing the nature of the challenge upon which to focus (Dorst, 2011; Buchanan, 1992), which creates the opportunity for second-order rather than first-order change. Design thinking perspectives, however, still can be limited by an emphasis on designing "for" stakeholders rather than "with" stakeholders, and design thinking may not bring the focus on alignment that can be emphasized by backward design perspectives. Participatory design perspectives, in turn, center stakeholders and stakeholders' understanding of their lived experiences, goals, strengths, and needs. Participatory design perspectives, however, could benefit from (a) design thinking perspectives in terms of the articulation of process to support deliberate attention to the potential of divergent thinking and reframing that could support transformational reconceptualization around those foci and (b) the potential of backward design to focus on the alignment between goals and means.

Thus, rather than incommensurable, these different perspectives offer substantial opportunities for synergistic integration. At the heart of the matter from the perspective of supporting fundamental second-order changes around equity are the dual needs for: (a) incorporating the voices of stakeholders, particularly those marginalized by the current social, cultural, political, and historical systems and (b) consciously and explicitly analyzing the frames through which the systems and challenges have been viewed to date as well as the potential affordances of other existing or new framings that could support fundamental second-order changes in light of those social, cultural, political, and historical systems.

Participatory design perspectives are obviously especially well suited to the former (i.e., incorporating the voices of stakeholders) while design thinking approaches are well suited to the latter (i.e., consciously and explicitly analyzing frames and considering new frames), but neither is necessarily sufficient on its own. Alone, both perspectives are capable of reproducing only first-order changes that may improve the efficiency or efficacy of stakeholder experiences without fundamentally transforming or contesting the status quo. Stakeholders in participatory design, like everyone else, may not immediately consider the arbitrariness of the figured worlds in which they live (Holland et al., 2001). Designers on design thinking teams may not bring the lived experiences that would allow powerful frames to be considered or even recognized as needed. Integrating participatory design and design thinking perspectives, however, would appear to provide great opportunity for synergy.

Perspectives on participatory design growing out of Cultural Historical Activity Theory (CHAT) (e.g., Engeström & Sannino, 2010; Sannino, Engeström, & Lemos, 2016) provide one possible foundation for such integration. We propose that the Change Lab approach with its double stimulus structure (described in the previous section) creates an excellent opportunity for synergizing participatory design approaches with perspectives from design thinking. In particular, design thinking ideas could help provide additional scaffolding to focus the design processes across Change Lab sessions (which have minimal articulation beyond the double stimulus structure), and design thinking models could be included as part of the second stimulus materials to help the group attend to and realize the opportunities for divergent thinking and fundamental reframing of the goals at the heart of the group's activity system. Such an integration would provide greater scaffolding to the actual processes of the group. This proposed synthesis would integrate strengths from participatory design as well as design thinking in a way

that could prove more reliably productive in terms of pursuing second-order rather than first-order change. Furthermore, the integration of the design thinking ideas and models might reduce (but not eliminate) the reliance of the Change Lab approach on highly skilled interventionists and researchers, which is currently an element of the Change Laboratory approach that prohibits broad scaling.

A synthesis of Change Laboratory and design thinking approaches is just one possible example of synergies that might be pursued, but it illustrates the opportunities that might be leveraged. Similar synergies are already being explored in models of Design-Based Implementation Research (as outlined in the previous section), which emphasize the integration of participatory design with elements of design thinking (e.g., Penuel et al., 2011) to pursue second-order change in the form of "infrastructuring" to create and sustain new cultural practices and mechanisms to transform education (Fishman & Penuel; 2013).

Another point of synergy and educational literature more broadly would involve more active leveraging of models from critical theory perspectives as explicit foci for reframing in design thinking and as second stimuli in Change Laboratory approaches or other participatory design approaches. A danger across all design teams is that the design team will not consider alternatives to the figured worlds in which they already operate. As Dorst (2011) makes clear, the distinction between successful and less successful designers often hinges on how frames are considered and created. A novice designer or team may default to simply adopting the existing frame without even questioning it. More sophisticated designers or teams may be able to consider a range of other frames provided by others. The most transformative design teams create or discover or identify frames that have not been considered previously in terms of the challenge they are attempting to address. Explicit consideration of critical perspectives may thus prompt possibilities for reframing challenges in ways that have not yet been considered.

Ultimately, the goals of design should move beyond first-order refinements of efficiency and effectiveness. These first-order refinements of efficiency and effectiveness most likely only replicate or reinforce existing inequitable neoliberal structures and figured worlds in education (and society more broadly). In order to move beyond these first-order refinements of efficiency and effectiveness, education needs to move beyond its reliance on backward design processes alone to guide design. Integrating and synergizing perspectives on design thinking and participatory design, particularly if guided by insights from critical analyses of the power structures and figured worlds that currently organize our activity systems, provide opportunities to pursue second-order changes that introduce new goals, structures, and roles to transform education in service of a more equitable future.

Using Reference Models as a Springboard for Ontological Innovation: Analyzing a Central Theory Building Move in the Learning Sciences

Hillary Swanson, Utah State University, hillary.swanson@usu.edu,
Mariana Levin, Western Michigan University, mariana.levin@wmich.edu

Abstract: The development of learning theory is of core importance to the learning sciences. Despite its importance, little is understood about our own theory building processes. This paper analyzes one case of theory development to better understand a particular theory building move associated with design-based research: ontological innovation. The case features the invention of a new category of knowledge and therefore exemplifies ontological innovation. Conducting a retrospective analysis, we identify seven steps, which were critical to the development of the new category of knowledge (meta-theoretic competence) in response to an existing reference model (meta-representational competence). These steps suggest the coupled nature of data and theory, and the importance of the researcher's own knowledge, which they bring to bear on their theory building practice.

Introduction

The development of learning theory is of core importance to the learning sciences (diSessa, 1991; Roschelle, 2021; Sandoval, 2014). In the last thirty years there have been many exciting developments in the field that have fundamentally shaped how we view the very nature of knowledge and learning processes, including a turn towards recognizing how learning is embodied in nature and socially and culturally organized (Abrahamson et al., 2020; Nasir et al, 2021; Nathan, 2021). Many of our most impactful advances have come via the strong commitment to interdisciplinarity in the learning sciences: building upon advances in cultural studies, sociology, anthropology, and educational neuroscience, to name a few. Together with these perspectives, the field has developed ethnographic and design-based methodologies that provide sources of insight into real-time learning processes (Bakker, 2018; Brown, 1992; Cobb, et al, 2003; diSessa, Sherin & Levin, 2016; Hall & Stevens, 2016). One of the hallmarks of theory building in the learning sciences is that theories that are developed in the context of real-world learning and performance data can generate novel theoretical ideas of wide scope. diSessa and Cobb named these novel theoretical ideas *ontological innovations* — "theoretical constructs that empower us to see order, pattern, and regularity in the complex settings in which we conduct design experiments" (diSessa & Cobb, 2004, p. 84). Ontological innovation can also be viewed as a theoretical move involving the recognition of new theoretically-relevant categories based on observations in data.

While it is widely agreed that the development of learning theory is an important goal, processes of theory development in the learning sciences are still not well understood. By its nature, theory building in the learning sciences has a strong commitment to being accountable to the moment by moment details of learning processes. Given this commitment to theorizing involving emergent categories based on empirical data, many moment-by-moment analyses of learning interactions describe the process of building theory as being informed by Grounded Theory (Glaser & Strauss, 2017/1967). However, while Grounded Theory shares with learning sciences researchers the commitment to extracting categories for research from empirical data, the description of the theory-building process is not well-tuned to modeling moment-by-moment learning processes (Parnafes & diSessa, 2013). Previous descriptions of theory building within the learning sciences have resulted in descriptions of general processes, such as researchers engaging in *observe*, *schematize* & *systematize* cycles (diSessa, in Parnafes et al., 2008; diSessa & Levin, 2021) in the case of generating new theoretical constructs, and general phases of theory building, such as *incubation*, *theory negotiation*, and *theory appropriation* phases (described in Parnafes & diSessa, 2013) in the case of analyses that extend and elaborate an existing theoretical construct. While these case observations offer helpful heuristics, the details of how these cycles and phases function require more elaboration, and exemplification in a broader set of instances. Our aim in this paper is thus to offer a case analysis of a theory building process, focusing in particular on the way existing theoretical constructs can serve as reference models that then lead to ontological innovations. The case we present comes from an analysis of the theory building process of the first author.

Theoretical foundations

 © ISLS

We begin by describing the theoretical framework that guided the theory building work featured in the case study: knowledge in pieces (diSessa, 1993). We then describe the theoretical framework that we use to characterize the theory building process: epistemic forms and games (Collins & Ferguson, 1993).

Knowledge in pieces

Knowledge in pieces (KiP) is a name for a broad class of theoretical models of knowledge—models in which knowledge is seen as consisting of a *complex system of elements of diverse types*. This broad epistemological perspective grew out of studies of individuals reasoning about the physical world. DiSessa showed that the way individuals thought about physical phenomena was well-modeled by a large number of knowledge elements that were often inarticulate and applied in a manner that depended sensitively on the context at hand (diSessa, 1993). This formulation of the organization of knowledge has strong implications for instruction: instead of replacing "misconceptions" about how the world works, instruction in formal physics needed to engage individuals' intuitive knowledge and re-contextualize it more appropriately for given contexts.

Knowledge in pieces has influenced studies in many other domains beyond intuitive physics, including algebra (Izsák, 2000; Levin, 2018), multiplication (Izsák, 2005), proportional reasoning (Izsák, Beckmann & Stark, 2021), calculus and linear algebra (Adiredja, 2014; Adiredja & Zandieh, 2020), geology (Barth-Cohen & Braden, 2021), and computer science (Lewis, 2012). As well, the framework has influenced the study of naive epistemology (Hammer & Elby, 2002), the role of emotions in cognition (Gupta, Elby, & Danielak, 2018), and ideologies about race and racism (Philip, 2011). Common themes across this body of work are that (a) intuitive knowledge based on experience in a domain provides a rich source of resources for learning, (b) the recognition and use of such knowledge resources are not necessarily articulate and that (c) the activation and use of knowledge resources depends sensitively on context. More extensive lists of principles and counter-principles for studying knowledge in a way that is consistent with knowledge in pieces is given in diSessa, Sherin & Levin (2016).

Ontological innovations may occur at the system level or at the element level, and sometimes both. A number of novel knowledge categories have been proposed over the years, including *phenomenological primitives* (p-prims; diSessa, 1993), *explanatory primitives* (e-prims; Kapon & diSessa, 2012), *naturalized axioms* (Philip, 2011), and *symbolic forms* (Sherin, 2001). More extensive knowledge systems such as *coordination classes* (diSessa & Sherin, 1998; diSessa & Wagner, 2005, Levin & diSessa, 2016) have been generated to explain how individuals obtain measurable information from the world and *strategy systems* (diSessa & Levin, 2021; Levin, 2018) have been used to explain how individuals coordinate knowledge in problem solving processes. In this paper, we show how an existing knowledge category (meta-representational competence; diSessa, 2004) is used as a springboard for ontological innovation.

Epistemic forms and games

Collins and Ferguson (1993) characterized the theory building work of scientists using a framework they called epistemic forms and games. Epistemic forms are abstract structures or templates, which scientists fill out in answering a particular research question. A form guides the game that is played to fill it out, in the same way that the cross-hatch structure of tic-tac-toe imposes certain constraints on how the game can be played. The completed form embodies theoretical knowledge, the form and game are therefore connected with knowledge and knowledge building. Collins and Ferguson present three kinds of epistemic games: structural analyses, functional analyses, and process analyses. They describe examples of typical forms produced by games within each category (e.g., lists, stage models, system-dynamics models), and unpack some of the moves in the associated games. For example, a scientist might play the list-building game to produce a list when their research question is something like "what is the nature of x?" and x can be decomposed into a smaller set of elements (e.g., a list of material substances found in the world). If the items on their list can be characterized in terms of multiple dimensions, the scientist might transfer to a cross-product or table game (e.g., the periodic table of the elements). In our analysis, we use the framework of epistemic forms and games to schematize the moves made by the first author in her theory building trajectory.

Methods

In order to understand the smaller steps involved in ontological innovation, we conducted retrospective analyses of our own theory building processes as case studies. In this paper, we report on the findings from the analysis of one case study. The case study was conducted by the first author; the Analytic Process and Findings sections are therefore written in first person. The case study examined the development of a knowledge category called meta-theoretic competence (MTC), which was developed to characterize 8th grade students' productive engagement in theory building, in the context of a science elective course (Swanson, 2022).

Context of research on student theory building

Data were collected in the context of a class designed for 8th grade students – the "Patterns" class – that met three mornings a week for forty minutes, both fall and spring semesters. The Patterns class was designed to engage students in the construction and refinement of a unique kind of theoretical artifact: a pattern theory. Pattern theories were essentially written descriptions of patterns in behavior underlying phenomena across domains. For example, a pattern of threshold can be seen in both the tipping point of a tower of blocks and the testing of a person's patience. Pattern theories were meant to serve as conceptual footholds for moving towards more mathematical, aggregate-level understandings of phenomena through the lens of dynamical systems theory. Twenty-one students participated in the course (11 girls, 10 boys). The teacher was also the researcher. Data were collected in the form of video footage and student work.

The course included units on patterns of threshold, equilibration, exponential growth, and oscillation. Each unit followed the same general sequence, meant to embody a simplified process of theory building and refinement. Students began by exploring two phenomena that exemplified the focal pattern. They were then invited to individually write descriptions of the pattern in behavior the two examples had in common (these were their first theory drafts). They evaluated their pattern theories against a third example and then revised their pattern theories to either clearly include or exclude the example. They then generated lists of examples that followed the pattern and discussed those examples in the context of a whole class debate. They were then invited to revise their thinking and write third and final pattern theory drafts.

For example, in the threshold unit, the students explored phenomena that exemplified the pattern of threshold (adding coins to a spaghetti bridge until it broke; adding drops of water to the surface of a coin until it overflowed) and then wrote descriptions of the pattern in behavior demonstrated by both examples. They then compared their pattern theory with another example (adding scoops of salt to a cup of water until a submerged egg floated) and refined their theory to more clearly include or exclude the example. They generated a list of additional examples that followed the pattern (e.g., "bothering someone till they burst," "getting a haircut") and argued about the fit of those examples with their classmates in the context of a whole class debate. By the end of the unit, they had refined their pattern theories (e.g., "adding something to something until it changes").

Analytic process for the case study of researcher theory building

The aim of the research described above was to characterize students' theory building in the context of the Patterns class. My KiP orientation made me interested in characterizing their theory building at a microanalytic scale and in understanding how their engagement in the activities I'd designed could be seen as seeds of scientific theory building. This orientation also placed the goal of modeling naive knowledge in my awareness, though it was not initially foregrounded in my thinking.

In order to understand my own process of theory development, I conducted a retrospective analysis of several sources of data. The first was a document containing reflections, which I had written throughout the course of my analysis of student work and video transcript. The second source consisted of the notes I had written on student work and video transcripts of class activities. I used the reflection document to reconstruct a narrative of my process at a level of detail that captured milestones in the development of my theoretical artifact (e.g., initial characterizations of the data, identifying a reference model). I used my notes on student work and transcripts to illustrate my narrative with specific examples. I read through the narrative of my process and partitioned it into seven steps, to capture what appeared to be key moves in the development of my theory. I present the narrative of my theory building process below, unpacking each of the seven steps in chronological order.

Findings

In this section, I describe the theory building process that emerged as I worked with the data. I partition my process into seven steps. The first step maps with Parnafes and diSessa's *incubation* stage. The second step maps with their *theory negotiation* stage. The third through seventh steps align roughly with their *theory appropriation* stage and offer a closer look at how a reference model can act as a springboard to ontological innovation.

Step 1: Examining data and assigning initial characterizations

The initial goal of my inquiry was broad: to understand the nature of student engagement in theory building in the Patterns class. I began by looking through the data and characterizing, at no particular grain size, elements of student work and activity, which seemed relevant to elements of theoretical science. In this way, my work during this step aligns with both Parnafes and diSessa's *incubation* stage, and diSessa's *observe* and *schematize* stages. As in the *incubation* stage, I began by looking across the data without hunting for evidence of existing theoretical constructs. However, in contrast with the *incubation* stage, my initial look wasn't purely open. Instead, my initial

interaction with the data resembled a combination of the *observe* and *schematize* stages. I viewed my data with the expectation that students would be doing productive things related to theory building, and I loosely schematized the productive things I saw the students doing.

For example, to students' pattern theories, I added notes such as "general language" and "pattern in behavior." To the margins of the video transcript, I added notes such as "offered intuitive causal explanation" or "challenged explanation on grounds of logic." In reviewing my notes, it became clear that many of my characterizations of student theory building could be categorized as *theory building moves* and those that were not (e.g., "general language") could be recast as moves (e.g., "used general language"). I conceptualized these theory building moves as *resources* for theory building. Though it seemed advantageous to characterize the resources as moves where possible, I felt using the term "resource" had an advantage over "move," in that it was less constrained and could involve a wider range of seeds for theory building, such as general aesthetics and intuitive explanations, which I also saw in the data. This move in my own theory building process is related to diSessa's *systematize* stage. My shift in schematization of the data inspired a clarification of my research aim and my question became more focused: "What resources do the students bring to their productive engagement in theory building in the Patterns class?"

Step 2: Identifying a reference model

I recognized that answering this question would yield a collection of resources students had for the construction of pattern theories. This cued to memory a collection of resources for engaging in another set of scientific practices, which already existed as a category of knowledge in the KiP framework. This category of knowledge was meta-representational competence (MRC; diSessa, 2004). MRC supports work with representations, which transcends their mere production and use. It includes skills for the invention and design of new representations, for their critique, for understanding the purposes of representations (both in general and in specific contexts), for explaining representations, and for learning new representations quickly with little intervention. MRC includes resources that are "gradually developed through cultural practices in and out of school." It is therefore concerned with naive knowledge that extends beyond the realm of intuition.

DiSessa and colleagues documented resources for the invention and design of new representations, such as the ability to draw and sensitivity to representational possibilities of visual elements (e.g., color, length, width). Resources for the critique of representations include criteria such as completeness, precision, and parsimony. It seemed sensible to use MRC as a reference model for organizing a class of resources for scientific theory building. Both models are concerned with a broad range of resources on which students can draw to engage in scientific practices, and both are concerned with elements of naive knowledge, which may have their origins in social interaction and schooling. To make the connection between my work and this reference model explicit, I decided to call this new category of knowledge "meta-theoretic competence."

Step 3: Abstracting the epistemic form underlying the reference model

Meta-theoretic competence (MTC) is a new category of knowledge. It is therefore an ontological innovation. To develop MTC, I drew inspiration from an existing ontology: MRC. In order to understand how my ontological innovation was seeded by a reference model, it is helpful to view my theory building activity through the lens of epistemic forms and games. My theory building was an epistemic game, the moves of which were driven by the epistemic form I was trying to produce. My target form was inspired by MRC, but MRC itself was not my target form. My target form was the *general structure underlying MRC*, which is a list of resources for productive engagement in a particular activity. Whereas MRC is concerned with students' engagement with representations, my concern was theory building.

The form I sought to produce was therefore a list of resources for productive engagement in different aspects of theory building. It is worth calling attention to the fact that I sought the general form underlying MRC and used that as the template to guide my theory building work. This move is likely idiosyncratic and reflective of my own interest in the nature of scientific theory building and my attention to schematizations of theory building that have previously been described in the literature, including epistemic forms and games.

Step 4: Organizing initial characterizations according to the epistemic form

Having determined the epistemic form I would need to fill out to answer my research question, I turned to organizing the initial resources I had identified in my data in the form of a list. Because MRC partitions resources according to aspects of work with representations such as invention, critique, etc., I anticipated that I would ultimately partition the elements on my list according to parallel aspects of theory building. However, at this point

in time, I didn't know what those categories should be, so I merely wrote the list in an order that matched my notes in the data.

Step 5: Refining the emerging model by creating categories

Looking across the resources, I thought of categories of theory building activities that could be used to organize my list. The categories that initially emerged were: theory articulation, evaluation, and refinement, and specification of a theory's domain of application. This move also connects with diSessa's *systematize* stage. To see how this worked, I organized the elements on the list according to these four activities.

Step 6: Going back to the data and reanalyzing it in terms of the model

With my revised template, I went back to the data and in addition to checking the appropriateness of my existing list of resources, I looked carefully for other examples in the data that might be resources for articulating, evaluating, or refining theories, or for specifying a theory's domain of application. I added resources to the list, filling out the template more fully. The activity of this step corresponds again with diSessa's *observe* and *schematize* stages.

At this point, I created two copies of the list. The first copy presented the resources simply in their categories as a partitioned list. For the second copy, I expanded the list by describing each resource in detail and illustrating it with student work or segments of transcript from the Patterns class.

Step 7: Further refining the model by changing the epistemic form

Working more closely with the data and explaining how it illustrated each resource on the list surfaced a pattern I hadn't previously noticed. What the examples revealed was that there was another dimension along which the theory building resources could be organized. This was a dimension of characteristics that were particular to Pattern theories. These dimensions included deeper structure, generality, and causal relationships. I tried reorganizing the list of theory building resources according to these aspects. The result was unsatisfying because, while it highlighted which aspect of pattern theories a resource could be used for, it obscured which theory building activity it corresponded with. As I rearranged the examples from my illustrated list, it became clear that the resources I had found were accountable to both dimensions (aspects of pattern theories and theory building activity). For example, in some of the data, students were demonstrating resources for *articulating causal relationships*, while in other examples, they were demonstrating resources for *evaluating a theory's level of generality*.

This led me to wonder if a cross-product form might be used to organize the theory building resources. I constructed a table to see what it would look like to have theory building activities in rows and pattern theory characteristics in columns. In my data, I found examples of resources for the articulation, evaluation, and refinement of pattern theories along the dimensions of deeper structure, causal relationships, and generality. It didn't make sense to cross the specification of the domain of application (essentially naming examples of things that followed the pattern) with characteristics of pattern theories. The product of this with deeper structure, for example, didn't mean anything. I struggled with what to do with "specifying the domain of application." It was a key component of the pattern theory building process and resources for it would need to be included in my ultimate model of MTC demonstrated by students in the Patterns class.

Because "specifying the domain of application" was so particular to pattern theory building, I decided to try moving it from the dimension of "theory building activity" to the dimension of "aspects of pattern theories." This shift required a refinement in the names of the two dimensions, as the table now consisted of a dimension of stages of theory building (articulating, evaluating, and refining - in rows), crossed with pattern-theory-specific elements (deeper structure, generality, domain of application, and causal relationships - in columns). A reduced version of the table is shown below (Table 1), to give the reader a sense of the kinds of resources that were included in the category, and to illustrate how they were organized in tabular format.

Table 1. Resources for theory building, which belong to the category of meta-theoretic competence

Stages/Pattern Characteristics	Deeper Structure	Generality	Domain of Application	Causal Relationships
Articulating	Articulating the pattern in behavior	Using general language to describe a pattern in behavior	Generating examples from physical and psychosocial domains	Articulating intuitions about

	instantiated by examples			causal relationships underlying behavior
Evaluating	Comparing examples based on similarities and differences	Questioning the generality of the language used	Challenging and defending the fit between examples and pattern theories	Challenging and defending the logic of intuitions
Refining	Removing surface features from the pattern theory	Removing context-specific features to make the pattern theory applicable to more examples	*There was no opportunity in the course for students to demonstrate resources for this category	Responding to challenges by unpacking or modifying ideas

In the language of epistemic forms and games, my shift from a list form to a table form is an example of a "transfer" from one epistemic form to another. This is an appropriate move in playing an epistemic game, if it becomes apparent that the original form is insufficient. Because it is focused on the larger organization of the elements, the activity of this step corresponds with diSessa's *systematize* stage.

High-level sketch of the theory building process

The theory building process described above consisted of seven steps: 1) examining the data and assigning initial characterizations, 2) identifying a reference model, 3) abstracting the epistemic form underlying the reference model, 4) organizing initial characterizations according to the epistemic form, 5) refining the emerging model by creating categories, 6) going back to the data and reanalyzing it in terms of the model, and 7) further refining the model by transferring to a new epistemic form. Figure 1, below, illustrates the seven steps of the researcher's theory-building trajectory.

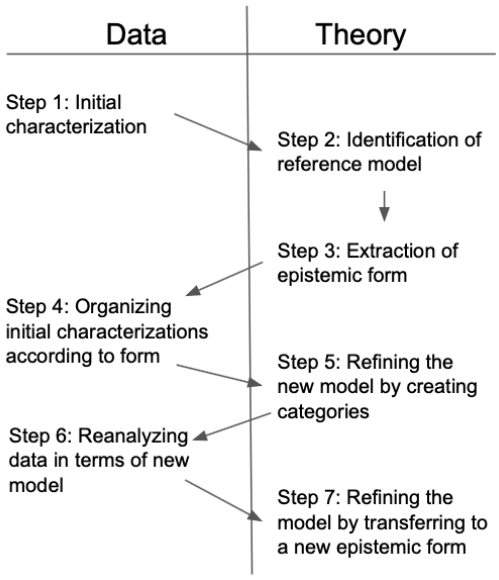

Figure 1. High-level sketch of the researcher's theory building trajectory.

Looking across these seven steps gives us a general sense for how the reference model acted as a springboard for ontological innovation in the examined case. There was a general pattern in which the researcher moved back and forth between data and theory, but the two were never quite separate. When the researcher gave the data an initial look, for example, she was looking at the data through the lens of her theoretical orientation with the expectation that the students would be doing productive things with respect to theory building. She therefore saw characteristics of artifacts and activities that might be productive resources for theory building and lifted those

out of the data by schematizing them as moves, for example. When she looked across the list of resources she had identified, she cued to memory a potential reference model, based on perceived similarities in structure and function. She drew this model from a network of familiar models. Because she had read the work of Collins and Ferguson and viewed her own scientific inquiry through the lens of epistemic forms and games, she was motivated to extract the epistemic form of a list from the reference model. She then used the form as a template for organizing her initial characterizations (or in the words of diSessa, she used the template to systematize her initial schematizations). Because she valued the construction of theory grounded in data, she continuously tested her model against the data and refined it so that there was a close fit.

The sequence illuminates a general pattern of moving back and forth between the data and the form, where the researcher keeps the one in mind, while looking at the other. It also shines a light on the importance of the knowledge the researcher brought to her theory building, or the role of her own meta-theoretic competence. Her theory-building knowledge included her epistemological orientation, which, typical of a KiP perspective, viewed naive knowledge as potentially productive and likely containing seeds for scientific theory building. Her theory-building knowledge also included a network of existing KiP models, which provided a number of possible reference models. Her theory-building knowledge also included an epistemological stance on the nature of scientific theory building, which was that scientists played epistemic games to fill out epistemic forms, which were general structures underlying particular models. She therefore thought to draw the deeper form out of the reference model and use it as a template for driving her epistemic game. Finally, her theory-building knowledge included an aesthetic for building theory grounded in data. All of these elements of her theory-building knowledge came together in her attempt to make more formal sense of her students' engagement in theory building in the Patterns class. It was their synergy that led her to use the reference model as a springboard for ontological innovation.

Conclusion

In this paper, we sketched the theoretical genesis of the ontological innovation of meta-theoretic competence (MTC). In particular, a seven-step trajectory from the initial look at the data to theory-in-progress captures one learning scientist's process of theory building, focusing particularly on unpacking the process of using reference models in the process of ontological innovation. We hope that our work in elaborating how a particular theoretical move functioned will help other researchers in the learning sciences recognize similar moves in their work, and to unpack processes of theorizing, for both newcomers and oldtimers in the field.

Kites in the wind: Response cries as evidence of listening

Emma D. V. Reimers, Vanderbilt University, emma.d.reimers@vanderbilt.edu

Abstract: Ingold (2007) argues that we hear in sound just as we see in light. The immersive media of sound and activities of everyday listening have largely been neglected in the field of the learning sciences. Reflecting on Ingold's metaphor of a kite in the sky, I discuss the importance of Goffman's (1978) concept of response cry in beginning to show us listening in learning. This paper describes three qualitative studies that all center sound as the primary medium for meaning-making. Findings demonstrate the ways in which response cries constitute evidence of listening and the tension of doing the complex work that is being a listener, particularly in the setting of listening together.

Centering sound

Sound is all around us, within us, moving through us. Ingold (2007) argues that we hear in sound, just as we see in light. It is like breath, like air. Despite the similar immersiveness of these media, our world has been dominated by the hegemony of the visual, as well documented by media scholars (Levin, 1993; Cox, 2011). Still, academic and everyday pursuits alike are hesitant to take listening seriously. This is epitomized in the legitimacy of "eyewitness" and its dismissible counterpart, "hearsay". While the field of learning sciences has dedicated resources to investigating the process of seeing as a way of knowing (e.g. Stevens & Hall, 1998; Christidou & Diamantopoulou, 2016), the immersive context of hearing and listening is an aspect of the sense-making process that rarely takes center stage in learning sciences research.

I have a personal stake in making this claim, as I believe worthwhile research should be personally meaningful: I am a life-long musician and someone who has spent hours being formally trained to listen (as many of us have with our current school systems). I have been struck by how beautifully complex listening is both in my own experience as a listener and in my study of it as a researcher. I believe we have an incredible opportunity to better understand how listening is constructed as a social practice. In this way, the phrase "active listening" is redundant.

Listening in the literature

Listening, which is distinct from hearing in that it is a conscious process of meaning-making rather than a physiological one (Low and Sonntag, 2013), is notoriously complex to understand, accounting for its neglect (Rowley-Jolivet, 2002). Certainly, the complexities of listening became apparent and even visceral in the COVID19 pandemic and the shift in modalities of hearing and listening from classroom co-presence to digital and long-distance. Historically, findings describe listening is the primary communicative activity of students, accounting for much more time than writing, reading, or speaking (Barker, Gladney, Edwards, Holley, and Gaines, 1980; Emanuel, Baker, Daufin, Ellington, Fitts, Himsel, Holladay and Okeowo, 2008). Overwhelmingly, early research praises the teachability of listening as demonstrated through comprehension exams, in which students who were instructed to summarize, draw inferences, and recall facts accurately and in order (Devine, 1978). This, however, reduces the nuances of sonic communication to a version of spoken text, a reduction that colors most of the past century's work on listening and leaves students to "prove" their listening by the rote regurgitation of information that plagues reading comprehension. While both listening and reading involve internalized, interpretive thinking, they are two very different activities (Bostrom, 2011).

Other research has theorized listening by comparing it to mathematical communication via signals and noise (Shannon and Weaver, 1949), to computers via information processing (Brown, Anderson, Shadbolt, & Lynch, 1985), and to the evolution of language via hunters and gatherers (Barsalou, 1999). Some have even offered theories of listening that are one-way as opposed to two-way, proposing that listening to an instructor 'transmit' knowledge is a mono-directional transaction (Lynch and Mendelsohn, 2010). Even in the case of diminished or lost hearing, embodiment of hearable interaction like the movement of lips, singing, facial expression is an essential mode of communication (Friedner & Helmreich, 2012).

 © ISLS

Much of the interactive process of both formal and informal learning environments relies on listening: lecturing, discussion, conversation, music, ambient sound, as well as environments that leverage audio performances that are subject-specific (Shapiro, Hall & Owens, 2017; Hall & SLaM, 2020; Silvis, Taylor & Stevens, 2018). If we did not assume both the power and potential of listening, we would not have the study of rhetoric, discourse analysis, conversation analysis, and communication studies. Since making and attending to sound is an interpretive, meaning-making process, we as a research community must seriously examine experiences of listening, including song and story.

Yet how do we know that someone is listening? This is a problem in daily life, in education broadly, and in research on the processes of listening. What is hearable is wider than what is heard, and what is heard is wider than what we might have listened to. We know there are certain performances associated with listening: making eye contact with a speaker, nodding our head, or repeating a certain phrase that was just heard. These, however, do not constitute sufficient evidence that what was said (the hearable) was actually processed and understood (listened to). How do we study listening, then?

Theoretical approach

This paper examines three studies which are linked by the centrality of auditory media to make an argument for the value of examining listening in learning. Here, listening is defined as a complex, meaning-making activity that leverages sound and the perceptual apparatuses of hearing. Listening provides similar opportunities as looking in the sense that there are ways of attuning one's perception. Listening *to* something is similar to looking *at* something, a stance of observation. Listening *for* something, however, is akin to looking *for* something, a stance of searching. The negotiation between these two modes of listening constitutes the experience of listening that Ingold describes when he writes against soundscape (2007):

> If sound is like the wind, then it will not stay put, nor does it put persons or things in their place. Sound flows, as wind blows, along irregular, winding paths, and the places it describes are like eddies, formed by a circular movement around rather than a fixed location *within.* To follow sound, that is to listen, is to wander the same paths. Attentive listening, as opposed to passive hearing, surely entails the very opposite of emplacement. We may, in practice, be anchored to the ground, but it is not sound that provides the anchor. Again, the analogy with flying a kite is apposite. Though the flyer's feet may be firmly planted on the spot, it is not the wind that keeps them there. Likewise, the sweep of sound continually endeavors to tear listeners away, causing them to surrender to its movement. It requires an effort to stay in place. And this effort pulls against sound rather than harmonizing with it. Place confinement, in short, is a form of deafness. (p.2)

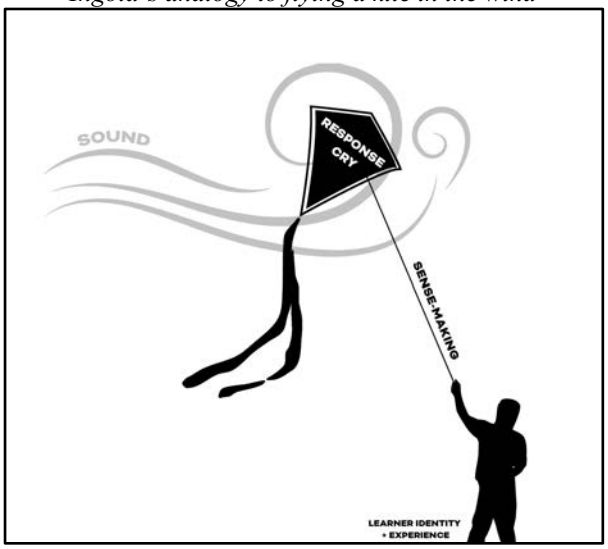
While I disagree with some of Ingold's other arguments around soundscape conceptually, his identification of the inherent movement of sound and his analogy to a kite are useful. Flying kites, proverbially, also allows us to learn something about both the construction of the kite and the wind with which it interacts. While the wind, like sound, is invisible, it is made evident through its interactions with other objects. So too is listening to sound made visible through interaction. This visibility is key since listening is uniquely a private sense-making experience: we cannot listen precisely like anyone else yet listening happens in social contexts.

Here, Goffman's work on response cries (1978) becomes helpful in understanding the internalization of a social other: we move throughout public life with an awareness that others might see or hear us. In Goffman's example, to trip on a sidewalk while sober and of sound mind often produces an utterance like, "They really ought to fix that sidewalk" not because there is a direct recipient of the utterance, but because the tripper lives in a world where clarifying to any onlookers that he is sober and of sound mind is socially valuable. Response cries demonstrate a figured world (Holland et al, 2001) of public perception which Goffman calls "response presence"; importantly, the winds of sound are an ever-present part of this world, its weather. It is in this world, then, that we might design activities to better understand listening's role in learning.

The *kite* is the response cry that we toss up in the air to twist in the wind, be upheld by it, and demonstrate the wind's very existence. The string between the kite and the person flying it is sense-making, the activity of staying in attuned connection with the motions and qualities of the wind, being in productive tension with time and place. It is our own tugging on the string and the wind's tugging back that co-produces a felt concept of "windiness". This tension is felt against the ground where we stand, our existing identities and experiences we as learners bring to the act of listening. The *wind* is that which is hearable all around us and, in the case of the studies in this paper, the eddies that we designed to represent place and time. The entire process of flying a kite constitutes *listening* (Figure 1).

Figure 1. Listening

Ingold's analogy to flying a kite in the wind



Does a listener stay grounded or is there re-positioning, new footing required to keep with the kite? What kinds of kites might be on display? What kinds of strings might connect listeners to the abstraction of sound?

In this paper, all of the designs for listening are such that no one is listening *alone*. While listening is an internal and private experience, it is always socially contextualized and most often happens amongst people as a part of communication. Using Hall & Ma's lens of ensemble learning (2018), I posit that ensemble listening—listening that we do together—is a different animal than solo listening. In short, there are things that we can learn when we listen together that perhaps are unavailable when we are listening alone: there are no solo kite-flyers in these studies.

Designing for listening

Three Studies

Let me orient us to the three studies in this analysis. These studies come to us as a part of ongoing design-based research (Barab & Squire, 2004) by the Space, Learning and Mobility (SLaM) lab. The content in the first case is quite different from the other two in that a single song is the focus of the session. In the latter two studies, a collection of digitized songs and oral histories is embedded along a mapped route. In all three, however, the idea of controversial or contested narratives arises. While separate analysis has been conducted for each study with its respective set of research questions and findings, this paper presents an analysis of the studies' shared interest in centering listening and presents findings that cross-cut all three.

Context for study 1: listening session

In the summer of 2015, sixteen high school students enrolled in a summer course at an elite Southern university program for rising high schoolers nominated controversial songs for analysis by the whole class. One nomination that was selected by facilitators was the song "Blurred Lines" by Robin Thicke and Pharrell. Since its publication, the song has garnered appropriate critique of its lyrics and themes regarding consent in sexual encounters and the gendered power dynamics of inter-personal relationship. In short, the singer comes across as someone who does not respect women. Using two cameras set on tripods and four microphones distributed across the four-person table groups, a record was compiled to show how students responded to listening to the song together.

Context for studies 2 and 3: listening on the move

The SLaM lab has been engaged in a long-term partnership with a community-based music museum wherein efforts have focused on preserving under-told stories about Black history in the area. Since music and oral history is at the core of our projects together, we had begun to ask questions about how students made sense of the recordings in relationship to the places about which the music and historians talked.

Through design-based research, we built a series of activities related to learning on the move (Marin, Taylor, Shapiro, & Hall, 2020) where students would encounter a qualitatively themed map with digital archival material of songs and oral histories while walking along a path of points of interest on the street where the museum is

located. A majority of the students participating in these walks were white, middle class, and had characteristics of identity and experience which were disparate from those that were represented in the DSSLs. The tension that Ingold identifies can be leveraged in design to amplify the experience of palimpsest, of being simultaneously here and *then* (Hall, R. & Space, Learning and Mobility Lab, 2020) which was of interest to our research team.

In the spring of 2019, thirteen master's students in followed two modes of a digital spatial storyline (DSSL) (Hall, R. & Space, Learning and Mobility Lab, 2020). DSSLs are a form of qualitative thematic mapping that attach multimedia sources to points in space as a way of telling (hi)stories about place. The master's course was oriented around the goal of developing a deep understanding of designing experiences for social studies learning. Our lab's interaction was positioned as an opportunity for students to be participants in a design-based research study in order to gain insight into how they might conduct their own future studies.

The DSSL contents were identical: both involved digital media of oral histories by local experts, songs related to themes from the neighborhood's history, and a map which coordinated real time GPS data and the view of the corridor. The first version of the DSSL involved a web app designed by our lab, called Storyliner, which serves up map-located media that requires users to opt-in by clicking on a map icon. The second version of the DSSL is in an app called Echoes, which uses the media from Storyliner but involves geofenced circles that automatically play the sonic content.

The design of this particular study called for the students to be paired up, with half of the pairs using Storyliner on the first part of the walk and the other half using Echoes. Both DSSLs were used while students were walking down a historic Black music and civil rights corridor in the South. We later coordinated the chest-mounted GoPros that students wore with some iPhone and iPad screen captures in order to examine how students connected their interaction with the media with the interaction within the pair.

In the third study, during the summer of 2019, two high school SLaM interns participated in a new iteration of the second study (see Figure 3) with an ear toward what they could glean from the design of the story walk in terms of strategies to make their own story walks. As a pair, they used a shared iPad and connecting their headphones through a splitter so that our record captured what they heard and what they said in perfect sync.

Data Analysis

For all three studies, I collaborated with colleague researchers, advisors, lab members, and participants to conduct interaction analysis (Jordan & Henderson, 1995) of the rich audio-video records through our standing Interaction Analysis Lab. Following the theoretical basis of response cries, we identified 'hot spots' in the record, paying close attention to how listening was being made evidence through gesture and utterance (Hall & Stevens, 2015). Additionally, we analyzed the video record through the lens of a question: "what resources do students leveraging in making sense of contentious or counter-story audio media?" In the case of both the 2019 studies, member checking was performed with participants to ensure that our analytical understanding of their experience was true to their memory and their own understandings.

Findings

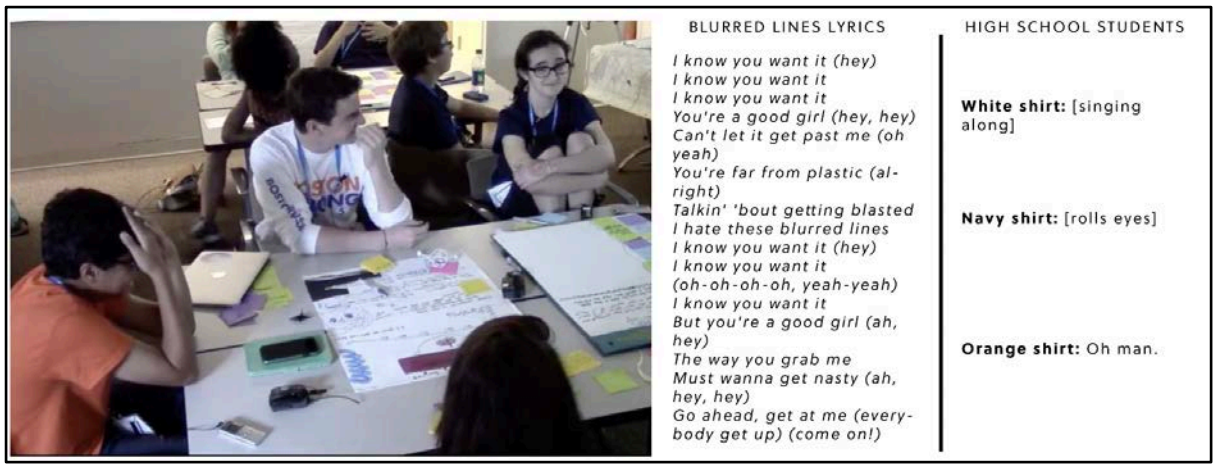
Kites

Students across all three studies used utterance, embodiment, and other methods to perform their private listening experience of song or story to those within their response presence, constituting response cries. We noticed *kites* or response cries of two main kinds related to the stances of listening as observation or listening as searching.

Listening To

One set of response cries can be grouped as more moment-to-moment reactionary and demonstrated a broad attendance to the sound. This connects with the observational stance of listening: listening *to* something. In the case of the high school students, the recording of 'Blurred Lines' sustained a tension between the students' existing social positions and their presence with one another while the song was playing. Alignment against the singers of 'Blurred Lines' became visible as students responded to hearing lyrics which they disagreed by shaking their heads, raising eyebrows, and hugging their knees to their chests (see Figure 3).

Figure 2. High schoolers produce response cries
Students are visibly reacting to that which they are listening to.

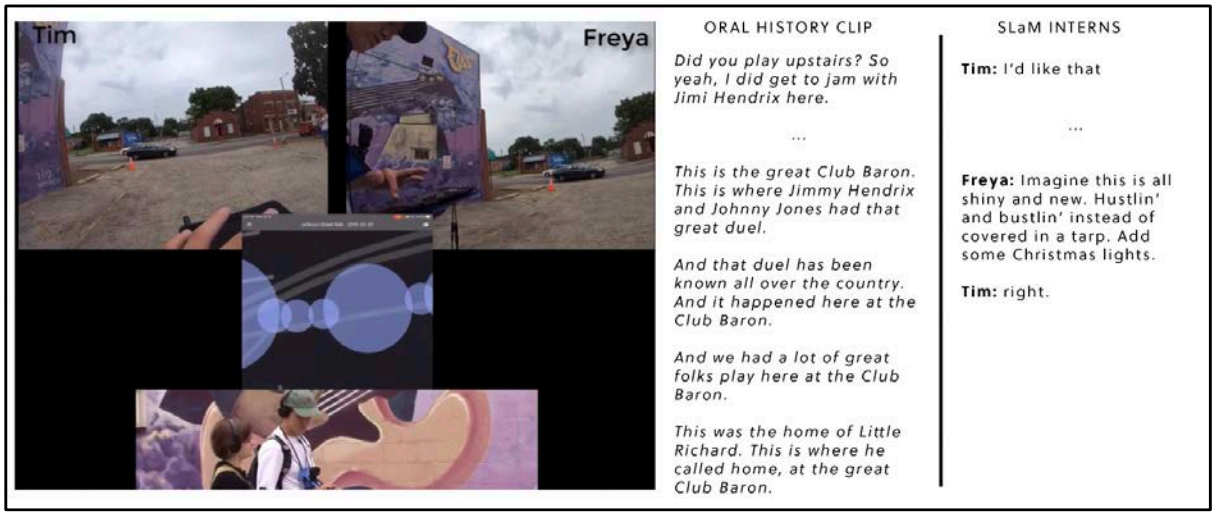


Realization of what may have been an alignment with the was evident as some students started by singing along but dwindled in their singing as the content of the lyrics became apparent. Response cries often precipitated each other, with one student exclaiming "oh man!" and making eye contact with a peer who then said "yikes" to the same lyric. Masters' students performed their private experience of listening into the response presence by walking in time to the beat of a song or consulting with their partner, asking, "Did you hear that about the interstate?" referring to an oral history clip.

Listening For

The other category of response cries relates to the searching stance of listening: listening *for* something. In the masters' class, a student returned to an audio clip to listen *for* the interstate story that her partner mentioned. For the summer interns, the idea of listening *for* the future emerged in their utterances about what a historic club must have been like overlapping with ideas of what it could be like "with some Christmas lights" and a band with Tim.

Figure 3. Summer interns use Echoes, a DSSL



The shift between these two modes of listening is obscured when it is not the explicit framing of the activity, but is evident in how learners are able to filter out audio information irrelevant to their pursuit (e.g. for the pair of masters' students, content not related to the Interstate was ignored).

In identifying these two modes and their accompanying response cries, the categories fall short of accounting for the ways in which each person has a different approach to listening, which likely includes some predispositions for certain types of listening *for* in a first listen (or a listening *to*) stance. Someone with a musical background may naturally gravitate toward noticing the instrumentation of a song; someone with a background in politics may

hear the story about the interstate through that particular lens. This is where strings come in to represent the connections between individual listeners and their response cries.

Strings

Students drew on a range of resources to connect where they current were (both literally in space and time and conceptually in their own positionality) to what they were listening to. The quality and texture of these strings is likely innumerable. Some brought in personal stories tied to themes in the music and others brought in original sources related to the sonic content like court records and news articles. One masters' student related a colorfully muraled overpass to a similar site she had visited in New Orleans despite the vast difference between the communities' respective use of these two spaces. Another student drew on a story a classmate had told her about the neighborhood to make sense of the oral history clip about the neighborhood's once-vibrant music scene. These connections create and sustain tension between the performance of listening and the personal history of the listener.

Discussion and Implications

Being moved by sound

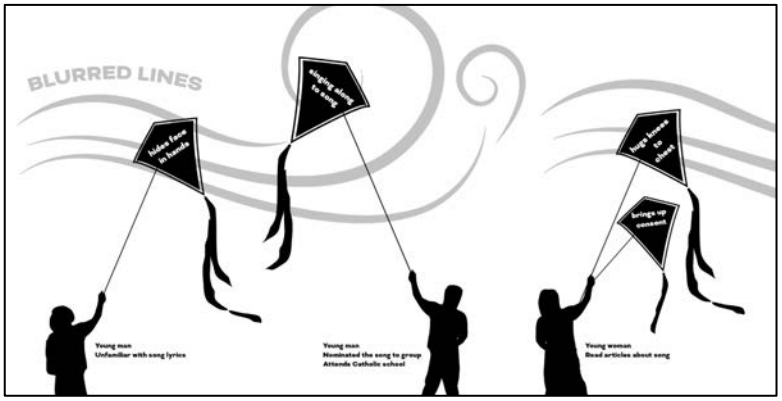
Earlier, Ingold described the possibility being swept up by sound, noting the effort it requires to stay in place when pulled by the sonic wind. Now, we can consider the difference between where we started when we unspooled our thread and launched our kite to where we stand as the wind whips it around. It is unlikely, though not impossible, to stay still. Ingold decries standing still: you might as well not have heard the sound to begin with.

Then a change in position must reflect being moved by the sound. Listening produces learning in this way. We are not where we found ourselves before we listened and responded. This movement and tension shapes us as learners, strengthening us and bringing us to new places. Listening is both the means and product of constructing new information in conversation. Doing this work of listening, however, might lead to entrenchment if we are only listening to that which already aligns with our personal experiences and understandings: we will see slack in the line and feel no windiness. It is essential to have a critical perspective of listening that honors the undeniable socio- and geo-politics of listening. Songs, counter stories, erased or undertold stories, public histories, personal narratives specifically of women (as 'Blurred Lines' goes to show) and Black people in the U.S. (as seen in DSSLs), and other forms of historically undervalued information must be revisited with the new commitment.

Listening together

Embedded in these findings are three clear methodological, epistemological, and ontological implications for what it means to listen *together*. Firstly, that kites *do* fly (so to speak) is a phenomenal thing. Because of response presence, listening inscribes itself in the record through interaction. Methodologically, this means that while noticing or proving listening as an activity is difficult, examining listening from an ensemble learning perspective makes visible the otherwise invisible personal experience of listening. It also provides the opportunity for understandings of sound to be expanded and challenged by co-listeners. For the high school students, it was pivotal that their utterances and accompanying takes on the song's meaning were so contrasted (see Figure 4).

