Participants were 63 undergraduate students in an introductory course of media and education at a private university in Japan. Participants were randomly assigned to the four conditions. Participants first answered a pre-reading survey in which they were asked to rate (a) their degree of agreement with the pro-supplement or anti-supplement positions for the effectiveness on health in general on 7-point Likert scale (1 = strongly disagree; 7 = strongly agree) (*pre-position*). Next students read the assigned two documents, which varied by condition as described above. After this, they completed a post-reading survey in which they rated their degree of agreement with the pro-Serenade and anti-Serenade positions (*post-position*) and the trustworthiness of the two sources (*post-trustworthiness*). In addition, they rated the relative amount of evidence for each position (1 indicated that all the studies supported the anti-Serenade position, and 7 indicated that all the studies supported the pro-Serenade position) (*post-amount*). Participants also provided written explanations for their level of agreement for both the pro-Serenade and anti-Serenade positions. In the analysis, each pair of responses on the pro- and anti-Serenade stances (pre-position, post-position, and post-trustworthiness) was merged into one variable by subtracting the anti-Serenade rating from the pro-Serenade rating, so that a large value indicates a relative preference for the pro-Serenade stances (see Table 2). In addition, student explanations were analyzed to determine whether students commented on cherry picking as part of their explanation of their level of agreement with the pro-Serenade anti-Serenade positions.

Results

The summary of results is shown in Table 2. The only significant difference between conditions was on the variable *amount of evidence* (F (3, 59) = 4.47, η^2 = 0.19), whereas differences on the other variables across condition were not statistically significant (Table 2). Participants' pre-position ratings were statistically equivalent across conditions. Post-reading positions and trustworthiness ratings were also not statistically different across conditions, except that students' judgements of the relative amount of evidence supporting Serenade (versus the amount of evidence opposing Serenade) differed across conditions. Post-hoc multiple comparisons with Bonferroni corrections indicated that students in the super-explicit condition rated the relative amount of evidence in favor of Serenade significantly lower than students in the none and hinted conditions. These indicate that participants in this condition recognized that there was more evidence in favor for the anti-Serenade position in this condition, yet they did not make a corresponding adjustment to their evaluations of the trustworthiness of evidence or of the overall benefits/harms of Serenade. However, the lack of statistically significant differences may result in part from insufficient statistical power.

Table 2

Descriptive and ANOVA Statistics for Study 2

Variable	None (n = 15)	Hinted (n =15)	Explicit (n = 16)	Super Explicit (n = 17)	F (3, 59)	η^2
	M (SD)	*M (SD)*	*M (SD)*	*M (SD)*		
Pre-position	1.93 (2.09)	1.93 (1.53)	2.56 (1.63)	2.41 (1.80)	0.53 n.s.	0.03
Post-position	–0.33 (2.19)	–0.67 (1.84)	–0.69 (2.63)	–1.59 (1.77)	1.04 n.s.	0.05
Post-trustworthiness	–0.47 (1.36)	–0.60 (1.96)	–1.44 (2.00)	–0.18 (2.46)	1.19 n.s.	0.06
Post-amount	4.13 (1.06)	4.20 (0.56)	3.69 (0.87)	3.24 (0.83)	4.47 **	0.19

* < .05, ** < .01

In the analysis of students' written explanations for their ratings, only four students mentioned cherry picking of evidence as a problem—two students each from the explicit and super-explicit conditions; there was no statistical difference across conditions). (A fifth student expressed approval of the cherry-picking tactic!) Student explanations were also coded to identify student mentions of larger bodies of evidence favoring one side or the other. There were no such mentions. Combining these results with the results in Table 2, we conclude that students attended very little to the cherry picking of evidence even in the explicit conditions.

Discussion

In two experiments, we examined whether undergraduate students adjust their epistemic judgments in response to cherry-picked evidence when they read multiple texts with conflicting claims. In Study 1, students adjusted their epistemic judgements when cherry picking was explicitly indicated, whereas in Study 2, students did not adjust their judgments (except for ratings of the amount of evidence) when cherry picking was explicitly or super explicitly indicated. Across the two studies, there was one condition in which one source's cherry picking was explicitly criticized by an opponent (Condition 2 in Study 1); this was the only condition in which students adjusted their epistemic judgments in response to cherry picking. This factor may account for the differences across the two studies. Perhaps students are sensitive to the problem of cherry picking only when an opponent explicitly explains that a source as cherry picked evidence that is inconsistent with a much larger body of evidence. Alternatively, the non-significant results for Study 2 may arise from insufficient statistical power; the sample size for Study 2 was much less than that for Study 1. Further research is needed to investigate instructional methods that can help students become more vigilant in noticing cherry-picked evidence and adjusting beliefs accordingly.

Racism with Antiracists: Examining Sensemaking in a School-University Partnership for Antiracism

Leema Berland; Nicole Louie; Mariana Pacheco and Laura Roeker
lberland@wisc.edu; nlouie@wisc.edu; mariana.pacheco@wisc.edu; laroeker@wisc.edu
University of Wisconsin--Madison

Abstract: In this paper we explore dialogue between members of an RPP who shared a goal of developing an antiracist learning community. We use one area of disagreement that emerged throughout the partnership to depict how antiracist discourses can align with racist narratives. In our analysis we identified three ways in which RPP partners justified focusing on anti-Black biases over a broader definition of racism, including the need: to uproot internalized anti-Black biases; choose how to use limited resources towards antiracist goals; and create conditions that mitigate Black students' behaviors. Each of these justifications reinforced racist ideologies by separating racialized groups, putting them in competition for attention rather than promoting solidarity and collaborative change, centering white people and their thoughts, and promoting a racist/non-racist binary. We conclude with implications for supporting the design of antiracist, transformative learning opportunities for educators.

Eduardo Bonilla-Silva (2020) describes "racism without racists"—or, how white supremacist structures, systems, and practices could persist in a society in which most people disavow racism and would never consent to characterizations of themselves as racist. While "color-blind racism" certainly persists (ibid), the current moment of blatant white supremacist violence (e.g., the recent wave of anti-Asian hate crimes, the January 6 insurrection, etc.) and highly visible resistance (e.g., Black Lives Matter) has spurred many people, including educators, to adopt the label "antiracist," explicitly rejecting racism and race-evasive approaches to change. Antiracist movements are not necessarily free of racism themselves, however. In this paper, we present our analyses of an RPP that actively sought to develop an "antiracist learning community," exploring how we and our partners made sense of antiracist goals through particular narratives and discourses. As we show, racism may be not only present but actually reinforced in discourse that takes up an explicitly antiracist stance. Thus, in this paper, we explore the question: How can ostensibly antiracist discourses support racist ideologies?

Theoretical Background

Race is a social construct, created to differentiate racial groups and to justify white supremacy as a system of racial domination (Solórzano & Yosso, 2001). This system involves racist structures, practices, and outcomes; it also involves sociohistorical narratives that position (American) white ways of thinking, learning, feeling, and being as normal and good while others as obviously and self evidently less than (e.g., Ferguson, 2000; Menchaca & Valencia, 1990; Shah, 2019). Further, racism and antiracism are complex and intersectional. In the words of Lorde (1984), "there is no such thing as a single-issue struggle, because we do not live single-issue lives" (p. 138). Systems of oppression based on race, ethnicity, gender, sexual orientation, language, class, disability, and other socially constructed categories function simultaneously and in concert to produce inequality in schools as elsewhere (Grant & Zweir, 2012). Thus, to be truly antiracist is to fight all forms of hierarchy and recognize all humans as "levelly human" (the Combahee River Collective, as quoted by Kendi, 2019, p. 187). Coordinating this understanding of racism with literature characterizing multicultural, antiracist, and socially just education, we conceptualize antiracist learning communities in schools as contexts that value and respond to the full humanity of each student, particularly each student of color (e.g., Kendi, 2019). Our partnerships with schools have led us to conceptualize *radical belonging* as a way to center the social and academic needs of students of color in a democratically constituted antiracist learning community (Louie, Berland, Pacheco, Roeker, Grant, under review).

Literature Review

As we partner with a school to develop an antiracist learning community—a community that fosters the radical belonging of each of its students, particularly students of color—we understand that "in the attempt to correct so many generations of bad faith and cruelty, when it is operating not only in the classroom but in society, [we] will meet the most fantastic, the most brutal, and the most determined resistance" (Baldwin, 1963). Resistance to

 © ISLS

antiracism takes the form of deliberate violence, now as it did sixty years ago. It also manifests in the unconscious disruption of antiracist projects, even by those who claim antiracist or equity-oriented projects as their own. For example, Louie (2020) found that teachers actively working to create environments that would support *academic belonging* did so in ways that reproduced ability hierarchies. In this and other examples (e.g., Ladson-Billings, 2014), "determined resistance" came in the form of unconscious ideologies that disrupted teachers' conscious intentions. Despite those intentions, teachers did not have the political and ideological clarity (Bartolomé, 1994) to enact antiracist goals, nor were they supported to develop such clarity. In this study, we explore how systemic racism continued to pop-up and "resist" the process of working towards an antiracist learning community throughout the discourse of our partnership.

Methods and Context

This study stems from a partnership between our university and Eastwood Elementary, located in a mid-sized Midwestern city (the names of the school and participants not on the university team are pseudonyms). Eastwood teachers and administrators invited us (pre-pandemic) to support them on their commitment to become an antiracist learning community. Most of Eastwood's students are students of color. The staff is 90% white. We were invited to partner with Eastwood because, despite their efforts towards addressing race-based harm in their school, racism persisted throughout the school: English monolingual students were bullying peers who spoke other languages, Asian American students were being mocked by classmates squinting and stretching their eyes, students with disabilities were being called the R-word, and a white student repeatedly called Black educators the N-word. Moreover, as a Black teacher at the school explained, the school lacked a shared understanding of racism and commitment to antiracism.

Over the course of a year and a half, we met monthly with the school-based leadership team, spent time in classrooms, and facilitated two summer retreats. For the present analysis, we draw on field notes and recordings from the second summer retreat (in 2020) and field notes from debriefing/planning meetings between the University team and Eastwood leadership. The Eastwood principal encouraged all teachers and staff to attend the retreat and invited parents; 21 teachers and staff and four parents participated.

The 2020 retreat ran for 5 days. Our analysis focuses on a topic that emerged repeatedly throughout the retreat, and which stood out to us because of the strong emotions it evoked (for the paper authors as well as other participants) and the ways in which it repeatedly disrupted discussions of other topics. Specifically, our analysis focuses on our discussions about whether our developing antiracist learning community at Eastwood should specifically and exclusively target Black students and families or take a broader lens to the work. Particularly active in these discussions were the principal (Amy, a white woman), the vice principal (Keith, a Black man), the school social worker (Neal, a white man), the district restorative justice coach (Josh, a Black man), the teacher who initiated our partnership (Malik, a Black man), and the mother of an Eastwood student (Che, a Hmong woman). These discussions occurred during debriefing/planning meetings with the Eastwood leadership team as well as during the retreat itself.

Our analysis of the discussions had two phases. In the first phase, we sought to understand the justifications offered by participants for either a) focusing on anti-Blackness or b) defining racism more broadly. To that end, we employed a process of in-vivo coding, constant comparison of coded episodes, and team discussion to identify themes in the justifications for the different perspectives. We present these themes in the findings section. Our second phase was to interpret the themes in terms of how they disrupted or reproduced racist and white supremacist narratives and/or created opportunities for antiracist learning. We offer these interpretations in our discussion section.

We locate ourselves in our analysis as both researchers and co-partners with the Eastwood educators. Not only were all members of this partnership learning together, but each of our contributions to the discussion shaped the shared (or unshared) meanings that were being co-constructed. Our team is racially diverse (including Black, Chicana, Chinese American, and white individuals) and brings different areas of expertise (e.g., learning sciences, and math, science, teacher, and multicultural education) to the work.

Findings

We identify and illustrate each of the themes that emerged in our analysis of participants' (including university team members) justifications for whether the focus of our antiracist school community should be exclusively about the experiences of Black members of the community or more broadly defined, in Table 1.

Table 1

Emergent themes from across participant justifications

Justifications	Themes	Illustrative quotes
For focusing on Black students' and family members' experiences	Theme 1: diluting the mission of our collaboration	Keith (the vice principal) said, "My worry is that if we're not intentional about the work that we're doing, there won't be any change. We're aiming too wide. …"
	Theme 2: Black students experience the most race-based harm	When directly asked whether the partnership should also address the needs of Latinx and Hmong students, Amy (the principal) responded that "...the racism at our school happens more blatantly and disproportionately to Black students and staff."
	Theme 3: white teachers' biases are uniquely anti-Black	Malik (the teacher whose call to action had initially launched the partnership) said, "I think that the teachers at Eastwood feel more comfortable with other races than they do with Black students. They talk about them climbing up the walls…They talk about them like they're animals!"
For taking a broader perspective on antiracism	Theme 4: Latina/o/x and Hmong students experience significant harm at Eastwood	Che (a Hmong mother of an Eastwood student) told the group that she did not feel welcome at Eastwood. She elaborated: "I have to sacrifice my culture to teach my kids to make it in this school. … My kids aren't seeing themselves represented…[The assumption is] since I'm Asian American … I don't really need anything because I'm smart."
	Theme 5: competing for resources distracts from whiteness	Josh argued that " If we focus on one group, that is separating and further marginalizing…Focusing on individual groups causes tension and makes others feel invisible...

Discussion

By publicly acknowledging race-based harm and calling for work to combat it, participants positioned themselves discursively as critically conscious antiracists. However, we argue that the narratives embedded in some of these concerns ultimately reinforce white supremacy. In particular, we see three ways in which the explicit justifications for exclusively focusing on Black students and anti-Black sentiment implicitly align with the maintenance of white supremacy. We believe our Eastwood partners had good intentions, but racism persisted in and through them—a phenomenon that becomes clear when contextualizing and historicizing their justifications within the systems of oppression upon which the United States is built.

- *Erasing Latina/o/x and Hmong students and families*: elevating the experiences of Black students and family members to the exclusion of all others devalued Latina/o/x and Hmong students and their families, dismissing their school experiences as unimportant and ultimately rendering them invisible.
- *Obscuring Black students' full humanity*: emphasizing behavior reduces (anti)racism to externally visible outcomes that can be measured, observed, and compared, rather than nuanced experiences that can be shared, understood, and improved. That is, by making Black students' behavior hyper-visible, participants made students' capacities and needs as learners, knowers, and thinkers invisible.
- *Undermining efforts to build interracial solidarity*: by making it seem as though the school had to make a choice between *either* addressing harm to Black students and families *or* addressing policies and practices steeped in white supremacy more broadly, antiracism was framed as a limited resource for which marginalized individuals must compete.
- *Centering white people*: while engaging white individuals in confronting their internalized racial biases and white privilege is valuable, emphasizing the internalized racism of white educators at Eastwood served to center the thoughts of white people without attending to the experiences of students of color—the very individuals and experiences that motivated our collaboration. Further, focusing on individuals' internal biases does not move to transformation of practice, so it does not have a clear impact on the experiences of the students of color.

In summary, while each individual in our partnership was there to disrupt racism in Eastwood, we see ways in which the discussions in which we engaged unintentionally reinforced white supremacy.

How could the RPP have built a shared understanding and collective commitment?

Members of both the university and Eastwood portions of our partnership experienced one another's positions as racist—as harming students of color—and this racist/non-racist binary that implicitly emerged in our discussions eroded collective trust in the partnership. Indeed, toward the end of the debrief about the first day of the retreat, Keith said: "I've been disheartened by the conversation today. Last summer we were making a lot of progress. I don't think right now there is respect for our ideas … It felt to me like the conversation wasn't a dialogue, [Eastwood] was attacked." And, this was not resolved. At the end of the retreat, the partnership did not have a shared vision for our joint antiracist work. Instead, the contradictory views of the focus of our partnership remained throughout the summer retreat, repeatedly coming up and disrupting other discussions. Learning theories (pick your flavor, they agree on this point!) tells us that deep conceptual change takes time, and willingness to be wrong. We had neither and we now wonder about strategies for resolving such fundamental disagreements hidden by superficially similar discourse but based on very different ideological underpinnings.

One possible strategy for moving forward could have been to collaboratively unpack the different justifications for the exclusive focus on Black students and to co-construct a new vision that brought the implications of the different positions into alignment. Another possibility could have been using Eastwood educators' interest in focusing on Black students to motivate a careful exploration of the cultural wealth (Yosso, 2005) that different Black students and their communities have. The goal of this work would have been to acknowledge the diversity within the label "Black students," and using that nuance to motivate antiracist pedagogical and curricular practices that make space for the diverse ideas, experiences, and cultural practices of Latina/o/x and Hmong Eastwood students as well. Regardless of the specific strategy we took, we would need to focus on building the "politicized trust" (Vakil et al., 2016, p. 199) that could have enabled us to identify ways in which we were using words differently and the implications of those differences.

This analysis returns us to a question Carl Grant (a member of the University team) repeatedly asked throughout our partnership: "Can you create an antiracist school in a racist school system?". While this study does not answer this question, it suggests that time and politicized trust are necessary for taking the first steps of envisioning what that antiracist school community could even look like.

Revisiting revoice: An inductive method for capturing revoice in classroom discussions

Edith Bouton, Christa Asterhan, Hebrew University of Jerusalem,
edith.bouton@mail.huji.ac.il, christa.asterhan@mail.huji.ac.il.

Abstract: Within the scholarly field of academically productive classroom dialogue, several elusive, yet rich and potent discourse moves have received special attention. However, their rarity and complexity also poses significant challenges to meeting interrater reliability thresholds, and they are often omitted from quantitative research efforts. We propose a different approach for coding that circumvents these issues, called DECCA. In this presentation, we showcase this methodology by focusing on teacher revoice. We demonstrate how it is possible to deconstruct this complex phenomenon into smaller and simpler elements. We then code each turn in the corpus for the existence or absence of each element (which we term Dialogue Elements, DEs). Adding a post-coding, pre-analysis stage allows us to extract turns which contain the specific combination of DEs relevant for revoice and distinguish it from similar teacher dialogue facilitation moves. Theoretical and practical implications are discussed.

Introduction

In academically productive dialog (APD hereafter), teachers engage their students with open ended, authentic questions or tasks, encourage them to share their ideas and thinking processes, to build on each other's contributions, to (critically) explore alternative viewpoints and to use external knowledge sources to evaluate them (Asterhan & Schwarz, 2016; Howe & Abedin, 2013; Howe & Mercer, 2017; Kim & Wilkinson, 2019). This form of classroom dialogue has been identified as beneficial for learning and scholars of dialogic teaching and learning have identified the foundations and characteristics of classroom talk that promotes student learning and cognitive development (Resnick, Asterhan & Clarke, 2015; 2018).

Expert teacher facilitation has been proven crucial for APD in classrooms (e.g., Pauli & Reuser, 2015; van der Pol, 2010; Webb, 2009) and research has documented how specific dialogue moves can stimulate (or stymie) intellective student engagement. One teacher facilitation move that stands out in terms of the scholarly attention it has received is "revoice" (Michaels & O'Connor, 2015; O'Connor & Michaels, 2019; 1993; 1996). Revoice occurs when a teacher reiterates a particular student contribution in her own words, while acknowledging the student's ownership of the original contribution, elaborating on its content, and finally asking for the same student's confirmation on her inferences. The phenomenology and affordances of revoice have been documented extensively (e.g., Alozie et al., 2009; Ferris, 2014; Fitzgerald & Palincsar, 2019; Glenn et al., 1999; Hmelo-Silver & Barrows, 2006; Kwon et al., 2008). Yet, despite this attention in conceptual, descriptive, and qualitative research, revoice has been largely absent from quantitative research efforts on APD.

A possible reason for this absence is that revoice is a collateral victim of common top-down coding practices, while adhering to strict standards of scientific measurement. Quantitative research on dialogue requires the systematic categorization of selected characteristics, that is: coding (Hennessy et al., 2020; Shaffer & Ruis, 2020). Yet, when attempting to capture a phenomenon such as revoice with a standalone, dedicated coding category, coders encounter two challenges: First, "true" revoice is not a common speech event in classroom discourse (Enyedy et al., 2008; Inan, 2014). When a particular feature is rare, reliability thresholds for the coding category that intends to capture it cannot be met. Second, revoice is a high-inference construct that is a particular composite of different speech moves and can serve multiple purposes. The more multi-faceted the phenomenon is, the less likely it is for the judges to agree.

Some tools give only ambiguous information on this front (see Thurlings & den Brok's 2017 review) whereas others deal with rare and nuanced dialogic constructs by either omitting them from analysis, or by clustering them together in more inclusive categories (Chiu, 2015). Either way, the intended aim of providing a comprehensive and sensitive account of classroom dialogue, is sacrificed at the altar of interrater reliability, and analysis is limited to common and/or coarser dialogue features.

Instead of searching for higher-order discourse constructs (such as revoice) in a top-down manner, we suggest adopting a bottom-up approach according to which we first code for a small and reliable set of basic dialogue elements (DEs). The DEs were systematically identified by comparing seven renowned and well used coding schemes for quality of classroom discourse. This is then followed by a post-coding phase, in which we search for co-occurrences of particular combinations of these elements that represent higher order, compound discourse constructs (such as revoice). In a recent paper (Authors, under review), we presented the reliability and validity of this approach which we call Dialogue Elements to Compound Constructs Approach (DECCA).

 © ISLS

In the current work, we explore whether this small but (hopefully) pivotal change in common coding procedures will enable the systematic identification of instances of revoicing in classroom discourse, while still maintaining scientific rigor in its measurement, and thus its inclusion in quantitative research. This approach to coding has an added benefit, since it also captures approximations of revoice, that can be of particular interest to researchers looking into emerging processes and implementation efforts of new practices. Whereas in traditional coding tools the turns that fail to meet the full requisite list of the full construct are left uncoded.

Method

Data was collected from a pedagogical development effort aiming to encourage APD in upper elementary Hebrew Language Arts lessons. Over the course of 1.5 school years (2018-March 2020, start of the Covid 19 Pandemic) 18 classroom discussion recordings were collected from seven teachers (4 teachers experienced in APD and 3 teachers who were novices). Each transcript involved the teacher and her students (20 - 34 per class) and was collected by a research team member. Students without active parental consent were seated outside of the scope of the camera and their answers were not transcribed. Four lessons were collected from the veteran teachers in the first year of the project (4) and additional two lessons from each of the seven teachers (14) were collected in the second year (18 lessons total, approx. 45 min each). The lessons, conducted in whole classroom format, were video- and audio taped and then, transcribed (parsing on level of speech turn). Each dialogue protocol was then coded with DECCA (nine DE coding categories in all, each turn coded for the existence of one or more of the 9).

Revoice deconstructed

The facilitation move of Revoice can be deconstructed into several components (O'Connor & Michaels, 1993). The teacher gives the original speaker ownership of the content. (in DECCA, the DE Refer). Another component is 'retroactive contextualization' (Lemke, 1990): A combination of repeating the student's contribution (DE Repetition), while elaborating on its meaning (DE Elaborate). Finally, the teacher gives the student a chance to affirm or deny her inferences, captured with DEs Invitation and Evaluation. Interrater reliability for these five DEs ranges from $\kappa = 0.7$ to $\kappa = 0.85$. Then, we extracted only turns with specific combinations of these five DECCA elements. Finally, we compared those turns to search for similarities and differences among them and common constructs from the APD literature.

Results

Teacher revoicing

Results confirmed the rarity of Revoice moves in classroom discourse: Out of the total of 7,405 conversational turns coded, only nine received all five DEs that make up Revoice. Only seven of these were identified as instances of "true" Revoice, all occurring in three of the four veteran teachers' lessons.

Due to shortage of space, we will only discuss one example in depth. The students and teacher had just read the story 'Fly, eagle, fly!' a tale about a farmer who finds an eagle nestling and raises it with the rest of his chickens, on the ground, until a friend comes and convinces the eagle to fly. The question under discussion was about the sort of change that occurred in the story. The student speaking in this example is Nicolay (all names were changed to protect the identity of our participants), for whom Hebrew is the second language, his mother tongue is Russian.

> Nicolay: In the beginning the eagle. Then a chicken. Then an eagle again.
> Teacher (Meital): So, what are you trying to say?
> Nicolay: He (the eagle) changed the behavior in his life.
> Teacher (Meital): He tried to change a behavior. Great, Nicolay! So, I'm writing [writes on the whiteboard] 'change of behavior'. The farmer, Nicolay says (to the class), and tell me if I understood you (to Nicolay), tried to change the eagle and turn him into a (chicken).

In the fourth and final turn in the transcript the teacher's utterance begins with a word-by-word repetition of the student's answer, therefore, the DE Repetition will be marked with 1. Next, the coders indicate the DE Refer here because the teacher refers the idea to Nicolay by using his name (and writing it on the board next to his contribution). The DE Evaluation is present also as a standalone since the teacher gives Nicolay explicit positive evaluation (that's great!) as well as implicit positive evaluation (by putting his response up on the whiteboard).

Throughout her response, and by inserting few key words into her repetition, the teacher manages to elaborate and elevate Nicolay's answer. For example, she adds the word 'tries' before the phrase 'changed the behavior' that Nicolay used, thereby stressing the rigorous and not necessarily successful process this entails.

She also adds the words 'The farmer' to clarify Nicolay's utterance (instead of 'he') and again repeats the word 'tries', this time to describe the actions of the farmer character. Finally, she invites Nicolay's evaluation on her interpretation, asking him to correct her if he does not agree with her interpretation. Therefore, the coders will mark 1 for the Invitation DE and Evaluation DE. To sum, this turn of speech by the teacher contains a combination of five specific building blocks that we have pre-defined as crucial to the revoice construct.

Reoccurring combinations, signs of emerging practice

Using DECCA enabled the distinction among actual Revoice, and cases of Revoice approximations. For example, the revoice move starts with the teacher noticing and repeating a student contribution (O'Connor & Michaels, 2019) and then broadcasting it to the rest of the class (Michaels & O'Connor, 1996). When it stops there, it is a simple Repeat move. Another recurring example is Reformulate, a combination of the DEs 'elaboration' and 'repetition'. The difference with Repetition is that the teacher in addition elevates the student's response (for example, by highlighting its contribution to the topic, adding exact and discipline specific terms and concepts to it, and so on). Another, but less common, compound construct is Reframe, formed by the combination of the DEs Elaboration, Refer and Repetition. The main difference from Reformulate is that in this construct, the teacher explicitly credits the idea to the original speaker. Yet, it is not a full Revoice, as the teacher does not ask the student to indicate whether this is what he or she meant.

Teacher Repetition. The excerpt is taken from the first lesson of Meital the teacher, and her classroom discussion of the story 'fly eagle fly', introduced earlier.

> Teacher (Meital): So what does that mean? What are you actually telling us?
> Nitzan: (I'm saying) that it's pretty hard to adjust to a different environment.
> Teacher (Meital): It is hard to adjust to a new environment.

Other than changing the word 'different' to the word 'new', the teacher repeats her student's contribution word by word.

Teacher Reformulating. Students and teachers discussed how they felt while reading another story, 'The king who did not know how to cry', and shared things they found interesting or important. This story tells about a good king who never cried because his life is so good he never had a reason to be sad or stressed. His advisors to help him cry because it is his only wish. Yet only as an old man when he sees a couple with a young child and cries tears of happiness which fill a whole lake.

> Ronen: What was pretty (interesting) is that the small counselor tried to kill the doctor, but the king did not agree to (do) that.
> Teacher (Liati): The king did not agree. They said (in the story) that he was very good, and he did not agree to give out punishments.

In the example, the teacher performs a reformulating move, by adding reasoning and thus modeling justification practices.

Teacher Reframing. The example shown here was taken from a lesson discussing the story 'Generous deed'. In this story, four students bully a handicapped boy, Carosi, during recess time, and in his fury, he throws an ink bottle at them, but misses and hits the teacher who just walked in, instead. The teacher investigates who threw the bottle, and another student, Garone, takes the blame so Carosi will not be punished. The teacher immediately knows Garone is not the culprit, after Garone whispers something in his ear, the teacher forgives the bullies.

> Revital: They told him sorry and he forgave and that was very touching (because) he could have said no for what they did to him.
> Teacher (Dalit): You understood that the child forgave (them) and that was touching to you that this was the end of the story.

By applying the reframing move the teacher is creating an alignment of Revital's contribution with the way she interpreted the text. The teacher manages to perform this affirmative move, despite the mistake in Revital's understanding of the narrative, as the bullies never apologized to Carosi in the story, and did not ask his forgiveness, the teacher was the one who forgave them.

Discussion

This paper uses the construct of revoice to showcase how a slightly altered coding procedure paves way to *both* keep the inter-rater reliability indices at acceptable levels *and* still be able to capture compound and less frequent

dialogue moves. Moreover, using the same DEs we have been able to distinguish revoice from close approximations moves, closely related yet qualitatively different teacher moves (Repeat, Reformulate, Reframe). For the sake of simplicity, this paper has only focused on the 5 dialogue elements that in combination create the compound construct of Revoice. DECCA currently includes only nine DEs yet is able to distinguish among 52 qualitatively different coding categories, taken from renowned, existing coding frameworks.

One challenge that should be further explored in future research is the finding that out of the nine cases that were deductively identified with DECCA as "Revoice", in two of these, a teacher had acknowledged the student's ownership of the repeated content, but she then evaluated it herself (instead of inviting the student's evaluation) and she did not elaborate on it but, instead, invited the original speaker to do so. Although this is indeed a compound and potentially valuable teacher facilitation move, it is not a classic instance of Revoice, at least not as described in the literature. Future research on larger data sets will show whether these instances were particular to this study's setting, and if not, whether these subtle differences will prove to be important vis-a-vis their impact on student learning and other correlates.

In any case, we believe that the advantages of the DECCA framework outweigh its limitations and hope it will prove to be an important first step toward creating a bridge between the richness and validity afforded in qualitative research methods, and consistency and reliability offered by quantitative research methods.

Design of personalized instruction using learner data

Hyunkyung Lee, Young Hoan Cho, Sunyoung Keum
maso28@snu.ac.kr, yhcho95@snu.ac.kr, keum0815@snu.ac.kr
Seoul National University

Abstract: With the development of advanced technologies, teachers can overcome the limitations of traditional teaching and learning practices by giving personalized instruction. Although personalized instruction can be enhanced with online dashboards showing learning progress and achievements, teachers should develop competencies in how to use the dashboards to design personalized instruction. This study explored how teachers (n = 20) designed personalized instruction using learner data. The think-aloud method is used to explore how teachers create a lesson plan using learner data such as prior knowledge, learning motivation, participation, and so forth. This study found that in-depth learner diagnosis and repetitive design activities play crucial roles in personalized instructional design. Furthermore, the instructional design process had a significant effect on the design outputs and lesson plans. This study has significant implications for teacher education, revealing challenges that teachers encounter in designing personalized instruction with learner data.

Introduction

With the development of information and communications technology, data on learner characteristics, the learning process, and results are collected and analyzed quickly, which creates an environment for designing personalized instruction. Personalized instruction refers to a class that provides an optimized learning experience by tailoring learning activities and resources to the characteristics and needs of individual learners or groups of learners. Previous studies have reported that personalized instruction has a positive effect on learners' academic achievements (Smale-Jacobes et al., 2019; Tomlinson et al., 2003) and makes learning more attractive to learners (Subban, 2006). It was also reported that it could effectively support the learning of underachievers who have been excluded from traditional instruction (Patrick et al., 2013).

However, providing teachers with learner data does not make them better at designing personalized instruction. (Lai & Schildkamp, 2013). The reasons why teachers might avoid using given data include workload, ethical issues, lack of competency, and difficulties in finding meaningful information from the data. To effectively support personalized instructional design using learner data, it is necessary to deeply understand how teachers use data for instructional design. In this study, we explore the personalized instructional design process using learner data by applying the think-aloud method and examine the influence of the process on the personalized instructional design output (i.e., lesson plans). The research questions are:

First, how do teachers design personalized instruction using learner data?

Second, how does the instructional design using learner's data influence the quality of lesson plans?

Personalized instructional design using learner data

It is important to understand individual learners' characteristics and their needs in order to design personalized instruction more effectively. The personalized instructional design uses the learner's data to accurately diagnose the educational needs of learners. The starting point for learner diagnosis is generating questions in order to answer with data, such as whether the students are well-understood and whether there are students who have not completed learning activities (Wise & Jung, 2019). Next, it is necessary to identify the data related to the questions and to understand the structure and content of the data (Mandinach & Gummer, 2016). The final step for diagnosis is interpreting the data. The process of finding meaning in data is a process of discovering educational value by understanding data in an integrated way and connecting it with context (Herodotou et al., 2017).

Diagnostic results from learner data can be used to design activities for the entire class, specific learner clusters, and individual learners. First, teachers can design the whole class activity by modifying the contents and tasks of the textbook according to the characteristics of the entire class. Next, the activity for a specific group of learners can be specifically designed for those whose characteristics are very low or high and who are diagnosed as requiring differentiated treatment. Wise and Jung (2019) referred to this as "scaffolding" for the target cluster. Finally, learning activities or instructional strategies can be designed for individual learners by utilizing adaptive digital resources (Pane et al., 2015; Patrick et al., 2013). This strategy will allow individual learners to learn along a personalized learning path (Pane et al., 2015; Patrick et al., 2013).

Research methods

Participants

A total of 20 elementary school teachers (17 females, 3 males) participated in the study. They had worked for over five years and were interested in using data and personalized instruction. The average teaching experience of participants was 9.6 years (SD = 4.37); three teachers (15%) had a master's degree, and 15 teachers (75%) had education and research experiences related to data use or personalized instruction.

Research process

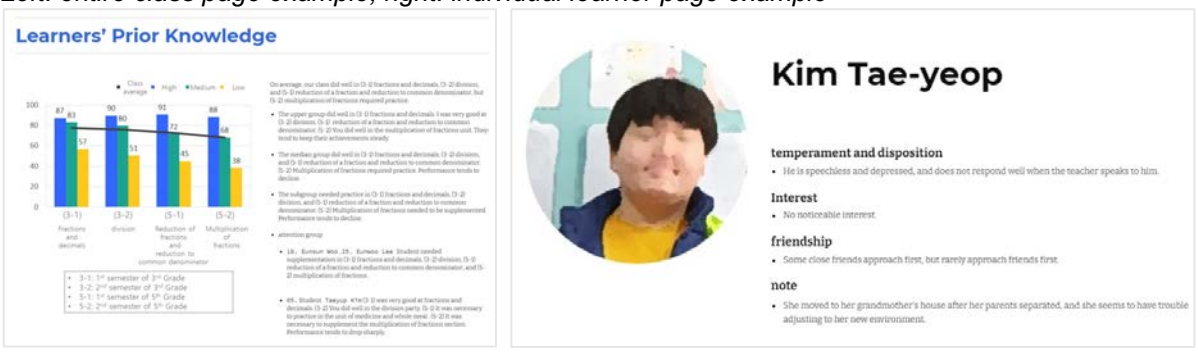
To explore how teachers use learner data to design personalized instruction, the think-aloud method was used in a laboratory context. First, participants practiced the think-aloud method and the research tools. Second, participants were asked to design a personalized instruction session using learner data for 60 minutes and write a lesson plan. Last, an interview was conducted to investigate their perceptions of the instructional design process and outputs.

Data collection

This study collected data using the video conference tool, Zoom, because of the COVID-19 pandemic. All tasks were performed on an online webpage, and the whole process was recorded. Participants were asked to create a lesson plan by designing a personalized instruction that teaches "the division of fractions" in a 6th grade math class using the given learner data and considering the design context (e.g., school characteristics, classroom environment). Participants carried out the think-aloud method for 60 minutes while designing the instruction. For personalized instructional design, the learner data, including learner characteristics, prior knowledge level, mathematics learning motivation, comprehension, participation, and learner cluster information, were provided to the participants. The learner data were presented in raw data, graph, and text formats throughout the class page and individual learner pages (See Figure 1). The goal of designing a lesson that reflects the characteristics and needs of the learner was also presented, along with the context. Furthermore, we collected the lesson plans written by participants. Teachers were asked to fill out a lesson plan form that could describe the lesson's objectives and instructional procedures, and they could modify the form if necessary. They were asked about what types of learner data were mainly referenced in the interview, what was considered in order to design a personalized instruction, and whether there were any difficulties in the design process.

Figure 1

Left: entire class page example, right: individual learner page example



Data analysis

A total of 1,056 analysis units were generated by segmenting the video of the instructional design process video into 1-minute increments. The video was coded according to the coding scheme: (1) learner diagnosis; (2) instructional design (personalized design, traditional design, monitoring and revision); and (3) searching for information related to the lesson. When it was difficult to code with video, interview data was used to supplement it. The inter-rater reliability (Cohen's Kappa) ranged from 0.80 to 0.99. We calculated the ratio of time for each category of the coding scheme and then used it for statistical analysis.

The instructional design outputs were evaluated with a rubric developed based on previous research (Shin, 2021). To understand and evaluate the lesson plan accurately, we conducted an interview with a teacher. The

 © ISLS

rubric consisted of (1) personalized learning plans, (2) competency-based learning, (3) continuous assessment, (4) learner-directed activities, and (5) using technologies for personalization. Using the rubric, two researchers independently evaluated the lesson plans, scoring 1 to 3 points for each category. The possible total score ranged from 1 to 3. The inter-rater reliability (Cohen's Kappa) ranged from 0.88 to 0.95.

To analyze the process of instructional design, we conducted a descriptive statistical analysis and a chronologically ordered representations of discourse and tool-related activity (CORDTRA) analysis. Two researchers classified the teachers' design patterns into two types based on learner diagnosis-instructional design activity. Furthermore, an independent sample t-test was performed to compare the differences between process types. An independent sample t-test was conducted to check whether there was a significant difference in the quality of design outputs between process types.

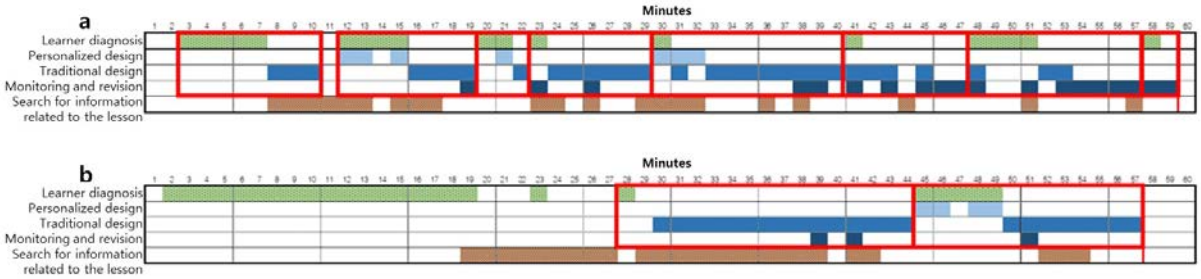
Results

The process of personalized instructional design using learner data

The learner diagnosis activity occurred for 31.54% (*SD* = 11.58%) of the total design time on average among the personalized instructional design activities using learner data. Instructional design activities accounted for 55.91% (*SD* = 16.26%) of design time on average. Among the instructional design activities, the most frequent activity was the traditional design activity (*M* = 59.37%, *SD* = 12.27%)—followed by the personalized design activity (*M* = 17.07%, *SD* = 10.73%) and the monitoring and revision activity (*M* = 9.49%, *SD* = 8.36%). The search for information related to the lesson activity took up 31.59% (*SD* = 13.63%) of the total design time on average.

Using the CORDTRA diagram, learner diagnosis and instructional design patterns were explored to derive design process types (See Figure 2). According to how often learner diagnosis and instructional design patterns were observed, the process types of personalized instructional design using learner data were divided into two types. The first type was the iterative design type. In this type, learner diagnosis and instructional design patterns occurred repeatedly throughout the design process. The second type was the linear design type, in which the pattern of repeating learner diagnosis and instructional design seldom occurred. This pattern was found less in the linear type (*M* = 2.10, *SD* = .99) and in the iterative design type (*M* = 6.20, *SD* = 1.87).

Figure 2
a. iterative design type, b. linear design type



An independent sample t-test was carried out to check whether there is a difference in the ratio of design activities according to the process types. First, a significant difference was found between the iterative design and the linear design type in the learner diagnosis activity ($t(18) = 2.30$, $p = .034$). Teachers of the iterative design type (*M* = 36.91%, *SD* = 9.83%) spent more time diagnosing learners than the teachers of the linear design type (*M* = 26.16%, *SD* = 11.06%). Next, a significant difference was found in the personalized design activities, which is a sub-activity of the instructional design activity (t (15.56) = 3.19, $p = .006$). The iterative design type (*M* = 23.36%, *SD* = 10.41%) had a higher ratio of personalized design activity than the linear design type (*M* = 10.79%, *SD* = 6.84%). No statistically significant difference was found in other design activities.

The influence of instructional design process on the quality of lesson plans

An independent sample t-test was conducted to investigate whether there was a difference in the quality of the lesson plan between the iterative design type and the linear design type. Consequently, there was a significant difference according to the process types (t (18) = 2.72, $p = .014$). The lesson plans designed by teachers of the iterative design type (*M* = 13.10, *SD* = 2.64) were qualitatively better than those designed by teachers of the linear design type (*M* = 10.00, *SD* = 2.45).

 © ISLS

Discussion

This study explored the process of personalized instructional design using learner data. It was desirable to repeatedly conduct learner diagnosis and instructional design in the design process for personalized instruction. The teachers of the iterative design type created higher quality lesson plans than those of the linear design type. The former tended to interpret more learner data and design more personalized activities than the latter. This means that the checking and interpretation of learner data must be continued in the instructional design process to develop a personalized lesson plan.

Even if teachers use data to diagnose learners well, they will not be able to successfully design personalized instruction without appropriate educational support. Therefore, it means that abilities beyond data literacy are required for teachers (Mandinach & Gummer, 2015). However, many teachers do not adapt instructions according to the learners' abilities and have difficulties in designing personalized instructions (Al-Lawati & Hunsaker 2007; Latz et al., 2009); time and experience do not naturally increase the ability to design personalized instruction (Tomlinson, 1995). It is necessary to support teachers so that the learner's diagnosis results can be well-connected to the personalized instructional design. For example, prompts can be inserted in the learning analytics-based dashboard so that teachers can interpret data well in considering pedagogy or context, or data requiring attention for interpretation can be displayed with data from various sources. In future research, it is necessary to specifically develop a tool or instructional model that supports the teacher's personalized instructional design using learner data.

Multilevel Connected Teacher Learning for STEM curriculum innovation

Pakon KO, The University of Hong Kong, kopakon@hku.hk
Nancy Law, The University of Hong Kong, nlaw@hku.hk

Abstract: This study investigates how differences in teachers' learning outcomes may be related to the Architecture for Learning (AfL) at multiple levels of the education ecosystem available to the teachers as well as their own individual characteristics. The MultiLevel MultiScale framework was adopted for the analysis of the AfL available to ten teachers in five schools participating in a University-School Partnership programme targeting pedagogical and curriculum innovation in STEM. The study found that the AfL available to teachers varies across schools and within the same school in terms of exposure intensity and their foci of interaction. Teachers may also have different learning foci depending on their experiences and types of leadership roles. The findings have implications for customization of teacher learning for teachers at different career stages and in different school settings.

Introduction

Evolving social demands on education calls for changes in educational practice, often in the form of curriculum or pedagogical innovation. This in turn puts pressure on teacher professional learning. Yet, we notice there are variations in teachers' learning outcomes even when they have engaged in the same kind of professional learning communities. Evidence shows that within the same project network, there can be variations in terms of teacher learning across schools (Horn & Kane, 2015) as well as across teachers within the same school (Horn, 2005; Horn & Little, 2010). These observations can be explained by an ecological perspective on learning—that teacher learning depends on their intentional learning orientation in relation to their personal characteristics, and their interactions with their professional context (Opfer and Pedder, 2011). Affordances that support teacher learning within their professional context are associated with the architectures for learning (AfL) (Law, et al., 2015; Stein & Coburn, 2008; Wenger, 1998) available to them. In this study, we investigate how different AfL could influence teachers' learning outcomes, as well as whether and how these outcomes depend on teachers' personal characteristics through a set of comparative case studies of teachers taking part in a design-based innovation network (Fishman, et al., 2013) of schools in Hong Kong focusing on the promotion of self-directed learning pedagogy and curriculum integration in STEM related subjects. Two main research questions are explored:

(1) What AfL at network, school and teacher levels were available to different teachers within the same innovation network within their respective professional contexts, which may vary across schools, as well as across roles within the same school?
(2) Whether and how the AfL available to teachers could affect their learning outcomes?

Conceptual framework

This study adopts the MultiLevel MultiScale (MLMS) model (Law, et al., 2015) as an analytical framework. This model posits that within an education ecosystem, learning takes place at student, teacher, school, network, and system levels (Law, et al., 2016). Such learning is influenced by interactions across these levels (thus multilevel), as well as interactions across entities within the same level that may or may not belong to the same organizational unit (e.g., interactions among teachers in different schools, thus the term multiscale to capture the different spheres of influence). This model can guide the examination of learning conditions and learning outcomes at multiple levels in the context of educational innovations. To identify the conditions for learning at different levels of the ecosystem, we adopt the construct of architectures for learning (AfL) (Stein & Coburn, 2008; Wenger, 1998). According to Law, et al. (2015), AfL comprises four key components: (a) organizational structures (e.g., teacher design teams), (b) interaction mechanisms (e.g. co-teaching), (c) reification artifacts such as guidelines and resources, and (d) technology to facilitate actions and interactions within the ecosystem. Guided by the AfL construct, the MLMS model examines learning conditions at different levels by looking at organizational structures of learning environments and differentiating learning interaction mechanisms within and across organizational units (e.g. school as an organizational unit) (Law, et al., 2015). The MLMS model regards reification artifacts and technology as boundary objects (Stein & Coburn, 2008) for embodying ideas and shaping focus in negotiations (Wenger, 1998) travelling across multiple communities of practice.

Research Design

 © ISLS

Research context

This study adopted multiple case studies (Yin, 2003) as its methodological approach, with an individual teacher as a unit of analysis. The research context was in the second phase of a series of funded university-school partnership projects formulated as design-based implementation research (Fishman, et al., 2013). The projects aimed at promoting self-directed learning in Science education in the first phase (2014-2017) and STEM education in the second (2017-2019), which was in response to the STEM education initiative in Hong Kong (EDB, 2016a). In the second phase, the network consisted of experienced and novice teachers from existing and newly joined schools in the network. Schools were expected to design and implement two school-based STEM curriculum units in the first year. The network shared two key design principles for STEM curriculum innovation: (i) self-directed learning (SDL) (Hew, et al., 2016; Knowles, 1975) as the pedagogy of choice, and (ii) interdisciplinary integration as the preferred model of school-based STEM curriculum design. Interdisciplinary STEM units should contain intended learning outcomes related to learning elements from STEM related subjects (EDB, 2016a). Scientific investigation and engineering design process were introduced to teachers as forms of disciplinary practice that teachers could use to model their design of STEM curriculum units around authentic problems/scenarios that provide SDL learning experiences involving different disciplinary elements for learners to engage in.

Sampling, Data source and analysis

This study focused on teacher learning in the first year of phase 2 in the STEM innovation project series. Of the 32 participating schools in that year, we selected 10 teachers from the five schools for which the first author of this paper served as the project consultant. The backgrounds of these teachers are shown in Table 1.

The analysis was guided by the four key components of AfL at different levels. Transcriptions of year-end principal and teacher interviews were coded based on the AfL framework. The investigation of the AfL components for individuals and their practices were supplemented and triangulated by other data sources, including audio records of co-planning meetings, transcriptions of debriefing meetings after lesson observations, teachers' project participation data, and individual school reports. These records facilitated the examination of the focus of interactions in different kinds of AfL experienced by individual teachers. Advances in teachers' practices were analyzed based on the SDL processes (Hew, et al., 2016) and the interdisciplinary elements in STEM (EDB, 2016a). Checklist matrices and contrast tables (Miles, et al., 2020) were constructed respectively for exploring and comparing the teachers' practices as well as the key AfL subcomponents they experienced.

Table 1

Case schools and teachers selected from the second phase of the partnership project

Sector	Secondary school sector				Primary school sector					
Schools	A		D		X		Y		Z	
Teachers	A1	A2	D1	D2	X1	X2	Y1	Y2	Z1	Z2
Teacher's network experience	2	1	2	0	1	0	2	0	0	0

Findings and discussion

Different sets of architectures for learning (AfL) among teachers

To answer the first question about the AfL experienced by individual teachers, we identified and summarized in Table 2 key AfL subcomponents under each of the four AfL components at the network, school and teacher levels experienced by each teacher. The results show that even teacher implementers working within the same school experienced different distribution profiles of AfL. Teachers' participation at the network level interaction mechanisms such as *workshops* and *open class* differed due to school level implementation strategies. There were also differences in AfL sub-components in relation to organizational structures at the school level such as the *laboratory technical team* and *e-learning team*. Only some teachers (A1, D1, X1 and Y1) had access to interaction mechanisms (discussing or reporting) to inform the school administration or the principal about the project progress because of their leadership roles in their schools. There were other self-initiated interaction mechanisms such as *co-teaching* arrangement in school A and emerging *internal COLO ((*COplanning, Lesson Observation & debriefing) *cycles* for improving STEM lessons among teachers in schools A, X and Z. Wenger's (1998) duality of the designed and emergent learning architectures was observed. Such duality can exist when learners are given autonomy to co-design their learning environments.

Variations among teachers because of different sets of learning foci

 © ISLS

For the second research question, the study found that the AfL available to teachers can affect their learning by shaping their contextual learning focus. Three major types of foci were classified with reference to working foci in the school environment for evaluating school performance (EDB, 2016b): (i) learning and teaching (L&T); (ii) management and organization (M&O); and (iii) technical issues (Tech). As shown in Table 2, all teachers were exposed to AfL with an L&T focus. However, only teachers with certain types of leadership roles, such as being a project coordinator or an e-learning team coordinator, would be involved in AfL with contextual learning focus on M&O. Different profiles of AfL with different contextual learning foci explains why even teachers in the same school could demonstrate different intentional learning orientations. For example, A1, with an additional focus on M&O, could orient his learning also at the leadership level, thinking about how to create conditions for teacher learning such as co-teaching and lesson study as well as scaling up cross-subject collaboration, while A2 was only concerned with his own improvement of pedagogical innovation and new understanding of STEM education in the post interview. Similar patterns were found in the comparison between X1 and X2, and between D1 and D2.

Table 2

Architecture for learning and contextual foci of interactions experienced by teachers

Level	AfL subcomponents	A1	A2	D1	D2	X1	X2	Y1	Y2	Z1	Z2
Network level *cross unit*	*-Monthly PD workshops*	58%	25%	17%	8%	83%	75%	58%	75%	33%	58%
	-Other Open classroom		L&T	L&T		L&T			L&T		L&T
School level *within unit/ cross unit*	Lab Technical team	Tech	Tech	Tech	Tech						
	E-learning team	M&O	Tech					Tech	Tech	Tech	Tech

Note: L&T= Learning & Teaching; M&O = Management & Organization; Tech = Technical issues; CO = Coplan; LO= Lesson Observation; COLO= COplanning, Lesson Observation & debriefing

Variations among teachers because of innovation experience and their roles

Individual characteristics like types of leadership roles and prior innovation experience affect learning orientation (Opfer & Pedder, 2011) as well as the impact of AfL on teacher learning outcomes. As mentioned, experienced teachers, A1, D1 and X1, with leadership roles in a cross-subject project team had to take on additional M&O related learning foci. These teachers were able to demonstrate their learning outcomes in facilitating professional development of their colleagues and sustaining cross-subject collaboration. Another experienced teacher Y1 was with M&O related foci, but in a single-subject project team and not given any leadership role for steering cross-subject collaboration in the project. She showed her learning outcomes mainly in terms of designing integrated STEM curriculum units instead. Compared with experienced project teachers, the impact of contextual learning focus of L&T on novice teachers' learning outcomes is more obvious in terms of SDL pedagogical innovation. Particularly, learning trajectories of novice teachers from new network schools were more salient in terms of SDL pedagogical innovation. The two novice teachers, Z1 and Z2, from a new network school demonstrated the biggest changes in their classroom practices. In the first COLO cycle, Z1, Z2 and their other team members learned how

not to follow the canned approach in textbooks and let students plan for their investigation as informed by the operational framework of the SDL processes. However, in this first cycle, school Z teachers did not give opportunities for students to revise their methods of investigation. Students were given to accepting a pre-set conclusion irrespective of their results. Compared with the other four schools with experienced teachers, the SDL opportunity provided to students and the extent of STEM integration in school Z was the least. In the second cycle, they improved the SDL opportunities and STEM integration for students. They brought in practices of engineering design process and let students plan, create, evaluate, analyze data, and revise their prototypes. Students were able to exercise more self-direction with greater use of e-learning platform. The *inexperience* of Z1 and Z2 amplified the impact of the L&T focused AfL on their improvement of SDL practices.

Conclusion and implications

This study shows that AfL available to different teachers within the same innovation network may vary across schools, as well as across roles within the same school. The AfL available to teachers can affect teacher learning outcomes by shaping intentional learning orientations. The influence of AfL on learning outcomes is complicated by individual characteristics like types of leadership roles and innovation experience. This could have implications for personalized designs for teacher learning in innovation networks customized for experienced and novice teachers in different school contexts to advance the sustainability and scalability of curriculum and pedagogical innovations. The present study is limited in scope not only in terms of the number of teachers and schools involved, but also that it is limited to the study of only one innovation network with a focus on STEM innovation. Further research is needed to develop more nuanced understanding of how teacher learning is influenced by the interactions between AfL at different levels and the teachers' individual characteristics.

Abstract: This paper reports on a study of nine middle-grades mathematics teachers' interpretations of a novel representation of practice that featured students' perceptions of the classroom learning environment for a given lesson. Based on a sequential qualitative analysis of interview data, we found that teachers' interpretations of students' perceptions (1) tended to open opportunities for future inquiry about instructional decisions and (2) provided insight into teachers' current pedagogical commitments, specifically their current instructional visions and views of the students' capabilities. Implications for professional learning are discussed.

Introduction

In ambitious and equitable mathematics teaching, instructional decisions are centrally shaped by students' current understandings and experiences in the classroom (Franke et al., 2007). Representations of practice, such as student work samples, video-records of instruction, and narratives about teaching play a critical role in providing teachers with windows into students' current reasoning, and in prompting analysis of the relationship between instructional decisions and the understandings students develop (e.g., Ball & Cohen, 1999; Kazemi & Franke, 2004). In this study, we explore teachers' interpretations of a novel representation of practice intended to support generative inquiry: brief, student-facing surveys that elicit *students' perceptions of key aspects of the mathematics classroom learning environment* that research suggests matter for students' learning and mathematical identities (Jackson et al. in press). Specifically, we examine how nine middle-grades mathematics teachers' interpretations of their students' perceptions opened, and, in some cases, closed opportunities for future inquiry into instruction (Little, 2002). Furthermore, we explore how a focus on students' perceptions of the classroom learning environment provides insight into teachers' pedagogical commitments (Erickson, 2011), which is especially valuable for professional development design and facilitation.

Theoretical concepts

Although constructing and investigating representations of practice appears to be necessary to engaging in analysis of teaching, doing so does not guarantee generative inquiry (Horn, 2020). An important distinction concerns whether teachers' interpretations open or close teachers' opportunities for future inquiry about instructional decisions (Little, 2002). *Openings* are characterized by teachers posing questions (van Es & Sherin, 2021) or offering tentative or multiple, possibly "conflicting" explanations of an observation's meaning (Mason, 2011). Conversely, *closings* are characterized by "explaining away" evidence that could have otherwise been used to raise important questions (p. 40). Once an opening has been established, another critical distinction concerns whether and how teachers investigate relationships among the three vertices of the instructional triangle: teacher, students, and content (e.g., mathematics). "The extent to which [teachers consider] issues of teaching, students, and mathematics as independent or interdependent aspects of instruction" distinguishes the potential of teacher inquiry to support the development of ambitious teaching (Horn, 2020, p. 329).

While the surveys were designed to enable inquiry into instruction, how they function is an empirical question. This is because making sense of a representation of practice is necessarily an interpretive act (Coburn & Turner, 2012). On the basis of existing literature, we conjectured that mathematics teachers' *pedagogical commitments* (Erickson, 2011), including their *instructional visions* (Munter et al., 2015) and their *perspectives on their students' current capabilities* (e.g., Horn, 2007; Jackson et al., 2017), would shape how they interpreted students' perceptions of the classroom learning environment.

Methods

This study was guided by the following research questions: (1) How, if at all, do teachers' interpretations of students' perceptions of the classroom learning environment open or close possibilities for inquiry? (2) How do

 © ISLS

teachers' interpretations provide insight into their current pedagogical commitments?

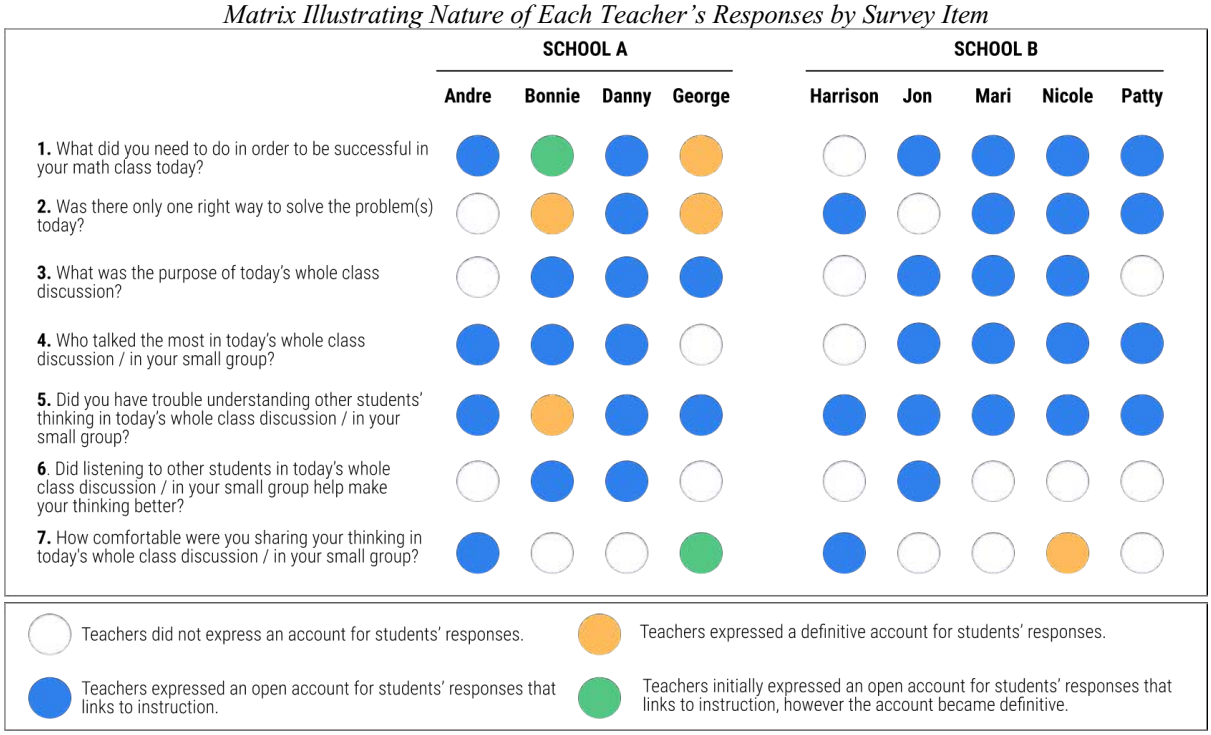
In the 2017-2018 and 2018-2019 school years, the first two authors and other members of the research team spent extensive time in nine middle-grades mathematics teachers' classrooms (located in two schools in one district) to understand the value and challenges of using the surveys in instructional improvement efforts. The primary data source for this analysis is one approximately 45-minute interview with each of the teachers, in which the teacher made sense of students' survey responses from a lesson they had either taught that day or the prior day. Secondary data sources include another 45-minute introductory interview, in which we directly asked about teachers' current pedagogical commitments, and field notes from classroom observations. Analysis took place in four phases: (1) an inductive, descriptive analysis of the sensemaking interviews in which we iteratively developed a coding scheme to characterize each teacher's interpretations of students' responses; (2) a finer-grained analysis of teachers' interpretations, in which we applied codes for whether teachers interpretations of students' responses to each item opened and/or closed opportunities for future inquiry (see Figure 1); (3) an analysis of how pedagogical commitments were expressed in teachers' interpretations; and (4) triangulation of the pedagogical commitments made visible in the sensemaking interviews with additional data sources.

Teachers' interpretations of students' perceptions of the learning environment

Figure 1 provides an overview of our assessments of each teacher's interpretation of students' responses to each of the survey items, in terms of opening or closing opportunities for future inquiry.

Figure 1

Matrix Illustrating Nature of Each Teacher's Responses by Survey Item



As illustrated in Figure 1, overall, teachers' interpretations of their students' perceptions of the classroom learning environment tended to open opportunities for future inquiry into issues of instruction. However, there were seven instances in which teachers provided definitive accounts that "explained away" students' responses to the survey item, and ultimately closed possibilities for future inquiry. Regardless of whether teachers' interpretations opened or closed possibilities for future inquiry, their interpretations provided insight into their then-current pedagogical commitments. To substantiate these claims, given space limitations, we briefly discuss three teachers' interpretations (Mari, Jon, and George), who represent a range of pedagogical commitments.

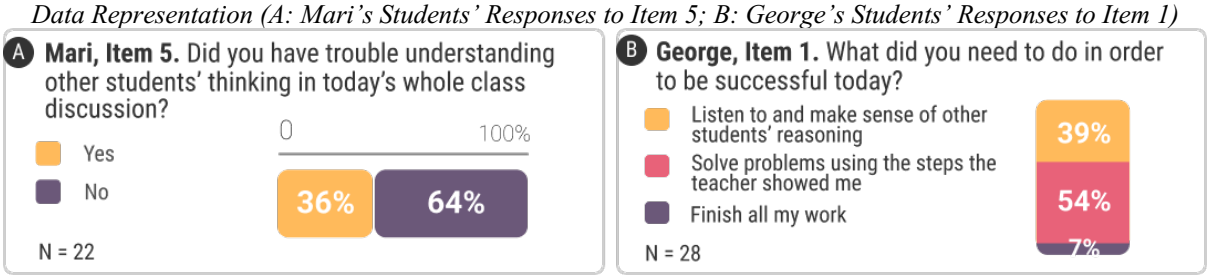
Mari, a second-year teacher, gave the survey to a class of sixth graders after their discussion of a number talk focused on whole-number division. As evidenced in Figure 1, Mari's interpretations consistently provided openings for future inquiry. For example, in response to Item 5 (see Figure 2a), in which eight students indicated they had trouble understanding their group members' explanations, and 14 chose no, Mari reflected on her role in supporting students to understand one another's ideas: "When kids explain themselves and I see that someone

 © ISLS

doesn't understand I really try to be like, 'Can someone else explain?' or, 'You might need to say it louder,' so they know that they have to understand each other." She also commented on the importance of the classroom environment in relation to students' willingness to share ideas: "I don't think [discussion] would work if they didn't feel safe." In Mari's interpretations, we consistently found evidence of her commitment to a *dialogic vision of instruction* (Munter et al., 2015). For example, she voiced her intent to use discourse to support students' understanding ("they have to understand each other"). Further, her interpretations suggested that she was actively considering her role in supporting students' understanding of one another's ideas ("I really try to be like: 'Can someone else explain?'"). Mari's interpretations were consistent with how she described her commitments in interviews and what we observed in her classroom instruction.

Figure 2

Data Representation (A: Mari's Students' Responses to Item 5; B: George's Students' Responses to Item 1)



Jon was in his first year of teaching in a general education setting after 16 years as a paraeducator. He administered the survey to a class of eighth graders after discussion of a task focused on factoring polynomials. Like Mari, Jon's interpretations consistently provided openings for future inquiry into instruction. Different from Mari, Jon's interpretations provided insight into how his instructional vision was in *transition*, reflecting both aspects of direct and dialogic visions. For example, when interpreting students' responses to item 2, "Was there only one right way to solve the problems today?" Jon was intrigued by the fact that half said yes and half said no. Jon indicated that he was focused on providing students steps to follow in his lesson on factoring polynomials ("I'm looking at the overall picture of there's only one way to factor polynomials"). However, he also said, "That would be interesting to hear [students'] thoughts and if they come up with a different way." Indications of Jon's transitioning instructional vision was consistent with what he expressed in interviews and classroom observations. Jon's responses also highlighted his view that students' perspectives are reasonable and worth learning from.

George had been teaching mathematics for 15 years and gave the survey to a class of eighth graders after a discussion of common errors on a recent end-of-unit assessment. As shown in Figure 1, different from Mari and Jon, George's interpretations of students' perceptions both *opened* and *closed* opportunities for inquiry into instruction. We found that, overall, his interpretations reflected a deficit perspective of his students' capabilities. Further, while he indicated that he aspired to a dialogic vision of instruction, his assumptions about his students resulted in him enacting a direct vision of instruction. For example, consider George's interpretation of students' responses to Item 1, "What did you need to do in order to be successful today?" (see Figure 2b). George focused on the students who chose "solve problems using the steps the teacher showed me" (15 students) and "finish all my work" (two students): "…it's what they're accustomed to. Whenever we give them work that they have to talk to each other and reason things out, it takes them so long to do it … they get so easily distracted." He next identified a few students in the class who he suggested would engage in reasoning, and then characterized "the rest of them": "they want to be spoon-fed." He elaborated: "That's what I'm trying to get away from, but maybe I'll do it next year, because it didn't happen this year." Different from Mari and Jon, George's interpretation closed off possibilities for future inquiry into instruction. From George's perspective, the students' responses reflected their current dispositions and traits – students who "want to be spoon-fed" and the few exceptions who "try to figure it out." Here, George also indicated that in response to these perceived traits of the students, he enacted a pedagogy of direct instruction, which was consistent with what he shared in his introductory interview.

Discussion and conclusion

In this paper, we reported on an exploration of teachers' interpretations of a novel representation of practice that features *students' perceptions of key aspects of the mathematics classroom learning environment*. It is rare to bring students' perceptions to bear in making sense of instruction in professional learning, yet this exploratory study suggests the potential value in doing so (alongside evidence of student reasoning) for two reasons. First, we found that, overall, these teachers tended to interpret their students' perceptions in ways that opened possibilities for future inquiry into instruction. Second, teachers' interpretations of their students' perceptions often provided

 © ISLS

insight into their then-current pedagogical commitments, specifically their instructional aspirations and perspectives of their students' capabilities. Teachers' pedagogical commitments shape what teachers do in their classrooms and how they engage in professional learning; however, their commitments often remain out of view in professional learning (Horn, 2020). The incorporation of students' perceptions of the classroom learning environment could help surface and make instructional aspirations and views of students explicit objects of inquiry in professional learning. That said, interpreting a representation of practice can result in the reification of unproductive commitments regarding teaching and students (Little, 2003). This could very well be the case with George. Cases like George's suggest the importance of supporting professional development facilitators to learn how to respond productively to the insights gained into teachers' commitments.

A limitation of this analysis is that the sensemaking interviews took place with researchers, outside of a formal professional learning context. Future research will involve investigations of the use of surveys in professional learning, including when and how to introduce the tool, given teachers' current commitments and goals, and how to respond to a range of interpretations in ways that are supportive to teachers as learners. Of course, teachers' commitments do not develop in a vacuum; they are shaped, in part, by the discourses that circulate about teaching and students in the workplace, administrative expectations, and norms of interaction (Little, 2003). We will therefore also attend to features of the organizational context that undoubtedly shape how teachers interpret students' perceptions.

Applying Deweyan Perspective of Inquiry to Teaching Experimentation Using Simulation

Gey-Hong Gweon, Physics Front LLC, Sam@physicsfront.com
Hee-Sun Lee, The Concord Consortium, hlee@concord.org

Abstract: We investigated whether and how learning of experimental inquiry can be facilitated with computer simulations. As a theoretical framework, we built upon Dewey's concept of the continuum of inquiry and identified three types of requisite knowledge that provide support for, and evolve with, experimental inquiry. Preliminary findings from two teachers' classrooms indicate that teacher framing styles identified in the classroom discourse may be a factor in explaining contrasting student experimentation behaviors.

Introduction

The current vision for science education calls for engaging students in science practices so that they can learn how to *do* science, not just learn the end products of science, thereby being able to understand how scientific knowledge is developed (National Research Council [NRC], 2012). The pivotal role that experimentation has played for the development of scientific knowledge, especially in physical sciences, is well described in the philosophy of science (Hempel, 1966). Hence, an important aspect of physical science learning has to do with experimental inquiry, which is carried out by asking an investigative question, making hypotheses, collecting, and analyzing data, formulating explanations and conclusions based on evidence, and communicating findings (NRC, 1996).

As the emphasis on learning scientific content through science practices has grown in recent years (NRC, 2012), the need for reconceptualizing the practice of planning and carrying out investigations has increased (Manz, Lehrer, & Schauble, 2020). We found Dewey's concept (Dewey, 1938) of the *continuum of inquiry* useful in building a theoretical foundation for experimental inquiry. Inquiry process seeks to obtain a warrantable assertion (knowledge *objective*) while building on and making use of knowledge *resources* available. Inquiry is dynamic not just in the trivial sense that the knowledge objective is formulated over time but also in the nontrivial sense that knowledge resources go through concomitant re-examinations and temporal modifications. In turn, the knowledge attained at the conclusion of the inquiry can act as a resource for a new inquiry and will go through its own dynamic update. In this continuum of inquiry, no knowledge, even that of logic, can be absolutely taken for granted; there is only *the self-corrective process of inquiry* whose conclusions approximate the truth *in the long run*. Applied to students' experimental inquiry, this dynamic nature of inquiry requires students to adapt their conceptual and practical resources by constantly responding to new experiences. The resources include, as we discuss below, three types of knowledge: what students understand about the phenomenon under study (science *content*), what students know about how to conduct scientific experiments (*method*, logic of inquiry), and how students interact with the external world entities (*materials*) such as the physical setups with which to create a scientific phenomenon, measurement tools, and software to collect, simulate, or analyze data.

Scientific experimentation can be used to confirm an existing theory in the form of hypothesis testing or to discover patterns in the data while a theory to explain the patterns is yet fully developed (Hacking, 1982). In both cases, especially for the latter, students not only need to reason between their knowledge space and the empirically obtained data space (Klahr & Dunbar, 1986) but also must productively interact with materials to obtain the data so that they can make warrantable conclusions based on the evidence (Miller et al., 2018).

In this study, we focus on scientific experimentation of a physical system based on a computer simulation. Part of interest in employing simulation-based experimentation is to take some cognitive load off from physical experimentation. Especially in a remote-learning situation, computer simulations can be valuable for the purpose of enacting experimental inquiry. Simulations are "dynamic computer models that allow users to explore the implications of manipulating or modifying parameters within them" (Honey & Hilton, 2011, p. 2). Simulations are theory-based models and capture some but not all aspects of reality being experimented. Thus, simulations act as materials through which students can gain access to a theory-laden version of the real physical world. Using the classroom videos and computer log data of two teachers' classrooms, we investigated two research questions: (1) how the teachers framed simulation-based scientific experimentation and (2) how students' experimentation patterns were impacted by the teachers' framing styles.

Theoretical framework: three legs of an experimental inquiry

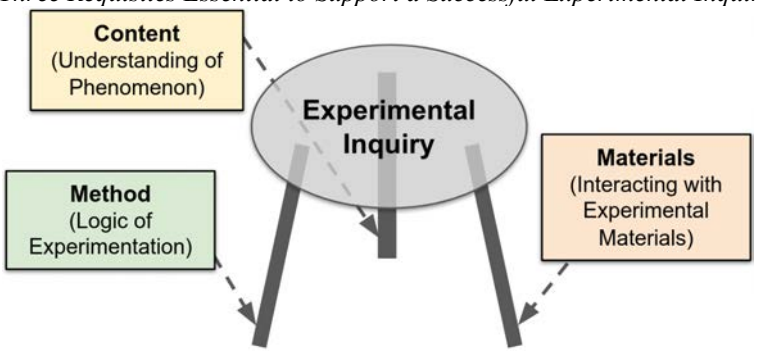
According to Dewey (1938), the outcome of a competent inquiry is a w*arranted assertion*, i.e., a piece of knowledge. In experimental inquiry, a common form of knowledge to be created would be a data-based answer

 © ISLS

to the question "Does the quantity Y depend on the quantity X, and, if so, how?" We assert that three legs of requisites as shown in Figure 1 are necessary for the completion of a competent experimental inquiry. In describing these three requisites of experimental inquiry, we shall use an example question, "Does the acceleration of the car on a ramp depend on the mass of the car?"

Figure 1

Three Requisites Essential to Support a Successful Experimental Inquiry



1. **Content**: The experimenter's scientific content knowledge of the phenomenon under investigation is a necessary element. Adequate understanding of the main science concepts and their relations is necessary not only for motivating, designing, and understanding an experiment, but also for dynamically steering the experimental inquiry in the productive direction when faced with unexpected outcomes along the way. For the above example question, the experimenter's disciplinary content knowledge must cover the kinematics of the motion (position, velocity, acceleration) and the variables of the setup that affect the motion (mass, friction, gravity, and ramp geometry).
2. **Method**: The experimenter should know how to carry out experiments towards a clearly formulated result without involving confounding variables. This required knowledge is not a type of understanding that applies to a particular experiment or a particular science domain but is *a formal and logical understanding of the practice of experimentation* typically acquired through experiences with epistemic reflections. Namely, it is understanding of scientifically valid experimental strategies to achieve the most unambiguous outcome that can identify or establish causality. For the above example question, the target strategy is control of variables (COV) (Chen & Klahr, 1999; Kuhn, 2000; Schwichow et al., 2016), where all variables (such as friction, ramp angle) are fixed other than one independent variable (mass). COV is an ideal strategy, if available, for deducing the relationship between the dependent variable and the independent variable. While outside the scope of this paper, statistical understanding of data also belongs in this category.
3. **Materials**: This category concerns interacting with the external world. The experimenter should be able to competently interact with equipment, specimen, software, and the general physical setting of the experiment to produce quality data with confidence. In the simulation-based experimentation, simulation itself becomes the material setup. Different from the method, this falls into the category of *an actual doing* of a specific experiment under a specific circumstance and concerns the knowledge necessary to recognize not just how the materials operate and how they can be controlled but also how the phenomenon under study is represented in the material setup and how measurements should be drawn from that setup.

While the three legs of support are formulated as requisite *resources* for an experimental inquiry, their characteristics are also *dynamic*, *a la* Dewey (Dewey, 1938); they are also a *result* of the inquiry in the sense that they change or grow with the inquiry process. They need not, and cannot, be in a perfect state when the inquiry begins. The experimenter's knowledge of phenomenon, method, and materials needs to be only sufficiently settled for the inquiry to begin. In Dewey's words (1938), "In scientific inquiry, the criterion of what is taken to be settled, or to be knowledge, is being *so* settled that it is available as a resource in further inquiry; not being settled in such a way as not to be subject to revision in further inquiry" (p. 8-9). This view of inquiry and knowledge is summarized by what Dewey terms as the *continuum of inquiry*: "It is the convergent and cumulative effect of continued inquiry that defines knowledge in its general meaning" (p. 8). Therefore, any one inquiry process must be viewed as an *open* process spawning further inquiries, not a process closing upon conclusion. All involved knowledge evolves through inquiry. In the symbolism of Figure 1, the inquiry process will transform the *whole* table. It will transform not only the tabletop, representing the *inquiry activity* that occurs to produce the knowledge objective ("Y vs. X"), but also the legs, the *three knowledge requisites* of the inquiry. In a classroom setting where

the experimenter is a student or a group of students, which legs of knowledge will have progressed most prominently through the inquiry may be influenced by how the lesson is structured by the teacher.

The analytical distinction among three types of requisite knowledge is valuable, but we realize that they cannot be cleanly separated in any given situation. Dewey noted (1938), without "the sensitivity to the quality of a *situation as a whole*" (p. 70; emphasis by us), an experimenter cannot avoid "two evils" (p. 70): (1) mindlessly collected data leading to nowhere and (2) prejudiced data collection forced into the predetermined conceptual and theoretical scheme. Thus, it is critical that an experimenter be situated in a holistic mixture of all three requisites. In sum, the continuum of inquiry perspective characterizes inquiry to be *open*, *dynamic*, and *holistic*.

Learning context and methods

This study examined a simulation-based experimentation activity embedded in a four-week, technology-enhanced physics module for high school students. Two participating teachers, Teacher S and Teacher J, taught the physics course to 17 and 27, respectively, ninth grade students in the Northeastern part of the US. Teacher S had 20+ years of teaching experience and held a Ph. D. in microbiology while Teacher J had 10+ years of teaching experience in physics. Teacher S's school was in the moderate to high socio-economic neighborhood while Teacher J's school was in the moderate socio-economic neighborhood. We collected and analyzed videos of the whole class as well as students working in small groups. Among the students, 48% identified as male and 48% as female; 22% had minority backgrounds; 99% spoke English as their first language; 68% used computers regularly for science learning prior to the module. The module addresses physics concepts such as displacement, velocity, and acceleration related to a car's motion on a ramp. Students carry out the sensor-based physical experimentation with a toy car on a ramp and then simulation-based experimentation. The ramp simulation allows students to vary five independent variables such as car mass, ramp angle, distance up the ramp, gravity, and friction. Students investigate how the acceleration of the car depends on one of the independent variables (of their choice).

Table 1

Summary of Different Teacher Framing of the Simulation Experimentation Activity

Three requisites		Teacher S	Teacher J
Content	Address content knowledge of velocity and acceleration	Content as a resource for experimentation	Content as the final goal of experimentation
Materials	Discuss simulation affordances	Emphasized	Emphasized
	Demonstrate how simulation works	Yes, through a student	No
	Encourage exploration	Yes	No
Method	Allow students to select an independent variable	Yes	Yes, but with constraint (by whole class)
	Allow students to experiment with other variables	Encouraged	Discouraged ("Vary only one variable!")
	Characterize the experimentation process and present the goal	- Explore the setup - Select a variable of interest and settle on COV - Take really good data - Obtain trends in data that are trustworthy	- Confirm or learn content knowledge - Use COV - Create community knowledge through each group's contribution

Results and discussions

Table 1 summarizes the major themes emerged from the video analysis. We characterize Teacher S as the supporter of individual experimental inquiry and Teacher J as the orchestrator of the whole class experimental inquiry. Teacher J emphasized the conceptual modeling (i.e., content knowledge) of the ramp system while Teacher S let students explore and experiment freely. Teacher S used content as a resource for carrying out experiments and making measurements and did not go over the content as forcefully or intentionally as Teacher J. While Teacher S's goal for experimentation was to explore the system under study and carry out investigation to collect data that was worthwhile, Teacher J's goal was to create community knowledge based on the contribution from each group. Nonetheless, the affordances of the simulation (e.g., adjustable gravity or perfectly reproducible data) were emphasized by both teachers as the simulation became the main tool of experimental inquiry. Teacher S had a balanced emphasis on all three requisites of content, method, and materials, while Teacher J over-emphasized the content requisite. Students in Teacher S's class were given ample time to get to know the materials with a holistic goal of carrying out the experiment to get "really good data eventually." In

contrast, students in Teacher J's class were urged to experiment only one single independent variable with the simulation so that each student group could contribute to the class wide discussion of the physics content. Surprisingly, in Teacher J's class, nearly half (48 %) of the log data sessions related to simulation usages showed no COV enactment (showing chaotic exploration of the independent variables) despite the fact that the COV was forcibly directed at students. In Teacher S's class, only 30 % showed such a behavior. We postulate that playing as a way of familiarizing with the material such as simulation naturally happens whether the teacher explicitly allows it or not. We further postulate that familiarizing material as a tool for inquiry was critical for students in Teach S's class to make transition from pure play for exploring the tool to productive experimentation for collecting serious data. Indeed, in Teacher S's class, more than half (52 %) of log data sessions showed evidence for "rich" COV enactment: COV behaviors mixed with other variable exploration or showing consecutive COVs with different independent variables. In contrast, only 17 % showed the rich COV in Teacher J's class. The remaining data showed a "strictly regimented" COV behavior (pure single-variable COV with no play), 35 % for Teacher J and 17 % for Teacher S.

While a potential connection between teacher framing and student experimentation patterns exists, it was not possible to tell whether there was any causal relationship between the two due to a small sample size and other student, teacher, and classroom factors that were not considered in this study. What seems to be clear, though, from the Deweyan perspective of inquiry is that Teacher S's framing was more conducive to student learning of an experimental inquiry as a dynamic whole supported by the balance among the three knowledge requisites. On the other hand, Teacher J's framing might have devalued students' engagement with the method and materials legs of inquiry, which diminished their chance to, in Dewey's sense, sensitively and productively interact with the inquiry situation as a whole.

Our results show that it *is* possible to use computer simulation in a productive way to teach important aspects of the experimentation practice. Simulations can be more effective in teaching the experimentation practice such as COV than physical setups thanks to their affordances such as the absence of noise/imperfection in physical data. However, simulations' affordances are also their weaknesses (lack of fidelity to the phenomenon under investigation), thus requiring teachers and curriculum developers to prudently mix physical experimentation with simulation experimentation to maximize student learning. Lastly, this paper focused on experimental inquiry, but the theory outlined in this paper may be applicable to other types of inquiry such as observational inquiry if each requisite knowledge is recharacterized accordingly.

Considering, Recognizing, and Valuing Culture in Afrikan Contexts

Tutaleni I. Asino, Oklahoma State University, tutaleni.asino@okstate.edu
Patricia A. Young, University of Maryland at Baltimore County, pyoung@umbc.edu

Abstract: Afrikan countries and cultures create solutions for the needs and conditions of their people, yet their contributions to technological innovations continue to be overlooked. In this paper, we argue that app developers on the Afrikan continent have been accepting educational responsibility by creating mobile applications that specifically meet the needs of the people. From a qualitative research perspective, we conduct a systematic review and cultural studies analyses to explore Afrikan innovations in mobile applications. The findings reveal that mobile developers are 1) building apps that are specific to the Afrikan context and 2) making use of existing apps and appropriating them to the Afrikan context.

Introduction

Promoting diversity, equity, and justice in educational settings cannot be accomplished without considering, recognizing, and valuing culture. Although acknowledged as a crucial component of everything about being human, the concept of culture is often abstract. This difficulty is perhaps what leads to culture, at best being understudied, misunderstood, or at worst being ignored. UNESCO defines culture as "the whole complex of distinctive spiritual, material, intellectual and emotional features that characterize a society or social group, not limited to the arts and letters, and including modes of life, the fundamental rights of the human being, value systems, traditions and beliefs" (UNESCO, 1982). For this paper, considering culture means taking into account the ways of knowing and experiencing of different learners, based on who they are and where they originate. Recognizing culture means being aware of the whole complexities of individuals, where they come from, and how their communities and experience influence their being. Valuing is consideration and recognition put into practice. In the educational context, this can mean valuing different knowledge systems in the way they want to be understood and incorporating the complexities of realities in the design of learning experiences and environments.

Afrikan countries and cultures create solutions for the needs and conditions of their people, yet their contributions to technological innovations continue to be overlooked. Worldwide 2.7 billion people use smartphones (Blair, 2020). Afrika ranks highly as one of the fastest-growing developer communities, as evidenced by contributors to GitHub, a cloud-based repository platform (Kazeem, 2019). From a qualitative research perspective, we conducted a systematic review and cultural studies analyses to explore Afrikan innovations in mobile applications.

At the core of our submission is the notion that culture is a crucial component of one's identity. Our paper explores the ways in which culture manifests in the design of mobile devices, which are common learning devices across educational settings.

Purpose

We explore mobile learning literature to demonstrate how people on the Afrikan continent are considering, recognizing, and valuing culture as they take responsibility for their localized needs by building apps within the African context or appropriating apps to fit the educational needs of their communities. Localization, in this context, means adapting content or a product to a specific locale. In this study, 'environment' is defined as extended reality (XR), which includes virtual reality (VR), augmented reality (AR), mixed reality (MR), and other XR technologies that support and enhance learning and human performance, and to provide users a better immersive experience (Truman, 2019). We refer to standalone products as those things made by man's hand, tools, or systems; products are created manifestations of human thought and ingenuity.

Theoretical framework

> "A theory as it is understood here--does not present a prediction of the results; it only suggests a particular, explicitly defined framework within which the details of a case or the data can be assessed. One must make a clear distinction between a theoretical framework and the particular case being analyzed within it. A theoretical frame presents a general viewpoint and is applicable to a number of cases, whereas the object of a study is a particular case, whose details can only be given a local explanation (Alasuutari, 1996, 376-377)."

 © ISLS

Given Alasuutari's explanation of a theory as a general viewpoint applicable to a number of cases, this research situates itself with The Culture Based Model as a theoretical framework for analyzing culture-based information and communication technologies (ICTs). Specifically, Young's Culture Based Model (2009) proposes that all ICTs are culture-based, but some are more culture-neutral (internationalized) and others more culture-specific (localized). Further, there is a much broader space in which to design. Young situates the design and analysis of technologies from a culture-based context to better understand target audiences and build technologies (Young, 2009, 2008). Similarly, this research seeks to understand the mlearning applications and the culture-based contexts in which they were built, used, or appropriated.

Method

The methodologies used in this study are twofold and represent those mostly cited across interdisciplinary fields for systematic reviews and cultural studies. The entire study is grounded in the qualitative research method of cultural studies that suggest "reality and social life are always and essentially mediated through meanings" (Alasuutari, 1996, p. 35). Next, we conducted a systematic review consistent with the research of Petticrew and Roberts (2006) that proposes the following path to maintain internal validity:

1. clearly defined research questions;
2. the inclusion and exclusion criteria;
3. comprehensive literature review (excluded from this paper)
4. critically appraise the included studies
5. synthesize the studies and assess heterogeneity of study findings

A. Clearly defined research questions ass

Qualitative research questions inform this study. They are defined as:

1. RQ1. Was a product produced, utilized, or appropriated? If so, by whom and for what reason?
2. RQ2. In what cultural context was the product created or used?
3. RQ3. What conditions, problems, or limitations are addressed from the product's creation? What solutions manifested from the product's creation, if any?

B. The inclusion and exclusion criteria

Based on our research questions, we examined only studies that met the inclusion criteria (table 1). We discussed the research bordered on an environment's criteria, process, service, or program. However, we ultimately chose only those focused on a standalone product or environment. Although we had an inclusion criterion, we were uncertain as to what we would find. We expanded on the inclusion and exclusion criteria as we moved past 200 reviewed publications. This is consistent with qualitative research as it is a discovery of knowledge.

Table 1

Inclusion and Exclusion Criterion

Inclusion criteria	Exclusion Criteria
Must reference a product or environment	Articles that only mentioned culture or cultural in the reference list only?
Must be in a peer-reviewed journal between from January 2015 to May 2020	All articles prior to 2015 were excluded as well as books, book chapters, conference proceeding
Must be specific to mobile learning (mlearning)	All other languages
Must include a cultural aspect	Articles from the popular press (magazines, newspapers)
Standalone product or environment	Part of a Commercial suite of products or environments

We searched one of our university's library systems for academic articles using the following keywords: "Mobile learning + culture +Africa," "Mobile learning +Cultural, +Africa" "Mobile learning + international +Africa," and "Mobile learning + localization +Africa." The choice to use a university library system search was informed by the idea that such a system included academic databases such as EBSCO, PsycINFO, Academic Search Premier, ProQuest, Scopus, Google Scholar, JSTOR, PubMed, PsycARTICLES, or Science Direct, etc. The results are presented in Table 2. The search parameters were limited to 2015 to 2020, representing five years from the year our paper was authored.

Table 2
Search Results

Search Term	Results
Mobile learning + culture + Africa	185
Mobile learning +Cultural + Africa	203
Mobile learning + international + Africa	348
Mobile learning + localization + Africa	10
Total number of abstracts	746

Next, we divided up the 746 amongst the three authors. Then, we reviewed manuscripts based on the inclusion and exclusion criteria. We documented our findings on an excel sheet and weekly discussed our progress. For the borderline articles, meaning they may have, for example, developed a temporary web-based tool, we discussed whether those articles should be included or excluded. This was a 3-month process. The comprehensive literature review yielded 746 self-contained articles under the four categories in table 2. A total of 31 articles matched the inclusion criteria; therefore, we reviewed those articles based on the research questions.

Critically appraise the included studies

Critically appraising the information means assessing the original data, and many times this information is limited (Petticrew & Roberts, 2006). We have not altered any findings, results, or conclusions as we did not use these as part of our analysis. Our critical appraisal is finite and specific to the product or environment and needs or conditions.

Synthesize the studies and assess heterogeneity of study findings

This review considers "social heterogeneity" that incorporates sociodemographic differences, historical differences, cultural differences, and other differences across the research (Petticrew & Roberts, 2006). These cultural differences may affect the impact and delivery of the review. Specifically, our reviews are aligned with the research questions. This means that only certain information was extracted from the literature per the research questions. Other information like the findings and results are discarded, not because the study is unimportant, but because this study focuses on the cultural context that surrounds the development of the product or environment.

Data sources

The PRISMA (figure 1) flow diagram for the literature review provides an overview of the processes. It goes from the included (inclusion and exclusion criteria), eligibility (initial review of the literature 746), screening (critically appraise the included studies), and identification process (synthesize the studies and assess heterogeneity of study findings (Moher et al., 2009).

Results

Worldwide 2.7 billion people use smartphones (Blair, 2020). Afrika ranks highly as one of the fastest-growing developer communities, as evidenced by contributors to GitHub, a cloud-based repository platform (Kazeem, 2019). Mobile devices, specifically mobile phones, remain the most widely used technology on the Afrikan continent. Preliminary findings of the research indicate that scholars and app developers are accepting educational responsibility through building technologies in Afrikan cultures in two ways: 1) developing mobile apps that are specific to the context and 2) making use of already existing apps and appropriating them to the Afrikan context. There are a growing number of mobile applications that have been designed by and for Afrikan contexts. Some of these in-house mobile applications remain local to the country and the contexts (e.g., Mixit).

Others continue to use existing Apps such as Whatsapp to fit their educational context. This use is consistent with early thoughts on mLearning that recognised the importance of the mobile phone as a personal device. The importance was not on what was being created by educators for learning, but rather on the apps that were already on the device, which people were using in their everyday life that was not being repurposed for learning.

While there are multiple ongoing software and mobile app development projects around the Afrikan continent, much of these data are not published in academic journals. When it is published, it is through online news outlets, articles, and software development forums. Hence, it is impossible to entirely capture low-key outlets describing how products are produced, utilised, or appropriated.

Significance of the study

Hence if learning sciences research desires to address and disrupt such inequities that are interconnected with diversity, equity, and social justice, as noted in the call, perhaps one of the components is to become more aware of how culture is considered, recognized, and valued in educational settings and in tools for learning. The research in Afrikan contexts is growing, and there is much to learn. Afrikan mobile developers and their localized mobile applications are on the rise. This is significant as the contributions of indigenous cultures to educational technology and beyond is history in the making. As a society with limited human resources, the United States, in particular, will be poised to seek Afrikans to fulfill the growing technological needs and conditions of the present and future generations.

Abstract: Teachers adapt science curriculum materials in planned and unplanned ways to address a variety of goals. This professional learning design seeks to support 18 elementary science teachers in biweekly professional learning (PL) sessions during COVID 19. They discuss and share their own adaptations for enhancing opportunities for productive disciplinary engagement and equity by collaboratively analyzing one another's teaching artifacts. Findings from transcribed interviews, PLs, and video of teaching are synthesized toward five adaptation principles.

Studies show that science teachers can make use of teacher-facing materials to guide their teaching decisions and the sequence of learning activities. At the same time, teachers make in-the-moment decisions to adapt those materials and learning contexts. Teachers adapt lessons to scaffold student learning, differentiate instruction, and respond to student ideas and questions (Drake & Sherin, 2006). When teachers do not adapt curriculum by responding to students' questions and ideas, they may miss opportunities to foster an equity-centered environment that makes available cultural and linguistic intellectual resources. Similarly, teachers can use in-the-moment feedback from students to make lessons more cognitively engaging for students (Chi, et al., 2018), such as fostering students' shared construction of new ideas. Little is known about how to support teachers to make principled decisions related to project-based learning (PBL) and adaptive practices that move toward goals for equitable practices and productive disciplinary engagement in science.

PBL's student-centered instructional approach presents a framework in which students generate artifacts that can take the form of actions (i.e., short play, social action) or physical objects (i.e., bird feeder, drawn model) to collaborate using disciplinary practices in engaging learning environments. The features of PBL include meaningful driving questions, collaboration, extended projects, orientation to standards-based goals, and community connection. Research suggests that positive results can be traced to fidelity to the PBL features, which is the degree to which teachers support meaningful questions and collaboration, shift to a student-centered approach, and create authentic experiences (Grossman, et al., 2021).

Our collaborative professional learning (PL) design (Swan, et al., 2014) responded to the challenges of maintaining the integrity of PBL during virtual contexts, created by the urgency to adapt instruction. Teachers needed to address the learning goals of the designed PBL units but also adapt the lessons to foster engagement and equitable access, participation, and outcomes for learning. To this end, we welcomed adaptations as part of robust teaching and learning. The PLs were based on co-creation, leveraging, and reflecting on adaptations among communities of teachers and researchers. Hence, our PL design adhered to three commitments: 1) PBL features; 2) positioning teachers as experts; and 3) productive adaptive practices that support equity and engagement. During the PLs, all partners - teachers, researchers, and curriculum designers - shared their knowledge and expertise. The study offers insight into PBL environments and highlights adaptation potential for enhancing engagement and equity.

Theoretical foundations

We build on the theory of principled adaptations (Potvin, et al, 2021), in which the change in lesson enactment from the lesson-as-written deepens the PBL learning trajectory. We use affordance to describe opportunities for action for learning (van Lier, 2008), and how a lesson feature can be adapted for specific purposes in situ. In this view, every PBL feature presents myriad opportunities for learning, and so adaptation is the mobilization of a particular opportunity that can be realized. The context, including aspects of the environment, participants, and teachers' instructional goals, determines the selection of a particular affordance of a feature. For example, a teacher may select

 © ISLS

among affordances of the feature "artifact development." Affordances include the opportunity for informal assessment, making a physical representation of thinking, or support for comparison of ideas across student groups. Teachers can be supported to adapt PBL lessons in ways that are principled, meet learning goals, and ultimately lead to increased engagement of students, including students from groups underrepresented in science.

Student engagement and equity describe processes and outcomes for learning in a PBL classroom. Student engagement is a multidimensional, dynamic interplay among individuals' academic, cognitive, and social involvement in specific activities (Fredricks, et al., 2004). Chi and colleagues' (2018) ICAP framework describes engagement as "*pragmatically based on the absence or presence of overt, observable behaviors, as well as whether the products contain information that went beyond the instructional materials* (p.1791)." According to this framing, other latent forms of engagement may be present, but as teachers can only respond to observable forms of engagement, this definition renders it productive for classroom use. Observed evidence of engagement includes students exhibiting behaviors such as using disciplinary ideas and practices to gather evidence and construct new understandings, productive manipulation of materials, and interaction with others to solve problems.

Equity in PBL classrooms is conceptualized as processes of access, participation, and outcomes of students from groups that are underrepresented in STEM, and advocacy for the inclusion of all students in the classroom (Tzou, et al. 2010). In this manuscript, we focus on the observable behaviors, interactions, and resources in the classroom that support equitable participation and engagement in science practices. For example, evidence of equity might be a teacher providing opportunities for students to utilize home and community resources and interactions where underrepresented students position themselves as knowers and doers of science (Miller, et al, 2021).

This study sought to develop a set of guiding principles that could inform teachers' adaptation of PBL features in ways that enhance equity and engagement of students during COVID-19, with the purpose of extending these supports for adaptation in non-COVID-19 contexts. Figure 1 shows the conjecture map that frames the research study. Within this design-based study we ask: *What principles can guide adaptation of the features of PBL to foster equity-centeredness and student engagement?*

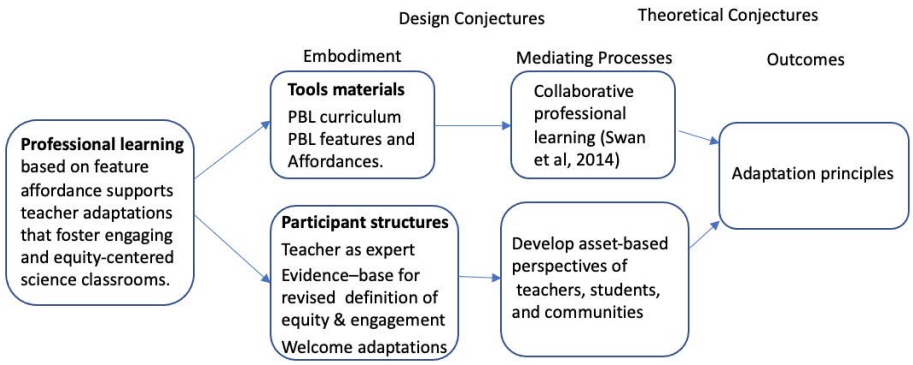

Figure 1
Conjecture Map detailing the mediating processes and outcomes for high-level conjecture

Methodology and data analysis

This research project is in the context of Multiple Literacies in Project-based Learning (ML-PBL; Miller & Krajcik, 2019), a 3rd-5th-grade coherent interdisciplinary curriculum system for meeting the science standards in the USA, designed for face-to-face contexts. Participating teachers (n=18) taught grades 3-5 across two great lakes states and represented schools from a variety of regions, economies, and student demographics. During the study, in 2020-2021, schools shifted among fully virtual, face-to-face, and hybrid formats of instruction. Teachers participated in 14 PLs designed to forward three foundational constructs: 1) Deepening enactment and reflective practices of PBL; 2) Positioning teachers as experts, with collaboration among teachers and researchers as critical agents of learning; and 3) Creation of productive adaptive practices, meaning that researchers encouraged teachers' adaptations (planned, enacted, and reflected on) in the service of collectively realizing goals for learning.

The collected data included transcribed teacher interviews (n= 36), video-taped observations and field notes of classroom teaching (n=154), and transcribed teacher PL sessions (n=14). Teacher interviews were semi-structured

and conducted three times across the school year (beginning, middle and culmination of the academic year). The biweekly, 2 hour, PL meetings, had three parts: 1) Teachers presented artifacts from prior adaptation to interrogate and refine the groups' definition of equity and engagement; 2) They reflected on PBL features and their affordances; 3) They co-planned adaptations that would foster engagement and equity.

ML-PBL adaptation principles were designed through investigation of instances of student productive disciplinary engagement and equity processes, and related lesson events. Coding across data employed thematic analysis using grounded coding (i.e., characterizing instances of criticality, accessing student intellectual resources) and a priori coding (i.e., PBL features, ICAP Framework). After identifying preliminary equity and engagement instances in classroom videos, we generated codes and then looked across classrooms and similar contexts to reach consensus. Next, we characterized the teacher adaptations and related factors that may have contributed to those processes. As some adaptation codes and features became salient for repeated and pronounced associations with equity and engagement, agreed-upon themes were created and then triangulated with the PL transcription and teacher interviews to seek confirmatory and disconformity evidence. In disconfirmatory cases, the team returned to the original example to better understand the event; in confirmatory cases, themes were further supported.

Findings

Findings from the project include five adaptation principles that can be used to enhance equity and engagement: Adapt features to 1) bring in and leverage students' identities and intellectual resources from home; 2) provide student-centered choice; 3) elicit different ideas and diverse perspectives about the same event; 4) make use of different modalities; 5) disrupt the traditional classroom structures. The adaptation principles can guide the adaptation of PBL to support equitable science learning opportunities and student engagement. We expand on the first adaptation principle with evidence from videotaped observations, transcription of PLs, and teacher interviews related to enactment in the science classroom.

Adaptation Principle 1: Adapt features to bring in and leverage students' identities and intellectual resources from home. Using and leveraging students' identities and intellectual resources from home or community is actionable and can be used to guide adaptations. Equity and engagement were associated with instances in which the teacher created investigations that foster students' intellectual and home resources.

Observation video notes

A 5th grade Latine student brought her sister outside their home to investigate shadows. They brought their virtual classroom with them as they figured out how shadows work in their backyard. During the lesson, other students commented in the chat, asking their peer to explore the stretched shape of the shadow.

The lesson called for students to generate questions as they explored shadows as a group in the schoolyard, which was impossible during distance learning. However, the adaptation of including the local place and family corresponded with observable evidence of equity and engagement. Students added new ideas for exploration in the chat, evidence of constructive engagement, and the student and sister from a group traditionally marginalized in STEM, became positioned as experts, adding cultural intellectual resources and family engagement. Related adaptations implemented in a third-grade unit involved a teacher asking students to collect and use home-based recycled material to investigate forces in front of the camera, instead of using teacher-provided identical materials.

Interview transcript

T: "This time I switched it up a little bit. I thought if it's about making toys, we're going to have to use what the kids already have at home.... So, they came up with some really good and interesting ideas. One student made a paper airplane with a face mask that had stretchy bands. ...then he talked about the multiple forces involved. Even though it wasn't following the lesson plans, the students were able to get the science concepts."

In this example, students created new designs and added their thinking to explain the forces involved with motion of the toy, which corresponds to evidence of constructive disciplinary engagement. Additionally, the student in this example is an immigrant from Gambia, and labeled ELL, a member of a group underrepresented in STEM.

Further triangulation confirmed this theme. During one PL, a 4th-grade teacher shared a way she had adapted the Energy unit. She adapted the feature of driving questions to bring in local events and community connections. Later, other teachers tried this idea in their classrooms and corroborated the value of this adaptation.

PL transcribed

"And so we watched the videos of the mills, and we watched the video of the homemade water wheel. And then we have a water wheel in town, that's not too far from my school and I went there and took a video of that water wheel and me. Yeah, so I think they really understand water wheels, they really enjoy it, they understand how the energy transfers from the water to the wheel."

This 4th-grade teacher went on to describe how the adaptation to a place-based context enabled students to draw from experiences in their community from which to build understandings. This practice enables equitable processes for learning by allowing students to use local knowledge. The teacher reported that the class participated in discourse to use the experience in their artifact design, observable evidence for interactive engagement.

Conclusion and Discussion

Teachers, when supported with collaborative professional learning design, can adapt lessons based on feature affordance, and maintain the coherence of the unit and learning trajectory. By focusing on features of PBL and their affordances for student engagement and equity, teachers were able to create principled adaptations that deepened teacher expertise and student learning. Thus, we add to the field's understanding of the benefits of welcoming teacher-driven adaptations that adhere to principles of learning environment design, while elevating the singular expertise that teachers can offer researchers.

This study provided a set of five adaptation principles that can be expanded and further iterated in face-to-face and cross-disciplinary settings. Further research is needed to investigate how principles can be introduced to teachers to promote sustained disciplinary learning on the part of students and promote shifts in practices for teachers. Additionally, teachers in this study were responding to extraordinary circumstances. More research is needed to understand how teachers might develop and utilize principled adaptations in business-as-usual learning contexts. Furthermore, research is needed to investigate whether use of adaptation principles can strengthen the main tenets of PBL and translate to student learning outcomes.

Crafting Paper Circuits: Gendered Materials for Circuitry Learning

Joey Huang, Ariel Han, Mishael Sedas, Kimberly Telfer-Radzat, Kylie Peppler

University of California, Irvine

Abstract: Given the persistent issues of equity in technology-rich fields, this study argues that our choice of tools and materials significantly impacts both what is possible to be learned as well as who participates. This study examined students' learning of basic circuitry concepts through the use of paper circuitry toolkits in art-based activities. The data was collected in a 4-day workshop for middle school students (N=17). Findings showed that arts integration promoted the creation of paper circuits that leads to artistic exploration into STEM engagement. Pre- and post-tests results showed improvement for students by gender. Although the boys outperformed the girls on paper circuits, the girls outperformed the boys on e-textiles which is considered more "feminine" than others. The findings imply the nuances between material property and gendered practice to understand how we can better design tools and materials to rupture stagnant norms around educational practices.

The persistently lopsided gender makeup of the workforce in science, technology, engineering, and math (STEM) in the U.S. (e.g., only 28% of women work in STEM related occupations) suggests that the gender gap in STEM education is still obstinately wide (Corbett, & Hill, 2015). Yet, despite several national initiatives to diversify participation in STEM fields, the underlying culture of computing and engineering education remains relatively stagnant, with curriculum, tools, and materials that continue to emphasize areas historically aligned more closely with male interests than women's (Margolis & Fisher, 2003). Furthermore, these tools and materials seem to be failing today's youth, as they are arriving at college without an understanding of the big ideas important to electronics and computing (Peppler & Glosson, 2013).

Given the persistent issues of equity in technology-rich fields (Prey & Weaver, 2013), this study argues that our choice of tools and materials significantly impacts both what is possible to be learned as well as who participates. For instance, materials and tools such as sewing with textiles are often seen as the domain of females (Beaudry, 2006), whereas actions and materials such as building electronics are often seen as the domain of males. Recent studies focus on ways to resolve lopsided gender participation in STEM fields by addressing the tools we teach with (i.e., pedagogy), what is created with them (i.e., robots vs sculptural artifacts), and what audiences can be formed around their practice (i.e., girls-only robotics clubs) (Sullivan & Bers, 2016). However, little attention is paid to the role of tools and materials as the initial drivers of these outcomes, both in terms of who participates as well as what is learned. The marginal gains in gender representation due to these prior efforts (e.g., Corbett & Hill, 2015) may start to explain a different root cause of this persistent problem.

This study is part of a larger research project that aims to examine students' learning of basic circuitry concepts (i.e., current flow, connection, and polarity) using paper circuitry in art-based activities. From its inception, *Chibitronics*™ provided a new way to learn and create circuits but with the affordances of paper crafting and possibilities for expressive art creations (Qi & Buechley, 2014). The purpose of this study is to explore how this circuitry toolkit impacts learning by gender, and simultaneously, how it presents multiple possibilities of artistic expression for youth. Therefore, in this study, we aim to address the following research questions: *(1) To what extent does the art-based workshop support students' learning of basic circuitry concepts via paper circuits? (2) To what extent do the learning gains vary by the types of toolkits and by gender?*

Social Constructionism: Designing Art-based Learning Activities

In this work, we draw on sociocultural understandings of constructionism in a way that seeks to understand both the social nature of learning and the power of designing and creating artifacts that can be shared and iterated upon. Much of this notion comes from Papert (1980), who in his elaboration of Piaget's constructivist ideas posited that learners construct their own knowledge through their experiences with meaningful tools and artifacts with others.

Studies have shown that arts integration benefits student performance in STEM areas (e.g., Hardiman et al., 2014). Particularly, arts-based activities can serve as effective mediators for learning (e.g., Halverson & Sheridan, 2014) because of their focus on the creation of meaningful artifacts and social interactions with others. From the perspective of constructionism, the creation of art artifacts in a social context not only affords learning as it promotes an internalized mental structure of physical experience, but the learner and the artifact actively can create meaning as the learners make sense of their world (Peppler & Thompson, under review).

 © ISLS

Through the lens of the constructionist approach, we examine art-based activities as cultural practices, along with the related tools and materials which carry historical expectations for what counts as expertise. These expectations evoke *social scripts* that may prompt gendered patterns of participation. According to our prior work (Peppler & Thompson, under review), we found that the intersection of practices created by the tools and materials also created space for the performance of gendered scripts. For example, e-textiles is a science and engineering activity (fields often dominated by men); however, the integration of the sewing materials invited girls to take leadership roles and have more "hands-on" access to the projects than is typically expected or allowed in classroom science activities. Building on our prior work, in this study, we are interested in exploring the performance by gender with the use of paper circuits and examining how the concepts which students learned through paper circuits can possibly be transferred to other types of circuitry toolkits.

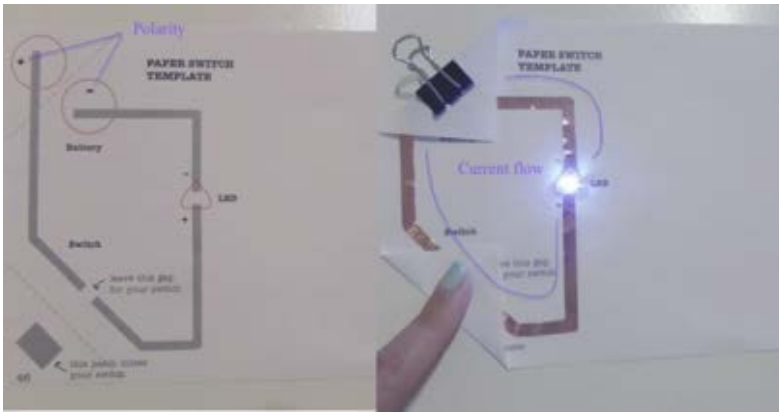
Methods

Setting, Participants, and Workshop

To answer the aforementioned research questions, we measured learning gains of middle school students after participating in a circuitry workshop with *Chibitronics*™ paper circuit toolkits. Building on the previous studies (Peppler & Glosson, 2013), we modified and created a 4-day workshop (90 minutes a day) for a charter class located in Southern California, USA. A total of 17 students (F= 9, M = 7, unidentified = 1) between the ages of 11 and 13 participated in the workshop. Nine out of 17 participants self-identified as White, and the others identified as either Asian, Hispanic, multiracial Asian, or multiracial Hispanic. For each day, we introduced circuitry concepts, such as current flow and polarity using Chibitronics (see Figure 1). Simple daily activities led from learning how to light up one to three LEDs (lights) using a coin battery and finished with one final project by creating a greeting card and a microcontroller board to automatically light up the lights.

Figure 1

Examples of Basic Circuitry on a Paper Circuit



Data Sources and Analysis

At the beginning and end of the workshop, we administered paper-based pre- and post-tests which included circuit diagram questions to assess the concepts of circuitry: current flow, connections, and polarity across three separate electronic toolkits, including e-textiles, breadboards, and paper circuitry. The content of the workshop and the measurement instrument have been refined and improved over previous study implementations. The pre- and post-tests had three sections, one section corresponding to one circuitry or computational toolkit: breadboard, e-textiles, and paper circuits. These sections compared how youth formed working circuits using materials familiar to them (i.e., Chibitronics) against less familiar materials (i.e., e-textile and breadboard). To understand how learning with paper circuits serves as indicators to prepare for future circuitry learning, we analyzed students' learning gains while youth were exposed with less familiar materials (i.e., other circuitry toolkits). These gains can serve as indicators of preparedness for future circuitry learning across settings.

In the pre- and post-tests, students were provided engineering components (e.g., LEDs, battery, microcontroller) as stickers to simulate the functions and draw lines across the components to accomplish the tests. We then developed coding schemes to examine students' competence of basic circuitry concepts from pre- to post-tests. The highest scores of pre- and post-test is 18. The inter-rater reliability of the coding scheme was

 © ISLS

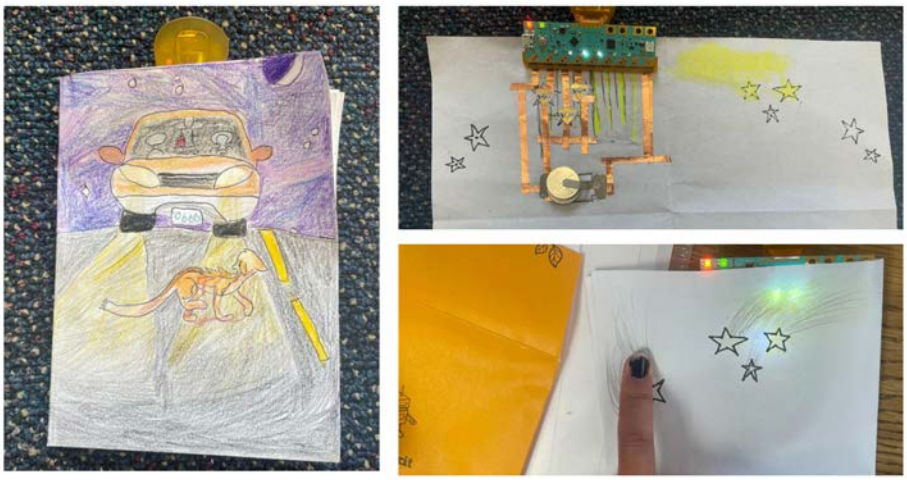
calculated by Cohen's kappa with k =.82. Two researchers scored the pre- and post-tests based on the coding scheme. Building on the coding results, a paired sample t-test and one-way ANOVA were applied to examine the changes and differences between pre- and post-tests by gender and types of toolkits.

Findings

In the workshop, we found that arts integration promoted the creation of paper circuits that leads to artistic exploration into STEM engagement. Figure 2 shows examples of how creating a circuit using copper-colored tape and paper provides additional flexibility and possibility for exploration with aesthetics, color, shape, unexpected uses of circuits, and more. This is a similar pattern found in other toolkits that promote artistic engagement such as e-textiles or playdough circuits (Peppler & Glosson, 2013). In addition to a more artistic output, the process of crafting these types of circuits seem to deepen opportunities for applications of STEM concepts for greater learning. Further, arts integration seems to demonstrate a broader applicability for transfer of circuitry concepts from one set of context and materials to another. With flexible materials that require deep embodied actions, such as pressing down copper tape along its entire trace, circuitry kits like paper circuits create a unique relationship between the materials and the elements that are necessary to build a working circuit. This leaves space for learners to apply parts of that close relationship to other toolkits and potentially learn the new materials more easily.

Figure 2

Examples of Students' Work



The results from pre-test (M = 3.5, SD =6.5) and post-tests (M = 21.4, SD = 11.9) showed significant improvement for both girls and boys on basic circuitry concepts (M =17.94, SD = 11.77), $t(15) = 6.1$, $p < .001$ with a large effect size (d=1.58). The results indicate that all students improved on the circuitry concepts (i.e., current flow, connection, and polarity) from pre- to post-tests. To answer the second research question, we then further examined the differences between gender and types of toolkits.

Building on the findings from the first research question, we examined the differences among three types of toolkits by gender. The results showed that both girls and boys improved significantly on e-textile and paper circuitry (see Table 1 for details). Particularly, girls performed better on the e-textile than breadboard and paper circuitry from pre- to post-tests, whereas boys performed better on the paper circuitry than the other two toolkits. The results of descriptive statistics on gains indicated that boys outperformed the girls on all items except for e-textiles, which are arguably more feminine than the other two toolkits. Interestingly, girls scored the highest on e-textiles among the three toolkits, whereas e-textiles were not introduced in this workshop, and all students did not have prior experience on the toolkits. Paper circuits are considered as gender neutral based on our prior work (Peppler & Thompson, under review). Breadboard was not intuitive for either group based on the results.

Table 1

Paired Sample T-test Results of Learning Gains by Toolkits for Girls and Boys

	Girls				Boys				Girls & Boys Comparison
	Gains (Post-Pre)	SD	*t*	*p*	Gains (Post- Pre)	SD	*t*	*p*	Differences between Gains by Points (pts)
E-textiles	9.14	7.08	3.42*	.014	5.44	4.85	3.37*	.010	Girls 3.7pts > Boys
Breadboard	0.43	1.13	1.00	.356	1.33	4.56	0.88	.405	Boys 0.9pts > Girls
Paper circuitry	8.43	7.72	2.89*	.028	11.11	5.67	5.89**	.000	Boys 2.7pts > Girls

Highest scores = 18pts; *$p < .05$ **$p < .001$

Discussion and implications

The findings suggest that all students' competence of circuitry concepts improved from the paper circuits workshop, which indicates that paper circuits are a sufficient toolkit for meeting the relevant standards in basic circuitry/physics. The results showed significant differences by the types of toolkits. Students showed significant improvement on both e-textile and paper circuitry toolkits, indicating that learning circuitry in the context of paper circuits allows individuals to transfer this understanding to similar contexts, like e-textiles but not to breadboards or other more distal contexts. This may also be an artifact of the way that the workshop was taught to emphasize learnings that would easily transfer to e-textiles kits and conditions. Particularly, the findings supported our prior work that there are gendered patterns of practices and materials which may impact the performance of the circuit.

Moreover, the power of the more arts-based toolkits is echoed in studies where learners who used such kits outperformed their peers. Maker toolkits and the integration of new materials bring promising new ways to rethink how concepts are taught, and help educators and designers imagine new approaches for electrical engineering to advance societal needs unmet by our current uses of electrical energy. For future work, we will examine the qualitative aspect of the data to understand how these toolkits are perceived by gender and how these differences impact the ways they approach learning in specific domains. Building on the results of the study, we will investigate the inextricability of material property and gendered practice in an effort to understand how we can better design tools and materials to rupture stagnant norms around educational practices.

Creating Synergistic Scaffolding Between the Tools of Discourse and Technology

Melanie Snow, Mike Stieff, and Sidney Spurgeon
mjsnow@uic.edu, mstieff@uic.edu, sspurg2@uic.edu
University of Illinois at Chicago

Abstract: Research has looked at how teachers use discourse to develop aspects of the learning environment such as argumentation or autonomy. However, few studies have focused on how teachers utilize discourse surrounding educational simulations in practice (Erduran, 2019; Tabak & Kyza, 2018). More specifically, attention has not been given to how teachers use discourse to create synergistic scaffolding as characterized by Tabak and Kyza (2018) between tools such as discussion and technology. This case study uses two analytical frameworks, Rasmussen's Inquiry Oriented Discursive Moves (IODM) and Lidar's Epistemic Moves Analysis (EMA), to reveal how a teacher uses discourse to create synergistic scaffolding between the discussion and simulations. This case also demonstrates that by creating synergy between discussion and simulation the teacher positions students with opportunities to support shifting practical epistemology around chemical concepts.

Introduction

Providing students with opportunities to evaluate knowledge surrounding scientific phenomena can lead to epistemic shifts (Jiménez-Aleixandre & Brocos, 2018). Interactive technologies, such as simulations, have been developed that support students as they engage in these types of explorations by guiding students to reason, defend, and critique claims and explanations about the natural world. Research on educational technologies mainly focus on how designs achieve learning outcomes (Perkins, 2014) or how students interact with the tool (Smetana, & Bell, 2012; Price, 2019). Similarly, research on teacher discourse is often used to understand how teachers develop student inquiry through argumentation alone, rather than how teachers create epistemic opportunities for students to engage in reasoning. Surprisingly, little attention has been given to teacher discourse around the use of educational simulations, even though teacher discourse plays a role in developing students' scientific practice (Tabak & Kyza, 2018). We know that teachers orchestrate the learning environment through their practice choices, yet we have not captured how teachers use tools, like discourse, to purposefully integrate technology into the existing learning environment. Here we use two analytical frameworks to observe this interaction with a focusing on question: How do teachers' discourse choices create synergistic scaffolding between tools in the learning environment?

Theoretical frameworks

Argumentation has often been looked at as a means of replicating scientific sense-making in the classroom (Ford, 2012; Kuhn, 2013; Osborne, 2019). When teachers place students into roles that require them to use evidence to reason toward a conclusion rather than accepting answers given by the teacher, students participate in science practices that develop reasoning (NRC, 2011; Erduran, 2019). This creates the ability for students to engage in evidence-based argumentation that can support revising practical epistemology (Berland & Resier, 2011; Linn, 2018).

Two theoretical frameworks were used to characterize how teachers' discourse and the role of technology impact students' learning and potential for epistemological change. The first is Inquiry Oriented Discursive Moves (IODM; Rasmussen, 2008) defined as moves that involved questioning, telling, managing, and revoicing. These moves provide specific attention to discourse related to teacher and student inquiry as they are situated in settings of argumentation. By looking at inquiry-oriented discourse, we can observe the social setting of the learning environment created by the teacher. The second framework is Epistemological Move Analysis (EMA) developed by Lidar, Lundqvist, and Östman (2006) defined as discourse moves that are instructional, reconstructing, reorienting, generative, and confirming that allows us to examine how teachers use discourse to guide and support students in noticing information is important to the construction of knowledge. While the ultimate responsibility for shifting practical epistemology lies with the students, the teacher can, through their discursive and epistemic moves, provide the opportunities for this to occur.

Tabak & Kyza's (2018) scaffolding functions were utilized to reveal how discourse created synergistic scaffolding to support student reasoning. The role of technology, and in this case educational simulations, is

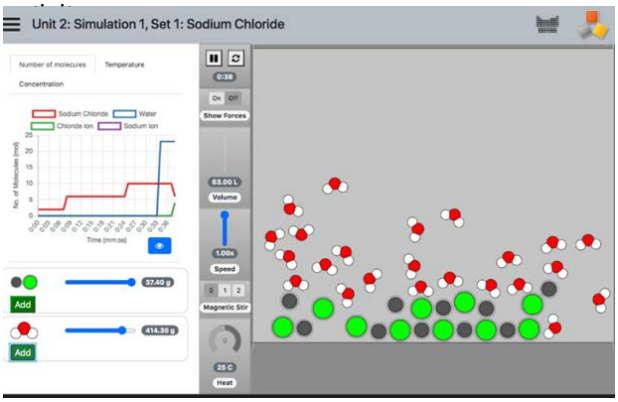
 © ISLS

investigated to look at how teachers use discourse in classrooms utilizing educational simulations. Specifically, how teachers use discourse to create a synergistic relationship between discussion and simulation tools, in such a way that supports students' development in scientific reasoning.

Present study and context

The present study analyzed a subset of data collected during the Connected Chemistry Curriculum (CCC; Stieff, 2019) project that implemented chemistry curriculum accompanied by visualization software. As part of the project, video recordings of teachers were analyzed using the Reformed Teaching Observation Protocol (RTOP; Piburn et al, 2000, p. 34). Data of teachers who utilized the simulation while also demonstrating reformed teaching practices were identified and considered for further study. Here we present one case study out of a collection that demonstrates how teachers use inquiry-oriented and epistemic discourse moves to create synergistic scaffolding between the discussion and simulation tools of the classroom. This case takes place during the last 25 minutes of a 90-minute class period where CCC materials were in use. The topic of molarity, or concentration of a solution, is discussed and then observed using the simulation. A screenshot of the simulation screen for this activity is shown in Figure 1. Discussion takes place in a whole class setting whereas simulation use is done in smaller groups of 2-3 students. The teacher walks around to engage students in questions about their work during the simulation time.

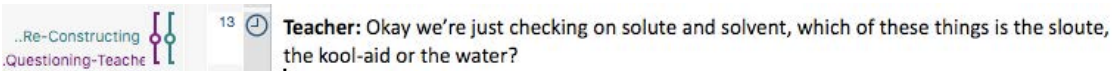
Figure 1.
Example of a simulation screen from the Solutions



Results

The teacher in this case, begins with a whole class discussion to initiate interest in the topic of concentration. The topic of concentration is first connected to an everyday scenario by the teacher asking students if they have ever had a drink that was too strong and had to water it down. Using a telling discourse move the teacher explains this phenomenon is called concentration. The teacher then uses instructional discourse move to create an epistemic reconstruction of the task of thinking about concentration in terms of the chemical words, *solute* and *solvent*. The teacher does this by drawing a representation of a mixture of Kool-Aid™ and water. The teacher then asks students to label the solute and solvent in the diagram (See Figure 2).

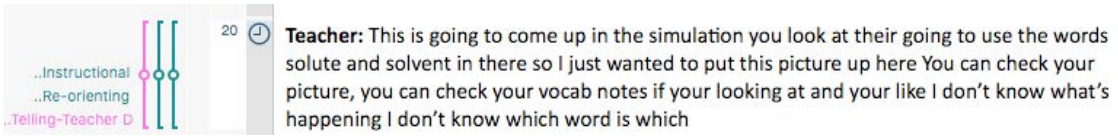
Figure 2.
Labeling the diagram with terms solute and solvent.



This demonstrates how the teacher creates synergistic scaffolding to connect discussion and the simulation by pointing out that this diagram will be a reference when using the simulation (See Figure 3). The teacher, using instructional and reorienting moves, make explicit the terminology is important to understand because it will "*come up in the simulation*" (Figure 3). Using Tabak & Kyza's (2018) scaffolding lens, we can see the function of the notes aim to reduce complexity of using the simulation.

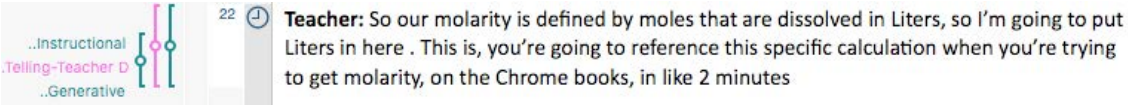
 © ISLS

Figure 3.
Modeling language important to understanding molarity.



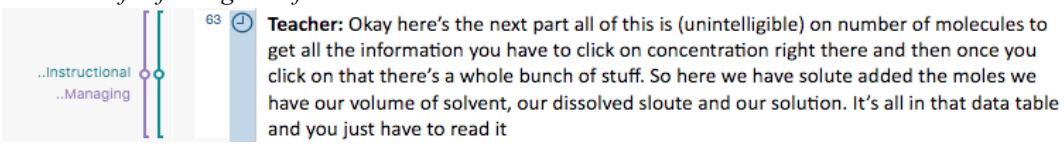
The teacher continues using instructional moves to provide students with a way to calculate the concentration called molarity. This equation specifically identifies the concentration as number of moles of solute per liters of solution. The teacher uses this generative epistemic move to reduce complexity and create synergistic scaffolding between tools stating, "*reference this formula*" when they switch from discussion to using the simulation (See Figure 4).

Figure 4.
Equation for molarity calculations.



Students in groups of 2-3 collect a worksheet, and one Chrome book to begin work with the simulation. The teacher uses managing and instructional discourse moves to help students navigate the simulation while also providing instruction on what data to collect and how to manipulate the variables to create that data. The teacher also uses these moves to tell students what to notice and how to use this information to complete the task of calculating molarity (See Figure 5). These epistemic moves support students in finding the information they need to reason.

Figure 5.
Directions for finding data for calculations.



Variable manipulation is left up to the students giving them epistemic agency to explore the simulation while executing the task. A problematic scenario is created for one group seen in Figure 6. At line 19 a student observes that the simulation is displaying only one type of particle. The teacher uses a questioning discourse move creating an epistemic reorientation for students in the group to pay attention to the variable of temperature (line 22). The teacher uses a questioning move to reveal what prior knowledge students have about what happens to water at 100°C, the temperature the group has used in the simulation (line 22). The student's response is not audible due to data quality however based on the teacher's response, "*so if it's not liquid,*" we can deduce the student concludes that the water has vaporized. The teacher also uses this moment to ask the question "*how are you going to dissolve stuff*?" creating an epistemic reorientation that signals the student now has the knowledge to be able to reason about the initial observation that only sodium chloride was present in the simulation.
Multiple groups create the same problematic scenario, setting the temperature either too high or too low, inhibiting the mixing of the solute. This teacher repeats the use of inquiry-oriented and epistemic discourse moves creating a dialogue that helps students make sense of their observations from the simulation.

Figure 6.
Students ask what happened to the water?

 © ISLS

Discussion

While classroom technologies have been integral in giving students access to scientific phenomenon, we demonstrate here how the teacher makes this technology accessible such that epistemic shifts and student reasoning can occur. By using the IODM and EMA frameworks we see how the teacher creates this accessibility by using synergistic scaffolding between the tools of the classroom such that tools function to scaffold one another. This is created through the deliberate discursive moves that use the basis of argument to support inquiry and epistemic agency for the students. How students understand observations are revealed by the teacher through discourse moves that develop and draw attention to conceptually important details. Using these details, the teacher prepares students to make observations that provide opportunities to reason and create epistemic shifts.

Revealing how the teacher integrates discussion and simulation using discourse moves demonstrate how creating synergistic scaffolding can provide Between tools. Students could have made similar observations while using a simulation without the presence of the discourse, however, what would be missing are the scaffolds provided from the discussion that students can tap into when attempting to make epistemic shifts. The same can be said in the reverse; that discussion alone may have afforded some students enough to reason through concepts, but by providing the visualization of phenomenon with opportunities to create a problematic scenario, students were able to observe a phenomenon giving them a visual opportunity for solidifying their reasoning.

Distributed Creativity Mediated by Social and Material Interactions in a Collaborative Pop-up Makerspace in India

Alekh V, Chandan Dasgupta
alekhv@iitb.ac.in, cdasgupta@iitb.ac.in
Indian Institute of Technology, Bombay

Abstract: Collaborative making involves the coming together of makers, sharing resources in the situated environment, influencing each other's ideas and design processes. The article aims to contribute to the understanding of social and material interaction in making, which can inform the design of socio-technical spaces that promotes creative outcomes. In this study, we investigate how makers engage with each other and with materials while working in ill structured problem-solving making context. We specifically look at data from a medical device innovation camp which is a pop-up makerspace setting, to assert the distributive nature of creative making. Our analysis suggests that social and material conversations are significant in shaping the making process, engendering distributed form of creativity.

Introduction

Places like hackerspaces, FabLabs, schools, museums, libraries, homes, online communities, and temporary 'Pop-Up' makerspaces have been explored as part of the growing Maker movement to promote maker engagement with technology, afford knowledge sharing, and collaborative creative production (Halverson & Sheridan, 2014). Making often involves events of problem solving, where makers work in groups and utilise the available resources to arrive at feasible solutions. In this context, group creativity has become increasingly important with emphasis on understanding how creativity emerges from sites of collaborations. At the group level, creativity is not an individualistic mental process but it is embedded and distributed in social groups and collaborative networks (Sawyer & Dezutter, 2009). As per this perspective, creative thinking is *distributed* via interaction between people, dialog between people and objects, or interactions over time (Glăveanu, 2014; Sawyer & Dezutter, 2009). The idea of design as a conversation with the situation (Schön, 1983) opens the path to understand the interplay of social and material aspects in making, where makers converse with fellow makers and materials, resulting in creative design possibilities. Often the maker-material interaction leads to *being*, *doing* and *becoming* material conversations in finding creative solutions to design problems (Gravel & Svihla, 2021). *Being* material conversations considers the materials as well-known and not improvable, whereas *doing* material conversations involve exploring known material affordances that can be utilised to make progress in solving a design problem. A *becoming* material conversation is characterised by transformed purpose, reconfigurations and modifications of materials (Gravel & Svihla, 2021).

Drawing from all these prior literatures, in this paper, we investigate how maker and material interactions involving being, doing, and becoming conversations contribute towards the distributed form of creativity in a pop-up makerspace. The temporary makerspace for this study consists of a five-day medical device innovation hackathon attended by medical, design, marketing, and engineering domain experts. Drawing on the perspective of design as an inherent practice within the making process (Halverson & Sheridan, 2014; Dougherty, 2012), we consider the domain experts as makers, the process they engage in as the making process, and the medical innovation camp setting as the pop-up makerspace. We position the creative aspects of the making process as distributed phenomena (Hutchins,1995; Glăveanu, 2014; Sawyer & Dezutter, 2009).

Analysis

Data for this study was collected as part of a larger five-day medical device innovation camp organized by the Biomedical Engineering & Technology Incubation Centre at a leading engineering institute in India. The organizers facilitated team formation by enabling participants to form clusters around a predefined set of twenty medical problems generated by multiple doctors. Teams were provided with prototyping kits consisting of: basic hand tools (knives, screwdrivers), power tools (hand drill, pillar drill), marking pens, pencils, rulers, drawing chart papers, plastic sheets, tapes, glue, sticky notes, basic electronic components (e.g., breadboard, LEDs, jump wires, battery). The audio and video data along with field notes and observation logs for day 1 and day 2, of two teams - Team A and Team B- formed the data set for our analysis, as the rest of the data was not available due to hard-disk storage failure. We follow the case study methodology (Merriam, 2007) to investigate the role of social and material elements on distributed creativity in making. We used the content logs to conduct interaction analysis (Jordan & Henderson, 1995) focusing on talk and use of artifacts and technologies, to unpack the moment-by-

 © ISLS

moment emergence of distributed creativity during group work. We identified 'significant moments' for analysis by looking for discussions on design decisions, participants talking with and through materials, ideational dialogic exchanges between participants, and shared agency (Gravel & Svihla, 2021) in our dataset. Further we used the approach of being, doing, and becoming material conversations to analyze these episodes (Gravel & Svihla, 2021).

Findings

We found that makers in the pop-up makerspace demonstrated episodes of collaborative idea transfer, negotiation, building shared knowledge, and taking part in *being, doing,* and *becoming* material conversations. We present these episodes in the form of two cases to show the kinds of social and material conversations and the interplay of human and non-human factors that shape the distributed creative making processes.

Figure 1

The prototypes made by Team A, PVC model (a), Mask-PVC model (b), Team B's SME drawing circle and making markings on the sheet (c), Mobile phone-plastic sheet prototype (d)

(a) (b) (c) (d)

Case 1: Blow through unit

The particular episode discussed in this case is from Team A's first design session (Day 2 of the medical innovation camp). Team A worked on medical needs arising out of obstructive lung diseases to extract the sputum that gets deposited in the patients' respiratory system. Team A consisted of a doctor - Subject Matter Expert (SME) (male), designer (male), mechanical engineer (male), and an electrical & electronics engineer (female). The team has at their disposal a nebuliser mask, an intermediate PVC prototype previously made by the SME, plastic balls, steel balls and marbles, in addition to the prototyping kit. The following excerpt illustrates how maker and material conversations together contribute to the creative making process of addressing the problem of air leakage.

Designer:	[looks around] what if I have this mask [takes the nebuliser mask from the work table and inspects the profile].. and attach it to the pipe... not with the holes [points to the holes in the mask].
SME	[connects the PVC prototype with the mask by pressing the pipe entry to the mask hole] You want to have it like this, right angles?
Designer:	We need to seal the holes to make it work.. we can tape it.
Designer:	It should be taped from inside, otherwise. [tapes the holes in the mask]
SME:	Let me try it now. [wears the mask and PVC assembly, then blows]
SME:	I can feel it now.. the air, but it is reduced.

Here, Team A members are sitting around the assigned work table, investigating the intermediate PVC prototype (see Figure 1(a)) and subjecting it to tests and manipulations. Even though the nebuliser mask was present at the table for a long time, the designer is the one having a *doing* material conversation with the material, by inspecting the profile and suggests using it along with the pipe. The SME acknowledges the idea, initiates material negotiation by connecting the PVC prototype and nebulizer mask in angular configurations (see Figure 1(b)). The makers move towards *becoming* material conversations through manipulating the joint affordances of PVC prototype and the nebulizer mask, integrating into a single unit and covering the holes with tapes, thus giving the unit a transformed purpose for ease-of-use and minimized air leakages.

Team A continued to work on designs which were based on the heuristic of air column vibrations. The following excerpt shows an episode where externally prompted questions from the mentor are embedded in interactions and facilitate the material conversations resulting in a shift in guiding principle from that of *air column vibration* to *pressure difference in layers of air*.

Mentor:	[points at the PVC prototype] Why is it vibrating?
SME:	I believe that it is vibrating because the air is just escaping from the top end and the marble drops, then air vibrates.
Mentor:	I will try with the plastic ball [places the ball in the prototype and blows]. Still, I can feel it but very less.
Mentor:	What if it's a heavier ball.? [takes a steel ball, places it in the prototype and then blows] vibrations, vibrations.
Mentor:	You must have seen the tractor with the chimney and its lip? What happens there? it also vibrates, right? Why does it vibrate?
Designer:	[thinks for a moment] It is a buildup of pressure, there comes a point where the pressure exceeds the weight of the chimney lip, it goes up, then again when there is not enough pressure, the lip falls back.
Mentor:	So.. that is why it vibrates.

In the above episode, the mentor joins the team at the work table and questions the team members about the principles used. The mentor tests the prototype with different kinds of loads (e.g., plastic ball, steel ball, marbles) to understand the solution approach and show the possible prototype responses to Team A, by utilizing the properties of the size and weight of different types of balls available. Thus he engages in *doing* material conversion with the balls, prototype, and enters into conversation with the team about the various outcomes. The prototype thus becomes an anchor point for further interaction thereby leveraging the social and material conversations for co-construction of knowledge required to improve their design.

Case 2: Angular measurement unit

The episode shown below is from Team B's ideation session (Day 1 of the medical innovation camp). Team B is focused on monitoring clubfoot deformity to help doctors monitor the changes in deformity during the course of treatment. Team B consisted of a doctor - Subject Matter Expert (SME) (male), designer (male), software engineer - S/w engineer (male), and market expert (male). The team has at their disposal a soft foot model and a skeleton foot model, in addition to the prototyping kit.

SME:	So.. what I am thinking is to use mobile phone, to take photo and process it.
S/w Engineer:	That means..we need a device, which has some scale sensor, added to a mobile phone and software.
SME:	[draws sketches on paper with pencil and explains] If we standardise foot position and mark the points on foot with stickers, it is possible to capture those in photos and then we can connect dots to get the angles..
S/w Engineer:	mm.. if we move the entire set up to a box, [gestures the imaginary walls with hand] and we keep the top open, bottom with a footrest.. then we use a selfie stick like attachment for camera.. and with clean backgrounds..we can use cardboards and white chart papers for making it and a dial.
SME:	That's why I want to have the mechanism prebuilt in the device, then we don't have to carry the dial.. like an app..our mobile phone.

Here, team members are sitting around the work table, discussing ways in which the concept of measuring deformity and continuous evaluation can be achieved. We find *doing* material conversations coming into play when SME considers using the mobile phone for image processing, satisfying portability, by exploring the affordances of the device. The software engineer identifies cardboard to build the frame and white chart papers for clean backgrounds, where both the materials get tangled in *being* material conversations. As the making progressed, the SME interacts with a thin plastic sheet by examining the transparency. Then, he cuts the sheet into a rectangle shape, draws a circle at the centre of the sheet, marks angular measurements and fixes the sheet over the mobile screen with transparent tapes (see Figure 1(c)). The Mobile phone was part of *being* material conversations initially, meant for only capturing images and later got extended to *becoming* material conversations through the various modes of interactive operations between SME, mobile phone and plastic sheet. (see Figure 1(d)).

As in the case of Team A, the mentor interaction has significant influence in Team B's making process. At multiple instances during the ideation and prototyping sessions, we observed the mentor problematizing the

use of *reference planes* and *reference lines for angular measurements*, which further refined the particular guiding principle for the solution approach.

Discussion and Conclusion

We have presented two cases of making in a pop-up makerspace having the theme of medical device innovation, where domain expert makers and materials involved in *being*, *doing,* and *becoming* material dialogues through which, they traverse through the problem and solution space. As the makers and materials get into such conversations, we find makers trying to explore the available materials and related affordances, to which the materials respond, effectively entailing creative formulations. The makers are found to approach materials with preconceived material properties, which are either embedded in the making as such, or transformed into other qualities so as to address the problem scenarios. In Case 1, we have seen the translation of *doing* to *becoming* material conversion in a sequence of interactions involving the designer, SME, PVC model, and nebuliser mask while negotiating the problem of air leakage. Similarly, in Case 2, we have shown instances where SME involved in *becoming* material interactions leading to the creation of a proof-of-concept with a combination of mobile phone and plastic sheets. These sociomaterial conversations show materials are more than just mediators, but taking up the roles as actors, similar to that of makers (Latour, 1996), which reiterates the material aspect of creative actions (Pickering, 1993). The findings point towards the distributed creative process, where team members and material resources were actively contributing to tackle uncommon problems (Glăveanu, 2014; Sawyer & Dezutter, 2009). In both cases, the mentors played a crucial role in problematizing and refining the guiding heuristics, which enabled the teams to make progress towards a useful solution.

The findings from the study suggest that makers, materials, and mentors collectively contribute to the making actions thereby upholding our argument that creative making processes are distributed across the social and material elements of the situated environment. Analyzing distributed creativity in makerspaces using the social and material conversations lens, may help us reframe our outlook towards the natural emergence of creativity in making and calls for more attention towards human and non-human factors in situated learning contexts. Further studies are required to expand our understanding related to the sociomaterial entanglement in creative making contexts.

Co-Construction of Third Space of Joy and Playfulness Through Critical Transdisciplinarity: Land-Based STEM Learning With Refugee Children

Mahati Kopparla, Miwa Aoki Takeuchi, Jenny Yuen and Anita Chowdhury
Mahati.kopparla@ucalgary.ca, miwa.takeuchi@ucalgary.ca, jenny.yuen@ucalgary.ca, anita.chowdhury@ucalgary.ca
University of Calgary

Abstract: People from non-dominant farming communities have rich engagement with STEM concepts, rooted in their families' everyday lives, intergenerational cultural practices, and environments. However, such culturally embedded knowledge and associated STEM literacy often remain separate from STEM learning at school. Particularly working with Yazidi and Syrian refugee families from rural regions, we co-designed land-based STEM learning opportunities that center embodied knowledge of traditional farming practices. In this paper, we present examples where facilitators and child participants co-created spaces to express their intergenerational and emerging understanding of land, farming, and STEM, with joy and pleasure. Particularly, we decenter damage-centered narratives associated with refugee children by centering their agency, creativity, and desire for joy in the learning spaces. Participants co-created a Third Space where they engaged in the learning activity on their own terms, while challenging and reimagining some underlying socio-political ideologies and power dynamics.

Disciplinary formation under the hegemonic institutionalized practice of knowledge production can be regulatory and constraining. In the disciplined spaces of learning, learners paradoxically become subjugated as docile bodies in hegemonic disciplinary practice, as they gain more "aptitude" or a "capacity" as a form of capital (Takeuchi et al., 2020). Critical transdisciplinary perspectives to STEM education acknowledge this hegemonic production of learners through the western capitalistic gazes and urge us to move toward reimagining disciplinary boundaries to center embodied and community-based knowing of historically marginalized communities (Strong et al., 2016; Takeuchi et al., 2020). In this reimagination, we need to understand disciplinary contexts that youth and children co-construct for their joy, pleasure and meanings *on their terms* (Alim, Paris & Wong, 2020). We draw on the concept of Third Space, where the formal and informal learning spaces intersect to create a space for emerging student-teacher interactions that are expansive, generative and historically profound (Gutiérrez et al., 1995). Third Space emerges when diversity, conflict or tensions within the learning space are directed towards rupturing, innovating, and reorganizing the official learning activity (Gutiérrez et al., 1995). Within Third Space where playfulness of children and youth are embraced, opportunities arise for challenging the traditional learning hierarchies, collectively redefining what counts as knowledge, and transforming pedagogical spaces into "a site where no cultural discourses are secondary" (Gutiérrez, 1995, p. 447). In this paper, we present examples where facilitators and child participants co-created spaces to express their intergenerational and emerging understanding of land, farming, and STEM, with joy and pleasure.

Methodology

We draw from participatory social design-based experiments research methodology (Gutiérrez & Jurow, 2016) that centers historicity, diversity, equity, and ecological resilience as design principles with aims to co-design just practices and futures in partnership with a range of communities. Our co-design was centered around a vision to design and study land-based learning through Soil Camp to amplify learning opportunities for refugee children and youth in STEM that are relevant and connected to intergenerational and community knowledge of soil, ecosystems, and farming on a regenerative farm (see Takeuchi et al., 2021). Our university team, composed of educational researchers, teacher candidates, and teachers who are mainly racialized multilinguals with diverse disciplinary expertise (e.g., mathematics, sciences, arts, and social sciences) designed and led activities to understand the soil and ecosystem better. In 2021, 65 youth and children (aged from 5 years old to 15 years old) and over 20 families joined our program. All attendees were refugees from Syria, Northern Iraq, Kurdistan, New Guinea, Pakistan, South Sudan, Ethiopia, and Eritrea who had resettled in Canada within the last five years. The activities during the two weeks of Soil Camp in July 2021 were documented using Go Pro and still cameras (total of 31.43 hours of video data) by both the participants and researchers, and

 © ISLS

Handycam video cameras held by the researchers. In addition, each member of the research team has taken field notes right after each activity.

The analytic focus of this paper is one of the activities that participants engaged in where participants accepted and designated roles involved in a farming season and acted them out. The setting of the activity involved participants sitting in a circle on the land at the urban farm. The activity began with the facilitator prompting the question, "What is a farm?" and inviting participants to enact the events that happen during the growing season. Participants interacted with props made by the facilitator which included seeds, plants, farmers, worms, bees, weeds, butterflies, and vegetables, but they also spontaneously added additional props. Our analysis focuses on instances where the participants shared their knowledge about the soil, ecosystem, and community farming practices. Instances of intersection between the formal and informal script of the learning activity, co-creating a Third Space became our analytical focus (Gutiérrez et al., 1995). Through collective watching of these instances, we observed that the interactions during the activity were immersed in a sense of joy, humor, and playfulness among the participants. The sense of joy was evident both during planned pedagogical activities and unplanned moments through smiles, humorous interactions, and creative engagement with the activities, as the pedagogical approach supported and encouraged the identities, strengths and autonomy of the participants. Any interruptions to the planned activity were viewed as agentic and creative attempts by the participants to engage on their own terms. Participants not only showcased their intricate informal knowledge of farming, but also exercised their agency in choosing when and how to participate in the activity. Particularly, two representative episodes of activity were chosen to demonstrate children's participation in the learning activity on their own terms.

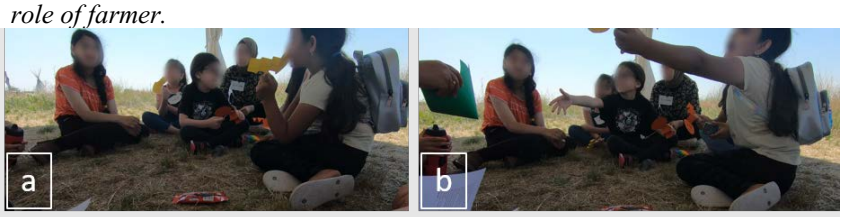
Findings

Who wants to be a farmer?

This group was composed of six students and four facilitators. After acting out the roles of soil and worms, the discusion was directed towards including the role of farmers. When the facilitator asked for volunteers to become farmers, participants in the circle refused to take on the role and become physically disengaged (Figure 1a). As many of the participants were from farming backgrounds and had experience of farming on the land with their families, enacting the role of a farmer was assumed to be familiar and relevant to their life experiences. However, the refusal to take on the role of farmers could be related to multiple contextual powers and social hierachy and social valorization (de Abreu & Cline, 2007). When all children refused the role of farmer, one of the facilitators accepted the role and was given a green paper hat. This hat caught the attention of some of the children who immidiately became interested in taking up the farmer role (Figure 1b). In the context of the activity, the participant and facilitators overcame the hesitation to take on the role of the farmer by building on elements of joy and playfulness. In this interaction, this hat became a "pivot" (Vygotsky, 1978) that invited children to enter into a playful world, shifting the frame of the ideological world where the role of farmer and farming was valorized to one of playful engagement with farming.

Figure 1

(a) Participants become disengaged when asked to play the role of farmer, (b) when the green aper hat is associated with the role of the farmer, participants are enthusiastic to assume the role of farmer.



Once the role of the farmer was accepted, the facilitator invited the farmers to sow their seeds on the make-believe farm at the center of the circle. Lamiya took the role of the lead storyteller. When asked "how are you going to do it?", Lamiya gave an embodied overview of the process with the help of Wassim and Farida as shown in Excerpt 1. For the next few minutes of the activiy, the participants enacted the sowing of seeds and dynamically recreated a scenario where the worms, sun and water played a role in helping the seeds grow. The intricate knowledge of farming expressed by the students (excerpt 1) indicate that their initial hesitation to take the role of farmer was not due to a lack of knowledge or understanding. Instead their participation in the activity

 © ISLS

was motivated and influenced by their desire for joy and playfulness (eg., wearing the hat). During the activity, the students used their unofficial understanding of farming and associated STEM literacy to negotiate and enact events in an official learning space, thus creating a collective Third Space (Gutiérrez et al., 1995).

Excerpt 1		
1	Lamiya:	We are going to dig over here ((removes some grass)) put a seed in it ((places the cardboard seed and covers it with grass)) then we plant some, we put some water in it ((enacting with fingers spread out)) then we wait for a long time ((Farida places her worm near the buried seed)) then the worms come in the soil and rub ((picks up the worm and moves around)) they go around everywhere
2	Farida:	[And they eat this ((taking out the buried seed))
3	Wassim:	[What about the sun?
4	Lamiya:	And they eat ((takes the seed from Farida, but is interrupted))
5	(F) Mahati:	What about the sun?
6	Lamiya:	The sun shines on the soil till (1.0) till it makes the plants grow
7	Farida:	This could be the sun ((brings a green ball and places it in the circle))

Dinosaurs and Rabbits

This group was composed of nine students and four facilitators. In this episode, it was harvest season, towards the end of the activity. The facilitator introduced rabbits as animals that would visit the farm. There were only two props available to play the roles of rabbits. Instead of being passive observers of the events on the farm, the participants exercised their creativity and agency to take up active roles. Bringing in dinosaur toys from their ongoing games outside the context of the soil camp activities, the participants grouped dinosaur toys as 'animals' who were trying to eat the vegetables along with the rabbits. Participants initially navigated tensions around incorporating carnivorous dinosaurs into a farm where the only available food was vegetables. This created a temporary impasse, where the dinosaurs were unable to participate on the farm (utterances 1 to 4 in excerpt 2). However, when the facilitators prompted the participants to save the produce, they creatively distorted the behavior of carnivorous dinosaurs, who immediately proceeded to consume the vegetables. The act of resisting the collection of the produce from the farm was a source of humor and joy for the participants (utterances 6 and 7 in Excerpt 2).

Excerpt 2		
1	Usub:	I (.) eat(.) meat(.) ((holding a dinosaur toy with both his hands))
2	Emine:	((inhales deeply to show shock, then picks up a tomato and extends his hand towards Usub's dinosaur toy)) Okay, here you go. [You need to eat healthy now. Eat(.) eat a tomato ((waves the tomato near the dinosaur)) eat a tomato
3	(F) Mahati:	[let's pick our vegetables so that we can eat it ourselves (,) oka:y?
4	Usub:	<I hate tomato> ((Emine takes back the tomato))
5	Raneem:	Let's protect all our toma:toes, all our ca:rrots, all our zucchinis
6	Usub:	((places a tomato in the dinosaur's mouth and turns towards Raneem)) they're going to be protected in my stomach
7	(F) Mahati:	((Hazim puts down a robot toy, picks up a dinosaur and slowly moves his dinosaur towards a zucchini in front of him to eat it)) No:: <I'm going to take it> ((Hazim looks at Mahati as she grabs the zucchini from him and smiles slightly))

Participants introduced dinosaur toys from their informal games in the formal learning space to recreate a unique farming scenario. Altering the course of the activity by bringing in dinosaurs to the farm reenactment, students supported the emergence of a Third Space with renewed opportunities to participate and rewrite the script (Gutiérrez et al., 1995). With the conclusion of dinosaur rampage, one of the children who assumed the role of farmer turns his storyline back to the rabbits. Earlier in the activity, he described potential interactions with rabbits, "there is a rabbit that wants carrots or anything, if it can't pull it out, the rabbit will be scared. When he goes away, you can pull some carrots out and leave it. They will come and eat it". Building on the

same narrative, he created a physical separation from the rest of the farm where he placed a few carrots, a tomato, and a rabbit. Ignoring the facilitator's plea to pick up all the remaining produce from the farm, he offers to put on a show. Through the enactment of a compassionate farmer who allows a rabbit to eat his carrots and tomatoes, the participant challenges the facilitators' goal of saving all the produce for human consumption. Instead, he draws on his understanding of the values of farming and depicts care for more than humans. Throughout this episode, participants constructed a layered and complex learning space not only based on their intergenerational knowledge and values of farming but also based on their everyday games and toys. Through their unique interactions with dinosaurs and rabbits on the farm, participants demonstrated that their ways of knowing and being "both remains rooted and continues to shift in the ways culture always has" (Alim, Paris, & Wong, 2020, p.267).

Discussion

In the context of STEM education where the formal curriculum is deeply rooted in Eurocentric knowledge systems, we presented co-constructed interactions where non-dominant ways of STEM knowing and doing can be made visible. Specifically, we draw attention to the emergence of a Third Space (Gutiérrez et al., 1995) driven by participants' desire for joy and playfulness. In this space, interruptions to the planned learning activity through play and humor were not acts of disruption, but agentic and creative attempts by the children to bridge formal and informal knowledge of farming and embedded STEM literacy. Our paper highlights how participants and facilitators co-constructed ways of challenging prominent socio-political ideologies around the discipline of STEM through moment-to-moment interactions that center joy and pleasure. This research builds on critical transdisciplinary approaches to STEM teaching and learning that aims to decenter the western capitalistic discourse and center knowledge and experiences of historically marginalized communities (Strong et al., 2016; Takeuchi et al., 2020). Through this study, we learned that making STEM discipline relevant to *fixed* cultural knowledge around farming, building on refugee families' farming background, is not sustaining or transforming (Alim et al., 2020). The findings highlighted how children exercised their agency to participate and bring in relevant knowledge around farming *on their terms* and co-determine the trajectory of the learning activity. While being cognizant of relevant STEM knowledge, participants created unique narratives to humorously and playfully engage with their peers and facilitators. These observations advance critical transdisciplinary approaches to STEM education towards accounting for complexity of non-dominant learners, dynamically shifting relationships with their communities and evolving cultural practices (Alim et al., 2020). Particularly, to effectively advocate for the interests of non-dominant communities, our work advocates for adoption of desire-based pedagogical approaches (Tuck, 2009) that build on learner creativity, agency, and joy.

Tensions in extending visions for social change through educational research in Indian contexts

Abstract: Newly evolving methodological approaches in Learning Sciences that use critical and ecological lenses to design provide ways to identify and address emergent tensions regarding social change through educational research. Such tensions get uniquely manifested in different socioecological contexts. We analyse them in the three studies that we conducted in India. Based on intersubjective insights into the data, we identify '*how do'* different tensions manifest in four categories (educators/researchers, practices, learners, and learning environments) and '*how to'* engage in various ways to address these. Our work attempts to contribute to the discussion around educational approaches to social change making with the help of cases from contexts other than where the approaches were developed.

Introduction

We, the authors of this paper, along with many other Learning Sciences researchers, care about translating our evolving personal visions into the domains outside the academic field of Learning Sciences. As different methodological approaches in the Learning Sciences evolve with the intention of 'social change making'; from the iterative approaches of design research to design-based research (DBR) to community-based design experiments to participatory design research (PDR) to Social Design-Based Experiments (SDBE) (e.g., Gutiérrez, Jurow, & Vakil, 2020), it is also important to think about how the goal of 'social change making' and the methodological approaches to getting there extend in educational contexts outside the United States where almost all these approaches have been developed and studied.

The evolving methodological approaches in Learning Sciences such as Social Design-Based Experiments (SDBE) try to address a gap between theory and praxis by engaging with members of communities outside academia (Gutiérrez, Jurow, & Vakil, 2020). SDBE approach seeks to co-design learning ecologies in which learning is made equitable and consequential for youth from nondominant communities. SDBEs are different from DBR because they focus on joining equity and learning goals that centre people's lived experiences as the driver of possibilities for learning such that participants become intentional designers of their own futures. Extending these approaches beyond the contexts in which these are developed requires deep consideration of some of the foundational ideas such as nondominant participants, experts, communities. For instance, such extension in Indian contexts would require treating these contexts as sites of knowledge production by recognizing ground realities, diversity of ideas, and lived experiences (Sarukkai and Guru, 2012).

As learning sciences researchers, we attempt to extend our personal visions for social change through education by learning about these methodologies and partnering with members of our communities. In this paper, we analyse our work to answer the research question: *Which tensions surfaced when we used critical and ecological approaches to social design to analyse our visions for social change through educational research?*

Methodological approach

Our methodological approach is inspired by an approach of Jackson and colleagues that builds on academic friendships and shared histories to generate analytical and theoretical insights into developing a Learning Sciences research agenda (Jackson et al., 2020). The academic friendships of the three authors of this paper led the authors to discuss the possibility of reflecting together on their Learning Sciences research visions and tensions. We used auto-ethnographic (Ngunjiri, Hernandez, & Chang, 2010) methodologies to identify and analyse tensions. Using the grounded theory approach (Charmaz, 2006) we developed emergent themes based on our intersubjective insights into the empirical data from prior case studies. We identified four common constituent categories in educational ecosystems. For each category, we developed questions that see the common emergent tensions in a broader light to enable further conversations and develop actionable directions. Our positionalities, positions, and shared histories influenced our collaborative auto-ethnographic work.

Cases: Contexts and Tensions

In this section, we present three studies, each conducted and written by an author of this paper. In each study, we highlight tensions that surfaced as we attempted to extend our visions through our works. We then present tensions cutting across the studies, which allow us to extend the discussion to broader contexts.

Case 1 - Epistemically Agentic Science Learning: My (Sugat's) evolving vision for my contributions to the field of Learning Sciences and education is about designing learning environments to support the development of epistemic consciousness. The idea of epistemic consciousness is inspired by Morales-Doyle's (2017) operationalization of Freire's Conscientização, or critical consciousness (Freire & Macedo, 2005), in his justice-centered science pedagogy (Morales-Doyle, 2017). Epistemic consciousness is about an in-depth understanding of one's relationship with knowledge and knowledge-producing practices. My goal is to study if and how such epistemic consciousness develops and translates into changed participation in different contexts.

Research context: I conducted two related studies in the US and India to design for participation in knowledge-producing practices in science classrooms. The first study investigated a learning environment designed for students to engage in investigating molecular mechanisms of gene regulation using computational microworlds (Dabholkar & Wilensky, 2020) in extra-school settings with middle school students (n=41). I was a teacher in these iterations and studied how the design features of the learning environment, both technological and pedagogical, supported students' epistemic agency. The second study was a shift towards participatory design. It was about a program called CTSI (Computational Thinking and Scientific Inquiry) to co-design science and mathematics curricular units with high school teachers.

Tensions: My vision is aligned with the SDBE impetus of designing for potential opportunities for meaningful and consequential participation for the social futures of students and teachers. Such participation is meant to transform their relationship with 'knowledge', from seeing knowledge as something to be acquired to something to be evaluated and generated by them. This matters more in the Indian educational context, in which textbooks are considered a prime source of knowledge, and students are often put in the position of accepting even problematic content at the face value (Darak, 2018). However, the first tension arose when I positioned the values of the community of practice of 'scientists' as desirable values, which are mainly influenced by Western ways of doing science to design (Bang & Medin, 2010). The second tension was about co-designing learning experiences that use contexts that youth from nondominant communities find meaningful to engage with contemporary ideas and practices in science. Meaningful integration of contemporary disciplinary ideas and practices into contexts that are relevant to students of nondominant gender, caste, religion requires identifying ways that would support equitable participation. Since the discourse around supporting such participation is severely limited in India, I found it hard to press for these design goals while working with Indian teachers.

Case 2 - Urban farming as a transformative space: As an activist-researcher, my (Deborah's) vision includes creating learning environments that can enable sustainable transitions through developing critical skills and agency amongst youth; To empowering them with tools and perspectives required for reimagining just socio-ecological systems. This effort, however, entails a radical rethinking of the role of environmental education as a crucial scaffold for creating the political, techno-scientific, and cultural mobilisation to bring about desired systemic changes. There is an urgent need to pay attention to the particular histories, contexts, and perspectives underrepresented in the environmental education discourse to create alternate imaginaries that are not dominated by superficial technocratic visions of 'fixing' a problem.

Research context: My efforts to expose students to alternate forms of learning and critical inquiry took the shape of an urban terrace farm that was co-created with them. I chose food-garden as a topic of physical engagement because farming naturally provides a space to raise questions, and develop an integrated understanding of weather, food, nutrition, the economics of food production, water, and local geography. I worked with 40 students from grade 8 who were studying in a private school in the suburbs of Mumbai. The school I worked with is situated in the backyard of a landfill. The project was ungraded, and the school managed to allocate an hour every week in the morning for the activity. I worked with the students as a co-facilitator for an entire academic year along with two school teachers. The broad goal of the project was to understand and facilitate students' evolving engagement with the space, in terms of knowledge, practice, and motivations.