Figure 4. Different kites, same sky



Since listening is inscribed in interaction, so too are the two main modes of listening to (or, observing) and listening for (or, searching). While it will take future work to better untangle the transitions between these modes and what prompts them, epistemologically, this opens the door for future investigation of how these modes constitute ways of knowing within the medium of sound.

Lastly, the context of listening *together* means that students draw on many resources to make sense of a song or story's meaning. It is a context where narrative and counter-narrative, personal experience and evidentiary documentation sit side-by-side as legitimate interpretations. This togetherness foregrounds the diverse ontologies, building intersubjectivity and co-constructing a meaning that otherwise—having listened alone, as is often our practice—would be less rich. Initial understandings of the song or story's meaning were complicated and made rich by the context of listening with others. Toward the end of each record, students express an idea of what was learned through listening that is specific to the context in which they listened, namely the meaning constructed between their own listening and the listening of their peers collectively.

A sky full of kites

I am reminded of a county-wide festival that was held near my hometown each year called Art and Wind. Beyond the regular festival offerings of snacks and folk art, the central feature of the day was collective kite flying. Nearly every person at the event had one or more kites: a purple octopus, a rainbow, a classic yellow quadrilateral. Flying a kite was its most fun when yours was one of thousands dotting the sky with fantastic color, all of them sweeping about like dancers in the air. The visual impact of seeing the kites together was the main attraction for Art and Wind Fest. With listening, I believe the same may be possible. Listening is a practice that stretches us outside of ourselves, to attune our hearing to the sound around us and make meaningful connections to what we hear. The main event could very well turn out to be how powerful it is when we reflect on our experiences of listening in a social context, when we listen together.

Abstract: The work of ecologists entails structuring variability by parsing random and directed variability. Middle-grade students are often introduced to ideas about probability and statistics in mathematics, but these ideas are rarely employed in science investigations. This paper reports on a design study in one 7th-grade science classroom that participated in a citizen-science project investigating changes in invasive crab populations. Students surveyed crab abundance at one field site, contributing observations to a citizen-science database. Finding an unexpected ratio between male and female crabs in their sample, students compared the ratio obtained in the field to a simulated sampling distribution of ratios in light of an equiprobable assumption. Finding that their sample's sex ratio was improbable yet consistent with samples in the larger database instigated a search for ecological mechanism. Evidence of student thinking in classroom conversations point to seeds of distinguishing random from directed variability.

One fundamental task in ecological investigations is to understand the abundance and distribution of organisms across space and time. Abundance and distribution of organisms is not uniform across space and time as species vary, individuals within a species vary, and environmental gradients vary. Distribution-generating processes include random (e.g., genetic recombination or small fluctuations in temperature) and causal mechanisms (e.g., organism-environment interactions, organism-organism interactions, seasonal variation in temperature). Additionally, ecological sampling inevitably introduces chance variability: repeated samples vary just by chance. Sampling is key in ecological investigations as ecological processes occur across multiple spatial and temporal scales, making a census approach impractical. Teasing apart variability due to chance and variability due to other underlying patterns and processes is a messy but critical activity in ecological investigations (Albert et al, 2010). This critical activity is often hidden from students' view. Conceptual underpinnings for understanding variability and changes in ecology and evolution take time and coherent forms of support to develop. Students from younger ages need repeated opportunities to encounter and build on these foundational ideas (Lehrer & Schauble, 2012). This research addresses ways of supporting the development of foundational ideas about variability and change in ecosystems by positioning students as participants in classroom approximations of professional ecological practices, particularly those of visualizing, measuring and modeling variability in ecological investigations.

Research Context & Design

The work reported here takes place within a larger, multi-year design-based research study investigating how students' conceptions of and practices for representing variability inform their construction and revision of models of ecosystems, and how students come to view the function and utility of the ecosystem models they have constructed, as well as relations between different models. The context of this work is a statewide middle school citizen science curriculum focused on monitoring and mapping species of interest in the Gulf of Maine intertidal ecosystem with the particular goal of understanding how the relative abundance and distribution of native and invasive species of crabs is changing due to climate-driven factors. In addition to classroom work, students survey native and invasive crab abundance at local field sites and contribute their collected data to a larger database of survey data collected by students up and down the coast of Maine. In this paper we report on the first implementation of a data modeling trajectory co-designed with two middle-school science teachers. Our design focused on cultivating an appreciation of the role of chance in sampling so that as students collected and analyzed samples during their citizen science investigations, they had the means to account for uncertainty due to chance in their observed samples, and in this light, to anticipate when sample variability indicated a need to search for an ecological mechanism.

Instructional design

This instructional design builds on a data modeling perspective (Lehrer & Romberg, 1996). This perspective positions students as participants in approximations of statistical practices in professional science, especially those of visualizing, measuring, and modeling variability (Jones et al., 2017; Wild & Pfannkuch, 1999). Conceptual and representational cornerstones of these practices include mathematical descriptions of distribution and mathematical models of chance. These cornerstones in turn support model-based inference in light of uncertainty due to chance variability.

School curricula often allocate topics in probability and statistics to mathematics. Ideally, students come to science classrooms equipped with mathematical tools that they can utilize in science investigations. However, probability and statistics are often treated separately, and students may not meaningfully connect them in a way that this otherwise connected network of concepts and practices can readily be employed in service of scientific inquiry (Konold & Kazak, 2008; Moore, 1990). In this work, our instructional sequence aimed at both supporting students to develop mathematical means for visualizing, measuring and modeling variability while simultaneously advancing their scientific investigations (Lehrer, Schauble & Wisittanawat, 2020).

Prior instructional sequence: Visualizing and measuring variability

Prior to the instructional sequence that is the focus of this paper, we first supported students in developing ways of visualizing and measuring variability by challenging them to invent displays of data that they had generated. Students as novices to visualizing and analyzing data tend to focus on individual cases (e.g., the biggest crab or the crab they personally found) rather than on the aggregate (Konold et al., 2015). To support students to extend the view of data as mere cases to also encompass the view of data as an aggregate of distributed cases, we asked students to invent data displays that highlight characteristics (e.g., center and spread) of the data aggregate. Constructing data displays provided students opportunities to consider how to order, group and organize data, leading to structuring data as a distribution.

We searched for a candidate task (Lehrer & Schauble, 2021) in the invasive-crab investigation. That is, we searched for a task that provided opportunities to capitalize on children's conceptual resources in ways that would potentially support both the development of statistical practices and students' current scientific investigation. In this citizen-science investigation, students would record data of sizes of crabs found during their field survey. Prior to the field visit, students practiced measuring the size of a classroom's crab in residence (from their classroom's saltwater tanks). We posed the question: *How big is this green crab?* Each student measured the same crab and recorded their measurement. We then combined class measurements and provided groups of students with a copy of the class's batch of data. We asked students to develop displays of their class's measurement data to help other people quickly see what the crab's size really was. Consistent with prior work (e.g., Lehrer, Kim & Schauble, 2007), students generated different types of displays. The displays differed in how cases were grouped (e.g., no groupings, groups of same/similar values, groups of same size), how cases or groups of cases were ordered (e.g., by value or by frequency) and how cases were organized in relation to each other (e.g., on a consistent scale or not).

Next, we supported students to invent or use measures of center by posing the question: *What is our best guess of the crab's size given our class's data?* Students had already learned different measures of center, namely mean, median and mode, and they made use of these measures as estimates of the actual crab's size. To support students to invent or use measures of spread, we posed the question: *How precise were our class's measurements?* Here, students used range and interquartile range (and other similar invented measures that described the size of the middle or the biggest clump). Students also measured the same crab a second time, this time following a standard measurement protocol for measuring crab sizes—measuring the widest part of the carapace. This second data set invited comparisons between two data distributions and provided a situation for a test for robustness of measures of center and spread (e.g., whether changes in measures reflected changes in distributions). In this instructional sequence, students first invented both data displays and measures on paper, and we later introduced a digital tool, the Common Online Data Analysis Platform (CODAP), to facilitate future work with data.

Focal instructional sequence: Modeling sampling variability

The remainder of the paper focuses on this next phase of instruction. In this section we describe the tasks, tools, and rationale comprising the anticipated instructional sequence. In the Findings & Analysis section, we describe the enacted instructional sequence.

With ways to visualize and measure variability in hand, we aimed to extend students' conception of variability to include the role of chance. Again, we searched for a candidate task that served as an entrée into modeling chance processes within the context of the invasive-crab investigation. From the existing large citizen-science data set, we learned that school groups often found sharply unequal ratios between the number of male and female crabs in their quadrat surveys, with the majority finding more males than females. Across four years (sample sizes between 127 to 311 crabs), the sex ratios ranged from 68%-75% males. Across 19 field sites (with more than 10 crabs found in quadrats), the majority of them (17) sites reported more males, ranging from 56%-92% males. The other (2) sites reported more females (42% males and 45% males). We thus anticipated that in their upcoming field trip students would likely find an unbalanced sex ratio of the crabs in their quadrats, and most likely vastly more males than females. As in any ecological sampling, students' observed sample outcome would need to be considered in light of sampling variability. The key question we worked to support students to consider was as follows: *How likely could our sample's observed sex ratio occur just by chance?*

To consider this question, students first needed to develop a grasp for the structure of random variability. Individual outcomes of a random process are uncertain, but outcomes of long-run, repeated random process exhibit structure in the aggregate. We supported students to develop ideas about the structure of chance variability by engaging them in examining behaviors and outcomes of random devices (here, a physical and later digital spinner). We asked pairs/groups of students to conduct an experiment by spinning an equal-split "male-female" spinner 10 times. Students recorded the number of males per 10 spins and repeated the experiment to collect a total of 10 samples of 10 spins. We planned to have each pair represent the results of these 10 samples (each of which was comprised of 10 repetitions of the equiprobable process) as a dot plot of a sample statistic (the number of "males."). Our conjecture was that this would help students start to consider sample to sample variability that could be attributed solely to chance. Next, we planned to ask students to predict shape, and statistics of center and spread of a distribution constituted by growing the number of samples to include all those generated by every pair. The aim was to promote a conception of potential structure in a sampling distribution corresponding to elements of the variability-generating process (i.e., a center statistic representing the signal of its equiprobable structure and a statistic of variability that could be attributed to the randomness of the process and the sample size). Students would then organize the sampling distribution, examine its shape, and reason about the relations between the structure of the spinner and the shape of the sampling distribution. We planned then to introduced a digital spinner (in CODAP) as a way for students to explore effects of sample sizes on sampling distributions.

Next, we planned to ask students to use a (digital) spinner to construct models that represented a situation where there was roughly the same number of male and female crabs in the ocean. Students would then use the models to simulate repeated sampling of a sampleof crabs equal in number to that collected in the field. Based on the model-generated sampling distribution, students would consider how likely their observed sample's sex ratio could occur just by chance. Asking students to make inference about the sex ratio of crabs in the ocean, we anticipated that students would suggest collecting more data, especially if their observed outcome was unlikely to occur by chance. This would then motivate further exploration of the larger citizen-science data set to consider whether other school groups also found similar outcomes as theirs. As mentioned earlier, the sex ratio in the large data set skewed towards males. We would engage students in the discussion on whether and how they wanted to revise their chance models given new information they gained from exploring the larger data set.

Analysis & Findings

We reviewed fieldnotes and video recordings of classroom conversations with an eye towards how students constructed and revised models of chance to represent random variability in the crab sampling process. We attended to key moments in classroom conversations when students modeled random variability, and how students' emerging conceptions of and practices for representing variability supported their reasoning about the ecological system under investigation.

Exploring local data

Students surveyed invasive crab abundance at a state park near the school and catalogued twenty-six crabs found in 16 1-m^2 quadrats sampled along a 60-meter transect. Field protocols specified identifying species of all surveyed crabs, measuring carapace length, recording the number of claws, and identifying sex. Students' exploration of their own sample revealed, as anticipated, a curious outcome: twenty-three of the twenty-six crabs were male, a "wild ratio" of 88% male to 12% female, as noted by the students. Although the outcome was

 © ISLS

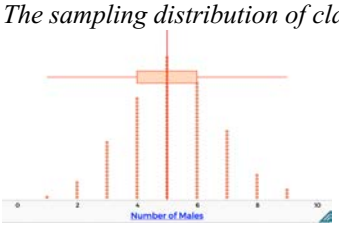
surprising to students, they readily inferred characteristics of the entire population from their single sample. For example, students suggested that the male crabs were "overpopulating" the female crabs, that female crabs were "not surviving very well," and that the overall population of invasive crabs was actually *declining* due to a shortage of female crabs. The classroom teacher, Ms. S., pivoted student attention away from the sample at hand and invited them to imagine other possible samples. She asked, for example, whether it was possible to collect a sample with 88% males and 12% females just by chance? And, if we collected a second sample, could the sex ratio be 50/50? Students considered the "odds" of finding the same ratio of male crabs to female crabs in a second sample unlikely but also suggested several sources of natural variability which might have influenced their outcome including the time of day, the water temperature, and the protocols themselves (sampling the intertidal zone only versus sampling both the intertidal and the subtidal zones).

Examining chance variability with random devices

To consider the structure of variability in a repeated random process, students conducted experiments with random devices. Student groups conducted an experiment, collecting 10 samples of 10 spins on an equipartitioned Male-Female spinner as a way to simulate outcomes of repeated samples of 10 crabs. Each group made a distribution of their sample outcomes, and the teacher collected outcomes from all student groups to make a sampling distribution of 150 samples of 10 spins. Before examining the distribution, the teacher asked students to predict its shape. One student predicted a "hill in the middle," suggesting there could be a few outliers, but most outcomes would be "compacted to the middle." Another student thought the distribution would clump around 5, because the outcomes of his groups' 10 samples also clustered around 5 and included no outcomes of 1, 2, 8, or 9. A researcher asked if they expected more extreme outcomes in the 150-sample sampling distribution. The students thought there would be more extreme outcomes, but concluded most outcomes would still be in the middle. When Ms. S. showed students their aggregate sampling distribution, students noticed that their predictions bore out. Students noted that, as they predicted, "you can see...a clear hill and that five is the median and also the tallest." Additionally, students observed that extreme outcomes, such as 9 males, only happened 3 out of 150 times.

Figure 1

The sampling distribution of class's 150 samples of 10 spins on a 50M/50F spinner



Ms. S then introduced a digital spinner in CODAP, a resource she now framed as a "statistical tool" that expedited explorations of chance processes. Ms. S asked students to predict what happened if they ran the same experiment again, collecting 150 samples of 10 spins. Students predicted that the simulated sampling distribution would look similar to the one produced using hand-held spinners. Ms. S. ran the model while students watched, with much anticipation, in real time as the sampling distribution took shape and saw that the general shape of the distribution was similar to the previous one generated by physical devices. Ms. S then invited a student volunteer to draw on the whiteboard what the shape of the distribution might be if they were to continue the experiment and collect 150 more samples. The student drew a shape that traced the current distribution with a central clump around 5 (or 50%) males, and similar spread. Again, Ms. S. ran the model while students watched in real time as the sampling distribution took shape and saw that the general shape of the distribution did not change.

Using random devices to model chance variability in our crab sampling

Having explored chance variability, the class now turned to consider their own observed sample in light of chance variability under the assumption of equiprobable sex ratio. Ms. S focused her students to the question at hand: *How likely could our sample's observed sex ratio occur just by chance?* She then asked students to return to the digital spinner and to use the spinner to help them answer the question.

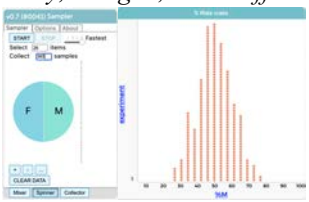
Running their models, students noticed that more extreme outcomes, such as 80% or 90% males, were even less likely with this larger sample size of 26 crabs. For example, during small group work, Anna's model collected 150 samples of 26 crabs using a 50M/50F spinner, and she noted that her model produced no outcomes "over 80 or under 20 [percent male]." A researcher asked Anna if her model's outcomes made her think differently

about how likely the class' observed outcome of 88% male could occur just by chance. Anna responded, "It makes me think that's it's even less likely. Like, I was thinking before that it probably was just by chance when we were [modeling] with 10 [crabs], but with 26 [crabs] it shows that it's even less likely because I didn't even get one point that was above 80 [percent male]."

In the subsequent whole class discussion, other students shared their models and similar observations as Anna's. Lacey, Morgan, and Griffin built a model they described as simulating the collection of "26 crabs a day every day of the year," that is, they used a spinner of 50M/50F and ran 365 samples of 26 spins (Figure 2). Ms. S asked the group about their outcomes:

Figure 2

Lacey, Morgan, and Griffin's model for collecting 26 crabs a day every day of the year



1. Ms. S: On any of those 365 days would we have had a day that we found 90% male crabs just by chance?
2. Lacey: Nope.
3. Ms. S: Really, not a single time in your model?
4. Lacey: Yes.

Having established with the class that outcomes like their observed outcome of 88% male rarely occurred in their simulated sampling distribution, Ms. S asked the class to consider:

5. Ms. S: What does this tell us about the likelihood of getting 88% male at [our field site]? Do we still think that could be attributed because of random chance or are we more convinced there might be something happening?

Ms. S's wondering invited a few students to propose ideas for revising the structure of the spinner to reflect a different sex ratio. Ben wondered if the "actual real" ratio was something different than 50/50, and suggested a ratio of 60 males to 40 females. Denver agreed, excitedly interjecting that he had been "trying to [share] *every single day,*" that there could be more male crabs than female crabs in the ocean. Some students wanted to investigate Denver's claim by going back to the field and collecting more data, with Caleb suggesting, "collecting every crab in the ocean." Other students thought they could first investigate by revising the chance model to reflect class members' guess that there were more male crabs. One student suggested making the spinners 4 slots males, and 3 slots females.

Exploring citizen-science data and revising models

In the following class, Ms. S. revisited students' earlier suggestion to revise the structure of the spinner and solicited the class for proposals for how to revise. Recalling Denver's exasperated statement at the conclusion of the last lesson, Ms. S. invited Denver to restate his proposal. Denver had consistently proposed that "there could just be more male crabs," and he now guessed the ratio to be "65 male, 35 female." As an alternative hypothesis, a researcher proposed maintaining the 50/50 spinner because that was the case for most animals and it was possible that crabs were incorrectly sexed during the field survey. Ms. S., on the other hand, proposed revising the spinner to resemble their observed sex ratio, citing "We practiced the protocol, we did a good job in the field, it's definitely 88% males." The teacher drew each of the proposed spinners—65/35, 50/50 and 88/12—on the whiteboard, and asked the class to discuss which one they wanted to put their votes behind. A handful of students thought it could still be 50/50. Most other students disagreed, however, but were unsure what the ratio should be:

6. Ben: I agree with Denver because I think the [50/50] spinner was inaccurate. I think what we should have is we should have 65 percent of the [spinner] be covered with males, and then 35 covered with females. I think that might be more accurate to our data. We found 88% males, it would just be crazy to find that on our first try if it was really 50/50. I don't think it's 88% males all the time because they would have trouble reproducing.
7. Denver: I agree with Ben, like, when we did the 50/50 spinner, we almost didn't have it up towards 90%, so I think that there's just going to be more males than females out in the ocean.

 © ISLS

8. Anna: I agree, but I don't [know] if it's like the whole ocean has more male than female crabs, it might just be at [our field site]. I definitely think the number of male crabs to female crabs is more than 50/50.

In this exchange, students recalled the outcomes from the equiprobable model (e.g., "almost didn't have it up towards 90%") to argue the equiprobable assumption was inaccurate. At the same time, students were not convinced that the overall sex ratio could really be 88/12 as the crabs "would have trouble reproducing." Other students started to wonder whether their field site was exceptional in some way. As the class was leaning away from 50/50, but also away from 88/12, the researcher made connections to other students' ideas about other ways to find out what the sex ratio might be:

9. Researcher: I've also heard [another] idea, that we could just measure every crab in the ocean. But I'm wondering, is there another place we could look for the kind of data you're craving, Denver?
10. Denver: Well, there's all those other schools that went to those other beaches and we could see their data.
11. Researcher: And what could we do with their data?
12. Denver: We could see if it's close to ours because we found 88% males. If they found 85% males, we know that it's going to be close to more males than females.

As it was not feasible to "measure every crab in the ocean," the class followed Denver's suggestion and consulted "all the data from the other schools" by exploring the large citizen science crab survey data. Here, students also explored trends in sex ratio in relation to sites, time of year, shell conditions, etc. Through their explorations, students also determined the overall sex ratio (of 902 green grabs collected in the intertidal along the coast of Maine) was 71% males and 29% females.

Ms. S posed a challenge: "How could you revise your model to be a better representation of what we think is going on in the intertidal?" Students sketched their ideas for a revised spinner on paper, mostly drawing either a 71/29 spinner or an approximation of it (e.g., 70/30). The class agreed on revising the spinner to 71/29, and before running the model, several students predicted that, now that the structure of the spinner was 71/29, it would be more likely to get a sample of 88% males compared to the previous run with a 50/50 spinner. Because this model was difficult to accomplish on the spinner in CODAP, the class's revised model had to be run on a central computer using TinkerPlots (Konold & Miller, 2011). The 71/29-spinner model was projected on the board and the first sample of 26 spins was collected:

13. Ms. S: We got 66% [males], what should we do now?
14. Griffin: Run it again.
15. Ms. S: Run it again! How many times?

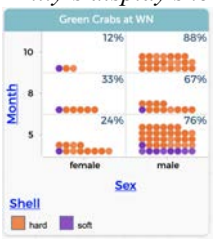
Students suggested running the model more times. This suggested a shift from viewing a single outcome as isolated to viewing an outcome as part of a long-run repeated random process, a shift foundational to understanding the structure of chance variability (Konold, 1989). Students were still developing a sense for how "long" the "run" needed to be, however, and only collected a relatively small number of samples. In response to the teacher's question, one student suggested collecting as many samples as the number of times middle-school students across the state went to collect samples in the field. The class took up that suggestion, and collected 70 samples, i.e., the number of field trips in the data set. As the model was running, the teacher asked the class to consider what the sampling distribution might look like, and students predicted the middle clump would be in the 70s. The resulting sampling distribution had a clump around 70% males, as students had predicted, and it included outcomes in the 80's and 90's, which rarely (or never) occurred in the sampling distribution generated under the equiprobable assumption. This led the class to conclude that their sample was consistent with the overall sex ratio in the larger data set.

Exploring mechanisms for sex ratio differences

Having established that their observed sex ratio was consistent with the overall sex ratio in the larger citizen science data set, the class now searched for possible mechanisms to account for this disparity between the sexes. Earlier, students had explored different data sets: their own field data, data from their site, and the multi-site citizen science data. In their explorations, one student, Emily, discovered an interesting pattern in the number of soft-shell crabs by sex at their field site. Ms. S. shared Emily's CODAP display (Figure 3) with the class, and students noticed that while there were more male crabs across the months, the percentages of male and female crabs surveyed were also changing. In particular, students noticed there were more female crabs found in May and August compared to in October (when they surveyed the site).

Figure 3

Emily's display showing shell hardness by sex and time of year



Ms. S revoiced many students' noticing that the sex ratios appeared to be changing from month to month and asks the class why the ratios might be changing. She notes, "We saw this in our data. … Why would this pattern exist *over the course of the year*?" Students considered variables such as temperature, as well as how molting cycles might influence foraging and refuge-seeking strategies:

16. Denver: We were thinking that it might be because of temperature but we were also thinking that if they're soft shells, they might want to hide and not be on the beaches.
17. Ms. S: Totally, what have we seen in our own tanks, do soft shells last very long? Unfortunately, no.
18. Bella: We thought that maybe it's because of the season, because the most male crabs were in colder … Like [August] and there were very few [male crabs] and that's like summer. And in October, it's colder.

Anticipating connecting students' ideas to scientists' account of the mechanism driving seasonal sex ratios, Ms. S. introduced a video clip of a conversation among the partner scientists on the citizen science project as they interpreted data on crab's sex ratios. Ms. S asked students to listen for explanations for why they see more males than females, and why those ratios "vary so much throughout the year." In the video, the scientists are considering a graph showing the percent male and percent female by year and county.

19. Ms. S: What have we heard so far?
20. Madison: It's mostly because of the molting that we don't see many females. We checked only in the Fall and that's when females go and hide and males are hard shells and don't need to hide.

Ms. S. called attention back to the question the class had been considering: Are there really more males or are the females just harder to find? She notes that the molting cycles, as Madison has suggested and that Emily investigated in their site data, have helped them think about "one part of our question: maybe the females are just hiding more and we can't find them." But she immediately followed this statement by asking "Or maybe there are just fewer of them?" In the video, the partner scientists consider this same question: Are males more easily observed in the Fall or are there more males in general during that time of year? The scientists discuss both movement and habitat preference as possible causes. However, the scientists conclude that this question is still not well understood, something Ms. S. calls attention to to make explicit the epistemic game they, and the scientists, are playing as well as the broader purpose of the citizen science project itself.

21. Ms. S: What did we hear there? Do we know for sure? Are there actually fewer females or are they harder to find?
22. Griffin: They're just harder to find. The males are molting in the spring and summer, and the females molt in the Fall and are harder to find in the Fall.
23. Ms.S.: And even [our scientist] isn't totally sure because they're harder to find or because there are actually fewer of them. So, we don't have a definitive answer and that's the point of all of this [citizen science], so that we can help [our scientist] get to the bottom of this.

Discussion

Ecology is both a challenging and fruitful context for supporting distinctions between random and directed variability. It is challenging because variability-generating processes in ecology occur across temporal and spatial scales that are not immediately tangible to students. Yet, when students have a hand in construction of samples, their direct experience in a sampling process supports their image of long-run repeated process (e.g., running the model to simulate visiting the field every day), and how their decisions about sampling can influence their outcomes.

In this iteration of our design study, we supported students in visualizing, representing, and modeling variability in the context of a citizen science ecological investigation. At the beginning of the focal instructional sequence, students did not consider their observed outcome in light of sampling variability. This was evident in

how students immediately made inferences about crabs in the ocean from their single sample before they considered whether such a sample could be explained by chance. We supported students to consider how likely their observed sample could occur just by chance. Students' developing ways of representing and modeling sampling variability supported them to reject the earlier equiprobable assumption. Students then revised their model to consider whether their observed outcome was consistent with data collected by other schools in the citizen-science data set. Finding that their outcome was consistent with the larger data in turn motivated their search for plausible mechanisms that explain the observed difference in sex ratio.

The current study suggests two potentially fruitful areas for future iterations. First, we can further investigate students' connections to and use of publicly available data. The learning sciences community seeks a vision of Data Science education that is "grounded in consequential investigations in which learners pose questions, obtain data, and communicate findings within meaningful disciplinary contexts" (Wilkerson & Polman, 2020, p. 3). Grounded in consequential investigations, students can use and develop data science tools and methods to employ public data in purposeful ways. Here, we saw evidence of students making connections from their local investigation to publicly available data to further their investigation. Second, we elaborate and extend our instruction design to address relations across different forms of models, and we saw evidence of this practice emerging in this classroom. For example, when students noticed patterns on molting in the large-scale data, the teacher made the connection to their classroom microcosms which had emerged as a site for studying predation avoidance in relation to foraging and refuge seeking. We continue to consult our partner scientists, who employ field study and microcosms to craft models of climate impacts on intertidal ecosystems, to consider how students' inquiry can be supported to coordinate field and microcosm study to get a grip on sources of variability and change in these systems.

The effect of different sequences of examples and problems on learning experimental design

Eman Ganaiem, Ido Roll
Ganaiem.eman@gmail.com, Roll@technion.ac.il
Technion – Israel Institute of Technology

Abstract: Example-based learning refers to a pedagogy in which learners are provided with a step-by-step solution to novel problems early in the learning process. Worked examples are most effective when used in tandem with open problems. However, there are still questions regarding the ordering of examples and problems. We compared the effect of sequencing examples and problems on learning and cognitive load. One hundred thirteen middle-school students were randomly assigned to one of three conditions that varied presentation order within each example-problem pair: example first, problem first, or simultaneous presentation. We evaluated students' performances on knowledge application and the transfer of learning on the topic of experimental design. We found no effect neither on learning nor on cognitive load. We compare these results to parallel studies in the literature and identify possible reasons for the null effect.

Introduction

Worked-Examples (WE) is a teaching approach in which students are invited to study the problem formulation, its solution, and the steps leading to this solution prior to receiving open problems to solve (Renkl, 2005). Studies show that for novices, WE improve learning and reduce cognitive load (Gerven et al., 2002; Sweller et al., 2011; Van Gog et al., 2006). Optimal use of WE interleaves them with Problem-Solving (PS) in which learners apply the taught procedure to a new problem (Renkl, 2005; Sweller & Cooper, 1985). Alas, while the benefits of using WE and PS are well documented, results about the timing of WE in relation to PS are inconclusive.

The question of sequencing WE and PS is an interesting one, as it helps clarify (and optimize) the role of examples in learning. Which element within each example-problem pair should be introduced first? One option is to provide learners with WE prior to PS. The rationale for this sequence is allowing learners to devote their cognitive capacity to studying the worked-out solution procedure and construct a cognitive schema for solving similar problems (Sweller & Cooper, 1985). Another option is to introduce PS prior to WE. The rationale for this sequence is that providing challenging questions to learners prior to instruction was shown to better prepare them for future learning from subsequent instruction (Loibl et al., 2017; Sinha & Kapur, 2021). The third option is to present WE and PS simultaneously. The rationale for a parallel presentation is that when learners are challenged with a particular problem, giving an example in parallel could guide them in the solution process, thus could help them develop strategic knowledge. This approach is based on the analogical reasoning literature (Gick & Holyoak, 1980; Renkl et al., 2013).

The current study explores the effects of different sequences of examples and problems on knowledge application, the transfer of learning, and cognitive load. We do so with middle-school students learning about research competencies and focus in particular on learning how to design experiments. To date, most studies of WE have focused on topics such as physics and mathematics (cf., Renkl et al., 2013; Salden et al., 2010). To the best of our knowledge, the effectiveness of this approach to learning research competencies has yet to be studied.

Theoretical framework

Worked Examples

WE include the problem itself, the steps of its solution, and the final answer (Atkinson et al., 2000). Empirically, learners who receive WE followed by PS performed better than learners who receive problems only (Renkl et al., 2013; van Gog et al., 2011). Learning from WE allow learners to form problem-solving schemas that are stored in long-term memory, and these schemas can later be retrieved when solving related or advanced problems (Sweller, 2006). In addition, WE reduce students' cognitive load compared to PS (Sweller et al., 2011; Van Gog et al., 2011).

The WE effect is particularly strong for novice learners (Kalyuga et al., 2001). Example-based learning may become redundant for students with a higher level of prior knowledge as they no longer need the guidance

 © ISLS

provided by WE (Kalyuga et al., 2001). This effect is commonly referred to as the Expertise Reversal Effect (Kalyuga et al., 2003; Salden et al., 2010).

Most research on WE has been done in well-structured domains such as mathematics, physics, and programming (Glogger-Frey et al., 2017; Renkl 2013; Salden et al., 2010). Recent studies show the impact of the WE also in less structured domains such as writing, literacy, and music (Kyun et al., 2013; Nückles et al. 2020; Owen & Sweller, 2008). However, the effectiveness of this approach to learning research competencies has not yet been studied.

The combination of WE and PS

In recent years, extensive research has documented the beneficial impact of the combination of WE and PS on learning (Renkl, 2005; Sweller & Cooper, 1985). However, there is still uncertainty regarding the timing of providing WE in relation to PS. Should the WE be provided before, during, or after the PS? Results vary, and sometimes conflicting results were found by the same researchers. For example, Van Gog et al. (2011) found that WE before PS is most effective for learning, but several years later received different results showing no effect for order (Van Harsel et al., 2020). Similar null results were also reported by Chen et al. (2020). Reisslein et al. (2006) reported a more nuanced finding, where low-prior knowledge students benefited from example-problem pairs, while high-prior knowledge benefited from problem-example pairs. There are strong rationales for the benefits of each sequence:

PS before WE (PS→WE)

When starting with PS, learners search for ways to solve the problem without having sufficient knowledge. While learners may experience this order frustrating, studies show that grappling with novel problems supports learning from subsequent instruction (Chowrira et al., 2019; Sinha & Kapur, 2021). This sequence of PS followed by Instruction (such as WE) is commonly known as PS-I (Loibl et al., 2017; Sinha & Kapur, 2021). These early solution attempts facilitate activation of prior knowledge and recognition of the deep features of the problem, thus preparing students for future learning (Loibl et al., 2017; Sinha & Kapur, 2021). PS-I instruction especially improves students' ability to transfer the taught knowledge, for example, when learners are asked to correct a given faulty model (Holmes et al., 2014). In addition to these cognitive benefits, several studies suggest that initial WE can increase learners' motivation as well as their focus on the unsuccessful steps (Hausmann et al., 2008; Reisslein et al., 2006). However, to be effective, learners need to be able to diagnose their own attempts, which may not be the case with complex skills such as experimental design.

WE before PS(WE→PS)

Presenting WE followed by PS follows a teaching approach known as Scaffolding (Tropper et al., 2015). Scaffolding refers to providing students with support during early stages of learning before removing support and shifting the responsibility to them (Jumaat, 2014). In the context of WE and PS, providing learners with WE before they attempt the problem can equip them with resources to draw upon as they construct their answers. WE have been shown to reduce the demands of complex problems while allowing students to construct their own knowledge schemas (Sweller et al., 2011).

There are several reasons for the advantages of a scaffolding approach for teaching experimental design. The initial use of WE gives learners the opportunity to acquire the correct processes and knowledge, thereby reducing the probability of mistakes and misconceptions (Nigam & Klahr, 2004). In addition, when learners lack the knowledge necessary to solve a problem, they may solve the problems through resource-intensive processes such as trial and error, which increases their cognitive load (Atkinson et al., 2000). However, this approach may be less effective, especially for students with high prior knowledge (Reisslein et al., 2006), for which learning from examples can be ineffective or even impair the learning process (Kyun et al., 2013). In addition, and according to Cooper and Sweller (1985), learning from WE may not support skill transfer to other topics, a crucial feature in learning about experimental design.

Concurrent presentation of WE and PS

Learning from WE and PS is essentially a process of Analogical problem-solving (Gick & Holyoak, 1980), as learners identify key elements in one domain using a source problem and transfer these to a parallel (yet seemingly very different) target problem. The analogical processes are fundamental to human cognition and learning (Gentner, 2010). However, mapping targets on sources is challenging even across short time periods (Gick &Holyoak, 1980; Cushen et al., 2018). To optimize this transfer, one may present the source and the target side by side (Ngu & Phan, 2021). This presentation can support the mapping process and reduce cognitive load. On the other hand, providing a single WE based on a single solution may lead learners towards a single solution

process rather than considering alternative solutions. Furthermore, parallel presentation of source and target may encourage a rote process of read-and-apply, without in-depth encoding of the solution process that supports future independent performance (Pol, 2008).

The present study

As presented above, despite substantial research on example-based learning, the sequences of PS and WE remain an open question. In addition to both types of sequential presentation, as far as we know, no studies to date have contrasted the traditional sequencing with a parallel presentation of PS and WE. The present study aims to investigate the effect of different sequences of examples and problems on novices learning research competencies, a topic that has yet to be studied in WE research. Specifically, we address the following two research questions: RQ1) What is the effect of the sequence of WE and PS on learning, as assessed using application and transfer items? RQ2) What is the effect of the sequence of WE and PS on students' cognitive load during the learning process, as reported by the learners?

Method

Design

We evaluated the three approaches using a pre-treatment-post experiment. The topic of the study was experimental design, as it covered learning outcomes that are required by the curriculum presented by the Israeli ministry of education for seventh-grade students. The curriculum emphasized aspects that students need to consider, such as fixed factors, sample size, control group, measuring a dependent variable, manipulating independent variable and repetitions in a specific context.

Participants

214 seventh-grade students from two Arabic-speaking schools in Israel began the study. All Arab schools in Israel are run in Arabic, and only Arab students attend them. The study ran during the last few weeks of the school year (with a post-test being administered during the last week of classes) and thus suffered a high attrition rate. Our inclusion criteria were that a student had attended school during the study and completed at least half of the activity in the training phase to be included in the analysis. This leaves us with 113 participants overall. There was no relationship between condition and attrition (WE first: 74 students began the study, 40 completed it; PS first: from 68 to 38; PS in parallel with WE: from 72 to 35). To maintain anonymity, students were assigned an arbitrary code on their participation form and the exam.

Procedure

The experiment took three days, with a week between each two days. During Day 1, students were administered a pre-test and confirmed their participation. A week later, during Day 2, participants were randomly assigned to one of 3 conditions: Example-Problem pairs (n=40; WE→PS), Problem-Example pairs (n=38; PS→WE), or an example and a problem in parallel (n=35; WE || PS).

Each participant was given 2 sets of WE-PS pairs. The only difference between the three conditions was the order within each set. After finishing each set, a cognitive load rating scale was administered. Each task had a limited time to finish (see table 1). During the learning phase, there was no intervention by the researchers, and the tasks were solved individually by participants under the supervision of the teacher and the researcher. The post-test was administered a week after the learning phase.

Table 1*: Task Order by Condition in the Training Phase*

Condition	Set 1 (30 minutes)	Cognitive load rating scale (1 minute)	Set 2 (30 minutes	Cognitive load rating scale (1 minute)
WE→PS	WE_1-→PS_1		WE_2→PS_2	
PS→WE	PS_1→WE_1		PS_2→WE_2	
WE || PS	WE_1PS_1		WE_2PS_2	

Materials

Pretest:

The pre-test consisted of one question that asked the students to design an experiment for a given research question with one independent variable and one dependent variable (see Figure 1). The test was analyzed using a multidimensional rubric, as described in the Analysis section.

Figure 1: *The Pretest Question (translated from Arabic)*

16:8 intermittent fasting is a form of time-restricted fasting. It involves consuming foods during an 8-hour window and avoiding food, or fasting, for the remaining 16 hours each day. the effect of this diet on the hormone leptin, which is responsible for the feeling of satiety in the body, is not yet clear.

Design an experiment that would examine the effect of this diet on participants' leptin levels.

Learning materials

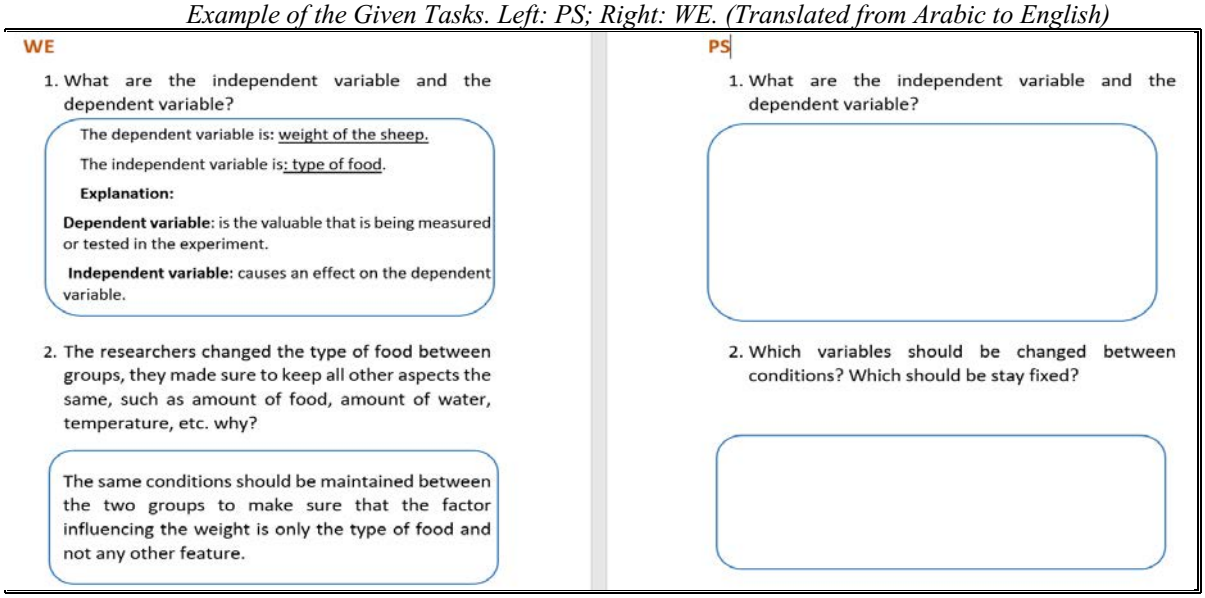
Learning materials were identical across conditions. The learning materials included two sets of WE-PS pairs. The first set included cover stories with categorical independent variables, and the second set included cover stories with scale-independent variables. Within each set, the PS and WE problems were aligned in terms of their content, questions, and topics (see figure 2). The only differences between the WE and PS in each set were (i) the cover story, (ii) whether the question was given with an answer (WE) or without (PS), and (iii) exact values (e.g., 2 groups vs. 3 groups). Each PS and WE problem included 4-5 questions. Each question highlighted a key feature of experimental design, as identified in the Israeli Ministry of Education learning outcomes. The targeted features were: fixed factors, sample size, control group, measuring a dependent variable, and manipulating independent variable. Students were given 15 minutes to solve each task in the 3 conditions.

The cover stories in the first set talked about the effect of types of food on sheep's Weight (WE) and the effect of types of soil on growing plants (PS). In the second set, the first item talked about the effect of grazing hours on the amount of milk produced by goats (WE) and the effect of watering hours on the number of flowers in plants (PS).

In the WE→PS and PS→WE condition, the problems were sequenced so that students first analyzed all questions in their first problem (WE or PS, depending on condition) and then moved to the other problem. In the WE || PS condition, the WE and PS worksheet were presented side by side, with matching items aligned next to each other (see figure 2).

Figure2

Example of the Given Tasks. Left: PS; Right: WE. (Translated from Arabic to English)



Cognitive load rating scale: After each set in the training phase, participants were asked to rate their mental effort during the learning task using Paas's 9-point rating scale (Paas, 1992). This scale is widely used across educational researches (Van Gog et al., 2009, 2011). The scale used by Paas consists of a single item: "doing the preceding problem, I invested...". Responses vary from very, very low mental effort (1) to very, very high mental effort (9). Studies have shown that this measure is an indicator of participants' cognitive load and is sensitive enough to detect small variations in task complexity (Paas, 1992).

Post-Test: The post-test included three items. The first was identical to the item on the pre-test and was analyzed similarly. This item measures the application of the taught knowledge to design a new experiment. Two additional items measured transferability. In one item, students were asked to debug and correct a flawed experimental design (see figure 3a). In the other item, students were asked to design an experiment to a given research question with two independent variables (see figure 3b).

Figure 3: Post-test: *Transfer Items.* (a) debugging and (b) multiple variables

Figure ***3a.***	**Figure** ***3b***.
Jana, a seventh-grade student, claimed that the water we drink contains a lot of microorganisms, and in order to keep the water pure and free of microorganisms, we have to boil it. Her friend Marah wanted to test this claim. Marah brought a glass of water, poured it into a pot, and heated the pot until the water started to boil. She then examined the presence of microorganisms and found none. Her conclusion was that the boiling process killed the microorganism. **The described experiment cannot answer the research question accurately. Specify the error in it and improve the experimental design accordingly.**	Students were discussing the best way to arrive at school in the morning. Several students live in an area close to the school (up to 1 km), others live in the center (1-3 km away from school), and the rest live in an area far from school (over 3 km). Students can walk to school, come by car, or come by bicycle. **Design an experiment that will allow you to determine the best way to get to school.**

Data Analysis

All items were analyzed using a multidimensional rubric that mapped onto the taught features. For each feature, students received a grade of 0 if they neglected to mention it or 1 if they used it correctly. For example, the following answer: *"to have two people, one with diet, one without diet, to check their weight before and after the experiment "*, received 0 for the feature "number of individuals", and 1 for the features "measuring dependent variable" and "control group". The pre-test and application questions included 5 features that were analyzed. The transfer items had 9 features combined. Scores were scaled to 100% on each scale for convenience. 20% of the items were analyzed by the first author and another researcher from the research team. For each of the features, the interrater agreement was greater than 87%, showing a high degree of convergence.

Each student was assigned four values: (i) pre-test score, which was used as a covariate; (ii) post-test application score; (iii) post-test transfer score; and (iv) cognitive load rating, which was the average of the two cognitive load measures (during both sets).

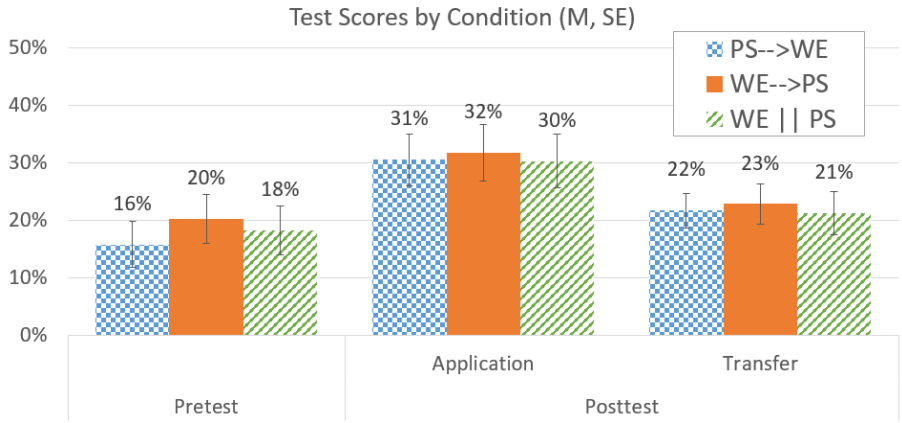
Results

An ANOVA showed no difference between conditions on pre-test: $F(2,110) = .291$, $p = 0.75$. A paired t-test showed a significant improvement from pre- to post-test (application score): from 0.181 ± 0.256 to 0.309 ± 0.289; $t(112) = 4.837$, $p < 0.001$, Cohen's $d = 55$, which correspondences to a medium effect size.

RQ1: Effect on learning.

A 3 (conditions) × 2 (measures) between-subject MANCOVA was performed on two dependent variables: application and transfer scores, controlling for pre-test scores. The Independent variable was condition (WE→PS, PS→WE, WE || PS). There was no significant main effect for condition: Wilk's $\Lambda = .994$, $F(4, 212) = .15$, $p = .963$, partial $\eta 2 = .003$. There was also no significant condition * pre-test interaction (Wilk's $\Lambda = .988$, $F(4, 212) = .315$, $p = .870$, partial $\eta 2 = .006$. Pre-test had a significant main effect on scores: Wilk's $\Lambda = .743$, $F(2, 106) = 18.371$, $p < .01$, partial $\eta 2 = .257$ (see Figure4).

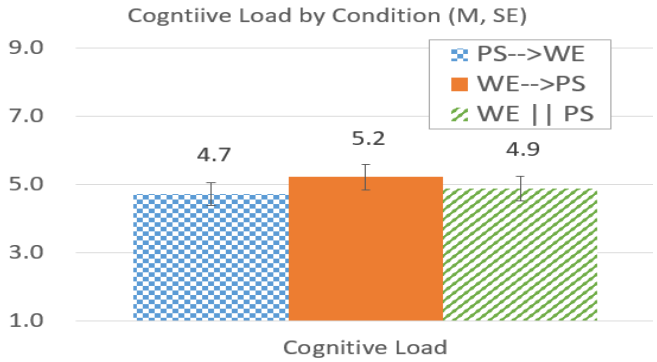
Figure 4: *Pre and Post (application and transfer) scores by condition (M and SE).*



RQ2: Effect on cognitive load.

19 participants had missing values on at least one of the cognitive load measures. That leaves us with 94 participants for this measure. A one-way ANCOVA, controlling for pre-test, found no significant effect for condition: F (2,93) =1.776, P=0.175 (see Figure 5). There was also no significant condition * pre-test interaction: F (2,93) =0.378, P=0.686. Pre-test was a significant predictor of cognitive load: F (1, 93) =4.334, P=0.04

Figure 5: *cognitive load scores in each of the conditions.*



Discussion

The present study investigated the effect of different sequences of examples and problems (i.e., WE→PS, PS→WE, and WE || PS) on learning (as assessed using application and transfer items) and on cognitive load among novices learning experimental design. Results showed no effect for condition on learning nor on cognitive load, and there was no significant interaction between condition and prior knowledge. The question, therefore, is: why was there no observed effect on learning or on cognitive load?

One possible explanation is that the study materials or procedure did not support learning. Furthermore, the post-test was delivered a week following the study, and the short manipulation might not have been sufficient for the effect to carry forward. Alas, analysis found a significant increase from pre-test to post-test, one that corresponds to a medium effect size, regardless of condition. This suggests that the learning materials helped students learn this set of skills without any additional intervention by the teacher or the research team. This also shows that the measurements used in this study were sensitive enough to identify this improvement. Thus, while assessment timing may play a role, we look for a fuller explanation.

A second explanation may be that indeed there is no effect of the sequence of WE and PS on learning each of the studied conditions supports learning by triggering a different cognitive mechanism, thus having its own benefits: scaffolding students, offering opportunities for exploration, or supporting analogical transfer. It may

 © ISLS

be that for this scenario, all approaches are similarly effective. This result echoes earlier findings (Van Harsel et al., 2020; Chen et al., 2021). This is not to say that order never matters, as also suggested by previous results (e.g., Van Gog et al., 2011; Reisslein et al., 2006). Perhaps there are other factors that moderate the effect of the sequence of WE and PS, such as motivation, domain, attitudes, etc. One of these factors may be type of knowledge. Studies that have examined the impact of the order of PS and WE mainly focused on procedural rather than conceptual knowledge. In this study, we investigated the skill of experimental design which is much more conceptual. A study of Chen and colleagues (2021) investigated the effect of types of knowledge comparing different order of WE and PS (WE→PS, PS→WE). Interestingly, also they found that there were no significant differences between WE→PS and PS→WE for learning simple and complex conceptual knowledge. Thus, the interaction of various factors on example-based learning needs to be further studied.

A third explanation has to do with factors specific to this study. One of these is timing. The study ran in June (the last month of the semester), and many students chose not to engage with the study materials. While students who completed the study devoted enough attention to learning the basics, they might not have truly challenged themselves. One indication that this may be the case is the fact that students were far from mastering the skills even on the post-test. This also explains the lack of effect on the measures of Cognitive Load. Self-reported cognitive load was similar across conditions not because instruction had no effect but rather because students regulated (and limited) their effort. Future studies should explore the role that factors such as motivation, interest, and attention play in example-based learning. While certainly not ideal, this aspect highlights the ecological challenges of everyday teaching.

The study has several limitations. One is timing, with post-test being delivered during the final week of classes. Engaging in learning activities during this period is uncommon, which probably affected students' motivation. Another limitation is that this was a single-topic study, and the topic was a challenging one.

Conclusion

A study of different sequences of examples and problems found no effect for order. In this, it adds to the divergent results that similar studies have found over the past few years. Taken together, these results suggest that additional factors that mediate learning from examples and problems should be investigated and studied. It may be that topical factors (such as type of knowledge and complexity), contextual factors (such as timing), and cultural factors (such as school norms and culture, as this was the first WE study in Arabic) affect example-based learning in ways that remain to be explained.

The Role of Epistemic Emotions During Engagement with Online Information Encounters

Christiana Varda, Eleni A. Kyza

Abstract: This exploratory case study aimed to understand to what extent epistemic emotions are connected to effortful engagement when young adults were incidentally exposed to textual information snippets on a simulated social media timeline. Using discourse analysis, we draw on think-aloud data from fifteen young adults, to identify participants' emotional reactions to different textual snippets and to examine when these might prompt effortful engagement, as indicated by reliance on epistemic beliefs, source evaluation, evidence evaluation or science literacy. Our findings provide two important insights. We found that during online information encounters, frustration, curiosity and confusion were co-occurring with effortful engagement and were triggered, in particular, by posts that included negative words. We also found that epistemic engagement occurred even when boredom was verbalized first and was followed by frustration or confusion. We discuss the implications of this work for informal and formal learning environments.

Introduction

The COVID-19 pandemic, and the viral spread of misinformation through social media outlets, highlighted the importance of citizens' critical consumption of information in online social networking spaces, such as Twitter or Facebook. Amidst an information-saturated environment, snippets of information are constantly vying for people's attention on social media. Given growing concerns about people's ability to critically reason with information when the boundaries of accurate and inaccurate information are not always clear, evaluating information online has emerged as a pressing education challenge, which necessitates new approaches that facilitate learning (Chinn et al., 2020), especially for those outside formal education (Lee, 2018).

Our work is motivated by the belief that the learning sciences should increase efforts to understand social media as contexts where learning can potentially happen and investigate how the experiences in such spaces can be scaffolded to afford more opportunities for learning. These inquiries can also help us examine how we can prepare youth in formal educational settings so that they can develop skills to navigate the plethora of information confronting them in everyday social media use outside of formal educational settings. Recent efforts to conceptualize how informal learning happens during incidental exposure to information online (Greene et al. 2020), situate learning in people's routine online *information encounters*, a term we use to refer to the information that individuals are incidentally exposed to while navigating online spaces.

The data we report on are part of a larger study seeking to understand what influences epistemic engagement with misinformation on social media. During online information encounters, people's knowledge, skills and cognitive biases may limit one's ability to evaluate information using appropriate criteria or processes (Barzilai & Chinn, 2020). However, so can emotions (Martel et al., 2020). In prior work with a representative sample of 177 adults, we found that epistemic beliefs were statistically significant when examining sharing patterns on Twitter: participants who held more salient epistemic beliefs about science were less prone to share misinformation. We continue this work by reporting on efforts to understand the role of epistemic emotions during incidental encounters with online information on social media. In this context, we ask if epistemic emotions are manifested during such encounters, and whether they are connected to epistemic engagement.

Theoretical framework

Online information encounters, emotions and learning

Our work draws from research on informal learning on social media and the role of emotions in cognitive engagement. We next present the main arguments from the literature that informs our work. First, we seek to expand our conceptualization of learning to include learning from incidental exposure to information on social media. Even though social media platforms used for everyday communication were not structured with learning

in mind, it has been argued that they hold potential for informal learning (Greene et al., 2020; Greenhow et al., 2019; Tabak & Dubovi, 2021). According to Greene et al. (2020), merely coming across and noticing information online does not necessarily predicate engagement. Instead, they posit that noticing can result in automatic processing, which is unconscious, or deliberate information processing, which is effortful. Effortful activity directed at achieving epistemic aims, either individually or with others, can constitute engagement with information when it is supported by cognitive and motivational processes (Hendricks et al., 2020). This is in line with dual process models of cognition (Evans, 2008) though the place that emotion holds in this configuration is less clear (da Sousa, 2009). Second, we know that emotions play a role in whether individuals choose to process information more effortfully, with the literature supporting that reaching an impasse during information encounters is more likely to result in less engagement (D'Mello & Graesser, 2012), which could potentially lead to endorsing information that is inaccurate. Finally, a growing body of empirical research suggests that epistemic emotions, whose focus is the generation of knowledge (Pekrun & Stephens, 2012), can encourage effortful engagement with information (Vogl et al., 2020). However, less is known about the epistemic emotions that emerge during information processing, which have a knowledge-generating focus (Pekrun & Stephens, 2012), and their connection to learning during information encounters on social media.

Epistemic engagement with online information

Hendriks et al. (2020) posit that ***epistemic beliefs***, ***source evaluation***, ***evidence evaluation,*** and ***scientific literacy*** can support effortful engagement with information. Building on the work of Chinn et al. (2014) effortful engagement with online information is grounded in epistemic practices. During online information encounters, individuals effortfully engage with information when they set epistemic aims, such as seeking knowledge; rely on epistemic criteria to evaluate the information at hand; and when they rely on processes and strategies that ensure their epistemic aims are achieved. To this end, ***epistemic beliefs*** can instigate effortful engagement which can lead to the achievement of epistemic aims (Barzilai & Zohar, 2016).

Epistemic engagement can also take the form of ***source evaluation*** when individuals assess the epistemic authority of the person behind the information. The use of scientific language may suggest expertise in a scientific topic (Thon & Jucks, 2017), but evaluating the underlying motives for posting a piece of information – whether to persuade or inform, or when the information is two- versus one-sided – also factors into how a source is evaluated. Evaluating information that comes into conflict with one's prior beliefs about a topic can also encourage more effortful engagement with information (Bråten et al., 2016).

Examining how and if knowledge claims are justified (***evidence evaluation***) can lead to achieving one's epistemic aims. Sinatra and Lombardi (2020) suggest that effortful engagement can stem from plausibility reappraisals, whereby individuals evaluate the connections between evidence and alternative explanations. The amount of evidence that is provided in support of a scientific claim also matters (Corner & Hahn, 2009), as does the type of evidence (Hornikx, 2008). When it comes to evidence, effortful engagement is also aided by ***scientific literacy*** and an awareness of the tentative nature of scientific knowledge claims. Public understanding of science may be bounded, and effortful engagement may be hindered by challenges in reasoning about processes in knowledge and knowing, as well as cognitive biases and misconceptions (Sinatra et al., 2014). During effortful engagement individuals consider how scientific endeavor produces reliable knowledge through epistemic processes (Duncan et al., 2018). By being mindful of the epistemic quality of the information they are incidentally exposed to, individuals' effortful engagement is intentional, guided by the goal to arrive at epistemic ends.

Epistemic emotions and effortful engagement

How individuals experience epistemic emotions is also influenced by one's epistemic cognition (Chevrier et al., 2019). Seven epistemic emotions (***surprise, curiosity, confusion, enjoyment, anxiety, frustration and boredom***) have garnered the most empirical and theoretical attention (Muis et al., 2018). ***Surprise*** arises when information is appraised as novel and involves an incongruity between what one already expects or believes (Meyer et al., 1997); it can often precede confusion when the information encountered is assessed as incomprehensible. The level of surprise may also play a role in what epistemic emotions individuals experience during information appraisals. When the level of surprise is high, individuals are likely to experience curiosity or confusion, depending on the complexity of the information or task at hand. When new information cannot be integrated into existing mental schemata, an impasse is reached, and individuals may also experience ***confusion***, which can trigger ***frustration***, and eventually ***boredom***, which leads to disengagement, if the impasse is not overcome through a thoughtful and reflective process. Overcoming the impasse through cognitive engagement can result in ***enjoyment*** (D'Mello & Graesser, 2012). On the other hand, ***epistemic anxiety*** can lead to more engagement since it alerts to important weaknesses in one's epistemic position (Hookway, 2011); the higher the stakes for not knowing, the greater the epistemic anxiety. Such occasions lead to greater engagement in order to gather more

evidence (Nagel, 2010). Similar engagement can result when experiencing ***curiosity***, which emerges when one becomes aware of a gap between what they know and what they do not (Loewenstein, 1994) and this can influence whether individuals engage with information in a deliberate and intentional manner. However, experiencing curiosity alone may not be enough to ensure that more effortful engagement occurs. Muis et al. (2018) found that curiosity positively predicted a more reflective stance towards information, but the type of textual information (expository or refutational) played a role in this. Prior work by D'Mello and Graesser (2012) has examined the interplay between emotions and engagement — which the authors conceptualized as being in a state of concentrated flow — during complex learning, but what happens during incidental online encounters, where individuals may often be predisposed to approach information with goals other than learning, is less clear.

Methods

Participants and Procedure

Participants were recruited through an open call posted in a Facebook group with 123 members. Fifteen respondents (12 females), ages 20-28 years old, opted to participate in the study. All participants reported using at least two, and as many as seven, social media platforms in their daily routines.

We chose to focus on health as a topic, and specifically on COVID-19. Think-alouds were used to capture participants' reactions as they viewed social media posts using a simulated Twitter timeline. Due to COVID-19, all interview sessions took place online using a video conferencing software. As this study was part of a larger effort examining socio-technical approaches to mitigating online misinformation, all participants viewed the same set of stimuli, which consisted of two baseline posts, without credibility labels, and then six other social media posts that included credibility labels. Posts were a mix of accurate or misinformative posts; four accurate posts were retrieved from news organizations such as The New York Times, and official health organizations such as the World Health Organization and the US Center For Disease Control, while four misinformative posts were retrieved from the International Fact Checking Network (IFCN) Coronavirus Alliance database.

Each participant was asked to share their screen and to externalize their thoughts as they were deciding on whether to take an action (i.e., "like" a social media post). The interviewer first shared the link to the two baseline posts and asked participants to externalize their thoughts. The aim of this task was to familiarize participants with the think-aloud method, but also provide a baseline for comparison for emotions experienced when viewing information with credibility labels. Participants were then presented with the simulated COVID-19-related social media posts on Twitter and were asked to explain whether they would "like" any of the posts. To avoid priming the participants' information evaluation processes, they were not informed of the presence of the credibility labels during the think-aloud. The average duration of each think-aloud session was 14 minutes.

Data Coding and Analysis

All sessions were recorded and transcribed verbatim; they were coded in NVivo, using a coding scheme for epistemic emotions by Chevrier et al. (2019) capturing the seven epistemic emotions that have received the most attention in the literature (Table 1). Data coding occurred in iterative cycles; part of the data were coded by two researchers, then discussed to resolve discrepancies, and the process was repeated. We coded emotion only when it concerned information relating to the social media posts. To answer our research questions, we also analyzed the data using a second coding scheme to capture epistemic engagement by Hendriks et al. (2020): *epistemic beliefs*, *source evaluation*, *evaluation of evidence* and *scientific literacy*. To identify the emotions connected with most epistemic engagement, we examined the coding intersections between the verbalized epistemic emotions and the epistemic engagement episodes, and how these varied across each of the eight social media posts.

Table 1
Coding Scheme For Epistemic Emotions

Epistemic emotion	Description	Example
Surprise	Astonished, amazed	[reads post aloud] '*Experts warn that protective face masks can reduce oxygen flow to the blood by 20%.' What?*" P9
Enjoyment	Excited, enthusiastic	*"OK, it's pretty great, I mean… any person that gets a Nobel, I mean. I see an emphasis on the fact that it's women, which tells me that it's not common for a woman to get a Nobel prize in Chemistry. And it makes it even greater." P3*
Curiosity	Interested, intrigued	"*But I'm also, like, just wondering…where. What is this COVID-alert? Like, who is this account? Like, is it a health*

		organization? Is it just someone compiling loads of information and putting it out there as a sort of COVID account?" P1
Confusion	Puzzled, muddled	"*[reads post aloud] 'Belgian study proves hydroxychloroquine is effective against COVID-19. Specifically, it can help prevent breathing problems.' Yeah, I mean, I don't even… hydro-chro-loro-qui… I don't know what that is.*" P9
Frustration	Irritated, dissatisfied	"*So it makes me feel like someone who wrote it is a bit unreliable and doesn't actually have a clear thing… or a clear understanding of what they are trying to say. And I'm not sure what kind of point… what is the goal of this tweet?*" P11
Anxiety	Worried, nervous	*"I wouldn't like it because then I would also spread panic, without knowing if this statement is true or false, if it can help. Not panic… but to spread this misinformation that, you know, take this thing [hydroxychloroquine] to get better, which might be false, might be true." P13*
Boredom	Dull, monotonous	"*To be honest, if this was on my feed, I probably wouldn't read it. But… I'd probably, like, click on the Covid Alert and click unfollow.*" P19

Findings

This study investigated the extent to which epistemic emotions manifested during incidental information encounters and if these were connected to epistemic engagement. To do this we coded for epistemic emotions and epistemic engagement. All participants expressed epistemic emotions, but these varied across different posts and participants. This suggests that the topic and individual characteristics matter when experiencing epistemic emotions during information encounters. Boredom was the emotion that was most frequently experienced, which is perhaps not surprising considering that the simulated timeline was not customized or curated to match each participant's interests and motivations. However, our findings suggest that even when boredom was the first emotion verbalized during a post, this did not always lead to disengagement. Participants who transitioned to other emotions following boredom, were able to effortfully engage in assessing information reliability. Frustration, confusion and curiosity also emerged as emotions experienced frequently, as did enjoyment. Epistemic anxiety and surprise were not experienced as much. Table 2 provides the frequencies for verbalized epistemic emotions.

Table 2

Frequencies Of Verbalized Epistemic Emotions

	Boredom	Frustration	Confusion	Curiosity	Enjoyment	Anxiety	Surprise	Total
#	40	32	30	29	28	9	4	172

Participants effortfully engaged with information in combination with emotions such as frustration, curiosity, and confusion. Epistemic engagement mostly manifested as source and evidence evaluation. Participants questioned references to abstract sources (e.g., "US scientists"), expressed the desire to check the source, or questioned the lack of URLs to support the claims made in the tweets. These suggest that even though participants could only verbalize their intentions, their engagement was motivated by epistemic aims which could lead to learning. They sought to achieve these aims through follow-up actions, or by maintaining a critical stance towards the information they encountered.

Additionally, participants epistemically engaged with some social media posts more than others. Participants engaged more effortfully with the two media posts which included negative words such as "dangerous", "worse", "death", "kills", and verbalized emotions such as frustration, confusion, and curiosity during these information encounters. Most notable, however, was the post that received the highest count for verbalized boredom, which also received the most effortful engagement; we found that when boredom was experienced first and then other emotions occurred, it led to epistemic engagement. We next present the two main themes connecting the most frequently reported emotions with epistemic engagement.

Theme 1: Frustration, curiosity and confusion were connected to epistemic engagement

Our examination of the coding intersections between the participants' verbalized epistemic emotions and epistemic engagement revealed that frustration was connected with most epistemic engagement episodes (30

coded episodes), followed by curiosity (27 coded episodes), and confusion (15 coded episodes). Frustration was sometimes predicated by confusion. However, frustration frequently served as a catalyst for participants to more consciously engage with the information epistemically, by calling into question the source of information or the evidence used to support the information claims in a post. For instance, in the excerpt below, P11 first experiences confusion, and then frustration, and it is during this emotional response that P11 pays closer attention to the epistemic qualities of the information at hand:

(Confusion) I wouldn't like this tweet because I'm reading it and I don't really understand part of it, because it says that it's only very marginally worse, so the word only and very marginally – only and very contradict each other.

(Frustration) So it makes me feel like someone who wrote it is a bit unreliable and doesn't actually have a clear thing… or a clear understanding of what they are trying to say [**source evaluation]**. And I'm not sure what kind of point… what is the goal of this tweet? [**source evaluation]**.

(Confusion) Because I'm not … I can't understand if it's trying to get me more relaxed or if it's actually trying to make me more alarmed because the combination of "only very marginally" is confusing.

In the above excerpt, the participant more closely evaluates the source and questions the author's intent. The participant is responding to a post comparing the COVID-19 death rate to that of the flu, and which included negative words such "death", "kills", "worse". The emotional reactions to this post suggest that the inclusion of such words may have triggered emotions such as frustration among participants, as they were trying to make sense of the information at hand. Participants responded similarly to a post characterizing the COVID-19 vaccine as "dangerous"; the use of this negative word, possibly in conjunction with the controversial nature of the topic, prompted frustration alone, or frustration experienced with emotions such as curiosity and confusion. In both contexts, participants questioned the evidence in support of the claim. For instance, the excerpt below illustrates how frustration led to paying closer attention to the epistemic aspects of the information encountered.

(Frustration) "It says about a big scientific study, but of course again it doesn't have some… it doesn't have some link, like, 'go here to see this study'. It's just a few words, just like I can write this tweet, with no knowledge **[evidence evaluation]**. Because it says here it's uncertain [reads the credibility label], it's not a very credible Twitter account. Again, personally I wouldn't spread this statement. Even if it's right or wrong. Not right or wrong, but if it's true. I wouldn't like, I wouldn't retweet or share, or even say it myself **[epistemic beliefs]**. And I'm one of those people who mostly think scientifically, not in conspiracies, and I would like more… the evidence of this study to believe it **[evidence evaluation]**." [P13]

In other instances, the use of the word "dangerous" led participants to experience curiosity because they were aware that the topic was controversial or held potential for misinformation, as illustrated by P6:

(Curiosity) "For this one I might search for more information, because there are a lot of hoaxes about microchips, and that the COVID-19 vaccine is dangerous. So, I would search to find out more about why they are saying it's dangerous, and what is this study? Because it doesn't refer to it at all **[evidence evaluation]**."

However, the uncertainty surrounding the topic of vaccination, also played a role in how participants emotionally responded to this post. For instance, in the following excerpt, P5 verbalizes confusion about what to believe on the topic, and also expresses anxiety, albeit it, not epistemic anxiety, since it does not prompt increased engagement with the information, but a tendency to escape it:

(Confusion) "I don't know about this one 'cause I heard that most vaccines, even though it might help with this specific virus or flu, or whatever, it can have some side effects in the future. So, yeah. It's kind of dangerous but we don't know about that because it didn't… we don't know the future, so it is uncertain **[epistemic beliefs]**. Like, it makes my mind go weird like with all of this information, because it does increase anxiety. 'Cause it does conquer our lives, unfortunately. And having a lot of information about it is not nice."

Frustration, curiosity and confusion were also expressed sequentially for individual social media posts, and the transition between different emotions during the online information encounters suggests that far from blocking engagement, frustration may be conducive to prompting more epistemic engagement. The following excerpt by P12 exemplifies epistemic engagement and highlights how frustration may serve to sustain engagement longer while assessing the quality of information claims online.

(Confusion) "So, obviously the "Not Credible" has completely thrown me off **[source evaluation]**.

(Curiosity) 'The Ioannidis study'… the fact that there's a specific study makes me question… I would, obviously, again, go research this study. I want to see more towards what they actually… what variables they used to convey the study **[scientific literacy]**. I also believe that this is just a very generic statement. The fact that "it's only marginally worse than the standard flu", although I… a part of me initially agreed with this statement, I feel it's also very limited. I feel there's no proof towards this… there's not credibility to this, within this statement.

(Frustration) […] I feel like this is a statement that is said… It's my thought process is that this feels like this is a very unprofessional statement. The way it's also written, I don't know why **[source evaluation]**. I don't know if there is hardly any…[pauses] I don't know! I can't think about this.

(Confusion) I just feel like I wouldn't like this statement. I feel like I'd validate… I definitely, again, this "not credible" source is throwing me off **[source evaluation]**. Definitely the fact that there is no… I feel also, when it comes to any statement that has statistics, I believe it more. Even though the first one, with the 20%...I don't, because I feel like that's too much of a perfect number **[evidence evaluation]**.

(Frustration) But it's also this "it's only very marginally worse than the standard flu virus that kills hundreds of sick and elderly every year." It seems very unprofessionally written as well. I don't know why **[source evaluation]**."

Theme 2: Experiencing boredom first does not always preclude epistemic engagement

The post which received the highest count for verbalized boredom was also the one that received the most effortful engagement, as suggested by the source and evidence evaluation statements. When participants verbalized boredom first, and then transitioned from this state of disengagement to verbalize other emotions, epistemic engagement occurred. This was observed during the participants' verbalizations relating to a social media post on research in relation to COVID-19 decontamination using UV light. When participants experienced only boredom, no epistemic engagement was observed. When boredom was followed by other emotions, such as confusion or frustration, participants engaged with the information epistemically. In the excerpt below by P5, the initial emotional response of boredom suggests disengagement, yet P5 is able to transition from boredom to epistemically engage with the information:

(Boredom) "For me, it's irrelevant to me, even though, like, Coronavirus is kind of, like, dictating our lives in a way. There's too much information on the topic so I don't know if I would want to follow it, just because I know cookies exist and more information about the virus would bombard me, so I think…

(Confusion) it's good information, but I wouldn't like it. Cause I don't know what to believe nowadays, like. 'Cause there's so much information going on about it, that I don't know if it's true or not. And I don't know the username. […] And there's no picture in the username, so I don't know if it's a valid point or not, to believe **[source evaluation]**. So yeah, that's it.

(Frustration) And also, Coronavirus is not in capital letter, so it's a bit unprofessional in my opinion **[source evaluation]."**

Another participant (P4) clearly expresses boredom based on the way the information is presented. However, this initial reaction does not prevent epistemic engagement, and in fact the transition from boredom to emotions that enable the participant to interrogate the information quality of the post is illustrated in the following example:

(Boredom) "I don't think I would click it because it's not attracting me to be like, 'Oh yes, like, I like this'. It's something positive, obviously, because it's concerning the pandemic, but it's not something, I guess. It's not worth, I guess, clicking the screen. It's, I guess, good news, yay!

Research! But that's it. It's not really saying who really made the breakthrough or something, it's just saying the statement about the research **[source evaluation]**. Yeah, I don't think I would click like. It's not saying anything else. It doesn't make me want to click the page.

(Curiosity) Actually, I would click the page to find something more available about this statement, but I think it's a bit plain what the research is about. Like, "US scientists" – is it the university, is it private lab? If it is… **[evidence evaluation]**

(Frustration) It's 'Latest News', OK. It doesn't sound like a scientific page because if it was a scientific page, a science-related page, I would assume it would mention more details about the research, but maybe it would be nice if they tagged maybe the page of the scientists that made the breakthrough **[source evaluation]**."

Discussion

During online information encounters, the information individuals are incidentally exposed to can trigger emotions that can impact one's online actions; this has consequences in the context of misinformation. These encounters also hold serious implications for sustaining an engaged and informed citizenry online given that information that appears on social media is often emotionally appealing. In this exploratory study, we sought to gain further insights into the role of epistemic emotions when individuals assess the quality of information they encounter and whether these emotions are connected to effortful engagement with information. Our findings suggest that during online information encounters, frustration, confusion, and curiosity are connected to epistemic engagement. This connection was particularly observed for social media posts that used negative language and for controversial issues. In such posts, participants paid closer attention to the source of information, or requested more evidence to support the claims raised in the post, and sometimes verbalized intentions to take additional actions such as searching for information or checking the source. Our study design prevented participants from following up, which is a limitation; however, these verbalizations signify an intentionality towards achieving epistemic aims. Even when boredom was experienced first, epistemic engagement can occur if boredom transitions to confusion or curiosity. Further understanding the contexts in which experiencing boredom first in a sequence of emotions can preclude disengagement online merits further exploration.

We believe this exploratory study contributes to understanding how epistemic emotions may prompt epistemic engagement with information online. It also underlines the need for new instructional approaches in formal education that can promote epistemic engagement online by supporting students during their online information encounters in differentiating between evidence-based claims versus speculation. Additionally, epistemic engagement in this study mostly manifested through source and evidence evaluation, with fewer instances of epistemic beliefs and scientific literacy. How might instructional approaches to evaluating information quality online be reimagined to strengthen epistemic practices and scientific literacy? Information environments online are not usually designed for learning, and even constrain effortful engagement by design (Hendriks et al, 2020). In such spaces, how might scaffolds aid users outside formal education deepen their epistemic engagement? Understanding the role that emotions play during effortful engagement can also inform the design of authentic online environments that learners routinely navigate to access and retrieve information (Chinn et al., 2020). This may narrow the gap between formal and informal learning.

Abstract: Careers in science, technology, engineering, and mathematics (STEM) increasingly rely on computational thinking (CT) to explore scientific processes and apply scientific knowledge to the solution of real-world problems. Integrating CT with science and engineering also helps broaden participation in computing for students who otherwise would not have access to CT learning. Using a set of emergent design guidelines for scaffolding integrated STEM and CT curricular experiences, we designed the Water Runoff Challenge (WRC) - a three-week unit that integrates Earth science, engineering, and CT. We implemented the WRC with 99 sixth grade students and analyzed students' learning artifacts and pre/post assessments to characterize students' learning process in the WRC. We use a vignette to illustrate how anchoring CT tasks to STEM contexts supported CT learning for a student with low prior CT proficiency.

Introduction

Preparing pre-college students for careers in science, technology, engineering, and mathematics (STEM) requires them to engage in authentic STEM practices. These practices increasingly rely on computational thinking (CT) to explore scientific processes and apply scientific knowledge to design solutions for real-world problems (Freeman et al., 2014). The emergence of computation as the third pillar (alongside theory and experiment) of science and engineering and the inclusion of CT in the U.S. *Framework for K-12 Science Education* require that primary and secondary schools incorporate CT into existing STEM curricula (National Research Council [NRC], 2012). Integrating CT with required STEM subjects also helps broaden participation in computing for students who otherwise would not have access to CT learning.

A computational model (CM) is a mathematical representation of a system created using a formal notation (e.g., a programming language) so that the system behavior can be studied using computer simulations (Melnik, 2015). The collective practices of developing, testing, refining, and using CMs (National Research Council, 2012)—can be the central link between students' scientific understanding of a system and engineering a problem solution related to the system, especially for systems that cannot be easily investigated using physical materials. This approach merges the benefits of developing computational artifacts with simulation-based learning and problem solving.

This paper examines how CT can be promoted through science-engineering integration using computational modeling, particularly for younger students with no or limited prior exposure to computing. Recent research on how students develop CMs of science phenomena has mostly focused on integration of CT with either science (e.g., Waterman et al., 2020) or engineering (e.g., Magana & de Jong, 2018) but not both. Introducing CMs for elementary school students presents challenges such as students' limited mathematics proficiency, class time needed to develop programming/modeling skills, and the training needed for elementary teachers who are typically generalists and may not have deep CT, engineering, and/or science expertise. We describe curriculum design guidelines that can promote integration of CT with science and engineering via computational modeling and report on the implementation of an integrated STEM+CT unit designed for fifth and sixth grade students.

Theoretical and Empirical Perspectives

Synergistic learning of STEM and computing

Past research on synergistic STEM and computing learning (e.g., Hutchins et al., 2020; Sengupta et al., 2013; Waterman et al., 2020) has shown that computational modeling can deepen students' science learning. Complex scientific systems become easier to understand when the system structure and behaviors are explained computationally. CMs provide explicit mechanisms for constructing and visualizing scientific phenomena and reasoning about scientific processes as a sequence of step-by-step changes as opposed to creating aggregated mathematical models (Hutchins et al., 2020). Learning to program CMs involves learning how to formally

 © ISLS

articulate mechanisms and explanations, a core scientific practice. In turn, programming also becomes easier to learn when anchored in real-world problem contexts (Sengupta et al., 2013). Alongside documenting the benefits of computational modeling, research has also identified that students may have significant difficulties with developing scientific CMs. Students may struggle with both understanding the science concepts underlying CMs and representing system variable relationships using computational expressions (Sengupta et al., 2013). Students may also have trouble generalizing or abstracting the scientific processes into variables and expressions (Basu et al., 2016). These findings indicate a need to scaffold students' computational modeling experience as they grapple with the multi-fold complexities of scientific knowledge, modeling practices, and computational representations.

Framework for integrating science, engineering, and CT

Relatively little research has examined how CMs can enable the developing or testing of engineering solutions related to science phenomena. We integrate science, engineering and CT via computational modeling by leveraging a design framework (McElhaney et al., 2020) that involves (1) defining an engineering design challenge whose solution is governed by an underlying science phenomenon, (2) supporting students to develop a CM of the science phenomenon, and (3) supporting students to use their CMs to design, test, and refine solutions to the engineering challenge. The framework integrates research on designing computational environments that enable students to model science phenomena (e.g., Hutchins et al., 2020; Sengupta et al., 2013), and research investigating how students use simulations to engage in problem-solving (e.g., Magana & de Jong, 2018; Weintrop et al., 2016). To implement this framework, we leveraged the following design perspectives to integrate science, engineering, and CT. These perspectives guide the design of the Water Runoff Challenge (WRC), the integrated STEM+CT unit used for this study (described in further detail in the Methods section).

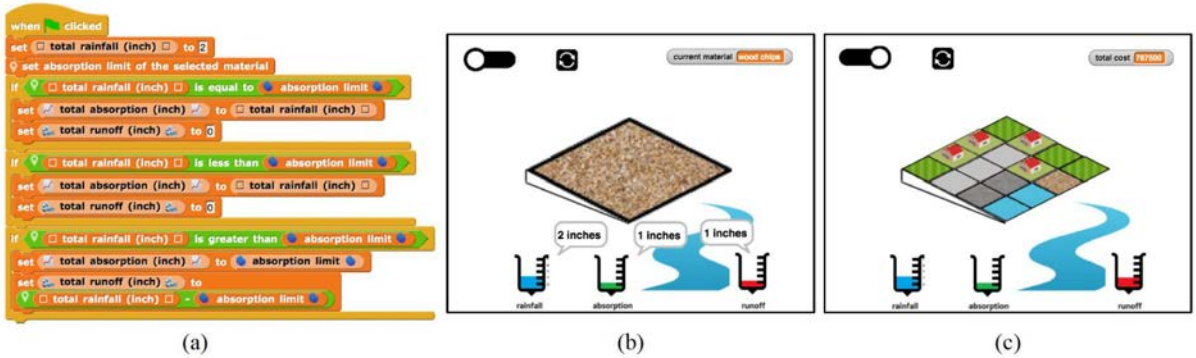
- **Create an explicit need for computational modeling.** To achieve authenticity in the design of a STEM+CT curriculum unit, the overarching design challenges should make the use of computational tools consequential. Students should be able to recognize the unique affordances of CMs for solving STEM problems, making scientific predictions, and designing engineering solutions (Weintrop et al., 2016). This design guideline also promotes the CS practice of Recognizing and Defining Computational Problems.
- **Maintain coherence across system representations.** In a STEM+CT unit, students must interact with and/or generate multiple system representations (e.g., pictorial, mathematical, narrative, and computational) of the science phenomenon being investigated. In order to work together to promote integrated learning, these representations need to be conceptually coherent (Ainsworth, 1999) and consistent with respect to the system variables and their relationships and the computational and scientific terminology employed.
- **Employ a Domain Specific Modeling Language (DSML).** DSMLs reduce the challenges that learners face when modeling scientific scenarios by adapting the level of system abstraction to conceptual levels appropriate for learners (Hutchins et al., 2020). Relative to using a general-purpose programming language to develop scientific models, students can focus on the relevant science concepts and system variables without having to attend to the program syntax. The use of DSMLs for computational modeling reduces the cognitive load associated with learning to program and shifts the focus toward science modeling.

Methods

Designing to promote CT learning in integrated STEM+CT instruction

In activities integrating science, CT and engineering, whether learning CT will promote or interfere with science and engineering learning depends on the learner's ability to manage the challenges of disciplinary integration. The ability to successfully leverage synergies between computing and STEM learning requires scaffolding, especially for younger students. We describe a set of six design guidelines to scaffold young students and improve their understanding of CT with specific examples from the WRC, a multi-week unit that integrates CT with Earth science and engineering for fifth and sixth grade students (Zhang et al., 2020). The WRC uses the design perspectives described above to engage students with the problem of a schoolyard that floods during periods of heavy rainfall. Students are challenged to resurface the schoolyard to minimize the water runoff while meeting design constraints on cost, accessibility for students with physical disabilities, and practical use. Based on the science principle of matter conservation, students create pictorial models explaining how a part of the rainfall is absorbed into the ground based on the surface material properties, while the rest remains on the surface and flows downhill (runoff), resulting in flooding of nearby areas. Students then use a block-based DSML to develop a corresponding CM (Figure 1a) for a unit surface area (one square). The DSML used in the WRC includes domain-specific constructs such as rainfall, water absorption, runoff, and surface material, as well as CT constructs that are needed in the runoff CM. This CM determines the amount of water runoff based on the amount of rainfall and the (predefined) absorption limit of the surface material. As students build the CM, they test it using different

values of rainfall and different surface materials (Figure 1b). After students develop a working CM, their model code is then incorporated into a simulation environment comprising 16 squares for the engineering design task (Figure 1c) where students need to configure a set of appropriate materials for resurfacing the schoolyard.



(a) (b) (c)

Figure 1. *(a) A Working Runoff CM (b) Single Square CM Testing (c) 16-Square Engineering Design*

Below, we synthesize the WRC unit design features into a set of emergent design guidelines encompassing three categories of support for promoting CT in integrated STEM+CT instruction. These design guidelines have emerged from iterative implementation of the WRC unit for fifth and sixth grade students and its refinement using insights from classroom studies (McElhaney et al., 2020; Zhang et al., 2020).

Preparing Students for CM Development

1. **Support conceptual modeling of science phenomena prior to CM development.** In order to successfully develop a CM, students first need a strong scientific and mathematical understanding of the system behavior, which they can then express using CT constructs in a computational modeling representation. Having students first develop a conceptual model of the science phenomenon helps learners establish a firm scientific understanding of system behavior and variable relationships before representing the system computationally using the same variable names and relationships. In the WRC unit, students engage in a series of conceptual modeling activities: (1) a hands-on activity to observe differences in absorption characteristics among surface materials; (2) a pictorial modeling activity (Figure 2a) where students illustrate relationships among rainfall, absorption, and runoff; and (3) articulation of mathematical rules that express water runoff in terms of rainfall and material absorption limits.
2. **Introduce CT concepts required for developing CMs using a familiar context**. In addition to science understanding, students must have adequate proficiency with CT concepts and practices and an understanding of the computational modeling language in order to develop a CM. To design broadly accessible computational modeling experiences for fifth and sixth grade students, one cannot assume that students have prior familiarity with programming or CT. Hence, activities should engage students in CT concepts and practices required for developing the target CM by first presenting them in a familiar (non-scientific) context and in an isomorphic way to the CM. For example, in the WRC unit, we developed unplugged activities that engage students in a series of dice games of increasing complexity before students develop the runoff CM. The dice games introduce students to the concepts of conditionals, variables and expressions by assigning players different scores based on their dice values (Figure 2b).

Supporting CM development

3. **Engage a limited and age-appropriate set of CT concepts and practices**. When engaging fifth and sixth grade students who have no assumed prior knowledge of CT in computational modeling of science phenomena, curriculum units need to limit students' engagement to a small set of CT concepts and practices that are needed to model the phenomenon in a compelling fashion and can be learned with a limited amount of classroom instruction. Because science and CT learning are so tightly integrated in such units, limiting the target CT concepts may also require simplification of the science concepts and system representation by limiting the number of system components and abstracting their relations. In the WRC unit, we target the CT concepts of sequences, variables, expressions, and conditionals (Figure 1a) and the practices of developing, testing, and debugging computational artifacts, as well as using computational artifacts for problem-solving. We arrived at this target CM after several previous implementation iterations that involved several temporal and rate-based variables and the CT concept of repeated conditionals. Although scientific CMs are typically temporal in nature, the temporal runoff CM turned out to be too complex for typical fifth and sixth grade

 © ISLS

students. Hence, we omitted the CT concept of iteration from the current version of the CM to make it mathematically and computationally tractable for young students.

4. **Support model decomposition**. For fifth and sixth grade students using a programming environment for the first time, it can be helpful to decompose the CM development process into conceptually meaningful chunks. For example, in the WRC unit, because the system behavior is modeled according to three rules (rainfall less than, equal to, or greater than the surface absorption limit), we designed one classroom activity for students to program each rule. Each activity guides students through an incremental process of prediction, model development, testing, debugging, and reflection by adding the code for one rule at a time.

Supporting CM Evaluation

5. **Support CM testing and the selection of test cases.** Learners need support on CT practices such as systematically and thoroughly testing CMs and identifying appropriate test cases for CM evaluation. Our initial studies revealed that selecting appropriate test cases is not trivial for fifth and sixth grade students. In the WRC unit, students are prompted to use three test cases corresponding to the three conditional rules in the CM (Figure 2c) and to test their CMs with at least two different surface materials. Students model the CM in parts over three class periods and document outcomes with all three test cases each day.
6. **Include opportunities for students to engage with debugging**. Debugging CMs goes beyond merely identifying and fixing errors in code; it integrates CT and science by requiring learners to determine whether the CM correctly represents the underlying science model. Debugging CMs involves identifying and correcting computational errors as well as errors stemming from incorrect representations of the underlying science content. Embedding explicit debugging opportunities in STEM+C units can help shed light on causes of student challenges during CM development. In the WRC unit, we started some CM development lessons with a short debugging task. Tasks were based on code students had written the previous day and prompted reflection on previous coding activity. We also embedded debugging tasks as part of formative assessments (e.g., Figure 3) that students could complete in class or at home.

(a) (b) (c)

Figure 2. *(a) A pictorial conceptual modeling task, (b) A dice game CT task, (c) A test case selection task*

Classroom study using the WRC unit

We conducted a classroom study with 99 sixth grade students in the southeastern United States. Students completed the WRC unit over 15 class periods in the Fall of 2019, with identical pre-post tests administered before and after the intervention. Students worked for 45 min per day, three days per week during their regular science classes, and 75 min, twice a week, with additional personalized-learning time. Some students had prior programming experience with Scratch, while others had no previous programming experience. The participating teachers were highly experienced with teaching science and received four days of training before the study.

Data sources, scoring, and analysis

We examined four primary types of student data: pre-post assessment performance, final computational models, responses to activities in student workbooks, and responses to formative assessment tasks.

Students completed a paper-and-pencil **pre-post assessment** that was split into a science and engineering component and a CT component (McElhaney et al., 2019). Science/engineering tasks were aligned with several Next Generation Science Standards (NGSS) Performance Expectations in Earth science and engineering (NGSS Lead States, 2013). Of the five science/engineering tasks, three asked students to apply an engineering practice to the solution of a water runoff problem, one asked students to develop a model of water runoff in a context different from the WRC, and one asked students to apply an engineering practice to the solution of a problem unrelated to water runoff. For example, in one task, students compare two street designs based on criteria related to water runoff performance, usage, and cost. The science/engineering task rubrics measured the extent to which students could apply the focal science/engineering practice to the water runoff context and/or other engineering design criteria. The CT assessment tasks were aligned with the CT concepts and practices addressed in the runoff CM.

Students could score a maximum of 23 points on science and engineering and 13 points on CT. The rubrics used for coding and scoring the tasks were updated from our previous work. Two researchers received 5 hours of training on the rubrics, graded 5% of the test submissions (randomly selected) together to establish initial grading consistency, and then graded another 20% to establish inter-rater reliability (Cohen's κ at ≥ 0.8 level on all items). All differences in the coding were discussed and resolved before the remaining 75% of test submissions were graded by a single researcher.

Students' **final runoff CMs** were logged and scored using a rubric targeting conservation of matter rules and conditional statements for the different rules. The rubric rewarded four main criteria of the CMs: (1) assigned appropriate values to the total rainfall and absorption limit variables, (2) included code for three conditional statements that compared the total rainfall and absorption limit variables, (3) updated the absorption and runoff variables correctly for each of the three conditions, and (4) code is generalizable (e.g., assigned variables to expressions rather than to hardcoded numeric values).

Students completed a paper-and-pencil **workbook** over the course of the unit. We scored and analyzed student responses to specific workbook activities such as the conceptual modeling tasks, dice game activities, test case identification tasks, and a CM debugging task. A series of four student **conceptual models** and corresponding written explanations were scored based on their adherence to the conservation of matter principle and articulation of the causal relations governing the flow of rainwater. We also scored student performance on the **dice games** that introduced students to CT skills. Each of the four games were scored based on whether students could correctly evaluate conditional statements and interpret variable assignment statements. We report dice game scores only for students who documented outcomes from all four games ($n = 62$). We scored students' **choice of test cases** for testing the three rules in the runoff CM for a material of their choice based on whether the test cases address each of the model's three rainfall conditions. We scored a **debugging** task where the variable assignment for the absorption and runoff variables were flipped for a particular condition. Finally, we scored student responses to three select **formative assessment tasks** that assessed students' ability to predict the output of given CMs, identify errors, and fix buggy CMs.

We performed paired *t*-tests to measure students' pre-to-post learning on science, engineering, and CT. We also examined correlations among students' pre-post performance and performance on various CM development and evaluation activities to better understand students' learning process in the WRC unit.

Findings

Overall STEM and CT learning gains

Students' science/engineering scores improved significantly with a high effect size ($p < .0001$, $d = 0.81$) from an average of 13.3 (*SD*=2.8) points at pre-test to an average of 15.6 (*SD*=2.9) points at post-test. Students' CT scores also improved significantly with a high effect size ($p < .001$, $d = 0.83$) from an average of 6.2 (*SD*=2.6) points at pre-test to an average of 8.4 (*SD*=2.7) points at post-test. These pre-post changes reflect improvement in students' ability to develop scientific models, define engineering problems and design criteria, and engage with the CS concepts of variables, expressions, and conditionals. Below, we describe relations among students' pre-post changes and performance on curricular activities, and illustrate how students' science/engineering proficiency may be supporting students' CT learning using a vignette.

Student interactions with the computational modeling scaffolds in the WRC

Students demonstrated large variation in their CM construction behaviors, but about two-thirds of the students finally constructed a correct implementation of the runoff CM with instructional support. The average CM score was 13.6 (SD=2.5) out of 15. For students who were not able to construct a correct CM implementation, common challenges included omitting conditional statements (resulting in not covering all comparisons between the rainfall and absorption limit variables), not assigning values to both absorption and runoff variables in each of the conditions, and not assigning variables to correct values or assigning variables to hardcoded values. In particular, many students found it challenging to express the relation "set total runoff to (total rainfall − absorption limit)" when "total rainfall is greater than absorption limit."

These challenges with CM development align with challenges observed when students worked on the conceptual modeling and unplugged dice game activities prior to the runoff CM development. While both these activities prepare students with the science and CT understanding needed to create the runoff CM, both activity performances have small, non-significant correlations with students' CM scores, indicating that the relations may not be linear. Students scored an average of 27.0 (*SD*=4.5) points out of a possible 32 on the conceptual modeling tasks. Students were generally able to conceptually model the conservation principle and numerically predict the values of absorption and runoff given values of rainfall and absorption limit. However, many students struggled

to provide mechanistic explanations for their numeric predictions or articulate generalizable rules to express the system variable relationships. On the dice game activities, 36 students earned the maximum total score of 8 on all four dice games. Students scored an average of 7.2 points (*SD*=1.3). Students were least successful with the fourth dice game, which was designed to be the most difficult - it involved evaluating conditional statements comparing two variables and interpreting variable values assigned to other variables and expressions. Most of the challenges stemmed from interpreting the variable assignment statements correctly.

We observed wide variation in students' performance on the activities designed to scaffold CM evaluation (selecting test cases and debugging). As we expected, model evaluation practices, in particular debugging, were challenging for sixth grade students. Students scored an average of 3.5 (*SD*=2.2) out of 6 points on the test case selection activity and an average of 8.0 (*SD*=3.0) out of 22 points on the debugging activities. Students' debugging performance was significantly correlated with their conceptual modeling scores (ρ= .27, p< .01) and CM scores (ρ= .23, p < .05). This result highlights the nature of debugging CMs in STEM+CT units, which entails both determining the accuracy of the underlying science model and its computational representation. Some common debugging challenges included: (a) the "superbug" challenge (Pea, 1986) where students thought the computer has a mind of its own and will always generate the correct result, (b) identifying and correcting all errors when the CM comprised multiple bugs, (c) believing that variable values cannot be re-assigned once assigned to initial values, and (d) incorrectly switching operands of logical operators and assignment statements.

Relations among computational modeling and pre-post performance

We conducted a correlational analysis among the pretest and posttest scores for science/engineering and CT and students' performance on the learning artifacts described above (see Table 1 for correlation coefficients and significance values). The significant correlations between (i) conceptual modeling and post-science/engineering, (ii) unplugged dice games and post-CT, and (iii) computational modeling and post-CT are consistent with expectations based on the alignment with their respective disciplines. The significant correlation between test cases and post-CT scores reflects how test cases can engage CT constructs such as variables and expressions, conditional logic, and code comprehension in a science modeling context. The significant correlations between students' debugging performance and posttest scores in both science/engineering and CT further illustrates the extent to which debugging a CM is an integrated activity—debugging a CM entails evaluation of both the code itself as well as the underlying scientific system model.

Table 1. *Correlations among pre-scores, post-scores and curricular activity performance (** p < .01, * p <.05)*

	Pre - science & engineering	Pre - CT	Conceptual modeling	Unplugged dice games	Computational modeling	Selecting test cases	Debugging
Post - science & engineering	.390**	.064	.247*	.127	.061	.176	.251*
Post - CT	.432**	.609**	.125	.319*	.215*	.206*	.310*

Finally, we note that there was a higher correlation between pre-science/engineering scores and post CT scores than between pre- and post-science/engineering scores. This somewhat unexpected finding may reflect the extent to which students' science/engineering knowledge and skill could be "bootstrapping" CT learning by enabling students to leverage STEM concepts and practices toward the advancement of their CT proficiency. We illustrate examples of how the integrated performance tasks may be enabling students' science/engineering proficiency to support their CT learning in a vignette below.

Improved CT through science & engineering integration and CM scaffolds

We highlight the work of a particular student, Taylor (pseudonym), who illustrates how science/engineering proficiency may be supporting CT learning across the STEM+CT integrated computational modeling activities in the WRC unit. Taylor achieved a high pre-science/engineering score of 17.5 (93rd percentile) and maintained the same score on the posttest (67th percentile). They achieved a low pre-CT score of 4.5 (25th percentile) and improved to the maximum post-CT score of 13. The pretest scores suggest that at the beginning of the study, Taylor was a proficient science student with little previous exposure to programming.

Despite achieving a low pre-CT score, Taylor exhibited a particularly high level of performance on activities associated with post-CT performance. Taylor earned the maximum score of 8 points on the dice game activities, achieved by only about one third of the students in the study. Taylor also exhibited a strong conceptual

understanding of test cases, earning 5 out of a possible 6 points on the test case selection task and with the only error being arithmetic in nature (incorrectly transforming the number 0.09 to 0.9 prior to performing the test). Taylor's strongest performance was in the difficult debugging tasks, earning 14 points (the second highest among all students in the study). For instance, in response to the task shown in Figure 3(a), Taylor identified both instances where the system variables were incorrectly reversed, writing "In many occurrences (sic), Sumi needs to switch the Total Rainfall and Total Absorption twice on the second IF THEN statement." In response to the task in Figure 3(b), Taylor correctly predicted that the code in the nested 'if' block would not be executed for an absorption limit of 0.8 inches and correctly articulated that moving the nested 'if' block to the end of the program would debug the model. Taylor's responses to both the test case activities and debugging activities illustrate how designing CT tasks to be embedded in STEM contexts have the potential to help students leverage STEM understanding toward advancing their CT proficiency (including programming skill).

Discussion and Conclusion

This paper illustrates how CT learning can be promoted for upper-elementary school students through the coherent integration of science, engineering, and computational modeling. We describe activities such as conceptual modeling, unplugged dice games, test case identification, and CM debugging that support the integration of STEM and CT disciplines and discuss how students' engagement with them may be associated with learning in STEM and CT disciplines. These activities enable students having no prior programming experience to successfully develop CMs with minimal programming instruction and offer the potential for students to use their science and engineering knowledge to bootstrap their CT proficiency. Though students' pretest and posttest scores were strongly correlated, the design guidelines related to CM development and evaluation informed scaffolding for students' CT learning even when students started with low CT proficiency.

Our design for promoting CT for fifth and sixth grade students using computational modeling in an integrated science-engineering context also contributes to ongoing research on the nature and extent of CT integration and the feasibility and usefulness of programming and deep CT integration for upper-elementary students and teachers. Analyses of elementary teachers' plans for integrating CT in science lessons (Coenraad et al., 2022) reveal the use of computer simulations and data as some of the most common CT practices integrated while programming is one of the least common practices. When programming is used, it is often used to exhibit science knowledge gained through other means rather than further science learning. Overall, the integration is often limited to the bottom two levels of the CT integration framework (Coenraad et al., 2022) - *exist* (identify science practices that also count as CT) and *enhance* (use small CT activities to support science learning). This finding highlights the importance of presenting teachers with usable models of deeper CT integration that include a range of CT practices. The WRC demonstrates the feasibility of a science and engineering curriculum for fifth and sixth grade students involving numerous CT practices (computational simulations, programming, systems thinking, using data) and a deep level of CT integration where CT and science learning are mutually supportive.

Further, our findings add to a growing body of research examining the relationship between learning in CT and STEM disciplines (Lee at al., 2020). The framing of CT as a science and engineering practice in the US Science Education Framework, as well as schools' typical implementation of STEM as core subjects into which CT can be inserted, position CT as domain-general skills that advance STEM learning and prepare students for success across STEM disciplines. Our findings provide preliminary evidence of the converse relationship, where STEM disciplinary proficiency supports CT learning. Additional research studies are needed to clarify the mechanisms by which CT and STEM proficiency support each other. For instance, our findings align with studies (e.g., Hutchins et al, 2020) that identify debugging as an especially important connection between CT and scientific modeling.