Tensions: The question of authenticity and legitimacy remained constant tensions that I had to negotiate with, while facilitating the project. On one hand, students' prolonged exposure and experience of creating a terrace farm from scratch led to a range of interesting responses and helped them connect ideas of waste, resource, pest-predator relationships, the role of biodiversity, respect for labour, and so on (Dutta & Chandrasekharan, 2019). However, the terrace farm failed to be seen as a legitimate space for inquiry within the curriculum. While it was positively received in the school by teachers, its definition as an 'extra-curricular activity' rendered it ineffective in expanding or subverting the conventional science/ social science topics in the school, even as students raised critical questions such as the relation between farm labour, livelihood and food price, consumption patterns in cities, rural-urban migration and so on. The possibilities were thus curtailed because teachers found it difficult to

transgress their own disciplinary boundaries and embrace the 'possibilities of radical openness' offered at the farm site. In fact, the space to a certain extent got appropriated as a tool to teach 'better science'. The question I wrestled with throughout was, 'What voices can radical, transformative experiences assume if they don't find a legitimate space in mainstream educational practices?' Additionally, though the experience of growing food was transformational for the students in many ways, it was still an isolated activity that did not engage with other aspects of their life or aspirations, unlike a rural population who are engaged in farming as means of livelihood, and thus would have a lot more at stake in terms of practice.

Case 3 - Contours of just and sustainable technology design: Designing solutions, including technologies, to address the unmet needs of the marginalised while mitigating the threats of climate change, is an imminent messy challenge that educational systems want to build agency and competency for. Towards this vision, as a Learning Sciences researcher, one of my (Geetanjali) efforts has been to characterise the examples of alternate practice, such as that of grassroots technology design, and draw takeaways to supplement, augment, or redesign learning systems or environments.

Research Context: In the Indian context, grassroots technology designers have developed micro hydropower systems as sustainable and renewable energy solutions for communities that the mainstream systems have failed to serve. I characterised the design practice of two such innovators: 1) a grassroots innovator[1] and 2) an engineering professional[2] (Date, 2019). An insight, from analysis of these and other documented cases, supplemented by a simulation-based probing of the design thinking of these innovators, suggests that the society-technology connection can be just and equitable when the design process starts with need identification and problem formulation, and not context-sanitised technical specifications (Date, 2019).

Tensions: Since one of the designers had studied only up to grade ten, a major underlying tension that surfaced from this study was the legitimacy of other forms of knowledge (procedural, experiential, place-based, traditional) and thinking (situated, distributed, embodied) vis-a-vis the formal, declarative, disciplinary bodies of engineering sciences and mathematics knowledge. This reflects in the mainstream industry's success criteria for a technology - efficiency, replicability, mass-manufacturability through standardisation leading to profit - and the values of the innovators that prioritise addressing the problems of the underserved, creating livelihoods for the local community, and supporting entrepreneurs, while causing minimal disruption to the natural ecosystems. The tension translates into the question of whether the alternate practice gets a legitimate space in the education, practice, and identity of future engineers, alongside the dominant formal knowledge. Another tangible aspect of the tension was how the other designer - a B. Tech from a top Indian Institute of Technology - negotiated the hierarchy between him and the uneducated villagers, to arrive at *their* desired solution. Expertise, when understood as formal training, and knowledge of formal structures, concentrates the power to define the 'desirable' into the hands of the trained engineers, even if they aspire to design *for* the nondominant. This generates the question of how students can be trained to recognize other forms of 'expertise' so as to develop the sensibilities to design *with* the nondominant, including the non-human species whose voice it is hard to capture?

Findings and Discussion

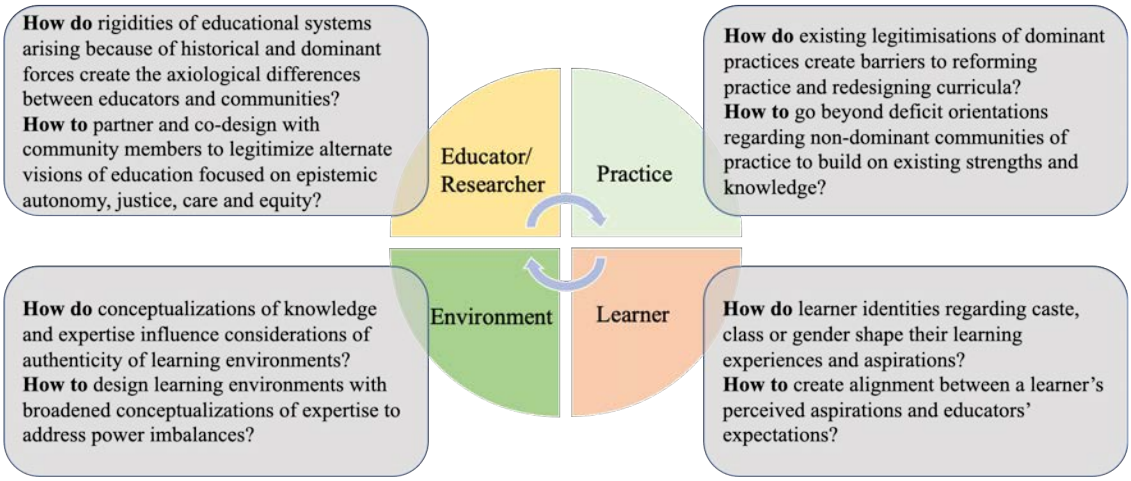

Figure 1: 'How do' and 'how to' questions to consider for translating our visions into realities

[1] Innovators recognised by National Innovation Foundation (see http://nif.org.in/) for their novel solutions to societal problems.

[2] A trained engineer who took up the design of micro hydro power systems for underserved grassroots communities.

Our analysis revealed that the tensions were spread across the range of stakeholders in the education ecosystem. The present and historical considerations of dominant and nondominant communities manifested in various ways for researchers, practices, learners, and designs of learning environments. In the further analysis of the tensions, we focused on these four categories (Figure 1). Based on the crosscutting tensions across our studies, we developed ‘how to’ and ‘how do’ questions. The first - 'how do' – question in a category captures tensions that we see as generative outcomes of our work. Building on these, we further developed 'how to' questions, which are intended to generate ongoing conversations and enable evolving ideas for future work.

The main commonality across these studies in different Indian contexts is that they aim towards reimagining learner participation in different communities of practice - scientific knowledge production, organic farming, and technology design. Such reimaginations requires questioning rigidities in educational systems - the ontological (who are considered experts in a particular field?), the epistemological (what practices of knowledge construction and evaluation are privileged?), and the axiological (what value considerations govern decision making in these systems?), which manifest in designs of the learning environments and educational practices. Given the existing legitimization of dominant educational practices, such as, focusing on student performance in standardised exams, our visions entailed a certain normative imagination regarding the desired direction of envisioned social futures and educational design. As we hold our axiological positions as researchers, regarding designing educational experiences (epistemic autonomy, justice, care, equity), and had other curriculum-specific goals such as computational thinking or organic farming, we need to be open for continuous re-evaluation as we seek to align those with our design partners who work in the existing rigid education systems with severely limited epistemic autonomy.

Our research engagements with the nondominant individuals and communities in diverse Indian contexts highlight some tensions that need to be explored, understood, and clarified as we engage with SDBE and similar methods. Rather than seeing these tensions as limitations, we treat them as generative outcomes that could be used to identify existing lacuna and build newer imaginaries. These may help the research community better understand what elements of the design and processes of social experiments need to be foregrounded in such work.

A Framework for *Assessing* Teachers' Readiness for Pedagogical Transformation

Bonni Jones, Utah State University, bonni.jones@usu.edu
Hillary Swanson, Utah State University, hillary.swanson@usu.edu

Abstract: Creating conditions that empower science teachers to innovate in their classrooms is important yet challenging. The Next Generation Science Standards (NGSS) invite teachers to educate in ways that differ markedly from traditional pedagogy. We posit that this transition requires more than asking teachers to implement novel instructional approaches after participating in a few professional development sessions. We present a preliminary framework for assessing whether teachers and learning communities have the beliefs, abilities, and motivations necessary for sustainable transformations.

Introduction: The need for readiness evaluations

Science teachers feel pressure to align with the Next Generation Science Standards (NGSS) and embrace innovative methods and technology. Yet, their daily classroom practices rarely incorporate these innovations (van Driel, Beijaard, & Verloop; 2001). Research into this phenomenon includes studies of professional development (PD) effectiveness and teacher learning, beliefs, and resistance to change. Findings have yet to uncover how to reverse the trend (Wang, Olivier, & Chen; 2020).

Tensions surface when teachers and students are expected to replace traditional activities, including lectures, worksheets, teacher-led step-by-step labs, and tests, with innovative activities, including student-led inquiry, developing and using models, arguing from evidence, and constructing explanations. The aim of the present study is to identify the specific elements creating tensions and barriers that undermine teachers' readiness for change.

Video recordings of a summer PD and follow-up interviews provide insights into these tensions and barriers. Themes that emerged during a grounded analysis of the data were found to relate to Bandura's human agency work and the influencer framework by Grenny et al., (2013). Drawing on our grounded analysis and these two literatures, we present a new framework, which we call the *agency influence* framework. The framework points to areas within an education system that need evaluation and intervention before change can begin. This education-specific change-readiness framework provides direction for in-depth investigation of any educational entity's fitness to fully embrace innovation. We hypothesize that following a framework like the one presented can facilitate pointed inquiry and discussion that increase the chance for successful uptake of educational innovation in the classroom. Our discussion of the framework below documents its chronological unfoldment.

Empirical context

Data were drawn from a 4-week professional development institute, during which three middle school science teachers created NGSS-aligned instructional materials. These materials introduced students to computational modeling microworlds and scaffolded their use of the microworlds to construct their own theories of different phenomena. During our time together, the teachers spontaneously expressed the tensions and barriers they experience when asked to implement new pedagogies and technologies in their classroom. Recordings of the PD sessions were transcribed and then coded to capture and categorize teacher utterances like the ones below.

> "We have to move on [to] keep the pace, because we have to cover all the standards that the tests are going to assess students on."

> "What you can do with one kid in 4 hours is probably equivalent to what you do with 35 kids in 8-12 hours. With more kids, it takes a lot longer."

 © ISLS

> "It's because we have this evaluation system in place, that we have to give the tests, that we have to focus on the grades, because we're held accountable to the grades. "

> "I'm going to be like the typical 8th grader because I don't like coding. I'm not engaged in it. I don't like to do it [and] don't want to do it. I'll do [it] as a means to an end."

These utterances conveyed that our teacher partners were not empowered to take a new approach to scientific inquiry in their classrooms, despite their desire to do so. We have created the agency influence framework for making sense of the tensions and barriers experienced by our own and other teachers. The framework integrates components from both Bandura's and Grenny's work on agency.

Making sense of the influences on teachers' readiness for change

Bandura's (2001) work suggests that underlying influences deterring teacher action can be found within their beliefs, sense of self-efficacy, abilities, and motivation. Teacher utterances during the summer PD contain evidence of reduced ability and self-efficacy, as well as lack of motivation and negative beliefs. Bandura (1997) found that these kinds of affective traits can limit individuals' experience of agency. While Bandura's findings describe individual agency, they lack insights into educational resistance toward pedagogical transformation. Grenny et al. (2013) investigated influences that constrain agency and prevent people from changing behaviors in schools and societal situations where change is difficult. Grenny's key findings build upon Bandura's ability and motivation work by creating three subcategories: personal, social, and structural. A matrix showing the cross-product of *ability* and *motivation*, with dimensions of *personal*, *social*, and *structural* influences, is shown below in Table 1. These subcategories form the backbone of our agency influence framework, shown on the next page in Figure 1.

Table 1: Personal, social, and structural sources of influence on ability and motivation

	Ability	Motivation
Personal	The individuals have skills, understanding, strengths or tools to do the right thing.	They want to engage in the new behavior.
Social	Resources, training, encouragement & support are provided by the community.	Leaders and community members encourage and reward the new behavior.
Structural	System constraints or expectations and environmental characteristics such as space, time, tools, or other elements are provided.	Systems are rewarding the right behaviors that are effective in the new behaviors.

Grenny et al.'s (2013) findings show that people are more likely to change behavior when all six sources of influence support that change. We evaluated the six sources of influence against the utterances of the teachers (Table 2). Evaluating the teachers' talk in this way brought to light structural systems, social relations, and personal states of being that influence behavior decisions. Other phrases like, "I'm not good at coding," correlate with Bandura's (2001) belief influences. These are also included in the table below.

Table 2: Evaluating teacher utterances to determine sources of influence

Teacher utterance	Source of influence	Explanation
We have to move on, [to] keep the pace, because we have to cover all the standards…	Ability structural	A structure is causing and rewarding things the teacher doesn't feel capable of changing.
	Motivation personal	The teacher doesn't enjoy or want to engage in the behavior.
… I don't like coding. I'm not engaged in it. I don't like to do it, [and] don't want to do it. I'll do [it] as a means to an end.	Ability personal	Skills, resources, or training are needed.
	Ability social	The community doesn't provide support.
	Motivation structural	Ineffective actions are rewarded.
	Motivation personal	The teacher doesn't enjoy or want to engage in the activity.
It's because we have this evaluation system in place, that we have to give the tests, that we have to focus on the	Ability structural	Systems don't enable choice .
	Motivation structural	Systems don't reward actions outside tests and grades.

 © ISLS

grades, because we're held accountable to the grades."	Motivation personal	The teacher doesn't enjoy the activity.
	Motivation social	People are measuring test and grade performance not NGSS skill development.
I'm a little overwhelmed right now, because I've had no experience with the aggregate-pattern theory building.	Belief personal	The teacher is questioning their ability with something new.
	Belief social	The teacher is questioning getting the support they need.

Recognizing the importance of belief, we crafted personal, social and structural influence questions following the pattern of Grenny et al., (2013). We present these questions in Figure 1. When Bandura discussed agentic action he included self-reflectiveness, self-reactiveness, self-influencers and intention. We saw that self-reflectiveness plays a role in evaluation of beliefs, self-reactiveness helps define ability, and self-influencers get to the root of motivation. Intention is included as a final step to help leaders and staff clarify their courses of action and commitments.

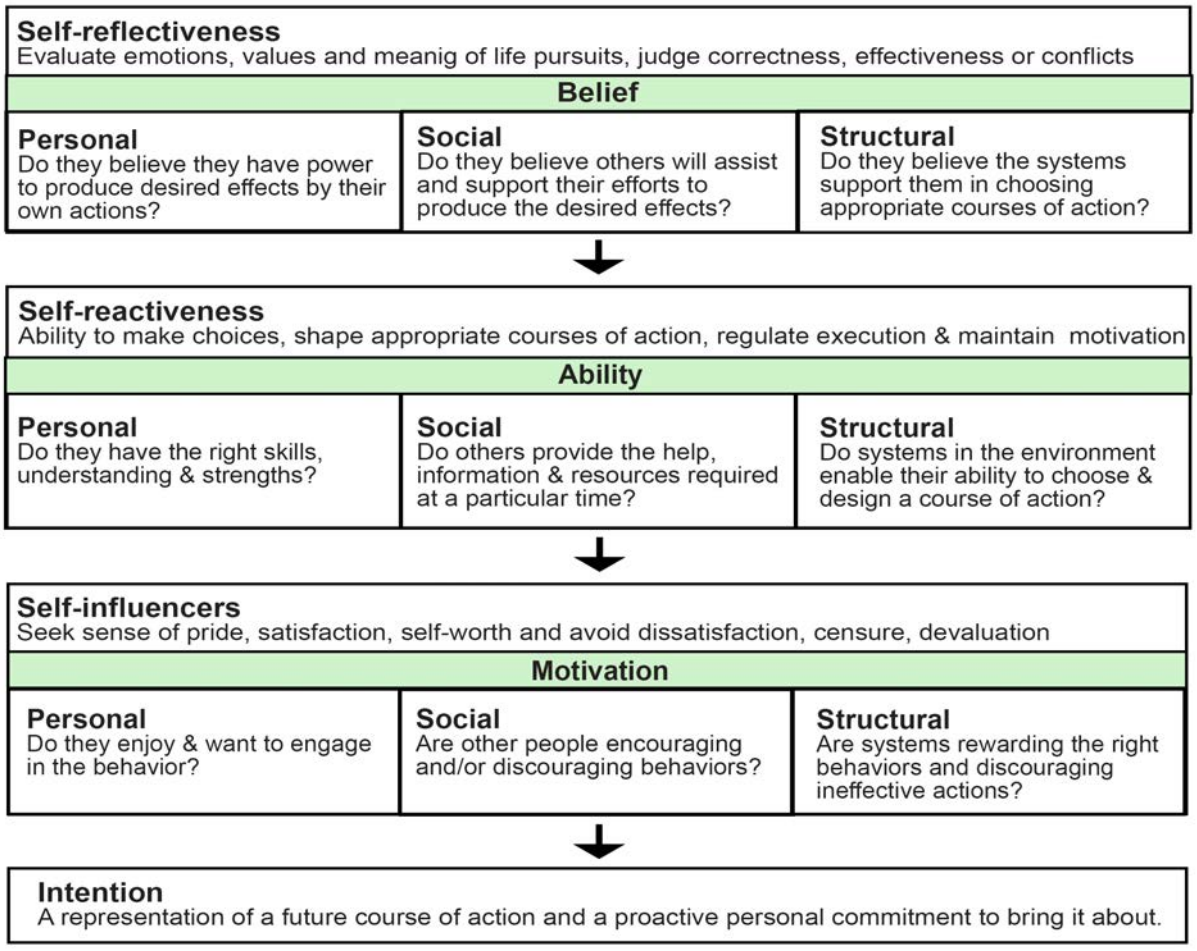

Figure 1: Agency influence framework

This framework can be used to guide education leaders through self-reflection, where they consider and discuss the state of their communities' beliefs, abilities, and motivations with respect to the proposed pedagogical changes. The discussion outcomes can be used to set a course of action supported with personal commitment to the new goal. If it is determined that the community is not ready, areas that need preparation are illuminated. Table 3 takes each part of the framework and provides possible questions education leaders can ask as they follow the guide to investigate their learning community's readiness for pedagogical transformation.

Table 3: Example of questions a leader might ask to implement the framework and evaluate their community's readiness for change

Framework component	Questions a leader might ask as they go through the readiness assessment.
Self-reflectiveness	What school culture elements cause teachers or students to feel unsafe evaluating emotions, values, judging effectiveness, or addressing conflicts? What changes do we need to make?
Belief: Personal, Social, Structural	When do teachers or students believe they do not have power to do what they feel is best for their classroom or learning? Do they believe others will assist them? When do they feel that culture/systems restrict their ability to make choices incorporating new ideas? What in our culture/systems need to change?
Self-reactiveness	Armed with beliefs, teachers need time to contemplate courses of action, regulate execution and maintain their motivation. What adjustments are needed to give this time?
Ability: Personal, Social, Structural	What skills, understandings or strengths are the teachers lacking to accomplish this goal? What do they need? When do they need it? What systems/culture are restricting their ability to take this course of action? What changes need to be made? How will we do it?
Self-influencers	When someone has taken risks to try something new, what are the responses? What are unhealthy ways we censure, devalue, or communicate dissatisfaction? What changes need to be made so that a sense of pride, satisfaction, recognition is given for the risk they have taken and value the have provided to the community?
Motivation: Personal, Social, Structural	Are cultures/systems requiring actions that are ineffective, lack time, space or engagement? Do rewards/milestones encourage or discourage people taking actions they value as most important? What culture/system changes are necessary?
Intention	Do our teachers and students have the stewardship to plan a learning course of action and a personal commitment to bring it to fruition? What prohibits this? How do we change it?

Conclusion

The agency influence framework provides a systematic approach for evaluating a learning community's readiness for change. It asks us to consider the multidimensional, complex, and complicated conditions associated with enacting change in pedagogy, tools, and practices. This new framework is intended to encourage readiness evaluation before attempting to implement new technologies, practices, or pedagogies in learning communities. Future directions include studying the capacity of this framework to help learning communities identify and create supports before attempting a pedagogical transformation.

INDIGENOUS LEARNING LAB: INCLUSIVE KNOWLEDGE-PRODUCTION AND ENACTED UTOPIAS TOWARDS DECOLONIZING SCHOOL SYSTEMS

Abstract: The United State was built on settler colonialism, slavery, and capitalism. Settler colonialism strives for the dissolution of Indigenous societies by establishing a new colonial society on seized land with the elimination of Indigenous societies as an organizing principle. Through the education system, Native Americans experienced downward assimilation and cultural genocide. Today, Native American youth disproportionately receive exclusionary disciplinary actions more frequently and severely in schools. Disproportionality in school discipline is a result of historically accumulated contradictions such as widening disparities in health, justice, housing, and wealth. As an enduring systemic contradiction, disproportionality demands sustained collaborative systemic transformations led and owned by local stakeholders. This paper presents a new formative intervention model, *Indigenous Learning Lab.* In a partnership with an Anishinaabe nation, Indigenous students, educators, and family and community members and non-Indigenous school staff, our research team worked at a rural public high school to collectively design and implement a new, culturally responsive, decolonizing school-wide behavioral support system.

Objectives

Settler colonialism strives for the dissolution of Indigenous societies by establishing a new colonial society on seized land with the elimination of Indigenous societies as an organizing principle (Wolfe, 2006). Through the education system in U.S., Native Americans experienced downward assimilation and cultural genocide. Today, in the U.S. education system, Native American youth receive exclusionary disciplinary actions more frequently and severely for more subjective reasons such as disrespect (Whitford et al., 2019). Disproportionality in school discipline is a result of historically accumulated contradictions arising from a racist, settler colonial society (Bal, 2017). Addressing inequity requires a situated conceptualization to help develop systemic solutions led and owned by community members in response to school communities' diverse and often opposing histories, interests, and goals.

In this study, we examined how Indigenous Learning Lab, a community-based, inclusive systemic design intervention that aimed to facilitate the inclusive design of a culturally responsive school-wide behavioral support system in partnership with a tribal nation of the Anishinaabe people and school staff at Northwoods High School, a rural high school in U.S. We addressed the following question:

> How did Indigenous Learning Lab facilitate the collaborative problem-solving and systemic design process with Indigenous and non-Indigenous members of the school community for the systemic transformation?

Theoretical Framework

Indigenous Learning Lab is a formative intervention model (Sannino et al., 2016). It is grounded in Cultural-Historical Activity Theory (CHAT) and Decolonizing Epistemologies (Engeström, 2016; Smith, 2012). Indigenous Learning Lab builds upon "refusal" of metanarrative in social science research and leverages "resistance, reclaiming, recovery, reciprocity, repatriation, [and] regeneration" (Tuck & Yang, 2014, p. 244).

Methods

Indigenous Learning Lab included 14 participants (See Table 1). Members participated in 11 video recorded sessions. They followed a cycle of expansive learning actions consisting of forming Learning Lab, questioning, analyzing, modeling, testing, and stabilizing new solutions to resolve the systemwide problems of practice (Bal, 2017).

Results

Forming Inclusive Problem-Solving Group

The research team worked with the community and school liaisons to hold initial meetings on the reservation to disrupt asymmetrical power relations embedded in the bureaucratic school system. Each session started with a pipe smudging ceremony by lighting up traditional tobacco and sage. The American Indian education mentor led the pipe ceremony. As suggested by the Anishinaabe community members, the research team introduced the

 © ISLS

Seven Grandfather Teachings of the Anishinaabe as inclusive group norms to run a mutually respectful problem-solving process. The Seven Grandfather Teachings are orally passed-down moral and ethical principles elders have used to educate future generations on living a good life: Nibwaakaawin (Wisdom); Zaagi'idiwin (Love); Minaadendamowin (Respect); Aakode'ewin (Bravery); Gwayakwaadiziwin (Honesty); Dabaadendiziwin (Humility); and Debwewin (Truth).

The collaborative examination of systemic contradictions (e.g., racial disparities) and the creation of new instrumentality aimed to resolve daily disturbances and conflicts resulting from the inner contradictions. Learning Lab facilitated the expansion of the school discipline system's object from the punishment and exclusion of students with challenging behaviors to prevention and inclusive, positive support for *all* students and adults in a school community. A new, culturally responsive system was designed around the expanded object. The following academic year, the Learning Lab members worked on the implementation of the new system.

Analysis of Systemic Contradictions in Settler-Colonial School System

Learning Lab utilized multiple mediating tools to stimulate a critical analysis. Members mapped out the school's exiting discipline system and identified multiple systemic breakdowns in the existing system that contribute to (re) production of the racialization of school discipline.

Designing Systemic Solutions for an Enacted Utopia

Members designed a new, culturally responsive school-wide behavioral support system. Members used the system map to generate solutions for the inner contradictions in their system. In the 2020-2021 academic year, the school implemented the new system.

Significance

To offset the cumulative effects of colonial harms through education systems, critical indigenous scholarship has emphasized the necessity of building culturally decolonizing systems (McCarty & Lee, 2014). Learning Lab can be utilized to address historically accumulated contradictions through strategic community-school-university coalitions for building a socially just school systems. In the learning sciences, design-based research moved toward more situated, collaborative forms of research (Bang et al., 2016).

Forming inclusive, productive, and sustained design teams requires time, commitment, interest convergence, negotiations and more importantly robust methodologies and theories of organizational learning and transformation (Adler, 2015). The present study shows how CHAT and formative interventions can be instrumental in this paradigm expansion and may contribute to recently emerging inclusive, community-based research methodologies such as DBIR and social design experiments. Indigenous Learning Lab may add more to the field's toolbox for facilitating the decolonizing knowledge-production activities and systemic transformation of the oppressive social systems towards *buen vivir* – collective well-being.

Comprehensive Student Records as a Tool for Networked and Connected Learning: Using Social Media Research to Frame Inquiry

Steven L. Cederquist, University of Michigan-Ann Arbor, cedsteve@umich.edu

Abstract: Comprehensive Student Records (CSRs) are an emerging model for life-long and life-wide learning transcripts. As they are currently conceived, CSRs would allow students to track and curate learner profiles aligned with industry recognized skill frameworks, making them potentially powerful tools for promoting pipelines to future learning and employment. How CSRs could support connecting and networking within these pipelines is, however, undertheorized. In this paper, social media research is used as a frame to inform future work of designing CSRs as tools for connecting and networking students to learning and employment opportunities. Special attention is paid to the need to focus on the design of CSRs to promote equitable access to employment.

Introduction

In 2015, the American Association of Collegiate Registrars and Admissions Officers (AACRAO) partnered with the National Association of Student Personnel Administration (NASPA) to implement the *Comprehensive Student Record Project* to imagine the future of student records for lifelong and life-wide learning (Green & Parnell, 2017). Comprehensive Student Records (CSRs) differ from typical student records in that they allow for richer accounts of skill and ability by shifting the measure of learning away from seat-time metrics to competencies demonstrated through experiential learning. CSRs also take advantage of the affordances of digital technology to include micro-credentials and other digital evidence of learning. It has been argued that CSRs can be a powerful tool for students to construct learning profiles that can be aligned to industry-recognized skill frameworks (Shendy et al., 2019) making them useful tools for scaffolding future learning and connecting students to learning employment opportunities.

Research on CSRs has so far focused on demonstrating their viability as a medium for communicating more explicitly about experiential learning. This has been demonstrated through the *CSR Project* that saw CSR models expand from twelve models in the pilot study to over 150 models in Phase II of the project. Another line of research has sought to understand student (Parish, Parks, & Fryer, 2017) and employer (Cederquist, Fishman, & Teasley, 2022) perspectives of CSRs as tools for communicating learning. Findings from both studies suggest CSRs are perceived as more informative than traditional transcripts in that they more holistically communicate the broad range of skills and competencies students are developing within and outside classrooms. While this line of research has done well to demonstrate the viability of CSRs as an alternative transcript model, additional work must be done to understand their viability as a tool for connected and networked learning. In this paper, I use social media research to frame challenges and opportunities researchers should consider when designing and scrutinizing CSR systems for their ability to equitably and capably connect and network students to future opportunities. What emerges is the importance of understanding producer (student) and consumer (e.g., employer) behavior as it relates to CSR curation and consumption. Before moving into this discussion, I first describe CSRs as a tool for "connected learning" (Ito et al., 2013) by highlighting the unique features of CSRs.

CSRs as a tool for connected learning

As they are currently conceived, CSRs largely reflect existing static academic transcripts with the addition of experiential learning outcomes documented on the transcript. To understand the potential of CSRs as a tool for connecting and networking to opportunity, it is important to highlight two key features: 1) the emphasis on their interoperability with different employment and learning platforms, and 2) ownership of the record is vested in the student rather than the credentialing institution (Torres, 2020). Torres (2020) argues this is particularly useful for those students who ultimately leave postsecondary education with some credits but no degree; with a CSR system, any learning achieved or competencies demonstrated could be stacked and credentialed. This would allow students to "translate their full education, training, and work experience to a record of transferable skills" (Torres, 2020, p. 46). As a personally-managed digital record of one's achievements and interests across time and space, CSRs would support models of connected learning: socio-cultural models of learning that are interest-driven, peer-supported, and production-centered and powered by networked technology (Ito et al, 2013). This interpretation of CSRs as a tool for connected learning is further supported by ethnographic work on social media as a tool for job-

 © ISLS

seeking—notably the work of Gershon (2017). Gershon documented how the changing technological infrastructure of networking and hiring (e.g., LinkedIn) presents a scenario in which the individual is encouraged to view themselves "as a business" in which their bundle of curated skills are viewed as business solutions publicly displayed for the purpose of networking and gaining employment (p. 11).

The possibility of curating one's bundle of skills is supported by a feature of CSRs often highlighted by their proponents—the possibility for collecting rich and granular data on student activity through digital learning tools (Black, 2016). Black argues that an increased level of detail in data collection and representation "can lead to a fuller analysis of strengths, weaknesses, and opportunities" in a world in which continuous assessment of skills is becoming increasingly important (Black, 2016, 4th para.). In theory, data collected on student behavior could be analyzed by admissions officers, hirers and applicant tracking systems to support decision-making in applicant screening and evaluation. While intriguing, Teasley and Kelly (2020), in their report on the potential of linking learning and employment data, have noted there are short and long term issues that must be addressed before this idea can be fully realized in practice: for example, defining higher education outcomes as competencies and developing methods for communicating these competencies. Ultimately, as issues of data measurement and communication are addressed, it will become increasingly important for researchers to understand how questions related to CSR platform features may impact consumer and producer behavior. In the following sections, I point to research from social media studies that can help scholars examine these issues.

Framing CSRs through social media research

As discussed above, CSRs have the potential to be a tool for managing one's self-presentation as employable, or ready for future learning, through data derived from a wide variety of learning experiences. From this perspective, we can assume there are implications for how students (producers) would utilize the affordances of CSR systems to document their learning and connect prior experiences to new opportunities. There are also clear implications for how both humans and machines will interpret the data contained within CSRs to support recruitment and hiring decisions. In the following sections I use social media research to further explicate the two perspectives of producer and consumer, showing how both are vital to understanding the potential opportunities and pitfalls of CSR systems as tools for connecting and networking to opportunity.

Self-presentation: Audience and affordances

Social media research into self-presentation has a long history and finds its roots in Goffman's *Presentation of Self in Everyday Life* (Donath, 2020; Goffman, 1959). An issue often addressed by self-presentation research is whether the unique environmental cues of social media result in distinct affordances for self-presentation (Donath, 2020). This question is crucial because it points to two social media theories—audience and platform affordances—that may help researchers better understand how CSR-users might manage self-presentation in networked environments. For example, Duffy and Chan (2019) documented emerging adults' response to "imagined surveillance." Duffy and Chan's participants described using privacy settings on social networking sites to manage an imagined audience's access to certain content, thus controlling their identity presentation. (Duffy and Chan, 2019, p. 125). Viewed through the lens of *affordances*—the "multifaceted relational structure between an object/technology and the user that enables or constrains potential behavioral outcomes in a particular context" (Evans, Pearce, Vitak, & Treem, 2016, p. 36)—Duffy and Chan's participants were able to control their visibility on platforms because of these privacy features. This allowed the participants to manage who saw what information, and as a result the impressions they believed potential employers would form about them. The framing of affordances will be particularly useful for understanding the unique advantages a digitally networked record of student learning has over traditional transcripts. Additionally, as CSR designs evolve over the course of students' lives, taking an affordances perspective will allow for a contextually stable object of inquiry. This points to the moving target problem in social media research, i.e., "the challenge of researching media artifacts and effects that are constantly in flux" (Bayer, Trieu, & Ellison, 2020, p. 472). Employing an affordances perspective with CSRs will help researchers and designers understand how changing features of the technological system either support or hinder the presentation of one's self as competent in order to align with evolving standards and expectations of professional communities.

Impression formation: Signaling and warranting theory

Proponents of CSRs typically frame the process by which evidence of competence contained in CSRs could help people find jobs as follows: 1) CSR data connects a student to an opportunity, 2) a student presents evidence of competence, 3) the evidence is interpreted by human or machine, and 4) the student is accepted as competent. CSR research would benefit from a consideration of how information cues, or the hidden signals given off by characteristics of the information and channel, specifically affect impression formation. Additionally, while hirers

do review work portfolios, less is known about how they would interpret the granular data on learning that differentiates CSRs from portfolios. Interpreting these issues through signaling and warranting theory can help explain how a focus on CSR design can help us understand how impressions are formed through digital media.

Signaling theory argues the perceived reliability of information relates to the perceived cost of producing the information; two types of signals are noted in the literature. Assessment signals are those that are more costly to produce and are thus deemed more reliable because "their production mandates the possession of the quality." Conventional signals, because they are believed to be more easily produced, are viewed as arbitrary signals of a quality (DeAndrea, 2014, p. 197). Warranting similarly describes how people interpret information cues, but unlike signals which convey reliability through production cost, warranting conveys reliability based on cues presented by the source of the information. The more control a user has over the source of the information cue describing them, the lower the warranting value. As a result, third party warrants are generally believed to be more reliable.

Taken at face value, we might assume evidence within CSRs would be interpreted as assessment signals with high warranting value: student competency data and examples of work can be reviewed to determine if a job applicant is qualified for the job, and the validation of the credential issuer would imbue the evidence with high trust. However, findings from CSR research suggest additional research into the signaling and warranting powers of CSR features is needed. For example, to understand the advantages and challenges of implementing CSRs into entry-level hiring, Cederquist et al. (2022) presented hirers with a publicly available exemplar of a CSR designed around mastery- and competency-based learning known as the Mastery Transcript™. While perspectives were generally positive, two potential challenges emerged from the study. First, how complex non-cognitive skills could be presented through the CSR's data visualizations was unclear to the hirers—they were unsure how such a contextually situated competency like teamwork could be represented through data on a digital transcript. The second challenge relates to the similarities hirers drew between the Mastery Transcript™ and LinkedIn. Due to the school's verification of learning, hirers viewed the personally curated competency profile in the Mastery Transcript™ as a more reliable presentation of competence than what students curate on LinkedIn. While we can interpret this as a potential advantage CSRs could contribute to social media professional networking sites such as LinkedIn, it is unclear if this opinion would be held by other hirers. Cederquist and colleague's population size was too small (n=12) and the background of informants too similar (participants came from one professional pathway) to draw generalizable findings. Future research should include larger and more diverse professional pathways to determine if CSRs maintain their high warranting value.

The importance of designing CSRs for equity and inclusion

Before concluding, it is important to note why it is of vital importance to consider the social networks through which job seekers access labor markets when studying CSRs. Referring back to Gershon (2017) we see that professional networking sites such as LinkedIn are designed with a specific type of worker in mind—white collar professionals. Similarly, research on low-resource workers' use of social media for job-seeking shows that when using Internet-based tools to look for work, low-resource workers tend to rely on social network sites like Facebook and Instagram and job posting sites like Craigslist to find information about work (Lu & Dillahunt, 2021). Lu and Dillahunt (2021) show that this has implications for equity as the design of communication channels on sites like Facebook reinforces power asymmetries between employers and low-resource job seekers; employers interviewed in the study framed Facebook recruitment as a process of "accessing a *pool* of low wage workers" (sec. 5.3, emphasis original). Lu and Dillahunt argue that this framing potentially makes low-wage workers both "more accessible" but also "more expendable and replaceable" (sec. 5.3). A focus on equity and inclusion also highlights the necessity to vest control of CSR data with the student. Failure to do so opens low-wage workers to potential exclusion through surveillance of the digital traces of their education and employment records.

This asymmetry between hirers and job-seekers echoes McDonald and colleagues (2019) study of two online labor markets—Monster.com and LinkedIn. The former site was described by hirers as "black holes" in which the ease of uploading resumes to the site resulted in information overload as thousands of applications came in for only one position. LinkedIn, however, was described as a site for looking for and recruiting "specialized superstars" away from their current jobs. Sites liked LinkedIn are not designed with the great diversity of job seekers in mind. Thus, designing CSRs with only LinkedIn in mind would likely obscure the needs of a wide swath of the labor market. These findings suggest it would be prudent to focus the work of designing CSRs with those typically left out or disadvantaged by the existing technical infrastructure of job-seeking. Dillahunt and colleagues' body of participatory design work with underserved job seekers provides a useful starting point for the design of such an agenda (see Dillahunt, Lam, Lu, & Wheeler, 2018; Wheeler & Dillahunt, 2018).

Conclusion

As CSRs develop as tools for connected learning, it will be important to develop a more rigorous theoretical understanding of their design and use within networks. Findings from social media research can help in framing studies with these objectives. Studies of CSRs should pay particular attention to the affordances offered by features unique to CSRs, particularly the affordances offered by interoperability and student ownership (as opposed to institutional ownership). Additionally, research on the imagined audience can help scholars understand how CSRs help students curate self-presentations of competence and network within communities of practice. Research into consumers of CSRs should examine how both humans and machines interpret evidence, including granular data on learning, to form impressions of the individuals represented through CSRs. This should include the unique environmental cues communicated by diverse information sources and channels. This also strongly suggests a focus on developing CSR systems that support the job-seeking behavior of those typically left out of the labor market. Such a focus will forefront the needs of low-resource job seekers and help promote the development of equitable pathways to employment.

Exploring Elementary Teachers' Perceptions of Teaching a Science, Engineering, Mathematics, and Computer Science Project

Sarah Lilly, Anne M. McAlister, Jennifer L. Chiu
scl9qp@virginia.edu, amm8km@virginia.edu, jlc4dz@virginia.edu
University of Virginia

Abstract: While national frameworks call for the integration of science, technology, engineering, mathematics, and computer science (STEM+CS) in K-12 contexts, few studies consider elementary teachers' perceptions of implementing STEM+CS projects in science classrooms. This single case study explores elementary science teachers' perceptions of enacting STEM+CS curricular materials. Survey and interview data were collected over the four-week project and qualitatively coded. Findings demonstrate teachers' reported struggles to implement unfamiliar disciplines and leverage students' prior knowledge in familiar disciplines as well as unanticipated consequences of instructional decisions based on perceived student engagement and pacing. Results underscore the value of teacher voice for curricular and professional development and highlight the need for further investigation of how teachers' perceptions may influence enactment of STEM+CS curricular materials.

Introduction and background

Interdisciplinary science, technology, engineering, mathematics, and computer science (STEM+CS) curricular activities involve deeply integrated practices for developing knowledge. National frameworks in the United States describe a STEM+CS vision involving students developing science knowledge and engineering design solutions by using mathematics and developing computational models to solve authentic problems and create scientific arguments and explanations (i.e., ASEE 2020; K-12 Computer Science Framework, 2016; National Research Council, 2012). In the elementary grades, implementing interdisciplinary STEM+CS projects includes integrating mathematics, computational thinking, and engineering concepts and practices into science classrooms where students define problems, analyze and interpret data, model solutions and science phenomena, and develop, test, and communicate solutions while considering constraints (NGSS Lead States, 2013).

Teaching this type of interdisciplinary curricula is challenging (Fulmer et al., 2018), especially for elementary teachers who may have differing amounts of knowledge of each individual discipline. For example, elementary teachers report feeling well prepared to teach mathematics and science but not engineering and computer science (Plumley, 2019). Although elementary teachers typically teach multiple disciplines to their students, interdisciplinary curricula require making connections across disciplines. As teacher education programs largely focus on siloed domain approaches to disciplines, teachers may need support to implement interdisciplinary approaches effectively in their classrooms. For instance, teachers may perceive content from integrated disciplines as skills instead of content, which may then affect how these disciplines are integrated and taught (Estapa et al., 2017). For example, mathematics can be implicitly integrated in STEM+CS activities (Lilly et al., 2021) and often takes the form of calculations or data representations (Baker & Galanti, 2017). However, making mathematics more explicit could change the student perspective from only focusing on a contextualized problem to a more explicit use of mathematics and disciplinary epistemologies (Fitzallen, 2015). In engineering, it may be challenging for elementary teachers to center engineering practices when they feel like they must prioritize the logistics of implementing engineering activities (i.e., Diefes-Dux, 2004). Additionally, elementary teachers may also be challenged in supporting students when content and practices are unfamiliar (Lilly et al., 2022). For example, elementary teachers may not be familiar with engineering analysis and so struggle to respond and guide students' varied design ideas to meet project constraints (Brophy et al., 2008).

This study then investigates how elementary science teachers perceive enactment of a STEM+CS project and aims to privilege the teachers' own voices to provide insights into their perceptions of challenges and necessary supports for the consideration of curriculum designers and professional development facilitators.

Methods

This study uses an embedded, single case study methodology (Yin, 2018) to examine teachers' perceptions of implementing a STEM+CS project in a public elementary school in the southeastern United States. The project challenged fifth-grade students to engineer a design solution to solve the authentic problem of water runoff at their school grounds by developing scientific models of runoff and absorption and using mathematics and computational thinking to develop computational models to test different engineering solutions. We define the

 © ISLS

case as two fifth-grade teachers, pseudonyms Mr. Skelton and Ms. Banet, who implemented the project in their two co-taught classrooms. We focus on this specific case as these teachers both hold an undergraduate science degree and thus have atypical content knowledge for elementary teachers. Further, both teachers have more than five years of teaching experience. Both teachers also have knowledge of project goals and educative supports as co-developers of the project who implemented a pilot version of the project the previous year.

Over the four-week project, both teachers answered open-ended questions on daily written surveys and weekly face-to-face interviews. Two researchers worked together to inductively code (Miles et al., 2020) the data through first and second level coding. First, the researchers identified if a teacher's answer demonstrated (1) perspectives about STEM+CS disciplines or (2) implementation of the STEM+CS project and then coded these statements for challenges, changes made to support student engagement, and additional supports that teachers perceive as necessary for equitable facilitation of STEM+CS activities. The researchers then looked across coded statements for patterns and wrote analytic memos (Miles et al., 2020).

Results

Teachers reported challenges with supporting computational modeling and mathematics and customizing and adapting the activities. First, both teachers discussed challenges with supporting students in computational modeling, including technical aspects of how to access and save students' computational models. For example, Ms. Banet discussed the difficulties that students faced saving and accessing their code within the computational modeling environment, "Explaining to the students how to save your computer, just in case something happens. That's pretty key. Because that kept happening, it kept disappearing." Ms. Banet also reflected how they could have addressed these difficulties by having more whole-class demonstrations of these problematic areas, "We should have done it at the beginning, showing how to shrink and enlarge the stage … That was a struggle."

The teachers also reported struggling with using pedagogical strategies for computing, such as debugging students' programs and supporting students to understand computing concepts such as variables. For example, Ms. Banet stated, "Students' programs were malfunctioning, I didn't know how to help other than having them close out their program and bring up a whole new copy … they ended up having to start over because I didn't know what to do." Here Ms. Banet reported on one debugging strategy that she used, starting over from scratch, but also recognized that she did not use any other strategies like stepping through each block together or asking the students to explain their code. Similarly, Mr. Skelton stated, "I also struggled to predict the sorts of observations kids make about their models and thus transition from those observations to useful questions that students could answer." In this comment, Mr. Skelton discussed his challenges for appropriate questioning strategies with the computational model. Teachers also found it challenging to support students using terminology or concepts from mathematics in science contexts. For example, Ms. Banet said, "A lot of students struggled with the word *relate*. They don't understand 'How does hourly rainfall relate to total amount of water'. And I don't know how to simplify that myself." Furthermore, even though Ms. Banet also taught mathematics classes, she reported struggling to support all students to use the mathematics concept of *ratio* with the science phenomena of absorption and run-off.

The teachers reported modifying the project to attend to these challenges. First, teachers reported adapting activities to maintain student engagement. For example, teachers reported adding an activity that was not in the curriculum in which students went outside to take pictures of their water runoff problem. The teachers considered the lesson to positively impact student engagement, as students "were able to connect pieces of the curriculum", the activity "reminded them of why we are doing all this in the first place", and it "sparked so much creativity." Adding this lesson enabled the teachers to see students that they perceived would struggle more with these lessons as capable of making connections within the curriculum. Additionally, the teachers reported altering activities as a result of time constraints. For example, Ms. Banet reflected that, "Due to time, we cut out all the math … so the kids didn't do pages, the last page we did was 18 and then we had them skip to page 26." When faced with pacing concerns, the teachers often chose to remove mathematics. However, teachers also acknowledged difficulties that may have emerged from their choices to skip parts of the project. Ms. Banet said, "I struggled to rush through the lesson without having students really understand why we were developing this model. Many students have lost interest … there's a disconnect between the hands-on experiments and how this relates to the computational model." As the mathematical tasks were designed to serve as connections from the hands-on activities to the computational modeling activities, Ms. Banet noticed the consequences of skipping activities.

Discussion and conclusions

This study focused on teachers' perceptions of challenges when implementing a STEM+CS project (i.e., Johnson et al., 2020; Pleasants et al., 2019). Even in this unique case, where both teachers have science degrees and

extensive curricular knowledge of the STEM+CS project, teachers discussed a range of challenges during classroom enactment. Teachers reported struggling with integrating disciplines with which they had more experience (i.e., mathematics into science) as well as disciplines with which they had less experience (i.e., computer science through computational modeling). For example, teachers noted the difficulty with mathematics terminology and concepts in science contexts. Results highlight how teachers may need support not only to integrate more unfamiliar disciplines like engineering and computer science into familiar disciplines of mathematics and science, but also to integrate mathematics and science content and practices.

Enacting STEM+CS curricular materials requires teachers to have pedagogical knowledge about each individual discipline (i.e., Johnson et al., 2017), and how pedagogical strategies in one domain (e.g., debugging in computing) may relate to pedagogical strategies in other domains (e.g., problem solving in mathematics) or how to use pedagogical strategies across domains (e.g., questioning). Teachers reflected on struggling with the broader, interdisciplinary nature of the curriculum in terms of recognizing how to enact such strategies across disciplines. Specifically, they did not feel as if they had the pedagogical content knowledge to make in-the-moment instructional decisions. Future research should explore how the kinds of pedagogical knowledge and strategies that teachers utilize for enacting STEM+CS curricula may affect student outcomes.

The teachers also reflected on their concerns about pacing and how to adapt the project to stay on pace (e.g., what to cut or what to focus on if students struggle). Although teachers reported challenges that stem from students' lacking foundational skills from integrated disciplines, they did not make connections about how their customization of the project may have compounded these challenges. For example, teachers reported students struggled with implementing their coding but did not make a connection as to how altering their project by cutting mathematics from early activities might have impacted later activities in which students were expected to code conceptual models. Specifically, without recognizing how knowledge would build and the importance of specific activities for students to understand concepts and engage in activities later in the project, the teachers may have cut important activities due to their beliefs about their students' abilities to engage in those activities in face of pacing concerns. This demonstrates unintended consequences in teachers' adapting an STEM+CS curricula without support to understand how practices and concepts may build across disciplines and supports prior research of teachers' challenges in STEM+CS contexts (Baker & Galanti, 2017). An implication is that curriculum developers need to support teachers' knowledge about how concepts and practices will progress throughout a STEM+CS project so that students are able to successfully engage in activities across disciplines.

Further, teachers used the challenge of implementing ratios to recognize that they must safe-guard against allowing students' abilities and individualized needs, as well as teachers' beliefs about students' abilities in mathematics, to dictate students' opportunities to engage in science activities. For example, the teachers reflected on the challenge of leveraging students' prior mathematics knowledge and attempted to differentiate for students with different prior mathematics knowledge to equitably support all students to engage with this challenging interdisciplinary curriculum. However, although they also recognized that students' prior experience with coding affected their ability to engage in computational modeling, the teachers reported being unsure of how to support struggling students. Throughout the data, the teachers did not consider how or if their beliefs about students' abilities or individualized needs may have filtered students' opportunity to engage in engineering or computer science. Teachers may then need additional support to consider how to differentiate activities across disciplines to attend to differing levels of prior knowledge and equitably support all students.

By giving a voice to teachers and sharing their perspectives, we hope to help curricular makers to support teachers in their ability to adapt STEM+CS curricula to meet students' needs. This is particularly important as our results show that the teachers reported struggling more to adapt activities to resolve a challenge when implementing less familiar disciplines and suggested that they may need additional support in predicting, responding, and evaluating students' ideas (Brophy et al., 2008) and attending to technical difficulties that students may have (Diefes-Dux, 2004) across different disciplines. However, our results also highlight ways in which teachers adapted interdisciplinary activities, such as teaching students mathematically about ratios and then drawing connections to absorption ratios in science. This enabled the teachers to integrate mathematics into science and support the epistemic understanding that mathematics is part of real-world, science experiences in line with prior literature (e.g., Fitzallen, 2015). Such examples demonstrate that the teachers were capable of modifying the project to support students' needs. Thus, it is important to ensure that teachers have the support that they report is necessary to equitably implement STEM+CS projects across disciplines.

Does it Work for Everyone? The Effect of ELCII on Kindergarteners' Inference Skill Development

Joseph Burey, Jasmine Kim, Kristen L. McMaster, and Panayiota Kendeou
burey001@umn.edu, kim00002@umn.edu, mcmas004@umn.edu, kend0040@umn.edu
University of Minnesota

Abstract: We sought to identify the extent to which an innovative educational technology called ELCII (Early Language Comprehension Individualized Instruction) improved inference making for various populations of kindergarten students. Analyses examined student performance based on individual-level demographic characteristics (i.e., gender, race/ethnicity, home language, English Language Learner status, and Free or Reduced Lunch eligibility) to shed light on whether ELCII addresses the needs of learners from marginalized communities. Results showed that all students, on average, improved in their inference making performance over time and that growth in inference making performance did not differ across subgroups. However, the results also highlighted persistent gaps that were present at the onset of the program, and unfortunately continued to persist. To bridge such gaps, the standard of 'working for all' is a necessary first step, but not sufficient. Future research should identify ways to accelerate growth of core skill development among students who need additional support.

Introduction

Our history in the field of education is dominated by the persistent efforts of researchers, policymakers, and educators to improve reading performance of all children across grade levels (e.g., Patton-Terry, 2021). Despite these efforts, yearly reports from the National Assessment of Educational Progress (NAEP) consistently show one in three U.S. students, on average, performing below basic proficiency levels in reading, and persistent achievement gaps across demographic characteristics, such as race/ethnicity, gender, home language, English Language Learner (ELL) status, and Free or Reduced Lunch (FRL) eligibility (NAEP, 2019).

These persistent achievement gaps are due to equally persistent and well-documented opportunity gaps. Poverty, one of the main predictors of reading comprehension (Ransdell, 2011), contributes significantly to racial and ethnic differences in achievement. Census data indicate that Black and Hispanic students, for example, are significantly over-represented in the population in poverty relative to their representation in the overall population (Shrider et al., 2021). Recent data indicate that only 53% of students who qualify for FRL achieved at or above basic reading levels compared with 83% of students who were not eligible (NAEP, 2019). Related opportunity gaps exist for ELLs who are more likely to be enrolled in under-resourced, low-performing schools and are at a greater risk for reading difficulties than non-ELLs (Roberts et al., 2021).

Early instruction in language comprehension skills such as inference making has the potential to prevent long-term negative reading outcomes across diverse groups of students (Silverman et al., 2020). Based on developmental research showing that young children can generate inferences well before the beginning formal reading instruction (Kendeou, 2015), an innovative educational technology called ELCII (Early Language Comprehension Individualized Instruction) has been designed to provide inference making instruction as early as kindergarten. ELCII is implemented via a web-based, interactive application called Inference Galaxy and includes twenty 20-minute learning modules that engage students to: (a) learn academic vocabulary words that are key to ideas in a video they are about to watch; (b) view age-appropriate videos (fiction and nonfiction); (c) respond to inferential questions during viewing of the video at points where inferences are needed for comprehension; and (d) receive scaffolding and specific feedback after each response. For example, after watching a video about how polar bears walk on ice, students will answer a multiple-choice question like, "Why don't polar bears fall into the water while walking?" If answered incorrectly, students receive scaffolding and feedback that guides them to the correct response.

ELCII has a strong theoretical and empirical basis (Kendeou et al., 2019), building on cognitive and developmental work highlighting that (a) early language comprehension skills that are developed in non-reading contexts (e.g., video comprehension) contribute significantly to later reading achievement (Kendeou et al., 2009), (b) language comprehension skills—and specifically inference skills—transfer across different media (Magliano et al., 2013), (c) children's inference skills can be improved using questioning that includes scaffolding and specific feedback (McMaster et al., 2012), and (d) technology provides cost-effective, standardized, individualized delivery of instructional tools in classroom settings (McCarthy et al., 2020). The efficacy of ELCII

 © ISLS

in improving inference making in kindergarten has been evaluated in quasi-experimental research showing good promise for improving inference making performance and the positive effects of scaffolding (e.g., Butterfuss et al., 2021).

The primary aim in this paper is to identify whether ELCII works for everyone, and specifically whether it addresses the needs of learners from marginalized communities. Thus, in these analyses we examine the efficacy of ELCII based on students' individual-level demographic characteristics (i.e., gender, race/ethnicity, home language, ELL status, and FRL eligibility). Knowledge of how different subgroups of students respond to ELCII is an essential first step in bridging any gaps that may exist. Only after understanding the program's effectiveness at this level of granularity can steps be taken to develop the program through an equitable lens with each student's unique needs in mind.

Methods

The final analytic sample used in this analysis consisted of 191 students (*M*age = 5.66, *SD* = 0.32) recruited from a mid-sized suburban school district in the United States Midwest. There were no exclusion criteria. Demographic characteristics of the sample were analyzed by gender (47.6% female, 52.4% male), race/ethnicity (34.0% white, 64.4% non-white, 1.6% missing), home language (62.8% English, 35.6% non-English, 1.6% missing), FRL eligibility (52.4% eligible, 46.0% not eligible, 1.6% missing), and ELL status (29.3% ELLs, 69.1% non-ELLs, 1.6% missing).

The efficacy of ELCII was examined using a quasi-experimental pretest-posttest design. Fidelity of implementation was confirmed based on students' high engagement during the intervention across the observation measures developed by the research team. ELCII was implemented in classrooms with diverse groups of students with no significant clustering as a function of demographic characteristics.

Mixed-effects models were used to assess students' inference making performance over time and whether trajectories varied across subgroups. The unit of analysis was one time-period, equivalent to two weeks. In each time-period, students completed four ELCII modules (two fiction and two non-fiction). Scores assessing inference making were aggregated for a total score out of 20. Plotting mean trajectories of students' inference making ability over time suggested that a linear function could be used to explain student trajectories. Thus, a linear model was fit to the data using the lme4 package in R. The model included a fixed intercept and a time predictor. Students' demographic variable characteristics were included as additional covariates. Demographic variables serving as covariates were race/ethnicity (White vs non-White), gender (male vs female), home language (English vs non-English), ELL status (ELL vs non-ELL), and FRL eligibility (eligible for FRL vs not eligible for FRL). One demographic variable was included at a time in separate models to facilitate interpretation and to reduce multicollinearity issues for interaction terms.

Results

Figure 1 shows the estimated ELCII mean score trajectories for all students and by race/ethnicity, gender, home language, ELL status, and FRL eligibility. Parameter estimates for each model are shown in Table 1. Highlighted in bold are the main effects of each covariate.

The base model without covariates showed a main effect of time for all students, with all students, on average, showing improved inference making performance across 4 timepoints (Figure 1a).

The model with race/ethnicity as a covariate showed a significant main effect of race/ethnicity but no significant interaction with time (Figure 1b). White students performed significantly better than non-White students across all ELCII modules. However, the learning trajectories for the groups did not differ over time.

The model with gender as a covariate showed no significant main effect of gender and no significant interaction with time (Figure 1c). However, the learning trajectories for the groups did not differ over time.

The model with home language as a covariate showed a significant main effect of home language but no significant interaction with time (Figure 1d). Students who spoke English at home performed significantly better than students who did not speak English at home across all ELCII modules. However, the learning trajectories for the groups did not differ over time.

The model with ELL status as a covariate showed a significant main effect of ELL status but no significant interaction with time (Figure 1e). Students who were not ELLs performed significantly better than students who were ELLs across all ELCII modules. However, the learning trajectories for the groups did not differ over time.

Finally, the model with FRL eligibility as a covariate showed a significant main effect of FRL eligibility but no significant interaction with time (Figure 1f). Students not eligible for FRL performed significantly better than students who were eligible for FRL across all ELCII modules. However, the learning trajectories for the groups did not differ over time.

Table 1
Parameter estimates for ELCII trajectory model by covariate

	All Students	Race/ Ethnicity: White	Gender: Female	Home Language: Non-English	ELL Status: ELL	FRL Eligibility: Eligible

Discussion

Computer-based learning environments aimed at improving literacy skills help adapt instruction to an increasingly diverse student population (McCarthy et al., 2020) and have the potential to bridge persistent opportunity gaps that manifest as achievement gaps (Patton-Terry, 2021). We investigated whether the effect of such a program, called ELCII, differed based on students' demographic characteristics to identify how well the program works for all students in kindergarten. Results indicated that all students, on average, showed improved inference making performance over time and that growth in inference making performance did not differ across gender, race/ethnicity, home language, ELL status, or FRL eligibility. However, the results also highlighted persistent gaps that were present at the onset of the program, and unfortunately continued to persist. Specific factors relevant to initial gaps in inference making performance were race/ethnicity, home language, ELL status and FRL eligibility.

Promisingly, ELCII works equally well for all students, which is a necessary first step in the eventual bridging of opportunity gaps. However, for gaps to be bridged, future research must identify ways to accelerate growth of core skill development among students who need additional support. In the context of ELCII, such acceleration may be possible by, for example, increasing dosage. This would allow students who struggle initially to receive additional opportunities for developing inference skills (e.g., four modules per week instead of two). The use of language supports should also be examined (Roberts et al., 2021), which may serve to tailor the program more adequately to students learning English or to students who do not speak English at home. Since pre-existing background knowledge has been found to influence socioeconomic differences in children's learning and comprehension (Kaefer et al., 2014), future research should also determine how to minimize prior knowledge demands in educational interventions. Considering the complex relationship between socioeconomic differences and race/ethnicity (Shrider et al., 2021), future analyses must first improve on the rudimentary race/ethnicity categorization used in the present study before more precise interventions can be developed. Without question, each learner's identity is represented across each of the groups defined in the present study.

With the ideal in mind of an intervention that is responsive to every component of a learner's identity, we hope for this study to serve as an initial step. Importantly, the findings from this study not only identify the benefits of ELCII for developing inference making skills generally, but also identify groups of students who may need additional support. We believe that this identification is critical in the evolution of such interventions from equal to equitable.

"Do we have to do this every time new germs come out?" and other questions from children about Covid-19

Rose K. Pozos
rkpozos@stanford.edu
Stanford University

Abstract: Uncertainty and concern marked the spring of 2020 as the Covid-19 pandemic rapidly disrupted daily life and brought up highly consequential questions about living in a public health emergency. In this paper, I present an analysis of questions that 109 caregivers of elementary schoolers reported receiving from their children about the early pandemic. Understanding what questions children were asking of their caregivers and how the caregivers respond to their questions helps reveal both children's informational needs and caregiver approaches to handling those questions. Findings indicate the salience of questions about daily life and highlight the importance of the affective valence of the questions and responses.

Introduction

The start of the Covid-19 pandemic was a massive disruption that introduced new, highly consequential questions for people around the world. Parents and other caregivers of young children found themselves in the tricky position of answering questions about daily life that did not necessarily have clear-cut answers. "What is the coronavirus?," "Will we have school next year?," "Do we have covid?," "Will you die?," and "Did China make the virus?" are all examples of questions from children that reflect the uncertainty of pandemic while varying in the level of factual and emotional difficulty. For some caregivers in the U.S., the pandemic may have been the first time they were confronted with questions from their children that they were not sure how to respond to. Others may have had more practice fielding difficult questions, but not in times as uncertain as the beginning of the Covid-19 pandemic.

Asking questions is a purposeful information-seeking mechanism that children use to respond to and understand the events in their lives (Chouinard et al., 2007). Research in child development suggests that questions are sparked by "first-person cues (such as novelty or surprise), third-person cues (such as a knowledgeable adults' surprise or question), and future-oriented cues (such as expectations about information gain or future value)" (Linquin & Lombrozo, 2020, p. 14). As children encounter concepts and ideas for which they do not have direct evidence or experience, such as gravity or the existence of a God, they depend on more knowledgeable others (Vygotsky, 1978) for testimony. Through these processes, children learn ways of knowing and questioning that are culturally salient to their communities in interactions with their caregivers (Callanan et al., 2012; Menendez, 2020; Crowley et al., 2001; Sak & Shain-Sak, 2020). The dynamics around question asking and responses are complicated, yet they provide insight into the norms of communities and how they mediate information.

Specifically with regards to the Covid-19 pandemic, understanding what questions children were asking and the responses from the caregivers to those questions help us understand the children's information needs and how caregivers supported the mental, physical, and emotional well-being of their children in adjusting to the pandemic. An early study in June 2020 by Nelson and colleagues (2020) surveyed a sample of caregivers of 5-10 year-old listeners to the science education podcast BrainsOn! found that 97% of the caregivers reported their children asking a question about the coronavirus, and 62% indicated that they were "very uncomfortable" answering questions their children had about the coronavirus. Nelson and colleagues (2020) also found that 68% of caregivers said their children expressed worry or fear about the pandemic, primarily about loved ones catching the virus and the uncertainty of how long the pandemic would disrupt their lives. This paper presents a complimentary analysis of elementary school-aged children's questions close in time to Nelson and colleagues' study (May 2020). Examining children's questions from early in the pandemic reminds us that our youngest participants in communities are paying attention to the forces that structure their routines and are concerned for the well-being of their communities.

Methods

This paper presents preliminary findings from an analysis of questions caregivers reported hearing from their children. I ask, what can we learn about children's information needs in times of crisis from the questions they asked of their caregivers about Covid-19? To explore this question, I describe the topics of questions that caregivers reported their

 © ISLS

children asking about the pandemic and offer examples of conversations caregivers had with their children about the major categories of questions that emerged from the analysis. The data used in this analysis is part of a larger five-part diary study conducted with 109 families of elementary school children from across the U.S. in May 2020 (c.f. Barron et al, 2021; Pozos et al, 2022). The caregivers were recruited through the *dscout* platform which was also used for multimodal data collection via smartphone. They lived in 28 states and were mostly women (67%) with children in public elementary schools (84%). Racially, 55% self-identified as white, 16% as Black, and 15% as Latinx, 9% as Asian, and 4% as Middle Eastern or North African. Slightly over half (55%) of the caregivers reported an annual household income of at or above the national median income of $75k.

In one part of the study focused on learning about Covid-19, the caregivers responded to a series of prompts eliciting reflections on the questions their children were asking, conversations they were having, what resources they were using to learn about Covid-19, and any challenges they faced in communicating with their children about the pandemic. We collected two sets of child-initiated questions: general questions about the pandemic and questions about the pandemic that the caregivers found difficult to answer. Both sets of questions were coded using the same codebook consisting of deductive drawn from Chouinard et al. (2007) and Nelson et al. (2020) and inductive codes generated from open-coding (Saldaña, 2013). Inter-rater agreement was calculated to be 0.88 using Cohen's Kappa, indicating strong agreement (McHugh, 2012).

Findings

Most frequently asked questions point to daily concerns

In total, 353 examples of general questions were coded ($M = 3.0$, $S = 2.0$) Seven caregivers did not offer an example question in their response or stated only that their children were not asking questions (five also stated the latter, but also offered examples of questions.) Overall, 75.2% of the caregivers gave an example of at least one question that was coded as one of the four most common topics (school, impact on self, length of the pandemic, changes in routine, see Table 1.)

A few significant differences were found between families with higher/lower incomes. Children from higher income families were more likely to ask questions about impacts on themselves (impact on self, $X^2 = 5.825$, $p = 0.015$). Children of lower income families were more likely to ask about the nature of the virus ($X^2 = 7.568$, $p = 0.006$). Girls were more likely to ask about virus transmission ($X^2 = 11.293$, $p = 0.004$). Any further interpretation as to why these differences may have been significant would be speculative. However, it is interesting to note that there were few significant effects within the categories that make sense to run those tests on (i.e., there are enough questions included in those participant groups to make a Chi-Square meaningful). Importantly, the data do not indicate differences in how caregivers were responding to girls compared to boys, a pattern that has been documented in multiple studies about sensitive topics (e.g., sex; Sak & Sahin-Sak, 2020) and science talk (e.g., Crowley et al., 2001).

Table 1

Frequency of Question Topics, Clustered, with Sample Questions

Count*	Topic	Sample Questions
Personal Impacts (n=187)		
55	School	Will I go back to school in the fall? Why are schools closed?
50	Impact on self	When can I play with my friends?
39	Changes in routine	When is it safe for me to go with you to the store? Can I go outside and play with the neighbors if I wear a mask?
18	Impact on family	When will we see our family again? Will Daddy be ok at work?
13	Kids and corona	If kids don't get it, why can't we play with our friends?
12	Personal protection	How do we stay safe when we do have to go out? What is the point of wearing a mask?
Virus & Treatment (n = 75)		
19	Infection	Are you infected mom? Do we have coronavirus? How do people get

		sick? If our cat can get sick?
15	Nature of virus	What is it? Why is it so dangerous? How does the virus work?
14	Virus transmission	How is it spreading? How many cases are in our area? Why can't we just wipe away the germs?
13	Virus origin	Where is it from? What caused it? Did China make the virus?
9	Virus treatment	What medicine will help? Is there going to be a cure for it? How can we beat it?
5	Vaccines	When will they have a shot for it? Will there be a vaccine and is it safe? If I [mother] would get the vaccine if they had one
Future (n=61)		
49	Length of pandemic	When will the virus be over? How long until things are normal again?
12	Death	Can the whole world die from it? Why have people died? If [our] grandparents were going to die?
Misc (n=30)		
16	Not asking questions	
14	Other	What are some things we can do to help? Why are things closing down?

*Number of questions reported

Difficult questions

In total, 91 difficult questions were identified from 51 caregiver responses (M = 1.6, SD = 0.99). Again, the most frequently asked questions were about how long the pandemic would last (n=29), how the pandemic restrictions were impacting them personally (n=13), and when schools would reopen/ how they would operate (n=9). Caregivers found questions that did not have specific answers at that point in the pandemic, questions that they were unsure about themselves, and questions to which they had an emotional reaction the most difficult to answer. As one mother of an 8 year-old daughter commented, "It's hard telling children their [*sic*] is no cure for something that has killed so many and has affected thousands of people." A father of a 6 year-old son confesses that he responds to his son's question about if they will all be safe, "I say yes but its [*sic*] not something I can garuntee [*sic*] and I feel a little poorly when I say it." Another father of a kindergartener wondered if his son would still trust him as an information source after not having answers: "to be honest I would not trust us either, just because we just don't have a lot of answers to critical questions in his mind." The caregivers' reflections on their responses to their children's questions, especially their young children, show concern for their mental wellbeing and also conflict as their desire to protect their children meet the reality of the all-consuming nature of the pandemic in the early months.

Discussion & directions for future research

In May 2020, children were most concerned about how the virus was going to impact them personally as they experienced significant disruptions in their routines, especially concerning school. However, they also showed interest in knowing about the virus itself and how the pandemic would shape the future. Some of the questions were sparked by disruptions in routines, while others came from what children were hearing through the media or from friends and family. The reflections caregivers shared on questions they found difficult show discomfort with the questions that did not have concrete answers. The lack of concrete answers sometimes meant that children kept asking, as they are known to do when they want to check in case an answer has changed (Linquin & Lombrozo, 2020). Though this study did not ask caregivers to record the frequency with which their children asked each question, many caregivers volunteered that they regularly responded to the same questions from their children. For some this may have been their first experience of not being able to be the expert or authority on a topic that was consequential for the health and well-bring of their children. This raises an interesting issue for learning and media designers about what children's information needs actually are and how to meet them. Emotion regulation and the knowledge frameworks that the caregivers draw on to offer reassurance shape the home learning environment and implicitly teach children ways of knowing and questioning during emotionally difficult times. What do children need to know about sensitive topics, like severe illness and death, if people in their sphere of influence are not being directly impacted? How should we

think about the potential differences between what the caregivers are comfortable answering and what questions children have that caregivers might not have answers to or feel that they cannot be completely honest about?

As the Covid-19 pandemic continues to unfold, new questions emerge, and old ones are revisited as new scientific studies are released and political battles shape discourse about health and social responsibility. As new developments occurred, the children likely began to ask different questions based on the national news (e.g., mask-wearing controversies, vaccine approvals and hesitation), as Nelson and colleagues (2021) found in their follow-up study. Further research might continue to explore the role of children's questions about health topics and caregivers' affective responses in the development of health literacy and decision making.

Children's Place-based Gesture: An Understudied Resource in Socio-Ecological Sensemaking

Kathryn Lanouette, William & Mary, lanouette@wm.edu

Abstract: In the learning sciences, there has been a growing focus on the body and place, elevating the multi-modal and situated dimensions of learning. I bring attention to children's place-based depictive gestures, revealing how such gestures are a generative but often overlooked resource in science sensemaking. Analysis focused on 11 and 12 year-old children's gestures as they discussed what organisms needed to thrive in their schoolyard, within a late elementary school curriculum that centered on place-based approaches to teaching science and data science. Findings reveal children's depictive gestures made visible their rich and varied knowledge of the schoolyard in collective discussions. Such gestures were also integral in children's conjecturing, contesting and clarifying relationships within a socio-ecological system, layering together multiple ways of knowing. Implications for teaching and learning about socio-ecological systems are discussed.

Introduction

Children have rich and varied knowledge about the social, natural and built world around them, steeped in the routines and rhythms of their daily lives (Nespor, 2010; Seyer-Ochi, 2006). Across childhood studies, geography, environmental education and science education fields, there has been detailed documentation of such understandings, enmeshed in smells, sights and sounds of local places shaped by broader cultural, political and historical forces (Lim & Barton, 2010; Mitchell & Elwood, 2012). Yet rarely do children have the opportunity to meaningfully interweave this multi-modal, multi-temporal knowledge into their disciplinary learning.

Such place-based knowledge appears particularly generative for youths' understandings of complex socio-ecological systems. Conceptualizing socio-ecological systems entails considering multiple interacting parts of a system, and their relationships with one another, across varying spatial and temporal scales (Pugh et al., 2019). This includes considering the abundance, scarcity and distribution of organisms and the relationships within and between these organisms and their environment (Korfiatis & Tunnicliffe, 2012) but also, how such systems are shaped by broader socio-political institutions and historical legacies (Davis & Schaeffer, 2019). Yet to date, there is limited research in this area because common approaches to teaching about socio-ecological systems often removes learning from actual places that children know by focusing on far away, virtual, or simulated settings.

In this study, I examine how children's place-based depictive gestures emerged in discussion, supporting weaving together understandings of socio-ecological systems in relation with children's knowledge of the built, natural and social worlds central to their daily lives, particularly children's memories and histories. Existing accounts of gesture in science education have pointed to the importance of this semiotic form (Crowder, 1996; Mathayas et al., 2019) but nascent research, especially in science education, learning sciences and environmental education research, has documented how place-based knowledge is depicted through gesture. In this study, I aim to understand how children's place specific knowledge emerges and becomes visible in science discussions through gesture, examining how such depictive gesture supports children's sensemaking about complex socio-ecological systems as children interweave multiple ways of knowing (Warren et al, 2021).

In this analysis, I ask, What place-specific gestures emerge in collective discussions? and How did this gestured local knowledge support sensemaking about complex socio-ecological systems? In the sections that follow, I describe the context of this study and methods of analysis, followed by sharing key findings and discussing implications for research and practice.

Methods

Study Context

Data presented are drawn from a larger multi-year design-based research project that aimed to support children understanding socio-ecological systems through engaging in science and data science practices, with a participatory GIS mapping technology, *Local Ground* (Van Wart et al., 2020) and local places central to the design (Lanouette, 2022; Lanouette, 2019). Key to this work was a commitment to expand what ways of knowing could be brought to bear as children learned about how socio-ecological systems functioned and thrived. The author and colleagues collaborated with a K-5 public elementary school in the Western United States, working closely with

 © ISLS

two late elementary classes, the school's science teacher, and the 4th and 5th grade homeroom teachers (Lanouette et al., 2016). In this analysis, the focus is on year 3 of the project, where I worked with one 5th grade science class with 27 students (Lanouette, 2022).

Across 9 weeks (18 class sessions, lasting 60-90 minutes each), I designed and taught the multi-week curriculum during the students' science class time, in collaboration with the science teacher. The curriculum engaged students in two cycles of sampling, data visualization, and discussion. During these earlier lessons (Lessons 1-4), children conjectured potential important "parts" of the schoolyard soil ecology, with the teacher posing the question "Who lives underfoot and what do they need to thrive?" Children then visited different schoolyard locations of their choosing and selected an initial site for sampling to study in greater detail. At their sites, children collected a range of data about earthworms, other invertebrates, and plants' root structures, as well as soil characteristics such as moisture, compaction, and composition. They also recorded notes about schoolyard activities that they thought might be important to understanding who might thrive and where, such foot traffic, sound levels, and other children's play activities. After several class sessions devoted to exploring relationships in the aggregated data using *Local Ground* participatory GIS maps and canonical data forms (L7-L12), students had the opportunity to select a second sampling site in Lesson 13 to further support studying relationships emerging in the class data, as well as to explore puzzling patterns, outliers, or anomalies in the data.

Data sources relevant to this analysis included five class sessions where children discussed emergent relationships or patterns in their aggregated data (Lessons 11, 12, 16, 17, 18). These five lessons were selected because they involved children discussing what organisms needed to thrive in their schoolyard, using their aggregated data to conjecture, contest or clarify their claims drawing on multiple sources of evidence.

Analysis

Drawing on multi-modal interaction analysis techniques (Stivers & Sidnell, 2005), a research assistant and I analyzed video recordings of several whole class discussions. We focused on children's *depictive gestures* (Streeck, 2008) where the "hands depict by enacting their familiar, "real-world" capacities as users, transporters, experiencers, assemblers, molders, and shapers of things" (Streeck, 2008, p. 285). In the first phase of video analysis, we reviewed conversations in the five class sessions where children conjectured, contested, and clarified potential relationships or patterns in their data, related to who could thrive underfoot and where. Using video coding software (MAXQDA), we documented all instances of children's gesture depicting place-based knowledge of the schoolyard. In the second phase of analysis, we returned to these highlighted instances, examining how depictive gesture supported children's collective sensemaking about relationships within the data and the schoolyard socio-ecological system. We also noted what place-based knowledge was being depicted (e.g., natural, built, social), what socio-ecological relationships were being discussed, and the work of depictive gesture in this collective sensemaking (e.g., elaborating on data points, clarifying relationships among vertebrates, invertebrates and the soil, showing transient elements like sunlight and rainfall), to better understand the work these gestures were doing.

Findings

In this section, I first provide a brief overview of the place-based depictive gestures emergent in children's sensemaking as they conjectured, contested and clarified understandings of socio-ecological relationships and processes. Next, I show one sequence of place-based depictive gestures in more detail, briefly describing the context in which the gesture appears, what place-specific knowledge was elevated, and how the gesture supported children in refining understandings about how multiple parts of a local socio-ecological system come to function together and thrive.

Overview: Children's place-based depictive gestures

Children's place-based gestures communicated varied knowledge about their schoolyard, evoking natural, built, material and social dimensions of the schoolyard occurring across days, seasons and years. For example, such gestures included knowledge about *environmental phenomena,* such as the pathways of sunlight and shade throughout the day as well as seasonal patterns of rainfall and related puddle formation. Such knowledge was often shared with sweeping hand gestures over the *Local Ground* map or creating imagined landscapes in front of themselves where varied environmental phenomena were overlaid. Children's gestures also depicted knowledge of the *social rhythms of the day,* such as where people in the school community gather and activities they engage in. This included mimicking running bodies along a walkway with marching fingers or showing how 3rd graders dispersed during recess using undulating hands. Lastly, children's place-based gesture included detailed knowledge of *built and material configurations* about their particular sampling sites or specific schoolyard locations. Gestures showed knowledge about the perimeter, composition and height of buildings, fences, and

playground structures, depicted through fingers tracing building footprints in the air or bringing hands together to show angles and areas created by structures.

Example: Preeti and Isaac's tucked away sampling site

In this instance, Preeti and Isaac are contesting classmates' earlier claims that earthworms need roots, shade and moist soil to thrive. Using their own experiences at their selected site and their site data, the pair argues that even though they had moist soil, shade and roots, they only found one earthworm at their hidden garden site. As the discussion ensues, a student asks about additional aspects of their garden sampling site to understand their discrepant data and counter claims, asking "Do a lot of people walk around there?" Isaac replies, "In our area? *(pointing towards the map).* Not at all! It actually is in a tight little corner."

As shown in Figure 1, Isaac then steps away from the interactive data map and orients his body towards his classmates on the rug below. Using gesture to provide an on-the ground perspective, Isaac says, "Because ours [our site] is like … See, the classroom is here, actually here (*moving his hands together to classroom wall*, see Figure 1a) and this wall is here and our site is fa::::r from where kids walk a lot (*shifting hands to show his groups' site to peers seated below and wiggling his right thumb to show walkers at a distance,* see Figure 1b).

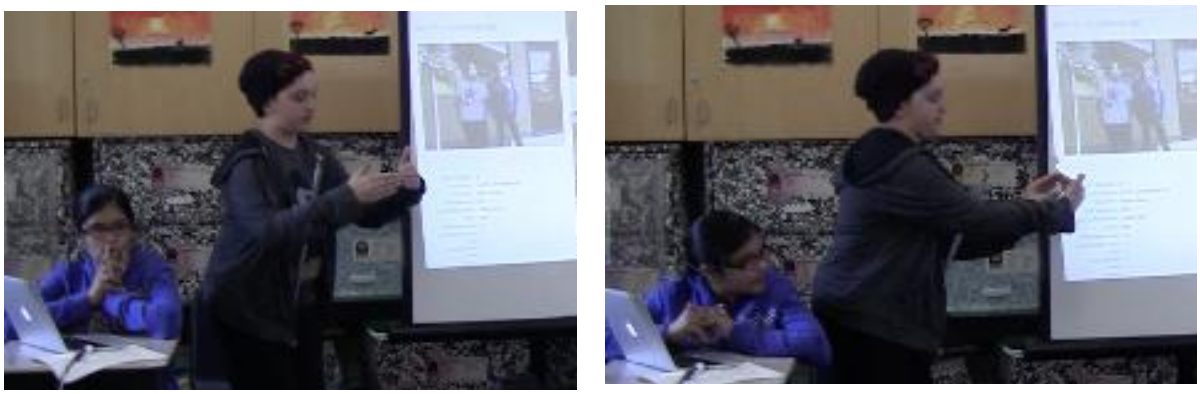

Figure 1 (a, b): *(a) Isaac's initial gesture depicting their garden site in relation to the classroom buildings, facing towards himself, (b) Isaac at the end of a series of gestures, depicting his actual site location in relation to children's daily foot traffic and the school building wall, from his classmates' perspectives.*

Through this series of gestures, Isaac recreates his and Preeti's tucked away garden site, depicting built structures (e.g. "the classroom is here") and children's movement through the space (e.g., "where kids walk a lot", wiggling his thumb). In the process, he interweaves his first-person experiences collecting data with his daily understandings of being in that garden as he reasons about what earthworms need to thrive and considering the classes' aggregated data. In doing so, multiple intersecting elements of the schoolyard ecosystem are considered and made visible to one another, interweaving the natural, built and social layers of the schoolyard into the collective discussions about how socio-ecological system function and thrive. Here, children making sense of multi-variate relationships in their aggregated data (earthworm counts, soil moisture measurements) are interpreted in relation to more dynamic (e.g., shade, footsteps) and less dynamic (e.g., build structures) elements of the socio-ecological system across varying time spans.

Discussion

Children's descriptive gestures about the schoolyard were shown to be a powerful resource in making visible emplaced knowledge in collective sensemaking about what organisms need to thrive. Additionally, children's gestures made possible coordinating together multiple parts of complex socio-ecological systems, blending together natural, built and social dimensions of the schoolyard across days, weeks and years to reason. Such coordination supported further considerations of underlying mechanisms and explanations for relationships emergent in the classes' aggregated data. Together, this coupling of depictive gesture and place-based knowledge supported children bringing together expansive knowledge about a socio-ecological system as they conjectured, contested and clarified emergent relationships in their data and the system at large.

Significance of this study are two-fold. First, analysis suggests the depth and breadth of children's local knowledge as a generative resource in learning about complex socio-ecological systems. To date, existing research on learning and teaching about complex systems has tended to overlook children's emplaced, historical and social

knowledge about place, particularly embodied forms. Second, this work contributes to existing research related to gesture in science learning, elevating how depictive gestures showing emplaced local knowledge can be a powerful resource in learning about complex socio-ecological systems. Combined, this analysis extends existing work on gesture in science education to become further situated within and about place while also making visible the ingenuity and expertise children bring to science sensemaking drawing on multi-modal resources like gesture. As the learning sciences and science education fields further focus on place-based approaches to teaching and learning, particularly approaches that elevate heterogenous and expansive modalities for expression and sensemaking (Warren et al., 2021), young peoples' place-based depictive gesture appears a generative resource warranting further study.

Becoming Visible in a New Learning Environment

Candice Love, Candice.love@Vanderbilt.edu

Abstract: This paper explores an episode of a Black student seeking attention from a classroom adult at a majority white, middle-class coding camp. I explore how the theory of perceptual affordances and attunement intersect with racialized experiences at school to understand how attention moved in a classroom and was ultimately distributed in a way that the Black student's needs were missed.

Introduction

The racialized practices of policing and disciplining Black children while at school is well-established in the field of education (Monroe, 2005; Lewis et al., 2010; Skiba et al. 2011, etc.). In particular, research has consistently shown that Black boys are more likely to be suspended, referred to the office, and expelled than their White peers (Welsh & Little, 2018). This creates a culture where doing the exact right thing at all times becomes pertinent for Black students' survival of school. Understandably, one survival tactic for Black students is to be less visible. This is necessitated particularly in contexts such as charter networks using behavior management strategies based in the theory of broken-windows policing (Lemov, 2010, p. 195), which encourage teachers to monitor even the smallest behaviors, and settle for no less than 100% compliance.

But what happens when students who were socialized to behave in this way once they enter new environments? Research has raised concern about such behavior management practices due to their mis alignment with cultures found in the colleges and workplaces students will encounter after they leave school (Golann, 2015). To highlight this lack of alignment more concretely at the micro level, I explore a case study of a Black boy from a low income, high discipline urban middle school attempting to gain attention in a coding summer camp with a majority White, middle-class student population. Even though the summer camp had a student/teacher ratio of 2:1, the boy remained mostly invisible for 7 minutes as he tried to seek help on his coding project. In my analysis I seek to show not only that a student was missed in a highly supervised environment, but I also try to make sense of why, and how he attempts to understand the adults' system of attention, that does not at first seem to operate in familiar ways.

Conceptual framework: How attention works in classrooms

Attention and its distribution is a joint accomplishment between group members, environmental affordances, and attunement. However, there are certain patterns in identity that have been demonstrated to be predictive of who will gain the most attention, which is often highly inequitable. For example, students who receive the most attention in a classroom are most likely to be high achieving white males (Martin, Milne, & Scantlebury, 2006). There can often also be a socioeconomic divide, with wealthier students being more likely to actively seek help than their economically disadvantaged peers (Calarco, 2011). The expectation of "seeking help if you need it" is also commonly upheld by teachers, in alignment with the culture of middle-class students (Calarco, 2011). The picture of a white, middle-class, high-achieving male student as the most likely collector of attentional resources is central to this analysis of a focal student: a Black boy named Prince.

Methods

I used interaction analysis (Jordan & Henderson, 1995) as well as Gibson's theory of affordances (1979) to explore an episode where Prince, is attempting to gain an adult's attention for help on his coding challenge. Prince was stuck on his code for 20 minutes, and the focal 7-minute clip encapsulates the moments where he sought attention from an adult. This is an anomaly during this activity, as all other students during this time can be seen receiving substantial support during the same focal minutes.

Data

The focus episode occurred on the first day of a week-long camp called *Code Your Art,* an introductory coding class in which students learn how to create various art projects using NetLogo (Tisue & Wilensky, 1999). During the clip, students were engaged in an independent "coding scavenger hunt" where they were challenged to use code to create different images, such as stripes or a border.

The focus student for this analysis is Prince, a rising 9th grader. Prince attended East Middle School, a majority Black and Latinx urban school with a suspension rate of 15%, compared to the district average of 9%. At camp, he was the oldest student in the class of 10, one of two Black students, and the only Black boy.

 © ISLS

Before the focal episode begins, Prince is trying to complete the first scavenger hunt challenge: changing one half of the interface to one color and the other half to a different color. However, as commonly seen, he was writing code using plain English, and continuously received error messages. The clip begins when Prince started attempting to ask for help. The adults relevant to the analysis are "Researcher," Ms. Turner, the lead teacher of the class, and Victor, the classroom TA and coding expert. While the activity lasted about 30 minutes, Prince struggled for the first 20 minutes to accomplish any of the challenges. The focal clip details the final 7 minutes of his struggle with the code as he is trying to troubleshoot this new system of adult attention.

For this piece, I analyzed both screencapture and webcam data from Prince's laptop. The screencapture software depicts both what Prince was currently seeing and doing on his laptop while the webcam and laptop microphone recorded Prince and his immediate surroundings.

Analytic Framework

Gibson's (1979) theory of perceptual affordances states that what can happen in any particular moment is made up of possibilities that are co-constructed by the affordances of the environment, effectivities of the people in the environment, and the dynamic intentions of those in the environment based off of the current situation (Gresalfi, Barnes & Cross, 2011). *Affordances*, are the actions that particular objects or stimuli invite in an environment (Greeno, 1994). For example, in a classroom a raised hand often invites a teacher to call on that student. The ability for student bids for attention to become affordances in a classroom setting can strongly depend on the attunement of the adults in the room. *Attunement* is shaped by a person's culture, identity, and previous experiences, and therefore poses a situated set of limitations in what can become possible for a given individual. For example, in a culture that values students who are quietly following directions, it will be common for the teacher to be more attuned to the activity of the active student, sometimes at the expense of missing quieter bids from others.

Findings

Figure 1 shows an overview of Prince's four attempts at interacting with adults in the space. A common strategy he employed throughout the episode was using eye contact and other quiet bids for attention. However, as will be shown below, the organization of adult attunement during this activity left his requests for help unanswered for 7 minutes.

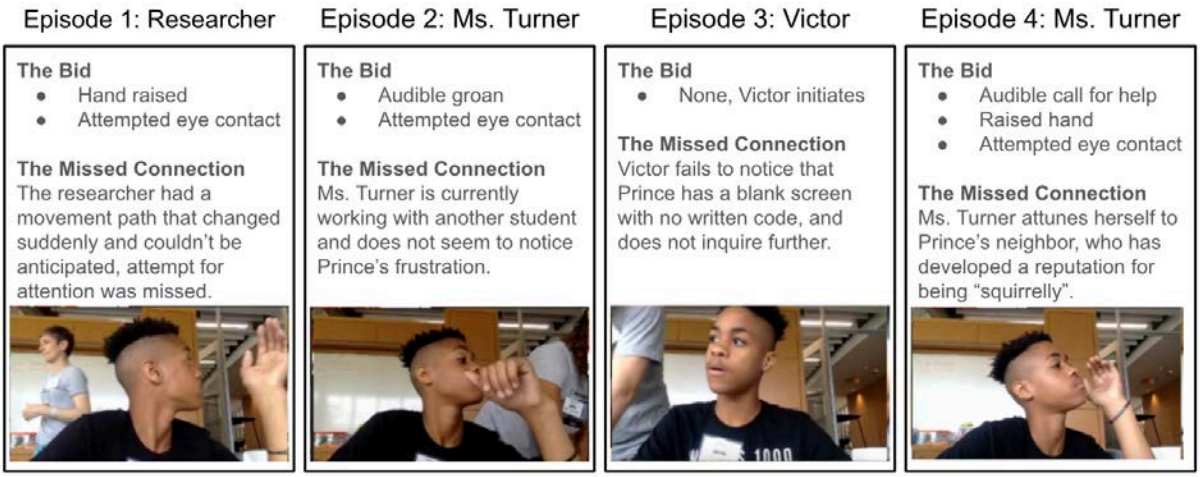

Figure 1. An overview of the interactional bid that outlines the attempt and the reasons adults did not respond.

Episodes 1 & 2

In the beginning, Prince offers interactionally quiet bids for attention as he is trying to understand how to interact with the adults. To begin, "Researcher" was working with the student sitting directly to the right of Prince. After she finished, she looked quickly at Prince, turned back to her original position, and then exited the room. From the first image in Figure 1, we can see that Prince was anticipating Researcher's appearance on his left side. Because we can see that Researcher was not looking when the hand is offered, we know that Prince's raised hand did not become an affordance for help, and he was missed.

The second moment of Prince's bidding to lead teacher Ms. Turner seems to, in part, be a response Researcher's failure to recognize Prince's silent hand. As Ms. Turner was working with the student directly to

the left, Prince let out a long, audible groan, and looked toward Ms. Turner. However, it is unclear from the record if Ms. Turner heard the groaning or not, and Prince was missed a second time.

Episode 3

Later in the activity, Prince was approached by Victor, the class TA. In the approximately 9 second exchange, Victor asked how it's going, to which Prince replied, "It's good." Prince also nodded when Victor asked if he was "getting this figured out." However, by this time, Prince had still not been able to complete a challenge of the scavenger hunt, and his screen remained blank. The challenge here, then, was in Victor's position in the camp was that of "coding expert," as he spent the class period solving various errors and debugging code. Although Prince's screen remained blank due to not yet solving any of the coding problems, it is entirely possible that since Prince didn't have buggy code, Victor was not attuned in a way to help him get started.

It is unclear from the record why Prince says that things are good after a string of error messages. It could be that in this moment Prince was developing an idea that he wanted to try before asking for help. Seconds before this interaction, Prince let out a verbal "mmmm!" as if he had an idea. Nonetheless, "How's it going" did not become an affordance for Prince to ask for help, and Victor moved on.

Episode 4

The moment on the record where it is most obvious that Prince was needing of attention was when he verbalized it directly to Ms. Turner. Approximately one minute after Prince expressed to Victor that things were "good", he employed his new idea, which again received an error message. With signs of exasperation, Prince offered a strong bid with three potential affordances: eye contact, a raised hand, and verbal confirmations that he needed help. However, Ms. Turner's attention was not on Prince. She was instead attuned to his more vocal and active neighbor, and at the same moment Prince asked for help, Ms. Turner was already asking what the neighboring student was working on. After his bid, there was never a moment where Ms. Turner cycled back to Prince, or acknowledged that she would get to him soon, so these bids for attention, though interactionally strong, did not ultimately become affordances for Ms. Turner to help.

Much could be said about this interaction when it comes to the movement of Ms. Turner as well as her attunement. It could, for example, speak to Ms. Turner's attunement toward certain children and behaviors. Prince's neighbor was, as Ms. Turner described, a "squirrely" kid, while Prince was extremely compliant. Prince, for example, had thus far not done anything on his laptop that he was not explicitly told to do. On the other hand, his neighbor had consistent redirects to maintain his attention to the task at hand. This shows up as well in adult attentional patterns. In the same 7 minutes, Prince's squirrely neighbor is attended to by adults four separate times. It is possible that Ms. Turner's attunement was seemingly toward the kid with more "squirrely" tendencies, with less of an urgent need to attend to the activities of student who was extremely compliant.

Finally crossing the threshold

The moment where Prince was finally able to be noticed and receive help from Ms. Turner was still fairly quiet, in line with Prince's other gestures and potential bids. In a moment where she was standing behind him, Prince simply turns to make eye contact and says, "I don't know how to separate it," which alludes to the first challenge of having a split screen that is half one color, half another. This sets off an extended interaction between Prince and Ms. Turner that puts him on the path to understanding how to use NetLogo syntax to accomplish his goal. Ultimately, Prince did not have to change his strategy to finally receive attention. However, by the time Prince had received meaningful help, every other student had had significantly more interaction and help from adults in the room. What seems to have made the difference for Prince in his actions becoming affordances in the end was his ability to correctly understand and anticipate Ms. Turner's movements in a way that he could employ eye contact and gain attention.

Discussion

When Prince did seek attention, he generally relied on quiet bids such as eye contact to signal his need for help. Due to his identity as a Black boy in a new environment, and the consequences for expressing defiance for Black boys has historically been severe, expressing silent bids for attention can be seen as reasonable on his part. However, these quiet bids seemingly took adults longer to notice in this environment. It is clear that temperaments such as his neighbor's "squirreliness" was worthy of a great deal of attention, but historically, a squirrelly disposition is not one that is available to Black boys. Prince's quiet demeanor paired with his ultra-compliance and status as the oldest student seemingly created a "perfect storm" of adults perceiving Prince as a kid that that didn't have to focus on as much. This was not the story of Prince throughout the whole camp: eventually, he

 © ISLS

would go on to become incorporated into the classroom and even receive special recognition for some of his work. However, this case has implications for educators serving marginalized students, as it presents a concrete example of the unequal weight that many may carry into new environments. Creating educational spaces in urban contexts that necessitate quiet compliance may create order in the short term, but disadvantage marginalized students in the long term as they need to negotiate how to participate in new spaces. And in learning environments that bring together students from different contexts, the tacit assumption that students are asking for help if they need it can lead to less visibility for marginalized students, who may be more used to environments where being silent is imperative for survival.

Conclusion

This paper explores a 7-minute episode of Prince, the focus student, attempting understand the workings of adult attention in a new, less formal coding environment. In the beginning, teachers were seemingly attuned elsewhere (e.g. to the more "squirrely" kid), but there was seemingly, at first, a learning curve for Prince to understand how to seek help in such an environment. Learning how teachers moved was consequential for Prince, who relied heavily on quiet but reasonable methods to get noticed that were unsuccessful in the new learning environment. Further analysis around how other students gained attention is needed.

"What a Lovely Discussion!" Reconciling Disparate Assessments of Small-Group Interactions from Teacher and Student Perspectives

Heather Fink, University of California, Berkeley, hfink@berkeley.edu

Abstract: This study examined student participation during one small-group calculus task, comparing students' firsthand accounts of their learning experiences to observations made by their teacher, student teacher, and peers. Taken together, these varying perspectives paint a more comprehensive (though sometimes contradictory) picture of what happened during the task. Working toward participatory equity – cultivating classrooms with fair (not necessarily equal) opportunities to participate – requires a deep understanding of students' learning experiences. Findings revealed students' accounts of the task differed in consequential ways. Despite the teacher's positive assessment, considering student perspectives suggested this experience was equitable for the three male students, but not for Guadalupe, a young Mexican woman. She earned A's in the course, yet still encountered barriers to participation resulting in her disengagement from the task. Exploring further how students' learning experiences are shaped by gender, race, and other contextual factors are important directions for future research.

Introduction

Working toward participatory equity – cultivating classrooms with fair (not necessarily equal) opportunities to participate (Esmonde, 2009; Secada, 1989) – requires a deep understanding of students' learning experiences. As researchers, we can observe how students participate during lessons, we can compare participation patterns across groups of students by gender and/or race, and we can judge what seems equitable based on expected distributions of talk (e.g., Shah & Crespo, 2018). However, if our analysis stops there, we are missing critical pieces to the equity puzzle. Fairness is connected to power, privilege, and participatory expectations (Rasooli et al., 2019) and is not always visible to outside observers. To assess the extent to which every student has *fair* opportunities to participate in support of rich content knowledge and positive mathematical identity (Esmonde, 2009; Schoenfeld, 2014), we must examine learning experiences from classroom participants' perspectives (Sengupta-Irving & Vossoughi, 2019). Specifically, we need to privilege the perspectives of females and racially minoritized students, who often face additional barriers to participation in mathematics classes (Leyva et al., 2021).

This study examines the experiences of four students working on a small-group calculus task from multiple perspectives. I pay particular attention to what each perspective adds to the story of what happened for these students. Questions are: *1) How did the teacher and student teacher make sense of student participation during this task? 2) How did students make sense of their own and their peers' participation during this task?*

Theoretical framework

Teaching and learning are considered sociopolitical endeavors through which power is distributed, either perpetuating persistent inequities or challenging existing hierarchies and injustices (Gutiérrez, 2013; Philip et al., 2017; Valero, 2018). Learning is defined as changes in students' participation in collective classroom practices (Lave & Wenger, 1991) and is a function of students' opportunities to participate (Gresalfi et al., 2009). Opportunities to participate are shaped by the roles and responsibilities students are assigned through acts of positioning (van Langenhove & Harré, 1999) and influenced by racialized and gendered narratives about who can and should do math (Esmonde & Langer-Osuna, 2013). As students interact, expectations are negotiated for how each student should participate, distributing power among students (Herbel-Eisenmann et al., 2015). Students positioned with competence and authority have more opportunities to participate in consequential ways, offering better access to rich math learning and identity development (Langer-Osuna, 2011).

Methods

Data collection

This study took place during the 2020-2021 school year; all classes used Zoom. The focal group consisted of four 12th-grade students in a Calculus AB course at a US public high school: Yonas ("Black"), Guadalupe ("Mexican"), Hosein ("Mixed"), and Elijah ("White"). Guadalupe was the only female student. Ms. B was the calculus teacher ("White" female). Mr. K was the student teacher ("Mexican" male). Quotation marks indicate words used by

 © ISLS

participants to describe themselves. Names are pseudonyms. Students were given a "related rates" group task without formal instruction on the topic. The teacher wanted them to think about the underlying ideas before formalizing strategies. The problem read: *1. A ladder leans against a wall. It begins to slide down the wall. Does the top of the ladder move at the same rate as the bottom of the ladder? 2. Suppose the bottom slides away from the wall at a rate of 1 ft/sec. How fast is the top of the ladder sliding down the wall when the bottom of the ladder is 6 ft from the wall? Assume the ladder is 10 ft.* The group was video recorded through Zoom. Students spent 10 minutes on the task. During one-on-one stimulated-recall interviews (Erickson, 2006) with the teacher, student teacher, and the four students, participants were shown the video and asked to share their observations of the task. Questions included: What stands out to you as noteworthy? What do you wish had gone differently? In what ways were these interactions typical and/or atypical? Students were also asked: How comfortable were you working on this task? How easy was it for you to participate? Would you say that you enjoyed this experience? Follow-up questions probing for more details included: Can you say more about ___? And what does that mean to you?

Data analysis

Interviews were transcribed then divided into *observation units*, operationalized as talk in which a person attended to or interpreted a particular part of the task video. When the subject, topic, or timeframe of the observation changed, a new *observation unit* was assigned. I developed codes through an open-coding process to identify similarities and differences in data and to facilitate comparison across the participants' observations (Corbin & Strauss, 2014). I used an iterative process of redefining codes to eliminate redundancy and group similar codes together. For each observation unit, codes were assigned to capture the subject ([student name], teacher, student teacher, group, task); topic (e.g., actions, feelings, thinking, ways of being); timeframe (this day, different day, this year, previous year(s)); observation type (person, interaction, other); and tone (positive, neutral, negative).

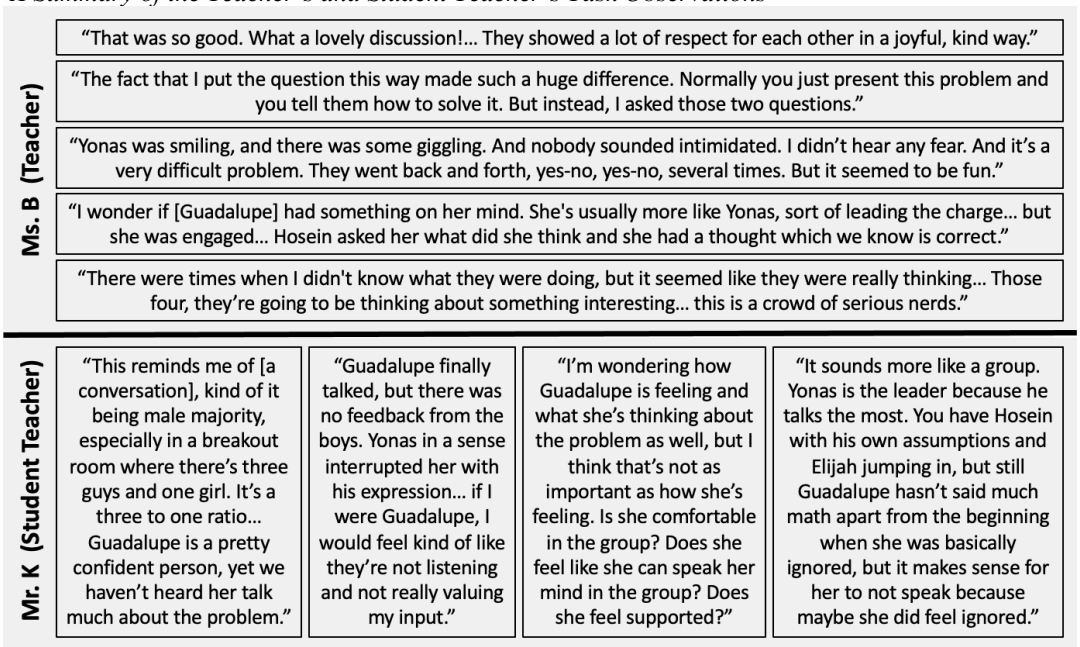
Findings

Teacher and student teacher perspectives

The teacher and student teacher shared their thoughts during interviews after watching the video (Figure 1).

Figure 1

A Summary of the Teacher's and Student Teacher's Task Observations



After watching the video, Ms. B exclaimed, "What a lovely discussion!" She went on to talk about the importance of task design and how the questions supported engagement. She described the interactions as joyful, kind, and fun. She spoke positively about the students' abilities ("this is a crowd of serious nerds"), their collaboration ("they went back and forth"), and their confidence ("I didn't hear any fear"). Ms. B noted Guadalupe spoke less than expected, suggesting she might have had something on her mind, but thought she was engaged.

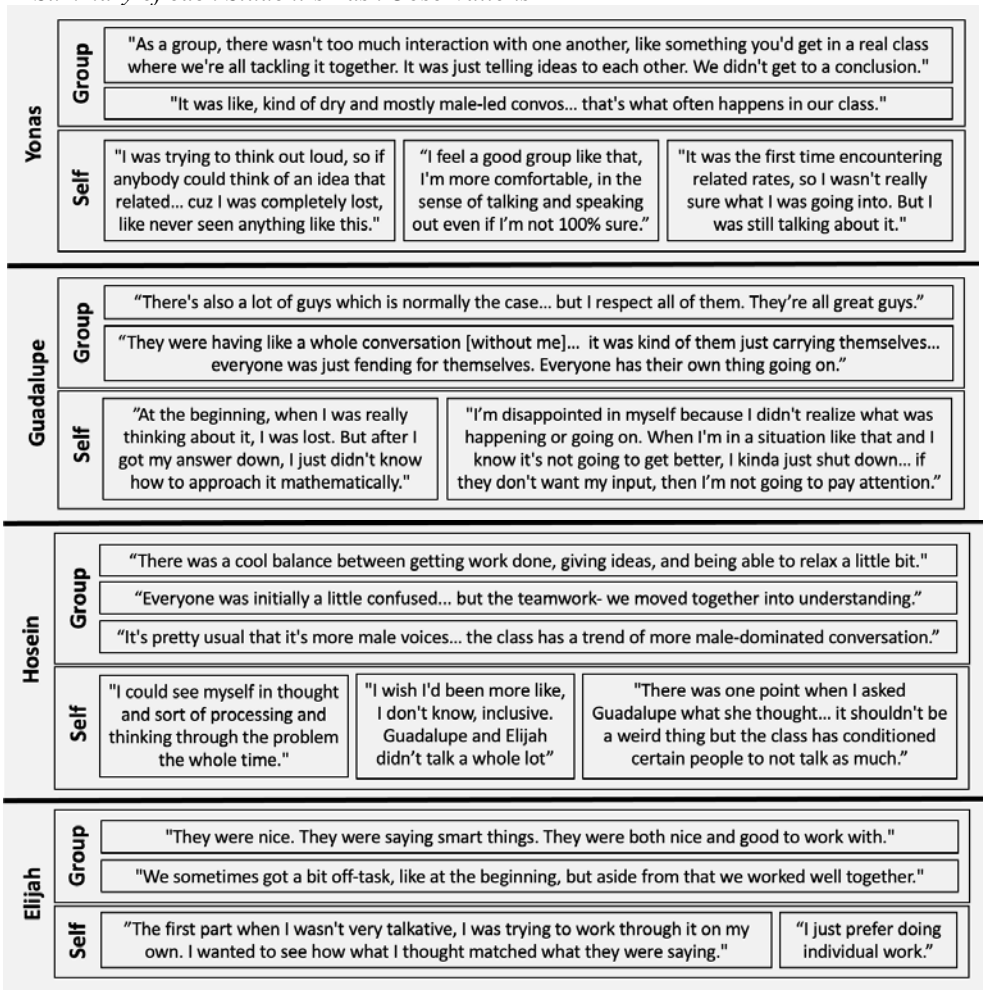
Because Mr. K shared his reflections throughout the video, his observations were sequential as opposed to holistic like the teacher's. He began by pointing out gender imbalance ("male majority"), noting that Guadalupe had yet to say much. Later, Mr. K noticed Yonas's interruption while Guadalupe was sharing and "no feedback from the boys." Mr. K imagined himself as Guadalupe ("I would feel… they're not listening and not really valuing my input"). He reflected further, wondering what Guadalupe was feeling and thinking, noting her feelings were most important. At the end, Mr. K described the group interactions positively, and yet, Guadalupe still had not "said much math stuff." Mr. K speculated that she might have felt ignored.

Student perspectives

The four students reflected on their own and their group's participation after watching the video (Figure 2).

Figure 2

A Summary of each Student's Task Observations



Yonas was confused but still comfortable sharing because it was "a good group," but expressed disappointment that they did not work together and did not reach a final solution. He also noted the conversation was male-led. Guadalupe was thinking hard about the problem but felt her ideas were not valued by her peers. She felt excluded from the conversation and felt it was not going to get any better, so she disengaged. Hosein enjoyed this experience because he felt they "moved together into understanding." He also acknowledged the conversation was male-dominated and talked about wanting to be more inclusive. Elijah thought hard about the problem and seemed to enjoy it but would have preferred to work alone. He thought everyone was nice and worked well together.

Discussion

In this case of four students working on a small-group task, findings revealed students' learning experiences differed in consequential ways. From the teacher's perspective, the group's "lovely discussion" was respectful,

 © ISLS

joyful, and fearless, and the students thought deeply about the intended math. But, to assess participatory equity, the question is… to what extent did *every* student have opportunities to participate and be seen as an important mathematical contributor? From the students' perspectives we learned that Yonas, Hosein, and Elijah felt comfortable thinking and talking about the math, but Guadalupe did not. She was confused, felt unsupported by her peers, and eventually disengaged. Everyone except Elijah noticed Guadalupe spoke less than her peers. Yonas and Hosein reasoned it was related to the pattern of male-led class conversations. Ms. B thought Guadalupe had something on her mind. Mr. K got closest to Guadalupe's reality with his speculation that she felt ignored. Despite the teacher's overall positive assessment of the group's work, a closer look at students' accounts suggested this small-group task experience was equitable for the three male students, but not for Guadalupe, a young Mexican woman who was "a pretty confident person" and was usually "leading the charge." Guadalupe got As in this course and earned a full scholarship to a top US university, but she was not immune to the barriers to participation faced by many females and students of color in advanced math courses. Exploring further how students' learning experiences are connected to gender, race, and other contextual factors are important directions for future research.

International Society of the Learning Sciences

Supporting remote programming instruction with real-time collaboration and awareness tools

Stephanie Yang, Harvard Graduate School of Education, szhang@g.harvard.edu
Allan Jiang, Stanford University, jiangts@stanford.edu
Bertrand Schneider, Harvard Graduate School of Education, bertrand_schneider@g.harvard.edu

Abstract: Learning to program remotely can be difficult for novices due to a lack of adequate online communication and coding tools. The current paper empirically assessed the impact of real-time collaboration and awareness tools on improving remote programming learning and instruction. Novice programmers were randomly assigned to use either screenshare, a shared online programming notebook (with real-time collaboration), or a shared notebook with awareness tools (shared gaze, mouse and scroll position) with an instructor. Findings revealed that students learned better in the condition where they had access to both real-time collaboration and awareness tools. A discussion of the results reveals the differential benefits of shared gaze and shared cursor for instructors and students and explores the efficacy of sharing web-based eye-tracking data to assist programming instruction. A notable contribution of this work is an open-source chrome extension that enables real-time sharing of awareness tools for online collaborative programming notebooks.

Introduction

A rapid increase in online programming instruction has forced many CS educators to seek out novel tools for remote pedagogy. However, existing technologies for programming instruction, such as screen sharing, github and google docs are not adequately meeting student needs, particularly for novice programmers (Ying & Boyer, 2020). While a number of tools, such as real-time collaboration online notebooks and shared awareness visualizations, offer promise in improving learning, they have not been researched in instructional contexts for novice programmers. In the current study, novice programmers and instructors were either assigned to work through a remote lesson using screen share, a shared notebook (with real-time collaboration tools), or a shared notebook with a chrome extension that enabled awareness tools (shared gaze, shared mouse and shared scroll position). The primary goal of this research is to assess the impact of real-time collaboration tools and awareness tools in improving remote programming instruction, and the differential benefits of shared gaze and shared cursor for instructors and students.

Related Work

Instructors often utilize screen share to help students with their code in a remote setting (Kawash et al., 2021). Screen sharing affords many advantages for programming instruction. For example, when students are sharing their code, instructors can see what they are seeing, which provides a shared reference for discussion and can provide insights into what the student is thinking. However, instructors do not have proper tools to direct student attention or provide real-time code-input (Kawash et al., 2021). During learning, these communication barriers can overburden a students' cognitive load, which is already high for novice programmers.

Real-time collaboration tools for programming, which allow multiple users to edit the same code synchronously, can alleviate some of these issues. Instructors can enter a shared coding environment with a student, and both parties can contribute real-time code input. Several studies have shown the benefits of real-time collaboration tools during pair programming to facilitate peer debugging (Goldman et al., 2011). However, given the novelty of mainstream synchronous programming tools, to our knowledge, they have not been studied in the context of coding instruction and in relation to student learning gains.

While synchronous programming tools allow both instructor and student to work collaboratively on a piece of code remotely, they still lack many advantages afforded during in-person learning. For example, when an instructor and student are working side-by-side, the instructor can point with their finger to direct attention and read the student's nonverbal cues, such as their eye gaze and facial expressions. These can help the instructor infer the students' thought process and tailor their teaching accordingly (D'Angelo & Schneider,

 © ISLS

2021). The ability to point at a location on the screen or to see the other person's eye gaze or scroll position is not afforded in traditional real-time collaboration tools for programming. However, recent advances in low-latency interfaces and eye tracking software can enable transmission of nonverbal cues in a remote setting. These are known as awareness tools. Sung et al., (2021) found that when instructors could remotely see a student's eye gaze, students learned more, and instructors were better able to predict their understanding. In a review of shared gaze technology, D'Angelo & Schneider (2021) explain that shared gaze enables joint-visual attention, which provides a common ground for collaborators to ensure they are on the same page. However, it is yet unclear whether other awareness tools, such as a shared cursor, can better convey these cues. Additionally, these previously mentioned studies have only assessed the effect of instructors visualizing student eye gaze. Given that student-directed awareness tools can be beneficial for learning (Sharma et al., 2016), the current study seeks to differentiate the benefits of awareness tools for students and instructors during a two-way sharing session. Lastly, to our knowledge, prior studies leveraging shared gaze have all used high-cost, external eye trackers, such as a Tobii Pro. These trackers are often expensive and not widely accessible to instructors and students in a real-world context. In the current study, shared gaze was enabled through webcam-based eye tracking, which is more low-cost and accessible. Understanding the benefits of sharing gaze data from a webcam is a first step in democratizing this technology for education.

Methods

Students in the study were 39 English speaking adults between the ages of 19 and 43, who self-reported no prior programming experience. A total of 13 instructors taught the sessions and were recruited through a mailing list sent to teaching fellows for an introductory computer science course and through word of mouth. Each instructor participated in three one-on-one sessions with a student and experienced each condition once. Each one-on-one session was 90 minutes long and took place remotely on Zoom. Together, students and instructors worked through learning content in a Deepnote notebook (deepnote.com). Deepnote enables users to run iPython notebooks in a browser and supports real-time collaboration. The content of the notebook contained exercises and examples for the instructors to teach the learning content. Students were randomly assigned to one of three experimental conditions: Screenshare, Shared notebook and Shared notebook with Awareness Tools.

Based on the interviews with instructors and evidence from other studies (Ying & Boyer, 2020) screenshare is a widely prevalent tool for conducting remote programming instruction. Thus, this was chosen to be the control condition, and a comparison against more advanced instructional tools. In the **Screenshare condition**, instructors and students were given different instances of a notebook containing the same content. The session began with the student sharing their screen and the instructor looking on. The instructor and student were free to switch off screen sharing at any time as they felt convenient. The impact of real-time collaboration tools was assessed in a **Shared Notebook condition** where instructors and students worked on a shared notebook that updated edits and run results in real-time. Both instructors and students were only allowed to reference the shared notebook on their screen. In the **Shared notebook with Awareness Tools** condition, students and instructors worked on a shared notebook, like the previous condition. In addition, they were able to see each other's gaze, mouse and scroll position on the page (Figure 1). The other person's eye gaze was represented by a circle (50px radius), the other person's mouse position was indicated by an orange cursor, and the scroll position was represented by an orange rectangle on a mini-map representation of the notebook on the side of the page. These awareness tools were enabled by a chrome extension (github.com/jiangts/GazeCoder) that users enabled at the beginning of the session. The real-time gaze, cursor, and scroll position was broadcasted to the other user through our websockets server. We used the GazeCloudAPI (gazerecorder.com) for eye tracking, which uses computer vision to determine the position of a user's gaze on the screen.

At the beginning of each session, students watched a 10-minute video sourced from Udacity (udacity.com) which introduced them to the basic building blocks of python. After, they took a pre-test consisting of 6 questions to control for prior knowledge. Students were then introduced to their instructor, who was also in the Zoom room, and both were sent a link to the Deepnote notebook. In the conditions with awareness tools, instructors and students set up the chrome extension and calibrated their eye gaze. After, the students and instructors were given 45 minutes to complete as much of the notebook as possible. Instructors

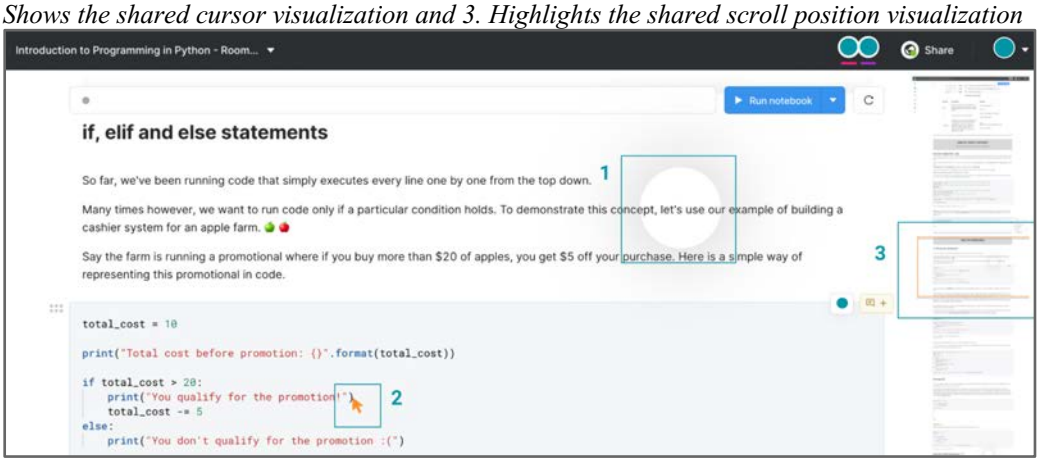
 © ISLS

were encouraged to cover all the new content, even if they couldn't complete all the exercises in the notebook. At the end of the 45 minutes, students and instructors completed a survey about their experience, and students then took a 12-question learning post-test that closely mirrored the content of the pre-test, with an additional question for each original pre-test concept. This completed the students' participation. After instructors completed their three student sessions, they were interviewed about their experience teaching in each condition.

Student learning gains were measured using the pre- post-test taken before and after the learning session. The assessments contained multiple choice, short answer and coding questions, and assessed understanding of types, variables, if statements and for loops. Learning gains were calculated by subtracting the pre-test score from the post-test score. Additionally, the usefulness of the shared gaze and cursor tools were assessed based on responses from instructors' and students' post-experiment survey.

Figure 1

Screenshot of Shared Notebook with Awareness tools in Deepnote. 1. The shared gaze visualization, 2. Shows the shared cursor visualization and 3. Highlights the shared scroll position visualization



Results

A one-way ANCOVA was performed to compare the effect of the three different conditions on learning gains. The results revealed that there was a statistically significant difference in learning gains between at least two conditions ($F(2, 36) = 9.91$, $p < .001$). A post-hoc test found that learning gains were significantly different between the Shared Notebook with Awareness tools condition and Screenshare condition ($p = .002$, 95% C.I. = (1.87, 7.42)) and the Shared Notebook with Awareness tools and Shared Notebook condition ($p = .02$, 95% C.I. = (.61, 6.22)). There was no statistically significant difference in learning gains between the Shared Notebook and Screenshare condition ($p = .376$). In these analyses, we controlled for the age of participants based on prior evidence of a relationship between technological learning and age (Charness & Boot, 2009). Additionally, in our data, age was negatively and significantly correlated with learning gains ($r(39) = -.54$, $p < .001$).

In the post-experiment survey, students and instructors were asked to rate the shared gaze and shared cursor tools on a 5-point Likert scale in terms of the tool's usefulness for their learning/teaching. On average, students rated the shared gaze as "Not at all useful" (M=1.2, SD=0.4), and the shared cursor as "Moderately useful" to "Very useful" (M=3.4, SD=1.4) for their learning. Instructors rated seeing the students' gaze as "Moderately useful" (M=2.9, SD=1.4) on average, and the shared cursor tool as "Moderately useful" to "Very useful" (M=3.5, SD=1.2). In general, the instructors found the shared gaze to be more useful than the students, and both instructors and students thought the shared cursor was useful for their learning/teaching.

Discussion

In a one-on-one tutoring setting, students working in a shared notebook with an instructor, who could also see their eye gaze, mouse cursor and scroll position learned more than students who could only see the instructor's shared screen. No difference in learning gains was found between a student working with an instructor in a shared notebook and a student and instructor screensharing. These results suggest that real-time collaboration

tools are not sufficient in supporting learning, and that the addition of awareness tools are necessary for significant learning gains. Preliminary analysis of instructor interviews uncovered potential reasons for these findings. When instructors only had access to real-time collaboration tools (Shared Notebook condition), they recalled that they could easily write out code for students and took advantage of this when making small syntax changes or writing example code to further explain a concept. However, instructors also lost affordances offered in the screenshare condition. For example, they could not see where the student was scrolled to or where their cursor position was. Instructor's recalled feeling "lost" or "blind" in this condition when the student was silent since they could not tell if they were thinking, zoning out, or stuck. In comparison, when instructor's had access to both awareness and real-time collaboration tools, the awareness tools compensated for cues afforded during screensharing, providing both grounding and feedback.

Generally, instructors rated the awareness tools as more useful than the students did. Notably, the instructors found the shared gaze tool to be "Moderately useful" whereas students thought it was "Not at all useful". One instructor reflected that the shared gaze conveyed "thinking", whereas the shared cursor conveyed "intent". Indeed, during a learning situation, it is more useful for an instructor to receive cues about what the student is thinking or confused about so they can tailor their instruction. On the other hand, it is less useful for a student to know what the instructor is thinking, but more useful to know their intent, and what they want the student to pay attention to. This could explain why instructors found the shared gaze to be more useful than students, and why students thought the shared cursor was more useful than the shared gaze.

A few limitations caveat the findings of this research. First, the small sample size may hinder the reliability of these findings. Additionally, since a less accurate web-based eye-tracker was utilized in the study, the results may not be generalizable to other instructor-student gaze-sharing scenarios.

Conclusion

In this paper, we assessed the impact of real-time collaboration and awareness tools on improving remote programming instruction. The results show that synchronous code editing tools can benefit remote programming instruction, but only when supplemented with awareness tools that aid the communication and grounding between students and instructors. Given the rising number of commercial synchronous code editors, such as Deepnote and Replit (replit.com), and the open-source nature of the chrome extension developed in the study, these findings have real-world applications to many CS learning settings, such as office hours or tutoring.

Abstract: Prior research is somehow divided about the importance of authenticity in simulation-based learning, but in simulations designed for fostering diagnostic competences, there seems to be no general relationship between authenticity and diagnostic competences. In the present study, we investigated perceived authenticity and its role for learners' diagnostic accuracy in a simulation that was designed to foster pre-service teachers' diagnostic competences. Pre-service teachers completed the video-based simulation and composed a written diagnosis of a student's scientific reasoning skills before rating the authenticity of the simulation on three dimensions (realness, involvement and spatial presence). The results showed that the simulation was perceived as authentic – except for spatial presence – and that only the relation of involvement to diagnostic accuracy was statistically significant. This is partly in conflict with previous findings and suggests that the design of simulations for fostering pre-service teachers' diagnostic competences should focus more on involvement rather than on realness.

Introduction

During a regular school day, there are many occasions on which teachers employ diagnostic competences. These diagnostic competences play an essential role in successful teaching (Helmke & Schrader, 1987) and especially as a prerequisite for the specific support of individual students (Schrader, 2009). Diagnostic competences can be defined as the ability to collect and interpret information for the purpose of making high-quality decisions or assessments (see Heitzmann et al., 2019), for example regarding students' knowledge, skills and so forth. Even though previous research pointed out that teachers' diagnostic competences are on average rather high, there is still room and a need for improvement (Südkamp et al., 2012). This is especially true for pre-service teacher education, as diagnostic competences often do not play a central role in university-based teacher training programs. Consequently, (pre-service) teachers need a sufficient amount of opportunities to improve their diagnostic competences. Since practicing with actual students may often not be an option due to organizational obstacles and ethical requirements, practicing with simulations can offer a convenient alternative.

Using authentic simulations to foster diagnostic competences

Simulations represent certain segments of reality and offer learners the opportunity to interact with these segments and thereby develop specific skills and competences (Heitzmann et al., 2019). Therefore, simulations are considered highly useful for fostering a variety of different competences, including diagnostic competences. This appears to be true in the field of medical education, where simulation-based learning already plays a significant role (see Peeraer et al., 2007). Meanwhile, it has also been gaining more and more popularity in teacher education (see Chernikova et al., 2020). This increasing interest in using simulations for learning in teacher education is also associated with an increasing interest in design guidelines for creating simulations and the question: What is an effective simulation?

The relationship between realness, involvement and spatial presence of simulations and diagnostic competences

Because of fast technical progress and increasing opportunities (like e.g. "virtual reality"), there often is a specific focus on the authenticity of simulations and on whether or not an effective simulation needs to be as authentic as possible. Prior research regarding the importance of authenticity of simulations is somehow divided. Henninger and Mandl (2000) emphasized that more authenticity is not always better, because it is sometimes advisable to simplify certain facets of a learning environment and therefore reduce the authenticity in order to avoid excessive cognitive load resulting from too many different sources of information (see e.g. Ayres & Sweller, 2014). However, a recent meta-analysis found higher learning effects with more authentic simulations than with less

 © ISLS

authentic simulations (Chernikova et al., 2020). Nonetheless, empirical research investigating the effects of authenticity in learning environments covers a variety of aspects of authenticity that range from evaluations of more objective criteria, such as whether a simulation contains all critical elements of the corresponding real life situation (see e.g. Norman et al., 2012), to learners' individual perceptions (see e.g. Frank, 2014; Schubert et al., 2001). Thus, in answering the question of effectiveness, a more differentiated analysis is needed, comparing different aspects of authenticity in order to understand which aspect of authenticity matters most in simulations. In line with a factor analysis conducted by Schubert et al. (2001), the most important facets of learners' individual perceptions of authentic learning environments might be perceived realness, involvement and spatial presence. Perceived realness is the realistic feel of a simulation. Perceived involvement is the feeling of being fully involved in an experience. Spatial presence is the feeling of really "being in the situation" (see Schubert et al., 2001; Vorderer et al., 2004). Research in the field of medical education suggests rather low correlations between perceived realness, involvement as well as spatial presence and diagnostic competences (Fink et al., 2021), but there are no findings yet on whether similar correlations can be found in the field of teacher education.

Aims and research questions

The purpose of the present study was to measure the perceived authenticity of a simulation that was designed and developed for the purpose of fostering pre-service teachers' diagnostic competences. We assume high perceived authenticity to be indicated by high ratings for perceived *realness*, *involvement* and *special presence*. Further, we aim to examine the relationship between the perceived authenticity of the simulation and pre-service teachers' *diagnostic accuracy* within the simulation.

RQ1: How do pre-service teachers rate the video-based simulation regarding the perceived *realness, involvement* and *spatial presence* of the simulation?

RQ2: Is there a meaningful relationship between the perceived *realness, involvement* or *spatial presence* and pre-service teachers' *diagnostic accuracy*?

Method

Participants

Participants were recruited at three different German universities. All 160 participants were enrolled in university-based teacher programs (53.8 % female, 43.8 % male; age: $M = 22.91$, $SD = 2.90$; semester: $M = 4.99$, $SD = 1.77$).

Simulation environment

To mimic a specific classroom situation that involves the process of diagnosing students, we created a video-based simulation focused on diagnosing students' scientific reasoning skills. This simulation contained staged videos showing pairs of students conducting inquiry tasks in class. Based on the respective school subject (physics or biology) the students' task was to find out whether or not certain independent variables influence the focused depiction of an object through optical lenses (physics) or the growth of plants (biology). Those tasks were limited to four independent variables (e.g. the distance between object and lens in physics or the amount of water in biology) in each of the two subjects. The videos were staged because we wanted to make sure that both versions (physics and biology) were fully parallel in structure. While working with the simulation, the participating pre-service teachers' task was to collect information about one specific student's scientific reasoning skills and to later compose a written diagnosis about his or her skills. In addition to the videos (displayed on the upper left hand side of the screen), the simulation featured a table containing information about the experiments conducted by the students in the videos as well as their observations (displayed on the upper right hand side of the screen), a note pad, offering participants the opportunity to write down individual notes (displayed on the lower right hand side of the screen) and a navigation area (displayed on the lower left hand side of the screen). In the navigation area, certain pre-formulated questions appeared and disappeared throughout the video. This was designed to give participants the possibility to interact with the students featured in the videos and collect additional relevant information. If a participant decided to ask a certain question (e.g. "What do you want to find out now?"), he or she had to click on the respective link and received the answer of the student via an additional video that was inserted in the main video. A limited overall amount of time was available for asking questions to ensure that participants would only ask deliberately selected questions.

Measurement of variables

After working with the simulation, participants rated their perception of the simulation on three different scales. All statements were rated on a 5-point Likert scale ranging from (1) disagree to (5) agree. *Realness* was measured by three items (e.g. "I think the learning environment is authentic") from an adapted scale (Schubert et al., 2001;

see also Seidel et al., 2010) with satisfactory reliability (Cronbach's $\alpha = .77$). *Involvement* was measured by four items (e.g. "I have immersed myself in the situation") from an adapted scale (Vorderer et al., 2004; see also Frank, 2014; Seidel et al., 2010) with acceptable reliability (Cronbach's $\alpha = .61$). *Spatial presence* was measured by three items (e.g. "I felt like I was actually there in the simulated situation") from an adapted scale (Vorderer et al., 2004) with satisfactory reliability (Cronbach's $\alpha = .79$).

For the purpose of quantifying participants' *diagnostic accuracy*, the written diagnoses were coded on the basis of the different sub-skills of scientific reasoning. Two independent raters coded for each of 11 specific scientific reasoning sub-skills (e.g. the skill to formulate specific hypotheses or the skill to manipulate the examined variable – while keeping all other independent variables constant) whether the sub-skill was mentioned in the written diagnosis and – if it was mentioned – if the sub-skill was diagnosed correctly. An additional coding variable captured whether the diagnosis noticeably indicated awareness of the difference between actual behavior and underlying latent sub-skill. The score for *diagnostic accuracy* was the percentage of the variables coded as "present" or "correct", respectively. Overall the two raters achieved a high agreement; $ICC_{absolute}$ (159,159) = .82. Averaged scores of both raters were used in the statistical analyses.

Results

The descriptive results indicated that on average participants perceived the *realness* and the *involvement* of the simulation as relatively high (see Table 1). The differences between these average ratings and the midpoints of the corresponding scale were statistically significant and amounted to a small effect in the case of *realness*; $t(159) = 4.04$; $p < .001$ (two-sided); $d = 0.32$ and a large effect in the case of *involvement* $t(159) = 10.32$; $p < .001$ (two-sided); $d = 0.81$. The ratings for perceived *spatial presence* were lower and below the midpoint of the rating scale (see Table 1). This difference was also statistically significant and amounted to a moderate effect; $t(159) = -6.75$; $p < .001$ (two-sided); $d = 0.54$.

Table 1
Descriptive statistics for perceived authenticity

	M	*SD*
Realness	3.29	0.92
Involvement	3.56	0.69
Spatial presence	2.47	0.99

In a multiple regression analysis with *diagnostic accuracy* as the criterion variable, *involvement* was found to be a statistically significant positive predictor ($\beta = .36$, $p < .001$), whereas *realness* ($\beta = -.08$, $p = .32$) and *spatial presence* ($\beta = -.12$, $p = .19$) were not statistically significant predictors.

Discussion

Pre-service teachers rated the authenticity of our simulation as rather high, as they stated that they felt involved during participation (*involvement)* and perceived the learning environment as a realistic depiction of a classroom situation (*realness*). Only the feeling of "being in the actual situation" was rated rather low (*spatial presence*). The results of the regression analysis only partially agreed with findings from previous research, as we found a statistically significant relationship between *involvement* and *diagnostic accuracy*. In line with the results of Fink et al. (2021), the relations between *realness* and *spatial presence* on the one hand and pre-service teachers' *diagnostic accuracy* on the other hand were not statistically significant. As the *involvement* ratings for the simulation were the highest among the three aspects of authenticity, these results further strengthen the validity of the developed simulation.

In summary, our findings suggest that it may be useful to take a more differentiated look at the role of authenticity, as our results point in the direction Henninger and Mandl (2000) suggested: It may not be sufficient to only increase the *realness* of simulations and therefore this aspect of authenticity perhaps should not be the sole focus of interest. Instead, it might be more important to get learners cognitively involved. Obviously, this does not mean that creating a realistic experience is not important as both facets are interconnected to a great extent; yet it may be useful to consider how increasing the degree of realness of a simulation can lead to more learner involvement.

Nevertheless, these findings stand in need of replication using more elaborated methods. In line with the idea of Norman et al. (2012), it may also be advisable to include additional measures of authenticity that also consider whether a simulation contains all critical elements of the corresponding real life situation. This may also require assessments by experts, since learners may not be able to evaluate respective critical elements themselves.

In conclusion, we still suggest that the statistically significant relationship between *involvement* and *diagnostic accuracy* provides some indication of what really matters when developing simulations for fostering diagnostic competences in pre-service teachers and that developers of simulations should focus more on inducing learner involvement than on maximally realistic simulations.

Information Architecture as Theory: Sociotechnical Dimensions of Learning and Learning about Learning

Philip J. Piety, PhD, University of Maryland College Park, ppiety@umd.edu
Neha Hareshkumar Wadhwani, University of Maryland College Park, neha8109@umd.edu

This paper looks at technological advances in the collection and use of information about learning. Updating earlier discussions on transcripts and videorecording, this paper draws on examples from a digital simulation and pedagogical approaches using videoconferencing as a post-pandemic alternative to table-base groupwork and then submitted transcripts of the meeting for evaluation and feedback. The transcripts were computationally analyzed producing visualizations of conversations. These data were combined with records of students working on collaborative documents and the learning analytics for a digital simulation. Congruent with prior reflections on transcription of recordings and the recording process, this paper highlights the ways, old and new, the inscriptional process is not theory-neutral, but privileges certain activities to play an agentive evidentiary role.

Education and educational research are richly semiotic practices

Education involves richly semiotic processes that are often inscribed for analysis or lost to the research process. Whether the indicators and information used to study what goes on in learning settings are proximal to the activities we see as consequential for learning—classroom activity, groupwork, engaging with digital tools, etc.—or distal activities including tests and surveys, our research is constituted in part by the records that are made of student work. Over the last fifty years, the tools used for recording details related to learning have advanced from audio tape to video recordings. Video has evolved from single general-purpose cameras to multiple and special equipment (Goldman, et al., 2014) all in search of better representations of what is occurring to enable learning. Today, these familiar approaches have been joined by digital platforms with new ways to collect information about student activity that these platforms often structure. This paper shows some contemporary methods of creating transcripts and other digital traces of student behaviors. These records show some things with clarity. Other things are less clear. Together these new inscriptional technologies provide important capacity to understand student actions over large numbers of individuals and events. In the past, advances in education and social science research have prompted reflections on the nature of these inscription/transcription processes and their impacts on researchers' epistemological/theoretical positions.

Research, Inscription, and Theory

This paper's intellectual lineage begins with Ochs' (1979) essay titled *Transcription as Theory* that provided a complementary perspective to technological optimism that recording equipment was dramatically reducing the filtering of researchers. Ochs focused on the transcription process and choices researchers and transcribers make to render the recorded event ready for analysis. Her work was drawn from studying language acquisition in small children. In 2000, Hall wrote *Videorecording as Theory* that expanded the discussion drawing on examples from educational research. Hall discussed issues of context and how contextual information is depicted through choices of camera placement, cropping, and editing. He looked at interactions between participants and each other and technologies. He considered the sharing of video records in datasets and how the use of those datasets align with the nature of the data collection and how sharing of video records may raise privacy and ethical concerns. This paper includes the concept of *Information Architecture* that has historically been visual where presentation choices impact comprehensibility (Wurman, 1995; Piety and Palincsar, 2006). This project includes several kinds of student interactions that have been recorded (transcribed) through automated digital methods. It extends Ochs' (1979) and Hall's (2000) work in four ways: 1) computationally derived data transcription streams with visualizations (Figure 1); 2) collaborative textual practices as students interact with shared documents (Figure 2); 3) integration of multiple data streams, including conversational and textual (Figure 3); and 4) multimodal discourse from students interacting in a digital simulation (Figure 4).

Teaching STEM career awareness and intent

The curriculum in both its document and its simulation portions uses a three-part pedagogical pattern where students were assigned some work to do with documents then meet and discuss the documents and produce an artifact for grading. The work the students do in the first part of the narrative is conducted on shared Google documents (Google Docs).

 © ISLS

Using recordings/transcripts of videoconference-based groupwork

Part of the implementation of this project was altered because of pandemic safety protocols. What was intended to be table-top groupwork was replaced with students working in videoconferencing sessions and submitting records of that meeting (video and transcript) for grading/analysis. This pattern was typically conducted over several days with the assignment on a Thursday and the students able to complete tasks for group submission on a Sunday night. By submitting their artifact, video, and transcript the students provide the instructional team information to grade and provide feedback (as well as automatically identifying participation for grading).

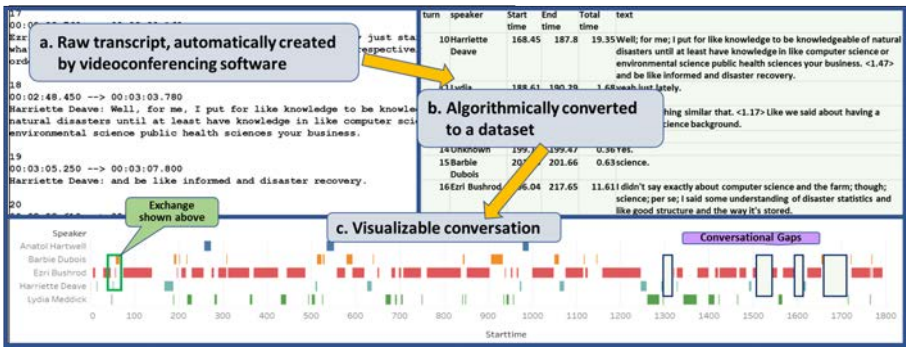

Figure 1 - From autogenerated transcripts to visualizing conversations

Computationally derived data transcription streams with visualizations

While creating a moderately accurate transcript of audio is commonplace. These generated transcripts have specific properties and affordances. As shown in Figure 1, a transcript with timings of speech comes from the videoconferencing software (a). The verbal interpretation is not always accurate, but the timing is. This file can then be converted into a dataset (b) that can be directly used in visualization software[2]. While the visualization (c) does not show specific detail about what is being said at different points in time, the information about who is speaking when and how much of the conversation is being produced by which participants is largely accurate. The depiction can be used to ask questions about the collaborative processes of the individuals present. The conversational gaps presented in the transcript files have generated new research questions for this project with various theories as to whether these gaps represent time the students are working on the collective artifact and whether there are any discourse patterns associated with the periods.

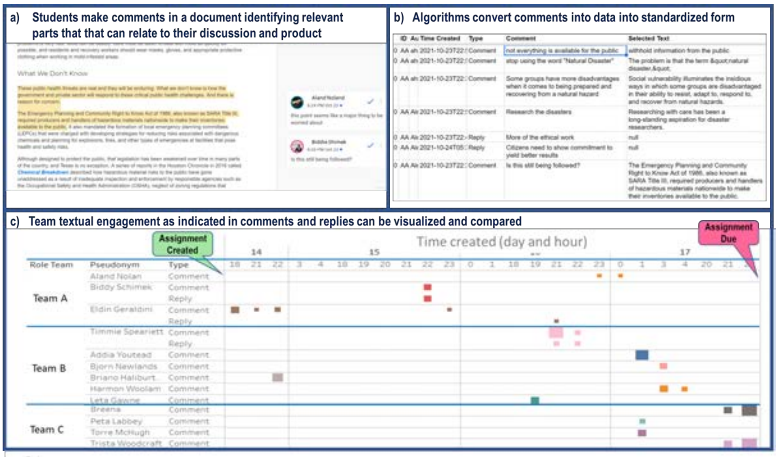

Figure 2 - GoolgeDoc comments showing team activity over days

A literature exists around collaborative document practices has largely been focused on direct observations of students working synchronously (Lowry, Curtis & Lowry, 2004) or in editing on collaborative web platforms (Stoddart, et al., 2016). Little work has shown how students work on shared documents asynchronously over time. Figure 2 shows the path that comments take from their state as students experience them in the margins of the document to a tabular format to then a data display like the one used for transcripts but showing activity over days. This visualization allows different team engagement patters to be readily seen and compared. The size of the squares is related to the number of actions (comment or reply) taken. Team B, for example works over the course of several days well in advance of the deadline. All members of Team B comment and two also reply. Team C, however, only does the minimum, right before the deadline.

In several the conversational transcript visualizations like the one shown in Figure 3, gaps appear in the conversation when no students are speaking. The research team speculated these gaps might be when the team is working to produce a shared document (see Figure 2). The research team further speculated that when there is an asymmetry in conversational time (as shown in Figure 3) that there might be a counterbalancing activity in editing. In other words, as one student is leading the conversation then other students are working on the

document. When the shared document is a Google Doc, it is possible to see when edits and are being made to the document. This information is limited to only knowing when edits were made and by whom rather than the details of the edits, including which material was added/changed by a person[3]. Rather, Figure 3 shows the same person making edits and speaking.

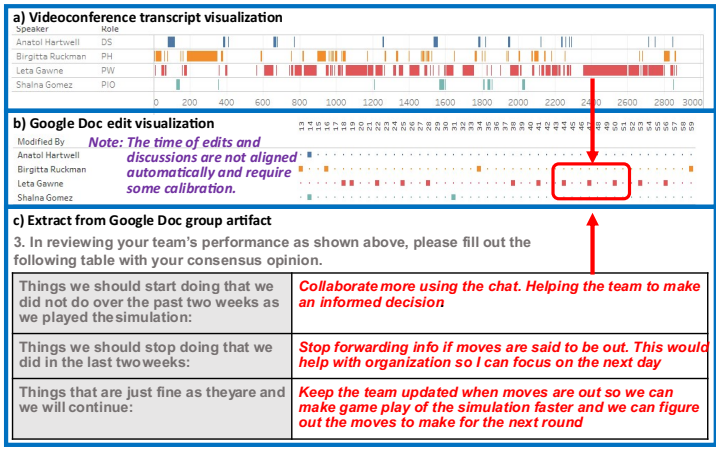

Figure 3 Document edits and conversations

The digital simulation embedded in the curriculum

The second portion of the narrative uses a digital simulation within a similar pedagogical pattern that was used with professional documents in the first portion. Rather than having a commenting activity that precedes the group discussion to develop a team artifact, the team plays a simulation. Data from the simulation is then used in asking the team to reflect on their group dynamics and understanding of collaboration in STEM careers.

Virtual emergency operations center with three intra-team communication options

The students engaged with a digital simulation of an emergency operations center (EOC) for a community. The EOC simulator presents each team has a different set of incidents and unique copy of a virtual world, but where all teams played simultaneously different variations. Players have three ways they can communicate with their teammates inside the simulation:1) a group chat that operates like other chat systems allowing direct text messaging within the team, 2) forwarding of notifications, and 3) placement of indicators (a digital pushpin). The simulation produces an activity log that shows the kinds of things that team members do and when. Figure 4 shows two different simulation teams' activity records. They show how the simulation unfolds and the kinds of actions different roles are taking. The technology produces 25 visualizations with the same effort to produce two enabling analyses on a large scale, albeit with less attention to nuance and detail. Many important factors may be less visible than with more focused methods. As with the prior visualizations, the game simulation representations show activity over time. With the first team in Figure 4, there is not much activity until the fourth member joins. The second team was able to begin much more quickly. There are then differences in how each team used the moves they are allowed. The first team spends more time moving on the map compared to the time they spend scoring. The second team is more efficient. These representations are shared with the students so they can reflect on who did what in their simulation.

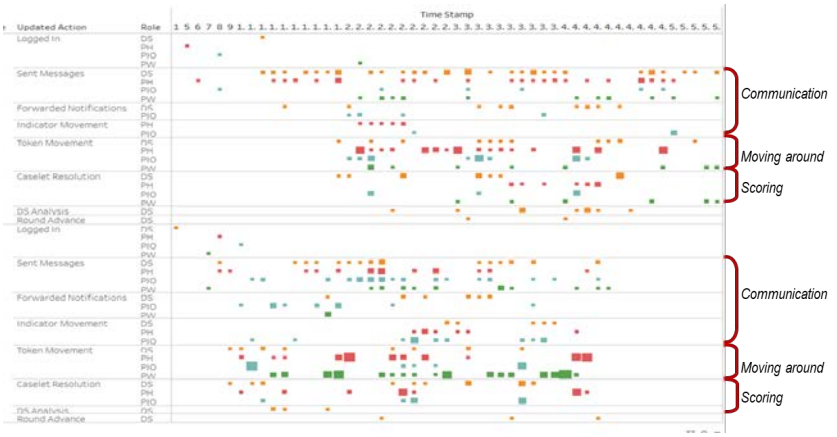

Figure 4 - Visualization of simulation activity for two different teams

How these visualizations are helping shape the research

An important part of this paper is the relationship between the depictions of human activity (formerly called transcripts) and research possibilities. The representations are computationally created and benefit from the ability to combine with other digital data. These new ways of seeing student activity in these group settings is supporting new ways to structure both teaching and research. They allow insights into asymmetric team member

participation in group activities. Instructors that assign groupwork, especially in some undergraduate programs, have become familiar with reports of how some students do less than others. as well as how some students dominate others. Understanding what happens is now more possible because of these data.

Discussion: Information architecture as theory

The world of social science and education research today is greatly changed from what it was just a few years ago. The advances in creating research artifacts from recorded activity are emblematic of broad changes that have occurred and are occurring with computational tools. These computational tools and their data streams are interconnected in a web of technologies that can operate instantaneously at great scale. The ability to collect information similar to that shown in this paper efficiently at scale suggests three areas for consideration.

1. **Reconsidering evidentiary classifications.** The kinds of data and visualizations presented in this paper do not fit neatly into quantitative or qualitative paradigms. The data and visualizations shown here are not specific to the research dimensions of this project. They are used for both grading and student support.
2. **Sociotechnical structuring.** As Hall (2000) indicated, the recording methods can structure what might appear to be naturalistic in edited video. In this research, Google Docs structures the comments and replies. Video conferencing software (Zoom) places participants in certain places and automatic transcriptions does not capture overlapping speech. The research adapts to these constraints.
3. **Automating surveillance.** The techniques used to collect traces of activity in meetings and from documents could be considered a form of surveillance. The meeting transcripts are required to show who was at the meeting, which addresses a common challenge with many undergraduate students: group project absenteeism. The technologies make this kind of surveillance easy and there are instructional situations where being able to pinpoint participation is helpful. However, it raises questions about ethics and privacy.

Researchers tend to work in comfortable patterns using techniques that have been successful before. This is especially true for emerging scholars who will use templates developed by those already established in the field. The kinds of approaches shown in this paper will likely become commonplace in the coming years. Researchers may be tempted to see in these new technologies a revolution in inferential possibilities. This paper like the ones it follows provide an optimistic, but cautionary perspective.

Can Mental Rotation Predict Performance in an Online Geometry Assignment?

Hannah Smith, Worcester Polytechnic Institute, hsmith2@wpi.edu
Kay Ramey, Northwestern University, kayramey@u.northwestern.edu
Neil Heffernan, Worcester Polytechnic Institute, nth@wpi.edu
David Uttal, Northwestern University, duttal@northwestern.edu

Abstract. Mental rotation knowledge has been linked to math performance, specifically in geometry, but it is unclear when, why, and how mental rotation affects achievement. We extend prior research by examining the relation between mental rotation skill and performance in two online geometry assignments on different topics (e.g., translations, rotations) and presented in two different ways to prime problem-solving strategies (e.g., analytic, visuospatial). Within each problem set, students completed four mental rotation problems, then an online problem set. The results indicated that: (1) mental rotation skill predicted assignment mastery speed regardless of topic; (2) problem presentation did not affect mastery speeds; (3) there was no interaction between mental rotation skill and problem presentation. We conclude that mental rotation skill may be more important in solving geometry problems than problem presentation and strategy use.

Introduction

It is well documented that spatial skills predict math achievement (e.g., Geer et al., 2019; Uttal and Cohen., 2012; Wai et al., 2009), specifically, in geometry (Pittalis & Christou, 2010; Weckbacher & Okamoto, 2014). However, arguments still abound as to when, why, and how spatial skills affect students' math achievements and later success in STEM disciplines (e.g., Wai et al., 2009).

Research has suggested that spatial skills are malleable (Uttal and Cohen., 2012), but one question is how transferable skills are from one domain to another or even within one domain on different topics. In their analysis of over 200 studies on the malleability of spatial skills, Uttal and Cohen (2012) reaffirmed the malleability of spatial skills, but their findings regarding the transferability of the learned skill were inconclusive. Not all problems involve the same steps or cognitive processes to solve. For example, in geometry, some problems, like rotating figures on a coordinate plane, might map better onto certain spatial skills, like mental rotation. Typical psychometric assessments might only test one specific type of spatial skill (e.g., mental rotation), so it is unclear whether mental rotation performance only impacts performance on geometry problems involving rotation or whether it would impact performance on other types of problems as well (e.g., translations; moving across a coordinate grid in a given direction). Here, we explore whether spatial skills are predictive of success across different topics within geometry (e.g., rotations and translations) and whether their impact extends beyond geometry rotation problems.

In addition, other studies have shown individual preferences for particular problem-solving strategies, visuospatial or verbal/analytic (Stieff, 2007). Prior work has shown that the use of different strategies, such as analytic as opposed to visuospatial, may mitigate the impact of individual differences in spatial skills (Stieff, 2007). Much work has been conducted in chemistry (Stieff, 2007), however, it is still unclear how spatial skills may influence different problem-solving strategies in geometry, and how the representation of the problem may influence the use of different strategies and ultimately impact performance.

The Present Study

In the current study, we explored whether mental rotation skills are predictive of performance above and beyond problem presentation and problem-solving strategies. We hypothesize that spatial skills may be more or less helpful depending on how problems are presented. Specifically, geometry problems can be presented in both visuospatial and analytic ways. [KR1]In a visuospatial presentation, students are prompted to solve the problem using visual perceptual cues and spatial reasoning. Conversely, in an analytic presentation, students are prompted to solve the problem with an analytic strategy using a coordinate grid and numeric coordinates. We also hypothesized that spatial skills may affect performance in geometry rotation problems that directly relate to mental rotation skills but may not in translation problems. We present a randomized control trial with eighth-grade

 © ISLS

students in ASSISTments (Heffernan & Heffernan, 2014), an online tutoring system. We asked the following research questions:

1. Does mental rotation skill predict math performance in online geometric problem sets?
2. Does problem presentation affect math performance in online geometric problem sets?
3. Does problem presentation moderate the effect of mental rotation on math performance within each problem set?
4. Does this relationship change depending on the topic of the problem set (e.g. translations, rotations)?

Methods

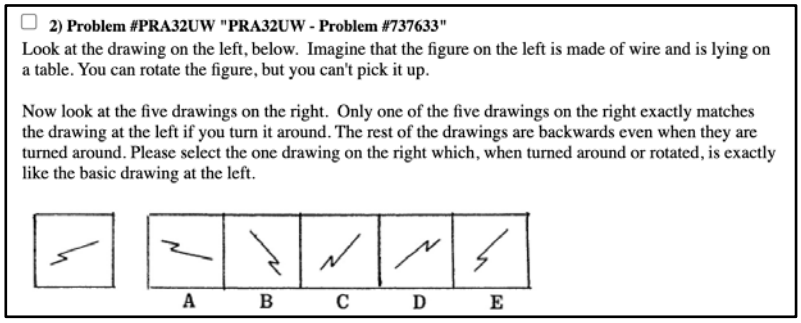
This study was an available problem set for 8th-graders covering translations and rotations within ASSISTments. The problem sets each consist of a pretest on mental rotation and a 10-problem skill builder. A "skill builder" is a problem set based on Common Core State Standards which present problems in a randomized order on one topic. The goal is for students to "master" a specific skill by answering three problems correctly in a row. Once they answer three problems in a row correctly, they are identified as having content mastery of that topic and are labeled as, "mastered". If a student answers a problem incorrectly, their count starts over, and they keep receiving problems until they get three correct in a row. A total of 398 students completed the translations set, and 942 students completed the rotations set and were included in analyses.

Procedure & Materials

First, students completed the mental rotation task (Hegarty, 2018), with four mental rotation problems (Figure 1). Then, they entered a skill builder, consisting of 10 problems, where they were instructed that they would complete the skill builder if they answered three questions correctly in a row. If a student failed to master the skill builder within 10 problems, they were given a skill builder score of 10.[KR2]

Figure 1.

An example of the mental rotation problems students saw

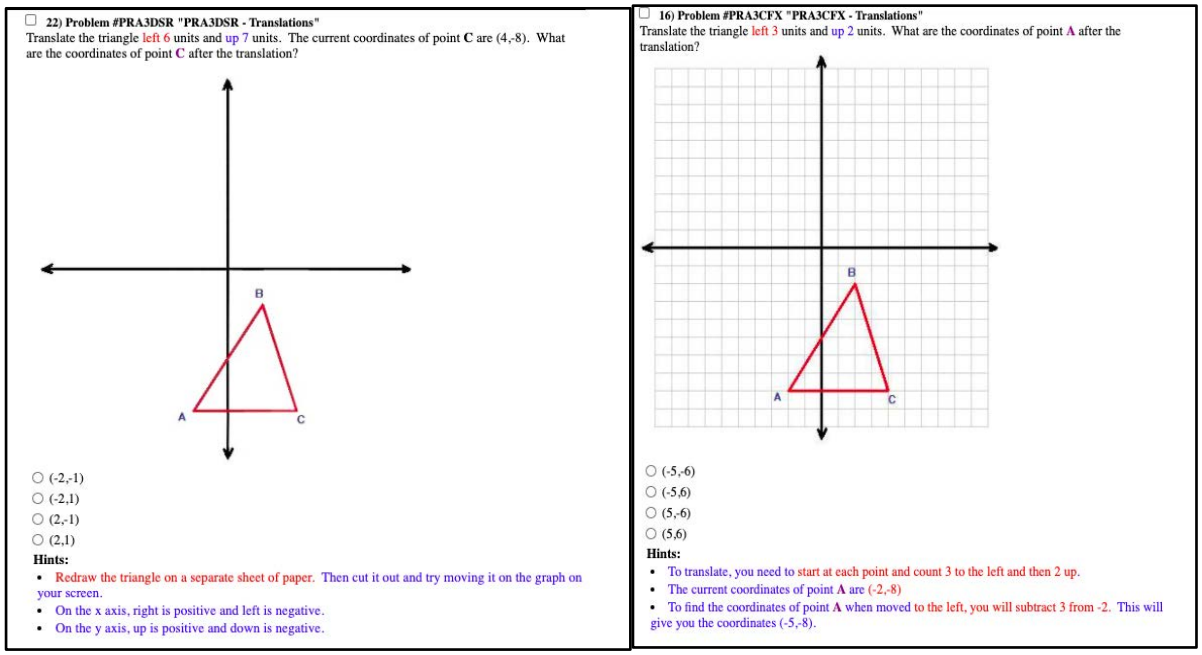


Within each skill builder, students were assigned to the visuospatial or analytic condition, differing in how problems were presented. The visuospatial condition presented the problems in a coordinate grid system without gridlines and with starting coordinates (Figure 2 left). The analytic condition presented the problems in coordinate grids with gridlines but without starting coordinates, which could easily be inferred by counting squares (Figure 2 right). We used the following two measures: (1) mental rotation score: how many questions a student answered correctly out of the 4 questions; 2) mastery speed: how many problems it took a student to complete the skill builder (e.g., answer 3 problems correctly in a row). A lower mastery speed indicates they mastered the problem set in fewer attempts.

 © ISLS

Figure 2.

An example of a translation problem and hints in the visuospatial (left) and analytic (right) condition

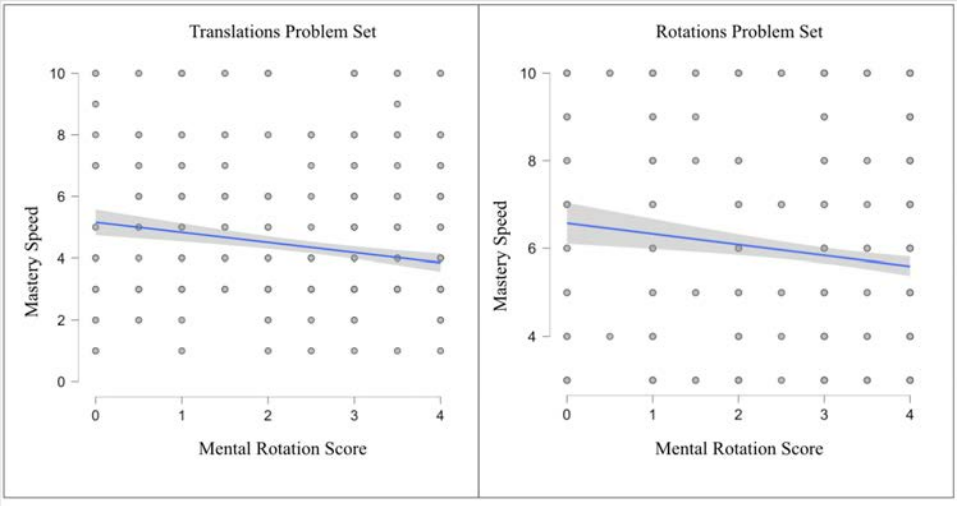


Results

For our first research question, we ran two linear regressions predicting mastery speed based on mental rotation score. Within both problem sets, we found that mental rotation score significantly predicted mastery speed; translations, $F(1, 397) = 28.91$, $p<.01$, $R^2 = .068$; rotations, $F(1, 941), = 11.60$, $p<.01$, $R^2 = .012$. A higher mental rotation score led to a lower mastery score (Figure 1), meaning that participants who performed better on mental rotation mastered the problem set in fewer attempts.

Figure 1.

Mastery speed based on mental rotation score for the translations and rotations problem sets



For our second research question, we ran two independent samples t-tests comparing mastery speed between the analytic and visuospatial conditions for each problem set. For both problem sets, there were no significant differences between conditions; translations, $t(1,396) = 1.28$, $p = .20$; rotations, $t(1,940) = .27$, $p = .79$. Students in both conditions and across problem sets had similar mastery speeds (Table 1).

 © ISLS

For our third research question, we ran two linear regressions predicting mastery speed based on condition and mental rotation score. Within both problem sets the condition X mental rotation score interaction was not significant, *ps* >.05. However, mental rotation score remained a significant predictor of mastery speed across both problem sets.

Discussion

The results replicate the effect that spatial reasoning skills have on math performance. We found that higher mental rotation scores predicted assignment mastery speed among both problem sets in Geometry. Importantly, this association held across both conditions (spatial and analytic), indicating that problem presentation does not impact the effect of mental rotation skill on geometric problem solving. It is also important that mental rotation scores predict performance not only on the rotation problem set but also on translation problems, as this suggests some transfer or domain generality of spatial skills. In addition, we were able to extend prior research into an online environment, suggesting that spatial skills still matter while learning geometry online.

While we hypothesized that spatial skills may be more or less helpful depending on how a problem is presented, we were unable to find differences in performance based on problem presentation. While we found no differences in performance, there may have been strategy differences we were not able to detect with our measures. It is also possible that our specific problem presentations did not sufficiently direct students toward one strategy over the other. Therefore, future studies should look into the specific strategies students employed while solving these problems and possibly iterate on aspects of problem presentation to further support or constrain particular problem-solving approaches.

In conclusion, we showed that mental rotation skill predicted performance above and beyond problem presentation and that the effect of mental rotation skill is consistent across two types of geometry problem sets. This has important implications for math instruction, as it suggests that students' spatial skills are more important than problem presentation. This reaffirms the importance of engaging students in activities to build their spatial skills and suggests that math teachers' and curriculum designers' time and energy might be better spent designing those sorts of spatial skill-building activities than on designing problems in specific ways to elicit spatial versus analytic strategies.

Promoting Cognitive Strategies for Processing 360° Videos in History Learning Contexts

Selina Yek, Elena Lewers, Valentina Nachtigall, Christian Bunnenberg, Nikol Rummel
selina.yek@rub.de, elena.lewers@rub.de, valentina.nachtigall@rub.de,
christian.bunnenberg@rub.de, nikol.rummel@rub.de
Ruhr-University Bochum

Abstract: 360° videos can be characterized as immersive representations that may cause an illusion of reality. This illusion can be overwhelming or lead to a lack of distancing while processing the contents presented, which is exacerbated when learning with history-related 360° videos containing emotionally charged content. One way to counter these dangers could relate to the use of cognitive strategies. Cognitive strategies could help students to use a structured approach for processing the immersive and emotionalising videos and, thereby, to focus on aspects that are fundamental for reflective interaction with the content. Cognitive strategies can be promoted through self-regulated learning (SRL) trainings. Thus, the present study investigates whether a SRL training can promote school students´ acquisition of cognitive strategies for processing history-related 360° videos. The results of our quasi-experimental study ($N = 164$) suggest positive effects of the training on both students' use of and knowledge about cognitive strategies.

Introduction

In recent years, 360° videos have been developed to intensify learning processes in history learning contexts. These videos can be characterized as immersive representations that may cause an illusion of reality (Cummings & Bailenson, 2015). This illusion of reality might be particularly problematic in history learning contexts. Specifically, history-related 360° videos may not only create immersion, but are also often characterized by highly emotional content. This emotionalized and immersive presentation of the content could overwhelm the recipients or lead to a lack of distancing, whereby they may not realize that the content shown in the video is only a representation of the past (Bunnenberg, 2020; Brauer, 2019). Thus, the impression of actually experiencing history could hinder a cognitive and critical engagement with what is being presented. Consequently, watching immersive videos with emotionally charged content in history learning contexts requires recipients to critically analyse the contents presented (Gautschi, 2015). Therefore, in history classes, students need to be supported in applying dedicated methods for analysing the videos, for instance, by using cognitive strategies.

Cognitive strategies refer to learning techniques for taking up, identifying, classifying, memorising, elaborating as well as critically examining and storing information (e.g., Schiefele & Wild, 1994). If students learn to use cognitive learning strategies adequately, they can use a structured approach for processing the immersive and emotionalising history-related 360° videos and, thereby, focus on aspects that are fundamental for reflective interaction with the video content. In research on history education, it is also assumed that activities, such as summarizing, elaborating and contextualizing the learning content, aid students' reflective and critical processing of history-related content. While these activities are denoted as competences or skills in research on history education (e.g., Gautschi, 2015), they are conceptualized as cognitive strategies in research on self-regulated learning (SRL). SRL research on how to be acquire such strategies has revealed that students need to *know* how and why to use them, and they need to be able to *apply* them (e.g., Wischgoll, 2016). Moreover, we can learn from SRL research that both cognitive and metacognitive processes should be trained together (e.g., Dignath & Büttner, 2008; Stebner et al., 2015).

SRL trainings may be a promising way to promote the cognitive as well as metacognitive strategies required when learning with 360° videos in history education. However, while ample research has investigated the effects of SRL trainings in the context of the *natural sciences* (e.g. Stebner et al., 2015), there are barely any studies on such trainings in history education and, more specifically, for learning with history-related 360° videos. To the best of our knowledge, only one study has investigated self-regulated learning in museum sites (Dold, 2020), but this study did not focus on learners' processing of immersive and emotionalising 360° videos.

Against this background, the present study aims to investigate the effect of a SRL training on students' knowledge about and use of cognitive strategies when examining history-related 360° videos. Building on relevant characteristics of SRL trainings uncovered by previous research (e.g., Stebner et al., 2015), we developed a SRL training that combined cognitive and metacognitive strategies. To examine the effects of our training, we conducted a quasi-experimental study comparing two conditions: *explicit SRL training* (experimental condition)

 © ISLS

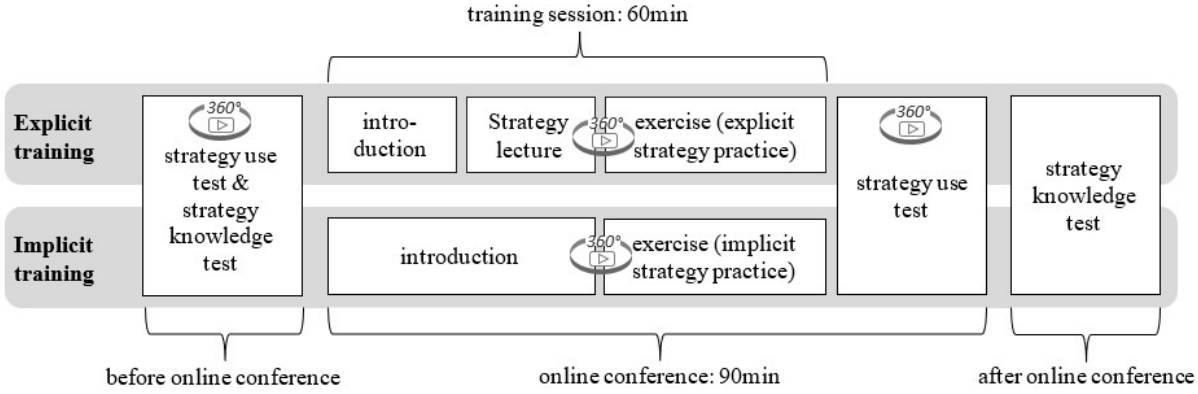
with explicit instruction on the functionality of cognitive and metacognitive strategies and explicit guidance on using these strategies for analysing history-related 360° videos, and *implicit SRL training* (control condition) without instruction on the names and functionality of cognitive and metacognitive strategies and implicit guidance on the use of cognitive strategies for analysing history-related 360° videos. In the analyses presented here, we focus on examining the effect of our SRL training on students' use of and knowledge about *cognitive* strategies. We hypothesize that students who receive an explicit SRL training will – in contrast to students who receive an implicit SRL training – improve their *use of* cognitive strategies (H1a) and their *knowledge about* these strategies (H2a) when examining a history-related 360° video. Consequently, we further hypothesize that – after the training – students of the explicit training condition will use (H1b) and mention (H2b) more cognitive strategies for analysing a history-related 360° video than students of the implicit training condition.

Method

Design and Sample

164 9th to 13th graders (52% female) from 10 classes of 10 German secondary schools participated in our study that took place in the form of an online video conference due to the pandemic situation. The 10 classes were randomly assigned to either the explicit training condition (n = 70) or the implicit training condition (n = 94). Figure 1 depicts the procedure of the present study.

Figure 1
Procedure in both conditions



In the *explicit training condition*, students first received a brief introduction to historical terms and then participated in a strategy training that is based on a SRL training from previous research (see Stebner et al., 2015) and includes a strategy lecture and an explicit strategy exercise. During the strategy lecture, the supervisors discussed the definition and usefulness of the following five strategies in history-learning contexts with the participating students: (1) summarize content, (2) check medium, (3) check perspective, (4) check mood and (5) formulate conclusions. Afterwards, the participating students practised to analyse 360° videos with the help of the supervisors. This exercise explicitly included guidance on the use of cognitive strategies. In the *implicit training condition*, students received a more detailed introduction to historical terms than students in the explicit training condition. Afterwards, in contrast to the students of the explicit training condition, the students of the implicit training condition did not receive explicit instruction on cognitive and metacognitive strategies (i.e., no strategy lecture) and only indirectly practised to analyse 360° videos with the help of cognitive and metacognitive strategies. Specifically, the supervisors did neither explicitly name the cognitive and metacognitive strategies nor explain their functionality during the exercise.

In addition to the 360° video that students watched and analysed during the exercise, all participants watched – as part of the strategy use tests – a 360° video before and after the training session (see Figure 1). We administered a strategy use test as well as a strategy knowledge test before and after the training session in order to assess the number of cognitive strategies used when analysing a 360° video (strategy use test) as well as the number of cognitive strategies mentioned when explaining how to analyse 360° videos in general (strategy knowledge test) as our dependent variables.

Measures

The strategy test is based on the multi-strategy test by Stebner et al. (2015) and measures spontaneous recall as well as the intended use of cognitive and metacognitive strategies. In our study, we adapted the test to the history-related context and divided it into two parts: The strategy use test measured the *use* of cognitive strategies by asking the participants to watch a 360° video and to examine its presentation of the past. The strategy knowledge test measured the *knowledge* about the cognitive strategies (indicated by students' mentioning of the cognitive strategies) when examining a 360° video in general. The instructions in the strategy use test differed slightly depending on the video content between pre- and posttest, but included the same type of task. In the pretest, we used the video "A VR journey to the Middle Ages". In the posttest, we used the video "What did they [member of the German State Security Service] want in Berlin?!". The videos are available on YouTube.

We coded the student answers in the strategy tests by using a system of categories that builds on the definition of historical deconstruction competence (Gautschi, 2015), elements of film analytics (Kühberger, 2013) and processes of self-regulated learning (e.g., Schiefele & Wild, 1994). For example, *applying* the strategy *check the medium* in the strategy use test was defined as describing the medium and its influence on the representation (example of a respective student answer: "The whole situation is presented as a 360° video, which means that the viewer can look around and has an all-round view during the event."). In the strategy knowledge test, *check the medium* was defined as mentioning that the medium and its influence on the representation have to be taken into account when analysing 360° videos in general (example of a respective student answer: "It´s very important to look at the video critically and to recognise interpretations. With these videos it´s very important to get an all-round view of the situation and also to pay close attention to the sounds."). We coded the answers in a binary way. Thus, we only coded whether one of the strategies occurred (1) or not (0), and did not analyse the frequencies of the occurrences of the individual strategies within a student answer. Two independent raters coded 30% of the pretest and posttest datasets and reached, on average, a satisfying agreement ($\kappa = 99{,}88$). To test our hypotheses, we calculated the sum of the coded strategies, leading to a total number of 0 to 5 strategies that students could use or mention in the strategy tests.

Results

To test H1a and H2a, we investigate the pre-post differences within each of the two conditions by conducting Wilcoxon tests. To test H1b and H2b, we compare students' use of and knowledge about cognitive strategies after the training between the two conditions by conducting Mann-Whitney U tests.

Prior to the interventions, students' performance in the two pretests did not significantly differ between the two conditions, neither with respect to the total number of applied strategies in the strategy *use* pretest (explicit training condition: $M = 0.91$, $SD = .93$; implicit training condition: $M = 0.93$, $SD = .79$) nor with regard to the total number of strategies mentioned in the strategy *knowledge* pretest (explicit training condition: $M = 0.36$, $SD = .61$; implicit training condition: $M = 0.27$, $SD = .56$).

With respect to our H1a, the results of the Wilcoxon test show a significant pre-post difference in the total number of strategies *applied* by students of the explicit training condition ($n = 44$, $r = .56$, $p < .001$, M(pretest) = 0.89, M(posttest) = 1.73) and, as expected, no significant pre-post difference in the implicit training condition ($n = 50$, $r = .25$, $p = .07$, M(pretest) = 0.98, M(posttest) = 1.28). Thus, in line with our H1a, while students of the explicit training condition improved their use of cognitive strategies for analysing a history-related 360° video by the end of the study, students of the implicit training condition did not improve their use of these strategies. Consequently, in line with our H1b, the results of the Mann-Whitney U test show a significant difference ($U = 2092.00$, $Z = -2.70$, $r = .22$ $p = .007$) in the number of used cognitive strategies between the students of the explicit training condition ($n = 66$, $M = 1.62$, $SD = 1.21$) and their counterparts of the implicit training condition ($n = 83$, $M = 1.07$, $SD = .85$). Thus, students who received the explicit SRL training used significantly more strategies for analysing 360° videos than students who received the implicit training.

With regard to our H2a, the results of a Wilcoxon test show a significant and large-sized pre-post difference in the number of *mentioned* cognitive strategies in the explicit training condition ($n = 26$, $r = .75$, $p < .001$, M(pretest) = 0.42, M(posttest) = 2.42), but also a significant and medium-sized pre-post difference in the implicit training condition ($n = 30$, $r = .69$, $p = .000$, M(pretest) = 0.37, M(posttest) = 1,63). Thus, against our H2a, students in both conditions increased their knowledge about cognitive strategies by the end of our study. However, looking at the differences in participants´ knowledge about cognitive strategies between the two conditions (H2b), the results of the Mann-Whitney U test show a significant and small effect of condition ($U = 543.50$, $Z = -2.26$, $r = .25$, $p = .024$) on the total number of mentioned cognitive strategies after the training. Thus, in line with our H2b, students who received the explicit SRL training ($n = 32$, $M = 2.28$, $SD = 1.75$) mentioned significantly more cognitive strategies than students who received implicit training ($n = 48$, $M = 1.4$, $SD = 1.44$).

Discussion and conclusion

The present study investigated the effects of an explicit SRL training on the knowledge about and use of cognitive strategies when watching 360° videos with history-related content.

We found that students who participated in the explicit SRL training used (H1a) and mentioned (H2a) a higher number of cognitive strategies in the posttest than in the pretest. However, against our hypothesis, students in the implicit training condition also improved their *knowledge* about (but not their *use* of) cognitive strategies. This finding may be due to the fact that, at the time of the pretest, students did not exactly know what they were supposed to do in the task. During the intervention, however, students in both conditions got at least an impression that the examination of 360° videos requires some kind of analysis. Consequently, students with implicit SRL training might have activated relevant prior knowledge they had previously gained by performing similar tasks (e.g., film or text analysis) in school. Nevertheless, students of the implicit training condition were seemingly unable to transfer this knowledge to their actual video analysis, as they did not *use* these strategies for analysing the history-related 360° video. However, although students of both conditions improved their knowledge about cognitive strategies by the end of the study, our further results suggest that students of the explicit training condition acquired more cognitive strategies than students of the implicit training condition. This finding is supported by both the total number of strategies that students used in the strategy use posttest (H1b) as well as the total number of strategies that students mentioned in the strategy knowledge posttest (H2b). This finding is particularly interesting in light of the fact that we designed the training in a greatly reduced form due to the pandemic situation. The duration of an intervention can be crucial for its effect on learning outcomes, or in other words, the effectiveness of an intervention can be affected by the number of training sessions and the number of months one participates in it (Dignath & Büttner, 2008). But as our study indicates, a 60-minute training can already evoke beneficial effects on especially the use of cognitive strategies. Future research on SRL in history education could build on this finding, for example, by providing students with multiple lessons in a history learning project in which students practice the use of strategies for examining different forms of presentations of the past.

To conclude, our results are in line with previous studies on the effectiveness of SRL trainings (e.g., Stebner et al., 2015, Dignath & Büttner, 2008), and may provide a new impulse for empirical history education research on learning with 360° and virtual reality media. Moreover, our study demonstrates the potential of interdisciplinary research in this area, as we attempted to build a bridge between history education with its mainly theoretical approaches on how to teach historical competences on the one hand and empirical research in educational science with well-researched approaches for promoting cognitive strategies on the other hand.

Abstract: Co-design has become an important resource in supporting instructional reform in science education. Various studies of teacher learning in co-design have focused on the outcomes of this work, including teacher content learning and use of co-designed resources in their practice. In this study, we focus on how the co-design process created opportunities for teachers to develop their interpretive power of students' STEM learning to identify varied forms of participation and learning in STEM activities through the co-design of an afterschool STEM program. We found that observations of students engaged in out-of-school STEM activity supported teachers to view STEM learning in varied ways and that the organization of students' activity mattered for what they paid attention to in relation to student learning.

Introduction

Science teacher co-design has emerged as an important tool in support of science instructional reform (Penuel, Roschelle, & Shechtman, 2007). In this work, science teachers engage with researchers to design instructional resources that align to science reform and take into consideration the localized expertise of science teachers. Research on science teacher co-design has demonstrated a variety of learning outcomes of the co-design process, including teachers' greater use of resources they have designed alongside researchers (Furtak & Heredia, 2014), supporting teachers' engagement in reflection of their instructional practice (Matuk, 2016), and a focus on teacher learning of content knowledge for teaching (Kelter et al., 2021). In this paper, we seek to understand how the co-design process supported science teachers to identify multiple forms of student learning in STEM activity. To do so, we explore the initial phases of the co-design process as science teachers work to design an afterschool STEM program for their schools as part of a larger STEM ecosystem (National Research Council, 2015). In what follows, we introduce the design problem related to teacher recognition of various forms of student learning in STEM environments and a conceptual framework used to organize the co-design process.

Design Problem

In this project, science teachers were supported to co-design a STEM afterschool program organized as part of a STEM ecosystem designed to support students to develop varied STEM identities and interests. However, fostering variety in students' STEM identities is not necessarily a key feature of formal classroom instruction (Tan et al., 2013). Rather, science teachers tend to focus on standardized curricula, geared toward local and state-level accountability measures, including high stakes testing contexts (Settlage & Meadows, 2002). Such curricula generally offer a narrow conception of learning in science that emphasize evaluating student learning of discrete facts and vocabulary (Otero & Nathan, 2008), rather than the myriad ways students can demonstrate growth and learning in science, such as increasingly sophisticated forms of participation in science practices over time (Rogoff, 2003). Therefore, science teachers need opportunities to build their interpretive power to learn to recognize the varied ways that students make sense of science content and phenomena to support multiple pathways to develop interest and identities in STEM (Roseberry et al., 2016).

Conceptual Framework

Guiding our work is the recognition that when teachers engage in learning of new practices, they do so as actors in complex organizations, enmeshed in their day-to-day work practices (Spillane & Hopkins, 2013). Therefore, we leverage constructs from organizational sensemaking (Weick, 1995) to guide our approach to co-design. Organizational sensemaking is the process by which individuals interpret changes to their work environment and make decisions about how and what to change in their work practices (Weick, 1995). Teachers' sensemaking can be supported through intentional opportunities for them to see what's new or different about a

 © ISLS

reform instruction, and then have access to resources that support their design and implementation that make the integration of new practices feasible, given their local expectations (Allen & Heredia, 2021).

In this study, we anticipated that science teachers' interpretive power in student activity aligns with accountability systems and that they would privilege students' correct use of science vocabulary in science activity, which would cause some ambiguity when observing student learning in out-of-school settings that work to develop a variety of ways students can engage with science. Therefore, we intentionally designed their learning activities to surface this ambiguity through observations of students engaged in out-of-school science activity. Then we provided opportunities for teachers to make sense of students' learning and to recognize the ways in which science learning can be organized to support varied pathways in STEM.

Methods

We used a design-based approach (Barab & Squire, 2004) to develop and study our work with teachers in co-design. Here, we focus on early phases of this co-design process and explore how anticipated sources of ambiguity about student learning surfaced and how designed activities in the professional development triggered science teachers' sensemaking about student STEM learning beyond conceptual understanding.

Participants and professional development context

Participants included six middle school teachers from three schools who worked in teams (two teachers were each from the same school). The teachers ranged in teaching experience from 4 - 27 years in the classroom. They were all certified science teachers and have degrees either in science or elementary education.

The teachers chaperoned students from their school to the university for an out-of-school STEM program called Saturday Stormwater Investigations (SSI). The SSI program engaged students in STEM activities that were designed to support them to understand local problems related to stormwater and how to use best management practices to solve these problems. While students participated in the SSI program, the teachers engaged in professional development learning in parallel with their students. The primary focus of the professional development was to support science teachers to design and implement an afterschool program that extended students' engagement in the campus-based SSI program. In the professional development, the teachers learned about the design of the SSI as a pedagogical model for their afterschool STEM clubs. Professional development activities included applying the pedagogical framework to the designed activities for the SSI, observing students as they engaged in the activities (facilitated by university staff and faculty) and then reflecting on their observations.

Data sources

Each of the six teachers participated in a total of 45 hours of professional development over the course of three years. We collected video and audio recordings of the professional development meetings with teachers. Here, we focus on data from the first year of the professional development when teachers participated in a total of 20 hours of professional development. Additionally, we interviewed teachers prior to the start of the project and again after their first year in the program. The initial interview asked teachers to describe their educational background, their teaching practices, and experience with afterschool programs. The second interview happened over the summer to support teacher reflection of their learning, as well as to provide feedback to the research team about student programming.

Data analysis

We sampled conversations from the professional development meetings that asked teachers to debrief and reflect on their observations of students' activities during the SSIs (Table 1). We transcribed these conversations and coded teacher utterances according to the nature of student activity they noticed and discussed with the group. Codes included teacher discussion of student conceptual understanding of science (right/wrong, conceptual sensemaking, scientific language), student's social and emotional learning, students' cultural resources (asset-based and deficit-based), and student identity work. We coded each transcript independently and discussed how we applied codes, refining, and adjudicating differences in our discussions. We wrote short research memos about the nature of the teacher post-observation conversations. We similarly coded and wrote memos for teacher interview responses to questions about student learning in the SSIs. Finally, we organized these memos into a time-ordered matrix (Miles & Huberman, ?) to look for changes over time.

Table 1
SSI activities observed and discussed by the teachers

Date	SSI activity observed
Meeting 1	Students walked to a wetlands on campus and they looked for aspects of stormwater management. At the wetlands, they were given a variety of science tools to explore the living and non-living aspects of the wetland environment.
Meeting 2A	Students traveled with their teachers on buses to the university for the SSI program.
Meeting 2B	Students self-selected into different activities: science activity - monitoring biotic and abiotic indicators of water health at the wetlands, engineering activity - exploring permeable pavement, and technology - exploring various tech tools for advocacy.

Findings

The data revealed shifts in the ways in which teachers recognized and noticed different aspects of students' science learning in the out-of-school setting as compared to their descriptions of student science learning in their classrooms. In initial interviews, teachers highlighted the importance of school growth data to inform if and how their students were learning science. While they initially focused on the use of science vocabulary in student activity during the SSIs, they also noticed other aspects of students' learning, including student affect during the activity, their collaboration and interaction with students from other schools, and student science identity work.

Not surprisingly, all six teachers focused on students' conceptual understanding of science as a measure of growth at the on-set of the study. In their pre-interviews, they discussed a variety of methods and tools to assess student learning in science, including quizzes, technology, end of year state assessments and benchmarks, and students' explanations of science content. For example, one teacher described how he makes teaching decisions based on students' scores on assessments: "I then also analyze my data ... really the best place to get it is that test, and I can look at the tests I give them or the quizzes I give them, because I use Schoolnet, and I get instant data." Each of the teachers focused on data related to content understanding, with some attention to students' behavior and general engagement.

During the first year of professional development, the teachers had multiple opportunities to share their observations of student activity in the SSI. The focus of those conversations related to students' engagement with the activity and with each other and their science content learning. The teachers made connections to their observations of students in their classroom or at the school and their modes of participation in the SSI activities. For example, after observing students engaged in a creek and wetland exploration on the first day of the SSI, one teacher noted, "And not knowing how they were going to interact and be so happy about...the different interactions you saw between your own students that you didn't expect and then how they also interacted with others. It was really good, really good reinforcement." The teachers also recognized the lack of access that their students have to this kind of science activity and were excited they had an opportunity to explore a creek in a disciplinary way.

While they did recognize other forms of learning, they also paid attention to the ways in which students were developing science conceptual understanding. For example, in a debriefing conversation after teachers observed students in breakout activities in computing, science, or engineering, the teachers focused more on students' conceptual understanding as they engaged in the activities and expressed frustration at the lack of science vocabulary. One teacher noted that the students described the concept of permeability and talked about it, but never named it. "They didn't directly make the connection immediately, so when the kids- she was asking them about what did you see, about the different materials they were using. They were giving all of the words that are permeability, but no one said it until later." Here he was focused on their conceptual understanding that was being developed during the activity and expressed frustration that the students did not use scientific vocabulary in their explanations.

During their interviews following the SSIs, teachers mentioned that in the SSI program, students learned science, but also how to communicate and interact with different people and about the college campus. One teacher talked about how youth gained sensitivity and an awareness of the environment around them and they learned to use science to solve problems. When asked about what they noticed during student activity in the SSI program they talked about students' interactions with one another, the conversations they were having and the questions they were asking, and the connections they were making between the content and the real world. The shift evident in their interviews suggests that the teachers' experiences observing students in the SSI supported them to move beyond simply did my students get the science content to recognizing other forms of learning, such as developing identities to care for the environment and their interactions with other students.

Discussion

This study presents an initial analysis into the ways in which observations of student activity in out-of-school science settings can support in-service teachers to build their interpretive power to see varied forms of student learning in STEM activity. We found that teachers identified students' content learning in the SSIs, but they also paid attention to how students interacted and collaborated with other students, how the activity supported (or not) students' STEM identity development, and student affect as they engaged in SSI activities. Similar to research on pre-service teacher learning in informal settings (Jurow et al., 2012), we found that observations of students in the informal setting are productive sites for learning for in-service teachers as well. Next steps would be to collect data on science teachers' classroom practices after participating in the professional development to see if and how they are applying these varied views of student science learning in their classrooms. This study provides evidence that science teachers have the capacity to see other forms of learning. However, our understanding of the role of context suggests that it's possible that teachers may not apply different lenses for recognizing student science learning in their classrooms given the organizational focus on content learning.

Artificial Intelligence (AI) in Education: Addressing Societal and Ethical Challenges in K-12 Settings

Selin Akgun, Michigan State University, akgunsel@msu.edu
Christine Greenhow, Michigan State University, greenhow@msu.edu

Abstract: Artificial intelligence (AI) incorporates the applications of algorithms, machine learning, and natural language processing within automated assessment and facial recognition systems, personalized learning tools and microblogging systems. These AI applications have the potential to increase capacity within education by supporting the social and cognitive development of students. Despite these affordances, AI applications pose critical ethical and societal drawbacks which are rarely considered in K-12 education. Integration of these algorithms in education may amplify societies' existing systemic biases and discrimination, perpetuate privacy, autonomy, and surveillance concerns for students from marginalized and underserved groups. In this paper, we interrogate applications of AI in K-12 education, highlighting their ethical risks. We introduce instructional resources to help educators navigate the challenges of integrating AI and advance students' understanding of AI and ethics. The paper concludes with recommendations for research.

Keywords: artificial intelligence (AI) in education; AI and ethics; teacher education

Introduction and purpose

Artificial intelligence (AI) and its applications have become an inseparable part of our lives as we perform Google searches, read articles and emails, or join online tutorials and courses (Iman et.al., 2020; Regan & Jesse, 2019). During the COVID-19 pandemic, AI systems became even more important to everyday functioning; it is now nearly impossible to live in a modern society without using the applications powered by AI (Iman et.al., 2020). AI leads the fields of science, engineering, and technology, but also is actively present in education through machine-learning systems and algorithms (Ali et. al., 2019). AI has a variety of algorithmic applications in education, such as through automated assessment systems to lessen teachers' workload and support them in evaluating what students know; facial recognition systems to bring insights about student behaviors; and personalized learning systems to cultivate students' learning experiences (Remian, 2019). Algorithm systems are also dominant in education through various social network sites and social media outlets, especially within mobile applications and microblogging systems. Therefore, AI applications have the potential to increase capacity within education by leveraging the cognitive and social development of students (Murphy, 2019).

Despite this promise, these applications also pose critical societal and ethical drawbacks in education. In essence, AI algorithms do not occur in a vacuum; rather, they shape and are shaped by society's ever-evolving historical and institutionalized systemic biases, which ultimately transform into algorithmic bias (O'Neil, 2016). The biggest risks of integrating these algorithms in education (particularly in K-12 contexts) are: (a) amplifying societies' existing systemic bias and discrimination, (b) perpetuating privacy, surveillance, and autonomy concerns for students from mostly marginalized and disadvantaged groups, and (c) amplifying exiting gender bias, racism, xenophobia, and other forms of inequity and injustices (McMurtrie, 2018). As Ruha Benjamin's (2019, p.15) points out that: "New technologies reflect and reproduce existing inequities, but they are promoted and perceived as more objective or progressive than the discriminatory systems of previous era."

Considering these pressing concerns, we argue that it is our responsibility (as learning scientists, educators, and teacher educators) to educate teachers and students to recognize, critique and challenge the ethical and societal implications of algorithm use in education. To create a future generation where an inclusive and diverse citizenry can participate in the development of the future of AI, we need to study and develop AI- and ethics-based curricula and professional development opportunities for teachers and K-12 students as they engage with AI and apply a critical perspective (Akgun & Greenhow, 2021).

Toward this end, in this paper, we synthesize existing literature on how applications and ethical dimensions of AI takes place in K-12 education. We first unpack the definition, benefits, and drawbacks of AI applications. Then, we provide strategies for practitioners to reap the benefits while navigating the ethical challenges of AI use in K-12 settings. Toward this end, we introduce different instructional and pedagogical resources, such as MIT Media Lab's "*AI and Ethics*" curriculum for elementary schools (Payne, 2019) and Code.org's "AI for ocean" investigation for elementary and high schools. We conclude with suggested directions for learning scientists seeking to build on such resources in future design studies.

 © ISLS

Applications and benefits of AI in K-12 settings

Considering its capacity and affordances in fields of science, engineering, and education, we define AI as a form of technology that constructs systems to think and act like humans with the capability of solving problems and achieving goals (Iman et. al., 2020; Remian, 2019). Powered by algorithms and machine learning systems, AI takes place in education in the forms of a) personalized learning systems, b) facial recognition systems and predictive analytics, c) automated assessment systems and d) social networking sites and chatbots.

More specifically, ***personalized learning systems***, are one of the most common applications of AI in supporting students during their individual learning process. These systems provide students with access to various learning resources by considering each students' individual learning needs and based on specific subject area goals (McMurtrie, 2018). For example, rather than engaging in ideas and solving problems in physics on a worksheet or reading a textbook, students can use an interactive, multimedia space to help them progress toward learning objectives in their subject matter (McMurtrie, 2018). Microsoft's recent report (2018) from Singapore, the U.K., the U.S., and Canada shows that such personalized learning platforms promise to identify gaps in students' prior knowledge by offering different learning tools to promote students' growth. With the drastic shift to online education during the COVID-19 pandemic, personalized learning systems have become one of the promising distance learning options for students (Remian, 2019). Second, ***facial recognition systems*** are used to monitor and capture students' facial expressions. These systems aid teachers in recognizing and evaluating students' behaviors during the learning process. They also provide teachers with a space to intervene, which, in turn, can support teachers in developing student-centered classroom environments by increasing students' participation and engagement (Dishon, 2017).

Another prevalent tool powered by AI: ***automated assessment systems,*** can help meet the need for scoring students' exams, essays, and assignments, which are usually assessed by teachers. Assessment algorithms offer course management tools to decrease teachers' workload by increasing their productivity and capacity. For example, a scoring tool called "Gradescope" has been used by several universities to improve and streamline the assessment process (Blank et al., 2014). These systems have the potential to support students' learning process by giving them feedback and offering guidance to develop and revise their writing. Finally**, *social networking sites*** (SNSs) monitor students' well-being, provide space to deepen teacher-student relationships, and widen learning opportunities for students beyond the formal classroom setting (Asterhan & Rosenberg, 2015). Different scholars point out that the integration of social media can promote students' collaboration skills, active learning, and connections with their communities (Asterhan & Rosenberg, 2015; Akgun & Greenhow, 2021).

Ethical and societal risks of integrating AI applications in education

In addition to their affordances, AI systems pose serious ethical risks and challenges. In essence, the risks become visible as AI systems are introduced and marketed as value-neutral and objective tools. In contrast, algorithms carry the values of their builders who hold positions of power (Holstein & Doroudi, 2021). In the process of building algorithms, society's systemic and historical biases are represented within the codes, which ultimately transform into algorithmic bias. Even though the biased code is not integrated into the algorithmic model with an explicit intention, such representation can perpetuate existing racial and gender biases in different AI platforms (Benjamin, 2019). In the sections below, we focus on four major concerns in relation to privacy, autonomy, surveillance, and bias and discrimination (see Figure 1).

Figure 1. Ethical and Societal Challenges of AI applications in Education (Akgun & Greenhow, 2021)

 © ISLS

One main ethical issue raised in AI use in K-12 education relates to ***privacy*** concerns for teachers and students (Remian, 2019; Kang, 2021). As people expose an intensive amount of personal data (their language, location, biographical data, racial identity) in different online platforms, privacy violations can occur. Although legislation has been created to protect sensitive personal information, tech companies' violations (such as the privacy lawsuit aimed at Facebook (Kang, 2021)) with respect to security and data access, escalate concerns about privacy and human agency as independent and introspective individual thought is reduced (e.g., AI users may not realize the extent to which personal data is being shared) (McMurtrie, 2018). ***Surveillance*** is another notable ethical concern which relates to tracking preferences and actions of students and teachers. AI-based surveillance or tracking systems not only monitor activities but also determine the future actions of their users (Regan & Jesse, 2019). Patrolling and monitoring students' actions can be interpreted as part of a teacher's role and responsibility (e.g., to intervene in cases like exposure to sexual content or cyber-bullying). However, these systems may limit students' learning by making them feel uncomfortable and unsafe. How can students feel secure and safe to take ownership for their ideas when they realize the AI systems are policing and surveilling their actions and thoughts?

Connecting to these surveillance concerns, concerns about ***autonomy*** also stem from limiting and diminishing people's ability and freedom to act based on their own values and interests. For instance, predictive algorithms' predictions in relation to people's future actions based on their metadata raise serious questions about amplifying existing bias and prejudices of social stratification (Murphy, 2019). Finally, ***bias and discrimination*** concerns introduce another critical issue for AI ethics in K-12 education (Asterhan & Rosenberg, 2015). For instance, gender bias and gender-specific stereotypes become one of the visible forms of this problem. As just one example, when students in language learning courses use Google Translate, they see the Turkish equivalent of "S*he/he is a nurse*" translated into the feminine form, while the phrase of "*She/he is a doctor*" translated into the masculine form (Johnson, 2020). Racial bias against non-dominant groups is also present in voice-based assistants Murphy, 2019). Similarly, racial bias is present in facial recognition systems towards darker skinned people that has led to wrongful arrests (Murphy, 2019).

Teaching ethical and societal dimensions of AI in K-12 settings

The four major concerns above illustrate the need to introduce students and teachers to risks of AI use in K-12 education. To meet this need, nonprofits, and research groups (e.g., IBM's Educator's AI Classroom Kit, Google's Teachable Machine, and Machine Learning for Kids) have created open-access instructional resources related to AI and ethics. Next we highlight two such resources: the MIT Media Lab's *AI and Ethics* curriculum and Code.org's *AI and Oceans* activity.

The MIT Media Lab provides an open-access AI and ethics curriculum for the middle school level. Through lesson plans and activities, the curriculum aims to support students' in learning the terminology of AI systems and their ethical implications (Ali et al., 2019). The curriculum includes learning objectives, such as introducing students to basic components of AI (supervised machine, datasets, and algorithms) and helping them to figure out the process of creating bias in algorithms. For instance, through the "Algorithms as opinions" investigation, students consider algorithms as recipes. First, they write an algorithm to make their **"**best" jelly sandwich and peanut butter. In doing so, they raise the question of what it means to be **"**best." They see how their thoughts and definitions are reflected in their algorithms. Thus, students engage with the idea that algorithms can have various goals and motives. Following this investigation, students also build their own "Ethical matrix." They refer to their "best" jelly sandwich and peanut butter algorithms. They further discuss what counts as the "best" sandwich for themselves (most practical, healthy, delicious). Using the ethical matrix (chart), they identify different stakeholders (their parents, friends, teacher) who care about their jelly sandwich and peanut butter. In this way, stake-holders' opinions and values are also embedded into their algorithms. These investigations assist students and teachers in realizing a) the role and agency of different stakeholders in a society (or system), and b) how they can build their values and biases into the algorithms in the ethical matrix.

Another resource for practitioners is provided by Code.org, a nonprofit organization focused on increasing students' participation and involvement in computer science. Sponsored by tech companies like Microsoft and Google, Code.org aims to bring opportunities for students (grades 3-12) to learn about machine learning systems, algorithms, and algorithmic bias (Code.org, 2020). Through their online activity called "AI for oceans," students build their own machine learning models by exploring how to train, classify and model data**,** as well as how personal bias takes place in machine-learning systems. Students initially classify the objects as either "not fish" or "fish" to remove trash from the ocean and develop their data set by adding other sea creatures.

Creating such instructional and curricular resources are extremely crucial to support teachers and their students a) in negotiating the meaning and role of AI systems within the machine learning applications and b) in figuring out the potential risks, limits, and ethical risks of AI applications in education to reap the benefits and minimize the costs of AI use.

Conclusion and implications

In this paper, we emphasize four potential ethical and societal drawbacks of using AI applications in education. To highlight these risks, we focused on several instructional resources and strategies for practitioners who are seeking to incorporate AI applications and their ethical issues in K-12 settings. These instructional strategies might help students and teachers to reap the benefits of AI while criticizing and disrupting the ethical challenges related to privacy, autonomy, surveillance, and bias.

Existing research on how best to support practitioners in teaching AI and ethics is still in its infancy; it is critical to conduct future research on designing professional learning opportunities for teachers as well as on the integration of ethics-focused curriculum where AI is adopted in schools by centering culturally responsive and relevant pedagogies. In other words, centering students' funds of knowledge (Bang et. al., 2012) and family and community background are important to addressing the concerns of surveillance, privacy, autonomy, and bias within the AI systems. More specifically, further research is needed that focuses on questions of a) how existing AI curriculum materials and activities on AI and ethics are developed and taught and b) in what ways do professional learning sessions support teachers in coming to understand and teach the risks and benefits of using AI in K-12 classrooms are needed. In such collaborative research projects, students might have a space to voice their own contextual and cultural experiences while trying to critique and disrupt existing power structures (Ladson-Billings, 1995).

We believe that this work is essential for learning scientists and teacher educators to understand and build on existing instructional materials and resources with respect to AI and ethics. It would also contribute to the work of the Learning Science community by increasing awareness and action on the critical use of AI and algorithms to create more inclusive, fair, and equitable AI education in K-12 settings.

#WhiteRibbonAgainstDictatorship: Youth participation in Thailand's 2020-2021 political movement

Panarat Anamwathana, Thammasat University, panarat@tu.ac.th
Sawaros Thanapornsangsuth, Chulalongkorn University, United Nations University, Tokyo Institute of Technology, sawaros.t@chula.ac.th
Fuangarun Preededilok, Chulalongkorn University, fuangarun.p@chula.ac.th

Abstract: A large number of Thai high school students participated in pro-democracy protests on all levels: from organizing rallies to small symbolic actions such as wearing white ribbons during 2020-2021. We engaged 691 Thai students from diverse backgrounds to write a letter to a recipient on the other side of the political divide to examine this phenomenon. Participants were asked to reflect upon their hopes and fears for Thailand's political future and explain why their civic engagement is personally, socially, and politically important. Utilizing the ladder of youth participation and other succeeding frameworks in the field, we explored the high school students' perception of their youth participation: their aspirations, justification for their participation, and responses from the adults in their lives. We find that while the students have clear and well-articulated reasons for their participation, they are hindered and resisted by their parents or teachers who disagree with their political views.

Introduction

Current Thai youth (aged 12-18) have grown up in this political change and polarization. Resentment towards the junta government had been brewing for almost a decade. This dissatisfaction exploded in protests, many at university campuses ('Student Flash Protests,' 2020). Student-led protests revived not only at the university but also at the high-school and middle-school levels. These students expressed their solidarity with anti-government protests creatively, such as wearing white ribbons and raising the three-finger "Hunger Games" salute during the national anthem (Wongcha-um, 2020). A hashtag that translates as #WhiteRibbonAgainstDictatorship was used nearly 1 million times on Twitter in August 2020 (In Pictures:'Thai Students "Hunger Games" Protests,' 2020). The situation escalated after a mass rally on October 14, 2020, when the government declared a state of emergency in Bangkok. A series of warrants and arrests of student leaders inflamed youth anger and pushed high-school students to be more politically active ('The names of 15 student protest leaders', 2020).

While the United Nations (UN) has fully recognized young people's right to freedom of expression in the 1991 Convention on the Rights of the Child and scholars have developed theoretical models for youth participation, there is a paucity of research that focuses on Thailand and its current political insurgency. This study examines youth participation in Thailand and embeds their experience within the conceptual framework of youth participation and the broader scholarship on youth and politics in Asia. We assigned a non-graded homework called "A Letter to Bridge the Divide" to approximately 700 high school students representing Bangkok and three regions in Thailand. These students were asked to write letters to friends, teachers, or adults with different political views. We have worded the assignment's prompt so that those who disagree with the protests can also write to fellow students to explain their views. Participants' students will reflect upon their hopes and fears for Thailand's political future and the reason why the movement is vital to them. These key experiences may involve but are not limited to past and current political turmoil, social inequality, generational gaps, and students' future aspirations.

Literature Review

Youth Participation

Checkoway (2011) defines youth participation as a process of involving young people in the institutions and decisions that affect their lives. It requires active engagement and the real influence of young people, not a passive presence or a token role under adult agencies. This study utilizes Hart's (1992) "Ladder of Participation" framework to determine how much adults in Thai society engage with young people, classifying participation hierarchically across eight levels using each rung of a ladder as a representation. Hart (2008) later emphasized that framework is about the degree to which adults and institutions enable children to participate (p.23). Thus, the ladder portrays different degrees to which children are allowed, enabled, and supported (often by adults) to initiate civic actions and make decisions in carrying them out with others. In addition to Hart's original ladder, we also utilize Reddy and Ratna's (2002) work which extends Hart's ladder framework beyond the "Model of Non-participation'. They suggest two additional bottom rungs of non-participation to Hart's model: "Hindrance" when

 © ISLS

adults intentionally or unintentionally undermine children and discourage them from participating, and "active resistance," in which adults actively work against children's participation. The reasons for active resistance resonate with Checkoway and Richards-Schuster's (2006) argument that young people are too often displaced and disengaged from the process by adults, even in their schools and communities, because adults may feel that young people should not be involved in decision-making processes because they cannot do so. "It is difficult when adults view young people as deficits rather than resources or show 'adultism' which flows from the assumption that adults are better than young people, and entitled to act upon them without their agreement because of their age" (Checkoway, 2011, p. 342). Adultism can lead young people to question adults' legitimacy and suppression. Moreover, viewing young people through a deficit lens can stifle their potential to change.

Thailand 2020-2021 Youth Participation

Much research remains to be conducted on Thailand's 2020-2021 youth participation in politics. McCargo (2021) has conducted one of the first scholarly surveys on the current wave of youth participation. More in-depth studies by Sinpeng (2021) and Lertchoosakul (2021) shed light on different aspects of the movement. Sinpeng (2021) analyzes the use of Twitter in the current political movement. She argues that social media is mainly used to air grievances and categorizes the tweets into six topics: democracy, youth rights, education, government opposition, the economy, and the Thai Monarchy. On the other hand, Lertchoosakul (2021) interviews university and high school students at protest sites. She finds that dissatisfaction with the authoritative and conservative education systems, corruption, and inequality in Thai society are the main reasons driving the protests. Lertchoosakul (2021) also emphasizes that Thai youth participation is motivated by grievances against political institutions, particularly the monarchy. Our study extends previous scholarship by engaging Thai students at schools--not the protest sites nor Twitter, whose opinions may not represent all students. It highlights Thai high school students' political participation and embeds this experience within the conceptual framework of youth participation and the broader scholarship on youth and politics in Asia.

Methodology

This study was a qualitative research project. We reached out to six teachers from six different public schools in various parts of Thailand, who agreed to participate in the study and assigned "A Letter to Bridge the Divide" as non-graded homework to their high school students. The assignment asked participating students to write a letter to teachers, parents, adults, or peers who hold different political views while reflecting upon their hopes and fears for Thailand's political future and why the movement is vital to them. The teachers were responsible for disseminating and collecting the assignment in their classrooms. The students have the right to opt-out of the research or leave the homework blank without consequence. Students' names, genders, and protected characteristics were anonymized, and thus the recruitment process did not exclude participants based on gender, class, or race. The homework was assigned to roughly 1,200 students from the six schools. Since the homework was non-graded and anonymized, 691 students turned in the assignment.

To analyze the letters, document analysis was employed to examine the specific language used by the participants in the study to understand their hopes and fears for Thai political insurgency (Creswell, 2002). We addressed the coding based on the conceptual framework used for the study (Saldana & Omasta, 2017). Specifically, we used behaviors and characteristics of Hart's (1992) Ladder of Participation and Reddy and Ratna's (2002) Adult-Children Engagement as initial codes to develop themes. We looked closely at segments of the letters related to the participants' 1) self-perception of current political situations, 2) experience with civic engagement, 3) experience with generational clashes and adult engagement, and 4) hopes and fears for the Thai political future.

Findings

This section investigates how Thai high school students perceive their political participation. It is important to note that not all students support the protests. Roughly around 27% of the letters indicate their neutral stance by writing: "I'm not taking sides;" "I'm neutral and reasonable;" "I understand that a lot of my friends want to express their stances. I think it's their right to do so. I don't think we can always agree, but we have to respect each other. It's natural in a democratic society." Less than 3% are supportive of the government.

Thai high school students view their freedom of expression as one of their inalienable rights. Two hundred nine students (30%) explicitly mention their "rights" and "freedom" to political expression. For example, a student from eastern Thailand argues, "FREEDOM OF SPEECH [capitalized by original source] is a human right by law and international standards. It means that we can express or communicate our thoughts and opinions through words, action, or writing." Since freedom of expression is their fundamental right, the students just want

the space to speak their minds. For instance, a Bangkok student states, "We are not asking for very much. What we're doing is exercising our rights. And I believe this right is not causing anyone any trouble."

Moreover, the students believe that the policymakers should listen to their concerns because they are taxpayers and thus can hold politicians accountable for their actions. Though most young people do not yet pay income taxes, they point to VAT (value-added tax) to contribute to the country's economy. Forty-three students (6%) explicitly mention taxes in their letters. According to these students, since they pay taxes, they have a right not only to question how the government spends public funds but also to demand better infrastructure and welfare from the state. The students believe that their taxes should be used to improve people's well-being. Still, the current government is not spending these funds transparently or effectively.

Since young people are almost universally denied the right to vote, Thai high school students believe they can exercise their rights through symbolic actions, such as the Hunger Games three-finger salute or wearing a white ribbon. Since their civic participation is primarily symbolic, the students feel that they are not harming anyone and are well within their rights. For example, a student writes, "Wearing a white ribbon and the three-finger salute have no physical effect, do not break any rules or laws, do not hurt anyone, involve no weapons."

Many students expressed dismay at the resistance to their political participation and what they feel are violations of their fundamental rights by adults in their lives. Three hundred five students (44%) experienced generational clashes and/or misunderstandings with their parents and teachers. At the fundamental level, Thai students feel that it is only "natural" to have a variety of political opinions. A student from Bangkok asserts, "Having different political opinions is normal because everyone has different ideas and viewpoints." Similarly, a student from the Northeastern region writes, "It is normal that even when [people] are brought up in the same environment, they can have different views only in different periods." Some students have cited a rule from the Ministry of Education that allows political expression in schools and question why their teachers are not abiding by these regulations. In their letters, the students recount how teachers and school administrators have infringed upon their rights to political expression. For example, some teachers reportedly threaten to deduct grades or have explicitly banned the three-finger salute in school. A teacher from eastern Thailand even allegedly slapped a student for wearing a white bow to class. While the students are demanding real changes from the government of General Prayut, their expectations of their families and teachers are different: the students are not trying to change their elders' minds. Instead, young people want the adults in their lives to keep an open mind and listen to what they have to say. For example, a student writes, "We want the people who disagree with us to understand us. Not for them to switch sides, just to understand what we are protesting."

Discussion and Conclusion

The students' beliefs in their unalienable rights and their criticisms of the Prayut regime motivated and justified their political participation. Our findings underscore that the students were not merely acting out or misled into holding rallies or wearing white ribbons. We thus argue that Thai students were operating at high levels of Hart's (1992, 2008) and Reddy and Ratna's (2002) youth participation models - despite adult resistance and unwillingness to communicate (further discussed below).

The students can be placed on one of the highest levels of Hart's (1992, 2008) model of engagement: "children initiated and directed." The contents of the letters indicate that Thai students' beliefs in their fundamental rights and experiences fueled their actions - meaning that they were initiated by the students themselves. The students believe strongly in their freedom of expression and rights as democratic citizens. Therefore, they should voice their opinions and concerns against what they perceive as inappropriate, whether corruption, ineffective use of tax money, or unjust democracy. As mentioned above, this political participation was also by students in many forms: from large protests, such as the ones outside the Ministry of Education in August 2020 (Lertchoosakul, 2020), to everyday symbolic actions, like raising the three-finger salute and wearing white ribbons.

We thus gain insight into students' political participation beyond traditional forms. Studies in various countries have challenged the dichotomy between "apathetic" teenagers and activists (Fisher, 2012; Harris et al., 2010). These scholars find that young people in Australia and the United States engage in "everyday participatory practices" that reflect their political views - such as recycling, signing petitions, and supporting or boycotting businesses. Our findings concur with these arguments. Thai students wearing white ribbons to schools or raising the three-finger salute during the national anthem have incorporated their political participation into everyday life. They have found a new way to participate in Thai politics. Those who participated were not all passionate activists who organized rallies and gave speeches at protest sites but were not politically apathetic. The different forms of participation further substantiate that the students were operating at the "child initiated and directed" level. These political actions weren't something mandated by an authority figure. Students had the independence and decision-making abilities to take action in ways that were within their limits and means, regardless of the economic situation, availability, and comfort level.

Though Thai students had taken the initiative and were already operating at high levels, we believe that the students are facing a combination of "hindrance" and "active resistance" on Reddy and Ratna's (2002) extension from Hart's model. A high number of students writing of misunderstanding and generational clashes (44%) are made to feel inadequate and/or unfit to voice their political opinions by the adults in their lives, thus being "hindered" from participation. According to the students' letters, adults viewed them as "children"; therefore, their role was to study, not solely participate in political movements. This resonates with Reddy and Ratna's (2002) findings when some adults believe that children don't have the capacity to participate and hence cannot make informed choices for their actions. Adults under the "active resistance" category tend to hold a strong position against youth participation and mobilize their resources to lobby against it. This is seen in the cases of teachers deducting marks from politically active students or even going as far as being verbally and physically abusive. Overcoming this resistance will be a necessary step toward bridging the generational gap. A 16-year-old student nicely sums up solutions for the current generational clashes, "We should talk with facts and reasons that would lift the country up. Both sides should listen without bias. Reasons should come before feelings. [...] Age shouldn't be a factor. No matter how old you are, we should be able to express our opinion freely."

Our study holds significance in showcasing the motivations of student political participation, particularly in Thailand. The messages from the Thai students' letters are universal and almost too apparent. These young people find issues with the status quo, believe that their rights to express their discontent are irrefutable, and are driven by their aspirations to secure a better future for themselves. Therefore, those in power everywhere should at least heed, if not welcome young people's political opinions and let them truly have a voice in society.

International Society of the Learning Sciences

Participation and Success with Optional Self-Explanation for Students in Online Undergraduate Chemistry Courses

Steven Moore, Huy A. Nguyen, John Stamper
StevenJamesMoore@gmail.com, hn1@cs.cmu.edu, john@stamper.org
Carnegie Mellon University, Pittsburgh, Pennsylvania, USA

Abstract: The benefit of self-explanation in learning has been well researched, but the extent to which students engage with such activities in a real-world course setting is often overlooked. To investigate how students participate and perform on such a task, we embedded an optional self-explanation activity into an introductory online chemistry course consisting of 129 students. We analyzed their participation and performance in the course, and how it relates to the quality of their self-explanation. We found that 53% of students participated in the optional self-explanation activity and 25% of their self-explanations were reviewed by experts to be sufficiently specific and detailed. Our results suggest that students are willing to engage with an optional self-explanation activity; however such interventions may be targeting the already high performing students in the course.

Introduction

As a constructive learning activity that fosters deep learning by encouraging students to generate inferences to themselves while they engage with the learning material, self-explanation acts as a medium for developing students' thinking and is specifically important for fostering transfer between concepts (Margulieux & Catrambone, 2017; Wylie & Chi, 2014). In a variety of domains, prompting students to self-explain while learning has been shown to positively impact the development of both conceptual and procedural knowledge (Rittle-Johnson, 2006). Understanding the structure and the quality of students' self-explanations can provide a foundation for examining their learning progression and their ability to communicate science (Sandoval & Millwood, 2005). Self-explanation can occur through different modalities, such as explaining out loud to a person (e.g. Jacob et al., 2020), selecting an explanation from a list of options (e.g. Asano et al., 2021), and constructing your own via an open-ended prompt (i.e., self-explanation - Rittle-Johnson & Loehr, 2017). This set of previous work has shown that it is effective for both in-person instruction in the classroom and online in a digital environment. Oftentimes students are required to perform self-explanation as part of their coursework or participation in a study, so claims can be made in relation to the quality of the student explanation and their success in class (Menekse et al., 2011). Additionally, systems are sometimes developed and deployed specifically to engage students in the self-explanation process (Williams et al., 2016). As a result, the participation and success of self-explanation activities may be inflated, as students in online courses often lack motivation and have low participation rates when the material is not required (Shapiro et al., 2017). This is not necessarily reflective of what occurs in the classroom or online, where students often make use of more low-stakes learning opportunities intended to give students feedback that are not required for the students to complete.

As prompting students for self-explanation has been proven to be an effective instructional intervention, garnering the participation of students that are struggling and could benefit the most from it is critical. While often neglected by previous work around self-explanation, identifying which students are engaging in the task, particularly when it is optional, can improve understanding of how self-explanation is leveraged by students. As stated in Asano et al. (2020), optional open-ended prompts to self-explain can readily be applied into many courses without the need of additional grading or ed-tech systems. However, we need to first understand how students will interact when the self-explanation activity is optional and for those that do interact, what the quality of their self-explanation is like. We addressed these questions in the current work through including an optional self-explanation prompt in an online chemistry course taken by over a hundred students. Specifically, in this study we present students with an optional self-explanation prompt embedded in their online coursework. We then utilize a 5-item rubric to assess the quality of students' self-explanations. The two research questions we address are: (1) How often do students engage with an optional self-explanation activity in the context of their online chemistry course? and (2) How do students respond to optional self-explanation prompts in an online chemistry course?

Methods

Study context & students

The present study takes place in a digital courseware platform known as the Open Learning Initiative (OLI). OLI is an open-ended learning environment that offers courses from a variety of domains (such as chemistry, biology,

 © ISLS

statistics, economics, etc.) and consists of interactive activities and diverse multimedia content (Bier et al., 2019). OLI activities are presented in two distinct categories: low-stakes/formative, providing students with feedback, or high-stakes/summative, used to evaluate student learning at the end of a structured unit. The low-stakes formative assessments in the system are all optional, allowing the students to scroll by them and focus purely on the instructional content. These assessments consist of a variety of question types such as MCQs, short answer, and dropdown style questions. Each question in OLI is broken down into one or more problem steps, where each step corresponds to an opportunity for student input. For instance, if a question asks a student to set the value of three dropdown boxes, then it consists of three unique steps that each have their own set of feedback and correct or incorrect responses. This distinction between a problem and its steps is important, since students may work on a problem, but not complete all of the steps due to a number of reasons such as not knowing the answer to some of them, wanting to skip them to save time, or getting distracted (Chen et al., 2018).

We used data collected from a week-long unit in four instances of an introductory chemistry course taught at a community college in the western United States. The course is geared towards freshman and sophomore undergraduates from varying degree backgrounds, with a majority of the students pursuing a chemistry-related degree. Our data comes from the fall semester of 2020, when the introductory chemistry course was offered in the OLI system. In total, our data consists of 129 students, with 68 of them participating in the self-explanation activity.

The OLI content the students used for the course covers the topic of elements and compounds and consists of thirteen separate modules. Each module consists of several topic headers, containing paragraphs of instructional text and low-stake activities embedded throughout. There are a total of 35 low-stakes and completely optional problems embedded throughout the thirteen modules of the course. These problems include multiple choice questions, selecting the correct option from a dropdown, drag-and-drop exercises, and submitting a short answer to compare against an expert response. Each of these problems is broken down into steps, depending on the components of the activity, for a total of 178 unique steps. For instance, if a problem has three fill-in-the-blank boxes, then that problem would consist of three unique steps. Additionally, students have unlimited attempts to answer these questions, so they can continue until they are correct or choose to advance, regardless of a correct or incorrect response. Additionally, all the instructional materials in OLI were optional to the students; there was no requirement for them to access or complete the materials outside of the summative quiz that was also accessed and implemented in the OLI platform. Previous research using the OLI platform has found that students have varied participation levels with the optional activities found throughout the material (Moore et al., 2021). However, students were assessed on the concepts covered by the OLI materials elsewhere in the course, so it was beneficial for the students to utilize them.

Data collection

We focus on an activity that was added to the course that involves each student generating a self-explanation as to why they chose their answer to a particular problem in the course. In the chemistry course, this activity is found in the second module of the content for this section of the course. This module provides several paragraphs of instructional text, two worked examples, and several low-stakes multiple-choice and short-answer questions on the topic of atomic mass. The self-explanation activity is presented in the same low-stakes and optional format as the other activities found throughout the course. In the activity (1), students are prompted to self-explain why they chose their answer to the short answer question above the prompt. The instructions for the self-explanation come from a related study by Asano et al. (2020) and are worded in a way to maintain the motivation of the student and briefly explain the concept of self-explanation. We intentionally wanted to keep this low-stakes and optional, to examine the students' participation with the task and the quality of their contribution.

Analysis

The student-generated explanations were coded by two experts to assess their quality and specificity. The two experts had content knowledge in chemistry and had ample previous experience coding qualitative student data. The inter-rater reliability was calculated and the Cronacbh's alpha value was .98, as the raters only disagreed on the rating of four self-explanations. These discordant explanations were discussed among the two raters until they reached a consensus on the categorization of them using the coding schema. This coding schema was adapted and used from Menekse (2020), which has also previously been used in several studies (Asano et al., 2020; Menekse et al., 2011). Explanations were assigned scores from the rubric ranging from 0 to 4. The exact coding schema that was utilized by the two expert reviewers can be found at (2).

A score of 0 "No Submission" means that the student left the self-explanation text box blank, they did not submit anything. Explanations received a score of 1 "None" if the student submitted something, but it was not relevant to the problem or the course content in any fashion. For example, a student wrote "I had no idea what to

say, but I had to say something". While the student did input a self-explanation, it has no relevance to the context of this course and it appears as if they were just submitting text to have something input for this question. A score of 2 "Vague" was assigned to explanations that were not specific to the current problem, but were still relevant to the context of the course and potentially borrowed some language from the question's text. One example submitted by a student was "they have to be within range of the isotopes". While part of the problem does involve isotopes and they are mentioned in the text, this explanation only mentions the isotopes and does not reference how the isotopes impact the outcome of the problem. Additionally, it is not clear what the "they" is referencing in this explanation.

Explanations received a score of 3 "General" if they discussed the topic of the problem, but did not provide enough details. For example, one student wrote "It is the number closest to 39.098 amu." for their explanation. This explanation directly relates to the problem and even a number used in calculating the correct answer, but does not mention specifics on how to use the amu number or the isotopes to determine the correct answer. Finally, a score of 4 "Specific" was given to explanations that were both detailed in nature and specific to the problem, for instance "The atomic mass is the average mass of all the isotopes present in a naturally occurring sample of this element. If the amu for K is 39.098, then that means that K-39 is more abundant since it is the closest to the atomic mass". Note that this explanation is also much longer than the previous, which was a trend for the explanations scored in this category. The explanation, in sufficient detail, clearly demonstrates how the student used their knowledge of atomic mass and isotopes to determine the correct answer.

Results

Student participation and self-explanations

We found that over half of the students in the four courses wrote responses to the self-explanation task. In total there were 129 students in the instances of the course and 68 (52.71%) of them made a contribution to the self-explanation activity. The chemistry course used by all four instances consisted of 35 problems that were composed of 178 total steps. On average, students completed 22.66 problems (*SD = 14.67*) and 112.96 steps (*SD = 78.54*), meaning a majority of the activities were worked on by the students, despite being completely optional. A t-test showed a significant difference in the number of completed problems, $t(127) = 9.369, p < .0001,$ and steps, $t(127) = 9.319, p < .0001$, between students that did the self-explanation activity and those that did not do it.

The self-explanation task was in reference to a short-answer question found towards the beginning of the course that was completed by 83 (63.34%) of the 129 students. Even though 83 of the students completed the short-answer problem, only 68 of those students contributed to the self-explanation task. This means 15 students did the problem, but chose to not participate in the self-explanation. Additionally, students on average spent 99.82 (*SD = 82.99*) minutes actively working on the problems found in the course, meaning they were typing or had their cursor somewhere present in the activity box. The average time spent by students on the self-explanation activity was 103.58 seconds, with the least amount of time being 17 seconds and the greatest being 433 seconds.

Description and quality of student self-explanations

The self-explanations students provided were input into a multiline textbox that had an adjustable size, capable of fitting any length of text. On average, the student-provided self-explanations were 107.5 characters long, with the shortest response containing 1 character and the longest 363 characters. There was a significant and positive correlation between the amount of time a student spent on the self-explanation task and the length of their explanation, $r(67) = .28, p = 0.019$. This might suggest that students spent their time thinking and typing the explanation out for the task, rather than having their cursor idly on the activity. A Spearman's rank-order correlation test indicated that the time students spent working on the self-explanation task was also positively correlated with the rubric score they received for their explanation, $rs(67) = .26, p = .032$.

A summary of the rubric scores for the student self-explanations can be found in Table 1. There were 61 students (47.29%) who did not submit a self-explanation response. For the 68 self-explanations provided by students, a majority (66.18%) of them were scored as a 3 or 4, indicating they were relevant to the problem; some were general (score 3) while others were sufficiently detailed and specific (score 4) to the problem. The highest percentage of score 4 was found in the c2 course at 19.23% across all students in that instance of the course. However, a one-way ANOVA revealed there was no significant correlation between the four courses and the distributions of rubric scores in the range of 0-4 for student self-explanations, $F(3, 125) = 1.309, p = .274$.

Table 1 Distribution of the rubric scores assessing the quality of the self-explanations that students received across the four instances of the chemistry course.

	Rubric Score					
Course	0	1	2	3	4	**Total Students**
c1	30	3	2	15	7	57
c2	9	1	3	8	5	26
c3	12	3	3	2	3	23
c4	10	4	4	3	2	23
Total (%)	61 (47.29%)	11 (8.53%)	12 (9.30%)	28 (21.71%)	17 (13.18%)	129

Future Selves in STEM: An Epistemic Network Analysis of Past and Present STEM Minority Program Participants

Yiyun Fan, Amanda Barany, Aroutis Foster
yf366@drexel.edu, amb595@drexel.edu, anf37@drexel.edu
Drexel University

Abstract: STEM minority participation programs have been widely implemented in higher education institutions to diversify and expand the U.S. STEM workforce. Research highlights the potential of targeted exploration of STEM roles and careers, and of intentional reflection on the self in relation to STEM (identity exploration). This work examines how engagement in a federal-funded STEM minority participation program shaped these processes in current students and alumni. Epistemic Network Analysis visualized connections between inductive identity themes in interviews, highlighting differences between interviewees at different stages of their careers and identity work: students discussed action-taking as they explored less-certain possible future STEM roles, while alumni integrated more diverse and holistic identity facets when conceptualizing their futures. Results offer insights into the identity-related impacts of STEM minority participation programs and longer-term trajectories of minoritized students working toward STEM majors and careers.

Identity and STEM participation

Shortages in the science, technology, engineering, and mathematics (STEM) workforce have been a persistent issue in the U.S., exacerbated by a representation gap in terms of minority participation (Camilli & Hira, 2019). Programming is needed to encourage URM youth to declare STEM majors and work towards degree completion. To address this, STEM minority initiatives that foster facets of identity exploration have been highlighted as a tool to broaden participation in STEM education. Research on STEM minority participation emphasizes identity work as supportive of student self-efficacy (Syed et al., 2019), self-authorship (Morton & Parsons, 2018), and motivation to persist in STEM (Hernandez et al., 2013). Reflection on *future possible selves* in STEM, or the roles and characteristics an individual hopes or expects to one day embody (Markus & Nurius, 1986) has been shown to play a key role in student's STEM learning, academic development, and career certainty (Syed et al., 2019; Verdin et al., 2018).

Identity exploration (Flum & Kaplan, 2006) is grounded in the idea that self-reflection in one moment is meaningfully built upon prior experiences and conceptualizations of self. Learners craft future possible selves as an awareness of what they might, would like, or fear of becoming based on an understanding of current and past roles (Markus & Nurius, 1986). Despite affirmations of the value of identity-focused interventions on institutional outcomes (Crawford et al., 2018), identity exploration research has found mixed results. While large-scale studies on the impact of university STEM programming connect current science identity (feeling part of the scientific community) to beneficial outcomes such as goal-setting and academic achievement, others suggest having a current science identity and values may not be predictive of STEM career success beyond four years post-graduation (Estrada et al., 2018). This disconnection could be representative of research that emphasizes reflection on the "current self" as a science community member, but not on a future possible self in STEM. Existing longitudinal studies of URM STEM identity exploration also tend to be survey-based (Habig et al., 2020), which may not elucidate how URM participants engage in identity exploration at different stages. This work adds to knowledge about long-term outcomes of higher education STEM minority programming through an examination of how participants at different stages of their STEM trajectories engage in identity exploration around future possible selves. The research question asks, "What patterns of identity exploration emerged when students and alumni discussed their future possible selves in STEM?"

Research methods

This work is a part of an NSF-funded project through the Louis Stokes Alliance for Minority Participation (LSAMP), which supports underrepresented students earning degrees in STEM. We examined individual interview data with eleven current and ten former LSAMP participants. The sample represents four LSAMP participating institutions,

 © ISLS

various STEM disciplines, and different stages within the STEM pipeline. Semi-structured interviews were conducted via zoom where participants discussed identity exploration processes as they related to their future possible selves as they participated in LSAMP programming. A priori themes/codes were selected using an inductive thematic analysis; however, codes were broadly framed based on the theoretical positioning of identity exploration and future possible selves research discussed above (See Table 1).

Table 1
Codes Related to LSAMP Participants' Future Selves in STEM

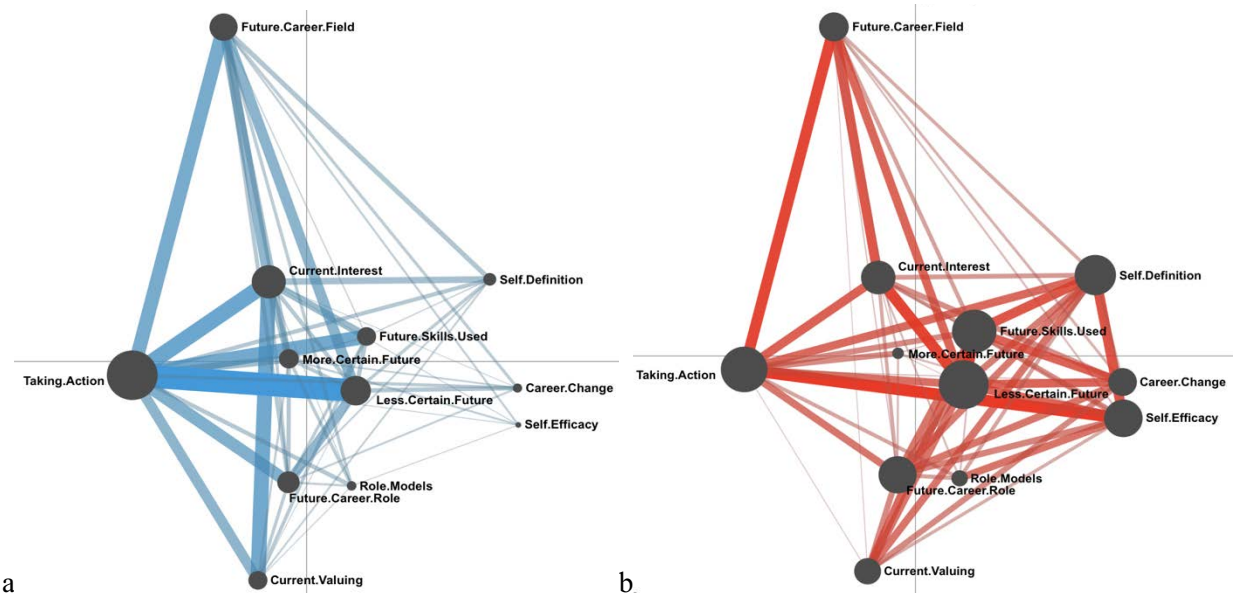
Code	Definition
1. Career Change	Expected change in STEM major or career
2. Current Interest	Describing liking or enjoyment of a STEM topic
3. Current Valuing	How a topic, domain, etc. is personally valuable
4. Future Career Field	Expected field or discipline in which participant may work
5. Future Career Role	Expected role or position which participant may hold
6. Future Skills Used	Expected skills to have and/or use in future
7. Less Certain Future	Lack of certainty or specificity in discussions of the future
8. More Certain Future	Expressing certainty and/or specificity in future career, role, field, or skills
9. Role Models	Describing individuals who inspire future major or career choices
10. Self-definitions	Descriptions of current identity labels and features; self-concept
11. Self-efficacy	Expressing confidence in one's ability to achieve desired results or goals
12. Taking Actions	Describing actions or steps taken to achieve desired results or goals

Once identified, codes were deductively applied to the interview data, with each sentence coded for occurrence (1) or non-occurrence (0). Interrater agreement was reached using social moderation (Herrenkohl & Cornelius, 2013). To understand differences in the ways that current LSAMP students and alumni conceptualized future possible selves, we applied epistemic network analysis (ENA) (Shaffer, 2017), a quantitative ethnographic technique used to model the relationships between codes in discourse. ENA generates network visualizations of the co-occurrence of codes within a moving stanza window, which means that code connections are determined and measured when they co-occur in the same sentence or a few sentences from each other (in this case 3 sentences). To generate the epistemic networks, units of analysis were set as the alumni and student groups, subset by each participant. Conversations were segmented by each interviewee and any breaks (i.e., off-topic discussion) in their interview. Nonparametric Mann-Whitney U tests were conducted to test whether differences between student and alumni discourse were statistically significant. Network findings are supplemented with qualitative findings.

Results and discussion

The epistemic network model had strong goodness of fit across the first (0.97 Pearson, 0.97 Spearman) and second dimensions (0.99 Pearson, 0.99 Spearman). The alumni network (Mdn=0.81, N=10) was also statistically significantly different (alpha<0.05) from the student network (Mdn=-0.54, N=11, U=108.00, p=0.00, r=-0.96), suggesting meaningful differences in their patterns of connection-making across identity themes. Figure 1a shows the epistemic network of associations that students made across the 12 identity constructs, while 1b shows the network for alumni.

Figure 1
Epistemic Networks of Associations Between Identity Themes for Student (left) and Alumni (right) Interviews.



Student discourse was driven by connections between "taking action" and codes such as (1) a "less certain future" (.24), (2) discussions of "current interests" (.17), (3) a desired "future field" (.14), and (4) an expected "future career role" (.13). A robust connection manifested between students' current interests and their current values in STEM (.15). Interpretive examination confirmed a pattern where students would detail STEM-related steps they were taking as part of an academic program, followed by a discussion of general or "less-certain" roles for which these actions were intended. One student alternated discussions of her current activities with potential, less-certain roles:

> I was trying to do a gap year at [company], they might have semiconductor research [actions taken]. This was going to depend on COVID, you know, kinda set all of this stuff, so I want to keep my options open [less certain future]. I'm even considering, you know, working as a professor, and I recently participated in a faculty exploration in [place] [less certain future, actions taken].

Relationships between "interest" and "taking action" manifested as students exploring multiple roles, such as the student who described looking for research positions in biomimicry to satisfy her passions. Some students knew the actions they took were working toward future participation in a general STEM field but had not yet settled on a specific career. These findings illustrate how engagement in STEM-focused programming may have at least tacitly encouraged students to take actions to explore facets of different STEM interests and career fields, but that student conceptualizations of their future selves in STEM had often not coalesced around concrete future roles or careers.

The alumni epistemic network reveals a more balanced pattern of association across identity themes, rather than centering around any single code. Alumni discussed "taking action," but were more likely to connect it to self-efficacy (.13) in their STEM career. Alumni often described a "less certain future" regarding careers and STEM identities but were more likely to connect this to a discussion of the "future skills used" (.13), as well as to "current interests" (.12). Other stronger connections included discussions of "taking action" in relation to "future career field" (.12). A visual examination shows "taking action", "less certain future", "self-definition", "future skills used" and "self-efficacy" as the most heavily connected constructs. Interpretive examination confirmed that alumni were more likely to integrate different facets of their identity exploration processes in interviews. Trajectories of reflection tended to be more diverse across alumni, with different participants making different connections in unique ways. Compare the following interview examples from two different alumni:

> Career goals... I would like anything that could pay me well and keep me using my engineering brain and my lawyer brain [current valuing, self-definition, future skills used]. I'm an engineer, a lawyer, a problem solver and a critical thinker and that's what I want to do [self-efficacy, self-definition]. It's kind of general, but I've

> no plans on leaving my current employer unless I found a better deal…that still allows me to do what I'm doing [current valuing, future skills used, less certain future].
>
> I'm trying to get hired with a process or a scale-up commercialization sort of role, because I want primarily to be able to get a couple of years of industry experience [taking action, future career role]. The positions that I'm really looking at and working with, let's say sustainability units within chemical manufacturers or working with the more - [future career role] I've recently started to understand this space a little bit more [self-efficacy].

Not only are alumni discussions more likely to integrate different facets of the self in a more complex and detailed way, but each pattern of reflection may be more conceptually distinct in terms of their socio-cultural situation; alum 1 and 2 differ in terms of the specific job they currently have, their STEM experiences since graduation, the skills they use, and the amount of time that has passed since they engaged in LSAMP programming. These features place them not only on unique STEM career paths, but also at different points in their distinct STEM trajectories.

Conclusion and implications

Results highlight the distinct discourse patterns and conceptual connections that emerged as current and former LSAMP participants discussed their future identities in STEM. While students were more likely to describe the current actions they were taking in relation to their exploration of more diverse and nebulous STEM interests, roles, and topics, alumni reflections revealed more holistic discussions of self that diverged into unique career and context-specific trajectories. As alumni move further along their increasingly unique STEM trajectories post-graduation, whole-group claims may start to obscure their socio-culturally distinct yet contextually valid patterns of growth and self-reflection they enact over time. This work contributes to research on STEM identity and minority participation by highlighting patterns of connection-making enacted by past and current participation and suggesting how and when individual trajectories might start to diverge post-graduation. Future work may extend this exploratory application of ENA to larger student and alumni datasets and secondary sources to understand identity exploration with greater nuance.

Visualization and Reflection to Scaffold Time-Management in a Computer-Based Learning Environment

Judith ter Vrugte, University of Twente, j.tervrugte@utwente.nl
Elise H. Eshuis, Saxion, e.h.eshuis@saxion.nl

Abstract: Facilitating practice of time-management skills in education is imperative due to its impact on short and long term academic achievement. By bringing tacit processes into students' conscious awareness via visualizations, computer-based learning environments offer unique opportunities to enhance such practice. Nonetheless, there is a dearth of knowledge on how this impacts students' learning and time-management, especially when it comes to secondary vocational education. Therefore this study explores how visualizations of performance combined with guided reflection impact students' (N = 40) time management accuracy and their knowledge acquisition. Technical vocational students who worked in a computer-based learning environment that included a visualization of estimated time accuracy combined with guided reflection, were compared to students who worked in the same environment without this support. Results indicated that higher accuracy and learning gains align, that the added support may have induced an adaptation in time-management, but that learning was not affected.

Introduction

Training of processes needed to acquire academic skills -often referred to as self-regulated learning skills- in education, can have direct as well as indirect effects on students' academic achievements (Ifenthaler, 2012; Palalas & Wark, 2020; Viberg et al., 2020). But teachers are uncertain how to properly support such training, especially within the practical-oriented secondary vocational training programs (e.g., Christoffels & Baay, 2016; de Bruijn & Leeman, 2011; Eshuis et al., 2021). And research addressing support for this population is rare (Viberg et al., 2020). An example is the process of time management, a key factor of self-regulated learning (Khiat, 2019; Winne & Hadwin, 2013), but to date an underdeveloped and underexamined topic (Wolters & Brady, 2020).

In the context of education, time management is the process of scheduling time to complete the learning tasks that are tied to the desired learning goals (Claessens et al., 2007; Khiat, 2019). Researchers established that *good* time-management has both direct and indirect effects on students' learning effectiveness (Khiat, 2019). A key component in good time management is the accuracy of the estimated time required to achieve the desired goals (e.g., Claessens et al., 2007; Landy et al., 1991). Experience combined with a continuous cycle of adaptation is needed to achieve this. Providing instructional guidance, like prompts that trigger students to plan and reflect, can help students to successfully engage in the required cycle of adaptation and improve their time management.

Prompts are instructional directions that stimulate and support students to carry out specific actions (Bannert, 2006). They are widely studied, often in the context of reflection, and their effectiveness is generally endorsed (Davis, 2003; Kori, et al., 2014). Though prompts can trigger and support students' planning and reflection, the outcomes of these activities is subject to many factors. One of these being that students tend to underestimate the time they need(ed) to complete their tasks (König & Kleinmann, 2007). This impacts the benefits of reflecting; when students start from inaccurate information their reflection is probable to result in wrong conclusions, even when all steps (i.e., collection of information, evaluation of information, goal setting) are carried out successfully (as also described in Eshuis et al., 2019). Here, computer-based learning environments can provide valuable support. Digital tools can track students' performance in learning environments and provide timely feedback for reflection, for instance via a visualization of students' estimated time in comparison to their actual time spent. Studies have demonstrated that such 'comparative feedback' (feedback that offers a comparison source) is a promising instructional means that can serve as a promoter of reflection (Eshuis et al., 2021).

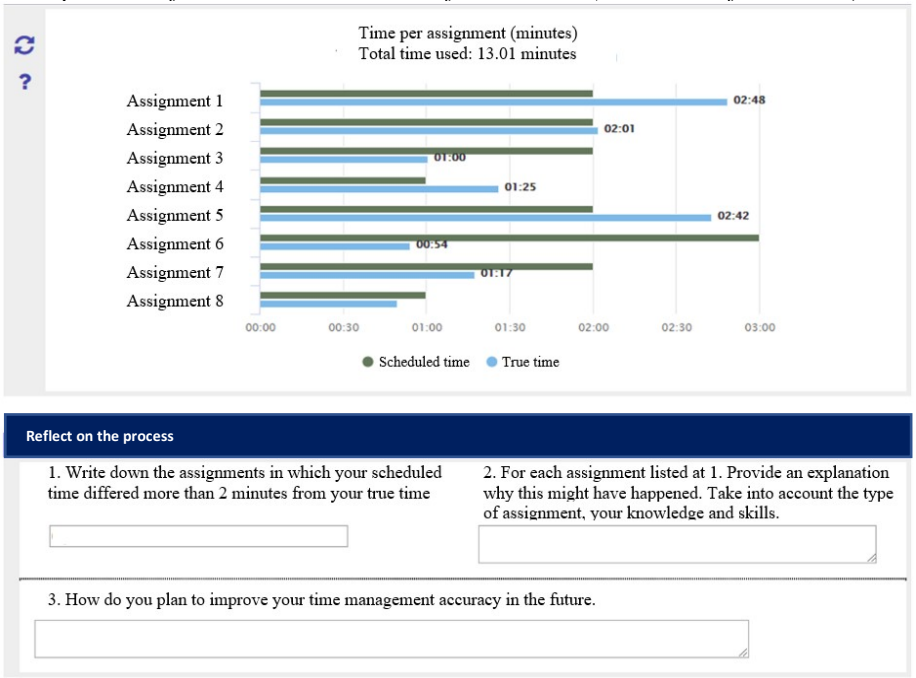
This paper explores such a digital tool. The tool employed visualizations (comparative feedback contrasting students' estimated time with their actual time) and guided reflection prompts, in order to support students' time management (see Figure 1). Two groups of students were compared. All students worked in a digital environment that required self-regulated learning. Only one group of students had access to the time management support tool. Because self-regulated learning processes play an essential role in students' success in computer-based learning (e.g., Broadbent & Poon, 2015; Lehman et al., 2014; Wong et al., 2021) and time-management is a key component in self-regulated learning (Winne & Hadwin, 2013), it was expected that more effective time management would positively impact students' success in the computer-based learning environments. More specific, it was expected that more successful time management would relate to better

 © ISLS

performance on domain knowledge tests (1); that students' time management accuracy would improve over time (2); and that the support would improve time management and consequently improve learning (3).

Figure 1

An Impression of the Visualization and Reflection Tool (Translation from Dutch)



Method

This study utilized an experimental pretest (domain knowledge test) - intervention (two sessions in a digital learning environment) - posttest (domain knowledge test) design with two conditions. All students completed two online learning environments (copies of the environments used by Eshuis et al. (2021)). They contained two online labs, eight assignments each, and instructive multimedia material related to electricity and electric power transmission. For the experimental condition, the time management reflection support was added to both learning environments. This was a digital tool which consisted of three steps: planning, evaluation, and reflection. The planning step was carried out at the start of each learning environment. Here students were invited to check the learning goals and the tasks in the environment and schedule how they would spend their 60 minute lesson. After students spent 60 minutes working on their assignments (or when they were done) they completed the second and third step: evaluation and reflection. Here, the tool presented the students with 'comparative feedback'. This comparative feedback comprised an overview of students' scheduled time per assignment and the actual time they spent on it (see Figure 1). Via a series of prompts students were invited to check the overview and reflect on their findings. More specific, the prompts requested students to 1) indicate significant differences between their scheduled time and their actual time spent, 2) explain this difference while taking into account the type of assignment, their prior knowledge, and skills, and 3) think of ways to improve their time management.

Measurements

Students' *domain knowledge* was assessed with two parallel versions of a paper-and-pencil test. To avoid order effects counterbalancing of the two versions as pre- and posttests was employed. Each test consisted of 11 constructive response items that aligned with the learning objectives lined out in the learning environments. Each item had two sub questions: one assessed factual knowledge (i.e., recalling a definition or formula) and one assessed procedural knowledge (i.e., applying a formula or explaining a principle). A sub question was awarded one point when answered fully correct. Three scores per test were calculated: total knowledge (all items), and factual and procedural knowledge separately. Cohen's Kappa for both pre- and posttest was >0.9.

Students' *time management inaccuracy* (i.e., the average deviation in time from the scheduled time) was calculated using the differences between students' scheduled time and their actual time spent per assignment. Where a positive score indicated an overestimation of time needed to complete the assignments, a negative score indicated an underestimation of this. A score of 0 indicated perfect time management.

Results

The data comes from 40 students (all male, M_{age} 17.3 years, SD_{age} = 8 months) of secondary vocational education (in Dutch: MBO) who completed all four sessions of the experiment. Participants were first-year students from three classes divided over two schools in the Netherlands. Students were enrolled in a technical training program preparing them for a vocational profession (e.g., car mechanic, electrical engineer).

Table 1
Descriptive Statistics

	Experimental condition (n=17)		Control condition (n=23)	
	mean	SD	mean	SD
Domain knowledge pretest (max 22)	5.14	3.47	4.96	2.58
factual (max 11)	2.37	1.41	2.53	1.21
procedural (max 11)	2.20	1.53	2.30	1.61
Domain knowledge posttest (max 22)	6.89	4.52	7.12	3.54
factual (max 11)	3.28	2.19	3.46	1.74
procedural (max 11)	3.17	2.31	3.22	1.83
Total time spent (minutes)				
learning environment 1	56.03	8.36	58.74	8.58
learning environment 2	52.31	10.05	50.01	14.66
Time management inaccuracy (minutes)				
learning environment 1 (TMI-1)	-0.45	1.84	n.a.	n.a.
learning environment 2 (TMI-2)	0.44	1.50	n.a.	n.a.

Pearson correlations demonstrated significant relations between pretest and posttest ($r(15) = .812$, $p < .001$), TMI-1 and TMI-2 ($r(15) = .505$, $p = .039$), and TMI-2 and posttest ($r(15) = -.617$, $p = .008$). There were no significant correlations between students' domain knowledge pretest score and TMI-1 ($r(15) = -.294$, $p = .252$), nor TMI-2 ($r(15) = -.481$, $p = .051$). Furthermore, from the descriptive statistics of the experimental condition it seems that students in learning environment 1 were more likely to underestimate the time they needed, while in learning environment 2 they seemed to be more likely to overestimate the time they needed. A paired sample t-test demonstrated a significant difference between these two average levels of inaccuracy, $t(16) = -3.93$, $p = .001$. Though there was a significant change from learning environment 1 to learning environment 2 it should be noted that the deviation from 0 in each appears about equal.

Mixed-design multivariate analyses with 'condition' as between-subject factors, and 'time' as within-subject variable demonstrated significant learning effects overall, but no effect of support. The within-subject variable represented the students' multivariate scores on the domain knowledge pre- and posttest with the factual and procedural scores as underlying univariate measures. Results showed a multivariate main effect for time, $F(2,36) = 10.11$, $p < .001$ (Wilk's $\Lambda = .640$, $\eta_p^2 = .360$), no multivariate main effect for condition, $F(2,36) = 0.097$, $p = .908$ (Wilk's $\Lambda = .995$, $\eta_p^2 = .005$), and no multivariate interaction effect, $F(2,36) = 0.36$, $p = .965$ (Wilk's $\Lambda = .998$, $\eta_p^2 = .002$). Univariate effects demonstrated that there were no significant univariate interaction effects underlying the insignificant multivariate interaction.

Discussion

The findings of the current study add to our understanding of how digital tools designed to support time management can impact students' behavior in an online learning environment. Specifically the focus group of the current study (i.e., students from technical secondary vocational education) makes this a unique contribution; as Viberg et.al. (2020) justly noted in their review, research often addresses higher education and only rarely addresses secondary education (in their review only 4% of the studies did so). Despite the moderate sample size, the current study provides some evidence that a relatively simple and short intervention has potential to foster adaptation. A change was established, but it should be noted that the change is not yet completely in line with what was desired. When looking at the average time, students were off by a similar time in both environments. It could be that a longer intervention is necessary to move from mere adaptation to adaptations with higher accuracy, or maybe added instructional support is required. The same goes for the transfer of higher accuracy to higher learning gains. The results of the current study corroborate the general assumption that more accurate time management aligns with higher learning gains. Nonetheless, the intervention in the current study was unable to elevate students' accuracy to such a level that significantly higher domain knowledge scores would be achieved. Also here a longer duration of the intervention might be necessary to establish substantial effects that translate

into a difference on this indirect level. It should be noted that the result is not unusual; Viberg et.al. (2020) concluded in their review there is little evidence of self-regulated learning support tools that manage to significantly improve learning outcomes. It could be that differences within the population impact the effectiveness of tools (as also discussed by ter Vrugte & de Jong, 2017) and that certain design choices, like the comparative feedback, may only benefit certain students.

Instructional Landmarks: Describing a Novel Intermediate Knowledge Structure for Physics Learners

Jared Arnell, Utah State University, jared.arnell@usu.edu
Hillary Swanson, Utah State University, hillary.swanson@usu.edu
Boyd Edwards, Utah State University, boyd.edwards@usu.edu

Abstract: Mapping the intermediate stages of developing knowledge structures is a critical endeavor for educational researchers. The influence of formal education on knowledge structures is particularly relevant to instructional designers. During an exploration of intermediate physics learners' knowledge of the Coriolis force, a novel knowledge structure was observed as the students discussed isolated systems, frictionless surfaces, and the law of inertia. We call these structures "instructional landmarks" as they appear to emerge from classroom instruction and serve to orient students in conceptual spaces and resolve conflicts during problem-solving. These structures, if found in other physics domains, could be useful for describing and modeling the cognition and development of intermediate physics students.

Introduction

Participating in formal instruction can help students construct more elaborate mental models for making sense of the physical world. In response to educational interventions and experience, novices reorganize their prior knowledge to construct higher-order structures that can meet the increasing functional demands of more complex problem-solving (Vosniadou & Brewer, 1987). During this restructuring, novices can build intermediate structures which act as a sort of conceptual bridge between their previous, naïve understanding and the rigorous, methodical, mathematical operations that are exemplified by experts (Niedderer, 2001). Identifying and describing these intermediate structures can help instructors develop alternative teaching approaches, which can further develop these intermediate conceptions into productive expertise (Brown & Clement, 1992).

In the course of developing a conceptual teaching approach for the Coriolis force for undergraduate physics, our team conducted a series of task-based interviews with intermediate physics students in order to observe how their prior knowledge, both intuitive and from their introductory physics education, played a role in their sense-making. We observed patterns in student reasoning, which may implicate a new category of intermediate knowledge structure in physics learning. We call this category of knowledge *instructional landmarks*. The role of instructional landmarks in learning could inform instructional design across multiple domains of physics.

Theoretical framework

This work builds on a theory of knowledge and learning called Knowledge in Pieces (KiP; diSessa, 1993). KiP postulates that knowledge is a complex web of atomized knowledge elements with context-dependent connections. The connections which exist within the knowledge structures of novices are highly localized and sparser in general than those employed by experts. Novices also tend to lack the higher-level, abstract schemas that govern large-scale cognitive organization in the minds of experts. Part of the transition from novice to expert involves reorganizing and repurposing existing knowledge elements to align with accepted scientific understanding. As the knowledge network becomes more reliable, clusters of related elements fuse into more developed structures which can be used productively in sense-making. By examining learners at various stages of development and across a broad range of topics, researchers can catalogue the various available resources, understand the relationships and interactions between them, and explore their evolution and development over time. This would allow for the creation of adaptive educational materials, which utilize the students' cognitive resources to their fullest extent.

Methodology

In order to get a sense for the conceptual resources undergraduates bring to their learning of the Coriolis force, our team interviewed eleven undergraduate students from a large university in the U.S. Intermountain West. All participants had finished the university's Introductory Physics course, which covered basic physics concepts that were necessary to understand the Coriolis force. Six of the participants had also completed the Classical Mechanics course that included traditional instruction about the Coriolis force. During each one-on-one interview, students were presented with a series of thought experiments, which explored the motion of a puck as it moved across the surface of the earth under various circumstances.

 © ISLS

Interview transcripts were analyzed using Knowledge Analysis, which focuses on the structure, genesis, and evolution of knowledge within an individual's mind (diSessa et al., 2015). Specifically, we used a microanalysis to identify participants' resources for reasoning about Coriolis force phenomena. Knowledge Analysis is a grounded approach, meaning it allows patterns and interpretations to emerge from the data rather than looking at the data to find evidence of existing components of a theory (Corbin & Strauss, 2008). After transcribing the recorded audio from the interviews, the students' responses were analyzed to identify the ideas they featured. Similarities in student ideas were then compared to previously documented knowledge elements and structures to identify the existence of previously documented resources and highlight ones that were novel.

Results

Among the data, three patterns in student reasoning stood out. They shared enough similarities with each other that they appeared to be instances of a common structure and the three together offered enough detail to form a rudimentary outline of the structure. They appeared to be heuristics that the students relied upon as they interacted with intermediate physics concepts, which had strong roots within the students' formal education. Their primary function seemed to be orienting the students within a conceptual landscape during problem solving. We named these structures "instructional landmarks" and began documenting their common traits:

1. *Central Node:* Instructional landmarks have a focal point that is a common physics term, phrase, or rule (e.g., "Newton's 2nd Law"). The highlighted term is one that would have little importance to a lay person but is instantly recognizable to anyone with an introductory level of physics education. This demonstrates that instructional landmarks are not intuitive knowledge elements, but rather are constructed in the same environment where novice physics learners are introduced to the technical terms of physics.
2. *Loose Organization:* Concepts which share an association to the central node are cued when learners activate the instructional landmark. The strength of cuing is proportional to the frequency at which the concept was relevant to problem solving involving the central node during physics instruction. The connections surrounding the central node are still unrefined; students may mistakenly use the wrong term when describing the central node even when their understanding of the central node is correct.
3. *Authoritative:* Instructional landmarks form around central nodes which were taught in an axiomatic manner: within a specific context, the rules imposed by the central node are assumed to be of the highest priority. Due to this assertion, students grant these structures an enormous amount of trust, rarely questioning them. The reliable nature of the central node also allows students to confidently and repetitively cite the central node to demonstrate the validity of their own arguments.
4. *Orientation:* When exploring the cognitive space around a landmark, students will use the central node to orient themselves as they attempt to determine the range of acceptable solutions and weed out irrelevant ideas. Before brainstorming, students will try to verify that the problem space is within the central node's conceptual boundaries. Once confirmed, they branch outwards from the central node, working through related concepts while maintaining their view of the central node. The students may reiterate the central node during the cognitive exploration to assure it has not been neglected, and if they get lost or become unsure, they will try to reestablish their view of the central node before continuing.
5. *Conflict Resolution:* Students will measure potential solutions against the central node to determine if the suggested answers are acceptable; in cases where multiple instructional landmarks are relevant, the rules of all visible central nodes will be applied. If the solutions disagree with the postulates of any relevant central node, they must be relinquished (even if the solution is supported by the students' intuition). When multiple ideas clash, preference will be given to whichever best aligns with the nearby landmarks. If the students fail to discover a solution which meets these requirements, they will abandon the search rather than suggest an answer which knowingly conflicts with the central node.

Some landmarks exhibited certain traits more strongly than others, and in some cases did not exhibit a trait at all (though this was usually because the interview did not provide an opportunity for the trait to be demonstrated). During our observations, we noted three distinct instructional landmarks built around the central nodes: isolated systems, frictionless environments, and the law of inertia.

The isolated systems landmark

At the start of the interview, each participant was asked to give a simple description of the laws of conservation of energy and conservation of angular momentum. These concepts were covered as part of the Introductory Physics curricula and are fundamental to describing the Coriolis force. As part of their explanations, six of the eleven participants stated that these conservation laws were only applicable in isolated systems. The language of

isolation was not prompted by the interviewer, yet it was included by more than half of the participants, sometimes repeatedly. The repetitiveness of the statement indicated that the participants viewed the rule as extremely important, one that must not be neglected when interacting with any conservation problem. The participants were practicing a routine of delineation which is taught to every introductory physics student; it is imperative to clarify the boundary of your system at the start of most physics problems. Without this step, it becomes impossible to know which rules or precepts will apply to which objects.

Our team was unable to resolve the finer details of this landmark, primarily because the conceptual approach did not incorporate scenarios in which the isolated system of the earth is intruded upon by outside forces. Without those conflicts, there was no reason for the students to utilize the landmark beyond its initial mentioning when explaining the general rules of the conservation laws. Further study would be necessary to confidently identify the internal structure of this landmark, explore other contexts in which the landmark might be cued, and determine the manner in which students rely upon it during conceptual problem-solving.

The frictionless environments landmark

Our conceptual approach, like many thought experiments in physics, made use of an idealized frictionless surface. The participants were familiar with frictionless surfaces as they play an integral role in Introductory Physics. Throughout the intervention, several participants regularly stopped to verify with the instructor that the frictionless environment was still in effect, asking questions like "You said it's frictionless, right?" for clarification. As the participants began to vocalize their own predictions, they commonly cited the frictionless environment before they offered their answer. This manifested in statements like "Because there's no friction, there's not going to be a force that inhibits the motion," and "With the planet being frictionless, the rotation underneath shouldn't matter." This habitual reiteration seemed to a) ensure that the frictionless state was not being neglected or forgotten and b) lend credence to their proposals by showing that they were obeying the rules of the scenario.

It was clear that the participants were treating the impositions of the frictionless state as an essential component of the problem-solving process, but the greatest utilization of the landmark came when the students realized that their current intuition was at odds with the frictionless assumption. The students would immediately abandon their idea and search for an alternative that would adhere to the frictionless ruleset:

> Interviewer: *Why would the puck be moving…?*
> Student: *Because the earth is rotating … and because the puck is on the earth... Actually, if we're still negating friction, I would say the puck still is in the same stationary spot.*

With very little pushback, the participants discarded ideas that were incongruent with what they had been taught about frictionless surfaces. These real-time corrections exemplify one of the primary functions of instructional landmarks: because the rules associated with each landmark can be reliably assumed to be true within a conceptual space, they can serve as a litmus test for detecting flawed ideas or uncovering contradictions. Interestingly, the frictionless landmark encompasses a ruleset that does not exist in the real world, but the usefulness of an instructional landmark is specific to the problem-solving contexts in which it can be applied. The students appeared to have a great deal of experience navigating using the frictionless landmark, and we predict that the Introductory Physics classroom would be a perfect environment for exploring students' use of the frictionless landmark in greater detail.

The inertia landmark

Throughout the interview, the participants were asked to make predictions about the motion of a puck subjected to a variety of initial conditions. Within these predictions, the participants expected the puck to move if it was pushed and to remain stationary otherwise. At this stage in their instruction, the participants were well acquainted with kinetic physics problems: a significant amount of the introductory curriculum involves enumerating and analyzing the forces acting on an object in order to calculate the resultant motion. We refer to the structure which arises from these practices as the "inertia landmark," although the central node of this landmark had a far weaker association with proper terminology than any other observed landmark. In fact, across all eleven students, not one used the word "inertia" when predicting the motion of the puck (even though they were using the concept to inform their predictions). Despite the weaker jargon, the landmark still proved decisively useful: the students tended to vocalize which forces were (or weren't) present as they started to formulate their predictions, saying things like "there's just gravity pointing down, there's no friction keeping it in place," and "there's no force that is changing where the puck is, other than gravity and the normal force." Even though the word "inertia" wasn't being offered as a part of these propositions, it was clear that the students had formed a habit of enumerating forces as a preliminary step when predicting motion during their introductory physics education.

What's more, this structure appears to have been refined further in the students who had completed Classical Mechanics: three of the advanced students mentioned the term "inertia" when centrifugal forces came up in their discussions. Interestingly, the inertia mentioned in these contexts activates the same landmark as before: the students recognized that a state of motion will remain unchanged according to an inertial observer unless acted upon. The strong contextual association of inertia with the centrifugal force (which is covered in Classical Mechanics but not Introductory Physics) demonstrates that the connection has been developed further during the advanced instruction; the same conceptual framework that applied in kinetics is now relevant in the new territory of inertial forces. To put it another way, the conceptual landscape from which the inertia landmark was visible had been increased as a direct result of additional instruction. This is a prime example of the continuous nature of knowledge as it is refined from a naive state to expertise: existing knowledge elements and structures are repurposed and expanded to facilitate complex understanding and enable more advanced problem-solving.

Discussion

All three landmarks had a strong central conceptual node, though the association of that node to specific terminology or neighboring concepts varied. The connections displayed by all three landmarks bear a significant resemblance to traditional instruction methods and practices, suggesting that the refinement of these structures rely on student-teacher interactions. These landmarks occupy an elevated status in the students' minds, where they are given priority over other intuitive or instinctual knowledge. Once built, the landmarks serve the students during conceptual problem solving, providing a yardstick with which the students can measure possible solutions, eliminate erroneous suggestions, or differentiate among competing hypotheses. The landmarks display a wide range of applications which vary in specificity from broader physics topics to specific problem-solving scenarios.

Given the similarity in traits between the trends documented here, the construct of instructional landmarks could provide education researchers with an interesting perspective from which we can deconstruct and analyze intermediate knowledge structures in physics learners. The three landmarks documented here are merely those which were relevant to discussions about the Coriolis force and are not at all a comprehensive list. We expect to find similar landmarks built on other conceptual nodes throughout physics. The nodes will most likely be those which have high experimental confirmation (which are taught in an axiomatic way) or wide-reaching conceptual utility (such as idealizations or simplifications). The high degree to which context determines activation will mean that instructional landmarks will most easily be identified by examining students' cognitive decision-making within specific conceptual neighborhoods. Instructional landmarks should also develop into more refined models as the students pursue deeper and more complex guidance from physics experts throughout their formal education. Ultimately, these instructional landmarks could prove to be a precursor to larger, more systematized structures that provide support across domains for experts.

Describing and investigating intermediate knowledge structures such as instructional landmarks will be a critical step in advancing toward a computational model for conceptual physics understanding. Expanding the vocabulary for describing intermediate structures will not only empower the communication between students and teachers, but among educational researchers as well. The intermediary stages that exist between novices and experts are among the most crucial to understand, as they have the potential to redefine priorities and revolutionize strategies within classrooms, workspaces, and academic communities.

In Pursuit of Creativity in *Minecraft*: A Mixed-Method Approach

Seyedahmad Rahimi, University of Florida, srahimi@coe.ufl.edu
Justice T. Walker, The University of Texas at El Paso, jtwalker@utep.edu
Lin Lin, University of North Texas, Lin.Lin@unt.edu
Jinnie Shin, University of Florida, jinnie.shin@coe.ufl.edu

Abstract: Despite *Minecraft*'s incredible popularity, we know very little about how the game might enable creativity. To assess and support the creativity of the structures that players create in *Minecraft*, we need to understand how Minecrafters describe creativity in their communities, and how similar or different those descriptions match the creativity literature. In this study, we used a modified rubric for creativity and investigated if we could find evidence for this rubric in how *Minecraft* builds are being evaluated in YouTube. We also used natural language processing (NLP) to develop automatic coding algorithms for future use. Insights here would inform the literature, research, and educational practices of creativity.

Introduction

Creativity is one of the essential skills for success in life in the 21st-century (Gray, 2016; Glaveanu et al., 2020). In our ever-changing world, we need people to think, feel, and act creatively to solve new or unexpected problems (Resnick, 2018). Since the beginning of the COVID-19 pandemic, creativity has been quintessential to designing effective vaccines (e.g., Tan et al., 2021) and sustaining economic infrastructures. For instance, restaurants, schools, and businesses have had to come up with creative means to remain open. Because creativity is valuable to society, attention has been placed on understanding the various ways creativity manifests in everyday life, the so-called *little-c* creativity (Kaufman & Beghetto, 2009; Richards, 2010)—the focus of this study. To assess little-c creativity, researchers use divergent thinking to examine creative thinking or creative potentials (Runco & Acar, 2012). Guilford (1956) operationalized divergent thinking using its four facets: *flexibility* (e.g., the number of categories or themes used when solving a problem or the ability to come up with relevant ideas from different categories or themes); *fluency* (the ability to produce a large number of relevant ideas); *originality* (the ability to produce statistically rare ideas); and *elaboration* (the ability to implement and expand on an idea in detail and high quality).

One promising medium to assess and enhance creativity is video games (e.g., Rahimi & Shute, 2021a; Shute & Rahimi, 2021). This is because video games, in their ubiquity, reach broad audiences all around the world (Rahimi & Shute, 2021). Through the often-repeated practices, people obtain creative skills that may transfer to other parts of life, thus enhancing their overall creativity in life (Green & Kaufman, 2015). Well-designed video games may enable people to practice being creative (Rahimi & Shute, 2021b). To support creativity in video games, one must first accurately assess it, however, assessing creativity is challenging. For instance, assessing creativity could be subjectively in the eyes of the beholder. Some researchers have even suggested we need to drop the idea of objectively assessing creativity (Amabile, 1996). However, others have used new assessment techniques such as stealth assessment to objectively (i.e., automatically) assess creativity (Shute & Rahimi, 2021). Stealth assessment uses log files generated in an immersive environment (e.g., digital games) to make inferences about learners' level of competency on the skill at hand (e.g., creativity). Before a stealth assessment is designed and embedded in a digital game environment, it is essential to find appropriate indicators in the assessment or learning environment (e.g., a digital game) to provide evidence for the competency of interest (e.g., creativity).

One of the most popular games of all time is *Minecraft* (Gilbert, 2018). *Minecraft* has shown promising results in improving people's creativity (e.g., Blanco-Herrera et al., 2019). *Minecraft* includes five modes of gameplay: creative, survival, adventure, spectator, and hardcore. In the creative mode, players usually create various structures (e.g., a recreation of real-world buildings, creating fantasy worlds). These structures has been showcased online via various platforms such as YouTube which consistently ranks *Minecraft* as one of the most popular terms searched on the platform globally (Hardwick, 2020). In fact, others have fruitfully leveraged YouTube to examine *Minecraft* productions (Walker et al., 2019) to find out how they are represented and constructed at scale. Therefore, YouTube content about *Minecraft* has a lot of potential for creativity researchers to investigate how creativity is manifested in this video game.

To assess and support the creativity of the structures that players create in *Minecraft*, we need to understand how Minecrafters describe creativity in their communities and how similar or different those descriptions are compared to the classical creativity definitions in the literature. Among the YouTube videos about *Minecraft* are some videos created to showcase and evaluate top *Minecraft* constructions created by others that

 © ISLS

could be classified as creative (e.g., top 10 constructions in *Minecraft*). These videos usually have a voice-over describing why those 10 builds, for example, are among the top *Minecraft* constructions. The evaluators' descriptions could potentially include the language used to describe creativity discussed in literature. In this study, we will focus on analyzing the evaluative videos' transcripts to address the following research questions:

1) *To what extent the YouTube-based Minecraft evaluators' comments are consistent with our rubric of creativity (see Table 1; adapted from Rahimi, 2020)?*
2) *Are there new facets of creativity emerging in how Minecraft content evaluators describe creative structures on YouTube?*

Insights here would extend our understanding about the ways creativity manifests in online, sandbox video games such as *Minecraft*; thus, enhance learning-interventions and assessment of creativity in the future.

Method

The current study uses a combination of traditional deductive and inductive qualitative coding (Ravitch & Carl, 2019) and natural language processing (NLP) to examine the transcripts of a set of evaluative *Minecraft* videos hosted on YouTube. We specifically looked for patterns of common descriptions of creative constructions in the video transcripts and categorized them into the seven categories defined in Table 1. We also looked for new emerging categories if any.

Table 1
The Initial Codes for Creativity in Minecraft

Code	Description
Elaboration	The amount of detail. Any time the evaluator remarks on a Minecraft build in terms of the level of detail regarding the materials, mechanics.
Originality	How rare is the building? Any time the evaluator refers to the construction being unique, rare, or states something similar referring to the building being novel.
Aesthetics	Is it aesthetically pleasing? Well-thought-out designs, symmetrical elements, great choice of color?
Surprise	Was there any sense of surprise in the evaluator's narration? If the narrator was amazed, impressed, wowed.
Humor	Was there any laughter in the evaluator's narration? This the evaluator used words such as "funny" or even laughed like "hahahah" or "hilarious"
Complexity	refers to ideas from different categories. If the narrator referred to Variation of shapes, colors. Combining different elements in the building.
Novel use of materials	If the narrator refers to the use of a material in an unusual way.

Selection of videos

To find the most appropriate YouTube videos, we first consulted with two *Minecraft* experts (with more than three years of experience in *Minecraft*), and then we came up with appropriate search terms and video selection criteria. The search terms included "Minecraft builds" "top Minecraft buildings" "best Minecraft constructions" "top ten" "top five" "Minecraft" and "creative." Our search terms and inclusion criteria yielded thousands of results on YouTube. After several iterations, we developed the criteria to only include videos that had narrations. In addition, we included videos evaluating *Minecraft* builds and excluded videos about competitions or about the other *Minecraft* modes (e.g., survival). With the criteria, each author created a list of videos with the YouTube links they found. After individual screening and consulting with our *Minecraft* experts, we collectively selected a sample of 61 videos. Then, three authors went through an additional screening to determine the duplicates and apply the inclusion/exclusion criteria until 100% consensus was reached. The final data set included a collection of 36 videos (about 360 unique builds in our analysis). Next, we briefly explain how we extracted the transcripts.

Extracting the transcripts

Using YouTube's publicly accessible application program interface (API), we wrote a code to read the YouTube URLs from a Google spreadsheet, extract each video's transcript, and generate a dataset with all the transcripts

for each video in it. The variables in that dataset included: video ID, caption (as they would appear on the screen), time stamp, and duration for each caption. Our final dataset included 14,860 lines of caption.

Coding process

For this study, which is a work-in-progress, we chose the first two videos in our dataset (20 builds), created three separate spreadsheets for each of the authors, and applied the codes in Table 1 to this unit of analysis. Codes were applied deductively to the transcripts. We also inductively reasoned on parts of the transcripts that could be coded as a new category but were not captured in our existing codebook. In doing this we identified themes that were then consolidated into a formal code (see Table 2). Codes were not mutually exclusive and could co-occur in each excerpt. In the first round of coding, three authors independently coded a subset of the transcripts and met to compare and resolve code application disagreements until 100% consensus was reached. To get a sense of code distribution for each build and across the entire sample we generated descriptive statistics in the form of frequency counts per code. In addition, we invited another author, who has expertise in learning analytics to help us understand and focus on connecting human codes with NLP and machine learning classification algorithms. Developing an NLP model can help us automatically code transcripts of similar videos in the future at scale.

Results

In the process of coding, we developed two new codes: (1) *effort* referring to how much effort it seemed a build took to be created. For example, "almost a full year of work was put into bringing this creation to life" was coded as evidence for effort. We found ten incidents for effort in the ten builds we coded; and (2) *realism* which refers to how real the build was in evaluator's view. It is hard to create real-looking constructions using blocks in *Minecraft* because the scales should be accurately estimated, and it takes a lot of detail. Therefore, when a building resembles a real building, the evaluators found it as doing something creative. We found 28 incidents for realism in the ten builds we coded. The rest of the codes' appearance are listed in Table 2. The most frequent codes were elaboration, aesthetics, surprise, and complexity. We have not found any explicit statements to be coded for humor in the ten builds that we coded. However, it is too soon to decide if we need to drop these codes as we still have about 34 videos to code.

Our preliminary analysis using NLP and machine learning classification algorithms revealed insights about the possibility of automated creativity evaluations. We achieved close to 70% accuracy (using 5-fold CV) to distinguish the sentences that showed evidence of creativity. Similarly, close to 90% accuracy was acquired to categorize the sentences based on the proposed dimensions of creativity. We used a logistic regression algorithm and a multi-label adapted kNN classifier with the term-frequency inverse document-frequency vectorization.

Table 2
The Initial Codes for Creativity in Minecraft

Code	Frequency	Example for the Captions
Elaboration	39	"Wow look at the details" "this is a very dense design"
Originality	15	"I have not seen something like this before" "This is a unique built"
Aesthetics	30	"Wow, this is beautiful, look at the colors!" "Such a symmetrical shape"
Surprise	44	"Wow, this is really unexpected!!" "Can it get even more complicated?"
Humor	0	"Wow, this is funny!" "This looks really hilarious" "Hahahaha this reminded me of…"
Complexity	13	"This is a complex design as the builders combined multiple materials"
Novel use of materials	3	"Look, they used a torch as the eyes of the devil"
Effort	10	"Almost a full year of work was put into bringing this..."
Realism	28	"... a highly detailed recreation of The Lord of the Rings."

Discussion & Conclusion

In this study, we used a modified rubric for creativity and investigated if we could find evidence for this rubric in how *Minecraft* builds are being evaluated in YouTube. Due to lack of time for this proposal, we have so far coded the caption related to 20 builds. We found evidence for most of the codes or sub-facets of the rubrics we used except for humor and novel use of materials. We also found two new codes: effort and realism. These codes are significant because they highlight how platform-specific features shape how creativity manifests itself. In other

words, creativity codes can in many ways be generalized, however, video games and their diverse context may manifest creativity in different terms. Because of our small sample of builds so far (only 20 builds) we cannot make a conclusion about which code has appeared more compared to the other codes. However, it is noticeable how often surprise, elaboration, aesthetics, and realism appeared in the captions from those 20 builds.

Moreover, our NLP analysis and classification algorithms could successfully identify the syntactic and semantic differences among the creativity dimensions. However, the analysis was conducted with a relatively small set of sample sentences for both training and evaluation, which may limit the generalizability of the findings. Hence, we encourage a future focus on expanding the labeled dataset to evaluate the capacities of our algorithms for automated coding.

"With statistics, that's supposed to take bias away": Divergent teacher views on engaging students with race in data sets

Victoria Delaney, Stanford University, vdoch@stanford.edu
Victor R. Lee, Stanford University, vrlee@stanford.edu

Abstract: This study examined what pedagogical potential teachers see in data sets that include race as a variable. Through interviews with 11 secondary teachers, we show a range of views about the role race plays with respect to students' opportunities to engage with data analysis. From analysis of teachers' noticings of pedagogical potential and justifications for what data sets they would prefer in a constrained choice task, we identify areas where the learning sciences can support teacher learning and curriculum design with race-inclusive data sets.

Introduction

Recently, there have been a number of urgings for youth to learn more about data science as part of their K-12 education (e.g., Bargagliotti et al., 2020). Our concern is to explore how teachers whom we anticipate are among the most likely to be enlisted in teaching data science – namely, secondary statistics and mathematics – think about the pedagogical potential of various data sets (Lee & Delaney, 2021). As data sets are already abundant but also being continuously generated, we are examining how teachers judge the suitability and usability of data sets in their teaching. Developing a model of teacher thinking about the pedagogical potential of different data sets could help inform future efforts to design curricula, curate data for pedagogical use, recommend possible uses of data in the classroom, and enhance teacher professional learning experiences. In the early stages of research shared in this paper, our aim has been to explore how teachers think about teaching with data sets that prominently feature race. In the United States, where we are based, race is a complex social construction that is deeply connected to longstanding issues of power, privilege, and injustice. These are topics that the learning sciences, particularly in North America, are actively discussing (Booker & Esmonde, 2016). While our work directly speaks to challenges in the US, we believe it still has implications for other nations as matters of equity and injustice are concerns that transcend geopolitical boundaries. Our primary question in this paper is: What considerations are statistics teachers making regarding matters of race when appraising the pedagogical potential for quantitative data sets?

Theoretical Perspectives

This work is based on the premise that, while popular discourse would suggest otherwise, data are not objective. They are the product of human decisions, subject to their own biases. They are markers of the social world rife with matters of unevenly distributed power, injustice, and oppression. Enthusiasm about what the potential of data science is rooted in "imagined objectivity" of data (Benjamin, 2016).

With respect to race and data, learning scientists have observed important opportunities where teachers can engage students. Philip et al. (2016) proposed the field attend to racial-ideological micro-contestations as a space for conversations about race with data. These are social interactions where the meanings and consequences of race are raised, contested, and negotiated. In Philip et al.'s work, this took the form of dialogue in a class viewing data about movie rentals in different regions of a large, segregated city. Their analysis showed how a specific classroom teacher needed to make immediate decisions on how to respond to the topic of race as it was raised in classroom discussion and was unable to use that moment to navigate students through a potentially powerful discussion involving both data and racial literacies.

This is a challenge noted by other learning scientists. Enyedy & Mukhopadyay (2007) described a design experiment to provide students with culturally-relevant mathematics pedagogy. Students were intimately familiar with inequities represented in the geospatial data that Enyedy & Mukhopadyay brought to a high school classroom such that the utility of the mathematics being taught was unclear. The design experiment made prominent the tensions in goals and norms of their intended culturally-relevant pedagogy and those of their mathematics pedagogy. Reconciling those tensions is complex design and teaching work. Some cases model promising potential new approaches (Rubel et al., 2017). Still, there is much to be examined, especially as it relates to the prospect of high school statistics teachers taking on the work of teaching data science.

Methods

Research Participants

 © ISLS

Eleven high school mathematics and statistics teachers from public, private, charter, and magnet schools were recruited for this exploratory study through existing contacts and snowball sampling. All teachers taught in 'majority minority' schools where White students consisted of less than 50% of the student population. These teachers had an average of 16 years' experience, ranging from 4.5 to 35 years, and some taught other courses (e.g., computer science) or held other professional roles (e.g., coach, administrator). 3 of the 11 identified as teachers of Color, and 5 of the 11 identified as female.

Procedure

Teachers participated in 60-minute interviews that were videorecorded on the Zoom conferencing platform. During the interview, teachers were presented two pairs of publicly provided side-by-side data sets (Figure 1) regarding the same topics. Of the two pairs of data sets presented, one set was on policing and the other set contained technology company employment data. Teachers viewed four data sets in total, and all contained racial variable columns, with some mixing race and ethnicity. Teachers were asked to think aloud and comment on what they noticed when viewing them. Then the interviewer posed a series of questions, designed to target teachers' perceptions of student interest in the data, potential elements of student struggle with or about the data, authentic appearance of the data, and pedagogical affordances of the data. Each viewing session concluded with the teacher's decision and explanation as to which data set they would choose to teach with, and why.

Data analysis

The interviews were transcribed and subject to multiple coding passes, parsed into two analytical phases. The first phase focused upon which data set was selected and why. Here, we analyzed teachers' expressed preferences toward a particular data set, observed when and how teachers referred to race as a rationale for selection (pedagogical or contextual), and identified a set of 12 rationale-based codes across teachers (e.g., "Opportunities for inquiry about race," "Examine a trend over time,"). The second phase examined in what ways teachers conceptualized race when the data sets were presented. Specifically, we explored the degree to which race was framed as a pedagogical concern for students' inquiry of data and learning about contemporary issues of power and injustice. The authors met for joint data review sessions, focusing on what was being discussed in a data set and how social phenomena were being evoked by the teacher in relation to their learning goals for students.

Results

How do teachers engage with matters of race in their judgments of data sets?

Teachers varied in the extent to which they centered race in their noticings and its role in student learning. Some articulated the importance for students to learn about contemporary social issues while others expressed pedagogical affordances provided by race (for example, the ability to make statistical comparisons by racial subgroupings). Others expressed hesitation or resistance toward the centrality of race within the data. The following sections represent teachers' divergent responses toward race and pedagogical potential of data sets.

Race as essential to consider

For three teachers (one Black, one Latinx, and one White), their final choice of a data set was supported by their perception that data could better enable race to be a discussion topic informed. For the two teachers of color, this appeared for only the policing data. For the other teacher, who is White, it appeared across both policing and employment data. As was the case across teachers' judgments about data sets, there was much complexity in what

 © ISLS

pedagogical value was recognized. To illustrate, we provide an excerpt from Gavin, a Black male teacher in an urban school, who elaborated upon his preference for selecting policing data set 2:

> "So, if I had to pick one, I think once again, the one on the right [data set 2] is just more interesting. I think it's more mature, and I would definitely do it with a mature set of students. But I think the conversation doesn't have to be White versus Black. I think it's important that we do talk about Native Americans, that we talk about Hispanics, that we talk about Asians. I feel like our society is so Black and White sometimes that's what we focus on." (Gavin, interview transcript, p. 22-23)

Key aspects of this portion of Gavin's comment that we noted include: the data pertained to a topic that would be more interesting to students, (perhaps relatedly) they engaged topics requiring certain levels of maturity, and that they would support the teacher's desire to have students develop expansive, rather than dichotomous, recognitions of how race is present in society. Gavin further expanded on his preference for data set 2 with:

> "But here, we have a diverse amount of crimes, we have a lot of data about different groups of people, and, murder, rape, prostitution, sex offenses, we don't talk about these things, but these things are real. And when are you ever going to talk to kids about these things?" (Gavin, interview transcript, p. 23)

Here, we noted that Gavin was attending to breadth and diversity in the data. The data had exploratory possibilities with numerous possible categorical values to examine. Being under-engaged as a topic ("we don't talk about these things") and relevant "these things are real" also factored into Gavin's justification. As will be illustrate below, this quality and its use for teaching varied. Several other teachers in our study cited the association between race and crime as a reason to *avoid* data set 2 because such topics featured prominently could unknowingly trigger some students or reinforce specific negative discourses regarding race and crime. However, with teachers like Gavin in mind, we could envision that valued data sets would have a breadth of categories to consider, would not shy away from complex social concerns, and might be made even more helpful if they were coupled with some recommended analyses and variable selections that Gavin could use with his students to explore and challenge assumptions and narratives that might exist around the topics of race and policing.

Race as a useful variable

While Gavin's statement that data set 2 provided affordances toward necessary classroom discussions about race as a general societal construct, far more teachers in our study (6 of the 11: 2 for policing, 2 for employment, 2 for both) emphasized pedagogical opportunities the race variables provided with respect to data inquiry more than the underlying matters of injustice that can appear in the data. In these teachers' purview, race as a variable might lead students to better query the data and make comparisons between subgroups. The following utterance by Brent (White male teacher) illustrates one such instance:

> I think what you have a great opportunity here to look at running your conditionals two ways. Which is, let's say I have side-by-side pie charts. Do I want to compare White people to non-White people? Or, do I want to compare the ethnicity breakdown of murder versus, what's a non-violent crime...property crime? … So, I think in that way, there's two different types of questions you could ask. You could compare one ethnicity to another, versus comparing one crime to another." (Brent, interview transcript, p. 19-20).

As Brent describes, the provision of two categorical variables (race and offense) affords students the opportunity to examine conditional variables, data displays of conditional variables, and appropriate graphical representations of conditional variables. In addition, a deeper investigation could be conducted by "running your conditional two ways," permitting students to learn various strategies and interpretations of data arrangements in association to statistical questions. Brent seemed comfortable seeing the ways in which common statistics topics could be engaged, yet this utterance did not show active consideration of the challenging history and the emotional dimensions of race. Teacher educators may see this as illustrating a need to help Brent and others learn how to recognize matters of injustice and how to thoughtfully and sensitively engage students so that they can see statistical ideas without disconnecting from the more complex social injustices reflected in the data.

Race as too sensitive to be paired with student learning

One other judgment of racial variables came in the form of anticipating students' sensitivities. Two teachers described words within data sets, or more broadly, the presence of race paired with offenses in policing data set 2, with negative valence as they envisioned how their particular students might feel about data. Acknowledging race was something teachers cold envision as being too uncomfortable. For example, when Iris (White female teacher) was asked where her students would struggle, she explained:

> "Every person has a different story and perspective and background, and is maybe triggered by this information more than others. When you're talking about sensitive topics like this, I think that people are going to be triggered. How do you come at this from an unbiased perspective? Biased. I think your bias...does bias have an effect on how we look at data? So yeah, can you totally take your bias out? With statistics, that's supposed to take bias away, you're just looking at numbers. But is that something we need to look at...this could be sensitive to a person or group of people." (Iris, interview transcript, p.19)

Iris suspected that "people are going to be triggered" with the policing data. Iris's utterance and justification reflects tensions regarding bias and objectivity in our thinking about data. According to Iris, data – "just looking at numbers" - should take bias away. At the same time, Iris is aware human bias does exist. Her statement seems to suggest that the bias may not be within the data but rather in the interpreter. Recall that our perspective is that data are social constructions that are made by humans with biases. This view that data are objective may be the type of issue that needs to be explored more deeply with teachers. Seeing bias as residing only on the side of the human who views data runs the risk of delegitimizing the experiences and concerns of students and limit teacher supported classroom examination of why the data look the way they do, both in their creation and in what may be inferred. At the same time, productively engaging with data (while also recognizing that bias exists within data) is another matter that teachers need support to explore.

Discussion

While it is a modestly-sized study, this examination of teacher judgments about data sets where race is a prominent variable suggests there is visible variation in how teachers think about race and data. The variation among even our small sample of teachers regarding if and how race should be engaged in data sets invites questions about how to best support teacher growth – through professional learning and with designed curriculum.

Notably, the teachers in this study were attending to both their conjectures of data science instruction and perceptions of race within data sets simultaneously. Our findings do not yet take teachers' uncertainties of data science (Manz & Suárez, 2018) into consideration. Future analyses will develop a more nuanced coding scheme that considers the interaction of race, data science, and teachers' inherent uncertainty when making in-the-moment judgments. Yet, our work thus far offers preliminary insights to how teachers consider race in data sets in relation to their students' opportunities to learn. In the learning sciences, important learning interactions such as racial-ideological micro-contestations are beginning to be recognized. The work here may help us identify means to ensure that teachers can make such moments thoughtful and informative about the nature of data and the social world of which they are a part.

The Emotional and Corporeal Dimensions of Belonging to STEM Education

Sarah El Halwany, Jennifer D. Adams
sarah.elhalwany@ucalgary.ca, jennifer.adams1@ucalgary.ca
University of Calgary, Canada

Abstract: This paper explores the politics of belonging in STEM education contexts by foregrounding emotions as an analytical lens. We show how political projects of belonging are constructed/resisted *affectively* in two different STEM postsecondary contexts, within a technical college and a university in Canada. Belonging is examined along two interrelated dimensions: having the 'right' kind of body and emoting in the 'right' kind of way. Those dimensions reveal subtle and pervasive practices of exclusion and marginalization as science students experience their belonging to STEM fields and to Canada. We discuss how a multi-scalar analysis of bodies and emotions in relation to various spaces and various social relations could reveal more layered understandings of how bodies become distributed/valued within STEM fields.

Theoretical background and purpose

Research on emotions in science education have been garnering increased attention (e.g., Bellocchi et al., 2016). This is in response to a cognitivist bias in science education, that has been attributed to "a long-standing Newtonian–Cartesian tradition of separation, prizing apart the mind and body, divorcing and polarizing reason from feeling" (Alsop & Watts, 2003, p. 1044). Various methodological, theoretical, and empirical approaches have highlighted how emotions are part and parcel of social practices of teaching and learning in science learning environments (e.g., Tobin & Llena, 2014). For instance, inquiries into classroom's emotional climate take situated and sociocultural perspectives when studying emotions and as such "overcome the limitations of examining emotions as individual psychological constructs" (Tan, 2013, p. 553) that could naturalize emotions and fixate learning within individuals. Other similar research traditions have examined how emotions are not just passive impulses that happen to us but are "fabrications manufactured and maintained through corporeal and discursive means" (Butler cited in Chubbuck & Zembylas, 2008, p. 279). Drawing on poststructuralist thought, researchers have argued that analyses of emotions from socio-cultural traditions have been limited to micro-processes of interaction without addressing how emotions are discursively and materially constituted and constituting. Focusing on the performative nature of emotions (Zembylas, 2015), responds to calls from within the learning sciences to develop "theories of power, to explain how power circulates in contexts, how it aligns with structural oppression, how it challenges oppression, how it is subtle, and explicit, pervasive, and yet often invisible" (Esmonde & Booker, 2017, p. 2).

Notions of belonging elicit emotional attachments to collectives and imaginaries and are especially relevant when considering institutional practices of exclusion and marginalization within STEM education (Nxumalo & Gitari, 2021). Avraamidou (2019) argued that emotions could be a valuable lens for studying experiences of inequalities and othering and what it means to 'become' a science person in relation to various systems of oppression and recognition. This paper explores the politics of belonging in STEM education contexts by foregrounding emotions as an analytical lens. We demonstrate how political projects of belonging are constructed/resisted *affectively* in two different STEM postsecondary contexts. We examine emotionality in students' lived experiences not only as *reflective* of the "dirty work of boundary maintenance" (Crowley, 1999) but as *constitutive* of how particular collectivities are made to belong. We draw from Sara Ahmed's work who looks at what emotions *do* and less on what they *mean*. A performative view of emotions examines how emotions work "through signs and on bodies to materialize the surfaces and boundaries that are lived as worlds" (Ahmed, 2013, p. 191).

Inspired by Sara Ahmed's various writings including but not limited to the *Cultural Politics of Emotions* (2013), this paper attempts to release belonging from its self-referential associations and positive undertones (sense of belonging and feeling 'at home') to consider the political landscapes of belonging (see also Yuval-Davis, 2006) as they are formed and reformed through daily affects and emotions experienced by Black, Indigenous and People of Colour (BIPOC) in postsecondary STEM programmes. 'Positive' emotions are not necessarily positive, as they might be connected to narrow conceptions of happiness (Ahmed, 2008) and lives of normativity (Berlant, 2011), inherited from within Western, colonial, capitalist, middle class societies. This helps to situate the

 © ISLS

micropolitics (of lived/bodily experiences of racialized bodies) in relation to macropolitics (of racialized and racializing systems) (Mulcahy & Healy, 2021). Political views on belonging allow us to explore how STEM educational contexts extend the "political and affective economies of normativity" with the "production of a collective will to imagine oneself as a solitary agent who can and must live the good life [read also happy life, Ahmed, 2008] promised by capitalist culture" (Berlant, 2011, p. 167). This has particular significance to contexts of postsecondary STEM, that prepare future workers to enter in relationship with the economy and places of labour and livelihood.

Methodology

To explore the corporeal and emotional dimensions of belonging we bring together two data sets; one is from an ethnographic study of a college microbiology laboratory at a Canadian technical college and another data set draws from BIPOC students' responses to an exploratory survey of their experiences in postsecondary STEM university programmes in a university setting in Western Canada. The ethnographic study comes from the first author's doctoral research whereby notions of belonging to Canada via STEM education became salient through her various interactions with international students from India. The other data draws from an exploratory survey of BIPOC students' lived experiences navigating STEM institutional structures, the first author's postdoctoral work alongside the second author. Together, these data sets allow us to view how students' emotions work "to create the very distinction between the inside and the outside" (Ahmed, 2004, p. 28), vis-à-vis STEM as a disciplinary space and STEM as connected to nation-belonging.

Data sources from the ethnographic study included video recordings accompanied by fieldnotes of laboratory practices (e.g., students testing the effect of different products on bacterial growth), semi-structured interviews with the students at the beginning of the course related to their experiences coming from India and living in Canada and ongoing discussions with the instructor about their emerging observations. For the purposes of this paper, we only draw on those data sources to focus on data excerpts where themes of belonging were particularly apparent. For our analysis, we combined thematic coding with collage as a data analysis practice (Morgaine, 2018) involving a juxtaposition of fragments of data, arranging and rearranging them together to enable an analysis of the micropolitics (Bazzul, 2017) of belonging in relation to different scales (to STEM as a belonging to discipline or STEM as belonging to a nation) and in relation to students' actual practices in the lab at the college level alongside students' reflections on their general STEM experiences at the university level. Hence, this study takes a space-sensitive approach to the study of intersecting social relations to examine how "different aspects of belonging such as class (socio-economic), gender and race (body or corporeal aspects), ethnicity, and ethical/political value systems (representative and performative aspects) assemble in certain locations and situations" (Youkhana, 2015, p. 15-16) and how emotions work to constitute and reconstitute those assemblages.

Discussion of findings

Our analysis of the data from the two data sets enabled us to examine political work of belonging being exhibited along two interrelated dimensions: Belonging as having the 'right' kind of body and belonging as emoting in the 'right' kind of way. We present those two dimensions separately to examine how political projects of belonging circulate and are enacted/resisted through bodies and emotions.

Belonging as having the 'right' kind of body

Most of the students in the college microbiology lab were international students from India. In various interviews with students, they discussed their experiences of being channeled into this program by college recruiters and agents back in India as their only entry ticket to Canada. Intersecting with students' ethnic and immigration status, another noteworthy observation was that women formed the majority of students in this lab, constituting 17 out of 18 students. Nived, the instructor, commented how this is not surprising since "most students will become biotechnicians, following protocols". This comment demonstrates how the program extends women as docile and compliant, doing what they are told, by 'following' protocols. In this sense, what it means to have a body in this particular context is configured along racial and gendered lines, reducing bodies to "their working parts" (Kimmerer, 2013, p. 49) through tedious and repetitive lab practices and an overemphasis on performing the 'right' techniques (as was evident through observations of pedagogies of the lab). STEM college programmes along with formal and informal channels of migration contribute to differential valuations of bodies, perpetuating gendered and racialized allocations of labour (Vora, 2015) for Western economic gains. This helps to complicate what it means to belong to STEM beyond acquiring the right bodily dispositions of a biotechnician to consider how learning/belonging in this context are situated within larger gendered, racial, and capitalist formations. We

juxtapose this analysis with an undergraduate student response on a survey describing his experiences of marginalization and discrimination as a South Asian inside a university lab setting:

> Often in science labs, sometimes when paired with people who are Caucasian, I have experienced lab partners who would disregard my physical being and *turn towards other white people* with whom they prefer to talk with. I don't think that was an intentional racist instance, I just have found that often when I am paired with Caucasian males in particular, that they *don't know how to converse with me, want to converse with me or know how to relate to me*. Feel somewhat lesser than them.

In this case, we witness how practices of exclusion take place through bodily orientations that reinforce the idea that to belong to the lab, one needs to have the 'right' kind of body (in this case, a Caucasian male body). Those self-reflective and narrated experiences of marginalization could be equated with the subtle and pervasive practices of inclusion/exclusion, evident in the context of the college microbiology lab. These analytic examples gesture at how material places (the college lab vs. the university lab) intersects with social relations to produce the ways that belonging to STEM is encountered/experienced. They both center belonging through corporeality as particular instances of having the right kind of body in STEM places, though each data segment is more nuanced in how different STEM bodies become constituted as 'less'; this might happen in the moment (in transient bodily orientations of turning towards/ away) or in more pervasive and infrastructural arrangements (with the prevalence of particular bodies in specific places).

Belonging as "emoting in the right kind of way"

When students were working in the lab, they often turned to each other or to their instructor to discuss their plans for working and living in Canada. Hence, accompanying their ordinary lab practices, appears to be a spectral presence (with its associated fears, anticipation, anxieties, and hope) of wanting to belong with Canada through their labour in STEM. Such 'positive' and hopeful outlooks for the future work to further normalize precarious conditions (Veldstra, 2020) faced by international students as they experience their belonging to Canada. Asked to project themselves five years into the future, many mentioned having emotional and financial stability in Canada:

> Anushka: After 5 years, either I am working in my pharmaceutical industry, or I will clear my pharmacy test and become a pharmacist here, *I don't want to go back to India.* In between I will get married and have 2 babies. I just need the perfect husband for me.
> Nisha (jokingly): Don't worry, we will *find a Canadian husband* for you.

Careful not to downplay international students' visceral dreams and hopes for a better future, for Anushka, STEM was a pathway for belonging to Canada. However, becomes quickly gendered and racialized through becoming a wife to a "Canadian" man and mother. Juxtaposing the positive with the negative, emoting "wrongly" works to reproduce exclusionary boundaries, as evident in a student's response in the survey data:

> I am constantly seen as *an angry person when I am outspoken about my mistreatment*. Sometimes it feels as though my value is to entertain white folks in STEM, something to make fun of, something to tokenize.

This student self-identifies as Korean and, in this statement, we could see how anger turns to a technology of racism (Zembylas, 2015) that produces bodies in opposition to other 'composed' bodies, the white folks in STEM. But also, anger serves to disturb and challenge the "ordinary affects of racialization" (Mulcahy & Healy, 2021). Being an angry person is likened to a "kill-joy" (Ahmed, 2008), someone who disturbs belonging to/of whiteness in STEM education contexts. Reading students' practices in the microbiology lab alongside students' responses to the survey, we notice how students in STEM "acquire certain subject positions based on regulatory norms of social and political affect" (Zembylas, 2016, p. 206), that delimit/resist imaginaries of belonging at multiple intersecting scales, spaces of STEM education and Canada.

Conclusion and implications

Attending to the *work* of emotions enables an appreciation of how constructs of belonging conceal non-innocent relations with possible implications for justice-oriented efforts in STEM education. Our study also showed the possible merits in analytically attending to the affective and corporeal aspects of belonging within situated practices and discourses in STEM contexts to examine how micro-meso-and macro levels of analysis are co-

constituted (Philip & Gupta, 2020) and to better highlight and along with that, imagine pedagogical possibilities within microlevel interactions, where agentic individuals "improvise with ideologies and practices that may otherwise appear static and inevitable" (p. 196). This is an area that we hope to keep expanding on. Our analysis also showed how a multi-scalar analysis of bodies and emotions in relation to various spaces and various social relations might reveal more layered understandings of how bodies become distributed/valued within STEM fields.

Using Design-Based Research in a computational thinking and programming course with Pedagogy students

Claudia de Oliveira Lozada, Federal University of Alagoas, clalloz@yahoo.com.br

Abstract: In this paper we approach the importance of Design Based Research (DBR) as a tool for redesigning learning architectures in extension courses aimed at the continuing education of Basic Education teachers in order to improve professional learning and promote the development of Technology, Pedagogy and Content Knowledge (TPCK) and its subdomains. Therefore, we present a qualitative research carried out during an extension course on computational thinking and programming language aimed at future teachers who will work in the early years of Basic Education promoted by the Federal University of Alagoas (Brazil). The research results showed that the DBR made it possible to redesign the course activities in a collaborative way, observing the participants' difficulties, which led to the beginning of the development of the TPCK by the researched group, requiring that skills in computational thinking and programming language evolve to that TPCK is fully developed and manifested in pedagogical practices.

I. Introduction

The Common National Curriculum Base (2018), BNCC, a new guiding document for Brazilian Basic Education, places as one of its general competences the insertion of digital culture in schools, as well as citing the use of technologies in the specific competences of the different curriculum components, teaching and learning process. In the characterization of the area of Mathematics and its Technologies, BNCC recommends for Basic Education that topics such as robotics, automation, artificial intelligence, programming and digital games be addressed.

Although the BNCC brings these curricular innovations related to technology and its themes, there are other factors that directly influence the implementation of these proposals in Brazilian public schools, such as the lack of equipment and teaching resources and lack of teacher training to apply the proposal in your classes. This issue is basically due to the lack of more effective public policies in relation to the insertion of technology in public schools of Basic Education, which implies a huge investment and generally the justification is that the existing resources are not sufficient, and in view of that, little is invested, which does not generate large-scale effects. On the other hand, it is necessary to reflect on the didactic resources that are used in these technological proposals aimed at Education in Brazil. In general, we have few technological didactic resources for teaching programming language that are genuinely Brazilian, that is, that are developed for the profile of Brazilian students and teachers, and thus, adapted foreign didactic resources are used. Thus, it is necessary to invest in software development considering the characteristics of the student and Brazilian education, considering the assumptions of Design Based Research and Learning Sciences - areas that have not yet been consolidated in Brazil as a field of research - which are fundamental to contribute to improve the teaching-learning process of topics such as computational thinking and programming language. Therefore, in this paper we present the results of a research that addresses Design Based Research (DBR) as a tool for redesigning learning architectures in an extension course on computational thinking and programming language aimed at the continuing education of Basic Education teachers of the State of Alagoas, Brazil, to improve professional learning and promote the development of Technology, Pedagogy and Content Knowledge (TPCK) and its subdomains.

II. Preparing teachers to work with technology and the importance of Design Based Research in teacher training courses

It is important to plan the training of Basic Education teachers in Brazil to use technologies in the teaching-learning process and the digital skills and abilities that need to be developed so that they can implement educational proposals in the classroom. It is necessary that the curricula of the Pedagogy and Licentiate Degree courses expand the workload of the subjects focused on the use of technological resources, deepening their approach in order to train teachers on the use of different resources even in their initial teacher training, as in general, in Brazil there is little emphasis on this aspect, and this is reflected in teaching practices. In general, the use of technological resources in the teaching-learning process has been emphasized in continuing education courses or refresher courses, which are often opportunities for many teachers to learn how to handle the resources, as many teachers were unable to develop handling skills when they were attending graduation (due to the short time that the courses devoted to practices with these resources) or they graduated at a time when these resources

 © ISLS

did not exist or were not yet used in the teaching-learning process of public Basic Education schools, therefore, there was no in his initial formation a discipline that addressed technologies in Education.

BNCC (Brasil, 2018) has ten general competencies as pillars to ensure the learning and development of Brazilian students in Basic Education. Among these ten general competences is general competence 5, which concerns digital culture, which is structured around three basic elements: digital literacy, digital literacy and digital fluency. This competency must be developed so that Brazilian students can understand and use digital information and communication technologies in a critical, reflective and ethical way in various social practices to communicate, access and disseminate information, produce knowledge, solve problems and exercise protagonism. However, the insertion of digital culture in the Brazilian school context is not only aimed at students, it also encompasses teachers. The BNCC (Brasil, 2018, p. 17) states that Brazilian teachers should be encouraged to "select, produce, apply and evaluate didactic and technological resources to support the teaching and learning process", integrating technology in their classes, renewing their pedagogical practices, and, in this way, bringing them closer to technological contexts that are part of the daily lives of students.

In this sense, Mishra and Koehler (2006) proposed a theoretical framework called Technology, Pedagogy and Content Knowledge (TPCK) stating that teachers need an integrated knowledge of technology, pedagogy and content to develop professional skills that allow the adoption of activities oriented towards the use of technology in the teaching and learning process of specific content in classes. The authors subdivide the TPCK into three subdomains: knowledge of technology (TK), which concerns knowledge about how to use hardware, software and associated peripherals, knowledge of technology content (TCK) which refers to knowledge about how to use the technology to represent and create content in diverse ways and the knowledge of pedagogy and technology (TPK) which concerns the choice of a technological tool based on the aptitude for the learning activity.

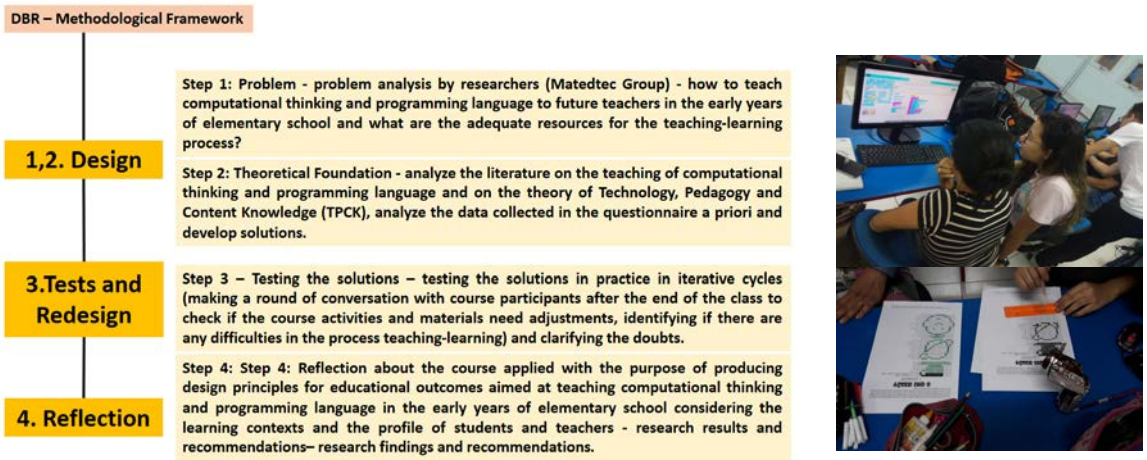
To improve the acquisition of integrated knowledge, Mishra and Koehler (2006) state that teachers must work collaboratively to redesign the curriculum for the TPCK approach, likewise breaking down beliefs and resistances regarding the use of technology in the classroom. Bennison and Goos (2010) also defend this integration with technology for teaching specific content through courses that enable the professional development of teachers, as they improve knowledge, understanding of the use of technological resources in classes and enhance skills. Drijvers (2015) emphasizes the importance of integrating the use of digital tools with activities that use pencil and paper (unplugged) in the teaching-learning process, demonstrating that these resources are complementary and not exclusive, and that neither one overlaps the other. Thus, considering the importance of computational thinking and programming language and its insertion in the early years of Basic Education in Brazil, we held an extension course with the purpose of improving professional learning and promoting the development of Technology, Pedagogy and Content Knowledge (TPCK) and its subdomains (with emphasis on TCK and TPK), enabling teachers in relation to computational thinking and programming language, and for that, we used Design Based Research to configure and redesign the extension course.

Design Based Research (DBR) is still little known and used in Brazil, being an approach that enables educational innovation from collaborative practices considering the needs and problems that teachers point out in their classrooms. There is disagreement regarding how to name the DBR, as there are authors such as Easterday, Lewis and Gerber (2014) who call it a process, Herrington *et al* (2007) claim that the DBR consists of a research approach and Barab and Squire (2004) argues that DBR consists of several approaches. Wang and Hannafin (2005) define Design Based Research as a systematic methodology and flexible aimed to improve educational practices through iterative analysis, design, development, and implementation, based on collaboration among researchers and practitioners in real-world settings. We conclude that the DBR is an approach that implies a process of analysis, design (redesign), development and implementation, which is collaboratively built to trigger a pedagogical solution more suited to the characteristics of subjects and their contexts, contributing to the emergence of theories and design principles for the learning environments of schools, with the classroom being the most common and most used, which may extend to laboratories and maker spaces.

The themes of computational thinking and programming language in Brazilian public schools have always been addressed in a timely manner or through isolated projects, usually with few resources (lack of teaching material such as robotics kits, software, laboratories), but which promote a lot of engagement of the students in the proposed activities, stimulating their interest in participating in the classes. These themes are usually addressed in Mathematics classes because teachers are able to establish a direct relationship with the notions of logic. The computational thinking and programming language gained prominence after the publication of the BNCC (Brasil, 2018) when these themes were recommended to be developed in Basic Education. But, when placing computational thinking in the school context, it is necessary to remind teachers that they will design, apply the activities and select the didactic resources that will be used in pedagogical practices, and for that, teachers must develop skills to deal with the technological resources and also with the concepts that involve computational thinking. This contact with computational thinking should still occur in initial training, but if it

doesn't, continuing education is also a space for it to be developed along with the programming language. In this sense, considering the theoretical bases briefly exposed, we carried out a qualitative research with the purpose of contributing to the initial teacher education in relation to computational thinking and programming language, and for that, we raised the following research question: Which subdomains of TPCK the Will future teachers from the early years working in schools in Maceió (Brazil) be able to develop a course on programming language and computational thinking considering the contributions of DBR as an approach for setting up and redesigning the course based on the needs of the participants? To identify these TPCK subdomains that future teachers could develop, we designed and applied an extension course based on a cycle of DBR that we developed. This research qualitative was carried out during the month of August 2019 through an extension course that was a partnership between the Federal University of Alagoas and the Pedagogy course of a Private University in the city of Maceió, Alagoas, located in the Northeast region of Brazil. Below, we bring our cycle of DBR - Methodological Framework - developed for the extension course on computational thinking and programming language:

Figure 1 – Methodological Framework DBR Cycle (Lozada, 2019) and Extension Course classes on computational thinking and programming language



The DBR cycle that we developed allowed us to visualize the learning route for the development of the TPCK for future teachers and the movement of redesign and reflection on the activities developed for the course. In this cycle of DBR, we highlight the importance of the iterative process in which it was possible to make changes in course activities based on the needs of the participants.

The a priori questionnaire identified the profile of the course participants and the knowledge they had so that we could design the course adapting to their profile, and for that, we used Design Based Research (DBR), making previous tests of the activities that would be applied in the course and changes that were made throughout the application of the course with the collaboration of the participants. After critical and reflective analysis of the a priori questionnaire and cross-referencing with educational data, we designed the DBR cycle that we would go through to elaborate the activities that would be applied in the course, considering the technological infrastructure that public schools in Maceió had at the time the research was carried out, since most schools did not have technological resources and this aspect was essential for us to find an alternative so that future teachers (Pedagogy students) could develop computational thinking and programming language in their classes. The DBR cycle that we developed brings research into the problems and needs of teachers in Maceió, offering tools for improving teaching and for decisions in Education, especially those related to public policies for the implementation of technological resources in the teaching-learning process considering the real contexts of Maceió and its schools where teaching is offered. The course was taught in the computer lab and consisted of a theoretical and a practical part. The theoretical part addressed the fundamentals of computational thinking (decomposition, pattern recognition, abstraction and algorithm) and programming language (language by blocks and by script) for Basic Education and the practical part consisted of unplugged activities (with activities of pencil and paper) and plugged in (with programming activities using Scratch, Code and Kodable). Of the 30 enrolled in the course, 23 completed it.

III. Findings and Discussion

The survey data collection instruments were questionnaires (three questionnaires: a priori, intermediate and a posteriori) and activities (unplugged and plugged in). The a priori questionnaire indicated that 57.1% had already heard and read about the programming language and 33.3% had never heard the programming language. We

highlight some answers from the intermediate questionnaire: Regarding having had some difficulty with unplugged activities, 11.1% said they had no difficulty, but one of The activities in which they presented difficulties were in the pizza ordering algorithm activity, which involved mathematical calculations about the value of the pizza, and in the pizza delivery activity, which involved the calculation of the time spent in moving from one place to another. About understanding the notion of algorithm, 57.1% said they understood the notion of algorithm; about understanding the notion of programming logic, 66.7% said they could understand and 33.3% said they understood more or less. About understanding programming language types (by syntax and by blocks), 66.7% said that they understood the programming language by syntax and by blocks. About the game "Paper computer programming with the human robot" that was played in the University courtyard: 28.6% said they had difficulty understanding the commands, 14.3% said they had difficulty organizing the programming sequence, 23, 8% said they had difficulty understanding how it is performed (how the human being moves in the space given from the commands). Regarding learning objects, 52.4% considered the Kodable to be an easy level, about the Bee Code, 33.3% had no difficulties with the commands, 42.9% more or less understood the commands. Regarding Code Angry Birds, only 9.5% had difficulties in understanding the block commands and the sequence. About the a posteriori questionnaire, we highlight some questions and their answers: about the Scratch level, 78.3% considered it to be of average level and 56.5% managed to learn the commands, with 43.5% learned more or less the commands, what we had already seen during classes and conversation circles when they talked about the difficulties. About the commands with which they had the most difficulties, they pointed out the following: 30.4% with the sensor command, 26.1% with the variable command and 17.4% with the operator command.

From the results of the course, we were able to identify some aspects that are essential to reflect on teacher education in the Pedagogy course: the responses to the intermediate questionnaire, to the a posteriori questionnaire and the dialogue in the conversation circle during the iterative process of the DBR demonstrated that that group of students in the Pedagogy course had little ability to program and this is due to the lack of contact with the language of programming and computational thinking and basic notions of logic, in addition to not being able to associate the composition of an algorithm in a situation of the day daily life with a typical language of writing an algorithm with sequences and commands (formalization of the programming language); it was easy to identify errors in the execution of commands by the course participants, but they had some difficulty in correcting them, as the writing of the algorithm demands a logical sequence with specific commands that were often not fully understood by the participants. The lack of contact with digital learning objects for learning the programming language triggered the beginning of the development of knowledge of technology content (TCK) which refers to knowledge about how to use technology to represent and create content in different ways and the knowledge of pedagogy and technology (TPK) which concerns the choice of an aptitude-based technological tool for the learning activity. The evidence of these subdomains in the questionnaires and in the activities was evident when they showed improvement in the understanding of most of the commands and in the performance of the activities. This advance stems from the DBR cycle, with the iterative process that allowed Pedagogy students to present suggestions for changes and adjustments in activities and clarification of doubts, in a collaborative redesign movement, without harming the level of activities. Finally, we consider this work as a starting point for other actions that promote teacher training on computational thinking and programming language, recommending that this work is also carried out by the education departments in training processes that expand to schools during their working hours. collective pedagogical work (HTPC), as the development of the TPCK is an ongoing process.

An Exploration on the Individualistic and Collective Moves in Relation to Equitable Participation in Collaborative Game-Design Processes

Yu Xia, Charles Keith, Shulong Yan, Marcela Borge

Abstract: Collaborative learning environments are not inherently equitable. Learning opportunities might favor some group members over others and an inequitable collaborative learning environment would emerge. To promote equity in participation structure, we explore the relationship between individualistic/collective patterns and (in)equitable participation of one group of three girls. We analyzed a 75-minute session of game design using Bloxels and revealed the complexity in the nested relationships between individualistic and collective moves and (in)equitable participation structure for learning groups. We further discuss the implications for supporting an equitable learning environment.

Designers often work in collaborative teams to solve design problems (Brown & Wyatt, 2010). Integrating design into learning environments could provide plenty of opportunities for children to develop collaborative competence. The current study takes place in such collaborative design learning environments for children where student groups were engaged in a game-design activity. Collaborative learning is a complex phenomenon that involves cognitive, socio-emotional, metacognitive, socio-cultural, and historical aspects where individual and social processes play critical roles. For this reason, collaborative learning processes are often inequitable, with some group members having less access to learning opportunities than others. The understanding of collaboration as a complex phenomenon calls for a research method that looks at the collaborative process from iterative relationships between individualistic and collective moves (Gillespie & Cornish, 2009). Thus, there is a need to move beyond individuals or groups as units of analysis toward identifying individualistic and collective learner moves and their effects on collaborative learning processes and outcomes more generally (Borge & Mercier, 2019). Each individualistic or collective move can contribute to the overall social process to amplify or attenuate the learning opportunities for individuals or the group. As such, we answer the following research question: what is the relationship between individualistic/collective patterns and (in)equitable participation in small group collaborative learning? To answer this question, we conduct interaction analysis to first explore the different individualistic and collective moves, and then analyze how those moves help or hinder the equitable participation from all members.

Methods

In the afterschool program, small groups of 3rd to 6th graders were tasked with solving design challenges. One activity was to use Bloxels to design, play, and share their games using various tools, such as paper and pencils, iPads, and Bloxels kits. Student designers began by using grid paper or the Bloxels kit to create game elements such as characters, backgrounds, and bonuses. Then, designers needed to use the iPad Bloxels application to scan sketches or the Bloxels board to import, edit, and store designs, and further link game elements together. In this paper, we analyzed Group 4 (G4) of three 4th-grade girls– Sadie, Serena, and Evelyn (pseudonyms), as they were sketching, importing, and editing designs in the Bloxels application during Session 3. We conducted multimodal interaction analysis, drawing upon Jordan and Henderson's (1995) and Jewitt et al.'s (2016) works. We identified "hotspots" of individualistic and collective moves as G4 interacted with each other and with tools and artifacts. We analyzed discursive practice (Stahl, 2006), spatial practice (Xia & Borge, 2020), and mediational tools/artifacts (Wertsch et al., 1993). Two types of spatial practices were examined: 1) the participation structure of the group members (i.e., the bodily posture that group members assume, how they position themselves) and 2) the spatial organization of tools and artifacts (i.e., how and where the tools and artifacts were placed in relation to the participants), as who was using the tools and producing the artifacts for how long and where these tools were placed and by whom are key to understanding the inequity issues.

 © ISLS

Findings

We found six discursive and tool-based actions and practices associated with individualistic moves. Discursive actions included 1) seeking teacher/facilitator support before asking or problem-solving with groupmates, 2) refusing collaborative work invitations and insisting on individual design, and 3) not take responsibility to communicate ideas clearly to the group. In relation to tool-based practices, 4) tools and artifacts are physically placed in ways that offer partial or zero access from other group members, 5) individuals dominate the use of tools or artifacts, or 6) members fight over the use of tools and artifacts. Overall, individualistic actions did not contribute to the group design process nor create opportunities for group members to learn and grow. For example, seeking out facilitator support without first seeking group support did not create prevented opportunities for collaborative problem-solving. Also, dominance over iPad use, created inequitable participation. However, it is possible to transform these individualistic actions into collective moves. In the case of seeking help from facilitators, if the facilitator or other group members address the problem in front of the whole group, it can create opportunities for collective reflection and problem solving. Also, if the group member who insists on doing individual design can find ways to incorporate their designs into the collective design, they can still contribute to the group design process. However, individualistic actions need early intervention or else risk developing into more problematic patterns detrimental to collaboration.

We found ten discursive and tool-based actions and practices associated with collective moves. Discursive actions included, 1) actively engaging each member in social interactions; 2) actively bringing members to the group design process by explaining what they have done, or propose/accept joint working; 3) actively self-disclosing: group members speaking out loud about what they work on; 4) actively seeking feedback or patiently waiting for input from each member, integrating all members' ideas into the group design artifacts; 5) proposing rules or social scenarios that are inclusive to all ideas; 6) actively volunteering expertise in technology or design; and 7) actively volunteering perspective or information, positioning oneself as a valuable group member and her knowledge as resources. Tool-based practices included, 8) placing tools and artifacts in ways that offer access from other group members, 9) respecting other member's access to the tools, and 10) positioning themselves in ways that grant easy participation. These collective moves favored collective sense-making processes and indicated inclusive intentions. Nonetheless, some collective moves could inadvertently lead to inequitable participation. For example, if one member's active discursive moves did not get uptake from others, they might retreat into individual work. Also, we recognize that volunteering expertise is important for the volunteer in developing identity as a capable collaborator and designer, but in one example, one group member volunteered her expertise multiple times, and the other member responded, "yeah, and you just want to use my TURN," which showed how this move barred the other from engaging.

In this session, we describe an instance from the data to further explain different types of actions and their relations to inequitable participation in the small group. Session 3 began with a brief introduction between the three girls. Sadie and Serena had worked together in previous sessions, but Evelyn had not. Sadie took Evelyn's feelings into account when introducing the existing designs to her, saying "you're gonna be mad at us [herself and Serena], but we kind of have a lot of designs." Presenting shared ideas with Evelyn created an opportunity for her to become an equal contributor, leading to continued reasoning within the group throughout the activity (Mercer, 1996). Collective moves such as this provided a foundation for team equity and effective collaboration. However, around 9 minutes into the session when Evelyn introduced the story block that she had designed, Serena, who did not understand the story block process, quickly asked for the facilitator without consulting teammates first. This was one of the many times that Serena used this individualistic move; she often sought facilitators and did not rely on her teammates as reliable resources. Evelyn nevertheless responded to Serena's question after the facilitator responded, which was a collective move to help ensure the team understood her meaning of the term "story block." Even though groups might encounter problems that may eventually require external help, problems are learning opportunities where members can turn to each other as valuable resources (Simpson et al., 2017) and allow for more creative problem-solving to occur. Seeking early facilitator support eliminates this potential learning opportunity. Furthermore, this individualistic move could potentially lead to trust issues as other members do not feel valued as intellectual equals (Edmondson, 1999). Halfway through the session, the group showed a drastic change from distanced interactions with individualistic moves to closer interactions with the three working together, displaying the complex relationship between individualistic and collective moves and the participation structure, shown in the episode.

<tr><td colspan="3">[52:00] Group members worked on different tasks with Evelyn working on papers and Sadie started to dominate the use of the iPad (Individualistic). Serena kept closely watching the iPad. Evelyn later joined after she finished the paper design. They all contributed ideas (Collective).</td></tr>
<tr><td colspan="2">[56:00] As they all centered around the iPad and worked on their design, Sadie reached out the iPad so that everyone could see better and have easy access to the screen. This closely knit participation structure continued through the end of the session.</td><td> </td></tr>
</table>

This episode started with a domination of resources, mainly the iPad, by Sadie. Failure to communicate from Evelyn led to continued fighting over resources between Sadie and Serena. Additionally, this failed communication led to her lack of involvement and accessibility to resources. However, this shifted as the activity continued as Sadie began acting more equitably with resource availability within the group. While the iPad remained in her hands for the first part of this episode, it slowly became the centerpiece within the group as each group member crowded around and had equal access to the device. This positionality continued to play an important role in participation and equity within the activity, as Sadie took note of where to pull up a chair for her group member as she was cognizant of the positioning of the design materials and her partners in maintaining an equal structure. Sadie’s awareness of the positioning of the iPad in relation to the availability of material equity marked a significant collaborative move within the activity. While her actions remained dominant within the group, her awareness of her teammates’ lack of access to the device and her shift in position showed that she trusted and respected their contributions to the project (Edmondson, 1999). Sadie’s proactive actions led to effective synchronous groupwork.

Discussion and conclusion

This study examined the specific interaction moves while focusing on the equity issues in participation structures. Our group of three girls showed less individualistic types of moves than collective ones. In general, collective moves are encouraged since these moves are oriented towards achieving group level learning processes. However, our findings show that not all collective moves equate to equity. For example, while we encourage help offering and seeking to foster peer learning and group solidarity, if this type of learning behavior is not coordinated well and one group member constantly offers expertise by taking away the critical tool, i.e., the iPad application in this case, and directly working on the tool, this takes away other members' opportunities to learn. One suggestion in this case is to go beyond encouraging students to help each other, but also sensitizing them in terms of how to offer help such that all can learn from the experience.

We also want to highlight that in the illustrative episode, one student dominated the use of the iPad but then transformed the individualistic pattern into a collective one by consciously adjusting the tool and artifacts while incorporating every member's idea. Though the commonly used digital technologies, such as personal computers or mobile tablets, are easier for individual users given that it is designed for single users, our group of three girls showed their transformational agency in using tools that helped them break free from the given limits of tools. As such, we believe that in collaborative learning, student agency needs to be considered at the group level, which requires the members to be aware that the way they and the tools are positioned could be inclusive or exclusive and thus they need to be cognizant of each other and their group work.

All these findings are important to facilitators in such learning environments. For example, while facilitators might naturally identify the help seeking from group members to be desirable and showing their willingness to learn, our findings indicate that this might compromise the group's problem-solving opportunities. As such, facilitators are encouraged to be more cognizant of when and how to offer their own expertise. In future work, it would be interesting to factor into gender and conduct analysis on all male groups or mixed gender groups to see if there are other individualistic or collective moves that are not captured in the current study. Also, conducting a longitudinal study such as following the same group over one semester and even longer would yield insights into how children learn to balance their individual and group efforts to achieve equitable participation and, more importantly, how facilitators can help ensure the goal of achieving equity.

Middle School Students' Learning in Energy flow and Matter Cycling in the Ecosystem

Xuesong Cang, Dana Gnesdilow, Indrani Dey, Sadhana Puntambekar
xcang@wisc.edu, gnesdilow@wisc.edu, idey2@wisc.edu, spuntambekar@wisc.edu
University of Wisconsin, Madison

Abstract: An ecosystem is a complex system, including multiple layers of organization, complex interconnections among components, and invisible dynamic processes. Research shows that learners' often see energy and matter in ecosystems as mostly a linear, not cyclic, pattern. This study examined 35 students' energy and matter models at three points (pre, mid, and post) and interviews from 7 students during a Compost unit focused on ecosystems. We coded the models to examine students' understanding of energy and matter over time and included excerpts to show students' ability to identify system components and understand energy flow and matter cycling. We found that more students explained energy flow by including observable and non-observable organisms and process. Even though more students explained matter cycling as cyclic by including invisible process (decomposition), this was mostly at a superficial level. Students also conflated the terms "matter" and "energy", often using them interchangeably. This indicates a need to better assist students explicitly understand the two processes and how they are connected.