Abstract: In the current "post-truth" era, there is a growing need to promote apt epistemic practices in science education. In this study, we investigated two high-school biology students' epistemic practices during a modeling unit and appraised them for aptness using the Apt-AIR framework. Additionally, we analyzed their responses to a post-implementation focus group interview, designed to elicit their metacognition regarding epistemic practices, as they answered probing questions about practices within the curriculum and reflected on video clips of other students engaging with the units. We document the epistemic practices that students engage in during a modeling unit and evaluate the extent to which they are apt. Findings suggest a disassociation between students' cognitive engagement in modeling practices and their metacognitive understanding.

Introduction and Theoretical Background

In the current "post truth" era, science denialism and the spread of misinformation are prevalent, and science education has failed to meet these challenges (Chinn et al., 2020). The widespread rejection of well-justified scientific consensus on matters such as COVID- 19 risks, vaccination safety, and climate change demonstrates the urgent need to develop and implement instructional strategies that enable students to accurately appraise scientific information (Barzilai & Chinn, 2018; Chinn et al., 2020; Duncan et al., 2018; Kavanagh & Rich, 2018). To address these challenges, we examined an existing high-school science learning environment that seeks to promote apt epistemic practices in science classrooms. Our approach builds on Barzilai and Chinn's (2018) analysis of apt epistemic performance, defined as successful performance (e.g., reaching an accurate conclusion about vaccination safety) that is produced through competence (e.g., one's ability to evaluate the evidence, identify scientific consensus, and integrate the relevant information). Apt epistemic performances are further unpacked in terms of:

- *Aims* (e.g., aiming to reach an accurate conclusion)
- *Ideals* or standards for evaluating whether an aim has been achieved (e.g., fit with relevant evidence and the consensus of experts as ideals for determining whether an accurate conclusion has been reached)
- *Reliable processes* (RPs) that are used to achieve the aims (e.g., evaluating multiple sources of information, evaluating the expertise of sources, and so on)

Apt epistemic practices (AEPs) are clusters of interrelated apt epistemic performances that are governed by shared community norms. Examples of such clusters of AEPs are constructing scientific models, running and interpreting simulations, and engaging in argumentation. The various aims, ideals, and RPs used in these practices are shared by a community; for example, a community can share the aim of reaching well-justified conclusions, adopt ideals such as fit with ample evidence, and employ processes such as gathering and weighing large numbers of studies to ensure ample evidence. Our goal is to promote growth in AEPs that can be used inside classrooms in inquiry and that can be adapted for use outside classrooms to evaluate scientific claims encountered in the contemporary information society.

The first objective of this study is to examine the interrelations between cognitive and metacognitive aspects of epistemic practices. AEPs encompass both cognitive uses of relevant aims, ideals, and processes (e.g., members of a community regularly conduct multiple experimental trials to improve the reliability of data) and a metacognitive understanding of these aims, ideals, and processes (e.g., understanding as a community that multiple trials are needed to avoid being misled by outliers) (Barzilai & Chinn, 2018). Both cognitive and metacognitive aspects are important to epistemic competence (Ford, 2008; Hofer, 2005; Barzilai and Zohar, 2012, 2014). Although some research suggests close connections between metacognitive and cognitive aspects of performance (e.g., Barzilai & Zohar, 2014), other research suggests that associations between cognitive

 © ISLS

performance and metacognitive understanding is low (e.g., Van der Stel & Veenman, 2010). Yet there are reasons to think that metacognitive understanding might help support improved cognitive performance. For example, if students metacognitively grasp that multiple trials are needed in experimentation to establish stable, average effects, then the students may be more likely to use such practices themselves and to notice if others do not use them. Accordingly, this study uses a comparative case study approach to examine the relationships between students' metacognitive understanding of AEPs and their cognitive use of these practices in their own inquiry.

A second goal of this study is to contribute to the field's understanding of what growth in epistemic practices looks like during inquiry. There is a need to develop more comprehensive accounts of what epistemic growth involves as well as how to promote it (Barzilai & Chinn, 2018). In this paper, we seek to apply the Apt-AIR framework developed by Barzilai and Chinn (2018) to understand students' epistemic practices, and thus explore the affordances of this framework in identifying epistemic practices that students engage in, and how these epistemic practices might be improved. This approach is line with other approaches to define and promote epistemic growth (Berland et al., 2015; O'Neill & Polman, 2004; Osborne et al., 2003). Thus, we employ the Apt-AIR framework as a lens to characterize epistemic growth in terms of aims, ideals, and RPs, and we ultimately intend to promote growth in aims, ideals, and RPs in science classes.

The focus of this study was to examine the epistemic practices of students using the Apt-AIR lens, and to examine the extent to which students' metacognitive understanding of epistemic practices was similar to the epistemic practices they demonstrated in their own inquiry. To address these goals, we used a comparative case study method: We investigated two students' epistemic practices while they participated in a widely accessible, agent-based modeling curriculum titled BioGraph, in which students experiment with and learn about complex biological systems (Yoon et al., 2017; Yoon at al. 2018). Additionally, we analyzed post-implementation focus-group interviews in which students metacognitively identified ideals and RPs. We address the following research questions: (1) What ideals and RPs did the students discuss in the focus-group interviews? (2) What ideals and RPs did students demonstrate in the classroom as they participated in the BioGraph unit? (3) What was the relationship between the cognitive classroom performance of these students and what they metacognitively identified in their post-implementation focus group interview?

Methods

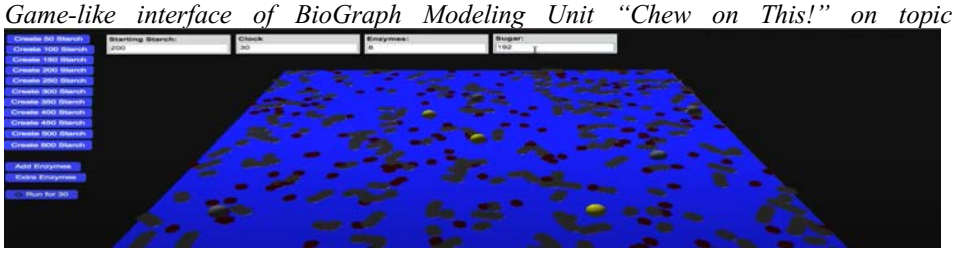
Context

In 2013, BioGraph researchers conducted an exploratory study in which students worked in groups of 2 to 4 with two to three units of the BioGraph curriculum, which offers five biology units on the topics of Genetics, Evolution, Ecology, Sugar Transport, and Enzyme Kinetics. In the units, students worked with agent-based simulations that combine graphical blocks-based StarLogo programming with a 3-D game-like interface (see Figure 1). The curricular materials for each unit took 2–3 days to complete and included popular and academic literature about complex systems as well as short movies, PowerPoint presentations, and teacher and student activity guides (Yoon et al., 2016; Yoon et al., 2017).

In the present study, we used two sources of data: students' classroom interactions while actively participating in the BioGraph unit *"Chew on This!"* from the 2020-2021 school year. In this unit, the learning objectives were: (1) Recognize that enzymes speed up chemical reactions that take place in cells, (2) Explain the shapes of the reaction rate curves both with and without enzymes, (3) Understand that enzymes and substrates interact with one another due to random (not directed) motion of molecules. Additionally, some students volunteered to participate in a focus group interview, post implementation. According to teachers, the students in the focus groups represented a broad range of students. In the focus group interview, we used for some questions previously collected video footage from the BioGraph research project from 2013. The clips included students interacting with the *"Chew on This!"* unit and the *"Gene Regulation"* unit. There were minimal changes made from the 2013 modeling curriculum to 2020-2021; thus, the clip content was familiar to the students.

Figure 1

Game-like interface of BioGraph Modeling Unit "Chew on This!" on topic of Enzyme Kinetics



Participants

In this comparative case study, we focus on two students—pseudonyms Nate and Hannah—who were ninth grade, accelerated biology students from a public high school in northeastern USA. Both students were in the same biology class and were in the same group of four students while they participated in the BioGraph unit. Nate was a male student, and Hannah was a female student. Both identified as White, non-Hispanic. Nate was a vocal member of the group while he engaged with his groupmates as they worked through the BioGraph unit as well as when researchers asked questions in the focus group. Hannah made fewer verbal contributions than Nate in both formats yet participated relatively frequently in the focus group. Nate and Hannah were selected for this case because of their participation within the same group both in class and in the focus group.

Data Sources and Analysis

We analyzed classroom data from February 2021, when the class was virtually conducted over Zoom due to the COVID-19 pandemic. Nate and Hannah were in the same student group participating in an Enzyme Kinetics unit titled "Chew on This!" with two other students. We video recorded the students as they engaged in inquiry with the modeling unit for one class period, or roughly 30-minutes. Additionally, we conducted a 60-minute post-implementation focus group interview in May 2021. In the interview, we prompted students to examine and reflect metacognitively on scientific practices. The questions were designed to elicit comments about the ideals they endorsed for good models (whether normative or not) and the processes they viewed as reliable for engaging with simulations on complex systems (see Table 1). In the focus groups, students were also shown clips from previously collected data of students participating in BioGraph units, and they evaluated and reflected on the epistemic practices demonstrated in the clip.

Table 1

Examples of questions asked by research team and the AIR components (Ideals and RPs)

Questions and goals of questions
What are the most important criteria or characteristics of good scientific models and/or good explanations? Which is most important and why? [This question invites students to express what they view as ideals for good models such as: Models should fit the evidence. Models are understandable. Models have mechanisms that show unseen entities and step-by-step processes.]
When working with BioGraph models, what steps did you or might you take to make your prediction? In other words, how would you justify that your prediction was reasonable when answering a question (i.e., what sources or knowledge would you use to make a prediction)? Do you think it is useful to make a prediction before conducting an experiment? Why or why not? [In response to this question, students might mention ideals such as fit with prior knowledge or the use of good models to make accurate predictions. They might also mention processes such as checking predictions against outcomes, basing their prediction on their last experiment, discussing ideas with their team, etc.]
Students watch a video clip of two students working on a unit on enzymes. In this unit, the students enacted some less RPs , including considering only one prediction, cherry-picking data to match their prediction, using data points as distinct, instead of computing averages Then they were asked: **How would you describe what the students are doing to collect data?** [With this question researchers probed students' ability to metacognitively critique the videorecorded students' use of ideals and RPs. The question provides an opportunity to identify the less RPs evinced in the clip and to suggest what ideals and processes that are better, such as checking for random variation, evaluating evidence consistently, aligning beliefs with evidence, etc.]
Researchers showed some example graphs from the student worksheets to jog memories about how they may have used them. Then asked: **Why do you think this is useful to create graphs when learning about science?** [This question elicits the ideal of emergence—that micro interactions produce macro level patterns which can be depicted through graphs. Students might also suggest processes such as comparing the qualitative pattern on the screen with the graph, which can aid in describing trends and synthesizing information.]
Averaging data and creating graphs are two scientific skills. Can you think of any other scientific skills that you practiced when working with the BioGraph lessons in general? [In response to this question, students might consider RPs such as using evidence to justify a claim, collaborating with peers in inquiry, collecting and recording data, etc.]

Students' ideals and RPs were analyzed based on student discourse in both the classroom inquiry and in the focus group data. (Students seldom mentioned aims explicitly, so we will not analyze them here.) Ideals and

 © ISLS

RPs were coded using both top-down and bottom-up methods. As a starting point, previous research on ideals and processes on science tasks provided a guide to possible ideals and RPs that might emerge (Barzilai & Eilam, 2018; Schwarz, et al., 2009; Pluta et al., 2011). Yet the data were coded with the expectation that new ideals and processes would emerge that had not been previously found. The team developed a comprehensive code book through a constant comparative method with multiple iterations, views, and negotiations of the data sources as well as interactional analysis (Jordan & Henderson, 1995). From this code book, Table 2 presents those codes that are most relevant to the data presented in this paper. Note that students sometimes used or advocated processes that could be considered less reliable. For example, for some students, many trial runs of the simulation were needed to establish stable conclusions (more reliable), but for others, two or three trials, or even just one trial (less reliable), was sufficient.

Table 2

Coding List of Ideals and RPs with their Explanations

Ideals	***Explanation***
Fit with ample evidence	Good models fit not only some evidence but a sufficient amount of evidence (e.g., fit with multiple simulation runs rather than just one run).
Fit with systematic evidence	Good models fit not only evidence from single trials, but from careful, controlled experimentation that tests many combinations of variables.
Understandability	Good models are clear and understandable.
Incorporation of underlying biological processes	Good models incorporate underlying, step-by-step biological processes hypothesized to produce the phenomenon.
Fit with prior knowledge	Good models fit with prior well-established knowledge.
Randomness	Good systems models include random variation in their processes.
Successful prediction	Good models can be used to make accurate predictions.
Causal complexity	Good models are complex with many causes and many effects.
Processes viewed or treated as reliable	***Explanation***
Develop arguments with evidence-based reasons	Giving reasons grounded in data/evidence to support ideas.
Consider and test multiple hypotheses	Making predictions based on two or more alternative hypotheses and testing them together.
Consider and test single hypotheses (less reliable)	Making and testing a single prediction.
Run and gather data from multiple trials	Running simulation multiple times to establish average phenomena under the same starting conditions.
Run and gather data from single trials (less reliable)	Running a simulation only once and using the results only from that single run.
Conduct careful experimentation	Planning/running systematic series of controlled experiments carefully contrasting different starting conditions.
Evaluate evidence consistently	Treating information that supports your ideas consistently with information that contradicts your ideas when gathering data (e.g., don't dismiss a single simulation trial that goes against your ideas while accepting a single trial that contradicts your ideas).
Cherry-pick data (less reliable)	Selecting data points in biased ways to confirm prior prediction/beliefs.
Align beliefs with evidence	Revising explanatory models when there are large or even small discrepancies with evidence.
Evaluate evidence based mainly on prior beliefs (less reliable)	Deciding to believe evidence is "correct" to determine whether to keep or discard a data point.
Average data from trials	Calculating the average of data across multiple trials.
Identifying trends	Identifying trends in the data output.
Determine biological processes	Examining simulations carefully to determine underlying biological processes.

Table 2 (continued)

Using prior scientific knowledge	Using scientific knowledge developed or learned previously to evaluate and understand simulation phenomena.
Checking whether agents are behaving randomly	Observing agents' behaviors in the simulations carefully to judge whether the behaviors are partly random.
Explaining using multiple interacting agents	Explaining that multiple interacting agents produce system level outcomes rather than a single leading agent.
Compare simulation phenomena with graphs	Comparing the qualitative pattern on the screen with the graph.
Collaborate with peers	Collaborating with peers and working together to develop a consensus of ideas.
Apply ideas out of school	Applying what is learned in class inquiries to outside-of-school situations.

Results

We present the results in three parts. First, we analyze Nate and Hannah's responses relating to ideals and processes in the focus groups, including their reflections on the presented video clips. Second, we present the ideals and processes that Nate and Hannah used while they participated in the modeling unit. Lastly, we integrate and investigate the results from both contexts to bring forth the relationship between students' cognitive and metacognitive grasp of ideals and RPs.

Ideal and Processes Present in the Focus Group Interview

Analysis of the focus group responses indicate that Nate and Hannah explicitly and implicitly invoked an impressively wide range of RPs and ideals (See Table 3). Nate made multiple references to the ideals *Fit with ample evidence* and *Fit with systematic evidence,* as well as to the RPs *Evaluate evidence consistently* and *Align beliefs with evidence.* He explicitly identified seven of the eight ideals captured in our coding scheme and articulated a wide range of different RPs, as shown in Table 3, which presents several of his comments. Hannah articulated three of the eight ideals: *Randomness, Successful Prediction, and Understandability.* She also identified several RPs. She specifically mentioned the following RPs at least twice: *Run and gather data from multiple trials, Conduct careful experimentation*, *Utilize graphs for insight, Align beliefs with evidence,* and *Evaluate evidence consistently.* Several of her contributions are also highlighted in Table 3. Hence, the two students successfully identified an impressive range of ideals and RPs when they were metacognitively asked to reflect on probing questions and video clips from other students engaged in BioGraph units.

Epistemic practices present during classroom inquiry

In the classroom data, there were two instances in which Nate explicitly engaged with appropriate ideals and RPs. He employed the RP of *Running and gathering data from multiple trials*, as he said, "I clicked for 30 multiple times…" Additionally, he implicitly demonstrated the ideal *Incorporation of underlying biological processes* when considering models to explain the phenomena of enzymes breaking up the starch molecules. He slowed the simulation to make sense of this phenomena before he articulated the underlying processes. Hannah demonstrated use of only one ideal and no RPs in the classroom data. Like Nate, she implicitly demonstrated the ideal of "*Incorporation of underlying biological processes"* by saying that she would slow down the simulation to grasp the biological phenomena to express how enzymes were breaking up the starch molecules.

Nate and Hannah also employed less RPs and less appropriate ideals in the classroom inquiry. Indeed, their inquiry practices included some of the less RPs that they had criticized in the focus group. Both students exhibited *cherry picking, considering and testing a single hypothesis, and evaluating evidence based on prior beliefs*. These practices directly conflict with the normative ideal *Fit with systematic evidence* and the RPs *Evaluate evidence consistently, Consider and test multiple hypothesis* and *Align beliefs with evidence*. For example, Nate endorsed the group's practice of cherry-picking data in comments about trials such as "Don't use the 17" and "I think 54 is very off" (because these were not close to his prediction of 30). Instead of considering all data as evidence, it was clear that Nate and his groupmates (including Hannah) selected data points that justified their favored group hypothesis. Although Hannah did not actively contribute to her group's evidence selection, she also did not push back on the groups' practices, and she reported the same answers as her group in her student activity guide. Thus, both students used less RPs more frequently they used more RPs, and their judgments were guided more by the ideal of fit with prior expectations than by the ideal of fit with evidence.

Table 3
Examples from Transcript of Focus Group with researchers coding of the excerpt

Examples of students' responses to the focus group questions	Ideals/RPs metacognitively discussed
Nate's responses	
Nate: A lot of the different things require ATP for energy, ATP is going to be created using other things. Everything requires certain factors in order to work, and then to create those factors it requires other factors. So all these processes rely on other processes.	*Ideals:* Causal complexity; Incorporation of underlying biological processes *RPs:* Explaining using multiple interacting agents
Nate: The graph there in the Gene Regulation, that's useful. So it's not just that I think there's more of these over time and then they decrease, you can see the graph, you can see it's actually happening. Also, I think the randomness.... In all of these, if you run the simulation multiple times, it's not just the same exact thing. The factors are working off each other with a bit of randomness. You can tell that whatever is happening is actually happening. In the real world, it's not going to be the same every single time. It's more realistic.	*Ideal:* Randomness *RPs:* Utilizing graphs for insight; Explaining using multiple interacting agents.
Nate: And also, one very important thing in science is going to be building off of other scientific research that's already been done. By doing these CER questions, we're able to do this research ourselves and learn about how to use other people's studies that they've conducted to create our own.	*Ideal:* Fit with prior knowledge *RP:* Using prior scientific knowledge
Nate: If you're looking for a specific result, you can make the data match that. For example, as soon as they saw the result that there's 49, they went with that instead of looking at the overall average which disproved their hypothesis.	*Ideal:* Fit with ample evidence *RPs:* Evaluate evidence consistently; Align beliefs with evidence; Average data from trials
Nate: Also, to help you stop conforming your data to your hypothesis, you need to know how many trials you're going to do ahead of time. Otherwise, you might just keep saying, "One more trial" until you get a result that matches what you want to see.	*Ideal:* Fit with systematic evidence *RPs:* Run and gather data from multiple trials; Evaluate evidence consistently; Align beliefs with evidence.
Hannah's responses	
Hannah: It's different every time, so that way when you see it again you don't necessarily get the same data over and over again. That can give you the impression that there is going to be the same data over and over again when of course there wouldn't be. Interviewer 2: Can you explain that a little bit, by "of course there wouldn't be the same data every time"? Hannah: In the case of lactose, for example, if you consume more lactose, there'll be more lactose in your body, as a base point. But if it always came up with 20 lactose, for example, at the beginning, that could give you the impression that there's always going to be 20 lactose at the beginning instead of, you eat more of a dairy product and now you have more lactose in you.	*Ideal:* Fit with ample evidence *RP:* Run and gather data from multiple trials [to deal with the randomness that can affect results from a single trial)
Hannah: We were seeing the same thing, but we had completely different ideas. Interviewer 1: Do you remember what you did to work out the conflicting ideas that you had? Hannah: We just looked at everything else we had said and tried to piece together a step-by-step process that would make sense. That's how we decided which one was correct.	*Ideal:* Incorporation of underlying biological processes *RPs:* Gather and use conclusive, systematic evidence through careful experimentation; Consider and test multiple hypotheses

Table 3 (continued)

Examples of students' responses to the focus group questions	Ideals/RPs metacognitively discussed
Hannah's responses (continued)	
Hannah I was going to say the same thing. It's bad if someone's stuck to one idea even when all the evidence is going against that. Interviewer 1: That's an important point. Interviewer 2: What do you do when that person is stuck on an idea, even if all the evidence is going against that, what would you do to try to convince the other person? Hannah: I would try to explain what the evidence is actually supporting."	*Ideal:* Fit with ample evidence *RPs:* Align beliefs with evidence; Develop arguments with evidence-based reasons
Hannah: If there's a graph provided, I would definitely try to use the quantitative data and identify the trend.	*RPs:* Identify trends, Utilizing graphs for insight
Hannah: I would say the ability to make a prediction is very important in everyday life because there are a lot of times you just need to guess based on what you know. Interviewer 1: … do you mind, if you have one in your head, can you give an example of when you might make a prediction in everyday life? Hannah: If there's rainclouds out, you'd be able to make a prediction that it's going to rain. Then you might have to change your plans…."	*Ideal:* Successful prediction *RP:* Apply ideas out of school

Relationship between the Cognitive Performance and Metacognitive Identification

The findings revealed a disassociation between students' metacognitive grasp of ideals and RPs. Students identified and elaborated on significantly more ideals and RPs when asked to metacognitively reflect on probing questions and critique other students participating in a BioGraph unit in video clips. Even more tellingly, Nate and Hannah both identified and suggested the use of RPs such as *Evaluate evidence consistently, Consider and test multiple hypothesis* and *Align beliefs with evidence*, whereas they violated these very RPs in their own inquiry learning as they engaged in less RPs such as *Cherry-pick data, Consider and test a single hypothesis, and Evaluate evidence based on prior beliefs*. Thus, these students' metacognitive understanding on ideals and RPs surpassed their use of these same ideals and RPs in their own inquiry.

Discussion and Conclusion

In this contrastive case study, two students excelled at metacognitively identifying appropriate ideals and RPs, in contrast to their cognitive engagement with these ideals and RPs while working with the BioGraph unit. Classroom data suggested that students engage in less RPs, whereas in the focus groups, the students expressed impressive metacognitive knowledge of what ideals and RPs are apt. Interestingly, students engaged in the same less RPs in the classroom that they critiqued in the focus group video clips. Thus, they expressed a good metacognitive grasp of AEPs that they did not implement in their own inquiry.

This study expands on Van der Stel & Veenman's (2010) work by showing the dissociation between the cognitive performance and metacognitive understanding in an inquiry task. Further, it provides valuable insights for researchers on what epistemic practices are present in science classrooms by using the Apt-AIR framework (Barzilai & Chinn 2018) to promote educational efforts to encourage better epistemic practices (e.g. Berland et al., 2015; O'Neill & Polman, 2004; Osborne et al., 2003) We acknowledge the limitations arising from our analysis to date of only two students; research with larger samples is needed to see if these initial findings are borne out in analyses of larger samples.

An important implication of this study for the design of inquiry environments is that at least some high school students have a metacognitive grasp of AEPs that designers and teachers can build on in classroom inquiry. Designers and teachers might incorporate metacognitive discussions within inquiry units to help students make the connections between their metacognitive grasp of AEPs and the practices that they are actually using in the classroom. These metacognitive discussions might serve to help students develop publicly endorsed norms for engaging in their own inquiry (cf. Barzilai & Chinn, 2018).

Investigating Synchronous & Asynchronous Feedback in an Elementary School Maker Education Classroom

Monica M. Chan and Nathan Holbert
monica.chan@tc.columbia.edu; holbert@tc.columbia.edu
Teachers College, Columbia University

Abstract: Providing and receiving feedback is a crucial aspect of K-12 education, and is foundational to building a strong student-educator relationship in project-based learning. Previous research has highlighted the importance of student documentation, thus we study the implementation of a mobile application prototype (CoCreator App) that encourages student documentation along with features for asynchronous educator feedback. We observed and analyzed how educators provided synchronous feedback when conversing in-person with students. Our analysis indicates a variety of differences between synchronous and asynchronous feedback. Asynchronous feedback was typically used for praise and encouragement, but also offered additional opportunities for educators to notice student struggles that may not have been visible in class. Synchronous feedback was largely used to provide process-oriented feedback. Looking ahead as the COVID-19 pandemic prevails, we suggest practices and workflows for maker educators to consider as they provide both synchronous and asynchronous feedback in interdisciplinary (and potentially hybrid) learning environments.

Key terms: feedback, formative assessment, maker education, synchronous, asynchronous

Introduction

Feedback is regarded as a primary component of formative assessment (Black & Wiliam, 1998), where the intention is to communicate new information to the learner to modify his/her thinking to improve learning (Shute, 2008). Using Hattie & Timperley's definition, feedback is information provided by an agent (such as a person, experience, or self) regarding aspects of one's performance or understanding, a "consequence" of performance in a spectrum from instruction to feedback (2007). For feedback to be helpful, the provider needs to take into account the many ways learners might interpret feedback, and characteristics like timing and how information is delivered (Havnes, Smith, Dysthe & Ludvigsen, 2012).

In maker education, a particular form of project-based learning where students are tasked with using a variety of traditional and highly technical tools to create physical artifacts, feedback is vital to ensure students progress down a productive path. Feedback has typically been given synchronously, where teachers visit students' work areas, providing feedback and encouragement throughout the construction process. In interdisciplinary settings such as a makerspace, synchronous in-person feedback has demonstrated huge benefits to students, as students and educators can troubleshoot problems quickly by using demonstrations and sharing tools. However, the prevalence of digital portfolio systems and the expansion of remote learning experiences (especially due to the COVID-19 pandemic) has meant that maker educators are often providing feedback asynchronously. Asynchronous feedback has also positively impacted students' self-efficacy and self-regulation too (Tseng, 2016; Litts et al., 2016). We are interested in exploring situations in maker education where there are avenues for both synchronous and asynchronous feedback.

In this study, we explore the following research questions: What types of feedback do maker educators provide at various stages of students' interdisciplinary maker projects, and how do asynchronous and synchronous modalities impact the nature of this feedback?

Literature Review & Prior Work

Educators often use technology as part of their pedagogical and formative assessment practices. Using learning management systems or collaborative editing software has helped educators support their students' needs asynchronously and synchronously (Ames, Harris, Dargusch & Bloomfield, 2021; Irons & Elkington, 2021).

In Hattie and Timperley's (2007) systematic review of literature on feedback processes, they identified four main types of feedback students typically receive: *Task Feedback, Process Feedback, Self-Regulation Feedback,* and *Praise/Self Feedback*. Task feedback provides students with information about whether their work is correctly executed or not; Process feedback encourages deeper reflection on the extent of success to which a task was done and areas for improvement; Self-Regulation Feedback challenges students to self-assess their work and develop self-directed learning skills; Praise/Self Feedback focuses more on the student rather than the task at-

 © ISLS

hand, and may not necessarily encourage students to invest more effort in a task (Van Boekel, Weisen & Hufnagle, 2021; Hattie and Timperley, 2007). Later in data analysis, we use Hattie and Timperley's categories to identify instances of synchronous and asynchronous feedback that we observe.

Synchronous In-Person Feedback as Formative Assessment

During in-person maker experiences, educators are generally able to quickly determine students' progress and struggles. These formative assessment opportunities emerge either when students come to educators for clarifications or when educators notice students' progress while pacing around the class, particularly when similar misconceptions surfaced across a sizable proportion of students (Jayathirtha, Fields, Kafai & Chipps, 2020). Maker educators also often facilitate peer-to-peer feedback so that students interact with and learn from each other by discussing each other's code or prototypes. This mode of feedback has its advantages because educators can command all students' attention to troubleshoot or clarify their misconceptions immediately (Jayathirtha, Fields, Kafai & Chipps, 2020). The in-person setting also allows educators to improvise in the moment with just-in-time ideas (Vossoughi, Escudé, Kong & Hooper, 2013).

Asynchronous Online Feedback as Formative Assessment

Educators might use online platforms for formative assessment, as online platforms afford higher visibility of patterns across artifacts that students upload (Wong & Yang, 2017). A maker education class may take place online too, as observed during the COVID-19 pandemic when schools switched to emergency remote teaching, or in distance learning when students and educators are at different geographic locations. In such cases, the educator's feedback would usually be personalized for each student. Educators may be able to spot patterns in students' submissions, and thus identify common struggles (Jayathirtha, Fields, Kafai & Chipps, 2020). However, there may be missed opportunities where the entire class could learn together, as there are fewer or minimal opportunities for peers to view each other's work, depending on the type of platform (Fields, Jayathirtha & Kafai, 2019).

Methodology

Our literature review has demonstrated affordances of both synchronous in-person and asynchronous online feedback, thus we decided to conduct a study where maker classes occurred in-person during formal school curriculum periods, with an added component of asynchronous online documentation for students and educators to use. This was an eight-week in-person classroom study with 24 fifth-grade students (11-year-olds) and 2 maker educators (one primarily taught music, the other visual art) in a public school in Singapore. All participating students had prior experience in maker education from activities in third and fourth grade. In these previous maker experiences, students kept a booklet to occasionally jot ideas or sketches down and had intermittently used Seesaw, a commercial mobile application, to share photographs and videos with other teachers and their parents of the work they do in school for various subjects. However, the students were generally new to regularly documenting their own work and receiving feedback via a mobile application. The participating maker educators are strong advocates of documentation and iterative feedback, and were very familiar with using Seesaw to document their students' activities. The maker education classes were held once a week for 1h 20 minutes during the time these teachers would normally provide visual art and music instruction. The first author observed the in-person classroom sessions during the study.

Content & Curriculum

The participating teachers Mrs Lee and Mr Tan (name altered) created this maker education curriculum for their fifth-grade students three years ago when this school's makerspace first began running. The school itself was designed by Singapore's Ministry of Education to be a lead school of maker education, therefore the schools' teachers participated in additional professional development with the ministry's Education Technology Division. As Mrs Lee is a visual art teacher and Mr Tan is a music teacher, both decided to collaborate to develop an interdisciplinary curriculum for the term (2-3 months long) where students would incorporate both elements of visual art and music in their projects, and also learn other concepts such as computer programing, circuitry, and material science.

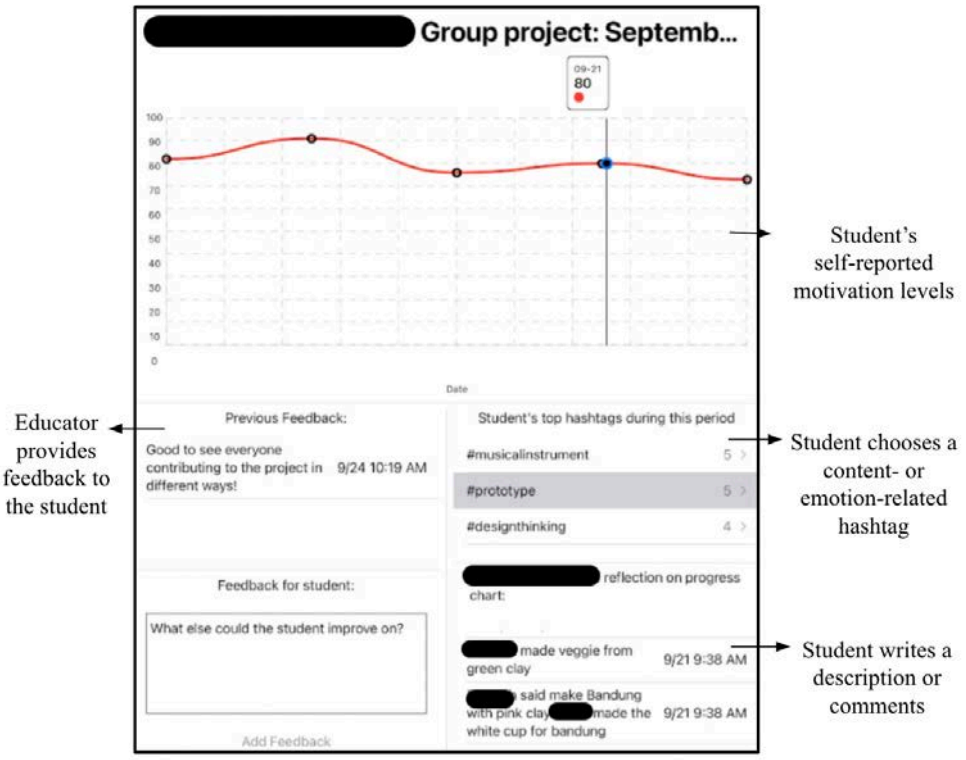
For this eight-week study, Mrs Lee and Mr Tan's primary learning objectives for their students included: 1) to understand and implement the design thinking process that the Stanford d.school established - Empathy, Define, Ideate, Prototype, Test; 2) learn to compose Singaporean folk songs with the right chords and notes through computer programming with Scratch; and 3) apply aesthetic design principles and knowledge of various types of art materials to sculpting. For the first two lessons, students embarked on individual assignments to learn computer programming with Scratch and circuitry with the Makey Makey microcontroller, then worked in groups

of 4 to 5 to develop their projects for the remaining weekly lessons. The maker educators tasked students with using the design thinking process, requiring students to interview non-teaching staff members to identify their hobbies and interests, and then construct a musical instrument using recycled and craft materials following the non-teaching staff members' preferences. Each group assigned one or two students as "documentation leaders" who were responsible for taking and uploading photographs of work in progress and self-reporting their group's motivation levels.

Features of the CoCreator App

The CoCreator App (Figure 1) was developed to encourage students to upload photographs of their works-in-progress with hashtags related to content and emotions, to self-report motivation levels throughout their maker classes, and to input comments or descriptions about their work in a text box below. Educators are notified about new posts that students make on their account, and also have text boxes where they are encouraged to provide feedback to students. Students receive a notification when the educator comments on their posts.

Figure 1
Screenshot of the CoCreator App's interface



In class, the educators instructed students to use the CoCreator App throughout the 1.5-hour period to document activities and assignments they are working on. The educators encouraged students to document photographs of works-in-progress, instead of only showing finished work. To provide a bit more structure to documentation, the educators assigned at least one student per group to be the "documentation leader" so that this student will be responsible for taking photographs of his group's work and reminding his group mates to document any individual work. The educators also suggested that students should take at least five photographs spaced out throughout the 1.5-hour period, and not a bunch of photographs during the last few minutes.

The objective of the CoCreator App is to assist educators in noticing information about students or groups that they may not have observed during in-person classes, through data from students' photographs, comments and/or self-reported motivation levels. From this study, we observe that educators choose the modality in which they provide the feedback (i.e. either synchronous or asynchronous or both), then ponder over the feedback they are about to provide. Usually, the modality where they encounter students' work prompts them to consider certain aspects for feedback, thus the type of feedback they provide synchronously and asynchronously usually differs for similar tasks or stages in students' projects.

Data Collection & Analysis

We examined three primary types of qualitative data: educators' asynchronous feedback on students' posts using the CoCreator App, educators synchronous feedback given to students as captured by in-class video-recorded observations, and field notes that the first author took during the in-person observations.

For in-class synchronous feedback sessions, we observed how educators interacted with students to deliver the feedback. Although the first author took field notes during the class, we added additional context and observations to these notes by watching video recordings of in-class sessions. We base our analysis on traditional interaction analysis (Erikson, 2006), where we ground our observations focused on modalities of interaction such as pace of speech, tone of speech, shifts in body language and posture, changes in facial expressions, hand gestures etc. We generated transcripts of selected observations of feedback sessions to document their content and attributes related to student-educator interaction. From these transcripts, we locate key moments where the educator modifies tone and expression to emphasize certain points while providing feedback, and where the students ask clarifying questions or respond to the educator's questions. We would mark a phrase or behavior as "feedback" if the educator provides additional ideas, support, clarification, or correction to a student's activity or work in class. Examples are demonstrated in the next section.

We categorized educators' feedback into the four main types of feedback that Hattie and Timperley had identified: Task Feedback, Process Feedback, Self-Regulation Feedback, and Praise/Self Feedback (2007). Next, for each type of feedback, we further categorized them into sub-codes based on emerging themes we observed from content and tone: *encouraging*, where the educator wrote positive comments meant to motivate the student, *checking in*, where the educator suggests that the student follows up either on the application or in class, and *troubleshooting*, where the educator points out where a student may be stuck or is doing something wrong, unplanned, or unexpected.

For select situations where data is available for both synchronous and asynchronous settings on the same stage of a group's project, we compared how educators delivered feedback via two different modalities, using field notes to capture synchronous feedback observed during in-class sessions and log data on the CoCreator App to capture asynchronous feedback.

Findings & Discussion

The following examples show educators providing students with feedback synchronously in class and asynchronously through the CoCreator App, where students document their project work by uploading photographs they had taken in class and self-reporting motivation scores for specific tasks.

First, we tallied the types of asynchronous feedback we observed from the CoCreator App. Overall, there were 10 occurrences of asynchronous feedback - 2 of which were task feedback, 0 process feedback, 1 self-regulating feedback, and 7 praise/self feedback. The total number of asynchronous feedback occurrences paled in comparison to the total number of synchronous in-class feedback (100+ occurrences) across 5 observation sessions. On average, both Mr Tan and Mrs Lee individually rotate to each of the 5 student groups at least twice during each class to provide feedback. This means each group should receive at least four instances of synchronous feedback in one class, and over the 5 observation sessions, each group will have received at least 20 instances of synchronous feedback, hence totaling to 100+ expected occurrences overall.

During each weekly class, we observed at least 1 out of 5 groups. For synchronous sessions that we observed in detail with fieldnotes, task feedback occurred overall 18 times, process feedback 5 times, self-regulation feedback once, and self/praise feedback thrice (although one of which was criticism, not praise). Task feedback occurrences were in the majority, and task and process feedback mostly intersected with the sub-codes *checking in* or *troubleshooting*. Synchronous self-regulating feedback happened the least number of times overall, and the particular instance we observed intersected with *encouraging*, where the educator told a group of past emotional challenges that a student group from last year had faced. Two instances of self/praise feedback intersected with *encouraging* because the educators praised students for completing a certain stage of their project; the third instance of self/praise feedback intersected with *troubleshooting* as the educators realized students ran into issues in their project, not because they did not understand a task, but because they executed the task in a lackadaisical manner (as perceived by the educators). We demonstrate examples that highlight the various types of feedback and interactions.

Theme 1: "Teacher Moves" supported in Synchronous Feedback

For asynchronous feedback, the most prevalent codes are *praise/self feedback* + *encouraging*. For synchronous feedback, they are *task feedback* + *troubleshooting* (an example shown in the quote from Mr Tan). Group A had interviewed the school's security guard and noted that his preferences and hobbies are: chicken rice (a local dish), Shih Tzu dogs, the color blue, and soccer. The students wanted to create a musical instrument that represented at

least one of his preferences, but were indecisive. Upon noticing that Group A had rather disparate ideas and had not settled on a direction to start making, Mr Tan strongly emphasized the importance of time management and brainstorming feasible ideas with repeated phrases (left out in the quote due to space constraints), which we classified as *task feedback*. He stood at the group's table where Group A's 5 students were seated around it, and verbally highlighted a few points:

> If the project is going to be chicken rice, how are you going to make chicken rice look like chicken rice? … Think about it; don't throw out ideas blindly without thinking about the processes ahead! … If at the end you know you are going to struggle to make a physical product, then that idea I would think - don't even consider it because you need to think ahead, because you don't have time.

After Mr Tan left this group, while searching for images of chicken rice made of clay, the students stumbled on an aesthetic image of nasi lemak (a different local rice dish but with some similar ingredients as in chicken rice) made of clay. They latched onto this new idea to create nasi lemak instead of chicken rice, and started assigning amongst themselves on items to create. In class upon noticing this sudden change, Mr Tan prompted the students: "So now you're making nasi lemak (a Singaporean Malay rice dish) instead of chicken rice (a Singaporean Chinese rice dish)?" Mr Tan used a surprised questioning tone, raised his eyebrows and widened his eyes, and looked around the table to gauge students' reactions. This was meant to be a subtle hint to students questioning why they had changed their idea suddenly, as Mr Tan was trying to make them aware that nasi lemak is ***not*** one of the preferences that their interviewee had listed. Mr Tan used an inquisitive questioning tone, rather than an instructional tone, which made his hint more subtle when delivered in-person instead of through asynchronous feedback (text) if it were written on the CoCreator App. Out of the students' earshot, Mr Tan let the researcher know:

> (Group A's students) might not pass their project because they've missed the objective, which is to create a sculpture in line with the user's preferences, not a random thing they thought of suddenly. But don't tell them! I want to see how this all turns out, and let this be a teaching moment for this group and the entire class about the Design Thinking step *Empathize*.

It is interesting to note that *task feedback + troubleshooting* did not surface in asynchronous feedback on the CoCreator App. On the CoCreator App, Mr Tan commented with a message that responded to the comments the student documentation leader had written, and we classified this as *praise/self feedback + encouraging*. This comment was a response to Group A's documentation leader's comments about various tasks that each student is doing, and the relatively high self-reported motivation scores (70-80 out of 100) from the group throughout the lesson.

> Documentation Leader Deepak (student names altered) recorded the comments below on his team's work:
>
9/21 9:38am	Dara made veggie from green clay
9/21 9:38am	Dara said make Bandung with pink clay. Ivan made the white cup for bandung
9/21 9:39am	Sahil wrote chicken rice idea and presented
9/21 9:39am	Aaron made the egg and yolk from white and yellow clay

> Mr Tan commented a few days later:
>
9/24 10:19am	Good to see everyone contributing to the project in different ways!

This example is a strong representation of asynchronous and synchronous feedback instances, as we observed multiple instances of asynchronous prase/self feedback and synchronous task or process feedback.

Theme #2: Extracting New Information from Asynchronous Feedback

Different from the previous theme, the educator here discerns new information about Group B and C students' progress and understanding of concepts through their documentation, comments, and self-reported motivation levels. Keeping in mind that these are subjective scores, we do not compare students' scores with one another, but we compare how students rate their motivation levels multiple times during the same class period, or across different weeks.

Group B was generally on-task in class and completed their coding portions swiftly. As a checkpoint, the educators instructed students to check in with them before proceeding to work on the portion with the MakeyMakey. Below is an extract of the first author's fieldnotes:

> When Mr Tan checked that Group B had completed coding their musical chords on Scratch correctly, he signalled to the group to follow him to the corner where MakeyMakey microcontrollers were kept in the classroom. He prompted them "You know the difference?", holding up a couple of alligator clips. He instructed them to collect the wires and microcontrollers and move on to the next step to connect their Scratch code to the MakeyMakey. This interaction lasted nearly 1 minute.

During the in-person interaction, it seemed that Mr Tan did not recognize or was unaware that Group B students still felt somewhat uncertain about the coding assignment even though they had completed it. Perhaps this is because the students did not voice out their questions directly to Mr Tan, and he checked for task completion, then moved them swiftly to the next stage. On the CoCreator App later, we noticed that Mr Tan wrote "Do approach me if the group needs more help" on a Group B student Pratama's post. During our interview with Mr Tan, he stated that he noticed the students lowered their motivation score from 100 to 50 in the same lesson with no written comments from the student, thus he felt that there could have been an unresolved issue from the class. We classified this as *task feedback + checking in*. Mr Tan noted that this specific student is typically conscientious and grasps new concepts well, but is soft-spoken and lacks confidence in the activities he does, which may have been a factor that led to a dip in self-reported scores.

During our interview with the student Pratama, he explained that he still felt unsure about coding on Scratch although he seemed to have completed the assignment correctly in class, thus he chose to go with the flow when his group started the next MakeyMakey stage, but decided to note his drop in motivation level on the CoCreator App. Here, Pratama's self-reporting and documentation on the CoCreator App provided Mr Tan an indication of his lack of confidence in the coding assignment that he did not feel comfortable articulating in class or in front of his groupmates - a separate avenue that could spark a follow-up conversation with Mr Tan.

Group C's situation was slightly different from Group B's. For a particular session, the researchers observed minimal synchronous educator feedback for Group C. Group C's students completed the coding assignment in class, and asked each other within the team for help if one of them ran into issues.

> Group C's documentation leader Zi recorded comments below on his work (Figure 2 below):
> 9/14 8:58am Coding the chords and changing the numbers were hard. I didn't understand what the chord numbers mean
> 9/14 9:01am It means that each number has a letter to make the chord. Which means that 48 is the letter C, 52 is the letter E and the number 55 is the letter G.
>
> Mr Tan commented a few days later:
> 9/17 10:17pm Do take note of the octave for your notes. Remember Mr Tan said notes 42-60? [Mr Tan wrote this on the school's learning management system, a different platform.] Check your codes if you have the time and identify the error.

Through the CoCreator App, Mr Tan noticed that Zi actually struggled with coding the musical notes during class, although Zi had not asked for help directly in class - this would not have been obvious in the synchronous session as Mr Tan would have assumed that the entire Group C had understood the concept and could move on to the next activity. We classified this piece of feedback as *task feedback + troubleshooting*.

Discussion & Conclusion

This study explores feedback given from an educator to students in an in-person maker classroom where both asynchronous and synchronous modes are available. The educators used synchronous feedback to provide detailed process-related suggestions for all groups and to offer immediate help when students ran into difficulty, whereas they used asynchronous feedback mainly for encouragement. However, there were a couple of occasions where students indicated confusion in concepts or processes in the CoCreator App, rather than during face-to-face interactions with the teacher.

In this study, it seems that the educators mostly used the CoCreator App to check students' work briefly and provide simple feedback, leaving more detailed feedback for synchronous time in class. During a post-implementation interview, educators indicated they worried asynchronous feedback might not be noticed by

students as they are only able to use the CoCreator App when using the school's iPads during their once-a-week class sessions. Results from this study may have been different if the educators allotted more time to provide various kinds of feedback on the CoCreator App, and if the educators structured the in-person session for students to review feedback they received through the CoCreator App.

More attention to in-person and synchronous feedback, when it's available, is a good thing! Future iterations of the CoCreator App could optimize this face-to-face feedback by automatically evaluating student posts and notifying educators of potential concerns. For example, the app could detect a drop in motivation levels or increased use of hashtags related to emotions such as frustration or dejection.

Another area for potential research is to study self-regulation feedback - educators providing feedback to students about self-assessment of their work. For this participating school, the educators had organized a peer feedback session where students rotated to different groups to provide feedback to one another based on rubrics and criteria. Although we observed minimal feedback from the educators about students' participation in this peer feedback session, in another study, we can investigate students' processes and perspectives of peer-to-peer feedback (Parenti, 2013). For future design iterations, the CoCreator App could also support asynchronous peer-to-peer feedback by providing students with features to comment on other groups' work. This would hopefully enhance the amount of self-regulation feedback that occurs in the maker classroom, as educators will have more opportunities to identify how students are assessing their own and their peers' work.

Abstract: This paper introduces a sociocultural framework called the zone of proximal self to reimagine how higher education institutions can support students from first-generation, low-income, and marginalized backgrounds. Employing mixed-method approaches, we analyze diary entries, surveys, and interviews of 50 students who met with a counselor/advisor during the Covid-19 pandemic. Thematic qualitative analyses reveal a model of effective practices characterized by creating a brave space, validation, and strengthening students' social-emotional competencies in culturally mindful ways. Case examples highlight features of this model including building working partnerships, understanding students' cultural backgrounds, validating students' experiences, and organizational brokering. Results from multiple linear regression models suggest that students, on average, have higher growth towards their professional and personal goals when exposed to more of these model practices. Taken together, the findings call for future research directions and designs of learning environments to consider cultural, relational, and social-emotional interactions in improving equity in higher education.

Introduction

In higher education, students' professional and personal development are impacted by educational inequities in socioeconomic privilege, resources, and access to opportunities (Tinto, 1987). The negative impact of educational inequities was exacerbated during remote education in the Covid-19 pandemic, which surfaced challenges including students' basic needs, social emotional well-being, and familial obligations (Fain, 2020). Thus, it is imperative for educators to reimagine how higher education institutions can support students' learning and development in a way that is situated in cultural contexts. The purpose of this study is to contribute to this reimagining by understanding an empirically grounded model of practices that can advance the professional and personal development of students from first-generation, low-income, and marginalized backgrounds (FLM). Since previous literature noted how out-of-class spaces such as counseling and advising can be promising for learning, the present study focuses on effective practices that happened virtually during the pandemic between counselors/advisors and undergraduate students from FLM backgrounds (Astin, 1993).

Literature Review

Culturally organized learning pathways

This work conceptualizes learning as a cultural process by drawing on the learning pathways framework in which learners engage in activities that draw them towards or away from competencies in context-specific situations (Nasir et al., 2020). Culturally organized learning pathways 1) are in relation to a sense of identity with relational, affective, and motivational components, 2) are built from socially constructed practices over time, and 3) reveal power dynamics from structural institutions experienced through interactions with families, peers, and school. This study focuses on the culturally organized learning pathways of undergraduate students from FLM backgrounds: how their identities, or who they are in the process of becoming, are impacted by interactions with counselors and advisors across time and settings which are influenced by college institutions and structures. This work aligns with the literature on culturally organized learning pathways by shifting the unit of analysis from academic learning outcomes to "specific and consequential learning resources or experiences that learners are able to access" which include counselors and advisors in their institution (Nasir et al., p.198).