Key words: complex system, energy flow, matter cycling

Introduction

Complex systems consist of interactions between multiple components at different levels of organization as well numerous patterns that emerge from these interactions (Ladyman et al., 2011; Yoon et al., 2018). Although complex systems commonly occur in the physical and natural world, students find it difficult to comprehend their non-linear, dynamic, and sometimes invisible nature (Wilensky & Resnick, 1999). Being able to recognize and reason how these patterns emerge and behave is critical to understanding ecosystems (Hmelo-Silver et al., 2017). Instead, students tend to recognize visible, linear relationships among components of an ecosystem (such as a predator-prey relationship), as opposed to understanding invisible and cyclic relationships (Hayes et al., 2017). Making sense of the more complex, non-linear, invisible, relationships are fundamental for understanding the dynamic nature of ecosystems.

Liu & Hmelo-Silver (2019) found that virtual models can help students focus on the interdependencies among the different components in a complex system. Instructional supports, such as a combination of virtual and physical models, could assist students in focusing on the important aspects while the learning content is complex (Puntambekar et al., 2020). For our study, we developed a 14-week, design-based "Compost" unit combining virtual and physical models, aimed at helping students understand energy transfer (manifest in the macroscopic process) and matter cycling (a microscopic process) in an ecosystem. We investigated students' understanding of the relationships between the different ecosystem components. Our research questions were: 1) How did students' understanding of energy flow and matter cycling change over time? and 2) How did students illustrate their understanding of the ecosystem components?

Methods

Context of the research

Thirty-five eighth-grade students in one science teacher's classes from a midwestern middle school in the United States participated in this study. Students participated in cycles of inquiry to iteratively learn about the science of decomposition and ecosystems to solve a design challenge to create a compost that broke down quickly and contained a lot of nutrients. Students built a physical compost bioreactor, where they input materials (such as food scraps) and observed how their compost broke down (or not), based on what they added to the bioreactor. They also used a compost simulation to isolate, investigate, and visualize how specific abiotic factors (such as water, particle size, and carbon to nitrogen ratio) impacted the microorganisms in compost ecosystems, thereby affecting decomposition.

Data sources and analysis

 © ISLS

Energy and matter models

Students drew models to show how matter and energy flow at three points: before, at a midpoint, and at the end of the unit. Students included concepts such as sun (S), producers (P) (i.e., different plants), consumers (C) (i.e., different animals), dead organic matter (M), decomposers (D), and other abiotic factors. We created a coding scheme to assess students' models, with five levels of connections. A higher-level connection indicated an understanding of more complex connections between observable and non-observable elements. For example, the PMDP connection in level 3, PCMDP and SPMDP connections in level 4, and SPCMDP connection in level 5 showed that students understood the cyclical nature of how matter *cycles* through an ecosystem, i.e., decomposers break down dead organic matter down to its constituents, which is then available as nutrients in the soil for plants to uptake. Lower-level connections showed students' understanding of the linear relationships in the complex system, such as SP or PC.

Two researchers independently coded 23% of the data and achieved a 91.07% interrater reliability. The first author coded the remaining data. We used the non-parametric Friedman test to evaluate the overall differences from pre, mid, to post models. We then used the Wilcoxon Signed-Rank test to compare the connections that students made over time in each level, separately. We also examined the connections representing the cyclic nature of matter cycling.

Student interviews

Of the 35 students in this study, we conducted semi-structured interviews (about 30 minutes on average) with 7 students and asked them to interpret and explain their models. Excerpts from the transcribed interviews were grouped by three main topics: identifying system components, understanding energy flow, and understanding matter cycling.

Results

Changes in students' understanding of energy flow and matter cycling over time

We calculated the frequency of the number of correct connections between ecosystem components (e.g., SP, PCM, CMDP, etc.) in each level for all 35 students' pre, mid, and post models to examine learning over time. Using a Friedman test, we found that students included significantly higher-level connections in their models over time ($\chi^2_{(14,\ N=35)} = 362.97$, $p < .001$). Our follow-up pairwise comparisons using Wilcoxon signed rank tests, with a Bonferroni correction to control Type I error, showed students included significantly more level 5 connections from their pre to post, and mid to post models.

Students' connections of energy flow and matter cycling

As mentioned earlier, students often struggle to understand non-observable and cyclic aspects of complex systems. To understand how the Compost unit may have supported students' ability to recognize these relationships, we examined students' understanding of non-observable organisms and their interactions with other organisms in the ecosystem. The connections we examined are displayed in Table 1.

Table 1

Number of students who made connections at higher levels

Connections	Prior to curriculum	End of curriculum	Decomposition included or not	Linear or cyclic
SPCM (level 3)	10	19	No	Linear
PMDP (level 3)	0	10	Yes	Cyclic
SPCMD (level 4)	7	15	Yes	Linear
PCMDP (level 4)	3	13	Yes	Cyclic
SPCMDP (level 5)	2	12	Yes	Cyclic

When looking at students' connections related to energy flow at a visible and non-visible scale, we compared the number of SPMC (level 3) and SPCMD (level 4) connections students included in their models over time. Students made fewer SPCMD (level 4) connections than SPMC (level 3) connections both prior to and at the end of the unit. This indicates that understanding the direction of energy flow from matter to decomposers, which is unobservable in most cases, was challenging for students. However, when we compared the number of students who identified a SPCMD (level 4) connection prior to and at the end of curriculum, eight more students were able to incorporate these ideas into their model, showing that some students were able to build this understanding over time.

Next, we examined students' understanding of matter cycling as cyclic. We compared the number of students who made higher-level connections that incorporated the cyclic aspects of the complex system, PMDP (level 3), PCMDP (level 4), and SPCMDP (level 5) prior to and at the end of unit. We found that 10 more students included connections in each of these levels at the end of curriculum, showing that they made growth in understanding that matter cycling is a cyclic, rather than linear process.

Even though some students did make progress in understanding the cyclic aspects of the compost ecosystem, we found that the number of students who made linear connections was higher than students who were able to identify cyclic connections. Specifically, at the end of the curriculum, 19 students identified the SPCM (level 3) linear connection versus the 10 students identifying cyclical PMDP (level 3) connection; and 15 students identified the SPCMD (level 4) linear connection in comparison to 13 students with cyclical connection of PCMDP (level 4).

Students' explanations of their energy models

Students were generally able to identify system components within the ecosystem. However, we found that students had difficulty explicitly articulating what "matter" was. Further, some students conflated energy flow and matter cycling, using "matter" and "energy" interchangeably. For example, one student defined matter as "things that could be eaten, and the energy is compacted into food".

Energy flow in the ecosystem

We found that all 7 students were able to explain both the microscopic and macroscopic scales of organisms in the ecosystem (i.e., SPCMD) when discussing energy flow in their models, such as:

> "I started with the sun...our main source of energy for the producers sun goes to the producer ... grass gives energy to the cow...the consumers eat the producers and it's in chemical energy form, ... and then it goes as the consumers transfer energy ... I have some bacteria up here that ... could get energy from a decaying apple, and it eats part of it, and that's how it gets its energy"

In this example, the student explicated the process of energy being transferred from producers to consumers and further transferred to decomposers by breaking down (dead) plants/animals or leftovers from humans. While this student did not discuss breakdown of matter and uptake of these nutrients by plants, other students (incorrectly) discussed that energy is directly reused by plants at the end of the decomposition process.

Matter cycling in the ecosystem

Unlike in their descriptions of energy flow, where all students included information about the macro and microscopic scales, students' discussions about matter cycling as a cyclical process varied (see Table 2 for examples). In general, in more successful examples, students were able to articulate how matter was broken down by decomposers so that it could be used again by plants to start another cycle; Whereas, in less successful examples, students did not explain this. Further, even if students discussed matter cycling, their explanations were often vague and inaccurate.

Table 2

Examples of students' discussion of cyclic nature of matter cycling during interview

More Successful	Less Successful
"the matter is what humans, they eat it, and then what's left over that goes into the compost and then, earth worms and mold...eat that matter and then whatever is left that others things can't really eat is, um, is good for the soil and then producers can use it."	"when things die…the mold eats the matter, the dead matter, and the matter is mostly like it eats these because it's not like from the sun to the plants…[matter] is an actual thing, and it's not like just an energy flow. It's like the dead things...it's really hard to explain"

Discussion

We found significant gains in the complexity of students' understanding of these dynamic processes by including more components from mid to post models, demonstrating that some students could understand their interconnections. The students' increasing ability to see relationships between the ecosystem components revealed that their understanding of energy flow and matter cycling changed from simple to complicated over time. These findings are in line with prior studies which have suggested that students find it challenging to understand interconnections between components of complex systems (Grotzer & Basca, 2003; Hmelo-Silver et al., 2007)

We also observed that students could explain energy flow through both the observable and unobservable organisms in the ecosystem in their interviews. As other researchers have noted, students in this study found it less challenging to make connections between observable organisms and their interactions with the biotic and abiotic factors, as was evidenced by the frequency of level 1 and 2 connections made in their models. However, in line with Hayes et al., (2017), we found that a deeper understanding of the invisible processes such as the decomposition was less prevalent in students' written models. This highlights the importance of scaffolding students to see both the structures and dynamic changes in the systems (Opitz et al., 2017) to help them link the components to the processes.

Even though we made the unobservable processes of decomposition more observable via the compost simulation, many students did not include explanations about how matter is recycled and conserved (Grotzer et al., 2017). Similar to Lee & Liu's (2010) findings, few students included the highest-level connection (SPCMDP), between multiple levels of organisms in the ecosystem in their models and most were also unable to discuss connections at this level during their interview. Understanding decomposition at the microscopic scale is important for explaining the cyclical nature of matter cycling in the ecosystem.

Conclusion and Future Work

The combination of a physical bioreactor and a compost simulation in this unit may have helped students notice and learn about the unobservable processes (i.e., decomposition) occurring in ecosystems, since they showed a better understanding of decomposers' role in the ecosystem as well as the interrelationships among multiple organisms over time. Although some student's explanations showed growth in understanding energy flow, this was only a part of understanding the complex and interrelated nature of ecosystems. This indicates a need to better assist students in developing a more sophisticated understanding of the macro and microprocesses underlying the complex relationships between energy flow and matter cycling in ecosystems, specifically about decomposers' role in breaking down matter during decomposition. To help all students achieve a deeper level of understanding, more supports that enable students to explore and understand the role of decomposers and matter are needed. In future work, our aim is to understand how the compost simulation could better support students' understanding of the unobservable phenomena in an ecosystem, and how the simulation can be better integrated with the physical experiments.

Abstract: This work expands on process-based accounts of the intersection between play, learning, and failure. We examine middle school and college players navigating *Baba Is You*, a puzzle-based video game, based on prior scholarship in debugging and problem-solving. We document how players notice deviations, generate causal explanations, and revise their approach when problem-solving. Using qualitative interaction analyses and quantitative sequential analyses, this work shows how players approach the puzzle through persistent tinkering guided by generating causal explanations of game mechanics and providing revision rationales. In addition to nuancing the field's understanding of the relationship between failure and learning, the study has implications for theorizing about and designing for learning through play and problem-solving.

Introduction and literature

Play is a perennial childhood activity and an enduring quality of adult life, considered by many to rise above the status of a privilege and toward recognition as a human right (Souto-Manning, 2017). In the learning sciences, play is recognized as a common and generative context for learning (Gee, 2005). Numerous mechanisms have been proposed to describe how play supports learning. In the context of a puzzle-based video game named *Baba Is You*, we examine one of these mechanisms in this paper: how play-based learning productively facilitates responses to impasses, breakdowns, incompatibilities, or failures. These terms are heterogeneously defined in the literature, but are primarily concerned with moments (however brief) in which actions lead to outcomes that are out of sync with a player's goals (Clifford, 1984). Scholars have developed many arguments to account for how failure during play supports learning, including collaborative discourse about the game mechanics (Anderson et al., 2018; DeLiema et al., 2019), just-in-time feedback (Gee, 2005; Williams-Pierce, 2019), play-based framings of failure that curb the otherwise aversive experience of struggling (Juul, 2013), and flow during the play activity (Kiili et al., 2012). A central challenge for the field is to build on these accounts to document process-based views of what players are doing following moments of failure during play to generate learning. Building on DeLiema, Bye, & Marupudi (2021), the backbone of our approach is scholarship that has over decades consistently recognized three components of debugging (Katz & Anderson, 1987): (a) noticing a deviation between the programmer's preference/goal and the outcome when running their code; (b) forming a causal explanation of why that deviation arose; and (c) formulating and implementing a plan to revise the code and resolve the discrepancy.

Deviations are not neutral, objective characteristics of goal-oriented play. Particular situations stand out to players as deviations from intention/expectation based on the player's goals and their awareness of some form of misalignment between those goals and their approach. In the problem-solving literature, this type of problem finding is non-trivial (Hayes, 1989). Following moments of deviation, there is a robust human tendency to search for a *causal explanation* (Weiner, 2018). In the debugging literature, causal explanations for why a program is failing drive how the programmer fixes their code (Ko & Myers, 2005). Lastly, when moving through a goal-directed play activity, players *revise* their approach to resolve deviations. Without having a ready-at-hand fix, players engage with problem-solving, in that players do not have "a prescribed set of actions to reach the goal," and have to consider multiple parts and possible solution paths (Salehi et al., 2020, p. 157).

Study goals and context

We center the following exploratory research question: How do players (middle school and college students) of a puzzle-based video game notice and respond to deviations during play in ways that foster their learning of game mechanics? The play context for this study is an independent video game, *Baba Is You* (see a screenshot in Transcript 1). Players use a keyboard to move Baba, a small sheep-like creature. The game's core conceit is that players see the game's rules within the playable game field (e.g., the phrase WALL IS STOP is out in the open), enabling the player to interact with particular words in the rule phrase. Moving a word, and thus breaking (or creating) a rule, changes the physics on that level (e.g., a previously impenetrable wall is now permeable) as the

 © ISLS

player tries to find a winnable arrangement. The player must add the WIN attribute to an object (e.g., FLAG IS WIN) and then touch it, but the player does not know at the outset what object will allow them to win. We selected *Baba Is You* because the player's interactions with explicit rules makes their problem-solving process particularly visible. Furthermore, the game requires no previous content knowledge, while having a unique structure with a consistent rhythm of new rules, which make it accessible but challenging for a diverse body of players, and hence calls upon authentic problem-solving practices previously identified in the literature (Salehi et al., 2020).

Method

Middle school students (n=13) and college students (n=12) with no *Baba Is You* experience participated in the study. Participants played the game on recorded Zoom sessions with a researcher for an hour once a week for three weeks. We used a think aloud protocol for the sessions and the researcher did not intervene unless the participant needed help. For data selection, we examined data across all players, focused on *Baba Is You* levels in which players were (a) progressing after learning core game mechanics; (b) grappling with new mechanics; and (c) solving the level typically in under 5 minutes. We chose two levels – Float and Changeless – that met these criteria. We transcribed the video data from these two play sessions for all participants following conversation analysis conventions and including multimodal detail. Our research team worked over several months on interaction analyses (Jordan & Henderson, 1995) of other transcribed *Baba Is You* levels. Over time, we iteratively refined our problem-solving framework and codebook. Our 5-member researcher team then broke into (rotating) teams of 2, each team member coded a transcript while watching the primary data, team members met to compare their interpretations, and then worked toward a consensus. Each team kept a record of interrater discrepancies. Discrepancies were then discussed with the full team and used to update and formalize our coding scheme, before we re-coded the data and reached a new consensus. Below, we present interaction analyses (Jordan & Henderson, 1995), and sequential analyses (Faraone & Dorfman, 1987) to investigate players' problem-solving processes.

Study outcomes

Our analysis amounted to a refined problem-solving framework (see Fig. 1 below) and coding scheme. Higher levels in each category refer to a greater level of detail provided by the player (e.g., ND-1 refers to noticing the deviation; ND-2 refers to partially describing the deviation; ND-3 refers to fully describing the deviation).

Figure 1

Our framework for describing the Baba Is You puzzle environment and player's puzzle approach

Goal-oriented action (revisions) - AR. Goal: What proximal and distal goals are players pursuing? Strategy: What manipulation rules and meta manipulation rules are they using/changing/linking together?

> ***Noticing deviation - ND***. Does the player notice anything deviating from their approach (e.g., misalignment; obstruction; unknowns; unexpected/unplanned) that they judge needs addressing? How do they describe the deviation, including descriptions of actions and inputs that preceded it?
> ***Causal explanation - CE***. What from the game's manipulation rules (implicit or explicit) or meta manipulation rules does the player position as responsible for causing the observed deviation?

(Revise goal-oriented action above)

Interaction analysis applying the framework

We apply this framework in an interaction analysis to demonstrate how the framework operates. The transcript is from a college student playing Changeless. The player, Aya (a pseudonym), has read aloud the rules on the screen, including re-reading the WIN statement. Transcript 1 begins when Aya moves Baba and reacts when the flag changes into a rock. Aya doubles back with Baba toward the now-rock, followed by a pronounced "oh:::" and a raised eyebrow (Lines 4-5), but does not explain what they find surprising. Aya then articulates the deviation from expectation: "okay (.) flag turned into rock" (Line 6). Immediately after, Aya intervenes, breaking off ROCK from FLAG IS ROCK, and saying "we're gonna change that" (Lines 9-10); these words do not include an account of why this revision might work. This action leads Aya to notice a new deviation, indicated by the pause in action and the surprised reaction (Lines 11-12). Aya then articulates an explanation for why their most recent revision did not work as expected: "cuz its gone" (Line 6). In this stretch of play, Aya notices a deviation (ND-1), describes in detail what deviated from expectation (ND-2), attempts to resolve the deviation without providing a rationale (AR-1), notices a new deviation (ND-1), and proposes a causal explanation (CE-2). Interaction analyses like this

one drew our attention to how participants were tinkering by noticing deviations and then deepening their inquiries by providing explanations about the game's core mechanics and accordingly revising their approach.

Sequential analysis of problem-solving moves

We combined ND-2/3s, CE-2/3s, and AR-2/3s for the sequential analysis to focus on any moments players described the game mechanics. The clearest pattern in the sequential analysis (see Fig. 2) is that the moments of deviation noticing (both ND-1 and ND-2/3) were most commonly followed in the adjacent problem-solving action by players revising (but not justifying via causal explanations or rationales for their revisions) their approach to the puzzle (AR-1), and vice versa. However, players also investigated the game mechanics by generating causal explanations of deviations (19/21 players of Float; 11/17 players of Changeless) and/or explanations for why their revisions might work (9/21 players of Float; 8/17 players of Changeless). When did these inquiries into the game mechanics take place? Though ND-1s and ND-2/3s were mostly followed by AR-1s (as noted above), ND-1s and ND-2/3s also almost exclusively preceded causal explanations (13/16 times in Changeless, and 23/27 times in Float). Similarly, in Changeless, ND-1s and ND-2/3s primarily preceded high level ARs (9/12 times), while in Float, both NDs and CE2/3s preceded high level ARs (6/11 and 4/11 respectively).

Discussion

We aim in this work to extend a long-running inquiry in the learning sciences into how players respond to deviations during play in ways that deepen their exploration of the game world. First, we note that it is somewhat misleading to say that players only respond to deviations; they first have to notice them. This process of noticing deviations is active work in its own right, and ignites the player's exploration of new game mechanics. Second, and in alignment with prior scholarship on the productivity of tinkering (e.g., Berland et al., 2013), we found that players tended to operate within a baseline pattern of alternation between noticing a deviation and revising their approach without outwardly stating what had gone wrong and how their revision might work; they were seemingly 'playing with' the game mechanics to understand the puzzle at hand. Third, the vast majority of players eventually branched out to generate causal explanations of their deviations and/or provide rationales for why their revisions might work, clear indicators of their sense-making about the rules of the game world. Fourth, we found that efforts to explain the game's mechanics by generating causal conjectures and revision rationales primarily trailed moments of noticing deviations. These findings introduce a nuanced description of problem solving in a puzzle-

based video game: players primarily respond to noticed deviations by tinkering with revisions, and secondarily respond by conjecturing about the game mechanics in the form of causal explanations and revision rationales.

Figure 2

Problem solving moves (left of each dotted line) that precede other problem-solving moves (right of dotted line) in Changeless and Float. The width of each arc corresponds to the number of times the transition occurred.

How Different Types of Teacher Dashboards Impact Teachers' Problem Detection Accuracy

Meltem Irmak, Gazi University, meltemsavas@gmail.com
Judith ter Vrugte, University of Twente, j.tervrugte@utwente.nl

Abstract: Little is known about how design choices in teacher dashboards (i.e, digital tools that summarize and visualize information to support the teacher in the teaching process) impact teachers' monitoring and interpretation of critical events. Therefore, this study examined how designs that offer different levels of support impact pre-service teachers' monitoring. Three dashboard designs (from least to most supported: mirroring, alerting, and advising) were compared. In three conditions teachers (n = 50) processed nine teacher dashboards of a particular design. Teachers were required to detect the critical situations in each dashboard. Results demonstrated that the alerting dashboards resulted in more successful problem detection than the mirroring dashboards. Though advising dashboards, in theory, offer more support, no additional benefit over alerting dashboards was found.

Introduction

Teacher noticing refers to teachers' successful monitoring and management of students. It is imperative for effective education and encompasses teachers' cognitive processes about *attending* to noteworthy events, *making sense* of such events, and *responding* to these events to make informed decision in a teaching context. In short, teacher noticing includes three main aspects: (a) identifying what is important in a teaching situation, (b) making connections between specific events and broader principles of teaching and learning, and (c) using what one knows about the context to reason about a situation (van Es & Sherin, 2002). The introduction of computer-based learning impacts teacher noticing, but also presents opportunities to enhance it with for instance, teacher dashboards.

Teacher dashboards are accumulations of learning analytics that aid teachers' monitoring and management of students' progress (Verbert et al., 2013). They often contain visualizations (e.g., social interaction, time spent, and test results) that enable teachers to get insight into processes that would otherwise go unnoticed (Verbert et al., 2013). Research shows that teacher dashboards can facilitate teacher noticing (Vrikki et al., 2021) but also that their effectiveness to do so depends on specific design features that offer guidance (Leeuwen and Rummel, 2019; Soller et al., 2005). For example, dashboard that contain features that make relevant information more noticeable, can foster *attending* (Mottus et. al., 2015). Dashboards that support teachers to interpret and give meaning to the data to decide what is relevant or useful for their teaching can foster *sense making*, (Verbert et al., 2013). Dashboards that, for example, help teachers to assess the urgency and gravity of a detected situation and decide on how to follow up can foster *responding* (Molenaar et. al., 2019; van Leeuwen et. al., 2019).

Based on the presence or absence of guiding features, teacher dashboards can be grouped differently. Soller et al. (2005) categorized them as *mirroring* and *guiding* tools. A similar categorization was created by van Leeuwen and Rummel (2019) who distinct between *mirroring*, *alerting* and *advising* dashboards. Both agree that *mirroring dashboards* provide the least support and leave the interpretation mainly to teachers. In these dashboards, teachers decide what information should be paid attention to and how to respond without any alert (Soller et al., 2015). When guidance is added, this is usually in the form of alerts and/or advices. In *alerting dashboards*, possibly relevant information is pointed out to teachers (Schwarz et al., 2018) while in *advising dashboards* teachers receive guidance in the process of interpretation of the given information and the actions they could take (Martinez-Maldonado, 2019). Van Leeuwen and Rummel (2020) showed that guiding tools benefit effectiveness. They found that advising dashboards, compared to mirroring dashboards, lead to an increased amount of detection of problematic situations, decrease in effort, and an increase in confidence about decisions.

Though a general conception might be that all steps of teacher noticing are ideally supported in teacher dashboards, presenting too much information can be burdening instead of facilitating them (Van Leeuwen, 2015). Research demonstrates that there is a risk of increased orchestration overload when the information provided to teachers increases (Martinez-Maldonado, 2019). Redundant or confusing information can result in increased cognitive load which will negatively impact effectiveness (Mayer & Moreno, 2010). Moreover, over structuring can create an ambiance of overreliance and reduce effortful processing and critical thinking and narrow teachers' focus. For example, when the designed support intentionally highlights something, teachers could become over reliant on what is highlighted and might neglect other potentially important things (Brunvand & Fishman, 2006).

To conclude, teacher dashboards have unique affordances, but their effectiveness depends on how they are used. They should be carefully tailored to achieve their full potential. Teachers should be supported but not

 © ISLS

overwhelmed (Mottus et.al. 2015) or limited in their noticing (Brunvand & Fishman, 2006). Understanding how support features in teacher dashboards impact teacher noticing can advance dashboard design, theory, and praxis. This study explores the impact of three levels of support: 1) *mirroring*, 2) *alerting*, and 3) *advising* dashboards.

Method

The study followed a quasi-experimental design with three conditions. Conditions only differed in the type of teacher dashboard: mirroring, alerting, and advising. Data was collected through virtual meetings where teachers processed nine simulated dashboards. After the teachers were introduced to the study, they went through the dashboard simulations one by one, at their own pace. Teachers were required to detect critical cases in each dashboard and report this on a questionnaire. For each reported case they were asked to clarify why this case was critical by answering a selection list (indicating problem) and open question (asking for rationale).

Participants were preservice science teachers enrolled in a four-year science teacher education program of a public university in Turkey. To ensure that they had sufficient pedagogical knowledge, the sample was drawn from teachers in the 3rd and 4th year of their education. In terms of gender distribution (male/female) the sample was representative of the population of preservice science teachers in the university. Conditions were similar in terms of size and demographics (Table 1).

Table 1

Demographics and Means for Each Condition and One-way ANOVA Results

	Mirroring	Alerting	Advising	F	*p*
N (male/female)	17 (2/15)	16 (2/14)	17 (2/15)	-	-

Experience with collaborative learning*	3.00	2.88	1.06	1.73	.188
Experience with instructional technology**	2.47	2.56	1.76	2.62	.083
Experience with teacher dashboards**	0.94	1.50	1.12	1.38	.262

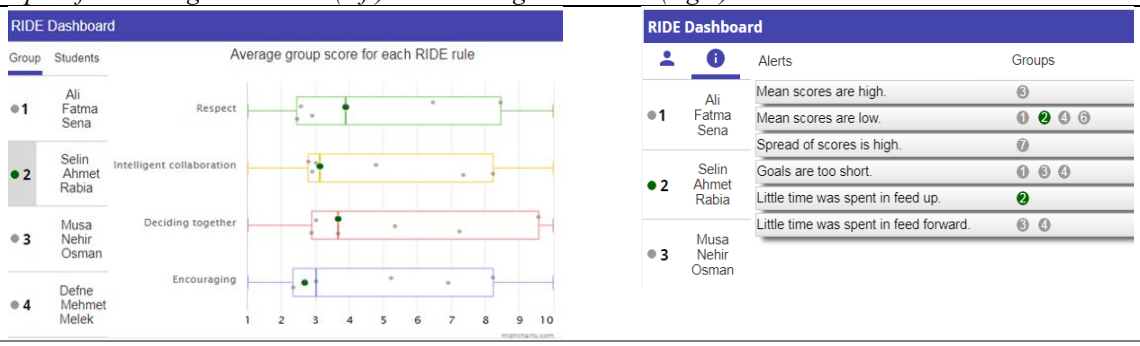
* measured in 'class periods' (i.e., class periods in institutions are 40 to 50 minutes in general)
** range 0-5 (i.e., never used to always used)

Teacher dashboards types

The *teacher dashboards* presented data gathered from a collaboration reflection tool, called RIDE Assessment Tool designed by Eshuis et al. (2019). RIDE is an abbreviation of essential characteristics of successful collaboration (i.e., Respect, Intelligent collaboration, Deciding together, Encouraging). This tool required students to collaboratively reflect on their collaboration and logs data on student's self and peer assessment for each RIDE rule (in a 10-point Likert scale), student's written reflections, and their time on task in the tool.

Figure 1

Example of Mirroring Dashboard (left) and Alerting Dashboard (right)



In total nine simulated dashboards were created, each dashboard presented 'fictitious' data of a class that had collaborated and reflected on their collaboration using the RIDE tool. Each dashboard presented data of 21 students (a common class size) who collaborated in triads (a common collaboration set-up used in education). Data in each dashboard would include one or more groups with common collaboration problems. For each of the nine dashboards, three versions were created: *mirroring dashboards* only provided visualizations of the data, while in *alerting dashboards*, alerts were added to highlight groups that might have specific issues (see Figure 1). In *advising dashboard*, the alerts were complemented with advice for teachers on how to follow up on the provided

alerts (e.g., for the alert 'mean scores are low' teachers would receive the advice that students might not understand that RIDE rule and additional instruction could help them)

Measurements

The amount of participants' *identification of 'intended' problems* in each dashboard was coded. If all intended problems in a dashboard were identified correctly, they received the score of 1, if only part of the problems was identified the score would be a derivate (i.e, 1 out of 2 scored as 0.5). The total score was the sum of the score of all dashboards, ranging from 0 to 9. A high score meant that the participant identified all urgent problems.

Participants were not restricted to detect only one problem in dashboard simulations. Participants might think some situations as a problem, although they were not intentionally illustrated. Participants' rationale for stating a specific problem were inspected in detail. The number of agreed problems were decided after checking whether they had a clear rationale for those problems by referring to the related data. The percentage of agreed problems among all detected problems in a specific dashboard was calculated. Mean score for *detection of unintended problems* refers to the mean of these percentages for each dashboard.

Results

A one-way between-groups ANOVA was conducted with *condition* as independent variable (i.e., mirroring, alerting, and advising), and the number of detected *intended problems* as dependent variable. The results revealed a significant difference, F (2, 47) = 5.04, p = 0.010, eta squared 0.18. Post-hoc comparisons using the Tukey HSD test indicated that teachers in the mirroring condition (M = 1.51, SD = 1.20) performed significantly poorer than the teachers in the alerting condition (M = 3.00, SD = 2.04, p = 0.023) and advising condition (M = 2.98, SD = 1.33, p = 0.023). There was no significant difference between advising and alerting condition (p = 0.999).

In addition, a one-way between-groups ANOVA was conducted with *condition* as independent variable (i.e., mirroring, alerting and advising) and *detected unintended problems* as dependent variable. The results revealed a significant difference, F (2, 47) = 4.01, p = 0.025, eta squared 0.15. Post-hoc comparisons using the Tukey HSD test indicated that, on average, teachers in the mirroring condition (M = 51.06, SD = 23.10) performed significantly poorer than the teachers in the alerting condition (M = 70.76, SD = 23.50, p = 0.032), but did not differ from the teachers in advising condition (M = 67.65, SD = 18.04, p = 0.076). There was no significant difference between advising and alerting conditions (p = 0.910).

Discussion

In this study, the impact of different levels of support provided in teacher dashboards on teachers' noticing was investigated. In line with our hypothesis, teachers' noticing improved when they worked with dashboard types that included some form of support (i.e., alerts or advices). Teachers using alerting and advising dashboards detected the critical cases that were indicated via the support more often than teachers who worked with a dashboard that merely 'mirrored' the data. In general this aligns with findings in literature where researchers found that providing support increased teachers' detection accuracy of critical situations (Casamayor et al., 2009; Schwarz et al., 2018). But the results seemingly contradict with findings by van Leeuwen et al. (2019). In their study, dashboard type did not affect successful problem detection, but they did notice that teachers using advising dashboards demonstrated more in-depth interpretation of the provided information.

Though the previous finding indicates that providing support might be the ideal option, it should be noted that over-structuring or providing too much support can cause less effortful processing. Meaning that note-worthy information might go unnoted. Teachers in the current study were encouraged to interpret all the data, instead of just looking at the summary page. Therefore, their detection of problems that were not addressed in the alerts or advices was also evaluated. The results revealed that the participants using alerting dashboards detected unintended problems better than the participants using mirroring and advising dashboards. Unexpectedly, the participants using advising dashboards (with the highest level of support) performed similar to participants who worked with the mirroring dashboards (no support). This showed that although the advising dashboard supported teachers in the detection of 'intended problems', the high level of support might have limited teacher's noticing. This finding corroborates the idea that a high level of support for pre-service teachers might cause a "mimicking" effect (Gaudin & Chalies, 2015). That is, when highly structured support is provided, pre-service teachers might over rely on the support and might simply express what they perceive as "right" based on support, instead of evaluating the data critically (Brunvand & Fishman, 2006; Gaudin & Chalies, 2015). Based on this, we carefully conjecture that more support does not always equal more effective use. This supports the general consensus that the level of support in dashboards should be tailored to the needs of the users (Brouwer & Robijns, 2014).

Overall the findings support the conclusion that teacher dashboards with support (like alerts or advises) are likely to be more effective than dashboard that only mirror the data. However, designers should be wary that

more detail (like advices for further pedagogical actions) might not necessarily benefit teacher's interpretation of the provided data. There is a risk of mimicking and suboptimal processing. With these findings, it should be noted that the sample size was relatively small and that the participants were pre-service teachers who were relatively inexperienced on teaching collaborative learning and using teacher dashboards. Therefore, they are more likely to demonstrate a tendency to over rely on support. Based on the insights of this study, it can be said that, further design attempts for this kind of dashboards should be careful with providing too much support, but different target groups might respond differently. The findings emphasize that dashboards should be carefully tailored to the experiences and needs of the users.

“Can Molecules Change their Color?” Exploring Students' Non-Canonical Ideas while Programming a Model of Diffusion

Tamar Fuhrmann, Teachers College, Columbia University, tf2464@tc.columbia.edu
Cassia Fernandez, Escola Politécnica, Universidade de São Paulo, cassia.fernandez@usp.br
Paulo Blikstein, Teachers College, Columbia University, pb2755@tc.columbia.edu

Abstract: This study investigates students' non-canonical ideas while creating computational models. Four 5th-grade students individually observed a diffusion experiment and created a model to explain the experiment using domain-specific programming blocks. Results illustrate that translating ideas into code reveals various non-canonical ideas. We argue that a limited number of blocks does not interfere with students expressing their ideas. However, creating domain-specific blocks for modeling needs to be a thoughtful and carefully designed process.

Introduction

Designing computer models is a promising approach to science learning. It combines the advantages of traditional modeling with computational literacy, opening new possibilities for inquiry-based learning (Weintrop et al., 2017; Wilkerson, 2015). In the past decade, many new environments have been designed to allow kids to create their own models using block-based (as opposed to script-based) programming languages and other innovative user interfaces such as NetTango (Horn et al., 2014), Deltatick (Wilkerson et al. 2015), StarLogo Nova (Klopfer et al., 2009), ViMap (Sengupta et al., 2015), or the phenomenological Gas Particle Sandbox (Aslan et al., 2020). Domain-specific block-based programming environments often use a small library of blocks based on canonical scientific ideas, thereby allowing students to focus on a particular aspect of a phenomenon. In science classes, these modeling environments are often used to confirm a theory rather than as an inquiry tool, so students don't have the opportunity to use models to test and explore their own hypotheses. Students are given a final, canonical model that scientists have developed over numerous years, and little time is spent showing them the evidence for the model or allowing them to construct models by themselves (Krajcik et al. 2012). In some cases, students are asked to use or manipulate a model from existing blocks/elements that present a “canonical" scientific explanation of a phenomenon. In doing that, students may not understand that scientific inquiry is necessary to design models and that model building is an iterative process that builds on the results of inquiries verified by data. With this context in mind, we designed domain-specific blocks of the scientific phenomenon of diffusion as an extension to the visual programming environment Scratch (Fernandez et al., 2021).

Diffusion is a fundamental concept in many fields, including chemistry, biology, and physics (Friedler, Amir & Tamir 1987). However, during the last 30 years, several studies have shown that it is extremely difficult for students to master the concept of diffusion (Odom, 1995). In this paper, the term "idea" is used to refer to the understanding that students have developed about the phenomena of diffusion of ink in hot and cold water. For the purposes of this paper, we define "canonical ideas" as science ideas that are typically found in textbooks, and "non-canonical ideas" as explanations for scientific phenomena that are not commonly used in textbooks or in traditional lab activities; this includes students’ initial ideas that are different from normative scientific concepts. In this sense, designing a model with domain-specific blocks can be a valuable way to disclose students' non-canonical ideas about diffusion while students are still in the midst of an inquiry activity. In this paper we present students' non-canonical ideas on the topic of diffusion while they design a model using a block-based computer modeling environment. These alternative ideas can be a starting point for teachers, curriculum designers and designers of educational environments to design activities and environments that allow students to test and develop their ideas. Our paper asks: What non-canonical ideas do students have about diffusion? How do they express these ideas while designing models using a computerized modeling environment?

Methods

The Scratch scientific diffusion model using domain-specific blocks

We created nine domain-specific blocks related to diffusion as a Scratch extension for younger audiences who lack programming knowledge (Fernandez et al., 2021). Each block was designed to embed a set of commands that perform a specific key procedure related to diffusion. The idea was that, rather than spending time dealing

 © ISLS

with the complexity of the code, students could focus on testing and refining their ideas about the mechanics of diffusion while designing a model. While we felt it was important to have specific blocks that allowed learners to engage easily with the big ideas related to diffusion we defined, we also wanted learners to be able to represent and test their own ideas about the phenomenon rather than being restricted to only the scientific ideas we had previously considered.

Participants, settings, and instructional sequence

The first two authors recruited seven US 5th-grade students (10-11 years old), four boys and three girls, to participate in this study. Five out of seven students (71%) were familiar with Scratch before the study. Each student participated individually in a one-hour Zoom call with the authors, wherein the authors instructed the diffusion session for the present study. We analyzed data from the four students (two boys and two girls) who had the richest sessions in terms of detailing their thoughts. The hour-long online session was based on the Bifocal Modeling approach (Blikstein, 2014; Fuhrmann et al., 2018) and was split into four "mini activities" followed by a short reflection interview. In the activities, students: (1) watched two diffusion videos with food coloring in water at different temperatures, described what they observed, and created a hypothesis to explain the phenomenon observed; (2) were presented with several examples of models and were asked to define and explain the function of a scientific model; (3) were introduced to the Scratch extension and the domain-specific blocks and explored the environment in an open-ended way; (4) were asked to work on three models (of cold water particles, of ink spreading in water, and of ink spreading in cold and hot water) that scaffolded them to design their final model of diffusion.

Data sources and analysis

Data included four hours of video recording. Students and parents signed consent forms for the Zoom sessions to be recorded. Videos were transcribed and analyzed with a focus on students' ideas regarding the process of diffusion that were expressed and captured during their programming session. We scanned the transcripts and selected the non-canonical explanations regarding diffusion.

Results and Discussion

We illustrate five different non-canonical ideas expressed by students while designing a model for diffusion using the Scratch Scientific Modeling Extension. For each idea, we present examples of how students stated it and how (if at all) they expressed it with blocks from the environment. All names are pseudonyms.

1. Water particles change their color when touching ink particles

Another non-canonical idea expressed by one student was that the phenomenon of diffusion can be explained by the propensity of water particles to change their color when touching an ink particle. Alice was designing her model of diffusion in hot water when she was looking for a new block that would make the color of a particle change, explaining "*I am trying to change the color of the particles. I think that since the color is dispersed...this will be the change in hot water.*" Her hypothesis was that when an ink particle touches a water particle, it "infects" it with its color, so the water changes color to become the same color as the ink. However, she could not translate her idea into a working code, and thus she couldn't test her hypothesis (Figure 1).

Figure 1
Blocks used to represent particles changing their color when touching

2. Ink and water particles move at different speeds

One student, Alice, expressed the idea that ink and water particles do not move at the same speed when mixed in one receptacle, saying "*I think that water will be a little slower than the food coloring.*" To represent this idea in the model, she used the "set speed" block to set different speeds for the two particles (ink particles with high speed, and water particles at medium speed). When she ran the model and watched the results, she changed her mind regarding this explanation, saying that "*Actually, they will be the same speed because I think that they [food coloring particles] are mixing with the water [particles].*" She then adapted her model, setting the speed

of all the particles to high and concluding "*yes...they are all the same speed and mixing together.*" In this case, the existence of a block to change the particles' speed enabled Alice to test her ideas using the model. Thus, she shifted from a non-canonical idea about ink and water particles moving at different speeds to the canonical idea that both particles move at the same speed, even without explicit instruction from an external source.

3. Temperature is related to the "weight" of the particles

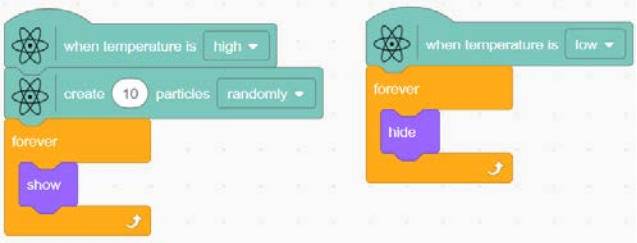
Introducing the variable of weight to the system, Tonia thought that the particles in hot water were lighter than those in cold water and floated on the surface: "*I guess the hot water particles are maybe lighter and they float to the surface faster.*" She mentioned that the behavior observed and the density of the particles is related to the bubbles in the hot water: "*I don't know, but this relates in my mind to the bubbles... I don't know why.* " Tonia expressed these ideas verbally without translating them into a model.

4. Temperature is related to a particle's appearance and disappearance

This non-canonical idea was that in high temperatures more particles are appearing, and that they disappear as the temperature gets lower. When designing his model of cold and hot water, Owen related the behavior of particles at different temperatures to their appearance or disappearance. When researchers asked him to further explain his idea, he only said, "*What I want to do is this: when the temperature is high my costume shows and when the temperature is low my costume does not show*." However, he faced challenges while coding his model and could not test his ideas since he was not able to create a working code (Figure 2).

Figure 2

Blocks used to represent particles appearing and disappearing



5. Temperature is related to the number of particles

Three students expressed the non-canonical idea that hot water and cold water contain different numbers of particles, and that that explains why ink behaves differently in the two temperatures.

Alice was designing the diffusion of ink in cold water when she suggested that "cold water particles move slower and there are less of them." When asked to explain her idea, she stated that "in cold water, they are all bunched up. In hot water, they are all mixing and stuff. In the hot water there are more particles because they disperse more." To adapt her model to express this idea, she said: "For the cold water, I will change the speed and make less amounts of particles." and changed the number of particles in her model from 30 to 20.

Mark expressed this same idea, relating it to a "chaotic movement". While designing his model, he reasoned about ways to make it more similar to the experiment and said, "I would change the water molecules to be really, really chaotic. And I would change the food coloring molecules to be about as chaotic as the water molecules." To make the particles more "chaotic," he started by changing the number of particles: "To make it more hectic I can make this one [ink] 20 and this one [water] 35." After changing the number of particles in the code and observing its effects, he confirmed his idea that more particles make the water movement more chaotic: "Yes, that's way more hectic. (...) If I wanted it to be less hectic, this [ink] would be 10 and this [water] would be 15." In this case, his non-canonical idea resulted in a model that behaved similarly to the experiment.

Tonia's initial thought was also that hot water had more particles than cold water. While designing her model for hot water, she stated that "In cold water I guess I will make less particles. My hypothesis is that cold water has less particles than hot water." When creating the hot water model, she said: "[In hot water] I guess there are more particles because it is hotter, but I don't know... The cold water does not have so many particles." So, she started by creating 100 water molecules and then changed it to 500 to represent hot water.

Conclusions

This study presents examples of non-canonical ideas expressed by 5th-grade students while designing a model of diffusion using a block-based programming tool. These non-canonical ideas were not imagined by the

designers of the original tool. These ideas are related to phenomenological primitives, or p-prims (diSessa, 1993; Hammer, 1996) defined as relatively minimal abstractions of simple common phenomena, often hard to access and not easily put into words. Often, the p-prims, these self-contained explanations based on students' intuitive background knowledge, are non-canonical ideas. In science learning, it is important to offer students opportunities to explore these ideas, using them as epistemological resources to get to the accepted explanations (Hammer & Elby, 2003). However, designers are reluctant to present them in their environment, and teachers are concerned about using them to guide instruction. We argue that in order to incorporate these non-canonical ideas into science instruction and environments, it is essential to identify them for different reasons. Being aware of students' prior knowledge and identifying possible sources of confusion allow science educators to mediate the scientific knowledge-building process for learners; help them make sense of how scientific models are generated and validated; and scaffold learners' conceptual understandings rather than merely giving them the "correct answer." While learning how students' reason about a phenomenon, designers and researchers can create more domain-specific blocks that acknowledge students' initial ideas and sensemaking processes. As in Alice's reasoning about particles' speed, equipping students to model their non-canonical ideas can lead to their independent development toward disciplinary norms. Also, for designers, these ideas can guide the development of tools that acknowledge students' non-canonical ideas as a way to scaffold their sensemaking process based on their own hypotheses about the phenomenon. Although this study included only four students, future work could determine the degree to which these non-canonical ideas are shared among learners, helping prioritize their inclusion in block-based modeling environments.

Addressing challenges in changing science teaching in the Global South: an integrative model for science education reform in Brazil

Tatiana Hochgreb-Haegele, Teachers College, Columbia University, tatiana@fablearn.net
Cassia Fernandez, Teachers College, Columbia University, cassia@fablearn.net
Paulo Blikstein, Teachers College, Columbia University, paulob@tc.columbia.edu

Abstract: Development of sustainable science education reforms requires transformation, and therefore involves integrative approaches that result from collaboration between researchers, teachers and policymakers. Using a DBIR approach, we developed a model for design and implementation of new science standards that addresses three main challenges identified throughout the research: fostering teachers' agency and deep conceptual knowledge; translating principles into lesson plans; and creating resources and expertise.

Introduction, background and context

In recent years, there have been significant efforts to develop new science standards and frameworks that emphasize not only conceptual knowledge but also the practices of science and engineering (e.g. ACARA, 2016; British Columbia Ministry of Education, 2017; National Research Council, 2012). However, implementation remains an important challenge. If the goal is to sustainably develop innovative standards, the "document" itself is not sufficient, and the process of implementation must also be prioritized (Levin, 2010). Moreover, to allow for transformation, teacher buy-in is perhaps the most important factor for successful implementation of curricular reform (Burt & Boesdorfer, 2021). This is even more critical in developing countries like those in which our research takes place.

In this paper, we describe a science education reform project that was developed over four years in a city in the northeast region of Brazil (Fernandez et al., 2020). The project was initiated in 2017 by the city government in collaboration with a US-based research team to redesign science education for the city's 49 K-9 public schools. Members of the research team designing the program and working with teachers were Brazilian and the work was conducted in Portuguese.

In Brazil, science teaching is often based on lectures, using the textbook as the main reference for lesson planning and students' activities (Andrade & Massabni, 2011; Bassoli, 2014). Most teachers do not have the necessary infrastructure and human support to conduct science activities in their schools, because of classroom size (usually more than 35 students/classroom) and lack of space and materials (Andrade & Massabni, 2011). Official reports in Brazil show that only 8.6% of public schools have adequate science labs, and 11.5% have access to science kits (BRASIL, 2020).

Methods and Design-Based Development of the Integrative Model

Educational systems in developing countries are very different from those of the US. In Brazil, expenditure per student is one order of magnitude smaller, infrastructure for professional development is lacking, and there is much less funding for research and implementation. As such, reform guidelines developed elsewhere might not work in the Brazilian context, and therefore we had to create a new implementation model to account for those specificities. The work described in this paper comprises three cycles of implementation and data collection, in which different components of the project were evaluated and refined using a design-based implementation research approach (Fishman et al., 2013). We worked with a group of elementary and middle-school science teachers invited by the secretariat to be part of the curriculum committee, as well as with teacher educators from the city's provider for in-service teachers' PD (School of Teacher Professional Development) and municipal coordinators for elementary and middle school levels at the Secretariat of Education. A total of eight teachers actively participated throughout the project (1 elementary and 7 middle school teachers). Three other teachers started the process but, due to individual constraints (such as not having enough time, being reassigned to other schools, or not showing interest in trying new approaches to teaching), only participated in the initial meetings and then left the project. New teachers joined the project during the process, and as such the number of participating teachers varied from one implementation cycle to another. Our data sources include extensive field notes, evaluation meetings, interviews, questionnaires and documented interactions with teachers and administrators. Based on the data and on our assessment of local educational policies, we identified challenges that informed our initial design, as well as further redesigns.

 © ISLS

Findings and discussion

At the beginning of the project, we set out to develop a collaborative approach in which the new curricular standards would be designed together with elementary and middle school science teachers. In preparation for this work, we conducted a pre-survey among the teachers participating in the working group, and found that science teaching in the city was often very traditional: Teachers usually started a lesson by reading the textbook or presenting a lecture, followed by exercises from the textbook (Fuhrmann et al., 2018). Experiments were rare, and when used, followed very strict, step-by-step procedures, serving as a way to illustrate theoretical content previously presented by the teachers.

After gaining this understanding of the context of science learning in the city, we developed an integrative approach to reform science education with four elements: (1) development of new city-wide science standards co-designed with teachers; (2) professional development for elementary and middle-school science teachers, (3) implementation of infrastructure (low-cost makerspaces with science lab resources), and (4) hiring a dedicated pedagogical redesign teacher who co-designs curricular units with other teachers, develops toolkits for the units, and conducts research on student learning, and who we called the "pedagogical redesign teacher". Below, we describe the main strategies deployed to achieve each of these elements.

Table 1
Overview of the process

Cycle	Description
Pre-Cycle 1 May 2017	**Workshop with Stakeholders** (city's Secretary of Education, Teacher Educator from School of Teacher Professional Development, local university Professor involved in the implementation of educational technology in schools)
Cycle 1 Aug 2017	**Workshop** for science teachers: teachers participated in an introductory two-day workshop (work in small groups on science activities and lectures about science education from researchers). **Online meetings:** periodical small group co-design sessions between teachers and researchers; whole group instructional meetings on central themes of science teaching and student learning. **In person meetings**: classroom observation and reflection interview
Cycle 2 Apr 2018	**Online meetings:** periodic small group co-design sessions between teachers and researchers; whole group instructional meetings on central themes of science teaching and student learning **Implementation of makerspaces** at two schools and **reassignment of two science teachers as pedagogical redesign teachers**
Cycle 3 Oct 2018	**Online meetings** between researchers and pedagogical redesign teachers focused on co-design and on reflections about their daily practices

Strategies

1. Development of new city-wide science standards co-designed with teachers

This was the initial primary interest of the city's administration. They had previous experience with setting up groups of teachers led by specialists developing their math and language (Portuguese) curricular documents and envisioned a similar process.

1.1 Fostering teacher agency and deep conceptual knowledge

Our goal was to develop novel science standards in a participative way, considering teachers' perspectives in order to provide the conditions to enable sustainable implementation in an agentive manner within the local reality. Teachers were presented with findings from the learning sciences and their implications in science education (e.g., selection of central ideas, spiral progressions, science and engineering practices), and analyzed how science standards worldwide (such as NGSS, British Columbia, Australia) implemented these innovations. The group analyzed and explored the science component of the Brazilian National Standards (BNCC), and did extensive work to integrate new pedagogies aligned with BNCC's requirements. Doing this work together with teachers was fundamental to building agency, deep knowledge about the theory behind standards, and a sense of ownership.

1.2 Translating principles into lesson plans:

To connect teachers' practice with the science education principles we intended to incorporate into the curricular document, teachers had the opportunity to co-design curricular units with the research team in three cycles, and to progressively incorporate into their practice the main principles guiding the development of the standards. This allowed teachers to experiment and better understand what these strategies could mean in real contexts.

Subsequently, these learnings helped guide the choices made in the design of the document and provided teachers with a greater sense of how these principles can be translated into classroom activities and their potential for students' learning.

2. Professional development in science teaching for teachers

Our initial survey indicated that it would be necessary to build a common vision of science education within the teachers' group, and most importantly, that teachers should be given opportunities to implement and test in their classrooms the concepts and principles of science education that were being proposed for the new standards, rather than just learning about them through theoretical discussion.

In the professional development program, teachers redesigned curricular units that they would implement in their classroom(s) in the near future, with a focus on the connection with their teaching practice. Participating teachers in this working group were middle school science teachers and elementary teachers, as well as teacher educators from the School of Teacher Professional Development. Through periodic small group co-design sessions with researchers, intercalated with whole group instructional meetings where central themes of science teaching and student learning were reflected upon, teachers were encouraged and supported to adopt new concepts and strategies in their lesson planning as well as in their teaching. After implementation in the classroom, teachers and researchers reflected upon the outcomes and teachers' personal perceptions. These learnings were then incorporated into the next cycle of redesign. This process was repeated in three cycles of redesign throughout a period of 16 months.

At each new cycle, new increased levels of sophistication/complexity were expected in the planning and/or implementation. To define these requirements, researchers were informed by the experiences and outcomes of the previous PD cycle.

In all cycles, teachers received continuous support and mentorship from researchers, in the form of periodic meetings and 1:1 encounters in more specific moments (such as when individual teachers were refining their learning goals, researching and designing classroom activities aligned with these goals, or refining and planning their teaching strategies for upcoming implementation in the classroom). Teachers in the group were encouraged to collaborate and share experiences during the course of the PD. They planned in groups, and also reused and built upon curricular units that their colleagues had designed.

3. Implementation of infrastructure

It was important that teachers were given access to rich resources and materials, thus in our strategy we designed new spaces for learning (low-cost hybrid makerspace/science lab). Two pilot labs were implemented in one full-time and one part-time school (the two models of service in the city). We worked with architects that designed a laboratory blueprint for modular areas that include woodwork, electronics/electricity, digital fabrication, crafts, sewing machines, and science. These laboratories were the site for teacher training as well as for the pilot implementation of curricular units by teachers. Currently, the municipality is working on expanding these laboratories to another eight schools, and has a goal of ultimately expanding them to serve all schools.

4. Creating local expertise

An important takeaway from this project is the importance of the co-design partnerships between researchers and teachers as a strategy to support teachers in redesigning and implementing their lesson plans. Researchers held periodical meetings to discuss the big ideas and learning goals, helped to research resources and design activities that could support students' engagement with science practices and promote learning aligned with the established goals, and gave feedback and support for implementation. From this experience, we established a new school position of a "pedagogical redesign teacher" centered on the co-design of curricular units with other teachers, development of resources for teaching and learning, and on researching student learning (rather than on teaching technology classes).

In the second cycle of co-design, the two middle school science teachers designated as pedagogical redesign teachers started participating in co-design meetings with researchers and teacher(s), as well as additional reflection meetings with the researchers as part of their professional development. In the third cycle, the pedagogical redesign teacher took the lead in the partnership with the classroom teachers, with the support of researchers. This strategy contributed to the sustainability of the program, by creating local resources and expertise.

A new cohort of pedagogical redesign teachers is currently being formed to oversee the upcoming new labs. Moreover, one of the pedagogical redesign teachers has taken a manager role within the Secretariat of Education that involves collaborating, supporting and training new pedagogical redesign teachers, and overseeing the implementation of the new labs.

Outcomes

We are currently working on the implementation of the new science standards. The core team of teachers involved in the development of the document is now leading the implementation workshops with support from the researchers. New labs will be implemented in the city and the core team is involved in providing the professional development for the new pedagogical redesign teachers – through technical workshops and by partnering with them in the redesign of curricular units. In the group of teachers that participated in the professional development, some presented their work as research papers at conferences. Two teachers entered a masters' program based on their science teaching practice during the development of the project.

Insights from the study have been integrated into the permanent program of the center of in-service teacher PD, thus reaching all middle-school teachers in the system.

Sustainability is a major concern in this project. Working closely and collaboratively with teachers, teacher educators from the school of teachers' PD, and administrators has been critical to establishing an integrated system that is also reflected in policy.

Conclusion

To integrate modern science pedagogies to the Brazilian reality, considering the lack of resources and teacher professional development, our model identified challenges related to teacher agency, translation to lesson plans, the creation of materials, and the development of expertise. Taking into account the local context and school culture, working with teachers and policymakers, we co-designed ongoing solutions for those challenges, and created a culture of design-based iteration. Further research is in progress, and our data so far – in the form of classroom observations and analysis of lesson plans delivered by participant teachers – indicate that classroom practices and pedagogy are significantly different than at the onset of the project.

Cognitive Apprenticeship: A New Lens for Better Understanding Online Doctoral Provision

Murat Öztok, Lancaster University, m.oztok@lancaster.ac.uk

Abstract: By and large, the specific characteristics of online doctoral education is unknown. This qualitative study is the first attempt to unpack what it means to be an online doctoral student. I employ the concept of cognitive apprenticeship to help us better understand the individual trajectories of students in online programs. The data show that when the technological affordances are coupled with the structural design, doctoral students in online programmes seem to encounter further challenges that hinder their development as scholars. This research provides both theoretical and practical accounts for further discussion and debate on online doctoral provision in general and doctoral students' experience in these programmes in specific. It concludes that rethinking the theory and practice of online doctoral provision in relation to the concept of cognitive apprenticeship can provide more nuanced means for understanding the specific characteristics of online doctoral provision.

Research Background

Doctoral experience is a "journey from apprentice or novice to master (Bastalich, 2017, p. 1146), during which "the successful student will typically develop from a state of relative dependency to competent autonomy over the period of candidature" (Gurr, 2001, p. 85). Here, I want to understand one fundamental component necessary for this transition: apprenticeship. In specific, I want to understand the individual trajectories of online PhD students through the lens of cognitive apprenticeship. Whilst apprenticeship is hardly a new concept for doctoral education (Jones, 2013), research on this topic limited its scope with explaining supervisory relationships. I propose to utilise the concept of apprenticeship to understand doctoral experience, particularly the process of enculturation of online doctoral students.

As a natural way to learn, "apprenticeship was the vehicle for transmitting the knowledge required for expert practice" (Collins, Brown, & Holum, 1991, p. 6). It is possible to extend this definition to doctoral education: students acquire sophisticated research skills or practical tacit knowledge (e.g., interview skills, research ethics) through their interactions with their supervisors and other experienced researchers, as well as their peers. It is through this relationship that discipline-specific knowledge is communicated, utilised, and cultivated. This type of apprenticeship, however, often operates at the cognitive level. I employ the concept of cognitive apprenticeship to explore both the implicit and explicit processes by which online doctoral students can acquire the knowledge and skills necessary for scholarship. Research I report in this manuscript is concerned with one of the four dimensions of the cognitive apprenticeship framework: sociology.

Theoretical Framework: Doctoral Education as Cognitive Apprenticeship

Research has long shown that apprenticeship is one powerful framework for conceptualising learning implicit knowledge and skills (Lave & Wenger, 1991). According to this framework, learning occurs through various apprenticeship arrangements through a relational process of legitimate peripheral participation, suggesting that "activities, tasks, functions, and understandings do not exist in isolation; they are part of broader systems of relations in which they have meaning. These systems of relations arise out of and are reproduced and developed within social communities" (Lave & Wenger, 1991, p. 53). In this model, learning is about acquiring domain-specific methods through a combination of observation, coaching, and practice (Lave, 1991).

The concept of cognitive apprenticeship is built on these principles, but it goes beyond practical skills and focuses on cognitive skills. Cognitive apprenticeship is concerned with knowledge required for expertise: not only learning subject matter specific concepts, facts, and procedures but also acquiring nuanced knowledge about how to learn and when to apply, new concepts, facts, and procedures. Two major differences between cognitive apprenticeship and traditional apprenticeship should be noted here. First, in traditional apprenticeship, the demands of the workplace define the nature of the relationship between the apprentice and the master, not the concerns with pedagogical scaffolding; whereas, in cognitive apprenticeship, problems are designed with increasing complexity to demonstrate the skills or techniques required for the task. Second, traditional apprenticeship is context specific whilst cognitive apprenticeship prioritises generalizing knowledge. These two major differences operate to produce different relationships; that is, "individual learners and groups of learners navigate complex matrices of intersecting

 © ISLS

sociomaterial and epistemic practices" differently (Simmons, Parchoma, & Koole, 2018, p. 1).

Research Question

How and what are the ways in which the patterns of relations performed and recursively emergent within the socio-material environment of online doctoral courses?

Research Design

This phenomenological study was conducted in five different online doctoral programmes in two different research-intensive public universities based in the UK and Canada. I only focused on the students who were close to the completion of their thesis project or recent graduates of the programmes within the past five years per discussed above in the introduction.

I employed the descriptive and critical discourse analysis in order to construct meanings across participants (Fairclough, 2003). Several meanings emerged through this process and I combined, compared, and contrasted them in order to create more comprehensive yet more distinct meanings.

Findings

There are four characteristics affecting the sociology of cognitive apprenticeship: situated learning, community of practice, intrinsic motivation, and exploiting cooperation (Collins et al., 1991). Here, I present the findings with respect to these four categories.

Situated Learning

The data suggest that sense of support and being able to personalise the tasks were deemed essential for situated learning in online doctoral programmes. For example, Judith, a fourth year PhD student, stated that she felt that the instructor and the members of the cohort did a great job of supporting each other and she felt especially "really got a lot out of the [synchronous] collaborative sessions". Till found it easy to use the synchronous and asynchronous communication. For him, the text and multimedia-based broadcast resources were "essential for completing assignments". Bruce stated that he appreciated the ability to "chat about the assignments using the audio [synchronous] feature" with both peers and the instructor. Maggy particularly valued opportunities to "talk in real time via ongoing [asynchronous] text and periodic [synchronous] audio" with both her peers and the instructor provided within the course website. Sherry stated that she wanted to "talk with the instructor and the scheduled synchronous sessions provided those opportunities". Elaine echoed this sentiment and went on to say, that "2-way communications… during the live [synchronous] session(s) was easy". These accounts are important: if students are to understand the purposes or uses of the knowledge they are learning, they should be able to "learn by actively using knowledge rather than passively receiving it" (Collins et al., 1991, p. 45). I was, however, not able to find evidence that students acquire knowledge in a dual form, both tied to the contexts of its uses and independent of any particular context. The abstraction of knowledge is an important goal for situated learning: the unbinding of knowledge from a specific context fosters its transfer to new problems and new domains. It is this fluidity of the patterns of relations that allows movement of knowledge depending on the emergent characteristics/membership of the assemblage.

Community of Practice

The sense of community of practice was strong; however, the sense of isolation caused by the impersonal nature of online spaces seems to dissolve relatively strong social ties that may have developed earlier in the programme. For example, Josh, a fourth year Ph.D. student explained how he failed to continue these relationships:

> we had the residential [meeting] in the first year, we had the residential [meeting] in the second year … Because we felt that we really wanted to maintain that sense of community and it was actually really important to us. So, we tried to extend it as long as we could, and then we all went off after the residential [meeting]…. we were really motivated. And then it all sort of started to [fade] unfortunately.

For Josh, sense of community was important but despite their best efforts, they failed to maintain these relationships:

> I think the community aspect just sort of dissipated really, and having spoken to a few people in previous cohorts, I think they felt the same thing. How do you maintain a sense of community? I don't know, I … would have managed to sustain it, it would have been nice because we had a really strong sense of community, but we couldn't find a way [to maintain it].

When the patterns of relations within the assemblage are not maintained, students can struggle with developing a sense of personal investment and mutual dependency. Along with time, geographical proximity emerged as an important factor for online doctoral students' socialisation. For Russell, a fifth year Ph.D. student, physical distance

was played a role in his attempts to keep the social ties and connections:

> there's one of my cohort who's here in [my country], and the beginning of [thesis work] we still help each other out and chat. I think like it's good if you have someone geographically sort of close, which is really, really helpful.

However, whether it is due to time constrains or geographical proximity, individual attempts to promote a sense of community of practice seemed to have a short life span.

Unfortunately, students seemed to internalise and normalise the sense of isolation for their development as a researcher or scholar. In fact, the personal nature of the doctoral thesis was the main theme in their explanation of the thesis process.

Intrinsic Motivation

The data show that students were able to comprehend their position shifted within the pattern of relations. Participants in this research unanimously acknowledged learning academic writing as the catalyser for the transition from student-like mindset to developing their own identity as a scholar.

I was able to find traces of intrinsic motivation in our data, albeit scarce and weak. Angela, a recent graduate, for example, explained that:

> Learning to write academically and learning to [give] feedback was very important to me. The process of doing it; looking at other people's work was very interesting. I learned my peers have very different perspective. The most important thing I learned is that you can you can argue anything; you just have to explain why.

When Angela was asked to articulate as to why she identified learning academic writing skills was an important process for her, she continued:

> Learning how to write helped me so much into becoming an independent researcher and also someone who can … um, who is able to defend her position. My self-confidence was just, yeah, that has changed completely. Now I see PhD as something sensible to achieve. I managed to get something published last year and there was a great sense of achievement in it.

Angela's accounts can explain how doctoral students internalise their role expectations through the integration of the self and the professional role. "Individual and social roles, personalities and social structures become fused" and students "form a professional identity" (Weidman, Twale, & Stein, 2001, p. 14). Students, then, can identify themselves as full members of academic or professional community. In terms of sociology of cognitive apprenticeship, this means that a new identification emerges out of a new pattern of relationships.

Exploiting cooperation

Whilst the asynchronous text-based group discussions were intended to support triads of students in peer review processes, these fora were not strictly private. Anyone in the class could read and even respond to posted draft work. This design within the course was intended to be an optional way for individual learners to engage with variety of their peers in order to gain insights into what additional peers in the course were doing and discussing. Maggy noted that the group discussion provided opportunities to "get feedback" on draft work and "offer feedback on others'" draft work, which resulted in her "using the [assessment] rubrics several times" and this process provided opportunities to also check on "other people's feedback". Till commented that he was "able to understand and learn some new principles for supporting others' learning". These accounts indicate that the online space provide flexible patterns of relations that can support group work. Scarcity of opportunities for cooperation, however, suggest that these opportunities are not inherent in online doctoral provision.

Peer and instructor feedback both in the asynchronous threads and during synchronous sessions provided opportunities for students to review their peers' sets of expertise. For example, Maggy noted that she "learned a lot from others". Jenny noted that engaging in the course tasks "introduced us to a variety of skills that could be applied to support learners in many different settings". Sherry remarked that she became a proficient multimedia developer: "not only did I learn how to create using different programs I feel I learned how to learn new programs/techniques". Sherry's articulation is important to note because it shows that the online component of the assemblage played a role in her identity formation.

Discussion and Conclusion

Doctoral experience can be understood as "networks of learning relationships", whereby students are positioned "at the centre of a constellation of others" (Cullen et al. (1994) as cited in Boud & Lee, 2005, p. 502). Precisely because the contextual and situated nature of this experience, doctoral education, particularly in online programmes, requires different level of understanding and commitment depending on individual needs, goals, profession, and the nature of

the discipline. Cognitive apprenticeship, I believe, is the most productive theoretical framework to understand and appreciate these nuances: it is a useful paradigm to explicate and instil the notion of scholarship to doctoral students rather than a packaged formula for teaching. The level of expert support doctoral students receive should gradually reduce as they move from peripheral participants to central members; and, completely fade when doctoral students slowly become independent scholars. Data I reported in this manuscript explains this process.

I can provide some key observations for this process in online doctoral programmes: 1) the choice of tools (and other elements of the assemblage) permits a variety of patterns of relations; and, 2) as learners engage with the assemblage, their needs, desires, and activities co-structure the assemblage, and as such, the development of broad and/or sub-groups emerge. This process, nevertheless, as the data show, does not naturally occur in online doctoral programmes. In fact, it is evident in the data that the lack of scaffolding for apprenticeship appears to be disconcerting: as the nature of the assemblage shift, the identity of doctoral students shifts; however, this transference is not enough for students to identify themselves as a scholar. Doctoral students need a sense of community of practice; in specific, they need a cognitive scaffolding for this metamorphosis to occur. Our challenge, then, is to inscribe potentialities into programme designs to allow for multiple assemblage formations that can help with situating different learners in the complex virtual continuum.

Data of this research show that structural elements inherent in online doctoral programmes occasionally support the characteristics affecting the sociology of cognitive apprenticeship. Participants in this research confirmed that some opportunities exist for situated learning to occur and community of practice to be formed; however, these are not pedagogically designed elements of teaching/learning but serendipitous experiences. Opportunities for intrinsic motivation and exploiting collaboration, on the other hand, are poor and short. Taken altogether, the findings convincingly show that students lack enculturation in the principles of cognitive apprenticeship. This lack of enculturation is manifest in how they internalised their isolation as a natural process inherent in the thesis work. The result is that they are inaccurately equating the unstructured and personal nature of the thesis work with the experience of working alone which has resulted from the lack of program structure at this phase of the doctoral journey.

Overall, there is a lack of knowledge and frameworks for understanding online doctoral provision. I suggest a shift in the research agenda concerning this issue. Perhaps, the first step towards a more effective direction is to focus less on quantitative measures for success, like enrolment statistics or graduation rate but rather to employ qualitative judgements for the evolution of the doctoral experience. What might be the guidelines for such qualitative approaches? Here, I explored one option: cognitive apprenticeship. According to this perspective, doctoral education is not just about completing a series of coursework followed by a thesis work; rather, it is a transformation from that of a knowledge consumer to a knowledge producer. I believe cognitive apprenticeship can be utilised as a framework for studying this metamorphosis.

The infancy of research agenda for understanding doctoral experience as cognitive apprenticeship warrants that I should be cautious with the conclusions. However, it is evident that we have to rethink the theory and practice of online doctoral provision. It can be argued that when the technological affordances are coupled with the structural design, doctoral students in online programmes seem to encounter further challenges that hinder their development as scholars.

LEARNING LAB METHODOLOGY FOR EXPANSIVE LEARNING AND INCLUSIVE EDUCATION DURING THE COVID-19 PANDEMIC IN BRAZIL

Abstract: The global policies of inclusive education often ignored local knowledge and cultural-historical ecologies. As a result, the top-down policies become either irrelevant or oppressive. This study presents a formative intervention study, Learning Lab, conducted in Brazil to design a new system at specialized school for blind and visually impaired students. Fourteen practitioners engaged in nine meetings with the final goal of producing a new system of inclusive education for students with multiple disabilities during the COVID-19 Pandemic. We will present the expansive learning actions, which educators took as a conduit for critical dialogue, collective agency and expansive learning for designing the future of their school.

Objectives

The global movement of inclusive education "as a global travelling policy and practice" (Singal, 2016, p. 7) has often ignored local social-historical-spatial contexts that leads to practices that do not hold or have unintended results. A seemingly unifying set of international recommendations to ensure inclusive education for children with disabilities will take different flavors mediated by culture in specific contexts in Global South (Artiles & Dyson, 2005). In Brazil, for instance, cultural and historical aspects of education (e.g., quality of public school system and political hegemony of specialized school organizations) shaped an initial full inclusive education agenda to a different direction (Mendes, 2019). Though inclusive education legislation asserted students with disabilities the right to access age-appropriate regular education classrooms, it also established a continuum of provisions for those students whose intense and continuous support as well as significant curricular adaptations was beyond what other schools can provide.

Specialized schools for the blind and visually impaired in Brazil

Following a national inclusive education policy, the number of blind students with additional disabilities gradually increased in Brazilian specialized schools for the blind and visually impaired (Mendes, 2019). Internally, the specialized schools for the blind and visually impaired discontinued a self-contained program for blind students with additional disabilities (e.g., autism, intellectual disabilities, and cerebral palsy) to place them in the regular classroom having access to general curriculum content alongside peers with visual impairments. On the other hand, re-structuring of the public regular school system also meant the placement of students with disabilities in the regular classrooms with specialized educational services support. However, in the hierarchy of disabilities, inclusion of students with significant support needs is met with resistance.

Though schooling of students with significant disabilities, historically segregated within segregation, is an uncharted terrain for both specialized and regular schools, they are typically sent to specialized schools taking for granted their collective self-efficacy for addressing the emotional, social, and academic needs of students with significant disabilities (Mendes, 2019). The re-structuring of both specialized schools and the general schools prompted by an inclusive education agenda, placed the specialized schools in a double bind. On one hand, specialized schools historically were envisioned to develop the academic potential of students with visual impairments. On the other hand, the entrance of students with significant disabilities as residues of an inclusive education agenda. These "competing alternatives" take teachers into a need state in which practitioners are "unable to determine the direction of their efforts" (Engeström, 2015, p.133). The need state "manifested in threats and conflict situations" (Engeström, p.154) within spaces struggling to redefine their practices, represent opportunities for potential expansive learning.

Learning Lab: A formative intervention

Informed Cultural Historical Activity Theory (CHAT), Learning Lab, a formative intervention model, aims to empower local practitioners facing daily contradictions in their practice and facilitate expansive learning. Expansive learning stems from the articulation, identification., and resolution of challenges or contradictions in an activity system (e.g., the specialized school). For instance, educating blind students with additional disabilities means adaptations that go beyond Braille, tactile graphics, contrast, or large print books to encompass modifications in content or assessment which disrupt the normative center and trigger contradictions between a previous historical activity and an emerging new form of activity and practice.

To our knowledge this is the first formative intervention for collective systemic design in a specialized school. Furthermore, though using the first generation of Vygotskian CHAT is more prevalent in Brazil, only a

 © ISLS

few studies has ventured into the third or the fourth generation of CHAT which takes activity systems and social movement as the unit of analysis (Cenci et al., 2020).

Theoretical framework

CHAT provides analytical tools to examine and intervene in activity systems (e.g., hospitals, schools, factories, and social movements) facing historically accumulated contradictions (Bal, 2017)). In a formative intervention, participants actively follow a cycle of change ascending from the abstract to the concrete. When accomplished, this movement supports an understanding of challenges not as a mystical form but as a conceptual one articulated in both social relations of the here and now as well as in the larger cultural-historical context (Ilyenkov, 2009). Daily disturbances, dilemmas, or conflicts experienced by practitioners in the local specialized institutions should be analyzed in relation to the evolving activity system of the school which in turn is examined across the larger national and international discourses of special education and inclusion. As individuals progressively understand how the elements of a phenomenon are constituted by the whole, consciousness about reality expands embodied into expansive learning actions towards a transformation process that has the potential to re-mediate practice through innovative pedagogical solutions (Bal, 2017).

Activity systems

Expansive learning stems from the articulation, identification, and resolution of contradictions in an activity system. Across cycles, the subjects within a community of practice and, according to their expertise and related tools, simultaneously shape and are shaped by the object – the element that gives meaning and direction to the activity. Multivoicedness the source of conflict of motives around the object, give rise to the internal contradictions, "the driving force of change and development in activity systems" (Engeström, 2015).

Contradictions

Contradictions are part of every component of object-oriented activity system evolving historically in the context of global capitalism. In the current neoliberal era, the primary contradiction in the activity system of a school, for instance, is the competing motives between accountability (exchange value) and meaningful pedagogy (use value). In this case, contradictions harnessed by dialogue and collective work become a driver for innovation. Contradictions are only visible through their discursive manifestations. Engeström and Sannino (2011) identified four types of discursive manifestations of contradictions: Dilemmas, conflicts, moral conflicts, and double binds. Double binds, the highest level of consciousness and, thus the most aggravated contradiction, demands a collective call for change. Usually, the result is a "third way" in which practitioners generate "novel mediating models, concepts and patterns of activity that go beyond and transcend the available opposing forces or options, pushing the system into a new phase of development" (Engeström & Sannino, 2011, p. 371). This third way depends on multivoicedness embodied in the manifestations of contradictions or level of consciousness.

Learning Lab: A formative intervention model for education systems

Learning Lab is a formative intervention that takes expansive learning theory and respective methodological cycle of expansive learning with a commitment to give voice to historically underrepresented groups in schools' knowledge-production and decision-making activities such as Black, Indigenous, People of Color (BIPOC) and low-income families. Expansive learning is defined as the formation of a new, expanded object and an expanded activity system organized around the new object (Engeström, 2015). Learning Lab differs from other activity theoretical formative intervention approaches) for its commitment to participatory social justice (Bal, 2017). Contributing to the newly emerging fourth generation CHAT, Learning Lab builds heterogenous coalitions and deals with complex societal problems or runaway objects such as racial disparities in educational opportunities and outcomes or inclusion. Drawing from critical education and radical pedagogies, Learning Lab engages school stakeholders in collective decision-making that address disparities in educational outcomes and opportunities experienced by BIPOC students and families. A full cycle of change in Learning Labs encompasses the following expansive learning actions: (1) Forming Learning, (2) Questioning "Here and Now", (3) Analyzing, (4) Modeling, (5) Examining, (6) Planning for Implementation, (7) Reflecting on the Leaning Lab Process and Outcomes, and (8) Actual Implementation.

Methods

The goal of this case study is to examine how practitioners design a model of inclusive practice through expansive learning actions to respond to their local challenges. Learning Lab took place during the COVID-19 outbreak which made a Virtual Learning Lab as a natural choice.

Setting

The setting of the study is a specialized school for the blind and visually impaired students facing organizational changes (e.g., student profile, teaching methods). Regarded as a landmark in the history of special education in Brazil, the specialized school was influenced by the different trends in the field: segregation, integration, and inclusion (Jannuzzi, 2017). After studying for six years at the Institut des Jeunes Aveugles a Paris, Álvares de Azevedo pursuit the idea of building in Rio de Janeiro an institute like its Parisian counterpart. The institute for students with visual impairment was developed under the influence of the Jesuit model of education in which the objective was to separate students from the world. In a pedagogical universe, students under constant surveillance had access to an elementary school with religion, music, and crafts for manual work (Januzzi, 2017).

In the late 80's, the identification of some blind students with additional disabilities, initiated the activities of an Alternative Educational Program (AEP), opened in 1991. This separate self-contained program catered for the need of blind students with additional disabilities with activities based on a functional perspective. In 2016, following the national inclusive education policy guidelines (Brasil, 2008) the new administration closed the self-contained program and the blind students with additional disabilities entered the regular classrooms with access to grade-level general curriculum. The school took the role of an 'inclusive' specialized school and following the inclusive education initiative (Brasil, 2008) in which special education was no longer a place but a service for blind students with additional disabilities within the age-appropriate regular classes.

Participants

Learning Lab consisted of 14 practitioners: eight teachers from the different school levels (e.g., early childhood, elementary school, and middle school), three special educators, two administrators and a former staff from the early intervention department.

Data collection

Data was generated through video recordings of nine monthly meetings, two agenda meetings and one subcommittee meeting. Artifact analysis included historical and institutional documents from the specialized school (e.g., audio-recorded past community meetings and institutional videos), field notes and collective map of the activity system. All transcribed data was transferred into Nvivo 12™, a qualitative data analysis software.

Data analysis

To understand how Learning Lab facilitated practitioners' expansive learning, the study utilized two complementary methods of analysis. The first method offers a method for the identification and analysis of discursive manifestations of contradictions (Engeström & Sannino, 2011). The second method included analysis of expansive learning actions (Engeström, 2015).

Findings

Participants completed the cycle of change and designed a new model of inclusive practice. The following expansive learning actions were identified: The action Forming Learning Lab occurred nine times in the first two meetings, questioning actions occurred 21 times so far, and analyzing twelve times. Questioning school's existing inclusion support system and questioning school's practices emerged as subcategories of questioning action. The analysis of the discursive manifestations of contradictions indicated dilemmas are the most frequent discursive manifestation with 33 occurrences, followed by conflicts that emerged 20 times, nine critical conflicts and two double binds. In the initial sessions dilemmas were linked to discussion topics related to the pandemic outbreak. On the one hand participants were excited about the collaborative project and possible outcome, on the other hand they expressed concerns with the current events and explained they would participate "as much as possible."

Other dilemmas were tightly related to the inclusive practices in the school and in the classroom. Learning Lab members acknowledged the importance of access to the curriculum for students with additional disabilities. They also communicated uncertainties about the feasibility of an individualized instruction in the collective environment of the classroom. Margarida, former head of the early intervention department, highlighted the challenges of instruction in the classroom contrasting with her experience in the early intervention department. She compared early intervention as a one- on- one "craft work," while described learning and teaching in the classroom as challenge for the teacher that needs to involve everyone the process.

Conflicts were related to diverging views between the access of a functional or academic curriculum. Disagreement with the position of the institution in relation to blind students with multiple disabilities. Pedro, the history teacher, was very straightforward and criticized the laissez-faire position of the institution which led to some teachers going above and beyond to include students with additional disabilities while others did nothing.

According to Pedro, families with students with additional disabilities demand very little from the school because the institution itself allows teachers to be less accountable for students with additional disabilities than students with visual disabilities: "There is a tacit hierarchy and that is accepted by the school."

Critical conflicts were highly emotional and related to the current pandemic. Practitioners felt guilty or had inner doubts about the best ways to support students with additional disabilities in the online mode of instruction. Isabor, Language Arts teacher, admitted that because of the pandemic she did not know most of the students with additional disabilities; some came to the first class and then disappeared: "I punish myself for not trying to learn what happened to those students. I thought to myself 'Oh, they gave up.' This was my mistake; I should not have done this." Finally, double binds as unequally unacceptable alternatives in the activity system emerged in the tension about the need of new staff such as paraprofessionals supposedly prepared to mediate appropriate services for students with multiple disabilities.

Discussion

Through Learning Lab, participants designed a new model of inclusive practice as they articulated contradictions and collectively found the means to resolve them. Initial analysis of discursive manifestations of contradictions and expansive learning actions reinforce the non-linearity of the cycle of change. The cycle of change offers a blueprint to guide facilitators and members towards expansive learning actions. However, it does not entail linearity in the process. For instance, analyzing the historical-genetic occurred in the second meeting during the questioning of the 'here and now.' This shows the importance of the historical development of the activity to understand the challenges of the present moment. The personal sense that gives meaning and direction to the activity seems to be paramount for the involvement of practitioners in the collaborative process. Though many were uncertain about the future and had many other additional responsibilities, they participated actively and engaged in serious reflective conversations. Learning Lab formative intervention accomplished its promise bringing practitioners together in a virtual space where they were able to discuss the new identity of the school, the inclusion of a new group of students in the specialized school and concrete ways to respond to the changes and challenges in their practice.

Abstract: This study explores how the interplay between data and model design shifts 6th graders' students' ideas about diffusion as they build a range of models ("paper and pencil" and computational models). We present a new web-based environment and approach that integrates model-based and data-based features in the same display which facilitates the comparison of models and real-world data. Further, we illustrate how this environment and approach lead students to converge on one canonical scientific model.

Introduction and Background

Modeling has become a core element in scientific practice (Harrison & Treagust, 2000, Pluta et al., 2011; Halloun, 2011). Data plays a fundamental role in the development and evaluation of scientific models, anchoring the modeling process (Fuhrmann et al., 2018; Schwarz et al., 2009). However, model-based practices remain largely separated from data-based ones in science classes. Recent work shows that linking experimental data and scientific models in science activities has strong potential to improve student learning. For example, activities designed using Bifocal Modeling (Blikstein et al., 2016), which enables real-time model and experimental data comparisons, can support conceptual understanding, modeling, and meta-modeling competencies (Blikstein et al., 2016; Fuhrmann et al., 2018). Other researchers suggested that interlocking models with one another to draw attention to microscopic entities and their behaviors supports meaningful practice (Georgen & Manz, 2021). Gouvea & Wagh (2018) showed that coupling experiments and modeling in learning activities helps students learn how to engage in scientific practice by focusing on the goals of their investigations, allowing for comparison and triangulation. Much of the existing research on integrating modeling and data practices has involved students using pre-designed models. Little work has focused on students designing their own computer models using data to validate their models. This research is needed to understand the learning opportunities that arise from comparing real-world data and computational models, and, per the conference theme, how innovative technologies can support more effective science learning experiences.

In this paper, we ask how the interplay between data and model design shifts 6th-graders' ideas about diffusion as they build a range of models and refine their explanations based on data. We present a web-based environment and approach that integrates model-based and data-based features in the same display, facilitating the comparison of models and real-world data. Further, we illustrate how the environment and approach lead students to explore the interplay between observed data and the designed model during a unit on diffusion.

Methods

Design, settings, participants & instructional sequence

This study seeks to investigate ways to make computational modeling a sustained practice in middle school classrooms. We developed a domain-specific block-based online modeling environment based on scientific modeling research and previous studies on linking model-based and data-based practices (Blikstein et al. 2016; Fuhrmann et al., 2018; Gouvea & Wagh, 2018). The domain-specific blocks make the computational modeling accessible for students to focus on testing and refining their ideas about mechanisms underlying phenomena (Kahn, 2007; Wagh & Wilensky, 2017; Wilkerson, Wagh & Wilensky, 2017). Figure 1 shows the modeling platform, with the model and the display of the experiment side-by-side. This paper uses data from a pilot study with 43 students from two 6th-grade classes taught by the same science teacher in a middle school in California.

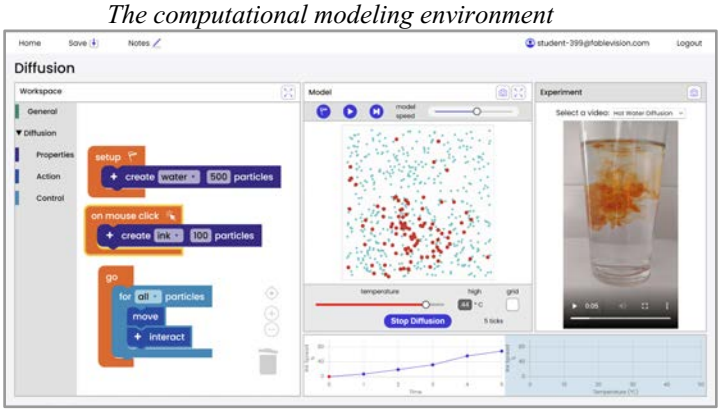
We designed the diffusion unit based on the Bifocal Modeling framework (Blikstein, et al. 2016). Students worked in pairs over five class periods. First, they conducted an experiment in which they compared the rate of spread of ink in hot and cold water. They ran two iterations and documented their measurements before

 © ISLS

plotting the data. Next, they designed a paper model to explain how dye spread in hot and cold water. Students then used a computational modeling environment to implement and revise their paper models. Finally, they tested their various models by comparing models' behavior with the experiment to select the model that best explained diffusion. Through class discussions, students eventually converged on a single model.

Figure 1

The computational modeling environment

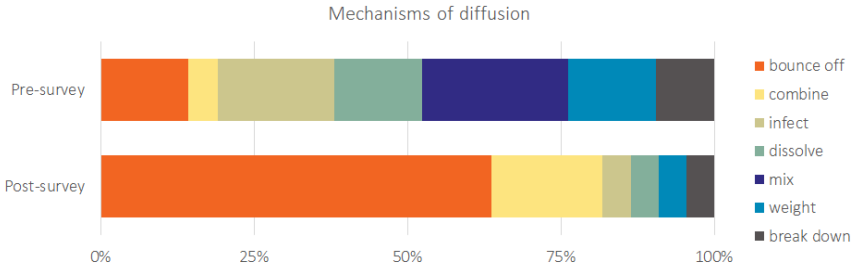


Data sources and analysis

Data included observation notes, student artifacts, and pre/post-tests. We analyzed whole-class and student-pair data. In the observation notes, we identified critical junctures when students were, (1) constructing conjectures or explanations for the phenomenon, and (2) comparing the experiment and model. We analyzed open-ended responses to see how they shifted from pre to post. We focused on the action words students attributed to the process of diffusion (e.g., spread out, bounce off, infect), indicative of mechanistic reasoning about the phenomenon (Russ et al., 2008). These terms also align with the programming blocks in the environment. Our initial rubric was developed through open coding and further refined through reference to 10 example responses. Initially, our agreement was 60%, but we reached 89.12% agreement after several cycles of refinement.

Figure 2

The mechanisms of diffusion as reflected in pre- and post-test open-ended answers

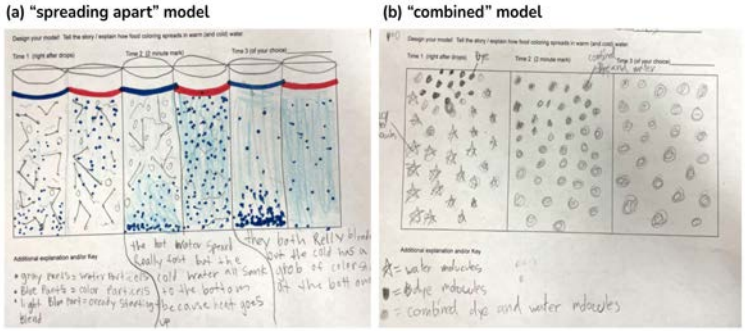


Results

Results from pre- and post-test analysis (Figure 2) showed a shift in the mechanistic language students used to describe ink spread. At the pre-test, student responses varied greatly. By contrast, in the post-test, a majority of students drew on the "bounce off" model, a canonical explanation for diffusion. For example, one student said on the post-test: *"The paint particle will bounce off the water particles, making it spread around. If it was in cold water, it would move slower than in hot water. The paint will sink before it starts spreading."* Below, we examine how this shift in language might have come about through the instructional sequence.

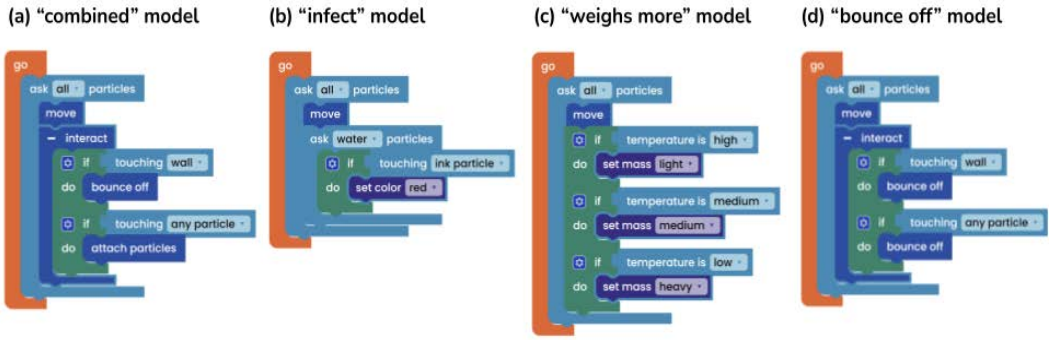
1. *Generating ideas for how ink diffuses in water:* In their paper models, students drew their explanations of experimental results. While students did not talk about particles to describe the phenomenon during the experimentation phase, they included particles in their paper models (e.g., mentioning type and color of particles). After completing this activity and discussing their ideas, students began to converge around two potential models: a "spreading apart" model that did not directly explain how particles interact with each other, and a "combined" model, in which dye particles and water particles combine to create larger particles.

Figure 3
Students' "paper and pencil" models: a. the "spreading apart" model, and b. the "combined" model



2. Translate from paper to computer, discard ideas that cannot be explained based on experiment, create new models (Figure 4). Students who drew the "combined" model used the code to create the same model (Figure 4a). When running their model, they noticed that the particles in their model attached to each other when interacting, resulting in big blobs. After comparing their model with the video data, this student pair realized that these blobs were missing from the real experiment and therefore discarded the "combined" model. These students explored other more ways to explain the dye behavior in the water using the modeling environment.
3. Converged on three candidate models. At a class level, students converged on three candidate models: the "infect" model (color particles infect water particles, which then turn blue; Figure 4b); the "weighs more" model (particles are heavier in cold water than in hot water; Figure 4c) ; and the "bounce off" model (particles spread by bouncing off each other, and they bounce off at different speeds according to temperature; Figure 4d).

Figure 4
Students' design of four models: a. "combined" model, b. "infect" model, c. "weighs more" model and d. the "bounce off" model.



This persistence of three models created noticeable tensions in the classroom. Students are used to being given the correct answer by the teacher at this stage rather than seeking it themselves. Additionally, the teacher was concerned about students using incorrect models and anxious to tell them how diffusion is defined. Nonetheless, the students and the teacher had to figure out how to navigate the situation by running additional experiments.
4. Converging on one model. To resolve the situation, students discussed with their partners potential experiments that could help prove or disprove their models. For example, to disprove the "weighs more" model, students came up with an experiment in which they used a scale to weigh the water when it was hot or cold; they discarded the model when they noticed the weight was the same. To evaluate the "infect" model, they decided to boil the diffusion water to examine the condensation on a cold plate; since the evaporated water was transparent, students agreed that the dye had not infected the water molecules and then discarded this model. Students in this class thereby converged on the "bounce off" model, which is the canonical explanation of diffusion.

Conclusions

Our findings indicate that creating models with real-world data provides students with learning opportunities that would hardly arise if they focused on model-based and data-based practices separately. We observed a shift in the mechanistic language students used to describe diffusion, shifting towards language aligned with a final canonical model. Contributing to existing work on how such convergences occur in classroom settings (see Lombard &

Weiss 2018 for a review), our findings suggest that the juxtaposition of video data of a real experiment and the model facilitated the process of generating multiple models, followed by subsequent comparison, evaluation, revision, and rejection. The scope of this paper did not allow for analyses of how the teacher guided this convergence, though previous research suggests significant influence (Millar, 2010). In future work, we intend to continue to examine the types of learning opportunities that arise from comparing real-world data and computational models, the conditions under which such opportunities arise and what designers and educators need to do to scaffold students' learning while using models authentically as tools of inquiry. Such lines of inquiry could additionally explore the ways that students' model building shapes their perception of science practices and of their agency as scientists.

The Role of Color in Debugging Lego Structures

Sezai Kocabas, Laura Bofferding, Yi Zhu, Yiheng Liang
Skocabas@purdue.edu, Lbofferd@purdue.edu, Zhu966@purdue.edu, Liang273@purdue.edu
Purdue University

Abstract: This study blended the fields of debugging, spatial thinking, and change detection. We explored 12 K-2 students' debugging skills as they fixed a Lego structure by using multi-color or grayscale manuals. Students in both groups were most likely to debug the bugs on the top and bottom of the structure, while the multi-color group was more successful at debugging bugs in the middle of the structure than the grayscale group, possibly because they were also more likely to trace the steps in the manual and use an understanding the structure strategy. Overall, students used debugging strategies similar to those found in programming, providing initial evidence that young students can successfully engage in debugging during unplugged, non-programming activities such as Lego building.

There has been increasing attention to the importance of computational thinking (CT) across the elementary curriculum in the United States. Two key aspects of CT that are found in unplugged activities are abstraction and debugging. Abstraction involves focusing on important components by ignoring unnecessary details, and debugging is identifying and fixing problems (Caeli & Yadav, 2020; Wing, 2008). In spatial activities such as Lego building, abstraction and debugging might be used in the process of 3-D shape composition and decomposition. In fact, one area where both CT and mathematical practices align (and debugging can play a significant role) is in analyzing and comparing three-dimensional shapes in different sizes and orientations and composing and decomposing three-dimensional shapes (Brennan & Resnick, 2012; Lye & Koh, 2014; National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010; Kotsopoulos, et al., 2017). To demonstrate that CT is an encompassing framework we also need to understand how children use CT in domains other than programming. Building on the popularity of spatial, block building activities in early childhood, we investigate CT in unplugged, non-programming-based activities by targeting debugging in Lego structures using a visual perception lens with a specific focus on how color plays a role in students' debugging.

Debugging in programming, offline, and visual-change-detection tasks

The greatest difficulty for novice programmers is debugging their code (Fitzgerald et al., 2008; Murphy et al., 2008; Wing, 2006). Students have been successful when debugging familiar code (Katz & Anderson, 1987) and easily found obvious bugs (Fitzgerald et al., 2008). Unplugged spatial activities such as block building and puzzles (e.g., Bell et al., 2012; Bofferding et al., 2021; Dietz et al., 2019) can also involve or support debugging. Bofferding et al. (2021) asked first and third graders to debug a non-standard shape puzzle, where students had to layer tiles on top of each other to create a composite design. More students debugged the puzzle on the posttest by using their spatial thinking skills, such as visualization and rotation of the tiles. Likewise, to complete change detection tasks (i.e., tasks where students must identify what is different between two scenes), students draw on visualization skills (Shore et al., 2006). Thus, spatial activities could support emerging debugging skills.

Finding bugs in spatial tasks requires visualization skills, such as detecting visual differences in change detection tasks. In such tasks, participants must determine what is different between two pictures. In one version, they see the original and changed picture side-by-side, similar to "Hidden Pictures" in the children's *Highlights* magazine (https://www.highlightskids.com/games). Prior studies have shown that visual differences are easier to detect if they are central to a scene (Rensink et al., 1997) and when there are fewer elements in the scene (Shore et al., 2006). Further, changes in object location or orientation were easiest to spot, followed by changes in color, and deleted parts were the most difficult to find (Rensink et al., 1997; Shore et al., 2006). Learning how children debug block structures could influence task design and bring this CT practice into classrooms.

Debugging strategies

Two main debugging strategies include forward reasoning and backward reasoning (Katz & Anderson, 1987). Forward reasoning involves searching for bugs starting from the initial lines of code or while paraphrasing or representing the code; whereas, backward reasoning involves searching for incorrect behavior by mapping output to lines of code (Katz & Anderson, 1987). Novice programmers and those unfamiliar with the code use forward reasoning more than backward reasoning (Fitzgerald et al., 2008, Katz & Anderson, 1987). Murphy et al. (2008) investigated novice programmer's debugging strategies, adding different categories to the classification of

 © ISLS

debugging strategies. These include strategies such as tinkering, tracing, and pattern matching. Tinkering refers to unproductive or random changes, pattern matching is recognizing differences by focusing on looking, and tracing is physical or mental checking of outputs with inputs in a linear fashion. Further, some young students rewrite the entire program instead of fixing buggy lines of the program (Bofferding et al., 2022).

Our Study

Our study blended ideas of debugging, spatial thinking, and change detection. We used a version of a side-by-side change detection task by giving students a complete Lego structure and asking them to fix the Lego structure to match a modified version of the structure. Our task involved students debugging multiple differences in one structure. In addition to exploring the features of size (e.g., a 6 x 2 versus a 4 x 2 block), thickness (e.g., flat versus standard block), and location or orientation, we also explored the extent to which seeing the pictures in color versus grayscale play a role in students' change detection and debugging. Finally, we explored the role of being able to see the larger picture in smaller chunks by providing students with a picture of the Lego structure versus a manual that shows how pieces are put together. Our main research questions were (1) What strategies do students use to debug a Lego structure? and (2) Which bugs (i.e., changes to the structure) do they fix? For each of these questions, we considered the role of seeing the manual in multi-color versus in grayscale.

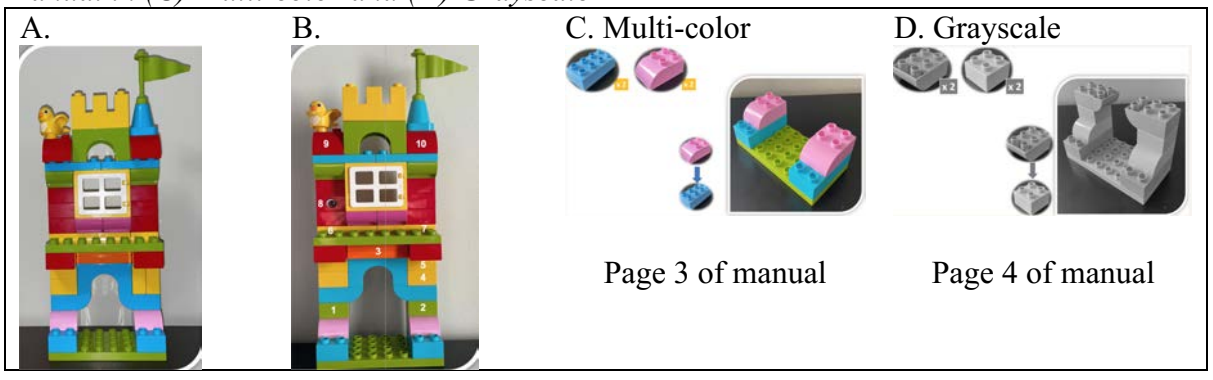
Methods

Participants and study design

We worked with four kindergarten, four first grade, and four second grade students during their afterschool program at a Montessori school in the midwestern United States. We targeted a balance of genders. All names in the paper are pseudonyms. The data in the study comes from the first out of three sessions of a project where we explored students' composing, decomposing, and debugging process through Lego building activities. During this session, students composed a Lego structure using multi-color or grayscale pictures versus step-by-step manuals. The focus of this paper is on the debugging activity that came next. Starting from their completed Lego structure (see Figure 1A), we wanted students to use a new manual to find and fix the differences (see Figure 1B). The new manual had a picture of a modified structure on the first page, followed by the steps needed to correctly make the Lego structure (see Figure 1C and 1D). This version of a change detection task involved 10 bugs or changes (labeled in Figure 1B) including missing pieces (bugs 1 and 2 in Figure 1B), incorrect pieces (bugs 4, 5, 6, and 7 in Figure 1B), incorrect placement (bugs 3, 9, and 10 in Figure 1B), and incorrect orientation (bug 8 in Figure 1B). Because some students saw the modified manual in grayscale, we did not include color differences as bugs. We worked with students individually and video recorded each session with two cameras.

Figure 1

(A) Initial Lego Structure, (B) Modified Structure, and Example Pages from the Building Manual in (C) Multi-color and (D) Grayscale



Analysis

We first identified each bug students fixed (and in what order) for a total of 10 bugs. We also made notes of whether they introduced a new bug while debugging, i.e., changed something that was correct or added in a piece that was not needed. Then, drawing on debugging strategies in programming (Murphy et al., 2008) and strategies used in change detection tasks (Shore et al., 2006), we classified students' debugging strategies (see Table 1).

Table 1

Program Debugging Strategies and Potential Application to Block Debugging Strategies

Debugging strategy	Programming description (Murphy et al., 2008)	Application to finding bugs in block structures or block composition
Tinkering	Students randomly make changes.	Students randomly add or remove pieces.
Tracing (top-to-bottom or bottom-to-top)	Students follow each line of code and match it with the result, reasoning forward or backward.	Students start at the top or bottom of the structure and match it sequentially with the steps in building the structure.
Pattern matching	Students just know what is wrong or recognize the bug based on experience.	Students quickly notice a difference by looking at the overall structure.
Rebuilding	Students reprogram from the beginning. (Bofferding et al., 2022)	Students take apart the structure and rebuild it.
Understanding the Structure	Students reason about how the code works and why there is a problem.	Students turn the physical structure or take apart parts to see how they are composed.

Results

Overall, students debugged 65 bugs out of 120 (M=5.4 out of 10). Interestingly, first graders found the most bugs (33 bugs), followed by kindergarteners (17 bugs) and second graders (15 bugs). Second graders' low performance may have been due to disinterest in fixing a Lego structure they had already put together. Students using multi-color manuals were more likely to debug than those using grayscale manuals (42 bugs versus 23 bugs, respectively). Further, students were most likely to debug the bugs on the top and bottom of the Lego structure. For example, bugs 1 and 2 (see Figure 1B), new pieces in the structure, were fixed by all six of the students in the multi-color group and three students in the grayscale group. Likewise, four students in each group debugged bug 8, which had an incorrect orientation, and bugs 9 and 10, which had an incorrect placement (see Figure 1B). Bugs in the middle of the structure were harder, especially for students using grayscale manuals.

Overall, nine students debugged by keeping the main structure intact as much as possible. However, two students (Carter A., a kindergartener from the grayscale group, and Yellow, a first grader from the multicolor group) used a *rebuilding* strategy and started over using the manual. Further, five students in the multi-color group, compared to two students from the grayscale group, used an *understanding the structure* strategy by turning the whole structure to identify bugs. This strategy might have been particularly useful for helping students notice bug 3 (see Figure 1B) because the pieces were no longer flush on the backside. Seven students relied on *tracing*, starting with the bottom of the structure (i.e., first step in the manual). Most of the bugs occurred symmetrically on left and right sides of the structure, encouraging students to use pattern matching. At one point, a few students started to remove the pieces symmetric to the location of bugs 4 and 5 (see Figure 1B) until they realized that those were already correct. Three students used a combination of *pattern matching* and *tracing*. For example, one first grader, Ashley, alternated between identifying changes in the picture and going through the steps of the manual. First, she noticed the uppermost differences in the structure (bugs 9, 10, and then 8 in Figure 1B), and then she fixed bugs 1 and 2 (see Figure 1B) while starting to go through the manual. After fixing the bugs at the bottom, she went back to the picture of the final structure and identified and fixed most of the middle bugs (bugs 4-7 in Figure 1B). Finally, she found and fixed the final bug (bug 3 in Figure 1B) using the manual.

Discussion and significance

Overall, students' success at identifying the bugs at the top and bottom of the Lego structure is interesting because in the visual change detection tasks, students have the easiest time identifying changes in central features (Rensink et al., 1997). If *central* means "toward the middle," students should notice bugs 4 and 5 (see Figure 1B) most often. However, students may have interpreted the top pieces as central to defining the structure or the base as central because it holds up the structure. Future work could incorporate student interviews about the nature of the structure and their impressions about the structure to better understand what parts they might consider central.

Another possible reason for students' focus on the top and bottom bugs is that they were easier to spot visually, consistent with programming studies (e.g., obvious bugs are easy to find, Fitzgerald et al., 2008). In fact, bugs 9 and 10 were under two visually striking pieces (a bird and a flag). However, based on prior change detection studies (e.g., Rensink et al., 1997; Shore et al., 2006), students should have had a hard time identifying missing pieces (bugs 1 and 2). Having the manuals that highlight pieces to use at each step likely reduced the difficulty of identifying the missing parts. Of particular interest were the differences demonstrated by students in the two groups: multi-color versus grayscale manuals. Students who did not identify the missing pieces were all in the grayscale group. Further, two of these three students did not look at the manual's steps, debugging by looking at

the picture of the final structure. Identifying the bugs in the middle of the Lego structure was more difficult, especially for the grayscale group. One reason may have been because the line designating a break between pieces was black, which may have been more difficult to discern in grayscale pictures.

The results of this study provide initial evidence that young students can engage in productive debugging tasks that are unplugged and that CT skills are broader than programming. Further, students' processes in working with the materials suggests a few implications for promoting debugging skills. First, children should be encouraged to understand Lego structures by rotating them and even investigating how certain pieces are put together. Second, Lego structures could involve both symmetric elements to encourage pattern matching as well as sections that do not lend themselves to pattern matching in order to encourage students to question how pieces are put together. Further research could then investigate to what extent debugging in these Lego environments might correspond to students' debugging in tangible, block-based programming environments.

Reflective Use v. Rote Use: Engaging Students in Computational Thinking for Science with Computational Tools

Sara Allan, Timothy Hurt, Eric Greenwald
sara.allan@berkeley.edu, thurt@berkeley.edu, eric.greenwald@berkeley.edu
University of California, Berkeley

Abstract: As computational tools are becoming increasingly common in scientific practice, developing students' computational thinking for science (CT-S) skills is a priority in science education. To support educators in meeting this need, we present a theoretical construct that distinguishes between science activities that engage students in CT-S through interactions with computational tools and science activities in which students use computational tools but do not engage in CT-S. We discuss how this theoretical construct can support educators in developing or modifying science learning experiences to promote CT-S.

Introduction

Contemporary science is becoming increasingly computational. Scientists employ computational tools to conduct investigations and contribute to the design of new computational tools for their specific research. To learn authentic science practices, students must have opportunities to think deeply about how to leverage the computational nature of tools for scientific purposes (Denning, 2017; Kaczmarczyk & Dopplick, 2014). This necessity is reflected in new science standards in the United States—most notably, the Next Generation Science Standards (NGSS), which mandate that computational thinking be taught as a practice of science (NGSS Lead States, 2013). Although it is becoming more common for science lessons to incorporate digital models, simulations, and other computational tools, the use of these tools alone does not guarantee that students will engage in computational thinking (Li et al., 2020; Yadav et al., 2016). We offer a theoretical construct that specifies whether a student using a computational tool is engaged in Computational Thinking for Science (CT-S).

Methodological and theoretical approaches

The theoretical construct presented in this paper contributes to an ongoing multiyear study investigating the role of computational thinking in middle school science learning. The project aims to create an instrument that can measure middle school students' CT-S abilities. At the commencement of this project, we convened a panel of experts in relevant fields—including educational research, learning design, computer science, and computational thinking—for a two-day retreat at the University of California, Berkeley. Participants reviewed a series of activities involving computational tools in the *Amplify Science Middle School* curriculum. Discussion centered on the potential of each activity to engage students in CT-S—defined as the cognitive processes involved in building or modifying a mental model of a computational tool's functionality within a given science activity. Participants concluded that for CT-S to occur, students would need to attend to the functionality and positionality of the computational tool within the given science activity. This was consistent with ideas about computational tool use in the literature (e.g., Grover & Pea, 2013; Sengupta et al., 2013; Weintrop et al., 2016).

We understand computational thinking as situated in activity and distributed across the actors and tools involved in an activity (Engeström, 1987; Greeno, 1998). These intrapersonal cognitive processes are only a piece of broader goal-directed activities, but are critical to understand nevertheless (Greeno, 2015). With this perspective, our team reexamined a set of science activities, employing Activity Theory as a framework for analyzing students' use of computational tools and cognitive processes in each situation (Vygotsky, 2012; Leont'ev, 1978; Engeström, 1987). This approach builds on an established tradition of using Activity Theory to analyze outcomes of technology-centered learning experiences (e.g., Brine & Franken, 2006; Murphy & Rodríguez-Manzanares, 2008). Activity Theory is a framework that considers an entire activity system that extends beyond the individual, or *subject*, engaged in activity to include the components that contribute to the outcome of the activity—like tools (Engeström, 1987). In an activity system, the subject's efforts are motivated by and directed toward an *object*, or *goal* of the activity (Kuutti, 1996; Engeström, 1987). Through the subject's employment of *tools*, an *outcome* of the activity is reached (Engeström, 1987). Tools in an activity system can be either physical or immaterial. Activity systems are dialectically structured, such that components mutually influence one another. Through using a tool, the subject may come to new understandings about the tool or the activity's goal—informing the subject's subsequent actions.

 © ISLS

For each middle school science lesson analyzed, we devised a series of activity systems—each with the same subject, computational tool, and context, but with a slightly different activity goal. We examined how the shift in goal would impact the students' use of the computational tool, their subsequent cognitive processes, and activity outcomes. Across lessons, we determined that computational thinking was most likely to be an outcome of activity systems in which the goal was to understand the functionality of the computational tool itself. This goal would arise, for instance, when students would tinker with a computational tool that they had never previously used, when students would investigate how to employ a computational tool in a novel way, or when students would encounter a glitch or an unexpected outcome during tool use and would need to reinvestigate an aspect of the tool's functionality accordingly. Aggregating examples resulted in a generalized Reflective Use construct.

We analyzed student interactions with computational tools without explicit attention to the cultural-historical mediators of activity characteristic of modern Activity Theory (Engeström, 1999). With measurement development as the primary motivator of our work, we made this choice in order to focus on the individual contributions of the subject within each activity: what are the cognitive resources brought to bear in tool-mediated, goal-oriented activity, and how might those resources and those mental models, become visible and get revised through activity? However, a complete understanding of CT-S within an activity system must attend to the complex situativity of learning represented in the "bottom row" of the modern Activity Theory triangle: the rules, community, and divisions of labor within activity systems (Engeström, 1999). We will address this in future work.

Reflective use construct

Activity Theory positions intelligence as being distributed throughout an activity system such that knowledge emerges from a subject's interactions with tools (Engeström, 1987; Greeno, 1998; Pea, 1993). It follows that when students use a computational tool, their activity could engender critical thinking about the functionality of the tool itself (Kaptelinin & Nardi, 2006; Kuutti, 1996; Jonassen & Rohrer-Murphy, 1999). However, students do not necessarily engage in CT-S every time they use a computational tool. Our construct distinguishes between science activities in which students engage in CT-S as a result of using computational tools, *Reflective Use*, and science activities in which students use computational tools but do not engage in CT-S, *Rote Use.*

Reflective use

A Reflective Use activity system is one where the subject builds a mental model of a computational tool's functionality by interacting with the tool. Imagine a student is investigating bacterial growth to better understand how bacterial populations change over time. This student has a graphing calculator (the computational tool) and data on a bacterial population's size at different timepoints. However, this student has never used a graphing calculator. Before this student could employ the calculator to investigate population growth, they would need to determine what computations this tool can perform that may support their science investigation. To do this, the student could engage in Reflective Use. The student might begin by manipulating the calculator, selectively pressing certain buttons, and observing the results of those actions. The student could then reflect on the outcomes of these actions and form an initial mental model of the graphing calculator's functionality. As the student continues to interact with this computational tool, their discoveries may reinforce, revise, or supplement their developing mental model. In this way, Reflective Use is bi-directional in terms of information transfer: the student takes actions, the student reflects on what the computational tool does, and the student takes new actions based on their reflection. Through this process of Reflective Use, the student builds a mental model of the graphing calculator's functionality with respect to their goal of graphing population growth: the student has engaged in CT-S. (Figure 1).

Rote use

Reflective Use stands in contrast to Rote Use of a computational tool. When a student is engaged in Rote Use, they do not build or modify a mental model of the computational tool's functionality. Building on the previous example, once the student has formed a mental model of the graphing calculator's functionality through Reflective Use, the student can now employ that mental model alongside the graphing calculator in a new activity system to create a graph of the bacterial growth data. (Figure 2). Since the student already knows what the calculator can do in this context, they do not need to engage in CT-S. As demonstrated, it is possible for Rote Use to immediately follow Reflective Use of a computational tool. However, these do not need to occur at the same point in time. Notably, Rote Use would also take place when a student uses a computational tool by merely following a step-by-step instruction set.

Significance

Attending to the distinction between Reflective Use and Rote Use can support the development and implementation of science learning experiences that effectively engage students in CT-S. Imagine, for instance, a science lesson in which students use a computer-based simulation to investigate the Guiding Question: *how are the Moon's phases related to the Moon's orbit around Earth?* The instructor could choose to begin the lesson by teaching students how to manipulate the simulation. The students might then employ the simulation, in accordance with what they have learned from the instructor, to make observations. Through using the simulation to make observations, students may arrive at an answer to the Guiding Question. In this Rote Use scenario, students would engage in thinking about the moon's phases and orbit; however, students would not need to engage in CT-S because the activity did not require students to construct a mental model of the simulation's functionality in relation to their science goal. To promote CT-S more effectively, the instructor could instead structure the lesson to begin with Reflective Use of the computational tool. For example, the instructor could start the lesson by asking students to consider: *how could this computer-based simulation support us in answering our Guiding Question?* Students would need to investigate the functionality of the simulation in relation to their goal of answering the Guiding Question—in other words, students would *reflectively* use the tool. After this Reflective Use, students could proceed to investigate the relationship between the moon's phases and orbit and formulate a response to the lesson's Guiding Question. When the lesson is structured in this way, using the computational tool could promote students' computational thinking in addition to their thinking about the moon's phases and orbit. Moreover, we posit that designing lessons to engage students in Reflective Use could motivate additional science learning opportunities. For instance, perhaps during their Reflective Use, the student observes that the moon sometimes enters into an eclipse but does not do so every month; this observation could inspire students to manipulate the simulation further to figure out how a 2-D model of the sun-earth-moon system is insufficient for understanding the 3-D interactions between the three objects. Overall, attending to the distinction between Reflective and Rote Use of computational tools could enable educators to design learning experiences that more effectively meet expectations for contemporary science education and that may lead students to engage with scientific phenomena more deeply.

University of Utah

Abstract: Cases have been used in teacher education to engage pre-service teachers (PSTs) with realistic situations that they might encounter in the classroom. While research suggests affordances of using cases for PST learning, little research has systematically explored productive features of cases or principles for case design. We use design-based research to develop design conjectures about the use of cases to support equitable mathematics and science instruction among PSTs. We describe a project in which we engaged in-service teachers in the development of cases grounded in their own teaching experiences and then implemented those cases as pedagogical tools in elementary mathematics and science teaching methods courses for PSTs. We share two design conjectures emerging from this work and discuss paths forward.

Introduction

Case-based scenarios, or cases, have been used to engage pre-service teachers (PSTs) with challenging classroom situations they might encounter. A case is typically presented with questions, asking PSTs to analyze the scenario and discuss potential responses. Cases have been shown to represent the complexities of teaching (Baier, Maurer, Dignath, & Kunter, 2021; Shulman, 1992), create opportunities for reflection (Abell et al., 1998), elicit PSTs' beliefs (Katsh-Singer et al., 2016), and enable PSTs to build connections between theory, practice, and teaching contexts (Shin, Brush, & Saye, 2019). Yet, little research has systematically explored productive features of cases and principles for their design. Here we see the potential for the learning sciences and, in particular, design-based research (Cobb et al, 2003; diSessa & Cobb, 2004; Sandoval, 2004). In this work, we focus on cases as a pedagogical tool to engage PSTs in exploring issues at the intersection of equity and elementary mathematics and science instruction, given persistent historical inequities in these domains.

Case-Based Scenarios in Teacher Education

Cases, or narratives depicting specific teaching situations, critically engage and challenge learners (Shulman, 1992). Scholars have employed cases for many purposes, from promoting growth of teachers who design cases (Arellano et al., 2001) to collecting data on teachers' beliefs (Katsh-Singer et al., 2016) to illustrating exemplary practices (Carter, 1999). We argue that cases could foster learning environments for PSTs that allow for links between theory and authentic practice. Yet, the development of cases is rarely discussed or problematized in existing research, leaving questions about how to produce cases that could support such an environment. While some aspects of case development have been identified, such as authenticity (e.g., Shin et al., 2019), these have not emerged from systematic investigations into design principles. Further, few studies have examined cases that forefront equity, yet developing equitable teaching practices is a key priority of teacher education.

Design-Based Research Approach

We use design-based research (DBR) to iteratively generate cases that foster PST learning. Aligning with the goal of DBR to build theory (diSessa & Cobb, 2004), in this paper we present design conjectures (Sandoval, 2004) that contribute to knowledge about how to design cases that forefront issues of equity in STEM education. We conceptualize equity in line with Aguirre et al. (2013) who describe the need for responsive instruction that centers learners' identities, competencies, and varied knowledge resources, while providing opportunities for all learners to engage deeply with mathematics.

Case Development, Implementation, and Data Collection

A team of teacher educator-researchers worked with in-service elementary teachers (ISTs) to design cases in three virtual workshops. ISTs first explored ideas about equitable instruction from Aguirre et al. (2013) and discussed their relevant experiences. ISTs then used their experiences to design cases for use with PSTs.

 © ISLS

Here we draw on data from two cases designed by two pairs of ISTs during the workshops. In the *Daily Schedule* case, a new teacher in a Title 1 elementary school with a large multilingual population is given their schedule and notices that they have been allotted only 1 hour for science each week and 45 minutes a day for math, compared to 3 hours per day for literacy. When the teacher inquires about the lack of science and math time, a coach replies, "That's not what these kids need." Discussion prompts explore the coach's perspectives and actions the teacher might take moving forward. In the *Group Dynamics* case, three students work together on a science activity about plants' water and nutrient needs. A dialogue is presented in which two students, Ramon and Roman, start working with materials rather than first doing the required computations stated in the instructions. Meanwhile, the third student, Keza, quietly works on the computations until the boys realize what she has done and take her work. Discussion prompts ask PSTs to analyze group dynamics and potential contributing factors and to discuss pathways to equitable group engagement.

The *Daily Schedule* case was administered in an elementary math methods course in two consecutive semesters. The *Group Dynamics* case was administered during two consecutive semesters in an elementary science methods course. PSTs first responded individually to prompts in writing and then engaged in discussion in small groups, followed by the whole class. Discussions were audio recorded, and written responses were gathered virtually. After each implementation, our team reviewed the data, noted key themes, discussed themes as a group, connected with prior research, and finally made changes to each case. To support our conjectures, we draw on artifacts, notes, and video recordings from our workshops with ISTs; documentation from research group meetings; written responses and audio recordings from implementation with PSTs; and prior research.

Design Conjectures and Lingering Tensions

Here we articulate two conjectures for case design at the intersection of equity and STEM instruction, providing supporting evidence and articulating tensions related to each. We also describe ways in which the conjecture can support deep engagement with cases at the intersection of equity and mathematics and science education. Our ultimate goal in this research is to share formalized design principles to be used by others; this work is a first step in that direction, proposing in-progress conjectures and describing initial evidence to support them.

Design Conjecture 1: To engage PSTs in deeper critical thinking and offer a framing of teaching as a complex activity involving continual learning, case prompts should ask PSTs to unpack and analyze situations, not come up with solutions.

While cases often ask participants to develop a solution to the presented challenge, we have observed that moving towards a solution limited PST thinking and encouraged simplification of the situation. For example, in the *Daily Schedule* case, the original third prompt asked PSTs how they might provide students with rich math and science learning opportunities despite stated constraints. All students who submitted written responses to that question mentioned integration as a/the solution – several excitedly so (e.g., "Integrating with other subjects!" and "Integrate!!! We can do reading comprehension with science and math with phonics!") These responses seemed to diminish the richness of responses to the first two questions, conveying a sense that the challenge is easy to solve. Here, we do not blame the PSTs; rather, we felt that asking for a solution to such a complex situation was unfair, as even the ISTs who designed the case based on their experiences were at a loss for what to do. In fact, they had previously discussed the possibility of integration but felt that the situation was more complicated than that. Given PSTs' tendency to turn to this solution, in part reducing the complexity and thinking brought forth by the first two questions, we revised our initial prompts (Figure A). In particular, we removed the final question and expanded the prior questions to draw out more deep thinking. We concluded with a prompt for PSTs to think about how they might work to advocate for students' math and science learning moving forward. This question conveys a sense of action as a process, rather than a simple solution, and encourages PSTs to brainstorm various types of information they would want to gather to engage in advocacy.

coach, administrators, or other stakeholders moving forward? a) What kind of research might be helpful to know about as you work to advocate for your students' math and science learning? (e.g. It would be helpful to know if researchers have studied… It would be helpful to know what research has found about…) 3. Knowing the constraints that currently exist, what are some things you might do in order to still provide your students with rich math and science learning opportunities?	engagement? What are the drawbacks of that perspective for student learning and engagement? 3. What is your own personal perspective, and what experiences have you had or ideas have you encountered to support that perspective? 4. Given the circumstances, how do you think you can best advocate for your students' math and science learning moving forward? a) What information would you want to gather and what research might be helpful to know about to inform your advocacy? (e.g. I would want to learn more about… It would be helpful to know if researchers have studied…)

We recently implemented the revised case and are analyzing the data; preliminary observations reveal some new emergent themes. In response to question three, many PSTs cited their own experiences as evidence for the drawbacks of emphasizing literacy at the expense of STEM subjects (e.g., "I have had a lot of language arts and English experiences...Mathematics was not a focus...I would argue that I feel more comfortable with writing and reading than with mathematics for this reason."). Additionally, question four elicited many responses about the value of data gathering and finding research to support your arguments with stakeholders (e.g., "I think that if I could present research and data that shows that there are not only studies outside of this school that support the idea of teaching math and science as a way to assist in reading, but that this concept has been applied and is working with my own classroom as well, it would be pretty helpful in making my point that we can use math and science as a way to help teach reading."). While some students did still write about integration, a wider variety of approaches were mentioned, and many PSTs focused on areas for teacher learning and strategies for arguing against the current schedule, rather than simple solutions to fix the problem.

Design Conjecture 2: Provide comparable demographic details about all students depicted in the case.

While we know specificity in cases is important (Nemirovsky & Galvis, 2004), prior research lacks theory around what kinds of details to include and how to include those details. One aspect we have investigated is the comparability of detail provided about each student. This conjecture emerged as our research team discussed the following paragraph that teachers wrote about the three students depicted in the *Group Dynamics* case:

> Keza, Roman and Ramon were put in a group together. Keza, a refugee from Rwanda, is good at math, has been in the U.S for a year and is part of the ELL class. She is the only student from an African country in a class mixed with other students of color. The two boys in the group are rowdy on the playground and good at math in the classroom.

One key challenge we noted is that details provided about the students in this description are not equivalent. Keza's refugee status, country of origin, and language are highlighted; while the boys' rowdy disposition and math competency are highlighted. In our prior work, we have seen PSTs perceive demographic details as cuing the solution pathway; such assumptions seem even more likely given the unevenness of the descriptions. This concern is supported by research about the tendency to name minoritized identities but not white students' identities (e.g., Gilliam et al., 2016), as well as how such naming can cue implicit biases and perpetuate stereotypes (e.g., Godsil et al., 2014). Subsequently, we rewrote the paragraph as follows:

> Keza, Roman, and Ramon were put in a group together. Keza tends to perform well and seems comfortable in math. She is a refugee from Rwanda, has been in the U.S for a year, and is multilingual while still learning English. Roman and Ramon are good friends, and they both perceive themselves as good at math. Roman is white and grew up on the Wasatch front. Ramon is Chicano and grew up in the Salt Lake area. Both boys are monolingual English speakers.

Here we attempted to provide comparable details about all students, including language spoken, ethnicity, where they grew up, and comfort level with math.

While our group agreed that presenting comparable details supports more equitable discussion, we continue to grapple with many tensions related to student demographic details. For example, we wonder which demographic details to include and how much detail to include overall such that those details are not perceived as the only – or even primary – keys to the solution, thus removing agency and critical thinking from PSTs. We

are currently exploring these questions by examining PSTs' responses to prompts in which we ask them to consider what factors might be playing a role in the situation. We will explore whether factors emerge that are not included in the case description, and how such answers differ in cases with few versus many details. Also, we have included prompts asking PSTs to discuss what else they would want to know to better understand the situation; we will analyze those responses to see if inquiries arise regarding additional demographic details.

Conclusion

In this work, we offer preliminary design conjectures for systematically designing case-based scenarios at the intersection of equity and STEM instruction. While the context for which we are designing is university methods courses for PSTs, we aim for these conjectures to be applicable to cases designed for a variety of purposes – for example, for both PSTs and ISTs. These conjectures can also be applied to cases designed by a range of stakeholders, from researchers and teacher educators to practicing teachers. Additionally, as we work to solidify these conjectures, we believe they might prove useful for designing activities beyond the types of case-based scenarios we describe, such as video cases and sample anecdotes provided in teacher education textbooks.

Moving forward, we hope that these conjectures will serve as a springboard for other scholars to systematically explore the design of case-based scenarios and prompts. While these conjectures certainly are not sufficient to cover all issues related to case design, we hope they offer a fruitful first attempt at moving the research field towards a rigorous, robust process for developing cases.

Designing for More Than Just Product: Student Co-design of Digital Badge Systems

Gavin Tierney, California State University, Fullerton, gtierney@fullerton.edu
Theresa Horstman, University of Washington Bothell, thorst@uw.edu

Abstract: Student co-design – the process in which students participate as an integral part of designing learning programs and curriculum – is one avenue for including student perspectives and experiences into the creation of curriculum and learning environments. Historically, the goal of co-design has been to finalize a product (video game, curriculum, badge system, etc.) and/or to validate the usability of a product. Examining data from student co-design of badge systems of three university courses, this paper provides a framework that expands the goals of co-design, specifically the co-design of digital badges, to focus on 1) impacting designers (youth and adult) and 2) impacting educational systems and processes. Findings indicate the value of the co-design of digital badges as a metacognitive process for learners, an assessment tool of learning for instructors, and an evaluation tool for programs.

Major issues addressed

With the goals of equitable and consequential learning, educational curriculum and programs often face the challenges of how to make learning meaningful, engaging, and authentic to students' lives. Student co-design – the process in which students participate as an integral part of designing learning programs and curriculum – is one avenue for including student perspectives and experiences into the creation of curriculum and learning environments (Pitt, et al., 2019; Tierney, Horstman, & Tzou, 2021). Co-design bridges learners' experiences, perspectives and expertise to that of the expectations designed into the educational program (Pitt, et al., 2019; Tierney, Horstman, & Tzou, 2021; Yip et al., 2017). However, when enacting co-design, it is valuable to address what the goals or outcomes of the co-design are. Broadly speaking the goal of co-design has historically been to finalize a product (video game, curriculum, etc.) and/or validate the usability of a product. Typically, with this goal, student and youth co-designers are involved as end-users. Yet, co-design, and specifically co-design of digital badges, creates a unique opportunity to accurately reflect the needs of the learners and at the same time enable the group to challenge implicit hierarchical structures embedded in curriculum design. To understand this further, we have identified three additional goals for co-design: 1) For the learners, it reveals their own thinking and perceptions of the content, prompting reflection and redirection when necessary, and is responsive to collaborators and experts. 2) For the teachers and educators, it brings to light the different perspectives of the learners, captures the unique dynamics of the community, making visible a scaffolding trajectories of learning content, and providing an opportunity for teachers and educators to observe their own learning and teaching. 3) Lastly, the structure of the badge system creates a vantage point from which both the learners and teachers can reflect how they view the hierarchy and relationships of the content itself. However, it is important to understand what the outcomes are when involving students. How does co-design of digital badges impact… a) The learning and development of students involved? b) The learning and development of teachers and educators involved? c) The educational structures and content in which the co-design is situated?

Potential significance

This paper describes a research project that used the co-design of digital badges as a design tool for student co-designers to map out their development and learning. This work is distinct from other research on the creation or co-design of digital badge systems, in that we used digital badges to design, without intention to create badges as an end product for future students to use. In this way the badge systems that were created act more as a conceptual map of learning and development. The badges describe activities and markers of successful completion but within the larger context of a learning trajectory. The close integration of co-design strategy with the structure of a badge system as an organizational mechanic, allows for highly tailored or customized learning experience for the group that creates it. The potential significance is developing a practice in which this model is scalable across different content types and communities.

Theoretical perspectives

Co-design can be a powerful approach for designing a curriculum that reflects the needs and priorities of its participants. In student co-design, students are asked to be an integral part of designing learning programs,

 © ISLS

curriculum, and assessments (Pitt, et al., 2019; Tierney, Horstman, & Tzou, 2021). In this model, students are treated as *design partners* in which they are "part of the research and design process throughout the experience." and "…considered to be equal stakeholders in the design of new technologies." (Druin, 2002). For educational equity, it matters who is involved in design. Student co-design as a process centers students in the design of the learning environments in which they participate. We argue that without utilizing a co-design approach, products such as digital badges may represent only hierarchical concerns while overlooking important but subtle aspects of learning and program experiences that are highly valued by learners. Further, through co-design, students can identify learning trajectories that are of importance to them and reflect the contexts and cultural practices of their communities in combination with the content and pedagogy taught in school courses.

Our approach to designing digital badge systems focuses on leveraging badge systems as a mechanism to involve students in the design process as collaborators (Pitt et al., 2019; Tierney, Horstman, & Tzou, 2021). Digital badges are part of what can be described as an achievement system (Hickey & Chartrand, 2020; Horstman, Tierney, & Tzou, 2020). One promise of digital badge systems is how they mark the combined social, emotional, and academic achievements that learners accomplish (Horstman, Tierney, & Tzou, 2020) and create visible trajectories for learners to follow (Pinkard, Barron, & Martin, 2008). Taken together, individual badges can create a pathway that, when followed, indicate what participants have learned, but also indicating membership of a learning community, having achieved valued practices and rites of passage. When badge systems are not used for motivational purposes but for educational program design, it serves as a mechanism for tracking a design framework in addition to highlighting the shifts in perspective around power, participants, and what is valued. Co-design of badge systems shifts the focus of the badge system as a design tool instead of an end product; its value is in its development. Combined, co-design of badge systems creates a unique opportunity that reflects values associated with socio-cultural models of program design. It makes visible and prioritizes the needs of the community, it is responsive to the uniqueness of the community it serves, it redistributes power and equity, and enables the agency of learners (Lave & Wenger, 1991; National Research Council, 2000; Rogoff, 2003). We believe this unique combination creates the right amount of space and structure to capture and reflect the unique needs of different learning communities.

Methodological approaches & data sources

In the spring, summer, and fall of 2021, students in the co-design of digital badge systems for three courses connected to a single-subject credential program in a teacher education program in the United States. The first course, Adolescent Development, is a prerequisite for entry into the Single-Subject Credential Program and is often one of the first courses students take in the College of Education. The students co-design for the Adolescent Development course focused on first creating a digital badge system that represented the course as it existed and then revising the badge system to focus centrally on equity and inclusion. Adjacent to this work, separate students and author one co-designed a digital badge system for two courses in the Single-Subject Credential Program: a General Pedagogy course and the Science Subject Methods Course. These two courses both occur in the first semester of the Credential Program and include fieldwork components, as candidates begin their student teaching. For all three courses, student co-designers had recently completed the course. Together, the three courses were chosen to understand developmental trajectories in and across courses at various points in the program.

Data for this project includes video recordings of virtual design sessions for three separate courses (19 sessions total). In addition, student co-design participants were interviewed following their participation in the design process. Analysis for this presentation focused on, first, an examination of digital badge systems as a design tool for mapping developmental trajectories and, second, the co-design of the digital badge systems with students in the credential program in order to identify learning and engagement in and across courses. More specifically, we analyzed video and documents from co-design sessions using grounded theory (Corbin & Strauss, 2008) to understand how students were making sense of the co-design process. The videos were reanalyzed and coded for using a previously developed coding scheme (Tierney, Horstman, & Tzou, 2021) that focused on negotiation of design content, as well as identified learning and development. We then analyzed interviews for perspectives on the design process and individual learning that occurred through co-design. Memos and associated vignettes of data were generated around emerging themes.

Major findings

While badges have traditionally been used to track and mark achievements in learning programs, this study demonstrates that the co-design process, in conjunction with badge structure, enables learning through program design. Though the final badge structure is important, it is evidence of how the participants interpret and prioritize learning content and activities as discovered through a badge co-design process.

Impact for learners

Co-design of digital badges reveals designers' thinking and perceptions of the content, prompting reflection and redirection when necessary. Across all three badge design processes, students were asked to identify aspects of their learning and development from the course of focus. Then, as a group, designers organized the content into a system of badges, each badge representing significant learning that had been identified. Across all three design processes, designers identified the personal value they gained from the process.

One student designer discussed how the co-design process had helped her transition into her role as a student teacher, helping to solidify what she had learned, while also pushing her learning through collaboration.

> I think it helped me realize how much I did learn so that I prepped me for the next semester. Like okay, these are all the things that I know and tools, I have in my back pocket now let's take them into the classroom and develop them, so I thought it was a cool way to like reflect but also move forward at the same time. And that the fact that over the summer I didn't just let it fall through the cracks I got to like discuss it and collaborate, I feel, stronger like in the classroom doing it.

The student then went on to discuss the collaborative nature of the reflection, how it highlighted new aspects of the course and sequence of the badges that she would not have gained on her own.

> And so, I had like my linear point of view of what I had learned and then I looked over at others. And they had totally different branches and we're making connections that once I looked at it, I was like that totally makes sense and it's like an aha moment. And then, when we combine them, all together was like I was saying, like the most well rounded version of that class. And I think if I was to do that, alone, it would have just been that like linear view um without, like the other things that they took away that made it unique for them, so I think the co-design made it like a learning experience but also made the badges like more than just like a one point of view, it was just everyone's once you put it together.

Similar statements were echoed by other student designers. One designer, who was involved in two of the badge design teams, reflected on her participation in general:

> I think it was fun, on a personal level for me just to review what I learned and kind of synthesize the class, especially since I'm becoming a teacher. That seeing the back end of design and being involved in it in a class I had just experienced was a really cool experience and I also felt like voices would be heard, without it being like in the class itself, so I think it's a great method to hear student voices.

Other students discussed how the conversations in the co-design sessions had transformed how they thought about education. One student who was an aspiring teacher noted how a discussion on whether or not teachers should accept late work changed how she thought about how she would approach and work with adolescents. In this way, the digital badge co-design sessions created a space of collaboration, reflection, and socializing that was distinct from other educational contexts that designers experienced.

Impact for teachers and educators

For the teachers and educators involved in co-design, the process can bring to light the different perspectives of the learners and learners' experiences. In this way, co-design of digital badges can act as an assessment tool for teachers on what learners took away from their course. To demonstrate one aspect of teacher/educator learning in the project, we highlight how the digital badge system captured concepts and pedagogy focused on equity and inclusion (a central tenet of the teacher education program in which the courses reside).

The first course, a science methods course, focuses on the epistemic practices for science teaching. This course focus was clearly represented in the digital badge system that student designers created. However, despite conversations around equity and inclusion in the program, these ideas did not initially emerge in the badge system for the course and, when they did, equity existed in a separate node of badges, removed from the primary interlocking system. The results indicate that equity concepts and practices were an add-on to students' learning about science pedagogy, which mirrored the actual design process of the science methods course.

In a second badge co-design process, a general pedagogy course, the course had recently undergone a revision during which equity was built in as one of the major pillars of the course. In the badge system, student designers both created equity-focused badges, but also discussed the ways in which equity pedagogy intersected with other badge nodes, such as building classroom community. While the course centered equity and inclusivity as central ideas, the badge design process introduced new connections and extensions that could be made.

The third badge co-design process focused on an undergraduate adolescent development course, which is a prerequisite for entering into the teacher education program. This course was already identified as needing to be more centrally focused on equity and inclusion. For this co-design process, student designers first created a badge system of their learning and development in the course. Then they redesigned the badge system to center

ideas focused on equity. This process required a reconceptualization of many of the course topics and ideas, a process that both co-design and badge design afforded.

Impact on educational structures and content

By involving students to be an integral part of designing the digital badge systems, they introduced concepts more directly linked to their experiences and development in and across the university courses. One key element of this process was how student participants drew links between existing course content and issues of race, equity, and inclusivity. This suggests the value of combining co-design and digital badges as a design tool to integrate development and engagement more deeply into learning environments. For example, after an initial brainstorming session where the participants captured main content ideas they felt should be included in the course, the participants began to organize and sort these topics by using funds of knowledge (Gonzalez, Moll, & Amanti, 2005) as the primary filter or lens. The following topics represent the highest priorities of the learners and the educators of what should be covered in their program: Student Wellness; Educator Role; Identity & Autonomy; and Puberty/Development. It should be noted that Puberty/Development is the only content category that is broken up into three sub-categories: biological, social and cognitive development. The sequence of topics identified by the group represents not only the agreed-upon priorities of the community, but also shows how the group views and interprets the relationship between topics. For these participants, the artifact of the badge system created a vantage point from which both the learners and educators can reflect on how they've represented the hierarchy and relationships of the content itself.

When failing generates math anxiety instead of productivity

Venera Gashaj, Dragan Trninić, Cléa Formaz
venera.gashaj@gess.ethz.ch, dragan.trninic@gess.ethz.ch, clea.formaz@gess.ethz.ch
ETH (Swiss Federal Institute of Technology), Zurich, Switzerland

Abstract: Experiences of failure and confusion can be intentionally purposed for learning tasks. In the Productive Failure instructional design, students attempt to solve problems before they are formally instructed on the relevant content. However, confusion and the perception of failing can elicit negative emotions in learners, even more so in students who already feel anxious about failure. Although research has demonstrated that failure can lead to math anxiety, and vice versa, the role of math anxiety in instructional designs that leverage moments of failure has not been investigated. This negative emotional cycle may negatively impact some students' learning and interest. We argue that future research would benefit from considering potential tradeoffs between enhanced learning and increased anxiety. We ground our arguments in an exploratory mixed-methods design that combines behavioral data with a task-based interview.

Affect and Math Anxiety in Math Education

The various elements of affect, attitudes, and student beliefs—such as those concerning one's understanding of math, or beliefs concerning success and failure—are increasingly acknowledged to play an important, yet poorly understood, role in math learning. For example, students' affective disposition can be a more critical predictor of entry into STEM subjects than enrollment and grades (Maltese & Tai, 2011).

When experiencing a negative emotion, we may focus on our negative sensations. Psychologically, this is done to find the means of eliminating the negative feeling. Thus, it is not surprising that there is an effect of emotions on learning, and studies have shown that learning is negatively influenced by unpleasant emotions, unless the tasks are simple (attention allocation elsewhere; see Hascher, 2010). Regardless of their valence, emotions can also be beneficial for learning, such as happiness (Kim & Pekrun, 2014), confusion (D'Mello et al., 2014), and even frustration (Liu et al., 2013). On the other hand, boredom and anxiety are associated with reduced learning (Pekrun, Elliot & Maier, 2009), while frustration can be destructive (Kort, Reilly & Picard, 2001).

While uncertainty has been shown to be beneficial for learning, it may also be detrimental (Lamnina & Chase 2019). In short, instructional designs that intentionally generate uncertainty could contribute to either:

(1) negative emotions about knowledge (Sinha 2021): a focus on the uncertainty of the problem, or

(2) negative achievement emotions (Pekrun & Linnenbrink-Garcia, 2014): a focus on personal failure.

Thus, fostering uncertainty could lead to (1) curiosity to learn what the student is (now aware to be) lacking—but may also lead to (2) self-preoccupying thoughts that interfere with learning. The latter may even feed into vicious cycles of anxiety and failure (Pekrun, Elliot & Maier, 2009). Some affective aspects in math learning appear to be rooted so deeply that they are difficult to diminish by instruction (Gomez-Chacon, 2000).

Because there is more to a learning situation than the *local* affect, we also must attend to the *global* affect—the lingering presence of experiences that made the learner the person they are (Gomez-Chacon, 2000). We argue that it is important to also attend to the more global affects, such as *math anxiety*, when designing for uncertainty. Math anxiety, which develops through various educational and non-educational experiences throughout the learner's life, has been described as a feeling of panic, helplessness, paralysis, and mental disorganization that arises when one is solving a mathematical problem or managing numbers (Ashcraft, Kirk & Hopko, 2000). In interviews with math anxious individuals (Sloan, 2010), the most reported causes of math anxiety were: negative experiences with math classes, teaching practices in school, memorization of procedural knowledge, math avoidance—low math achievement, test anxiety—failure, lack of confidence. Thus, pre-existing math difficulties cause or aggravate math anxiety (Núñez-Peña & Suárez-Pelliconi, 2014), and poor math performance can lead to math anxiety. Taken together, math anxiety is not merely a local affect but is better understood as a global affect that influences learners' behavior and cognition. This global affect ought to be considered when designing instruction that generates instances of failure and uncertainty, because this approach could generate or reinforce a student's already existing negative attitudes, beliefs, and feelings towards math.

Productive Failure and Affect

Productive failure (PF; Kapur, 2016; Kapur & Bielaczyc, 2012) is a subset of Problem Solving followed by Instruction designs (PS-I; Loibl, Roll, & Rummel, 2017), that broadly follow the paradigm of preparation for

 © ISLS

future learning (Schwartz & Bransford, 1998). In PF, the problem-solving phase is intentionally designed as an initial generation and exploration phase, which offers students the opportunity to activate existing and intuitive knowledge. Since the problems are based on concepts that have not been formally taught to the students, the problem-solving phase typically generates feelings of uncertainty and moments of failure (e.g., incorrect solutions). In a subsequent instruction phase, the desired concepts are conveyed to the students.

PF designs, like impasse driven learning (Van Lehn, 1988), lead students to an impasse in their learning that forces a transition into "repair" strategies, such as seeking help, to overcome the impasse. Piaget (1964) formulated in his theory of cognitive development that we experience a state of imbalance when encountering information that requires us to develop new schema or modify existing schema. This uncomfortable state of imbalance drives us to the assimilation of new schema or the adaptation of old schema. Without accommodation, we are left with old schemas. For some, this might be "I am not good in math; I don't know how to do it".

Present Study

Only a few studies investigated the role of affect in PF (e.g., Lamnina & Chase, 2019; Sinha, 2021). To our knowledge, we are the first to investigate math anxiety specifically in a PF design. Math anxiety affects all stages of cognitive math processing (e.g., Ashcraft, Kirk, & Hopko, 1998). Therefore, we hypothesize that students with higher levels of math anxiety will benefit comparatively less from the PF design on learning outcomes.

Method

Participants

Sixty-two students (age range = 18-24) were randomly assigned to one of the conditions (PS-I or "Direct Instruction followed by Problem solving - I-PS"). Two students dropped out due to their high level of math anxiety. Those two students took longest on the task and vocalized their perceived difficulties and feelings towards the situation. The first author took notes of these comments and conversations and translated them to English. All participants were naïve to the goals of the experiment and provided written informed consent. The study has been approved by the local Ethics Committee following the Declaration of Helsinki.

Procedure and Materials

A classical PF design (Kapur, 2014) was used along with questionnaires about different cognitive and affective mechanisms such as knowledge gap awareness, state curiosity, cognitive load, learning goal orientation, and attitudes towards mistakes (Sinha & Kapur, 2021). In addition to that and relevant to the present study, math anxiety was measured with the Abbreviated Math Anxiety Scale (AMAS; Hopko et al., 2003). The participants responded using a 5-point Likert-scale, ranging from 1 (low anxiety) to 5 (high anxiety).

Results and discussion

Quantitative results

An ANCOVA was performed to investigate whether the conditions would differ in the posttest scores. The results are shown in Table 1. Contrary to expectations from previous research, the students in the PS-I condition (M = 19.37) did not significantly outperform those in the I-PS condition (M = 19.03). Moreover, there were no differences on any other cognitive and affective measurements. However, the impact of math anxiety—as a covariate in the analysis—was highly significant and could explain why the students in the PS-I condition did not perform better on the posttest. This supports our hypothesis that math anxious students—who were more prominent in the PS-I condition—do not benefit as much as non-math anxious students from the PF design.

Table 1
ANCOVA for Achievement by Instruction Type, Attitudes and Feelings

		Achievement		
Type of Instruction		**Mean**	**SD**	**N**
I-PS		19.03	4.00	30
PS-I		19.37	3.45	32
Source	**SS**	**MS**	**F**	**η^2_p**
Condition	12.59	12.59	1.17	0.02
Math Anxiety	121.30	121.30	11.31*	0.16
Learning Goal Orientation	4.12	4.12	0.38	0.01

Qualitative results and discussion

The quantitative results do not capture the experience of the excluded participant Belinda (name changed; highest AMAS score in the sample: 43). The inclusion of interview notes illustrates the challenges faced by math-anxious individuals when dealing with designs that intentionally introduce feelings of uncertainty and failure.

> Belinda: [looking at first author after reading the problem] "Oh, I don't know how to do this!"
> First author: "It's okay, it's about learning something new, the solution doesn't have to be right."
> Belinda: "Okay, but this is math, and I am *not* good in math." […]
> [solving the task shows motor restlessness, changes sitting position, fidgets, sighs heavily]
> Belinda: "Can you please give me clues? I don't even know what to do. […] If I don't get an example of how to solve [a math problem] or an explanation I don't know how to solve it."
> First author: "[…] It's not about doing it correctly, just about trying. […]"
> Belinda: "Okay, I'll try. If I do this [shows notes] is it going in the right direction?"
> First author: "See, you're coming up with something without being instructed."
> The problem-solving phase ends, and first author explains the next step of the instruction phase.
> Belinda: "Oh no, now I will see how wrong I was."
> First author: "You'll see a standard way to solve the problem. You're not wrong but creative."
> Belinda: "Erm… So… my nervousness has increased quite a bit over time, and…I'm actually very nervous. Maybe also a bit afraid… afraid that I will fail. I am not sure if I will recall…"
> First author: "[…] it is okay if you don't recall the formula, maybe you recall some parts of it or comprehend what the formula said. That's all fine and you're already learning. […] even if you wouldn't recall the formula, you'll be okay… you can stop whenever you want."
> Belinda: "Okay, thank you... [sighs] …" [reads the questions and attempts to solve the tasks, sighs heavily and buries her head into her hands, but continues, persevering for 20 minutes]
> Belinda: "I can't do this. I am trying but I'm frustrated, I'm also afraid to fail, it makes me think of my fear instead of focusing on the questions. Can I stop please?"
> [Task is stopped. Conversation continues with support for anxiety, not relevant to task]

The case of Belinda highlights how this instructional strategy had a severe impact on one participants' math anxiety during the learning process, leading to them dropping out in the posttest.

Conclusion and Future Directions

While PF designs tend to produce positive effects on student understanding, they also generate moments of failure and feelings of uncertainty. This is not a criticism *per se*: after all, learning math *is* difficult. However, the concern is that certain learners might experience increased math anxiety and more negative opinions regarding their abilities and knowledge. Even if learning can be increased with such designs, do we not also court the risk of losing potential STEM students? As Maltese and Tai (2011) suggests, it may be possible to simultaneously *increase* students' math achievement yet *decrease* their interest in majoring in STEM fields.

Further research should be done to determine whether the present results can be generalized. Future experimental studies should contrast math anxious and non-math anxious students in a PF design (i.e., a 2x2 design, PS-I vs I-PS, math-anxious vs non-anxious) to investigate if math anxiety leads to lower posttest scores. Nonetheless, the present results offer support for our central argument that math anxiety plays a significant and thus-far unexplored role in instructional designs that generate moments of uncertainty and failure.

Course instructors and teachers should be aware of these findings, such that appropriate help and support can be provided to. In an ideal setting, students can experience curiosity and benefit from such designs, yet "ideal" is not something we can intentionally design for. Increased attention to affect in the learning of math, and particularly to math anxiety, would bring us closer to our shared goal of "educational innovation for all."

The Role of Action-Prediction in Mathematical Reasoning

Fangli Xia, Kelsey E. Schenck, Michael I. Swart, and Mitchell J. Nathan

University of Wisconsin - Madison

Abstract: Action-cognition transduction (ACT) posits how body movements support actors' inference making by activating feedforward and feedback mechanisms in consideration of plausible outcomes. Following ACT, we investigated whether prompting people to predict future body states (i.e., feedforward processes) facilitates mathematical reasoning. In this randomized 2x2 factorial experiment, undergraduate students (N = 127) *performed directed actions* (Yes/No) or *generated predictions* (Yes/No) prior to justifying the veracity of geometry conjectures. As predicted by ACT, directing participants to mimic cognitively relevant directed actions facilitated mathematical insight, though moderated by task demands. Moreover, merely prompting participants to predict movements, with or without performing directed actions, also enhanced proof performance. This study provides insights into how body-based simulation induces inference-making in support of conceptual understanding for mathematical transfer and generalization.

Introduction

Theoires of grounded and embodied cognition (GEC, Barsalou, 2008) adhere to the premise that cognitive processes emanate from and are influenced by one's body-based actions and simulations of actions. Goal-directed actions engage both feedforward and feedback processes that assess current states of the world in order to anticipate all of the plausible future actions, thereby integrating information from both actual and anticipated outcomes (Pezzulo, 2008). The continuous interplay between acting in the world and anticipating consequences of those actions illustrates the close reciprocity between sensorimotor and cognitive processes (Neisser, 1976).

In the current experiment, students observed the movements performed by animated avatars and were prompted to predict which body movements the avatars will make next. It is hypothesized that engaging in these action-predictions activates spatial-motoric processes that facilitate one's reasoning about space and shape (Nathan & Walkington, 2017). By connecting anticipatory nature of actions with reasoning processes, this study investigated whether action-prediction influences people's mathematical reasoning in geometry proof.

Theoretical framework

One of the core assumptions for embodied learning is that cognitive processes operate as a *predictive architecture*. People do not passively wait for input to act but continually anticipate what is to come in streams of sensory input, and we are poised to respond (Clark, 2015). *Action-Cognition Transduction* (ACT; Nathan, 2017) is consistent with this philosophical view of cognition, by framing action and cognition as reciprocal processes operating in close concert: Thoughts drive goal-directed actions; and actions induce cognitive states commensurate with those goal-directed actions. ACT offers an account of how actions and simulations of actions activate feedforward (i.e., predictors) and feedback (i.e., reaction) mechanisms that anticipate and respond to outcomes, thereby influencing the actor's behaviors and cognitive states.

When the actions are deemed as *mathematically relevant* they can contribute to enhanced mathematical reasoning. This occurs in cases of spontaneous co-speech and co-thought gestures (Nathan et al., 2021). It also occurs in cases when people are prompted to perform specific mathematically relevant *directed actions* as part of a designed intervention (Nathan et al., 2014). Some studies have shown that directed actions can prime gesture production during learners' explanations, which, in turn, contribute to superior cognitive performance (Donovan et al., 2014). Similarly, Nathan and colleagues (2014) found that compared to those who performed unrelated arm movements, participants who were directed to perform conceptually related movements were more likely to generate key mathematical insight for conjectures. However, similar to Walkington et al. (under review), relevant directed actions by themselves may not directly improve mathematical reasoning, but do so through moderated effects of "gestural replays" of these actions during their multimodal explanations.

Prior results suggest that relevant directed actions can prompt reasoning through nonverbal means. However, their connection to more complex processes like proof production might require additional pedagogical tools to fulfill their purpose. Prediction, or the combination of directed actions and prediction, might be needed to support students' reasonings about mathematical transformations. Thus, we investigated three research questions: (RQ1) Does predicting actions impact students' geometry insight, proof, or gesture? (RQ2) Does performing

 © ISLS

relevant directed actions impact students' geometry insight, proof, or gesture? (RQ3) Does predicting relevant directed actions that they perform impact students' insight, proof, or gestures?

Methods

Participants

Participants included adult students (N = 127; 63.0 % female) recruited from a large university in the Midwestern United States. Out of these participants, 33.9% had not taken Calculus I, 46.5% had completed or were enrolled in Calculus I or II, and 19.6% had taken or were taking a mathematics class above Calculus II.

Procedures

Participants were randomly assigned into one of four groups using a 2x2 between-subjects design: (1) perform *directed actions* (DA=Yes; DA'=No) and (2) generate *predictions* (P=Yes; P'=No). They took part individually with an interviewer. After going through the instructions and completing a practice-trial example conjecture, participants started the actual conjecture tasks. Participants were prompted to read a mathematical conjecture (see an example in Figure 1). Next, they adhered to one of four conditions: (1) Condition DA+P' participants (n=30) mimicked the complete series of three directed actions without any prompt to make predictions (see directed actions in Figure 1); (2) DA+P participants (n=30) mimicked an incomplete sequence of directed actions and were then shown the "?" symbol and asked to predict a "possible" third movement; (3) DA'+P participants (n=37) were not exposed to any directed actions but were asked to "imagine" movements that could enact the geometric transformation of each conjecture; (4) DA' +P' (i.e., the control group; n=30) participants received no directed actions and were not prompted to make predictions. Finally, participants completed each conjecture by answering a prompt to consider the statement's veracity (i.e., *always true* or *false*) and to provide a verbal justification. Each participant completed a set of eight conjectures with order counter-balanced.

After giving video-recorded responses to the eight conjectures, each participant was asked to complete surveys about demographics, general geometry knowledge, and spatial reasoning. Prior study have revealed that gender, math expertise, and spatial ability are correlated with geometric reasoning (Nathan et al., 2021).

Figure 1

An example conjecture "If you halve the length and the width of a rectangle, then the area is exactly halved."

Note. These directed actions are intended to convey a key insight related to this conjecture – that the area would actually be smaller than a half by halving both the length and width.

Coding

Video recordings of participants' responses were transcribed and coded. Insight (reliability κ = .93) was measured by the participant's understanding of key mathematical ideas for each conjecture. Each participant's verbalized proof (reliability κ = .96) was coded following Harel and Sowder's (2005) three criteria: (1) *generality* of the argument, (2) use of *operational thinking*, and (3) exhibit a chain of *logical inference*.

Representational gestures (Alibali et al., 2001) were classified as either non-dynamic or dynamic depictive gestures (reliability κ = .95). *Non-dynamic gestures* reflect only static properties of the mathematical entities, such as tracing along a shape. *Dynamic depictive gestures* enact motion-based transformations of mathematical entities, such as dilating triangles (Garcia & Infante, 2012).

Results

Data analysis employed mixed-effects logistic regression models for binary outcomes on insight, proof, non-dynamic and dynamic depictive gestures. Models were fit using the *glmer* command of the *lme4* package in R. *Participant ID* and *Conjecture* were included as random effects. All models included the *experimental condition* as the primary predictor. Three student characteristics, *gender*, *students' most advanced previous math course*,

and *spatial score,* were retained in the models as covariates that significantly improved the fit of our models. Finally, we report odds ratios that are exponentiated raw coefficients.

Research Question 1: Effects of prediction on performance

To address RQ1, we used the experimental condition prediction (P) vs. no prediction (P') as the main predictor. The regression model predicting insight showed that having a math course above Calculus II strongly predicted insight (OR = 4.48, d = .82, p <.001). Similary, having a math course above Calculus II (OR = 1.59, d = .25, p = .048) and high spatial scores (OR = 1.17, d = .09, p = .001) were associated with valid proofs. Consistent with the primary hypothesis of this investigation, students who predicted the movements, whether or not they actually performed them, were significantly more likely to formulate a mathematically valid proof (OR = 1.45, d = .21, p = .035), even when controlling for gender, prior math courses, and spatial ability.

Additionally, the models predicting gestures show that the spatial score was positively associated with dynamic depictive gestures (OR = 1.17, d = .08, p = .007) while negatively associated with non-dynamic gesture (OR = .9, d = -.05, p = .018). However, the prediction condition (with prediction versus no prediction) was not a significant factor for predicting the production of dynamic depictive gestures or non-dynamic gestures.

Research Question 2: Effects of directed actions on performance

To address RQ2, we used the experimental condition of performing cognitively relevant directed actions (DA) vs. no directed actions (DA') as the main predictor. As with the model used for RQ1, having a math course above Calculus II predicted insight (OR = 4.56, d = .83, p < .001). And the spatial score still predicted proof performance (OR = 1.16, d = .08, p = . 002). The models predicting gestures showed that males were less likely to produce dynamic depictive gestures (OR = .63, d = -.25, p = .045). Spatial scores predicted dynamic depictive gestures (OR = 1.17, d = .09, p = .006), while negatively associated with non-dynamic gesture (OR = .90, d = -.05, p = .017). However, the experimental condition (DA vs. DA') was not a significant predictor of insight, proof, or gestures. The results, which were not collected during game play, are not consistent with studies of embodied video game play showing advantages of directed actions (Nathan & Walkington, 2017).

Considering the overall high performance on geometric reasoning (i.e., around 70% produced correct insight), we further analyzed participants' behaviors (n = 381) on three conjectures that showed a relatively lower percentage of correct proof performance (less than 33%) but did not show a floor effect (higher than 10%). The results showed that performing directed actions predicted insight (OR = 1.85, d = .34, p = .043) for these difficult conjectures. However, there were no differences in proof performance or gesture production with or without relevant directed actions. These results show that participants performing relevant directed action were more likely to generate insight compared to those who did not while justifying difficult conjectures.

Research Question 3: Effects of predictions of directed actions on performance

To address RQ3, we used four experimental conditions as the main predictor. Having a math course above Calculus II was still a strong predictor of insight (OR = 4.45, d = .83, p < .001). When controlling for prior math courses, there was a trend that participants were more likely to produce correct insight if they predicted the relevant directed actions that they performed (DA+P; OR = 1.65, d = .28, p = .081). For proof, males and high spatial scores predicted proof performance (OR = 1.61, d = .26, p = .045; OR = 1.16, d = .09, p = .002, respectively). Similarly, there was a marginal trend suggesting that participants were more likely to construct a valid proof if they predicted movements without directed actions (DA'+P; OR = 1.54, d = .24, p = .080).

Gesture models show that males were less likely to produce dynamic depictive gestures (OR = .63, d = -.25, p = .045). High spatial score was associated with dynamic depictive gestures (OR = 1.17, d = .09, p = .006) but negatively associated with non-dynamic gestures (OR = .91, d = -.05, p = .021). However, the experimental condition was not a significant predictor of either dynamic or non-dynamic gestures.

Discussion

One of the central premises of embodied theories of learning is that people continuously operate in an anticipatory manner (Clark, 2015). This predictive stance allows us to engage in simulated actions that model how the state of the world—us included—will change in response to our behaviors. Because our motor system is constantly projecting how our actions will change the world, Action-Cognition Transduction (Nathan, 2017) is one account for how actions can construct grounded, situated "abstr-actions" (Abrahamson et al., 2020).

In answer to RQ1, as predicted by ACT theory, prompting people to predict actions led to significant advantages for formulating valid mathematical generalizations. In response to RQ2, mimicking cognitively relevant directed actions helped students generate accurate mathematical insight about difficult conjectures. The benefits for difficult tasks suggest this is where cognitive processes may benefit most from both actions and

simulating actions. Concerning RQ3, predicting cognitively relevant actions that were also performed showed only marginally significant benefits above and beyond predicting those actions. These findings suggest that action-prediction may facilitate participants' mathematical reasoning by simulating the future states of geometric transformations needed to support mathematically valid generalizations and proofs.

These findings contribute to the emerging theories of grounded and embodied cognition (GEC) in two ways. First, our results provide direct evidence to support ACT theory: motor behaviors and cognitive processes are closely coupled; movements – even when they are simply imagined – can benefit cognition. Second, this study extends prior research by providing an interactive environment where students engaged in actions and action-predictions as a path toward more advanced reasoning. Prior research has shown that students' proof performance was improved when they were told that the directed actions were mathematically relevant (Nathan et al., 2014). Because action-prediction is an integral component of most action sequences, it is rare to methodologically isolate the influences of action-prediction from action on thinking, as was done here.

This study has several limitations. One is that there may be additional interpretations of these results other than ACT, as a rich set of cognitive and post-cognitive frameworks for embodied learning emerge (e.g., Abrahamson et al., 2020; Danish et al., 2020). Another is to explore replication of these findings with a broader set of tasks and participants, and in face-to-face settings.

Nonetheless, these findings offer implications for mathematics education. First, there is educational value in engaging learners in mathematically relevant actions. Second, math educators can capitalize far more on the value of imagination and action-prediction for fostering reasoning that supports inference making. Third, the emerging designs of embodied interventions offer students active contexts and invite students to step into their roles as interactive learners who utilize rich body-based resources for supporting mathematical transfer.

When Care is Not Enough: A Call for Critical and Sociopolitical Conscious Care

Gavin Tierney, California State University, Fullerton, gtierney@fullerton.edu
Rebecca Smith, University of Portland, smithre@up.edu
Paul Sutton, Pacific Lutheran University, suttonps@plu.edu

Abstract: Noddings' (1988) argument for reframing of the aims of education around care centers modeling, dialogue, practice, and confirmation. Roberts (2010) calls for *culturally relevant critical teacher care* (CRCTC), which integrates tenets of culturally relevant pedagogy (Ladson-Billings, 1995) and critical race theory. In this study, we use culturally relevant critical care within the context of multiple teacher education programs. Results include a) considering socio-political contexts of learning and being when enacting care and b) modeling care and vulnerability. This work contributes to a revisioning of Noddings' (1988) framework to be more inclusive and racially conscious.

Major issues addressed

In Noddings' (1988) argument for reframing the aims of education around care, the pedagogical practices of modeling, dialogue, practice, and confirmation take center stage. She defines modeling as when "teachers treat students with respect and consideration and encourage [students] to treat each other in a similar fashion" (p. 223). She defines dialogue as ongoing conversation where "conclusions are not held by one or more of the parties at the outset" (p. 223). In dialogue, teachers model respect and consideration by co-constructing solutions with students. Noddings states, "in a classroom dedicated to caring, students are encouraged to support each other; opportunities for peer interaction are provided, and the quality of the interaction is as important as the academic outcomes" (p. 223). By confirmation, Noddings describes a dynamic whereby teachers empower students to identify and clarify their purpose in life and work to support them in that effort. These practices both constitute specific teaching moves, and they work in concert to re-establish classrooms as places where teachers work with students to establish more ethically- and morally-just learning spaces.

Noddings' (1988) care framework has provided meaningful guidance for educators seeking to care for their students. Research exploring the use of this framework over time varies in both application and understanding of care. For instance, one qualitative study (Walker & Gleaves, 2016) explored higher education teaching faculty perceptions of care in teaching. Results indicated that caring teachers had four key characteristics: (1) a relationship at the center (i.e., quickly learning students' names, responding to emails in a timely manner, initiate contact with students when challenges arise); (2) compelled to care (i.e., spending multiple hours supporting students, facilitating learning in various ways, explicitly support student diversity); (3) caring as resistance (i.e., defend students when needed, question policies); and (4) caring as less than. This final point referred to teachers who felt passionately about teaching but who felt the need to justify their positions through awards or publications rather than focusing on students. Another study (Anderson et al., 2020) that focused on student perceptions (n = 55) of good teaching at a New Zealand research institution found: "[Students] described good teachers as people who care about their discipline, care about teaching and care about students, powerfully influencing students' engagement with subject matter, enthusiasm for learning and aspirations for the future" (p. 1). Perceptions of care from both the teacher and student perspective have variations, but they appear to focus on relationships. However, other studies focused on the use of care with marginalized populations highlight the need to support students beyond the care framework. For instance, one ethnographic research study (Hos, 2016) explored the experiences of refugee students who were recent immigrants to a U.S. urban secondary school. The study found that the teacher exhibited ethical care for these students, and yet these students needed additional support in order to be successful in their new lives in a U.S. school. Another study exploring the intersection of race and care analyzed the experiences of middle school girls from Puerto Rico (Rolón-Dow, 2005); this research advocates for the use of "counternarratives to provide more intimate, caring connections between teachers and the Latino communities where they work" (Rolón-Dow, 2005, p. 77). While a care framework is still necessary, the need to expand its application is critical for supporting all learners.

These studies demonstrate the benefits of care within teaching, while also identifying the need to examine a) how care is being defined and bounded and b) question who is defining care. Care is typically defined and enacted within powered relationships and structures within education (Noddings, 2012; Roberts, 2010). An authentic narrative of care must consider factors beyond the classroom that impact student learning

 © ISLS

and could redefine how care is understood by educators and students alike. This understanding of care shifts the role of protagonist to students within teacher-student relationships, where students help define care within the contexts of their lives (Roberts, 2010). Framed within the context of teacher preparation, culturally relevant critical care requires both providing this form of care to teacher candidates and also supporting candidates' learning and teaching practices focused on culturally relevant critical care. For our study, we sought to understand socially conscious perspectives of care within teacher education programs during the first year of the COVID-19 pandemic.

Potential significance

This study highlights the need for teachers to listen to the expressed needs of their students, particularly as those needs relate to the sociopolitical context of the time. Demonstrating care for students should not be a simple show of values, which could be detrimental in promoting imbalanced power dynamics (Noddings, 2012) or deficit models of students, perpetuating racist thinking (Matias & Zembylas, 2014). Rather, care entails co-construction of learning between the teacher and the student. This collaborative relationship can relate to assignments, instructional activities, and discussions. Au (2017) calls for teacher activism to disrupt the injustices seen in schools and districts across the U.S. to "help build student and teacher critical consciousness around what is happening right now in the United States. For instance, we ought to complicate students' understandings by analyzing the history, economics, politics, environment, and human experiences of the U.S.-Mexico border" (Au, 2017, p. 148). Addressing immigration is only one issue that is relevant to our students and teachers alike. These social and political issues must be integrated into the curriculum as we prepare teachers to respond to the calling to be an educator. This collective consciousness focused on working for justice can help to create honest, authentic, and caring learning environments that honor the lived experiences of our diverse students. Doing so can contribute to a revisioning of Noddings' (1988) framework to be more inclusive and racially conscious.

Theoretical and methodological approaches

Research studies that focus on critical care for students utilize a variety of terminology in their understanding of care and advocacy for students. Rector-Aranda (2018) calls for teacher education programs to integrate *critically compassionate intellectualism* (CCI), which combines critical pedagogy, authentic caring, and social justice curriculum. Authentic caring is defined as relationship-focused teaching that promotes a respectful teacher-student relationship filled with admiration and love (Cammarota & Romero, 2006). Additionally, Roberts (2010) calls for *culturally relevant critical teacher care* (CRCTC), which integrates tenets of culturally relevant pedagogy (Ladson-Billings, 1995) and critical race theory. This framework entails a focus on students' voices, counternarratives, and student futures in addition to a consideration of political and ideological thinking, especially related to race and power (Roberts, 2010).

One caution in the literature is to avoid deficit model thinking of students shrouded as caring. For instance, Matias and Zembylas (2014) argue that predominantly white teacher candidates must interrogate their emotions of care and sympathy, particularly towards students of color, and how these emotions intersect with whiteness. These authors argue that antiracist teachers must explore their own narratives around caring that "are sometimes hidden expressions of disgust for the Other" (p. 319). They advocate for patience on the part of teacher educators in working towards an authentic care narrative:

> We, as teacher educators, have to be prepared to accept that this process is long and painstaking, and it will be full of emotional landmines, but it is of utmost strategic importance to expose the insidious emotional power of racism and its affective investments in white teacher candidates' identities (Matias & Zembylas, 2014, p. 333).

This call to action regarding antiracist pedagogy in teacher preparation can help inform understandings and enactments of care in teacher education.

Methods and Data Sources

This qualitative study analyzed transcript data from seven focus group interviews. These interviews occurred with students from five separate methods courses at four universities, in the fall semester of 2020. These universities spanned the Northwest, Midwest, and East Coast of the U.S. All students were enrolled in a teacher preparation program at their respective institutions.

The data analysis entailed a multi-step, collaborative process. First, the research team collaborated in real time via Zoom to review focus group transcripts, which had been uploaded to Dedoose. The research team utilized protocol, or a priori, coding, in which we identified a set of pre-established codes that could be assigned to the data based on the literature review and our own experiences as researchers in this study. This form of

coding is recommended for research teams analyzing data collaboratively (Saldaña, 2016). This form of coding was also useful due to the use of Noddings' (1988) preexisting care framework from which we were framing our exploration. In addition to the protocol codes, the team also conducted open coding of the data, where parts of the qualitative data were broken down into meaningful codes for comparison across the data set (Saldaña, 2016). After this first cycle of collaborative coding, the research team individually coded the remaining transcript data utilizing the existing codes. After all data were analyzed by each researcher, the codes were transformed into broader themes that assigned meaning to our initial codes.

Major findings

Considering sociopolitical contexts of learning and being

In creating a setting for care, we wish to highlight the ways in which teacher educators were aware of the social and political contexts in which their students existed. We frame this first theme as teacher educators considering the contexts of learning and being because of ways that the socio-political contexts of students' lives impacts their learning and the ways in which they exist in the world. Further, we argue that not considering our students' socio-political contexts of learning and being at best creates contexts of siloed care, where the care we show students does not help them navigate the world outside of our classrooms, and, at worst, perpetuates racism, sexism, homophobia, xenophobia, transphobia, and additional phobias. In this way, we view critical care as a method for dismantling systems of oppression through the individual relationships we build with students.

Some of the ways that teacher educators demonstrated their consideration of their students' socio-political contexts of learning and being were supporting students as they navigated the dual contexts of a global pandemic with COVID-19 and the Black Lives Matter social movement following the murder of George Floyd. One student reflected on their professor's support during these contexts:

> And I think I sat in a call with him and I just started crying about like how hard my teaching and teach classroom placement has been going because of my situation. I was homeless. I like got kicked out. My mom kicked me out of my house because I'm dating a Black woman. And then my dog almost died because people wouldn't, the vets wouldn't take my dog in because my fiancé was Black. And it was all in the midst of the Black Lives Matter protest and it was just really fucked up and like in the midst of all of this, I was just trying to figure out how to do schoolwork.

In this quotation the student does not necessarily highlight what responses the teacher educator had, but that they felt open to reaching out and discussing the contexts in which they were struggling. The socio-political contexts that teacher candidates participated in did not only emerge when discussing their personal struggles, but also when thinking about teaching as a practice. Another teacher candidate from a different institution talked about how their practice as a teacher existed in the context of historical racism and racial injustice.

> I just speak a lot of truth when it comes to racism and making sure that people are seen, especially if it's the indigenous people or Black people and just making sure that the validity and white fragility isn't just taking over the conversations because I'm - and I know that my ego showed up - and my triggers of, like, I'm sick and tired of white fragility taking over the conversation and me being attacked - took over the conversation and I definitely apologize for that.

In this quotation, the teacher candidate speaks to how teaching practice cannot exist outside of the socio-political contexts in which students and teachers exist. Doing so perpetuates white fragility and racism. This quotation recognizes teaching as an act in participation with the world and how teaching can be an act of social justice, seeking to influence and change the socio-political contexts in which we live.

Modeling care and vulnerability

Another key theme that arose in the data was modeling care for students. This modeling was largely on the part of the teacher educator modeling care for the student teacher. However, there were instances where the student teacher also mentioned experiences where they were modeling for their own K-12 students as well. Modeling occurred in multiple ways: modeling vulnerability through reflective practice, modeling teaching methods, and modeling social and emotional health.

First, when teacher educators modeled vulnerability, the student teachers voiced really appreciating this learning experience. The vulnerability within these classes was not only for the teacher educator, though; students also highlighted feeling vulnerable as learners, particularly when they had to watch and analyze videos of their own class, but this experience appeared to be a positive one. For instance, one participant said:

> It was a lot of the meta-analysis where we would record our own classes, and then the next class period, watch ourselves and go, oh, what were we doing and what we weren't we doing, so I think that

> meta-analysis via video was odd for me to analyze a video of our own class period, but I think it was also really helpful.

Furthermore, the vulnerability of the teacher educator in this meta-analysis was also valued by the students. For example, one participant discussed an instance when the teacher educator highlighted in the video the point at which she gave instructions to the class as being a poor example of how to provide instructions. The student participant reflected:

> She gave us all of these instructions that we were supposed to do in a video and then we were talking about it afterwards. And she was like, that was just that was bad, like, don't, don't do that...There was no way you guys were going to be able to focus on all of that stuff because I had you all doing like four or five things once. And it was really helpful for her to do that because, I mean, obviously I had partaken in the activity, cuz I was in class. And I think when I was doing it, I think I remember trying to do all the things, but I didn't cognitively realize that it was difficult. I think I was just attempting to do it all for her. But then, having her step back and be like, this is too much, don't put that on your students was really helpful for me when I have been planning lessons since then, to be like okay, I need to step back and make sure to pare down a lot of what I'm expecting from people, expecting for my students and having to see her struggle with that…was super helpful and something I've implemented.

The student appreciated the reflectivity of the experience of watching their own learning, but they also mentioned the transferability of this experience into their own teaching practice.

Further, another student highlighted the struggles one teacher educator was having in facilitating online discussions: “It felt nice knowing she was in the same, our professor was in the trenches with us in some sense, and I think that was really admirable to watch her go through.” The teacher educator and the student teachers were learning together how to navigate online learning spaces, and the vulnerability of this experience demonstrated the care the teacher educator had for the students, and vice versa. An additional student said of another teacher educator: “[He] is very, very good about introducing his own vulnerability to the classroom and leading with that...it's definitely one of the biggest lessons that I've taken from this whole program is how our students are not going to be vulnerable.” Perhaps the vulnerability modeled by the teacher educators in these courses will help students model their own vulnerability for their K-12 students. One specific quality of vulnerability that we wish to highlight is how modeling vulnerability was done as part of a process of building trust and creating a safe space from which the sociopolitical contexts of students’ lives can be incorporated, discussed, and supported. It was necessary for teacher educators to model vulnerability and establish safety as a component of the classroom community in order for students to then make themselves vulnerable. Doing so, we argue that teacher educators need to be responsive to these lived realities in order to care for students.

Inform, empathize, inquire: How youth use participatory storytelling to engage with social issues

Abstract: We explored how youth created participatory stories—a genre of interactive fiction that logs players' choices as data to be analyzed—to advocate for social change. We designed a workshop to guide 22 high-school-aged youth in creating participatory stories about social issues of their choice. Analyses of their vision statements, stories, and reflections, revealed three ways that youth used this medium: to inform players, to provoke empathy, and to inquire into human behavior related to their chosen social issues. This study shows the potential for participatory storytelling to amplify youth's agency to take social action.

Introduction and background: Storytelling and social change

Whereas research has examined youth's creation of games and stories to engage audiences in reasoning and empathizing about social issues (Dasgupta & Hill, 2017; Lee & Garcia, 2014), few tools exist that allow youth to conduct socially engaged inquiry. We examine how youth created *participatory stories*, a genre of interactive fiction that logs player data, to both engage audiences with social issues, and to generate player data to pursue personal inquiries into those social issues.

Participatory stories build on the emotional impacts and empathy-building qualities of stories (Junker & Jacquemin, 2017; Koopman & Hakemulder, 2015), immersing players in a role, and prompting them to make choices that have narrative consequences. When stories are themed around social issues, these choices allow audiences to reflect on how their actions contribute to those social issues, and to even replay and observe different outcomes. Designers can furthermore create participatory stories that investigate particular questions, and analyze players' data to gain insight into the answers. Such inquiry, performed by and/or for those impacted by a social issue, can be an act of social change, in that it can engage and highlight marginalized perspectives (Freire, 2018).

To understand the potential of this novel medium as a tool for social action, we ask: (1) How do youth use participatory storytelling to address social issues that matter to them?

Methods: Context, participants, and data

Workshop design

The authors designed and facilitated—with 3 other colleagues—a virtual summer workshop (1 hour-long Zoom meeting/week for 4 weeks) that guided high school aged youth in creating participatory stories to address social issues of their choice. Through whole group and breakout room activities, we introduced youth to the value of player data in games for social change, and facilitated their identification and selection of social issues (Day 1). We guided youth in using the free interactive fiction creation platform, StudyCrafter (studycrafter.com, see Figure 1) (Harteveld et al., 2017), offered written feedback on their ideas, and assisted them in recruiting players by sharing links to their stories to members of our graduate programs (Days 2 and 3). Each story accumulated ~4-25 players by the end of the workshop (stories completed and posted earlier had more time to attract players). Finally, youth shared insights from their player data, and on their experiences (Day 4). Between sessions, we used Slack to prompt youth to share updates, assist them with technical issues, and offer feedback on their work.

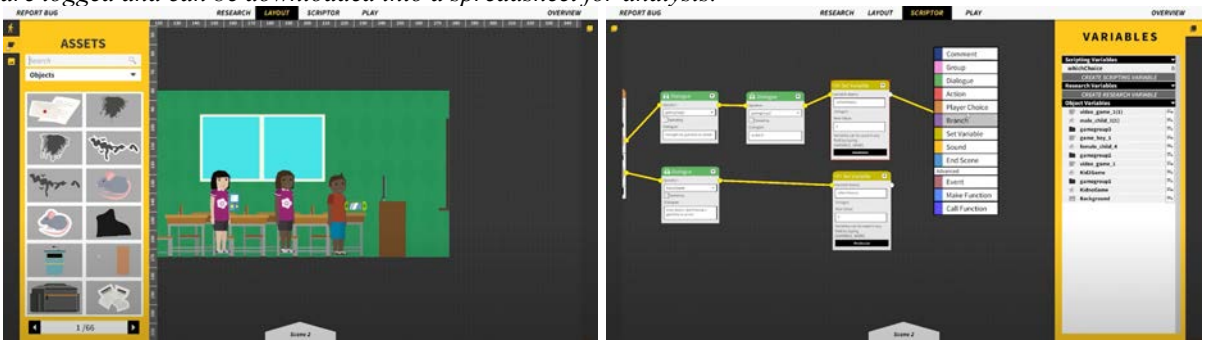
Participants, data and analysis

Participants were 22 high school youth (50% female, 10 Asian, 6 Latinx or Black, 3 Caucasian, 1 Middle Eastern) accepted into a competitive STEM program hosted by a public university in a large Eastern United States city. Our workshop was one of their program requirements, the main of which involved working with faculty on STEM research projects (e.g., cancer research, bioengineering). Our data consisted of (1) youth's vision statements, in which they responded to the prompts: "I'm interested in… My target players are… In playing this (story), I want players to feel/be curious about… What I want to learn from players' input is….";

Figure 1

 © ISLS

Left: StudyCrafter's asset library and scene layout interface; Right: Scriptor tools for coding interactivity and scene transitions. A typical StudyCrafter story unfolds through text-based narration and character dialogue. Through players' selections of text-based choices, the story can branch along different paths. Players' choices are logged and can be downloaded into a spreadsheet for analysis.



(2) youths' StudyCrafter stories; (3) youth's reflections on their design process, shared in the Zoom chat during workshop sessions, and in Slack between sessions. Because three youth did not complete their projects, and two worked as a team, we analyzed 17 stories in total and their associated artifacts.

To describe how youth used storytelling to address their chosen social issues, we first categorized youth's chosen social issues in terms of their broader domain (education, environment, etc.). Using an open coding approach, three researchers then read and discussed each of youth's vision statements, StudyCrafter stories, and final written reflections to identify salient or recurring themes (Corbin & Strauss, 1990). To achieve inter-rater reliability, we used a consensus building process (Baxter & Jack, 2015), in which three researchers developed and iteratively refined categories through joint discussion of each set of artifacts.

The result was three, non-mutually exclusive categories describing the spectrum of youth's purposes for their stories (see Table 1): to inform, to provoke empathy, and to inquire. We present a qualitative descriptive analysis (Sandelowski, 2000) of selected stories chosen to best illustrate how youth used the medium to fulfill these different purposes. All names in the findings are pseudonyms.

Findings

Overview

Youth chose topics from their personal or community experiences, which covered the domains of environment (e.g., climate change attitudes) (N=5), education (e.g., school budgeting priorities) (N=4), mental and physical health (e.g., supporting friends suffering from depression) (N=4), socioeconomic (e.g., healthcare access inequality) (N=3), and technology issues (phone addiction) (N=1).

All 17 stories sought to *inform* players about a social issue, such as by providing information about its prevalence or impact (e.g., I want players "to really consider all angles of [an environmental] problem [and] to understand the [impacts on all involved.]"). A subset of these 17 stories had the additional goal of encouraging players to *empathize*, such as by allowing them to experience a situation from the perspective of someone impacted (e.g., I want players to feel "the emotions and thought process that a family with limited resources would go through."). A further subset of stories also aimed to use player data to *inquire* into some question about the chosen issue (e.g., I want to know "When most people think they should get [mental health] help," and when to "push others to get help."). Categorized in terms of the main purposes that youth described, 12 stories sought mainly to *inquire*; 4 sought mainly to provoke *empathy*; and 1 story sought mainly to *inform*.

Stories that inform and empathize

While each of the stories sought to inform players of a social issue, only one youth in our sample, Emily, had 'to inform" as her sole goal. In her story, the player is the town mayor, and needs to decide how to address the issue of increasing sargassum algae on its beaches while mitigating impacts on tourism. For Emily, awareness of the complexity of this environmental issue was the ultimate goal. As she writes, she wanted players "to really consider all angles of the problem before making a decision for them to understand the complexity of these issues."

Four stories had the additional goal of generating players' empathy for an issue. Youth who created such stories expressed a desire for players to feel "stressed," and "upset," and to appreciate the unfairness of certain situations. These stories had players experience issues such as mental health stigma, inequitable resource access, and the lack or burden of power felt by people with different societal roles (e.g., managing a school budget, deciding to help a friend with depression, considering unaffordable medical treatment). For example, Yuka wanted

her players to feel "conflicted by the difficult choices ppl make abt their health based on affordability." In her story, players make a family's budgeting decisions, each of which is a compromise between the family members' individual health needs (therapy, medication). Players then observe the unavoidable impacts of their choices (the father's ER visit, the mother's burnout, the daughter's failing grades).

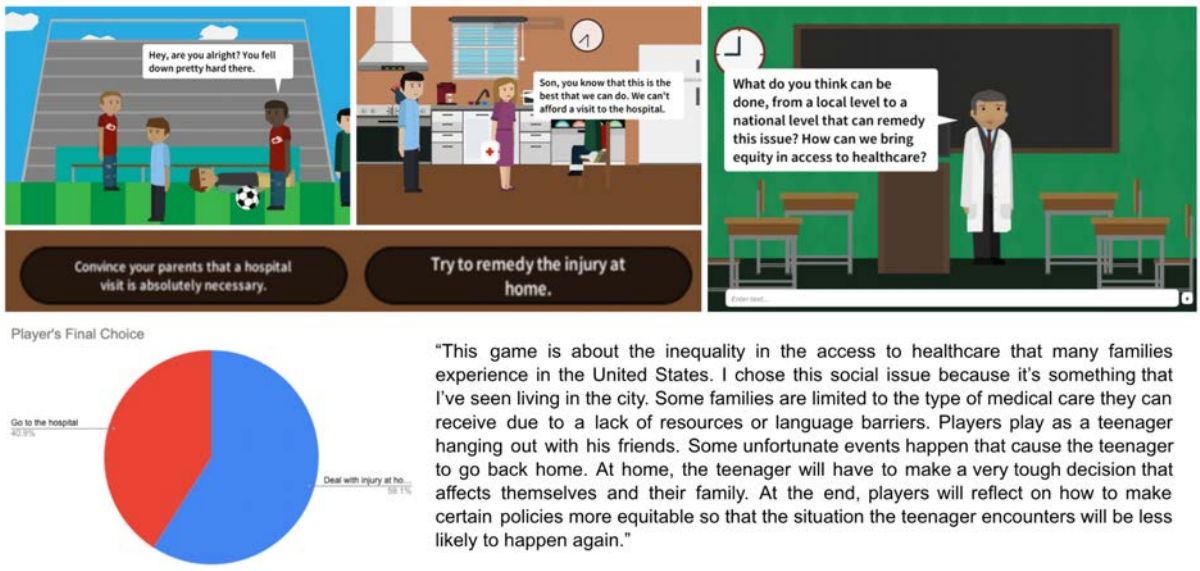
Similarly, Angela sought to generate sympathy for those impacted by socioeconomic disparities. In her story, players follow two characters—one wealthy, the other in poverty—and make a series of choices for them (e.g., to take a job, to apply for college). By making different decisions on replaying the story, it becomes clear that these choices are inconsequential to the characters' outcomes. Thus, Angela sought to challenge the myth of meritocracy by showing that "no matter how much [the characters] try, the economic disparity between them clearly hold the poorer one back." By offering inconsequential choices, her design sought to give players the sense that there is no escaping the path determined by one's existing resources.

Stories that inquire

Twelve of the youth's stories were designed to generate data that would address a question about their chosen social issue. For example, Sang's story (see Figure 2) had players take on the role of an injured teen who must decide whether to ask for medical treatment that his parents cannot afford. While this story aimed to inform players about healthcare equity, and to promote their empathy for people with limited healthcare access, it also collected data on players' choices to better understand the healthcare choices people make when financially constrained. Sang created a pie chart of his 25 players' choices, and observed that 40% chose to go to the hospital while 60% chose to deal with the injury at home. He hypothesized that "people were valuing their family over themselves and/or the injury not being serious enough to warrant a visit," and wondered about the "severity of an injury that is necessary to warrant a visit to a clinic no matter what financial situation." These observations prompted Sang to propose a follow-up inquiry that he might conduct through an iteration on his story: "I would make the injury more severe to see if there would be a more even split among players on whether they would go to the hospital or not. With a minor ankle injury, it's easier for players to think that a hospital visit isn't necessary. But, a more severe injury would eliminate that variable and give much harder choices with bigger consequences."

Figure 2

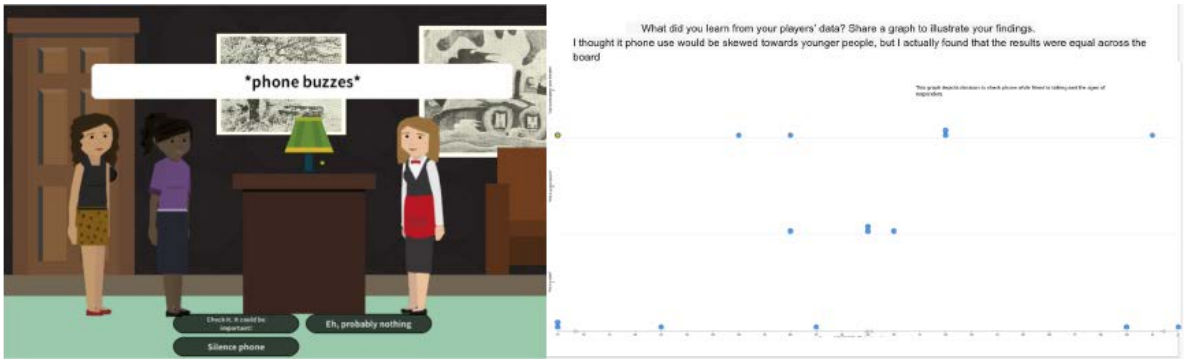
Top: Scenes from Sang's story about healthcare inequities, with both closed and open-ended player choices. Bottom left: The data generated from players' choices; Bottom right: Sang's vision statement.



Calla's story about phone addiction (see Figure 3) had players make various choices while at lunch with a friend (e.g., how to respond to and steer the conversation). During three moments, they must decide whether to check or silence their phone notifications. The game ends with an open-ended question: "Would you do anything differently if you were to play again?" Calla used her player data to measure the extent to which she raised awareness of phone addiction, noting that since "I don't mention anywhere that I am testing phone use, it was interesting to see how many people noticed they were using their phones a lot." Calla also used a dot plot to compare players' choices based on age, remarking that "I thought [the numbers of players choosing to check their phone] would be skewed towards younger people, but I actually found that the results were equal across the board."

Finally, when Calla's playtesters noted that they "couldn't really tell if their friend enjoyed the outing," Calla identified a design iteration to include a "way for the [friend] to react positively or negatively." As she reasoned, "it would be helpful (...) to have negative responses to demonstrate the rudeness of some of the choices."

Figure 3
Left: A scene from Calla's story about phone addiction, displaying a closed-ended choice. Right: Calla's dot plot of her player data, and a statement of her main findings.



Discussion and Significance

This study illustrates the potential of participatory storytelling for engaging youth in acting on social issues that concern them. By having players make decisions in particular roles and situations, youth creators used this medium to raise awareness of issues, to provoke empathy for those impacted, and to generate data for inquiry. Youth's analyses of their player data supported deeper explorations of their chosen issues, and also prompted ideas for iterations to improve the clarity of their message, and new directions for inquiry. These findings suggest that participatory storytelling can amplify youth's agency and voice to advocate for change. While some of our participants' stories were unclear or incomplete, our findings suggest that with sufficient guidance and support, participatory storytelling can be an effective tool for socially engaged inquiry by all youth.

Abstract: We present a comparative analysis of professional learning communities (PLC) of teachers in Canada, China, and India, in the context of a project called the Critical Action Learning Exchange (CALE). CALE is an international community of educators dedicated to designing, enacting and sharing critical action curricula that empower students in responding to complex socio-environmental issues such as climate change, social justice, pandemics, and more (Carvalho et al., 2021). We analyze the three PLCs through the lens of activity-theoretical formative intervention research (Engeström et al., 2014). Comparison of the three cases identifies a series of key factors for the successful professional development of critical action educators and informs the design of future CALE elements.

Introduction

This paper presents a comparative analysis of three formative interventions for the professional development of critical action educators. Activity-theoretical formative intervention research has its roots in cultural-historical activity theory (CHAT), building on the works of Vygotsky, Ilyenkov, Leont'ev, and Davydov, with the goal of understanding transformations in activities that are undergoing some sort of risk, crisis, or pressure for change (Engeström et al., 2014). Our study investigates formative interventions in professional learning communities (PLCs) of educators in Canada, China, and India, in the context of a project called the Critical Action Learning Exchange (CALE). CALE is an international community of educators dedicated to designing, enacting and sharing critical action curricula that empower students in responding to pressing, complex socio-environmental issues such as climate change, social justice, pandemics, economic inequality, and more (Carvalho et al., 2021). Educators that join CALE are presented with a pedagogical framework for critical action education, and a platform for peer support in the form of an online community for collaborative design, implementation, exchange, and advancement of curriculum that empowers students as agents for positive social change. Critical Pedagogy (Freire, 1970; Kincheloe, 2004) is applied within the context of empowering teachers to help students overcome the sense of powerlessness regarding overwhelming socio-environmental issues, and feel empowered as agents capable of contributing to solving those problems. Our hope is that a comparative analysis of the formative interventions in these PLCs helps us to identify key components, features, needs and obstacles of these communities that inform our own understandings of how teachers can develop new pedagogies and practices, and guide future implementations.

Theoretical framework

The research literature describes professional learning communities (PLCs) as groups of professionals collaborating in an ongoing, learning-oriented, critical interrogation of their practice (Toole & Louis, 2002). Supovitz and Christman (2003) stress the need for the community to be grounded in supportive structures and strategies. To design PLCs that help teachers adopt new approaches that reinforce students' sense of agency and collective responsibility, CALE draws upon the theoretical perspectives of Critical Pedagogy (CP) and Knowledge Building (KB). CP is based on a philosophy of praxis that stresses the importance of an educative process that interweaves theory, action, and reflection as a means to advance the broader society towards social change and justice (Freire, 1970). This perspective is grounded on the concept of *conscientização*, which Prilleltensky (1989, p. 800) describes as "The process whereby people achieve an illuminating awareness of the socioeconomic and cultural circumstances that shape their lives and their capacity to transform that reality". *Conscientização*, therefore, aims beyond critical thinking to include a sense of *critical consciousness* that enables students to make judgements on their current and ideal realities and empowers them as agents for positive change. KB, in turn, offers an important theoretical foundation for CALE's communities of practice, including fundamental principles of collective responsibility and epistemic agency, and constructivist practices to promote continuous improvement of ideas through dialogue and collective investigation (Scardamalia & Bereiter, 2010).

Engeström (2011) proposes formative interventions as a methodology that emphasizes the agency of practitioners, students, and users in the design process. The emphasis on fostering and leveraging the agency of participants in designing their own inquiry process makes this methodology particularly adequate to our research of a community of critical action educators who are dedicated to investigating their own practice. The formative intervention methodology relies on two epistemological principles, *double stimulation* (Vygotsky, 1978) and the principle of *ascending from the abstract to the concrete* (Ilyenkov, 1982). Through collaborative inquiry, participants generate future-oriented concepts and designs that open possibilities for changes in their own practices and processes, while allowing researchers to investigate the generation of actionable knowledge. Formative interventions use double stimulation to illustrate conflicts of motives. The first stimulus is typically a conceptual *mirror* that "reflects" the problematic situation being experienced. In trying to tackle the problem, the community may resort to external artifacts, or *visions*, which function as a second stimulus that supports or sustains the transformation of practices (Engeström et al., 2014). These stimuli help participants to visualize their collective *zone of proximal development* (ZPD) which is "the distance between the present everyday actions of the individuals and the historically new form of the societal activity that can be collectively generated as a solution to the double bind potentially embedded in the everyday actions" (Engeström, 2014, p. 138).

Methods

Members of CALE PLCs participate in professional development activities to advance their understanding of critical action education and engage in designing new curricula (Carvalho et al., 2021). Participants can find technology support within the CALE online environment, where they can share their experiences designing and enacting new critical action lessons and engage in further authoring, discussion, and resource sharing. In the CALE PLCs, our goal has been to understand how educators' critical interrogation of their practice leads to transformative action. This question has guided us to model distinct interventions that accounted for each PLC's socio-cultural context. The underlying questions we have asked in developing our modelling workshops were: (a) What interventions are productive in a particular context? (b) How can those interventions be conducted to generate actionable knowledge that enables transformation of participants' teaching practices? (c) How can our workshop model help teachers become critical action educators? Three teacher cohorts were organized, each of which can be considered an autonomous PLC in its own right: (1) 45 teachers in Canada who focused on climate change education; (2) 68 teachers in southern China who are also engaged in designing climate action curriculum; and (3) 60 teachers in Bangalore, India, coordinated by local partners.

The formative intervention in Canada was organized in four sessions, carried out in Summer 2021. A pre-survey and critical questions functioned as *mirrors*; lectures and resources on critical action pedagogy and the CALE pedagogical framework for designing critical action curricula (Carvalho et al., 2021) were offered to generate *visions*, and Zoom breakout rooms, Google Jamboard, and Google Docs functioned as a *discursive space*. As members of this PLC were interested in understanding the importance of changing teaching practices relating to climate change education and student climate anxiety, the socio-cultural context was adjusted to provide critical questions to help educators conceptualize and respond to these interests.

The formative intervention in China was organized in six one-hour workshop sessions that were conducted after a week of pre-workshop discussions and introductions. The aim of the pre-workshops was to function as a *mirror,* aiming to engage teachers with new ideas about 21st-century competencies. In the following five sessions, a pattern was implemented with detailed and specific expectations of topics and activities. Weekly questions were offered as *mirrors*, content videos, supplementary resources, and "micro-lessons" functioned as *visions*, and a second *mirror* of each week were reflexive questions on learning strategies. Zoom meeting rooms and Google Docs were provided as a *discursive space*.

The formative intervention in India was organized in four sessions. One distinction between the interventions in Canada and China was the inclusion of paper handouts that aimed to help participants interrogate their current educational approaches and reinforce their sense of identity as a professional learning community. The first two sessions were planned to function as *mirrors* of participants' current teaching practices and offer possible *visions* in the form of lectures, examples of critical action curriculum, and discussions with a teacher guest. The final two sessions included a representation of the ideas and understandings of participants as *mirrors* and reiterated the discussion of *visions* to reinforce the pathway toward transformations.

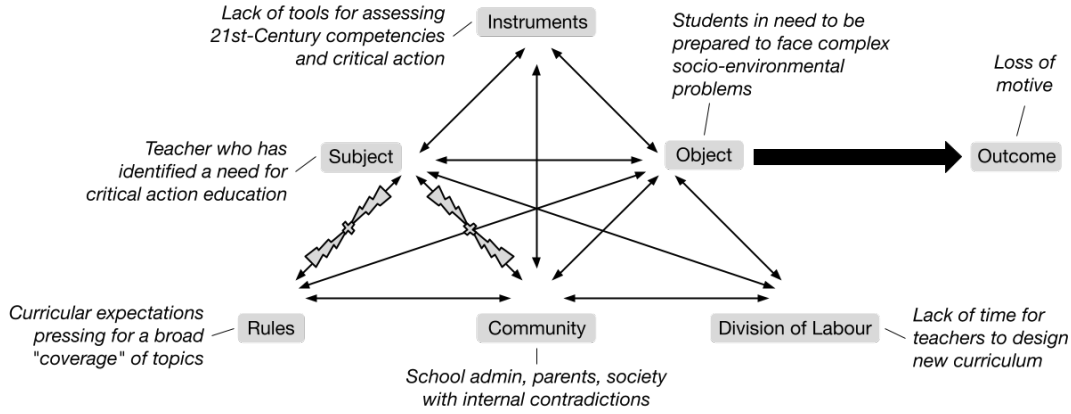
Findings

We describe our findings in terms of core concepts from activity-theoretical formative intervention research methodology. *Contradictions* and *conflict of motives* are concepts that relate to the initial state of the system. *Contradictions* refer to the main conflict identified by the researchers in the activity system. This takes form as a kind of working hypothesis, which is then submitted to the participants as an object of reflection to help them

articulate their own interpretation of the contradictions they face—referred to as *conflict of motives*. Finally, through the process of double stimulation, participants envision alternative possibilities and future directions, which constitute the *collective ZPD* (Engeström, 2014).

The *contradictions* in formative interventions are typically identified and represented through the modelling of an activity system (Figure 1). We identified the following contradictions in activity systems for all three communities, providing a set of working hypotheses: (1) the curricular expectations, which demand that teachers "cover" a broad range of topics, discourage the time-consuming deep exploration of topics needed for critical inquiry; (2) there are conflicting pressures on teachers, between the demand that students are equipped with "21st-century competencies" (e.g., critical thinking and collaboration) and the heavy content standards measured by student success on standardized tests or competitive selective processes for higher education. These contradictions were presented to participants as introductory objects for critical reflection and discussion.

Figure 1
Contradictions in the activity systems of the CALE PLCs in Canada, China, and India.



Participants' critical reflection on artifacts that functioned as *mirrors* of their contradictory states was found to be consistent with the working hypothesis. Participants reported some degree of anxiety or confusion, having identified a need for incorporating 21st-century competencies and critical action into their curriculum while also confronting barriers to doing so (e.g., heavy content expectations). After having identified and articulated these *conflicts of motives* with the help of activities that functioned as a first stimulus (*mirrors*), the three PLCs engaged in activities that operated as a second stimulus (*visions*). Through this process of double stimulation, participants were able to articulate their collective *ZPD*, which represents possible future directions for their activity. The collective *ZPD* of the three PLCs varied significantly, distinguishing the communities and pointing them in particular future directions. Participants of the Canadian PLC focused on ideas for increasing collaboration, exchange of ideas and resources, and sense of community. The primary focus was on climate anxiety and climate action, with the recognition that it is much easier to develop supplemental activities than ones that are central to the curriculum (i.e., that cover content through engagement in critical action and inquiry). Teachers in the Chinese PLC identified the enhancement of students' communication and collaboration skills as a fundamental need that underlies critical action inquiry. The assumption, manifested frequently, was that students are currently lacking those skills, which creates obstacles for critical inquiry. This was clearly a "slide back" from our initial discussions about pedagogy, to address an even more basic characteristic of Chinese classrooms (particularly at the high school level)—that they do not present a conducive climate for collaboration and inquiry. Students and teachers alike have strong epistemic commitments to a didactic approach to lectures and exams, and this climate must be addressed before any form of inquiry can be attempted. Finally, in the Indian PLC, after some reluctance to begin designing activities, there finally emerged a particular interest in art-making as a strategy to engage students in critical action. Accordingly, the initial activity designed and enacted by teachers used the *rangoli* traditional Indian art form as a medium for students to investigate and address diverse socio-environmental problems, such as the Indian farmers' crisis, population explosion, gender inequality, and more. This activity was a success, providing an illustration and grounding for other teams of teachers to begin their own process of designing for critical action.

Discussion

The use of a formative intervention approach has helped us to articulate important components of the design of effective PLCs in general, and of communities of critical action educators in particular. The study also highlights

some obstacles and eventualities that should be considered when designing such communities. One key design principle identified by this study is related to the importance of cultural responsiveness. The investigation of communities embedded within distinct cultural contexts (i.e., Canada, China, and India) reinforces our understanding that critical action education does not and cannot mean the same thing for different contexts. The principle of cultural responsiveness is especially relevant in the case of international collaborations, where teachers operate within very different cultures and educational systems, with strong norms of practice and diverse pedagogical understandings and epistemic commitments. Although the core principles of critical pedagogy have a universal character, their embodiment can take distinct forms that must be co-constructed with community stakeholders. In the formative intervention methodology, one important objective is to understand how an organization changes its existing state—deemed as problematic by the community itself—to a targeted improved state. It thus becomes crucial to recognize that each cultural context may contribute to producing very distinct starting and/or final states. This study also found that the target itself has to be adjusted to present a viable pathway, in accordance with the communities' respective starting places.

Finally, we must recognize that the forms of discourse and interaction employed in the intervention must also be culturally responsive. To engage participants in acknowledging and responding to the double stimulation and progressing through reflective activities, it is crucial to design pathways and employ forms of discourse that find resonance within the cultural context. In each CALE PLC, we recognized distinct forms of interaction and discourse. Canadian teachers preferred to be left to their own devices and did not stand for many lectures. They were good at self-organizing. In China and India, there was a more formal characteristic, where stronger central leadership was valued, and small groups still required close support. Chinese teachers valued the final presentations with feedback from visiting experts. Indian teachers felt the need for a strong "CALE identity", including certificates of membership. While such elements do not solve the problem of advancing critical pedagogy, it would certainly not be possible to solve it without them.

Conclusion

This study is significant in its application of a methodology from cultural-historical activity theory to the context of teacher professional development in critical pedagogy. It brings several distinct theoretical perspectives (i.e., critical pedagogy, activity theory, arts-based pedagogy, learning communities) to bear on the formation of three distinct professional communities, and studies the discourse and progression of those three through a lens of cultural responsiveness. The study helps respond to the persistent challenges of supporting teachers in developing new pedagogical understandings and practices. It will hopefully inspire other studies and serve as a reference for cross-cultural research within the learning sciences.

Understanding the Factors Influencing Persistence: What Can Novices Learn from Experts?

Gina Ristani, Keisha Varma, Martin Van Boekel, Sashank Varma

Abstract: Experts become experts in part because of their willingness to engage in thousands of hours of deliberate practice. What motivates them to persist in the face of constant failure? This question was addressed in a study of experts and novices in the domains of mathematics and English literature. We compared how experts persisted and spoke about their failures while thinking aloud during problem-solving on difficult tasks, in and outside of their domain of expertise. Experts persisted longer and gave different reasons for their failures than novices did, and their implicit theories of intelligence explained some of these patterns. Our findings document how an expert's failure attributions and implicit theory of intelligence may help them persist when tackling challenging problems in their domains.

Introduction

Experts are those who persist past proficiency to a level of competence in knowledge or skill that exceeds most others (Bransford, 2000). Their extensive knowledge libraries enable them to quickly understand challenging problems in their domain, and to select and apply relevant strategies to solve them (Ericsson, 2014). Thus, experts can efficiently solve complex tasks novices cannot. Beyond the cognitive, motivational behaviors of experts contributes to their ability to persist to achieve the elusive goal of expertise. *Everyone repeatedly fails on the path to expertise.* Chase (2013) showed experts exhibit persistence in the face of constant failures. The current study is the first attempt to replicate her findings in a larger sample, and we extend her work to directly investigate the role of motivation in persisting on challenging tasks and explaining attributions made during failure. Specifically, it views motivation through the lens of implicit theories of intelligence (Dweck, 2000).

Literature Review

Chase (2013) investigated the role of motivation in supporting persistence and understanding one's failures on the long path to expertise. She found experts and novices differed in how they attributed failure during problem solving. Attributing failure to external factors can support learners' self-esteem, while alternatively, attributing failures to internal factors can negatively impact persistence and performance (Weiner, 1979). Specifically, experts in a domain attributed their failures externally, such as to the complexity of tasks or limited resources of the environment, which they could accurately judge given their knowledge. Because of this, they persisted longer in tackling these problems. By contrast, novices in a domain attributed their failures internally, to their lack of intrinsic ability. Thus, they were less likely to persist in tackling these problems.

To further bolster the current understanding of the relationship between failure attributions and persistence, we considered an important construct in the motivation literature, Dweck's (2000) notion of implicit theories of intelligence. In this theory, individuals who hold an incremental theory view intelligence as a pliant trait developed through effort, while those who hold a fixed theory believe intelligence is stable within individuals and cannot be changed through effort over time. We predict those with more incremental theories of intelligence about their performance in a domain are more likely to persist in the face of repeated failure, and to continue to grow in their competence to eventually reach expertise.

O'Keefe et al. (2018) established that novice persistence was influenced by their theory of interest, which is parallel to theories of intelligence. Whether the focus is interest or intelligence, fixed mindsets believe the focus is stable and unchanging, while incremental (growth) mindsets see it as malleable and changeable with effort. But interest in a domain may not be enough to propel learners through expertise development. A learner's identification with a discipline can also impact their persistence, and this may be nurtured through experiences with the domain directly or by teaching it to others (Mercier et al., 2006). Whether learners see the experience of failures during exploration of a topic as a normal part of the process or as a reason to give up can vary (Williams-Pierce, 2019). These various potential responses to failure impact persistence after failure as well (Chase, 2013). As failure is inevitable, whether failure can be a productive source of future learning or not (Kapur, 2014) motivates our focus on experts as a model of how novices can persist following repeated failure.

 © ISLS

The current study is at the intersection of the expertise and motivation literature. We build on Chase (2013) because its foundational results have not been replicated to the best of our knowledge. This is important because of the very small sample size of the original study -- 10 math experts and 9 English experts. Following her study, we posit individuals might show differences in persistence and attributions of failure made while solving challenging problems in the domains in which they are experts versus the domains in which they are novices. Furthermore, we attempt to extend prior work by proposing individuals possess different theories of intelligence (Dweck, 2000) in their domain of expertise and versus domains in which they are novices. This puts them on the path to expertise in the former domain, whereas they will struggle to stay on it in the latter domain.

Objectives

The current study investigated the patterns of persistence and failure attributions in math experts vs, English experts. It also measured whether individuals have an incremental vs. fixed implicit theory of intelligence. This design enabled us to address the following research questions:

1. Do experts exhibit different patterns of persistence than novices when solving challenging problems?
2. Do experts exhibit different patterns of failure attributions than novices when solving challenging problems?
3. Are experts more likely to spontaneously revisit problems in their domain even when they are not "on the clock"?
4. In their domain, do experts have more incremental implicit theories of intelligence than novices?

Methods

Participants

Mathematics and English experts were recruited from a U.S. university to participate in this IRB-approved study. The experts were defined as faculty, postdocs, graduate students, or undergraduates researching or studying in a domain. This included 31 participants, 17 mathematics experts, $M = 25.65$ years, $SD = 3.12$ years and 14 English experts, $M = 28.36$ years, $SD = 4.77$ years, who completed both sessions of the study.

Design and Procedure

Participants were instructed to think-aloud during 12 minutes of problem-solving for each task and were allowed to cease problem-solving before time was up, if they desired. In the first session, half the participants in each expert group completed the math task first followed by the English task. The mathematics problem required proving a statement about prime numbers. The English problem required interpreting a poem with oblique language. The other half completed the English task first, followed by the math task. All participants then completed an online demographics questionnaire. They were then requested to return for a second research session. Finally, they were compensated $15 for the first session.

After at least 24 hours elapsed, participants returned for the second session. They revisited the tasks in the reverse order in which they originally completed them. They then responded to an online questionnaire including one question regarding whether they spontaneously revisited each task in between the two sessions. The remaining questions were drawn from a version of Dweck's (2000) theories of intelligence questionnaire, They were duplicated and specialized to query their implicit theories of intelligence for mathematics and for English. Participants were compensated $20 for the second session.

Data coding

Failure attribution statements from the verbal protocol, such as "I'm really bad at this" and "This problem is unnecessarily difficult", were categorized as internal or external, respectively, depending on the themes brought up by experts in the think-aloud sessions. These were used to compute a locus score for each task, defined as the number of external attributions minus the number of internal attributions, divided by the total attributions made during the task. Thus, positive scores indicate more external attributions of failure, and negative scores more internal attributions. Intercoder reliability was strong for failure attribution coding ($\kappa = .97$), and any discrepancies between coders were resolved via discussion.

Results

Expertise and persistence

Addressing the first research question, we performed a repeated-measures ANOVA with between-subjects

factor Expertise (math, English) and within-subjects factor Task (math problem, English problem) on the dependent variable persistence time. There was a main effect of Expertise, $F(1, 16) = 14.91$, $p < .001$, and also a main effect of Task, $F(1, 16) = 12.27$, $p = < .001$. Critically, the Expertise x Task interaction was significant, $F(1, 16) = 11.05$, $p = .0012$. As Table 1 shows, for the math problem, math experts persisted longer than English experts, as the earlier study found. However, for the English problem, the two groups persisted for a comparable amount of time in trying to solve it. This represents a partial replication of Chase (2013).

Table 1
Mean Persistence Time (seconds)

	Math Problem *M (SD)*	English Problem *M (SD)*
Math Experts	674 (119)	687 (81)
English Experts	480 (239)	670 (119)

Expertise and failure

Table 2 presents the mean locus score for each problem and expert group. Recall positive scores indicate that more external attributions were made, and negative scores indicate more internal attributions were made. We analyzed these scores in a repeated-measures ANOVA with Expert (math, English) as a between-subjects factor and Task (math problem, English problem) as a within-subjects factor, and locus score as the dependent variable. The main effect of Expertise failed to reach significance, $F(1, 20) = 2.80$, $p = .11$. The main effect of Task was statistically significant, $F(1, 20) = 7.72$, $p = .007$. Critically, the Expertise x Task interaction was significant, $F(1, 20) = 8.115$, $p = .005$. This replicates the Chase (2013) finding that the English experts could properly evaluate the difficulty of the problem, and therefore attributed their failure in interpreting the poem to its difficulty -- and not to their own, internal limits. However, the effect did *not* cross over: for the Math problem, both the Math experts and the English experts attributed their failure to solve the problem as reflecting their own lack of knowledge or ability, and not the inherent difficulty of the required proof.

Table 2
Mean Locus Score

	Math Problem *M (SD)*	English Problem *M (SD)*
Math Experts	-0.037 (0.86)	-0.047 (0.84)
English Experts	-0.57 (0.58)	0.12 (0.93)

Expertise and spontaneous revisiting

The third prediction was that experts will be more likely to spontaneously revisit the problem in their domain in between the sessions than the problem outside their domain? Descriptively, math experts showed the expected pattern: 30% chose to revisit the math problem in between the two sessions, whereas only 12% chose to revisit the English problem. Descriptively, however, the expected pattern was *not* present for the English experts who behaved unexpectedly: 36% chose to revisit the English problem between the two sessions. However, the same percentage (36%) chose to revisit the math problem.

Implicit theories of intelligence

Recall that we specialized the Dweck (2000) measure of implicit theories of intelligence for the math and English domains, and administered these measures during the second session. Higher scores indicate a more incremental (and less fixed) implicit theory. We analyzed these implicit theory scores in a repeated-measures ANOVA with Expert (math, English) as a between-subjects factor and Domain (math problem, English problem) as a within-subjects factor. The main effect of Expertise failed to reach significance, $F(1, 20) = 0.13$, $p = .72$, with the two groups evidencing comparably incremental implicit theories of intelligence. The main effect of Domain was statistically significant, $F(1, 20) = 4.95$, $p = .03$, with participants endorsing a more incremental theory of intelligence in the English domain than in the math domain. Critically, the Expertise x Domain interaction was significant, $F(1, 20) = 6.01$, $p = .016$; see Table 3. The math experts showed a more incremental implicit theory of intelligence for the math domain than the English experts did. By contrast, the English experts showed a more incremental implicit theory of intelligence for the English domain than the Math experts did.

Table 3
Mean Implicit Theory of Intelligence (higher scores indicate a more incremental theory)

	Math Domain *M (SD)*	English Domain *M (SD)*

 © ISLS

Math Experts	4.96 (0.79)	4.96 (0.70)
English Experts	4.52 (1.27)	5.31 (0.76)

Discussion

The current study replicated Chase (2013) and extended it to investigate implicit theories of intelligence (Dweck, 2000). The observed interaction of expertise and task domain on persistence time shows English experts tend to spend more time working on challenging in-domain problems than challenging out-domain tasks. If experts do indeed persist for longer in their domains of expertise, *how* are they able to do so in the face of constant failure? Consistent with the results of Chase (2013), English novices make internal attributions for the failures they experience, i.e., they blame their own lack of ability. By contrast, English experts know enough to understand the difficulties they experience as a consequence of external factors such as the difficulty of the problem or constraints on problem solving time. Spontaneous revisitation of either problem in the days between the first and second sessions was not statistically related to the domain of expertise or the domain of the problems. Descriptively, math experts tended to revisit the in-domain task more, while English experts revisited both tasks equally. The lack of significant findings here could simply reflect the small sample size. Although we have run 50% more participants than Chase (2013), both the math expert and English expert groups are small in size, limiting our power to detect significant differences between them. Finally, English experts tend to have increased incremental implicit theories of intelligence in comparison to novices. These results help illustrate the relationship between expertise and domain and how their interaction affects problem-solvers' beliefs about their intelligence in specific contexts.

The path to expertise is long, populated by challenging problems, and fraught with failure. We found that for a given domain, experts tend to have a more incremental implicit theory of intelligence and novices a more fixed implicit theory. Given this finding, and the other results here, how can we design interventions to support novices when they inevitably face failure? Perhaps these methods are relevant to consider in tandem with the expertise literature to supplement the effectiveness of deliberate practice.

Teacher Sensemaking of Potential Educative Features in Science Curricular Materials

Soo-Yean Shim, sys7829@illinois.edu, University of Illinois at Urbana-Champaign

Abstract: Educative curricular materials have been suggested as a primary lever for shifting instruction in science education, however, little is known about what NGSS-based curriculum materials communicate to teachers and how. This study explored how 9 in-service middle school science teachers made sense of and used educative features in two NGSS-aligned science curriculum materials. We interviewed the teachers about how they interacted with 12 potential educative features when planning and enacting a lesson. In this paper, we focused on one feature, "Lesson-level Performance Expectations." Our analysis identified three ways that the feature contributed to teachers' enactment and growth: the written performance expectations 1) shaped teacher-student interactions, 2) directed teachers' attention to the dimensions of NGSS in teaching and learning, and 3) were used to gauge progression of learning. These findings suggest multiple ways that educative features could open up opportunities for teacher learning.

Introduction and theoretical background

The adoption of the NGSS (NGSS Lead States, 2013) in the U.S. has led to significant nation-wide efforts to develop high-quality science curriculum materials that meet the high demands of these standards. The curriculum materials that emanated from the new standards share a set of design principles intending to shift science instruction from having students "learn about" content to having them "figure out" key ideas through their increasingly sophisticated participation in science and engineering practices (Edelson et al., 2021). These design principles include: 1) a phenomenon-based approach that students actively make sense of puzzling scientific phenomena throughout the unit, 2) engaging students in scientific practices (e.g., modeling, argumentation, explanation) to collaboratively build knowledge, and 3) valuing students' ideas and questions and making learning experiences coherent from students' perspectives (e.g., Krajcik et al., 2014; Windschitl et al., 2018).

Designing and enacting curriculum materials has been a recurring vehicle for driving instructional change in science education. However, in order for curriculum materials to be taken up as resources for transforming science instruction, we need to carefully consider the dynamic interactions between the teacher, students, and the new curricula. Specifically, Remillard (1999) argued that in order for curriculum materials to effectively support instructional transformation, features of the materials must speak *to* the teacher, rather than only speaking *through* the teacher (i.e., by directing teacher actions or providing materials for students). Features that speak *to* the teacher have been called *educative features*; they may provide specific content support, communicate curriculum designers' rationale for pedagogical choices, or help teachers envision and mobilize materials within their specific classroom context (Davis & Krajcik, 2005; Remillard & Kim, 2020).

This study builds on existing scholarship on teacher's sensemaking and use of educative features by investigating how in-service teachers interact with educative features in NGSS-aligned curriculum materials. The need for this work is twofold. First, the emerging scholarship around teachers' use of educative features has been predominantly focused on pre-service teachers. This work suggests that there is much to be understood is about how pre-service teachers attend to features that are intended to be educative (Arias et al., 2016) or use them in ways that lead to adaptive enactments across diverse teaching contexts (Drake et al., 2014; Land et al., 2015). These questions are even more critical to consider for in-service teachers, as open-education resources that are NGSS-aligned have become increasingly available (e.g. Edelson et al., 2021) and the use of curriculum materials are a key lever for shifting how in-service teachers engage students in science. Second, to date, there has not been a systematic investigation of what and how NGSS-based curriculum materials communicate to teachers about the instructional shifts that the NGSS require. At the heart of the vision of NGSS is the assumption that teachers, the curriculum materials, and students work together to create and then take up opportunities to co-construct explanatory accounts for relevant phenomena (Edelson et al., 2021). Thus, if NGSS-aligned curriculum materials are designed to be taken up in various ways by teachers, depending on their understanding of their students, the

 © ISLS

schools, and communities in which they teach, then a wide array of enactments are to be expected, and the various educative features that are embedded within these curricula should be designed to support meaningful adaptation. Here, we build on the rich scholarship in mathematics education on teacher's interactions with curriculum materials (see Remillard & Kim, 2020) and present an exploratory study that examines how in-service teachers make sense of educative features in a set of NGSS-aligned curriculum materials. In this short paper, we present findings from our analyses of one feature that revealed both variation and complexity in terms of teachers' sensemaking and reported use for planning.

Methods

We interviewed nine middle school teachers about how they interacted with two NGSS-aligned science curricular materials developed as part of a curriculum & professional development project. These two middle school units use a phenomenon-based approach to coherently support students' sensemaking and knowledge-building through collaborative scientific practices over time. One unit was focused on cell development (biology, grades 6-8), and the other was focused on ecosystem interactions (biology, grades 5-8).

Based on a review of existing literature about educative curriculum materials in science and mathematics (e.g., Davis & Krajcik, 2005; Remillard & Kim, 2020) and a review of 4 sets of NGSS-based curriculum materials from two developer organizations including OpenSciEd, we found 12 features that were consistently identified as potentially educative. Examples of these features were lesson-level performance expectations (Krajcik et al., 2014), assessment guidance, pedagogical rationale and additional guidance for specific activity structures such as Scientists' Circle discussion, and examples of teacher questions and student answers for class discussions.

Two members of the research team conducted teacher interviews over Zoom. 9 middle school teachers participated in the interviews, which lasted for approximately 1.5 hours and were recorded. Teachers' experience ranged from 4 to 18 years of teaching. The teachers had enacted either one or both of the focal units using the curriculum materials, except two teachers who were planning on teaching the units. All but one of the teachers who taught the units had attended a professional development session about the units before implementing them.

The goal of the interviews was to learn how teachers used the curriculum materials of a specific lesson to plan and teach. After several general questions about their teaching experience and overall approach to material use, the interviewers specifically pointed out each of the 12 potential educative features and asked: Did you use this feature? Was it helpful, neutral, or did it detract from your ability to plan/teach in the way that you wanted to? How and why? Teachers were also asked if they had any suggestions to improve the specific feature.

After transcribing the interviews, the six-member research team used an inductive comparative coding approach to analyze how teachers interacted with the 12 potential educative features. Each week, at least two members open-coded a portion of the interview data and brought it to the full group meeting. The team discussed patterns and variations, occasionally conducting an additional round of open-coding to clarify patterns or resolve discrepancies and uncertainties. From the analysis, we identified major ways that teachers interacted with each of the features. In this process, we regularly compared patterns across participants, and compared our emerging categories to findings from similar studies in the literature (e.g., Drake et al., 2014; Land et al., 2015).

In this short paper, we focus on teachers' use of one feature, "Lesson-level Performance Expectations" (Lesson-level PEs; Krajcik et al., 2014) because eight of the nine teachers described it as one they regularly used when planning for and/or enacting instruction. In addition, teachers' sensemaking about this feature reflected adaptive use of the materials. Thus, the variations in teachers' responses offer depth to the existing reports in the literature for how teachers read and learn from educative curriculum materials.

Findings: Teachers' sensemaking of lesson-level performance expectations

The Lesson-level PEs were presented in side-by-side sections titled "What students will do" and "What students will figure out" on the first page of each lesson in the curriculum (see **Figure 1**). The "What students will do" section color-coded the PEs along the three dimensions of the NGSS—science and engineering practices (color-coded in blue), disciplinary core ideas (orange), and crosscutting concepts (green). The "What students will figure out" section summarized the substance of the ideas that were to be expected as students would meet the PEs.

Eight of the nine teachers reported that they actively used the Lesson-level PEs during lesson planning and/or teaching. Only one teacher stated that they usually skipped this section of the curriculum because the content was repeated later. Our analysis identified three ways that the PEs contributed to teachers' self-reported enactment and growth: (1) shaping teacher-student interaction, (2) directing attention to the three dimensions of the NGSS; and (3) providing high-level information for gauging the progression of student learning.

Figure 1
Examples of Lesson-level Performance Expectations in the Curriculum

Shaping teacher-student interaction

Four of the nine teachers (Teacher JK, RP, RS, & JG) stated that the Lesson-level PEs directly impacted their classroom interactions with students. RP said that she used the PEs to set "talking points" and develop questions to ask in class discussions to support student sensemaking. JK said that she used the PEs for co-constructing a classroom tool called "project tracker" with students to support their reflection on their learning from each lesson and their progress toward unit-level objectives to understand puzzling science phenomena. RS shared that she summarized key activities in the PEs and posted those as "learning objectives" for students in the class. In these cases, the written PEs were used to mediate classroom interactions between the teachers and students.

Directing attention to the dimensions of NGSS

Five of the nine teachers (Teacher JK, RP, AH, DV, & JG) stated that the color-coded Lesson-level PEs supported them in developing their (and sometimes their students') capacity about the three dimensions of NGSS. They reported that it was helpful to have the dimensions highlighted in the NGSS colors so that they could easily find and work on the different dimensions in their planning and teaching and grow their capacity around them. For example, RP said, "So, I'm seeing some of the SEP *[science and engineering practices]* there. I really look for those things. I'm like, 'Ok, that's the SEP, this is the DCI *[disciplinary core ideas]* and the crosscutting concept.' *[...]* I really focused on the SEP and the DCI *[before]*. I felt like that's all I could really handle. Going forward, though, I am getting better at incorporating the crosscutting concepts." Another teacher, DV, said, "I find this one *["what students will do" section]* really useful because it's all in one place. It shows me the important DCI pieces, the important practices, and the key crosscutting concepts."

Two teachers (AH & JG) said that they used the articulated PEs to support the growth of their students around the NGSS dimensions. For example, AH said, "What I'm going to be working on this year is making sure that I focus more on the CCC *[crosscutting concepts]* and the science and engineering practices. *[...]* They're crosscutting, like, I can see them and I can watch how students grow in them all throughout the year. For example, today, we're looking at identifying patterns *[one of the NGSS crosscutting concepts]* and they *[students]* just, they couldn't. And I'm like, okay. So, hopefully, as I force more pattern recognition on them, that CCC is going to improve. So, you can see where students are about that, and you can see how they grow." Like this, the teachers used the color-coded PEs that matched the three dimensions of NGSS to assess and promote students' and their own growth about the dimensions and to better connect the three dimensions in their instruction.

Gauging progression of learning

Seven teachers (Teacher JK, RP, RS, AH, DV, JH, & JG) stated that the Lesson-level PEs helped them set direction and check the progress of their instruction; to check if they were on the right track and decide what to do next. Sometimes the written PEs worked as a reminder for them to address important ideas and concepts. For example, DV said, "Like, if we're on the right track. And as you get later in the unit, I would start to look at this more like a checklist." RP said that she often checked on the PEs while teaching to make sure that she was using time "correctly and usefully for students." Teachers also used the PEs to report their objectives and progress to their administrators, especially about which NGSS components they were addressing in each lesson. In sum, the PEs worked as a reference and guidance for the teachers to "move forward."

Discussion

The eight teachers who reported using the Lesson-level PEs in their planning did so in a variety of educative and adaptive ways. The feature informed their understanding of content and pedagogy in the context of the lesson and informed how they might customize enactment to their own specific classroom context.

Unit materials typically include learning goals aligned to standards, and therefore, this feature is familiar for teachers. Using this feature to, "Gauge progression of learning," aligns with the general role that learning

objectives serve in teaching: to help prioritize selection of content and use of time, develop classroom activities, and evaluate student progress in light of the objectives. This use also reflected teachers' need to meet school policies of writing learning objectives on the board.

The other two ways that teachers used the Lesson-level PEs ("Shaping teacher-student interaction" and "Directing attention to the dimensions of the NGSS") offer insights into how this information plays an "educative" role. In particular, RP's use of the right-hand list of "What students will figure out" to structure questions and talking points for discussion reflects its utility in shaping her practice of providing opportunities for students to reason through science ideas using talk, a central principle of instruction that meaningfully supports the NGSS's intent (Windschitl et al., 2018). Similarly, JK's use of the feature to help develop the project tracker highlights its utility in supporting another core instructional principle, students building ideas incrementally and through critique (ibid). In this way, the Lesson-level PEs provided educative support in shaping teachers' instructional practices. Similarly, regarding, "Directing attention to dimensions of the NGSS," both RP and AH reflected on how the color-coding of the crosscutting concepts in the Lesson-level PEs helped them to structure their own learning about how to incorporate crosscutting concepts in their instruction as well as helping them evaluate students' growth in using crosscutting concepts. Thus, this feature helped leverage their own pedagogical growth, an important prerequisite for teacher learning from curriculum materials (Arias et al., 2016).

We posit that the combination of the two lists—"What students will do" and "What we will figure out"—was important in making this feature educative and in driving the observed variations in reading and use. The familiar structure of a PE and color-coding offered connections to formal standards, while the bullet points on the right-hand side offered a snapshot of what enacting those standards in a classroom context could look like. Teachers attended differentially to one side or the other, depending on their needs. At the same time, the combination reflects a novel way of thinking about learning goals in that it emphasizes the "means" as well as the "outcomes" that the NGSS PEs are meant to achieve. Embodying the pedagogical practices that support these "means" is a critical challenge in the shift to NGSS (Windschitl et al., 2018); this study suggests that the Lesson-level PEs may be one feature that can provide educative supports for in-service teachers in shifting their instruction in meaningful ways.

Abstract: Representations of the health and resources of neighborhoods, particularly those made without a community's input, can be misleading, and can perpetuate inequities. We designed and implemented a two-week-long grade 8 unit to explore how photo walks—an arts-based methodology that involves capturing and reflecting on photos along one's walking route—can engage students critically with community data. We draw on a critical data literacy perspective, which views data as situated in social contexts and challenges the notion of data as neutral. Artifact analysis and post-unit interviews with two students revealed opportunities and challenges in supporting critical data literacy through planning and participating in photo walks.

Introduction

How communities are represented is a social and ethical challenge. It is also one that cuts across both data science and the arts (D'Ignazio & Klein, 2020). While a visual artwork, such as a photograph, can tell a story about people and places, it can also be used to overgeneralize. On the other hand, quantitative data can be challenging to collect and may overrepresent a community's problems (e.g., crime rates). In this study, researchers and teachers co-designed an 8th-grade, arts-integrated data literacy unit to engage students critically with community data through photography. In our design and analysis of student work, we draw on Philip and colleagues' (2013) framework for learning about big data for democratic participation, which outlines five goals: participating in the language and tools of data science, identifying as people who can use data for purposes that interest them, engaging in a process of inquiry to understand and address social issues, recognizing how data highlights and obscures perspectives, and making sense of and communicating data using the tools of multiple disciplines. To scaffold critical engagement, we draw on methods in photography that have a history of foregrounding discussions about representation and cultural narratives. Photovoice, for example, engages those who are often excluded from producing and analyzing data in creating bottom-up change through storytelling (Wang & Burris, 1997). Photo-walking, a collaborative activity that engages people in multisensory observations of their environments, further highlights how prior knowledge and experience affects data collection (Mainsah & Boe, 2019). This study builds on prior research in data literacy education that has sought to engage students critically with their communities through data (Rubel et al., 2016; Wilkerson & Laina, 2017; Kahn 2020; Stornaiuolo 2020). By comparing and contrasting the experiences of two students, we investigate *how planning and participating in photo walks prompted students to engage critically with data about their neighborhoods.*

Methods: Context, participants, and data

We co-designed and implemented a grade 8 unit called *Postcards and Photo Walks* with two teachers, one art teacher and one ELA/math teacher. Both taught at a private school in the U.S., in which the administration encouraged multidisciplinary connections between subjects. The art teacher wanted students to create an art piece that would generate pride in their neighborhoods and in their artistic abilities and that showed them real-world applications of art. The math/ELA teacher wanted students to be able to connect math to the real world. Through weekly co-design meetings over 6 months, teachers met with three researchers to identify the unit's focus on "healthy places," activities, and learning goals. We aimed to engage students critically with data through the following activities: reflecting on multiple ways to measure the health of a neighborhood, investigating community assets and issues through personal and public data, and drawing on the arts to connect personal experiences to community statistics. In this 9-day unit, students were asked to think about the question "What is a healthy place?" through photo-walking, and construct digital postcards that introduced their neighborhood to students living across the country. Due to pandemic-related restrictions in 2021, all students joined class meetings via Zoom, although some students were co-located in a classroom, while others were at home. Students contributed to class discussions and group work out loud as well as via the Zoom chat. On Day 1 and 2, students were introduced to the topic of healthy places by exploring data and engaging with a grounding artwork by the

 © ISLS

Anti-Eviction Mapping Project collective, titled *The Oakland Community Power Map* (AEMP, 2016). The participatory mapping installation first appeared in the Betti Ono Gallery and was subsequently transformed into a digital map to enable crowd-sourcing. The purpose was to enable residents of Oakland, CA, to resist displacement through gentrification by letting "the city know what we have, what we value, and what we want" (AEMP, 2016; p.17). We engaged students with the main prompt of the artwork, to describe and map places that have "influenced or sustained you physically, emotionally, spiritually?" (AEMP, 2016). On Day 3, students read about access to healthy foods and parks and created scatter plots using CODAP (Common Online Data Analysis Platform). On Days 4-7, they participated in a photo walk, discussed their photos in small groups, and selected a photo to represent their series. On Days 8-9, students wrote letters about their neighborhoods and participated in a voluntary salon-like exhibition, reading their letters aloud to their class peers and invited guests (project researchers and advisors). Students' artworks were collected into a class website by the research team to enable reflection across data and a way to share their work with friends and family.

Participants were 23 eighth graders from a private Catholic middle school located in a large urban area with a predominantly Latinx and Black or African American population (85%). About 70% of students are on a free or reduced price lunch program. Our data consist of (1) 45-minute, semi-structured interviews with two female students (whom we name Asami and Katara), in which we asked each student to reflect on their experiences during the unit; (2) two hour-long post-implementation interviews with each teacher, in which we asked them to reflect on how the unit met or failed to meet their learning goals, and on notable observations of student learning; (3) artifacts produced by the 2 students interviewed (letters, photography, maps, graphs, artist statements, and contributions to class discussions written in the Zoom chat); and (4) field notes from observations conducted over Zoom of 5 class sessions. Using a case study approach (Yin, 2009), we analyzed Asami and Katara's contrasting experiences working with data through a process of planning and participating in photo walks.

Findings

Both Asami and Katara produced and used data for personally meaningful purposes, recognized data as useful for understanding and addressing social issues, and drew on the tools of math and art to understand and represent data (Philip et al., 2013). *The Oakland Power Map,* a grounding artifact for critical data literacy, prompted discussion about who is able to produce data to address social issues and why it matters. According to the art teacher, the purpose of the artwork "clicked right away," with many students, who shared that "their neighborhood is [also] considered dangerous but that when you get there it's a beautiful place, with beautiful neighbors." Katara and Asami subsequently produced data about both community resources and problems, challenging single stories about their neighborhood. Their written letters also supported the importance of identifying more than just community problems. Katara wanted to "touch on stereotypes, specifically in [her county] because it has a reputation of being like a bad ghettoish community, but if you live there you'd see ...it's more like a kind of family…" Asami wanted to write something that was "very honest but also relatable to people like me who live in [my community]." Next, we explore how Katara and Asami integrated art and math to support these personally meaningful purposes.

Case 1: Photographing frequency and variability of sidewalk cracks

Figure 1

Katara's neighborhood walk (left), photographs of sidewalk cracks (right), and artist statement (bottom).

For this project, I chose to indicate life expectancy in my community with the quality of our sidewalks. Since sidewalks are used quite often, it is important to take care of them and make sure they function without issue. People that use walking aids, such as canes and scooters, have to watch sidewalks more carefully in case of cracks that can cause them to fall. In my community, cracks in sidewalks are quite common; it's easy to trip if your aren't paying attention. Although it is a small detail, having nice sidewalks improves a place's appearance while keeping its members happy and healthy.

Planning photo walks: Recognizing data as useful for understanding social issues

All students engaged in multiple planning activities to inform their photo walks. First, they drew maps of their neighborhood and explained their choices. Katara, for example, wanted to represent her own experiences *and* the

diversity of neighborhood resources. She identified places in her neighborhood that she regularly went to and that contributed to the health of her community (e.g., movie theater, grocery store, and park). She connected each place to different variables (e.g., population size, access to outdoor spaces, and affordable groceries) and thought critically about measurement. For example, she argued that "people [in her community] have options for what food to buy and consume" not only because a grocery store is geographically accessible but also because it offers quality food (e.g., "it tastes nice) and affordable prices (e.g., "lots of stuff up for sale"). Using her map, she then argued that her neighborhood was healthy because of the quantity of services available to meet public needs.

Next, students explored public data about their neighborhood to inform the subject of their photo walks. They made scatter plots to investigate variables such as average life expectancy and high-school graduation rates. Some students like Katara also proposed variables that were not represented in the data, graphing the change they wanted to see. Clean streets, for example, was a topic that Katara felt was "unique, that not a lot of people would think about...smaller things that would not really be thought of when you're looking at a map of a community." She reasoned that "cleanliness correlates to life expectancy because if there's a place with a lot of trash that means it's not really well kept by sanitation workers and it can grow mold and bacteria and be like a farming point for diseases which isn't healthy." According to Katara, analyzing data informed her photography by giving her "a general understanding of what to expect or what not to expect; it's like a hypothesis of the project."

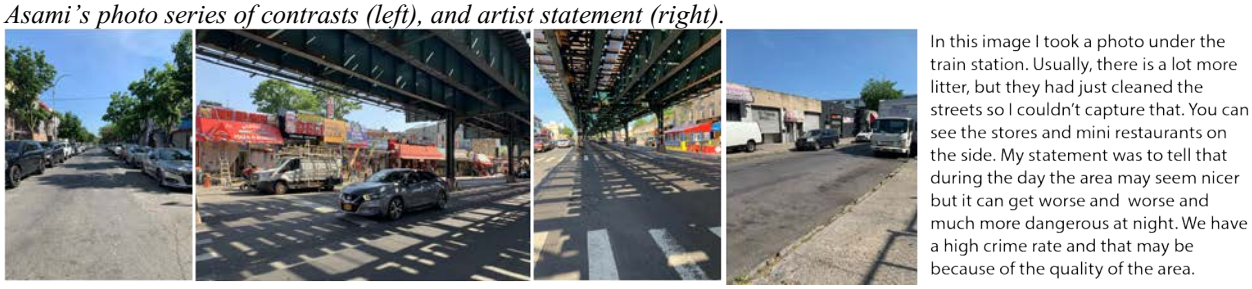
Participating in photo walks: Drawing on the arts to understand and represent data

During her photo walk, Katara's hypothesis was challenged by a lack of evidence. "I had trouble at first trying to see what I could take photos of…" she explained. But the lack of observable evidence of litter prompted her to shift perspectives, to engage in deep noticing, and to argue for the relevance of a different "small," overlooked issue. Sidewalk cracks, she explained, were problematic in her community because "sidewalks are used quite often" and people with disabilities are especially vulnerable to tripping (e.g., "if you're using a wheelchair or some kind of walking device, sidewalk cracks can be dangerous"). To support her claim, she generated data on sidewalk cracks by photographing the frequency and variation of cracks around her home. Using a consistent point of view, repeated sampling, and organization of images, she summarized this problem as a pattern rather than a point (see Figure 2). Each image showed variation in the number, size, shape, and location of cracks. Her focus on texture further highlighted the age, material, and quality of sidewalks. As a result, her photo series engages the audience in more than counting cracks. By mapping different areas in her neighborhood, explaining where she collected data, and visualizing variation in cracks, she enables informal inference-making about her neighborhood.

Case 2: Photographing neighborhood contrasts

Figure 3

Asami's photo series of contrasts (left), and artist statement (right).



In this image I took a photo under the train station. Usually, there is a lot more litter, but they had just cleaned the streets so I couldn't capture that. You can see the stores and mini restaurants on the side. My statement was to tell that during the day the area may seem nicer but it can get worse and worse and much more dangerous at night. We have a high crime rate and that may be because of the quality of the area.

Planning photo walks: Recognizing data as useful for understanding social issues

Asami's map highlighted *her* "tight community," which included a church, nearby homes of family members, the train, and local delis. She chose to represent only the few blocks around her home, centering the everyday places and experiences that help keep *her* healthy and occupied (i.e., exercising, commuting to school, seeing family). While Asami also investigated public data about her city, interpreting interactive data visualizations and making scatter plots, she largely drew on personal experiences to inform the subject of her photo walk. At the same time, analyzing neighborhood data confirmed her understanding that crime was a problem in her neighborhood and helped her identify significant consequences (e.g., lower average life expectancy). During class discussion, for example, she argued that average life expectancy was a good way to measure the health of a place because "you live longer when you live in a healthier environment. The area you live around affects how you feel. The cleaner

areas in my data have a longer life expectancy than others. [My community] had 4 points below the life expectancy of [other areas]."

Participating in photo walks: Drawing on the arts to understand and represent data

In her photo walk, Asami contrasted her neighborhood with a nearby industrial area known to be dangerous. The first two images show her everyday walk to the train and nearby businesses, while the second shows a neighborhood, a few train stops away, that she avoids due to a dangerous underground club. Her goal was to represent her community as a whole, showing positive and negative characteristics (see Figure 2):

> I went around the block looking for places that had some litter in it or have a bit nicer, more vibrant colour…there are nice stores, you have the train station, but you have this litter and then there's of course danger in the area, so having those contrasting things shows how the community really is as a whole.

Contrast is a theme in her artist statement and letter, and also emerges in how she talks about community action and health. She recognizes that there are decisions and resources that individuals cannot control but also opportunities for action, "work[ing] together...not throwing stuff on the ground, adding more trash cans, decreasing crime rates."

Discussion and Significance

Planning and participating in photo walks prompted students to engage with social issues through a process of inquiry (Philip et al., 2013). In planning their photo walks, Katara argued that her community was healthy based on the number and variety of available services on her map, connecting places to variables such as population size and access to parks. Asami argued for using average life expectancy as a measure of health, drawing on neighborhood data and personal experiences as evidence. When confronted with a lack of evidence, Katara identified evidence of an alternative topic and Asami recognized and attempted to explain a sampling problem (i.e., time of day). In their photo walks, both students demonstrated attention to informal inference-making (Makar & Rubin, 2018), visually summarizing data as a pattern or comparison and discussing context. These findings highlight future opportunities to reinforce statistical concepts, such as sampling and variation, by iterating on data analysis and photo walks.

Abstract: We report on a curriculum development project in which students explore environmental racism through data. Recognizing that quantitative data alone is insufficient to understand the sociohistorical contexts of racism, we draw from syncretic approaches to learning that put everyday experiences and qualitative evidence into direct conversation with quantitative datasets through storytelling. Through two focal cases, we demonstrate how one student leveraged personal experience to engage in deep integrative analysis of data, while another with fewer perceived personal connections to environmental racism focused more specifically on patterns, with less structural or racial analysis. Implications of the analysis include the need to carefully attend to the use of quantitative data related to race and to scaffold the integration of other sources of information with quantitative data sets.

Introduction

There are increasing calls for students in STEM classrooms to reimagine the use of data (Lee & Wilkerson, 2018), as well as to engage with issues of social and racial justice, like environmental inequities (e.g., Varelas et al., 2017). These two foci can be brought together through student exploration of socioscientific data. Recent studies have shown that race is a stronger indicator of exposure to pollution than income (Tessum et al., 2021). Yet, literature points to challenges in engaging students with issues of racial justice in STEM. Even when engaging with social phenomena, data literacy activities may fail to attend to the structural and ideological contexts in which data is situated and the embedded issues of power (Philip, Olivares-Pasillas & Rocha, 2016). Quantitative data alone is insufficient to understand racism; it must be supplemented with other information about local and historical contexts (Gilborn, Warmington and Demack, 2018).

The *Writing Data Stories* project seeks to address these challenges by engaging youth in expansive forms of learning that integrate analysis of data with students' own experiences and cultural repertoires of practice. We report on a youth workshop exploring environmental racism through data science inquiry in which students shared their own experiences, investigated and manipulated data sets, and engaged in journalistic research. We found that engaging students' personal experiences with environmental racism deepened their treatment of data as well as their analysis of historical and structural factors related to race. In some cases, however, students had more limited personal connections to the topic; in these cases, their investigations focused on correlative relationships among variables and included structural or racial analysis.

Theoretical Framework

Our work is grounded in a syncretic approach to development (Gutiérrez, 2008, 2014) that leverages the expansive forms of learning that occur when youth integrate everyday and school-based contexts and practices. Such approaches seek to reorganize the relationship between everyday and scientific practices while preserving tensions between them, maintaining the value of the everyday genre vis-a-vis the dominant form. In doing so, youth develop a deeper understanding of concepts and texts, consider the different spheres of life in which these texts function and are valued (or not), and have opportunities to use their knowledge to participate in disciplinary domains and civic life more broadly (Gutiérrez, 2014).

We build from lines of work that have established how students can leverage their personal connections to (and tensions with) data to make sense of it and how students can collect, explore, and manipulate data to create representations that matter to them (see Wilkerson & Polman, 2020). As they work with data, students can engage in data moves (Erickson et al., 2019), such as filtering to isolate cases of interest, grouping data in particular ways, or adding to and merging data sets to include new information. In our work, we are particularly interested in the ways that students use their everyday experiences as a resource to motivate or deepen their engagement with data sets. Students can transform data sets to reflect their own sociohistorical lives and engage in syncretic data reasoning, the ongoing interplay between everyday experiences and analysis

 © ISLS

of data.

In this work, we explore how students write "data stories." Data stories are a type of syncretic text that uses narrative to integrate data, personal experiences, and other forms of social, cultural, and historical knowledge and research (Wilkerson et al., 2021). Although narrative is not often employed in STEM contexts, students can use storytelling to organize their understanding of data based on previous experiences, thereby making sense of the connections between descriptive and inferential statistics and understanding data analysis as complex endeavor guided by human decisions (Gillborn, Warmington & Demack, 2018). For the topic of environmental racism, students can use data stories to critically examine how race has structured communities' exposure to environmental health hazards and to advocate for related social change.

Research Questions

Given our interest in the construction of texts that bring together disparate ways of reasoning, we ask:

1. What experiences do youth leverage to generate research questions about environmental racism?
2. How do youth use qualitative and quantitative evidence to reason about and advocate against environmental racism through the creation of a data story?

The *Writing Data Stories* project takes a syncretic approach to integrating narrative and data. This paper reports on a week-long, online summer workshop on the topic of environmental racism. Participants (n=12) ranged in age from 12 to 14, were from both dominant and non-dominant backgrounds, and were mostly from the greater Bay Area. In the workshop, students explored case studies of environmental racism around the world, interviewed family members, and listened to a presentation from a local African American environmental activist. They used the Common Online Data Analysis Platform (CODAP) data visualization tool (Finzer & Damelin, 2016) to engage in open-ended investigation and manipulation of public data sets on social indicators (e.g., income, race, asthma) and environmental indicators (e.g., air pollution, water pollution, pesticides) in addition to conducting internet searches and other forms of journalistic research. Many examples in the course and the initially provided data sets were grounded in the physical geography and history of the Bay Area. As a culminating project, participants developed a data story about a research question of their own choosing.

Data sources included video recordings of the class sessions and one-on-one conferences with students, student artifacts, and post-session student interviews. We analyzed these data for the subset of consented students who participated in all workshop activities (n=6). We identified the *questions* that these students posed and coded for the *experiences* that inspired the questions (e.g., personal experience, internet research, preliminary observation from provided data sets). We then identified the *claims* that students made in response to their question, coding for the type of *evidence* they leveraged (e.g., provided data set, external data set, personal experience, qualitative research) and the presence of any *data moves* (e.g., sorting, grouping, filtering, merging). Using the coding, we created a timeline of each student's reasoning about environmental racism and constructed a narrative case describing how their thinking developed over the course of the workshop. We then selected two students who served as contrasting cases and reflected broader patterns in the larger data set.

Findings

We describe two cases that represent distinct approaches that emerged in our analysis. One student, Elena, drew from her own experience and the narrative of an activist to explore pollution in North Carolina. She engaged in a wide range of data moves, merged new information with data sets, and considered race in her reasoning. Another student, Narun, generated his question about the relationship between air pollution and poverty from his initial observations of patterns emerging from the data set. In contrast to Elena, he incorporated fewer data sources and did not mention race as a factor in his reasoning. We describe these two examples below.

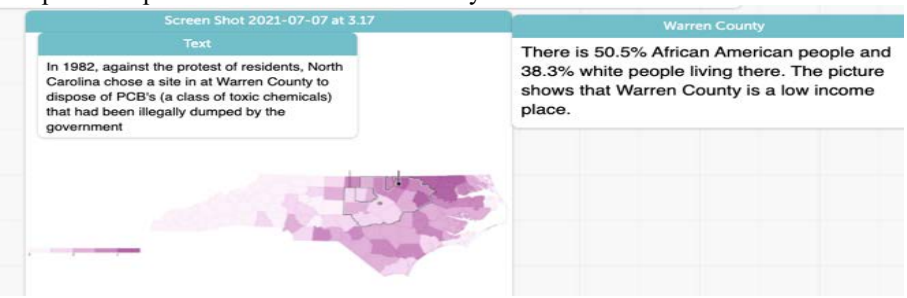
Case 1: Elena

Elena is fourteen years old, and her family immigrated to California from Central America. Early in the workshop, she reported on her own family's exposure to air and water pollution as farm workers in California's Central Valley. For her project, Elena chose to explore the history of Ben Chavis, an African American environmental activist from North Carolina she learned about through internet research (see Figure 1). She commented "I felt that I already had, like, covered the topic of the Latin community…and I wanted to also cover other kinds of races. [The activist of color who spoke to the group] talked about how they put factories next to an African American community and it inspired me." By grounding her story in the actions of activists protesting against the dumping of toxic waste in their community (see Figure 1), she sought to relate her family's own experience to those of other minoritized groups, revealing broader systemic injustice.

Elena explored a data set on pollution in North Carolina, engaging in multiple data moves that were motivated by Ben Chavis's story. She first *filtered* the data, selecting Chavis's home county and comparing it to

a nearby county with higher income, marking both on the map with a specific color. She then *merged* the data, looking for another source that reported the racial composition of the two counties (see Figure 1). Her argument thus coordinated data about income, race, and toxic waste to support Chavis' argument that the dumping incident constituted an act of racism. She also investigated the chemicals that were dumped at the site (PCBs) and searched internet articles for evidence of racial strife in the area, integrating quantitative and qualitative data to explain the historical event.

Figure 1. Data maps and explanations used in Elena's story

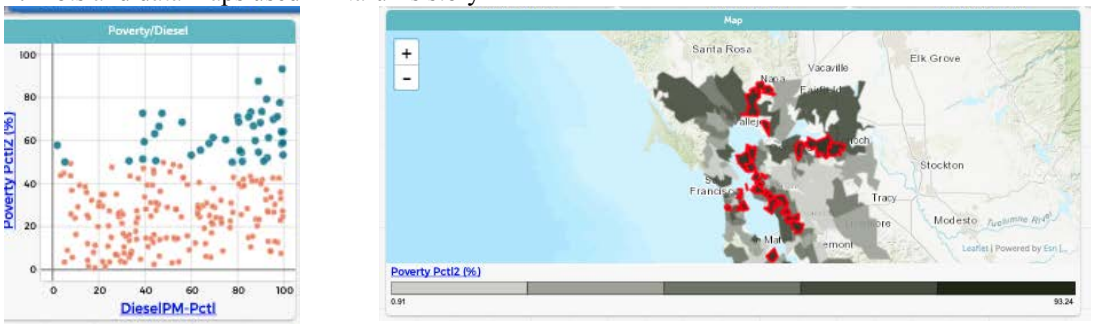


Case 2: Narun

Narun is thirteen years old, is of South Asian descent, and lives in a wealthy suburb of the Bay Area. In his interview, he reported that he did not have much personal experience with pollution. Early in the workshop, he reported researching Flint, Michigan. He commented "I think it was a racism case. It was basically a town in Michigan where they cut off clean water for the citizens of the town." However, in his own project, Narun chose to investigate the relationship between income and pollution in the Bay Area. He reported that he chose this topic because "whenever I'm in San Francisco or the Bay Area, I see lots of homeless people outside and it doesn't feel too good. It's important because being homeless is very difficult." Thus, he grounded his investigation in a situation that observed that invoked his empathy and concern.

Narun reported in the interview that he "looked at a bunch of …factors, but chose to do poverty and air pollution." He looked for which type of air pollution had the strongest relationship to poverty, and settled on diesel emissions. In his final presentation, he filtered to show the top quintile of poverty and demonstrated it on a map and a graph (Figure 2). He then drew relationships, referencing the map to claim that "poverty is high along the coast…and you also see that air pollution is high there too." However, Narun did not report on the racial composition of these counties, even though it was provided in his data set, nor did he discuss the history of residential segregation and industrial development in the area, even though it was presented in the workshop. Narun's analysis of poverty and income was well-reasoned and supported by the data; yet, it was incomplete in that it did not examine the relationships between race and income. While we have no direct evidence of why he did not incorporate race, we propose that we may not have adequately scaffolded the use of quantitative data and other sources of information related to race. We draw implications from this case in our discussion.

Figure 2. Plots and data maps used in Narun's story



Discussion

Through this analysis, we add to lines of work that have demonstrated the value of syncretic approaches to science learning. Specifically, we have shown how Elena's family experience with racism promoted the use of data moves (Erickson et al., 2019) that deepened her work with data, as well as expanded her understanding of environmental racism as a form of systemic injustice across minoritized communities. This case demonstrates

how a data story can act as a syncretic text (Gutiérrez, 2008) in which students integrate personal experience, data, and multiple types of evidence to forward claims about environmental racism. Such a text reorganizes disciplinary learning by elevating personal experience, narrative, and historical understandings as valued and connected resources for supplementing quantitative data sets in STEM contexts. Syncretic learning was supported by the open-ended nature of the inquiry, which allowed students to choose a topic that related to their own experiences, suggesting the value of integrating more student choice into explorations of data.

Yet, our analysis showed that some students explored income without considering race, which aligns with previous work showing race is often avoided in STEM contexts (Philip, Olivares-Pasillas & Rocha, 2016). A key implication of this analysis is that teaching about racial justice does not necessarily prepare students to adopt this lens in their own data reasoning and research. In considering Narun's case, and others like it, having less personal experience with structural forms of injustice like environmental racism may have made these students less likely to conduct an analysis with a racial lens. As a result, we are dedicating more time to discussing, modeling, and critiquing the use of racial categories and integrating more related data visualizations in our curriculum, as well as explicitly discussing the relationships between race and income.

Additionally, we are ever more aware of the limitations of quantitative data in exploring issues related to race (Gilborn, Warmington and Demack, 2018). This analysis surfaced a clear need to give more support to students to understand the social, political, and historical factors that could help explain the quantitative patterns they observed. As we develop the curriculum, we are carefully considering how to support students in linking historical policies and social structures to present-day environmental inequities. Contextualizing data in this way requires an interdisciplinary approach that draws tools from history/social studies to help students to understand how structural racism has been organized in the past and continues to be organized in the present, as well as tools from ethnic studies to help students to understand their own identities and relationships to systems of power. Overall, these findings underscore the importance of drawing from diverse pedagogical and disciplinary approaches that support students in considering race from multiple perspectives while analyzing quantitative data sets. Understanding the structural causes of current environmental inequities is critical to helping students to imagine more just futures and engage in related social action.

Making Home…Work: Codesigning Teacher Tools to Support At-Home Learning

Paul Hatch, University of Illinois Chicago, phatch2@uic.edu
Joseph E Michaelis, University of Illinois Chicago, jmich@uic.edu

Abstract: Learning sciences research has demonstrated the importance of personal guidance, where a teacher can help connect new knowledge to a student's own experiences and interests to promote deeper understanding. However, homework is often done in isolation where students lack the type of guidance a teacher would provide in the classroom. To explore ways to design technologies to allow teacher to provide effective homework guidance, we interviewed and conducted co-design sessions with middle school science teachers about their views on supporting student learning in the classroom and during homework. We found teachers place high value in students doing homework but have minimized giving homework due to practical and equity issues. The limitations of existing technologies to address this issue and the recent increase in teachers' use of online tools present an opportunity to reimagine the design of these tools by building on teacher views of how to revitalize homework.

Introduction

Students benefit from learning experiences tailored to their individual needs, particularly when it includes social interactions that foster the co-creation of knowledge (Miyaki & Kirschner, 2014). Often teachers engage in interpersonal social dialogue with students to provide *personal guidance*, where teachers use socially situated ways to build upon students' knowledge, interests or prior experiences to maintain engagement with the material and help construct lasting knowledge (Bernacki et al., 2021). However, homework activities are often done in isolation where teachers and families can struggle to support students or provide adequate guidance (Cooper, 2015). The use of online learning technologies surged during the pandemic and has driven more teachers to use these to facilitate learning at home, an increased use that is likely to persist (van der Spoel et al., 2020). However, recent work found that teachers struggle to foster collaboration or make meaningful connections to their students using these tools (Midcalf & Boatwright, 2020). These limitations, along with teachers' increased experience with online tools present an opportunity to reimagine the design of such tools to provide socially interactive personal guidance to students during homework. As part of a larger project, our goal is to co-design a tool for middle school science teachers that meets their needs for providing personal guidance during homework. To inform that work, we worked with science teachers through interviews and co-design sessions and examined, (1) how and why science teachers provide homework, and (2) how teachers would want a tool to aid creating homework and provide personal guidance.

Theoretical Framework

Our work takes a sociocultural perspective on learning (Miyaki & Kirschner, 2014), a perspective that recognizes how a student's acquisition and integration of domain knowledge is built upon their sociocultural experiences and social interactions. Classroom learning is socially situated, and students benefit from co-creating knowledge through social exchanges with teachers and peers (Cress & Kimmerle, 2018). As teachers plan classroom activities, they consider how to facilitate students to co-construct knowledge through interpersonal social interactions with peers (Cohen et al., 2003) which helps build lasting and deep knowledge. Teachers actively support their students' classroom learning by making references to student interests and experiences, verbally adapting content vocabulary, responsively attending to student questions and misconceptions, and prompting discussions and reflections on learning (Bernacki et al., 2021), these socially oriented interactions are tailored around the teacher's own knowledge of their students and thus constitute *personal guidance*.

Homework is a valuable instructional tool that can enhance students' learning, have a positive influence on students' academic achievements and self-responsibility, and can be particularly effective when connected to classwork and tailored to students' individual needs (Cooper, 2015). However, complex and challenging science homework, involving writing opinions on new topics, discussing ideas about reading and videos, and explaining science concepts, can require substantial scaffolding and guidance (Horsley & Walker, 2012). Given the focus in science education on collaboration and discussion (NGSS, 2021), socially interactive learning and personal guidance is critical for science learning at home as well as in the classroom. However, teachers struggle to design

 © ISLS

learning materials that would provide such personal guidance for homework, particularly in science, technology, and mathematics (Cooper, 2015, Horsley & Walker, 2012).

Recent online videos, articles and interactive media like Kahoot!, Kami and Gizmos, allow teachers to provide a range of content in a more efficient way than traditional book or worksheet homework. Some learning systems provide students automated feedback on answers, step-by-step problem-solving help, mastery tracking, or adjust activities according to performance (Aleven et al., 2016). However, these systems often provide scaffolding and differentiation based on student performance metrics and may be missing many aspects of the personal guidance a teacher would provide in the classroom. To meet this challenge, we begin with the research question (RQ): *How can we design a digital tool for teachers to provide personal guidance for their students in science homework, based on their students' learning preferences and needs?*

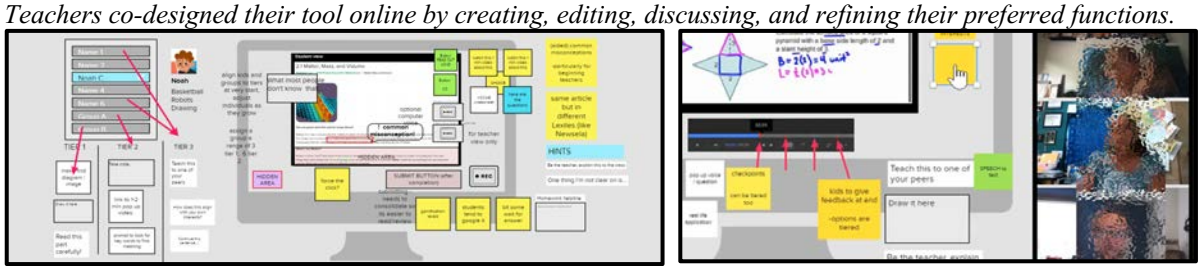
Method

To answer our research question, we conducted two phases of participatory design research with middle-school science teachers to probe for *what* personal guidance teachers would like to provide, and *how* they might use a tool to augment homework to support their students' at-home learning. We began by conducting 1-hour semi-structured interviews using Zoom with (n=9) middle school science teachers and probed for their views on the types of personal guidance they give in the classroom and their views on homework. We analyzed and transcribed the video data using a Thematic Analysis approach (Braun et al., 2018) to qualitatively identify patterns in the data from the teachers' perspectives. Four researchers, including the first author, generated semantic codes using an inductive approach and organized the data into major categories, such as 'Sharing Ideas' and 'Adapting concepts' from which we built, discussed, and refined emergent themes from meaningful patterns in the data.

We then used the teachers' reflections to guide the design of a set of functional features such as a 'record button', or an 'annotation pop-up'. These were each represented as simplified representations in three co-design sessions each with 2-3 teachers (n=7) on online whiteboard tool 'Mural', and could be edited and moved according to the unfolding discussions (see Figure 1). The teachers discussed what, how, and why each of the features would aid their homework creation and suggested additional features with the goal of building their own ideal homework authoring tool. Each of these 2-hour co-design sessions were analyzed using a similar Thematic Analysis approach as before. We used these new themes to (i) reflect and expand on our previous findings and (ii) to understand the pragmatic needs of the teachers specifically for such a digital tool.

Figure 1

Teachers co-designed their tool online by creating, editing, discussing, and refining their preferred functions.



Findings

Our interviews showed that (1) teachers see homework as a valuable but have minimized the use of it, (2) the pandemic revealed issues with at-home learning, expanded teachers' software usage and revealed new needs, and (3) teachers want to address homework issues through offering social tools and automated personal guidance.

Teachers view homework as an important tool to build on classroom activities and as a formative review of their students' understanding to address in the classroom. They also view homework can provide unique opportunities for students to reflect or analyze work at their own pace and to tie it to their own interests. Teachers prefer to avoid having students grapple with completely new concepts by themselves and some provide specific guidance in the classroom to prepare them for a homework task, however many remarked that there is rarely time to provide any form of personal guidance. Additionally, teachers have minimized the use of homework as they believe students face varying equity issues between students due to time constraints, technical resources, and lack family support. Teachers felt these inequities caused vast differences between student's homework and classwork.

During the pandemic teachers expanded their use of educational multimedia for at-home tasks and now regularly combine videos, articles, and interactive online content to meet their student's learning needs and amplify student engagement and learning. They also indicated that becoming more familiar with online tools during the pandemic makes them feel more confident and interested in using an authoring tool for providing

 © ISLS

personal guidance to in-home learning. However, expressed difficulties in providing personal guidance with existing tools, such as not being able to verbally walk-through tasks or support their students' engagement in the content. Given their new emphasis on incorporating multiple content sources, teachers indicated in the workshops they now need ways to rapidly curate and customize homework from a range of sources.

Teachers co- designed ways to help keep their students' engagement by adding social interaction options more typical of in-class personal guidance, such as vocabulary support, references to past experiences, and vocalization options. Audio-based, social tools were particularly desirable options, where the student could have the text read aloud to them, receive vocalized help with new vocabulary words, or the teacher could include personal messages. Teachers also wanted timesaving help from a system that would automatically add elements of personal guidance to the homework based on student's backgrounds, interests, and preferences they suggested would be surveyed by the system. This differs from many existing systems that base automatic 'personalization' on performance metrics alone and many teachers felt current online learning options do not support their needs.

Discussion

In this study we examined teacher perspectives on how they provide personal guidance in the classroom and their views on at-home learning, and co-designed a digital tool to aid providing personal guidance for students doing homework. We found that (1) the pandemic exacerbated existing issues with doing schoolwork at home, but also expanded teacher's experience and reliance on digital media, and (2) teachers want to address practical and equity issues of homework and want technologies that help them do so.

Exacerbated issues and increased needs

During the COVID-19 pandemic many technologies and online platforms may have rushed to meet the sudden increased demand of home-based learning, but teachers were frustratingly unable to provide the responsive, personal guidance and differentiated instruction they would provide in the classroom. Classwork and homework activities fused, with the teachers using the same online resources such as interactive exercises, videos or sets of articles for both classwork and homework, often leaving the students to work alone on the tasks in their own time. Many of the issues that were previously confined to homework became unavoidably present during class time.

The teachers happily described their recently discovered online resources for instructional content and media, from platforms such as such as Neslea, EdPuzzle, Edgenuity and even YouTube. Many had occasionally used some of these prior to the pandemic, but the teachers have now explored several new platforms and have greatly increased their usage. They may have developed a a more discriminating view on how such platforms provide content and how they personally use them, likely to influence how they provide future homework. They also commented on their students' increased access to computers at home, having been provided in part by many school districts during the pandemic. With teachers' increased knowledge and habits using online resources and student's increased access, the demand for homework tools that truly extend the ability of the teacher to provide guide their student's learning has never been greater.

Teachers want technologies to address practical and equity issues of homework

In the interviews teachers reported how they increasingly *minimize* the use of homework due to inequities in student's time and technical resources, but in the later co-design workshops they presented a greater optimism in being able to alleviate issues through the use of technology, especially in the use of automated personal guidance. One reason teachers feel limited by standard tools and technology is while they provide features for scaffolding and differentiation, the process of doing so is not only labor intensive but also do not provide the types of personal guidance they use in the classroom to effectively support. For the teachers, digitizing the personal guidance of the homework would not only provide levels of individualized guidance otherwise too impractical and time consuming to do, but also affords the chance to gain insights into the student's process of doing the homework, with a view to gain insights about student thinking and potentially reveal misconceptions to address in class. Although students' access to technology at home may have been substantially improved through the pandemic, many issues of inequity may still be unaddressed. However, teachers saw the ability of the system to provide personal guidance for individual's needs, preferences and circumstances would contribute significantly toward addressing some inequities and supporting those in most need.

The findings provide us with **theoretical insights** into how teachers implement homework, and that teacher views on inequities and limitations shape their decisions on the amount and type of homework they assign. The study's themes on teacher preferences demonstrated practical and equity issues related to homework, teachers' need for automation in providing personal guidance and visibility of their effectiveness at home. These results contribute to literatures on science and STEM learning by extending our understanding of how teachers need to

provide socially supported personal guidance for science homework that builds stronger connections to the material and support deeper conceptual learning.

We feel this work also uncovers **practical implications** on how to bring teacher-led personal guidance to a student's at-home learning environment in an effort to revitalize the use of homework. The timing of our study during the COVID-19 pandemic also revealed an urgency for improvements. These insights also have implications for learning sciences researchers in focusing our attention to teachers' needs to support their students' learning, and in guiding the design of learning environments to meet these needs. Teachers feel limited by current methods and need systems that: (1) aid teachers to rapidly curate and customize their own homework content across a range of resources; (2) augment teacher's ability to add personal guidance to homework based on student backgrounds, interests and preferences; (3) provide visibility of the students' homework process to inform future support; (4) provide students options to choose between a range of tools, response formats and timing to complete homework. We also consider these theoretical and practical implications may contribute outside of science homework and inform other home-based learning such as asynchronous class participation.

Conclusion

In this study, we explore teacher perspectives on providing guidance in the classroom and in homework, on how technologies may help them provide personal guidance and improve equity issues related to homework, and on perceptual and practice changes taking place due to the COVID-19 pandemic. One major limitation of this study is the small sample size, and that the majority of our sample includes teachers with significant experience in the classroom. As such, the findings have limited capacity for generalization and may not apply well to the perspectives and needs for inexperienced teachers. We also recognize limitations to our design implications as they are not derived from examining teachers' use of functioning tools or technology to support homework, but stem from teachers' desired affordances of a hypothetical teacher tool. While this work uncovered teacher's views and solutions based on their emotional and pragmatic needs, in future work we plan to explore and test the design guidelines through further participatory research with working prototypes of the tools they conceived.

In summary, we found that teachers need systems that augment teachers' ability to provide personal guidance in socially meaningful ways and they may welcome new technologies to facilitate homework creation that provides better and more equitable guidance for students during homework. These findings also suggest that providing technology-supported personal guidance may help teachers address existing practical and equitable issues in providing homework and revitalize its use as a meaningful extension of the science classroom.

Abstract: Since spring of 2020, our 'new normal' world pivoted towards online spaces. This changed *where* formal teaching and learning interactions unfolded, and also shifted the conditions for participation in teaching, learning and research activities calling into question how and where inequitable power dynamics are (re)produced in these 'new' spaces. In this paper, we reflect on the affordances and constraints of community-engaged research with middle school youth in online virtual design meeting 'rooms.' Drawing on critical postmodern and queer feminist constructions of space, the university researchers explicitly worked towards Rightful Presence when structuring and facilitating the online design meeting room. We argue that virtual spaces are not neutral and are shaped through settled power dynamics that can further (re)produce inequitable conditions for participating and/or open new possibilities for disrupting settled adult-youth powered relations by both youth and adults.

Introduction

Since the spring of 2020, the COVID-19 pandemic has required that schooling, research, and most in-person interactions pivot to virtual environments. Re-orienting towards online and remote learning changed the spaces within which we interacted; in-person classrooms and afterschool spaces were replaced with virtual Zoom 'rooms.' This not only shifted the conditions for participation in school-based teaching and learning interactions (Morales-Doyle et al., 2020) but called into question the ethical and pedagogical considerations for community-based research practice partnerships (Switzer et al., 2021). How, with whom, and with what trade-offs might different kinds of education research encounter, during such a pivot? This conundrum is especially pertinent for community-engaged research projects involving historically minoritized youth.

Community-engaged research informed by a critical participatory design (Bang & Vossoughi, 2016) and the Rightful Presence (Calabrese Barton & Tan, 2020) justice-oriented framework necessitates challenging settled adult-youth power dynamics by explicitly supporting youth agency and voice towards recognizing and positioning youth as experts (Druin, 2002; Pinkard et. al., 2017). To do so requires that researchers both pay close attention to pedagogical considerations when facilitating the design process and consider how the spaces within which we collaborate shape the conditions for and forms of participation that are legitimated by the group (Gutiérrez, 2021). The larger project within which this study is based is aimed at creating a 7th grade biology curriculum unit centered around a community-identified health concern. To build the unit, a design team of middle school youth, science teachers, and university researchers met virtually using multiple spaces such as Zoom, Padlet, Discord etc.

In this paper we examine the ways in which virtual learning spaces present opportunities to disrupt settled inequitable power dynamics while also reproducing injustices, when collaborating with youth in critical and participatory community-engaged research. ***We explore the ways in which our curated virtual room for collaborative design shaped affordances and constraints for disrupting guest-host power dynamics, in ways that supported (or not) youth designers' rightful presence.*** Our aim is to expand and nuance how we might work towards Rightful Presence through designing more equitable virtual learning and collaboration spaces.

Theoretical Frameworks that Inform this Work

In this work we designed and facilitated virtual community-engaged collaborative design team meetings with youth, informed by theories including: 1) the Rightful Presence framework (Calabrese Barton & Tan, 2020) that explicitly works towards centering youth voice and agency, and 2) critical postmodern (Soja, 2010) and queer feminist (Ahmed, 2010) theories that recognize 'space' as the non-neutral and non-static background, implicated in shaping the conditions for participation in the design process (Gutiérrez, 2021).

Rightful Presence (Calabrese Barton & Tan, 2020) posits that (in)visible inequities are (re)produced through the practiced repetition of settled power dynamics in everyday teaching and learning interactions and that

 © ISLS

within schools, teachers/adults serve as the *hosts* extending student *guests* rights to learning spaces. As hosts, teachers/adults along with institutions, hold power over how learning spaces are designed, pedagogies are enacted, resources are available for youth participation, and the conditions for participation. Extending rights to youth as *guests* (re)produces powered relations that position teachers/adults as not only in control of access to resources but also the power to *rescind* youths' rights in the space. Rightful Presence requires explicitly dismantling oppressive guest-host-youth-adult powered relations within learning spaces (Calabrese Barton & Tan, 2020).

Designing for Rightful Presence in virtual meeting 'rooms' requires examining the contours and boundaries of the space within which the interactions unfold. Rather than consider space as the neutral and static background upon which life unfolds, we draw on critical postmodern (Soja, 2010) and queer feminist (Ahmed, 2010) theories to nuance how social life is shaped by and shapes the spaces within which we interact. Importantly, this "socio-spatial dialectic" is not neutral but undergirded by power dynamics from the larger social world - such as settled guest-host-student-teacher relations (Soja, 2010). Indeed, as Ahmed (2010) argues, our orientations to, in and with the world, shape the spaces in which we exist by affecting "what is near or proximate to the body, those objects that we do things with" (p. 235). Settled powered relations shape which objects come to matter as important in the space. That is, the contours of the classroom space changed such that knowledge objects emerge as matter that is valued by the students and teachers (Krishnamoorthy, 2021).

In this paper we contend that virtual spaces or 'rooms' are non-neutral and shaped through power dynamics that can (re)produce (in)justices while also creating possibilities to resist these (in)justices (Switzer et al., 2021). The virtual design team meetings - hosted on Zoom - created a new space and mode for communication that changed the conditions for participation expected of all team members (Switzer et al., 2021). As we illustrate through the analysis, the contours of the virtual meeting room designed by the university researcher hosts - oriented explicitly towards disrupting guest-host youth-adult powered relations - shaped the possibilities for social interactions that unfolded in the meetings.

Methods

Design team context

Drawing on critical and participatory design research methods (Bang & Vossoughi, 2016) to collaborate with youth (Druin, 2002; Pinkard et. al., 2017), we began co-constructing the curriculum unit in the spring of 2021 with a design team that comprised eight youth from two local middle schools, a science teacher from each school and eight university researchers. The schools were located in South Lancaster (SL) (pseudonym) - a Northeastern U.S city. University researchers included individuals from diverse ethnic, racial, gender, and socioeconomic backgrounds. The youth on the design team broadly reflected the majority Hispanic demographics of SL (77% percent of families who attend SL public schools are socioeconomically marginalized). The virtual design meeting room was not a static space, rather it encompassed multiple spaces including whole-group Zoom rooms with slides shared to the group, virtual breakout rooms with 6 - 7 participants per room, as well as additional applications that support the design work for that meeting such as: Padlet, Discord, Spotify, Sketchpad, etc. The boundaries of our virtual meeting room were constructed by university researchers each meeting and included for example, Spotify, Zoom and a Sketchpad one week, and Zoom, Spotify and Padlet another. At the same time, as hosts, university researchers actively shifted the boundaries of the virtual meeting room in response to how youth participated.

Data and Analysis

We draw on data that included university researchers' planning and debriefing meeting notes (105 pages), reflective field-notes after each design team meeting (110 pages), along with artifacts (Google slides etc.) created during the design team meetings over eight months (i.e., 16 team meetings). The analysis of this data corpus was rooted in a grounded theory constant comparative approach (Strauss & Corbin, 1998) to (a) identify moments when the boundaries of the virtual room were made visible and/or changed, through a shift in how adults and youth participated in the meeting and (b) tracing the powered relations (e.g., adult-youth-guest-host relations etc.) that were disrupted and/or (re)produced in those moments. The analysis yielded narratives of episodes that illustrated the ways adult-youth-host-guest powered relations were shaped by and shaped the contours and boundaries of the virtual meeting room.

Results

We present two episodes that illustrate two emerging themes of when (a) the contours of the virtual room were shaped by youth designers' orientations, (b) the boundaries of the virtual room shifted when youth and adults disrupted settled adult-youth powered relations.

(a) Youth designers' orientations shape what 'matters' in the virtual room

In beginning the design process, university researcher hosts structured the virtual design meeting rooms in ways that relied on youth participating by unmuting their microphones and turning on their cameras. However, youth designers resisted invitations to turn on their cameras and chose to type their responses in the Zoom chat instead of unmuting their microphones and speaking. Initially the university researchers struggled with not being able to 'see' or "hear" youth. Although youth participated through the chat function on Zoom, the sedimented expectations informed by in-person teacher-student guest-host power dynamics shaped the university researchers' understandings of youths' participation. Unlike in-person interactions, the virtual room we inhabited allowed for youth to choose how they were visually present despite the adults discomfort and expectations.

Youth designers' choice to not participate in ways expected by university researcher hosts was an act towards authoring their (the youths') Rightful Presence in the space, and informed subsequent changes to the boundaries of the design meeting room in ways that support youths' preferred participation modes. In subsequent meetings, university researchers re-structured the virtual room so that virtual objects such as the Zoom chat box came to 'matter' and were brought into proximity (Ahmed, 2010). That is, the contours of the virtual room changed because of the youths' collective orientation towards the chat box as an object of importance when communicating ideas in the space. Recognizing youths' non-participation (Switzer, 2020) as an agentic disruption of powered adult-youth host-guest relations settled through in-person interactions (i.e., where youth are not offered the choice to show their face or not) was critical towards the adult hosts and youth guests reauthoring rights that defined how designers could participate in the meetings. Shifting the contours of the virtual room - when informed by youths' orientations to virtual objects such as the Zoom chat - better supported youth to participate in ways they preferred and chose.

(b) Collectively shift the boundaries of the virtual room towards Rightful Presence

Seven months into the design team's collaboration, university researchers invited youth designers to create a logo for the project to be attached to curricular materials and websites connected with the project. As part of the design meeting, participants were invited to draw a logo in any of three spaces within the virtual design room: on Sketchpad – an online sketching app, through searching for images and posting them on Padlet, or by drawing them on a piece of paper and sharing by turning on the camera. One youth asked the hosts for permission to use a different app to sketch her logo. The space in which the youth drew her logo was outside the boundaries of the virtual room designed by the university researchers. The youth's move to ask for permission to use a different space made visible the powered guest-host relations whereby the youth guests changed the boundaries of the virtual room during the design meeting, in this case, with permission from the university researchers.

When it came time for designers to share their logos, team members took turns describing the logo they created, through the various spaces within the virtual room. However, another youth asked the university researcher hosts if they could share their designs in the Discord app – a space that was not within the boundaries of the virtual meeting room that day. As the next few minutes of the meeting unfolded, the boundaries of the meeting room shifted again, to include the Discord chat where the youth shared her design. In this moment, participants were collectively oriented towards the Discord app space, engaging through the Discord chat, while continuing to 'sit' in the Zoom room. As a result, the non-static boundaries of the virtual meeting room changed based on the youth designer's orientations to include the Discord app, thereby disrupting guest-host relations and re-authoring her rights in the space. That is, unlike moments when university researcher *hosts* restructured the virtual room in response to youth designer *guests*' non-participation, in this episode the youth designer *guests* initiated changes to the boundaries of the virtual room, re-authoring their rights in the space.

Discussion

The global pivot to online learning has forced researchers and educators alike to adapt to the 'new normal' - a world in which virtual spaces dominate human interactions. However, the design and contours of these virtual environments are not neutral, shaped through settled power dynamics from the larger social world that can work to further (re)produce inequitable conditions for participating in online activities (Benjamin, 2019). Considering how and where power is enacted in ways that (re)produce inequities online is especially pertinent for researchers involved in community-engaged research with youth collaborators.

Rather than assuming a neutral background within which collaboration occurs, we illustrated the ways in which virtual spaces - or 'rooms' - were shaped and continue to be shaped by settled power dynamics, even as newer, more just dynamics are being provoked. Collaborating in a virtual environment offered youth *guests* new possibilities for participating in knowledge creation interactions. However, designing the online environment in

ways that better supported equitable ways of knowing and being required that university researcher *hosts* were grounded in a social justice approach (i.e., Rightful Presence framework) that explicitly works in collaboration with youth *guests* towards disrupting guest-host relations. That is, hosts are responsible for being attuned to the ways in which youth choose to participate in-the-moment, such that youths' acts of non-participation (i.e., episode (a)) and their movement to spaces outside the boundaries of the virtual room (i.e., episode (b)) are welcomed as a necessary disruption of settled guest-host powered relations.

As researchers and educators committed to justice, we maintain that engaging in collective, allied political struggles towards Rightful Presence for minoritized youth in critical participatory design is a necessary and overdue undertaking. This entails a commitment to positioning youth as experts in our design work through enacting youth-centered practices. We work to cede power to the youth by intentionally and continuously minding how we might be reproducing injustices that we are wont to do, when operating from the "norm". The challenge inherent in allied political struggles is that injustices are difficult to identify, not least because powered stakeholders (i.e., university researchers in our case) are entrenched and benefit from, these historical, unjust power structures. We endeavor to hold one another accountable and continue to seek for consequential ways to seed Rightful Presence for youth in STEM teaching and learning.

"For the RE[STORY]": How an adolescent Black girl reimagines computing technology through electronic textile quilting

Mia S. Shaw, University of Pennsylvania, mshaw12@gse.upenn.edu

Abstract: Despite computing technologies being positioned throughout society as neutral, the dominant framing of narratives in the field through white, masculine perspectives has manifested in artificial intelligence systems categorizing Black women and girls using historically-oppressive labels. To design for and center Black girls' multiple identities in computing education, I propose electronic textile quilting—creating quilt patches that could be programmed to blink lights or play sound using sensors—as a vehicle for engaging Black girls in the process of "restorying" dominant narratives about computing. After analyzing minoritized youth's quilt artifacts, video observations and field notes, I present findings from one adolescent Black girl participant, Larry, whose quilt patch restorying a WNBA-inspired video game reframed dominant computing narratives from an exclusive lens to one of gender representation. Through analyzing how narrative framing shapes which stories are told, youth can better discern how dehumanizing ideologies manifest in the design of emerging technologies.

Introduction

Despite computing technologies being positioned throughout society as neutral/objective, the dominant, "default" framing of the field through narratives centering white, masculine perspectives have manifested in artificial intelligence systems (e.g., Google search and automated image labeling) categorizing Black girls using dehumanizing, historically-oppressive labels (Noble, 2018). This study aims to design for the multiple identities of Black girls while interrogating and transforming the ways they are socioculturally "coded" through computing technologies. To conceptualize how marginalized youth's computing identities are raced or gendered, I draw from both disciplinary (Bell, Van Horne, & Cheng, 2017) and narrative (Sfard & Prusak, 2005) perspectives of identity. Broader societal narratives and their framing serve as identity resources in STEM and computing-related learning environments that position students relative to one another as well as the discipline at large, and through restorying, youth "narrate the word and the world, [analyze] their lived experiences and then [synthesize] and [recontextualize] a multiplicity of stories in order to form new narratives" (Thomas & Stornaiuolo, 2016, p. 318).

In this study, I explored the restorying practices of Larry (a pseudonym created by one of the adolescent Black girls participating in this study) in her creation of an interactive quilt patch inspired by her personal interests in basketball and gaming, which she titled "For the RE" (a play on the phrases "for the rebound" and "for the restory"). As a medium and context for engaging Black girls in the restorying process, I propose electronic textile (hereafter, e-textile) quilting, which involves designing and creating fabric-based, quilt patches that could be programmed to blink lights or play sound using sensors (e.g., Authors, 2021). As predominantly Black and Brown youth from a local, informal STEM program designed e-textile quilt patches, I ask: When restorying dominant narratives about computing technology, how do youth *frame* those narratives? Through analyzing how narrative framing shapes which stories and perspectives are told (and which are silenced), youth and researchers can better discern how dehumanizing ideologies manifest in the design of emerging technologies.

Theoretical framework

One of the resources people use to make sense of the events around them are frames—available storylines organizing their understanding of events—which help "specify how broader narratives come to have meaning in local spaces" (Gresalfi & Hand, 2019, p. 496). When designing equitable computing learning environments for youth to learn disciplinary concepts and practices and develop practice-linked, disciplinary identities (Bell, Van Horne, & Cheng, 2017), it is important to consider how broader cultural narratives and frames (e.g., ideas and stories about computing people and marginalized communities) shape youth's computing identity construction. When viewed through a lens of techno-determinism, computing technology is framed as an objective tool that can affect society without being shaped by society itself (Benjamin, 2019); however, when framed through the lenses of racism and sexism, computing technology is revealed to uniquely marginalize women, people of color, and gender non-conforming people (Jones & melo, 2020). In this study, I use the concept of framing to examine how marginalized youth make sense of narratives about computing technology, both dominant and reimagined. By providing Black and Brown youth opportunities to restory dominant narratives about computing technology, they will be able to deconstruct harmful narratives about those technologies (and how those narratives are framed in

 © ISLS

popular discourse) in order to reconstruct both narratives and future technologies in speculative, empowering ways.

In considering historical media and technologies for challenging oppressive narratives, Black women have used quilting as both an art form and sociopolitical tool to resist oppression and collectively record and share their cultural histories (Cash, 1995). In other words, Black women and girls have *been* restorying dominant and hidden narratives related to their experiences since their enslavement in this country, using quilting, fabrics, and each other to build sisterhoods and rewrite their stories (Cash, 1995). E-textiles, this study's medium for quilting, are fabrics embedded with microcomputers, lights, and sensors stitched together with conductive thread and programmed to perform various actions (Buechley, Peppler, Eisenberg, & Kafai, 2013). Given the success of combining narratives and e-textiles in supporting girls of color's STEM interests and identities (Pinkard, Erete, Martin, & McKinney de Royston, 2017), e-textile quilting serves as a novel approach for engaging marginalized youth in computing and restorying dominant computing narratives.

Methodology

Through examining minoritized youth's restorying practices through social design experimentation, this study intends to "[identify] and [address] consequential issues [...] that limit opportunities for learning and becoming," (Gutiérrez & Jurow, 2016, p. 593) particularly in the context of learning computing. In collaboration with two graduate student interns, we designed a workshop for a four-year STEM program at a local science museum. We implemented the workshop over the course of two weeks during Spring 2021 (10 hours) and 3.5 hours daily during Summer 2021 (35 hours) with the goal of sixteen, 14-15-year-old minoritized youth designing interactive, e-textile quilt patches that restory dominant narratives about computing technology. To support the identity and community building of participants, youth participated in regular icebreaker activities (e.g., creating "I Am" poems), as well as engaged in discussions about dominant, hidden, and counternarratives about computing technology and quilting, and how both can be leveraged as vehicles for restorying.

Data collected includes youth's artifacts (i.e., quilt patch with explanation video, online design journal, and exit tickets), video observations and field notes, and researcher memos, which were analyzed using constructivist grounded theory (CGT). A methodology for situating research in "the historical, social, and situational conditions of its productions" (Charmaz, 2017, p. 199), CGT uses comparative methods iteratively throughout the research process by inviting researchers to alternate between collecting and analyzing data. I decided to focus the analysis for this study on Larry, who out of the five adolescent Black girls in the workshop expressed having the most prior interests and knowledge about computing technologies. Through conducting three iterative cycles of multimodal analysis on Larry's restorying process, I reveal how narratives about computing are framed throughout Black girls' lived and shared experiences, as well as how those experiences are drawn from in order to restory and reframe computing technology.

Findings and Discussion

E-textile quilts as multimodal texts for reframing dominant narratives

Table 1

Multimodal analysis chart for Larry's quilt patch titled "For the RE"

Photos of quilt patch	Description of quilt patch design and interaction
	An orange WNBA logo is sewn on the left side of a tan-colored background, with the words "1999" written inside the basketball. To the right of the WNBA logo is a small piece of white fabric with the words "New Basketball Games" written in orange. Large orange words boldly titled "WNBA 2K" are glued on a rectangular piece of blue fabric and placed on top of the bottom of the WNBA logo. A brown basketball is sewn on the bottom-left corner of the "WNBA 2K" title. Between the "New Basketball Games" and "WNBA 2K" felt pieces is the Micro:bit, with a left arrow displayed on the LED screen. When the left button is pressed, the words "Now introducing…" flash across the screen, which is followed by a right arrow. When the right button is pressed, the words "WNBA 2K" flash across the screen. When the yellow touch sensor is pressed, an LED image of an explosion appears and then you then applaud. After clapping one's hands, the "explosion" blinks.

When designing a computational, e-textiles quilt patch that restoried a dominant narrative about computing, Larry was able to interrogate and reimagine the way narratives about computing technology are framed throughout media. In the video explanation for her quilt patch (see Table 1), Larry restoried the dominant narratives that video

games and basketball are "just for boys" by designing her quilt patch as an advertisement for an imagined WNBA 2K video game. Wanting her project to challenge developers creating the first NBA 2K video game in 1999—while also neglecting to create a WNBA version—she demonstrated how computing technologies like video games communicate messages to girls that they aren't afforded equal opportunities to play as their favorite basketball players from the WNBA.

Larry demonstrated how the multimodal nature of restorying through e-textile quiltmaking made it an ideal context for reframing the narratives the media communicate about computing technology. People make meaning about sociopolitical issues through "media-generated images of the world," and the "lens through which [they] receive these images" reveals the perspectives of those with the power to control the narrative (Gamson, Croteau, Hoynes, & Sasson, 1992, p. 374). However, the process in which these images and narratives are normalized can be invisible to people. When reflecting on the role designing her quilt patch played in helping her reimagine computing narratives, Larry shared that it helped her "recognize different narratives [from her everyday experiences] and break them down and see how changing something small would affect everything." By sewing and coding an interactive quilt patch based on her identity as an adolescent Black girl who likes basketball and video games, Larry was able to observe narratives surrounding these interests and frame those observations from multiple, distinct perspectives (including her perspective, the perspective of others, and the perspective of her imagined audience).

"There wasn't anything like that for us": Reframing computing technology from a lens of exclusion to a lens of representation

When framing narratives about computing technology like video games through lenses of exclusion and representation, Larry was able to tease apart both dominant and hidden narratives, particularly whose stories, identities, and interests are most reflected in the design of certain video games. "These stories compare to the history of computing and the belief that primarily or only men are involved in it. It's a counter narrative that women can be interested in video games, more specifically NBA2k games and that they also should have a game that includes their stories," Larry shared halfway through the workshop in response to the question "How do those stories/experiences compare to the history of computing technology?". This finding reflects both the underrepresentation of Black women in computing and gaming (Gray, 2020), as well as the need for more research examining their unique computing education experiences (Solomon, Moon, Roberts, & Gilbert, 2018). When observing narratives surrounding video games she played personally—such as the "world-renowned, best-selling NBA 2K basketball video game series" as stated on their website—Larry did not see the basketball part of her identity included in the gaming industry, despite identifying with other Black women who play basketball (e.g., women in the WNBA). Through speculatively travelling back in time and designing an advertisement for a game that doesn't exist (yet), Larry illustrates how restorying allowed her to (1) reframe computing through a lens of representation and belonging and (2) reimagine a technology that highlighted the stories of women and girls like her.

After being able to note and shift the way computing technology was framed through restorying the dominant narratives affiliated with it, Larry also expressed a desire to "go more into depth about more dominant narratives," so she could "teach more people about it and have more awareness of the issue" (7/30/21, exit ticket). Narratives connect to broader societal and cultural belief systems, stereotypes, and imaginaries, and given that they are leveraged by people to make sense of themselves and others (Gresalfi & Hand, 2019), providing minoritized youth with opportunities to restory deficitizing narratives can support them in developing their identity trajectories. Upon completing the workshop, Larry shared that she felt more "comfortable" and "okay" with being who she is around others. "The topic I made my quilt about heavily applies to me, and I have challenged this dominant narrative before without realizing," she reflected in her final exit ticket. This finding illustrated how designing a computational artifact that framed computing narratives from a lens of representation allowed Larry to restory learning computing to learning how to represent herself and her community.

Implications for the Field

The restorying approach centers the historical and present lived experiences of marginalized communities (in this case, Black girls) as its methodological contribution for reimagining STEM and computing education through social design experimentation (Gutiérrez & Jurow, 2016), which argues that "the coordination of past, present, and future-oriented actions and identities sets the conditions for new forms of agency central to realizing possible futures" (p. 567). Traditional, normalized forms of learning that are grounded in racist ideologies continue to "spirit murder" Black girls and boys by "robbing dark people of their humanity and dignity and [leaving] personal, psychological, and spiritual injuries" (Love, 2019). Through centering disciplinary narratives and how those

narratives impact the identity construction of Black and Brown youth, restorying provides youth opportunities to write themselves into computing stories. Methodologies that disrupt and think beyond dominant forms of learning (e.g., interdisciplinary activities such as e-textile quiltmaking) can provide not only authentic but also legitimate approaches for minoritized youth to imagine alternate outcomes about STEM and computing, technology, and their communities.

Comparing Subjective and Objective Estimates of Effort and Performance on Adaptive v. non-Adaptive Computerized Tests of Statistics Knowledge

Teresa Ober, Madelynn Denner, Yikai Lu, Cheng Liu, & Ying Cheng

University of Notre Dame

Abstract: We examine associations between subjective (self-reported) and objective (derived from behaviors or performance) indicators of effort and ability and whether the format of a computerized assessment (adaptive v. non-adaptive) moderates these associations. Participants (N=219; M_{age}=19.83) were randomly assigned to one of two conditions in which they completed either an adaptive or a non-adaptive version of a 20-item computerized assessment. They then self-reported their effort and the number of items they believe they answered correctly on the assessment. Self-reported effort was not significantly correlated with the behavioral indicator. However, self-reported ability was positively correlated with participants' test score, even after controlling for test condition. Test condition appeared to moderate the association between subjective and objective estimates of ability with participants with higher ability in the non-adaptive condition estimating a greater number of items answered correctly. Further work should examine whether effects of test condition differ for certain student subgroups.

computerized assessment, adaptive test, test mode, self-evaluation, effort, subjective v. objective estimates

Introduction

There are many advantages to computerized adaptive exams from a quantitative standpoint, but little is known about how they affect test-takers' experiences. Computerized adaptive exams have grown in popularity over the years since as they allow for more efficient assessment by using fewer items or less time to achieve the same level of measurement precision (Weiss & Kingsbury, 1984), can be scored promptly, and are usually thought to involve more secure test administration (Klein & Hamilton, 1999). As a result of the shorter testing time and the approximate matching of item difficulty to the test-takers' ability, they are thought to deliver a better test-taking experience than more traditional computerized linear fixed-form ("non-adaptive") exams. However, matching of items based on students' ability on adaptive exams may cause confusion for certain test takers, leading them to assume they have less aptitude than on test scores would in fact suggest.

Past research on the effects of different test formats on test-takers (i.e., "test mode") has largely focused on the influence of test mode effects on learners' performance with respect to computer versus paper-and-pencil administration modes (Clarina & Wallace, 2002). To the best of our knowledge, few studies have examined whether test mode effects differ on adaptive compared to non-adaptive computerized. Given that more and more tests are delivered on computers, particularly because of the COVID-19 pandemic's shift toward online and distant evaluation (Middleton, 2020), this seems a pressing question. Aside from test mode, certain factors unrelated to the construct or ability being tested may influence test-takers' score (Haladyna & Downing, 2004). According to the *demands-capacity model of test-taking effort* (Wise & Smith, 2011), students who have high ability may exert low effort on test items if they perceive items as too difficult. Thus, understanding how aspects of students' subjective experience of test-taking interacts with mode effects is important, particularly in an adaptive test, where test-takers are matched to items based on performance.

Research Aims

The present study seeks to examine the association between participants' self-reported and actual effort and ability on two versions of a computerized test. We expected to find that such associations may differ based on the test mode condition (adaptive v. non-adaptive).

Self-reported and Behavioral Estimates of Effort and Ability: Differences based on Test Mode

- **RQ1**: After controlling for test mode, to what extent are each of the following factors correlated with each other?
    - self-reported effort

 © ISLS

- self-reported predictors and self-evaluations of ability
- effortful responding behavior (RTE)
- estimated ability (theta)

- **RQ2**: Do these factors differ significantly as a function of test mode (adaptive v. non-adaptive)?

Self-reported and Behavioral Estimates of Effort and Ability: Moderation of Test Mode

- **RQ3**: Does the association between effortful response behavior (as indicated by response time effort) and self-reported effort differ based on test mode (adaptive v. non-adaptive)?
- **RQ4**: Does the association between participants' actual performance (as indicated by an item response theory derived theta estimate) and self-reported estimates of test-takers' performance differ based on test mode (adaptive v. non-adaptive)?

Methods

Participants were recruited predominantly from an undergraduate participant pool at a university in the Midwestern U.S. (N = 251; *Mage* = 19.86 years, *SDage* = 1.23; *%Female* = 69.7). Table 1 provides sample demographics. Participants were excluded if they did not complete all 20 items on the test (n = 13) and those with response time effort (RTE; Wise & Kong, 2005) less than .50 (n = 19) were also flagged for being unmotivated. The remaining analytic sample (N = 219; *Mage* = 19.83 years, *SDage* = 1.23; *%Female* = 68.9) did not differ based on age, gender, or race/ethnicity from the sample recruited.

Table 1

Sample descriptives

Variable	Count	Percent
Gender		
Female	175	69.7%
Male	76	30.3%
Race/Ethnicity		
American Indian/Alaska Native	0	0%
Asian/Asian American	41	16.3%
Black/African American	7	2.8%
Latinx, Chicanx, Hispanic, or Spanish origin	9	3.6%
Middle Eastern/North African	6	2.4%
Native Hawaiian/Other Pacific Islander	1	0.4%
White/European American	168	66.9%
Other	8	3.2%
Prefer not to say	3	1.2%
Multiple	0	0%

Participants were randomly assigned to complete one of two versions of a 20-question test of statistics knowledge: a computerized linear-fixed item test ("non-adaptive") and an adaptive test ("adaptive"). The study had IRB approval and all participants consented prior to participation.

Subjective effort (Self-reported mental effort)

A four-item self-report measure was administered after participants completed the 20-item test of statistics knowledge. Responses to the items (e.g., "*I tried hard to answer the questions correctly.*") were provided using a 1-5 Likert scale (*1 = Strong disagree, … 5 = Strongly agree*). Past work has found good internal consistency of the measure (Cronbach's alpha = .88; Ober et al., under review).

Subjective ability (Estimated number of items answered correctly)

Following the 20-item test of statistics knowledge, participants were asked, "*Out of the 20 questions you completed just now, how many did you answer correctly?*" Responses options ranged from "0 - None of them" to "20 - All of them".

Objective effort (Response time effort)

We used response time effort (RTE; Wise & Kong, 2005) to indicate responses that appeared motivated and effortful. Across all questions, fewer than 25% of all responses were submitted in under 30 seconds. Thus, any response that took under 30 seconds was marked as unmotivated. Participants with more than 50% of responses marked as unmotivated were flagged for removal.

 © ISLS

Objective ability (Test scores)

An estimate of the participants' objective ability was derived from a comprehensive assessment suitable for AP or an introductory college-level statistics curriculum. Test scores ("theta estimates") were computed based on a Rasch model, a type of item response theory model that can be used to compute estimates of ability based on test-takers' responses and item parameters, such as the item's difficulty (Embretson & Reise, 2000). More positive values indicate greater ability.

Results

As mentioned previously, we were interested in examining the associations between self-reported estimates of effort and ability in relation to more objective estimates. We first sought to establish the extent to which these variables were correlated with one another (**RQ1**). Controlling for test mode (adaptive v. non-adaptive), self-reported mental effort (based on an average scale score) was not significantly correlated with the behavioral indicator of effort used in this study (RTE; $r = .13$, $p = .057$). The behavioral indicator of effort (RTE) was not significantly correlated with any of the other measures. Instead, participants' self-reported effort appeared to be positively and weakly correlated with both the participants' estimated ability (after completing the 20-item test; $r = .17$, $p = .014$) and their test score (based on the theta estimate; $r = .13$, $p = .047$). Participants' estimated ability was positively and moderately correlated with their test score ($r = .54$, $p < .001$).

Next, we were interested in determining whether these variables significantly differed on the basis of test mode (**RQ2**) using independent samples t-tests. We found that participants in the non-adaptive test condition ($M = 4.19$, $SD = .93$) tended to report exerting more mental effort than those assigned to the adaptive test condition ($M = 3.81$, $SD = .75$; $t = 3.28$, $p = .001$, $d = .437$). By contrast, participants in the adaptive test condition ($M = .80$, $SD = .14$) tended to have higher estimates of behavioral effort as indicated by RTE than those in the non-adaptive condition ($M = .75$, $SD = .13$; $t = 2.93$, $p = .004$, $d = .395$). When comparing estimates of ability, we found that participants in adaptive test condition ($M = 11.34$, $SD = 3.87$) tended to report receiving a lower number of items correct out of 20 compared to participants in the non-adaptive condition ($M = 9.75$, $SD = 3.59$; $t = 3.12$, $p = .002$, $d = .425$). Comparing test scores (theta) appeared to reaffirm participants' self-evaluations with those assigned to the adaptive test condition ($M = -.18$, $SD = .79$) receiving lower scores than those in the non-adaptive condition ($M = .07$, $SD = .61$; $t = 2.70$, $p = .008$, $d = .359$).

Given the differences in each of the estimates of effort and ability based on test mode, we next wanted to determine whether test mode moderated the association between the subjective and objective estimates of each. Two separate ANOVA models were tested with the subjective estimates of effort and ability as outcomes (i.e., self-reported mental effort, estimated number of items answered correctly) with predictors including the respective objective estimate (i.e., RTE for effort, theta for ability), treatment condition (i.e., adaptive or non-adaptive), and an interaction between the two. In the model predicting self-reported effort (**RQ3**), there was a significant effect of treatment ($F(1, 215) = 12.67$, $p < .001$, *partial eta*$^2 = .056$) but no effect of either RTE ($F(1, 215) = 1.70$, $p = .194$, *partial eta*$^2 = .008$) or an interaction of treatment and RTE ($F(1, 215) = .22$, $p = .638$, *partial eta*$^2 = .001$).

We followed a similar procedure to examine variation in participants' self-evaluations of ability (**RQ4**). There were significant main effects of test score ($F(1, 215) = 97.17$, $p < .001$, *partial eta*$^2 = .311$), treatment condition ($F(1, 215) = 4.09$, $p = .045$, *partial eta*$^2 = .019$), and the interaction of the two ($F(1, 215) = 5.14$, $p = .024$, *partial eta*$^2 = .023$). The interaction term indicated that participants with higher test scores in the adaptive condition tended to report answering fewer questions correctly than those with higher test scores in the non-adaptive condition. Given the matching of items based on performance in an adaptive test, this is to be expected.

Discussion

The results provide information about how associations between subjective and objective estimates of effort and ability differ based on whether a computerized test is adaptive or not. Self-reported effort did not have a significant relationship with behavioral indications of effort, according to our findings. Even after controlling for the test format, individuals' self-reported ability was positively correlated with their test score. Participants with higher ability in the non-adaptive condition estimated a greater number of items answered correctly than those in the adaptive condition, suggesting that the test condition moderated the relationship between estimated number of items answered correctly and test score.

Self-assessment requires one to accurately monitor and appraise their effort and ability (Andrade, 2019) and can vary from person to person (Baars et al., 2014win). According to previous research, certain demographic factors (e.g., age, gender, parental education), the classroom learning environment (e.g., prior educational experience, interactions with teachers, engagement in learning), and the assessment context (e.g., low- or high-stakes) all influence self-assessment accuracy. Student background factors (e.g., subject matter experience) and

current behaviors (e.g., course involvement) are hypothesized to influence the inaccuracy and overconfidence bias of self-assessment, as well as effort and ability on a specific task (Ober et al., 2022). Furthermore, there is evidence that female and underrepresented students in STEM may tend to underestimate their effort and ability on evaluative tasks (Jacobs, 2005). This is regarded as one possible barrier that inhibits individuals of underrepresented groups from pursuing STEM careers (Museus et al., 2011). As such, future work in this project domain will examine the extent to which the effects of test mode are moderated by student background characteristics. Such findings in this area could contribute to a growing understanding of how assessment contexts contribute to differences in the accuracy of students' self-assessment and the implications of using it for instructional practice.

Abstract: Essential in this information landscape, digital curation is broadly defined as the practices of digitally organizing and re-presenting the cultural record of humankind for creating value and impact, producing visual and textual information for presenting a narrative to audiences. Despite the prevalence of our daily-life curatorial practices and being well-suited to a diversity of disciplines, training in digital curation knowledge and skills has not been democratized to be inclusive for students from non-technical backgrounds. This pilot study 1) proposes a maker activity, namely creating digital galleries of cultural heritage, in a general education course, 2) examines to what extent this learning activity helps develop digital curation competency of undergraduate students, and 3) investigates how this digital curation experience benefits their professional and personal pursuits.

Introduction

In this technological age, information is available in vast quantity and varying quality (Cherrstrom & Boden, 2020). In our daily life, we perform the social practice of information *curation* mostly without awareness, such as compiling relevant information for purchasing masks, organizing personal photo albums, and documenting social events in a community (Cherrstrom & Boden, 2020; Ungerer, 2016). Traditionally, curatorial activities for cultural heritage materials take place in memory institutions (e.g., museums, libraries) (Cherrstrom & Boden, 2020), while nowadays *digital curation* is broadly defined as the wide-ranging practices of "organizing and re-presenting the cultural record of humankind in order to create value, impact, and quality" (Sheffer & Hunker, 2019: p.80). Typically, it results in a series of visual and textual information for presenting a particular discipline-dependent narrative to both professional and public audiences (Cherrstrom & Boden, 2020; Sheffer & Hunker, 2019).

Due to the commonality of curatorial practices (Cherrstrom & Boden, 2020), digital curation has been increasingly integrated into students' learning process (e.g., content curation for assignments) (Ungerer, 2016). In the ever-growing information landscape, digital curation has evolved to be a transferrable skill that prepares university students for the demands of a digitally savvy workforce (Sheffer & Hunker, 2019). Training in digital curation has a strong pragmatic focus on students' competencies (Kim, 2015): their understanding of users' needs, ethical use of information, content organization and management, technical skills of using online curation tools, and so on (Cushing & Shankar, 2019; Feng & Richards 2018). This has led to pedagogical practices emphasizing hands-on experience (Cherrstrom & Boden, 2020), where students usually collaborate and work on topic-specific projects with real-world audiences (Sheffer & Hunker, 2019). Despite being well-suited to many disciplines, there is currently a lack of studies in digital curation education for students with diverse backgrounds, especially those with limited technology knowledge or support (Kim, 2015, Sheffer et al., 2019).

Towards democratizing digital curation training and making it more inclusive (Hu et al., 2017), this exploratory study proposes a maker activity namely creating digital galleries of cultural heritage, and examines how it could help develop digital curation competencies of undergraduate students with diverse backgrounds, and how this digital curation experience would benefit them. In the context of an undergraduate general education course, we pose the following two research questions:

RQ1: To what extent can digital gallery creation help develop students' digital curation competencies?
RQ2: What are the benefits of digital curation experience as perceived by students?

Findings to the first research question will improve our understanding about the extent to which students can develop digital curation competency through the maker activity of creating a digital gallery, whereas the second research question can offer empirical evidence on the values of democratizing digital curation education. Our findings will also yield pedagogical implications on how to optimize students' learning experience.

Research Context and Methodology

This pilot study was conducted in a university-wide undergraduate general education course in Hong Kong on the topic of digitizing cultural heritage. The course learning outcomes include having students "design user-centered digital products for presenting heritage information" and "apply principles and ethics of information to heritage preservation". The capstone of this course was a group digital curation project in which each group of 3 to 5

 © ISLS

students collaborated to create a digital gallery for a self-chosen cultural heritage. Built towards this assessment, classes comprised both weekly lectures on key topics (e.g., ethics of digital preservation) and tutorials with hands-on digital curation activities. Omeka.org, an open-source tool commonly used in digital curation education (Sheffer & Hunker, 2019), was used as the platform for creating the digital gallery, owing to its ease of use, flexibility, and affordances in presenting multimedia materials (Hu et al., 2021). Towards the end of the course, each group submitted the link of their public-facing digital gallery and a report documenting and explaining their work. They were informed that the best-performing galleries would be selected by the teaching team for display at a public showcase of student works. Fig. 1 shows some example galleries.

Owing to similar content and pedagogical implementations, students from the 2018 (n = 97) and 2019 (n = 102) cohorts were grouped into one population. With informed ethical consents which assured students whether they participated in this study would not affect their course grades, a total of 199 students (female = 60%) in 58 groups joined this study voluntarily without remuneration. 36% of them were Science, Technology, Engineering, and Mathematics (STEM) majors, while the rest (64%) were non-STEM (e.g., Arts, Business, Journalism, etc.).

This study employs qualitative methods including artefact analysis (RQ1), for the usefulness of artefacts in assessing student competencies (Kim, 2015), and thematic coding (RQ2). To answer RQ1, based on constructs in existing studies on digital curation (e.g., Sheffer et al., 2019), we developed a rudimentary analytic framework with six categories (e.g., user needs assessment) each indicating a digital curation competency (underlined in Table 1). Then, a more fine-grained coding framework was established from a bottom-up, data-driven approach, generating individual codes (e.g., awareness of users' needs). For RQ2, we collected open-ended responses from an optional course-end survey asking about students' perceived benefits of their digital curation experience. Adopting the grounded theory approach (Strauss & Corbin, 1994), excerpts were extracted and iteratively coded using the coding framework (Table 2). To ensure anonymity, a research assistant removed the students' names from the data before analysis. To ensure reliability, 25% of the artefacts (RQ1) (15 groups) and excerpts (RQ2) (n = 40) were randomly selected and independently coded by two researchers knowledgeable in digital curation, attaining excellent levels of agreement with Cohen's kappa of 0.90 and 0.96 respectively (MuHugh, 2012).

Figure 1

Homepage of Example Digital Galleries Created by Students

Preliminary Findings

For RQ1, upon analyzing each group's digital gallery and the corresponding report, we counted the number of groups (total = 58) satisfying each code (Table 1). First, most of the groups not only identified their target user groups (#1.1 in Table 1) (95%), e.g., "elderly residents" (Group 1), "foreign tourists" (Group 58), but also listed these users' information needs (#1.2, 86%), e.g., "proper ways to use the [heritage]" (Group 52), "detailed descriptions of the [heritage]" (Group 47). This shows students' basic understanding about user-centered design (Nelson et al., 2011). In terms of metadata quality, the majority (91%) followed the standard taught in class (#2.1), which has been widely adopted in the cultural heritage domain (Hu et al., 2021). Most groups completed their metadata fields (#2.2) (72%), while it was common for the remaining groups to leave some fields empty without justifications. These indicate the need for more time and efforts on teaching metadata as a functional competency in digital curation (Feng & Richards, 2018). Next, while all groups supplied photos or pictures for presenting their heritage items (#3.1) (some examples shown in Fig. 2), only less than half of the groups (40%) presented audio-visuals (#3.2), which were mainly for introducing the heritage's history (e.g., Group 20) or giving a guided tour (e.g., Group 57). It is thus desirable to encourage students to leverage multimedia materials in the future. As for facilitating users' information discovery (#4), many groups (69%) showed awareness of how users could leverage the default "basic search" (e.g., Group 25) and "advanced search" (e.g., Group 8) functions on Omeka. About two-thirds of them (64%) were also aware of user' browsing experience (#4.2), but only about half (48%) implemented tags, free short texts annotating heritage items (#5.3), for facilitating browsing. This demonstrates that students had the basic understanding of designing public-facing products of digital curation from users'

perspectives but were not sufficiently versatile in making use of all available functions (Cherrstrom & Boden, 2020). For information ethics (#6), a considerable number of groups (59%) showed awareness of ethical concerns (#6.1), mostly on avoiding copyright infringement, such as using materials with Creative Commons licenses (e.g., Group 8), seeking usage permission from the owner of resources (e.g., Group 22), and creating original materials (e.g., Group 35). Nonetheless, only one-thirds (31%) included copyrights statements in their digital galleries (#6.2). This suggests that more training on implementing intellectual property rights is needed.

Table 1

Coding framework and Code Counts for RQ1 on Students' Digital Curation Competencies

Category and Code	Definition	Count(%)
1. User needs assessment	To identify target user communities and their information behaviours before and during digital curation (Kim, 2015; Nelson et al., 2011)	
1.1 Awareness of target users	Artefact shows awareness of target users without their needs.	55 (95%)
1.2 Awareness of users' needs	Artefact shows awareness of target users and their needs.	50 (86%)
2. Metadata quality	Domain-independent measures of metadata quality (Feng & Richards, 2018)	
2.1 Standards and consistency	Artefact shows proper and consistent use of a metadata standard.	53 (91%)
2.2 Completeness	Artefact shows all metadata fields have been filled.	42 (72%)
3. Multimedia elements	Multimedia representation of information (Nelson et al., 2011)	
3.1 Still images	Artefact shows use of photos and/or pictures for presenting items.	58 (100%)
3.2 Audio-visuals	Artefact shows use of videos and/or sounds for presenting items.	23 (40%)
4. Information discovery	Facilities for users' information discovery (Lazarinis, 2011)	
4.1 Searching	Artefact shows consideration of users' searching experience.	40 (69%)
4.2 Browsing	Artefact shows consideration of users' browsing experience.	37 (64%)
5. Content organization and presentation	How the curated content is structured for users' navigation (Cushing & Shankar, 2019; Sheffer & Hunker, 2019)	
5.1 Collections and Exhibits	Artefact shows use of collections and exhibits (Fig. 2).	54 (93%)
5.2 Item tags	Artefact shows use of tags on items.	28 (48%)
6. Information ethics	Consideration of information ethics in digital curation, including copyrights and fair use (Feng & Richards, 2018; Sheffer & Hunker, 2019)	
6.1 Ethical consideration	Artefact shows consideration of information ethics.	34 (59%)
6.2 With copyrights statement	Artefact shows use of copyrights statements.	18 (31%)

Figure 2

Screenshots of an Item Page (left), a Collection (middle), and an Exhibit (right) from three Exemplar Galleries

For RQ2, a total of 147 excerpts were collected from 133 students (response rate = 67%). Table 2 displays the frequency information for each code. When asked about their perceived benefits of the digital curation experience, 37% of the excerpts (n = 55 out of 147) focused on areas of knowledge acquired whereas more than half (n = 82 out of 147) (55%) were on specific skills. Knowledge-wise, nearly half (25 out of 55) reported learning about metadata (i.e., information describing other information) as a major take-away from digital curation, which is encouraging as metadata are ubiquitous in daily lives but rarely taught to an interdisciplinary audience (Hu et al., 2017). In terms of skills, the majority of excerpts (53 out of 82) were on digital content creation related skills (#8.1), including how to "design" (Student 132), "build" (S8), or "create" (S61) a "digital gallery" (S23), a "[digital] collection" (S8), a "[digital] archive" (S131), or a "[virtual] exhibition" (S110), evidencing learning outcomes on digital skills among students with diverse backgrounds (Sheffer & Hunker, 2019). Notably, some students commented that these digital curation knowledge and skills would be useful for their future "project work" (#69), "business purposes" (#130), and "real life situations" (#96), indicating the potential transferability of digital

 © ISLS

curation competency to learners' professional and personal contexts (Ungerer, 2016). As digital curation is common across disciplines, future endeavours can focus on domains beyond cultural heritage.

Table 2
Coding Framework and Code Counts for RQ2 on Student Perceived Benefits of Digital Curation Experience

Category and Code	Definition	Count
Knowledge	Participant mentioned gaining knowledge from the experience in:	**55**
Digital gallery	Digital gallery, digital collection, and/or digital library.	10
User-centered design	Users, users' needs, and/or user-centered design.	13
Metadata	Concepts, usefulness, and applications of metadata.	25
Information ethics	Concepts, importance, and guidelines of information ethics.	7
Skills	Participant mentioned acquiring, developing, and/or enhancing a skill.	**82**
Digital content creation	Designing, creating, and/or disseminating digital content.	53
Information literacy	Collecting, screening, organizing and/or presenting information.	20
Technical skills	Other technical skills during the digital curation process.	9
Potential usefulness	Participant mentioned the potential usefulness of the experience.	**10**
Personal	Contexts and/or scenarios related to participant's daily life.	5
Academic/Professional	Contexts and/or scenarios related to participant's studies and/or work.	5

Conclusion and Future Work

Our preliminary findings reveal that, through the maker activity of creating a digital gallery, students largely demonstrated 1) a basic understanding about concepts (e.g., user-centered design, information ethics) and 2) functional competency (e.g., inputting metadata, avoiding copyrights infringements) for digital curation. Acquiring these 21st century knowledge and skills were perceived by the students as benefits of their digital curation experience, which they deemed useful for their professional and personal pursuits. As an ongoing study, we are conducting in-depth analysis of the student-inputted metadata and their reflective writing.

Abstract: Science writing skills depend on a student's ability to co-ordinate conceptual understanding of science with the ability to articulate ideas independently, and to distinguish between gradations of importance in ideas. Real-time scaffolding of student writing during and immediately after the writing process could ease the cognitive burden of learning to co-ordinate these skills and enhance student learning of science. This paper presents a design process for automated support of real-time scaffolding of middle school students' science explanations. We describe our adaptation of an existing tool for automatic content assessment to align more closely with a rubric, and our reliance on data mining of historical examples of middle school science writing. On a reserved test set of semi-synthetic examples of science explanations, the modified tool demonstrated high correlation with the manual rubric. We conclude the tool can support a wide range of design options for customized student feedback in real time.

Introduction

Constructing evidence-based scientific explanations is an integral part of science learning (Berland & Reiser, 2009; Krajcik et al., 2014), as emphasized in the Next Generation Science Standards (NGSS; NGSS Lead States, 2013). However, students often write incomplete, non-causal accounts of scientific phenomena (Seah, 2016), and find it difficult to use data appropriately (Sandoval & Millwood, 2005). With technological advances in Natural Language Processing (NLP), recent research has integrated automated scoring of and adaptive feedback on scientific explanations (Gerard et al., 2019; Liu et al., 2016; Riordan et al., 2020; Tansomboon et al., 2017), and on essays in other genres (Zhang et al., 2019), and across languages (Toma et al., 2021). Gerard, Kidron, and Linn (2019) used c-raterML to score 6th graders' scientific explanations in their web-based inquiry science environment and provide feedback for their explanation revisions. They designed automated feedback as well as associated guidance from the teacher to encourage students to use evidence in describing relations among scientific ideas. This work exemplifies *real-time* feedback for students and teachers. Previous studies have developed tools to assess students' scientific writing based on the inclusion of concepts or terms (Liu et al., 2016). Summarization Integrated Development Environment (SIDE) combines NLP and machine learning algorithms to score students' explanations based on the identification of scientific concepts in the responses (Ha et al., 2011). Similar tools include SPSS Text Analysis (SPSSTA) which identifies terms and patterns within students' writing. While these latter systems achieve high score correlations, and sometimes aim for general feedback, they do not provide real-time feedback on specific content elements within science explanation.

In the present study, we aim to create opportunities for students to develop scientific explanations while working on a roller coaster design challenge. We aim to provide real-time feedback that scaffolds students' written explanations of science *concepts* and *relationships* (National Research Council, 2012, p. 52).

An electronic notebook for classroom use

Building on previous implementations of our middle school physics curriculum using paper notebooks (Martin et al., 2019), we have been developing a digital notebook to support students' learning. A digital notebook has multiple advantages over a traditional paper version, such as the ability for students to submit their responses for immediate feedback, use of text mining to provide students with ongoing support, and allowing students to easily revisit previous work. A key feature of the notebook that we are developing is that it can pre-process students' text. Because the digital notebook is accessible through a web browser, students will be able to utilize common features such as spell-checking and grammar-checking, which will make their writing more readable to the teacher, and ensure clean input to an NLP system to support real-time scaffolding. The digital notebook will allow students

 © ISLS

an effortless way to reference data, which in turn makes it trivial to remove data from their responses or mark the sentences as being too incomplete for automated feedback.

Through the notebook, students will be given simple feedback based on a combination of data mining and NLP techniques. In our first iteration, data mining will support feedback to students to encourage uniform usage of equations, and to track frequency of key words in their writing. An adaptation of existing content-assessment software (PyrEval) will support feedback on students' written use of science ideas.

Adaptation of PyrEval for real-time scaffolding

PyrEval is a freely available software tool with source code originally designed to assess the content of paragraph-length summaries of source texts, e.g., for reading comprehension (Gao et al., 2019). Characteristics of PyrEval that are a good fit for real-time scaffolding of students' writing of short passages to a prompt are:

1. PyrEval is designed to assess each idea in a student passage for the importance of the idea.
2. It is a lightweight NLP tool that can be used "off-the-shelf" (no domain-specific training is required).
3. It produces **quantitative** scores about importance of ideas, and **qualitative analyses** of specific ideas.

The original PyrEval creates a model of content importance from reference passages written by four to five experts, or by more advanced students. Importance emerges from the frequency of the idea across the references. Emergence, however, does not fit with our objective here, which aim for students to learn specific ideas defined in the curriculum. We modified PyrEval in two ways to address this objective. First, we developed a method to curate a predefined content model based on the curriculum. Second, we adapted the automated analysis to account for features of middle school writing, and to improve the accuracy of the qualitative results.

One significant challenge we faced was to adapt the pre-existing software in the absence of reference texts or a set of examples of the range of inputs the software should handle. In the following subsection, we explain how we mined an existing dataset of passages from middle school students who had a different but related curriculum to synthesize examples like those we expect to see in our new curriculum. We also describe an essay rubric we developed for the new curriculum. The rubric was used both to guide the curation of a new type of PyrEval content model, and to serve as a benchmark against which to measure PyrEval results. Later we discuss the dilemma that arises when we shift PyrEval from reliance on an emergent "*extensional*" definition of content and content importance to also incorporate an "*intensional*" definition constituted by a rubric.

A new rubric with interrater reliability on a semi-synthesized dataset

For this study, we revised historical middle school students' responses to curate data which aligns with our new roller coaster curriculum, by selecting or rephrasing observed statements. We developed a rubric to assess students' writing in the curated essays in line with our expectations for the students. Each time an essay incorporated an explanation of a relevant science concept or relationship between concepts in their essay, it received one point (see examples in Table 1). A total score for each essay was calculated by adding up the total points received. A higher total score indicated that an essay included many important ideas, whereas a score of zero indicated an absence of relevant ideas. Two researchers independently coded a random sample of 13% of the entire sample of 76 essays and achieved a Cohen's Kappa of 0.94, which is considered almost perfect agreement (Stemler, 2001). One of these researchers then coded the remainder of the data.