Organizational brokerage

Previous research in learning pathways have shown how parents acted as brokers connecting children to experiences, people, institutions, or information (Barron et al., 2009). The present study examines the role of higher education counselors and advisors as organizational brokers. Organizational brokerage is defined as "the process by which an organization connects an individual to another organization or to the resources they contain"

 © ISLS

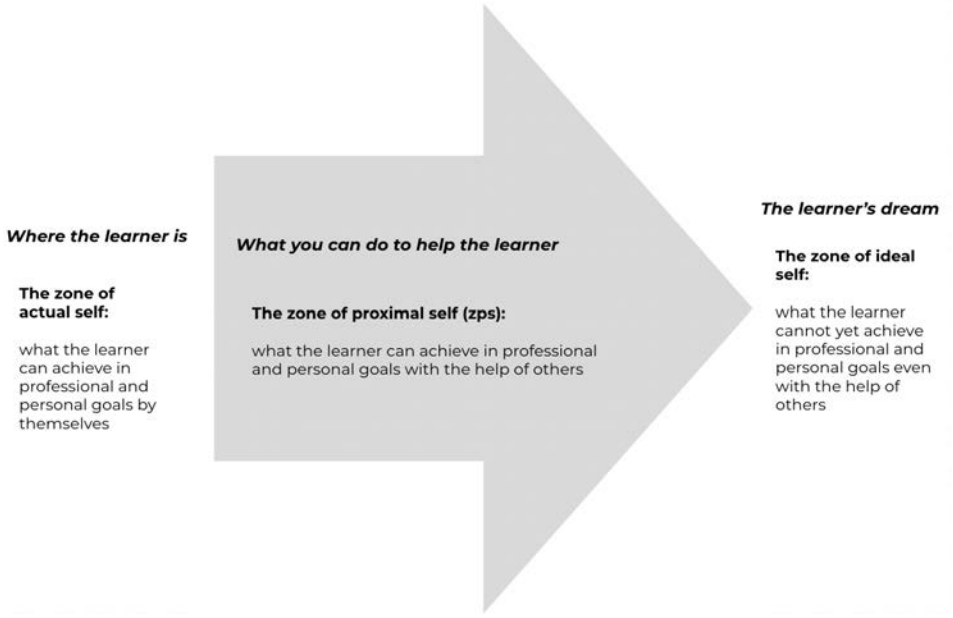
which can be implemented at the individual level through behaviors of school personnel and at the institutional level through administrative policies, infrastructure, and culture (Small, 2009, p. 19). There are different mechanisms in which organizational brokerage can occur including storage (i.e., broadcasting opportunities), validation (i.e., confirming right to use resources), referral (i.e., direct linking to an organization), and collaboration (i.e., working with another organization to provide social good).

Examining organizational brokerage and institutional roles moves away from a discourse of student independence and meritocracy to one about organizational and collaborative support of students from FLM backgrounds. The dominant narrative in higher education, especially in Science, Technology, Engineering, and Mathematics (STEM), have espoused the myth of meritocracy where successful students are the ones who "pull themselves up by the bootstraps" and navigate the hidden curriculum independently (Carnevale et al., 2020); however, this myth of meritocracy is detrimental to equity in higher education since it fails to recognize how students' lives are connected in critical ways to social opportunities and/or constraints. Hence, it is important to shift the narrative away from students' responsibilities in looking for resources by themselves and instead on the role of higher education organizations in supporting equitable learning pathways and resources.

The zone of proximal self conceptual framework

Aligned with a culturally organized learning pathways perspective and a focus on organizational brokerage, the zone of proximal self (ZPS) is a conceptual framework to theorize how learners interact with people, resources, and materials within their institution to develop competencies in pursuit of their possible selves. As illustrated in Figure 1, ZPS is the distance between an individual's actual and possible selves that can be bridged with the support of institutional people and resources. Furthermore, ZPS exists across a wide learning ecology in higher education, or the activities, resources, relationships, and interactions that occur across multiple contexts in physical and virtual spaces (e.g., classrooms, advising/counseling, peer groups, home contexts, programs, organizations, etc.) (Barron, 2006). This process transforms the relationship between the learner and learning environments, positioning students to explore new opportunities and identities within their institutions.

Figure 1. *The zone of proximal self conceptual framework*



Lev Vygotsky's sociocultural theory and zone of proximal development form the base of this conceptual framework. Vygotsky (1978) described how children's learning exists within a zone of proximal development, "the distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem-solving under adult guidance, or in collaboration with more capable peers" (p. 86). The ZPS framework extends Vygotsky's zone of proximal development from the context of developing problem-solving competencies to the context of developing social-emotional competencies to pursue possible selves in a professional community. Possible selves refer to the imagined selves that we could become, and also the selves that we are afraid of becoming (Markus & Nurius, 1986). ZPS regards possible selves as more than a dream job: they are dynamic visions of one's future self connected to holistic professional and personal goals influenced by cultural backgrounds, experiences, and home communities.

In this study, possible selves are operationalized through students' professional and personal goals for themselves which can be reached through the development of social-emotional competencies. Social-emotional competencies include cognitive, affective, and behavioral skills that can be developed over time, such as self-awareness, self-management, social awareness, and relationship skills (Kraft, 2019; Zins & Elias, 2007). Social-emotional competencies are similar to soft skills; however, the ZPS framework conceptualizes social-emotional competencies differently than skills discourses, or discourses commodifying soft skills for the job market without attention to cultural contexts (Hora et al., 2019; Urcioli, 2008). Instead, social-emotional competencies are envisioned as situated, culturally organized, and linked to new forms of social and learning-oriented activity.

Methods

Methodology and research questions

This study aims to refine the ZPS framework and contribute a ZPS model of practices grounded in empirical data of how counselors/advisors support students' professional and personal goals. Towards this aim, this study employs a mixed-methods approach to triangulate findings to the following research questions:

Research question 1. How are counselors and advisors supporting students from FLM backgrounds within ZPS? What are effective practices that constitute a ZPS model for supporting students?

Research question 2. Does the use of ZPS model practices in meetings between counselor/advisors and students predict greater gains in students' professional and personal goals over time?

Participants

Participants of the study include 50 undergraduate students who were recruited from equity-oriented programs at a large public R-1 university in California. Of the students, 74% were first-generation; 74% were female and 4% were gender-nonbinary. Students were from diverse racial/ethnic backgrounds: 52% Latinx/Chicanx, 22% mixed race, 12% East/South Asian, 8% White, 4% Black, and 2% Southeast Asian. Most students were sophomores (42%) or juniors (34%), with some freshmen (2%), seniors (16%), or super seniors (6%). Students were balanced between Social Sciences and Humanities (23%), STEM (22%), and interdisciplinary studies (10%). Additionally, 4 counselors from equity-oriented programs participated in an interview.

Study procedures and measures

Student participants were asked to meet virtually with a counselor or advisor at least three times throughout an academic 14-week semester. The meetings were about once per month corresponding to a pre-, mid-, and post-time period. For meetings, 42% of students met with the same counselor or advisor (n=21) and 58% of students met with different counselors or advisors (n=29). The following were the measures in the study:

Diary Entries

All student participants completed diary entry submissions after each meeting with a counselor or advisor. The diary entries asked for who they met with, the meeting duration, topics discussed, what happened, and how students felt about the sessions. Example questions include "Describe your meeting and what you got out of the session." Diary entries were completed through online submissions using the Qualtrics platform.

Pre- and post-surveys

All student participants completed an online Qualtrics pre- and post-survey assessing their growth towards professional and personal goals. Professional goals were assessed in an open-ended question of "What are your professional goals?" followed by a Likert-scaled response item on a scale of 1-7 to the question "Select the statement that best represents your progress in pursuing your professional goals." Personal goals were assessed with the same questions but with personal instead of professional goals in the question stem.

Interviews

44 students opted in to virtually participate in a semi-structured interview at the end of the semester which lasted between 30-60 minutes. Students were asked to elaborate on their diary entry submissions with additional details and specific strategies that their counselor or advisor employed. For counselor interviews, counselors were asked to describe their counseling philosophy and practices.

Data analysis

Qualitative inductive thematic coding

The diary entries were qualitatively coded using inductive thematic coding (Saldaña, 2015). The initial pass of open coding included breaking the data into codes with parent codes and child codes. The parent codes included codes such as connections and resources, strengths-based communication, motivation, professional goals, personal goals, mental health, introspection, and time management. Table 1 illustrates an example of three child codes within the parent code of connections and resources. The open codes were followed by axial coding to draw connections between the codes into categories. Finally, the categories were connected together in selective coding to form a core category grounding a model of practices.

Table 1. *Slice of codebook for parent code of connections and resources*

Code	Description	Example Quote
Professional resources	Connecting student to resources related to their professional goals, such as internships or the career center	Asked questions about graduate school (i.e. application, financial aid resources, timeline, etc.) and was able to learn about resources like [mentorship program] and how to set up an appointment with [a career center counselor] to talk about graduate school. (diary 1; student 26)
Academic resources	Connecting student to resources related to their academic goals, such as major specific advisors or course planning templates	[Counselor] provided me with an abundance of resources for looking into pre-health options and how I could fit some of those into my schedule before I graduate. (diary 2; student 39)
Basic needs	Connecting student to resources related to financial aid and basic needs such as grants or housing assistance programs	[Counselor] ended up discussing possible organizations I should reach out to because having a stable computer is essential for my learning and shouldn't be a reason for me to keep being stressed out. (diary 1; student 37)

Qualitative case study approach

To provide an information-rich description of the ZPS model, a case study approach was employed to select case examples between a counselor and two students (Yin, 2017). One of the four counselors was selected based on having cases of how they were able to support two different students — a student with a similar and a student with a different background — while using the same effective practices.

Quantitative regression analyses

The surveys and codes from the diary entries were used in quantitative multiple linear regression analyses to assess growth of personal and professional goals as it relates to the ZPS model. Continuous variables were normalized to interpret results in standard deviation units. The following variables were used in the analyses:

Gain score in professional goals. This score was the difference between the post-survey and pre-survey score of growth in professional goals that was on a scale of 1-7.

Gain score in personal goals: This score was the difference between the post-survey and pre-survey score of growth in personal goals that was on a scale of 1-7.

ZPS model score *(ZPS model)*. This was a score ranging from 0 to 9 which is the total number of times that ZPS practices were found across all 3 diary entries for a given student.

Meeting with the same or different person *(same person)*. This was a binary variable indicating whether or not the student met with the same counselor or advisor throughout all three meeting sessions.

High school preparation *(high school pre*). This was an ordinal variable on a 1-5 Likert scale in response to the question "How well did your high school prepare you for college?"

The following are the regression models used in the analyses with a 5% significance level:

$$professional\ \text{gain}_i = \beta_0 + \beta_1 zps\ model_i + \beta_2 same\ person_i + \beta_3 high\ school\ prep_i + \epsilon_i$$
$$personal\ gain_i = \beta_0 + \beta_1 zps\ model_i + \beta_2 same\ person_i + \beta_3 high\ school\ prep_i + \epsilon_i$$

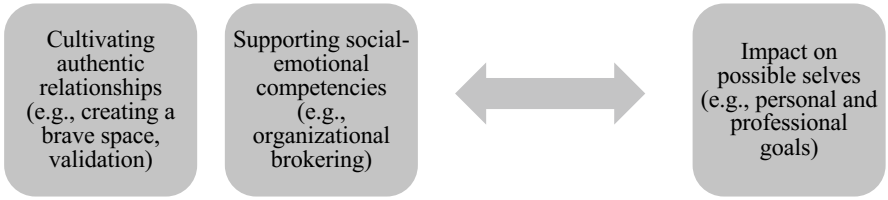
Gains in professional and personal goals were treated as separate outcome variables of interest. The main predictors included the ZPS model score, whether students met with the same person, and their high school preparation. The distribution of the residuals was approximately normal, and the outcome variables showed an approximately normal distribution. Nevertheless, a regression with robust standard errors based on a sandwich estimator was performed since they are more robust to violations of the model assumptions.

Findings

Research question 1: ZPS model of effective practices

Thematic coding of diary entries revealed three prominent categories of codes: counselors and advisors 1) cultivating an authentic relationship with students through creating a brave space and validation 2) supporting students with social-emotional competencies, and 3) students' perceived impact on their professional and personal goals. Taken together, these categories formed the core category: Creating a brave space, validating students, and supporting social-emotional competencies in culturally mindful ways is related to students' professional and personal goals. This core category forms the basis of the ZPS model in Figure 2.

Figure 2. *The zone of proximal self model*



ZPS model in action: Case example with counselor Sofia and students Emilia and Melody

To describe the ZPS model with real-world examples, this section details how a counselor, Sofia Aguilera[1], applied effective practices in the model to work with two different students. Sofia is female, first-generation, low-income, and Mexican American. Similarly, one of the students, Emilia Noguero, who met with Sofia, is a second-year public health major who also identifies as female, first-generation, low-income, and Mexican American. Meanwhile another student, Melody Hayashi, a third-year cognitive science major, is also female and low-income, but identifies as continuing-generation and Asian American.

Brave space: Building a working partnership. Sofia and both students discussed how Sofia cultivated an authentic relationship by creating a brave space for conversation and collaboration. One effective practice was to explicitly communicate the relationship as a relational and working partnership where the counselor works with students rather than acting as the expert holding all the knowledge. The following quote from Sofia expressed this: "I've had students call me dude and then say sorry. I'm like no, you can call me dude and that makes me happy because that makes me feel like you see me...I don't want to be seen as someone better than you or knows more than you, because I probably don't. We both know a lot and so it's a partnership." Sofia's intentions to be in partnership resonated with her students. Emilia mentioned how, "She was just in the process, and I never felt like she was in charge of me. She was riding along with me." Similarly, Melody expressed how she felt a sense of agency: "I think sometimes there's cases when you talk to people like your friends and family and they're like oh yeah you should make this choice. For her that's something she definitely did not do and she's still giving me a lot of agency to make my own decisions." As mentioned by the students, Sofia's expression of working in partnership created a brave space, fostering a relational power dynamic where students felt agency and were supported in pursuing life choices and possible selves.

Brave space: Understanding cultural background. Another effective practice was being culturally mindful of students' situations through active listening, which Sofia describes below:

> I'm not going into any session thinking that I know what they need, what they want, what they're trying to do. I'm asking follow up questions and open ended questions...and with a multicultural lens that everybody's identities play a role in their experiences. I know that I don't know everything about every identity and even the ones that I hold I still I'm always constantly like you still don't know it...there's always room to learn.

Instead of engaging in transference, Sofia is cognizant of the intersectionality of experiences that impact students. Emilia notes this as well:

> After I was done with all my academic issues, she asked "but how do you feel with your roommates?" because my roommates my first semester were from China and India, so it was a big change because I come from a very Hispanic community, so I'm not used to it. She asked "in college how is your relationship

[1] All names used in this study are pseudonyms.

> with your parents right now?" They recognized me so much more than a student and knew that my performance in school relies on how I feel going into class and how I feel coming out of class. And also who I'm connecting with outside of class and what's going on at home and the family life.

Emilia touched on how Sofia's understanding of her cultural background situates her learning within a cultural context including her home environment and peer groups. Similarly, Melody also mentioned how Sofia was able to get "an idea of my situation to be able to support me better." An important practice Sofia applied in creating an authentic relationship was not making assumptions about students, but instead assessing where they are in consideration of their cultural backgrounds.

Validation. Another important practice was validating students' strengths, challenges, and feelings towards their professional and personal goals. Sofia applied validation of students' feelings to combat imposter syndrome and support students' confidence in themselves and their identities:

> With imposter syndrome and students telling themselves that they don't belong here, for me it's validating their feelings. Your feelings are valid and they're real and you're not the only one...I think that once I validate their feelings, we go through that conversation of this is not you, this is the institution. It helps them create a new narrative for themselves that they do belong...I'll tell them I know that you're not just a student. You wear other hats, I don't know if you're a daughter or you're a sister or a mom, there's so many hats that our students hold. Building up their confidence and letting them know that their student identity is not a reflection of who they are. Really bringing into light all the strengths that a student brings that sometimes are forgotten.

Sofia connected the internal monologues students have to larger institutional signals and encouraged students to transform the narrative of their position at the university. This validation was important for students to hear, as portrayed in Emilia's quote:

> My first semester was full on imposter syndrome...But I think the biggest thing that she kept telling me was that my journey is not a journey that's going to be like others and that's okay. She would tell me about her non-stereotypical journey to where she is now...and that truly really did help me...and it was something that's funny because I know this. But the thing is it's kind of like when you tickle yourself, you can't feel it within you...but when she would tell me...it's like, you're right, I internalize it.

In validating Emilia's feelings, Sofia embraced being vulnerable enough to share her story and show how the learning pathway for each individual is unique. Melody also expressed how Sofia was adept at validating her feelings towards activities related to her professional goals:

> I think there was an understanding and validating of feelings definitely a lot of the time, because I was telling her all of my uncertainties and doubts regarding a lot of the opportunities that I was looking at... That was something that I think she was really good at handling and understanding. Giving me as much information as possible and really being transparent about that and also being vulnerable about herself and relating to my experiences and telling me straight out "It is okay to feel this way."

Emilia and Melody mention how Sofia validated a sometimes forgotten part of possible selves — the feared selves we are afraid of becoming, or in this case the fear of conforming to the narratives from institutional messages about who belongs and who succeeds. Sofia's validation encompassed validating these fears instead of dismissing them, and also overcoming these fears by drawing on students' strengths and holistic identities.

Supporting social-emotional competencies: Organizational brokering. Organizational brokering was an effective practice Sofia used to support students' social-emotional competency in relationship-skills building with communities. Sofia discussed how she plays the role of an organizational broker: "I'm constantly networking because that is so important so that I can help my students reach their goals." Emilia described how Sofia acted as a broker for her:

> It's going to be my third year so things are kind of more settling into what I want to do for career paths and I just didn't know who to reach out to to help me. She was able to connect me with the career center and their specific times that they have to help us...and then also she connected me to appointments with peer advising for public health...So she was a major segway into all of that, because I wouldn't have even known about them...I joined these little communities and now I have met with both of those communities, the career center and the public health advising, at least two or three times since.

Melody also discussed how Sofia helped connect her to the career center: "...that was something I was super surprised about and didn't know that they did in counseling, helping me check my progress and helping me set up other counseling sessions, like the career center, for example. That was one way she helped me take those next steps to learn more about what I wanted to do." In both instances, Sofia was able to help the students navigate resources within the institution and support them in building relationships with communities related to their professional goals.

Organizational brokering can only be effective if students are comfortable seeking the support they need to reach their goals. Sofia recognized that many students face emotional barriers: "When it comes to reaching out to others, if it's a professional staff, I will ask them, do you feel comfortable asking or reaching out?" Emilia, for instance, did not feel comfortable in the beginning:

> When I grew up, my parents never really encouraged me to ask for help. It's always just authorities, you respect them, you give them your ultimate yes, thank you, bowing down to them in a sense. And you only asked for help if you really needed it. You're gonna try your best yourself. But by her creating a space where you can ask for help, then it got me to walk into the career center meetings saying "I need your help", and this is why I'm here and feeling okay to ask for help.

Similarly, Melody also discussed how her family was hesitant to ask for more help:

> I also talked to her about the cost of adjustment and filing for that and how that works and asking for money when I need it. And she was the one who told me "Yes, you know if you do need it, ask for it and don't be afraid to do that" because I think especially within my family, I already get a lot of financial aid from the government and the school, so they are like "Oh don't push it, don't ask for more security, we're receiving a lot" and I'm already very grateful for that, but there are some situations where you do need additional support. That was something that she told me you have to advocate for yourself.

These accounts reveal how the act of seeking help, a part of the relationships building social-emotional competency, is also a new cultural practice for students whose families elevate respect for authority.

Research question 2: ZPS model impact on professional and personal goals

This section examines how the ZPS model impacts aspects of students' possible selves, specifically their professional and personal goals. Overall, the gains in professional and personal raw scores were varied for all 50 students. The raw score mean for gains in professional goals was .92 (SD = .997, min = -1, max = 4). The raw score mean for gains in personal goals was .18 (SD = 1.17, min = -3, max = 3). Tables 3 and 4 show the regression model estimates with normalized variables in standard deviation units. There was no evidence of collinearity between predictors in the models for professional goals (mean VIF =1.06) and personal goals (mean VIF=1.05).

Model 1 estimates: Professional gain. For every unit increase in the ZPS model (presence of brave space, validation, and social-emotional competencies mentioned in the diary entries), there is an estimated mean increase of .30 units (95% CI [.044, .553]) in professional gain when controlling for whether the student met with the same person and high school preparation (t = 2.36, df =46, p<.05). The estimated mean increase in professional gain is .44 units (95% CI [.182, .702]) per unit increase in high school preparation when controlling for whether the student met with the same person and ZPS model (t =3.42, df = 46, p<.001). The R^2 for this model is .31, suggesting that 31% of the variation in gains of professional goals can be explained by the ZPS model, meeting with the same person, and high school preparation.

Table 3. *Regression Model for professional gain*

Covariate	Coefficient	Robust standard error	P-value	Confidence Interval
ZPS model	.30	.13	.023	[.044, .553]
Same person	-.14	.25	.571	[-.640, .358]
High school prep	.44	.13	.001	[.182, .702]
intercept	.06	.15	.685	[-.233, .353]

Model 2 estimates: Personal gain. For every unit increase in the ZPS model, there is a predicted mean increase of .49 units (95% CI [.231, .747]) in personal gain when controlling for whether the student met with the same person and high school preparation (t =3.82, df = 45, p<.001). The R^2 for this model is .25, suggesting that 25% of the variation in gains of personal goals can be explained by the ZPS model, meeting with the same person, and high school preparation.

Table 4. *Regression Model for personal gain*

Covariate	Coefficient	Robust standard error	P-value	Confidence Interval
ZPS model	.49	.13	<.001	[.231, .747]
Same person	-.28	.23	.234	[-.739, .185]
High school prep	.11	.12	.358	[-.125, .341]
intercept	.12	.16	.471	[-.210, .447]

Discussion and significance

In sum, the findings reveal the significance of applying a ZPS model to support students from FLM backgrounds in pursuing their possible selves. The model, building on extant literature and empirical data from the present study, is characterized by effective practices of creating an authentic relationship with students (i.e., creation of a brave space and validation) and strengthening students' social-emotional competencies (e.g., relationship skills) in culturally mindful ways. Moreover, the case examples reveal the importance of relational interactions and cultural mindfulness in organizational brokering with students from diverse backgrounds. Results from multiple linear regression models suggest that students, on average, have higher growth towards their professional and personal goals when they are exposed to more ZPS model practices from counselors/advisors. Future research should examine how these interactions impact student experiences across different institutional settings and roles in higher education, including instructors, peers, and family.

Ultimately, this study was completed during a Covid-19 pandemic fraught with uncertainties in professional and personal lives; and yet, during virtual conference meetings with students, counselors and advisors were able to support students' goals. The ZPS model articulated in this study is a testament to the strength and potential of counselors and advisors in bridging the distance between students' current realities and future possibilities. This work is part of a greater reimagining of equity-oriented work in higher education that recognizes the cultural, social, and emotional processes of student learning and development.

Pandemic Board Game Redesigned: How Learners' Decisions Enable Emergent Learning Possibilities

Reyhaneh Bastani, University of Calgary, reyhaneh.bastani@ucalgary.ca
Beaumie Kim, University of Calgary, beaumie.kim@ucalgary.ca

Abstract: This paper discusses a study on students' exploring and creating emergent systems using mathematics and science while redesigning the cooperative board game, *Pandemic*. Grade seven students participated in the game redesign project co-developed with a teacher in an art immersion school in Western Canada. Their work was collected through video recordings, photos, and interviews. The analysis shows how the game redesign activities supported the divergence and convergence of ideas and group decision making. It highlights how learners' interests and choices acted as frames that enabled their ongoing inquiry and expanding their use of learning topics in creating a working system.

This paper describes a design-based research project on using a board game redesign approach to learning. It aimed to support students to engage with emergent systems and to imagine and model new possible structures using mathematics and science topics. Relying on a complexity perspective, we follow a notion of learning as an emergent phenomenon that involves expanding capacities to adapt to and participate in novel situations (Davis et al., 2015). Complexity perspectives propose learning designs that attend to creating a balance between setting constraints and stimulating learners' diverse responses. In this paper, we discuss how the board game redesign approach, and the materials and activities involved, not only set some structures, but also enable students' collective decisions that could expand their design space and engagement with math and science topics. Our analysis attends to the critical episodes of divergence and convergence of ideas in the groups and the role of structured and self-imposed constraints in supporting this process, using a frame informed by design and creativity research. The following questions guided our analysis: (1) How do the co-design spaces evolve through the redesign process? (2) How do the project structure and learners' decisions frame their design directions and use of math and science topics in creating their game system?

Perspectives

This study draws on a complexity perspective of knowledge and learning that address the emergent nature of learning and its nestedness (Davis et al., 2015). That is, individual understanding and collective knowledge are emergent learning systems at different but interwoven levels. Complexity views, therefore, seek for the conditions that could stimulate more emergent learning possibilities for learners. They use the notion of enabling constraints to indicate how design for learning should attend to a balance between enabling learners' idiosyncratic responses and setting structures that would limit the vast possibilities of approaching learning topics to support learners' shared goals and language (Davis & Simmt, 2003). Classroom structures that engage learners in design practices have showcased their potential to support collaboration based on their interests and skills toward shared goals (e.g., Kim et al., 2019). Design practices support learners to engage in intentional interactions with their peers, teachers and learning topics, using design materials and their developing artifacts. Approaching learning topics through balanced design practices with structures and openness speaks to the notion of enabling constraints, allowing learners to iteratively challenge their own assumptions of problems at hand and explore possible solutions and thus emergent learning possibilities.

Games have the potential for embodying disciplinary and interdisciplinary knowledge. Some studies have explored how designing board games, as models of systems, could support students' engagement with mathematics and science (Kim & Bastani, 2017; Ke, 2014). The present study was a design iteration of a previous learning design for supporting mathematics learning through collaborative re-design of a board game (Kim et al., 2021). The previous project indicated structuring game design projects as re-designing board games (rather than starting from scratch), in which learners play a common board game and change its elements to create their own games, enabled learners to creatively engage with disciplinary ideas. The common starting point and physical material (e.g., the components from the board game to be redesigned) could function as enabling constraints that help learners develop shared communication channels and collective goals, which supported their collective decision making. In the iterative process of design and getting feedback, learners' evolving decisions shaped and acted as frames that direct their further

 © ISLS

inquiry into design problems and possible solutions. This could stimulate unique paths of using disciplinary knowledge in learners' groups (Bastani & Kim, 2020; Kim et al., 2020).

Research design and data sources

We conducted this design-based research with grade seven students in Fall 2018 and early 2019. It aimed to engage students with mathematics and science through exploring emergent phenomena, in an art-immersion school in Western Canada. The school's approach is to deliver the subject matters not in isolation, but as connected and as the content of the problems that students can creatively engage with. We developed the activities with the math teacher who is also a game designer. The project mainly focused on engaging students with the math topics of numbers, statistics, and probability and the science topics of interactions and ecosystems and human impact. The cooperative board game *Pandemic* (Z-MAN Games, 2007; Figure 1), which models disease spread across the world, was selected as the game to be redesigned. We expected that the theme and the system of this board game could engage students with exploring emergent phenomena, connected to grade 7 math and science topics. Importantly, the game's inherent complexity could also engage learners' diverse interests and stimulate various ideas and viewpoints, as learners explore its multiple components and possibilities of changing them. In the game *Pandemic*, players take different roles and work together to treat infected populations to buy enough time to complete the ultimate objective which is the discovery of the cures. The main stages of the project included playing *Pandemic* and mastering the rules, brainstorming possible new game theme, narrowing down ideas for using math and science with the teacher, and designing and playtesting the game. We collected ethnographic data through field notes and video-recordings of students' in-progress and final designs. We also had a 30-minute interview with each group on their experience with their redesign project.

Analysis

This analysis aims to explore learners' game redesign processes and the underlying elements that stimulated learners' collective idea development and engagement with learning topics, using the data from two groups in this classroom. In framing our analysis of the groups' design practices, we draw on how the design and creativity research view the design practices' value in supporting learning. They include decision making, adapting to evolving goals, and imagining and examining various alternatives. Importantly and in line with the notion of enabling constraints addressed by complexity perspectives (Davis & Simmt, 2003), the design literature signifies how constraints in the process of design could prompt a pathway to creativity and innovation. They include external constraints such as materials and time limitations, and self-imposed constraints that emerge as designers' ideas interact and lead to design decisions. The design process is a continuous space of experimentation and reflection (Schön, 1992). With every decision, designers impose constraints on their work that not only restrain the next actions but also become tools to think with and to explore new possibilities (Biskjaer & Halskov, 2014).

Divergence and convergence of ideas in the transformation of the design space

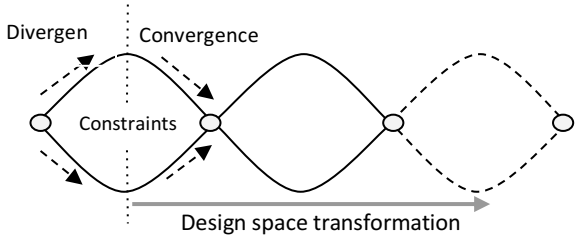
Exploring the design process, scholars point to the cycles of divergent thinking, i.e., exploring various possibilities, and convergent thinking, i.e., choosing from alternatives to come to a more focused understanding of a problem or arriving at a solution. Our analytic frame (Figure 2) attends to divergence and convergence of ideas that happen iteratively in the design process (Norman, 2013) and the role of constraints (Biskjaer & Halskov, 2014) including the activities' structure and learners' self-imposed constraints in transforming the design space. Self-imposed constraints are evolving frames that could open the space for designers' further exploration. Through identifying the critical

 © ISLS

episodes of divergence and convergence of ideas, we investigate how learners' interests and intentional choices enabled them to develop their designs and expand and deepen their use of learning topics.

Figure 2

The analytic framework model adopted from the double diamond model of design (Norman, 2013)



The process of interpreting data

Our coding of data was informed by Barab et al.'s (2001) process for identifying the critical episodes in which learners' ideas and practices evolve, through their interactions with one another, tools and activities. It also attends to the links among these episodes to address the research questions. The analytic frame was used in chunking the data from the groups, identifying the critical episodes and the elements of divergence and convergence of ideas (Table 1). This analysis sought the temporal links among the critical episodes, i.e., how learners' co-designs evolved. It also attended to the students' interim decisions that contributed to developing their designs.

Table 1

An example of the identified critical episodes (Reverse Pandemic)

Episode	Divergence Elements	Supporting Interactions	Convergence Elements	Supporting Interactions
Taking the perspective of bacteria and viruses	Exploring how bacteria and viruses spread and how they act in different environments	Discussing their game story with their science teacher/ using Pandemic to discuss their ideas	Discussing the mechanisms that could strengthen or weaken players (i.e., diseases)/ deciding what diseases they want to use	Researching bacteria and viruses/ drawing diseases' cards/ making parallels between their intended game components and the original game components

Findings

In the following, we discuss the redesign effort of two groups, whose redesigned games were named *Reverse Pandemic* and *Pandemic Theatre Edition*. Elaborating on the identified critical episodes of students' design practices, we address how learners could expand their ideas over time, transform their conceptions of problems and design possibilities, and find opportunities to research on and use learning topics.

Reverse Pandemic: Players acting as viral diseases

The first group developed the idea of reversing the *Pandemic* game story, i.e., creating a cooperative game in which players would act as diseases to overtake the cities and spread around the world. One significant aspect of this group decision was their building on the original game's narrative, and not changing the game's theme completely. The *Pandemic*'s game materials, e.g., the cubes representing viruses, board map, and infection and role cards, mediated the group discussions on their game's aspects and implementing their ideas. Notably, they initially tried to implement their idea of reversing the *Pandemic*'s story by defining opposite functions for the original game's components (e.g., cubes representing cures instead of diseases). This approach might not have been helpful in reversing the dynamics of a game system. For example, in *Pandemic*, the cubes represent the number of infected areas and possible outbreaks. Therefore, simply using them to represent cures would not make meaningful dynamics in the redesigned game. This step was still significant in realizing the need for a deeper exploration of the original game system.

Taking the perspective of bacteria and viruses: Developing the game's backstory and system

The students' focus and practices became more purposeful as they started evaluating the possibilities of implementing their initial ideas while using and creating different game components and rules. A transforming event happened for the group when they shared their ideas with their science teacher. They had a conversation about the theme and rules of *Pandemic,* including the idea of reversing the theme. It started with a question by Jess, one of the group members,

 © ISLS

"how players (diseases) could move ((on the board)) and overcome the cities in their game" and led to elaborating their game backstory and system. Their chosen game theme, as a self-imposed constraint, encouraged them to take the perspective of bacteria and viruses, exploring the mechanisms that players could progress through spreading the diseases. They discussed how bacteria could develop resistance against antibiotics and mutate and evolve. The teacher talked about how diseases spread as the group explained how the original game worked, showing the teacher the original game's elements and their own game ideas. The teacher built on Elaine's discussion on players' (diseases) moving between the cities, using the *Pandemic* game board, and explained how a disease could spread to far away locations due to international travels: "one of the biggest issues with our global community is we travel a lot. An infection that happens in Chicago can easily end up in Jakarta in a day. And then you will have two outbreaks ((pointing to the map))" (Figure 3a) (it should be noted that this project happened before the spread of Covid-19 and the widespread knowledge about pandemics). Taking the diseases' perspective, they then talked about how travelling between cities could advantage players. Discussing the possible defence mechanisms against diseases for cities, they also talked about how making new vaccines could cause widespread and long-term immunity.

We observed an intentional interaction between the students and teachers mediated by the game materials, e.g., the board map, which supported the integration of learning topics. Their design space with the goal of reversing the theme of *Pandemic*, therefore, changed to include more scientific exploration. Taking viruses' perspective supported their design of game components in a connected way (e.g., how players -- diseases -- could take advantage of moving between cities, and, at the same time, how it could be disrupted by other mechanisms such as vaccination). After these discussions, they did research on different viruses and bacteria and decided which one to use in their game. They worked on their idea of overcoming the cities based on their protection level and developed their player cards (i.e., diseases cards- Figure 3b), their infection cards, and the rules of spreading among the cities.

Numbers, percentages and probability as a tool in materializing ideas

The group found that to reverse the *Pandemic*'s story, they needed to understand this game's system deeply. They evaluated how infection cards, which determined the cities to be infected based on designed probabilities, work and how epidemic cards trigger an outbreak. Put differently, their choice of reversing the *Pandemic*'s story became about reversing the logic of the game, rather than reversing the role of the elements in the game. This self-imposed constraint involved exploring new possibilities of using math in creating a playable game. This exploration converged into using numbers to compare players' power (disease spread) against cities' defence (CD) in their own game. They also designed vaccination cards (Figure 3c), using probability (one out of ten players' cards were vaccination cards), which made cities' defence dynamic: "The city defence changes when 70 percent of the population get vaccination" (Jess).

Figure 3

a) discussing emergent outbreaks in distant location, b) player(diseases) cards (c) vaccination cards

(a) (b) (c) 
Incorporating the feature of their interest into the game

The group decided to have six players (diseases) to differentiate their game from *Pandemic* that has four diseases. They, then, needed to categorize the cities differently as hotbeds for the six different diseases. Grouping the cities, they also engaged with the geographical aspect of *Pandemic*, locating the cities on the map, discussing how to scale down the map and create one for their own game. After exploring how to have a 6-player game, their ideas, then, converged into drawing their own map. This became a challenge of how to connect the cities based on their game goal and designed system. They, therefore, faced a "graph" problem in creating their cities' network (Figure 4a).

Encountering complexities in balancing the game

Having a draft in time, the group could playtest their game. During playtesting (Figure 4b), they found that in their design, diseases (players) couldn't win. They re-evaluated *Pandemic* and noticed how the Event cards, which would give players random advantages, created a power balance (e.g., the ability to predict which cities will be infected next).

 © ISLS

They had created vaccination cards that would give advantage to the cities against players (diseases), but they hadn't used enough mechanisms to give players random advantages. They then designed their own event cards that would randomly allow players (diseases) to make "virus bases" in other countries to travel between them and spread. The group's intention of having a balanced and playable game, therefore, led to make a better sense of the interconnection of different elements in the original game and incorporate their understanding in their own designs, in a way that was meaningful to their redesigned game's narrative. Similar to what Kim et al. (2019) argued, as the students shared their work and confronted their own designs with their applications in the world, they could experience the problems in context and attend to further possibilities. Their more complex understanding was specifically supported through the exchange of group members' viewpoints on different aspects of their game, e.g., how to create a balance, how to modify the graph on their board according to their game goal, and how to make their game meaningfully more complex.

Figure 4

(a) Designing the board, deciding how to connect the cities b) playtesting their game

(a)  (b)

Pandemic Theatre Edition: Imagining a world balanced through science and art

The other group, *Pandemic Theatre Edition*, initially thought of the game theme of eradicating diseases, similar to *Pandemic* but using different mechanisms. After a few sessions of playing the original game, the teacher asked the students to specify their main ideas and the math and science topics they aim to use. As the students mentioned, this encouraged all the group members to put their ideas together, revisit their initial decisions. They chose to develop a new backstory about making a balance in the world in terms of people's happiness, connecting it to climate conditions. Their game backstory included hot and cold places impacted by climate change and areas with sad and "overly happy" people who would destroy the environment. They decided to have research stations, which could help people in hot and cold areas, and theaters, which could balance people's mood. It was notable how they separated the regions impacted by climate change and the regions that worsen the environmental conditions, and how they considered the role of both science and art in creating a balanced world.

Using Pandemic's components to create a form for their game and enact its story

Focusing on how to enact their game backstory, they evaluated how they could use or modify *Pandemic*'s components in their own game. Their ideas converged into using the cubes (representing diseases in the original game) as symbols of the populations moving among the cities. After considering possible geographical scopes for their game, using *Pandemic*'s board, they decided to use the map of the whole world and to not limit their scope. They also modified the infection deck in *Pandemic*, which added cubes to the board, to tell players how to move people between areas to make the intended balance in their game world. In moving people, they used the concept of percentages. Each player needed to calculate a specific percentage of the cities' total population to determine the number of people to be moved. They also talked about how their game represented the concept of negative numbers in a way, as players needed to move people between the cities with opposite conditions. Their developing game theme also allowed them to connect their game more to the science topics of interactions and ecosystem in a symbolic way. For example, they created a "world climate health meter" for the environmental condition. As the condition gets worse, moving between cities becomes more difficult: "when the world health meter gets to like a certain point, … you can no longer fly unless it's a shuttle flight at the research stations" (Ethan).

The group also decided to have different roles for players for creating the intended balance in the world, e.g., a director to "move people on their turn" and an actress to "cure depressed people", and an environmentalist who could "discard a card in research stations or theatre (and) move the climate health meter up." They also discussed these roles' gender and power, questioning perceived boundaries around gender roles. This led to an emergent discussion on politics and how gender played a role in the Clinton-Trump battle, referring to the 2016 US presidential elections. Such interactions suggest that the human aspect of the game theme provided the space

for the students to relate more with the task. In modeling their imagined world, symbolic representations of human actors became a venue for learners to express their perspectives as if they saw themselves in relation to others.

Engaging with complexities in materializing their imagined world

The group's decision on using the whole world as their game scope was an important self-imposed constraint that needed them to specify "too hot" and "too cold" areas and the overall "happiness" of people living in different cities and countries. Creating the actual game elements, then, needed them to explore deeper their idea of imbalances in their game world and the possibility of categorizing the countries based on opposing conditions. This encountered complexity encouraged the students' exchanging their viewpoints, exemplified in the following:

1. Eva: Oops! People in California are sad ((talking about their initial categorization)).
2. Ema: Why? It's so nice out there. There's Disneyland there!
3. Ethan: Yeah! No, the happy people are in California ((pointing to the map to show it))
4. Eva: Russia is sad.
5. Jacob (from another group): Russia is not that sad.
6. Ethan: It is sad in our game. Although if you say Russia is sad out of nowhere then you are kind of a hatist.

The group also discussed a possible destructive human impact on the environment in the areas where people are "overly happy" because they would not care enough about the impact of their actions on the environment. The decision of having a broad geographical scope for their game did not seem to be significant at the time. It, however, became decisive when interacted with the goal of designing a game with multiple interconnected elements. The group members engaged with complex issues that challenged their simplistic assumptions (e.g., with regards to "sadness" or "happiness" of different regions). Ethan's last utterance (Turn 6) presents a dilemmatic situation for him: although he implied that they would need to make simplifying decisions in modeling their game story, he challenged groundless assumptions. The group's emergent discussions also showcase how addressing a seemingly scientific issue, i.e., climate change in their game, entails attending to social and political factors. This signifies the complexity of the problem the students were engaged with in the context of designing a game system.

Envisioning and moving towards further developments in their game mechanics

Developing their game (Figure 5), the group thought of other design possibilities that could facilitate moving between cities and create "a new way for interaction" (Ethan). Although they could not use all these components in their final game, it was notable how their design process enabled them to expand their view of what would be possible in terms of game dynamics (and the supporting mechanics) and their use of learning topics.

Figure 5

a) The Pandemic Theatre Edition game board, b) Final role cards

(a) 
(b)

Adding chaos and an element of luck. One of these design ideas was adding "immigration cards" to the game to specify what cities players should move between. This might not be in line with what players need in terms of moving people on the board and could add an element of "randomness" and "chaos" as "things would be moving across the board" (Ethan). The group started by evaluating the mechanics of *Pandemic* and explored the possibilities of transforming their initial design to fit their complex backstory and make their game playable and more meaningful.

Using more science. The group used interactions and ecosystems through their "world health meter" marker on their board: as the environmental conditions get worse in the world, going forward would be more challenging for players. However, as Ema reflected, a deeper connection to science was missing. They aimed to use the heat and temperature topic, but it became limited to specifying hot and cold regions. Although it could be a good start, they envisioned possibilities of better connections between their game system and the learning topic.

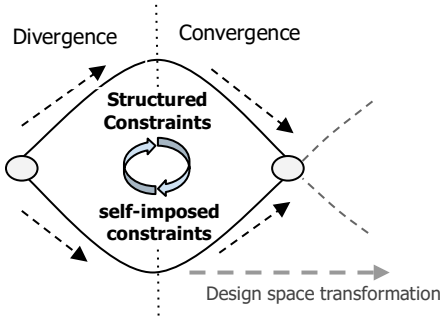
 © ISLS

Discussion: the groups' evolving designs and the role of constraints

Our analysis explored the divergence and convergence of ideas and the supporting settings in which learners' design goals and conceptions of solutions evolved (Biskjaer & Halskov, 2014). Here we discuss how the game redesign's structured constraints and the emergent constraints from the groups' interests and decisions enabled them to expand their use of learning topics, adopt new goals, and progress in their design. It also highlights a continuity between structured constraints and learners' self-imposed constraints emerging through the process (Figure 6).

Figure 6

Structured and self-imposed constraints in an evolving design



Structured constraints and tentative boundaries: Foundations for an open-ended task

The project stages aimed to provide a structure within which student groups could develop common languages and collective purposes as underpinnings of group interactivity and idea exchange (Davis & Simmt, 2003). The project structure, mainly starting from a selected common game and the groups' goal of redesigning it, acted as constraints for the broad range of possible design approaches the groups could take at the starting point. In the following, we discuss these structured constraints and how they could enable the groups' focus and progress in their designs.

Playing the original game to decode and destruct what is at hand. The groups started with playing *Pandemic* and, as they engaged with their designs, they needed to further decode this game's system. This, in turn, supported their idea development and decision making as they progressed in their design. The shared understanding of what is at hand and the agency to restructure it could stimulate their imagining of possibilities within the frame of the task. As the teacher put it, there is a mutual relationship between creation and destruction of what already exists, which could be supported in this game redesign project.

Using the original game's components as tools for communication and materializing ideas. The group discussions showed the original game's components acted as tools for students to interact and come up with the elements that would enact their game story. Notably, this supported the groups' focus on the core elements of their own design. The groups had the opportunity of modifying the existing components, i.e., using what already existed in a way that would fit their game (e.g., *Reverse Pandemic*'s use of a similar map as *Pandemic*), while creating what they needed for their unique game (e.g., changing the cities' grouping to have a 6-player game). This signifies an enabling aspect of redesign and its involved constraints, compared to designing from scratch where the broad scope might hinder the groups' focus and translating their ideas into sharable artifacts (Kim & Bastani, 2017).

Attending to project goals and deadlines: Staying within the boundaries of the project. The project had goals and limitations which set overall boundaries for the groups' work (Davis et al., 2015). They mainly included incorporating math and science topics in their redesigned game, the project deadline, and having a shareable game to be played with other groups and students. This overall framework supported students' shared understanding of expectations (Davis & Simmt, 2003), the convergence of ideas in groups, and the groups' making sense of other redesigned games' goals and systems. On the other hand, there were variations in how the groups approached these constraints. For example, the goal of having a balanced game by the deadline encouraged the group *Reverse Pandemic* to have early game drafts, which they could test and get feedback from. This is while the group *Pandemic Theatre edition* focused more on developing their game backstory making it more complex and meaningful, but less on playtesting before the deadline. We observed the important role of the groups' interim decisions as self-imposed constraints in shaping their emergent design process (Biskjaer & Halskov, 2014), which we discuss next.

A continuity between the structure and what emerges through learners' participation

 © ISLS

The open-ended process of design entails iterative goal setting and designers' revisiting their conceptions of problems and solutions, as designers get feedback from their prototypes (Norman, 2013). This could create the setting for learners to adopt intentions in approaching the problems and in using learning topics. The critical episodes of the groups' design practices showed how as learners participated in this design project, structured as redesigning a particular board game, they engaged in intentional interactions with their peers, teachers and learning topics, using design materials and their developing artifacts. It showcased an interconnection and continuity between structured constraints and learners' self-imposed constraints emerging through the process.

Learners' expanding and deepening the use of learning topics building on their design decisions. The groups' interim design decisions were self-imposed constraints, which acted as dynamic frames that not only structured their work but also became tools for idea development (Biskjaer & Halskov, 2014). Students' use of science and math topics emerged and expanded throughout the project. This was intertwined with learners' seeing more possibilities to expand their game backstory and implement their ideas to create a working system. As an example, the group *Reverse Pandemic* incorporated numbers, percentages and probabilities as they went through materializing their ideas and creating a balanced game. Their exploration of the possible mechanisms that could enact their game story helped them make a better sense of the emergent process of disease spread at the global scale.

Engaging with complexities in developing the imagined backstory and turning it into a playable game. The game redesign project was a context for modeling an imagined world developed by students. The groups iteratively developed the backstory of their interest to make it more meaningful. This became a self-imposed frame that triggered their design trajectory. The sophistication of *Pandemic-Theatre Edition*'s backstory encouraged divergent ideas through the design process. This included both adding details to their game story and goal and the design ideas that attended to the possible dynamics and mechanics in their game to enact their story. The groups engaged with emergent discussions on the multiple aspects of their game theme and making a better sense of the complexities involved as they intended to create a modeled world through different signs and symbols.

The Role of Augmented Reality in Multi-Device Small Group Learning Ecosystems

Taehyun Kim, James Planey, and Robb Lindgren
thk4@illinois.edu, planey@illinois.edu, robblind@illinois.edu
University of Illinois at Urbana-Champaign

Abstract: Augmented reality (AR) has shown benefits for individual learning with single devices and platforms. However, there has been sparse research on the learning effects of more complex technology ecosystems where multiple devices allow for different interactions with the same simulation. This study describes one such multi-device ecosystem where undergraduate students in an astronomy course were presented with a small group problem-solving task where both AR headsets and tablet computers could be used to explore a night sky simulation. We investigated whether students learned the targeted astronomy concepts, and whether the ways the devices were used affected students' learning and their perceptions of the activity. Results indicate an overall learning gain from pre to post, and while participants who used AR did not score higher than students who did not use AR, there was an association between how each device was used and one of the key learning outcomes.

Introduction

Augmented reality (AR) describes a genre of technologies that blend the virtual world with the real world, often through dynamic overlays of "context sensitive virtual information" (Klopfer & Squire, 2008, p. 205). A number of devices have been used to achieve AR, including camera-based applications on mobile devices and immersive headsets. Studies of the efficacy of AR technologies in education have shown benefits on assessments of individual learning outcomes in a range of content areas (Chen et al., 2017; Garzón & Acevedo, 2019; Ibáñez & Delgado-Kloos, 2017; Scavarelli et al., 2021). Many researchers have cited the affordances AR has for enhancing situated action—providing context-responsive visualizations that focus attention and alter a person's perspective in ways that promote learning (Dunleavy et al., 2009; Wu et al., 2013). Radu (2014) notes the potential of AR to leverage people's natural capacity for working with spatial information, and several others have pointed to the ability to create a more personalized learning experience given what the system knows about the individual learner and what data can be collected about their learning behaviors (Dunleavy & Dede, 2014; Huang et al., 2016).

Although a range of AR applications have shown benefits for individual learning with single devices and platforms, we know that learning in the future will increasingly take place in more complex spaces where there are multiple people, multiple devices, and multiple modalities with which to interact. The types of learning challenges that students will encounter in these spaces will require them to work with and reconcile multiple representations (White & Pea, 2011). There has been some research on face-to-face multi-user technologies such as large multi-touch display surfaces that have been shown to be effective for facilitating collaborative learning (e.g., Mercier & Higgins, 2013). Likewise, there have been a handful of studies on multi-user "mixed reality" environments (e.g., Kim et al., 2021; Lui & Slotta, 2014). To our knowledge, however, there has been little if any research on the learning effects of technology ecosystems where multiple devices allow for different perspectives and different interactions with the same phenomenon or simulation.

There are important and unresolved design questions concerning how to coordinate multiple devices to both support synergistic interactions between groups of students and ensure that individuals in those groups come away with robust understandings and the ability to flexibly apply their knowledge to new contexts. In particular, there are questions specifically about immersive technologies such as AR and the role that it can and should play in these layered ecosystems. In these more complex configurations, the question is more than whether or not someone uses AR, but rather how they are using it, for what purpose, and with whom? This opens up additional questions about how to assess the impact of AR integration into the learning process. These implementations must take a multidimensional assessment approach, examining learning in the context of users' perceptions of the technologies, tasks, and group interactions. While there has been some early work attempting to explore these dynamics (Bork et al., 2021; Radu & Schneider, 2019), the mixed results from these studies motivates the need for additional research.