Table 1

Example of types of concepts and relationships that received one point based on the rubric.

Example Concepts	Example Relationships
• "**Potential energy** is the amount of stored energy an object has based on it's position."	• "the **higher** the initial drop, the **more KE** (kinetic energy) you will have."
• "...the **Law of Conservation of Energy**...states that energy can't be created or destroyed in a system."	• "The more **mass** you have, the **more potential energy** you will have."

Challenges for modifications to PyrEval

PyrEval automatically assesses content by uniquely matching ideas in a student passage to a pyramid model of weighted content units (CUs), and normalizing the summed weights of the matched CUs. PyrEval achieves this through a three-stage pipeline, where the input is a set of reference passages, and student passages (Gao et al., 2019). A pre-processing module decomposes complex sentences into clauses using a rule-based parser and converts the output clauses into semantic vectors. In the second stage, EDUA, a restricted set partition algorithm, groups similar vectors from the reference passages into CUs. In this work, we use EDUA in a new way, to provide data for manual curation of a content model of pre-defined CUs that match a rubric. The third part of the pipeline

applies WMIN, a greedy maximal independent set algorithm (Sakai et al., 2003), to match students' ideas to CUs. For our present work, we investigated which WMIN configurations would perform best.

Table 2

Two distinct configurations of Modified PyrEval from the top 10% of the grid search with the baseline scores the original configuration, and the corresponding correlations. Here, APCS metric refers to the average pairwise cosine similarity, which is the average of the cosine similarity scores of each contributor to the CU with the clause being matched. StDev metric accounts for the standard deviation of the APCS while product metric also accounts for the weight of the CU being matched. These are more coarse grained than just the cosine similarity scores.

PyrEval Configuration	Set B	Set C
(Baseline) SCVP, MinSegLen=1, k=2, s=APCS, m=APCS	0.63	0.78
SCVP, MinSegLen=5, k=2, s=StDev, m=APCS	0.72	**0.85**
FDCP, MinSegLen=3, k=4, s=StDev, m=product	0.70	0.83

Modifications of PyrEval

Three objectives guided our initial experiments to modify PyrEval. The first was to curate a new type of pyramid to achieve a balance between the kind it was originally designed to use and the manual rubric. Our second objective was to investigate how much sentence decomposition would be appropriate for middle school writers. Our past work applied PyrEval to many samples of college writing, achieving high correlations with manual rubrics, but impressionistic comparison of college-level writing with our samples of middle school writing suggested that the latter had more repetition within sentences, and simpler structure. Our third objective was to improve the precision of the automated matching of student statements to pyramid CUs by changing the WMIN scoring parameters. These objectives are highly interdependent, therefore we investigated them in parallel. For example, if a repetitive sentence is decomposed into two segments, and an accurately matching CU is found for one of them, the second segment is likely to get assigned to a CU it does not match as well.

We divided our 76 semi-synthetic essays into three subsets. Subset A (N=10) was used for automatic creation of a variety of pyramid content models that we could mine to populate a manually curated pyramid. Subset B (N=46) was used for tuning PyrEval to middle school science writing, and for refining the curated pyramid. Subset C (N=20) was held in reserve for our final testing of the tuned parameters.

Two features of an emergent pyramid were important to retain. In the original content models, CUs have a Zipfian distribution (Zipf, 1936), which leads to the so-called eighty-twenty rule where twenty percent of distinct item types (here, statements within CUs or essays) account for eighty percent of the observed frequency (i.e., of the same idea stated in different essays), along with a long-tailed distribution of items (i.e., simple clauses) that occur rarely. Pilot experiments indicated that preserving this Zipfian distribution of CUs was important for PyrEval's scoring algorithm (WMIN) to accurately match student statements to the most similar CU, or to no CU. Instead of hard similarity thresholds, WMIN tries to optimize the overall quality of matches. The second important feature of our curated pyramid was to find ***n*** wordings for each important curriculum idea.

By using subset A to automatically generate 10 pyramids, we had multiple data points for defining the distribution of CUs of each weight. We designed the curated pyramid to have the same general distribution. Manual curation of high weight CUs (weights 3-5) was fairly straightforward. We aimed for four weight 5 and four weight 4 CUs, corresponding to the most important relational components of the rubric. To create these, we mined the pyramids that were automatically generated from set A, selecting relevant paraphrases to achieve the desired weight. We found it was also very important to mine the student data for realistic low-weight ideas.

We varied five PyrEval parameters and functions with a different range of values for 675 configurations. We aimed first for high correlation of the scores assigned to the 46 essays in Set B by PyrEval with those assigned by the raters using the rubric. We also inspected random samples of matches between student segments and model CUs to assess the overall quality of the matches as poor, moderate, or good. We identified two configurations representing fairly distinct hypotheses about how to adjust PyrEval for middle school writing, based on three WMIN parameters (top ***k*** matches, node sorting metric (***s***), and match weighting metric (***m***). The minimum number of words in a segment resulting from decomposition (MinSegLen) was also changed to account for the high proportion of short segments in middle school writing.

After choosing two WMIN configurations that performed well on Set B, and that represented different expectations about middle school writing, we tested these configurations on set C. Table 2 shows the two best configurations along with a baseline configuration applied in previous work. Correlations with the rubric are shown for subsets B (development set) and C (test set). The large difference in correlation between sets B and C seems to be due to a few outliers in Set B where a repetitive sentence matched more distinct ideas in the model

that it should have; dropping two outliers raises the Set B correlation to 0.78. Our future work to design custom feedback will investigate both WMIN configurations shown in Table 2.

Conclusion

As modified for a middle school roller coaster curriculum, PyrEval scores based on our curated pyramid model correlate well with manual scores from our highly reliable rubric. In addition, PyrEval provides a qualitative trace of how it computes its scores, which provides us with ratings on each sentence in a student's passage. We have demonstrated that PyrEval can utilize a predefined content model based on the curriculum and have developed a methodology to construct the content models we will need for the curriculum under design.

The University of Hong Kong

Abstract: Automated assessment of students' academic writing can provide timely feedback and alleviate teachers' workload. This study examined 199 undergraduate students' essays through metrics of metadiscourse, cognitive levels, and word network, and the relationships between these metrics and performances. Metrics were calculated under the framework of Hyland's metadiscourse model and Bloom Taxonomy whereas relationships were revealed by correlation analysis and classification with multiple algorithms. Findings show that students employed more interactive metadiscourse markers than interactional ones, and there were weak to mild positive correlations between some of these metrics and performance score. High-performing essays involved more higher-order thinking and stronger connections among words. Besides, classification models combining all three types of metrics were most effective in differentiating high and low-performing essays. The three types of metrics evaluated can be potentially used to provide fine-grained suggestions for improving students' academic writing.

Introduction

Students' performance in academic writing is a determinant of their academic performance, degree attainment, and even an important graduate attribute. Academic writing instruction is therefore an essential component in higher education. In the field of learning analytics, automated assessment of student writing has attracted much attention. Besides marking, automated means can also identify and compare textual features and writing strategies in high and low performance writing. These could be leveraged by writing analytic tools for providing timely, actionable feedback at scale to large classes of students (Gibson et al., 2017), and alleviating teachers' workload (Hu et al., 2016). Towards automating analysis of students' academic writing, this preliminary study aims to examine student essays from three linguistic and extra-linguistic aspects of writing: metadiscourse usage, cognitive levels, and word network. Specifically, we pose four research questions (RQs):

RQ1: What is the relationship between metadiscourse usage and performance scores of student essays?
RQ2: What is the relationship between cognitive levels and performance scores of student essays?
RQ3: What is the relationship between word network metrics and performance scores of student essays?
RQ4: To what extent can metadiscourse usage, cognitive level, and word network metrics predict high and low performances of student essays?

Results will reveal whether and how metrics of the three linguistic and extra-linguistic aspects of writing are related to writing performance and offer insights on generating automated feedback for academic writing.

Metadiscourse

As a universal feature of academic writing, metadiscourse represents textual devices for organizing text, engaging readers, and signaling writers' attitudes (Hyland & Tse, 2004). Unlike content words, metadiscourse markers do not present the topic, but guide readers through the text and help them interpret the content (Hyland, 2017). Hyland (2017) referenced the characteristics of previous metadiscourse models and proposed the interactive and interactional models. The former consists of features leading readers through the text by coherently organizing information, whereas the latter involves argumentation and expressing epistemic stance and attitudes to readers. Prior studies have analyzed metadiscourse usage in student writing, reporting that it facilitates writer-reader interaction and improves academic writing performance (Abdelrahim & Abdelrahim, 2020; Hu et al., 2016).

Cognitive Level

Academic writing entails different forms of writing targets, ranging from description to evaluation of information, which can reflect the writer's varying cognitive levels (Qiao & Hu, 2019), and hence their thinking skills (Palmer & Lomer, 2016). Based on Bloom's Taxonomy (Krathwohl, 2002), there are six cognitive domains of learning: knowledge (lowest), comprehension, application, analysis, synthesis, and evaluation (highest). As writing is a primary way of externalizing, evaluating and promoting student thinking, these cognitive domains have been proposed for assessing quality of undergraduates' writing (Penner, 2013). At a finer granularity, Qiao and Hu

 © ISLS

(2019) leveraged Bloom's Taxonomy to classify students' analytical writing into three cognitive levels based on semantic, syntactic, and lexical features. There is nonetheless a lack of studies examining the relationships between these cognitive levels and students' academic writing performances.

Word Network

In academic writing, some words are more likely to appear together (e.g., 'data" and "analysis"), establishing patterns throughout a text (Hong & Cao, 2014) and forming epistemic networks (Fougt et al., 2018). Epistemic Network Analysis (ENA) is a method for the identification and quantification of ties between elements in coded data and their representation in dynamic network models. It allows quantifying the relations between elements of the epistemic frame (Shaffer & Graesser, 2010). ENA has been used in analyzing student writing and visually differentiating their performance levels (Fougt et al., 2018). In this study, instead of manually coding student writing, we used word co-occurrences to form a word network (Oshima, Oshiima & Matsuzawa, 2012) for each essay and calculated the network metrics (e.g., density) for comparison across essays.

Research Context and Methods

The student essays were collected from an undergraduate general education course with students from different majors in a comprehensive university in Hong Kong where English is the medium of instruction. The course is on the topic of cultural heritage and digital technologies while the essays were submissions of an assignment on pros and cons of digitizing cultural heritage. As a typical academic writing task, this assignment required the student-writers to put forward relevant arguments and support them with evidence, experience and/or literature. Students were suggested to keep the essays around 2000 words long.

There were 199 essays (mean length = 2228.5 words) collected from two deliveries of the same course in the Fall semesters of 2018 and 2019. The course teacher assessed the essays from the aspects of addressing the topic, intellectual engagement with concepts and examples, critical thinking, and organization and language. The scores of the essays ranged from 25 to 100 (out of 100), with a mean of 75.3. The median of scores (75) was used to separate the essays into high and low performing groups. Those scoring higher than the median were regarded as high performing while those below were regarded as low performing ones.

For RQ1, we used the Hyland's (2007) metadiscourse framework (Table 1) which is both comprehensive and concise. It covers ten categories of metadiscourse markers with five under interactive and interactional models respectively. A web-based tool, Text Inspector, was used to detect metadiscourse markers based on this framework, and the frequency of markers in each category was used as metadiscourse metrics for each essay.

Table 1 *Categories of Metadiscourse Markers in Hyland's Framework*

	Category	Function	Example
Interactive	Transition	express relations between main clauses	in addition / but / and
	Frame markers	refer to discourse acts, sequences or stages	my purpose is / finally/ in conclusion
	Endophoric mrkrs	refer to information in other parts of the text	mentioned above / as follows
	Evidentials	refer to information from other texts	according to X / Z states
	Code glosses	elaborate propositional meanings	namely / such as / in other words
Interactional	Hedges	withhold writer's full commitment to statements	might / perhaps / possible / about
	Boosters	emphasize force or writer's certainty	in fact / definitely / it is clear
	Attitude mrkrs	express writer's attitude to proposition	I agree / surprisingly / unfortunately
	Self-mentions	refer to author(s) explicitly	I / my/ our / we
	Engagement mrkrs	build relationship with reader explicitly	note that/ consider / you can see that

For RQ2, we first adopted a set of keywords for each cognitive level on Bloom's Taxonomy, provided by Anderson (2001) (Table 2). Based on these terms on each level, we manually added other keywords and their different tense forms. Keyword matching was used to count the frequency of matched words on each cognitive level, forming the metrics of cognitive levels for each essay.

Table 2 *Cognitive Level and Example Key Terms*

Cognitive Level	Example Key Terms	Cognitive Level	Example Key Terms
Knowledge	recognize, recall, identify, retrieve	Analysis	analyze, distinguish, compare
Comprehension	illustrate, interpret, example	Synthesis	integrate, organize, decompose
Application	apply, carry out, implement	Evaluation	check, detect, assess, judge

To form word networks (RQ3), we first pre-processed the text data by removing stop words, stemming, and lemmatization. We then extracted pairs of words that co-occurred (e.g., "virtual" and "reality") in the same

sentence. Each essay was represented by a word network where each word in the essay was a node, and each tie between two nodes indicated the presence of this co-occurring word pair (i.e., "virtual reality"). The number of sentences in an essay containing a co-occurring word pair denoted the weight of the tie between the two nodes. For each essay, network metrics were calculated using the Python NetworkX package: density, diameter, modularity, degree centralization, betweenness centralization, closeness centralization, and clustering coefficient.

To answer the first three research questions, Pearson's correlation tests were conducted to analyze bivariate relationships between these metrics of essays and the performance scores. Classification models were constructed to classify low and high performing essays, which can reveal multivariate relationships between performance scores and combinations of metrics (RQ4). Several commonly used algorithms were applied, including Support Vector Machines (SVM), Ridge Classifier (RC), Decision Tree (DT), Gradient Boosting (GB), Random Forest (RF), and Extra Trees (ET). Ten-fold cross-validation was conducted to evaluate the classification performances which were compared across different classifiers. To compare classification power of different metrics, we also built classifier models based on each set of metrics, i.e., metadiscourse, cognitive levels and word network. Classification accuracy was used as the performance measure.

Results

The most frequently used category of metadiscourse markers was Transition (2799 times, 31% of all metadiscourse markers), followed by Hedges (1338 times, 15%), Frame Markers (1060, 12%) and Boosters (909, 10%). In total, there were 5593 (62%) interactive markers and 3534 (38%) interactional ones, indicating that students preferred using interactive metadiscourse. The usage frequencies of Evidentials ($r = 0.20$; $p = 0.004$) and Hedges ($r = 0.24$; $p < 0.001$) had mild positive correlations with the score, which corroborated the common use of nuanced stance with external support in academic writing (Hyland, 2017).

In terms of cognitive levels, Application had the highest number of keyword matches (2762, 40%), followed by Synthesis (1328, 19%) and Evaluation (893, 13%). If regarding the lowest three levels as lower-order and the highest three as higher-order thinking (Qiao & Hu, 2019), the total counts of matches were 58% and 42% respectively, where the highest two levels took 32%. These results indicate that students in general demonstrated fairly substantial higher-order thinking skills (Qiao & Hu, 2019). Correlation analysis (RQ2) yielded weak positive relationships between scores and word matches in Analysis ($r = 0.19$, $p = 0.008$) and Synthesis ($r = 0.15$; $p = 0.030$), corroborating typical requirements of academic writing (Palmer & Lomer, 2016).

The word networks turned out to be fairly dense (ave. density = 0.68 out of 1), indicating many words were inter-connected. Relatedly, the average network diameter (2.12) was small, meaning that, to connect any two words in a network, on average at most one other word in between was needed. The average degree centralization (0.04) was low, indicating the connections between words were scattered and few words dominated the connections. However, no significant correlation was found between each network metric and the performance score. To help us visually examine the networks, example networks of a high and a low performing essay are shown (Figure 1). The color of the node indicates subgroups of words generated based on their connections. The node's size is proportional to its degree centrality (i.e., no. of connections with other words), and the thickness of edges represents the frequency of word co-occurrences. As shown, the high-performing essay had more and stronger connections among words, constituting a richer network than the low-performing counterpart. Upon examining the actual words, connected words in the low-performing essay were mainly between topical words of this assignment, such as "cultural", "heritage", "digitization", and "preservation". In contrast, the network of the high-performing essay shows more varied connections such as those between "object", "visitor", "technology", and the topical words.

Figure 1 *Word Networks of A High-performing Essay (left) and A Low-performing Essay (right)*

 © ISLS

The classification accuracy across algorithms and metric types are shown in Table 3. The parameters of each algorithm were set with the default values and the linear kernel was used in the SVM algorithm. Results show that the SVM classifier with metadiscourse metrics and the combined metrics tied for the best performance (accuracy = 0.72). In terms of the metric types, those of metadiscourse and cognitive levels outperformed those of word network, across all classification algorithms. The comparison between metadiscourse and cognitive level metrics would involve different classifiers. Metadiscourse metrics worked well with SVM and RC, while cognitive level metrics worked better with DT and ET. Nonetheless, across classification algorithms, the combined metrics with all three metric types performed the best, indicating that different metric types might have captured different aspects of students' academic writing, and thus could potentially be used provide specific feedback on student writing in an automated manner.

Table 3 *Classification Accuracy across Algorithms and Metric Types*

Metric Type	SVM	RC	DT	GB	RF	ET
Metadiscourse	**0.72**	0.69	0.56	0.66	0.66	**0.69**
Cognitive Level	0.64	0.62	0.62	0.64	0.67	0.71
Word Network	0.52	0.56	0.51	0.52	0.54	0.53
Combined	**0.72**	**0.71**	**0.65**	**0.70**	**0.69**	**0.69**

Concluding Remarks

This preliminary study explores metadiscourse usage, cognitive levels, and word network in students' academic writing. For each of these aspects, we proposed metrics that are based on well-known frameworks and can be calculated through automated means. Results showed weak to mild correlations between few metrics and performance scores. The classification experiment indicates promising multivariate relationships between the proposed metrics and writing performance, and such relationships can be revealed through automated means (classification). Future work will continue fine tuning the parameters of the classification models for improving classification performances. We will also identify strong predictors in the classification models for providing feature-specific feedback on academic writing to students and teachers.

Unearthing Tensions in a PAR Project

Abstract: Learning scientists are increasingly shifting the epistemological and axiological basis of their research towards participatory approaches. In these approaches, tensions are viewed as sites for learning, as they reveal lines of power which can be reconfigured towards more just ends. Vignettes from a PAR project with mathematics teachers, leaders of youth-centered community organizations, and university scholars illustrate how tensions around *practicality* and *performativity* can be taken up or ignored in the research process, and the implications of these moves for new social arrangements. The importance of digging into tensions is underscored.

Introduction

Different instantiations of participatory approaches have emerged in the learning sciences, including social design experiments (Gutiérrez & Vossoughi, 2010; Gutiérrez & Jurow, 2015), community-based design research (Bang et al., 2016; Barajas-Lopez & Ishimaru, 2020l), participatory design research (Bang & Vossoughi, 2016), youth participatory action research (Cammarota & Fine, 2008) and others. A centerpiece of these approaches is a commitment to embracing tensions as sites for learning (Fine, 2018; Gutiérrez & Jurow, 2016; Mendoza et. al., 2018). Yet, it is difficult to uphold this commitment due to the discomfort it brings, as if the research is digressing and valuable time is being lost. As Fine argues (2018), however, tensions often reflect fault lines across lines of power, and are critical to revealing subjugated worldviews and knowledges.

Here, we illustrate the role of tensions in learning through two vignettes from a research study grounded in participatory action research, or PAR. The PAR project brought together high school mathematics teachers, leaders of youth-based organizations, and university scholars to theorize noticing for equity and justice in mathematics classrooms. Next, we provide a brief overview of PAR, including what we have found to be its basic commitments. Following this, we turn to vignettes to illustrate tensions, the first featuring Bang & Vossoughi (2016)'s notion of *practicality,* and second around the concept of *performativity* (Fanon, 2008). Lastly, we explore how ignoring or digging into the tensions can have implications for transformative activity.

Participatory action research

Often mistakenly treated as a methodological approach (Fals-Borda & Rahman, 1991), Participatory Action Research (PAR) is a research approach guided by a specific and unique set of epistemological assumptions and commitments. It is grounded in the participatory/cooperative research paradigm (Guba & Lincoln, 2000) characterized by an ontological commitment to systems of meaning that stem from practical, experiential, and relational activity concurrently (Heron & Reason, 1997). The centerpiece is the notion of "participation" (McTaggert, 1991) or "participatory consciousness" (Heshusius, 1994), which is "an awareness of a deeper level of kinship between the knower and the known" (p. 16). Beyond a rearrangement of subject-object relation to subject-subject relations, participatory consciousness is an embodied perspective that calls upon researchers to let go of the self and turn to the other with humility and curiosity, rather than want or need. Acknowledgement of the ways that power structures work to maintain knowers/known social positions and dominant systems of meaning-making makes PAR a critical perspective as well, focused on subverting dominant social relations and systems towards new arrangements and axiological re-imaginings (Fine, 2018).

While PAR cannot be defined through a specific set of practices or guidelines, key commitments in this research approach, similar to other participatory approaches, include: 1) historically minoritized communities are co-researchers, 2) disparate forms of knowing are brought into continuous contact with each other, 3) people, institutions, and practices are historicized, 4) tensions are embraced as sites for learning, and 5) practices are re-negotiated towards making social change (Osibodu et al., accepted).

The approach to knowledge production in PAR is aligned with the learning sciences, particular sociocultural theories of learning, that center attention to power, and the way expansive views of learning can facilitate collective learning and challenge the status quo (Mendoza et. al., 2018; Gutiérrez, 2008). Dominant and subordinated forms of knowing and doing are brought together to open a space for alternative knowledges and

 © ISLS

practices (Gutiérrez, 2008). However, this effort inevitably leads to tension between the status quo and the subordinated. In this paper, we focus on how tensions are viewed and valued, and the ways these decisions can constrain or expand new social imaginaries.

Tensions as sites for learning

Researchers who take participatory perspectives have identified several tensions common in their research. Below we examine two tensions -- practicality and performativity -- to explore what can happen when these tensions are either ignored or embraced. In the former, the unaddressed tension continued to plague the project and stifle productive conversation. In contrast, centering the tension of performativity in project activities created an opportunity for new learning and social arrangements, and fundamentally shifted the nature of the work.

Practicality

Participatory approaches easily reinforce dominant discourses and structures around learning and equity despite a commitment to including co-researchers centrally in the work. This can occur, for example, when the research is constrained by discourses around *practicality*. Discourses of practicality, as Bang and Vossoughi (2016) argue, can be "mobilized in ways that can deflate wider forms of social and pedagogical imagination, tethering the visioning and exploratory work of design to what is practicable given, at minimum, current disciplinary and political–economic structures" (p. 178). The focus on what is realistic given current educational structures and systems constrains the possibility of deeply interrogating and historicizing these structures, and ultimately, imagining new possibilities.

We explore a tension around discourses of practicality that emerged from the project described above, a failure to recognize this tension, and the narrowing of possibilities for shifting into new discourses. One aim of the PAR project was to co-construct a framework for noticing for re-humanizing mathematics that interrogated dominant ideologies of whiteness in mathematics education. The group read and discussed articles about ideologies (e.g., Louie, 2017), learning, and noticing in the context of watching videos of classroom mathematics teaching.

In this vignette, a mathematics teacher (MT), a community leader (CL), and a university scholar had a conversation over Zoom about ideologies present in noticing around the prompt: "What does it mean that our noticing practices often stem from dominant ideologies?" This prompt was embedded in a larger discussion about the nature of ideologies, noticing, and their connection to classroom practices.

The exchange opens when the university scholar points to the idea that one might articulate a commitment to anti-racist teaching but due to socialization could reproduce dominant ideologies in everyday interactions. The community leader responds by referring to the overarching question and article and describes the importance of recognizing that all noticing is necessarily "interested":

> CL: I think this is where you are going with this question, let me know. I know this article was talking about different frames of noticing and how you have to build habits. And we have to get into our inner subjectivities of even being able to notice. So, like, "Oh, I didn't notice that I thought of smartness in this way", or "I didn't realize that smartness could be exuded in this way by "these" particular types of students. Right? Which is why I think those frameworks are really powerful in thinking about noticing, and to be constant, incessant, and intentional. Because otherwise, we absolutely could end up failing to acknowledge that noticing is political. It's not neutral and we can't be color-blind towards it.

Here, the community leader reinforced the importance of noticing ideologies, such as the ones around smartness, in education. As a concrete instantiation of dominant ideology, the notion of smartness is powerful as it directly relates to mathematics learning, the labels that get organized for students, and broader systems of oppression. The mathematics teacher responds to this exchange by focusing on the importance of knowing subject matter to recognize the value of students' ideas. The teacher describes their own experience as a teacher learning enough mathematics content to be able to notice different forms of smartness.

> MT: …When I became a math teacher, I realized how much I didn't think like a mathematician and I didn't understand a lot of connections, and now that I've seen student work, I've seen different students produce different work. I've gotten better at not saying, "That's wrong, but I see what you're thinking. Talk to me more about it." I think content knowledge is also huge as we start to do that—notice what's smart.

Utterances by the teacher, while focused on expanding smartness, shifted the conversational space back to the practicalities of teachers' content knowledge, and away from race, ideology, and regularities in noticing. Content knowledge may support expansive noticing of students' mathematical activity, but it may also be coupled with colorblind or deficit discursive ideologies. Instead of diving into the tension that emerged in this exchange, however, the group moved on.

The tension between identifying anti-racist noticing ideologies and teachers talking about their current instructional practices is not unexpected since teachers are looking for ways to ground abstract discussions in concrete practices. This tension occurred regularly in the project discourse but was not identified by project participants until the project ended. We wonder what it might have meant to pause during moments like this one, and to think together why grounding discussions in existing classroom practices might dilute critical conversations. Instead, this tension became a reoccurring "stuck place" that constrained imagined possibilities for the group.

The next vignette is a contrasting case in which a tension that emerged for the group was taken up centrally into the project and inspired new activities and social arrangements.

Performativity

The second tension, performativity, refers to situations in which minoritized individuals are tacitly or explicitly expected to perform their racial, ethnic, or gender identities (Fanon, 2008). It is also a tension that occurs regularly in participatory work through racialized power dynamics that cause undue burden and racial battle fatigue to minoritized groups. As Patel (2015) writes:

> ...precisely because of the variances among and within dynamics, a closer attention and rigor should be paid to questions of coordinates and ongoing responsibilities and relations among peoples, places, and practices. This stance has a long history in many worldviews and even some research traditions, such a Participatory Action Research (PAR) approaches, but by and large is not common place in institutionally sanctioned research with the Western academy (p. 57).

Ongoing vigilance to positionalities, social arrangements, and patterns of interaction and destabilization of these is a focal point of participatory work. Yet, performativity is often mundane and ubiquitous as it is woven into the fabric of invisible racism, making it difficult to discern in moments everyday activity.

This vignette explores how the tension of performativity was experienced by project members, and steps taken by the team to examine them. The excerpt below is taken from an interview with one of the community leaders, who in response to a question about tensions they were experiencing as part of the project, mentioned that they were feeling the need to perform around race:

> I sometimes experienced it as a performance for me to have the discussions around race because it feels like it is expected. It's fine because it's something I embody and embrace, so it doesn't feel like it is a chore. But it feels performative knowing that expectation is placed on me. Since the summer, some healthy tensions have come up in that micro-moment when a question is posed like: "Who is going to bring up race, first?" I've been trying to play more of an educator, waiting eight seconds, instead of jumping in. The performative element comes in when I feel like I need to jump in right away.

Here, the community leader is naming the burden they experienced in deciding when and whether to bring a racial perspective to project interactions. They talk about the expectation that was "placed" on them by virtue of their body being in a space with whites, and the way they tried to navigate this tension by taking an educator point of view. The positioning of the community leaders, all of whom were BIPOC, as the ones to explain the system of racism and how it impacted BIPOC students was a regular feature of the conversations early in the project and was noted by the community leaders as a source of harm and fatigue. Instead of ignoring this tension, the project team decided to explore it further. The community leaders were interested in pursuing academic publications, so a self-selected group of team members (including all the community leaders) conducted a study on the tensions around performativity that emerged in the project. This group wrote a conference proposal, which was accepted and later co-presented (Authors, 2019). The group also presented the conference paper to the entire project team at a summer institute, and the topic became foundational to the group's decision-making, which was to take the burden of being vigilant about race off community leaders. This decision was represented, for example, in the group's design of a professional development (PD) for mathematics teachers on noticing. Instead of having

everyone participate in the PD, the group sought to protect the community leaders from once again having to perform with white teachers who were new to these issues. Thus, they designed the PD to be led by the primarily white members of the project team, with the community leaders serving as "outside experts", providing ongoing advice on design decisions. In this case, then, moving deeply into the tension led to new social arrangements for joint activity in ways that the group felt excited about.

Conclusions and Implications

Our goal in exploring tensions that emerged in a participatory action research project was to invite conversation about the importance and challenges of participatory epistemologies. As a foundation of the participatory paradigm, unearthing tensions is complicated, messy, and emotional work. Tensions often represent stuck places where lines of power are colliding and making waves in the social interaction. Because of this, we worry that learning scientists who desire smooth interactions and clear goals, boundaries, and outcomes will be hesitant to take up participatory perspectives. Researchers who adopt participatory approaches to research recognize that transformation only occurs when lines of power are made visible and recognize the potential of tensions to reveal these hierarchies. As we illustrate, when a tension around practicality was not explored, dominant discourses appeared to be maintained. When a tension around performativity was taken up, it appeared to prompt new imaginaries for the group's work together.

We believe that as learning scientists we are primed to take up participatory epistemologies, such as PAR, more centrally in our work, and that seeking out tensions will become an important way of pursuing equity and justice goals.

Empirical Validation of Early Mathematics Learning Progressions

Leanne R. Ketterlin-Geller, Jennifer McMurrer, Cassandra Hatfield
lkgeller@smu.edu, jmcmurrer@smu.edu, chatfield@smu.edu
Southern Methodist University

Abstract: Learning progressions describe the development of sophistication in students' thinking about discipline-specific topics, and specify the intermediary phases of students' understanding that lead from foundational knowledge to more advanced thinking. The specificity of this developmental progression can meaningfully inform the teaching and learning process, including the design of classroom assessment resources. The purpose of this presentation is to describe the theoretical and empirical evidence used to specify and empirically validate the learning progressions for two early mathematics learning progressions focused on numeric relational reasoning and spatial reasoning. Empirical evidence was collected from teachers' accounts of students' development of sophistication and task-based interviews with students. The resulting learning progression served as the foundation for classroom assessments designed to provide teachers with actionable data to use in instructional decision making.

Learning progressions to inform mathematics classroom assessments

Learning progressions and trajectories articulate the development of students' understanding within a domain. They reflect a research-based sequence of how students move from novice to advanced thinking within a domain (Corcoran, Mogat, & Rosher, 2009). In science and mathematics education, significant advances have been made to articulate learning progressions and trajectories, respectively. Based on a comprehensive review of learning progressions and trajectories, Confrey (2018) noted that there are no substantial differences between the definitions of these theories of learning; as such, we use the term learning progressions herein.

Learning progressions describe the development of sophistication in students' thinking about discipline-specific topics. This sequential progression of understanding moves from students' foundational knowledge to more advanced thinking (Bennett, 2015). Progressing from foundational levels of understanding to advanced thinking involves a network of intermediary knowledge and skills that characterize the learning progression. By nature, these intermediary knowledge and skills portray student thinking as a progression toward targeted understanding. Some have likened these intermediary skills to stepping stones along a path or to hand and foot holds on a climbing wall. Both are useful analogies for describing the knowledge, skills, and cognitive processes that students exhibit as they progress from less to greater understanding in the domain.

Three important structural components help define a learning progression: lower boundary, upper boundary, and intermediary knowledge and skills. First, the lower boundary of the progression represents the foundational knowledge and skills that students need to engage with the intermediary knowledge and skills. These may be conceptualized as pre-requisite knowledge and skills or prior learnings that form the basis for new learning. Second, the upper boundary of the progression reflects a greater level of sophistication that is expected at the culmination of a specific phase of learning, and may be determined by curricular expectations (e.g., content standards), canonical disciplinary knowledge, or societal expectations of competence (Corcoran et al., 2009; Duschl et al., 2011). The upper boundary of one progression may represent the lower boundary of another. The lower and upper boundaries can be characterized as the entry and exit points of the learning progression, respectively, and flank the intermediary knowledge and skills. Third, and finally, the intermediary knowledge and skills can be conceptualized as the incremental progression of understanding that accumulates over time to represent the nature of knowing in a domain (Duschl et al., 2011), and include knowledge representations, cognitive processing, and the structure and organization of concepts. The intermediary knowledge and skills are not a rigid set of understandings that must be mastered before progressing; moreover, the nature of the connections between these intermediary knowledge and skills may differ for each person.

As part of a larger project, we articulated learning progressions for two early mathematics concepts, numeric relational reasoning and spatial reasoning. These learning progressions are intended to form the basis of instruction and assessment in Kindergarten through Grade 2. The purpose of this presentation is to describe the theoretical and empirical evidence used to specify and empirically validate these learning progressions. We used an iterative development process that included a thorough analysis of existing literature, input from experts in the field of early mathematics, teachers' perceptions of the developmental appropriateness of specific knowledge and skills, and cognitive interviews with children.

 © ISLS

Numeric relational reasoning

Numeric relational reasoning (NRR) is often defined as the ability to mentally analyze relationships between numbers or expressions using knowledge of properties of operations, decomposition, and known facts (Baroody et al., 2015; Farrington-Flint et al., 2007). Numeric relational reasoning is closely related to number sense, the ability to work with numbers flexibly (Gersten & Chard, 1999). For example, students use addition facts that they know, such as 5+5=10, to solve unknown facts, such as 6+5 (i.e., "Since 5+5 is 10 and 6 is one more than 5, 6+5 must be one more than 5+5."). Numeric relational reasoning is not a rote procedure that can be followed step by step. Instead, it requires reasoning through a "strategic" decision making process based on the relationships between numbers (Whitacre et al., 2017).

Spatial reasoning

Spatial reasoning (SR) – the ability to interact with, navigate in, and understand one's environment – is a foundational concept for early mathematics (NRC, 2009). Spatial reasoning is thought to have two primary components: spatial orientation and spatial visualization. Spatial orientation refers to the ability to picture objects or settings from different perspectives, such as mentally re-orienting one-self to see something from above or below. Spatial visualization is used when a child imagines an object and transforms it mentally. Evidence suggests that spatial reasoning skills support students' overall mathematics knowledge and specific concepts such as place value, relationships between numbers, and operations (Newcombe, 2010). Students with strong spatial skills create mental images of numbers and situations, which strengthens their problem-solving and number sense abilities. The links between spatial reasoning and mathematics are so strong that "spatial instruction will have a 'two-for-one' effect, yielding benefits in mathematics as well" (Verdine et al., 2014).

Evidence to empirically recover learning progressions

Because learning progressions are intended to inform teaching and learning, they must be carefully articulated and sufficient evidence should be collected to evaluate the accuracy of the claims being made about students' development of understanding. Ketterlin-Geller and colleagues (2013) suggested an iterative process for articulating a learning progression that included four stages:

1. Specify domain-specific cognitive processes, strategies, and knowledge using theoretical propositions about learning, literature reviews, tasks analyses, and empirical models of learning.
2. Organize cognitive processes, strategies, and knowledge based on plausible interactions identified through theoretical propositions about learning, student interviews, and analyses by domain experts.
3. Differentiate levels of expertise through evidence from student interviews, experimental research examining performance differences, and examination of item-difficulty hierarchy.
4. Instantiate cognitive processes, strategies, and knowledge in test specifications with input from expert review panels, alignment studies, student interviews, and psychometric modeling.

Throughout each stage, data should be gathered from a variety of sources in an iterative process.

In this presentation, we describe the theoretical and empirical process used to empirically validate the numeric relational reasoning and spatial reasoning learning progressions. For each learning progression, we report results from several sources. First, we report results from an extensive review by experts. Second, we described descriptive and inferential statistical analyses of survey results from teachers in grades K-2. Third, and finally, we report analyses from cognitive interview data with children in K-2 to identify themes in their reasoning skills.

Theoretical evidence

To articulate hypothesized learning progressions for both NRR and SR, we used an iterative process that included meetings with subject-matter experts, literature reviews, internal reviews, and external reviews with subject-matter experts. As introduced earlier, each learning progression includes lower and upper boundaries as well as intermediary knowledge and skills. Because of the complexity of NRR and SR, we divided each construct into subconstructs or targeted learning goals. Each targeted learning goal includes core concepts which are comprised of fine-grained knowledge and skill statements. These knowledge and skill statements are ordered from least complexity to greatest complexity and specify the grade level range within Grades K-2 at which they are most developmentally appropriate.

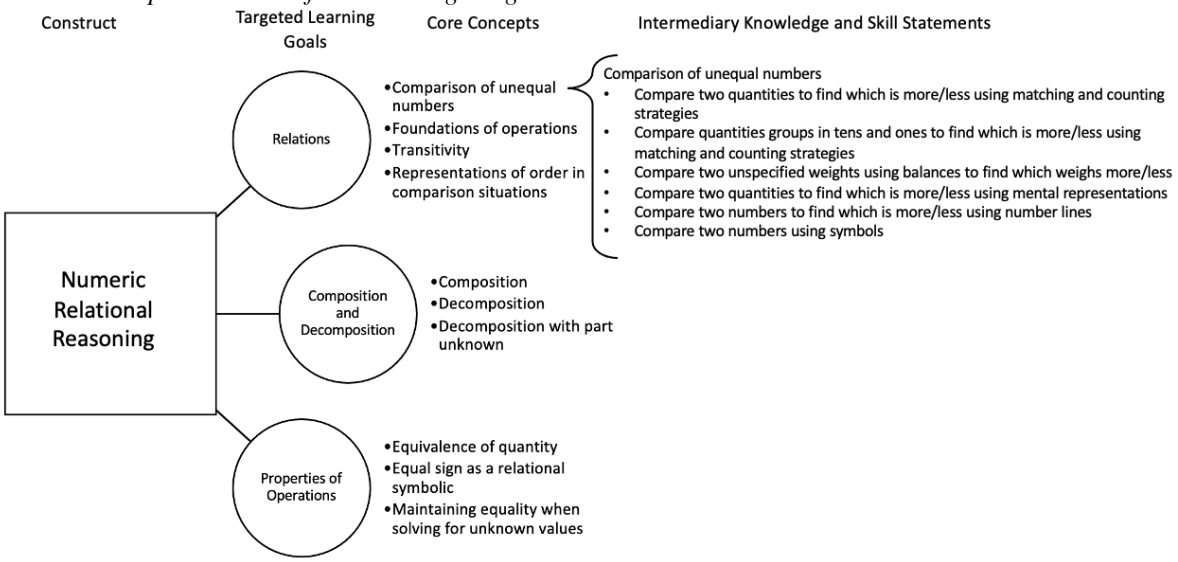
For NRR, we identified three targeted learning goals that are further divided into core concepts. For NRR, the three core concepts are (1) relations between quantities, (2) composition and decomposition of quantities, and (3) properties of operations. Each targeted learning goal is further divided into core concepts. For example, relations includes (1) comparison of unequal numbers, (2) foundations of operations, (3) transitivity, and (4)

representation of order in comparison situations. Within each core concept, multiple knowledge and skill statements that make up the intermediary phases of learning. The SR learning progressions include two targeted learning goals: (1) reasoning spatially within objects and (2) reasoning spatially between objects.

This structure is displayed for NRR in Figure 1.

Figure 1

Example Structure of the Learning Progressions



Study 1

After an initial draft of the learning progressions were articulated for both NRR and SR, we conducted cognitive interviews with children in Grades K-3. Cognitive interviews are grounded in psychological interviewing methods as a way of investigating participants' cognitive processes and understanding how participants store and structure their knowledge in long-term memory. During the interviews, participants work on tasks that are often open-ended and require multiple steps to complete. The interviewer asks in-depth questions designed to better understand the participant's thinking.

We included students in Grade 3 to test the upper boundaries of the learning progressions. For NRR, we interviewed 32 students across two timepoints for a total of 64 interviews. For SR, we interviewed 15 students across two timepoints for a total of 30 interviews. Interview protocols were strategically designed to provide (1) tasks aligned with each of the intermediary knowledge and skills in the learning progressions, (2) scaffolding questions, and (3) reasoning questions to better understand students' thinking. To collect confirming and/or disconfirming evidence, all students had an opportunity to respond to each task, regardless of the hypothesized developmental appropriateness. We examined correctness by skill statement by grade level to examine if the ordering and grade-level designations of our hypothesized learning progression could be empirically recovered. Qualitative analyses were also conducted to investigate if additional reasoning concepts were used by students that were not captured in the learning progressions.

Quantitative and qualitative analyses of cognitive interviews provided important information on students' conceptualization, students' prior knowledge to work through the content, the connection between concepts, and at what grade level students demonstrate emerging and mastery level of understanding. The results from the analyses of cognitive interviews provided us with evidence to empirically recover the NRR and SR learning progression and make some adjustments.

Study 2: Surveys with teachers

Another source of validity evidence comes from surveys administered to teachers in Grades K-2. We administered separate surveys for each learning progression. Educators are uniquely positioned within the teaching and learning process to provide meaningful input; Educators are very familiar with the grade-level curriculum and can often pinpoint areas where students tend to struggle. Moreover, teachers may be able to anticipate students' errors because of their recurrence over time and across groups of students. As such, educators may have insights into student learning that can help verify the structure of learning progressions.

Approximately 300 teachers responded to the survey on NRR, and 200 teachers responded to the survey on SR. The survey presented each of the intermediary knowledge and skills within each learning progression and

asked teachers to consider the grade level taught and respond about the developmental appropriateness of the skill, whether the skill was a focal or prerequisite skill, and how often and when they teach the skill during the school year. We investigated the alignment between our hypothesized learning progression and teachers' conceptions about the developmental appropriateness of the skill statements. Survey results yielded meaningful information to support or modify the hypothesized learning progressions for both NRR and SR.

Conclusions

In this presentation, we describe the theoretical and empirical evidence used to specify and empirically validate the learning progressions for NRR and SR. For each construct, we began by thoroughly specifying hypothesized progressions using input from subject-matter experts, literature reviews, internal reviews, and external reviews with independent experts. To evaluate the accuracy and sufficiency of the hypothesized learning progressions, we collected evidence from various sources, including cognitive interviews with children and surveys conducted with teachers. These data contributed to an iterative process in which revisions were made to the learning progression after each phase of data collection was complete. The process and resulting learning progressions will be disseminated during the presentation.

"It Appears to Be a Free-for-All": Designing for Audience Agency in an Immersive Theatre Environment

Lisa M. Siciliano, University of Illinois Chicago, lsicil2@uic.edu

Abstract: While there have been a handful of learning scientists who have championed research in theatrical spaces, there is still so much more to learn from these incredibly rich learning environments. *FORTS* is an immersive theatrical production and informal learning space where participants *actively* co-create knowledge through improvisational and collaborative processes. It was developed by a team of theatrical designers in much the same way that learning scientists design learning environments—through iterative cycles of design. This qualitative case study examines what the lead designer of *FORTS* learned through engaging in its design and implementation. A narrative of the design process was constructed from an interview with the designer which discussed her goals, original design decisions, expectations, feedback, reflections, and iterative design decisions. The theme of *agency* emerged as foundational to the designer's iterative process and to her shifting understanding of the relationship between immersive theatre design and its participants.

Introduction

This past year, the *Journal of the Learning Sciences* published a special issue entitled "Learning in and through the arts" addressing the need for more extensive research in artistic disciplines. However, even though the articles promoted arts environments as "valued sites for learning" (Halverson & Sawyer, 2022, p.1) and explored key disciplinary practices and socio-cultural learning processes, none of them presented work from theatrical learning environments. While there have been a handful of learning scientists over the decades who have championed research in theatrical spaces (Sawyer, 2003; Halverson, 2010), the fact remains that there is still so much more to learn from these incredibly rich learning environments. The present paper seeks to contribute to the clear need for investigation in the arts, specifically in the discipline of theatre.

FORTS: Build Your Own Adventure! is an example of an immersive theatrical production, an increasingly popular form of theatre which breaks down the separation between audience and actors and expands the possibilities of what is considered "playing" space. Unlike more traditional types of productions in which audience members *passively* receive information from the stage, immersive shows serve as informal learning spaces where participants *actively* co-create knowledge through improvisational and collaborative processes. In *FORTS*, audience members *replace* the actors and engage with the constantly changing environment in which they are immersed.

FORTS was developed by a team of theatrical designers in much the same way that learning scientists design learning environments—through iterative cycles of design, implementation, analytic reflection, revision, and retrospective analysis (Cobb et al., 2003). Since there is considerable wisdom often captured in designed objects and activities that is never made explicit (Schon, 1988), researching designer learning can help uncover and examine that wisdom. The purpose of this case study (Stake, 1995) is to explore the learning of the lead designer of *FORTS*. Specifically, this paper asks: *What did the designer learn through engaging in the design and implementation of FORTS?* Answering this question will help us better understand the kinds of learning that happen in immersive theatrical environments and will also help us understand what designers learn when they engage in iterative design processes for both these and similar types of spaces.

Theoretical framing

Machon (2013) suggests key features of immersive theatre are the centrality of audience members, the participants' physical immersion in a sensorial world, and the prioritization of space and place. She explains there are usually either tacit or sometimes explicit "rules of engagement" which guide participation. White (2013) calls the designers who create these environments "procedural authors" who decide the extent of audience agency within an event through setting limits, or "horizons of participation," and offer suggestions to navigate interactional possibilities within those boundaries. Nibbelink (2019) considers the role of the audience in an immersive performance as one that actively and continuously joins with the "compositional forces" in the piece to construct the event itself.

Given these features of immersive theatre, this paper takes up two related questions: How do designers create the learning spaces and set the stage for audience agency? What do they learn from iterative cycles of designing such spaces? In many respects, the *FORTS* designer confronts the same challenge that learning sciences

 © ISLS

researchers confront when they build learning environments intended to promote students' active involvement in the construction of knowledge. That is, in an immersive theatre production, the traditional role of audience member as spectator is intentionally disrupted. Audience members are asked to become performers (Heim, 2015). For example, people may be asked to become voyeurs to a private scene between two actors, make choices about where they want to go next in a giant warehouse full of performers, or even co-create the narrative of a play as it is being performed. Regardless of how the role of audience participant is designed, "the motive is consistent: to give agency so audiences can...choose their own adventure" (Tran, 2013, p. 31). Challenges for *FORTS* designers are similar to those of learning scientists and teachers in formal learning environments: What sorts of tasks, materials, and scaffolds support active engagement on the part of students/audience members?

Methods

The bounded case (Yin, 2018) and the focus of this study is the lead Creator (C) of *FORTS.* An hour-long, semi-structured reflective interview was conducted with C. Questions focused on C's role in the design process; her goals, design choices and their rationale; problems she encountered and her solutions; changes to the design over the years; her perspective on audience member participation including specific expectations; and any final reflections. The conversation covered *FORTS*'s three-year run and four variations of *FORTS* design: an "Original" *FORTS* show designed for both children and adults to attend together; Birthday Parties for a birthday child and their guests; Toddler Takeover Days for very young children and their adults; and Adult Nights for adults only. The basic *FORTS* design is framed as a journey from an ordinary world into a magical one. The 45-minute show takes place inside a black box theatre with sofas piled with pillows and cardboard box pyramids placed throughout. Adventure Guide facilitators cued by clock chimes run the practicalities of the performance such as when and how interactive objects (crayons, sheets, clothespins, and flashlights) get introduced. Lights change from day to night and back again to day. Music and sound effects such as doorbells, dogs barking, and crickets get played over a sound system. The one element that changes for each show is who is in attendance.

Analysis. A first phase of analysis focused on identifying C's design process. This phase involved *a priori* structural coding informed by Edelson's (2002) design decision categories (design procedure, problem analysis, design solution) as a framework for initial inquiry. The transcribed interview was parsed and tagged with respect to these design decision categories. The second phase of analysis focused on further parsing C's design process using six categories that reflect different phases of the design process. **Goal statements** (n=17) were identified as C's statements regarding desired outcomes of the design. **Original design decisions** (n=28) captured the original set of decisions regarding the structure and elements of the design. **Expectation statements** (n=15) reflected how C anticipated the audience might participate and behave. **Feedback statements** (n=27) were identified as comments about audience enactment. **Designer reflections** (n=27) were the designer's comments about her observations. **Iterative design decisions** (n=27; design changes=10, no changes=17) were identified as C's decisions whether or not to make any changes to the design following specific feedback and reflection comments. In a third phase, a narrative of the design of *FORTS* was constructed from design decisions, statements, and reflections that were related in space or time in the discussion of the *FORTS* design and enactment. A final analytic phase captured shifts in C's thinking. Throughout analysis, the author contacted C with follow-up questions when necessary.

Findings

Overall, the theme of *agency* emerged as foundational to the entirety of C's design process and to her understanding of the relationship between immersive theatre design and its participants. Initially, C conceived of *FORTS* as an environment that afforded an expansive view of audience agency. However, C's iterations, in response to design problems during implementation, set greater limits on audience actions in the space. Additionally, over the course of several years, C observed consistency in how people participated in *FORTS.* As a result, she then experienced shifts in her thinking about how much control the *FORTS* design exerted over audience members' actions, recognizing ways in which the design actually served to structure participation and limit audience agency. The specifics of the evolution of C's learning about agency in the context of *FORTS* are elaborated in the remainder of the findings.

Goals, design decisions, and expectations

While C had multiple goals for the show, a foundational one and the "kernel of the question that turned into *FORTS*" was a desire to support audience agency. She initially conceptualized agency as giving people "complete" and "total control" over the space, allowing them to be fully in charge of their interactional choices. In conjunction with the design team, C made design decisions which she hoped would facilitate audience agency. These decisions included: eliminating professional performers, and instead having audience members be the actors in the space;

making fort building the show's key activity as it was assumed to have a low barrier to entry; picking objects for people to play with that would be familiar and also open-ended for different uses; establishing two "boundaries" for the space that covered all behavior: *Be Safe and Be Kind*; and determining when and how Adventure Guides would "wordlessly" and "sneakily" leave items around the space to be discovered.

With these goals in mind, C designed with the expectation that any number of possible things might happen because every performance would consist of a different group of people, each with different personalities who might engage in an endless number of potential activities. She worked hard to "release" the traditional expectation of a "good audience" in that as long as people were safe and kind in the space, they could choose to interact with the design however they wanted. Despite "going in with a theory and the trust that audiences are going to be great," C admitted that she "really had no idea" how people would participate and was open to the possibility that the *FORTS* "experiment" might fail.

Figure 1
The FORTS *environment built by audience members*

Outcomes, reflections, and revisiting design decisions

C discussed several design iterations which were instituted in response to observing how various audiences interacted with the design. These changes, in contrast to her goal of supporting audience agency, served to set limits and provide more guidance for interaction. One such example is when the designer changed the ending of *FORTS* after a first preview weekend. The initial ending "just used to end with the end of the day," C explained. The lights came up, the sound went away, and audience members were expected to leave behind or knock down what they had created and played with. C noticed how upset children got at this moment and described how hard it was to get people to leave the space. "It was just a really terrible ending," she acknowledged. She wondered how to create a sense of ending for audience members with the absence of a formal curtain call. This design problem was solved by changing the ending in numerous ways: playing a celebratory song and having an Adventure Guide lead a dance party to it; more carefully crafting the "language of leaving"; and creating a ritual of "resetting the space" which encouraged people to rebuild the initial box pyramids together before departing.

Furthermore, after reflecting upon *FORTS* over three years, C was surprised how the enactment of the design seemed to hit the "same notes every time." There were multiple instances where she mentioned how consistent the show felt and how "similar dynamics crop[ped] up." C then mentioned receiving feedback from educators who attended the show and commented on how the design seemed to guide moments of participation. These combined observations contradicted what she had originally designed for and expected to see at *FORTS.* Prior to this, C had not fully recognized the power of the show's design to structure audience actions. But her thinking shifted when she began to see how the design exerted more control over the audience than she had previously envisioned. For example, C suggested that the "very deliberate" and "very crafted" way of how Adventure Guides wordlessly introduce new elements into the space—sneakily scattering them around for participants to discover - held a "tighter structure" than she had previously thought. C also mentioned the overall "container" of the production—the "one script, one aesthetic ethos, vibe"—which may have also facilitated consistent enactment. In contrast to how C originally conceived of *FORTS* as a "total free-for-all" she now says it "feels like, looks like—it *appears* to be a free-for-all experience."

Discussion, implications, and conclusion

Throughout the design and implementation of *FORTS*, C's understanding of the relationship between design and agency shifted, both implicitly through design iterations and explicitly as she recognized how the design created

consistent enactment. The discrepancy between the conception of agency that C sought to support and the structured design decisions that she made highlights the complexity of negotiating this design tension. C's altered understanding of the relationship between audience agency and the design of *FORTS* aligns with what scholars of the immersive theatre genre also assert. Gabelmann (2019) notes that even though audience member roles are changed in this type of theatre, the agency the shift in roles creates is "often illusory." She also suggests that: "Though it seems as though the audience has the power to completely control the narrative, this is rarely the case in immersive theatre. More often than not, spectators follow a series of guidelines that covertly shape their experience of the piece" (p. 26). Many of C's design decisions acted as invisible boundaries or a "series of guidelines" for audience members to follow—the choice of items to include in the show, how they were presented, the day-to-night lighting progression, the sound of a doorbell ringing, even the name of the show—every choice helped to guide audience members to a favorable outcome in their participation at *FORTS*.

While the tension between providing structure and supporting agency has been examined by scholars in the past, the present findings provide an important reminder for continued exploration of this topic. By C's own admission, an essential goal of hers was to fully empower participants in the *FORTS* space. Thus, even a professional with years of expertise in participatory theatre *still* had much to learn about power relations among herself, her design, and the audience.

This analysis has several implications for designers who design with agency at the heart of what they do, including teachers who value student-centered classrooms and learning scientists who attend to power in their designs of learning environments. Supporting agency is an issue to be aware of not just during the conception phase of a design process, but one that is in constant negotiation throughout the entirety of the design process. Additionally, *agency* can mean different things to different people at different times. Therefore, maintaining clarity regarding the specifics of what agency means in a designed environment throughout the design process is crucial to those who value centering learners in their work. For people who design with others, it might be beneficial to explicate what agency means for the team collectively rather than assuming everyone shares the same definition. Based on a common conception of agency, designers can then identify what would count as evidence of audience agency thereby providing agreed upon evaluative criteria.

Development of Students' Science Identities in a Biology Classroom: A Learning Community Approach

Elena Boldyreva, University of Toronto, elena.boldyreva@mail.utoronto.ca
Maria Niño-Soto, University of Toronto Schools, maria.nino@utschools.ca
James D. Slotta, University of Toronto, jim.slotta@utoronto.ca

Abstract: This paper describes the objectives, theoretical framework, design and outcomes of a research study conducted with 55 students in a Grade 11 Biology classroom in a diverse urban school in Ontario, Canada. Students worked as a learning community to explore and discuss authentic case studies and datasets, evaluate the credibility of resources, participate in scientific argumentation, and explore science-related careers. The year-long curriculum, co-designed with a teacher and guided by a theoretical model of Knowledge Community and Inquiry (KCI), engaged students in co-constructing a collective knowledge base, supported by technology environments, where students made connections across course topics, connected to real-world issues, and explored science careers. Through the Career Exploration activity, students learned about their peers' interests and became more knowledgeable about various careers; through their discussions, students were motivated to further explore their own science identities.
Keywords: learning community, collaborative learning, science identity

Objectives

A substantial research literature has addressed the benefits of a learning community approach, such as developing and advancing a shared collective knowledge base (Bereiter & Scardamalia, 2014; Slotta & Najafi, 2013) and supporting inquiry-oriented discourse (Fong & Slotta, 2018). This approach emerges from the Fostering Communities of Learners model of a community in which students use real scenarios and are supported by deep disciplinary content, and where students share expertise with their peers (Brown, 1997). In a science classroom, students are engaged with their peers in a model of a scientific community (Bielaczyc & Collins, 1999). Contributing to a shared and co-edited knowledge base, with a support of a technology environment, is fundamental for a learning community described in this paper (Fong & Slotta, 2013; Slotta & Najafi, 2018). By engaging in a model of a scientific learning community, students develop collaborative skills, create new ideas and learning opportunities for their peers (Song, et al., 2010). Through conversations during group work and participation in authentic scientific activities, students develop their science identities, including specific topic interests, and potential career directions (Thoman et al., 2007). This study examines the context of a scientific classroom learning community, and how students' interactions with peers, materials and activities can foster the development of career identity. Our main research question: "How does learning in a collaborative environment supported by the KCI Model and technology contributes to the development of students' career identities?"

Theoretical foundation

The notion of identity is described as an individual's sense of self within a group or a content, developed through interactions with others, which is evolving and can be regulated by culture and context (Leary & Tangney, 2012; Roeser et al., 2006). It has been shown that social context can improve an individual's motivation -- not only by providing support, but also contributing to an individual's interests (Thoman et al., 2007). Under the interactionist approach (Kim & Sinatra, 2018), it is the interaction between a student and the context that encourages or restricts the student's formation of science identity. Others suggest that interpersonal processes influence the self-regulation of motivation (Thoman et al., 2007). For example, if a student feels that other classmates are interested in a science subject, they may also express a higher interest – leading to the notion of an interest quorum to be established (Nazari et al., 2017). The role of conversations has also been studied as a means of gaining value about topics, where students can socially verify and build their perception of an activity as interesting and valued (Nolen, 2001). Moreover, in collaborative activities, students jointly develop their understanding of the topic and achieve shared representations of it (Clark, 1996). Talking with others about one's educational interests and receiving social recognition during these conversations have been shown to increase interest in science careers, even more significant for women than men, in particular for women with a lower science identity (Jackson et al., 2018).

Method

Our study explored how students' interactions within a classroom learning community, including authentic inquiry tasks, can impact students' science identity formation. For the development of this year-long curriculum,

 © ISLS

design-based research (DBR) methodology was applied: the curriculum was co-designed with a teacher of a Grade 11 Biology class consisting of three cohorts, totaling 55 students. Students worked as a class, in groups, and individually to explore case studies and datasets, evaluate the credibility of resources, participate in scientific argumentation, reflect in personal journals, and explore science-related careers. We applied the theoretical model of Knowledge Community and Inquiry (KCI), in which students construct a collective knowledge base and engage in scaffolded inquiry activities, with accessible learning outcomes (authors, 2018). Throughout the semester, students contributed their ideas to the emergent collective knowledge base and built on their previous ideas.

Through the course, students explored primary and secondary resources (i.e., scientific journal articles) concerned with the topics of the five units of the curriculum: Genetics, Biodiversity, Evolution, Animal Systems, and Plants. We also added a cross-cutting diet and nutrition theme. Guided by the KCI model, a series of inquiry activities was designed, using a variety of technology environments and materials to support students' collaborative work. Among those activities, we designed a Career Exploration activity where students collectively built knowledge about and connections amongst a wide range of science-related professions. Exploration of science careers was a focus of at least one lesson in each unit, in which students contributed to the community Career Folder (on Google Drive), collaboratively editing Google Docs and adding details to the careers posted by other students and/or adding a document with a new career. Up to six students from three cohorts could contribute to each career page. If more than six students wanted to contribute to the career, they were encouraged to create another document with the same career. Working in groups and discussing their choices, students gradually developed the Career Knowledge Base, which served as a platform for further discussions and personal exploration of potential science careers and their connections to other careers. While current study is completed, we are planning its iteration and we are also aware of the study limitations. The DBR is a complex process which includes many interconnected elements. Brown (1992) described the difficulty of conducting design experiments in situ, rather than in the controlled conditions where the designer has control over the task and other variables. When using the DBR approach, authors should provide descriptions of the contexts, theoretical framework, details of the design, and their impact on participation (Barab & Squire, 2004), included in this publication. Besides, authentic learning contexts are unique to each classroom, which is why findings of design-based studies may have a limited generalizability, but offer insights for other researchers (Fong & Slotta, 2018).

Data Sources

Data included tables, documents and personal journals created by students individually, in groups and as a class. Co-constructed tables and documents to which students contributed their responses represent a collective knowledge base built during the school year. In the Career Activity, students built a Career Knowledge Base which served as a platform for further discussions and career explorations by students. Students researched and added to the career description, made connections to other professions, explored university/college programs that would support the career, researched the level of demand for each career and the starting salary, and added interesting videos and articles. They also discussed how various careers related to each of the curricular unit. Students' answers to science identity questionnaires were also collected. The questionnaires asked three central questions: 1. What are some interesting career directions that were connected to this course, which you may not have considered before? 2.What is your current thinking about a career? Was it influenced by anything you encountered in this course, and if so, how? 3. Should teachers make a stronger emphasis on career connections within their courses? How can we help students keep thinking about their career?

Findings

Through exploring different careers and contributing to the class Career Knowledge Base, students built their understandings of various careers in science and of their own science identities. In their Career Pages (23 documents created), students identified connections to almost 100 different professions. The top three careers of interest were Neurologist (7 students contributed), Oral Surgeon (6 students), and Forensic Scientist and DNA Analyst/ Pharmaceutical Chemist (5 students per each). The maximum number of words describing a career in a collaboratively created document was 1432 (the career of Neurologist). Students connected their careers of interest to many other careers (e.g., the career of Epidemiologist was connected to 19 other careers). Some of the career connections are shown in Figure 1. Also, 60 links to various resources related to future careers were added by students. Pages on less prominent professions, such as astrobiologist, myrmecologist and genetic counsellor, were also created.

The Career Exploration activity helped students gain insights into specific career interests or discover careers of which they had not been previously aware. They also became informed about qualifications required to pursue certain careers. In the process of the analysis of students' responses to the questionnaire, several main themes were revealed (Table 1). Selected students' quotes regarding their participation in the activity are provided

in Table 2. The Career Exploration activity, including collective knowledge work and discussions about careers, was emphasized by a number of students as helping them see connections between different science fields, industry and other fields, such as business or law, and become interested in exploring various careers. Students indicated that the section where they explicated college and university pathways for each science career was very valuable. At the end of the study, some students still had questions about careers, such as about workload for certain careers, career integration and job market, changing career, and how technology will affect future jobs. Collaborating with each other as a classroom learning community, through the exploration and recognition of their peers' interests, social verification and building their perception of the activity as valued allowed students to develop their interest in the topics, which is believed to be a primary driver of science identity (Maltese & Tai, 2010).

Scientific and scholarly significance

This study demonstrates the potential of a learning community approach achieved through a collaborative student work by progressively adding to and making use of a collective knowledge base, through discussions in groups and as a class, in helping students to start developing interest to and knowledge of many science careers, and contributing to the formation of their science identities. This study contributes to the literature on the factors influencing the development of science identities and will be of interest to a broader educational community. Moving forward, we are interested in deepening our understanding of identity formation. Future work will explore the notion of Funds of Identity, and the various forms of intersections that may occur within a classroom learning community.

Figure 1

An example of career connections built by students in the Career Exploration activity

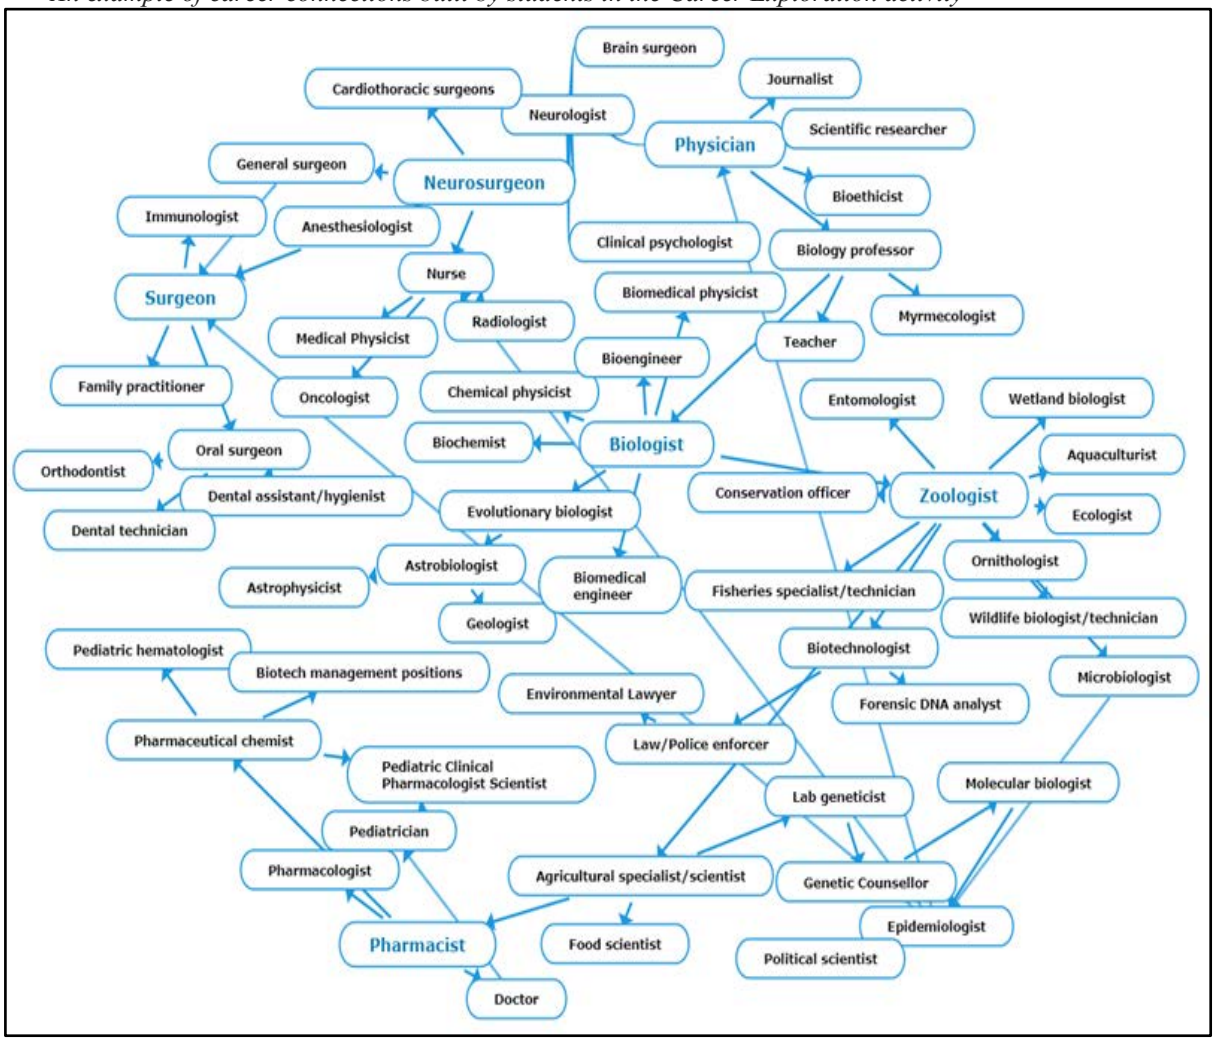

Table 1
Main themes identified in students' questionnaires

- Looking at everyone's else work gave students more insight about the career. - Students were interested in the area in general but after their participation in the activity they could narrow their interest to certain careers. - This activity has informed students about the qualifications and soft skills required for various careers. - This activity showed students many different ways how biology or other disciplines can be applied to the real world and industries. - Even if students were not interested in a science career, this activity helped them plan their future secondary education and job.

Table 2
Selected students' quotes about science career exploration activity

- Researching the different careers and looking at everyone else's work has given me some more insight. - I thought I would never venture into the STEM field. Everything looked too complicated. However, today after researching about neurology, I now realize how fascinating it is. - The ideas generated from today's class have inspired me to think about my own career path. - I wanted to get a job in the justice system, but for me the only viable option was to be a lawyer. Being a forensic DNA analyst keeps me in that field, while also being able to continue studying STEM. - It also impressed upon me the need for some planning for a future career and a strong friend network and communication skills to find new jobs and succeed in the workplace.

Insights about Helpful Covid-19 Learning Resources from Caregivers of Elementary School Children

Rose K. Pozos
rkpozos@stanford.edu
Stanford University

Abstract: Media resources are a central component of children's learning ecologies in the U.S. However, much of the coverage of the Covid-19 pandemic came through channels for adult audiences, and the "infodemic" added to the difficulty of interpreting information from media sources. This paper analyzes learning resources collected in a diary study conducted with 109 families with elementary school aged children at the beginning of the Covid-19 pandemic. Findings show that the resources caregivers found useful in communicating with their children about the pandemic are intertwined with their life experiences and interpretation of their children's information needs.

Introduction

> When COVID first started we were listening to the news on the television nonstop. So my girls kept seeing the news and what was going on. It was challenging for them because I would give them an answer to a question and literally rules and guidelines changed within an hour on certain days. *Layla, mother of 5-year-old Maia and 8-year-old Rachel*

When Covid-19 arrived and sparked a wave of lockdowns, parents and other caregivers (e.g., grandparents, adult siblings) had to decide what they were going to tell their children, how they were going to respond to their questions about the changes in their routines, and how much to shelter their children. Media resources such as national and local news outlets, government press conferences, and social media were flooded with coverage of the pandemic. In addition, an "infodemic" of conspiracy theories, misinformation, and fake news about the coronavirus and Covid-19 erroded public trust in health officials and spread fear and feelings of hopelessness around the world (The Lancet, 2020). Access to reliable health information and the ability to apply that information is a critical component of health equity (Gonzalez et al., 2020). Since families are mediators of both children's health learning (e.g., Squires et al., 2012) and interpretation of media (e.g., Takeuchi & Stevens, 2011), unpacking how families were using media resources to learn about Covid-19 is critical to understanding how families adapted to the pandemic.

Using digital media with young children is a contentious topic, with debates about the benefits and dangers of screen time cast in moralizing language. For years experts in child health, such as the American Pediatrics Association, have encouraged caregivers to limit their children's interactions with digital media (Lemish, 2021). Yet years of research on children and media demonstrate that well-designed media can promote learning (e.g., Sesame Street) and social interaction (e.g., cooperative multiplayer online games and virtual communities), and that joint engagement with media is a productive form of collaborative learning that can arise between caregivers and children (Takeuchi & Stevens, 2011).

To understand how caregivers approached learning about the pandemic with their families, this paper examines how 109 families of elementary school children were exploring pandemic related topics and concepts through the use of social and media learning resources. In this context, "media resources" include both information media designed for adults as well as educational programming for children. Given the dynamic nature of the infosphere and the limitations of our static data collection method, this paper does not aim to analyze the content of the media learning resources, but rather document caregiver perspectives and reflections on using media to learn about the pandemic with their families.

Methods

The analysis presented in this paper considers the research question: What resources were caregivers using to learn about the pandemic, and which ones were most helpful for talking to their children about the pandemic? The data come from a larger diary study conducted with 109 families from 28 states across the U.S. over the course of two weeks in May 2020 using *dscout*, a mobile qualitative research platform (Barron et al, 2021; Pozos et al., 2022). The participants were recruited from dscout's panel. The caregivers were mostly women (67%) with

 © ISLS

children in public elementary schools (84%). Racially, 55% self-identified as white, 16% as Black, and 15% as Latinx, 9% as Asian, and 4% as Middle Eastern or North African.

This paper considers data from one portion of the five-part study where participants shared how they were learning about the pandemic with their children. Participants provided a snapshot of their Covid-19 learning ecologies (e.g., Barron, 2006) by responding to checklists of pandemic learning topics and sources, and providing examples of learning resources they found most helpful. The checklists were analyzed with statistics by family demographics. Given the lack of a unified response to Covid-19 and the speed at which the news cycles were occurring at the time of the study, we felt it was important to differentiate between the resources caregivers were generally accessing compared to the ones that they found to be most helpful for talking to their children about the pandemic to give us insights that could help with the design of future crisis learning materials. The examples of learning resources were cataloged, specifying the name of the source, type of source (e.g., YouTube video, CDC website, PDF, family member), the caregiver's description of the resource, and why (if explicitly stated) they chose to use that resource in particular. Types of resources were standardized and one researcher independently applied the codes to the log of resources in order to understand the frequency with which the types of resources appeared in the sample. In total, 272 examples of learning resources were given by the caregivers.

Findings

While all caregivers indicated using at least one resource, there was a lot of variation in response to the prompts with a few caregivers explaining how they try to avoid Covid-19 being the focus of their day, others describing how their children bring sources to them to talk about, and yet others who wanted to help their children understand what was happening, but were not sure how to go about doing so.

Topics and sources families used to learn about Covid-19

Overall, the topics and resources that caregivers reported using with their children to learn about Covid-19 revolved around accessing information that they needed to navigate the "new normal" of life in the pandemic. The topics that the caregivers most frequently reported their families learning about were how to protect themselves (91.7%), public health orders (88.1%), what Covid-19 is (73.4%) and how Covid-19 spreads (71.6%). About half of the caregivers indicated that they were learning about the symptoms of Covid-19 (55%), the economic impacts of the pandemic (43.1%), and the global outbreak (40%). No meaningful differences were found by family demographics.

The most frequent types of sources caregivers used to learn about the pandemic were family discussions (85.3%), television (68.8%), social media (57.8%), and the CDC website (38.5%). Approximately one-third of caregivers were consulting local government websites (35.8%), online searches (32.1%), friends (32.1%), family members (31.2%), or teachers (29.4%). Again, no meaningful differences were found by family demographics.

Media resources caregivers found most helpful

Overall, caregivers found resources that helped them keep up to date and find explanations for questions that they and their children had to be the most helpful (see Table 1). TV news providers, websites with articles about Covid-19, the CDC communications channels, popular cartoons, and family/friends were the resources most frequently listed by caregivers to meet this need. The types and topics of the questions the caregivers noted their children asking and the conversations they sparked are the subject of a separate paper (Pozos, 2022). However for the purposes of understanding this analysis, it is helpful to know that 75.2% of caregivers reported their children asking them about daily pandemic disruptions, such as why schools were closed, when they would be able to visit family and friends, how long the pandemic would last, and why the families made changes to their routines. Many caregivers were challenged to provide satisfying answers to these questions.

Table 1

Media Learning Resources Reported Most Helpful Across All Families, by Overall Frequency

Count	Resource	Reasons caregivers found the resource helpful
News Resources		
60	TV New Providers - National, local, and global cable news outlets (e.g., CNN, Fox, NBC Nightly)	Keeping up to date on outbreaks and public health orders
32	Websites (articles) - Includes newspaper websites	Keeping up to date with latest outbreaks and finding

 © ISLS

	(e.g., NYT, Daily Courier, Washington Post), educational providers (e.g., NewsELA), medical providers, and unspecified online articles	answers to questions; for caregivers of young children, helpful to be able to find information and then relay to their children
11	Radio / Podcast - NPR, local stations, BrainsOn!, The Daily	Providing a family-friendly way to listen to Covid-19 info in the car or around the house
10	Unspecified news media - Mentions reading or watching the news generally	Keeping up with trusted news media sources; may also be a daily practice for the caregiver
Educational/Entertainment Resources		
22	Popular cartoons / shows - BrainPop, Daniel Tiger, Sesame street, Doc McStuffins, LEGO Batman	Finding age appropriate messaging about disease spread and prevention for their children
16	YouTube videos - Includes general "YouTube Videos" such as influencer accounts, educational videos, "kid-friendly" videos for younger children	Finding explanations about how viruses spread and for learning about how others are experiencing Covid-19
5	Other videos - Videos from specific websites, not found on YouTube (*Only reported from caregivers of 5-8 year olds*)	Finding explanations and demonstrations of the importance of handwashing that the young children understand
5	Books/Print Media - PDF storybooks about Covid, public health flyers	Providing interactive conversation starters
Social Resources		
18	Family / friends - Family members who are health care workers, children sharing with each other, the participants identifying themselves as resources	Clarifying and explaining the pandemic to children in accessible language
15	Social Media - Twitter, Facebook, TikTok	Following the news and family/friends experiences
11	School communications - Emails, announcements, morning messages	Providing educational content about the virus and personal protection
6	Teachers / Doctors - Child's teachers or doctors (*Only reported from caregivers of 5-8 year olds*)	Answering questions and reassuring children. Some teachers give assignments to learn about the virus or recommend videos
Institutional Resources		
32	CDC communications - Website, Facebook posts, YouTube channel	Explaining and clarifying trustworthy info and recommendations in text & visual form
6	Governor & White House Briefings - Specifically the governors of NY, NJ, VA, KY	Keeping up with the news at a state level. Learning what other states are doing.
6	Government websites (not CDC) - State or federal websites	Accessing simplified public health information with visuals
Other		
10	Email newsletters, Scripture, local news paper, web searches, local Covid-19 taskforce, lists of links	

Discussion & conclusion

Analysis of the learning resources that caregivers reported using to learn about the pandemic with their families showed caregivers drawing on a range of national media, institutional, educational, and social resources to make sense of the rapidly changing landscape of the early pandemic. The resources that ended up being the most helpful for them to use when discussing the pandemic with their children varied by the age of the children and the caregivers' perceptions of what information was necessary and appropriate to share with the children. Unpacking how caregivers interpret their children's information needs and what role media play in them also helps us think about what caregivers really mean when they say they are taking a specific approach, such as sheltering their children. There is also more to learn about how caregivers manage their children's access to information at home, beyond just screen time, building on this and brokering research by Gonzalez et al. (2020). How and why do they mediate content? How are their perspectives manifested in their goals for their children's engagement with media?

In what ways might they be learning through negotiating access to information with their children?

Finding and interpreting information about the Covid-19 pandemic became a particularly fraught topic when this study was conducted in May 2020. Since then, more educational programming about the pandemic for children and adults has been released, while partisan divides about everything from the nature of the virus to the vaccines have grown simultaneously. The Covid-19 learning ecology continues to be complex and families' decisions about how to engage with learning resources models for their children knowledge systems and values that are embedded in community practice. Thus, the findings from this study contribute to an understanding of how families assemble learning resources in times of crisis to fulfill the information needs of both adults and children.

Student Participation in Sociocritical Data Literacy: Shapes, Trends, and Future Directions from a Middle School Science Unit

Collette Roberto, Xinyu Wei, Edward Rivero, Michelle Wilkerson
roberto_c@berkeley.edu, weixinyu0820@berkeley.edu, edward_rivero@berkeley.edu, mwilkers@berkeley.edu
University of California, Berkeley

Abstract: Data science has increasingly integrated sociocritical theories and approaches, helping youth to not only learn data science but also relate data to their everyday and sociohistorical lives. Our project, Writing Data Stories, furthers these efforts by exploring sociocritical data literacies in a large-scale classroom enactment. We examine trends in middle school science student groups' (n=11) *data participation* and *sociocritical participation*, showing how these forms of participation ebb and flow across a 21-day unit. We then present focal group case studies to further unpack how participation shifted over time and suggest what factors contributed to these shifts. We found that data participation was affected by the tools at students' disposal, and sociocritical participation was shaped by the questions groups asked of each other and the data. These findings suggest that special attention to tools and guiding questions is critical when designing for sociocritical data literacy in middle school science contexts.

Introduction

Against the backdrop of an increasingly online and data-driven educational landscape, data science education has become an increasingly important field in its own right (Wilkerson & Polman, 2020). In order to be its most impactful and relevant to students, data science is also seeking to incorporate more critical and humanizing approaches to data (Lee et al., 2021). Writing Data Stories leverages sociocritical literacy (Gutierrez, 2008; Irgens et al., 2020) to provide rich data science learning, especially in non-dominant youth communities, through integrating scientific inquiry units into the K-12 science classroom. In these inquiry units, students are empowered to explore, visualize, and alter a dataset's contents, structure, or values using the Common Online Data Analysis Platform (CODAP) (Finzer & Damelin, 2016).

A key aspect of the project is supporting students to leverage both everyday and disciplinary genres to make sense of, contextualize, and reauthor datasets (Wilkerson & Polman, 2020). For example, in one of our classroom units, youth were supported to contrast advertising genres used to convince people to consume in the grocery stores with genres used to convince people in science, such as claims, evidence, and reasoning. Students then were invited to take their ideas a step further in exploring a cereal dataset to investigate which factors that might trigger diabetes to a more significant extent, such as sugar, fat, and cholesterol, and try to construct a convincing argument for what is the ideal cereal the school cafeteria should provide to students as their breakfast.

Theoretical Framework

Our work leverages notions of sociocritical literacy (Gutiérrez, 2008), a historicizing literacy that privileges students' sociohistorical lives to point out contradictions and tensions in the relationship between school-and-non-school-based knowledge. Other studies in data science have leveraged similar approaches that have seen success supporting students to critique and reauthor data in ways that invite new sociohistorical understandings of family, migration, and place. For instance, Kahn (2020) examined how students transformed datasets to write intergenerational family geobiographies, making new forms of data learning possible for students and families. Also, Van Wart and colleagues (2020) showed how remapping and envisioning youth's local neighborhoods troubled their relationship to normative data scripts and their relevance or hindrance to community improvement goals.

Building on these studies as well as sociocritical literacy, our study contributes a syncretic approach (Gutiérrez, 2008), which aims to reorganize the relationship between disciplinary knowledge and everyday knowledge as both valuable and needed in the process of knowledge building. We designed syncretic units spanning 21 days of in-school instruction, investigating nutrition, diabetes, and data literacy in a middle school on the west coast of the United States. At the same time, we set the goal to support youth to become agentive data practitioners (Wilkerson & Polman, 2020), primarily through their participation in data moves (Erickson et al., 2019) that inspire students to structure, calculate, filter, and transform datasets. Our preliminary findings showed how middle school students leveraged their everyday knowledge to create new forms of data literacy in the classroom while exploring the nutrition datasets on CODAP.

 © ISLS

Research Question

We were interested in how a syncretic design worked in the classroom context and whether youth's everyday knowledge came into a meaningful conversation to create new forms of data literacy, expanding the scientific disciplinary learning of nondominant youth. The research question is: How did youth's everyday knowledge mediate the development of meaningful conversations around data in a middle school science classroom?

Methodology

Various artifacts were collected for the qualitative data analysis, including classroom videotapes, student worksheets, student end-of-day reflections, and screen recordings of the students' Chromebook activity. A codebook was iteratively created to generate themes related to the research question, and there were six overarching subcodes under the two top-level codes, *sociocritical participation* and *data participation*. Based on their prior seating arrangement, 41 students were assigned into 11 small groups (from group A to K) and participated in this study simultaneously. Student participation has been analyzed using six subcodes to investigate how and when they engaged in the unit to develop their sociocritical data literacy across 21 days.

For the sake of space, we only elaborate on the subcodes that were most germane to our case studies. Under the code of *sociocritical participation*, syncretism is defined as using everyday and disciplinary resources to expand both everyday and disciplinary learning. Both had to be expanded to be syncretism, which we call our two criteria of syncretism. Here is a hypothetical example of student activities that would meet these two criteria of syncretism. Say for instance that students are engaged in a task naming food factors that are most important to them. If this group uses everyday ideas such as taste *and* disciplinary ideas such as sugar content on a Nutrition Facts label to choose their factors, they are expanding not only their reasoning about data but also expanding their personal connections to data that they might see in their everyday lives.

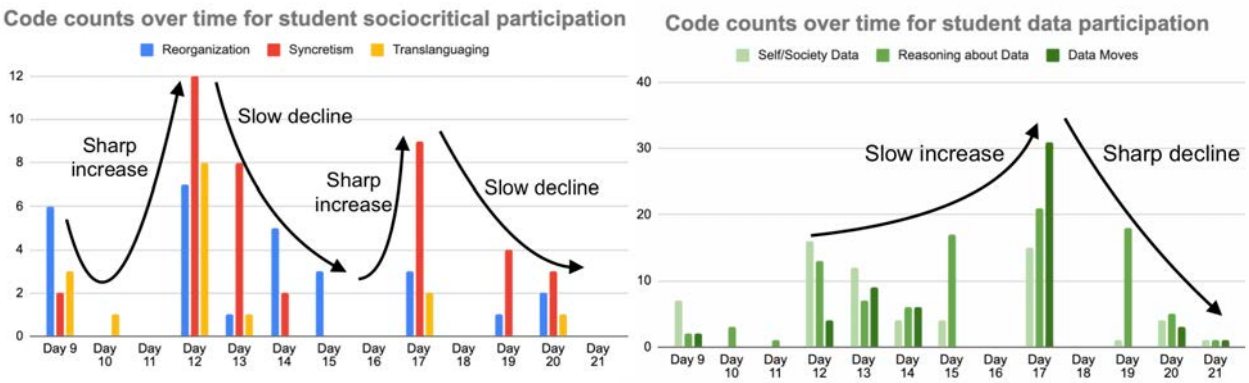
Next, two sub-codes of *data participation* need to be defined as these are examined in the cases. Reasoning about data is defined as students engaging in disciplinary data knowledge and practices already valued in the school context. For example, this code was used whenever students talked about patterns, center/trend/spread, case versus aggregate, construction of datasets. Data moves are coined as students filtering, grouping, sorting, aggregating, or otherwise transforming the data toward new purposes. For example, this code was used when students filtered out cereals on the dataset that were too high in sugar.

Findings

Figure 1 and Figure 2 present subcode counts and chronological trends in groups' *sociocritical participation* and *data participation*. Interesting trends are the spikes in all sociocritical participation in Figure 1 (Day 9, 12, and 17) and the spike in all data participation in Figure 2 (Day 17), which then experience a slow decline over the next few days.

Figure 1 and 2

Focal student groups (n=11) *sociocritical participation* and *data participation* across 21 days



Analysis of key student group cases

Next, we conducted case studies of key groups that seemed to have similar trends in participation to the overall trajectories in participation pictured in one or both the Figures. Analyzing these representative cases can illuminate the possible factors that contribute to these trends, especially those unique to the classroom context. We considered a trend robust if the pattern was present for individual group trajectories for at least two groups.

 © ISLS

Case 1: Syncretism decline from the Day 12 spike

Group K was one of two groups (Group J, Group K) whose participation matched the decline in syncretism from Day 12 into Day 15. Students in this group had pseudonyms Jonathan, Diana, and Yazmin. On Day 12, students were asked to discuss what nutrition factors in food were most important to them:

> Diana: We have to find two or more important facts.
> Dahlia: I think it's "fiber, sugar, and calories" (group agrees).
> Diana: Where can you find this information?
> Yazmin: The informational label. It'd be...it's on the cereal box huh!

This exchange met both the criteria for syncretism. Reasoning about data was expanded when this group demonstrated an emerging ability to pinpoint data sources in their everyday life (a cereal box that Yazmin was imagining). Personal connections to data was expanded when this group articulated which nutritional factors they were most interested in and began brainstorming where to look up this information.

On the following day, this group saw a decline in syncretism because their activities did not seem to expand reasoning about data even though they made personal connections to data. On day 13, students input foods they ate into CODAP, and group K began discussing how many calories were in each group member's favorite foods. For instance, Diana looked up the calories on her favorite snack, "Takis," and seemed shocked by how much sugar and how many calories are in it. In these moments, although students were learning more about their favorite foods using the language of nutrition facts, their reasoning about data did not seem to expand any further than entering the data into CODAP.

Case 2: Increase into Day 17 of all data participation and syncretism

Group E was one of two groups (Group E, Group J) whose participation matched the increase of data participation and syncretism leading to Day 17. Students in this group had pseudonyms Natalie, Lolita, Alex, and Bryson.

On Day 15, Group E seemed to expand their personal connections to data as related to their everyday lives, but did not necessarily expand their reasoning about data. In the following excerpt, students evaluated a cereal using both nutrition factors and their everyday experiences, creating an opening for syncretism that was not pursued by the group:

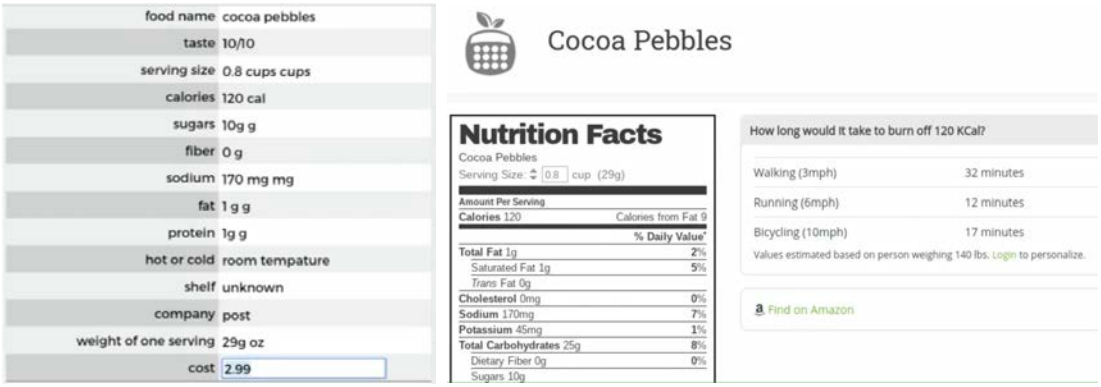
> Natalie: Oh, this one has no fat and no fiber.
> Alex: Which one?
> Natalie: Rice krispies.
> Bryson: [examining the Nutrition Facts printout] No total fat, no fiber.
> Natalie: Doesn't rice krispies taste like nothing? Like... not the bar, but the cereal?

This moment was not quite syncretism because although Natalie was beginning to make personal connections to the data with her question, the group's reasoning about data after this moment remained solely focused on comparing cereals based on nutritional factors. Thus, they did not meet the criteria for syncretism that both everyday and disciplinary participation be expanded. Had they leveraged Natalie's everyday experience to start comparing cereals based on taste and nutrition, these moments might have better aligned with syncretism.

On Day 17, Group E finally did see moments we categorized as full examples of syncretism, and they experienced a substantial increase in data moves. These data moves included adding a new case card for cocoa pebbles (Figure 3), adding new attributes to the dataset such as company, price, and taste, inputting values according to their everyday experience (Taste: 10/10), and leveraging other sources of information beyond CODAP (Google Search, NutritionX website - Figure 4) for other factors (Price, Company). We attribute the increase in data moves to the fact that Day 17 was students' first time using computers, exploring CODAP, and exploring the cereal dataset.

Using these data moves, Group E added a new cereal into the dataset and characterized it using information from both everyday and disciplinary sources. As far as everyday sources, they interviewed each other to decide that the Cocoa Pebbles was neither hot nor cold, but room temperature, that it had an excellent taste, and that the shelf was unknown. As far as disciplinary sources, they searched on Google for typical prices and searched on NutritionX.com for nutritional information (Figure 4).

Figure 3 and 4
Students added a new cereal case on CODAP and searched Cocoa Pebbles on NutritionX.com.



These moments met both the criteria for syncretism. Reasoning about data was expanded when students began to see their personal experiences as valid, inputting ideas like Taste = 10/10 into CODAP. Personal connections to data expanded when students seemed interested enough in their new attribute of cost to continue inputting costs for other cereals in the dataset.

Discussion

This work begins to suggest how sociocritical data literacy takes shape, ebbs, and flows in a middle school classroom context. For instance, Figures 1 and 2 suggest that data and sociocritical participation seem to mutually reinforce one another, such as the spike in both syncretism and data moves on Day 17. Across our focal groups, it was not surprising that data participation was affected by the presence of tools (i.e., CODAP, search engines, and the cereal dataset). However, it was interesting to see how students' sociocritical participation, namely syncretism, seemed largely to be supported or not by the questions students asked of each other and the data. For instance, in Case 1, syncretism emerged when Diana asked where sources of information could be found. Similarly, in Case 2, syncretism emerged when members of Group E interviewed each other about Cocoa Pebbles. These findings are significant because they suggest that additional attention to tools and guiding questions is needed for a syncretic approach to support sociocritical data literacy in a large-scale classroom context. A limitation in this work is that we centered syncretism, but more is needed toward *sociocritical* data literacy. Future work should support analysis of the politics of food, cultural practices, and other necessary elements supportive of nondominant youths' sociocritical literacies (Gutiérrez, 2008).

Stanford University

Abstract: When interacting with open-ended environments, students are free to use different learning strategies. In this exploratory study, we focus particularly on college students (n=47) and their use of inquiry and feedback strategies as they explore a science simulation game. By capturing their behaviors through both clickstream and gaze data, we can more closely examine the effect of different strategy uses on their learning. Backwards regression analyses were used to examine students' early behaviors in the simulation and results indicate that learning outcomes can be best predicted by a combination of inquiry and feedback processing behaviors. Of particular interest: quality over quantity of inquiry was more predictive of learning; and both clickstream data of feedback *use* and eye-tracking data on *earlier stages* of feedback processing (e.g., noticing, predicted learning). These results have implications for the design of future open-ended environments that can better support student learning.

Introduction

Scenario*: Laura and Heidi are students in the same major with similar GPAs. For a class activity, they interact with an open-ended learning environment that requires inquiry skills and provides feedback. Afterwards, they complete a test to measure their knowledge. Laura receives a lower score than Heidi.* Assuming they started with the same prior knowledge, what did they do differently in the simulation that affected their learning outcomes? This study contributes to the identification of learning strategies used by students as they study a phenomenon and highlights the importance of using multiple types of measures to understand students' learning processes.

I. Learning strategies and technologies

Inquiry and simulations

Simulations offer scientifically authentic environments for students to learn about natural phenomena. In STEM fields, a boom in online simulation environments (e.g., PhET) has provided students with opportunities to put their inquiry skills into practice (Wieman et al., 2008). Here, we define scientific inquiry, broadly, as the ability to design experiments, then gather, test, and analyze evidence to reveal patterns in the data. Specifically, in the environment discussed here, we focus on the strategies of simplification and finding equivalence (Käser and Schwartz, 2020). Students' behaviors in science simulations, captured in the form of clickstreams, offer rich information about their science inquiry processes as they explore the phenomenon of interest. Going back to the example of Laura and Heidi, it may be the case that in Heidi's exploration of the system, she designed better experiments that provided more information about the model behind what she is observing in the data than Laura.

Feedback and learning technologies

The increase in accessibility of digital technologies provides a unique opportunity to capture real behaviors of students' engagement with feedback instead of using more limited measures such as self-reports. To expand our understanding, we shift from a general perspective to a study of specific, individual behaviors that students take while processing feedback; interactive, digital environments provide students with expansive opportunities to not only receive feedback, but to act on it (Segedy et al., 2013). To the best of our knowledge, there is limited work studying feedback processing (e.g., Tärning et al., 2020). Returning to the example of Laura and Heidi, it may be that Heidi scored higher because she processed the feedback in the system more thoroughly than Laura.

Different students' behaviors while interacting with a learning environment should be analyzed to better predict student learning and design the correct scaffolds to support their understanding. The study presented here uses an open-ended science environment that provides affordances for both learning strategies to be used and measured, with an end goal of understanding how these strategies might interact to support better student learning.

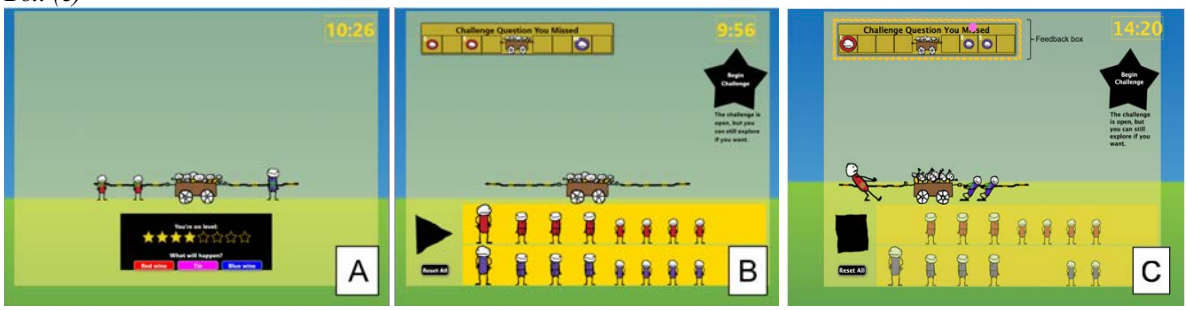
II. Pull!: An online environment for measuring learning strategies

Pull! is a physics game modeled on a PhET simulation, Forces and Motion Basics (Käser and Schwartz, 2020). Pull! is framed around a tug-of-war: teams of small, medium, and large characters on either side of a rope try to pull the other team across a center line. The object is to answer a series of eight questions in a Challenge mode and predict whether a given setup will go left, right, or end in a tie. In the simplified physics of the game, the winning side simply depends on the total "weight" of each team's characters; position does not affect the outcome. To succeed in the game, learners must understand the ratios between the characters. If learners miss a question in Challenge mode, they are sent to an Explore Room, where they have the opportunity (if they wish) to test any number of setups to learn about the simulation environment (see Figure 1). Questions progress in difficulty: three easy (e.g., a small character on either side), two medium level (e.g., a medium vs. 2 small), and three hard (e.g., 2 small, 1 large vs. 3 small, 1 medium); learners never see the same problem twice.

Figure 1

Pull! Screenshots Include an Example Medium-level Challenge (a), the Explore Room (b) and AOI Feedback Box (c)



The Explore Room is designed to provide feedback, as well as allow open-ended inquiry; upon entering the room, a player sees the question she missed in the top left corner as feedback and has unlimited choices to test setups among the provided characters by placing characters on the rope and pressing <play> to start the simulation. Some setups provide less information about the system, e.g., have identical characters on each side or have so many characters on each side that it would be difficult to discern relationships. Other setups are more informative, e.g., a medium vs. 2 small characters yields a tie. We hypothesize that certain behaviors in the Explore Room will predict better learning as measured by a posttest. It might be the case that more informative setups yield better learning, where more informative means students test setups which use principles of good inquiry, e.g., simplification. Another possibility is that feedback uptake yields better learning, where uptake is defined as students testing the same set-up as provided in the feedback box. In some cases, these factors will overlap, i.e., the feedback displayed shows an informative setup that is beneficial to students' learning.

Methods

Participants and Procedures

Community college students (n = 62) consented for the study and were compensated with a 0.5 class credit. Fifteen students with low-quality eye-tracking data or incomplete measures were removed, resulting in a final n = 47. Study procedures were approved by the Stanford Institutional Review Board. The study was conducted in 30-minute individual sessions, consisting of four stages: i) eye-tracking calibration, ii) interaction with the simulation, iii) learning measures, and iv) a debrief where experimenters provided a summary and answered questions.

Measures

For this study, we used several sources of data. The first two sources of data are measures of student behaviors while playing the game: 1) clickstreams extracted from students' interactions with Pull! and 2) gaze data extracted from the eye-tracking. The third source of data is the posttest administered immediately after students played the game and include two types of learning measures. More detailed information is provided below.

1. Clickstream data

All setups (experiments) run in the Explore Room were logged by the system, then characterized in two different ways. First, setups were categorized based on their simplicity and informativeness for discerning the ratio between character types. This included identifying tests that isolate one of the characters' sizes (one-sided), as well as tests

 © ISLS

that result in a tie (and thus are highly informative). Second, setups were categorized based on whether they likely resulted from feedback uptake or independent inquiry. They were classified as feedback uptake if after missing a question in Challenge mode, students test a setup with the same characters and same positions as the missed question (Exact Feedback) or the same characters in different positions (Inexact Feedback). Setups were classified as independent, self-driven inquiry behaviors if they were not related to the feedback. Metrics included the total number of setups tested, as well as counts of setups categorized by both informativeness and source (independent inquiry of feedback) as described above. Additionally, we coded for whether a player explicitly tested whether position had an effect by varying, in two consecutive tests, only the position of one (or more) characters.

2. Gaze data and feedback noticing

We used a screen-based eye-tracker (Tobii Pro Nano) to record students' eye movements as they played the game. Gaze data was cleaned using a smoothing algorithm (Hessels et al., 2016), then mapped onto the game coordinates and logged as a series of game events. For the purposes of this study, a question of particular interest was how the visual inspection of feedback affected student learning. Fixations were computed in the pre-defined area of interest (AOI), the feedback box in the top left corner of the Explore Room (see Figure 1C). The maximum time students spent looking at this AOI was calculated each time they entered the explore room.

3. Learning measures

Two types of learning measures were used in the posttest. 1) A performance measure focused on quantitative understanding of the ratio structure governing the system. It displayed a setup of characters on the left side of the screen. Students chose whether or not each of ten possible configurations on the right-hand side would result in a tie with the given left-hand configuration. Students received one point for every correct response and lost one point for each incorrect response. The maximum score was 10 and the minimum was -10. 2) In an open-ended response measure, students responded to the following statement: *Explain to someone what are the rules of the game you just played.* This prompt was included to measure how learners chose to verbally describe what they understood as important from the game and served as a measure of more nascent understanding of the system. Student responses were transcribed and coded using the following levels: 1=Qualitative response, 2=Mentioned arithmetic without including values, 3=Included general values, and 4=Included specific-detailed values.

Results

Overview of game play and learning measures

Individual students played until they either beat the game or timed out after 15 minutes. The average game play time was 8.8min (SD=4.4min). Most players beat the game (85%), with an average of 9.55 (SD= 8.35) Challenge attempts. The average on the learning measures was 5.23 (SD=4.22) on the performance measure and 2.72 (SD=1.31) on the open-ended response item.

Which student behaviors in the online environment predict their learning?

We present exploratory analyses to determine which behavioral measures among students' clickstream and eye-gaze data best predict their learning as measured by the posttest. Due to space restrictions, we present only those analyses that: 1) used a dependent learning measure, Z-Post score, that is the sum of the z-scores of the posttest measures described above; 2) looked at behaviors early in the game, examining data up to the first five Challenge attempts to equalize for game play length across students and 3) focused specifically on behaviors after missing medium difficulty questions (levels 4 and 5) as these are the levels that require basic understanding of the underlying rules of the system. And thus, best captured the learning strategies that students were utilizing.

The behavioral measures described in the measures section, in addition to the number of medium difficulty questions missed, were entered as independent variables into a backwards regression model (SPSS v. 27, default criterion: probability of F-to-remove >=.100) to predict students' learning performance. The final model achieved ($F_{(4,42)} = 6.46$, $p = .000$; R-squared = .38) indicated that the Z-post score could be predicted by four variables: two feedback-related variables (Number of one-sided tests that reflected exact feedback setups and Maximum gaze time spent on feedback in a single Explore room visit; standardized **β**'s = .40 and .26 respectively) and two inquiry-related variables (Number of informative, self-driven one-sided tests and Check position score, a variable indicating if learners tested for position; standardized **β**'s = .24 and .22 respectively). Interestingly, neither the number of medium level questions missed within the first 5 challenge room attempts, nor the number of total tests conducted during subsequent exploration remained in the model, indicating that it is not the quantity but the quality of experiments that lead to better learning outcomes.

Figure 2
Scatterplot of One-Sided Tests Driven by Feedback vs. Independent Inquiry by Z-Combo Posttest Score (Note, points jittered up to .4 above whole number value)

We further examined students' use of one-sided tests (see Figure 2). Students with the lowest Z-post scores were least likely to test setups that were one sided (and thus highly informative) within their first five Explore room visits. Of students who engaged in one-sided tests, most focused on *either* feedback driven setups *or* independent inquiry tests. Only a handful (8.5%) conducted *both*. Together, these results suggest that both learning strategies, using feedback and conducting independent inquiry, can lead to better learning, but that students do not naturally use both, at least in the context of this learning environment.

Interestingly, among those students who did *not* explicitly engage in any feedback-related tests, there was still a correlation between time spent looking at feedback (maximum feedback gaze time) and the combined Z-post score, $r(38) = .36$, $p = .03$) indicating that *noticing* feedback (and likely decoding and making sense of it) may be a productive learning strategy, even if it is not directly *acted upon*.

Discussion and Conclusion

We examined students' use of feedback and inquiry strategies in a simulation-based, open-ended learning environment called Pull! Both clickstream and eye-tracking data were used to capture students' learning pathways as they explored the phenomenon of net forces. Results indicate that both feedback and inquiry-based strategies may lead to better learning, but that students may not naturally employ both. Notably, the feedback strategies include both active *use* of feedback, as well as earlier stages in processing, such as noticing and decoding. This has implications for the design of future learning environments and the affordances that could be built into these learning technologies to scaffold students such as Laura and Heidi. For example, the technology could draw students' attention to feedback features or help them employ inquiry strategies, like simplifying or isolating variables, that lead to more informative experimental outcomes.

The analyses presented here are exploratory and have some limitations, including the relatively small sample size and a deliberately constrained problem space. Future research and analyses will examine how affective variables may influence students' use of learning strategies and incorporate findings into improving Pull! and other new learning environments with more complex science content.

Abstract: It is important in this changing world of technologies and careers for students to learn how to learn. Formal education can provide the opportunity to develop lifelong learning skills that are necessary to cultivate positive learning habits and new mindsets. For learners to build these skills, they must be embedded in their courses, making it necessary for instructors and teaching assistants to prepare content, resources, and knowledge to cultivate these skills. Building the capacity of teaching assistants gives them the means to support learners as well as helps them to become better learners too. This paper describes design and implementation of a training module for teaching assistants and the design decisions made to address the needs of the university and its students. This design work uses the Concerns Based Adoption Model to guide the design decisions and development of the formal training.

Introduction

In education it is important to focus on assisting learners to learn how to learn (Barron & Darling-Hammond, 2008) and build not just content knowledge but 21st century skills. These skills will help learners navigate formal learning opportunities as well as the demands of changing technologies, information, jobs, and social interactions with others throughout their life and careers. It is vital for learners to recognize the need for lifelong learning and the ability to re-skill and update competencies (Mawas & Muntean, 2018). Promoting knowledge retention and the transfer of knowledge and skills to new subjects, contexts, and problems are two important goals in education (Mayer, 2002). Formal education should prepare learners with the skills and desire to be lifelong learners so they can be flexible and successful as new expectations arise in whatever they do.

Within formal education, learners typically interact with content, instructors, teaching assistants, and peers (Moore, 1989). These interactions provide a means for learners to increase in their content knowledge. Fostering lifelong learning and 21st century skills in online courses is important in education today as more classes are online, and technologies and job expectations change. These skills cultivate new mindsets and learning habits that are essential for the future of society (Fischer, 2000). To foster these skills, they must be taught in the course (Saavedra & Opfer, 2012). Instructors and teaching assistants need to be prepared to teach these skills and provide resources related to them for learners. Providing training and support for instructors and teaching assistants is very important for student success. Building the capacity of teaching assistants gives them the means to support learners as well as helps them to become better learners too (Shannon et al., 1998). This design case describes the process and decisions in developing the Teaching Assistant Module (TAM) for online teaching assistants to support learners.

Context

This design case is part of a larger Research-Practice Partnership (Penuel & Gallagher, 2017) with administrators, design professionals, and educational researchers at a large, private university in the western United States. Since one of the main aims of this university is to foster lifelong learning skills, this work focuses on building these skills as well as learner readiness in online courses. This involves multiple people and design, including instructional designers, teaching assistants (TAs), instructors, resources, well designed courses, and preparation and training for people who implement the courses. This paper focuses on the teaching assistants.

The TAM was designed to help solve a number of problems identified by the university's online administrators. The most pressing problems arose from rapid growth with limited staff. When the university's online department began in the fall of 2012, the program had an enrollment of 316 students in 2 sections. By fall 2020 online enrollment had increased to 26,134 students in 426 sections. With the increase in students came a correlating increase in hiring TAs, which grew over 300% from 2017 to 2020. In addition to the rapid growth, another influencing factor was limited personnel resources. By mid 2019 the full-time staff to TA ratio was more than 1:200, making it difficult to provide individualized support.

Previous TA training was primarily focused on employment policies and procedures, with some learning management system (LMS) training. To begin the design of the new training, the existing online training resources

 © ISLS

were assessed for how necessary or pertinent the information was moving forward, with the majority of the materials being removed and not used. The need to improve TA interventions led us to focus on a new training course that could teach both student success strategies and pedagogical principles in the hopes to improve teaching assistant effectiveness.

Theoretical framework

The Concerns-Based Adoption Model (CBAM; Anderson, 1997) provides the theoretical framework for the design and implementation of the TAM. The CBAM functions under the premise that the adoption of new programs and initiatives are much more than materials and resources. Assessment of successful implementation must also address the attitudes and beliefs of all who will be involved and how they will respond to the changes. The CBAM consists of three diagnostic components: Stages of Concerns, Levels of Use, and Innovation Configure Map. These three stages function together to gauge effective implementation. With the design of the TAM, we were initially focused on the early informational, personal, and management steps of the Stages of Concern. The undergraduate student TAs wanted to know more about the module, how it would affect them personally, and how they would manage their time in learning and applying what they were learning.

Research methodology and design process

This partnership uses design-based research (McKenney & Reeves, 2018) to iteratively tackle problems of practice faced in online learning. As an exploratory study, we used surveys and reflections to capture the experiences, perceptions, and attitudes of the TAs related to the TAM and their classes. Data was collected over three semesters and analyzed so iterative improvements in the design, development, and implementation process could be made. This work is guided by the following research question: How effective is the TAM in building knowledge and capacity for TAs?

Participants

The primary participants in this work are TAs for online courses at the university. From fall 2020 through fall 2021, 1,455 TAs assisted with online courses. During the semester a TA works, we enroll them in the TAM as part of their job and then invite them to participate in the research activities. Data for the research is collected each semester using a pre/post surveys and a short survey to assess a specific unit in the TAM.

Design

With rapid TA growth and limited resources, we recognized a need to provide TAs with a more comprehensive learning opportunity that could be done completely asynchronously online and double as a resource and reference manual. The overarching goal of this new training module was to provide TAs with instruction on how to fulfill their job duties, how to connect with their students online and help them in their efforts to become better online and lifelong learners, student success strategies, and pedagogical principles in the hopes to improve teaching assistant effectiveness.

The TAM was created through a collaborative design process with stakeholders, designers, and researchers. The first unit focused on improving knowledge of the Canvas LMS. The LMS used in online courses was different from the LMS used in in-person sections, so LMS proficiency was an important goal in this first unit. The goal of this unit is for TAs to know Canvas and to be the main source of support to their students who are new to the LMS. This unit is to be completed before the semester begins. Unit 1 aligns with the first and second stages of concern in CBAM, *informational* and *personal*. They are learning about the LMS and becoming comfortable with it, while building their confidence with the technology.

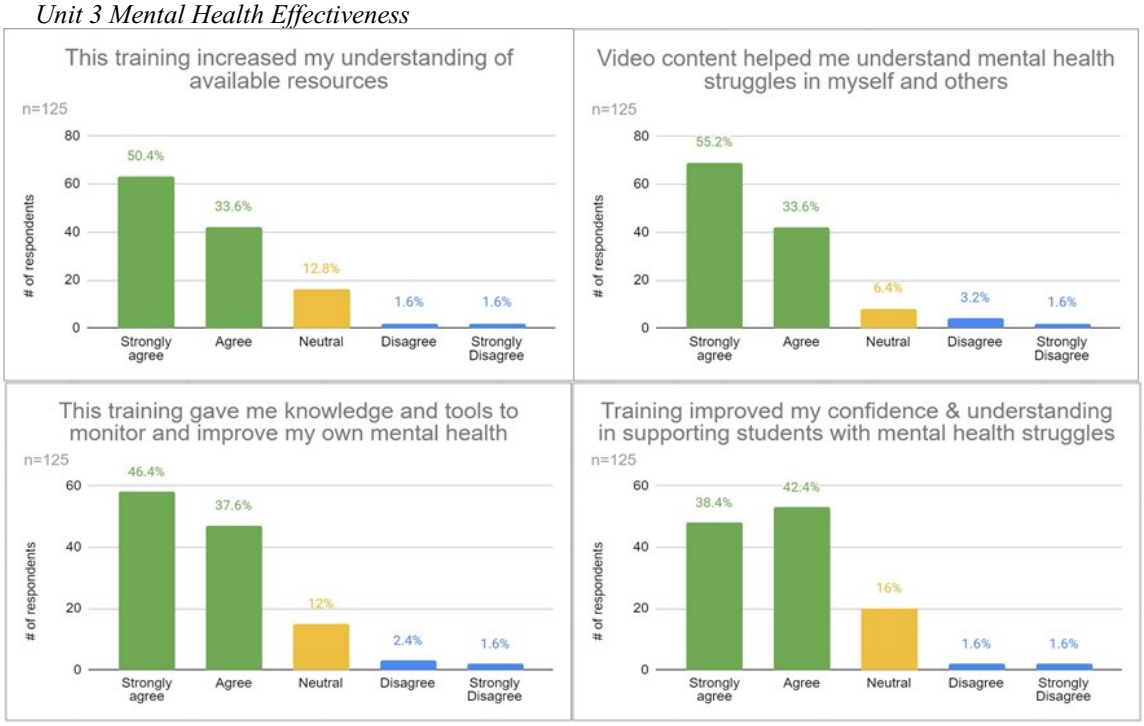
Unit 2 was created to help TAs connect with their students. Designed to be completed in the first few weeks of the semester, the unit focuses on providing timely feedback to students, creating a community of belonging through inclusion and safety, using course analytics to support online students and accommodating various needs of students. The major objectives of unit 2 included helping TAs to see *the why* of what they are doing; to act as students' success mentors and have the skills to improve student learning. This unit teaches them how to identify struggling students using data analytics and provides ways to offer support and encouragement. Teaching assistants are usually chosen because of their academic performance, but we did not want to make the assumption that they possessed any knowledge of or experience with utilizing effective learning strategies. So, this unit pushed for information as well as how what they learn might affect them and their student's learning opportunities.

The goal of Unit 3 was to provide personal growth and professional development opportunities for the TAs with the hope that the outcomes and benefits would be passed to the students they interact with. To navigate

this, we chose to provide several options to help TAs recognize their own strengths (and weaknesses) and learn how to improve on them. In line with the CBAM model, we hoped that these training sessions would help TAs to experience the importance of the material that we covered. Once they had a meaningful experience themselves, they could turn to their students, recognize their needs and help them. We acted under the assumption that if we could help TAs to become more capable and conscious students themselves, there would be some benefit that would trickle down to the students they are responsible for. In Unit 3 we ask TAs to choose their own adventure with the following topics: Happiness Advantage Bookclub, Growth Mindset, Mental Health, Active Learning, Critical Writing, Gallup CliftonStrengths, and Belonging. The format of this unit allows TAs to self-direct their training material to meet individualized growth while still maintaining training effectiveness. This design also allows returning TAs to have continued meaningful learning when they return in multiple semesters. The Unit 3 training has been the most well received unit. The most popular training chosen by TAs has been the mental health module. Working with professionals within the campus counseling center we created this unit to educate the TAs about the importance of mental health within the learning process. Survey data to evaluate this unit reports promising results about the effectiveness of the materials and movement in the right directions toward our learning outcomes for this unit (see Figure 1). TAs also have the option to earn a microcredential for each of the topics in Unit 3

Figure 1

Unit 3 Mental Health Effectiveness



One more problem addressed in our training was the lack of transfer of knowledge from one semester to another. Student positions have a high turnover rate. TAs interact with a course at a different level than instructors and can provide valuable insight into course design improvements as well as assignment management and support. We value the knowledge and experience the TAs gain and have seen it often go unnoticed. We created unit 4 to capture what was learned every semester to shorten the learning curve for the next TA. This final unit is essential to helping the online department maintain and improve their courses as TAs learn how to communicate and collaborate with the designers regarding issues in the course so that the university's online education can continuously improve. This wasn't part of the design when unit 1 was started, but it became apparent that a need for refocusing, as CBAM states, was needed each semester. At the end of this unit, the TAs complete a post-semester reflection survey similar to the pre-semester survey they take and aims to measure student learning through the semester and training effectiveness. The TAs are given the opportunity to write down how they have individually improved as both a learner and a TA and how they hope to continue to improve.

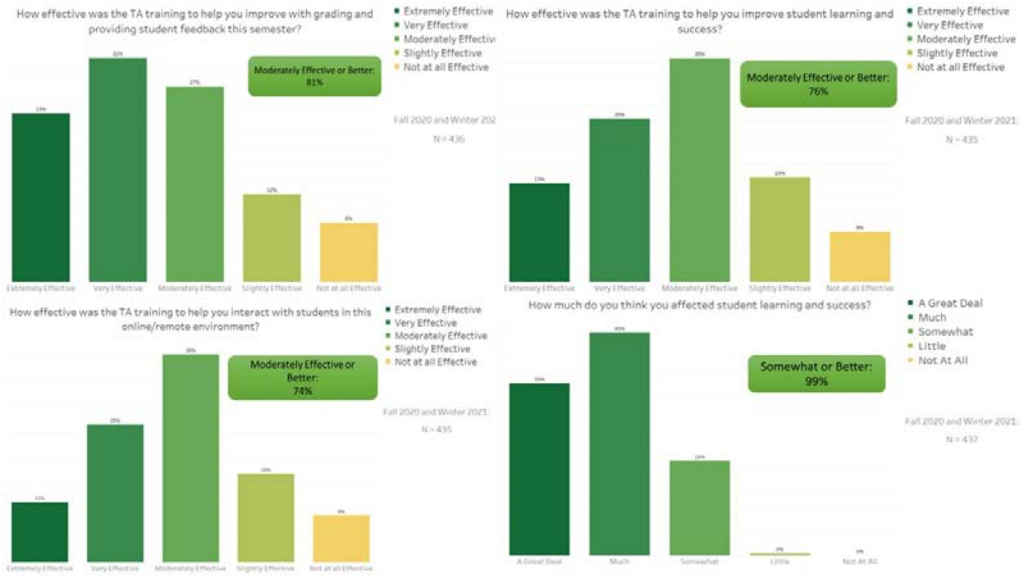
 © ISLS

Results and discussion

Using the results from the pre/post survey to answer our research question, we are optimistic as we see evidence of the training's effectiveness. Figure 2 reports on four questions from the surveys reporting that the TAs find the TAM effective in helping them with grading and feedback, improving student success, interacting with students, and their perceptions of affecting student learning and success. 81% of respondents reported that the TAM was moderately effective or better at helping them improve grading and providing student feedback. 76% reported that the training was moderately effective or better at improving student learning and success, and 74% reported being moderately effective or better at interacting with students in an online/remote environment. When we asked teaching assistants how much do you think you affected student learning and success, 35% reported a great deal, 45% much and 19% self-reported having somewhat of an effect on student learning.

Figure 2

Training Effectiveness



Implications

At this university there is a lack of campus standard training for teaching assistants. Many entities outside of the online department have expressed an interest in creating something that would work for all TAs. It is the online department's goal to improve peer teaching and support across disciplines by creating a version of the teacher assistant training that could be easily customizable to meet a department's needs. With data supporting the effectiveness of the TAM, this service could be beneficial for other departments.

Beyond Belief: Disinformation Strategies and Collective Knowledge Building Led by Jair Bolsonaro in Brazil

Renato Russo, Paulo Blikstein
rfr2126@tc.columbia.edu, paulob@tc.columbia.edu
Transformative Learning Technologies Lab, Teachers College, Columbia University

Abstract: The creation and distribution of disputable information is currently widespread and significant in the political debate. Explanations of this phenomenon usually imply that leaders exploit fragilities of their followers, such as lack of education or plain lack of understanding of the facts. We explore a competing interpretation: using a constructivist lens and building on scholarly work in the learning sciences, we investigate cognitive processes at play in political engagement that goes beyond "blind" belief in leaders. We conjecture that those leaders might be employing efficient learning strategies that legitimize their actions and inspire loyalty.

Introduction

The crafting and distribution of alternative versions of facts is particularly relevant to present-day political discourse. In this paper, we focus on this trend as it manifests in strategies employed by Brazilian President Jair Bolsonaro, who–in one of many similarities to Donald Trump–had allegedly made 2,700 false or distorted statements in 1,000 days in office (Freitas et al., 2021). A widely held belief about Bolsonaro and Trump is that their constituencies follow them "blindly" without understanding of the real contents of their messages, and that a "better educational system" would eventually enlighten these followers. Here, we investigate a competing explanation: *audiences' belief in these leaders is not necessarily blind; instead, these leaders and their followers work in tandem to build their own robust theories on the backs of flimsy assumptions and facts–but the resulting theories are strong and internally coherent.* Research in information science has found evidence of similar mechanisms at play among alt-right groups (Zuckerman, 2019; Lewis & Marwick, 2017; boyd, 2018).

We hypothesize that there are sophisticated cognitive mechanisms at play that go beyond blind belief in a leader, and that these mechanisms are powerful enough to justify the creation of strong theories that guide political behavior. Our investigation focuses on ways in which Bolsonaro employs sophisticated activators to engage his audience in an *active and collective knowledge construction process*, which results in the audience's feeling that they are creating their own knowledge. Thus, rather than telling followers what to believe, Mr. Bolsonaro might be (consciously or not) applying efficient teaching strategies.

This paper builds on our previous work (e.g., Russo & Blikstein, 2022; Russo et al., 2021) to explore potential contributions of the learning sciences to our understandings of how political leaders influence the construction of his or her followers' political knowledge. Despite bordering on conspiracism, that political knowledge might sound like robust, solid theories to those who own them. We draw on a classic constructivist perspective and on work from the information sciences to analyze video data containing informal conversations carried out by Mr. Bolsonaro and citizens (similar to Trump's "chopper talks"). With that, we hope to offer a contribution to the learning sciences in the form of new hypotheses to explain modern-day knowledge construction in contexts that affect people's everyday lives.

Theoretical framework

Constructivists propose that learners build their own knowledge in interaction with the world, and that individuals assimilate new information according to preexisting mental schemes (Ackermann, 2001). diSessa (1993) advanced constructivist theories with the Knowledge in Pieces" framework, an explanation to how "experience feeds into knowledge." He claims that children's intuitions about the workings of the world can be used to advance their understandings of science and, more specifically, physics. Those intuitions, diSessa argues, form phenomenological primitives ("p-prims"), mental structures that offer possible explanations to observed phenomena. As p-prims develop, they come to form more complex mental structures named "coordination classes" (diSessa and Sherin, 1998). These structures support individuals in their process of making inferences from observable phenomena, sometimes even getting in the way of knowledge supported by evidence. We transfer that concept from physics to political science to formulate our hypothesis that political knowledge built upon a learner's prior "pieces" would be much more solid than that formed by the unidirectional ready-made messages on which political leaders traditionally rely.

This transfer to the social sciences is not novel. Philip (2011) proposed the "ideology in pieces" (IiP) framework, employed originally to study notions of race and racial justice in schools and teaching. Part of the IiP

 © ISLS

framework is the notion of "naturalized axioms," the parallel of p-prims in the context of the social sciences. The researcher posited that individuals' observations about phenomena in society and politics are heavily contingent on historical and social contexts. In other words, naturalized axioms are described as elements of common sense that people employ as they make sense of the social world. For example, Philip (2011) identified that, to explain why some students are unsuccessful, teachers might use naturalized axioms like "kids would rather play than work." Like p-prims, the IiP framework implies, *naturalized axioms also form coordination classes*. One crucial difference from coordination classes formed by p-prims, however, is that there is no universally agreed-upon meaning of commonsense elements like "blame, responsibility, or fault," but they acquire socially shared denotations for specific groups, depending on the sociohistorical contexts. That is, although coordination classes are originally highly dependent on observable phenomena, the ideology in pieces framework ascertains a slightly different nature to it, now compatible with phenomena pertaining to the social world. These concepts become important when we investigate constructivist theory-building as a cognitive device that citizens employ to understand politics and society.

Data collection and analysis

Mr. Bolsonaro regularly confers with citizens and journalists from highly partisan media outlets. We initially watched 50 video recordings of those conversations (total length: 12 hours) that were published on YouTube between April 30th and July 26th, 2021. We then reduced the sample to pieces whose content included proper dialogues and that contained references to emergent, controversial topics (much of the initial sample resembled fan-idol encounters that are not relevant to the present analysis.) This filter left us with six recordings (total length: 1:18:50). Some of the selected clips had been edited after the original publication to exclude explicit disputable claims about authorities in the federal government, but we accessed the original versions using the Internet Archive Wayback Machine. Our analysis is based on those original recordings. After transcribing the videos, we employed grounded theory (Charmaz, 2006), developed initial codes over multiple cycles of discussion between the authors, and elaborated an analysis framework that draws on the concepts of coordination classes and naturalized axioms. Next, we assigned quotes and dialogue excerpts (N=78) to 3 naturalized axioms that form a larger coordination class and to groups of assumptions that compose those axioms. We then classified the quotes according to the kinds of activators employed in each one. Finally, we ranked the recurrence of activators across naturalized axioms.

Results

After extensive analysis and coding of the dataset, we converged on three main strategies that function as "activators" in Mr. Bolsonaro's utterances (Table 1). It is intriguing that these strategies are akin to many of the productive teaching strategies found in the education literature.

Table 1: *Activators, their frequencies, descriptions and examples*

Type of activator	Freq.	Description	Examples
Schemata	74 (94%)	A mental "template" to guide the learners (in this case, the citizens) in their interpretation of current facts	*"the individual is always in conflict with the collective" "all left-leaning governments are dictatorships."*
"Socratic" dialogue/ rhetorical questions	27 (34%)	In an interactive manner, the followers reach conclusions through strategically positioned questions. In this case, the speaker does not answer, but suggests ideas through subtle questioning, a process that leads followers to feel that they are actively building knowledge	*see dialogue example below*
Contrasting case	13 (16%)	Comparison between two or more contexts. In this case, the comparisons are usually between contexts that are known to the listener and ones of which they have but stereotypical mental images	*"Electronic ballots are only used in Brazil and Bangladesh; paper ballots are used everywhere else in the world, including Japan and the United States. Guess who is wrong?"*

Note: there is overlap between types of activators. Therefore, the sum of percentages is greater than 100.

Example Socratic dialogue:

Bolsonaro:	Have you heard of a hacker who is in jail?
Follower:	Yes, I saw that video.
Bolsonaro:	And why is he in jail?
Follower:	Because he invaded the SEC (Supreme Electoral Court)'s system.
Bolsonaro:	But didn't Barroso (head of the SEC say that the Court's system is inviolable?
Follower:	Yes, he did.
Bolsonaro:	But why is he in jail, then, if he didn't commit a crime? The evidence is clear!

Table 2. *Co-occurrence of activators and naturalized axioms*

Activator	Naturalized axiom		
	Hidden forces act against Brazil's development	There are ways to fight those forces	The Left can ruin Brazil
Schemata	28	10	29
"Socratic" dialogue/rhetorical question	15	2	12
Contrasting cases	3	0	10

A coordination class and its naturalized axioms

Our analysis identified one coordination class that pervades a significant part of Mr. Bolsonaro's speech: *"Bolsonaro is the best resource we have to avoid Brazil's downfall and the rise of communism."* Although this coordination class might sound like an acceptable political stance, a closer look at its underpinnings reveals that this "truth" is constantly reiterated and justified by naturalized axioms, taken-for-granted assumptions that, at the very least, resemble conspiracy theories. For example, one of the naturalized axioms is founded on the belief that there are *secret*, non-patriotic forces hindering the president's efforts to lead Brazil to greater development. The trio of excerpts below, stated by Mr. Bolsonaro, shows an example of naturalized axioms in practice: (1) a supposed conspiracy (*a hidden force*) against his plans to implement a so-called "verifiable ballot" (an alternative term to print voting system), (2) how this supposed plan has been devised by leftist leaders (*the Left can ruin Brazil*), and (3) the successful implementation of that plan would mean his defeat in the elections (*one way to fight the hidden forces* is to implement electronic ballots):

> *Excerpt 1:* Why, after Justice Barroso visited the House and spoke with party leaders, did these leaders replace their parties' representatives in the verifiable ballot committee, so that the print voting system sank? Why? Elections that are not clean, that are not transparent, <u>are not elections</u>. What we want is to avoid problems in 2022. Will we have elections? We will (have) clean elections. (2021, July 22)
> *Excerpt 2:* The people who took Lula (former president, leftist) out of jail and made him eligible again are the same people who will secretly count the votes inside the SEC. I'm not insulting Justice Barroso, I'm showing the truth! (2021, July 19)
> *Excerpt 3:* We have, for example, a Supreme Court Justice against transparency in the elections [...] As the old adage, the leftist adage goes: *the ones who count votes are the ones who win the elections.* This is what we have under way for next elections. (2021, July 20)

Bolsonaro's theory building starts with few assumptions, and progresses to making the final claim that there is a movement in course to "steal" the elections. *But he does not simply tell it to followers, instead, he takes them for a complex "theory-building ride."* First, there is the suggestion that Justice Barroso is violating the Constitution and deviating from his proper legal role by lobbying against the verifiable ballot bill. Second, the president implies that the "verifiable ballot" is the only way to ensure "clean" elections (second excerpt) and that the current electronic voting system is corrupted (elections that do not happen accordingly to his formula <u>are not elections</u>). Third, he adds that freeing former President Lula was another piece of this elaborate puzzle to steal the election–which he is helping people uncover. He concludes by associating Barroso with a "a leftist affair" in the elections. In our analysis, we found other examples that imply these types of nefarious associations between congresspeople, mainstream media, and the Justice system.

Conclusion and discussion

Our data show that Mr. Bolsonaro employs powerful cognitive strategies similar to those studied in the learning sciences, guiding his followers through an apparently efficient knowledge building process. Instead of simply stating that "elections will be stolen," Bolsonaro makes available a complex set of facts and assumptions that most likely will lead to his desired outcome. Thus rather than statements, he offers "templates" that support people in their understanding of current political affairs, and engage in Socratic dialogue with followers, techniques that are employed to "activate" a coordination class (that borders on conspiracy theories) and ensures loyalty among a consistently significant number of voters in Brazil.

Ironically, these strategies are frequently recommended by scholars in the learning sciences as mechanisms to enhance learning in classrooms. The fact a populist leader is engaging in collective knowledge building with followers using these advanced educational strategies offers a counterintuitive explanation of how they can convince followers about flawed theories to legitimize their controversial (and disastrous) programs. One implication of this preliminary research is that our development as citizens possibly requires a deeper understanding of mechanisms employed by contemporary political discourse that borders, feeds, and taps into conspiracism. Additionally, this complexifies the apparently simple idea that if people have access to more years of schooling, we will be successful in fighting disinformation. *Rather, our educational systems might have to do more than the "instructionist" business as usual,* and help learners strengthen their metacognitive skills, engage in deep cycles of inquiry throughout their school life, and become more aware of situations in which processes of critical thinking and theorizing about political affairs are being manipulated to advance harmful theories. As educators and researchers, it is our role to investigate how to avoid irresponsible exploitation of human's powerful capacity to build robust theories and make sense of complex phenomena even with faulty building blocks.

"Do I need to know what I am doing if I am the teacher?" Developing teachers' debugging pedagogies with physical computing

Colin Hennessy Elliott, University of Colorado, colin.hennessyelliott@colorado.edu

Abstract. This paper presents findings from a study of middle school science teachers' professional learning activities designed to support the development of their debugging pedagogies. In two iterations of a professional learning activity, teachers worked to find bugs planted by facilitators in physical computing systems they were learning to integrate into their middle school science classrooms. We examine how teachers navigated the tension between developing their own troubleshooting skills versus supporting students' skills in resolving inconsistencies between what they expect of the DaSH and what it actually does. We conclude with implications for the design of PL activities for supporting teachers' debugging pedagogies.

Introduction

There is a concomitant need for designing instructional approaches and tools that integrate computational and data practices into middle school science. As part of a multi-year research practice partnership, our team iteratively co-designed a sensor-based physical computing system, the Data Sensor Hub (DaSH), and accompanying curricular units. The DaSH integrates low-cost programmable sensor technologies to support students in a range of computational activities with data (Gendreau Chakarov, et al., 2021). In the accompanying units, students encounter problems with the DaSH, or bugs, and need to troubleshoot, or debug. For moments of material resistance (Manz, 2015) when the DaSH is not operating as students expect, teachers require pedagogical skills to help students resolve their observed issues and develop their own debugging approaches for future work.

This paper explores how teachers, most of whom do not feel comfortable programming themselves, develop pedagogies to support students to expand their debugging skills. We examine how teachers navigated the tension between developing their own debugging skills and supporting students' learning by analyzing two iterations of a professional learning (PL) activity. In the activity teachers worked collaboratively to find bugs planted by facilitators that commonly occurred in prior classroom implementations. Analyses were guided by the following research questions: RQ1) How did teachers approach debugging in two iterations of the PL activities? RQ2) To what extent did the PL activities foster teachers' evolving debugging pedagogies?

Conceptual Framework: Learning to teach debugging as a situated inquiry

We characterize debugging a physical computing system like the DaSH as a situated inquiry, which "cannot be reduced to pre-specified plans or generalizable procedures" (Flood, et al., 2018; p.1405). Bugs are interactionally produced through a public recognition of an inconsistency between a working expectation of the DaSH and the DaSH's output. Debugging, therefore, requires constructing an expectation, interpreting the DaSH's output, identifying the inconsistencies between the two, and taking action with the system. Debuggers construct expectations of the DaSH by layering inscriptions (Latour, 1986) of the physical system and representations of the environment it interacts with. Inscriptions are physical representations (e.g. charts, graphs, labels) of a process (or physical phenomenon) that social actors use and remake to communicate developing knowledge and associations. The computer program is an inscription of the DaSH's operation while wiring diagrams are inscriptions of the physical setup of a working DaSH. Facilitating students learning to debug as a situated inquiry requires that teachers have flexible knowledge of the physical computing system as well as pedagogical practices. These include teaching moves of modeling and supporting thinking strategies, questioning agendas, and reflecting on applied strategies (DeLeima, et a., 2019).

Methods, Data Sources and Analysis

Teachers in two school districts participated in ongoing PL activities toward implementing instructional units in which students ask questions about environmental phenomena and use the DaSH to measure and visualize data to

 © ISLS

investigate them. The DaSH is a physical computing system consisting of a micro:bit (microcontroller), a gator:bit, and several physical environment sensors which can be programmed using a block-based programming language to collect and display data using sound, an array of LEDs on the micro:bit, and a row of five LEDs on the gator:bit.

This study examines two iterations of a PL activity where teachers worked together to find bugs that students commonly encountered (columns 2 and 3 in Table 1). In the PL, participating teachers worked in groups to find and fix systems with planted bugs (building on Fields et al., 2021) and discussed how to support students. This builds on a "student hat – teacher hat" approach where teachers experience an activity as students would and then consider the teacher perspective.

Analysis centers on a group from both iterations: Episode A involved three participants (Brett, David, and Grace) from Iteration 1. Episode B involved two participants, Aaron and Chris from Iteration 2. Both groups were given the same planted bugs. The activity was designed for participants using the soil moisture sensor to get the DaSH to display a smiley face when the moisture level was ***high***, and an 'X' when the level was ***low.*** Participants were given a DaSH with two bugs: the wrong program was downloaded onto the micro:bit and the correct program listed the soil moisture sensor's connection to the gator:bit on the wrong PIN.

Table 1.
Overview of debugging PL from two iterations and a proposed third iteration detailed in Conclusion

PL Objectives	Participants practice, observe, and discuss how to facilitate debugging moments that students encounter with the DaSH during the Sensor Immersion Unit.		
	PL Iteration I	**PL Iteration II**	**Future PL Iteration III**
PL method, teacher role	Teacher & student hat	Student hat	*Round 1:* Student hat *Round 2:* Both, mostly teacher hat
PL method, participation	Participants rotate through roles as teacher and students pair programming (driver & navigator)	Participants debug together, no official pair programming roles	*Round 1:* Pair programming *Round 2:* Pair in teacher hat supporting the third
PL group size	Groups of three	Groups of two	*Round 1:* Groups of two *Round 2:* Groups of three
Post PL reflection	Whole group discussion focused on debugging with students	Brief whole group discussion that mainly highlighted what bugs people encountered.	*Round 1:* Reflect on debugging strategies *Round 2:* Reflect on debugging pedagogy
Timing	30 minutes of debugging 20 minutes of discussion	20 minutes of debugging 10 minutes of discussion	*Round 1:* 30 minutes *Round 2:* 60 minutes
Directions provided to participants	Teacher hat: One participant in role of teacher Student hat: driver and navigator pair programming	Given expectation for how program should work, told to fix the bugs	*Round 1:* Given notes about the program's expected behavior, told to fix bugs *Round 2:* Help teach debugging skills
Context provided	Participants were told planted bugs mirrored bugs students have encountered	Bugs were explicitly linked to specific lessons in the Sensor Immersion Unit	Bugs explicitly linked to specific lessons in the Sensor Immersion Unit
Challenges of debugging activity	Participants were confused about how those in teacher hat could help. Three minutes in, facilitators explained bugs to those in teacher hat	Because of time constraints, participants did not have the chance to move into teacher hat or adequately reflect on debugging pedagogy.	TBD: activity planned but not yet implemented

Table 1 shows PL activity structure in each iteration. After the first, researchers recognized that combining teacher and student roles created a complexity that would be better placed after all participants could participate as a student (see Episode A below). Researchers also found that providing participants with a written expectation of what the program was supposed to do (referred to as "Expectation" below) would create direction for debugging activities. Additional shifts were also required due to time constraints for PL in District 2.

We used two qualitative methods of analysis to address our research questions: interaction analysis (IA; Jordan & Henderson, 1995) and a grounded approach with inductive coding. To address RQ1, we analyzed video of teachers' debugging tracing the trajectories of inscriptions of the environment, the DaSH, and other resources. We selected a few episodes to view, following the inscriptions teachers developed, used, and rejected to uncover their approaches to debugging. To address RQ2, we used an inductive coding scheme on the PL activity, whole group discussions, and supplementary data (interviews and surveys) to trace the representations of the role of the teacher. Focusing on where these representations unfolded, and where they did not, we developed a view of how the PL activities supported teachers in developing debugging pedagogies, which we address in the discussion.

Analysis

Episode A: Iteration 1 (Grace, David, Brett)

In 30-minutes, Grace, David, and Brett they got the DaSH to perform almost as expected by debugging as a group. At the start, Brett organized them into prescribed roles appointing David the navigator, Grace the teacher (which she initially balked at), and himself the driver. Thereafter, Brett was the only one to physically interact with the DaSH or change the program, limiting Grace and David's access to related and important inscriptions. Brett's interactions consolidated his access to the DaSH and therefore his role as the driver. David's moves supplanted

his navigator role as a support for Brett's investigation by, for example, offering the wiring diagram as a useful inscription. When approached by the facilitator to show her the planted bugs, Grace shared: "*Do I have to know what I'm doing to be the teacher?"* After hearing what the bugs were, she showed a new confidence, saying "*I know the answer.*" Knowing "the answer" dramatically shifted Grace's contributions. Before, she was tentative. Afterwards, she asked Brett to clarify his actions and gave encouragement like "you're on the right track."

In this first iteration of the PL debugging activity, the concurrent need to develop participants' roles (teacher/student and driver/navigator) had a determining impact on how the three teachers approached debugging. They positioned debugging as a distributed process where the driver has access to the DaSH and all possible inscriptions, the navigator offers next steps and resources, and the teacher (who knows what the issues are) clarifies and encourages. Brett's regular narration of his actions (e.g., "I can look through the code) and his thinking (e.g., "there's nothing on P10… so there's a problem") developed a representation of the process for his collaborators. Yet, Grace and David's access to important inscriptions were limited.

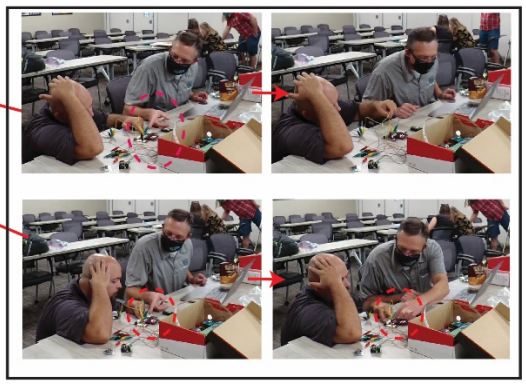
Episode B: Iteration 2 (Chris and Aaron)

In the second iteration of the debugging activity, Chris and Aaron worked without specific roles assigned and were given a written description of what the DaSH should do (*Expectation* below). In under ten minutes, they successfully got the DaSH's output to match the written Expectation. They initially took up distinct approaches to their collaboration: Chris narrated what he saw in the programming as compared to their Expectation and Aaron moved close to the DaSH and examined the physical setup. Collaboratively examining both parts of the system, Chris and Aaron determined the mismatch between the program's Pin and the Pin the sensor was connected to (Figure 3). They changed the program and downloaded the new program.

Figure 3

Transcript with screenshots of Chris and Aaron's production of a bug.

[10] Aaron: Whats::: It's supposed to be on Pin 10=
[11] Chris: =Hold it.
Umm::: According -- it say's get moisture on pin ten in moisture using power pin zero. ((leans to DaSH)). We're using power pin zero ((points to gator:bit)). And:: ((looks back to the computer)) moisture on pin ten, I don't know.
[12] Aaron: Is there a pin ten^. It just looks like one.
[13] Chris: I know there's a pin twelve ((points to micro:bit)). Pin two. Pin eight.
[14] Aaron: Sixteen, five eleven.
[15] Chris: So let's change it to different pin. And it looks like it's pin, one.



The excerpt in Figure 3 exemplifies the complex collaboration between Chris and Aaron. With Chris at the computer and Aaron at the physical setup, they layered inscriptions of the program, the Expectation, and the physical DaSH's wiring, finding the bug through joint work. For example, Chris' turn towards the setup in line 13 joined Aaron's location of the Pin (gesture during line 11) before he suggested they change the program to match the wiring (line 15). Their talk and gestures developed the association between inscriptions of the program and the physical setup to identify the issue. Generally, Chris and Aaron approached debugging as a collaborative, embodied process of collective noticing and decision making. While their emergent roles were somewhat static, they both had access to different inscriptions that, together, made clear what the issue was and what action to take to fix it. This experience has the possibility of developing pedagogies for both Aaron and Chris that support students building the embodied, and collaborative, skills of debugging such a physical computing system.

Discussion

Grace's question in Episode A ("do I need to know anything to be the teacher?") and her gained confidence once later knowing what the planted bugs were ("you're on the right track") highlights a key tension in learning to support debugging: teachers cannot know every issue that will arise and therefore need a different kind of confidence in supporting their students. DeLiema et al.'s (2019) teaching moves for supporting students each imply needing to know inquiry strategies, rather than the source of the issue. Offering teachers opportunities to work on authentic bugs created space for new teachers to develop inquiry strategies that they can model, prompt, and reflect on with their students. These strategies included different approaches to coordinating inscriptions of

the program and wired system (physical system and wiring diagram) and changing the conditions of the system to test. Strategies emerged differently due to differences in PL activity structures. Neither iteration adequately offered teachers opportunities to consider the in-the-moment moves that supporting debugging requires.

In Episode A, the group was asked to model teachers and students doing pair programming. This created varied opportunities for Grace, David, and Brett to experience debugging. Changes in the PL activity for the second iteration led to participants engaging in a more collaborative way with the DaSH, as shown by Chris and Aaron's embodied joint work of uncovering the bug (Figure 3). Post activity reflections confirmed this change: participants' discussion in District 1 revolved around strategies and resources (e.g. programming tutorials, wiring diagrams) they might use to help their students debug. Due to time constraints, discussion in District 2 included participants sharing what bug they found and how. Reflection surveys showed participants found great value in the activity. Yet, they had little time to translate their experience to an evolving debugging pedagogy.

Teachers indicated in surveys and interviews that they want more experience working with the system to gain relevant knowledge and practices. Supporting teachers requires a balance of helping them feel experienced with the technology and prepared to support students' developing situated inquiry skills even when a student comes to them with an issue they have never seen. In both PL iterations, the activity and facilitation foregrounded the importance of finding the bugs, rather than explicitly understanding the strategies participating teachers employed. The first iteration offered some room for participants to consider teacher moves but much less ability to develop their own strategies. The second iteration offered ample opportunity for Chris and Aaron to develop strategies for debugging but offered little experience considering how to engage with students' strategies. Our proposed third iteration (Table 1) offers teachers debugging experience and time to consider pedagogies.

Conclusions and implications: Planning a third iteration

Teaching debugging necessitates finding comfort in not knowing the answer. Professional learning experiences about debugging need to balance supporting teachers in developing debugging experiences and skills with the pedagogical dimension of supporting students to become independent and collaborative debuggers. Both dimensions are important and professional learning experiences should be explicit about which they address and when. Our third iteration addresses the need to support teachers knowing *the strategies* for students to take in-the-moment, not the source of the problem. Teachers need experiences engaging with practicing debugging to develop their own "perception and action" (Flood et al., 2018) so they have relevant experiences with embodied collaboration, noticing inscriptions and making flexible decisions, which is structured in Round 1 (Iteration III). Teachers can then leverage their experiences as they model, rehearse, and reflect on debugging pedagogies that support students developing debugging strategies and mindsets (Round 2), rather than giving them "the answer."

Caste and Queerness in Hindu India: Examining how Human-More Than Human Relations Shape Learning Spaces

Rishi Krishnamoorthy, Rutgers University, rishi.krish@rutgers.edu

Abstract: In the aftermath of the Section 377 judgement that decriminalized homosexuality in India, the positioning of Hinduism as historically welcoming and accepting of queerness has swiftly pervaded the Indian landscape. While a useful shift in the public sphere, the intersectional axes of caste, gender, and sexuality within everyday learning spaces is still fraught. In this paper, I examine how the cultural practices of caste-privileged and straight Indian teachers were privileged and shaped learning spaces. Drawing on Indigenous, queer feminist and feminist new materialist theories, the intra-action analysis methods developed in this study trace *how* dominant communities' ways of knowing become inscribed into the meaning that everyday objects in school spaces take on, making invisible, queer ways of knowing and being. This work offers an approach to examining precolonial histories that shape learning spaces in India towards fighting against the rise in Hindu nationalism.

Despite the Right to Education Act (Article 21-A) and state-wide reservation policies that require schools enroll students regardless of their caste and gender, intersectional forms of discrimination persist within schools in India. Briefly, rooted in the Hindu religion, the caste system divides human beings into four *varnas*– Brahmins, Kshatriya, Vaisya, and Sudras. These 'Savarnas' (with caste) are an inherited identity, distinguished in part by the level of purity their being is assumed to embody, with Brahmin cis-males considered the 'most pure' (Upadhyay, 2020). Those outside the caste system (e.g., the Dalit community) are considered 'Avarna' (without caste) and therefore 'impure' and 'untouchable' (Upadhyay, 2020). For centuries, Savarna communities have mobilized Brahminical ideologies around purity to enact horrific violence against Dalit communities, while simultaneously working to institutionalize caste, gender, and sexuality-based discrimination into India's sociopolitical, economic, and cultural spheres (Upadhyay, 2020).

Building on research that examines how Brahminical heteronormative ways of being are privileged and asserted as normative in India's sociopolitical and cultural spheres (Subramaniam, 2019), I examined human-MTH relations that shaped learning spaces. Specifically, I looked at how the cultural practices of Savarna and straight teachers at New School (NS) were positioned as normative (Hand et. al., 2012) and traced how this shaped learning spaces in ways that further oppressed marginalized communities. "Both caste and queerness are about who we can and cannot touch, intimately, privately, and publicly" (Chatterjee, 2018). As such, I recognize these forms of discrimination as a material practice whereby the MTH is deeply implicated in *how* Brahminical ideologies are (re)produced. I ask: *How do human-MTH relations contribute to positioning Brahminical and heterosexual ways of being as normative in school spaces?* Through the analysis I highlight the need for reform in everyday material-discursive practices within Indian schools as one way to fight against the rise in caste and sexuality-based discrimination.

Caste and Queerness at New School: The site of this study

NS was established eleven years ago as part of a township for families moving into the rapidly gentrifying rural area in South India, 2 hours from the closest city. At the time of this study, a large portion of the school identified as middle class families and Savarna castes, with none of the teachers openly identifying as queer. Barfi and Princess were teachers at NS who taught high school finance and psychology respectively. Barfi grew up a in middle class Tamil Brahmin family and did not face significant barriers in accessing an education. Her life was shaped through 'typical' expectations off middle class Tamil Brahmin women – prioritizing a marriage arranged by her family and only then pursuing a career. In contrast, Princess belonged to a Christian and caste-oppressed community from the North-East of India. The product of a matriarchal culture where women were very powerful and respected, being unmarried at 28 years of age (and therefore outside the gendered, heterosexual and Savarna expectations of women) was not an issue for Princess and her family. With Tamil and Brahmin ancestry, my positioning at NS was contextually dependent; I was an outsider to the school community and the country. However, my family's Brahmin lineage positioned me as an insider relative to knowledge of Tamil and Brahmin beliefs and practices. As a (then) unmarried 33-year-old who presented as female, Princess and I bonded through our desire to pursue a career over marriage. At the same time, I understood many of Barfi's cultural practices, having grown up within Brahmin communities in Tamil Nadu and Canada. I also learned to navigate the complexities of being a queer and genderqueer person within my family and the broader Brahmin community,

 © ISLS

"out of line" (Ahmed, 2006, p. 88) with the expectations of a cis-heterosexual Brahmin woman. At the time of the episodes analyzed, I was out as 'lesbian' to Princess and Barfi and as not out as genderqueer.

Theorizing Human-More Than Human Relations

Building on work that recognizes discrimination as a material, spatial and relational practice (Ahmed, 2006), I draw on theory that brings to the fore relations between (and within) humans and the MTH as the unit of analysis. Learning from Indigenous scholars (Bang & Marin, 2015), I build on practices rooted within India that decenter humans as an a priori individual unit and recognize the MTH as an active participant in interactions. Humans and the MTH world are not separated by an a priori static boundary. Instead, boundaries between entities are produced by enactments of power through material-discursive intra-actions. Here, I follow Barad's (2007) use of 'intra' versus 'inter' to recognize that humans and the MTH world do not 'inter'-act across a predetermined boundary. Instead, boundaries between entities emerge through power charged boundary making enactments when matter 'intra-acts' with(in) the world (Barad, 2007). Furthermore, meaning-making emerges through intra-actions within a world of non-static human-MTH phenomena, shaped through boundary-making enactments which are informed by human-MTH relations. In this way, recognizing knowledge creation as the process of engaging in intra-actions illuminates the human-MTH relations that "shape the contours of space" (Ahmed, 2006, p. 3), and the power charged boundary enactments that determine which human-MTH phenomena are allowed within proximity. As I illustrate through the data analysis, repeated power-charged boundary enactments shaped by human-MTH relations (re)produced Brahmin and heterosexual ways of being as normative in the space, what Ahmed (2006) describes as the product of repetition within the vertical and horizontal normative axes. I examined human-MTH relations that took "shape as the 'background'" (p. 88), whereby to deviate from the vertical and horizontal axes of "conventional genealogy" (p. 83) was to bring other human-MTH phenomena closer, "those that would not be allowed 'near' by straight [and Brahmin] ways of orientating" (p. 92) in the world (Ahmed, 2006). In the narrative that follows, I illustrate how Brahminical framings of heterosexuality emerged through human-MTH relations and arranged human-MTH phenomena with the goal of positioning Savarna ways of being as normative by resisting deviant 'acts' (Ahmed, 2006) that attempted to bring queer human-MTH relations and phenomena closer.

Documenting and Analyzing Human-Material Relations and Phenomena

Over six months, I engaged with field observations (Childers, 2013) both inside and outside of classroom spaces, and one structured intra-view (for this study) with each participant (Kuntz & Presnall, 2012). When conducting the structured intra-views, I built on Bang (2020), Marin's (2020), and Kuntz & Presnall's (2012) work to recognize the material world as part of co-constructing meaning-making. Building on micro-analytic interaction analysis (Jordan & Henderson, 1995) methods, 'intra-action' analysis (Krishnamoorthy et. al., 2021) revealed the ways in which different human-MTH phenomena – or intra-actants – intra-acted with each other. I paid close attention to audio recordings of moment-to-moment unfolding intra-actions by examining how human-MTH boundaries emerged through material-discursive practices. Then, I traced the consequences those boundaries had for knowledge creation – particularly whose ways of being were privileged within the ongoing activity. In the analysis, I paid attention to footing (Goffman, 1981) – the alignment of intra-actants with each other – to examine the different speaker roles (i.e., 'animator', 'author' and 'principal') that each intra-actant assumed, towards positioning certain ways of knowing as normative. Examining production formats contributed to identifying cultural frames emergent through the intra-action that allowed only particular types of human-MTH relations to shape the phenomena that emerged. The specific episode presented illustrates a 'hot spot' (Jordan & Henderson, 1995) in the data; a good example of how heterosexual Savarna ways of knowing were positioned as normative.

"I Just Wanted a Cool Nose Ring": Caste and Queerness at Snack time

This episode began when I entered the staff room during the morning snack break. Princess, Barfi, and a few other teachers were at their respective cubicles. I walked past Princess's cubicle and stood, leaning against a cubicle in the middle. Barfi was sitting in her chair by the wall and commented to me, "Look this is your, this nosepin is your grandmom's?"

In this moment, the nosepin emerged in the intra-action as a bounded material delineated as separate from my body and the surrounding matter through Barfi's utterance. I initially hesitated and explained that the nosepin was owned by "M.S Subbalakshmi" (M.S.) whom I authored as a "Carnatic singer", a "really old" and "dead" figure. Barfi and Princess's quick raised pitched overlapping utterances ["ha?", "why?", "you…how?] indicated surprise and shock at the nosepin-M.S. phenomenon that emerged through my utterance. Their reactions revealed a shift in alignment between the teachers and me, suggesting my utterance was a failure to provide the expected response that yes, the nosepin belonged to my grandmother. The intra-action, which began as a

seemingly casual question to me transformed into an unexpected and surprising material-discursive event through this intra-actional break. Princess further probed, specifically asking how *I/my body* came to be in relation with the nosepin-M.S. phenomenon. In response to Princess, I built on my previous utterance to repair (Schegloff, 1997) the shift in footing caused by the intra-actional break and authored the nosepin-M.S. phenomenon as "fake" and a "back up". Barfi didn't accept my efforts to position my relation with the nosepin as less significant through my authoring it as fake; which I authored to maintain the current footing amongst the other intra-actants. Instead, she continued to express her surprise with the nosepin-M.S. phenomenon. In a second attempt at repair, I then positioned myself as "not knowing the gravity" of this event and authored a story in which it was sensible that the teachers and I would not have a shared understanding about the importance of the nosepin-M.S. phenomenon.

The story I authored involved characters from my biological family whose connection with the story character M.S. and practices of material inheritance explained my relation with the nosepin-M.S. phenomenon. In the story, my aunt character – who did not have children – inherited and was wearing my great grand-mother's nosepin, and my siblings did not have their noses pierced so my aunt offered me the one she had received from M.S. In the story space-time, set in M.S.'s house, my aunt was drawn to M.S.'s nosepin and asked for it. M.S. rejected my aunt's bid for the nosepin entangled with her (M.S.'s) face but offered what M.S. authored as not the "real one". The nosepin offered to my aunt was positioned as fake because M.S. wore it when her "real one (was) getting cleaned". Here, I built on the repair initiated earlier to position 'fakeness' as determined by *when* the M.S. character was entangled with the nosepin she gave my aunt.

While listening to the story, Barfi did not challenge and therefore seemingly accepted the logic of inheritance and the history of human-MTH relationships that allowed me to be relation with the nosepin-M.S. phenomenon, revealing a taken-as-shared recognition of the straight vertical axis (Ahmed, 2006) that frames heterosexual genealogical inheritance within this context. Furthermore, Barfi did not challenge that the aunt character in the story space-time might be at the M.S. character's house and in a position to ask for an object of material significance (to the teachers in this context) from her. This is significant because the sociocultural and historic relations required to accept this story - specifically that the relationship between my aunt and M.S. might have existed and been intimate enough to allow my aunt to ask for and receive a nosepin reveals an acceptance of me (and my aunt) as someone with ancestral and current access to the largely Brahmin Carnatic music community.

A few minutes later, I then offered a bid to nuance how *I* was in relation with the Brahmin community through the nosepin-M.S. phenomenon by offering, "um. But I wear it because…". This attempt was not taken up by Barfi, who in overlapping Tamil utterances, continued to discuss the design of the nosepin with other teachers in the space. Then, a teacher who had just walked in paused when she heard the intra-action. She shifted her gaze, her eyes widened, and she reached over to my body and performed a movement in Tamil, referred to as '*otthikardhu*'. The act is often performed by touching the "eye or lip gently, after touching […] a revered or beautiful object" (Oxford University Press, 2009). This moment framed the MTH as sacred or that which was to be revered, further resisting my bids to shape *my* relation with the phenomenon. Once again, I attempted to refigure the nosepin-M.S. phenomenon as just "a really cool nose ring", but instead Barfi authored me at a "different level of respect now". That is, I was to be respected at a "different level" now that the sedimented framing of the nosepin-M.S.-Rishi phenomenon was aligned with a Brahmin-Carnatic music sociocultural and historic meaning. Importantly through the intra-action, my multiple bids to repair the intra-actional break initially and then contribute to meaning-making around *my* relation with the Brahmin community and the nosepin-M.S-Rishi phenomenon were ignored by the other intra-actants when not aligned with(in) this framing. My higher level of respect was emergent through and contingent on my position as a genealogical descendent and member of a specific Brahmin and Carnatic music community, and my entanglement with an object symbolic of those relations.

Heterosexuality, Brahminism and the Nosepin-M.S.-Rishi Phenomenon

Key to this analysis is that as a queer and genderqueer person, the ability to inherit valued materials and be a ratified member within the Brahmin community was also contingent on my gender and sexuality as invisible. Caste is inherited but only through the male lineage. As a queer, genderqueer, and (at the time) unmarried person, I was technically still considered a Brahmin with my membership in the community only accepted when hiding my queerness. Through the episode, the vertical axis of genealogical inheritance (i.e., inheriting from my aunt and M.S.) produced the nosepin-M.S. phenomenon as a heterosexual object "personalized as […] my background or as that which allow(ed) me to" (Ahmed, 2006, p. 88) be considered a human at 'one different level of respect now'. The sedimented framing of the nosepin-M.S.-Rishi phenomenon and the consequences of respect only held true when imposing Savarna heterosexuality as the background. As a queer and genderqueer person who is "out of line" (Ahmed, 2006, p. 92) with(in) the heterosexual Brahmin and Carnatic music community, my bids were evidence of my attempts to bring "other objects closer, those that would not be allowed 'near' by straight ways of orientating the body" (Ahmed, 2006, p. 92). In this episode, the heterosexual Savarna 'background' (Ahmed, 2006)

emerged through human-MTH relations that sedimented the nosepin-M.S.- Rishi phenomenon as a sacred material to be revered and me, as a human to be respected at 'another level', while silencing the queer 'slanted' frames.

In the aftermath of the Section 377 judgement that decriminalized homosexuality in India, the positioning of Hinduism as historically welcoming and accepting of queerness has swiftly pervaded the Indian landscape (Upadhyay, 2020). At the same time, this acceptance exists alongside caveats that consider queerness as "a 'psychological case' and queer relations (as) 'not compatible with nature'" (Sethi, 2018, as cited in Upadhyay, 2020, p. 472). Therefore, while a useful shift in the public sphere, the ways in which caste, gender, and sexuality intra-act within everyday learning spaces is still fraught. In this episode, the nosepin drew Barfi's attention the day I arrived at NS and did so once again when it entered the staff room the day of this episode. My Brahmin biological ancestry emerged through the nosepin's intra-actions and shaped the permitted human-MTH phenomena brought into proximity in the staff room space. Drawing on Kondaiah et. al., this episode illustrated that even though "no one talked about caste there […] everything gave (it) away" (2017, p. 75). In this case, my Brahmin biological ancestry emerged through the nosepin's intra-actions and shaped the permitted human-MTH phenomena brought into proximity in the staff room space.

Dalit feminists have long argued that the intersections of caste, gender, sexuality, and class cannot be ignored when working towards dismantling Hindu supremacy in India (Pawar & Moon, 2008). This paper builds on their work by illustrating that resisting the power of Hindu majoritarianism in education requires more nuanced analysis of how our learning spaces are shaped with/through human-MTH relations. I argue that resisting the power of Hindu majoritarianism in education requires more nuanced analysis of how our learning spaces are shaped with/through human-MTH relations by challenging Brahminical heteronormative framings of human-MTH phenomena that privilege Brahminical ways of knowing.

Museum-Led Design of Student-Centered K-12 Learning: Where Informal Perspectives Meet Formal Requirements

McKenna Lane, mllane2@illinois.edu, University of Illinois at Urbana-Champaign
Catherine Dornfeld Tissenbaum, catdoti@illinois.edu, University of Illinois at Urbana-Champaign

Abstract: Many museums create educational content for K-12 students and classrooms, bringing informal learning opportunities to formal educational contexts. The design considerations prioritized by these teams and the assumptions that influence these priorities impact the final product they create. In this paper, we describe how a museum-based design team created a learning module for use in K-12 classrooms. We report our analysis of five design team meetings and five individual semi-structured interviews, spaced strategically throughout the design process. We share what design considerations the team prioritized over time and highlight how team members verbalized assumptions about student-centered learning.

Introduction

Museum education departments are charged with carrying out the educational mission of museums, which often involves the design of activities, and materials for K-12 students and teachers. These learning experiences leverage museum collections and informal learning pedagogies while supporting and/or meeting educational standards (Feinstein et al., 2013; Garcia, 2012; IMLS, 1996; Kisiel, 2014; Kristinsdóttir, 2017).

For interdisciplinary teams of educators, curators, and researchers developing learning experiences, their design processes incorporate explicit and implicit assumptions and values about K-12 student learning (Garcia, 2012; Kisiel, 2014). However, these values and assumptions are not always visible, and different interpretations of the same concept may exist within the same team, especially with varying expertise on an interdisciplinary design team. Creating greater transparency into these design processes, and especially assumptions about student-centered learning, can help design team members to understand how they communicate and prioritize design considerations when making decisions that impact students and teachers.

To better understand how the assumptions of design teams influence the development of K-12 learning experiences, we examined how a museum-based design team developed a new inquiry investigation. Our goal was to identify the team's key design considerations and changing prioritizations based on analysis of meetings and semi-structured interviews. We also aimed to identify assumptions about student-centered learning based on team members' language about situating themselves in the minds of students.

We used values-led participatory design (Iversen et al., 2012) to identify the underlying values and assumptions that drove prioritization of design considerations and justifications. In examining how power is distributed among stakeholders, values-led participatory design specifically attends to stakeholders' values and their influence on the design process. In this study, we examined how individual design team members revealed their values and assumptions about science learning during meetings and interviews, with specific attention to the design considerations in play; the prioritization of different considerations over time; and the language used to communicate how team members situated themselves within the mind of a student. While the team under study did not actively invite students and teachers as co-designers, we found this lens helpful as a way to identify the values present and how those are shaping the design of the learning experience.

Methods

The design team at a museum in the American West has collaborated for approximately four years and consists of eight members. All team members agreed to take part in this study. The team's design efforts focus on an initiative about developing inquiry-based investigations for K-12 students and teachers that support engagement with NGSS science and engineering practices, especially gathering and analyzing data. Students receive guidance from museum scientists as they gather data and analyze data from digitized museum specimens, models, and simulations. Together, the activities incorporated into these investigations are designed to mimic the work of scientists at the museum as "authentic" science learning experiences.

The first author is an established member of the team and obtained consent to record team meetings over Zoom. She also conducted semi-structured interviews with one team member each week on a rotating basis. Interviews lasted an average of 20 minutes and included questions about how they felt the meeting went, what ideas stood out to them, and how decisions made during the meeting would impact the product and eventual users.

From video recordings of team meetings and interviews, we used informed grounded theory to develop a coding scheme that identified design considerations across meetings (see Table 1 below) as an extended design

 © ISLS

process (Derry et al., 2010). We selected five meetings and five interviews at regular intervals between May – November 2021 for binary coding of design considerations (i.e., discussed or not), then calculated the total frequency of codes across meetings and interviews. We created a CORDTRA diagram to show how prioritization of design considerations changed over time. Last, we identified quotes from team members that reflected their perspectives on student-centered K-12 learning as shared during meetings and interviews. These quotes illustrate how team members situated themselves in the mind of a student, and thus may indicate underlying assumptions and values about student-centered learning.

Table 1
Coding Scheme for Design Considerations Emphasized by Museum Design Team Members

Code	Description	Example
Student interest	Considerations about how to motivate and measure student interest.	"What makes it really fun and highly engaging?"
Student prior knowledge	Questions or statements about what students already know about the topic of the investigation.	"It feels like there are a set of questions that we could ask that would help us glean interest level, misconceptions, potential scaffolds that are necessary."
Student reasoning	Considering students' scientific and/or mechanistic reasoning processes while brainstorming and planning learning tasks.	"What would that allow [students] to conclude?"
Relevance to students	Looking for ways to integrate and highlight connections between a topic or activity and students' lives.	"Create some personal connection to it. You know, you need energy to survive, how do you get it?"
Authentic data and methods	Emphasizing the value of authentic science data, practices, and research method in the design process and in learning activities.	"What we are making is authentic. Whatever we ask students to do will be well-reasoned and authentic."
Alignment to NGSS	Alignment to Next Generation Science Standards (NGSS) and related state education standards.	"Science teachers are married to their core, to the NGSS standards…If you stray too far from that, they won't see the connection."
Constraints on scope/scale	Mentions of the ways that project resources and requirements constrain design.	"We're still negotiating where the [investigation] data is coming from."

Findings

Our findings are presented as three components: design considerations; temporal analysis; and student-centered perspectives. Table 2 reports the frequency of each design consideration across meetings and interviews. We found that "authentic data and methods" were mentioned most often (80% of meetings, 60% of interviews) by team members. "Student reasoning" was another frequently occurring design consideration (80% of meetings, 40% of interviews), as well as "alignment to NGSS" (60% of meetings, 40% of interviews). These considerations seem to be high priority to the design team. We also noted that several design considerations were mentioned in meetings or interviews, but not both. For example, "student prior knowledge" is discussed in 40% of meetings but no interviews, and "constraints on scope/scale" are discussed in 40% of interviews but no meetings.

The CORDTRA diagram (Hmelo-Silver et al., 2009) in Figure 1 below shows emergent design considerations in meetings and interviews over time. Overall, more design considerations are present in later meetings and interviews, with all design considerations appearing in the most recent two meetings and interviews. "Authentic data and methods" frequently occurred at each stage in the design process, both for meetings and interviews. "Student reasoning," another high-priority design consideration, appeared consistently in meetings. Though "alignment to NGSS" emerged as high priority, its discussion was late and inconsistent across meetings. We also examined how less frequently mentioned design considerations were discussed over time. "Student interest" was discussed in the May, July, and August meetings, but then was not discussed until the November interview. An earlier focus on "student interest" may have been replaced with greater emphasis on "alignment to NGSS" as the team decided on a topic and progressed toward active design of the investigations. "Student prior knowledge" was discussed during September and October meetings. "Relevance to students" was discussed in August and September meetings but did not occur otherwise. "Constraints on scope/scale" were discussed only in interviews for October and November.

Table 2
Frequency of Binary Codes Discussed During Meetings and Interviews

Code	Meeting Frequency	Interview Frequency	Total Frequency
Student interest	3	1	4
Student prior knowledge	2	0	2
Student reasoning	4	2	6
Relevance to students	2	0	2
Authentic data and methods	4	3	7
Alignment to NGSS	3	2	5
Constraints on scope/scale	0	2	2

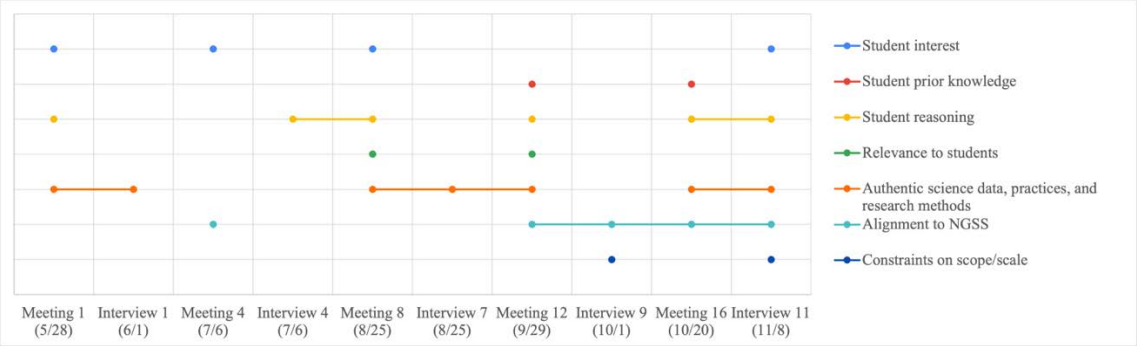

Figure 1
CORDTRA Diagram: Design Considerations Over Time

In analyzing team meetings and interviews, we noticed that design team members used specific language to indicate that they were taking on a student-centered perspective in their design considerations based on their assumptions of students' academic needs. The first two quotes below show how team members imagined each other or themselves as middle school students. The third quote illustrates how team members made assumptions about students' prior experiences with the investigation topic. The fourth quote shows how team members projected their understanding about students' capabilities regarding a given topic.

> Can you pretend like I'm a middle schooler actually? (Meeting 16, 12:33)
>
> As a student, I might look at that and be like, "Oh, that matters…" (Meeting 16, 1:33)
>
> I think students are used to thinking of tree rings for growth. But I don't know that they've ever really thought too much about the age, climate, related sort of health and, you know, robustness of the tree. (Meeting 16, 27:12)
>
> When I think about what a student could possibly walk away with… (Meeting 16, 29:08)

In these meetings, team members referenced what they think students feel, want, and need based on their range of personal and professional experiences. In turn, team members used these experiences to guide their interpretation of scientific information and the construction of learning tasks for students. These assumptions and interpretations ultimately impacted discussions of design considerations and decisions about design elements.

Discussion & Conclusion

Museum design teams are uniquely positioned to contribute to K-12 learning spaces by designing learning experiences that incorporate informal institutional assets. This study aimed to investigate a museum-based interdisciplinary design team's identification and prioritization of design considerations discussed during team meetings and individual interviews when creating inquiry-based investigations. We also noted language that indicated how team members situated themselves in the student role as a way to express and justify design decisions. In our analysis of selected meetings and interviews, we found that the team most frequently prioritized "authentic data and methods," followed by "alignment to NGSS" and "student reasoning." These design considerations became a greater focus of discussion later in the design process.

The emphasis on "authentic data and methods" and the "alignment to NGSS " throughout the design process illustrate two key goals of both formal and informal science education: authentic experiences and

 © ISLS

baselines for science understanding. Prior literature notes the importance of considering formal education contexts and assets when planning successful cross-over experiences between formal and informal learning environments (Garcia, 2012; Kisiel, 2014). The inclusion of NGSS alignment as a goal results from experience working with and designing for K-12 teachers and students. Meanwhile, "authentic data and methods" draws upon the team's experiences as informal educators and unique strengths of the museum's collections and scientists. The emphasis on both authenticity and educational standards in team meetings and interviews illustrates how the team considers both formal and informal learning assumptions and requirements. This finding highlights museums' role as spaces that blur the lines between formal and informal education settings (Kisiel, 2014; Kristinsdóttir, 2017).

As an interdisciplinary team, different team members have different experiences with both formal and informal education settings and likely hold different assumptions related to teaching, learning, and design. These assumptions became apparent in team meetings and individual interviews. For example, "authentic data and methods," "alignment to NGSS," and "student reasoning" appeared frequently throughout meetings and interviews, indicating that these are important design considerations for the whole team. In contrast, "constraints on scope/scale" appeared in two interviews, indicating that this design consideration may be more salient for some team members than others. The differences in assumptions held by team members mean that the common goal of designing student-centered experiences may be interpreted and acted on in a variety of ways, ultimately impacting the final product and its users (e.g., K-12 students and teachers). These findings have implications for other design teams situated in environments that span informal and formal learning. Future analysis of team data will use discourse analysis of negotiated meanings and their relationship to assumptions used to guide design decisions.

While this museum design team's approach does not explicitly incorporate participatory design, it does connect stakeholders representing different values, experiences, power dynamics, and goals to collaboratively create a product (Bang & Vossoughi, 2016; Kristinsdóttir, 2017). This attempt to democratize the design process is characteristic of participatory design projects and, in this way, the project resembles some of the challenges and opportunities that come from participatory design approaches. The lens of values-led participatory design highlights whose ideas are being heard, and whose are not, and draws on the ways values are being represented and influence the design process and products in ways that will ultimately impact the users.

In conclusion, this study provided insights into the design considerations prioritized by a museum design team and the ways that underlying assumptions about student-centered learning were expressed throughout different points in the design process. These insights serve as a first step toward deeper analysis of team members' discourse that shapes how design considerations are introduced, negotiated, and implemented. We plan to investigate how design considerations that appear to be the same on the surface (e.g., "alignment to NGSS") can be interpreted and applied differently based on the experiences and assumptions of individual team members. Understanding the underlying assumptions about and negotiation of design considerations can show a path for moving more intentionally towards shared consensus that benefits the design team members and eventual users.

Comparative analysis of the rule-based and machine learning approach for assessing student reflections

Ahmed Ashraf Butt, Purdue University, butt5@purdue.edu
Saira Anwar, Texas A&M University, sairaanwar@tamu.edu
Ahmed Magooda, University of Pittsburgh, aem132@pitt.edu
Muhsin Menekse, Purdue University, menekse@purdue.edu

Abstract: This study describes Natural Language Processing (NLP) and rule-based algorithms used to assess the students' written reflection quality. We used the CourseMIRROR application to gather student reflections from 120 engineering students and converted the reflections into an equivalent quality score using human coders and algorithms. We used Cohen's kappa statistics to explore the agreement between the algorithm's reflection quality and the human coding. The results revealed a strong agreement between the NLP algorithm and human coding. Furthermore, we used Spearman correlation statistics to evaluate the relationship between the predicted quality scores and the human coding. The results showed a strong correlation between reflection quality evaluated by the NLP algorithm and human coders. Overall results revealed that the NLP algorithm embedded in the CourseMIRROR application is a good fit for assessing students' reflections and can be used to guide them during the reflection writing process.

Keywords: Reflection quality, scaffolding, mobile application, learning environment, reflection specificity, NLP algorithms, rule-based algorithm

Introduction

Fostering reflective thinking is an important instructional practice (e.g., Bannert, 2006; Stark & Krause, 2009). It involves students in a meaning-making process that helps them make connections between their prior knowledge and learning experiences, deliberately systematizing their thinking with an attitude of valuing themselves and others in a community (Dewey, 1933). Studies have shown that the reflection writing practice can promote students' engagement (Menekse et al., 2020), help them identify their misconceptions (Tawde et al., 2017), and improve their learning outcomes (Miller & Jensen, 2016). Fan et al. (2015) developed a mobile application (i.e., CourseMIRROR) that gathers students' reflections by prompting them to reflect on their experiences after each lecture throughout the semester to facilitate the integration of reflective practices in the classroom. Also, it provides real-time feedback by assessing the reflection quality during the reflection writing process and guiding users towards writing specific rather than generic reflections. Here, the reflection quality indicates the extent to which the reflection is relevant to the reflection prompt and the course.

This study describes two quality prediction algorithms (based on Natural Language Processing (NLP) and a rule-based approach) that can be used to improve the application's ability to evaluate the students' reflection quality. For the study, we collected students' reflections using the CourseMIRROR application and converted the reflections into the equivalent reflection quality scores coded by two human coders. Then, we explored whether the reflection quality assessed by the NLP algorithm and the rule-based algorithm is similar to the reflection evaluation conducted by human coders. Specifically, this study is guided by the following research question: how does the reflection quality assessed by two quality prediction algorithms relate to human coding?

Related work

Based on the reflection literature, the commonly used method to evaluate reflection writing is through content analysis (Ullmann, 2019). A typical content analysis process includes 1) reading students' reflections, 2) manually labeling them with self-described categories, and 3) converting these categories into quality scores of the reflection. Furthermore, the focus of prior studies using content analysis was to identify the level of reflection quality (i.e., shallow or deep reflection) by analyzing students' reflection journals and essays (Kovanović et al., 2018). Hence, researchers are exploring ways to automate this reflection process and facilitate the adoption of reflective practice.

Researchers are utilizing computational advancements to design automatic text analytics for assessing the students' reflection texts among the ongoing efforts. According to Ullmann (2019), these text analytics are being designed by broadly using three approaches, i.e., dictionary-based approach (find the occurrence of predefined words in the text), rule-based approach (using the rule to get better inference from the text), and the machine learning (ML) approach (using ML algorithms). Based on the previous approaches, this study utilized two algorithms 1) Rule-based algorithm where the expert has defined the pre-set pattern and their associated

 © ISLS

weightage, and 2) NLP algorithm trained on different educational reflection sets. Further, this study investigated the relative efficacy of these algorithms in the reflection quality.

Participants and dataset

We recruited 120 first-year engineering (FYE) students enrolled in a required engineering course from a large midwestern university located in the United States for the study. The topics covered in the course were introductory computer programming concepts, development of mathematical models, data visualization, and designing solutions for engineering problems. Of the participants, 83% were male students, and 17% were female students. Also, 61.7% were White, 21.7% were International Students, and 16.6% were People of Color (POC). Furthermore, the dataset used for this study consists of 3452 individual reflections from 28 lectures.

Instrument

We used CourseMIRROR educational application to collect students' reflections. This application prompts students with two open-ended questions to reflect on the confusing or interesting concepts at the end of each lecture. Additionally, it uses Natural Language Processing (NLP) algorithms to create students' reflections summaries by combining the reflections based on common themes (Luo et al., 2015). For the study, students voluntarily participated and submitted 3452 reflections (i.e.,1726 reflections for each question) in 28 lectures throughout the semester. Furthermore, these reflections were analyzed by two human coders based on a rubric (Heo et al., 2018; Menekse et al., 2011) and then assigned a quality score. We calculated the agreement between the two raters, and they showed good agreement, as κ (MP) = .617 and κ (POI) = .652 (Altman, 1990).

Reflectivity quality models

Following are the two approaches used to design the quality prediction algorithms that are used to assess the reflection quality:

Machine learning approach

In this approach, we utilize recent SOTA models in NLP to automatically produce a quality score. Our work uses a basic model consisting of a feature generation module followed by a classification module for score generation. In order to generate features, we used a transformer-based bidirectional deep contextual language model to automatically generate features. The module operates on the raw input text and automatically converts the text into numerical features. We used DistilBERT (Sanh et al., 2019) model for feature generation. The model is a distilled version of the original BERT (Devlin et al., 2018) transformer-based encoder. DistilBERT reduces the number of parameters to around 60% of the original BERT (110M to 66M). This, in turn, allows the model to be faster and more suited to real-time quality prediction. We used a logistic regression classifier for the classification module that operates on the generated features and produces a score of 1, 2, 3, or 4. We only train the logistic regression classification module and keep the DistilBERT parameters fixed. This can reduce the load required for training the model and similarly allows us to easily fine-tune the model with new samples acquired through time.

Rule-based approach

In this approach, a team of educational researchers defined a set of patterns and their associated weightage to score the reflection quality. Based on these rules, we designed an algorithm used to predict the reflection quality. Table 1 describes the few rules and their associated score used to design this algorithm:

Table 1
Rules with associated weightage used for rule-based algorithm

Number	Pattern	Quality Score
1	"how|what|when|where|which"	0.25
2	Keywords (extracted from the syllabus, and learning objective of the class)	1
3	"compare|comparison|difference|differentiating|determining|determination |relationship|relation|between"	0.29

 © ISLS

6	"^pretty clear|straightforward"	-0.6
7	"^everything|^nothing|^none|^nope|^null|^no$|^no\\s"	-0.6
10	“understood everything”	-0.6
11	"I|explanation|example"	-0.3
12	"this lecture|the lecture|all|completely"	-0.3

To evaluate the reflection quality, this algorithm parses the students’ reflections and uses regexes to count the occurrence of each pattern in the string. After that, it calculates the reflection quality by rounding off the sum of the associated weightage of each pattern based on their occurrence. Furthermore, we modify the predicted quality score to either 1 or 4, if the values go less than score 1 or more than score 4, respectively. This way, the range of the quality score is between 1 to 4 points.

Results

We divided the reflection into two sets: 1) reflections discussing the interesting aspects of the lecture and 2) reflections discussing the confusing aspects of the lecture. For the remaining paper, we will refer to the first set of reflections as “Reflections 1.0” and the second as “Reflections 2.0,” respectively. Then, we converted the reflections into the equivalent quality scores evaluated by NLP and rule-based algorithms. The quality scores range from 1 to 4 points, where a score of 1 indicates poor relevancy, and a score of 4 indicates high relevancy with the course/question. For analysis, we calculated Cohen’s kappa to evaluate the agreement between the human, NLP, and rule-based algorithm’s reflection quality scores. The result of the analysis is shown in table 2:

Table 2
Cohen’s κ co-efficient among the reflection quality scores

	Reflections 1.0			Reflection 2.0		
	1	2	3	1	2	3
1. Human coding	-	-	-	-	-	-
2. Rule-based algorithm	0.042	-	-	0.068	-	-
3. NLP algorithm	0.775	0.033	-	0.773	0.067	-

As shown in the table, it is quite evident that the NLP algorithm has a strong agreement while evaluating the reflection of both reflection sets (i.e., κ (NLP) = .775 and κ (NLP) = .773) with human coding. The rule-based algorithm has close to no agreement (i.e., κ (NLP) = .042 and κ (NLP) = .0.068) for both reflection sets with human coding. We conducted the Spearman Correlation statistics to further enhance our analysis to explore the correlation between reflection quality evaluated by the quality prediction algorithms and the human coders. The result of the analysis is shown in Table 3:

Table 3
Spearman correlation among the reflection quality scores

	Reflections 1.0			Reflection 2.0		
	1	2	3	1	2	3
1. Human coding	-	-	-	-	-	-
2. Rule-based algorithm	0.479**	-	-	0.435**	-	-

 © ISLS

3. NLP algorithm	0.837**	0.496**	-	0.859**	0.485**	-

**Correlation is significant at the 0.01 level (2-tailed).

The results showed that the correlation between the rating evaluated by the NLP algorithm and the human rating has a strong correlation for both sets (i.e., r = 0.837, 0.8359), with each having 1752 reflections. Even though the correlation between reflection quality scores evaluated by the rule-based algorithm has a strong relationship (i.e., r = 0.479, 0.435; N = 1752) with human coding, it is much lower than the NLP algorithm.

Conclusion

The current study has described two approaches that can be used to evaluate the students' reflection quality. One approach used the expert's defined pattern, and the other used the NLP algorithm to evaluate the reflection quality. This study investigated the performance of both approaches in terms of their ability to produce similar results to the human coders. Our results showed that the NLP algorithm based on the DistilRoBERTa and DistilBERT with SVM is a promising model to evaluate the reflection quality.

"Love Struggle, Love Self, *regardless**:" Arts Organization Leader's Use of Socio-historical Analytic Artifacts in Their Determinations of Successful Teaching Artists

Jalessa Bryant, University of Wisconsin-Madison, jnbryant@wisc.edu

Abstract: Black artists fill the (art)world with images, objects, sounds, and experiences that disrupt sociopsychological functions shaped by anti-Black racism (Fanon, 1952; Wynter, 1999, 2005; Gikandi, 2011). Learning in and through the arts has been a major vehicle for animating Black communities' resistance to dehumanizing experiences across space and time. Out-of-school time arts organizations serve as fugitive learning ecologies where creative risks can be taken up and celebrated as material and embodied forms of resistance. This paper details the ways three Black women-identifying out-of-school time arts organization (BW-OSTA) leaders use social analytic artifacts (Vossoughi, 2014) derived from an historical art exemplar to determine what makes a successful teaching artist. Using a socio-historical approach to re-mediation (Cole & Griffin, 1983) and risk (Lee, 2009), this paper tethers the politics and ethics of an exemplary Black artist to the determinations of successful teaching made by three contemporary BW-OSTA leaders.

Key terms: Learning in and through the arts, risk, resistance, socio-historical, social analytic artifacts, re-mediation, successful teaching

Introduction

As Sylvia Wynter (2005) stated, the invention of "Man" in modern humanism was made possible by ontological and epistemic violence that rendered Black people antihuman (p.128-129). Black arts and Black aesthetic movements have long served as interruptions to this violence, as the material, ideological and sonic creations provided opportunities to create habits of mind within but not of the structuring violence of enslavement and its afterlife. Acts of risk-taking and resistance to anti-Black violence that occur through learning in and through the arts can be seen in the New Negro Movement This generation of formal artists includes the life and works of Miss Augusta Savage, a sculptress, teaching artist, and community-based organizational leader. Her story is of vital importance for demonstrating the way Black artists have used the means of cultural production to engage the symbolic material of daily life to recreate self-representations without rearticulating dominant relations (Gaztambide-Fernández, 2013, p. 227) and the risks involved in those pursuits. Miss Savage's everyday applications of symbolic creativity to symbolic materials and resources throughout her life shaped her political and ethical commitments in important ways. As James Baldwin and Frantz Fanon have stated, "the purpose of an education is to learn how to live" (Baldwin, 1963) and "in the world through which I travel, I am endlessly creating myself" (Fanon, 1952/2008, p. 179). As Augusta moved through the (art)world, she recreated herself to meet the needs of her community.

Arts Organization Leader, Miss Augusta Savage

Miss Augusta Savage began sculpting animal figurine "friends" using red clay in her backyard at an early age. Born to a family of 14 children and two working parents, her father discouraged her artistic skill, believing it was sinful and refusing to acknowledge the practice as a form of psychic refuge for the introverted young girl. As a result of her mother's encouragement, Miss Savage moved from Florida to New York where she trained professionally and met, during the New Negro Movement, many of the greatest race scholars, artists, and activist in history. As an employee of the Federal Arts Program (FAP), an effort under the Works Progress Administration (WPA) to boost morale after the Great Depression (Lance, 1982), she was a fierce and demanding advocate for young people's artistic development and gainful employment for professional artists. After teaching some formal and community-based arts courses, Miss Savage opened the Savage Studio for Arts & Crafts in 1932, became the first director of the Harlem Community Arts Center in 1937, and opened the Salon of Contemporary Art, the first gallery in America devoted to the exhibition and sale of the works of black artists, in 1939 (Hayes, Buick, Cook, & Savage, 2018). Her accomplishments allowed for the Harlem community to have free and work-as-you-go art classes, student teaching experiences, gainful employment in the arts, and opportunities to exhibit and sell artwork in an all-Black gallery (U.S. National Park Service).

 © ISLS

At the height of her success, Miss Savage fell on hard times. The Salon for Contemporary Negro Art closed within three months of its opening due to a lack of artists, collectors, and a dedicated audience who could contribute to the consistent creation, sale, and growing discourse of art by Negro artists. The paranoia of the emerging era of McCarthyism positioned Savage under a great deal of scrutiny for her activities with young people. As Sharif Bey highlights in his 2017 article, Augusta was seen as a nuisance to a great deal of WPA administrators for advocating for Black artists to have more gainful employment opportunities under the FAP. She also helped establish the Vanguard Club, a youth arts and activism guild that was supported by well-known communists (Bey, 2017). With hesitant support from the government, the Harlem Community Arts Center and with federal funding for the arts slowly being reallocated to war efforts, Augusta's professional and personal investments seemed to disappear from the public view.

Her latest piece was created in 1959, three years before she passed, while living in Saugerties, NY. While in Saugerties, Augusta purchased and renovated a home with a farm and art studio that met her basic needs. The contours of her life, seemingly coming full circle are too uncanny to be by accident. From a small girl imagining a life amongst the animals to a now 53-year-old woman with her own farm, income, and space to work on whatever art she pleases, Miss Savage continued to blossom in her own self-determination to create the life she imagined as a child. She continued to teach and create art for 15 years. She was diagnosed with cancer at age 69 and passed away in the following year on March 30th (Hayes, et al., 2018).

Theoretical framework

Learning risk & resilience in and through the arts

In my use of a socio-historical approach to re-mediation, I position the thinking of each BW-OSTA leader deep "into the past to trace the basics of [racial] literacy all the way back to the beginning" (Cole & Griffin, 1983,p. 69), mapping the moments of consequential learning within and across temporal, social, and spatial scales of action (Gutiérrez, Engeström, Sannino, 2016, p.278) during slavery and its afterlife. The life of Miss Augusta Savage is full of acts of refusal, fugitivity, and escape- important habits of mind, or social analytical artifacts (Vossoughi, 2014) that necessitate a cultural-ecological framework of risk that locates consequential learning in and through the arts in the everyday practices of Black survival.

Learning to live while constantly (re)creating yourself is an expansive notion of learning through everyday activity. In the life and works of Miss Savage, we see the ways that learning in and through the arts is a consequence of dynamic, adaptive processes linked to issues of identity (Lee, 2009, p.78). In both the telling of Miss Savage's story and the survival of her artwork, the many modes of risk and resilience present in her psychosocial resources for arts-based praxis can be discursively situated as a precursor to those of contemporary teaching artists. Using the cultural-ecological framework for learning and development, I view Miss Savage and her creative praxes as ideological resources or habits of mind. In arts-based organizations, whose daily work continues to be fraught with refusals to anti-Black racism and celebrations of creative risk-taking and resilience, young people, teaching artists and organizational leaders continue to make sense of and respond to the on-going and emergent ways they experience historical inequality (Lee, 2009, p. 78). These responses are access points to knowledge pathways that reduce cognitive labor and provide support for learners to persist (Lee, 2009, p. 86).

These arts-based knowledge pathways are funds of knowledge (Gonzalez, Moll, Tenery, Rivera, Rendon, Gonzales, & Amanti, 1995) that have developed over and across time and are historical examples of expansive learning and boundary crossing (Engeström & Sannino, 2010, p. 13). Black people have learned and continue to learn about the antagonistic relationship between Blackness and humanity. I use a socio-historical approach to re-mediation and risk to demonstrate the ways BW-OSTA leaders in this study are accessing psychosocial resources from the past and locating their determinations of successful teaching artists in opportunities for creative risk-taking, escape, and refusal of anti-Black inquiries and methods. In the next section, we review our methods for analyzing these resource and knowledge pathways.

Methods

The conditions of the historical moment call attention to the ways those methods have been culturally produced in crisis. Data for this study was collected through Zoom interview due to the COVID-19 social distancing and travel restrictions. We use critical visual discourse analysis to analyze each BW-OSTA leaders' sensemaking in their mission statements and interview data, alongside analysis of their activities during the interview context. Analyzing the visual alongside the textual re-mediates the discursive practices of Miss Savage into the methodology for data analysis.

Through web content and audio-visual recordings of interviews, we used normative-evaluative reconstructions (Carspecken, 1996) to conduct a critical discourse analysis using web content and Zoom interview data. Through several rounds of low and high level concept and value coding followed by meaning field mapping,

we determined each leader's conception of "success," "successful teaching," and/or "successful teaching artists" to understand what politics and ethics shape their thinking. Depending on one's proximity to power and their positionality within arts organizations, organizational values held by leaders are shaped by the politics and ethics they have about "success."

Findings

In her focus group interview "R" names that she is very intentional about preserving the rich artistic history of Detroit, particularly their Motown legacy and names that successful teaching artists know of this history and reclaim it through their arts practices. She connects these ideas to the young people of the city by stating that a part of the vision of success is to retain them through their "neighborhood growth strategy," which includes promotion and celebration of "what we have in Detroit." These practices bespeak Miss Savage's efforts to maintain art, crafting, and gallery space for Black artists and enthusiasts in Harlem. Similar to Miss Savage, "R" created pathways to art space and community membership as a means for young people to risk reinvesting in an art identity as citizens of Detroit.

"J" states that her organization's mission is to "eradicate racism and its damaging effects." In her organization Teaching Artists (TAs) need to be cultural matches and understand the endemic nature of racism to work towards that mission. The idea of teachers needing to be cultural matches is a long-held belief (Clark & Brown, 1986; Carter, Karani, Jackson, Jackson, Lucas, Neckerman, Podolny, Pollock, Tyson, 2003) of Black educational spaces. It helps teaching artists navigate anti-Blackness and racism in ways that reach the young people they serve and reduce the risk of additional institutional and interpersonal harm. Considering the many intersectional identities young people have, TAs need the cultural capital to creatively negotiate ideological and institutional constructs of power. J's ideas about successful teaching artists operate alongside a history of cultural repertoires of practice (Gutiérrez & Rogoff, 2003) that protect youth who are multiply minoritized. This is a belief held by Miss Savage who supported the efforts of black youth group The Vanguard, who was supported and advised by known communists, despite the threat of McCarthyism. Miss Savage was very much aware of the risk of being willing to assist but knew of the importance of young people being able to speak their mind and receive the political education they desired to protect their mind, bodies, and spirits.

"S's" organization unabashedly mirrors the spirit of the owner, herself. The organization's mission is interesting in that it intends to "interpret and mirror culture and community, investigate race, gender, and personal identity in relations to *post*-Blackness" or this idea that Blackness itself is an identity that can be transgressed. The erasure of Blackness would mean that all systems dependent on race (i.e., humanism, capitalism) would cease to exist as we know them. By shaping an arts organization around trans-ontological ideas like a post-black world, TA success is identified in the embodiment of these ideas. TAs uplift the times where S's essence shines through in both their teaching and the youth's learning and engagement. In a similar, albeit humble manner, this form of embodiment relates to one of Miss Savage's most infamous quotes: "I have created nothing really beautiful, nothing really lasting, but if I can inspire one of these youngsters to develop the talent I know they possess, then my monument will be in their work" (Hayes et al., 2018). These curiosities towards post-Blackness in "S" & Miss Savage demonstrates a desire to transcend the oppressive reach of racial discrimination and embrace the cultural-historical methods that work towards achieving that.

Conclusion

This paper positions the historical activities of Augusta Savage in relationship with the political and ethical commitment BW-OSTA leaders make in their determinations of who is considered a successful teaching artist. Following Carol Lee's (2009) ecological model of multiple pathways for access to psychosocial resources, these political and ethical commitments serve as pathways that inform the ways leaders view successful teaching. As is a part of the long history of Black arts and Black aesthetic movements, the preservation of city history, cultural representation at multiple levels of engagement, and understanding the individual body and collective creative space as locations for embodied risk and resistance are important mediating artifacts for successful teaching in contemporary art organizations.

Moments of Pedagogical Feedback with Explanations: Interactional Foundations for Supporting Educational Dignity

Ruben Echevarria, Northwestern University, re@northwestern.edu
Lauren Vogelstein, New York University, lev226@nyu.edu
Ava Jackson, Boston University, abjackson93@gmail.com

Abstract: This paper explores pedagogical design processes of educational dignity by analyzing data across three learning contexts and configurations–a facilitator and student in a museum-based tinkering environment, a professional choreographer and dancers in their dance studio, and two students in a high school history class–to show how moments of feedback with explanations can contribute to the process of coordination in joint activity, invite meaningful participation, and support educational dignity. In particular, we present three case studies to illustrate two primary findings: (1) through moments of feedback with explanations, participants invited one another to embody forms of meaningful participation, and (2) these invitations to engage in meaningful participation created a collective, educationally dignifying conceptual space in which activity was continued forward. These findings offer developing insights into the *how* and *towards what ends* of designing for educationally dignifying learning environments, contributing to discussions on the revisioning of equitable education systems.

Continuing the Reimagining of Equitable Education Systems

In the U.S., we are experiencing a public contestation around the design of education contexts sparked in part by the pandemic and growing racial justice movements. Nasir, Bang, and Yoshikawa (2021) reflected on this moment as "a once-in-a-generation opportunity to make real progress toward a system of education that truly serves all students, providing the kinds of teaching and learning that enrich lives, spur innovations, and reflect a deep and abiding commitment to equity" (p. 54). As more districts move back to in-person schooling, we have the opportunity–and responsibility–to continue this reimagining by offering empirical analysis on the potential cultivation of equitable education systems in the 21st century.

We heed this call by exploring the pedagogical design processes of educational dignity; "educational dignity is the multifaceted sense of a person's value generated via substantive intra- and inter-personal learning experiences that recognize and cultivate one's mind, humanity, and potential" (Espinoza et al., 2020, pg. 326). Understanding educational dignity as an interactional and discursive achievement, we offer data across three learning contexts to demonstrate one way meaningful participation and educational dignity unfold and move activity–or learning–forward. Specifically, we attune to moments of feedback with explanations, which reflect moments of one person sharing their perspective, ideas, questions, or concerns on another's participation/activity using forms of narrative, descriptions, and definition. We argue that moments of feedback with explanations can contribute to processes of intersubjectivity in joint activity and serve as indicia of educational dignity. This finding offers developing insights into the *how* and *towards what ends* of designing for educationally just and dignifying learning environments, offering empirical examples that expand current and future discussions on the revisioning of equitable education systems.

Literature Review

As more research incorporates the needed political interrogation of the ways sociopolitical systems shape and reinforce oppressive hierarchies, we continue beyond this interrogation by asking what systems or values *should* guide the design and joint activity in learning environments. For those committed to the creation of equitable and just education, researchers have explored the different aspects of research that must be reconsidered: from the design of the research collaboration (Bang & Vossoughi, 2016), the organization of social structures (Gutiérrez, 2008), to the ways of seeing learning as interrelated social and conceptual processes (Vossoughi et al., 2020); the cultivation of equitable education requires a multifaceted, multimodal, multi-epistemological integration. Across these different categories, we see a consistent theme: social interaction. What is the role of social interaction in pedagogically uplifting and sustaining educational dignity?

Espinoza and colleagues (2020) provide a detailed framework for seeing educational dignity as social accomplishment mediated by meaningful participation. Dignity itself is not something that can be created or destroyed, everyone has dignity; rather, the goal is to design dignity-affirming learning environments that uplift and feed students' dignities. The emphasis on social interaction in the experience of educational dignity has been explored through axiological innovations (Bang et al., 2016), epistemic heterogeneity (Warren et al., 2020),

 © ISLS

embodied pathways (Vossoughi et al., 2020), and pedagogical improvisation (Jackson, 2021a). Across these works and others, researchers continually evidence educational dignity as an ethical process supported through the moment-to-moment interactions. As the Learning Sciences continues to build a diverse pool of empirical evidence on what educational dignity looks like in practice, in this paper we aim to contribute with new examples that additionally address *towards what ends* (Philip, Bang, & Jackson, 2018) these dignity affirming pedagogies work. The participants providing feedback across our three empirical examples not only provide feedback interactionally, responding to other participants in situ, but pedagogically structure their explanations in dignity-affirming ways. Surfacing the interactional structure of this pedagogical move across contexts and configurations is essential for continuing to cultivate equitable educational spaces.

Methodological Approach

This paper explores the following research questions: what did moments of feedback look like across three different settings organized around values of educational dignity? How did these experiences with feedback contribute to –if at all–the fostering of educational dignity? To answer these questions, we explore three different learning contexts drawn from each authors' individual research projects: between a facilitator and high school student in a museum-based tinkering environment (Author 1), a choreographer and dancers in a professional dance company (Author 2), and tablemates in a high school US history class (Author 3).

Although each data set was collected around different questions of learning and development, we took similar approaches in the development of data sources, which included developing field notes, video-recording participants' activities, and conducting interviews that foregrounded documenting interaction from a sociocultural perspective of learning (Gutiérrez & Rogoff, 2003; Lave & Wenger, 1991). Having the benefit of similar data sources, we aimed to answer our research question by drawing on Matusov's (1996) participatory notion of intersubjectivity as a process of coordination among participants in joint activity. With joint activity as the unit of analysis, we traced activity directions by dividing the video data into activity directions, and transcribing verbal and nonverbal actions, such as gestures, to explore the ways the participants structured the interactions (Erickson, 1992). Then, we analyzed how the qualities of feedback with explanations contributed to the process of coordination between participants to progress activity. We also analyzed how explanations served as indicia of meaningful participation and educational dignity in joint activity using micro-ethnographic analysis (Erickson, 1992). To this end, we looked beyond the binary of adult-centered and child-centered models of pedagogy and explored joint activity as a pedagogical practice where all participants involved were seen as active co-participants (Vossoughi et al., 2021a). Since intersubjectivity, meaningful participation, and educational dignity are distinct interactional achievements, our findings suggest that moving joint activity forward does not automatically imply that participants' contributions are taken seriously or that their full personhood is seen and considered. Similarly, affirming learners' dignity does not necessarily entail moving joint activity forward. Thus, our empirical contributions help reveal how these three notions can come together when participants in joint activity offer feedback to move activity towards more meaningful and just ends.

Findings

We present three case studies to illustrate two primary findings: (1) through moments of feedback with explanations, participants invited one another to embody forms of meaningful participation and (2) these invitations to engage in meaningful participation created a collective, educationally dignifying conceptual space in which activity was continued forward. The potential for pedagogical action to shape dignifying learning processes is an argument made by previous scholars (Vosoughi et al., 2020); through these findings, we offer both an extended view of what one pedagogical practice–feedback with explanations– mediated forms of educational dignity across different social configurations and organizations of learning. Furthermore, by offering examples from different data sets, we highlight the potential for this practice to further activity and extend the learning of not just the individual, but the collective experiencing of (and contributing to) educational dignity.

The first case study draws from a 16-week ethnographic study of a museum-based tinkering program for high school students called the FabYouth program (Echevarria, 2021). During an interaction between Gerard (facilitator) and Darrius (student), Gerard crafted an explanation that invited Darrius to think and learn about troubleshooting, the flow of electrical energy, the manipulation of the flow of electrical energy, the terminology of short-circuiting, and the cause of short-circuiting. I found that Gerard, the facilitator, provided feedback with explanations that contributed to the process of coordination in joint activity, invited meaningful participation, and supported educational dignity. Feedback went beyond correct or incorrect evaluations and included explanations with learning as the endpoint. Therefore, explanations were directed towards understanding the roots of unintended outcomes. As a result, Gerard provided feedback with explanations in a way that affirmed students' potentials by creating openings for students to learn and iterate to work through activities.

The second case study takes us to a professional contemporary dance company, focusing on a 3-week period from a larger two-year ethnographic study (Vogelstein, 2022). During this time, Rebecca's position changed from peer-dancer to leader-choreographer and she shared how she approached developing choreography in pedagogical ways, drawing on her own experiences as a dancer to create dignity-affirming experiences for the dancers. Rebecca saw being transparent, or providing feedback paired with explanation, as caring for her dancers and intentionally giving them "what she feels like she needs from choreographers" (Field Note, 12/14/17). I found that Rebecca communicated changes to developing choreography typically not tied to dancers' abilities, but rather because of the experimental approach to creating choreography. Thus, when being transparent and providing feedback with explanations, dancers did not have to locate the reason for changes in any particular dancer. Instead, they focused their energy on the process of creation and fine-tuning as a group. Rebecca's feedback also invited multiplicity in dancers' interpretations of feedback, further demonstrating the co-creation of choreography.

Finally, the third case study is a moment between two students, Bolaji and Sarah, in which feedback and explanation encouraged new forms of collective, dignifying participation in a US history class. Drawing on a year-long ethnographic study (Jackson, 2021b), I found that during discussions, Sarah became a primary source of knowledge and validation to Bolaji by way of feedback and explanation. Sarah's explanation created the conditions for supporting Bolaji's educational dignity by reinforcing and continuing his meaningful participation in the developing collective inquiry when he quietly asked a question. Because Sarah made this pedagogical move towards her peer, she ensured Bolaji was still jointly-coordinated in thinking, allowing for both of their participation in the large-class discussion to continue. Therefore, Bolaji was able to not only receive a detailed explanation for his question but also have further validated in his positioning as a meaningful participant alongside Sarah in the class' collective thinking, demonstrating how engaging feedback and explanation functioned to create and extend educationally dignified activity.

Discussion and Conclusion

Feedback with explanations invited participants to embody forms of meaningful participation characterized by agency through positioning (Davis et al., 2020) and moved activity forward. In the first case study, Gerard offered feedback that positioned Darrius as a learner by affirming that Darrius was prepared for conceptual engagement with the circuit with proper support. Gerard did this by accompanying his feedback with an explanation that took the shape of storytelling and personification of electrical energy. As a result, Darrius was invited to engage with the feedback to understand the roots of unintended outcomes. In addition, although Darrius did not ask for an explanation, Gerard provided one. In doing so, Gerard showed Darrius that his wondering was important and affirmed Darrius' potential to learn the concept of short-circuiting and circuit design, when it was not necessary to move the activity forward in that moment but would be generative in the future for Darrius.

In the second case study, Rebecca positioned the dancers as co-participants, exploring the unknown of the final choreography through a process of experimentation and multiplicity of interpretations that opened up creative possibilities. Rebecca also carefully crafted her feedback to communicate that revisions to choreography were not critiques of dancers' abilities, but rather a part of the process to create a larger cohesive creation together. This is important because using dancers' artistic choices and ideas in a piece of choreography can feel exploitative when dancers are positioned as needing to be good enough to fit a choreographer's vision rather than contributing to the co-development of a shared inquiry.

In the third case study, Sarah's explanation answered Bolaji's question by first exploring shared knowledge and then providing a summary of a lecture. As a result, Sarah positioned Bolaji as having the answer to his own question, and then she provided Bolaji with a summary of a lecture to further support his memory, thinking, and participation in whole-class discussions. Together, all three cases show how the explanations that accompanied feedback worked to support participants by way of positioning to invite meaningful participation that invoked participants' agency and affirmed their dignity as valid and generative members of these respective learning communities. Feedback with explanations also invited participants to engage meaningfully, creating a collective, educationally dignifying conceptual space (Espinoza et al., 2020) in which activity is continued forward (Matusov, 1996). These three cases illustrate how feedback with explanations can serve as moments to shift activity in immediate ways, but can also serve as reference points in the future, suggesting that feedback not only drives activity, but it can also serve as a seed for continued learning (Gutiérrez & Rogoff, 2003; Lave & Wenger, 1991).

We are pedagogically inspired by the humanizing ends these instances of feedback with explanations move towards in their respective learning ecologies and we are excited at the new theoretical and pedagogical questions they raise. In particular we are interested in the new relations that these forms of feedback with explanations can support (Vossoughi et al., 2021b) in terms of the interwoven nature of intersubjectivity and ethical relations between participants and the domain, such as how Gerard positioned Darrius as a learner while

positioning himself as someone who Darrius could wonder with and seek support to learn more about circuitry. We are also interested in the motivation for when moments of feedback are paired with explanations in moments of joint activity because our three case studies illustrate times when participants supported one another without being asked to go into such depth. For example, Darrius did not ask for an explanation and neither did Rebecca's dancers. While Bolaji did ask a question, it was indirectly asked, and Sarah decided to answer his question pedagogically. However, she could have given Bolaji a one-sentence answer that would have omitted the kinds of positionings that her original explanation provided, or even positioned Bolaji in negative ways. Ultimately, we are inspired to continue to learn from and with our research collaborators and embark on new efforts to support the engagement of meaningful and dignity-affirming participation interwoven in pedagogical moments of feedback with explanations.

Tuning Perceptions and Inferences to See a Graph in a New Way

Hillary Swanson, hillary.swanson@usu.edu, Utah State University
Bruce Sherin, bsherin@northwestern.edu; Uri Wilensky, uri@northwestern.edu, Northwestern University

Abstract: This work examines the representational and social features of a computational modeling activity to understand the role they play in helping a student make sense of a simulation graph. Specifically, it examines shifts in the student's thinking as she reflects on the output of a computational model of thermal equilibration, which she has built. By analyzing the student's trajectory through the lens of Coordination Class theory, the paper illuminates how she comes to see the simulation graph in a more sophisticated way through her interactions with the technology and the interviewer. The paper shows how these features of the computational modeling activity support her transition from seeing oscillations of temperature about the mean as a visual effect caused by the computer screen, to understanding that oscillation amplitudes are related to microscopic fluctuations in temperature, which decrease as the number of particles in the system increases.

Introduction

Today, many scientists use computational models to represent and make sense of scientific phenomena. Science education research has investigated student engagement in computational modeling. Some research programs have focused on the design of environments that make the construction of computational models more accessible to younger learners and studied how these environments support learning (Bain, Anton, Horn & Wilensky, 2020). The present paper focuses on student learning in a block-based modeling environment, seeking to characterize, at a fine grain-size, how exploring a computational model of thermal equilibration helps one student find new meaning in a graph of temperatures.

Theoretical foundations

This study is informed by the Knowledge in Pieces (KiP) perspective, which views an individual's knowledge as a complex system of many different kinds of elements and structures (diSessa, 1993). One structure discussed in the KiP literature is a *coordination class* (diSessa & Sherin, 1998). Coordination classes are used to obtain measurable information about the world and are composed of both perceptual and inferential components. The perceptual component consists of *readout strategies*, which the individual uses to *extract* data from the world. The inferential component consists of an *inferential ne*t, which the individual uses to decide what data to extract, and to *draw inferences* from the extracted data. For example, suppose an individual wants to determine which of two objects is being pulled toward Earth with greater force: a bowling ball in their left hand, or a marble in their right. In this situation, the individual draws on their readout strategies to perceive the relative weights of each object. They draw on their inferential net to determine that the bowling ball feels heavier, and therefore must be experiencing a greater Earthward gravitational force. The individual's readout strategies are related to their sense of touch and their inferential net includes ideas about heaviness and force. This paper analyzes the development of one student's understanding of a graph through the lens of Coordination Class theory. Though the theory was originally developed to understand how individuals obtain information about measurable quantities (such as force or speed), a number of studies have borrowed the theoretical machinery to make sense of how individuals see other kinds of information in the world. This work uses readout strategies and inferential nets to characterize shifts in the focal student's extractions and inferences, which allow her to understand a graph of thermal equilibration in a new, more sophisticated way.

Methods

This paper analyzes data from a larger study focused on students' engagement in theory building through computational modeling. To lower the threshold for participation, our team designed block-based computational modeling microworlds using NetTango (Horn, Baker, & Wilensky, 2020), an interface to NetLogo (Wilensky, 1999). The present study seeks to characterize, at a fine grain-size, how theory building through computational modeling supports learning and asks the question: *How do the representational and social features of a computational modeling activity help a student make sense of a graph in terms of the law of large numbers?*
To address this question, we analyze one student's explorations in a NetTango microworld during a 1.5-hour interview. Data were collected in three forms: video, screen capture, and audio recording. The present report focuses on data from an interview with a student we call Sage (13 years old) who explored the *Thermal Equilibration* modeling microworld, pictured below (Figure 1). The screenshot shows a model that has been built

and initialized. The black box is the *world*, which depicts the activity of the agents (green and purple particles) that are programmed to behave according to the rules specified by the model. To the left of the world are parameters the user can adjust to prescribe initial numbers and speeds for green and purple particles. When the user presses the *setup* button, the world populates with particles that match these parameters. When they press *go*, the particles begin to behave according to the *act* procedure, which the user defines with blocks in the field to the far right. Just to the right of the world is a graph, which shows the temperature or average energy for the groups of green and purple particles over time. It is important to note that the graph shows quantities the model can calculate, which could never be measured in reality, as the particles mix over time. The student is asked to imagine that the particles constitute green and purple gasses at different temperatures, which are mixed together in a container, and to model the situation where the two gasses arrive at the same temperature

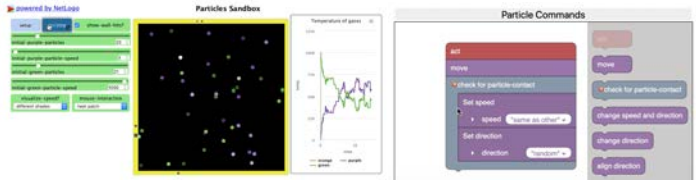

Figure 1. Screenshots of the *Thermal Equilibration* modeling microworld.

An audio recording of the interview with Sage was transcribed. Both screen capture (with audio recording) and transcript were analyzed to look for evidence of learning. A shift in Sage's thinking was identified during an activity toward the end of the session, where she attempted to make sense of the graph produced by her thermal equilibration model. A Knowledge Analysis (diSessa, Sherin, & Levin, 2016) was conducted to understand the smaller steps through which her thinking was refined. The data were analyzed using constructs from Coordination Class theory (readout strategies and inferential net) to understand how her extractions and inferences were refined, leading her to see a graph of thermal equilibration in a more sophisticated way. Her trajectory was divided into five episodes, which were analyzed to identify how her extractions and inferences, which determined what she could see in the graph, changed in relation to her interaction with the technology and the interviewer.

Findings and Discussion

Episode 1: Noticing the behavior of the graph

Sage had been tinkering with parameter settings and her model produced a plot (Figure 2, right) that resembled a graph she had drawn earlier to illustrate hot and cold liquids equilibrating over time (Figure 2, left). The episode opened with Sage commenting on the similarity between the NetTango plot and her graph.

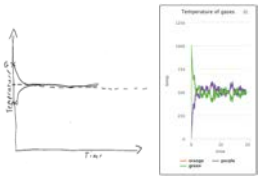

Figure 2. The plot on the left was drawn by Sage, the one on the right was produced by the microworld.

Sage: It's sort of looking like that graph [points at her drawing]. Well now it's like inverted. Well it's like correcting itself. So, I think eventually it will get to align or, well no, maybe.
Int.: What do you think is causing it to go...
Sage: Because I, I don't know. Every time I'm like, "Oh look, it's going smooth." They just like, just like straight up. It's like, um, it, they're like swapping each time.

In this episode, Sage extracts information from the graph. She first notices that it has the same global shape as the graph she sketched. As time goes on, she notices that the curves overshoot the mean and appear to swap places. Her extractions, which move from global shape to a finer-grained detail, are dictated by her readout strategies as well as her inferential net, which dictates what of the available information appears to her to be relevant to making sense of the graph. The particular readout strategies and inferential net she brings to her initial observation arise spontaneously in response to the activity. Sage's extraction of the fluctuation about the mean was afforded by the

modeling environment, which plotted the separate temperatures of the two gasses, despite their having mixed. In reality, such a graph, and therefore such an extraction, would be impossible.

Episode 2: Focusing on the aggregate-level behavior

Hoping to capitalize on the problem Sage has stumbled upon, the interviewer asks her to explain the phenomenon.

Sage: Maybe it's being set to random and then they're going the inverse of each other. So, if one is slowing down, then the other one is speeding up. Then the average will always be the same.
Int.: What is the average…? Temperature is going to be the measure of the average speeds…
Sage: So, the temperature. For green, the speed, it looks like it's centering like right around 500, which is good 'cause that's the middle. So, it should be just a little bit of both. So, it's like if, if the 500 was zero then it would be 500 and negative 500, then it would be like the inverse.

In this episode, Sage extracts more detailed information about the plot, observing that the oscillation of the curves is symmetric. She also draws an inference from the symmetric oscillations, determining that they represent the particle speeds going faster and slower in a mirrored way. The interviewer asks her about the temperature, or average speed of the particles. In response, Sage extracts quantitative information of the mean value about which the two curves oscillate. She infers that this value is sensible, given the values of the two particle groups she started with. She further extracts that the curves are oscillating about the mean value by the same amount. Importantly, Sage is extracting information and drawing inferences in response to the interviewer's questions.

Episode 3: Focusing on an agent-level mechanism

The interviewer asks Sage to explain the "jagged" nature of the curves.

Sage: Well, at the beginning I thought it was because this just happens over a long time. It was just pixels and if you zoomed out, it wouldn't be jagged, and it was just 'cause of the computer screen. But now that it's going up and down, I think that it's just because, if one bounces into a wall and gets a little bit slower, then the other one just has to get a little bit faster.

The interviewer's question prompts Sage to share two inferences. The first concerns her initial thinking, which was that when a graph exhibits oscillation it is an effect of the computer visualization. The second concerns her new thinking, which is that the phenomenon is real, and is caused by particles speeding up and slowing down. It appears the interviewer's question has activated these two inferential nets, which Sage uses to make sense of the phenomenon. Sage's extractions and inferences appear to occur in response to the interviewer's questions.

Episode 4: Comparing systems with different particle numbers

The interviewer is interested in helping Sage see that the amplitude of the oscillations decreases as the number of particles in the system increases. Towards this, she asks Sage to compare different numbers of particles.

Int.: So, it's really jagged around 500. Let's see if you raise the number of particles, if it's the same. Do you think you'll get the same jagged line around 500, but up 250 or down 250?
Sage: Um, uh, maybe, I think. Yeah. [increases each group of particles to 50].
Int.: Well it's definitely going fast towards 500. And then it's a little bit slow and then it's doing the thing you saw, which is a little bit of this dance around the 500.
Sage: Yeah. But it's a lot closer now. Like, like it's not going up.
Int.: Okay. What about if you made the particles even more -
Sage: Um, go to like a hundred [slides each group of particles to 100]. Um, I think maybe it will be, it might get all the way flat, but it might just be very close.

The interviewer's suggestion to compare the model with different numbers of particles leads Sage to run the two different models and observe the difference in amplitude heights. She extracts the amplitude information. She then uses her inferential net to compare the two different heights and establish that the one with more particles has the smaller amplitude. This prompts her to predict that 100 should flatten the amplitudes to zero, or close to zero. Here, as in the previous episodes, Sage's extractions and inferences appear to be influenced in important ways by her interactions with the interviewer. They are also afforded by the modeling environment, which allows her to run the simulation with different numbers of particles and compare the amplitudes of the temperature fluctuations. Sage appears to have recognized a relationship relevant to understanding the law of large numbers: the larger the number of particles in the system, the less any single particle will influence the average.

Episode 5: Connecting agent and aggregate levels

The interviewer asks Sage what happens to the curve as she adds particles.

Sage: Um, it's still not like quite a curve. As the number of particles increase, as the sample size increases, then the actions of one particle don't affect the big total as much.
Int.: That is such a cool thing to have said. What do you mean by that?
Sage: So, if you're doing a study like this, if you just had me, it wouldn't really be like a full and complete study because I am not the same as every person and if you have like a hundred people it will be way more accurate because a hundred people is closer to the diversity of knowledge that our population has than one person. And if you had every seventh and eighth grader do it, it would be a hundred percent accurate because everyone was represented.

Sage uses her readout strategies to extract the shape of the curve and describes it as not perfectly smooth. She activates her inferential net and offers an explanation for why increasing the number of particles smooths out the curve. Her inferential net includes information about sample size and how a sample more closely characterizes a population as it gets closer to the size of the population. Much of her thinking is left unarticulated, however, it appears that she has activated prior knowledge related to the law of large numbers, in that she understands the distance of deviations from the mean increases for smaller samples, since individuals within the population have a greater weight within the average. Her activation of this knowledge appears to be in response to her inference about the relationship between a large number of particles and a lower amplitude of fluctuation, as compared to a small number of particles and a higher amplitude of fluctuation about the mean. She drew this inference as a result of comparing simulation runs with different particle numbers, which she did at the request of the interviewer.

Summary and Conclusion

The interviewer asked Sage why the curve was jagged. Sage shifted from thinking it was an effect that would resolve itself (Ep. 1), to describing what was happening at the aggregate level (Ep. 2), to describing what was happening at the agent level (Ep. 3). The interviewer then asked Sage to compare different numbers of particles (Ep. 4). This caused Sage to infer the relationship: the more particles, the lower the amplitude of fluctuation. The interviewer then asked Sage what she noticed about the relationship between particle number and curve (Ep.5). Sage offered an analogy to explain her understanding, drawing on ideas that suggest intuitive resources for understanding the law of large numbers. This sequence illustrates Sage's trajectory from having an incorrect explanation for the graph, to a somewhat scientifically sophisticated explanation. The mediating influence of the technology and interviewer appear significant. The technology allowed her to see invisible fluctuations in average speed and the average temperatures of groups of particles that mixed together as soon as the simulation began. Though Sage initiated the discussion, the interviewer continued to focus her attention on the details of the curve, asking her what might be causing the fluctuations about the mean, and finally, how increasing the number of particles influenced the size of the fluctuations. Some of her questions activated Sage's readout strategies and allowed her to extract new information, while others activated Sage's inferential net, which she used to explain what might be causing the fluctuations and why increasing the number of particles decreased the size of the fluctuations. The interviewer's questions played a role in changing the composition of Sage's readout strategies and inferential net, which she used to make sense of the graph. Shifts in activation of the perceptual and inferential components of her knowledge system helped her make sense of the graph in a new and more sophisticated way.

What does 'Computer Science Education for All' Look Like in a Korean Middle School: an Ethnographic Case Study on an Informatics Teacher's Local Contentious Practice

Won Jung Kim, Santa Clara University, wkim2@scu.edu

Abstract: Along with the worldwide emphasis on computer science (CS) education for all, *informatics,* one of the CS subjects in Korean middle school education, has been expanded from the elective to the compulsory since 2018 to offer CS learning opportunities for all students. This study seeks to document how CS for all agenda is enacted in a local school context by exploring an ethnographic case of one informatics teacher. Using the construct of local contentious practice as a conceptual framework, I examine the teacher's actions and interactions for and related to teaching informatics in the particular school context where larger sociocultural assumptions and narratives about CS teaching and learning operate. Through a reflexive thematic analysis of the ethnographic case data, I identify three patterns of local contentious practice enacted by the informatics teacher and with the teacher's school community. Implications for future research and practice toward CS for all is discussed.

Major Issues and Purpose of Study

Young people are and will be living in a fast-evolving world operated by computing systems and applications grounded in computer science (CS) knowledge and practices (ACM & IEEE, 2020). It is crucial for young people to have sufficient and sustained opportunities to learn CS, which will help empower themselves as wise and ethical producers, consumers, and problem-solvers of computing-based applications, systems, and information. In this regard, many countries across the globe, including South Korea (Korea, hereafter), have utilized their public education systems as access points toward the goal of CS for all students (Hubwieser et al., 2015). CS for all is urgently required to work against injustice exacerbated by racial, gender, economic, cultural, and regional disparities in access to quality CS learning opportunities, and computing-informed lives and career pathways (e.g., Computer Science Teacher Association, 2020).

Since 2018, informatics, one of the CS subjects in Korea, has been expanded from the elective to the compulsory according to the national curricula policy revision to serve the goal of CS for all. Korean middle schools now provide their students with either one or two credits of informatics courses across three academic years. This policy shift is considered a meaningful step forward, given that CS subjects have long been offered as electives (e.g., informatics until 2018), or as parts of other subjects like technology or domestic science.

However, to better work toward CS for all, there is still much to be addressed in terms of policy and its implementation at local districts and schools. Utmost concern is inequity due to insufficient learning hours assigned to CS subjects. Most CS subjects at primary and high-school levels remain electives or as parts of other subjects, which hinders extensive and sustained learning opportunities across different grade levels (Kim, 2021). Although middle school informatics has shifted to be a compulsory subject, it only takes up one or two credits of a total 99 credits earned across three middle school years. One of other significant concerns is how schools maintain CS teacher workforce. In the case of middle schools, 77% of informatics teachers majored in CS-related disciplines while 23% are non CS-majors or minors (Korean Association of Informatics Teachers, 2021). Moreover, 49% of teachers who majored in CS-related disciplines circulate two or more schools to teach informatics while 51% work full-time at one specific school teaching other subjects in addition to informatics. In the situations like these, parents who believe the importance of CS for their children's future look for out-of-school private CS learning programs, particularly when they are affluent enough to afford the additional expenses.

Whether students can have sufficient CS learning experience is, therefore, highly contingent to and disparate by local communities, schools, and families students live in. It is the disparities that can contribute to perpetuating educational injustice. Furthermore, these are not only the issues within Korea. Similar injustice issues have been reported across the globe (e.g., Goode et al., 2020). Sustainable and concerted efforts to eradicate such issues and transform policy and implementation is in dire need to actualize equitable CS education and to use CS as a means toward justice, not as a sources of perpetuating injustice.

Despite the issues in policy shift and implementations of CS, there exists a dearth of research, particularly in Korean context, investigating how such issues may operate in and around informatics classrooms. Moreover, ethnographic understanding of what CS for all looks like is surprisingly underdeveloped. If the purpose of CS for all is to offer equitable learning experiences, how the policy-level shift has impacted students' learning via their teachers' practices in local school contexts should be investigated in ethnographic and case-specific details.

 © ISLS

As an attempt to address the need for investigation, therefore, this study explores an ethnographic case of one Korean middle school informatics teacher, Mr. G. Particularly in this study, I attend to Mr. G's actions and interactions *for and related to* teaching informatics in the particular context of his school. By actions and interactions *for* teaching informatics, I refer to those Mr. G directly aimed at teaching students the informatics subject. In comparison, the *related to* teaching informatics means those shaping and situating his teaching. I frame such actions and interactions with the construct, local contentious practice, which explains on-going formation of the sociohistorical self in the encounter with institutional narratives (Holland & Lave, 2001). By using this construct, I sought to articulate how CS for all policy agenda has shaped (and been contextualized in) local school implementations as Mr. G's case illustrates. The following research question guides this study: *Which patterns of local contentious practice do Mr. G's actions and interactions for and related to teaching informatics reveal?*

Conceptual framework

I utilize local contentious practice as the conceptual framework to analyze and articulate the ethnographic case of Mr. G, focusing on his actions and interactions for and related to teaching informatics in a Korean middle school context. Local contentious practice calls attention to two histories: history-in-person and history-in-institutionalized-struggles. History-in-person, as a personal narrative of self-making, takes shape via interactional practices with others in local spaces. By history-in-institutionalized-struggles, Holland and Lave (2001) refer to institutional narratives grounded in historicized and trans-local structures, which provide resources for people's actions and interactions and leave traces in their formation of history in person; as such, I call this history as historicized institutional narratives in this paper.

Local contentious practice takes shape via interactions between people and tensions that arise from people's different positions in historicized institutional narratives. Viewing teaching and learning through the perspective of local contentious practice helps to understand different forms of interactions shaped by multiple actors at different positions of power in their local learning institutions. In their institutional learning spaces (e.g., a school classroom, a teacher staff meeting, school events), multiple actors (e.g., students, teachers, principal) and non-human constituents (e.g., spatial structures, disciplinary knowledge, school-national curriculum) interact within historicized institutional narratives and dynamic networks of power.

Local contentious practice can be a means of transformation as people create and recreate their history-in-person as well as the historicized institutional narratives (Calabrese Barton et al., 2020). In this regard, examining local contentious practice in educational institutions such as schools can help to identify sources and processes of disruption and transformation brought to bear on the institutions. As such, I attend to identifying Mr. G's local contentious practice, and describing how his practice may have brought about disruption and transformation of his school community's assumptions, discourse, and practices around CS teaching and learning.

Methodological approach

I answer the research question, by undertaking an ethnographic case study that utilizes a reflexive thematic analysis. Taking an ethnographic case study approach allowed me to 'be with' participants—i.e., Mr. G, his colleague teachers, and his students in real world contexts. Conducting a reflexive thematic analysis allowed me to focus on how the construct of local contentious practice is enacted and contextualized in the specific case.

Ethnographic Case Study

Ethnographic case study method examines events and individuals real time within a bounded system situated in larger cultural and historical contexts (e.g., Angers & Machtmes, 2005). This method is appropriate for this study seeking to answer the research question by examining Mr. G's practices for and related to teaching informatics (inward attention) and the multi-scalar contexts in which the practices are shaped (outward attention).

Positionality To this study, I bring my positionality, which I would call my history-in-person as a researcher who seeks to work toward equity in and through CS and STEM education, and as a former teacher who once taught informatics in Korean classrooms.

Context This case took place between January and September 2021 in a middle school within a low-income neighborhood in one of the Korean metropolitan cities. A total of 220 students (76 6th, 73 7th, 71 8th graders) and 26 adult members (21 teachers, 1 principal, 1 vice principal, and 3 administrative) constitute this school community. Since 2018, this school has been designated as one of Innovation Schools aimed at educational transformation in economically disadvantaged communities. Regarding informatics subject, this school offers 2 credits of informatics, 1 for 6th and 1 for 7th graders.

Participants The case teacher is Mr. G, with 20 years' experience teaching informatics at four Korean public middle schools, including the one in the study. Seven additional participants were recruited through snowballing sampling: Mr. G's colleague teachers (Mr. D and Ms. P) and 5 students (three 6th, and two 7th graders).

Data Generation & Analysis

I generated data, including individual and group interviews, instructional and curricular documents, students' learning artifacts, and the researcher fieldnotes. I analyzed the data by using a reflexive thematic analysis. This analysis method facilitated me to find meanings from data through concurrent dialogue and contextualization of theory-based coding framework (Braun & Clarke, 2019). I took three analysis phases.

Open coding. Interview transcripts were major data for open coding. The unit of analysis was an instance the interviewees pointed out as important for and related to informatics teaching and learning; the instance was either interactional (involving different actors) or reflective (involving individuals' reflections on systems and practices). Each unit is coded in an exploratory manner as I first read transcripts through chronologically, and then triangulated the coded instances with other data. As codifying interactional or reflective instances, I also assigned sub-codes to the components constituting each instance—e.g., individuals, actions, spaces, and tasks.

Construct-informed coding. For this phase, I first established a coding framework drawing on the construct of local contentious practice, and iteratively refined both the coding framework and the codes and sub-codes. The coding framework involved concepts used to describe the construct, such as actors, relationships, interactions, tensions, community, institution, history-in-person, historicized institutional narratives.

Identifying patterns of local contentious practice. In this phase, I figured out relations among different codes and sub-codes refined in the second phase, from which I identified three patterns of local contentious practice as the main themes of Mr. G's actions and interactions for and related to teaching informatics in his school context. Instances described in the first analysis phase offer illustrations of how each pattern manifests.

4. Findings

Drawing on the reflexive thematic analysis of Mr. G's ethnographic case, three patterns of local contentious practice were identified from his actions and interactions for and related to teaching informatics in his classrooms and across his school community. The patterns are:

1. Creating a dialogic space that engaged colleague teachers in questioning the normalized practice of treating informatics teachers as school technicians;
2. Facilitating an agentic learning space where students engaged with academically challenging but achievable computing tasks, which disrupted the school-wide deficit view on their students as low-achieving;
3. Co-designing with colleague teachers the inter-subjects learning projects in which students utilized and integrated knowledge and skills across informatics and other subjects.

For this proposal, I briefly unpack how the *first pattern* manifested, and which histories (i.e., Mr. G's history-in-person and the historicized institutional narratives shared by the school community) operated.

The first pattern manifested through sociopolitical actions he took in his school community of colleague teachers and principal. By sociopolitical, I refer to how he called his colleagues' attention to long-held narrative that reduced the legitimacy of informatics teachers and informatics. For example, during the third teacher-staff meeting he had since he joined the school, he made a presentation, through which he highlighted and questioned how informatics teachers are easily treated in schools more as schools' 'tech person,' than colleague teachers. He decided to make the presentation after the first teacher-staff meeting, in which he as a newcomer found that he was already assigned to take in charge of the school's digital device-related administrative work. He recalled:

> There was no option to me. Managing digital devices, wireless connections, and remote class system, a big deal after pandemic, were all my tasks. One teacher told me, 'informatics teachers are experts.' Yes, *we* may know more. Also, I don't hate such tasks necessarily, but they are thrown to *us* because *we* are viewed as school tech guys than teachers. Some tasks are what every teacher should know. Some others are what can be cared at a higher level. Upsetting.. I experience this whenever moving to a new school.

This statement indicates two histories encountered. His *history-of-person* as an informatics teacher, shaped through two decades of similar experiences, critically recognized power dynamics that positioned informatics teachers as individuals who would deal with other school members' technical issues. This history-in-person is not just about him;. As he put 'we' and 'us,' the similar history-in-person is shared by other informatics teachers. This similarity explains *historicized institutional narratives*. One of the institutional narratives is that, as Mr. G's colleague said, informatics teachers are 'experts' about computers and devices. However, such a narrative worked to reduce, not legitimize, the presence of informatics teachers. The tasks these teachers were expected to do as 'experts' were far from enacting CS for all. As Mr. G noted, it was not that informatics teachers always refuse to take technical tasks. However, he pointed out the tenacity of the reduced view on informatics teachers, the view that can be extended to how informatics as a subject can is. Mr. G continued to recall the presentation:

> When I was a beginner teacher, I just did what was assigned to me, but now being in this game for about twenty years, I have something to say. This school is Innovation School, I thought. If so, the conversation should take place. They may not know what informatics teachers do and why informatics matter.

Although the historicized narratives about informatics teachers and informatics prevailed in the school, Mr. G held up a hope that he could create a dialogic space with his colleague teachers, because the school as one of Innovation Schools had tried to establish culture that allowed democratic and often contentious conversations among different school community members. After his presentation in which he put together questions about normalized assumptions on informatics teachers and suggestions about different task loads, the atmosphere apparently went full with tension, according to Mr. G's reflection. However, some teachers put themselves into Mr. G's and other 'minor-subject' teachers' positions. Some teachers acknowledged that they actually had not thought about the normalized discourse highlighted by Mr. G. As they conversed on, they examined critically the tasks given to teachers and the underlying rationales. As a result, some of the tasks assigned to Mr. G were shared with other teachers and staff. Instead, he took the lead in the interdisciplinary learning project, the project idea other subject teachers hoped to launch but hesitated as they did not know how to realize the idea.

This pattern of local contentious practice, describing how he sought to reclaim his presence as an informatics teacher, is closely related to other two patterns. The second pattern describes how he used informatics to disrupt school-wide deficit view on their students, by engaging students in computing projects (e.g., ENTRY, Korean educational programming language platform, and international BEBRAS challenges for computational thinking), and held school events in which students taught programming other subject teachers. The last pattern shows how some other subject teachers (such as Mr. D and Ms. P who participated in this study) joined disrupting between-subjects boundaries and sought to co-design with Mr. G interdisciplinary learning objects.

Discussion, Implication, and Significance

Findings of this study about Mr. G's local contentious practice show how one teacher can bring about exposure and disruption of a school's historicized narrative, drawing on one's history-in-person that has become struggles and pathways toward CS for all. Utilizing ethnographic case study methods with a reflexive thematic analysis enabled me to gain the place-based empirical evidence of and insights from local implementation of policy, undergirded and contested by larger historicized institutional narratives about CS teaching and learning. Although the findings highlight a promising case of teachers and school communities working as change agents, the ultimate source of struggles such as course offerings and teacher supply were left unresolved. Ultimately, concerted efforts should be garnered both from policy and research panes. The CS for all agenda should result from concerted policy revision and systemic support for schools and teachers, for example, about how to resolve inter-subjects tensions of course distribution and budget concerns of increasing CS teacher workforce. Meanwhile, research should support teachers from in-service and pre-service informatics and CS teachers to other subject teachers seeking for integration with informatics and CS subjects, by providing opportunities of professional development and research-practice-partnership. Some of such opportunities should also support teachers to recognize and readily respond to power structure that may hinder CS for all; as Mr. G's case exemplifies. Findings and implications of this study inspired by the goal of CS for all can interest worldwide education researchers focusing on CS education and inter-subject integration with CS, and those participating in this year's ICLS themed with collaborative education for all.

Sensing Someone Else's Pain: Ethical Historical Traces of Disciplined Interactions in Medical Care

Santanu Dutta[1], Pratim Sengupta[1] & Ariel Ducey[2]
santanu.dutta, pratim.sengupta, aducey@ucalgary.ca
[1]Werklund School of Education, University of Calgary; [2]Department of Sociology, University of Calgary

Abstract: This paper highlights the ethical and moral dimensions of relational work and dignity in technoscientific spaces which are elusive in normative disciplinary practices. Using the lenses of ethical perceptions and embodied actions, we locate how microinteractions within physician-patient interactions during pain diagnosis and care are intertwined with interpersonal dignity, racialized emotions and historicized violence on Indigenous people. We discuss the implications of our work in light of dismantling normative views of disciplinary authenticity that underlie technoscience education.

Introduction

Building on critiques of ethically neutral, ahistorical and apolitical positionings of science education (Bang et al., 2014) and disciplinary authenticity in technoscientific disciplines (Philip & Sengupta, 2021), we offer an empirical critique of professional expertise in medicine that excludes or undervalues the moral and ethical dimensions of relational work (Ducey, 2009; Ducey et al., 2020). Our work arises from the concern that professional work in technoscience is deeply intertwined with historical and ongoing enactments of militarism, nationalism, imperial and colonial violence (Banerjee, 2022; Benjamin, 2019; Sanyal & Sengupta, 2022), which also shapes educational research and praxis in STEM disciplines (Philip & Sengupta, 2021; Takeuchi et al., 2020). This paper advances scholarship on the relationship between the colonial matrix of power that shapes discipline (Mignolo, 2009) and moral and ethical dimensions of experience (Espinoza et al., 2020; Sengupta et al., 2022) that are often invisiblized in the professional practice of medicine. We report findings from an ongoing study of physicians' and caregivers' experiences of the relationship between medical care, technologies and pain. We illustrate: (a) how the misrecognition of pain within a physician-patient interaction is rooted in historical traces of Indigenous erasure and intergenerational trauma in disciplinary spaces; and (b) how a Métis physician, Dr. Campbell (pseudonym), the protagonist in our study, offers a possible re-orientation of disciplined interactions involved in sensing patients' pain through foregrounding ethical, relational and emotional work, based on her experiences of working with Indigenous patients.

Theoretical Background and Framework

Our work builds on the growing body of scholarship in the social and the learning sciences on the intertwined nature of moral and epistemological dimensions in technoscientific disciplines. Vossoughi et al. (2021) introduced the notion of ethical perception as educators' and researchers' "growing awareness of the pedagogical and ethical saliency of their own embodied actions" (p.137). They argued that embodied actions are "public expressions with political and ethical content (p.138), and urged us to reframe micro-interactions in disciplinary spaces through the lenses of dignity and meaningful participation (Espinoza et al. 2020; Tuck, 2011). In this paper, we adopt this lens of ethical perception to illustrate how embodied actions that represent *disciplined* ways of knowing (Sengupta et al., 2022) can invoke racialized emotions (Bonilla-Silva, 2019) for Indigenous and marginalized people of color who have endured a history of disciplinary violence in the context of medicine. These interactions are fundamentally moral and ethical in nature, which are not afforded in technical-rational views of disciplinary authenticity in technoscience (Philip & Sengupta, 2021; Sengupta et al., 2022). This is particularly important given that medical sociologists have also identified moral dimensions of care as often missing in accounts of professional expertise in medicine, particularly in contexts that involve the relationship of pain, harm and the use of new technologies (Ducey et al., 2020). Examining the wide uptake of transvaginal mesh, a surgical device procedure to treat certain pelvic floor disorders in women that resulted in extensive patient harm, medical sociologists have positioned "mindlines" as the collective moral-epistemological "ways of knowing and acting responsibly" (Ducey et al., 2020) that organize medical practice but often remain as ethical undertones in the technoscientific disciplinary practices that are centered in medicine. While initially, patients' bodies were framed as sites of problems that surgery must correct or improve, over time, patients' voices were centered in ways that enframed the medical practices around vaginal meshes in progressively more moral ways. And yet, as Ducey et al. (2020) noted, moral ambiguities continue to undergird medical expertise in this domain. We foreground feelings of responsibility and rightness as disciplined, and offer a fine-grained analysis of how these disciplined

 © ISLS

feelings inform acts of providing care—acts that are embodied and located in relation to specific histories, spaces, and technologies. Surfacing the *moral undertones* (Ducey et al., 2020) of medical carework is also important especially given the history between knowledge creation in Western medicine and violent, forced medical experiments on Indigenous peoples (Lux, 2016; Mosby & Swidrovich, 2021). As our analysis will show, such histories of disciplinary violence leave durable traces on micro-interactions between physicians and Indigenous patients, positioning *disciplined* interactions as inevitably grounded in histories of racial violence enacted by Western technoscience, thus making them ethical, historical and relational, not merely interpretive.

Methods

We report from an ongoing, interview-based study of physicians' experiences of the relationship between bodies, medical technologies and pain. Participants (n=7 and growing) are recruited both through snowball and targeted sampling, and then interviewed. We present here a single case of Dr. Campbell, a self-identified Métis physician of pain sharing her perspectives and experiences, particularly in the context of interacting with Indigenous patients. We utilize the constant comparative method (Charmaz, 2006) to identify examples of ethical perception (Vossoughi et al. 2021) in the participant's accounts. Our analysis involved coding the interview transcript to identify how she framed and oriented her medical diagnosis as being both grounded in disciplinary practices and ethical-historical. Our analysis centers how gestures, postures and language use in physician-patient interactions creates ethical-historical traces in the patients' clinical experiences.

Findings

Theme 1: Ethical-historical traces in physician-patient interactions

In this vignette, Dr. Campbell centers the elusive ethical dimension of professional practice to recognize interpersonal dignity and trauma, as she narrates the case of an Indigenous woman who suffered for a long time from an underdiagnosed case of rheumatoid arthritis. But her pain, as we will see in this case, is not merely a matter of being diagnosed in the moment, rather it is deeply connected with the history of disciplinary violence of Western medicine on Indigenous bodies (e.g., see Lawrence, 2000; Lux, 2016). Dr. Campbell learned that the patient felt traumatized every time her previous doctor, a white male person, turned his back towards her to draw up a syringe during a clinical procedure, evoking painful memories of the violent use of Indigenous bodies for medical experimentation. To the patient, the posture of the doctor represented a hidden view of Western medicine and a lack of acknowledgement of the patient's dignity from a historical perspective, thus hindering medical care. The apparently simple act of turning away is thus morally and historically salient. She further added:

> "When I started hearing that, I realized, like, wow, I have to be so transparent. I have to do everything in front of her. I have to explain everything. It'll probably take several visits for us to get [from] this scared point of being [to be able] to move ahead because she's just been traumatized by these prior experiences with this rheumatologist [….] And I can totally see it from her perspective. Like it's a very rushed, it's very, you know, not really genuine and wanting to get to know people. Lots of transactional medicine. Right? So I saw it from that perspective and realized that if I was going to be able to sort of reach her and help her, then I would have to be really very patient, very slow with proceeding very, very transparent and clear about what we were doing and what was being done."

In a more general sense, Dr. Campbell also noted in the above excerpt that it is important to be open to the patient about what the possible outcomes and effects of the intended procedures that might result from any diagnosis. But the ethical dimensions of the clarity of such communication is multi-faceted: it requires explaining what the diagnosis means or can mean to the patient, both in terms of the anxieties that the patient might experience as well as the benefits of the proposed treatment. For example, she noted that the previous physician could have engaged differently with the patient if he could have "actually balance[d] what are the benefits of this decision or benefits of this treatment or benefits of whatever [the doctor has decided] to do [with] this injection, with the risks." Even apparently simple and commonplace medical procedures such as injections may be difficult experiences for patients, as Dr. Campbell noted that patients themselves often find needles to be "intimidating" and "invasive." The physician-patient discussion of why a procedure like this may be useful should be dialogical, rather than authoritative, in which the patient needs to be presented with the benefits of the treatment while also acknowledging the perceptions of fear and apprehension on their part. Dr. Campbell also recognized the historically situated nature of this interaction, noting that for the patient, the syringe as held by the patient was interpreted as a marker of colonial violence. The syringe, held by the physician while turned away from the

patient, does not communicate transparency of the physician's intention to the patient. On the contrary, this produces anxiety for the patient because it is consistent with other forms of racialized experiences of Indigenous people in clinical spaces, both historically and on an ongoing basis. Dr. Campbell noted that the details of treatment, including medical tools, technologies, diagnosis and benefits of the proposed care are often not disclosed to Indigenous patients. She also noted that much of the relational and ethical aspects of physician-patient interactions are missing in clinical interactions because of the rushed nature of visits. For example, many Indigenous patients have shared with her that during examinations of joint pain, they felt that their joints were squeezed, "like, really roughly", and that they were prodded and poked "in different places" while not being afforded the dignity of clinical privacy. Offering another example, she noted that during the diagnosis of certain forms of arthritis that get activated by sexually transmitted infections, Indigenous patients were indelicately and invasively asked about their sexual lives, without providing any explanation for the pursued nature of questioning. Their accounts were also doubted by the physicians, and they would often be admonished for their lifestyle and social practices in racially offensive language: "Why are all of your people like this? Why don't you just get over it?" The use of such disdainful stereotypes in professional conversations reproduces feelings of being unwanted and unwelcomed at clinics. Dr. Campbell felt that clinics typically lack a deep understanding of what it means to live in an Indigenous community, which subsequently leads to a lack of care.

Thus, the overall picture that emerges from Dr. Campbell's interview is one where micro-interactions between physicians and Indigenous patients are sites of a historical present, where normative, *disciplined* (Sengupta et al., 2022) interactions may (inadvertently) further reify marginalization and historical trauma for the patients. The intertwined nature of expressions of pain with trauma and fear rooted in histories of medical violence on Indigenous patients in such contexts can also be understood as racialized emotions (Bonilla-Silva, 2019). How can such micro-interactions be oriented ethically and historically in disciplinary spaces? We offer such an illustration in the next theme.

Theme 2: Disciplined sensing as multi-temporal and multi-perspectival "weaving"

This theme focuses Dr. Campbell's metaphor of "weaving" that is rooted in an ethical and historical approach toward caring for patients during a diagnosis. Dr. Campbell explained weaving as an intertwining of various forms of observations and interactions, such as tactile examination of relevant parts of the patient's body, a mix of clinical procedures and tests, and the patient's verbal recounting of their lived and historical experiences. In the diagnosis of arthritic pain, perceiving a patient's condition can occur through sensory probing, technological sensing, and routine diagnostic examinations. For example, she uses both hands to palpate around each joint to feel the skin, bone and the gap between bones to assess the nature of inflammation or accumulation of fluids in joints. Dr. Campbell, thus, is careful to "never put all of [the] weight in that inflammatory marker" to decide upon the diagnosis, rather constructs the diagnosis as "a combination of [the physical] exam, the history and the labs." We have already seen the multi-temporal nature of moments of physician-patient interactions in the previous theme; the point here is that an apparently in-the-moment touch also needs to be reframed in light of histories of disciplinary hegemony and violence on Indigenous and marginalized peoples. A rough and unconsented palpation of an inflamed joint can simply recreate a historical trauma for Indigenous patients.

Weaving is also an essential interweaving of perspectives. Along one dimension, physicians sense through their disciplinarily grounded perception (e.g., seeing the inflammation, palpating the joint) and interpretation (e.g., interpreting medical reports, patients' life histories, etc.). The discipline, as Dr. Campbell noted, is historically present in such moments in the sense that she can "tease out" the diagnosis "based on the patterns that people have observed for… hundreds of years with arthritis" through interactions with a patient. However, along another historically oriented dimension, disciplines are often enacted oppressively on endarkened bodies (Philip & Sengupta, 2021). An ethical-historical re-orientation of disciplinary practices, as evident in Dr. Campbell's words, necessitates acknowledging and interweaving both these historical perspectives. Dr. Campbell noted that it is through such perspectival synthesis that a physician can "... get at what's the real situation with their disease", as the patient could be experiencing "psychosocial pain... emotional pain and intergenerational trauma". Thus, even an apparently simple act of touching a patient necessitates perspectival heterogeneity, because as Dr. Campbell noted, it is conjoined with "historical pieces of how patients are functioning".

Reflective Summary

To summarize, in this paper, we have highlighted interpersonal dignity, racialized emotions and historicized violence occurring in the spaces of medical care. At the heart of valuing patients' dignities, we argue, is an ethical reorientation toward perspectival heterogeneity, through which the disciplined gaze of the physician must be ruptured and interwoven with the patients' emotions, hidden fears, which in turn may be grounded in historical enactments of disciplinary violence. Dr. Campbell gifts us a metaphor—*weaving*—to describe the relational and

emotional work at the heart of a medical diagnosis and care, which is particularly striking given that technological professions, including medicine, tend to "disappear" and devalue such work (Ducey, 2009; Fletcher, 2001).

Our analysis suggests that ethical-historical re-orientations of disciplinary practices (e.g., Dr. Campbell's metaphor of weaving) are essential for *dismantling* (Sengupta, 2020) normative views of disciplinary authenticity that are emplaced within an ethical neutrality of "proper conduct or action" (Stevens & Hall, 1998, p.109) of disciplinary practices. As Philip & Sengupta (2021) argued, notions of disciplinary authenticity that underlie and shape technoscience education typically center epistemic and representational work while ignoring, and worse, further invisiblizing oppression of endarkened people that enables "discipline" in the first place. Our work illustrates how paying attention to the ethical-historical traces of physician-patient interactions may help acknowledge histories of oppression *within* disciplinary practices in ways that affirm dignity of Indigenous people on whom these practices are being enacted. This is an image of a fundamental re-orientation of disciplinary practices in a technoscientific profession, and as an obvious corollary, has implications for reimagining disciplinary authenticity in the context of technoscience education through ethical-historical lenses.

Proposing a Role-Based Framework for Data Literacy

Abstract: Efforts to cultivate critical data literacies in youth calls for further research that emphasizes supporting collaboration in team environments. We propose a role-based framework of four roles (Journalist, Detective, Scientist, and Artist) that seeks to go beyond just facilitating data analysis by representing the multitude of ways data literacy plays a role in people's lives. We pilot our role-based curriculum within an advocacy-focused summer program to study how our approach facilitates collaboration and critical data literacies.

Introduction

The advent of Big Data has spurred new theories and practices to prepare a new generation of learners for a future increasingly reliant on the epistemic powers of data. Given data's growing importance for communicating issues and establishing credibility, learners' ability to both comprehend and critique data could be fundamental to bringing about change in the world. Scholars have drawn comparisons between data and the emancipatory capabilities of literacy, extending aspects of *critical literacy* to form the theory of *critical data literacy*. While this theory establishes objectives of using data to empower and transform, the methods for cultivating critical perspectives in learners are not yet well established. Similarly, data literacy and science are often collaborative in practice, calling for a greater understanding of how to support data literacy in team contexts.

Data science teams can be composed of members with a variety of abilities, such as technical, narrative, theoretical, and visual, which can complicate how data literacy is framed and taught. Such diverse competencies call for frameworks that do not simplify data literacy or prioritize one dimension, but rather highlight the multifaceted nature of the domain. Critical data literacy itself has been decomposed into the technical abilities for using data and the critical capacity to understand the context surrounding data and the reality it portrays (Tygel & Kirsch, 2016). Forming critical insights requires going beyond technical or statistical knowledge sometimes favored in curriculum.

Accordingly, our main contribution was to develop and propose a role-based framework that can better represent the various elements of data literacy, while also supporting collaboration and fostering critical data literacy. These disciplinary roles aim to highlight pathways for contribution that can appeal to a wide range of learners and help them engage with the context surrounding data. Curriculum that breaks down data science into more recognizable disciplinary roles can better align with learners' reality, promoting the critical, and social aspects of data that provide various ways to co-construct knowledge. We report on the deployment of our role-based curriculum in an advocacy-focused summer program. Our primary research goal was to investigate how breaking data science into disciplinary roles facilitates collaboration and critical data literacies.

Critical Data Literacy

There has been growing interest in exploring how to support learners' critical engagement with data in the learning sciences community. Such an interest was well represented in a recent special issue of the Journal of Learning Sciences (Wise, 2020) as well as a symposium at ICLS '20 (Irgens et al., 2020) which specifically called for more research supporting critical sociocultural perspectives. To better engage learners and demonstrate a direct relationship with data, some scholars have developed curriculum around personal data. Such examples include data storytelling using personal data collected from daily lives (Stornaiuolo, 2020) or exploring family geobiographies and personal family migration stories (Kahn 2020). However, these studies noted the need for more explicit support or additional interactions to tackle issues of injustice or inequality (Stornaiuolo 2020; Kahn 2020). In contrast to personal data, which has a more individualistic focus, other scholars have utilized local community data which provides more opportunities for collaboration. Van Wart et al. (2020), described two participatory mapping activities where youth worked together to tackle local community challenges such as air quality and park planning. Similarly, Rubel et al. (2017) describes a classroom module where students investigate their city's distribution of various financial institutions (e.g., pawn shops and banks). We build on this work to explore how a collaborative framework related to data literacy roles can guide interactions in this context.

 © ISLS

Roles to Play in Data Literacy

Recent research has also explored the different facets of data science and literacy in curriculum, helping describe the various roles that can be played in collaborative settings. Such approaches highlight the interdisciplinary nature of data by integrating other creative fields, such as art and journalism. An arts-centric approach called *Data Murals* (Bhargava et al, 2016) engaged the community to reflect on their data and create a visual design that tells a data-driven story. The project, informed by critical pedagogy, aimed to utilize art's history of helping people engage and critique power structures in their lives. D'Ignazio (2017) further described such interdisciplinary uses of data as *creative data literacy*, which highlights non-technical aspects of data. Another related study integrated aspects of journalism by having students generate infographics in a science classroom (Gebre & Polman, 2020). Students were able to creatively communicate with statistics, labeled figures, and data visualizations about a topic of interest. These examples helps explore and inform the various roles youth can play when working with data.

While new in the context of data literacy, role theory has long been used as a framework for explaining characteristic behavior patterns (Biddle, 1986). The theory grew in popularity in collaborative learning for studying both naturally emerging roles as well as scripted roles to facilitate collaborative processes (Strijbos & Weinberger, 2010). In an effort to engage learners in interdisciplinary learning and integrate science and literacy, Jiang et al. (2019) implemented "discipline-specific roles," a type of functional role related to academic disciplines. In the study, students could assume the role of writer, scientist, artist, or engineer to produce multimodal science fiction stories in small groups. Though not yet applied to the domain of data literacy, using disciplinary roles could help capture the many dimensions of using data.

Curriculum and Framework Development

We developed our role framework by generating 8 aspects that are encompassed in using community data science for advocacy: narrative, artistic, investigative, activist, technical, making, scientific, and exploratory. Our next step was to consolidate aspects into roles by minimizing redundancy and preserving diverse ways to participate and engage with data. The roles of *artist* and *journalist* were conceived to cover the narrative, artistic, and making aspects of data. For the remaining aspects of investigative, technical, scientific, and exploratory we created the *detective* and *scientist* roles. Last, we reasoned that activism was an aspect all roles could adopt. We piloted initial role concepts in a youth advisory board, consisting of 3 high school youth from underrepresented groups in data science. Sessions were focused on understanding their attitudes and impressions on proposed disciplinary roles and identifying technologies to aid in data analysis. Using local datasets and data analysis software, youth assumed roles to work collaboratively with their own individual role-related objectives (such as forming a story). Feedback on the role and experience was collected through discussions at the end of each activity. The advisory board helped refine role concepts and identify Tableau (https://www.tableau.com), an interactive visualization and analytics software, as a suitable technology due to the affordances for tinkering and user-friendly interface.

After roles were finalized, we began planning to implement them in a broader curriculum for an advocacy-focused summer program. The research team mapped learning objectives of the curriculum to each role and developed four sessions, each focusing on a single role. Our goal for the sessions was to introduce each respective role and develop the proficiencies needed to enact them in a collaborative context. Each session began with instructional lessons among all youth covering learning objectives and role competencies which was followed by a collaborative activity in smaller groups with facilitators. Our four role-based sessions were:

- Journalist: Exploring personally relevant data (e.g. popularity of one's name over time), sharing results in groups, and writing headlines to communicate the most interesting insights.
- Detective: Learning how to explore datasets with Tableau through an interactive tutorial. Working in groups to find interesting insights in data using summary statistics (counts and averages) and charts.
- Scientist: Watching a video that introduced statistical hypothesis testing and confidence intervals. Applying confidence intervals in Tableau to draw insights from their own data.
- Artist: Introductory activity looking at examples of data art and engaging in sketching to represent data

The sessions were designed to empower the participating teens to use data to inform the advocacy campaigns they developed to redress systemic injustice in their communities, wherein all activities were designed to build towards their final projects (Figure 1). An additional fifth session was planned where students assumed a role according to their preference and collaborated to incorporate prior work with data into their own advocacy campaign.

Summer Program Curriculum

All sessions were in the context of a partnership with a non-profit organization, The Women and Girls Foundation (WGF). For the past fifteen years, WGF has run GirlGov, which is a civic engagement and social justice advocacy

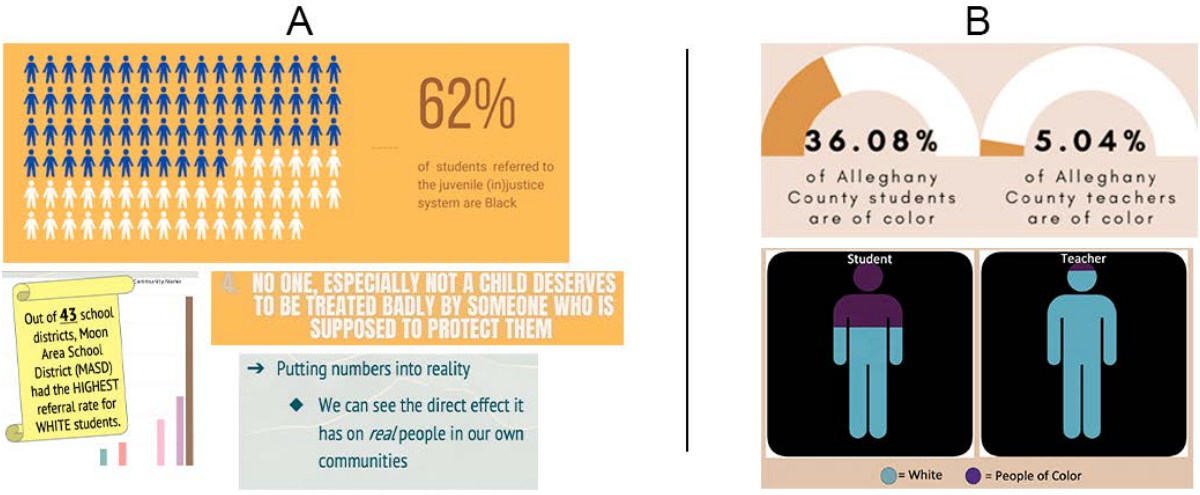
program for high school-aged women and femmes. The primary goal of GirlGov is to train teens to translate their passion for social justice and equity into tangible systemic change. The GirlGov curriculum is rooted in critical theory and community organizing and aims to develop teens' civic knowledge, critical consciousness, connection to community, and confidence as they develop an advocacy campaign around an issue they are passionate about. First, the teens break into groups based on their passions and identify an issue they want to address. After they identify an issue, they participate in a series of lessons, activities, and sessions to research root causes, learn from experts and other advocates, identify a SMART goal or intended objective of their campaign, participate in power-mapping to identify who holds the levers of power to create change, and identify the multiple strategies they will use to convince those in power to change policies. There were also additional opportunities for teens to use the arts and creative expression towards activism.

Program Deployment

The summer program occurred over three weeks and lasted 3.5 hours per day (4 days a week). In coordination with program leaders from GirlGov, we designed five sessions, each lasting approximately 75 minutes, occurring twice a week for the first two weeks and once for the final week. Due to the ongoing effects of COVID-19, all but the first of our sessions happened remotely utilizing video conferencing software and breakout rooms for small group work. As part of the program registration application, the youth provided advocacy-based topics of interest; for example, “education and desegregating school”, “racial equality”, or “school-to-prison pipeline.” Based on these topics, the researchers identified relevant datasets which they introduced in an initial session with the youth. The GirlGov team then held a session for teens to discuss their personal connections to each of the data sets and share examples of the issues in their own lived experience. Based on these discussions, youth formed their own groups around two prominent issues: *the school to prison pipeline* and *teacher and student racial disparities in high schools*. The first dataset contained records of juvenile referrals in the local county. The second described the school demographics of public schools in the county. A total of 24 students enrolled in the program with session attendance varying from 17 to 23 students (ages 14-17). For smaller breakout sessions, each advocacy group was divided further within the two topics by program leaders to create 4 subgroups (4-6 youth) for collaborating and 1-2 facilitators (including research team and GirlGov staff), wherein the youth worked on their selected dataset. Sessions and breakout rooms were recorded, transcribed, and de-identified for analysis

Figure 1

Collage of youth’s work developed for social media posts or final presentations that pertain to advocacy campaigns focusing on either the school to prison pipeline (a) or teacher and student racial disparities (b).



Results and Discussion

From a curriculum perspective, there was promising evidence that framing data science around roles facilitated critical engagement with data by helping youth form insights about reality, consider the context surrounding data, and use data to enact change. Specifically, roles were unique in which critical aspects they most fostered. For example, the Artists and Journalist roles promoted creative ways to connect with the human element of data while the Detective and Scientist roles supported critical reflection on how the data was generated. Such diversity suggests a role-based approach could provide more affordances for students to critically engage with data.

However, our analysis struggled to draw conclusions on how assuming a specific role facilitated collaboration. While roles seemed to demonstrate ways in which students could contribute, they did not always lead to clear division of labor or responsibilities. Groups often focused on a single role at one time, leading youth to sometimes shift to that role. This shifting, similarly observed by Jiang et al. (2019), could be embraced by a role framework where roles responsibilities are modeled as leading and coordinating the group in a task. For example, Detectives could be prompted to lead the group through data analysis, rather than conduct it alone.

Out of all roles, the Scientist was the least represented in the work produced by students. It proved the most challenging role to implement, as students struggled to latch on to ideas of statistical hypothesis testing. This was not surprising, as the role required more specialized knowledge making it the least intuitive to youth. Similarly, the term Scientist might draw connotations from natural sciences or chemistry, which differ in practices from data scientists. Furthermore, there may have been less clarity into how this role was to contribute to a final deliverable. Although fundamental to data literacy and data science, a role centered around Scientist may need to be reframed around a less statistical curriculum to be more intuitive and easier to engage with for youth.

Future Work

Our future work will further analyze the results of this deployment to support the refinement of our role-based data science curriculum. Our analysis will also attempt to describe collaborative aspects of the program, such as inter-role collaboration, and potential methods for future support. Insights will inform our plans to design and develop a collaborative learning system specifically for facilitating role-based critical data literacies in youth.

Abstract: Socio-ecological histories of places are political, contested, and intimately linked with ways of knowing and being in the world. Supporting students in perspective taking and reasoning through contested histories of places are equity practices that allow for multiple and diverse stories to be told, honored, and incorporated in science learning. In this paper, we describe an approach to teaching about socio ecological systems from the Learning in Places project using a framework called *Socioecological Histories of Places*. We first describe the framework and its design within the Learning in Places project. We then analyze one teacher's implementation of this approach and discuss implications for understanding issues of power, historicity, and ethical decision-making in field-based science learning and teaching.

Introduction

Socio-ecological histories of places are political, contested, and intimately linked with ways of knowing and being in the world. Supporting students in perspective taking and reasoning through contested histories of places are equity practices that allow for multiple and diverse stories to be told, honored, and incorporated in science learning (cf. McGrath & Jebb, 2015). Oftentimes, science education in the U.S. has positioned humans as separate from the natural world, or in ways that are ahistorical, which render the intersections of social and ecological systems invisible and thus ensures that students do not have access to powered and historical analyses of these intersections (Authors). Further, our failure to incorporate these histories reduces learners' opportunities to understand the complexities of social and ecological systems central to 21st century challenges.

The work we describe in this paper describes Learning in Places (LiP), a four-year, participatory design research study funded by the National Science Foundation. Learning in Places seeks to co-design (with classroom educators, families, and community-based organizations) learning engagements that support young science learners in Kindergarten to 3rd grade with equitable, culturally-based, socioecological systems learning and sustainable, ethical decision-making using field-based science education in outdoor places (e.g., gardens, parks, neighborhoods). The pedagogical model incorporates students' observations and wonderings, family cultural and community practices, critical historicity of place, and ethical deliberation and decision-making in the form of "should we" questions. The project intentionally designs porous learning environments, where learning happens across time and place, in classrooms, homes, neighborhoods, and community settings. To provide an exemplar of how and why exploring socioecological histories of places is critical to learning and teaching about complex socioecological systems, we analyze one teacher's implementation of this approach and discuss implications for understanding issues of power, historicity, and ethical decision-making in field-based science learning and teaching. **Research questions that guided this analysis are: (a) How does this educator use elements of the framework in their science-related planning, instruction, and reflections on their practice?, and (b) What challenges did this educator grapple with when attempting to embody and actualize the ideas and practices in the socioecological histories of places framework?**

Theoretical framing

We draw heavily from work in social design experiments (Gutiérrez & Jurow, 2016) and participatory design research (Bang & Vossoughi, 2016) to conceptualize our approach to co-designing field-based science learning environments toward just, equitable, and culturally thriving communities. Social design experiments work toward social transformation "by creating a significant reorganization of systems of activity in which participants becom[e] designers of their own futures" (Gutiérrez & Jurow, 2016, p. 566). Similarly, participatory design research requires a fundamental examination and critique of structural sources of inequity, and collective dreaming of alternative, more just forms of partnering (authors). In the Learning in Places project, we intentionally engaged in co-design with district leaders, leaders of community-based organizations, teachers, and families to support the development of co-designers as *historical actors* (Gutiérrez & Jurow, 2016), or "designers of their

 © ISLS

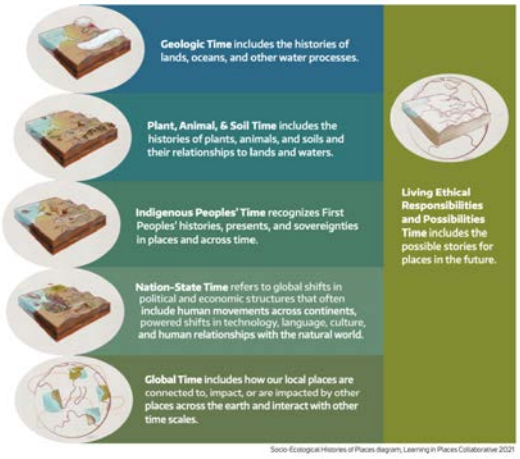
own futures" (p. 567). This involves not only a sense of one's own identity in broader cultural and systemic contexts, but also a historicized understanding of how certain practices--in particular, practices that perpetuate inequity--came to be and are sustained over time. We use this as a lens through which to examine the episode presented below.

Design

In the Learning in Places project, we have designed a set of *educator frameworks* that make visible core dimensions of practice for just and equitable field-based science education. We focus on one of those frameworks, called *Socioecological Histories of Places* (Learning in Places Collaborative, 2021). When scientists study complex systems phenomena in places, they need to understand those places across different scales of time and space. For example, when engaging in restoration, scientists need to first understand the history of a place and the various historical decisions that have been made to shape the land and waters of a place. They need to think across timescales–from geologic time to nation-state time to global time to the future–to understand how natural processes intersect with human decisions and the effects those might have on the future health of a place for all of its inhabitants (cf. Santos-Martin et al, 2019).

The socio-ecological histories of places framework involves thinking across six time scales. These provide a framework for supporting learner sense-making within and across time and place. A key reason to engage learners in this thinking is that it will support them in understanding how things may have changed slowly or rapidly, and how decisions lead to ethical, just and sustainable futures and possibilities. Learners should also reason across multiple time scales to understand the impacts of slow or rapid change in any one of these scales and how this affected/affects another. For example, learners can wonder about how rising temperatures (compared across geologic, nation-state, and global histories, for example) have impacted and are impacting plant, animal, and soil time.

Figure 1: Histories of Places visual graphic



Methods and analysis

For this analysis, data sources included video and audio-taped recordings from a classroom implementation involving the use of the Histories of Places framework with this focal participating teacher. Data sources also included affiliated documents (e.g., student work samples, transcript of a teacher post project interview). Video and audio recordings were transcribed and then coded in Dedoose. Codes included the six timescales in the Histories of Places framework (e.g., plant, animal, and soil time, Indigenous People's time), as well as elements of language use (e.g., past, present, or future tense).

Initial findings

As an exemplar of how these ideas were implemented, we present an episode from one second-grade teacher and co-designer, Ms. Poppy (all names used in this text are pseudonyms), and her subsequent reflection based on her post-interview. To get ready for this lesson, Ms. Poppy had created a timeline out of pieces of paper that spread across the length of the whiteboard, with a picture of Creekside Elementary (their school) at one point on a horizontal line that ran the length of the papers. To begin the lesson, Ms. Poppy engaged her class in a reflection

 © ISLS

using the question “What and who was here before me?”. Ms. Poppy asked students to go to their desks and draw their ideas, and when they returned to the front of the room, Ms. Poppy put their drawings on the timeline. Ms. Poppy then facilitated a whole class discussion during which students shared their ideas. At the beginning of the discussion, students shared that dinosaurs, bugs, trees, and grassy fields were all in the place now occupied by Creekside Elementary and its surrounding neighborhood. Then one student, Simon, shares the following idea:

> Like our great, great, great, great grandfathers, like, had developed guns and then we took like canoes and rode over here. Then we're like, "We have guns. You only have bow and arrows. We will shoot you if you don't come and give us some of this land." Since the Native Americans were nice, they gave the land to us. But then we were kind of not so nice to the people who were, the Native Americans who were nice and we like kept saying "We will shoot you with our guns unless you give us more land." And they were scared and then they kept giving us more and more land and they had smaller and smaller land until this was all ours. Then they only had like a small bit of land for them.

In this example, we see Simon engaging with Indigenous people’s time, nation-state time, as well as global time, as he made visible the deeply powered relationship between Indigenous peoples and European settlers. In his response, the complexity of his thinking spanned across temporal and spatial scales to connect past events and present positionings of both himself and others with a shared ancestry to the settlers. He uses the term “we” to refer to settlers, and “they” to refer to Indigenous peoples. This positioning shows a shared assumption of identity of Simon with the rest of the class, and the subtle ways that whiteness is present as implicit identities amongst students. We also see Simon attending to differences in orientations to nature-culture relations, particularly the relationship to land.

In addition, we see power and historicity emerging in Simon’s comment as well. Settler colonialism, which is premised on removal of Indigenous peoples from their lands, often through violent means, is acknowledged by Simon. He is making explicit how the immoral ethical decisions made by non-Indigenous settlers were displays of power imbalances, exacerbated by differential access to and use of tools and weaponry. Not only was this powered relationship something that led to the forced removal Indigenous peoples from their lands, but Simon also uses the terms “we” and “us” when referring to the settlers, recognizing his shared ancestry and implicitly acknowledging that this history is connected to the present day. Finally, Simon is surfacing the different orientations to land between the Indigenous original inhabitants of the land and the settlers. This orientation, and the relation between the two groups of people, reflect different values - what we hold to be right and ethical - as we see in the “nice vs. not so nice” sentiment.

As the class continues to delve into ideas of Indigenous presence in the region occupied by Creekside Elementary, the following episode emerges:

> Ms. Poppy: Do you think they go when Native Americans were-
> Class: No.
> Ms. Poppy: Oh sorry, I apologize. I just said "Native Americans were." We have plenty of people in this area who are Native Americans whose ancestors have been here for a really long time. So I meant to say, "When," or "Before Europeans came and started living here, do you think they were long before that, the dinosaurs?

At the end of this episode, Ms. Poppy engages in self-correction by recognizing that she referenced Native Americans in the past tense, a move that invisiblizes Indigenous presence and futurity. We argue that this form of humility is an important step in dismantling power hierarchies between educators and learners, and between educators and communities. This is a recognition of the limitations of the educator’s own knowledge and understanding, and indicative of the challenges of engaging across multiple timescales that are often left invisible in science education. This is also a model of making repairs in micro-moments of instruction, repairs that remediate epistemic violence against children when we make their histories invisible in classroom

interaction.

> In Ms. Poppy's post-interview, she reflects on this episode and what it taught her. She says:
>
> I think a lot about the history of places conversation that we had, and how just like really subtle language, but that ends up being really, really powerful language, like talking about Native people in the past, rather than the present, like these little things. And again, so much of this comes from watching tape and reading scripts. And I think that we get, when we're in the moment, we're responding to things. And we're not always like thinking it through every single piece of language. And then when you get to go back and look through it, you're like, okay, this is what I need to think about for next time, or this is how I need to word that differently. So I think those, you know, the history of places is really big for that power. And...historicity? And then I think equity. I mean, I really do feel that I needed a lot to grow as a teacher with my need for like, control of behavior, on walks was something that was so big for me to like, need to have that control.

We see a gradual attunement to the importance of language choice during instruction, and the connection between language and power. Ms. Poppy also reflects on the need to have time to "watch tape and read scripts" as a way to reflect carefully on her language and learn how to continually improve her teaching practice. In this way, Ms. Poppy is emerging as a *historical actor*, in deepening her reflections on how her own practices perpetuate invisibilization of Indigenous peoples, as well as how her actions reflect powered dynamics that carry across time and place.

Conclusion & implications

Shifting the dynamics of power and historicity in moment-to-moment interaction in learning environments is central to actually creating educational equity and forms of education that can contribute to just, sustainable and culturally thriving communities. However, as of yet we have a paucity of work that has traced the learning pathways of educators who are learning to shift their paradigms and to see and enact more just learning environments. This is particularly true as it relates to Indigenous peoples and histories. There is a dearth of empirically based classroom study of these learning dynamics. Further, there is nearly no literature about the role of Indigenous peoples in the scientific study of place. This study marks an important new dimension of how place and field-based science education can and should start to take up the complicated and layers social histories of places as central to learning.

Draw a place where you learn important and useful things: developing an analytical framework to investigate students' conceptions of learning environment

Katarzyna Potęga vel Żabik, Ilona Iłowiecka-Tańska
katarzyna.potega@kopernik.org.pl, ilona.tanska@kopernik.org.pl
Copernicus Science Centre

Abstract: In this study, we discuss the potential of a new methodological approach to assess children's educational ecology. 1444 drawings from 11-17 years old students were collected in order to ascertain how they conceptualize their learning environments. The drawings categorization scheme was based on the three elements of the Activity System Model (Engerström 1987, p. 115) – subject, instruments, and communities. The majority of the students' drawings portrayed traditional learning spaces like home or classroom, which is consistent with the literature on the subject. As for the analysis of the three elements of the model (subjects, instruments, and communities), the proposed coding scheme describes the community element particularly well.

This paper presents the methodological approach of analyzing drawings made by elementary school students (N=1444) as primary sources of data about their conceptual understanding of learning environments. We analyzed drawings elicited from school students in order to ascertain how they conceptualize their learning environments – including not only such spaces of formal schooling as schools and classrooms, but also informal learning situations (purposefully organized and spontaneous), and new environments like computer - and Internet-based activities (Sawyer, 2014).

Drawing has a well-established history in educational research as a way to document educational phenomena (Chang et al., 2020; Katz, 2017; Harris et al., 2014; Haney et al., 2004; Weber & Mitchell, 1995). For decades, draw-a-picture technic have been used to understand students' conceptions of scientists, e.g. the Draw-a-Scientist Test (DAST) (Chambers, 1983); to explore students' mental models and conceptual understanding of science concepts e.g. internal structure of trees (Rybska et al., 2017); and to investigate attitudes and beliefs toward science and learning (Quane et al., 2021). Hsieh and Tsai (2018) conducted a cross-sectional drawing study of 8-to 18-year-old students' conceptions of learning (i.e. students' views of what learning is) and found that most students held traditional conception of learning - teacher-centred classroom, with students as passive listeners.

The evident benefit of using drawings in educational research stems from the fact, that drawing enables the expression of complicated ideas and thoughts even under conditions of limited writing and reading skills (Selwyn et al., 2009). By using drawings to investigate students' conceptions of their learning environment, we sought to overcome certain limitations of traditional methods of obtaining quantitative data, like written questionnaires and expensive and time consuming interviews and direct observations. However, this decision in turn gave rise to further methodological issues regarding the data coding frameworks and procedures.

The usefulness of draw-a-picture method in educational research depends on its power of assesment. Even the well-known and frequently used DAST method has several modifications of the procedure and different coding schemes (Ferguson & Lezotte, 2020). To obtain results that are generalizable and comparable, we developed a checklist of features the drawings may contain based on existing model of learning enviroment. Directly invoking the concept of *Learning in Activity* (Greeno, Engerström, 2014), we view the learning process as a unit that is larger than an individual person – a group of people, a classroom or a community. On this approach, key roles in learning are played by the agent (student), the object, and the resources which the subject uses to transform the object in line with his or her goal. The process happens within a given community, with its own division of labor and rules. While this model is mainly used to analyze situations in which learning occurs, it also appears useful and relevant in attempting to categorize and analyze static concepts, i.e. the metal models of learning environments illustrated by children.

The primary research questions of the presented study are as follows:

- How do students conceptualize their learning environment? How rich is this conceptualization?
- What elements make up the space as the learning environment? Which of them are recurrent?
- What is the structure of the presented concepts?

 © ISLS

The research project presented herein formed part of an educational program developed by Copernicus Science Centre and financed by the Polish Ministry of Science and Education, aimed at bolstering the development of science capital among students from smaller towns and villages in Poland (in 2019, the program involved approx. 50,000 students, their families and teachers).

Method

Study participants

In total, 1444 primary school students (702 girls, 49%) participated in the study; they were between 11 and 17 years old (M = 14.00, SD = 2.00) and were students of 12 schools located in villages and small-to-medium sized towns and cities in Poland (below 130,000 inhabitants). Non-probability sampling was used to gather participants: the students who participated in this study were recruited from the schools participating in the "Science for You" educational program.

Instruments and Procedure

The "Draw your learning environment" task was a part of a 16-page questionnaire booklet. The questionnaire in a paper-and-pencil format was administered by teachers during school hours. Children were given 45 minutes to fill out the questionnaire. Data collection was anonymous. The school authorities and students were verbally informed about the study and their consent was obtained. Participation in the study was voluntary. Instruction stated "Draw a place where you learn things that are important and useful for you. Label it". Additional open question was placed under the drawing space ("What place is this?")

Data coding framework

To explore how the learning environment is conceived by students we developed a checklist based on the *Activity System Model* (Engerström 1987, p. 115). Of the six-element set that makes up the *Activity System Model*, we chose to describe only three, shown in the table below. We found it impossible to analyze the remaining three elements from the perspective of children's drawings (*objects*; i.e. the scope of the learning process; *rules*, i.e. the set of principles guiding the actors in the process; and *division of labor*).

Table 1

Categorization scheme, taking into account selected elements of the Activity System Model

	Description	Category	Indicators
1. Subject	People involved in the learning process	number	Are people present in the drawing? How many people?
2. Instruments	Tools / learning aids used in the process	number, characteristics	2.1 Traditional (book, notepads) 2.2 New technology (smartphones, laptops)
3. Communities	Varieties of spatio-cultural elements	number and characteristics of learning spaces	3.1 context: formal (school) / informal (forest) 3.2 type: public (museum, library) / private (home, garden) 3.3 dimension: physical (buildings, spaces, nature) / enacted: - symbolic (love to parents, my mind, whole life); -virtual (computer games, social media).

Each drawing was coded using the checklist developed by authors to determine if a feature was present or not.

Preliminary results

Subject

Most of the drawings (88.1%) did not include any people, while 8.4% of the images depicted a single person, and only 3.5% of drawings depicted more than one person (see table 2). There were no significant differences between

boys and girls. This result may be related to the way the task was formulated, which could be interpreted as only concerning space.

Table 2

Subject: Number of people depicted (N = 1444)

	n	%
No people	1272	88.1%
One person	121	8.4%
More than one person	51	3.5%

Instruments

Learning tools were presented in 22% of the drawings, including both traditional (books, notebooks) and modern sources of information (computers, smartphones, the Internet). Traditional learning aids are present in 11.1% of pictures, while modern sources are visible in 8.2% of pictures. Both types (traditional and modern) together are visible in 2.8% of drawings.

Communities

The number of learning environments depicted in the drawing

The vast majority of the respondents (88%) drew and described one learning environment in their drawing. Two such environments (mainly: home and school) were depicted by 7.34%, and only 2% of student drawings indicated 3 and more places of learning (table 2).

Table 2

Communities: The number of learning environments depicted in the drawing (N = 1444)

	n	%
1 learning environment	1276	88.38%
2 learning environments	131	9.08%
3 or more learning environments	51	3.5%
No place of learning declared	7	0.48%

Context and type

Most of the respondents depicted informal learning contexts (62.8%), of which the majority were domestic spaces (a home, a room or part thereof, pieces of furniture such as a desk or bed) 55.9% of all indications. More than 70% of the respondents depicted public spaces (school building, stables etc.), while private spaces were visible in slightly smaller number of drawings (60% of depictions). Most of the drawings contained representations of physical learning spaces, whereas less than 10% of the students depicted either symbolic or virtual spaces (see table 3).

Table 3

Communities: Context and type (N = 1444)

			n	%
Context	Formal		537	37.19%
	Informal		807	62.8%
Type	Private		874	60.53%
	Public		1045	72.37%
Dimension	Physical		1150	79.64%
		symbolic	13	0.90%
	Enacted	virtual	118	8.17%

Conclusions

 © ISLS

Our findings indicate that the "Draw your learning environment" method, presented herein, appears to be well suited to the study of learning environments in children. The relatively small non-participation rates (no drawing and description n=152, no drawing n =44, no description n =81) indicates that the task is suitable and understandable for 11-17 year old school students.

In the presented study, majority of the participants presented similar interpretations of the learning environment concept - mainly as a physical space. Most of the participants drew their home spaces as places related to the practice of learning. In the traditional model of formal education, students receive their learning at school and practice it at home by doing homework and preparing for tests. Although the drawings do not directly point to the home as a continuation of the school experience, the descriptions suggest describing this type of activity (*e.g.*"the desk where I do my homework"). Drawings depicting informal areas of education and free-learning settings such as museums, the forest, and dance were in the minority.

As for analysis of the three elements of the model, the proposed coding scheme describes the community element particularly well. However, it has a certain shortcoming in the sense that it does not allow for the assessment of processual elements and relations (dependencies, hierarchy) between particular elements of the Activity System model. Further limitations are as follows. Secondly, we think that while drawing might provide a promising way to investigate school students' mental models of learning environments, in future studies, it should be supplemented by interviews.

Abstract: This paper describes family member participation in an informal learning setting called Family Create Nights. With attention to the design of equity oriented STEAM learning experiences, we argue that looking at moments of tension or disruption in families' work together may reveal important needs and desires of learners. Our analysis reveals the ways families positioned themselves in terms of expertise, created collaborative arrangements for working together, and asserted creative control through their project creation. Findings point to the importance of holistically attending to families learning needs, to highlight parents' own curiosities as well as the roles of youth as facilitators and educators within their families.

Introduction

In recent years equity oriented researchers and educators have increasingly turned their attention towards the design of programs that engage families in learning with creative technologies. One model for this brings in families' funds of knowledge through storytelling for culturally responsive computation learning (Roque, 2018; Tzou et al., 2019). As researchers' exploration of this type of family learning is relatively new, there is a need to better understand families' social organization to support the design of pedagogical and facilitation practices..

In this paper we look at family members' participation in the Family Create Night (FCN) workshop series aimed at creating joyful and personally meaningful experiences with technology for families historically marginalized from computing spaces. In this learning context we asked: When did tensions or disruptions arise in families' collaborative work together, and how did families negotiate them? Through our analysis we identified moments of disruption or indications of tension as families made projects using creative technologies. We propose that these moments reveal the needs and desires of learners in ways that can inform program design and the development of facilitation practices. In looking at tensions and disruptions, we saw curiosity and a desire to make creative contributions from both youth and adult learners, and argue that parent's learning must be centered along with those of youth in these collaborative learning environments,

Theoretical Approach

The social organization of informal learning contexts is key to understanding how participants learn together (DiGiacomo & Gutiérrez, 2016; Rogoff et al., 2016). In this short paper, our analysis focuses on the social organization between family members in FCN, which we understand as joint activity. Joint activity positions youth and adults as, "active co-participants in knowing and learning" (Vossoughi et al., 2021, p.215, citing Rogoff, 1994). Each family has their own culture of interactional arrangements and values that all members contribute to shaping, and "while practices may be sedimented, they are nonetheless reified in particular moments of interaction and potentially transformed in those same moments"(Keifert, 2021, p.267). This means that facilitators and designers must attend to how the design of collaborative learning environments might contribute to reifying or reshaping families' cultural practices.

In the learning sciences, disruptions, tensions or breakdowns have been used to understand collaboration and joint work through theories of boundaries and infrastructure (Akkerman & Bakker, 2011; Penuel, 2019; Penuel et al., 2015). We take up these theories to see families as their own cultural communities with their own sets of cultural tools, roles, and practices. Penuel et al. (2015) describe joint work as the negotiation of differing goals and desires for individual participants within these cultural communities. From this theoretical perspective, points of tension or disruption can be leveraged to inform the redesign of collaborative structures, norms and activities. We define tension or disruption in the context of families' work together as: moments of negotiation that disrupt the flow of work, moments of dissent or refusal, disengagement or discontinuing work, and/or expression of an unmet desire. We do not place a value judgment on these expressions or moments of tension, but view them as places of negotiation in collaborative engagement.

 © ISLS

Context and Methods

This study draws on data from an iteration of Family Create Night (FCN) designed to serve Spanish-speaking families who recently emigrated to the US, and held in partnership with an elementary school in the mountain west region of the US. In this four-week workshop series, families engage in creative computing together, using ScratchJr, a block-based programming software designed to be accessible for young learners. The workshops use a four-part structure where families share a meal, connect with their peers, make a project together, and share their creations (Roque, 2016). A university professor, graduate, and undergraduate students acted as both researchers and facilitators to support families to create a favorite family story.

We recruited 9 families: 14 children (ages 5 to 10 years) and 11 adult caretakers. Our analysis focuses on the 5 families who attended at least 3 of 4 workshop sessions and participated in interviews. Ethnographic data collection from the workshops included facilitator fieldnotes, screen recordings capturing activity in ScratchJr, and post-workshop interviews with families. The research team applied a first round of iterative coding to fieldnotes and interviews to identify references to family interactions during project making. Authors then coded fieldnotes, interviews, and screen recording transcripts for moments of disruption or tension (as defined in the Theoretical Approach section above).

Findings

During FCN workshops, families took up a range of different collaborative arrangements in which they negotiated roles, contributions, and turn-taking. These arrangements included whole families working on one project, children working on projects individually while their parent took a hands-off role, and a parent working with their youngest child(ren), while older children paired-up to work on their own project. All families had moments where collaboration flowed; they took up each other's ideas, embraced complementary roles, and transitioned smoothly while turn-taking. However, families also experienced moments of tension or disruption, which emerged around the positioning and negotiation of roles, creative control of projects, and physical control of the materials and tools (often concurrently).

Collaborative Arrangements and Negotiating Contributions

Tensions or disruptions frequently arose when participants voiced a desire to increase their participation in a collaborative project. In these moments of disruption, we saw different styles of negotiation. Some parents, like Nina whose whole family worked on a single project, were very assertive in their establishment of turn taking across family members. In an exchange between Nina and one of her daughters, Lorena, Nina was selecting a character to represent herself, when Lorena asked, "Can I pick it?" Nina responded, "yo la escogo. < *I'm choosing it.*>" Lani, a volunteer from the school reinforced this by explaining to Lorena, "You chose yours, now it's your mommy's turn."

Another family, Julia (parent), Kiara, Cal and Hamid, worked in pairs, with Julia and Kiara on one iPad, and the two boys on another. Cal and Hamid argued throughout the workshops about who got to contribute to the project. During one workshop, a facilitator attempted to demonstrate how to work more collaboratively on the iPad, saying, "Here, put it on the table so you can both do it. Set it down so you can both work on it." The two obliged, but when they returned to fighting a few minutes later, Julia tried to intervene by inviting Hamid to help with her and Kiara's project, saying, "Ven, tu auydame aqui Hamid. < *Come, you help me over here Hamid*.>" Julia defused conflict in that moment by soliciting Hamid's help, and reconfiguring the family's collaborative arrangement.. These kinds of interaction were characteristic of the negotiations families engaged in as they tried to join their familial structures for collaboration with those required by the workshops.

Physical control of device

Tensions over contributions often manifested in a need to negotiate who had physical control of the device, as seen in the example above with brothers Cal and Hamid. This sometimes came up when one family member tried to help another with something they were struggling with by taking the iPad from them and performing the programming action. For example, in a moment of tension between Hamid and Kiara, Kiara rejected Hamid's help and started crying, while Julia affirmed that Kiara could do it herself, " Dejale, ella lo esta haciendo. Ella sabe que hacer. < *Let her. She knows what she is doing. She knows what to do*.>"

It was common to see both children and parents pushing family members hands away as they worked on projects. Sometimes this gesture was used to assert control or ownership of the activity, like when facilitator Amy observed Kiara push Julia's hand away and say, "yo muevo las cosas! < *I get to move the things!*>" after Julia tried to move some characters. In other instances pushing a hand away was done in service of scaffolding learning. As one facilitator Coreina observed, "Nina would push her daughters' hands away from the screens sometimes, which led me to actually closely observe the family's dynamic. What I noticed was that Nina was

very intentionally doing things in ScratchJr herself, but narrating her actions and what she was making happen to her daughters. Then, once she had completed her action, she would then get Mia or Lorena to do the same thing on their own from start to finish." This observation points to facilitators' ability to gain significant insights about family dynamics through attention to moments of disruption. However, caution must be exercised in initial interpretations of the meaning of a gesture or action in the context of a family's collaborative practice.

Creative control

Role negotiation also played out in moments of tension when both parents and kids expressed desires for creative control. For example, Julia discussed the challenge of everyone in the family, including herself, wanting to "make what I wanted to make." Negotiations around creative choices were most often around aesthetics (ie. "*No, I like the pink one more*"), or continuity or percieved fit (ie. "*We do not need flowers in a library*"). Within aesthetic negotiations, tensions over the visual representation of family members were by far the most common. In prior analysis (Roque et al., 2021) we found that families faced limitations and tensions in how they were able to visually represent themselves in ScratchJr, especially when it came to race and body type. We found here as well, that frictions emerged as individual family members tried to assert their agency over how they were represented in the projects.

Both parents and children commonly expressed displeasure at how they were portrayed when other family members selected or edited characters that represented them. In an exchange between Lucia and her daughter Jasmine, Lucia started to select a character for Jasmine saying, "ponemos una foto Jasmine? ¿Cuál quieres? Oh, esta, esa. < *Should we add a picture, Jasmine? Which one do you want? Oh this one, this one.*>" Jasmine dissented, "No, esa no. < *No, not that one*.>" Lucia responded affirmatively, "andale pues. < *Okay then*>," and let Jasmine select the one she wanted. In other instances, family members' expressed desires about their own representation was not respected. For example, Hamid became upset when his brother Cal represented him with a cat character, saying, "Noo that's not me." Cal responded by selecting a pig character and saying, "Okay you can be this one," which made Hamid more upset. Cal only agreed to change Hamid's representation to a human character after Hamid got their mother Julia to intervene.

Another form of tension related to creative control was caused by what we interpreted as discontinuities in participants' priorities regarding their projects. We saw several instances where one family member (usually a child) wanted to take more time to work on aesthetics, while another (a parent or sibling) wanted to move on to develop other aspects of a project, often in service of completing the project by the end of a workshop. In one example, daughter Camila fixated on the selection and aesthetics of a dog character, while mother Ana said, "Corrale que tenemos que hacer todos estos, y no hemos hecho ni uno. < *Hurry we have to make all of these, and we haven't even made one*.>" In a related dynamic common between children and parents in the workshops, parents shut down their child's assertions that they wanted to continue drawing instead of working on the ScratchJr project. These dynamics may point towards children prioritizing whatever form of creative expression was most compelling to them in the moment, while parents generally seemed to be more product oriented.

Expert/ Novice Positioning

In interviews, some parents discussed a dynamic where children were positioned as experts and parents as novices with technology. One mother, Marta said of her sons, "Arturo enseñó a Roberto, porque me quitó el tablet, 'no mami, es que tú no sabes.' <Translation: *Arturo taught Roberto because he took the tablet from me, 'No Mom, you don't know what you are doing.*>'" During the workshop that Marta described, Amy, a facilitator, had also observed that Roberto and Arturo "had taken over their mom's iPad and deleted her project so they could restart with their own… Marta, was sitting off a little from them and was not participating actively with the boys."

In an instance during the following workshop, facilitator Amy observed a further interaction between Marta and her son Arturo. "Marta asked Arturo if he would teach her how to do Scratch this time, and he said 'no' that he was the expert. After a bit though, he said he might be willing to teach her some." Even though Arturo had positioned himself as an expert (as did Marta by asking for his help), he was hesitant to teach his Mom. Later in the workshop families outlined their family story through storyboards and then translated them to ScratchJr. Marta said that because her kids wanted to draw and program their story quickly, "yo nunca traté porque ellos ya sabían*. < I never tried because they already knew how to do it.>"* While the positioning of youth as experts with technology did not always inhibit adults' engagement with the projects, it hindered collaborative learning between family members when youth did not take on a teaching role with their parents or pace their activity to actively engage them as collaborators.

 © ISLS

Discussion

While intergenerational collaboration in informal learning settings may often be positioned as joint activity, adult's learning often remains peripheral, as the lens is still focused on children's learning, placing adults in an assistive role. We found that parents were also curious learners who wanted to experiment and make creative contributions. Ignoring the presence of parents' curiosities and desires both marginalizes parents as active learners, and marginalizes the role of youth as potential facilitators and educators within their families, who shape family culture and dynamics. In earlier iterations of FCN, we noticed this curiosity from parents and created space and time in the design of the FCN model for parents to explicitly create with ScratchJr on their own before introducing their kids to the program (Roque, 2016).

Considering parents as learners is particularly important for technology-based family workshops where the expertise may be flipped from the norm of adults holding more established expertise than youth. Designers of these learning environments should consider how all family members can make valuable contributions and hold expertise in these dynamics, e.g. how to support youth as facilitators in their family and see their parents as curious learners too. Taking on a leadership role as educators within their families is something that may be modeled for youth.

While youth may have been more likely to be positioned as experts around technology, parents were more likely to take on roles structuring turn-taking and the negotiation of work together, as well as asserting their ideas about normative storytelling. Based on our findings on the challenges of negotiating turn-taking and legitimizing the contributions of all family members, initial activities that scaffold the practice of building off of each other's contributions could be beneficial. It may also be worthwhile to consider the tensions families had around normative narrative construction (ie. the continuity issue) and how expansive possibilities for world building, remembering, and dreaming together might be designed for in family's collaborative storying with creative technologies. Lastly, our findings suggest that when representations of the self and personal identity are incorporated into family learning activities, participants may benefit from activities that norm individual family members having agency over their own representation.

Indian Institute of Technology Bombay

Abstract: We explore the challenges of teaching "hardware-embedded Robotic Operating System (ROS) skills" online in a lockdown situation to participants through a hands-on competition. Teamwork is a vital skill in solving modern engineering problems. During Covid-19 lockdown situations, the interaction between teammates significantly reduced compared to regular times. This prompted us to design an engineering problem statement with scaffolding that improves engineering education learning efficacy. A total of 465 teams (1860 participants) were introduced to a problem statement comprising of a autonomous robot navigation, manipulation and a perception task for an indoor unmanned ground vehicle. We study the performance of teams based on several factors such as participant's score, task's difficulty level, number of resources given and the nature of online sessions by instructors. We found the scaffolding approach helped teams in implementing a solution by exploring alternative methods and thus their knowledge.

Introduction

e-Yantra Robotics Competition (eYRC) is an initiative hosted at Indian Institute of Technology Bombay to bring the experience of project-based learning to engineering participants using a competition to deliver hands-on training (Krithivasan, Arya, et al., 2014). In eYRC, participants are given a problem statement called a "theme" to be solved using a robot as a team of 4 undergraduate engineering students. In the past eight years of eYRC, teams collaborated on a hardware-based project physically coming together on their college campus. This collaboration and other aspects of eYRC such as hardware prototyping and fabrication have been challenged by the lockdown caused by the Covid-19 pandemic.

The theme called "Sahayak Bot (SB)" was introduced to 1860 participants (465 teams) in 2020. The problem statement was to program a simulated mobile cobot (a collaborative robotic arm mounted on an autonomous ground vehicle) to assist in inventory packaging activities (Bejarano, 2019). The mobile cobot assisted in packaging by finding objects and moving them to the required location.

The theme problem is divided into multiple tasks spread across six to eight months. The tasks are designed to train novice participants to program a simulated mobile robot to find, identify, and move objects to desired locations autonomously. The theme contains six tasks which focus on getting familiar with Robot Operating System (ROS) (Quigley et al., 2009), Gazebo (Koenig & Howard, 2004), control of mobile robots, mapping and navigation (Filipenko & Afanasyev, 2018), robotic arm manipulation (Chitta et al., 2012), and perception. The mobile cobot consisting of a Universal Robot, UR5 robotic arm mounted on a mobile base was modeled in a simulated environment.

Throughout six tasks, the participants were provided with reading resources, live sessions, and discussion forums to solve a problem statement. In the initial tasks, detailed support was given to ensure participants could gain momentum to tackle the challenges. As the participants progressed in tasks, support was gradually reduced to encourage independent exploration and learning. This approach was inspired by the widely used technique called "scaffolding" (Hammond & Gibbons, 2005) which refers to providing successive levels of temporary support. This helps participants reach higher levels of comprehension and skill acquisition that they might not be able to achieve without assistance.

The challenge is to design a method for teaching skills required to work on industry grade mobile cobot in a simulated environment. Our study analyses the performance of teams on factors such as interaction between teammates, scaffolding in a task's difficulty level, resources given and online interaction by instructors.

The significant contributions of this paper are as follows:

- Designing a scalable methodology to teach the skills required to work on industrial grade mobile cobot.
- Investigation of learning efficacy in the proposed methodology.
- The effect of scaffolding in the proposed methodology is explored.

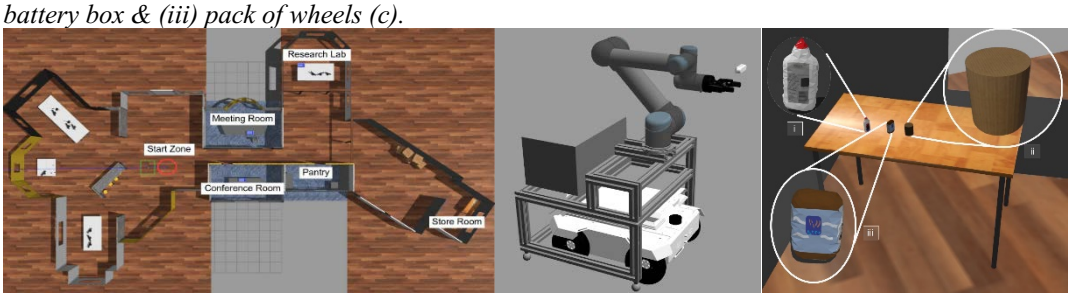
 © ISLS

Theme Design and Methodology

The simulated theme arena comprises different locations as shown in Figure 1(a). The start zone (red marker) is the coordinate where the robot spawns every time the simulation starts. Figure 1(b) shows the mobile cobot modeled in a simulation environment. Figure 1(c) shows the object for pick and place.

Figure 1

Theme and Arena (a), The Mobile Cobot (b) and Objects for pick-&-place task (i) blue box, (ii) battery box & (iii) pack of wheels (c).



(a) (b) (c)

The competition integrated hands-on engineering topics as part of the learning activity, inspired by quotidian activities in indoor environments. It was designed in a simulated environment and carefully broken down into several tasks to better understand the problem statement, as shown in Figure 2. After successful task implementation, the participants learned different robotics concepts inspired by this theme, and its efficacy was analyzed based on the gathered data and insights.

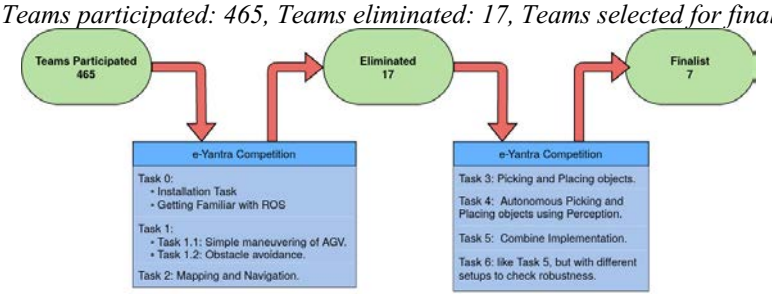
The teaching resources in this theme were mdBook (Klinke & Witzel, 2002), interactive live sessions, surveys, and discussion. The mdBook consisted of resources, learning material, and references for each task. Participants post their queries on the Piazza forum for asynchronous discussion (Andresen, 2009). In surveys, questions related to the task were asked based on participants' experience and time invested in theme. Interactive sessions were conducted to understand participants' problems and provide hints to solve them. Quantitative analysis is based on data collected through surveys, tasks, forums, and learning materials. In contrast, the qualitative analysis relies on resource statistics, performance in each task, and interactive live sessions.

Implementation

The tasks were created based on their difficulty levels which gradually helped the participants to solve a final problem statement There were six tasks given in the SB theme, which are described in Figure 2.

Figure 2

Task flow: Teams participated: 465, Teams eliminated: 17, Teams selected for final: 7



In summary, participants were expected to complete the theme which had several challenges such as autonomously navigating to different rooms (refer Figure 1(a)), searching for randomly placed objects (refer Figure 1(c)), correctly picking and placing these objects in their designated location.

 © ISLS

Resources & Scaffolding

The division of the tasks increases the theme efficacy (Krithivasan, Arya, et al., 2014; Krithivasan, Lala, et al., 2014) by helping the participants understand aspects of robotics gradually. Learning resources in mdBook, support from live sessions, and a discussion forum (as shown in rows 2, 3 and 4 in Table 1) were supplied to them till Task 3. The perception task (Task 4) incorporated scaffolding by removing the learning resources from the mdBook. However, different approaches were suggested to tackle the task. This technique encouraged the participants to look beyond the aid provided which broadened their knowledge of existing literature and eventually helped them to find the best approach for the task.

Results and Discussion

Analysis on performance

Table 1 shows the overall task performance in the competition. The difficulty index row in the table indicates that the higher the value, easier the task is. Note that Task 0 is the easiest and Task 5 the most challenging task. Considering that detailed learning material was provided till Task 3 along with live video sessions till Task 2 to give a better overview of the task and resolve common queries. The resulting teams were able to perform well till Task 3, with a low dropout rate. After Task 4, the support gradually decreased so that teams can learn to collaborate and work upon innovative solutions to solve the problems. We observe that the drop rate increased due to scaffolding. Most of the participants could not complete the task as they found it challenging to learn on their own.

Table 1

Task implementation and outcomes

Row No.	Subject	Task 0	Task 1	Task 2	Task 3	Task 4	Task 5
1	Task Duration (in weeks)	2	3	3	3	4	4
2	References and hints available	✓	✓	✓	✓	✓	×
3	Detailed learning material available	✓	✓	✓	✓	×	×
4	Live session conducted	✓	✓	✓	×	×	×
5	Total submission	390	270	182	139	69	43
6	Difficulty index	0.86	0.71	0.68	0.93	0.67	0.39

Note: Difficulty index (Johari et al., 2011) is calculated as the fraction of average score in a task and range of full score.

Task Difficulty

While designing tasks, the instructors scored task difficulties based on the questions that elicited the learning from that task. For instance, in Task 1, difficulty was rated based on *how difficult it is to make the cobot follow the curve path using either P/PD/PID controller? How difficult is it to avoid obstacles?* and finally, *how difficult is it to combine the overall task within a single script?* The task difficulty level trends are shown in Figure 3(a).

The effect of scaffolding on difficulty level (based on participants' feedback) of each task and their completion rate is shown in Figure 3(b). The gradient of color indicates the scaffolding. The green color suggests more support was provided, and the transition of color from green to light green shows the decrease in support. Figure 3(b) indicates, with the gradual reduction of support from Task 3, the participants' future tasks became more difficult. Also, the plot of task completion percentage signifies the difficulty faced in completing the task. As the task became more complex, only a few participants were able to complete the task.

Learning efficacy

All the problem statements, instructions and learning material were provided to participants in the mdBook. Until Task 2, live sessions were held to explain concepts, including verbal task descriptions, some hints and live Q&A. From the surveys, we observed the helpfulness of live sessions, and Figure 3(c) shows their task-wise feedback rating for provided help (Mdbook & live session) in completing the tasks. We see that resources were of significant support until Task 3, while later, the ratings dropped due to scaffolding. However, pedagogical research in engineering education has shown the importance of project-based learning in creating competent engineers (Mills & Treagust, 2003; Panwar et al., 2020). Moreover, from Figure 3(d), enhanced learning efficacy is observed through working on a real-life problem statement in a step-by-step approach.

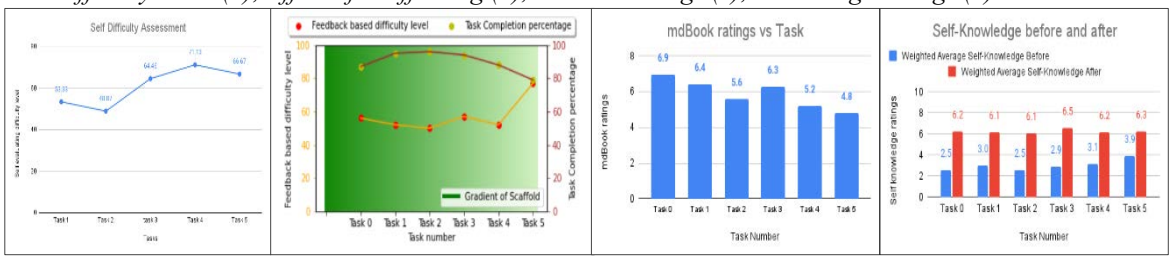
Task difficulty trend (a), Effect of Scaffolding (b), mdBook ratings (c), Knowledge ratings (d)



(a) (b) (c) (d)

Conclusion and Future Scope

The scaffolding approach encourages teams to work more efficiently by assigning roles and responsibilities that helps teams to find the best solution for a given problem. Based on the surveys and feedbacks, we analyzed that a step-by-step approach combined with temporary support that is eventually removed helps the teams gain confidence in the skills developed through the tasks in the competition. The effectiveness of teaching such concepts can be tested further by designing a theme that will take the students from simulation to hardware. The challenges in converting the software in simulation to code for hardware will thoroughly test how well the participants have absorbed the concepts being taught through the tasks.

University of Wisconsin- Madison

Abstract: This study represents the first USA-based qualitative investigation on assessment in out-of-school time (OST) arts education. While analysis for this project is ongoing, preliminary findings show how arts leaders conceive of assessment and how those conceptions influenced their practices for documenting and assessing arts learning. By mapping the current landscape of assessment in OST arts learning, we can more clearly identify existing practices and opportunities to adapt and reimagine assessment.

Major issue(s) addressed

Discussions around assessment in arts education environments can be fraught "if not overtly hostile...like two opponents in a boxing ring" (Soep, 2004, p. 579). In the United States (USA), concern endures that the current era of accountability testing precludes the arts from being featured regularly in classroom curriculum (Chappell & Cahnmann-Taylor, 2013). Debates persist about the extent to which arts education should conform to standardized testing culture or pave its own way (Willerson, 2019; Winner & Hetland, 2008). Additionally, arts educators continue to express sentiments of frustration at scholars' narrow assessment conventions that fail to capture many of the valued arts learning outcomes (e.g., Omasta et al., 2020). As evidenced by presentations at the 2021 World Alliance for Arts Education Virtual World Summit focused on arts assessment, such challenges transcend international borders.

However, the majority of scholarship and discourse on assessment of arts learning is derived from schools, leaving out-of-school time (OST) environments (e.g., children's museums, public libraries, youth arts programs) to either integrate formal assessment strategies that may not suit their learning goals, adapt or develop their own strategies, or forgo assessment altogether. To our knowledge, no investigation has been done to understand how assessment occurs in situ in OST arts education in the USA, nor how its inclusion is perceived by stakeholders. Without a rich foundation of scholarship, OST arts leaders and educators are left to make sense of fragmented research that was never conducted with their learning settings in mind. This study begins to fill those gaps in scholarship. Drawing from data collected for a nation-wide, qualitative research project on OST arts organizations, we begin to map the landscape of assessment in these learning environments. Analysis for this project is ongoing, but preliminary findings provide a foundation for understanding how arts leaders conceive of assessment, and how those conceptions influence their assessment practices. By mapping the current landscape of assessment, we can more clearly identify existing practices and potential opportunities to adapt and reimagine assessment in OST arts education.

Theoretical and methodological approaches pursued

Theoretical framework

The theory of educational assessment that guided our analysis is primarily based on the work of Pellegrino et al. (2001), which describes assessment as the relationship between "a theory of what students know and how they develop competence in a subject domain (cognition); tasks or situations used to collect evidence about student performance (observation); and a method for drawing inferences from those observations (interpretation)" (p. 36). We chose this theory of assessment as the foundation for our study for two reasons. First, it highlights the connection between theories of learning and assessment practice, which has been historically ignored in educational assessment and led to the proliferation of outdated assessment approaches (Shepard, 2000). Second, the framework does not employ complex terminology from education research, nor does it presuppose any specific theory of learning, which allowed us to be flexible in how we analyzed participants' varied understandings of assessment. Because this study focused on OST arts education, we adapted the model by Pellegrino and colleagues. We expanded the "cognition" element by replacing it with the phrase "models of success," which better described the broad array of outcomes possible in OST arts organizations, some of which have little to do with direct learning (e.g., feeling a sense of belonging among peers and mentors).

Data collection

 © ISLS

Data for this study was collected between September 2020 and June 2021, and was originally used for a report on OST arts organizations in the USA that predominantly serve BIPOC youth and youth from low-income families. In the summer of 2021, sub-groups of the research team conducted five mini projects using the same data to explore in depth several themes that emerged in the report. This study is one such mini project. The main data sources for this study include: (a) 12 individual interviews with nationally recognized experts in OST arts education; (b) 6 regional (1) focus groups with a total of 26 organization leaders; and (c) 7 program-centered focus groups with a total of 36 stakeholders that included organization leaders, teaching artists, and young people. In all, 72 stakeholders participated in the study, with 9 policy makers, 8 researchers, 28 organization leaders, 17 teaching artists, and 10 young people.

We identified potential experts for the individual interviews through nominations by our advisory board (consisting of researcher-practitioners in the fields of OST youth education and participatory design research for learning) and the literature review we developed for the project. We then asked each interviewee to nominate other experts and leaders who might participate in a focus group. This approach to purposive sampling is often referred to as "snowball sampling" (Merriam & Tisdell, 2016). This process led us to include stakeholders who predominantly identify as Black, Indigenous, and people of color (BIPOC), and who mostly serve BIPOC youth.

Data analysis

We approached data analysis by treating assessment as more than a pedagogical tool; we conceived of it as a complex phenomenon in which ontological constraints are interwoven with axiological commitments and implicit assumptions about epistemology that influence how stakeholders experience and facilitate learning in OST arts organizations. Our study was designed as a phenomenological exploration of assessment, a framework we adopted from Omasta and colleagues' (2020) study of assessment in theatre arts classrooms. To capture the full phenomenon of assessment, we sought to answer the following research questions:

- How do arts leaders conceive of assessment in OST arts learning?
- What and how do arts leaders assess?
- How are arts leaders' values for learning and conceptions of success reflected in discussions around assessment?

Analysis occurred in three phases. Phase one and two coincided with analysis for the larger study. Phase one consisted of a literature review on OST arts programs serving communities with a history of oppression. The literature review provided insight into promising practices, persisting challenges, and remaining gaps and tensions within the field.

In phase two, the interviews were transcribed, divided among the research team, and analyzed inductively using emic, open coding strategies: descriptive coding, in which the data was labeled by the response topic (e.g., assessment, art discipline, or success); concept coding, which entailed labeling the data by the response content (e.g., learning by saturation, place making); and in vivo coding, to highlight specific ideas verbatim (e.g., "community-based process") (Saldaña, 2016). Analyzing the interviews yielded a list of codes that were then used to analyze focus groups transcripts. Throughout this phase, scholars developed analytic memos (Merriam & Tisdell, 2016) that were used in weekly team meetings to discuss emergent themes and to triangulate and differentiate patterns of meaning-making. In phase two, broad themes surfaced ranging from descriptions of assessment tools to arguments about the purpose of assessment and were discussed.

For phase three, which focused specifically on assessment, three scholars from the full research team conducted the analysis. The first author had participated in both preceding phases of analysis, and so was familiar with participants' responses regarding assessment. No further data was collected for this phase. Phase three began with an iteration of structural coding, in which we applied a conceptual phrase representing a topic of inquiry to a segment of data as a method of coding and categorizing the data (Saldaña, 2016, p. 97). We used our research questions and related sub-questions as the conceptual phrases. The second iteration of analysis consisted of writing analytic memos about how each expert or focus group answered the conceptual phrases. To triangulate analysis (Merriam & Tisdell, 2016), transcripts were divided into three sets of data, and one researcher was assigned to each set. Moving into memo writing, researchers rotated data sets, so each data set was analyzed by at least two scholars who were then able to make connections and discuss discrepancies in the interpretations that emerged. The final iteration of analysis included compiling all the memos by theme. For instance, all memos about conceptions of success from all three data sets were compiled. Once compiled, the data was then coded by all three researchers simultaneously using concept and in vivo coding. Those codes were then "lumped" together or "split" apart through code mapping, in which codes are organized under a list of categories and then condensed to reveal the central themes (Saldaña, 2016, p. 218). Analysis for this project, including code mapping, continued

until the central themes had reached saturation, the point at which the same concepts or themes emerge over and over again, indicating that the data has been thoroughly analyzed (Saldaña, 2016).

Major findings

Data revealed assessment in OST arts education to be a source of tension and triumph. In this short paper, we focus our major findings on arts leaders' conceptions of assessment, and how those conceptions influence their practices for documenting and assessing arts learning.

Stakeholders in OST arts education define assessment in dichotomous ways. On one hand, they describe assessment as a formal practice of capturing and measuring the knowledge or skills young people acquire as a result of engaging in arts programs. On the other hand, participants allude to assessment as an informal, intuitive process of observation and conversation with young people to gauge their progress. Participants describe assessment results as "tangible" only if they are documented using quantitative data. However, participants also assert that certain arts learning outcomes can only be understood through qualitative evidence like stories. This qualitative evidence is usually considered more impactful than quantitative data, but is less often formally collected or considered credible assessment. It is clear that participants believe quantitative measurement is what "counts" as assessment in the field, even though they personally see the value of, and often prefer, attending to qualitative evidence of young people's progress.

All participants define assessment in OST arts organizations in relation to assessments used in schools. They refer to such school-based assessments as "traditional" or "typical," and associate them with quantitative measures (e.g., increased attendance, high school graduation rates, standardized test scores, and classroom grades) and assessments that seek to capture evidence of discrete skill and knowledge acquisition (Sfard, 1998).Despite the value and preference arts leaders indicate for more qualitative measures, participants rarely articulated an alternative to school-based assessment. One teaching artist suggested that checking off students' ability to play scales in music was characteristic of public school music education, and he set that in contrast to assessing how well a young person is meeting their own goals for learning music (e.g., to develop a joyful hobby, to gain mastery as an artist, or to pursue a specific job). Another participant had no alternative to offer, but asserted that

> one of the greatest things we could do, or try to train this next generation to do, is to change the evaluation process of what people think is supposed to happen or what we're supposed to measure. because if we don't measure differently, people will think we're not doing all the work that we're doing. And we're doing a lot.

Participants suggest that aligning with school-based assessment was either a necessary compromise or an undesirable association they tried to avoid. Many participants consider schools sites of marginalization where BIPOC youth have fewer opportunities to succeed, in part due to assessments that value narrow definitions of achievement. And yet, their conceptions of assessment are deeply tied to school-based assessment. Three categories emerged in participants' approaches to assessment: the **comply/ cooperate** with assessment approach, the **creatively compromise** on assessment approach, and the do it yourself **(DIY)** approach. The **comply/ cooperate** approach represents organizations that conducted school-based assessment practices regardless of whether they produced examples of success valued by organization leaders and teaching artists. We use both verbs to describe this response, signifying both the negative and positive valence participants associated with it. In the **creative compromise** approach, stakeholders engage in assessment in creative ways that both reflect and resist school-based expectations about assessment and achievement. The challenge of the creative compromise approach is to either find a middle ground between different assessment practices or to execute several assessments in parallel. Finally, the **DIY** approach to assessment essentially rejects school-based assessment practices and expectations outright. All three responses reveal that assessment in OST arts education largely revolves around notions of school-based assessment, even if arts leaders choose not to engage in school-based assessment at all.

Across all three approaches, arts leaders have formal tools and practices for school-based assessment and rely on informal processes for gauging qualitative evidence of learning and engagement. Formal assessments are characterized by assessment practices that are employed in systematic ways, and which collect concrete evidence for assessment. Informal assessments refer to instances where arts leaders casually check in on or take note of learners' progress toward goals and outcomes without documenting what they notice or hear (Ruiz-Primo, 2011). Michalchik and Gallagher (2010) refer to the latter as naturalistic assessments and argue that this approach to assessment is not an argument for anti-intellectualism, but an appeal to the idea that assessment is a natural part of everyday activity, a practice that can be honed even when it not accompanied by systematic, and formal documentation. Examples of formal assessments include logs for quantitative metrics (e.g., attendance, programs offered, college acceptance rates, etc.), observation tools that document student behavior, pre- and post-surveys,

and checklists. These were predominantly used to assess discrete outcomes that could be represented through quantitative data. Examples of informal assessment include talking with youth and their caregivers, casual observation, and collecting narrative-based evidence like quotes, impact stories, or testimonials. These were usually employed to qualitatively gauge a young person's level of engagement, joy, or sense of belonging, or the broader impact a program may have had on their life.

Surprisingly, despite how many participants valued qualitative evidence of their impact, most did not have systematic or formal ways of collecting this information. As an explanation for this gap in practice, most participants indicated that they did not know how to "measure" the outcomes they informally assess. Others admitted to feeling immense pressure from outside stakeholders (e.g., caregivers, policy makers, and funders) to use practices that align with school-based understandings of learning and assessment, or risk losing funding. There is a disconnect between the outcomes arts leaders think they should assess and what they perceive "counts" as assessment, indicating that dominant models of assessment do not sufficiently capture all that arts programs have to offer.

Conclusion

Perceptions about what "counts" as assessment greatly influence how assessment is practiced in OST arts organizations. Stakeholders in OST arts programs in the USA largely rely on formal assessment of discrete knowledge and skills or quantitative metrics, which is often associated with school-based assessment, despite their assertion that informal assessment of qualitative data on learning yields more meaningful evidence of their program's impact. There is an apparent lack of resources available (i.e., assessment tools, practices, or professional support) for stakeholders to formally assess the qualitative outcomes they value, or else a lack of access to readily existing resources. Ultimately, more research dedicated to OST arts education is needed to understand why current assessment practices are insufficient, and to identify what stakeholders need for improved (or reimagined) assessment practices that illustrate the full impact of their programs. We are pleased to present this study, which we hope is the first of many that begin mapping the landscape of assessment in OST arts education.

Endnotes

(1) The regional focus groups represent four cultural geographic regions characterized by their physical location and cultural landscape: Urban Midwest, the Indigenous Southwest, the Bay Area, and Texas-Mexico border towns.

Centring BlackJoy in Design for Learning and Research

Jennifer D. Adams, University of Calgary, Jennifer.adams1@ucalgary.ca

Abstract: This theoretical paper presentation will articulate BlackJoy as a framework for designing research-to-practice spaces that centre Black liberation and flourishing for authentically equitable learning engagements and to counter ongoing deficit narratives and corresponding oppressions that Black and other racialized/minoritized learners experience in schools and other learning environments. The BlackJoy heuristic has four key tenets: Black Excellence, Black Inventiveness, Black Kinship and Black Aesthetics. Data and vignettes from prior research projects will be described of examples of BlackJoy in education and used as a point of departure discussions about the design of research and learning environments that cultivate BlackJoy and expanded ways to think about evidences of learning.

"Centering on Black joy is not about dismissing or creating an "alternative" Black narrative that ignores the realities of our collective pain; rather, it is about holding the pain and injustice we experience as Black folks around the world in tension with the joy we experience in the pain's midst. Black joy is healing, resistance and regeneration."
-Kleaver Cruz

The global pandemic allowed for a collective witnessing of the ongoing and violent inequities experienced by Black and other racialized people especially in postcolonial and settler colonial contexts. For example, Black bodies in the United States disproportionately experienced the grave effects of COVID-19 than others (Poteat et al. 2020). This is compounded by the higher likelihood of Black people working in essential services (Lancet 2020). The circumstances of George Floyd's murder that ignited a global resurgence of the #BlackLivesMatter movement brings to the surface Sylvia Wynter's (1994) essay *No Humans Involved* that she wrote to her colleagues after the Los Angeles murder of Rodney King where she noted the acronym used by the judicial system, NHI, meaning "no humans involved," referred to "any case involving a breach of the rights of young Black males who belong to the jobless category of the inner-city ghettos and noted that "systems of classification direct our thinking and order our behaviors". This classifactory schema, Wynter argues, is based on the colonial logics of race science that emerged from Western Modern Science and contributes to the denial of humanity to Black people.