The current study explores the issue of learning effects in a multi-device ecosystem in the context of undergraduate astronomy courses. Astronomy is a well-suited content area for this investigation because it is a domain where students are frequently asked to reconcile multiple spatial perspectives to explain complex

 © ISLS

phenomena such as the causes of seasons (Plummer & Maynard, 2014). The specific research questions for this study are:

RQ1. To what extent did students learn the target astronomy skills and concepts while working in a multi-device (AR and tablet computers) small group ecosystem?

RQ2. How are learning outcomes and perceptions of/attitudes toward the learning activity different between students who used the AR device and those who did not?

RQ3. How did the ways that individuals used the devices affect learning outcomes and their perceptions of/attitudes toward the learning activity?

Methods

Participants and Study Design

The participants were 77 students recruited from an introductory astronomy course at a university located in the mid-western United States. All participants in the study consented to have their classroom activity data collected as part of this research. The study took place during participants' 50 mins weekly lab session for a consecutive three-week period during the Fall 2021 semester. In Week 1, the research team introduced the simulation software and let students explore it using both AR and tablet computers that were provided to them. This exploration was guided with a task sheet that highlighted the functionality that participants would be asked to use in the upcoming weeks. In Week 2, students worked on a seasons lab which was part of the students' regular course material. Students also had the opportunity to use our software and devices while they were working on the lab tasks in Week 2 of the study. The purpose of these first two weeks was to let students become familiar with our software and devices; no data from these weeks were used in the analysis described in this paper. In Week 3, the students engaged in a multi-device small group learning task designed by the research team called "Lost at Sea." During this week, students were randomly assigned to groups of three to four such that they could work on the task collaboratively.

There were a total of 8 lab sessions and each session had three to four groups (22 groups in total). Groups had the entire 50 mins of the session to work on the task together. One AR device (the Microsoft HoloLens 2) and two tablet computers were provided to each group. The research team encouraged the groups to use both devices while they explored the simulation in the first two weeks and in the introduction to the Lost at Sea task, but once the students started working on the task independently, they were able to make their own choices about which devices to use and when. All student interactions on the Lost at Sea task were video recorded using a tripod-mounted camera, and screen captures were taken from all the devices including AR. Students completed pre and post learning assessments as well as an individual post questionnaire administered at the end of the session.

Multi-Device Ecosystem Design

The digital sky simulation software utilized in this analysis was the product of multiple co-design cycles between the research team and collaborating astronomy educators. The system provides users with a stellar catalogue that can be explored across both space (location on Earth) and time. In addition, the system is networked between tablet and AR users, allowing all group members to annotate the night sky (e.g., sketching lines), highlight specific constellations of interest, share location information, and share their night sky perspectives collaboratively as they work. Interaction on the tablets is touch-based, while interacting in AR leverages hand and gesture detection to allow the user to tap interface items, pinch holograms to reposition them, and tap their index and thumb together to select distant objects such as stars.

Figure 1 shows a group accessing the three simulation representations available in the system, all accessible in both the tablet and AR platforms. The system was designed so that the interface was as consistent as possible across AR and tablets to reduce the need to "re-learn" the software when entering AR (see blue input and info panels in Figure 1). "Horizon view" (top-right) provides the user with a first-person view of the sky as if standing on Earth. "Star view" (bottom-right) removes the horizon limitations from the perspective, giving the user access to the full celestial sphere. "Earth view" (bottom-left) places the user in orbit above the Earth with the ability to place location pins with which to change their position on the Earth or confer with other users about potential sky viewing locations. All group software interactions (interface manipulations, view changes, annotations) were written to log files for later analysis.

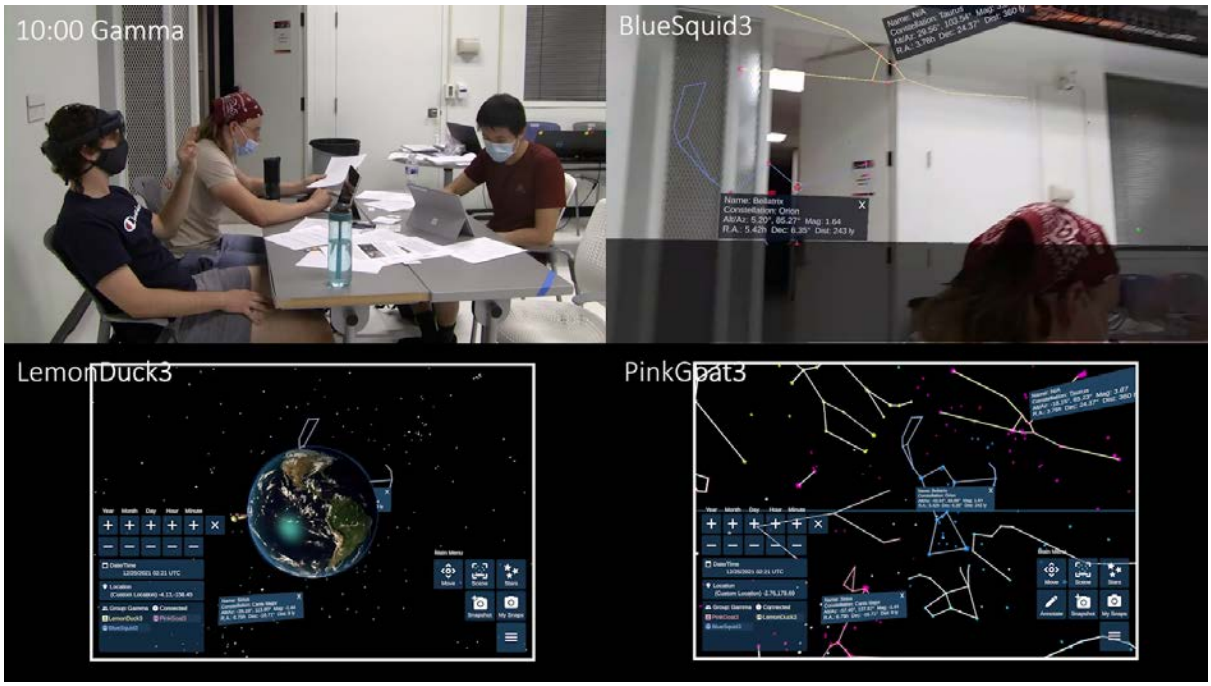
Task Design

A multi-part problem solving narrative was created for students to address in the "Lost at Sea" task. The goal was to promote authentic problem solving and in-depth utilization of the simulation. The narrative describes a crewed space capsule that has splashed down at night at an unknown location. The simulation contains a selection of

specially bookmarked locations with no associated latitude or longitude data, and students are tasked with using their night sky knowledge to determine the latitude and longitude of their capsule splash-down site. There are three parts to the task: Subtask 1 has the group locating stars or reference constellations to determine what hemisphere they are located in; Subtask 2 then asks the group to identify constellations that can serve as reference points for North, South, East, and West; finally, Subtask 3 asks them to formally calculate their latitude and longitude. The ability to use night sky data to determine the latitude and longitude is the overarching learning goal for this activity. Supporting task documents outlining the task goals, as well as supplemental information on the process of latitude and longitude calculation, are accessible to the group. What makes longitude calculations especially challenging is that the supporting instructions reference the most common process of leveraging the position of the sun, but groups must transform that knowledge to calculate longitude using the night sky instead.

Figure 1

Composite screenshot of the multi-device learning ecosystem showing the three views of the simulation: Top right (AR in Horizon view), bottom right (Tablet in Star view), and bottom left (Tablet in Earth view).



Measures

We conducted two paper-based assessments: pre and post learning assessments and post questionnaires about perceptions and attitudes. Pre and post learning assessments were designed to measure whether students' knowledge of how to calculate latitude and longitude changed based on their interactions with the multi-device learning ecosystem described above. Both learning outcomes entail a multi-step process, and a short open response prompt allowed the research team to evaluate the completeness and accuracy of students' understanding of this process. The prompts in both the pre and post learning assessments were the same: "Write as much as you know about the steps for calculating latitude/longitude based on the stars visible in a given location." To assess students' responses, two researchers (1st and 2nd author) looked through all students' answers together and scored them based on a rubric developed during pilot testing of the multi-device learning ecosystem (Kim et al., 2021). If students' answers did not contain any of the key astronomy concepts or they did not respond, we scored them as 0. If students' answers only contained basic concepts, then we scored them as 1 (e.g., we need to find a certain star's height to calculate latitude; calculating longitude is related to the time and location). If students' answers contained all desired astronomy concepts, then we scored them as 2 (e.g., we need to find Polaris and measure its height from the horizon, and it is the latitude for Northern hemisphere; we need to find when a certain star is at the highest point in both Greenwich and crash site to find the time difference then multiply it by 15 to calculate longitude). The post questionnaire consisted of five-point Likert scale items asking how they felt about their perceptions of and attitudes toward the multi-device group collaborative learning activity: "While working with your group, how often did you rely on your group members for help on a task or concept?", "While working in

 © ISLS

your group, how often did your group members rely on you for help with a task or concept?", "While working in your group, did collaborations occur frequently between students using AR and students using tablets?".

In addition, open-ended questionnaires asked participants what tasks they completed while they were using each device. The first and second authors also classified these open-ended post-questionnaire items based on the coding scheme detailed in Table 1. The coding scheme was applied for both types of device-use (tablet and AR), but for tablets only level 2 and 3 were employed, because all students used the tablets at least once for exploring or measuring.

Table 1
Classifying how students used technology

Level		Description	Example
0	Not used	Student did not use the device at all.	I didn't use AR this week.
1	Adjust to the technology	A student used the device but adjusted to the technology itself rather than using it for problem-solving.	Mostly focused on understanding AR.
2	Exploring	A student used the device to explore the night sky and clicked on some stars and constellations.	I selected a few constellations in the AR.
3	Measuring	A student used the device to calculate or measure for the task completion (e.g., location change, tracking time, etc.).	I used the tablet to change locations, set the time, and find constellations.

Results

Our first research question asks whether students learned the targeted astronomy content (calculating longitude and latitude) while they worked on the multi-device small group activity. Wilcoxon signed rank test (paired) was conducted on the students' pre and post learning assessment scores. The result shows that the pre assessment median score is significantly different from the post assessment median score for both latitude ($p < 0.001$, effect size $r = 0.56$) and longitude ($p < 0.001$, effect size $r = 0.54$). Table 2 shows that for both latitude and longitude, the number of students with 0 points decreased and the number of students with 1 and 2 points increased on the post-assessment. Since longitude is a more complex calculation, it is not surprising that scores for this measure were lower than for latitude.

Table 2
Pre-assessment and post-assessment score distribution

	Latitude		Longitude	
Score	Pre	Post	Pre	Post
0	59	31	74	48
1	12	17	3	21
2	6	29	0	8
Total Participants	77	77	77	77

Our second research question asks whether there is a difference between students who used AR devices and students who did not in terms of learning outcomes and perceptions of/attitudes toward the learning activity. First, we conducted the Mann-Whitney U test to measure the learning outcomes. The result shows that whether or not students use AR during the lab session did not affect either of the learning outcomes (e.g., latitude: $p = 0.82$, longitude: $p = 0.32$). Combining this with Wilcoxon signed rank test result (research question 1), we can conclude that students learned desired content regardless of their use of the AR devices. We did not conduct the same measurement for the tablet since all the students used tablets. In addition, we conducted a One-way ANOVA to measure perceptions of the learning activity. The result also revealed that whether students used AR devices or not does not impact these perceptions (e.g., Individual reliance on group: $p = 0.43$, Group reliance on individual: $p = 0.39$, Frequency of collaboration: $p = 0.74$).

Our last research question asks how the way in which individuals used each device affected learning outcomes and their perceptions of the learning activity. First, we conducted an Ordinal Logistic Regression to measure the relationship between how students used each device and learning outcomes. The estimated model shows that:

 © ISLS

For latitude

$$\text{Logit}(P(Y \leqq 1)) = 2.67 - 0.29 * \text{AR usage} - 0.95 * \text{Tablet usage}$$
$$\text{Logit}(P(Y \leqq 2)) = 3.65 - 0.29 * \text{AR usage} - 0.95 * \text{Tablet usage}$$

For longitude

$$\text{Logit}(P(Y \leqq 1)) = 0.14 - 0.12 * \text{AR usage} - (-0.21) * \text{Tablet usage}$$
$$\text{Logit}(P(Y \leqq 2)) = 3.65 - 0.12 * \text{AR usage} - (-0.21) * \text{Tablet usage}$$

Based on the model, the odds ratios are presented in Table 3. For *latitude*, for every one unit increase in students' AR usage (i.e., Adjust to the technology → exploring), the odds of being more likely to get a higher score (i.e., 1 or 2 versus 0) is multiplied 1.33 times (i.e., increases 33%), holding constant all other variables. For students who used tablets for measuring, the odds of being more likely to get a higher score (i.e., 1 or 2 versus 0) is 2.60 times that of students who used tablets for exploring, holding constant all other variables. For *longitude*, for every one unit increase in students' AR usage, the odds of being more likely to get a higher score is multiplied 1.13 times, holding constant all other variables. For students who used tablets for measuring, the odds of getting a higher score (i.e., 1 or 2 versus 0) is 19% lower [i.e., (1 - 0.81) * 100%] than the students who used tablets for exploring, holding constant all other variables.

Table 3
Odds ratios for each learning outcome

Latitude			
	OR	2.5%	97.5%
AR usage	1.33	0.88	2.03
Tablet usage	2.60	0.89	8.10
Longitude			
	OR	2.5%	97.5%
AR usage	1.13	0.73	1.78
Tablet usage	0.81	0.28	2.47

Furthermore, we conducted a Two-way ANOVA to measure the relationship between how students used each device and their perceptions of the activity (see Table 4). Results revealed that there is a significant difference in the extent to which they felt that they relied on their group members based on how the students used the tablet computers ($F = 3.92$, $p = 0.05$). How they used AR also has a marginally significant effect on students' perceived group reliability ($F = 2.23$, $p = 0.08$), so we decided to look more deeply using the Tukey post hoc test to see if there are any significant pairwise differences. There is a marginally significant pairwise difference between 3 (measuring) and 1 (adjusting to the tech), ($p = 0.06$). These findings indicate that the way students used tablets influenced students' perceived dependency towards the group, and there is a pairwise difference when students used AR as a measuring technology compared to when students used AR simply to acclimate to using the technology itself on the students' perceived dependency towards the group. This means that the students who used AR for measuring felt less dependency towards the group compared to the students who used AR solely to learn how to use the technology. There were no significant differences for other perception questions yielded by different types of technology usage (see Table 4).

Table 4
How different usage of each technology affects students' perceptions of the learning activity
(* indicates $p < .05$)

Discussion

The significant pre to post learning gains measured here suggest that productive learning can occur when students engage with problem-solving tasks within a multi-device small group ecosystem. In and of itself, this is a meaningful result, showing that the combination of AR and tablet technology integrated through a multi-part problem solving task did not detract from, and may have benefitted, the core instructional goals of the implementation. Interestingly, the learning gains experienced as a result of engaging with the multi-device ecosystem was not affected by whether or not a participant used the AR headset. One possible interpretation is that the learning effects of this intervention stem from the overall ecosystem and not from a specific device; a participant does not necessarily need to put on an AR headset themselves to receive the benefit of someone in the group having and sharing that perspective. Likewise, participants' perceptions of whether they relied on the other members of the group and whether the group relied on them were not affected by AR usage. This again suggests that participants felt that they were interacting with a dynamic system of people and technology as opposed to a single device.

In general, it was clear from this analysis that simply accounting for whether students used the AR device or not does not provide a complete picture of how the technology influences learning and perceptions of the activity. When we examined *how* the technology was being used, we began to see a more nuanced relationship between AR usage and performance on the problem-solving tasks. Specifically, the categorization of usage into exploring and measuring behaviors proved to be a useful lens for analysis. We discuss these results in terms of our two primary learning outcomes: calculating *latitude* and calculating *longitude*. We are keeping our discussion of these outcomes separate because the results were slightly different, and because the tasks themselves present different levels of challenges, as described below.

When examining student learning performance around the calculation of *latitude*, while the AR usage levels showed some benefit to the likelihood of an increased assessment score, tablet users showed substantially higher likelihood when engaging in tasks related to measuring as opposed to exploring. These relationships are potentially due to the affordances of the AR and tablet technologies, highlighting differences in the user interface actions required for exploration or measurement. Exploration interactions (such as panning the sky to locate a star) in the tablet required the use of arrow key touch buttons, while within AR a user needs no interface interactions (simply rotating their head and body) to modify their view. Therefore, it is much more natural and easier to explore and find constellations in the night sky with the AR environment. In contrast, measuring interactions (changing time, drawing annotations) use similar combinations of buttons (touch or holographic) and selection actions to complete. The condensed layout and faster response of the tablet interface (as opposed to "pressing" a holographic button) may have been a contributing factor in facilitating the likelihood of higher knowledge scores for the tablet users.

With the calculation of *longitude*, we see again that moving up levels of AR usage still shows a positive relationship with higher level post assessment scores although it slightly decreased compared to the latitude learning outcome. The result for tablet usage here is reversed, with tablet users engaging in exploration showing increased likelihood of higher assessment scores when compared to those who engaged in measuring. As we mentioned in the Task Design section of the paper, the longitude task was intentionally designed to be more difficult to solve since it requires students to do a higher-level calculation and transfer knowledge from a different scenario. Here the complexity of the longitude task potentially plays a large factor. To calculate longitude, a group needs to engage in a series of alternating exploration and measurement/manipulation behaviors, reducing the likelihood of one device type dominating the other due to an interface affordance. Although our RQ1 finding verified there is a pre to post increase on the longitude measure, it is also true that many of the students still remained at 0 or 1. This motivates us to investigate students' higher-level/complex learning outcomes by analyzing more diverse data (e.g., students' group discourse, log data, etc.) beyond their self-reporting.

When examining student perceptions of the activity, we see a significant relationship between their ratings of how often they felt they relied on the group based on their level of tablet usage. In other words, if the

students used tablets at a higher level (e.g., measuring), they perceived they were more reliant on their group members. This may mean that students tried to solve problems by interacting with group members rather than solving everything by themselves when trying to calculate or measure something. For example, in order to calculate longitude, information on two particular locations is required at the same time. To do this, a student using a tablet at a higher level may have sent other students to each of those two locations to find information. In addition, the notable pairwise difference for perceived reliance on the group in AR between level 3 (measuring) and level 1 (simply adjusting to the AR technology) may indicate that if students used AR for measuring, they did not think they relied on the group compared to when students use AR simply to get familiar with it. This makes sense because if students are using AR to get familiar with it, they are likely to ask group members some questions about how to use the device, while if students are using AR for measurement, they are likely more focused on the task and less in need of relying on their group.

Taken together, these results contribute to an increased understanding of how groups can begin to engage in a complex problem solving task with the support of AR technologies. The analysis performed here provides insight into the role of user perceptions of technology and group interactions and the relationship of these perceptions with learning outcomes. Moving forward, it is clear that effective designs that incorporate AR into small group learning environments alongside other technologies must be cognizant of the affordances attributed to each platform, and the role they can play in facilitating specific patterns of interaction and measurements of learning. In the current study, we primarily focused on the students' self-reports of their usage of the technology. Furthermore, this study was conducted during existing university class sessions, not in a controlled experimental environment. As to keep a classroom atmosphere, we wanted to give students autonomy over which device to use and how much to use, rather than force them to use all devices evenly. Therefore, this paper mostly focuses on the effectiveness of a multi-device learning ecosystem as a whole, and how the ecosystem should be designed based on the students' usage of each device. To have a more detailed understanding of how the students' different device usage affected their learning and what are the educational effectiveness of individual device usage, our future research will include discourse analysis (e.g., topic modeling and association rule mining) along with log data analysis. We will investigate how the students' discourse topics vary when they are using different devices, how those different discourse topics are associated, and if there are any relationships between the topics and certain types of student-software interactions.

Leveraging Students to Generate Skill Tags that Inform Learning Analytics

Steven Moore, Huy A. Nguyen, John Stamper
StevenJamesMoore@gmail.com, hn1@cs.cmu.edu, john@stamper.org
Carnegie Mellon University, Pittsburgh, Pennsylvania, USA

Abstract: Generating skill taggings for learning activities is a task typically performed by instructors and domain experts, which can be challenging to scale due to the required expertise. However, these skill tags are used by many learning analytic platforms. In this work, we investigate the feasibility of leveraging students to generate skill tags in an online learning setting. Across four instances of two online courses in chemistry and programming, we embedded an optional and low-stake activity, where students were asked to propose three skill tags to a given problem in the course domain. We found that 12% of the student-generated skill tags matched expert-generated ones used in the courses while 54% of them were unusable even with revisions. Our results suggest that students are willing to engage with an optional skill tagging activity; however such interventions should be accompanied by scaffolding the process for students to yield higher quality responses.

Introduction

Educational technologies, such as intelligent tutoring systems and digital learning platforms, often employ a mapping of skills to assessment items in order to measure student performance and guide them in the learning process (Bier et al., 2014). These skills treat student knowledge as "an acquired unit of cognitive function or structure that can be inferred from performance on a set of related tasks" (Koedinger et al., 2012). Typically the skills mapped to assessments in these technologies are at a fine granularity intended to measure the low level concepts assessed by a given activity, compared to the higher level skills often found in summative assessments that are often at the standard or learning objective level (Guilbert, 2002). This skill mapping is intended to capture the student's underlying cognitive process and is vital to many core functionalities of educational software, enabling features such as adaptive feedback and hints (Moore & Stamper, 2019).

While having these skills allows for student modeling and can assist in analytical pipelines like open learner models or learning dashboards, developing the mapping of skills to assessments poses several challenges. Traditionally an expert is employed to create the mapping of skills to an assessment, potentially with assistance from an instructional designer or learning engineer (Koedinger & McLaughlin, 2010). This process can be arduous and often requires methods such as think-alouds to elicit the skills from the expert while avoiding pitfalls such as expert blindspot (Nathan et al., 2001). As a result, scaling this process is challenging due to the time constraints, resources for eliciting the skills, and recruiting the domain experts to assist with skill tagging (Matsuda et al., 2015).

Attempts have been made to scale this process, as several studies have turned to crowdsourcing to recruit a pool of humans to skill tag assessments (Moore et al., 2020a, Moore et al., 2020b). While there was surface level success with this pool of human judgement, prior knowledge of the domain is often required to properly generate and map skills to assessments (Koedinger & McLaughlin, 2010). Enlisting students, who have varying domain knowledge and have been successful in related tasks, may offer a viable solution to this problem (Williams et al., 2016).

To explore how we could potentially engage and scale a group of humans in the skill tagging process, we sought to test a novel solution that utilized a more knowledgeable base. To utilize students in generating skill tags, we deployed a completely optional activity where students could input three skills, via free-text boxes, needed to solve a problem in the context of four undergraduate online courses. This study contributes new knowledge about student participation with optional tasks in an online course, particularly one involving skill tagging. It also supports how student performance correlates with the quality of their skill tags. The results provide insights into the feasibility of leveraging students to skill tag problems and challenge us to further investigate how we can deploy interventions that leverage student knowledge to develop stronger learning analytics.

Theoretical framework

A skill refers to a granular piece of knowledge that is required to solve a particular problem in a digital learning environment (Koedinger et al., 2012). These skills power a plethora of learning analytic resources: learning curves, open learner models, adaptivity, and many more (Stamper & Koedinger, 2011). Findings have demonstrated that

 © ISLS

digital learning environments that leverage this skill-powered adaptivity, such as cognitive tutors, can help students reach mastery in 26% less time compared to traditional classroom instruction (Koedinger et al., 2012). These systems and the advances they bring all rely on having accurate skill tags, meaning they are written at the correct level of specificity and model part of the knowledge required to solve the problem.

Skills used for these learning analytics systems are more fine-grained than learning objectives or common core standards that typically get mapped to sections or pages of a given course that encompass multiple skills (Badawy et al., 2016). For instance, a learning objective for an algebra course might be "Graph linear and quadratic functions and show intercepts, maxima, and minima". Learning objectives in contrast are fairly broad and encompass several larger concepts that could further be broken down. On the other hand, skills refer to a specific semi-granular subject area associated with a learning resource (Razzaq et al., 2007). An example of a skill tagged to a problem in an algebra course might be "Identify the slope from an equation in the form of y=mx+b". While the skill involves knowing other concepts such as slope-intercept form and arithmetic operations, it is specific enough to be assessed by a single problem and can be encompassed by the larger learning objectives for the course. Note, skills should be relevant to both the problem and the context of the course. For example, while knowing what "+" and "=" mean in the problem is required, a problem in an algebra course would not necessarily be assessing students for that knowledge.

Traditionally, generating and mapping skills to assessments is done by experts that are familiar with the process of skill tagging, their required granularity, and with knowledge of the given domain (Koedinger & McLaughlin, 2010). Frequently when an expert instructor is utilized to create skill mappings, a cognitive task analysis (CTA) or think aloud is conducted (Chipman et al., 2000). In CTA, an expert is interviewed and performs a series of tasks while articulating their thought process, which are intended to specify the cognitive processes associated with task performance. During this process, the interviewer records the skills being articulated by the experts. Studies have shown this leads to effective instructional designs and an accurate skill mapping, but requires substantial human efforts (Lee, 2004). These methods are done so the domain expert involved can potentially overcome expert blind spot, where the explicit steps taken to solve a problem can get grouped together when it becomes second-nature (Nathan et al., 2001). This can impede the skill tagging process, as the expert might otherwise overlook a skill that is innate to them, but one that is critically assessed by the given problem.

Compared to experts, students' knowledge of a domain can be classified towards novice, which may help them avoid some of the pitfalls of expert blind spot, as they can leverage the knowledge of their own previous misconceptions in the learning process (Edens & Potter, 2008). The same CTA methods have been leveraged on novices such as workers on a crowdsourcing platform to provide knowledge components for problems in the domain of geometry and college-level English writing (Moore et al., 2020a). This study had crowd workers complete several assessments and then prompted them to provide the skills, via free-text boxes in a survey, they needed to solve the last problem they completed. They found that roughly half of the skills generated by experts and previously used for the problems in both domains were able to be matched by the skills generated by the participants. While crowdsourcing skills demonstrated baseline success by matching some of the expert skills, the specificity of the skills was not at the appropriate level of detail, perhaps in part due to the lack of domain knowledge of the crowdworkers.

In the present work, we propose utilizing students to help skill tag problems, to create and scale high quality skill mappings that are at the correct level of detail to be utilized by learning analytic systems. As a first step towards this, we must first investigate if students can successfully provide accurate skill tags. To test this, we present students with an optional skill tagging activity embedded in their online coursework. We then utilize a 4-item rubric to assess the quality of students' skill tags and analyze how they relate to both expert-generated ones and the students' performance in the course. The two specific research questions we address are: (1) How accurately can students generate skill tags that domain experts have identified? and (2) How does the accuracy of students' skill tags relate to their participation and performance in the course?

Methods

Learning platform

The present study takes place in a digital courseware platform known as the Open Learning Initiative (OLI). OLI is an open-ended learning environment that offers courses from a variety of domains (such as chemistry, biology, statistics, economics, etc.) and consists of interactive activities and diverse multimedia content (Bier et al., 2019). OLI activities are presented in two distinct categories: low-stakes/formative, providing students with feedback, or high-stakes/summative, used to evaluate student learning at the end of a structured unit. The low-stakes formative assessments in the system are all optional, allowing the students to scroll by them and focus purely on the instructional content. These assessments consist of a variety of question types such as multiple-choice questions, short answer, and dropdown style questions. Each question in OLI is broken down into one or more problem steps,

where each step corresponds to an opportunity for student input. For instance, if a question asks a student to set the value of three dropdown boxes, then it consists of three unique steps that each have their own set of feedback and correct or incorrect responses. This distinction between a problem and its steps is important, since students may work on a problem, but not complete all of the steps due to reasons such as not knowing the answer to some of them, wanting to skip them to save time, or getting distracted (Chen et al., 2018).

Study context & students

For this study, we used data collected from four instances of two different introductory courses, one in chemistry and the other in Python programming. The two instances of the introductory chemistry course were taught at a community college in the western United States. This course provides students with fundamental knowledge of chemistry concepts, preparing them for future biology and chemistry courses. The course is generally geared towards freshman and sophomore undergraduates from varying degree backgrounds, with a majority of the students pursuing a chemistry-related degree. Our data comes from the fall semester of 2020, when the introductory chemistry course was offered in the OLI system.

The OLI content the students used for these two instances of the chemistry course in this study covers the topic of elements and compounds and consists of thirteen separate modules. Each module consists of several topic headers, containing paragraphs of instructional text and low-stakes activities embedded throughout. There are a total of 33 low-stakes and completely optional activities embedded throughout the thirteen modules of the course, not including the skill tagging activity used for this study. These activities include multiple-choice questions, selecting the correct option from a dropdown, drag-and-drop exercises, and submitting a short answer to compare against an expert response. Each of these activities is broken down into steps, depending on the components of the activity, for a total of 178 unique steps. For instance, if a problem has three fill-in-the-blank boxes, then that problem would consist of three unique steps. Every activity and their steps provide students with feedback after they have been answered. Additionally, students have unlimited attempts to answer these questions, so they can continue until they are correct or choose to advance, regardless of a correct or incorrect response.

The two instances of the introductory Python programming course were taught at an R1 university in the northeastern United States. This course provides students with knowledge on introductory concepts in the Python programming language, preparing them for their future coursework in computer science. This course was taught to incoming master's students in a human-computer interaction program who indicated by self-report they did have a sufficient understanding of programming concepts. The collected data we used comes from the summer semesters of 2020 and 2021, when the course was offered in the OLI system. The OLI content in the two instances of the programming course covers the topic of iteration and consists of twelve separate modules. There are a total of 41 low-stakes and completely optional activities embedded throughout the twelve modules of the course. Each of these activities is broken down into steps, depending on the activity, for a total of 113 unique steps.

While the four course instances were taught in different semesters by different instructors, students were provided with the same set of instructions regarding the use of the OLI materials. They were not required to answer the questions found throughout the OLI modules or even access them. Students were provided with an "Introduction to OLI" module, which is an overview of how to effectively make use of the system and the concepts that will be covered in the course. All the instructional materials in OLI were optional to the students; there was no requirement for them to access or complete the materials. However, students were assessed on the concepts covered by the OLI materials, so it was beneficial for the students to utilize them. A further breakdown of the course offerings, including the anonymized instructor, semester, and number of students that accessed the course materials can be found in Table 1.

Table 1, The four course instances used in this study

Course	Semester	Instructor	Student Count	Number of Activities
chem 1a	fall 2020	t1	23	33
chem 1b	fall 2020	t2	26	33
programming 1a	summer 2020	t3	33	41
programming 1b	summer 2021	t4	30	41

Data collection

We focus on an activity we added to this course that involves the students generating three skills that they believe are required to solve a particular problem in the course[1]. In the chemistry course, this activity is found in the ninth module of the OLI content for this section of the course. This module provides several paragraphs of instructional text, two worked examples, and several low-stakes multiple-choice questions on the topic of nomenclature for

ionic compounds with polyatomic ions, along with this single activity. In the programming course, this activity is found in the fourth module of the OLI course. This module covers the concept of python for-loops, consisting of several paragraphs of instructional text, multiple-choice questions, and two small programming exercises. In both courses, the activity is presented in the same low-stakes and optional format as the other activities found prior in the course. This task that prompts students to generate the three skills can be found in Figure 1. In the activity, students are prompted to generate three skills that are needed to solve the problem stated above this task. The students input the text in three different free-text boxes. The instructions for the task are minimal to encourage student participation, as lengthier text might deter students (Schmidt-Weigand et al., 2010). We also provide them with a domain contextual example of what a skill might look like for a different, non-related, problem in[1] the course. Aside from that, no training or scaffolding was provided to the students to help them generate three skills for the question. We intentionally wanted to keep this low-stakes and optional, to examine the students' participation with the task and the quality of their contribution.

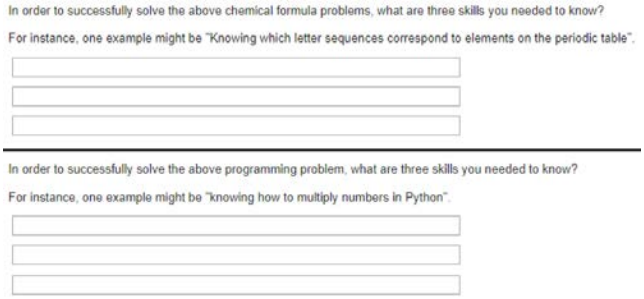

Figure 1. The self-explanation activity and accompanying question presented to the students.

Dataset

Student data was collected from their interactions with the 33 activities found in the chemistry course and the 41 activities in the programming course, in addition to the skill generation task. Since the skill generation task is our outcome, we focus our analysis on the other activities that the students completed in the courses, which consisted of a total of 178 unique steps in the chemistry courses and 113 unique steps in the programming ones. On average, an activity in the course consists of 3 unique steps, such as a single activity having the student select from three different dropdown menus. All of the activities found in the OLI course were completely optional; students could do as much or as little as they desired. For instance, sometimes a student would begin working on an activity, but did not complete all of the parts in it. As a result, the system logs them having worked on that activity and also provides the exact number of steps that they completed. For this data set in particular, it is more common for students to fully complete an activity if they start it, i.e., they will attempt all of the steps of a problem.

Our data also consists of three metrics related to student performance on the activities. When a student works on a step for a given activity, OLI records if their first attempt at that step was correct or not. A first attempt at a problem can be a strong indicator of a student's current understanding of the concepts being assessed (Corbett & Anderson, 1994). Relatedly, the total number of incorrect attempts made at a given step and the total number of correct attempts are recorded. These numbers can potentially exceed the total step count, as a student could correctly answer a question, then select an incorrect answer to see the feedback, then select the correct response once again, registering two correct and one incorrect attempt for that step.

Analysis

In order to assess the quality of the three student-generated skills, we had two item-raters evaluate each skill to determine how much it fit the problem, if it was at the appropriate granularity, and its match to the three skills previously assigned to it by other domain experts. Both raters had content-area expertise, ample experience in skill tagging, and experience applying coding schemes to student data. After familiarizing themselves with the OLI course module once again, they were instructed to go through each skill one at a time and place it into one of four categories. The inter-rater reliability was calculated, and the Cronbach's alpha value was .94, as the raters only disagreed on the categorization of a few skills. These discordant skills were discussed among the two raters until they reached a consensus on the categorization of them using the coding categories. Each of these categories was assigned to a numerical ranking (1-4) that also represented the goodness of the student-contributed skill. In this instance, a ranking of 1 was the best and indicated that the student-generated skill matched the expert-

[1] The full content of this activity is included in https://github.com/StevenJamesMoore/ICLS2022/blob/main/learnersourcing_activities.pdf

generated skill. A ranking of 4 was the worst and indicated that the student-generated skill was not relevant to the problem and therefore it did not match. A full description of the four categories can be seen in Table 2. These four categorizations are based evaluation rubrics from previous studies for assessing math problem solving skills and evaluating knowledge concept maps from novices and experts (Egodawatte, 2010; Kim, 2015).

Table 2. The four categories the student-generated skills were placed into along with an example student-generated skill from the chemistry course.

Category	Rank	Description	Examples
Expert Match	1	The skill matches one of the three skills originally tagged to the problem by an expert.	"Combine ions in the smallest ratio"
Match, Not Granular	2	The skill is very similar to one of the three expert-generated ones, however it could be more specific.	"Know charges on polyatomic ions"
Problem Relevant	3	The skill is technically utilized in the problem, but it is not necessarily what is being assessed given the context.	"Write the formula that reflects this ratio"
No Match	4	The skill is not relevant to the problem, it is not being utilized or assessed by it at all.	"Knowing nomenclature"

The two problems used in each of the courses were selected due to previous student data collected during their use indicating that students tend to struggle on both of them, with 40% of students getting an incorrect answer on their first attempt. Additionally, they each had three skills previously assigned to them by domain experts upon the creation of the courses. Our two item-raters verified that these three skills were appropriate for the problems and at the correct granularity for what was being assessed. While having experts evaluate student-generated skills is not scalable, in the scope of this study, we want to first investigate the feasibility of having students generate such skills. To assess the quality of these student-generated skills, we need to compare their outputs to that of experts that typically do this task. A list of the three skills tagged to each problem can be found in Table 3.

Table 3. Three expert-generated skills for chemistry (left) and programming (right)

Expert Skills - Chemistry	Expert Skills - Programming
1. Identify the cation and anion and their charges	1. Iteration over a value using the range() function
2. Write chemical formulas for ionic compounds that contain polyatomic ions	2. Utilizing a print statement in conjunction with numerical statements
3. Combine the ions in the smallest whole number ratio	3. Modify an existing program to fit a new set of instructions

Results

The student-generated skills were evaluated by experts to determine their quality. Then we analyzed how the student interactions in the course correlated with both student participation on the task and the quality of their contribution. We leveraged measures of central tendency to report the varying categories of the student-generated skills. Then we investigated the different patterns of student participation and performance in the course by looking at their interactions with the varying low-stakes activities and their steps embedded throughout the course. A Bonferroni correction was applied to post hoc analyses that follow (Armstrong, 2014).

Students generating accurate skill tags

Across all four course instances used in this study, a total of 112 students accessed the OLI course. Among those 112 students, 64 of them completed the optional skill generation task where they generated three skills for the presented problem. To assess the quality of these student-generated skills, we had two expert item-raters evaluate all 192 of their contributions. The raters checked if the student-generated skills matched an expert-generated one, indicating that they were accurate, meaning they are written at the correct level of specificity and model part of the knowledge required to solve the problem. This evaluation revealed that 23 (11.98%) of the contributed skills matched an expert-provided item and 65 (33.85%) matched a skill, but needed to be refined for further granularity. Table 4 shows the further breakdown of the item-rater categorizations of the 192 student-generated skills into the four different categories. Over half (54.17%) of the student-generated skills fell into the bottom two categories, which indicates that even with revision they are not usable or particularly useful. All of the skills labeled as the fourth ranking, "No Match", were one word or nonsensical responses by the students for the activity.

Table 4. The count of the four ranking categories assigned to skills in each of the courses.

Course	Student-generated Skill Count	Expert Match	Match, Not Granular	Problem Relevant	No Match
chem 1a	36	7	15	6	9
chem 1b	54	13	24	14	3
programming 1a	54	1	14	29	10
programming 1b	48	2	12	24	10
Totals (%)	192	23 (11.98%)	65 (33.85%)	72 (37.50%)	32 (16.67%)

Each of the activities in the two course domains had three skills tagged to it by domain experts, previously shown in Table 3. Student-generated skills from the chemistry courses were able to match all three of the expert skills for the problem, while only two of three expert skills were matched by students in the programming course. Table 5 shows an example of a student-generated skill from both domains that was categorized as an expert match by the two item-raters.

Table 5. An example of a student-generated skill that matches one of the chemistry expert skills (left) and one of the programming expert skills (right)

Expert Skill - Chemistry	Expert Skill - Programming
Identifying the cation and anion and their charges	Knowing how to use a print statement in conjunction with numerical statements
Student Skill - Chemistry	**Student Skill - Programming**
Identifying the cation, anion, and the charges	Knowing how to manipulate equation to have odd numbers printed instead of even numbers

Student participation and performance

In total, of the 112 students that were part of four instances of the courses, 19 of them did not access any of the course materials in the given modules. A total of 49 students were enrolled in the two chemistry courses, where 38 students accessed the materials, and 30 students did the skill generation activity. The chemistry course consists of a total of 33 optional low-stakes activities, not including the skill generation one, and on average the students completed 26.38 of the 33 (79.93%) activities. The two programming courses had 63 students enrolled in the courses, where 59 students accessed the materials, and 34 students did the generation activity. The programming course consists of 41 optional activities, not including the skill generation one, and on average students completed 30.48 of the 41 (74.34%) activities.

To determine which features of student interaction in the course were indicative of their participation in the skill generation activity, we performed a series of unpaired t-tests on their behavior with the other low-stakes activities found in the courses. This revealed a significant difference between the student participation with the other activities in both the chemistry and programming course and their participation in the skill generation task. An unpaired t-test showed there was a significant difference in the number of activity steps completed by students in the chemistry course who did the skill generation tasks $(M = 164.57, SD = 20.11)$ and those that did not do the task $(M = 39.47, SD = 52.45), t(47) = 11.819, p < .0001$. A similar result was found for the programming course, with students doing the skill generation task $(M = 111.03, SD = 18.41)$ and those that did not do the task $(M = 54.00, SD = 40.27), t(61) = 7.699, p < .0001$. Students who did the skill generation task were also more likely to complete all of the steps present in the activities embedded throughout the course. Similar significant results were observed for the number of activities done by a student and their participation for the skill generation task in the chemistry course, $t(47) = 11.483, p < .0001$ and the programming course $t(61) = 6.299, p < .0001$. This result supports the previous one, as the activities found throughout the course are composed of multiple steps and a subset of students completed all the 33 or 41 low-stakes activities respectively.

We then investigated whether student interactions with the other low-stakes activities in the course correlated with the quality of their generated skill contribution, to see how we might predict or promote better skills from the students. While there was a significant difference found between student participation in the skill generation task and participation in the other low-stakes activities throughout the course, it was not found to significantly correlate with the quality of the student contribution in the chemistry course $(\rho = 0.18, p = 0.333)$ or programming course $(\rho = 0.18, p = 0.303)$. Additionally, student performance on the activities as measured by their first attempt correct on the problems was not significantly correlated with the quality, measured by item-raters categorization, of their skill contributions for the chemistry course $(\rho = 0.29, p = 0.119)$ or programming course $(\rho = 0.09, p = 0.615)$.

Discussion

In this research, we investigated how we might enlist students working through online courses to assist in the skill tagging process. We found that even with the task being optional and only providing brief instructions with no scaffolding, some students were able to generate skills that matched experts, ones that could be utilized without any modifications. However, a majority of the generated skills were not sufficiently detailed, and even with revision, they would not be suited for use. The students who chose to participate in the task typically completed all of the other optional activities found in the course. In exploring what features of student interaction in the course correlated the quality of the skills they generated, we did not find any significant correlations with their performance on the other low-stakes activities. These findings suggest that students can generate and tag expert-level skills to problems from an optional and low-stakes activity within an online learning environment, but they might need more scaffolding to consistently do it.

Evaluation of the 192 student-generated skills indicated that, while not the majority, students across both course domains generated skills that matched all three expert ones in chemistry and two out of the three for programming. Students in all four course instances generated many skills that were categorized as a match but needed a bit more granularity to directly match an expert-generated skill. While these levels of skills cannot be as readily used as the direct match ones, they could still serve as an initial baseline to feed into a learning analytics system. We are hopeful that through more instruction or guidance, we can increase the quality of the student contributions by having them think deeply about the granular details of the skills they use to answer the activities.

With all the low-stakes activities embedded throughout the course being completely optional, including the skill generation one, there was still a high amount of overall participation from the students. This was particularly surprising for an optional activity, which generally has lower participation rates due to the lesser perceived value students see in completion of the activity (Farasat et al., 2017). While past skill generation methods have relied on experts (e.g., Koedinger & McLaughlin, 2010), our study presented the task as a low-stakes activity, seemingly fitting in among the fill-in-the-blank and drag-and-drop activities found on the other modules of course content. Leveraging just the native features of the system, in this case free-text boxes for short answer questions, we were able to provide students with the skill generation task seamlessly and without requiring them to utilize yet another platform. It is likely participation would be even greater if the task was required by students or embedded into a high-stakes assessment, such as a quiz question. However, this approach would introduce another series of potential complications, such as requiring it to be graded and potentially introducing an abundance of unacceptable questions contributed by students that do not wish to do the activity but are forced to in the context.

Our contributions should be interpreted against the following limitations. First, our study was conducted across two domains, chemistry, and programming. As skill tagging is directly influenced by the domain of the problems, this may impact the generalizability of the results. Second, students from each domain skill tagged a single problem in each instance of the course. Similar to the domain, the content of the problem is directly related to skills it assesses, so our results might differ depending on the problem or domain. Finally, we did not heavily investigate the background of the students doing the task. It is possible that some students were more familiar with the concepts of skill tagging or articulating this process more than others.

Conclusion

This research demonstrates a first attempt at directly engaging students in the processes of skill tagging problems across the domains of chemistry and programming. Our results highlight how student behaviors regarding their completion of activities in the course are indicative of their participation on the optional skill tagging task. Requiring the student to do the activity, such as putting it in a high-stakes assessment or having students use another system, is not necessarily required for contributions, some of which are evaluated as being on par with expert ones. Although rare, students can provide expert-level skills, without detailed instructions, prior training, or scaffolding. However, most of the skills students generated would not be usable, even with revision. As a result, we do not recommend enlisting students in the skill tagging process through this mechanism, as they might require training or better scaffolding to submit usable skills. This research demonstrates an attempt to help scale online learning analytics and improve educational resources, by leveraging the students in a course. This work opens further opportunities for both engaging students in the process of skill tagging and promoting their behavior that leads to a higher quality contribution for future tasks. Future research should consider expanding domains and experimenting with different amounts of training or scaffolding for the task.

International Society of the Learning Sciences

A model for shared epistemic agency

Natalie Spence, University of Sydney

Abstract: Based on seven ethnographic cases of student group projects, this paper describes knowledge creation enacted in assessment tasks in undergraduate units of study, gathered into a model of shared epistemic agency. Key characteristics, including initial framing and ways of creating and using objects, traced between teams indicated patterns of knowledge creation. Some individual students created substantial artefacts based on shared conceptual development. The infrastructure that students created to support their collaboration is integrated within the model. The elements of the model and their connection to types of knowledge creation suggest design principles for similar activities, and avenues for future research.

Introduction

Skills for complex problem-solving are an identified priority for tertiary education, but the processes by which students practice and acquire those skills are under-researched (Graesser et al., 2018). Designers should consider how to support students in developing epistemic fluency, the ability to effectively work with knowledge, and agency in that work: in using tools, resources and processes (Markauskaite & Goodyear, 2017). However, pedagogies that actively support object-centred knowledge creation are in need of further development (Damşa & Muukkonen, 2020). How students exercise epistemic fluency in 'mundane' (action-by-action) ways, a key source of understanding, has not been the subject of much detailed investigation: for example, two empirical studies of student knowledge creation (Damşa et al., 2010; Muukkonen et al., 2010) took snapshots of projects at stages of their work using interviews and collected objects, rather than observing the projects in full.

This study followed day-to-day activities of work within university student group projects, asking the question, 'How do students exercise epistemic agency?' From the ethnographic, case-based study of group projects in university courses, a comparison of cases produced patterns and key elements of their collaborative spaces. This resulted in a model (Figure 2) towards understanding sociomateriality in the exercise of shared epistemic agency: how collaborative processes, objects and material infrastructure are used to create knowledge. It combines epistemic with practical infrastructure to describe the inter-related parts of a group project.

Literature

The model of shared epistemic agency derived from the analysis of cases relates together the concepts, briefly outlined here, of dispositions, knowledge creation, shared epistemic agency, objects and infrastructure invoking distributed cognition.

The early formation of group projects are related to *dispositions*, which combine a sensitivity to the occasion, inclination to act and ability to apply skills and knowledge appropriately (Perkins et al., 1993). The way that a student frames the task and subsequently acts is influenced by previous experience as well as perceived future utility. If the situation is seen as familiar or novel, or could relate directly to a future career goal, for example, it will affect motivation and a decision on whether old or new ways of working are required. The framing of a task is the outcome to the question of "What is going on here?" (Goffman, 1974, p. 8). Framing can happen at the level of the whole project or in terms of personal long-term goals, and it also happens at the moment-to-moment level (Goffman, 1974; Scherr & Hammer, 2009), when students decide to pursue an idea or consider how to set up their communications.

The *knowledge creation* metaphor (Paavola & Hakkarainen, 2005) underpins the analysis of cases. In this view, learning is social and centered on the use and creation of "common objects of activity" (Paavola & Hakkarainen, 2005, p. 536), which include both material artefacts and concepts. The production of knowledge through objects results in a "public life" (Bereiter & Scardamalia, 2014, p. 35) that makes them available for review, interrogation, adaptation and extension by others. In the context of a collaborative project, shared objects are key to productive knowledge creation, placing ideas, discussion topics, resources and record of progress within the gaze and activity of group members.

Shared epistemic agency is where disposition meets knowledge creation in group actions. It is conscious collaborative work with knowledge towards a shared goal in a particular situation (Damşa et al., 2010; Scardamalia & Bereiter, 2006). Similarly to Perkins et al.'s (1993) dispositions above, agency involves reference to past experience, present evaluation and projecting towards an imagined future (Emirbayer & Mische, 1998). The situatedness is important: agency may be enacted differently depending on circumstances. Perceived

 © ISLS

relevance and challenge appropriate to abilities, for example, will influence how students apply effort to a task and shape their work with knowledge.

Objects can be both instantiated in artefacts as well as conceptual and are the focus of work in knowledge creation. The two types of objects relevant to this paper are *epistemic objects* and *technical objects*. Epistemic or knowledge objects are the produce of knowledge creation: their shape and content are unclear at first but emerge through making sense of, combining and representing ideas in activity (Engeström & Blackler, 2005; Knorr Cetina, 2001). An epistemic object holds contested and negotiated knowledge and can be a thinking tool towards a final product, or the emergent final product itself (Ewenstein & Whyte, 2009; Muukkonen et al., 2010). Technical objects (Ewenstein & Whyte, 2009) are used in collaboration but are generally accepted at face value rather than interrogated or changed. Examples might be the periodic table or a journal article. There may be some interpretation involved, but technical objects are used as referenced resources rather than the focus of work. There is some fluidity between types of objects in particular circumstances (Nicolini et al., 2011). An epistemic object may, once work is completed, be treated as a technical object, accepted in its final form, e.g. an earlier-created diagram may become an illustration within a report. Instructions for a task may temporarily be interrogated in detail, becoming for a while an epistemic object as students make sense of what is being asked of them.

Infrastructure to support collaborative work is an assembly of tools and processes worked out by the group to support their goals, accommodating to, or adapting, available tools (Damşa et al., 2019). The theory of distributed cognition extends knowledge work into the surrounding environment and social interactions (Hollan et al., 2000): in thinking through problems and their solutions, people use tools to inscribe, hold, discuss and remix ideas within physical and online spaces. The framework for distributed cognition for teamwork (DiCoT, Furniss & Blandford, 2006) outlines areas of focus useful for thinking about how knowledge work is done by groups. These include: an *information hub*, a shared place for relevant knowledge, communication and resources; *situation awareness* or visibility of progress, the ability to know how, and how well, a team project has advanced; and a *horizon of observation*, that is, the ability to see the current actions of team members. An information hub relies on team members adding relevant content to a shared repository. A way of thinking about how this information hub is developed comes from a piece by Perkins (1994). In writing about an ongoing dialogue between three academics, he described the way they, over repeated occasions, tossed ideas onto a *heap* of shared concepts that were retrieved and mixed, stirred or re-ordered in later discussions. The heap lies "anywhere that information can reside in the immediate environment – in your and others' working memories, notepads, blackboards, and so on" (Perkins, 1994, p. 90). This term referring to a purposeful if rather ad-hoc and semi-structured way of building and refining a shared set of concepts is an off-beat but evocative metaphor for a basis for knowledge creation.

Method

This study employs a sociomaterial perspective, which involves "a stronger focus on people, routines, and situated activity" (Johri, 2011, p. 209). To investigate the activity of student groups in detail, I took an ethnographic case-based approach, videoing in-person meetings and accessing online spaces used by groups. In transcribing activities, I took note of dialogue, physical gestures and actions in person and online. I observed how objects were used and created.

Cases and data collection

Selection criteria for cases included: an undergraduate task that had some level of complexity and open-ness in its solution, that is, students had a degree of control over what they produced and how they produced it; and collaboration within a small group (3-6 members). Ethics approval was received for the study.

Volunteer groups were recruited from two courses: four groups from education (first-year level) and three groups from engineering (second-year level). The number of group members ranging from three to five, to a total of 27 participants. Recordings added up to 36 hours, covering 29 meetings.

In the education task, students were asked to identify their own driving question on a relevant topic, create a media artefact in response and present that in class. In the engineering task, groups were required to identify one element of a larger given project and formulate a plan for executing their part of that project, creating a project plan and a class presentation. There were several overarching project scenarios to choose from. The education project included instructions to set up a shared online workspace and included a mind-mapping exercise at its start. The engineering students were not given instructions or tips on how to organize their collaborative work. The education task ran for approximately four weeks and was worth 30% of the total grade. The engineering task took most of the semester at 10 weeks and its components added up to 85% of the final grade.

For clarity of association in this paper, I have named groups using Edu/Eng to indicate the relevant course, a letter to distinguish between groups, and added a number for the type of knowledge creation allocated after

analysis. For example, 'EngB1' is an engineering group classified as the first knowledge creation type of 'divided work.'

Analysis

I used discourse analysis of multimodal transcripts of student interactions, analyzing actions, concepts, talk and object use in context, to trace how students made meaning of the task and their subsequent actions.

I produced detailed diagrams that traced and connected conceptual development, group members and object use and creation over the duration of each project. See Figure 1 for an excerpt of such a diagram.

I wrote project narratives based on the dimensions of framing and setup of the project and infrastructure for collaboration and knowledge creation. Putting each case narrative into the same structure enabled comparison across cases, summarized in Table 1. Within that structure, I analyzed specific episodes in detail, describing interactions using objects and the physical environment.

Findings

This paper concentrates on comparison of cases and the resultant patterns of collaboration, and here I present a summary of part of the results from the study. Data informed a detailed description of the framing and evident dispositions of the groups, the material infrastructure used for collaboration and their use of objects in knowledge work.

Framing and definition of the problem

Through diagrams of each project from start to finish, as well as coding the types of interactions and their use of shared objects, it was clear that the pattern for collaboration for each of the groups was established very early in the project. A higher density and complexity in the lines connecting objects, actors and concepts indicated higher levels of knowledge creation. I analyzed the set-up of projects in terms of framing and disposition: how the groups understood the task and what it was asking of them. The groups that recognized from the start a problem to be investigated and discussed it together tended to follow through with shared conceptual development and object-centered work. An exception to this was the EduB2 group, which had intended to pool research results but did not follow through. The EngC3 group showed high levels of conceptual development between two of its members, but the remaining two members working somewhat on the periphery on allocated tasks.

In all of the cases, students periodically placed their work in terms of future careers: what the engineering students understood to be a 'professional' report or software; the education students relating their project work to experiences in school and how they would use curriculum as teachers.

Patterns of knowledge creation

I analyzed each case across dimensions of shared conceptual development, collaborative infrastructure and use of objects (see Table 1). Commonalities between cases allowed me to classify them under three types of knowledge creation: 1) divided work; 2) shared conceptual development; and 3) shared conceptual development plus artefacts created by individuals. All groups had some degree of knowledge creation, that is, shared conceptual development centered on objects, but to varied depth and extent.

Two groups, EduC1 and EngB1, in their first meetings decided to basically divide work and assemble individual sections and continued in that pattern for the project, so formed the first category of divided work. These groups had few examples of shared conceptual development, either online or in person. They did not establish much in the way of an information hub or artefact repository and there was a lack of clarity as to group and individual progress. They did not know what each member had completed, although EduC1's online artefact, which was a timeline that they worked on together, showed eventual progress on the final product. One group member assured the others that they had made good progress but only added limited elements late in the project.

The EduB2 group intended to be collaborative but found it difficult to coordinate work, with a surface approach to their subject. There were no shared resources and the script for their product, a video, was worked out without much exploration of the problem and at the time of recording by the group. To that extent, there was some limited shared conceptual development.

Four groups showed sustained conceptual development around shared and created objects, and so higher levels of knowledge creation. EduA2 and EngA2 worked very much in concert with other group members: in person and online. Their conceptual development mostly occurred through coordinated discussion and simultaneous work on shared artefacts. They best represented the second classification of shared conceptual development.

Table 1
Comparison of cases on dimensions of shared knowledge creation and infrastructure

Case	Initially agreed work pattern	Shared conceptual development		Individuals created synthesizing objects	Shared artefactual repository	Visible progress	Pattern of knowledge creation - [] indicates category
		In person	Online				
EduC1	Divide tasks	limited	limited	somewhat – added separate posts to the timeline	yes, the timeline artefact itself	timeline posts, one obscured their lack of progress	[1] Division of tasks, no extra meetings
EngB1	Divide tasks	very limited	no	somewhat – wrote separate topics	no	no	[1] Division of tasks, no extra meetings
EduA2	Share work, extra meetings	yes – high levels	yes – high levels	no	yes, many notes and posts	yes	[2] Deeply collaborative, connected to future profession
EduB2	All contribute research	very limited	no	no – script created as they recorded	no	progress was slow but visible	[2] Surface approach, produced together
EngA2	Share work, extra meetings	yes	yes	no	yes: shared document for writing	yes	[2] Deeply collaborative, ongoing shared work
EduD3	Share work	yes	yes	yes	yes, posts and interim objects	yes	[3] Group conceptual development, specific production roles
EngC3	One said divide work, one able to persuade to share work.	yes – dyad	no	yes	no, but main dyad shared objects and discussion	mostly yes for main dyad, no for other two students	[3/1] Two students shared epistemic work and allocated tasks to the others.

Individuals' synthesizing objects

The remaining two groups of EduD3 and EngC3 worked together in a similar way to those in the second classification, but also showed an added dimension, leading to the third category of knowledge creation. The added dimension was the creation of substantial objects in artefact form by individuals, based on shared conceptual development.

The EduD3 group decided to make a video and in their first meeting ranged through a variety of ideas in an expansive discussion. Before the next meeting, one student had edited together a sample video and shared that with group members (a in Figure 1). The video elements represented ideas that the group had discussed and were linked by textual interstitials based on spoken and written words from their meeting. The student in an interview afterwards said that it was to progress the work of the group, which seemed to be slow in coming to a decision on what to do. Later in the same project, another student took images, videos and text shared and discussed by group members, and organized them into an illustrated storyboard with accompanying script (b in Figure 1). Again, this served to put concepts into a practical and organized format that allowed the group to finalize the structure of the video.

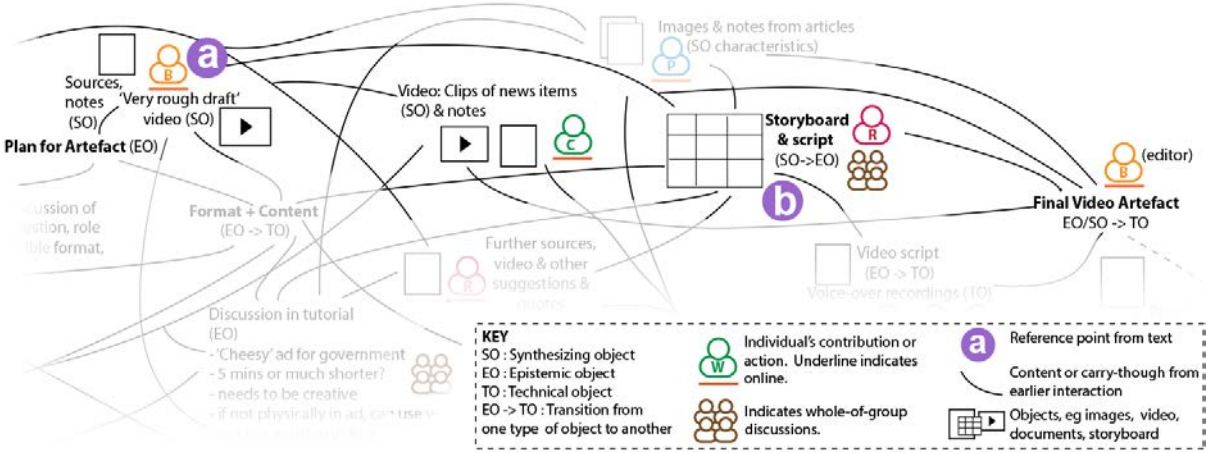
Two members of EngC3, Alex and Cameron, worked closely together on conceptual development for their project, a plan for building houses in a large village. After discussing materials and conditions for the housing with Cameron, Alex brought a paper sketch of a proposed house design to the next meeting. Discussion centered on the sketch, as Alex explained features and Cameron asked questions and suggested modifications. They each drew on the piece of paper as they considered how to lay out houses in clusters with common walls. Alex then brought a digital version of the house sketch to the next session, which the two students refined by searching materials and images online. Alex also started a diagram that planned the locations of houses. The initial layout frustrated Alex, as he likened the grid-like structure to a prison camp. Cameron then repeated an idea from an

earlier meeting related to a circular pattern with a community center, a model of which Alex found in a Google Images search. Alex then worked at home on a new version of the village layout that incorporated both Cameron's ideas as well as new information Alex found about optimal orientation to the sun.

The students who individually created objects in EduD3 and EngC3 did so because they saw a need for them: they were not directed or asked to build them as part of task instructions. The objects were each founded in work that the groups had done – concepts they had discussed and artefacts they had shared – but were shaped by the individual authors, who introduced further perspectives beyond that developed as a group. The objects served to put concepts into a practical form and progress the final product, organizing and expanding upon group ideas.

Figure 1

A segment of EduD3's project diagram, showing the draft video (a) and the storyboard and script (b). Parts are faded to highlight synthesizing objects. Interconnections illustrate the sharing of ideas and artefacts in the building of objects over time.



The (semi-structured) heap of shared knowledge

In the groups with higher levels of shared conceptual development, creating a common repository of knowledge, a type of 'semi-structured heap' of artefacts and concepts laid the foundation for knowledge creation. The heap could be comprised of various items: summaries of articles, images, spoken ideas, example videos, social media posts, budget tables, hand-written notes and diagrams. This provided a common reference and shared concepts and artefacts from which students could subsequently draw and relate to new ideas and resources. The project diagrams used for analysis supported this idea of a knowledge heap, showing, for example, how a concept introduced in an earlier week was reprised and mixed with new ideas in later discussion (see Figure 1 for an example). The building of this set of resources established the materials for the creation of shared epistemic objects, as well as for objects created by individuals. Students in EduC1, EngB1 and EduB2 did not build as much of a base compared to the other groups, had little on which to draw in class discussion and were perceptibly hindered from making progress.

Tools and processes supporting distributed cognition

Usage of tools in an infrastructure for collaboration facilitated a persistent shared set of resources, visibility of progress and a window into team members' activities. One element of infrastructure took the form in EngC3 of the two main collaborators seated next to each other and periodically using screens and paper diagrams to discuss parts of their solution. They had direct sensory inputs into each other's current activity: overlooking each other's computer screen; a frustrated sigh from one would prompt the other to look up and ask about the problem.

The students in EngA2 used a common Google document most of the length of the project, from recording initial ideas and links to resources, through to notes and final composition of the report. Progress in the document was immediately visible to all team members. This had been a new method set up for this project: they reported that they would use the same process for future collaborations.

EduA2 and EduD3 groups were both active on Facebook Group spaces, sharing links, commentary and images. The features of this tool such as a 'thumbs up' and indication that all group members had seen a post also afforded immediate visibility of progress and the activity of members. The EngC3 group used social media more simply as a message board and place to share files. Most of their knowledge work was done in person, which meant that the team members who were not present were necessarily uninformed of progress in the project.

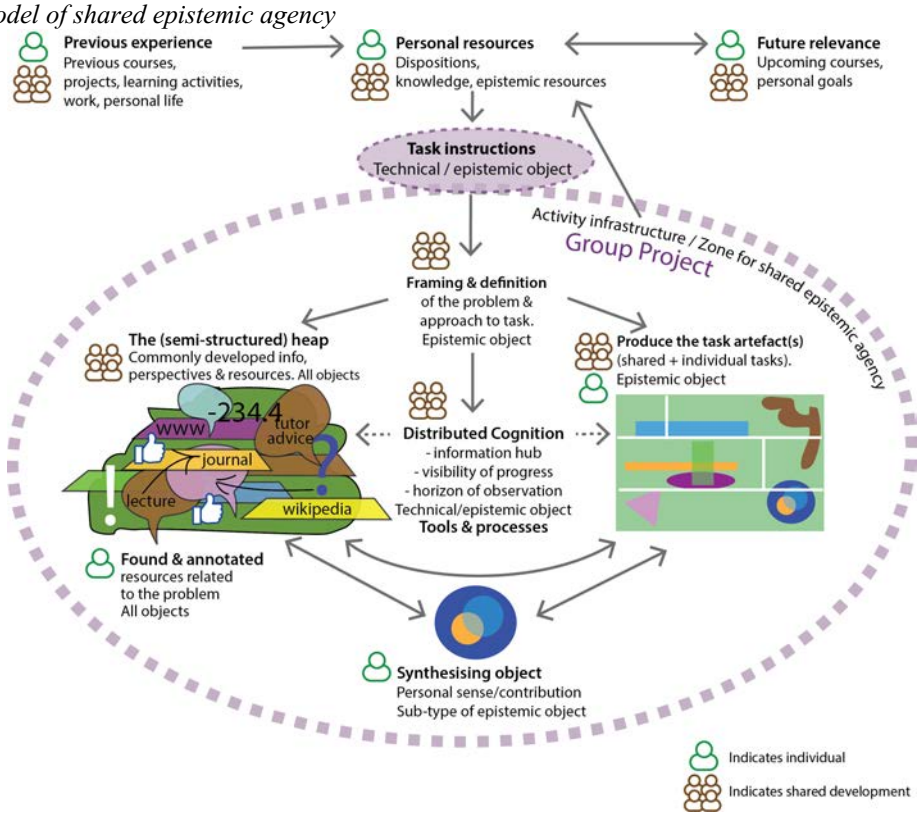
Discussion

The model of shared epistemic agency and activity infrastructure (Figure 2) relationally collates the elements I observed in the cases. The main elements are: 1) framing and definition of the problem, 2) the (semi-structured) heap of shared knowledge, 3) tools and processes supporting distributed cognition, 4) individuals' synthesizing objects and 5) work on the artefact(s) that are the final output of the task. All groups achieved some level of knowledge creation: those that paid attention to and established effective infrastructure across the elements showed higher shared epistemic agency in knowledge creation. A lack in one element tended to indicate less effective knowledge co-creation, with synthesizing objects optional though important contributions.

The epistemic work of groups was bound up in the material ways they worked together, their infrastructure of collaboration, for example, what and how they posted in social media groups, wrote together in a Google doc, shared on paper and on screen in class. Accordingly, knowledge work and infrastructure are intrinsic parts of the same model. In addition, while the final product went from initial ideas to practical construction, projects did not go through distinct phases: there were periods of making sense of the task, researching information and building constituent parts of an output along most of the timeline of each project. The model is therefore not linear, but relational, with each element built upon, and feeding into other elements, over time.

Figure 2

Model of shared epistemic agency



Initial *framing and definition* of the project influenced the type of knowledge creation and the infrastructure for activity that the group assembled. The die is cast at the start. Because the tenor of collaboration was set early in each project, the previous experience of collaborative work and related skills would seem to be a large influence on the framing of the task and level of knowledge creation. The context of experience as well as looking towards future use are informed by Perkins et al.'s (1993) dispositions as well as agency defined by Emirbayer & Misch (1998). In their first conversations, groups made decisive judgements of the type of work required as they read instructions for the task.

Student *dispositions* influenced the way they put the task in context and suggested ways of working. The dynamic of group discussion can change that framing, as in the EngC3 group, where they opted for a more collaborative approach, following one member's stated preference for dividing work. The dispositions of the individuals who created synthesizing objects were key to their actions: they saw the situation in a certain way

(sensitivity), elected to act on it (inclination) and brought their abilities to bear on a solution. The experiences during work on the project potentially feed back to the personal resources of students and in turn influence disposition towards, and constituent abilities for, future tasks.

Tools and processes helped improve the conditions for epistemic agency. An effective infrastructure to support distributed cognition that clearly shared ideas and showed progress on the project helped establish a foundation for group members to recognize where they could add value and progress the project. The way communication and collaboration tools were used tended to align with the initial framing of the project, for example, as either needing in-depth collaborative work or as one that could be divided into separate tasks.

Neither wholly the creation of the author nor a group object, the objects created by individuals in EduD3 and EngC3 were interesting phenomena that indicated a new type of epistemic object. The *synthesizing object* created by one team member allowed for expressing individual perspectives and goals in the context of shared conceptual development. While not required in group collaborative work–EduA2 and EngA2 constructed knowledge together effectively without major examples of such objects–it is a useful concept for understanding how individual contributions can translate or transform ideas, separately from but also contingent on group work.

The shape of a shared *semi-structured heap* of knowledge and resources relied on the group recognizing a need for shared conceptual development as well as establishing tools and processes that supported distributed cognition. Work on the task's final product and interim synthesizing objects helped organize, combine and make sense of the resources assembled by the group.

Production of the task artefact(s) in turn was influenced by the ways that the group framed their project, assembled knowledge and organized communications and collaboration. Synthesizing objects, where used, allowed individuals to contribute to the evolving product.

Supporting this activity infrastructure and zone for shared epistemic agency are the various *designed support activities and supplied resources* that a course teacher may provide for the task, although in the end group dynamics may have the stronger influence on the shape of collaboration. A lack in one part of the model can affect the level of epistemic agency and more effective implementation of an element could possibly assist in improving the conditions for knowledge co-creation. For example, sharing online working documents from the beginning may have helped increase shared conceptual development for the EngB1 group who, even when situated in the same physical space, tended to work on separate documents with limited discussion.

Conclusion

The model for epistemic agency in group projects offers a framework for how students work on their group tasks and the elements that they coordinate in that work. The model and the concept of a synthesizing object were derived from seven project cases within two undergraduate courses. Their applicability beyond that setting is an avenue for further research.

Framing plays a large part in how a task is defined and then the type of knowledge creation used in it. Some students will either be already disposed accordingly or agree through the group dynamic to create knowledge collaboratively. Understanding how teams do this effectively can assist in design for knowledge creation. The experiences that come before a project are potentially very influential on how students frame a new task: further research might consider the role of previous experience and expected future utility in framing of tasks, and how to translate this to design at a program level. The practical aspects of collaboration were set up to serve the task as students framed it, however these might be influenced by designed supports. Setting time and tasks for problem exploration, mandating a shared online workspace and suggesting cloud-based collaborative authoring of documents are some of the ways that the principles of distributed cognition can be made explicit for students.

The model pays attention to object use, which can inform design for learning as well as research: who creates or contributes; what previous activities, objects and discussion are included or expanded in the object; how the role of the object changes over time and how it contributes to the overall project. Iteratively tracing modifications that teams and individuals make to objects helps researchers see how students make sense of knowledge in the moment. Understanding the opportunities for contributions and the shapes those contributions potentially take can assist in designing supports and guidance for students.

Epistemic agency can be expressed both collaboratively and individually. The construction of a shared 'heap' of collective resources forms a basis for effective group knowledge work on epistemic objects and provides opportunities for individuals to modify and expand ideas through synthesizing objects. This foundational work in assembling shared resources helps set the conditions for conceptual development.

Abstract: Artificial intelligence (AI) is everywhere, with many children having increased exposure to AI technologies in daily life. We aimed to understand middle school girls' (a group often excluded group in tech) perceptions and knowledge gaps about AI. We created and explored the feasibility of a lightweight (less than 3 hours) educational workshop in which learners considered challenges in their lives and communities and critically considered how existing and future AI could have an impact. After the workshop, learners had nuanced perceptions of AI, understanding AI can both help and harm. We discuss design implications for creating educational experiences in AI and fairness that embolden learners.

Introduction

Youth have regular direct exposure to and face the consequences of Artificial Intelligence (AI), including through their use of social media and smart home technologies. However, unfairness and bias in AI that affects specific users has been well-documented (e.g., O'Neil, 2016, Buolamwini, et al., 2018), including digital assistants' difficulty comprehending or responding to younger users (e.g., Druga et al., 2017) and users with accents (Lima et al., 2019). AI also introduces concerns about families' privacy around data collection (e.g., Lau et al., 2018). Children's frequent interfacing with AI-based technology, and therefore its potential harms, calls for the creation of more learning opportunities for youth to become AI literate and aware of its risks and challenges. This becomes more essential for underserved groups in tech who are more likely to be harmed by biased algorithms. Girls are often a population excluded from tech design and education (Sultan et al., 2018) yet can be greatly impacted by algorithmic bias (e.g., Buolamwini, et al., 2018). It is important to focus on underserved groups in AI education, so they avoid misinformation, have learning resources, and lend insight into a more just future.

Researchers and curriculum developers have recently begun to create learning opportunities to address children's knowledge gaps in AI literacy. However, many focus primarily on the technical aspects, excluding analysis of the ethical implications of this technology. Additionally, learners in this work have often been predominantly male (e.g., Williams et al., 2019; Kahn et al., 2018), leaving researchers and those who develop educational opportunities with a limited understanding of how girls perceive and learn about AI, potentially compounding existing inequities in AI representation. Some research has looked at teaching K-12 AI with a focus on ethics and fairness, including interpreting the agendas of various stakeholders in AI technology design (Payne, 2019; DiPaola et al., 2020; Register & Ko, 2020) and family-based education around exploring, manipulating, and analyzing AI (Chklovski et al., 2019; Druga et al., 2021). Touretzsky et al. (2019) and Long & Magerko (2020) describe ideas that children should learn about AI, including technical aspects and ethics surrounding impacts on humans and society. Ali et al. (2021) explored teaching middle schoolers about generative AI and corresponding ethical considerations, finding it was necessary to take technical, applied, and ethical approaches. We build on prior work by exploring underserved learners' perceptions, opinions, and knowledge gaps around AI technology to leverage in creating learner-centered education, as well as explore a shorter workshop format.

In this work, we focused on middle school girls, with middle school being a prime time to develop STEM identity (Sadler et al., 2012). To explore middle school girls' perceptions, knowledge gaps, and opinions to inform future creation of AI literacy materials, we created a lightweight workshop with content that assumed no prior knowledge in computing and AI, encouraged critical and creative thinking about AI systems and ethics, and supported learners in thinking about training data. The lightweight (under 3 hours) workshop, compared to other programs that are longer and more intensive, was aimed at inclusivity, reducing common barriers to out-of-school time computing participation like time commitment, commute, etc. We aim to expand upon prior work by integrating both technical and ethical aspects of AI, first taking inspiration from Touretzky et al. (2019) and Long & Magerko (2020), in particular, learning from data and nuanced societal impacts. We took an asset- rather than a deficit-based approach (Garoutte & McCarthy-Gilmore, 2014) which involves centering learners' prior knowledge and interests as a base for further learning and engagement (Coleman & Davis, 2020). This approach is particularly appropriate to successfully support girls of diverse backgrounds in learning computing (Scott et al., 2015). To conduct our research, we used a lens of futuring in our activities, which is a method that encourages

 © ISLS

reflection and analysis around technology and problem-solving by speculating about possible future tools (Dunne & Raby, 2013). Through futuring, we also aimed to gain insight into what is motivating and important to learners, building on their existing knowledge. We strive to address the following research questions: (1) What are middle school girls' conceptions of AI and ethical considerations? (2) How do learners apply their knowledge to ideate and critically analyze AI technologies in short workshops? To create effective and empowering educational opportunities for these learners to gain information about both the technical and ethical aspects of AI, it is essential to understand and center their current funds of knowledge. We report findings about middle school girls' understandings of AI and ethics before, during, and after the lightweight workshop, then offer design implications.

Methods

Data collection and participants

This study took place over five months as a standalone workshop module situated within five individual computing camps (labeled Groups A-E), each held over three to five days. We took a design-based, iterative approach between each camp, slightly adjusting or adding activities to improve the workshop. Each program focused on elementary programming within the context of robotics and emphasized power and identity in techmaking. The programs and workshop sessions did not assume any prior experience with computing or AI. After Group C, we added an additional open-ended final project in a 90-minute session held two days after the initial AI and fairness session. We collected ~14 hours of video and interview data overall with the 5 groups.

Participants: Middle school girls (N = 32, see Table 1) were recruited through a robotics-focused organization, "BoltGirls," in the east coast of the US and a general girls organization, "AmazingGirls," in the southwest of the US. Girls recruited from BoltGirls had more prior experience with computing than girls recruited from AmazingGirls. Each camp included participants from either BoltGirls or AmazingGirls.

Data collection: The AI workshop with educational content and activities lasted about an hour and a half in duration for all groups. In our first group (A) we started with one AI-related session, after which we divided the session into two, but due to the drop-in nature of informal learning experiences, some learners only participated in one of the two sessions. Sessions were conducted synchronously online over Zoom (https://zoom.us) and recorded with chat logs saved. We utilized Jamboards for more efficient group work with peers and a common environment for learners and instructors to observe what others were doing during the virtual sessions, and the content of these boards was collected and analyzed. We also collected data on learners' prior knowledge in all groups via warm-up activities; to facilitate data collection, we decided to distribute these questions as a short pre-survey for groups D and E (N = 17), which asked them to give their best definition of AI, give two examples of AI, and their opinion on whether AI is smarter than them. This pre-survey was added for groups D and E as part of our iterative processes, and 3 of the 17 learners opted to answer a subset of the questions. We also invited learners from groups D and E to participate in follow-up semi-structured interviews, and 10 learners agreed. In interviews, we again asked for their best definition of AI and whether AI is smarter than them, and also what fair and unfair technology is, and where they may have gotten inspiration about AI (e.g., in the media or news). In all questions in the pre-survey and follow-up interviews, we also asked about their reasoning for their answers.

Qualitative coding

We conducted thematic analysis using inductive open coding (Corbin & Strauss, 1990) to uncover themes in video recordings, chat logs, survey and interview data, and learning artifacts (Jamboards and slide decks). Two researchers independently developed a list of themes using affinity diagramming (Beyer & Holtzblatt, 1999), with each source of data contributing to a single set of themes. They then met to discuss, combine, and justify themes, before discussing them with the other authors. The thematic analysis was iterative across camps, as additional data was collected. The researchers discussed the themes regularly with each other and the rest of the research team, until the team agreed on the final set of findings. The findings below describe major themes from our study, which address our research questions. The supporting data for each theme is derived from prompts in the learning activities, unless otherwise specified that the insights are from the pre-survey or follow-up interviews.

Learning content and activities

The learning goals for our workshop sessions included understanding AI and supervised machine learning on a high level and recognizing that AI can have nuanced (i.e., both helpful and harmful) societal impacts. Learners started the session by discussing what they thought the word 'bias' meant in a group discussion. We then played a guessing game, where learners guessed if the technology pictured has AI (e.g., personalized recommendations) and what technology does not (e.g., a hairdryer) and explained their reasoning. To understand AI, learners need a

Table 1
Participant demographics.

Group	*N*	Had prior exp	Organization	Ages	Reported race
A	4	2	BoltGirls	12-14	Asian (1), Black (1), white (1), Asian & white (1)
B	3	1	AmazingGirls	12-14	Hispanic/Latina(1), white (1), Hispanic/Latin & white (1)
C	8	6	BoltGirls	11-13	Asian (5), white (3)
D	4	2	AmazingGirls	11-13	Latina/Hispanic (1), white(2), did not say (1)
E	13	10	BoltGirls	12-14	Asian (7), Black (1), Indian American/First Nation (1), white (2), did not say (2)

working definition of an algorithm, which we gave in a short lesson covering how algorithms consist of three parts: an input, steps to change the input, and an output (adapted from Payne, 2019). After iterating our materials, we created an application activity for groups D and E to practice in an activity where they filled out sticky notes for their favorite food (output), with ingredients (input) and preparation or cooking actions (steps to change input).

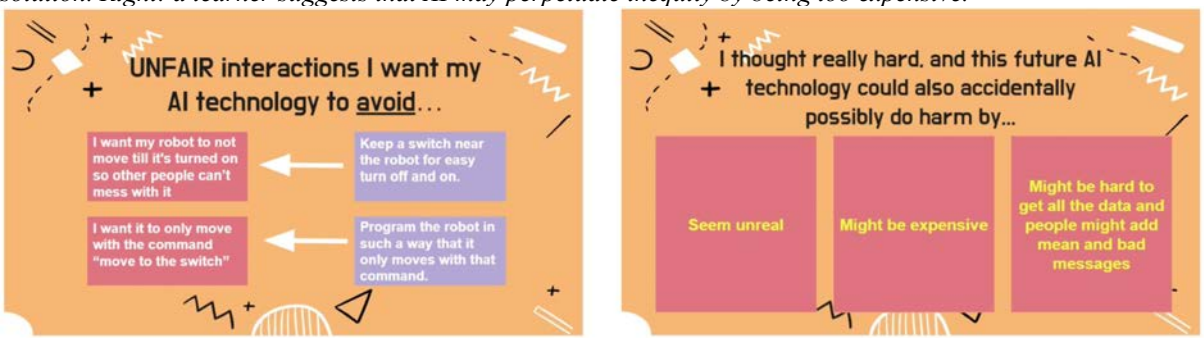
We then shifted over to AI, providing a definition of what AI is and how it relates to algorithms. We centered this lesson on supervised machine learning, emphasizing the concept of training data, since it is a pressing and relevant topic related to power and unfairness (O'Neil, 2016), as well as an important topic to cover in AI education (Touretzsky et al., 2019; Long & Magerko, 2020). Learners then played Google's QuickDraw (quickdraw.withgoogle.com), an interactive, short game leveraged in other AI education programs, e.g., Druga et al., 2021. We opted for this over other tools (e.g., Google's Teachable Machine) to fit within our lightweight workshop. We then discussed why and how the algorithm identifies or misidentifies their drawings, sifting through the data set that other users drew. While most groups concluded that the algorithm may not be able to identify certain drawings because they are not represented in the training data, the instructor made sure to emphasize this point before moving on. The learners then watched a 4-minute video on algorithmic bias stemming from systemic bias in society and data, discussing examples where biased data in AI could do great harm. Learners were then prompted to consider where else harmful effects of algorithmic bias could take place. Learners then took part in two Jamboard group activities and an individual, guided final project, which we go into more detail next.

After the lesson and discussions on AI and bias, we ran several activities designed to encourage learners to critically analyze technologies and apply concepts delivered in the content. We use artifacts generated from these activities as one of our main sources of data, alongside pre-surveys, follow-up interviews, video recordings, and chat logs. In Jamboard activities, the girls contributed to at least one sticky note and discussed the prompt. The facilitator helped with pacing and prompting. If girls did not want to write, they also had the option to type in the Zoom chat or speak, and the facilitator would fill out a sticky note for them.

In Activity 1, *Digital Assistants Help and Harm*, we first asked learners to consider how and who existing digital assistant technology, such as Alexa, Siri, or Google Home, could help and harm. We started by introducing what digital assistants are and brainstorming together what they are capable of. We then provided a Jamboard with prompts. Instructors helped to pace the learners through the Jamboard and offered an example when the learners were stuck, such as accent bias in voice recognition, but aimed not to scaffold too heavily. Jamboard prompts included inquiring what fair and unfair interactions digital assistants could do and who would be affected, as well as which training data to include or exclude for more equitable interactions (see Figure 1). In Activity 2, *Community AI Robot,* learners then considered a challenge in their community that they wanted to solve and were prompted to brainstorm a robot AI that could be a part of the solution. We chose a robot here as part of the prompt due to the context of the computing camps, since robotics were an emphasized theme. Similar to Activity 1, learners then brainstormed who it could benefit or be harmed by their AI robot. They then ideated on which training data they would include or exclude to facilitate fair interactions or avoid unfair interactions.

For groups D and E, we added a final project, which took place two days after the initial workshop session and involved learners brainstorming any futuristic AI technologies to help solve a problem that they are passionate about. On a Jamboard, we started by brainstorming AI technologies and what they can do (e.g., types of personalization, face/screen/object recognition, etc.). Then, learners brainstormed together different challenges in the world, and finally considered how the AI examples they came up with could be applied to support solving some of these challenges. After the group-wide brainstorm, they were given their own slide deck to create a presentation on a futuristic AI technology of their choice. Slide prompts asked learners to define the problem their AI technology could help solve and describe how and who the AI technology could help, what form the AI technology would take (e.g., a robot, website, app, etc.), how the AI could do harm and to whom. They then were further prompted to identify fair and unfair interactions that they wanted their AI technology to have and avoid, as well as what training data they would include or exclude to facilitate or mitigate such interactions (see Figure 1). Learners had opportunities to present their progress throughout the session.

Figure 1
Two screenshots of learners' final projects analyzed in this study. Left: learner suggests a human-in-the-loop solution. Right: a learner suggests that AI may perpetuate inequity by being too expensive.



Findings

(Mis)perceptions of AI: Understanding of AI

We wanted to understand learners' conceptions of AI before engaging in the workshop and consider how they shifted over the course of the experience. We consider a working definition of AI to be along the lines of e.g., 'algorithms that can learn to make meaningful output or decisions.' We observed that almost all 17 learners who took the pre-survey were able to give an example of a technology that uses AI, with 11 giving two. For instance, learners listed digital assistants (i.e., Siri, Google Home, (n = 7), self-driving cars (n = 2), and facial recognition (n = 2) as examples of AI. Some learners (n = 3) were able to give more technical definitions of AI, such as "*something that is developed by humans, to make robots think and solve problems."* or "*when a form of technology is able to do something without another person programming it to do that.*" Many (n = 12) gave definitions that were not technical but showed some awareness of the field such as relevance to programming, brains, or robots. Several learners indicated uncertainty in their responses (e.g., responding with a question mark). Afterward, some learners showed a more complex understanding of AI in the follow-up interviews, with 4 (of 7) learners able to give a technical definition of AI, of which two had already given working definitions initially. While the workshop may not have supported all learners in clearly defining AI, most learners in the follow-up interviews drew on new concepts and showed an increased ability to talk about AI and related topics.

We were further interested in understanding learners' mental models of artificial intelligence. For instance, some misconceptions potentially arise from believing machines have no faults, with past work finding that by age 7-10, children believe that AI is "smarter than they are" (Druga et al., 2018). Our middle school-age learners had varied perceptions to this question, e.g., in the second half of the pre-survey when learners were asked if AI was smarter than them, most (10 of 14) answered that `yes,' they thought so. However, by the time of the follow-up interviews, half (5 of 10) responded 'no' or 'neither' was smarter than the other. For those who believed AI was smarter, their reasoning related to intelligence comprising informational knowledge and facts, a finding consistent with Druga et al., 2017. On the other hand, the learners who considered themselves "smarter" than AI mentioned reasons such as the fact that humans build AI, and recognized that this creates limitations in AI capabilities, e.g., "*if the AI wasn't very trained at something, then a human would probably find a more accurate solution*". Other girls held a more expansive view of intelligence, that AI "*doesn't necessarily have emotions or think the exact way that I would think...*" Although some of their ideas about AI may not be completely unpacked, we found that all learners, even those with low prior knowledge in AI, were able to engage with and hypothesize about AI. Specifically, after the workshop, learners displayed more nuanced views of the concept of intelligence, and compared AI to human intelligence, where AI may be smarter regarding certain types of knowledge (e.g., semantic) and humans smarter in terms of other knowledge and judgments (e.g., emotional intelligence). Our brief AI and algorithmic bias content provided a foundation for them to gain some new mental models and make inferences about AI and be emboldened to share ideas.

Ethical considerations: Understanding of bias and harm

Foundational to AI and ethics is bias that arises from systemic inequity in data, as well as in the algorithms and from developers. We aimed to understand how learners understood bias. Their answers at the beginning of sessions on defining bias suggested that they generally thought that bias meant a preference for something (e.g., "*being in favor of one side or option over the other*"), which could have harmless or sometimes harmful consequences, given the context and outcome (e.g., "*it can be unfair when someone is biased without proper*

reasoning"). This is different from prior work that suggests younger children may not know what the term bias means (Druga et al., 2021). In all groups, multiple learners were able to articulate what bias means, and the instructor further solidified it before tying it into algorithmic bias later in the workshop. Learners engaged with a number of large-scale examples of algorithmic bias in the workshop content, emphasized through discussion prompts and were able to engage in critical discussion. After watching the short video further showing examples of algorithmic bias, learners voiced that racism in AI is salient and concerning. To support critical analysis, we encouraged learners to brainstorm the benefits and harms of AI technology. They quickly identified harms that might be caused by AI, though initial ideas were not always tied into data-driven algorithmic bias.

In another take on bias, and sometimes touching on algorithmic bias, learners also identified that AI could provide misinformation (whether intentionally or not), which the learners specified could cause bias in human consumers. One learner voiced that a fair AI "*gives a neutral opinion; it's not really siding with anything.*" Learners further connected that a preference in the algorithm may affect human preference, and some suggested that AI technology give users a message as a caveat that the suggestions are only just that. Data was also a topic that is intertwined heavily with AI, which we included in our curriculum and activities. Learners were eager to discuss and bring up data, especially as it related to privacy. Multiple learners were concerned about data and how it could be collected and used (similar to Skinner et al. 2020), although they did not always tie it back to AI. For instance, when discussing existing digital assistants and chatbot technology in the Digital Assistants Help and Harm activity, learners described how data could be taken without consent or people could be hacked (an activity which could be done by a human perpetrator without AI). They also noted how large companies could profit from data, although the AI implications were not specified (e.g., using data to personalize ads), and a few learners felt that it was important systems ask permission to collect data. Lastly, we saw that most learners were able to identify stakeholders and motivations (e.g., who would create, benefit, be harmed, by tech etc.) in our Jamboard and final project activities. Some learners mentioned businesses as stakeholders and harmful technology being lucrative, suggesting that they are aware of possible harmful impacts of big companies. Thus, there are multiple avenues to encourage learners to consider stakeholders and relate these ideas to how AI can both help and harm.

Attribution of harm and sources of awareness

To create learning experiences that encourage agency, it is important to understand how the girls perceive who has responsibility for harm caused by AI. Overall, learners had little focus on how human techmakers could be responsible for unfairness in AI beyond stealing data or intentionally providing misinformation, but rather, they often attributed harm and unfairness to the technology itself. This was particularly the case when learners mentioned embodied AI (robots) for intentional (e.g., a robot becomes 'evil,' a word learners used to describe unfair technology, and purposely does something bad) and unanticipated harm (e.g., a robot mistake resulting in injury to a human). We saw that harms learners brought up differed for existing technology versus their own future technology ideas—when the learners were asked to analyze existing digital assistant and chatbot technology in the Digital Assistants Help and Harm activity, the types of harms they identified were primarily intentional and characterized by purposely setting out to cause hurt (e.g., stealing data, spreading misinformation about a competitor, impersonating others, writing mean things online). While speculating about future robot AI they would like to build in their community, on the other hand, the harms identified were primarily unanticipated—specifically, a mistake or incorrect behavior from the AI (e.g., miscategorizing objects) rather than a bias.

Because learners brainstormed AI that was in the form of robots or had other ways of socially interfacing with humans, we observed learners' notions of fair interaction included kindness and kind language, in line with findings from Skinner et al., 2020. 'Kindness' associated with fairness and 'evil' associated with unfairness suggests that the middle school-aged participants in our study have a 'fairytale' mental model that equates fair with good and unfair with evil interactions, which may limit the ways in which learners engage with conceptualizing harmful AI. However, future work is needed to investigate how to best shift mental models to support learners in considering unanticipated (data-driven) ways AI could harm, as well as the prevalence of unanticipated bias in all technologies. Additionally, an indirect harm that learners often brought up was how AI could cause inequity indirectly by being too expensive and inaccessible to groups of people with lower income.

Sources of awareness from where learners get information about AI can inform how to relate learning content to their prior knowledge. We saw that learners' perceptions were in line with concerns presented in the media or by adults. Regular topics that came up across groups were concerns around data and privacy, and the rise of AI-driven automation taking away jobs from people, recent hot topics in the news and in line with parent perspectives (Chklovski et al., 2019). It often came up that learners believed AI could eventually become evil and turn against humans, a common sci-fi plot. All of these media-driven ideas are in line with findings in (Ali et al., 2019). However, in follow-up interviews when we asked about if any media sources influenced their ideas about

AI, only 2 of 9 said that media had an impact (1 interviewee was not asked due to time constraints). This suggests that perhaps learners may not be aware of the impact of media on their perceptions of AI.

Application of knowledge to ideate and evaluate AI: Unique and relevant ideas

Aiming to position learners as technosocial change agents and tech designers using futuring (Dunne & Raby, 2013), we investigated how learners thought of AI applications to come and found that they easily thought of pressing issues in their daily lives that were ripe for change and brainstormed future AI systems that could have a role in the solution. Despite concerns about AI noted above, learners were also very optimistic about how AI could be a part of the future. All learners who were present in all group and individual final project activities were able to consider how AI could help solve challenges. For example, learners saw possible benefits of AI in supporting accessibility needs (e.g., AI that could carry out tasks that may be difficult for a person who is physically disabled). Three specific common types of issues that learners felt passionate about in the group-wide Jamboard activities and final projects related to a) the environment and climate change (e.g., planting trees, reducing litter), b) animal well-being (e.g., rehoming animals in shelters), and c) challenges related to being a child in middle school (e.g., fitting in with peers). Many of the challenges they surfaced were highly specific to their lives (e.g., one learner focused on preventing human-environment conflict by deterring deer from eating plants in her backyard, and another on detecting crime in her neighborhood), suggesting that our asset-based approach successfully centered and worked to build off the life experiences of the learners. Creation of other AI literacy materials for middle school girls may also utilize these topics, since they may resonate with the learners.

Our data also showed that there were fewer mentions of discrimination, racism, and other forms of well-recognized unfairness that surface in algorithmic bias as issues that learners wanted to focus on in their future AI systems, despite the overarching computing program and AI curriculum mentioning some of these biases as examples (e.g., visual detection not working on all skin tones). There was less of a focus on people, identity, and nuanced types of bias overall, since in most projects and activity topics, learners chose to focus on topics related to nature or common concerns about being a middle schooler. Their brainstormed solutions also primarily focused on non-human solutions to the problem, such as a robot addressing environmental degradation by cleaning up local parks (as opposed to confronting or educating humans who litter in the first place). Across groups and activities, only one learner mentioned `sexism' as a broad problem that she was interested in using AI to solve, even though considering identity and power was a core focus of the all-girls program that the AI curriculum was a part of, and at least one salient example of sexism in AI was discussed by the instructors. Prior work has noted the contradiction that modern girls feel about sexism in their daily lives. With girls being more frequently told that they can be and do anything they want, Pomerantz et al. (2013) hypothesize that the current notion of gender equality in the US may cause young women to disregard or disbelieve existing gender injustice and threats to women's rights. Therefore, our learners may have chosen not to engage with these topics, as they may not have seen them as particularly pressing compared to other community problems. The salience of gender injustice may also have been lower due to the all-girls setting.

Tensions between asset-based, open-ended opportunities for applying AI knowledge

In an effort to center learners' interests, values, and prior knowledge, we also aimed to understand the benefits and challenges of how AI literacy could be supported using an open-ended and asset-based approach. After learners came up with ideas of their own for AI tech in group and individual final projects, we asked them to do the same analysis activity that they did with existing digital assistant technology. When learners considered their own ideas, they were particularly excited about the possibilities for AI to solve problems in their communities. Many AI systems learners discussed, ideated, and analyzed were embodied, including robots in the Community AI Robot activity and semi-embodied digital assistants. 9 of 16 learners chose to brainstorm AI technology in the form of a robot for their individual final project, perhaps influenced by Activity 2's focus on robots.

In contrast to recent prior work from Druga et al. (2021), which found that children 7-11 years old prioritize having fun with AI technology over ruminating on technological drawbacks, we saw that learners who participated in our workshop could easily pinpoint harms potentially arising from existing digital assistant technology. Yet, they were less likely to come up with possible harms with their own future tech ideas compared to when analyzing existing digital assistant tech. In both the Community AI Robot activity and final projects, we dedicated prompts and slides to brainstorming potential harms. In the group activities, we asked learners to identify as many benefits and harms as possible. 5 harms on average were identified for existing digital assistant technology, while only two harms on average were identified for future robot AI technology. Three explanations for this may be that it was harder to think of harms with a futuristic technology compared to one that already exists, it is difficult to consider how one's own idea may have negative impacts, or this may relate to the finding that learners were less likely to mention humans in general as the responsible for unfair interactions with AI.

However, three learners in the follow-up interviews reasoned that AI has at least the collective knowledge of its developers. We infer that learners may connect that AI may hold biases that human techmakers have.

While learners chose problems that mattered to them, we also saw that some of the AI systems may not have lent themselves to straightforward application of AI and training data knowledge to critically analyze bias, in comparison to algorithm-focused disembodied systems (e.g., recommendations algorithm). For example, our learners who chose to discuss robots mostly came up with harms that were mistakes and/or tangible (e.g., a self defense instructor robot mistakenly attacking a person). Due to the focus on physical harms and embodied AI, it was sometimes difficult to then apply training data concepts as solutions, as we describe more next.

Discussion

In this work, we approached AI education with a lightweight workshop approach including interactive group activities, in which learners analyzed existing and future AI technologies. Compared to other programs, our workshop content and activities included group discussions and ideation, with less use of interactive tools, as a means to understand opinions, perceptions, and knowledge gaps. We prioritized understanding algorithmic bias and help vs. harm of AI in our content and activities over technical aspects of machine learning and training data. We observed that while the lightweight workshop and activities did not offer an in-depth AI and ethics education, it appeared to `plant a seed,' with some learners we interviewed having walked away with a shift in their conceptions and gained more complex ideas about AI and related topics, as observed in follow-up interviews and final projects after less than 3 hours. This lightweight approach may be more accessible to learners who could otherwise not attend a longer, all-inclusive AI education program. Further, learners were able to understand important, overarching patterns and concepts related to algorithmic bias.

Limitations include the limited generalizability of our results by our small, self-selected sample. This may have had an impact on the types of challenges and solutions that learners focused on throughout the workshop sessions. Finally, as is common in design studies, we noticed that researcher examples (e.g., an example about accent recognition by digital assistants led learners to discuss language barriers) for specific prompts and the prompts themselves (e.g., 'how might this AI do harm') may have shifted learner responses.

Design Implications: Grounded in our data and findings, we recommend three overarching aspects to keep in mind when designing AI education opportunities that center historically excluded learners. First, we suggest ***emphasizing unanticipated bias as in all technologies, and specifically as it relates to data-driven ways AI could harm***. From our study, we saw that many learners paralleled fairness with kindness and unfairness with intentional evil, so learning content may need to directly address this mental model to be more flexible. Second, ***give training data more time and exploration***. If a learning goal is for participants to have a more in-depth, technical understanding of training data concepts, more opportunities to experiment and build a stronger mental model is needed, i.e., our lightweight approach is not as effective for particularly complex or technical learning goals in AI literacy. This is inline with prior work that presents the benefits of interactive tools (Hiltron et al., 2019). However, a comprehensive understanding of training data may not be needed for learners to understand high level patterns and concepts, since we found that learners demonstrated understanding and engaged in discussions in our lightweight approach. Third, ***opportunities to apply training data and AI bias in open-ended activities***. Since some of the topics that learners choose in an open-ended prompt may not lend themselves as easy AI and bias learning examples, we encourage instructional designers to create opportunities for more straightforward application. This may include a more specific, scaffolded prompt for learners to think of community challenges they would like to solve with AI, or breaking down their future AI ideas into considering different sensors as suggested by Touretzky et al. (2019) and considering bias from data for the sensors. Future work may also incorporate different types of bias in AI, e.g., from developers and algorithm design. We believe that these findings will help support the creation of inclusive, accessible, learner-centered opportunities for middle school girls to increase their AI literacy, engage in conversations around AI, and become empowered techmakers.

Learning From and About Failure in a Hybrid Collaborative Game Environment

Shulong Yan, Charles Keith, Yu Xia, Marcel Borge

Abstract: Traditional classroom culture and social norms might stigmatize failure and hurt learners' self-esteem. Consequently, learners might miss learning opportunities by avoiding failure to cope with the negativity. Scholars argue the importance of creating learning environments that allow learners to reframe failure as learning opportunities through iteration. This paper re-examines an instructional failure session in a hybrid collaborative game environment to understand how failure and learning processes emerged. We adopt a micro-ecological approach to analyze video format data collected in an afterschool design club. The analysis shows that failure and learning might begin as individual actions but can ripple across the small group and the community to create learning opportunities, especially when the environment supports playfulness and improvisation. Findings suggest that allowing the learning design and enactment to interact can support expansive learning.

Background

Failure can provide an opportunity to help learners realize that their current information, knowledge, and skill are not enough to solve the problem in the learning process (Vanlehn et al., 2003). This realization can motivate learners to deepen knowledge, understanding, and practice and benefit more from instructional explanations. Scholars in education argue that failure signals a time to provide support to approximate learning gains (Darabi et al., 2018). Though productive failure as an instructional approach was first introduced in the STEM context, scholars now argue that this approach can also support creativity and collaborative problem solving (Manalo & Kapur, 2018). This approach has been extended to art education (Sawyer, 2018) and fosters creative collaboration (Hod et al., 2018). However, failure alone does not lead to learning if learners avoid it and the learning process is not supported (Jackson et al., 2021). One of the supports identified in the literature frequently was to adopt a failure positive mindset (Canon & Edmondson, 2005; Ryoo et al., 2015).

Video game and design contexts are gaining more attention as scholars argue that both can foster learners to frame failure as a process that houses learning opportunities. Failure in gaming marks critical learning opportunities for players. While failures occur within a game, players are given more opportunities to develop a core understanding of gameplay elements. With educational games, these opportunities are greater exemplified in increased collaborative discourse moments between players that provide a deeper understanding of gameplay elements and learning goals (Anderson et al., 2018). Unlike many students' opportunities in class, video games can provide students with a playful and "optimistic motivational style" of learning (Granic et al., 2014). Games, such as Minecraft, allow students to explore creative design and choice-making with immediate visualization that promotes authentic dialogue between members (von Heland et al., 2015). Cultivating a failure positive mindset is also repeatedly discussed in the making, creating, and innovating activities (Martin, 2015). A failure positive mindset is considered a belief that designers embody through practice and is encultured in their environment and activities (Brown, 2008). In these activities, designers are allowed to learn from failure through tinkering and iteration (Ryoo et al., 2015).

Though game and design contexts can potentially support learners to frame failure with a positive attitude, the learning process to make that shift in mindset is a complex phenomenon involving interaction between participants in multiple levels, learning objects, and teachers. Persistence to overcome and learn from failure is influenced not by individual characteristics such as grit or a growth mindset (Ryoo & Kekelis, 2018) but by the sense of playfulness, collaboration, and ownership of projects (Yan & Borge, 2019; Ryoo & Kekelis, 2018). As conversing with materials and teams members are the core of the collaborative design process, learning from failure also ascribes to this socio-material nature which calls for an ecological approach to account for its complexity (Borge & Mercier, 2019; Hakkarainen et al., 2013; Mehto, 2020). This framing calls for abandoning the fixation on the arbitrary distinction to identity "success" or "failure" and focusing on understanding the conditions that construct learners' learning (Varenne & McDermott, 1998). The teacher who orchestrates the learning environment should also be able to see beyond failure as disruptive and appreciate the learning opportunities it can provide.

Theoretical Framework

 © ISLS

Learning from failure in a collaborative learning environment requires us to take a micro-ecological learning perspective where learning is transformational (Borge & Mercier, 2019). Students are creating novel digital objects, and the approach to that creation is constantly changing. As stated by Sannino et al. (2016, p. 600), "The collective design effort is itself the core of an expansive learning process." This is even more so in a technology-rich collaborative design environment. In this type of learning system, individuals, groups, and the whole community are interrelated where students' sense-making and meaning-making are constantly influencing each other. Looking from an expansive learning lens, we see failure events as potential learning opportunities rather than disruptive events that hinder learning.

We apply the playfulness perspective to understand the emerging learning opportunities and the interaction between video games and players. We follow the post-structuralist perspective and highlight the emerging nature of learning from failure in such an open virtual world of Minecraft as in this study. Looking through the lens of playfulness, we are in a better position to reframe learning from failure by fully conceptualizing the change in sense-making around failure events (Ryoo & Kekelis, 2018).

At the same time, as learning is unpredicted in such an environment, it gives rise to the need for both teachings and learning to be improvisational (Sawyer, 2000, 2004), where facilitators and student groups spontaneously respond to the happenings in a specific situation. Failure events could trigger negative feelings in both facilitators and students for facilitators who have designed the curriculum and instruction. These events hinder the achievement of learning objectives. For students, these events often destroy or hamper their design processes. Being improvisational in such emotionally challenging situations often requires shifts in interpreting these events from negative to providing learning opportunities such as socio-emotional regulation, problem-solving, design practices, etc. Playfulness, in turn, plays a critical role in promoting such a shift in sense-making around failure events (Mortensen & Younas, in press). With a playful mindset, facilitators and student groups could feel the lightness of those high-stakes events. They could venture more into risk-taking and take the failures as learning opportunities to problem-solve jointly (Lemke, 2013).

Synthesizing studies on game and design research around failure, we re-examine a curriculum failure event identified by the first author, who also served as the lead facilitator in the learning space. We aim to understand how failure and learning from failure emerged at the intersection of a collaborative game and design environment. Situating this work in the design context, we ask the following question to guide the study: How do failure and learning from failure events emerge in a collaborative hybrid game environment?

Research context and population

The study took place in an afterschool design club where the curriculum targeted fostering productive failure in a collaborative design context with elementary students. Design groups were asked to complete a butterfly garden challenge using different tools such as paper and pencil, LEGO Blocks, and Minecraft to iterate in the club. This study included 16 students from 4th to 6th grades, 5 female and 11 male students. Four returning students had been in the club for over two semesters. They were grouped as an expert group. We then grouped the remaining 12 students based on their ages, gender, and expertise.

The data reported in this study came from the penultimate in the club, which the first author planned as the last building session using Minecraft. The Minecraft creative game mode was chosen as a design tool. Four design teams shared the physical classroom space and the virtual space at the time of design. Since the world was shared among them virtually, each team decided to choose a faraway space from other teams to avoid trespassing. Several other features, such as teleport and build mode, were enabled to manage the server and make the building process more efficient (Table 1).

Table 1

Minecraft Features, Function, and Rationale

Minecraft Feature	Function	Rationale
Creative mode	Players have unlimited resources in creative mode compared to survival mode in which resources can only be gained through mining.	Its open world allows players to imagine and create. Also, given the limited time in the club, we use creative mode to focus on design rather than open-ended exploration.
Shared server	The whole class can join the shared server virtually to build their garden together.	To save the design and manage the Minecraft space as a whole club, we used a paid server where we gathered all designers in one virtual server.

Teleport	It is a teacher account function that brings players from one place to another.	We asked players to volunteer to use the teacher's account to give the students control. It was rotated among volunteers.
Build Mode	It is a creative mode function that allows players to create a large structure within seconds rather than a block-by-block approach.	Expert team members who used build mode in the previous semester asked the facilitator to turn it on to build more efficiently.

Data collection and analysis

Video cameras were used to capture activities in all four groups, totaling approximately 72 hours of video recordings. Guided by Interaction Analysis (Jordan & Henderson, 1995), we first created content logs for all the recordings to describe group verbal and nonverbal interactions. This step was critical to systematically selecting data from the large corpus of video data. Triangulating the content log with the first author's field notes, we selected the last Minecraft building session for in-depth analysis. We identified the episodes of failure, defined as the errors/mistakes committed by players in the Minecraft game that negatively affected design processes. We tracked the development of these events over time. The initial analysis showed that when failure events occurred in the shared virtual space, they created community-level interruptions that involved multiple students from different groups. These interruptions affected their groups' design process. As such, rather than analyzing each group as a unit, we conducted a multilevel analysis, i.e., individual, group, and community, to present the cascading effects of failure events and how, in this community, individual students shifted their perspectives on those events (Borge & Mercier, 2019). To organize the multilevel analysis, we followed Ash's (2007) three-level approach – *flow chart*, *significant events*, and *microgenetic*. Using the concept of *transecologcal event* from the micro-ecological approach (Borge & Mercier, 2019), we identified and analyzed two events where problems at one level of interaction (individual, group or community) became central across interactional levels. These two events showed how failure and learning in the collaborative game environment emerge and develop as part of an ecological system.

Findings

To understand how failure and learning emerge in a context that integrates the configuration of video games and design processes, we trace the structure of an instructional failure lesson identified by the authors using an expansive learning and playfulness perspective. This section describes the overview of both the instructional activities and the collective events that fall under it. Then we select two significant transecological events that emerged from those grand level activities to understand how they begin, end, and transit subsequently.

Event overview

After reflecting on a failure instance from team 2, each designer received a laptop and started working on their butterfly garden design project. At the same time, the lead facilitator announced that each team was expected to complete their iteration by the end of the class. Given the open space and absence of strategies to mark their build sites, almost all teams could not find the original building sites. Team 1 member Eric asked his teammate Marcos who logged in to the teacher account (Table 1) to teleport Eric to their team-building space. This instance triggered the first significant transecological event due to Marcos' mistake – other teams were teleported to team 1's site by accident. This error upset several individual students and teams, especially team 2, since they spent the next 25 minutes searching for their site after the accident. This fruitless search then led to the second significant transecological event – Ekon crashed the server by accident. Though some students' accounts were not affected by the crash, most were logged out of the system. Consequently, three members (four in total) from Team 1 spent the rest of the club time figuring out how to log back into the server. The crash also gave rise to two learning events – how to undo the last fill and break the server. Realizing that the lesson plan failed given all the technical issues, the lead facilitator reflected on the whole club's experiences in the last ten minutes before dismissal. The following section describes the two significant events' beginning, during, and ending.

Blaming and being defensive

Beginning – the good intention

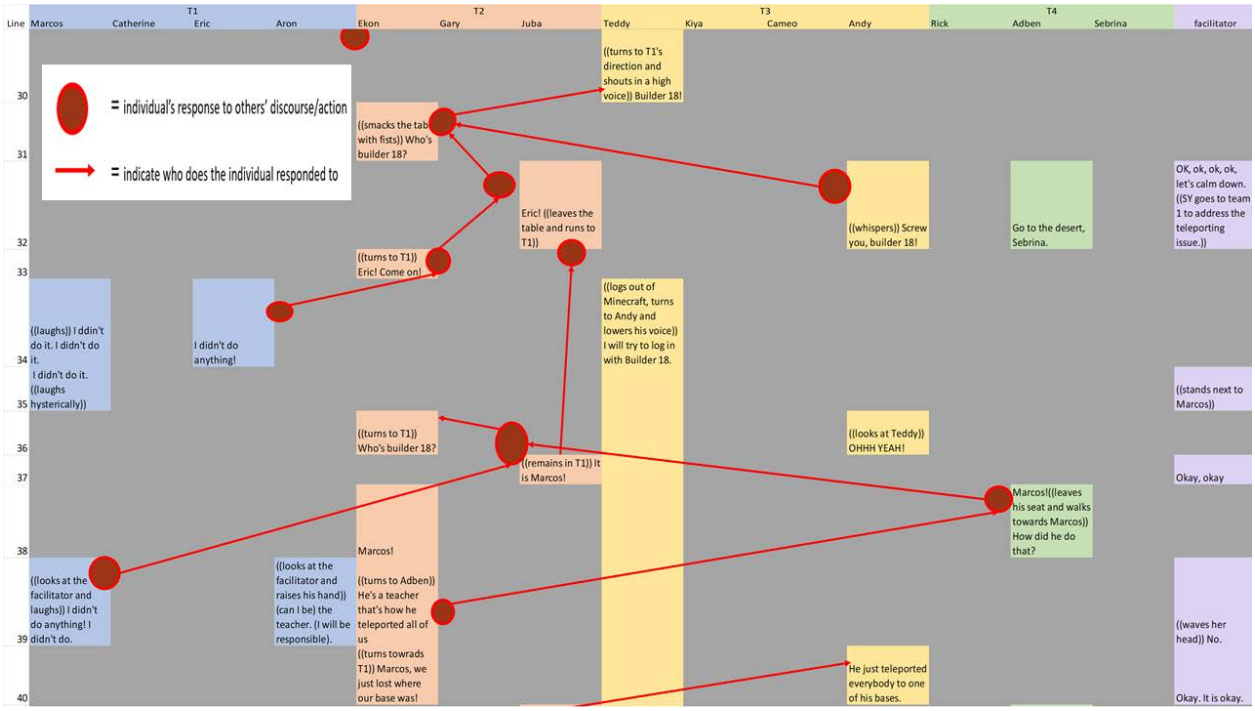
Historically, the teleport feature, unique to the teacher's account, was used to help lost players find their teammates in the vast Minecraft game space. To give the control back to the students, facilitators from the club decided to grant one student per session to use the teacher's account to manage the shared space. Marcos from team 1 volunteered to use the teacher account to help manage the Minecraft virtual space. When Eric from team 1 got lost, he asked Marcos to teleport him back to their team's building site.

Collective sense-making – who and how?

Within the body of this event, three collective sense-making dialogues occurred. The topic of the first dialogue was around figuring out who teleported the rest teams. While Eric (Team 1) and Marcos (Team 1) were figuring out the teleporting details, Juba (Team 2) shouted, "who just teleported me?" to the whole club. Marcos then realized that he and Eric might be responsible. He immediately turned to Eric, said "You! Eric!" suggesting that Eric was responsible for the teleporting. Eric laughed and said, "I didn't know" as a response. The event escalated as more students in the club shouted, "who just teleported me." Overhearing Marcos' accusation of Eric, Juba (Team 2) shouted to the whole club that Eric was responsible for the instance. Both Ekon (Team 2) and Adben (Team 4) expressed their frustration toward Eric without further investigation. Eric also became the center of blame. This triggered Eric to respond more strongly to the crowd compared to the first time. He shouted back to the crowd, "I didn't do anything."

Figure 1

A Screenshot of the Center of Blame



Just as the crowd started quieting down, Teddy (Team 3) shouted with a high-pitched voice, "Builder 18!" to show his frustration. This shout initiated the second collective sense-making dialogue. Students logged in to the server using the generic sequential naming system, from Builder 1 to Builder 18. Thus the only information about the player who teleported them was that it was "Builder 18". Ekon asked, "who's Builder 18". Juba first accused Eric (line 32) but soon discovered that Marcos was Builder 18 and announced it to the class (line 37). After this moment, the whole club shifted the center of blame from Eric to Marcos (lines 38 and 39). Marcos argued that he did not do anything. He explained that the intention was to teleport Eric to him. However, the rest of the players did not seem to accept his explanation. When the facilitator called it an accident, Andy (Team 3) stated it was a mistake. The third dialogue centered on how Marcos teleported everyone. This dialogue occurred between Adben and Ekon (line38 and line 40). Adben learned that teleport was a teacher account feature that he later used to bring his teammates back to their sites.

Ending and continuity

Gradually, the level of volume and inter-group dialogues reduced, and more intra-group dialogues occurred. This change indicated the ending of this significant transecological event. Consequently, the other three teams lost their building base. Teddy from team 3 and Adben from team 4 found their team's building sites not long after the search. Though teams were teleported to different land because of the teleport feature, both players asked the facilitator to use the teleport feature to bring their teammates to their building sites. As the whole club reflected in a later session, Teddy initiated, and Marcos maintained the argument around whether students should be allowed to use teacher accounts. Catherine from team 1 mentioned that the off-task behaviors that triggered the second significant event were a byproduct of the misuse of teleporting feature.

The ripple effect of a playful mindset and learning toward failure

Beginning – uncoordinated convergent play

Build mode in Minecraft allows players to construct a big structure, such as a wall for a house, in seconds. Historically, several club "experts", those in the club for multiple years, experienced the server breakdown at least once due to the large construction. Though, in the previous lesson, the "expert" team asked the facilitator to turn this feature on to build more efficiently. Some newcomers were still learning how to use this feature. This second significant event was triggered by a convergent action that three individuals from three teams carried out without coordination in advance.

At the beginning of the event, Team 2 members could not find their building site. Though Gary (Team 2) constantly regulated his teammate to focus on the searching task, Ekon (Team 2) decided to pause the task and play with the build mode. Later, Ekon claimed, "I'm about to break the world." While Ekon was attempting to break the world, Adben from team 4 (Ekon's older brother) also played with creating a giant pit of lava. Parallel to Ekon and Adben, Andy in team 3 announced that "Look what I did! By the way, I made a huge cavern". His self-revealing triggered a conversation between him and Teddy. Teddy encouraged him to make a bigger cavern using the build mode's filling feature. Teddy, though added, "It probably will crash the server."

Claiming responsibility after the server crashed

Aron (Team 1) was the first one affected by the uncoordinated convergent play. Eric (Team 1) asked why Aron (Team 3) left the game. Aron shared that the game crashed. As Adben (Team 4) shouted, "Oh my god! I think I almost crash the server", Aron told Adben that he had succeeded. Right after that, Ekon (Team 2) told Gary (Team 2) to "watch the sea it should fill up with gold any second now." As soon as Ekon (Team 1) finished his sentence, multiple players' screens showed they were logged out of the system. Shortly, Juba (Team 1) stood up and announced to the whole class with excitement, "Ekon! Ekon crashed the server!". Teddy (Team 3) and Adben (Team 4) all responded to Juba (Team 2) and claimed that "I crashed the game!". As server crashes became a fact, Teddy and Adben changed their narrative from "almost crashed" to "I crashed."

Ekon (Team 2), who realized that he did crash the server, started laughing (Figure 1 – blue circle). Gradually, several students from other teams rushed to Ekon's space (Figure 2). Along with Ekon, many players started laughing while looking at Ekon's screen, except Aron (Team 2). Aron (Figure 2 – red circle), instead, felt frustrated and called Ekon out, "Ekon! It is NOT FUNNY!" (line 24). Aron tried to take over Ekon's laptop (line 28) but was rejected by Ekon. They started wrestling with each other (Figure 2 – orange circle). Aron explained that he was trying to undo the last fill to solve the crashing server issue (line 28). Ekon finally let go of his laptop (line 29) and allowed Aron to operate it. Gradually, the crowds dispersed from Team 2's space.

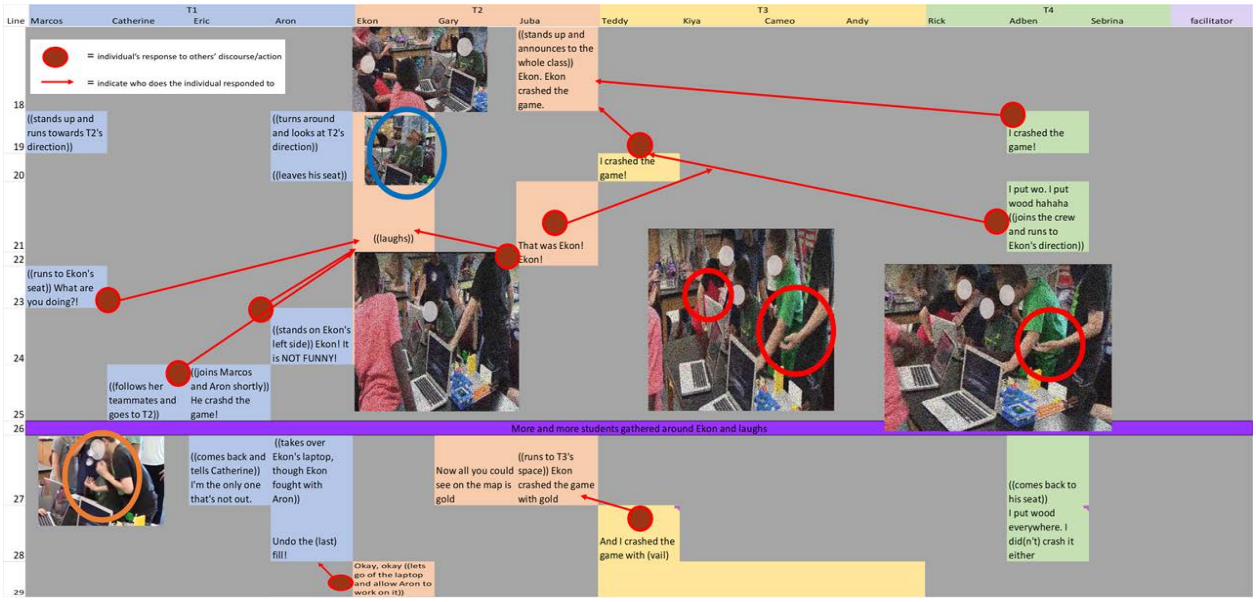
Though most players could log back to the games, team 1 members had no such luck. They were logged out of the system entirely, except for Eric. Without succeeding, Marcos (Team 1) walks to Ekon (Team 2) to ensure that Ekon did not crash the server again. Ekon defended that he did not touch anything. At the end, Ekon made a joke to the whole class, "OK, EVERYBODY I'M GONNA CRASH THE SERVER AGAIN ((laughing)) naa I am just kidding."

Playing with fire – attempt to re-crash the server

As each team resumed the building task, the inter-group interaction decreased. As team 1 tried to figure out how to log in, team 2 resumed searching their building sites. Team 3, with all members successfully logged in and no issue finding their building sites, continued working on their design. Adben (Team 4), though, started experimenting with

Figure 2

A Screenshot of Ekon (Team 2) Became the Center of Fun



the build mode to re-crash the server. He started with spamming woods in the world, which was noticed by Eric (Team 1) and Rick (Team 4) jointly. After Adben returned to his seat from Eric's (Team 1) space, he continued playing with the build mode. Suddenly, he shouted, "Yes! Build mode does help!". Rick (Team 4), who sat next to him, reminded Adben that "not if you do not use it properly." With a smirk on his face, Adben turned to Rick and whispered, "which I am about to." With Rick being the cheerleader who constantly laughed and verbally encouraged Adben, Adben enacted his plan. Once Adben finished his building, he called his brother Ekon's (Team 2). Ekon then joined team 4's space. After looking at Adben's screen, Ekon shared that Gary was the one who was responsible for the misuse of build mode, then went back to team 2. Adben and Rick both called out to Gary, which triggered Gary to join team 4's space. Feeling innocent and confused, Gary constantly claimed that "I did not do it!" and "I do not know how to do it." Adben, though, jovially called Gary out; his gaze fixated on the screen, and he stated, "really?".

The next moment, Adben repeated his play with build mode and invited Gary to witness his play. Similar reaction to Rick, Gary also cheered for Adben's testing, "Yeah, do it! Do it!". Adben's filling action was finally noticed by Juba (Team 2). He shouted, "who did this? Who spam the woods with build mode?". Adben claimed he was responsible, but he laughed, apologized, and stated, "I forgot I have build mode on." This claim attracted Ekon's (Team 2) attention. As someone responsible for the first server crashing instance, Ekon told Adben that he would consequently break the server. Juba (Team 2) echoed Adben's claim. Sebrina turned around and asked Adben to undo the last fill supported by Ekon and enacted by Adben.

Ending and continuity

The event ended when Cameo (Team 3) crashed the server again by watering the world. With the server crashing the second time, the facilitator seized the chance, ended the play, and transited to the last event – the whole class reflection. Interestingly, team 1 still suffered from the first-time server crash and could not log back for the rest of the session. However, they persisted in solving the problem jointly until they decided to create a new server for the team. Observing Adben's play with build mode, Gary learned how to fill and undo the fill. Called out by Ekon, Gary shared proudly that "I just learned how to do it, so it's fun". Then Gary used undo fill feature to erase all the gold he created.

When students reflected at the end of the session, this instance became their valuable prior experience to learn from. The whole class first debated on whether the build mode should be disabled. Students who advocated disabling it argued that the mode disturbed the design process, while those pros this feature stated that it helped speed up the building process. The class agreed that instead of disabling the feature, they should find solutions to make sure the build mode was used "correctly". Through building and negotiating on each other's ideas with the lead author's facilitation, the whole class came up with a solution that embraced the concept of learning community and mentorship, which allowed the experienced Minecraft players to teach newcomers, like Adben, to use the feature:

> "If you give the newbie some time to learn from the pros, the newbs will soon become medium newbies and then, and then they'll become pros, so then the newbies become pros and then they can

use build mode like pros instead of using it like newbs, filling the world with gold, turning the ocean into gold, filling the world with water."

Discussion

To understand how failure and learning from failure emerged in a hybrid collaborative game environment, we synthesized three analysis approaches (Ash, 2007; Author, 2019; Jordan & Henderson, 1995;) to analyze two significant transecological events. The analysis shows that the hybrid collaborative game environment supports transecological interaction, allowing players to learn game features from failure and take failure playfully. The findings also show how failure events, when supported by guided reflection, can support shared regulation processes.

The findings show a ripple effect of learning when the configuration of the learning environment allows transecological interaction. The interaction between physical club space and virtual Minecraft space allows failure to be experienced collectively, helps construct a shared understanding within the whole club and supports dialogues that aim to create collective solutions. One student or group's changed view on a failed event could ripple through other groups and change the community's perspective. In our hybrid collaborative game environment, learners expansively transformed their sense-making around failure. Students from other teams affected by the individual action learned valuable game skills in both significant events. In the teleport event, Teddy (Team 3) and Adben (Team 4) learned that they could use this feature to bring teammates back to their building sites which was the cause of the chaos in the first place. In the transition to the second event, we observed the shift from denying to claiming responsibilities and frustration to laughing. The playfulness behaviors such as laughing at breaking the server together emerged from the classroom in the second transecological event and fostered a learning and playful community. Instead of avoiding failure, players laughed and broke together to learn. The playful environment triggered the competitive sense to claim ownership of the failures. The second event started with multiple players trying to build giant structures and ended with students learning how to use build mode to create giant structures quickly and reduce the damage by using the "undo the last fill" feature. It also led to the student-led creation of shared community practices, rules, and values.

Taking a micro-ecological approach to re-examine an instructional failure, we see how the technical issues that disrupted the lesson plans could be transformed into joint learning activities for the community if the environment allowed playfulness and improvision to emerge and have the existing configuration to support learning. This finding implies the interactive relationship between design and enaction of the learning environment. The lesson plan set a structure that guided the general flow of the events. Though, its grand level structure allowed moment-by-moment improvisation and playfulness. It allowed students and the facilitator to collaborate creatively to advance a disadvantaged situation with playful attitudes (Sawyer, 2017). At the same time, the intentionally designed and cultivated guided reflection practice was there to support the whole club to learn from the failure. Failure in the Minecraft world can still be high-stakes and with real consequences, which was evident by some students' reactions toward teleporting and server crashes, but the feelings and meaning-making around those failure events promote playfulness (Juul, 2009; Lemke, 2013), and psychological safety (Edmondson & Lei, 2014), which offer opportunities for facilitators to help students learn. For facilitators in this environment, we argue that we need to incorporate a playful mindset to be more open to the emergence of problems and react accordingly. We argue that we should allow our teachers to treat every instance of failure as an opportunity to learn, let it play out, and then improvise on the emerging moment to support creative, collaborative learning (Sawyer, 2004).

Testing Simple Instructional Models to Promote the Spontaneous Transfer of Inquiry Strategies in New Contexts

Ana Saavedra and Daniel L. Schwartz
anamar@stanford.edu and daniel.schwartz@stanford.edu
Stanford University

Abstract: Science simulations enable students to conduct rapid experimentation. Many students conduct sub-optimal experiments, even after instruction in effective inquiry. Consequently, they may not discover the underlying scientific regularities. A study with 8th-grade students compared the effectiveness of three instructional models and a control condition. Students completed a pre-test inquiry task and a transfer task using simulations, and we analyzed changes in their inquiry patterns. The results indicate that the most effective instructional model showed students an effective inquiry strategy, acknowledged the effort of using that strategy, and explained that they should resist the pull of the more common ineffective strategy. There was also a strong main effect of SES in student inquiry strategies use. Results provide initial evidence that adding a cue to resist the lure of a poor strategy improves transfer over simply explaining the right strategy.

Introduction

The COVID-19 pandemic highlighted the need to prepare children to be independent learners. Ideally, students would be equipped with the strategies to self-direct their learning given a task. While this goal is not new (Meichenbaum & Biemiller, 1998; Schunk & Zimmerman, 2007), the pandemic amplified the learning challenges for students who were otherwise accustomed to strong teacher and parental learning guidance (United Nations [UN], 2020; United Nations Educational, Scientific, and Cultural Organization [UNESCO] et al., 2020). Despite many heroic efforts, the reality is that many students needed to learn on their own. This situation created high demands on students and their families as well as learning loss for students who did not possess the strategies to self-direct their learning (Engzell et al., 2021; Patrick et al., 2020).

Inquiry is one-form of self-directed learning. Modern standards ask students to collect, analyze and interpret data, as well as form hypotheses (National Research Council [NRC], 2013). Learner success often depends on having a set of strategies to help handle the potential complexity of a system or a task (Stender et al., 2018). Of particular interest here are inquiry strategies to help gather evidence that can reveal the underlying systematicity of a scientific phenomenon exhibited in a scientific simulation. During the pandemic there was an explosion in the use science simulations as a tool to learn science in the classroom, e.g., *PhET Interactive Simulations* use has increased in some countries by 500% (Wieman et al., 2008).

One potential inquiry strategy for making headway in many physics simulations is to find a base unit that can equate different types of quantities. Figure 1 provides two simple instances, which we also used in the current investigation. In *Balancelet*, students need to find the relative weights of the colored objects. In *Tuglet*, students need to find the relative pulling-force of the players. The four examples in Figure 1 include setups used by students while exploring these simulations. The two examples in the first row display the correct use of the base-unit strategy. In both simulations, *Balancelet* (balance scale) and *Tuglet* (pulling cart), students are using one element on one side and are adding two or more of another element to find the ratio among them. The examples in the second row display a typical but ineffective strategy. In this case, students keep adding elements in an unorganized way to find the "balance" point.

If a goal is to make independent learners, then instruction should prepare them to use the strategies on their own, often in a context that differs from the original context of instruction. For instance, if students learn the base-unit strategy for *Balancelet*, they will ideally use this strategy for *Tuglet*. How can we teach inquiry strategies that equip students to transfer those strategies (Bransford & Schwartz, 1999; Day & Goldstone, 2012)? For promoting inquiry in science, one instructional approach is modeling, which we will call the *Show Right* model – *SR*). When modeling, teachers show the correct use of a strategy. For example, when running a lab experiment, a teacher can model a base-unit strategy for using the balance scale: *If I want to find the equivalence between oranges and limes, I need to keep one orange on one side and keep adding limes until the scale balances*. When teachers show students how to conduct a practice, they may later use the practice while doing the activity (Boekaerts & Corno, 2005; Chen & Klahr, 1999; Klahr & Nigam, 2004).

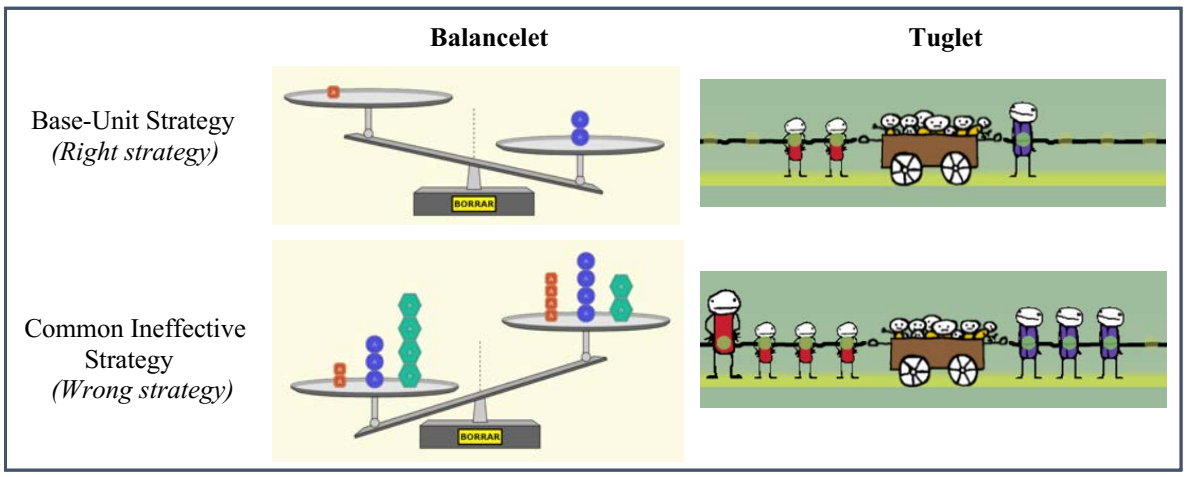
Figure 1
Instances of Two Types of Setups Use by Students in the Simulations



Another instructional approach is to combine showing the correct strategy and adding an explanation, which we will label – *SR+Exp*. For instance, an example might be: "*Keeping constant one side of the scale allows me to find the weight equivalence between fruits. Finding the ratio helps me to better predict what the scale will do when I put many lemons and oranges on it.*" Both *SR* and *SR+Exp* are good approaches. Our study examines whether we can increase spontaneous transfer by also alerting students to their natural but competing and often ineffective strategies. We hypothesize that strategy instruction can enhance transfer if it shows and explains the right strategy, and goes further to show students a common ineffective strategy and alert them to recognize when they start using the common ineffective strategy. This way, students' natural tendency to use the ineffective strategy becomes an internally generated cue to use the target strategy instead. We will call this the *Expanded* model.

The *Expanded* model approach added two elements (i) showing the ineffective (wrong) strategy and (ii) using the wrong strategy as an internal cue to overcome the demands of the cognitive effort. Students may be cued to transfer the right inquiry strategy into new environments by previously highlighting incorrect solutions (Clifford, 1984; D'Mello et al., 2014; Limón, 2001). When teachers share wrong approaches to solve an exercise, students see behaviors they want to correct and avoid (Manalo & Kapur, 2018; Vosniadou et al., 2001). Therefore, if students find themselves in a situation in which they are using a poor strategy, they may recognize it. Additionally, effective inquiry strategies may require more cognitive effort at first, at least compared to the common strategy of just changing things to see what happens. In the *Expanded* model, we also communicate to students that the common ineffective strategy may be easier at first than the target strategy, but that in the long run, the taught strategy will lead to more success in finding key patterns.

A factor that can affect students as they become independent learners is family SES (socioeconomic status). Prior research has shown that students from low-SES backgrounds have lower GPAs and standardized test scores (Reardon, 2011; Reardon & Bischoff, 2011). One contributing factor might be that schools don't focus enough in preparing independent learners. For example, in the United States, high school students from low-income backgrounds showed a learning loss of 0.4 standard deviations after 12 months of remote instruction during the pandemic (Agostinelli et al., 2022). The same pattern has also been found in other countries such as The Netherlands (Engzell et al., 2021). Therefore, we wanted to examine whether we saw less inquiry strategy patterns or different gains from instruction between students from two different SES family backgrounds.

We designed an experiment to compare treatments of no instruction (control group), *SR*, *SR+Exp*, and *Expanded*. In session one, students explore with a simulation (baseline measure), and shortly afterwards receive a brief video that uses one of the instructional models. Two weeks later, students complete a transfer task. We hypothesize that students assigned to the Expanded model will display a higher use of the taught inquiry strategy in the transfer task.

Methods

Participants

One hundred and nine students from two schools located in Bogota (Colombia) participated in the study. One institution is a public (run by a private organization) school where students (N = 59) come from a low socio-economic (SES) background. The second is a private school with students from a high-SES background (N = 50). The science teachers in both schools facilitated the activity. This study was approved by the University's Institutional Review Board. Parents provided passive consent and students provided active assent.

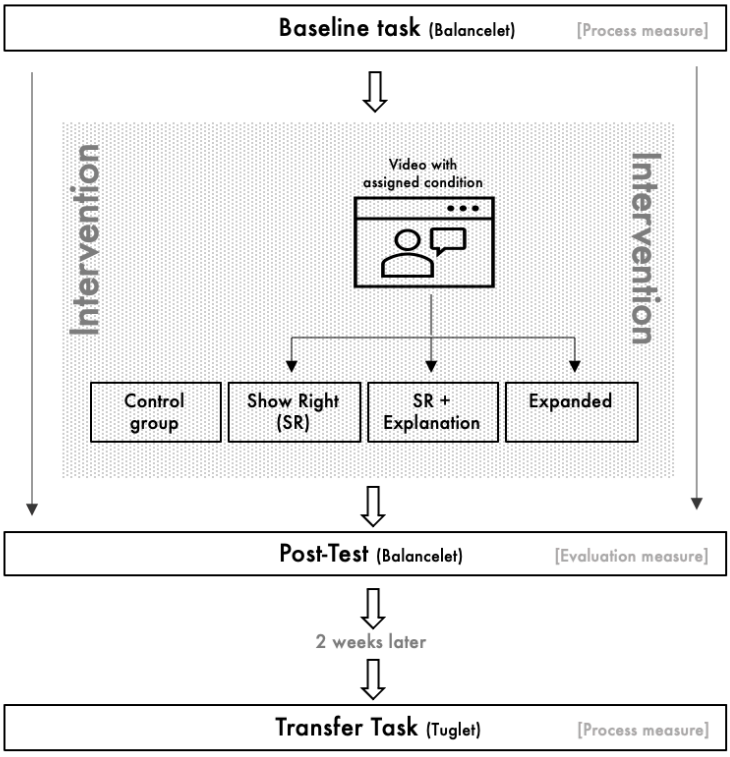
Design

The study design is composed of a control group plus three instructional models of inquiry instruction. Students assigned to the control condition do not receive the treatment video. In the first instructional model, *Show Right (SR),* a video shows students the right strategy. The second model is *SR+Exp* (Show Right + Explanation), where the video's instructor not only tells students the right strategy, but also explains the reasons why the right strategy is good. The last model is *Expanded,* which includes both components of the *SR+Exp* model and adds a brief component telling students a common wrong strategy and an explanation about why they might be inclined to use the wrong strategy even after they know that the right strategy is better. Students in both schools were randomly assigned to a condition. Randomization occurred within class.

We created one short video for each condition (<5 minutes). The videos are the key element of the intervention. All the videos feature the same teacher who follows a format used by *YouTubers*. Main messages are delivered using visual supports such as icons, images, and reinforcing text. The right strategy included in the videos is a particular strategy to learn the rules controlling a system, in this case, finding the equivalence between different types of units (e.g., how many red coins (base coin) equal a green coin?).

Procedures

Figure 2
Graphical Representation of Studies' Procedures



Studies occurred in the second half of 2021 and students in both schools were attending in-person instruction. In school A (public), students used the computer lab and in school B (private), they used laptops or tablets in the classroom. During the study, students in both schools used headphones. When needed, we provided

technical support to the teachers or the students (in school B, teachers shared the technical support session link with some students). Teachers followed a script to introduce and execute the study. Figure 2 presents a graphical representation of the procedures. On day 1, students provided assent and watched a short video with instructions on how to play *Balancelet*. Then they had five minutes to play with the simulation. We used this measure as a baseline of student inquiry. Once time elapsed, students watched the assigned condition video. They then took a post-test assessing their inquiry strategy knowledge (for space restrictions we don't include or report this evaluation measure in this paper). On day 2 (two weeks later), students played *Tuglet* for a maximum of 15 minutes. Again, they received short textual instructions about the interface. For *Tuglet*, the instructions did not state a specific task, though it becomes apparent that the inquiry goal is to predict whether any given configuration will go right, go left, or result in a tie. *Tuglet* served as the transfer task. The overall duration of the study, spread over two sessions, was approximately 60 minutes total.

Measures

We used choice-based assessments (CBAs) to measure students' inquiry processes (Schwartz & Arena, 2013). These CBAs (*Balancelet* and *Tuglet*) provided process measures about students' inquiry processes. In a CBA students are free to make choices about how to learn during the assessment, and we measure those choices directly from the logfiles of their actions. *Balancelet* provided the baseline while *Tuglet* the transfer measures.

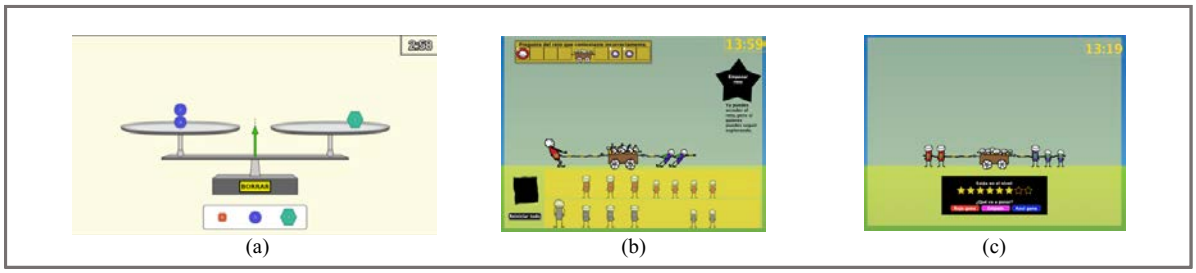
Taught (Right) Strategy Process Measures

Balancelet and *Tuglet* are CBAs about finding balance and equaling forces (see Figure 3). *Balancelet* uses weight; students need to learn to predict when a scale balances. *Tuglet* is about pulling; students need to learn to predict which team will win or tie when pulling a rope. *Balancelet* assesses students' exploration strategies to learn when a scale balances. *Balancelet* has a simple interface (Fig. 3-a): A scale, an eraser, a timer, and three types of coins. The coins have three different weights: red (*weight* = 1), blue (*weight* = 3), and green (*weight* = 6). Students stated learning task is to be able to predict what the scale will do for any combination of coins put on the scale – balance, tilt left, tilt right?

Tuglet is an analog of *Balancelet*. Students' task is to learn how to predict whether the blue or red team will win or tie in a tug-of-war. *Tuglet* characters come in three "strength" sizes: small (*pull level* = 1), medium (*pull level* = 2), and large (*pull level* = 3). In *Tuglet,* students do not receive a specific task, but they have the opportunity to run experiments every time they miss a question in the challenge room. Students can experiment in an explore room, and when they feel ready, they can move to a challenge room where they need to answer eight increasingly difficult questions in a row to win. If they make a mistake, they are sent back to the explore room where they can experiment or return to the challenge room at any time. Figures 3b and 3c show the explore and challenge rooms.

Figure 3

Interfaces Images Show a Balance Setup Using the Unit Equivalence Strategy in Balancelet (a) and in Tuglet (b). Image (c) Shows One of the Questions in the Challenge Room in Tuglet.



(a) (b) (c)

Setups run by the students in both CBAs are recorded and then extracted as logfiles. The clickstream data is later processed by classifying the setups performed by the students into meaningful categories. For the purposes of this paper, we only classified setups that displayed the taught strategy. The use of the unit equivalence (taught) strategy is calculated by counting each instance in which a student added elements when trying to isolate a specific unit (e.g., 1 red medium player on the left and 2 blue small players on the right). In essence, students got credit when they did not mix multiple sizes on either side of the scale or rope. We also count up the total number of setups run by the students in each CBA. The measure can be used as a raw frequency of strategy use, or it can be divided by the total number of actions to control for the total number of explorations. In this paper, results are reported using the latter option. Students could choose not to explore in the transfer task (*Tuglet*).

Instead of putting characters on the rope and seeing what happened, students can just go back to answer the questions. The bottom of Table 1 indicates the percentages of students who did not explore. They were treated as missing data and not included in the analyses.

Results

Table 1 shows a summary of the students' measures and interactions with *Balancelet* (pretest) and *Tuglet* (transfer test). As a reminder, numbers in Table 1 represent ratios of effective over total explores. We start by checking if there are differences between the high- and low-SES schools. Overall, high-SES students performed better than low-SES students.

Table 1

Descriptive Results and Interactions with the CBAs

	ALL				Control				Show Right (SR)				SR + Explanation (SR+Exp)				Expanded

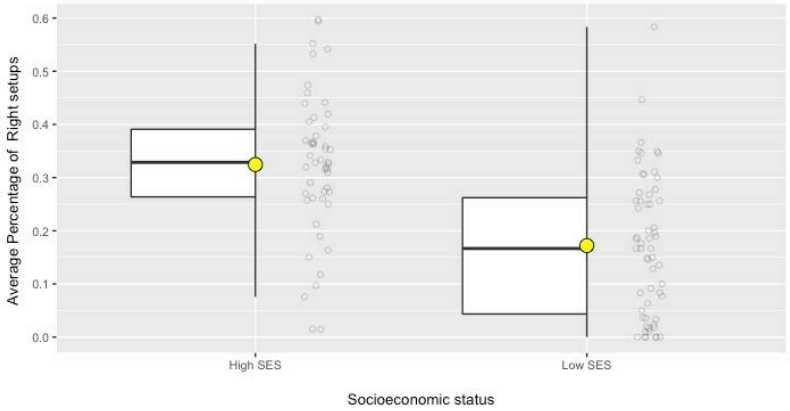
Figure 4 shows the combined inquiry measures by SES groups. High-SES students displayed higher scores of taught strategy in pre $F(1, 107) = 21.02$, $p < .001$ and transfer $F(1, 107) = 20.93$, $p < .001$ process measures regardless of condition. Within schools, there were no differences in the taught strategy use in the *Balancelet* task (Table 1).

Figure 4

Average Percentage of Overall Process Measures by SES background



Note. Large circles are group mean. Error bars are bootstrapped 95% confidence intervals. Small circles are individual students' scores (jittered along the x-axis for visibility).

Two weeks after students received the instructional condition, low-SES students in the *Expanded* condition showed a higher percentage use of the taught strategy (in *Tuglet*). The percentage of taught strategy use in pre (*Balancelet*) and post (*Tuglet*) operated as a within-subject measure. The different instructional conditions (N=4) operated as a between-subjects factor. However, when we look at the interaction between pre-post inquiry measures x condition x SES, the interaction is marginally significant indicating that the low-SES students may have particularly benefited from the Expanded condition, $F(3, 101) = 2.545$, $p = .060$. Nevertheless, given that there are non-significant interaction effects including SES, we collapsed results across by SES to simplify the reporting of the condition effects.

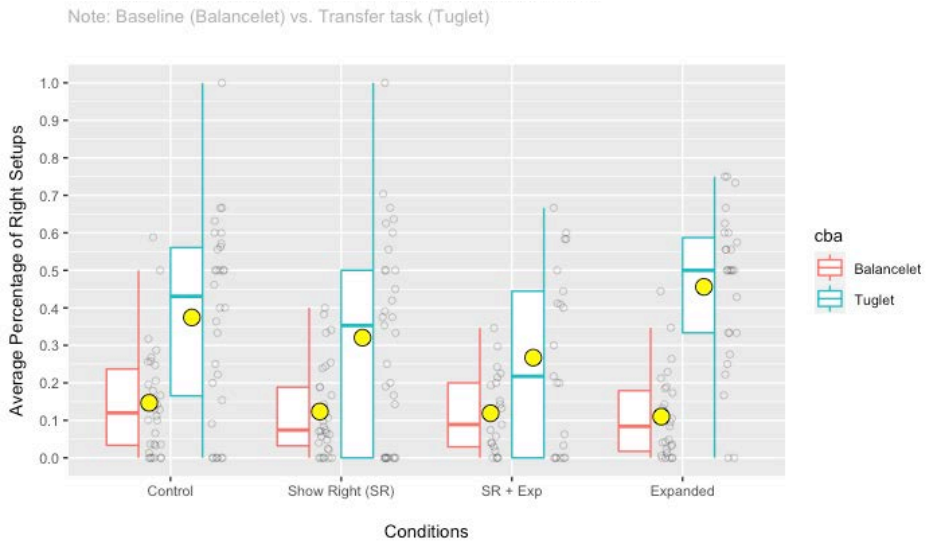
Figure 5 shows the use of inquiry strategies broken out by pre-test (*Balancelet*) and transfer test (*Tuglet*) by instructional condition (control, *SR*, *SR+Exp*, and *Expanded*). At pre-test there were no significant differences in the use of the target inquiry strategy. The two measures served as a within-subjects factor crossed by the between-subjects factor of instructional condition. Instructional condition produced a significant interaction with the difference between the pretest and transfer test measures, $F(3, 101) = 2.93$, $p = .037$. Visually inspecting Figure 5, the *Expanded* condition showed the greatest gain. One may see that the control condition also did well on the transfer test, but they were also relatively high on the pretest.

In this section we present the results of a linear regression model examining the relationship between percentage of taught strategy setups at transfer task and treatment, controlling for the percentage of right setups in *Balancelet*. Because there is a strong significant association between SES and percentage of right setups in *Balancelet* ($r = .41$, $p < .001$) this model didn't include SES to avoid collinearity. Above we show that high-SES students display higher use of the taught setup, so as expected we found that percentage of right setups in *Balancelet* predict students' right setups in the transfer task ($\beta = 0.46$, $t = 2.46$, $p = .016$).

We first compare transfer gains for each condition against the control group. None of the comparisons is significant. We found that students in the *SR* condition performed a lower percentage of taught setups than students in the control group ($\beta = -0.04$, $t = -0.70$, $p = .489$). Students in the *SR+Exp* condition on average, also performed a lower percentage of setups than students in the control group ($\beta = -0.09$, $t = -1.37$, $p = .175$). The estimate coefficient for students in the *Expanded* condition, showed that they performed a higher number of setups than students in the control group ($\beta = 0.10$, $t = 1.53$, $p = 0.129$).

Second, we ran additional parallel F tests to determine the contrasts among the other conditions. There are no significant differences in average percentage of setups between students in the *SR* and *SR + Exp* conditions ($p > .05$). The parallel F tests of *Expanded* condition with the *SR* ($p = .02$) and the *SR + Exp* ($p = .004$) conditions, showed that there are significant differences among them which confirms the patterns shown in Figure 5. While students in the control group on average made similar number of setups than students who received instruction, when we look at the different types of instruction, these results show that the expanded condition matters for transfer of the taught setups.

Figure 5
Average Percentage of Process Measures by Condition



Note. Yellow circles are group means. Error bars are bootstrapped 95% confidence intervals. Small circles are individual students' scores (jittered along the x-axis for visibility).

Discussion and Conclusion