In education this presents in schooling where Black students are framed with deficit lens and often positioned to be less capable than their non-Black counterparts, especially in science (Mutegi, 2012). Language such as "at risk" and, in certain contexts, "urban students" positions Black and Brown students as lacking in intellect, discipline, stable homes, etc. as impediments to success in the classroom, "the Black is constructed as always already Problem—as non-Human, inherently uneducable, or at very least, unworthy of education." (Dumas 2016, p. x). And yet in these spaces of pain, violence and oppression Black people still manage to seek joy, "…Black people's everyday commitment to locating joy in our lives often pierces through the troubled moments like the light shining in my room…[it] center[s] on our capacity to overcome despite all that might try to harm us (Cruz, 2017)

In North America and other antiblack settler-colonial and postcolonial contexts, Black pain and Black joy exist in a dialectic where Black joy is resistance, resilience and illumination in the darkness of the violence and pain. The lived experiences of Black people, including in learning contexts, like schooling, exist in what in what Sadiya Hartman calls the "afterlife of slavery," which entails "skewed life chances, limited access to health and education, premature death, incarceration, and impoverishment" (Hartman, 2008). It is within these circumstances that Blackness is constructed which is the "cultural material, and political signifiers associated with the lived conditions of African and African-descended communities; [it is] a series of strategic and spiritual identifications that subsume directed, desired, and ascribed connections between endarkended bodies in the afterlife of slavery" (Morton, Gee and Woodson, 2020).

Articulating Black Joy

This theoretical paper presentation will articulate BlackJoy as a framework for designing research-to-practice spaces that centre Black liberation and flourishing for authentically equitable learning engagements. Authentically equitable means a science education that does not simply remove conceptual statues that are

 © ISLS

symbols of the embedded coloniality, antiblackness and oppression, but rather a science education that disrupts and transforms the very foundation on which these oppressive ideals are based (Author, 2020). In authentically equitable contexts, teachers and learners become critically cognizant of the power structures that organize their learning and lived experiences and they work collectively to dismantle while co-creating new structures that afford the agency of all learners. These spaces are centered around cultivating Black joy, and allows all stakeholders to liberate the mind, various senses and emotions in order to move outside of a given reality (Davies, 2013).

BlackJoy, as a framework, could be first thought of as freedom space of imagining alternatives to given realities, "More than a method to endure, however, black joy allows us the space to stretch our imaginations beyond what we previously thought possible and allows us to theorize a world in which white supremacy does not dictate our everyday lives" (Johnson 2015, p. 180); envisaging life outside of the specter of the white gaze. BlackJoy as being able to use the radical tool of Black imagination and the centering of community and love (Cruz, 2017); freedom, imagination, community and love are central constructs of BlackJoy. It is a counternarrative to the poverty, crime, and overall despair as often depicted in media and an assertion of humanity through the experience of a range of emotions—joy, laughter, happiness and imagination—that were denied to Black people during enslavement through present times; it is resistance in a society shaped by oppression, racism, and violence" (Lu and Steele 2019).

Thus, in places that were not designed to support Black existence, Black people have used innovation, creativity and love for each other to generate joy. Language is used to create and shape learning spaces, therefore this framework explores ways to extend BlackJoy into research to practice spaces. The framework of BlackJoy emerges from the authors' various research projects were Black learners and those who teach them were central stakeholders as well as Black identity and learner focused research and theoretical works some of which are cited in this proposal.

Black Identity and Black Joy

Several Black researchers have put forward identity strategies, the moves that Black students do in order to ensure their success in STEM spaces that dominated by white, neoliberal culture and are hostile to Black students. These STEM spaces reflect larger society and are therefore also hostile to Black bodies. Black students who aim to succeed are compelled to find and cultivate Black joy. For example, Terrell Morton, Destiny Gee and Ashely Woodson (2020) named Black X Consciousness as a strategy that Black students use to understand and reconcile their identities in relation to STEM. It is an active, metacognitive process students used to navigate structures that were often unwelcoming. They noted that Black X Consciousness is not emancipatory, but rather it is an adaptive strategy that is "influenced but not organized by inequity and marginality"; Black students made sense of their Blackness in STEM spaces through the performance of signifiers of Blackness that included collectivism, language and love. Sharing spaces with other Black students contributed to their "comfort, connection and even salvation" even in the midst of hostile environments.

Similarly, in a different study Terrell Morton and Eileen Parsons (2018) found that Black women navigated STEM spaces through authoring their own identities while affirming their diverse and intersectional Blackness, , "Being a Black woman in STEM both equates to and transcends the oppression and struggle they endure as a result of social constraints on their identity; their identity as Black women being socially regulated yet self-determined to mean power, strength, and success that manifest through their positive and negative encounters (p. 1383)." In both examples, identity/Blackness is a strategy, a process that Black people use to sustain themselves and each other in challenging and unfriendly spaces.

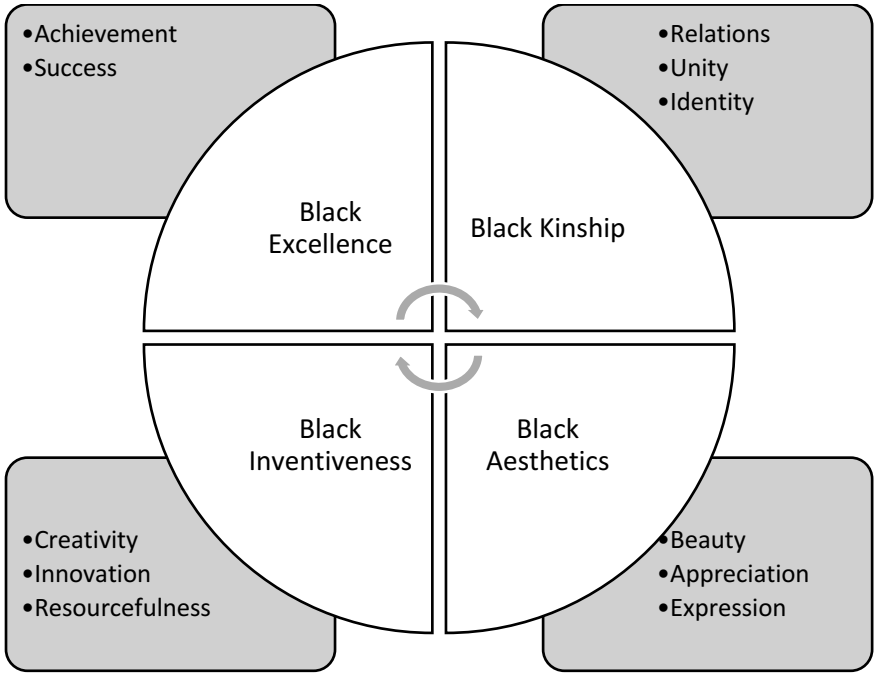
Cultivating Black Joy in Science Education

Miles and Roby (2022) advanced a Black liberatory science education that centres joy and liberation for Black learners, with practices of exploration, questioning, speaking and reminiscing in ways that allow for racial freedom. Building on Ridgeway and Roby, this presentation describes a heuristic for the design of learning environments that afford these and other liberatory and transformative practices for Black learners. Figure 1 shows the key emergent tents of the BlackJoy heuristic. This presentation will elaborate on these tenets with vignettes and interpretations from previous research projects with Black learners and educators and use these as a point of departure for a discussion about creating research-to-practice spaces that foster all four tenets as once and exploring other facets of BlackJoy that could be centred in teaching, learning and learning research.

The BlackJoy Heuristic

The BlackJoy Heuristic is meant to frame the design of research to practice and learning environments that afford liberation and transformative opportunities for Black learners. It includes four tenets that are highlighted in Figure 1 and briefly outlined below.

Figure 1



Black Excellence-this tenet emphasizes positive associations with race and learning. This entails celebrating the achievement and success of Black learners and creating learning environments and activities that allow them to build positive identities and associations with learning.

Black Inventiveness-focuses on leveraging the innate creativity, curiosity, resourcefulness, and innovation of Black learners. This means fostering open-ended explorations of phenomena and allowing Black students to guide the direction of observations and inquiry.

Black Kinship-centers collectivism, values kinships and integrates Black linguistic practices as central to relationships, learning and Black identity. This tenet emphasizes the interconnectedness of language and culture and fostering the role that these play in building trust, solidarity, safety and risk-taking in learning environments.

Black Aesthetics—recognizes things that Black learners find beautiful and pleasing and the ways that Black lived experiences intersect with artistic and creative practices. For example, music for focus, specially fabrics and hairstyles for significant events (i.e. graduations) and dance as a way of expressing community.

Black Excellence, Black Inventiveness, Black Kinship and Black Aesthetics allow us to assert a Black liberatory education and research paradigm that centers Black learning, Black humanity and BlackJoy. This is central to building race affirming frameworks that work towards elevating Black learners. All students come to learning contexts with values, orientations, and practices that are reflective of their culture and when these are supported, students engage more holistically and successfully in learning (Medin and Bang, 2014).

Abstract: There is relatively scant conversation about the details of processes through which research teams arrive at desirable thresholds of statistical measures for inter-rater reliability (IRR) in qualitative research. This paper used autoethnography to describe how a team of five researchers achieved a Cohen's Kappa of .7 between each pair of researchers over a period of two years while iteratively developing a codebook to be applied to science classroom discussion transcripts. Detailed meeting notes kept by the researchers were used as data. The findings describe factors that contributed to the complexity of the transcripts, strategies that worked for the team, and the role of the purpose of the analysis in shaping the process of the analysis. Some implications for the field of teacher learning are discussed based on these findings.

Introduction

Establishing rigor and reliability in the analyses is an important aspect of doing credible qualitative research. However, the process of establishing inter-rater reliability (IRR) could be a fraught one given the tension between the superimposition of an objectivity-oriented desired statistical value of consistency between raters (e.g. Cohen's Kappa) over a constructivist orientation of qualitative research. In addition, consistency is further perplexed when the analysis in question seeks to describe, through codification, features of data that require high inferences. Thus a methodological question is, what conventions can be used to achieve very good agreement between raters, and yet still preserve some of the rich description of data that qualitative analysis lends itself to. The field is guided by conventions such as good thresholds for agreement (e.g., O'Connor & Joffe, 2020; Banerjee, et al 1999), but less is reported about the social processes and methodologies used to develop shared ways of seeing data are captured in measures of interrater consistency. Few studies report on how to achieve interrater agreement in the context of dialogic and dialectical processes of team-based research, where *shared ways of seeing* are informed and enriched by histories, cultures, experiences, and expertise (Hennessey et al, 2016). We see these often underreported processes as critical for theory and methodology building. This paper focuses on the process of iterative development of a codebook which a team of five researchers utilized and achieved a .7 Cohen's Kappa. The primary challenge of the process was harmonizing the researchers' individual lenses toward the data developed through their unique professional and personal histories into a collective lens that retained the richness afforded by the individual lenses while also yielding a desirable statistical agreement. Through autoethnography, we seek to surface tensions in this process of codifying a large corpus of rich and complex discourse data within the context of a longitudinal team-based research project and illuminate decision points that led to new ways of structuring the coding process, i.e., iterating on a codebook and developing shared ways of seeing the data and categories to achieve very good IRR.

ClassInSight is a study of teacher professional learning around classroom dialogue. It is a 5-year research-practice partnership with two school districts in north and south county San Diego, which serve a diverse (ethnic and linguistic) population of students. Science classroom discussions of study participants were audio-recorded, transcribed, and verified. These lesson transcripts were then used for analyses to create visual representations in a web-based app to facilitate teacher reflection and learning. An important dimension of this work was to develop a Natural Language Processing (NLP) model to automate the process of coding the transcripts and creating the said visual representations.

The specific analysis task for us (the research team) was to decompose the transcript into codes that captured the dialogic function of the utterances in the transcript. For example, if an utterance was an invitation to elaborate on an idea then it would be coded as (I). The purpose of this analysis in part was to generate data to be used by a collaborating team to develop natural language processing models for automating the analysis and second, to represent codes in the form of analytics (visualizations) for teachers. The first iteration of the codebook started in Fall 2019. As we worked through the challenges of achieving IRR the codebook went through two more iterations and the desired Cohen's Kappa on the third iteration of the codebook was achieved in Spring 2021. This

 © ISLS

paper describes the iterative process and characteristics of refinements as a collaborative team developed a codebook and training of multiple raters on complex conversational data.

The question we intend to answer is *how do we develop reliable shared ways of applying a set of codes to complex classroom discussion data?*

Methods

We used autoethnography to reflect on and distill findings to be reported here from the two-year process of achieving IRR in the context of a longitudinal team-based research project. Our primary data sources for this autoethnography are detailed meeting notes recorded during our IRR-oriented meetings between Fall 2019 and Spring 2021. Two researchers conducted open coding of the meeting notes and identified preliminary codes related to excerpts that would provide insights into the 'how' of our RQ. These thematic codes were discussed and validated by the entire team of researchers that worked on the analyses. An autoethnographic codebook was developed based on the agreements reached during the coding process. For example, "decision point" or "corrective measures/strategies" are examples of thematic codes that were included in the codebook that sought to identify and characterize critical moments, roadblocks, and decisions in our process. The same two researchers then coded the remaining 106 pages of meeting notes using a qualitative data analysis software. A subsequent cross-code analysis of the excerpts resulted in the themes that are reported below.

Findings

Complexity of the classroom discussion data

Our data (meeting notes) is rife with explicit and implicit acknowledgments of the complexity of the classroom discussion data. While various factors contributed to this complexity, we describe below two major contributors to this complexity - context and transcript.

An enduring question in decomposing classroom discussion data for us was to define the limits of context we may use while applying the codebook to a transcript. For instance, it mattered if a researcher was or was not present in the classroom to conduct the observation which resulted in the transcript at hand. If the researcher was present then they had more context to the data than a researcher who was not present. If the researchers were to learn to code reliably, then accessing such information during the coding process, while valuable to the analysis, was not desirable. Similarly, information about the context of the school/teacher/student demographics, type of school - MAGNET, etc., and consequent linguistic practices often had a bearing on how we approached the data. This issue of context made it challenging to arrive at precise definitions of codes whose application relied on a multitude of factors. We resolved this in part through the strategies described in the next section, but this is a work in progress.

Secondly, there were limitations to the recording and transcribing of classroom discussions. In that, we had to wrestle with the question of whether we were coding the *discussion* or the *discussion transcript*. The latter eliminated several features of the actual discussion - modulations, pauses, crosstalk, unrecorded utterances, etc. If the teacher posed a question and the next utterance in the transcript was the teacher responding to the question themselves, then did it mean that there was no response from the students or that there was a response and the teacher then elaborated on that response? In the light of the considerations described in the previous paragraph (and some about machine learning to automate the coding process that will be described later), it was decided to code the *transcript* and not the *discussion*.

Strategies that helped in achieving greater inter-rater reliability

Segmentation

The work of Wells and Arauz (2006) and Hennesey et al. (2015) provided a solid foundation for the third and successful iteration of our codebook. These codebooks provided us with a framework for the mechanics of classroom dialogue in terms of episodes, sequences, and exchanges before trying to classify individual utterances, which focused on cognitive implicature of teacher elicitation and student responses. It was immensely helpful to break down the entire transcript into smaller chunks which helped us understand the relationship between each utterance (part) and the classroom discussion (whole). Then, Hennesey et al. (2015) provided us with a list of predetermined codes which we could then adapt to the requirements of our data. The codes made for rich deliberation about how they may apply to our data which allowed for a far deeper and more meaningful engagement with the complexity of our data than would have been possible if we were not rooted in these prior works.

Historicity as Part of the Coding Process

 © ISLS

Each researcher came to this work with their peculiar history with the processes of teaching and learning which shaped their approach to the classroom discussion data for this project. This afforded several possibilities for the analysis in that the definitions of the codes were made richer through diverse contributions. However, this also made 'sticking to the codebook' a challenging endeavor. The team referred to this as the peril and the possibility of coding in a diverse team. After the first few failed attempts of independently and reliably applying the self-developed first iteration of the codebook to the data, we decided that we needed to undergo additional shared experiences, beyond initial codebook training, that would offer us some common ground to work with while applying the codes.

Three things were done by the team to achieve this common ground. First, the team engaged in several rounds of collective coding where we individually coded 5-10 lines at a time and then immediately shared the codes we had applied with our reasoning for applying those codes. This allowed us to gain a better understanding of each others' heuristics in the coding process and, therefore, make changes to ours if necessary. Second, whenever it was difficult to reach an understanding over which code would be applicable in a particular instance or how a particular code would be applied, there was an emphasis on collective decision-making. The meeting notes repeatedly mentioned the verb 'discuss' at the close of meetings for disagreements that were left unresolved. Lastly, this approach of developing reliable analyses while also valuing the diversity of thought resulted in the codebook being a dynamic document that reflected the evolution of our thinking around the application of each of our codes through the course of gaining these shared experiences. While three researchers achieved a Cohen's Kappa of 0.7 in the current iteration of the codebook, there are several proposals for adding new codes or changing existing ones that are in deliberations for its next iteration.

Reflecting on the Process of Coding

The shared experiences were significant in moving us toward a better reliability statistic. However, they were not enough. At one meeting, as we uncovered the steps that each of us followed to code a particular lesson transcript, we found important differences in our approaches. Some read and coded the transcript simultaneously while others skimmed through the whole lesson to get an overview and then coded in the second, deeper reading of the transcript. Subsequently, all of us decided to follow the two-step coding process.

Systematic differences were also observed in the application of certain codes among researchers. When a question was repeated by the teacher, some researchers coded both utterances of the question as a question while others coded only one. Developing rules for such recurring but systematic differences was helpful. However, on some occasions, it was difficult to decide on the application of a code to a particular utterance. For instance, the distinction between E and I was often difficult to make. E refers to the invitation for a 'new' idea and I refers to the invitation to say more about an idea that is already on the table. Sometimes it was challenging to precisely determine whether a new idea was being invited or a previous idea was built upon. On such occasions, it helped to take a step back from our pursuit of a combination of individual and collective lenses and focus only on the collective (e.g., how can we all learn to think similarly while making decisions like these? What series of questions must we answer to make such a decision?).

Initially, we formatted the transcripts for coding such that each sentence was assigned a code. We realized that multiple sentences together formed meaningful utterances and as such should be coded as a group and not individually. However, these observations about what constituted a meaningful cluster of utterances were made only during the deep reading stage of the coding process. This led to the question of whether one member of the coding team would cluster utterances to be coded and share the segmented transcript with others, thus excluding the clustering aspect from the reliability calculations, or whether this process would be conducted by each rater themselves and clustering included in the reliability calculations? In the light of further challenges with the latter approach, it was decided to code at the turn level. In that, all the utterances in one turn of the speaker were assigned with a code. In instances where there were multiple applicable codes in a turn, the one that was taken up by the following turn was applied. For example, if one turn had both, a reasoning (R) and an invitation for elaboration (I) move, but the next turn responded to the (I) move then the turn was coded as (I). This was a significant step in moving us along in the inter-rater reliability process.

The Impact of the Purpose of Analysis on the Process of Analysis

The project's purpose was to generate representations of classroom discussion data that teachers would use as tools to reflect on their practice. These reflections and consequent inquiry or modifications in practice would constitute a form of ongoing learning for them. Additionally, one important aim of the project was to use machine learning techniques to automate this process of analyzing classroom data and generate representations of it. This would greatly reduce the turnaround time between a classroom observation and the generation of the representations based on it.

Concerning the purpose of facilitating teacher learning, the question of "what is meaningful for the teachers?" came up repeatedly in the meeting notes. This was an important consideration of the analysis process with which the team had been tacitly working with. To illustrate, Hennesey et al.'s (2015) coding scheme included a broad set of codes called cluster codes and a set of detailed sub-codes within each cluster. For example, invite elaboration or reasoning (I) was a cluster code within which there were sub-codes like invite possibility thinking or prediction (I5) and ask for elaboration or clarification (I6) (Hennesey et al., 2015). Early on while adapting the coding scheme to our purposes, we decided to stick to only cluster level codes because the sub-categorization of cluster codes did not appear to add significant value to the affordance of the representations in facilitating teacher reflection.

Another issue concerning the purpose of facilitating teacher learning was that codes like reasoning (R) or building on ideas (B) were not yet frequently occurring in the data. So the challenge was how to use *what is* in the practice of the teachers to help them reflect on what *could be*. Since this is an ongoing project, it is a question we continue to grapple with. A strong contender for a solution is to modify the code definitions such that they may apply to utterances that are proximal to a code but not quite satisfy the current definitions such that the teachers may start to see the beginnings of it in their data. As discussed in the next paragraph, the implications of such a move for machine learning have been a primary hindrance in realizing this possibility.

While we developed shared heuristics for making decisions about codebook applications to data we were also constantly mindful of their complexity vis-a-vis the possibilities of machine learning at a given time while acknowledging the quick strides being made in the field. This meant that we could not, for instance, use information from several hundred turns prior as context to code a particular turn in a transcript. Beyond constraints, machine learning also brought several affordances in our thinking about the analyses. When necessary, we were able to set aside our subjective individual orientations and focus on building a relatively objective collective one because that is what the machine needed to learn. We were also able to plan for the possibility of the machine applying some low-inference and already reliable codes before the researchers even looked at the transcript for the first time allowing them to focus on the more complex codes.

Discussion

Shared experiences, maintaining a dynamic codebook, repeatedly rooting ourselves in literature, and wrestling with the balance between mechanics and content were only some of the things that went into the team achieving IRR. The researchers' deep care for each other and the work were also important ingredients of the *success*. While we have a Kappa value of .7 between each pair of researchers, we acknowledge that there is a lot more work to do and we don't yet have *our* final iteration of the codebook or the final Kappa. These details are entirely masked by the reliance on a single statistic as a bar for rigor. An important question is how do we go beyond the Kappa in our sensemaking around objectivity and rigor in the IRR process? This experience has made us somewhat wary of very high Kappa values, especially in the context of complex data and coding categories. As a field, it may be worthwhile to adopt a healthy skepticism of only statistical values and to seek and provide descriptions of the processes that lead to very high IRR values whenever they are reported.

Lastly, the processes of these analyses described here were deeply intertwined with the purposes of the analyses, which were to facilitate teacher learning and to help develop machine learning models of the analyses. If the purpose were to solely theorize on the nature of dialogue in science classrooms, then many more nuanced codes would have been available for us to use, possibly making it relatively easier to deal with the complexity of the data. While we tacitly acknowledged these purposes throughout the process, becoming conscious of them has given us a new frame with which to approach decisions in the next iteration of our codebook. As such, it may be worthwhile for others engaged in similar work to be explicit about the purpose of their analyses and allow it to conspicuously shape the process.

How reward- and error-based feedback systems create micro-failures to support learning strategies

Allison S. Liu, Kirk Vanacore, & Erin Ottmar

Worcester Polytechnic Institute

Abstract: Feedback in educational technologies can teach and engage students in math, but questions remain on how to present failure feedback that supports positive learning behaviors. We explore how error- and reward-based feedback influenced students' choices to replay completed problems in *From Here to There!*, a math game-based educational technology. We conducted a multilevel logistic regression in 1,031 seventh-grade students predicting whether a problem was replayed, using whether an error was made during the first problem attempt and how many clovers were earned after solving the problem (with more clovers earned for more efficient solutions). Preliminary results show that making an error or earning two clovers increased the likelihood of replays, whereas earning one or three clovers decreased the likelihood. Our findings suggest that clovers and errors may be "micro-failures" that encourage replays by supporting feelings of competency and/or autonomy, which has implications for game design elements for learning and engagement.

Introduction

Educational technologies are becoming increasingly popular as an engaging medium for teaching math. One major benefit of educational technologies is their ability to provide immediate feedback on students' performance (Moyer-Packenham et al., 2019), but developers must consider how to show students where they can improve without causing them to disengage entirely from learning. It is important to understand how different types of feedback systems motivate students to adopt effective learning behaviors in response to failure. Here, we explore whether two feedback systems—errors made and rewards earned—influence the likelihood that a student will replay completed problems within *From Here to There!* (FH2T), a game-based educational technology that teaches algebra.

Feedback systems and failure in game-based educational technologies

Feedback is often conceptualized in terms of Self-Determination Theory (Ryan & Deci, 2000), which defines three types of motivation: intrinsic (pursuing activities because they are inherently enjoyable), extrinsic (pursuing activities because of some external outcome), and amotivation (lacking any intention to pursue an activity). Supporting learners' innate needs of autonomy, competence, and relatedness can maintain intrinsic motivation or self-determined forms of extrinsic motivation, which have been linked to greater persistence, positive self-perceptions, and engagement (Ryan & Deci, 2000). Thus, feedback may promote these forms of motivation if the feedback makes learners feel competent and in control over the feedback they receive.

Game-based educational technologies overlap with both educational and gaming spaces, each of which brings their own expectations; as such, these tools must grapple with the challenge of evoking "game-like" failure, which can lead to greater engagement and persistence akin to non-educational games, as opposed to "classroom" failure, which can cause students to question their abilities and feel demotivated akin to failing in a school context (Williams-Pierce, 2019). An open learning design question is how to implement feedback systems that increase feelings of game-like failure instead of classroom failure. One answer may be to implement feedback systems that feel low-stakes by using "micro-failures," defined as quiet and gentle failures that encourage the player to seek feedback (Williams-Pierce, 2019). Using feedback to draw students' attention to micro-failures may encourage optional but positive learning behaviors, supporting autonomy and competence. The question then is what types of feedback systems students will perceive as micro-failures.

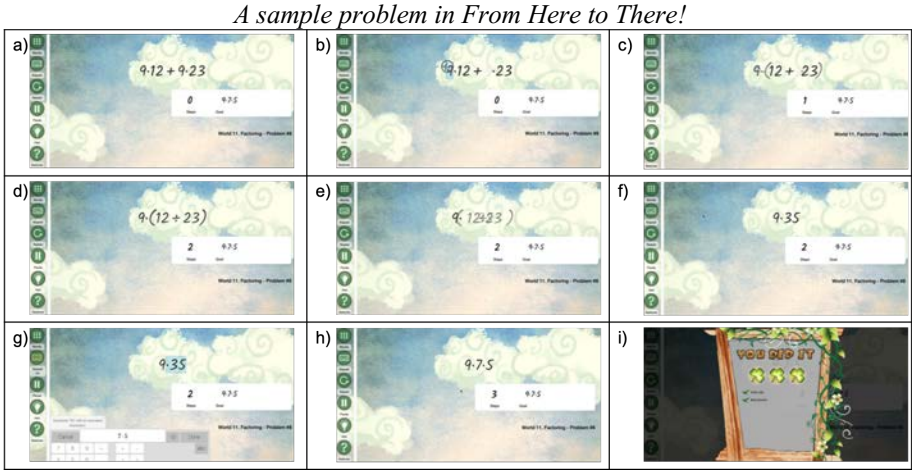
The current study: Feedback and replays in *From Here to There*

The current study explores error- and reward-based feedback as potential micro-failures, both of which are commonly implemented in game-based educational technologies. We use FH2T as our game context (https://graspablemath.com/projects/fh2t). Students are given a starting algebraic expression (Figure 1a) and must use learned gesture-actions (e.g., in 9·12+9·23, dragging the 9s together to factor them out; Figure 1b-1d) to

 © ISLS

transform the expression into a goal state (Figure 1h). After completing each problem, students can choose to replay the problem or move on. FH2T has been effective for improving elementary and middle school students' mathematical understanding (Chan et al., 2021; Hulse et al., 2019). A cluster analysis found that a sub-sample of FH2T users repeatedly replay completed problems, and these users show among the largest learning gains after using FH2T (Lee et al., under review). We investigate whether FH2T's error- and reward-based feedback systems incentivize replay strategies in students.

Figure 1
A sample problem in From Here to There!



In FH2T's error feedback system, if students make a mathematical error (e.g., attempting to add 12+9 in 9·12+9·23), then the expression shakes and does not change, providing implicit visual feedback that an error has been made. This feedback may help students to understand where they can correct their behaviors and motivate students to replay and fix these errors. On the other hand, students may feel that they have less control over error feedback (as they must fix the error to progress) or perceive errors as indicators of their lack of competence, reminiscent of classroom failure; such feelings may be less motivating to go back after completing problems. In FH2T's reward system, students earn one to three clovers after each problem based on the number of steps taken to solve the problem, with more clovers earned for fewer steps (see Figure 1i). Clovers are one of the primary ways students have to understand how well they are performing, though the rules that determine the number of clovers are never explicitly explained. These performance-contingent rewards could be seen as a gentle micro-failure because earning one or two clovers suggests that improvements can be made, but students are not penalized in any way. Because fewer clovers do not prevent progression, this optional aspect may feel game-like and promote feelings of autonomy, motivating students to replay problems to gain a higher number of clovers. However, failing to achieve three clovers may still be perceived as a form of "classroom" failure since clovers are tied to students' in-game performance, which may lead them to avoid replays. To begin exploring how these two types of feedback systems influence replay behaviors, we investigate:

RQ1: a) Does the number of clovers earned after the first problem attempt predict whether students replay problems? b) Does receiving one to two clovers encourage students to replay problems more than receiving the maximum three clovers?

RQ2: Do errors during the first problem attempt separately predict whether students replay problems?

Method

As part of a larger study comparing the impacts of three technology interventions, 4,092 seventh-grade students were recruited from 10 middle schools within a large suburban district in the Southeastern United States. The current study focuses only on students randomly assigned to use FH2T (N = 1,031). First, students completed a 40-45 minute pre-test of their algebraic knowledge (Star et al., 2015; α = .89) and math anxiety (Ganley & McGraw, 2016; α = .87). Next, students participated in nine 30-minute FH2T sessions across the school year. Because the study occurred between September 2020 and April 2021 during the COVID-19 pandemic, students chose their instructional modality (100% in-person or virtual) prior to the fall semester. Regardless of modality, all study assignments were administered online, and students worked individually at their own pace using individual devices. Students saw up to 252 unique problems; for each problem, FH2T recorded: 1) whether students made an error during their first problem attempt (error vs. no error); 2) the number of clovers earned after

 © ISLS

the first problem completion (three clovers for solving the problem in the optimal number of steps, two clovers for solving within two of the optimal number of steps, and one clover for all other solutions); and 3) whether students replayed the problem after completion (replayed vs. not replayed). Errors were not counted as solution steps and therefore did not influence the number of clovers earned.

Results

To investigate whether clovers and errors influenced the likelihood of replaying a problem, we estimated a multi-level logistic regression predicting whether a problem was replayed or not. The model was estimated using 74,359 problems in which students completed at least one attempt. The model contained two cross-classified levels—problem and student levels—because students attempted multiple problem sets and problems were attempted by multiple sets of students. Random intercepts were entered for both students and problems. Problem-level predictors were the number of clovers earned and whether the student made at least one error on the first problem attempt. Pre-test algebraic understanding and math anxiety scores were included as student-level predictors. The number of clovers earned on first attempt was dummy coded, such that two clovers and three clovers were both compared with a referent group of one clover; this split allowed us to compare whether receiving a specific number of clovers differentially influenced the likelihood of replaying a problem.

For **RQ1,** the number of clovers earned on the first problem attempt significantly predicted the likelihood of replay (Table 1). Additionally, there were differential associations between the likelihoods based on the number of clovers earned: students who earned two clovers were 1.45 times as likely to replay a problem compared to students who compared to students who earned one clover ($\beta_1 = 0.42$, $SE = 0.07$, $p < 0.001$), based on relative risk calculation of students with average pretest scores who did not make an error (Table 2). Those who earned one clover on their first attempt were less likely than chance to replay the problem ($\beta_0 = -2.38$, $SE = 0.11$, $p < 0.001$). As expected, students who earned three clovers had the lowest likelihood of replaying a problem compared to those who earned one or two clovers ($\beta_2 = -2.37$, $SE = 0.07$, $p < 0.001$).

Table 1

Logistic Regression Output for Model Predicting Replay

	β	SE	p
Intercept	-2.38	0.11	< 0.001
Two Clovers	0.42	0.07	< 0.001
Three Clovers	-2.37	0.07	< 0.001
Error Made	0.91	0.03	< 0.001
Pre-test Algebra	0.35	0.07	< 0.001
Pre-test Math Anxiety	0.05	0.06	0.46
Random Effects			
σ_2	3.29		
$\tau_{00\ \text{Student}}$	2.58		
$\tau_{00\ \text{Problem}}$	0.59		

$N_{\text{observations}} = 74{,}359$; $N_{\text{student}} = 1{,}031$; $N_{\text{problem}} = 252$

Table 2

Probability and Relative Risk of Problem Replay by Number of Clovers and Whether an Error Was Made in the Problem.

	Errors		
Clovers Earned	N	Y	Relative Risk
One Clover	.08	.19	2.38
Two Clovers	.12	.26	2.17
Three Clovers	.01	.02	2.00

Note: Probabilities were computed for students with average pre-test math and anxiety scores.

For **RQ2**, making at least one error on the first problem attempt significantly increased the likelihood of replay ($\beta_3 = 0.91$, $SE = 0.03$, $p < 0.001$). Table 2 presents the probability of replay based on number of clovers earned and whether they made errors, as well as relative risks calculations, which show how many more times students are likely to replay when they make at least one error compared to when they do not make an error. Students who made at least one error were at least two times as likely to replay compared with students who did

 © ISLS

not make an error regardless of the number of clovers earned (range: 2.00-2.38), with relative risk being highest for students who earned one clover and lowest for students who earned three clovers.

Discussion

In summary, both errors and clovers appear to incentivize students to replay problems. Earning two clovers on the first problem attempt may have been perceived as a "micro-failure", encouraging students to replay completed problems to improve their solutions and earn the maximum three clovers. Notably, the magnitude of the "micro-failure" appears to influence students' motivation to replay: earning two clovers was associated with a substantially greater likelihood of replaying than earning one clover. One potential interpretation is that students who feel closer to earning the maximum three clovers are more likely to exhibit internal motivation to replay, incited by their feelings of competence that come from being close to perfect. Alternatively, students who are further away from earning three clovers (i.e., earn only one) are less likely to display the internal motivation required to replay because of feelings of incompetence. Students who made more errors were also more likely to replay even though errors are not implicated in clover allocation. It is possible that students do not realize that clovers and errors are independent from one another and they return to the problem to complete it without making errors in the hopes of earning more clovers. The directness of error feedback may also build feelings of competence by helping students identify misunderstandings, encouraging them to replay.

Based on prior work suggesting that replays may lead to higher learning gains (Lee et al., under review), building on performance-contingent reward systems similar to FH2T's clovers may thus be an effective method for improving engagement and learning. In future work, we plan to delineate whether replays specifically are what lead to better learning in FH2T users, and to explore what mechanisms underlie this relationship. Further, because the percentage of students who choose to consistently replay problems on their own appears to be relatively low (especially being optional for progression), we will also explore methods that encourage more students to choose to replay (without taking away the feeling of autonomy from being untied from progression).

University of California, San Diego

Abstract: This paper informs designs for teacher learning and reflection that advance equitable discourse practices in secondary science classrooms. We share design insights from the initial iteration of a design-based research project, ClassInSight, that supports teachers' facilitation of dialogic-discourse practices in science classrooms through guided reflection on classroom discourse visualizations. We analyze transcripts of reflection sessions of the participants and ask: *How did teacher-researcher dyads interact with the initial design prototypes of classroom discourse data visualization and reflection practices? How were reflections on data visualizations constrained by design?* We found that teachers and researchers did not share an understanding of classroom discourse moves and that teacher reflections did not connect explicitly to issues of equity in the classroom. The findings show the need to design for shared meaning-making between teachers and researchers on classroom discourse categories and make visible the ways they conceptualize equity in science classroom discourse practices.

Design-Based Research to Improve Science Classroom Discourse Practices

Several studies have highlighted a systematic pattern of classroom dialogue that predominantly serve children from minoritized background, that is, a culture of low expectations, whereby the quality and intellective rigor of classroom talk requires low cognitive demand of engagement from students (McNeill & Pimentell, 2010; Kelly, 2008). Research has shown that when teachers lead students in discussions that externalize their reasoning and thinking, students benefit in terms of steep increases in learning (Resnick et al., 2015; Clarke et al., 2016; Alexander, 2018). Our work takes the view that equity (and inequity) can take shape in micro-level interactions in-classroom dialogue, and teachers play a critical role in constructing an intellective space that provides robust opportunities to learn science.

It is for these reasons that we sought to design teacher professional development to support teachers in reflecting on how opportunities to learn are structured in classroom discussions that teachers facilitate, and planning on how to utilize their pedagogical tools to support students' sense-making in science. We view teacher learning as a key opportunity space to make rich discourse in science classrooms more accessible. We conjecture that well-designed classroom discourse data representations and reflection practices can help teachers critically examine and improve their own classroom discourse practices, and have been designing an online application, ClassInSight, that visualizes science classroom discourse data through multiple representations, (Gomoll et al., 2021), as well as reflection practices for teachers and researchers to engage in shared meaning-making, goal setting, and pedagogical refinement with the discourse data (Schön, 1983).

Two threads of existing research frame our designs. First, we draw from research on dialogic science classroom discourse that has been shown to improve learning (Clarke et al., 2015). These discourse practices promote shared reasoning, and include types of talk, or what we here on call *discourse categories*, by students and teachers that surface rationales for claims, build on existing claims made by others, and questioning that connects content knowledge to prior student knowledge (Michaels et al., 2010). We are designing classroom discourse data visualizations to represent student and teacher speech types that are consequential to science learning and equity. Second, following the literature on teacher reflection and learning (Schön, 1983), we conjecture that teachers improve their pedagogy when they engage in reflection-on-action that question, ruminate on, and reason with their classroom practices (Clarke et al., 2020). We situate such teacher learning in their practice contexts, technological resources, and interactions with others, including the researchers (Korthagen, 2010). Our design embodies these theories on reflection and teacher learning in what we call "reflection dyads" - collaborative reflective sessions between teacher and researcher which closely

 © ISLS

examine and surface dissonances between teachers' stated equity-focused classroom discourse goals, intuitive interpretation of classroom discourse, classroom discourse data visualizations, culminating in the refinement of pedagogical actions. While our larger equity goal is to make discourse-rich science classrooms more accessible to students from minoritized backgrounds, here, we make theoretical contributions to the *processes* and *designs* for teacher learning toward these educational outcomes.

Using a design-based research methodology, we seek to contribute to theories and practices that reflect our core learning goals and conjectures by observing the use of designs that embody these conjectures "in the wild" (Lee et al., 2022). This paper seeks to refine theories and designs that support teacher reflection on classroom discourse data. More specifically, we ask: *How did teacher-researcher dyads interact with the initial design prototypes of classroom discourse data visualization and reflection practices? How were reflections on data visualizations constrained by design?*

Methods

Study Design and Background

The present analysis is situated within a larger design-based research project between three universities and two school districts in southern California which serve linguistically and ethnically diverse student bodies. ClassInSight shows visualizations constructed from discourse categories informed by the literature, such as *Teacher and Student Close Ended Statements and Questions*, *Teacher and Student Open Ended Statements and Questions*, *Teacher Lecture, Turn Taking Facilitation*, *Metacognitive Modelling Questions,* and *Student Explanation*. Science lessons are recorded on a monthly basis, transcribed, with talk turns by teachers and students coded as one of the discourse categories. Researchers then shared visualizations of this data with the teachers, before entering into a one hour reflection session with them.

Participants and Data Sources

The participants of this study were 12 middle and high school science teachers. For this analysis, we analyzed data from 12 reflection sessions conducted on video conferencing software (audio recording transcripts and screencasts) from the first round of reflection sessions that immediately followed the research team sharing the first prototype of the classroom data visualizations.

Analysis

In order to understand how teacher-researcher dyads were interacting with the designs for teacher learning and related constraints, we analyzed the interaction between teachers and researchers with the initial data visualization and reflection protocol. Transcripts and videos from initial reflection sessions were analyzed to examine how teachers and researchers sensemaking of the data and articulate pedagogical actions. Using the constant comparative method (Glaser and Strauss, 2017), we surfaced descriptive themes that paid attention to the constraints the teacher-researcher dyads experienced in accomplishing these steps to inform improvements in our designs and theoretical conjectures.

Findings

Developing Shared Understandings of Talk Category Definitions

In many reflection sessions, teacher-researcher dyads undertook a process of developing shared understandings of the discourse categories that were core to the data visualizations. Initially, the teachers' interpretations of the discourse categories often did not align with the theoretical definitions, which the researchers based their own design and analyses on. Two processes emerged in the way that teachers worked with the researchers to construct meaning for the different talk categories: developing a conceptual understanding of the talk categories, and connecting them to prior experiences.

First, teachers sought to develop conceptual understandings of the different discourse categories that were represented in the data visualizations. As a consequence, teachers reported challenges in determining what kind of talk would fall into what particular talk type. In such instances, they turned to the researchers to explain the researcher's conceptualization of these discourse categories. In the following excerpt from a reflection session, Evan, a middle school Science teacher, shared his struggle identifying the difference between two discourse categories :

> I guess if there was clarification on how each of the statements, or how the break down kind of works...I don't know what's the difference between assorted teacher talk and a teacher lecture... (Excerpt 1, [Evan])

Here, Evan asks for a clarification of not only the definition of the discourse categories. They additionally convey a lack of shared understanding about the differences between two of the discourse categories in the visualization.

Second, in making sense of the discourse categories, teachers related the different categories to their own practices. We saw participants connect discourse categories like "open ended questions" to terminology that their schools used, in this case, Inquiry-Based questions. Tom, a high school teacher, shares how some discourse categories are similar to the ones he uses in school

> Instead of *open ended questions*…[we use] *inquiry based questions* or *inquiry modeling*... So we use terms like that and we get instructions. So in that sense it could be helpful in terms of helping a teacher move towards a, a, the definition that the school uses. (Excerpt 2. [Tom])

Here, a teacher translated the discourse category of "open ended question" to language practiced in their own practice context (e.g.inquiry modeling"). Beyond developing an understanding of discourse categories by identifying instances in which they embody these talk moves, the teacher suggested that using categories like "inquiry-based or inquiry modeling" might be helpful in scaffolding teacher understanding as it relates to the definition that schools generally use. We see the distance between the teachers' meaning of the discourse category and the researchers' meaning as a constraint of the design for teacher sense-making.

Tethering Discussion Goals to Science Learning Outcomes and Equity

The initial reflection sessions typically led to teacher goal setting on classroom discourse that was unconnected to concerns of equity in science learning. Teachers set goals that were specifically related to characteristics of classroom discourse. However, these goals were not explicitly tied to broader visions for equity in science learning. When prompted to set goals for upcoming classes, the most common response by teachers was to state that they would like to increase student talk and reduce how much they talk. Even when teachers used specific discourse categories like "open ended" or "meta-cognitive modeling" to formulate their goals, it was challenging for the researcher to support teachers in tethering their goals to equity or specific student learning outcomes or equity. The following interaction between a researcher and Tom, a high school chemistry teacher, shows how a broad prompt by the researcher asking them to articulate a goal moving forward led to a response by Tom that included a specific goal for classroom discourse but was not tethered to particular science learning outcomes, or equity goals:

> Researcher: goals you might set or other things that you might want to keep in mind as we're continuing to refine the design?
> Tom: Well, the same thing I said last time[earlier in the session]. I mean… having students participate in the discussion is a goal. So having more student participation… I tend to think that if the number [of students talk] goes up, that's awesome. (Excerpt 3 [Tom])

In Excerpt 3, we see a teacher respond to the researcher's questions about goal setting. Along with the researcher, they formulate a goal to have more students participate in discussion. Then they provide the rationale for why they think that having more participation should be the goal by tapping into their belief of why it was good. The consequent designed interactions between the researcher and the teacher failed to create space to build on and connect the mentioned goals to student science learning outcomes and equity.

Discussion and Implications

Shared Meaning Making of Talk Categories

During reflection sessions, reflection dyads sought to build a shared understanding of the discourse categories. There was a dissonance between the discourse category codes as the research team understood them primarily through the literature (Clarke et al., 2015) and the ways teachers understood the language of the discourse categories, which were primarily informed by their practice. This constraint speaks to the challenge of leveraging theory and practice in a collaborative Design-Based Research where researchers work with practitioners in the field.

In designing for representations of classroom data and reflection practices, we suggest that there is a need to pay further attention to teacher voices and build on their experiential knowledge while planning the processes of creating and naming these categories. This would allow teachers to play a more active role in the collaborative process of design-based research by bringing in their rich experiences; additionally, it might also allow teachers to leverage their knowledge better to conceptualize their practices to address the project's goals. For the field, it reaffirms the need to be intentional and attentive to create space for dialogue between the theoretical knowledge of researchers and the practical and experiential knowledge of participants. As a research team, we revised the constructions of the codes to build upon the teachers' experiential knowledge in future iterations.

Scaffolding Thinking about Equity and Learning Outcomes

ClassInSight aims to work with teachers to reflect, identify, plan, and implement equitable discourse practices for their science classrooms. Hence, it is important that teachers make explicit connections between their classroom discourse and students' science learning outcomes for all their students in order to work towards equity. We see through the findings that teachers are making goals based on increasing participation in their classrooms. However, the researcher-teacher dyads are unable to extend teacher goals to explicitly connect to student science learning outcomes and equity**.** This is especially important as, as a research team, we are ultimately engaging teachers in a process of developing practice-based theory about equitable discussion in their science classrooms. In response, as a design team, we included further systematic probes into our reflection protocol to work with teachers to explicitly connect their discussion goals with student learning outcomes in science classrooms. Additionally, scaffolding teachers' reflection and goal setting with a mind towards equity must ensure that teachers have the opportunities to make sense of how their actions and decisions for talk in classrooms are linked to creating equitable spaces for *all* students to learn.

Supporting Empathy in Design Thinking - A Learning Community Approach

Rubaina Khan, Preeti Raman, James D. Slotta
rubaina.khan@mail.utoronto.ca, preeti.raman@mail.utoronto.ca, jslotta@gmail.com
OISE, University of Toronto

Abstract: Empathy plays an imperative role in human-centered design thinking processes. Our research explores how a learning community approach can help students become empathetic designers. By situating the design experience within a community of peers, there are increased opportunities for norming and exchange, shared strategies and resources, and a sense of collective progress. Such design activities allow students to bring in their voices and identities by offering empathetic feedback into the classroom discourse. Using the Knowledge Community and Inquiry (KCI) model, we explore how the diversity in the dispositions and experiences of students plays a unique and major role in framing and shaping design problems through peer feedback and perspective-taking. This paper reports the findings from six graduate-level courses that offered a design assignment in an education faculty taught over two years.

Introduction and Significance of Study

Within education, design thinking has been recognized as a critical 21st-century competency (Van Gompel, 2019), included widely in the curriculum standards (e.g., NGSS, 2010), and targeted within many reform efforts. Our research explores how a learning community approach can help students become empathetic designers. The graduate-level courses being investigated bring in students from diverse educational, cultural, and professional backgrounds. By situating the design experience within a community of peers, there are increased opportunities for norming and exchange, shared strategies and resources, and a sense of collective progress. In particular, we examine the Knowledge Community and Inquiry (KCI) model, which has been developed to support communities of learners engaged in collective inquiry (Slotta, 2013). Design, as a form of inquiry, is well suited to KCI as it draws upon resources and input from peers. We examine how a design assignment was implemented within six graduate-level courses in the domain of education, media, and society. We report our analysis of students' peer-supported designs, which made wide use of social annotations, scaffolded feedback, and community knowledge using Google Drive as a technology environment. This analysis informs our understanding of how a learning community approach can promote a collective understanding of empathy within the class, and deeply support human-centered design.

The research questions that framed this study are: (1) How can a learning community approach support students in learning about designer empathy? (2) What are some forms and features of a design-oriented inquiry assignment that support designer empathy, and how do they benefit from a learning community?

Theoretical and Conceptual Frameworks

The Knowledge Community and Inquiry Model

A learning community has been defined as "a culture of learning in which everyone is involved in a collective effort of understanding" (Bielaczyc & Collins, 1999, p. 2). The Knowledge Community and Inquiry (KCI) model has been developed to guide the design of "collective inquiry" curricula that integrate whole class, small group, and individual activities and ensure that all students progress on the learning goals (Slotta et al, 2018). Students engage in epistemic orientations (i.e., to the community pedagogy), in which they learn how to learn as a community and come to value the shared nature of artifacts and ideas. This form of the curriculum also prioritizes diversity and democratic forms of learning, student voice, giving students voice and ownership over what they want to learn and how they want to share it with others.

Definitions and Dimensions of Empathy

Training and practical experience can advance the designer's empathic understanding of users. However, in the context of learning design through a semester-long course, it is challenging for designers to engage directly with their communities and often must rely on secondary understandings to frame their design space (Li & Hölttä-Otto, 2020).

 © ISLS

In this study, we use three dimensions of empathy (cognitive, affective, and conative) as offered in literature to form our conceptual framework. Cognitive empathy refers to the study of the ability and accuracy of the understanding of other people's thoughts in different contexts (Cuff et al., 2016). Affective empathy is usually formed after the apprehension of other people's feelings and problems and sometimes entails some responsive actions (Decety & Lamm, 2006). Lastly, conative empathy refers to the study of the practical application of taking supportive actions in response to other people's feelings and problems (Adams et al., 2014). We use these dimensions of empathy for analyzing peers' feedback in a design thinking assignment and to understand the role of fostering empathy in a learning community.

Course Design and Data Sources

Within each of the six graduate courses, a design project was included in which small teams of 2 or 3 students engaged in designing an innovative media application for learning. All courses were taught by the same instructor during two consecutive academic years and were offered to cohorts of masters and Ph.D. students. Course enrollment was between 22-26 students for five of the courses, and 12 students for the 6th. A major course project was conducted by small groups of students who worked together on a design idea that applied course themes within a specific community or context.

Analysis of community feedback

For this study, 547 comments provided by peers during the design process were analyzed and coded by two researchers independently with an inter-rater agreement of 84.712%. While both affective and conative empathetic comments were visible in many designs, there were more cognitive empathy comments per design (see Table 1).

Table 1
Frequency and Dimensions of Empathic Comments

Dimension of Empathy	Number of comments	Designs impacted	Examples
Cognitive	70	30	"However, for beginner-level students, the "writing" part might be a bit overwhelming because writing sentences do need a lot of grammatical knowledge." "When students answer the questions, they might feel more like playing games instead of reciting vocabulary. "
Affective	10	4	"This app worries me as we are putting kids in buckets too soon. I am also very concerned with equity issues. The rich get richer" "My experience with people jumping into open-source coding projects is there is a whole lot of downtime and head-scratching in the beginning. You will need to get them all through this."
Conative	37	28	"Maybe can get students to create videos and demos to be attached with their modules" "Adding a live chat feature (either with a consultant or an AI) would be nice. This would be super useful when a student stressed and is filling in the OUAC application and needs some immediate clarification"

Semi-structured interviews

We interviewed 6 students at the end of their course to understand their perspectives on the use of the learning community approach. Specifically, through a semi-structured interview, we asked them about the identities and roles they brought into the learning community, in what ways did their peers influence or shape their design idea, and how would they advance their design idea in the absence of the learning community. The interviews

were transcribed and coded inductively to let themes emerge that allowed us to understand the nuances of how empathy from the learning community may have shaped the students' designs, as shown below:

Interdisciplinary perspectives

Our interviewees are teachers that gave them lenses from the real world to evaluate their peers' design process and final outcomes. As the nature of the course deals with the application of knowledge media in society and communities, several interviewees identified with others' design because of their situational and personal experience as immigrants, parents, international students, and/or curriculum designers. As one student aptly described what they saw as the purpose of their identity in the learning community:

> "…helped me to understand the complexity of intersectional identities as we shape our designs" (Tiara, 2021).

Hidden biases uncovered

Several interviewees identified that in a course-based design assignment, biases often creep into their assumptions, especially during a time crunch. One student believed that the learning community's comments brought awareness of some of her team's biases. She added that the comments that were made early in the design process led to influencing decisions on the final design.

Sophistication in design

Almost all interviewees indicated that their final design featured nuanced ways of addressing complex issues, connected to a variety of communities' needs and aspirations, and leveraged on state-of-the-art technology. They all attributed these achievements to their supporting learning community as seen in this statement:

> "I would have probably ended up with a less detailed and sophisticated idea. I would have also had more doubts about the value of the design. The community both encouraged me to continue working on my original idea and helped me fill different gaps in the design."

Case study of a design artifact

Using KCI principles, the instructor created scaffolds for design teams to gather feedback through empathy exercises at different stages of the design. Teams asked their peers for feedback informally in breakout sessions during class in the initial stages of the design process. Next a formal peer-review was conducted on a document that detailed the design's purpose statement and features. Students were given the agency to comment on as many designs as they wanted to and were encouraged to leave empathetic comments that would broaden the team's perspectives. Finally, teams showcased their elaborate designs by presenting user journeys. At this juncture, design teams had the opportunity to receive the last round of feedback that challenged their assumptions and pushed them to advance their designs. We present a case study of a design of a career identity formation application for K-12 students. Some of the comments that were given to the design team during the various review channels are indicated below. The commenter's identity has also been considered during this analysis.

Informal feedback during class

Jason, a doctoral student, served as a senior K-12 school administrator for several years before becoming a full-time student. He is interested in understanding how technology can be leveraged to create communities and drive education reform. The team documented the following comment in their learning journal:

> "What would incentivize the students to join your app? I would find ways to get parents trained and more involved. Also, I find that a culture is created if they knew their friends were using it."

Formal peer-review feedback

The design team documented several suggestions for technology enhancements and ways their users may be motivated to use their application during the formal peer-review feedback. An example of a comment that fostered empathy for the design team is shown below.

Zeba is a parent of four school-going children ranging from ages 15 to 5 years old. She is also an online learning experience designer engaging post-secondary students to develop stronger career

identities. She left the following comment on the design team's document which the team chose to highlight in their learning journal.

> "I see the potential for students to view it as part of the school or as an academic tool, hence not use it for intrinsic purposes. Kids would engage if you considered adding some gaming features an indication of progress."

Peer feedback during design presentation

The design team shared their design with their peers through a visual presentation and emphasized how a potential user would interact with their design. At the end of the presentation, the team highlighted several comments made including their colleague Valeria's comment. Valeria is a researcher who builds and studies technology scaffolds for instructors to engage learners and she commented:

> "I would consider an AI "coach" that helped students make progress on certain career goals, and even advocate for that student in the other communities of participants."

Discussion and Further Research

Building empathy in the design process starts with making space for self-empathy. When students approach design thinking by starting to reflect on the identities they bring into the community, they go through the process of "noticing, centering, sensing, suspending judgment, intention setting and attending to self" which allows them to reciprocate by providing spaces for others' experiences (Train & Niezink, 2021). As such, instructors can provide students with frameworks through which they can bring in their unique dispositions, knowledge of the communities they inhabit, and lived experiences. We noticed that the nature of the comments that students provided were often related to their research interests, lived experiences, and professional expertise. Therefore, exhibiting to students that their experiences and voices are valuable for the class community can make them eager to hear others' worldviews and practices (Cartaya, 2021).

This study is among a select few that explores the concept of supporting empathy using a learning community approach. Adopting such an approach enables the class as a community to engage in empathetic discourse. A learning community pedagogy embraces grounding in the theme of the course while engaging openly in dialogue - making student voice an integral aspect of the experience. In this study, we provided the space in which students' voice, their lived experiences, and positionality was an asset for design teams.

Further research must be done to establish the effectiveness in developing empathy with the help of the learning community. Therefore, we propose to conduct future research that seeks to explore the question: how does a learning community pedagogy impact students' generation of empathic solutions to educational problems and the development of empathy?

Examining Instructors' Adaptive Equity-Oriented Pedagogical Competency: A Validated Measure that Promotes College Students' Success

Andrew Estrada Phuong, UC Berkeley, andrew.e.phuong@gmail.com
Judy Nguyen, Stanford University, judynguyen@stanford.edu
Christopher T. Hunn, UC Berkeley, cthunn@berkeley.edu
Jimmy Vo, UC Berkeley, james.j.vo@gmail.com
Fabrizio D. Mejia, UC Berkeley, fmejia@berkeley.edu
Fan Huang, University of Macau, huang_fan@gmail.com

Abstract: This study validates an Adaptive Equity-Oriented Pedagogical Competency (AEPC) assessment, a measure of college instructors' teaching effectiveness. AEPC integrates core elements that have together been shown to improve student learning by over a letter grade. These elements include: 1) Clarifying learning outcomes, 2) Aligning formative assessment with learning outcomes, 3) Identifying students' competencies, needs and interests, 4) Understanding equity barriers to meeting outcomes, 5) Adapting based on needs and barriers, and 6) Iterating: Reflecting upon pedagogy to support continuous learning. Developed under Wilson's (2005) validity framework and calibrated using a partial credit Rasch model, the AEPC measure has both high reliability (0.94) and significant correlation with independent reviews of instructional quality. This measure includes materials that are often included in portfolios used in part to evaluate college teaching, such as teaching philosophy and practice statements, learning outcomes, formative assessment, and reflections on teaching (Seldin, Miller, Seldin, 2010). Unlike course evaluations, this measure shows no gender or URM assessment bias. A learning progression of inclusive practices shown to improve student success provides a measurement foundation for the AEPC assessment.

Introduction: Problem statement and research questions

Research shows that college teaching directly impacts student achievement and retention in STEM, especially for underrepresented students (URM; Seymour & Hewitt, 1997; Sax et al., 2018). It is, therefore, beneficial to equip STEM instructors with adaptive equity-oriented pedagogies that have been shown to increase student learning. The purpose of this study is to develop and validate an instrument to measure the progression of adopting adaptive equity-oriented pedagogical competencies (AEPC). This measure can be used for professional development since it helps instructors reflect and respond to students' learning needs. This measure was taken as an assignment by student-instructors who were enrolled in STEM pedagogy courses that taught adaptive equity-oriented pedagogies. The student-instructors were graduate and undergraduate students who served in an instructional capacity under faculty direction and were enrolled in pedagogy courses at an R-1 university.

We have not found other equity-oriented teaching measures in higher education that were validated using Item Response Theory (IRT). We found college-level, observation-based, equity-based checklist measures of universal design for learning (CAST, 2018) and culturally responsive pedagogy (Hammond, 2014). These measures ask observers to examine whether instructors use formative assessment, explain course content in different ways, and promote participation for all students, but these measures are not validated using IRT and we cannot find reliability estimates. We explore the following 3 research questions:

1. Is the AEPC measure valid and reliable?
2. Does this measure have gender and/or URM bias?
3. What are the consequences of using the assessment?

This study contributes to the learning sciences by offering an assessment that defines a learning progression of inclusive behaviors and practices that have been shown to improve student success. The assessment enables us to see where instructors are on a developmental learning progression so that we can further support their learning of inclusive practices. This information can enable professional developers to support instructors as they implement equity-oriented practices measured by the AEPC assessment.

Adaptive Equity-Oriented Pedagogical Competency

Adaptive equity-oriented pedagogy (AEP) is a framework for adapting teaching to address equity barriers to learning based on student data (e.g., formative assessment, observations, surveys) (Phuong et al., 2017; Phuong

 © ISLS

& Nguyen, 2019). Effective AEP practice is characterized by instructors' use of the 6 competency elements listed below, which build on each other and reflect a mastery learning model.

1. Clarify learning outcomes, equitable course policies, and prerequisite knowledge needed for a course
2. Align formative assessments and activities with outcomes
3. Identify students' competencies, interests, and needs
4. Understand equity barriers and contextual challenges to meeting outcomes
5. Adapt teaching practices based on these needs and barriers
6. Iterate: Reflect upon pedagogy to support continuous learning, adaptation, and growth

Methodology

We engaged in the four building blocks of the Bear Assessment System (e.g., construct map, item design, outcome space, and measurement model) (Wilson, 2005). We designed 6 items that aligned with construct map levels that reflect the AEPC learning progression. We defined an outcome space by creating 0-7 point scoring rubrics for 5 of the items and a 0-1 point scoring rubric for the 6th item. The construct measures varying degrees of AEPC on an ordinal scale, with higher positions on the rubric implying that criteria of lower positions have been met.

Table 1. AEPC Construct Map and Scoring Rubric 0-7

Item Score	**Construct Map Level**	**Description**
0	0	Provides an irrelevant answer, does not apply any elements
1	Low	Applies AEP element 1 and/or 2 (described above) Element 1: Clarifies learning outcomes Element 2: Aligns formative assessment with learning outcomes
2	Moderate	Applies elements 1-3: Diagnoses student learning competency ***Or*** Diagnoses interest
3	Moderate	Applies elements 1-4: Diagnoses learning competency and interest ***Or*** Diagnoses learning competency and learning barriers
4	High	Applies elements 1-5: Adapts based on full diagnosis, not only based on diagnosis of learning competency
5	Very High	Applies all 6 AEP elements
6	Very High	Applies all 6 AEP elements citing instructor and student evidence
7	Very High	Applies all 6 AEP elements with supporting instructor/ student evidence and explains how their practice impacts the student ***Or*** Applies all 6 AEP elements with instructor/ student evidence and explains rationale for how practice impacts student

Participants. We examined 124 participating student-instructors' assessments. There are 80 (64.52%) male and 44 (35.48%) female student-instructors. 13 (10.48%) are URM and 111 (89.51%) are non-URM.

Data Sources. We examined 124 student-instructors' responses to the 6 items of the AEPC assessment. This assessment was taken as an assignment in a graduate-level pedagogy course. Researchers scored responses using rubrics and used survey and interview data to assess instructors' experiences with the instrument.

Data Analysis and Measurement Model: Partial Credit Model (PCM). To answer research question 1, we fitted a Partial Credit Rasch Model (Masters, 1982) and estimated person locations on the construct and the item difficulty parameters.

Model 2: PCM with Latent Regression. To answer research question 1 and examine external validity, we conducted a latent regression to account for measurement error when examining the effects of covariates such as fidelity of implementation scores and gender.

Model 3: Differential Item Functioning (DIF). To answer research question 2, we fitted PCM Differential Item Functioning (DIF) models to ensure there is no AEPC item bias between different genders and between URM identities.

Consequences of Use. To answer research question 3, we inductively coded (Saldana, 2006) think aloud, survey responses about the assessment, and reflection questions that asked about instructors' perspectives on teaching and student learning, changes in beliefs, thought processes while completing the assessment, and experience with the assessment. Although this qualitative research is ongoing, we present frequent themes that we found in the findings below. Performing these statistical and qualitative analyses enables us to see if we meet Wilsons' (2006) strands of validity: Construct Validity, Reliability, External Validity, Bias, and understanding consequences of use. We explore these strands in the findings.

Findings

Research Question 1: Validity and Reliability

Construct Validity. The Wright Map is an empirical representation of the construct map (Wilson, 2006). The Wright Map displays the difficulty of each item, overall and by scoring rubric level, in relation to student-instructors' AEP competency. When items are built to align directly to construct map levels, the scoring rubric levels are expected to band together on the Wright Map. Such empirical banding demonstrates a coherence that contributes to strong construct validity. Based on the Wright Map in Figure 1, we see relative banding for each level since each color tends to group together. We notice that the banding is ordered in the way we hypothesized in the construct map. Respondents who tend to score high on the construct tend to score high across items. This mean location increase supports construct validity. According to the Wright Map, the items appear to cover most of student-instructors' competencies. Nonetheless, some respondents are above the highest items. In other words, the most competent respondents need more challenging items for optimal measurement.

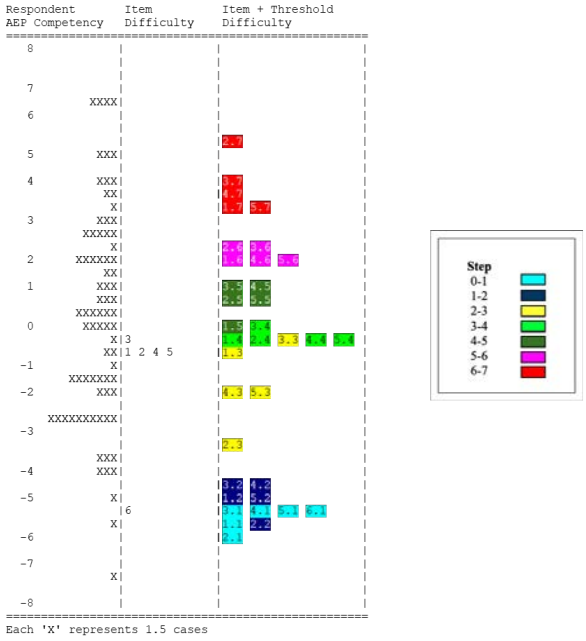

Figure 1. Wright MAP of AEPC

Reliability. We estimated Warm's Weighted Likelihood Estimate (WLE) for the AEP competency of each student-instructor. The reliability estimate of the instrument is 0.94, suggesting the instrument has high consistency in measuring AEPC. We examined infit statistics to ensure that items were behaving appropriately and that there was alignment between what was expected from the PCM and what was observed. An item with an infit statistic above 1.33 is exhibiting more randomness than expected, suggesting that respondents with high proficiency scores tend to score low on that item or vice versa. None of the items had high infit statistics.

External validity. To assess external validity, we conducted a latent regression and regressed student-instructors' AEPC on their fidelity of implementation scores, when controlling for gender. For each unit increase in the fidelity of implementation score, the student-instructor's location in the logit scale is estimated to increase, on average, 1.571 logits in position when controlling for gender (p<0.05). When a student-instructor scores higher on the fidelity of implementation score, there is a higher likelihood that the student-instructor will have, on average, demonstrated higher degrees of AEPC. Moreover, researchers' review of student-instructors' teaching materials and observations of their teaching tended to align with student-instructors' competency estimates. These results further support this measure's validity. When controlling for fidelity of implementation scores, gender does not significantly predict a student-instructors' AEPC at the 5% level.

Research Question 2: Investigating Gender and URM Bias

For all items, we found no evidence of Differential Item Functioning (DIF), or item bias, between males and females because no item by gender interactions (i.e., DIF Contrast) were both statistically significant and above the generally accepted threshold (i.e., 0.426) in magnitude (Paek & Wilson, 2011). In fact, none of our DIF contrasts were of above 0.426 in magnitude, so even had larger sample sizes resulted in statistically significant results, they would not have met the generally accepted threshold indicating a problematic level of DIF. In other words, for all levels of item difficulty, male student-instructors do not have significantly higher item scores than female student-instructors who have the same AEP Competency score, or vice versa. Using the same criteria, we also found no evidence of DIF between URM and non-URM student-instructors.

Research Question 3. Consequences of Use

Benefits. We collected validity evidence on the consequences of the assessment's use. One of assessment's goals is to help student-instructors document equity-oriented practices and demonstrate teaching effectiveness in ways that go beyond course evaluations. We examined the degree to which this occurred. We found evidence that student-instructors documented and improved their AEP practices. Student-instructors stated that the instrument

 © ISLS

helped them improve their instruction and student learning. Many student-instructors also discussed how the AEP framework helped them promote inclusive learning environments. In response to a think aloud exercise, one student-instructor stated the following when asked about what motivated his thought processes and responses to the assessment: "I relied heavily on the AEP methods because many of the principles of AEP agreed with my own teaching philosophy and I had found that based on my experiences with the students the AEP methods were the most effective." Multiple student-instructors also expressed that this assessment helped them apply AEP to adjust teaching practices they were passionate about (e.g., inquiry-based learning, modeling expert problem solving, growth mindset-oriented praise). Student-instructors' AEPC assessment reflections suggest that the pedagogy course impacted their models for effective teaching and learning. Preliminary research also suggests that success on the AEPC measure is associated with greater student achievement.

Discussion

Based on prior research (Phuong et al., 2017; Fink, 2013), we theorized that the highest AEPC level would be the most difficult to reach because it required instructors to demonstrate and act upon all lower-level elements. In theory, reaching the highest level requires ongoing planning, observation, active reflection, and adaptation based on data, which are the traits an instructor with high AEPC mastery would demonstrate. The levels and ordering of the construct and learning progression are supported by the Wright map and mean location increases within all the items of the instrument. We crafted multiple items that tap into all levels of AEPC. Based on the Wright map, these items targeted participants at different competency levels.

Limitations. This study faces challenges with generalizability since this instrument was administered in a graduate-level course in which student-instructors were provided with opportunities to learn and reflect on their adaptive equity-oriented practices and had little to no classroom-teaching experience.

Significance

This study contributes to the literature on communities of practice, groups of professionals who have shared goals and interests such as improving student learning (Wenger, 1998). We provide a way to assess the learning progression within communities of practice focused on equitable teaching practices and interactions with students in STEM. While we understand that such communities can promote learning of new pedagogies, there has not yet been a validated IRT measure on inclusive pedagogies in higher education that can empirically inform their progress.

If validated with a larger sample and elevated in the teaching evaluation process, this AEPC measure could help reduce instructor evaluation bias and incentivize instructors to focus more on high-impact equity-oriented teaching practices that drive student learning. Using item response theory, this study presents a clear and rigorously validated teaching measure that leverages artifacts that are already collected in higher education evaluation. For example, the AEPC items incorporate a teaching philosophy and practice statement, teaching materials (e.g., syllabi, formative/assessment), and evidence of student learning. This measure identifies instructors' developmental progress within a mastery model of learning based on AEPC elements. Using the AEPC measure in this way can prioritize equity in professional development and in conversations around effective teaching practices for all students.

Abstract: Learners' choices as to whether and how to use visual representations during learning are an important yet understudied aspect of self-regulated learning. To gain insight, we developed a *choice-based* intelligent tutor in which students can choose whether and when to use diagrams to aid their problem solving in algebra. In an exploratory classroom study with 26 students, we investigated how learners choose diagrams and how their choice behaviors relate to learning outcomes. Students who *proactively* chose to use diagrams achieved higher learning outcomes than those who *reactively* used diagrams when they made incorrect attempts. This study contributes to understanding of self-regulated use of visual representations during problem solving.

Introduction

In many modern societies, people have access to large amounts of information and resources. Learners therefore need to strategically choose to use available resources so that they can handle learning tasks effectively and efficiently (Schwartz & Arena, 2013). One important class of learner choices involves the use of visual representations. Visual representations can be used as instructional scaffolds that help learners' sense-making processes during learning and problem-solving (Ainsworth, 2006; Rau, 2017). From a cognitive perspective, engaging with visual representations during problem solving can help learners by reducing cognitive effort and making relevant information salient (Ainsworth, 2006). However, to reap these benefits, learners must use visual representations strategically (diSessa, 2004). The strategic, self-directed use of visual representations is an important, though understudied, form of self-regulated learning. To use visual representations strategically, learners need to regulate their behavior (i.e., choose when and how to use visual representations) based on self-monitoring of their own skills and knowledge (Pintrich, 1999).

Despite the importance of understanding learner choices with visual representations, past research has rarely allowed for or specifically measured learner choices in using visual representations during problem solving. Prior work has largely focused on student learning when students are *given* visual representations (e.g., Rau et al., 2015). A few studies have investigated learners' spontaneous use of visual representations (e.g., students constructing diagrams on their own) in problem solving and these studies have shown that students generally tend not to choose to use visual representations when it is optional to do so (Uesaka et al., 2007, 2010). Although prompts to engage with visual representations (e.g., drawing) have been shown effective in encouraging students to use visuals (Wu et al., 2020), past studies do not give deep insights into *how* students make choices in problem solving and how their choices might be related to learning outcomes and performance. A deeper understanding of students' choice-making processes and how they relate to learning could contribute to the understanding of self-regulated learning with visual representations (diSessa, 2004; Zimmerman & Campillo, 2003).

Choice-based Intelligent Tutor with Visual Representations

To investigate students' choices in using visual representations, we redesigned an existing Intelligent Tutoring System (ITS) for algebra problem solving (Long & Aleven, 2014; Nagashima et al., 2021) to develop a *Choice-based Diagram Tutor* (Figure 1). In this *choice-based* tutoring system, students can choose whether and when to engage with a visual scaffolding strategy called "anticipatory diagrammatic self-explanation" with tape diagrams, a representation that is increasingly being used in algebra instruction worldwide (Murata, 2008). Anticipatory diagrammatic self-explanation is a metacognitive scaffold in which learners *self-explain* ensuing problem-solving steps by selecting a diagrammatic representation of a next step (Nagashima et al., 2021).

Anticipatory diagrammatic self-explanation presents a fruitful context for examining students' self-regulated choices with visual representations. It is an effective metacognitive strategy that learners might not

 © ISLS

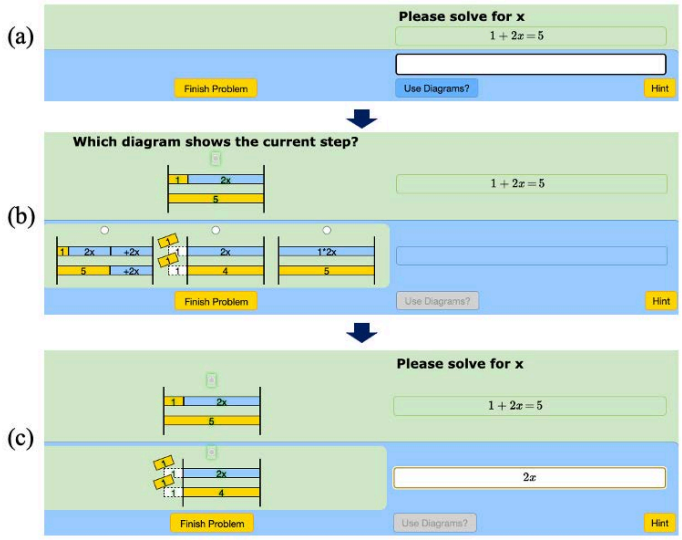
naturally choose to engage with, a critical prerequisite when designing a "choice-based" learning environment (Chin et al., 2019). In the tutor, students may be inclined to avoid using diagrams because doing so would require additional problem-solving steps. Also, tape diagrams are a new representation that students may find unfamiliar (Murata, 2008). However, anticipatory diagrammatic self-explanation has been shown to be beneficial for student learning and performance (Nagashima et al., 2021). Therefore, we investigated students' *spontaneous use of diagrams* (i.e., whether students spontaneously use diagrams when such use is optional; Uesaka et al., 2010).

Additionally, we distinguish the following choice behaviors involving spontaneous diagram use to get insights into students' self-regulated use of diagrams: 1) *proactive diagram use:* using diagrams *before* attempting to solve the corresponding symbolic step, and 2) *reactive diagram use*: using diagrams *after* making one or more incorrect attempts on the symbolic step. These choice categories are informed by the literature on help-seeking in ITSs (Aleven & Koedinger, 2001) and by Zimmerman and Campillo's (2003) cyclical model of self-regulation. Zimmerman and Campillo's (2003) model captures phases of self-regulated behaviors in which learners evaluate the difficulty of the target task ("forethought" phase), self-monitor learning strategies ("performance" phase), and evaluate and reflect on the use of the strategy ("self-reflection" phase). Under this model, in the Choice-based Diagram Tutor, students may choose to use diagrams by assessing the difficulty of the given equation, self-monitor how they perform by using diagrams, and adjust their use of the strategy through self-reflection. Therefore, we expected that proactive diagram use would represent self-regulated, *well-planned* use of diagrams, whereas reactive diagram use would represent *unplanned* diagram use.

The Choice-based Diagram Tutor collects learning process data (e.g., choice behaviors and problem-solving performance measures), enabling us to study students' learning processes, which have not been explored in studies on spontaneous diagram use (e.g., Uesaka et al., 2010). The present study asks: RQ1) *When given a choice, how will students engage with anticipatory diagrammatic self-explanation?* RQ2) *Are students' choice behaviors related to their learning outcomes, performance, and their perceptions regarding diagram use?*

Figure 1

(a) Students start with an interface showing a symbolic algebra problem. They can solve the equation symbolically or choose to use diagrams ("Use Diagrams?" button). (b) Students who choose to use diagrams will select a correct diagram that represents a good next step. (c) After selecting a correct diagram option, students will type in the step in mathematical symbols.



Method

We conducted a pretest-intervention-posttest study in two classrooms in a middle school in the U.S. Thirty 6th graders participated. The participating teachers noted that some students might have previously seen tape diagrams in learning materials, but the instruction had never focused specifically on tape diagrams.

We developed a web-based assessment consisting of seven items that measure conceptual understanding of algebra and four procedural knowledge items that asked students to solve symbolic equations. Of these 11 items, three conceptual and two procedural items included tape diagrams. For these problems, tape diagrams were presented either alongside a symbolic equation so that students could refer to them or integrated into the main task (such that students needed to understand the representation to reach the correct answer). Two assessment

versions were created and assigned as pretest and posttest in a counter-balanced way. Following the posttest, students answered five survey questions about their perceptions of tape diagrams (e.g., "Do you think that diagrams helped you solve problems?") and their confidence in solving equations (based on a questionnaire in Uesaka et al., 2007). All students were given the choice-based diagram tutor, which included 22 problems of four different problem types (called "levels" in the tutor): Level 1) $x + a = b$, Level 2) $ax + b = c$, Level 3) $ax = bx + c$, and Level 4) $ax + b = cx + d$, assigned in this order. According to the teachers, students had seen Level 1 problems but had never solved equations in a formal way (by subtracting "a" from both sides of "$x + a = b$").

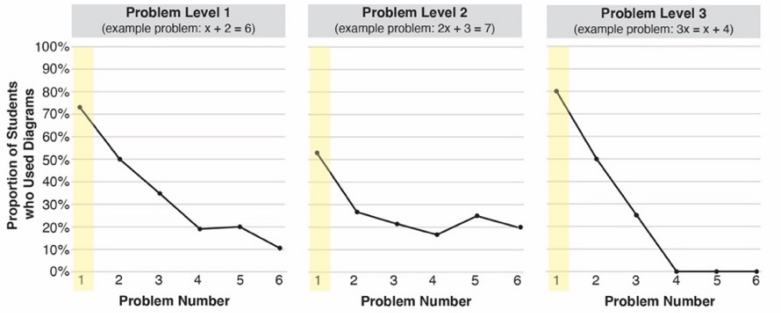
Researchers joined the classrooms remotely to conduct the study. On the first day, students worked on the 10-minute pretest. On the second day, one of the teachers gave a brief lecture on how tape diagrams visualize equations to all students at the beginning of the session. Students then used the tutor for about 25 minutes. Students then completed the posttest and the survey about perceptions of tape diagrams and their math skills.

Results

Four students were absent on the second day of the study; we analyzed data from the remaining 26 students. To answer RQ1, we calculated the frequency of diagram use. On average, students solved 9.12 problems ($SD = 5.14$) and chose to use diagrams 3.15 times overall ($SD = 2.88$). Students *proactively* used diagrams in 72% of cases ($Mean = 2.27$, $SD = 2.38$) and *reactively* used diagrams in 28% of the cases ($Mean = 0.88$, $SD = 1.21$). Students tended to use diagrams on the first problem in each problem level, and diagram use declined as students practiced the same problem type multiple times (Figure 2). The trend was not observed for Level 4 problems because very few participants advanced so far (therefore not included in Figure 2).

Figure 2

Proportion of students who spontaneously used diagrams at least once for each problem.



To examine RQ2, we tested whether self-regulated behaviors predicted learning and performance. We constructed separate linear regression models with the following dependent variables: posttest score, posttest score for problems without tape diagrams, average time spent per symbolic step, average number of hints used per symbolic step, and average number of incorrect attempts for the symbolic steps. We included each of the spontaneous, proactive, and reactive diagram use frequencies in each model as independent variables. Overall pretest score was included to control for students' initial knowledge level. Spontaneous diagram use predicted higher overall posttest scores; however, this relation did not reach statistical significance ($\beta = 1.47$, $p = .07$). Spontaneous diagram use did not predict any other dependent variables. Proactive diagram use, however, predicted higher overall posttest scores ($\beta = 2.01$, $p < .01$) and higher posttest scores on items without tape diagrams ($\beta = 1.03$, $p = .04$). Reactive diagram use, on the other hand, was associated with lower overall posttest scores ($\beta = -4.75$, $p = .03$) and lower posttest scores on items without tape diagrams ($\beta = -3.39$, $p = .01$). Reactive diagram use also predicted greater use of hints ($\beta = 5.21$, $p < .01$). Prior knowledge, perceptions of diagrams, and confidence in solving equations were not associated with spontaneous, proactive, or reactive diagram use.

Discussion

Although students' use of diagrams was generally low, students' *proactive* diagram use predicted higher learning outcomes. This association was also observed on test items that did not include tape diagrams, suggesting near transfer of learning. However, as we cannot establish any causal relationships from the results, it is possible that certain characteristics that we did not control for led both to more proactive diagram use and better learning. For example, proactive diagram use might be indicative of superior monitoring ability or a propensity to monitor one's comprehension more frequently, which might lead to other behaviors that might contribute to better learning.

The current work contributes understanding of self-regulated learning with visual representations. Specifically, it provides evidence that effective use of visual representations involves more than simply using the visual representations spontaneously; rather, proactive use, which we consider as a form of self-regulated diagram use that involves assessment of task difficulty and planning of whether or not to use diagrams, leads to better learning. In a related, pilot study with eight middle-school students who thought aloud as they used the tutor, we found that students who tended to proactively use diagrams thought deeply about the given problem before attempting to solve it and correctly understood diagrams. On the other hand, those with frequent reactive diagram use did not seem to understand the diagrams, and therefore seemed to process diagrams in a shallow way (e.g., selecting diagrams that *look* right). We acknowledge though that different interpretations of these patterns of diagram use may be possible.

Learners can use visual representations in a range of ways. Our data suggest that proactive use of visual representations is beneficial for students' performance. Future research could explore ways to motivate students to use visual representations proactively, help them make self-regulated decisions as to when to spontaneously *fade* visual scaffolding, and experimentally test whether such strategic diagram use might be facilitated.

Abstract: We used Natural Language Processing (NLP) to design an adaptive computer dialogue that engages students in a conversation to reflect on and revise their written explanations of a science dilemma. We study the accuracy of the NLP idea detection. We analyze how 98 12-13 year-olds interacted with the dialogue as a part of a Diagnostic Inventory. We study students' initial and revised science explanations along with their logged responses to the dialogue. The dialogue led to a high rate of student revision compared to prior studies of adaptive guidance. The adaptive prompt encouraged students to reflect on prior experiences, to consider new variables, and to raise scientific questions. Students incorporated these new ideas when revising their initial explanations. We discuss how these adaptive dialogues can strengthen science instruction.

Objective

Through a partnership among university education researchers, computer scientists, and science teachers from six middle schools, we exploit advances in Natural Language Processing (NLP) to detect the rich ideas that students use to explain science dilemmas. We test designs for computer-generated adaptive dialogues to affirm students' ideas and support them to refine and extend their understanding. We build on prior work demonstrating the value of adaptive guidance that models behaviors for integrated revision such as making connections between ideas (Chi et al., 2017; Gerard & Linn, 2022). The adaptive dialogue in this study promotes equitable science teaching by assisting teachers in encouraging each student to express and elaborate their ideas about the target science topic including ideas grounded in their lived experiences.

Adaptive dialogue for revising science explanations

We design and test an NLP based adaptive dialogue that elicits the different ideas students bring to science problems and models a path to developing those ideas. The adaptive dialogue may assist teachers by ensuring that each student receives guidance which identifies a spark in their explanation to build on. The dialogue is designed to guide students to engage in integrated revision. Integrated revision is grounded in a knowledge integration (KI) perspective on learning, suggesting that as students reformulate the connections among their ideas, distinguishing which ideas are supported by evidence and how they link together, they deepen their understanding and develop durable insights (Gerard & Linn, 2022; Linn & Eylon, 2011). Central to the process of integrated revision is eliciting the different ideas one holds about a problem. These initial ideas often reflect prior experiences or previous science instruction. Eliciting a learner's ideas promotes agency by enabling the students to generate their expectations before they test them, increasing their interest in the outcomes. In repeated studies across disciplines and age groups, retrieval practice, compared to review and retrieval, has shown learning advantages (Karpicke & Roediger, 2008). Articulating one's ideas allows learners to reflect on their many different ideas and distinguish which among their ideas are relevant and supported by evidence.

Eliciting a learner's ideas in science is tricky since students may be reluctant to express ideas that differ from those of others or that they feel will be rejected as incorrect. Research suggests students with non-dominant views may be hesitant to express these ideas in a classroom context. When the culture of school encourages students to "do school" rather than "do science", students are likely to dismiss their ideas developed from years of experience or prior courses and adopt the idea presented by instruction without distinguishing between the two (Carlone et al., 2015). Research shows that when instruction neglects the ideas students hold while introducing new ideas, students develop a fragmented understanding by holding both perspectives rather than evaluating their knowledge (diSessa, 1998). We build on these findings to design an adaptive dialogue that engages each student in integrated revision by affirming students' initial ideas, prompting them to add new ideas as they reflect on the topic, and supporting them to consider the valuable reasoning and evidence underlying their initial ideas.

 © ISLS

Methods

We investigate two research questions: (1) How accurate is the NLP technology for detecting ideas students hold about an open-ended science dilemma?, and (2) How do students respond to adaptive guidance that promotes integrated revision on a Diagnostic Inventory?

Participants, Diagnostic Inventory, and NLP-based Adaptive Dialogue

We administered a Diagnostic Inventory with one teacher's 98 7th and 8th graders (50 7th graders; 47 8th graders). The majority of the students identify as a part of historically marginalized racial, linguistic and socioeconomic groups (97% Latinx; 95% of parents speak a language other than English at home; 85% eligible for a free or reduced price lunch). We report on the *Car on a Cold Day* problem, described in Table 1.

To train the NLP scoring model, a corpus of 1000+ student explanations collected in prior research from 5 schools, including demographics similar to the school in this study, was used. Two researchers developed a 5-point Knowledge Integration rubric to score the student explanations for 'Car on a Cold Day', which rewards students for linking normative, relevant ideas. The researchers also identified the distinct ideas expressed by students (21 ideas, Table 1). One student explanation could include multiple ideas. The researchers refined the rubrics until they achieved inter-rater reliability (Cohen's Kappa > .85). Then, each researcher coded 50% of the explanations assigning a KI score, and a tag for each distinct idea within each explanation. Data was used to train an NLP model.

Table 1. *Sample of "Car on a Cold Day" Scoring Rubric and Guidance for Adaptive Dialogue Round 1*

Item prompt: *On a cold day Akbar walks to his car that is parked in the sun. The sun has been shining on the car for the whole day. How will the temperature inside the car feel? Use what you've learned about how the Sun warms the Earth to explain.*		
#	**Sample Ideas**	**Assigned Guidance in Dialogue Round 1**
3	car same temperature as outside	Can you tell me more about how the temp. inside the car changes the longer it sits in the sun?
4	car warmer than outside	Can you tell me more about how the Sun makes the inside of the car warmer than outside?
7	Heat comes from the sun	Can you tell me more about the forms of energy that come from the sun?
8	Direct sun warms the car	Interesting idea! How does the sun make the car warmer?
9	Metal/car attracts heat/cold	Can you tell me more about how the material impacts how the car gets energy from the sun?

To build the NLP model, we used a word classification or sequence labeling approach (Riordan et al., 2020). First, the words in each response are transformed into numerical vectors with state-of-the-art language models that have been previously trained to capture latent relationships in the English language via the self-attention mechanism. Second, for each word, idea detection is cast as a multi-label classification problem. Consecutive word-level predictions of a targeted idea form a predicted idea span. The idea detection model was trained, evaluated, and deployed with 10-fold cross validation for hyperparameter tuning and evaluation. Final model building used all available data. Adaptive dialogue prompts for each idea were designed to engage students in conversation, modeling an integrated revision process and promoting science understanding (See Figure 1).

 © ISLS

Data Analysis

We determined the most frequently detected idea across all students' initial explanations (idea 8). We then identified the subset of students (N=53) who expressed idea 8. Focusing on these dialogues enabled comparison of the students' paths of reasoning rather than the impact of different adaptive prompts. Next, we selected a sample of 10 students who would be likely to express unique paths of reasoning in the dialogue based on criteria that they had varied levels of English and prior instruction about the greenhouse effect. Three researchers individually annotated each response to characterize students' revision moves. Researchers discussed annotations until reaching agreement. One researcher used the resulting categories [Fig.2] to code the 53 dialogues.

Results

To evaluate the NLP model accuracy, word token-level micro-averaged precision, recall, and F1 scores were used. These metrics account for the imbalance in idea classes. Despite often inaccurately predicting the length of idea spans, the model accurately predicted spans for many of the idea classes. Aggregating across all targeted ideas, we obtained a word-level micro-averaged precision of 0.71, and a recall of 0.51, yielding an F1-score of 0.60. The F1 score (0.60) suggests the difficulty of achieving high accuracy across all idea classes from our relatively small dataset. The model is relatively conservative in predicting idea spans, resulting in higher precision (0.71) but lower recall of ideas (0.51). Some idea classes were sparsely represented in the data (e.g., idea was tagged with less than 300 words of the 27000 words in the data set), thus the model tended not to predict idea spans for these ideas.

Analysis of students' revisions indicated that overall, the dialogue supported students to revise their explanations: 91% of the students (87/96) revised their initial explanation after engaging in two rounds of dialogue. In contrast, in our prior research only 69% of students revised in response to two rounds of knowledge integration adaptive guidance (Gerard & Linn, 2022). Additional studies report that under 50% of students engage in sustained revision when the activity calls for it (e.g. Zhu et al., 2020).

The analysis of student revision moves suggests that the dialogue effectively elicited student ideas (Fig. 2). In response to the *adaptive* first prompt in the dialogue, 36 of the students (68%) added a new idea to elaborate the mechanism underlying their initial explanation. In response to the *generic* second prompt (same for all students), 16 (30%) of these students added another new variable they considered relevant, and 6 (11%) distinguished a part of the mechanism from their initial explanation that they were uncertain about. Twenty-five (48%) of the students however struggled to recognize another relevant idea in response to the generic prompt (e.g., "I'm not sure; IDK"). This could be due to the generic nature of the prompt or because it is the second prompt. After the dialogue, students were encouraged to consolidate the ideas they raised in the dialogue and revise their initial response. When revising, 24 (46%) of the students integrated an idea that they had raised in the dialogue to explain more fully the mechanism they had initially expressed. Fifteen (28%) expressed another new variable, in addition to those raised in the dialogue, in their revised explanation. Overall, the dialogue elicited an increasing number of ideas each student held about the problem. The adaptivity of the prompt in the first round was more effective than the generic prompt in the second round in supporting students to recognize and express the relevant ideas they held.

 © ISLS

Case analysis. We describe the dialogues for three students who started with a similar idea, yet had distinct sequences of revision to illustrate the revision moves. Each of the students started out by expressing a vague idea that the car will be warm inside because of the sun. The computer accurately detected this idea (idea 8: sun warms the car) and started the conversation with, "Interesting idea! How does the sun make the car warmer?". Each student responded by retrieving a new idea they held, likely by reflecting on their time spent in a hot car and distinguishing relevant evidence to elaborate their view (e.g. (student 1) sun is hot; (2) car windows up; (3) metal material of the car). The computer then asked the generic prompt (what's an idea you felt uncertain about?). At this point student 1 distinguished their uncertainty about how the mechanism worked (how does the inside of the car get hot). Student 2 recognized an additional relevant new idea (air is trapped inside the car) to elaborate the idea they raised in the previous round of dialogue. Student 3 explored the feasibility of their initial idea (will metal overheat and explode?).After these two rounds of dialogue, each of the students revised their initial explanation. Student 1 incorporated new details to elaborate their initial explanation [*When you leave your car parked in the sun it is usually warm when you get in and when you park in the shade it is cool inside.→The sun is very hot and when it shines on the car the car eventually heats up for many hours that it is parked on the road*]. Student 2 linked the new ideas they raised in the dialogue and integrated them with their initial ideas to create a more complete and accurate mechanism [*when its in the sun it gets warm inside the car→The sun hits the car and makes it warmer inside because the windows are [not] down. The heat is trapped inside the car*.] Student 3 abandoned their initial ideas in favor of new ideas they devised to consider and generated an alternative explanation [*sun warms the earth by its hotness Its kinda like a warm blanket wrapped around earth but its actually the sun hotness→The car will feel cold on the inside even though it was in the sun for a long time, it'll be the same temperature as outside*]. The analysis illustrates how the dialogue supported students to recognize the multiple ideas they held relevant to solving the problem, and to reflect on how these ideas link together to refine their science explanation.

Conclusions & Next Steps

This study suggests that asking adaptive knowledge integration oriented questions in a computer generated dialogue can encourage students to make steps toward integrated revision of their ideas. The dialogue supported students to generate many ideas, developed from prior experiences as consideration for solving the science dilemma. Once students added new ideas they either distinguished among these, or used the new idea to buttress or modify their initial ideas. Guiding students to reflect on the different ideas they have, initiates a process in which students raise scientific questions and consider new variables. This may position students to further explore the variables or seek answers in subsequent instruction. This analysis aligns with previous findings on retrieval practice, where prompts to retrieve more ideas from a passage fostered learning (Karpicke & Roediger, 2008). Future work will embed dialogs in instructional units to more closely test impacts of retrieval practice on learning, and to explore guidance strategies to support use of evidence for distinguishing among ideas. We will also explore how adaptive dialogues may support teachers to tailor their instruction to student's specific ideas, and to affirm the paths that lead the student to their ideas.

Implementation of Dialogic Teaching: Exploring Teachers' Perceptions, Attitudes, and Practical Challenges

Yang Tao and Gaowei Chen
ttaotaoy@connect.hku.hk, gwchen@hku.hk
The University of Hong Kong

Abstract: Research interest in discursive strategies for orchestrating vibrant classroom interactions has burgeoned. Few studies, however, have given details about teachers' perceptions and attitudes. This paper reports on an on-going study that explored elementary and secondary school teachers' perceptions and attitudes towards dialogic teaching and the challenges they encountered in the implementation. We recruited three elementary and middle school teachers from different subjects in China to participate in the video-cued interview. The results showed that some teachers with professional vision on dialogic teaching, though attitudinally in favor of this pedagogical approach, tended to be reluctant to adopt it for fear of losing face or being challenged by their students. In parallel, students' learning ability, learning efficiency, and willingness to participate in class may obstruct teachers' efforts to unfold classroom instruction in a dialogical way. These findings help enrich our understanding of the effective implementation of dialogic teaching.

Introduction

According to sociocultural perspectives (Vygotsky, 1978) and situated learning theories (Brown et al., 1989), classroom discourse is viewed as a vital role in influencing student learning (e.g., Resnick et al., 2015). Special emphasis has been put on the fruitful classroom dialogue, which is construed as a key feature of effective teaching and learning. Against this backdrop, a range of theories on dialogic teaching have been proposed to help teachers orchestrate productive classroom discourse (e.g., Alexander, 2017; Mercer & Littleton, 2007; Michaels et al., 2008; Pehmer et al., 2015). Dialogic teaching is a newly advocated pedagogical approach that engages students in the joint construction of knowledge by encouraging them to share their ideas with others and to interact with the thoughts of peers.

Although scholars have long endorsed classroom dialogue (Howe & Abedin, 2013), dialogic and vibrant teacher-student interactions are rare in authentic classrooms (Chen & Chan, 2022; Nystrand et al., 2003). In fact, teachers face many obstacles when they attempt to adopt dialogic pedagogical approaches as a legitimate means and successfully implement them in their classrooms (Chen et al., 2020; Resnick et al., 2018). In one sense, dialogic teaching skills are developed gradually (Clarke et al., 2016; Rapanta et al., 2021; Sedova, 2017); however, teachers are not given adequate time to acquire the necessary knowledge and skills to organize classroom discourse (Resnick et al., 2018). According to some researchers, lacking theoretical strategies and not being aware of the precious functions of language may be hindering teachers (Ruthven et al., 2017). On the other hand, even if teachers realize and value the virtue of dialogic teaching, their attitudes towards adopting this pedagogy are crucial, in particular when faced with intensive teaching tasks and fixed learning objectives.

Despite this, there is little research that delves into the teachers' perspectives on dialogic teaching. Therefore, this study aimed to explore teachers' perceptions and attitudes toward dialogic teaching through video-cued interviews, which could enhance our understanding of implicit teaching practices.

Video as a vehicle for teacher reflections

With the emergence of learning sciences, video research has become increasingly popular (e.g., Chen, 2020; Gröschner et al., 2018). As exemplified by Sherin's studies on the video club (Sherin, 2007; van Es & Sherin, 2010), video serves as a tool not only for capturing classroom interactions, but also for teacher reflection. Teachers can watch and discuss the videotaped lessons together and thus reflect on their own teaching practices. Teachers' perceptions of teaching phenomena can be discerned through their interpretation of the teaching behaviors demonstrated in video recordings. As Goodwin (1994) pointed out, individuals with a professional vision perceive and interpret events in a particular way.

Further, video-cued interviews have been developed and introduced into education research to further enhance our understanding of the implicit cultural practices of teaching and learning (Xiao, 2018). While watching video clips of other teachers' lessons, the videos can be used as interviewing cues to stimulate the teachers' relevant thoughts and reflections as insiders. Therefore, it is a promising avenue for researchers to tap into teachers' perceptions and attitudes, thereby contributing to their professional development.

 © ISLS

Accordingly, this study used video as a vehicle to investigate the following research questions: (1) How do teachers perceive dialogic teaching and what are their attitudes towards it? (2) What are the challenges involved in implementing dialogic teaching?

Method

Participants

In this on-going study, we are recruiting participating teachers from various subjects and grades in different regions of China, including Henan province, Jiangsu province, and Shanghai municipality. As a pilot, three female teachers were invited to participate in the interview, including Ms. Min (elementary school mathematics, from Jiangsu), Ms. Li (middle school Chinese, from Henan), and Ms. Gao (middle school science, from Shanghai). All three teachers have three years of teaching experience, and they each hold a master's degree in education.

Data collection and analysis

The video-cued focus group interview method was used to collect the data in this study. In this research method, we could gain insight into respondents' perceptions and attitudes towards an event or issue, as well as their experiences and the meaning of their behaviors. The video-cued interview allowed for impromptu discussions among the interviewees, which provided a collective exploration and interpretation of the issues. Such an interview would even break the shackles of the researchers' predetermined questions.

Three steps were involved in this interview: First, the researcher stated the purpose of the interview and described the basic characteristics of dialogic teaching to clarify interviewees' understanding. Next, the three teachers were shown a video clip of approximately ten minutes due to time constraints. The video clip we chose was from a fifth-grade math classroom in a public elementary school in Shanghai, China. In the video, the teacher was demonstrating how to calculate the volume of a rectangular object. After discussions among researchers and experts, this videotaped lesson was identified as a dialogic teaching style. Finally, we invited the teachers to evaluate the teaching style in the videotaped clip and to share their perspectives related to their own experiences.

Approximately one hour of audio from the interview was transcribed verbatim. Teachers' attitudes and perceptions of dialogic teaching, as well as the implementation challenges they faced, were noted in the transcription. These initially marked themes were then grouped into broader thematic categories. Finally, in order to answer research questions, we further scrutinized the interview transcript connected to these themes.

Findings

Teachers' perceptions and attitudes

Three teachers commented unanimously that the teaching practices presented in this video clip tended to be student-centered and dialogic. They think this teacher has attempted to delegate as much responsibility for discourse as possible to the students. Ms. Min commented, "*The questioning culture is good in this class. After answering the question, the student would ask other pupils if they agreed with his or her answer. And the next evaluator would state his/her position before giving reasons*." In fact, the video showed that misconceptions were corrected during peer interactions. Furthermore, when a child's statement was incomplete, "*appropriate reminders and corrections by teachers could help this child develop a deeper understanding.*" The teacher's comparison of the two students' ideas "*actually gave many other children a hint*" to awaken their attention. Ms. Li echoed Ms. Min and pointed out that this type of thinking exercise and expression could help students transfer their skills to other areas. Taken together, these comments by the interviewed teachers implicitly reflected their perceptions and claims about dialogic teaching, such as "say more", "agree/disagree", "explain others", and "revoice". These results demonstrated that teachers have a certain level of professional vision.

Though all three teachers favored dialogic teaching, they also acknowledged the difficulties of its implementation. Interestingly, the reasons for agreement and the concerns about the difficulties of implementation were both related to high-stakes testing (such as entrance exams). The interview transcript revealed that exams serve as a baton that requires teachers to deliver content with quality and quantity, but also examines students' higher-order competencies that need to be nurtured in dialogic, interactive instruction.

Challenges teachers face in implementing dialogic teaching

In addition to several objective factors (e.g., intense teaching tasks and busy schedules), the interview transcript revealed that teachers were hesitant to adopt dialogic teaching due to several factors such as *students' learning ability*, *learning efficiency* and their *willingness to participate in classroom discussions*. Ms. Min noted that,

especially in the early grades, the sequential act of listening carefully to others' utterances, comprehending their meaning, and then evaluating them places high demands on students' attention and learning ability. She said, "*For students who are able to concentrate, the interactions make sense*." Ms. Li continued, "*Otherwise, you will always find the same group of students raising their hands in a large class*."

Even though all three teachers acknowledged the importance of previewing before classes, *the unequal knowledge reserves* between teachers and students were identified as a potential constraint. As illustrated in the dialogue below, *the fear of losing face* was a concern when the power of dialogue was given to active students who asked questions beyond the teacher's capability. Students who were highly engaged in learning actives and who had a wealth of prior knowledge sometimes came up with unusual and quirky ideas that are difficult for teachers to deal with.

Ms. Min	Giving students the right to open discussions should be based on their pre-reading.
Ms. Li	I agree with Ms. Min. If I am required to complete all the teaching contents in a demonstration lesson, students' in-depth pre-reading ensures an effective lesson. Also, classroom interactions also require a high level of knowledge on the part of the teacher. For instance, Chinese lessons may involve other subjects, such as history, culture, and science. If I do not reserve this knowledge in advance, I may not be able to unfold the class better when the students refer to it.
Ms. Gao	Interactions may be less effective if (the students) don't have a knowledge base. But I am faced with a situation where many children have already studied in advance and they know the answers to my questions. In this case, the interactions are meaningless and the discussions are dull.
Ms. Li	What I just said is that the students' knowledge is sufficient. When it comes to extended knowledge beyond the current subject matter, the teacher may not be as knowledgeable as the students. Teachers may not be able to pick up the conversation.
Ms. Gao	New teachers like us are afraid to engage in open-ended conversations. Children have active minds, so it's humiliating when they challenge me and I can't answer.

Conclusion and implications

This study explores teachers' perceptions of, and attitudes towards, dialogic teaching, and to identify the barriers that hinder implementation of this pedagogy. Despite recognizing the virtue of dialogic teaching, the findings indicate that teachers have difficulties executing it effectively due to personal reasons and other considerations related to students.

This work provides a glimmer of evidence regarding the reasons for teachers' reluctance to adopt dialogic teaching. The success of innovative pedagogies in the classroom hinges on the teachers. Thus, teacher professional development entails more than just equipping teachers with teaching strategies; it requires that teachers be attitudinally, cognitively and emotionally fulfilled. Our on-going research is digging deeper into the influencing factors with a larger sample of teachers.

Understanding and Leveraging Contradictions of Instructional Activities for Fostering Students' Agency

Narasimha Swamy, Chandan Dasgupta
klnswamy@iitb.ac.in, cdasgupta@iitb.ac.in
Indian Institute of Technology Bombay, India

Abstract: Instructional activities are situated in a web of interdependent activity systems such as students' families, educational institutes, research programs, industries and governments. Historically accumulating tensions between these systems are said to impose contradictory demands on students. For example, during learning, students often feel compelled to choose between being a grade maker versus a sense maker. Such deep-rooted problems cannot be addressed by simply finding better ways of implementing existing practices. Hence we revisit key ideas such as instruction, feedback, competence and their interconnections by considering contradictions across activity systems. Then we carve out a space for students' agency within such interconnections by introducing and investigating a construct called 'students' feedback seeking actions' using cultural historical activity theory (CHAT). Finally, its affordances in further uncovering and leveraging contradictions of instructional activities for fostering students' agency are explored using a case study from undergraduate chemistry education.

Introduction

Currently, there are multiple notions of instruction and feedback varying significantly in terms of whether they limit or extend the scope for students' agency (Askew, 2000). Such variation arises from the underlying contradictions in how different learning research programs view knowledge, competence, learning and individuals (Engeström, 2018). Some programs view knowledge and competence that is worth learning as stable, well-defined and out there to be acquired and transferred; while others view it as distributed, evolving, or yet to be discovered, constructed and validated. Similarly, learning is a linear process for some and a non-linear process mediated by multiple cultural factors for others. Then some account for just students' and teachers' cognition while others consider their emotional, motivational and identity aspects. Acknowledging these contradictions has led to a shift in viewing both instruction and feedback as dialogue (Ajjawi & Boud, 2018; Skidmore, 2017). However, their relationship when both are viewed as dialogue is unclear. Also, studies with instruction as dialogue have focused mostly on different kinds of talk (Kim & Wilkinson, 2019). On the contrary, there is increasing recognition that instructional activities, culture and dialogue all shape each other. To address these and other contradictions discussed below, we use CHAT to reconceptualize key notions as follows:

- Instructional activity is a teacher's predetermined plan involving the organization of certain tasks, tools, representations, norms, individuals and ways of cooperation (division of labor) estimated to support students' learning towards particular valuable outcomes.
- Feedback is any information concerning the given instructional activity that addresses students' needs tied to their knowing, doing and being for accomplishing, modifying, or even avoiding the expected outcomes by the teacher. Students can derive feedback either by working with representations and tools or having a dialogue with themselves and multiple others or using a combination of these modes.
- Students' feedback seeking actions are those where decisions such as purpose, timing, mode, amount of feedback seeking, choice of feedback source and how feedback is used are all made by themselves.
- Competence is a set of students' interconnected actions tied to their knowing, doing and being judged as valuable in relation to particular activities and culture within which they are (or will be) enacted.

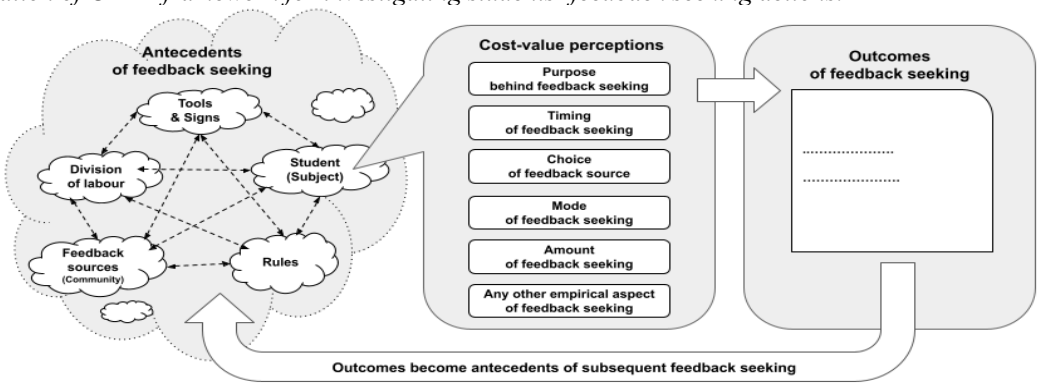
The above definitions also account for contradictions across interdependent activity systems. This idea of instruction acknowledges the complexity of any goal directed activity and does not reduce it to just tasks or talk. Further, instruction as an estimate and predetermined plan accounts for classroom realities such as student diversity, teacher workload and large pupil-teacher ratio. Consequently, we also do not view teachers' role as orchestrating instruction and feedback on a moment-to-moment basis. Then the idea of feedback acknowledges that it can be any information that meets students' diverse cognitive, emotional, motivational and identity needs. Especially, viewing feedback's role as not always accomplishing teacher's expected outcomes aligns with the notion of instruction as an estimate where it may or may not address students' diverse needs. This along with the idea of students' feedback seeking extends the scope for students' agentic actions significantly. That is, students

 © ISLS

can choose to seek feedback from multiple sources and through multiple modes for accomplishing, modifying, or even avoiding the aspects of instruction. This is unlike many prevailing practices where teachers initiate and drive feedback events even when peers exchange feedback. Moreover, the focus on students' feedback seeking aligns with Nicol's (2013) emphasis on getting students ready for life beyond university (like occupational settings) where feedback seldom comes from others proactively. Instead one has to identify potential sources from multicultural communities and elicit and judge feedback from them. Also, feedback thus received can be vague, ambiguous, and even conflicting. Compare this with the formative feedback guidelines in education which require an external agent such as a teacher to continuously monitor student performance, simultaneously account for various student and task characteristics and accordingly adapt the content, mode, timing and frequency of the feedback messages to be provided (Shute, 2008). Lastly, the idea of competence acknowledges that it is not an isolated set of stable skills but one which can also become obsolete with the changes in particular activities and culture within which it is situated. Overall, the above notions might help inform sustainable alternatives to prevailing unilateral, expensive and culturally disconnected classroom practices. This in turn may help address large scale educational challenges before governments. Additionally, CHAT also provides a framework to examine students' feedback seeking and its instantiation is depicted below.

Figure 1

Instantiation of CHAT framework for investigating students' feedback seeking actions.



In the above figure, individual smaller clouds and a larger cloud stand for factors of instructional activity and culture (interdependent activity systems) respectively. A cloud indicates that each factor may embody multiple qualities and at a given moment some qualities can be at the forefront in influencing students' feedback seeking actions while others remain in the background. Above instantiation also reflects CHAT's perspective on viewing the relationship between student agency, instructional activity and culture as reciprocal. Moreover, it makes a key CHAT principle explicit i.e, the object of an instructional activity like students' feedback seeking actions carries within it the foundational contradictions i.e, use-value and exchange value of interactions between student, instructional activity and culture (Engeström, 2018). More specifically, interactions between the student, instructional activity and culture are predicted to influence students' cost-value perceptions underlying their various feedback seeking decisions. Here students' cost-value perceptions can be of biological or cultural origins with cognitive, emotional, motivational and identity dimensions. Consequently, our research question aims at uncovering such interactions "How do the factors comprising instructional activity and culture interact to influence students' cost-value perceptions underlying their various feedback seeking actions?"

Methods

To answer the research question, we gave students a representational problem pertaining to the synthesis of a medicinal drug called warfarin. The choice of the problem aligns with the idea that knowledge worth learning is continuously evolving. While there were other methods of synthesis, the particular technique underlying the chosen problem is recent, precise, cheap, fast and environment-friendly. Solving the problem required students to employ major forms of representational reasoning like analogical reasoning and/or thought experimentation in order to predict expected drug's final structure. Complexity of the problem meant that students would experience numerous challenges nudging them to go beyond just verbal exchange and use multiple modes as part of their feedback seeking. Thus the problem helped us generate rich analyzable data where we could examine how aspects of instructional activity, culture and students' feedback seeking dialogue were all shaping each other. For data collection, we invited a group of three undergraduate chemistry students. The study was conducted in a lab setting outside their classroom. The given problem was an hour-long activity designed such that students could either work individually or choose to collaborate as and when needed. This was to ensure that there was no external

compulsion to seek or provide feedback. Besides, worksheets with task details were minimal in design i.e., we intentionally did not include any prompts for self/peer assessment, hints, or questions for reflection. Data collected included video recording of the students' interactions with each other and the researcher and their task specific responses on worksheets such as sketches, highlights and comments. It also included post-activity interview responses. Researcher's presence during students' problem solving was limited and occasional. Data analysis was done using a microgenetic method. It emphasizes tracing emergence of particular student actions to momentary processes by making high density observations (Chinn & Sherin, 2014). Unit of analysis is an episode of a student's proactive feedback seeking from peers and the researcher where one episode was distinguished from another by considering the change in the purpose for which the feedback was sought. During analysis we found emotions as significant markers of students' cost-value perceptions.

Findings

Analysis of students' feedback seeking actions revealed the complex and multilateral ways in which culture, instructional activity, students' characteristics and their actions shape each other. For e.g. in one episode, the purpose behind student's feedback seeking was determined by the task specific difficulty arising out of one's self-directed dialogue while comparing representations. In addition, the timing and choice of feedback source was influenced by the emergence of feedback availability signs with the peer working nearby, one's own hesitancy in seeking feedback due to perceived embarrassment shaped by the prevailing cultural norms (i.e. shaming ignorance or incompetence) and the norms of given instructional activity (i.e. freedom to work individually or collaboratively) which further heightened such embarrassment. Then the evaluative nature of feedback seeking and that the feedback received was subjected to constant verification reflected the student's perceived credibility of the peer as a feedback source. Also throughout the episode, both the student and peer were observed to constantly regulate shifting between having dialogue with each other versus having dialogue at self level to aid their mutual sense making. Over and above, the amount of feedback seeking was influenced by the extent of specificity, clarification or elaboration that was required to meet one's unique feedback needs, cooperation needed by peer to generate feedback, communicative affordances of available representations/tools and also peer's enthusiasm derived in part due to culture where feedback provision was perceived as an opportunity for self-enhancement. Here various emotions of student and peer triggered by the interactions between factors of culture, instruction and student reflected the cost-value perceptions tied to their cognition, motivation and identity aspects. This in turn steered the overall nature of student's feedback seeking dialogue.

Similarly when multiple episodes were analyzed and compared it was observed that in some episodes the purposes for which feedback was sought was influenced largely by students' cost-value perceptions tied to their motivation while in others it was mostly their identity or cognitive aspects. Also, in some instances the purposes were triggered by the emergence of salient feedback availability signs amongst feedback sources (e.g. an utterance signaling new info) without experiencing any prior need at the moment. Further, the purposes for which students sought feedback were not always aimed at accomplishing the goals of the activity, instead some were specifically directed at modifying or even avoiding the aspects of it. These observations suggested that students were probably making changes to the factors of instructional activity in order to adjust it to their actual zone of proximal development as opposed to the instructor's estimate. This inference was further probed and confirmed using post-activity interview. For instance in student group, even though it had members who successfully completed the given tasks, one student who faced difficulties expressed later in the interview that he would have liked to have more members in the group i.e. more feedback sources possibly due to the nature of emotional, motivational and identity aspects shared with the participating members. In addition, students were also observed to prefer feedback seeking at interpersonal level i.e., from peers in some cases and tools in others because of their perceived identity costs such as embarrassment. Here the underlying cost-value analysis was also observed to occur in an hierarchical manner highlighting the historical nature of feedback seeking. For example in a particular instance, where the student anticipated a possible testing event, the opportunity to exchange feedback at interpersonal level was perceived as valuable. In the subsequent instance, when the testing event was now ruled out, anticipated costs tied to interpersonal exchange, i.e., particular reasons for which asking others would be more embarrassing became a major concern.

Overall, students' sensemaking during the instructional activity was observed to occur as a constant comparison with their previous experiences. Here previous experiences were not just limited to their prior instruction but also included those related to family, friends, industry and state. For instance, a student's feedback seeking aimed at renegotiating norms around usage of mobile devices occurred as a comparison with the way mobiles are used in the context of family and friends. It is this comparative sense-making process that gives rise to the emergence of heightened cost-value perceptions culminating in their feedback seeking actions and determining various aspects of it. Also since the triggers for students' sensemaking are both multiple internal and

external factors, the nature of students' feedback seeking is a complex and multilateral phenomena.

Then in line with the CHAT perspective, we also observed that the multilateral nature of students' feedback seeking plays a crucial role in them harnessing as well as adapting to the distributed competence of participating members. For instance, sensemaking in activities rich with multiple representations requires perceiving, analyzing and synthesizing different representational features with the target phenomena. On one such occasion, where a student's feedback seeking from the peer emerged as a result of challenges experienced at individual level, it was observed that during feedback dialogue both became aware of the differences and also errors in their individual perception of representational features. In subsequent conversational turns they together abstracted, analyzed and synthesized different features of representations iteratively, thus gaining a deeper understanding of the target phenomena. Here in essence, feedback dialogue was driven by the distributed nature of their individual attention, memory and thinking. Moreover, the role of feedback seeker and feedback provider was constantly shifting amongst participants as they progressed in the tasks. This again indicates the distributed nature of knowledge and competence amongst participants. Students were also observed to adapt to each other's representational competence by revising use of different representations to get their message across.

Discussion & Conclusion

Findings confirm CHAT's prediction that the nature of students' agentic feedback seeking would be driven by their cost-value perceptions resulting from interactions of instruction, culture and individual characteristics. Findings also suggest that feedback seeking plays an important role in students harnessing as well adapting to the knowledge and competence distributed across peers. Further students' feedback seeking actions aimed at modifying instructional activity supports CHAT's key assertion that the nature of relationship between individual's agency, immediate activity and culture is essentially reciprocal. Together these findings validate the significance of reconceptualization of key notions such as instructional activity, feedback, students' agentic feedback seeking actions and competence by accounting for contradictions across activity systems. Narrow conceptualization of these interconnected notions naturally limits the scope for students to exercise their agency. Findings also suggest that teachers can further uncover and leverage contradictions of instructional activities by viewing them as open activity systems. That is, viewing instructional activities as open to student modifications will help invite individual student's culture into the classroom. It could in turn help foster students' agency along with their self-learning capabilities, eliminate culturally obsolete skills and trigger teacher reflections. However, student modifications can be a source of both problems as well as innovation. Here collective cost-value analysis as per CHAT can be used to help resolve such issues. That is, teachers should try to uncover both the underlying cost and value perceptions that might have guided students' modifications of instructional activity. Then regarding sustainability, if student groups of different academic years worked in a single classroom on activities of varying complexity and overlapping learning goals, then their various actions might help signal and elicit each other's feedback seeking on much more diverse purposes. This hypothesis is based on finding that feedback seeking also occurs as result of emergence of salient external feedback availability signs.

Abstract: This study examines what helps university STEM instructors learn and adopt inclusive teaching practices, such as Adaptive Equity-Oriented Pedagogy (AEP). AEP has been shown to improve student achievement by over a full-letter grade. This study randomly assigned 129 student-instructors to treatment and control pedagogy courses. While the control course *taught* student-instructors *about* AEP, the treatment course *modeled* AEP explicitly by using weekly student-instructor reflection data to continuously adjust course discussion and activities. Using multilevel-regression modeling, we found the treatment significantly improved student-instructors' AEP competencies over time compared to the control (p<0.001). Compared to the control, more student-instructors in the treatment used multiple data sources to adjust teaching and address equity barriers to advance student learning. Through the novel application of mixed-methods research and validated AEP measures, this study offers insights on what values, motivations, and practices characterize those who do and do not implement AEP.

Introduction: Problem statement and research questions

Research shows that college teaching directly impacts student achievement and retention in STEM, especially for underrepresented students (URM; Sax et al., 2018). To improve STEM teaching, we studied adaptive equity-oriented pedagogy (AEP). Experimental research has found that compared to an active learning control course, instructors applying AEP increased student achievement by over a letter grade for all students (Phuong & Nguyen, 2019; Phuong et al., 2017). This study examines how pedagogy courses teaching AEP principles can support student-instructors' implementation of inclusive pedagogies. The pedagogy courses primarily serve student-instructors who teach large introductory STEM courses. For simplicity, we use the term "instructor" for graduate and undergraduate students who teach and are enrolled in the pedagogy courses. The term "facilitators" refers to the pedagogy course instructors. 129 instructors participated in a treatment or control AEP pedagogy course where they completed a teaching portfolio that included written reflections, evidence of student learning, and feedback on their teaching. The treatment course was adapted weekly based on instructors' written reflections, whereas the control was not. Using mixed-methods, multilevel modeling and AEP competency assessments, we examine whether pedagogy courses impact instructors' learning progression of AEP. We explore 2 research questions:

RQ1: Is there a greater increase in mean AEP competency scores across time in the treatment vs. control pedagogy courses, controlling for gender, URM status, years of teaching experience, years of tutoring experience, and number of students?

RQ2: How do low- and high-growth instructors on AEP competency differ with respect to their data use and responsibility for learning lenses?

AEP Pedagogy Course Design and Conceptual Framing

The AEP pedagogy courses teach instructors about the key AEP principles. AEP is a framework for adapting teaching to address equity barriers to learning based on student data (e.g., formative assessment, observations, surveys) (Phuong et al., 2017). AEP practice is characterized by instructors' use of 6 competency elements: (1) Clarify learning outcomes, equitable course policies, and prerequisites; (2) Align formative assessments and activities with outcomes; (3) Identify students' competencies, interests, & needs; (4) Understand equity barriers and contextual challenges to meeting outcomes; (5) Adapt teaching practices based on these needs and barriers; and (6) Iterate: Reflect upon pedagogy to support continuous learning, adaptation, and growth.

AEP builds on culturally responsive pedagogy (CRP) by offering a framework to adapt CRP practices: engaging learners' experiences, critical consciousness, and cultural knowledge to make curricula more relevant and effective (Hammond, 2014). We draw on AEP as a conceptual framework to understand how pedagogy course facilitators adapt their practices to address instructors' learning needs and perspectives in the treatment.

Unique element of treatment: Facilitators modeled and applied the 6 AEP elements explicitly as a tool for instructor learning by using weekly instructor reflection data to continuously adjust pedagogy course

 © ISLS

discussion and activities. *We hypothesize that this process would promote greater reflection in the treatment, which we expect to increase instructor learning over time in the treatment relative to the control as measured by AEPC assessments.* Applying AEP, the facilitators adjusted the treatment based on instructors' reflections of their cultural perspectives and backgrounds, which include their lived experiences, racial experiences, discourse, and STEM department culture (e.g., what is valued methodologically). Both conditions prompted instructors to reflect on how they may have experienced stereotype threat and microaggressions based on their identities.

Lenses on instructional change. We are inspired by the notion of professional vision (Sherin, 2014), which refers to developing ways of seeing phenomena that reflect growing levels of expertise. Accordingly, we identified lenses that seemed to serve as important levers for instructional change. We conjecture that the treatment's effectiveness may be related to the focus on *data* and *responsibility for learning lenses* that instructors may reveal in written reflections. These lenses allow us to understand instructors' values, beliefs, and motivations for learning inclusive practices. The *data* lens is defined as the kinds of knowledge and data that instructors value to make pedagogical decisions. The *responsibility for learning* lens refers to how the instructor views their role and the student's role in learning--e.g., whose responsibility is it if a student doesn't learn a concept? This lens accounts for the systems, structures, and/or beliefs that foreground individualistic notions of learning that have contributed to STEM students leaving the major because they felt under-supported and isolated (Seymour & Hewitt, 1997). Identifying these lenses is beneficial for advancing instructors' learning.

Methodology: Experimental Design and Mixed Methods

STEM instructors at a R-1 public university participated in semester-long AEP pedagogy courses for first-time instructors where they completed a teaching portfolio. The pedagogy courses primarily served instructors who taught computer science, data science, math, and statistics. Instructors participated in either a treatment or control pedagogy course. The treatment and control courses were co-led by the same facilitators who employed exemplary active learning activities and provided an AEP curriculum. Table 1 compares the 2 conditions.

Table 1. *Comparison of Control and Treatment Pedagogy Courses*

Pedagogy course activity	Control	Treatment
Same AEP curriculum content, reflection prompts, assignments/assessments Same planning activities: examined course syllabi, learning outcomes, student data	✓	✓
Provides dialogue and activities based on instructors' expressed interest (e.g., conversation about pedagogical challenges/ needs) for 30-40 mins each week	✓	✓
Instructors write weekly reflections on teaching	✓	✓
Instructors discuss reflections with each other	✓	✓
Using weekly instructor reflection data, pedagogy course facilitators adapt activities to instructors' learning needs, thereby modeling and applying 6 AEP elements explicitly		✓

Instructors were randomly assigned to conditions. To ensure the treatment did not impact the control, treatment data were reviewed weekly by facilitators after they taught the control. The treatment (n=65) and control (n=64) groups have similar gender and URM characteristics. The control has about 31% women and 11% URM. The treatment has approximately 28% women and 9% URM.

In both conditions, instructors completed baseline, midterm, and final AEPC assessments. Each AEPC assessment elicits evidence about teaching philosophies, written reflections on teaching and assessment practices, evidence of student learning, student gain score visualizations, media, and peer/student feedback on their teaching. The AEPC assessment contained reflection questions that asked instructors to provide evidence of demonstrating AEP competencies. The scale was 0-22 with 3 items being scored 7 points each and 1 item being 1 point. A detailed rubric (See table 3 for a summary) was applied independently by two researchers to blindly score assessments. Higher positions on the rubric imply that criteria of lower positions have been met. Based on partial credit Rasch modeling (Masters, 2010), the AEPC measure has high reliability (0.94), has strong validity based on Wilson's (2005) strands of validity framework, shows no gender or URM bias, and correlates significantly with researchers' review of teaching and pedagogical materials (Phuong et al., 2022).

Table 3. *AEPC Scoring Rubric 0-7*

Item Score	Learning Progression Level	Description
0	0	Provides an irrelevant answer, does not apply any elements
1	Low	Applies AEP element 1 and/or 2 (described above)

 © ISLS

		Element 1: Clarifies learning outcomes Element 2: Aligns formative assessment with learning outcomes
2	Moderate	Applies elements 1-3: Diagnoses student learning competency ***Or*** Diagnoses interest
3	Moderate	Applies elements 1-4: Diagnoses learning competency and interest ***Or*** Diagnoses learning competency and learning barriers
4	High	Applies elements 1-5: Adapts based on full diagnosis, not only based on diagnosis of learning competency
5	Very High	Applies all 6 AEP elements
6	Very High	Applies all 6 AEP elements citing instructor and student evidence
7	Very High	Applies all 6 AEP elements with supporting instructor/ student evidence and explains how their practice impacts the student ***Or*** Applies all 6 AEP elements with instructor/ student evidence and explains rationale for how practice impacts student

Analysis. For **research question 1**, we use multilevel regression modeling to examine if there is a greater increase in instructors' mean AEPC scores across time in the treatment than in the control, controlling for gender, URM status, teaching experience, tutoring experience, and number of students. We use multilevel modeling for longitudinal data with random intercepts to account for dependency in repeated AEPC measures.

We examined growth in AEPC by estimating the increase from 1) pre-intervention AEPC scores to mid-semester AEPC scores, and 2) pre-intervention to post-semester AEPC scores, and how much the growth differs between the treatment and control. Models were estimated by maximum likelihood with robust standard errors to protect against misspecifications of the model's random part and residual covariance structure.

For **research question 2**, we randomly sampled 10 high-growth and 10 low-growth instructors from the top 25% and the bottom 25% of AEPC growth from pre- to post-semester. We coded for the *data lens* and *responsibility for learning lens* that these instructors use, and were blind to the instructor's name, condition, and whether they were in the low- or high-growth group. We analyzed the presence, frequency, and contingency of codes to determine similarities and differences in what characterize instructors who implement AEP.

Findings

Table 4 presents statistics on AEPC measures between both conditions. The treatment and control conditions were comparable because they had no statistically significant differences on baseline AEPC (p>0.05). Table 4 indicates that although both conditions experienced AEPC test score increases at each time point, the treatment had greater AEPC increases, on average. The treatment outperformed the control on the post-AEPC by about 8.38 points.

Table 4. Average AEPC scores and standard deviations (SD) across time by control and treatment conditions

AEPC Assessment (0-22 scale)	**Control (n=64) Mean (SD)**	**Treatment (n=65) Mean (SD)**	***p*-value**
Pre (Time 0)	0.16 (.37)	0.12 (.33)	0.590
Mid (Time 1)	7.99 (3.20)	15.65 (1.87)	<0.001
Post (Time 2)	12.27 (3.81)	20.65 (1.61)	<0.001

Research question 1. Table 5 presents model estimates at the 5% significance level. We examine the difference in growth between the two conditions from pre to mid, and pre to post AEPC. On a scale of 0-22, the increase in mean AEPC test scores from pre- to mid-semester is estimated to be 7.69 points (95% CI [6.80, 8.57]) higher in the treatment than the control, controlling for the instructors' gender, URM status, number of students, years of teaching experience, and tutoring experience (z=17.03, p<0.001). Moreover, the increase in mean AEPC test scores from pre- to post-semester is estimated to be 8.41 points (95% CI [7.42, 9.40]) higher in the treatment than the control, controlling for variables mentioned above in the model (z=16.65, p<0.001). Overall, the treatment by time interaction is statistically significant in the model (X^2(2)=327.80, p<0.001).

Table 5. *Regression table for multilevel model with robust standard errors*

	Parameter	**Estimate**	**Standard Error**
Fixed Part	Time Point 1	7.84***	0.39

	Residual Standard Deviation (Time-Point Level)	1.76	

*p<0.05, **p<0.01, ***p<0.001

Research question 2. For the bottom 25% of instructors (n=32), the average growth on the 22-point AEPC scale was about 9.22 points (*SD=1.93*) and all these instructors were from the control group. The top 25% of instructors (n=32) had a mean AEPC growth of about 21.84 points (*SD=0.37*). For the top 25% (n=32), we found that at least 31 instructors were from the treatment. 10 instructors were randomly sampled and qualitatively analyzed from the bottom and top 25%. Table 6 provides frequencies of qualitative subcodes for *responsibility for learning* and *data lenses* expressed by instructors in their reflections.

Table 6. *Frequency of selected responsibility for learning (RL) and data lens subcodes in bottom and top 25%*

Sub codes in instructors' written reflections	Bottom 25% Frequency (%)	Top 25% Frequency (%)
1. Indicates student is responsible for proactively addressing learning challenges (*RL* subcode)	10 (100%)	10 (100%)
2. Indicates instructor is responsible for proactively addressing learning challenges (*RL* subcode)	0 (0%)	10 (100%)
3. Values and cites multiple forms of data to adapt teaching (*Data* subcode)	0 (0%)	10 (100%)
4. Gives an example and rationale for how adapting teaching will improve student learning based on data (*Data* subcode)	0 (0%)	10 (100%)

Discussion and Conclusion: Why the Treatment Worked

The treatment provided a culturally responsive and adaptive learning experience that strengthened the scaffolding and accelerated the learning progression relative to the control. Prior to intervention, the facilitators identified that many instructors in the treatment defined equity as equality and placed the responsibility for learning only on the student. Thus, the treatment had conversations on interrogating long-standing beliefs and inequitable ideologies that the "good students are the ones who teach themselves". This approach expanded instructors' critical consciousness since it asked them to rethink common cultural norms, values, meritocracy, and larger systems (e.g., structural racism) that reproduce inequities, where students from underprivileged backgrounds may not have equitable access to resources and opportunities that enable them to teach themselves. Proactively sharing the learning responsibility shifts the pedagogical focus from an individualistic "pull yourself up by the bootstraps" approach to one that is more social and culturally responsive. Furthermore, this study contributes insights on how to increase instructors' adoption of inclusive practices, thereby addressing a long-standing barrier to STEM pedagogical reform. This research offers strategies to support instructors on how to reflect on and use multiple forms of data effectively-- rather than their assumptions-- to address equity barriers and increase student success.

Design-Based Research to Improve the Lesson Study Project for Co-evolution of Research, Development and Practices

Shinya Iikubo, Nahomi Institute for the Learning Sciences, iikubo@ni-coref.or.jp
Hajime Shirouzu, National Institute for Educational Policy Research, shirouzu@nier.go.jp
Moegi Saito, Kyoritsu Women's University, mosaito@kyoritsu-wu.ac.jp

Abstract: In order to demonstrate that applying design-based research (DBR) methodology to improve a lesson study project provides an arena for co-evolution of implementation research, system development and everyday practices, this paper analyzed a 12-year learning sciences project in Japan. The project consisted of DBR on three levels: 1) a continuous cycle of DBR on each of the practices in the lesson study cycle, 2) DBR on the development of technologies to support the lesson studies and 3) long-term implementation research on the whole socio-technical system to bridge theory and practice. The analysis revealed that the scheme of the project shifted to support *fast but constructive lesson study* for practitioners to create design principles based on an understanding of how students learn, requiring the co-evolution above.

Introduction

The gap between theory and practice in education remains a central issue in the learning sciences. This paper demonstrates that the issue is best handled by co-evolution of implementation research, system development and everyday practices through our design-based research (DBR) of the *lesson study* approach (Lewis et al., 2006).

The shift from "theory into practice" to "theory through practice" approach (Schon, 1983) requires researchers to support teachers to create their own theory or *principled practical knowledge* (PPK: Bereiter, 2014). To increase the *practicality* of PPK, Janssen et al. (2015) proposed *fast and frugal heuristics* (cost-effective procedures for design and enactment of educational innovations), which indicates the importance of continuous cycle of creating knowledge from lesson to lesson. Lesson study is one of promising candidates of the theory-through-practice approaches, but has swung back and forth between two poles: "teacher-centric" pole (*how and what teachers should teach*) and "learner-centric" pole (*how each student learned*). There is room for improvement in the approaches of lesson study towards integrating the strengths of the both, for example, combining subject matter knowledge with insights into student learning. In addition to the issue of this *how-to-do* lesson study, a *who-is-to-be-involved* issue remains. The aforementioned integration requires contributions from the boards of education (BOE) to create a partnership among teachers and researchers in order to afford teachers with opportunities of learning subject matters across schools and reflecting on their own students within schools.

Lesson study also develops with the help of technology. For the *how-to-do* issue, technology supports a lesson study cycle of *plan-do-reflect* in a timely manner for teachers; for the *who-is-to-be-involved* issue, it helps teachers turn the cycle collaboratively by allowing them to keep a record of lesson study beyond space-time constraints. Vrikki et al. (2019) developed a system for lesson study which made time-consuming dialogue analysis feasible. More importantly, their work came from the accumulated research where they found an integration of various elements essential: support systems, models of lesson study, a teachers' learning community and teacher-researcher partnerships. Their trajectory of research was an evolutionary one in the face of a *scaling-up pressure*, through shifting from working under favorable conditions to less favorable ones.

These findings imply that we should consider long-term implementation research on the whole socio-technical system to bridge theory and practice. For the approaches of lesson study and its supporting system, we need to design, test and improve them in order for teachers to be able to learn the sciences of how students learn. In order to clarify how such *DBR of lesson study* takes place and what is needed for that especially in the face of the upscaling pressure, we conducted a collaborative lesson study project utilizing an instructional framework, the "Knowledge Constructive Jigsaw" method (hereafter KCJ; Miyake, 2013), which was undertaken over a 12-year period by the Consortium for Renovating Education of the Future (hereafter CoREF) of the University of Tokyo and its regional board of education partners from the year 2010. The project builds on the theory of *constructive interaction* (Miyake, 1986) to design 1) a continuous cycle of DBR on each of the practices in the lesson study cycle, 2) DBR on the development of tools and technologies to support the lesson studies, and 3) long-term implementation research on the whole socio-technical system of the lesson study project.

Hereafter, we explain the initial research scheme of the project from the three aspects: research, practice and technology in the Method, and analyze changes in scale, practical and technological aspects through CoREF's eleven annual reports (CoREF, 2011-2021), in which we define the appearance of new ways, formats and digital tools for lesson study as *innovations* in the Results, followed by the analysis of research change in the Discussion.

 © ISLS

The Initial Research Scheme as the Method

Research aspect: Theory of constructive interaction

The project builds on the theory of constructive interaction which came from detailed dialogue analyses of collaborative problem solving in cognitive science (Miyake, 1986). A series of research demonstrates that two persons, when engaged in solving a shared problem, exchange the roles of a task-doer who proposes solutions and a monitor who reflects upon such proposals. Such role exchange potentially deepens each participating individual's understanding of the problem, and eventually leads her/him to arrive at their own solution. Miyake and her colleagues brought such a mechanism into the classroom, finding that students were able to modify their experience-based, folk concepts towards more scientific ones through dialogues (Miyake, 2013). The project also uses that theory as the implementation theory, that is, the core of educational reforms at every level from the classroom level to the policymaking level, in order to "craft coherence" of learner-centered, collaborative knowledge construction among all members including the students and teachers.

Practical aspect: Knowledge Constructive Jigsaw (KCJ) and lesson study

To bring constructive interaction into school learning, the project developed an instructional framework, the KCJ (CoREF, 2011), which consists of five learning activities for students: 1) pre-writing (individual), 2) expert activity (group), 3) jigsaw activity (group), 4) cross-talk activity (class), and 5) post-writing (individual).

The KCJ motivates teachers to engage in lesson study, as they are required to design the "problem (jigsaw task)" and "learning materials (for the expert activity)" by themselves and to be proactive in discussing the content prior to the lesson. It also gives teachers a tool for reflection on learning. Since it lets students write down answers to the same question twice, the improvement between the two answers gives hints to infer what each individual learns. Students' dialogues during the expert, jigsaw and cross talk activities inform teachers what kind of interaction deepens understanding of each. Such a shared framework makes planning, observation and reflection easier before, during and after the lesson, allowing the teachers to focus on the content and learning processes.

Technological aspects

The project uses a mailing list for online discussion on the planning and reporting of KCJ lessons in each subject group across the schools and the BOEs. Recording of class and students' dialogues was recommended, but the project partners were given discretion as to what device to use for the recording (video, IC-recorder, notes etc.).

Context of the study

CoREF started a "new learning project" from fiscal year 2010 with nine municipal BOEs from six prefectures (see Table 1). Each BOE registered one or more core teachers who volunteered to propel the research. The teachers also enrolled themselves in one of the subject discussion groups on the mailing list chosen from Japanese language, social science, mathematics, science, and English. Thirteen core teachers from elementary and middle schools participated in the first on-the-job training workshop run by CoREF to experience the KCJ lesson as students and understand the background theory. The teachers designed lesson plans in the subject discussion groups via face-to-face workshops and online means. They tested the lessons in their schools and opened select practices for the purpose of lesson study. Yet, each BOE was given discretion as to how they conducted the lesson study, which was often done in a *teacher-centric way*. At the end of the fiscal year, the teachers shared their experiences in an open research meeting to extract generalizable knowledge about student learning and lesson designs. CoREF summarized the entire activities in its annual report, including a DVD of the teaching materials of the core teachers complete with teaching plans, learning materials such as worksheets, and reflection sheets to review the lessons. The research team started with three university faculty members at its core, and has still not increased.

Results

Quantitative aspects of upscaling

Table 1 shows how the project was scaled up in quantity with its key events considered to be innovations, to be analyzed from the two aspects. The number of "BOEs" doubled from 2010 to 2011, but dropped in 2012, due to a reduction in financial support from CoREF to the BOEs. After 2013, the number gradually grew again, where the BOEs shifted to work with CoREF on a more equal basis. The number of "teachers" grew more than that of the BOEs; each BOE had more participating teachers than before, indicating that upscaling had been achieved but also the existence of an issue of the peripheral participation of diverse teachers. Similarly, the number of "emails" posted to the mailing list also grew from 2012. "Open classes" indicate the number of classes which the core

Table 1
Number of participating boards of education, teachers, emails, open classes, materials, and key events by year

Year	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021
BOEs	9	19	16	17	19	21	25	26	26	26	28	29
Teachers	13	38	33	79	148	298	452	633	657	849	978	1141
Emails	n/a	589	178	213	343	485	610	618	780	686	970	828
Open classes	76		n/a	32	129	105	303	351	624	565	470	521
Materials	17	53	46	55	92	96	117	115	147	127	114	116
(Adapted)	(2)	(6)	(6)	(5)	(17)	(5)	(24)	(12)	(22)	(16)	(19)	(29)
Key events (Practice)	Teaching plan and reflection sheet (2010)		Revised reflection sheet (2012); assessment of pre- and post-lesson comprehension and dialogue (2016)					Simulation sheet (2017); hypothesis-testing lesson study (2017)			-	
Key events (Technology)	-		Conversation Analyzer (2014)					Learning Viewer (2018); Learning Note (2018, 2020)			Learning Recorder (2020)	

teachers in that year had opened up to everybody. Teaching "materials" represent the materials that the teachers selected from their classes. Both numbers kept on fluctuating, but after 2016, the number of open classes was more than 300 and that of the materials was more than 100. In all, 1,095 teaching materials were accumulated by 2021, covering all subjects across all grades from 1st to 9th, providing the next-generation participants with reference cases to kick-start their trials. The numbers in parentheses ("adapted") represent the materials that were modified from the original and adapted for newer lessons. They totaled 163, accounting for 14.9 percent of all the materials. In sum, the project was scaled up enough for the research team to challenge a wider range of conditions. Such upscaling also generated a denser network of teachers within and across the BOEs and knowledge sources such as teaching materials and emails of discussions, yielding resources to overcome the challenge.

Practical aspects

"Key events" in Table 1, with the years of their first appearance in parentheses, were grouped into four periods in order to find commonalities among the innovations. The key events (practice) indicate that CoREF's lesson study shifted first to putting more weight on evidence of actual student learning (revised reflection sheet, analysis of pre- and post-lesson comprehension), followed by analyses of the learning processes including dialogues (multilateral dialogue analysis), and finally, the pre-lesson study to turn the cycle of lesson study as the hypothesis-formation and testing cycle (simulation sheet, hypothesis-testing lesson study).

CoREF revised the reflection sheet in 2012 to explicitly ask the teacher to pick any three students, copy their *pre- and post-lesson answers*, compare them with the learning outcomes he or she had expected, and find points of improvement in the lesson. This additional format was necessary to take advantage of the assessment functions built in the KCJ procedure, as CoREF (2020) reported that over 60% of the materials of 2010 and 2011 omitted pre- and post-lesson questions in the lesson, but less than 10% of them did so from 2012 onwards. In addition to the "assessment of pre- and post-lesson comprehension" using such data, CoREF introduced the "multilateral dialogue analysis" in 2016, by which the teachers analyzed students' dialogues collaboratively from various viewpoints such as cognitive, social, motivational and instructional.

Faced with a scaling-up issue, CoREF devised the "simulation sheet", by which the teachers simulate *how students learn* and make their own hypotheses about the students' learning processes, and a "hypothesis-testing lesson study (HTLS)" that combines hypothesis formation (*how students will learn*) and testing (*how they have learned*). Specifically, HTLS lets teachers 1) engage in the simulation activity before the lesson, 2) continue to observe the same student or group together with multiple teachers during the lesson, 3) share and discuss observations after the lesson on the learning processes of target students compared with the hypothesis of the main teacher who conducted the lesson, 4) make recommendations on the lesson design, 5) listen to the self-reflection of the main teacher and 6) write down their own findings from the lesson study. A typical lesson study often skips steps 1), 3) and 6), lets participants observe freely in step 2), and places step 5) before 3), resulting in negative comments from veteran teachers to the main, often young teacher and aggressive exchanges of lesson techniques and knowledge of the subject matter, lacking any evidence of student learning.

Technological aspects

Along with the changes in the practices, the technologies shifted towards a handier and quicker way of utilizing data to turn the cycle of lesson study as well as providing greater support for the step of designing the lesson. The former shift is well represented by the development of "Conversation Analyzer (CA)", "Learning Viewer (LV)"

and "Learning Recorder (LR)" systems. LV provides the function of auto-transcribing the students' dialogues in all of the groups during the class, and CA does that of providing transcripts, which were electronically searchable using keywords. Two systems were integrated so that the teachers analyzed the transcribed dialogues multilaterally while listening to the actual student voices. Yet, it consumed too much time, and thus CoREF developed the LR, which has a 360-degree video camera to shoot students in a circle when set in the center of the group, and sends the voice data to the LV or broadcasts it live. About half an hour after the lesson, the teachers were able to use the transcription of the dialogue of at least one jigsaw group synchronized with video data.

The latter shift is well represented by the development of a "Learning Note (LN)" system, a website specifically for the project members, which collects and categorizes the emails posted on the discussion list by lesson topic, displays posts with attached files in chronological order, enables searches by keywords and recommends related topics. The system is now equipped with a database page of 1,095 teaching materials, and a topic page that discusses 1,764 lessons, from which the teachers are able to freely download files to replicate and modify a lesson and read the discussions from where the lesson developed.

Discussion

The shifts in the practical and technological aspects coincided with the upscaling and involvement of diverse teachers around 2016 and 2017, implying that, in the face of challenges, CoREF had prepared for a more teacher-centered, self-propelled form of lesson study decentering the role of the researchers. Looking back at the inception phase from 2010 to 2011 and the transition phase from 2012 to 2016, CoREF worked closely with select teachers as if handing over our version of learning sciences along with the dialogue analysis skills. Yet, a full analysis of the whole class takes time, finding no place in a regular cycle of lesson study, and analysis without hypothesis tends to end in vain. Then, we supported the lesson design step, especially on *how each student will learn*, which leads to deeper understanding of actual processes, or *how each student really learned*. These changes imply that how CoREF utilized the theory of constructive interaction changed: we first presented it through student learning processes which were taking place in the KCJ lessons, then let teachers analyze them, and finally utilized the theory to set up the learning environment for teachers by reconstructing the activities of lesson study, where the teachers solved the shared problem of designing better lessons. The researchers stayed behind the scenes, expecting the *fast but constructive interaction* to take place among the teachers. Such DBR of lesson study project accompanied co-evolution of research, development and practices, in the sense that practically, the tools and activities expanded to support a *handier and quicker* lesson study at the sacrifice of *full-fledged and neat* works of analysis, yet securing opportunities to create hypotheses prior to the lesson and to test them with observed processes of student learning; technologically, the accompanying systems came to support such a *handier and quicker* lesson study, yet taking greater advantage of collaboration among teachers and accumulation of data.

Abstract: This paper examines the Young Scholars Program (YSP), a STEM enrichment initiative for middle and high school students in the U.S. that was funded by the National Science Foundation from 1988 to 1996. In particular, the analysis focuses on participation-level and long-term impacts of the YSP on the academic and professional trajectories of students. Guided by social cognitive career theory (SCCT), this paper applies epistemic network analysis (ENA) to examine the data collected from in-depth interviews with 8 YSP participants. It was found that YSP participation was linked to the development of motivation and self-efficacy and subsequent decisions to pursue STEM fields.

Introduction

Maintaining an adequate workforce in the science, technology, engineering and mathematics (STEM) fields has remained an issue of significant national interest in the U.S. To this end, numerous policies and programs have been implemented over the past decades to support the development of STEM-related skills among students and to encourage their pursuit of academic and career paths in STEM-related sectors. Such initiatives are diverse in format, scope and size and can range from scholarships and fellowships to school curricula and enrichment programs. This retrospective study examines the Young Scholars Program (YSP), a STEM enrichment initiative for middle and high school students in the U.S. that was funded by the National Science Foundation from 1988 to 1996. The YSP was intended to: (1) improve participants' knowledge of and exposure to STEM fields; (2) foster interest in STEM education and research; (3) increase awareness of academic for STEM careers; (4) gain familiarity with universities and research institutions; and (5) enhance confidence in making career-related decisions (National Science Foundation, 1993). This paper explores the impacts of the YSP on the academic and professional trajectories of student participants. Guided by social cognitive career theory (SCCT), this paper applies epistemic network analysis (ENA) to examine the data collected from interviews with 8 YSP participants.

Social cognitive career theory (SCCT)

Social cognitive career theory (SCCT) provides a framework for understanding the relationship and interactions among constructs that affect an individual's interests, goals and choice behavior in their own career development (Lent, Brown, & Hackett, 1994). SCCT builds on the assumptions of Bandura's (1986) social cognitive theory, which focused on the connections between variables associated with the person, their behavior and their environment (Lent, Brown, & Hackett, 2000). In addition to the personal-cognitive constructs of self-efficacy and outcome expectation, SCCT therefore incorporates personal attributes, such as predispositions and demographic information, as well as environmental factors and specific learning experiences (Lent et al., 2000). In this manner, SCCT emphasizes the role of self-efficacy and outcome expectation in mediating interest and goals, which lead to choice behavior. Also characterized within the SCCT is the notion of an iterative and dynamic feedback loop, whereby the outcomes of prior career-related action influence subsequent decisions (Lent et al., 1994). SCCT has been used to study career trajectories in STEM fields, both in analyzing academic choices of students (Wang, 2013) and career decisions-making processes. It has also been applied in examining the career paths of groups that are underrepresented in the STEM fields (Fouad & Santana, 2017).

Methods

This paper provides a preliminary examination of the impact of participation in the YSP on the academic and professional trajectories. It analyzes data collected from semi-structured interviews of 8 female YSP participants. Convenience sampling was utilized, as comprehensive lists of participant names and contact information were not retained for many of the YSP projects carried out in the 80s and 90s. As presented in Table 1, the YSP participants interviewed for this paper consist of women from diverse demographic and educational backgrounds, who are engaged in a broad range of professions.

 © ISLS

Table 1
YSP participants interviewed

Demographic Info				YSP Participation		Education	Profession
#	Age	Gender	Race/Ethnicity	Project Site	Year	Highest Degree (Field)	Current Position
1	42	F	Black/African American	Virginia Tech	1995	PhD (Biomedical Sciences, Biochemistry and Cancer Biology)	Research Administrator
2	45	F	White/Caucasian	N. Kentucky University	1990	MA (International Business Studies)	Commercial Banker
3	44	F	Asian	Montana State University	1990	JD (Law)	Judge
4	42	F	White/Caucasian	Buffalo State University	1995	MS (Teaching of Chemistry)	High School Science Teacher
5	46	F	Other	Clemson University	1992	BS (Electrical Engineering) Currently enrolled in MBA	Product Manager
6	38	F	Black/African American	Oregon State University	1995, 1996	MFA (Graphic Design)	Designer
7	42	F	American Indian/ Native American	Montana State University	1992	MA (Art)	University Professor (Art History)
8	40	F	White/Caucasian	Montana State University	1994	MA (Higher Education Administration)	College Administrator

Interview questions focused on the participants' experiences during the YSP, the academic and professional paths they pursued after the YSP, and their reflections on the impact of participating in the YSP. Interviews were conducted via online video conferencing software and were recorded and transcribed. The responses given by the YSP participants were then coded independently by two raters using a codebook consisting of a total of 15 codes organized around two categories: participation-level impact and long-term impact. Table 2 presents the codebook. The two coders reached agreement on the final coding of the data through a process of social moderation (Herrenkohl & Cornelius, 2013).

Table 2
Codebook of constructs included in the analysis

Category	Code	Description
Participation-level impact	Identity	Realization and/or attainment of a sense of oneself or sense of independence
	Self-efficacy	Enhanced belief and confidence in confidence in themselves, particularly in their ability to complete tasks and achieve goals
	STEM Knowledge	Acquisition of STEM-related knowledge & research and critical thinking skills
	Motivation	Development of interest in learning and finding a sense of direction
	Exposure	Experiencing new ideas or activities and a broader perspective of the world
	Interpersonal skills	Improved social and communication skills and the development of personal relationships and social networks
	Satisfaction	Sense of excitement and enjoyment
	Negative YSP experience	Difficult or challenging experiences within the program
Long-term Impact	YSP-related	Outcome associated with participation in the YSP
	External support	Support received from family/friends, teachers/mentors, school/community
	Career Opportunities	Opportunities for academic and professional development offered
	Career Challenges	Academic and professional challenges confronted
	Personal difficulties	Personal difficulties or uncertainties faced
	Towards STEM	Decision or action taken towards a STEM-related field or narrowing of focus within the STEM domain
	Away from STEM	Decision or action taken away from a STEM-related field

Next, epistemic network analysis (ENA) was used to model the connections, or co-occurrences, between the codes in the recent temporal context. ENA is a tool in quantitative ethnography that utilizes statistical and

visualization techniques to identify patterns in discourse (Shaffer, 2017). In particular, ENA models connections between codes in the data by quantifying their co-occurrences in the recent temporal context (Siebert-Evenstone et al., 2017). For this analysis, a unit of analysis (line of data) was defined as a single sentence contained within a turn of talk taken by the participant. A conversation was specified to be the set of lines that were related to the same topical question. A moving window of size 5 was used to model the co-occurrences of codes between a given line and four preceding lines in the same conversation. ENA networks were created at two levels to examine the participation-level and long-term impacts, respectively.

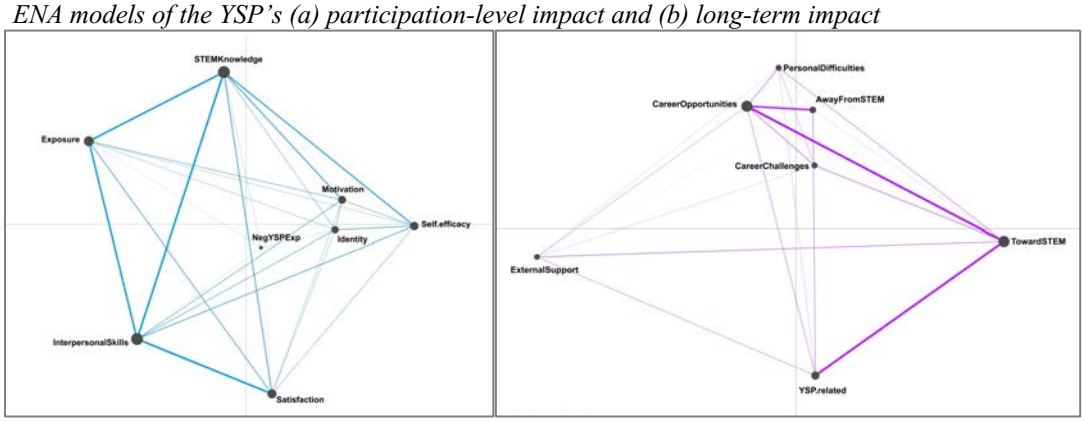
Results

Participation-level impact

The first analysis focused on the participation-level impact of the YSP. Figure 1a presents the ENA model reflecting the discourse pattern of the responses related to the YSP. Strong connections are visible among the codes of STEM KNOWLEDGE, EXPOSURE and INTERPERSONAL SKILLS. This suggests that enhancing knowledge in STEM-related subjects while having opportunities to make friends and gain new experiences was a significant feature of the YSP for the participants. As shown in the strong connections between STEM KNOWLEDGE and MOTIVATION as well as STEM KNOWLEDGE and SELF-EFFICACY, learning more about STEM topics was a key motivator for participants and allowed them to bolster their sense of confidence and achievement. The prominent association between INTERPERSONAL SKILLS and SATISFACTION indicates that social relationships contributed significantly to their overall positive experience during the program.

Figure 1

ENA models of the YSP's (a) participation-level impact and (b) long-term impact



(a) (b)

Long-term impact

In the second analysis, attention was given to the long-term influence of the YSP experience, particularly on the career-related choices made by the participants. Figure 1b displays the discourse pattern of participants' responses to questions focusing on their academic and professional pathways and the role that the YSP may have played in them. A strong relationship between TOWARD STEM and YSP RELATED can be seen, confirming that participation in the YSP had a positive impact for participants pursuing STEM fields academically or professionally. The prominent connections between CAREER OPPORTUNITIES and both TOWARD STEM and AWAY FROM STEM suggest that various opportunities that present themselves during the course of a life can be a double-edged sword for developing Stem workers. For some interviewees, educational and job opportunities allowed them to remain in a STEM-related field, while for others they led them away to other disciplines and sectors. It is interesting to note that PERSONAL DIFFICULTIES and CAREER CHALLENGES were found to have a much lower strength of connection to AWAY FROM STEM, indicating that they did not exert a high level of influence on the decisions of participants to move into other fields of study or work.

Discussion

This paper examined the participation-level and long-term impacts of the YSP on the academic and professional trajectories of young participants. Based on an ENA analysis of in-depth interviews of YSP participants, it was found that a combination of STEM learning, exposure to a diverse set of activities and connections to like-minded peers provided an experience that not only allowed them to develop interest and confidence but was also quite

 © ISLS

enjoyable and memorable. From an SCCT perspective, these findings point to the self-reinforcing nature of interest-driven learning processes. Given that the YSP projects were generally intended for high achieving students, it is likely that the additional learning experiences provided through the YSP often validated and expanded their interest in pursuing a particular STEM area academically or professionally. Participant #7 described this dynamic in the following way:

> And so being able to be among peers who also were academically engaged or at least engaged in learning new things, interested in learning how things work, just gaining knowledge for knowledge sake. That was the first time that that ever happened, and that gave me permission to really encourage that part of myself and not be ashamed of that and to fully embrace pushing myself to learn as much as I could and be okay with that.

The analysis of the long-term impact found that participation in the YSP was influential in some of the decisions made by interviewees toward STEM careers. However, it was also observed that educational and professional opportunities may not only help individuals to pursue STEM-related fields but also steer them away from these disciplines. An example of this was articulated by Participant #3:

> And I think…having that initial exposure to the college campus [through the YSP] made me more confident to apply for the apprenticeship program that I got into the next summer. So I felt pretty confident coming out of high school that I was going to be an engineer. And so I applied to a bunch of different schools. I thought and I was probably going to … [a] School of Mines here… and I got a scholarship and I thought that's what I was going to do. But then I got a music scholarship to [another university], and it was a better scholarship. And my mom was really concerned about debt and money, things like that. So that's the school that I ended up going to. And I started off in the honors program there, and the focus there was not so much science and math.

While SCCT stresses the role of internal factors such as self-efficacy and interest in career-related choices, this finding points to the importance of also accounting for external influences that may significantly impact the academic and professional trajectories of individuals.

The Multicompetent Learners

Greses Pérez, Tufts University, greses.perez@tufts.edu

Abstract: Engineering and science are meant to develop solutions and knowledge for a diverse population, yet Black and Brown communities often remain excluded from these intellectual enterprises. This work builds on prior literature in the learning sciences, sociolinguistics as well as science and engineering education to improve access for culturally and linguistically diverse communities. It aims at creating socially just learning spaces where individuals can bring their whole selves through introducing the notion of multicompetent learners described in terms of their language practices, cultural understandings and cognitive resources.

Introduction

American society has traditionally viewed the practices of non-dominant communities as problems to overcome (Moschkovich, 2012) and has dealt with people who have any cultural or linguistic variability by attempting to transform them into monocultural monolinguals. While there is an implicit embrace of diversity in the melting pot metaphor, in fact the expectation has been that people of color should gravitate to the culturally-dominant model (Ortega, 2020). These societal expectations are inextricably linked with notions of learning as they shape what counts as knowing and speaking, perpetuating structures of power and domination and ignoring the socio-historical contexts that created them (Ladson-Billings, 2006; Lee et al., 2020; Lee et al., 2020; Philip & Sengupta, 2021). Such an approach ignores the strengths that different populations bring to the table – especially in science and engineering (Hofstra et al., 2020; Layne & Arenberg, 2002). This paper puts forward the notion of multicompetent learners to honor and center the cognitive, linguistic and cultural practices of Black and Brown communities that too often are made invisible in the technical and scientific spheres.

Multicompetent learners

People who see the world through different cultural, cognitive and linguistic lenses are multicompetent learners. They come from diverse backgrounds, which equip them with the potential to draw on their experiences and knowledge, including the language practices, cultural understandings and cognitive resources of home and their local environments (Lee, 2003). When provided with opportunities to learn that draw on their background, these individuals are "transformative intellectuals" with multifaceted understandings of social justice issues and disciplinary knowledge with commitments and credibility in their local contexts (Morales-Doyle, 2017).

Although they have dynamic and rich strengths, multicompetent learners are often seen through a deficit perspective as lacking language and understanding of the world around them (Nasir et al., 2006). Labels like English Language Learners (ELLs) or at-risk students limit the potential of these learners by focusing on the quantification of languages and ways of knowing, taking as a standard the dominant society instead of mobilizing the intellectual resources students develop in their lived realities through which they index via language (both cognitively and culturally). But even in instances where the ways of knowing and speaking of non-dominant groups are valued, it is often with the purpose of ushering their resources into dominant, Westernized, and monolithic conceptions of human identity around language, histories, racial and ethnic groups, class and gender (Bang & Medin, 2010). From this perspective, diversity is addressed through helping multicompetent learners become more like dominant learners (Nasir et al., 2006).

In truth, multicompetent learners have many experiences developed through navigating different audiences, which requires a great deal of sophistication in tailoring speech, particularly when it comes to technical and scientific talk. Through the dynamic activity of language choice, multicompetent individuals acquire experiences working with people from a wide range of backgrounds. As compared to monolinguals and monoculturals, multicompetent learners have also lived many realities. While monolinguals in engineering may produce a single exclusionary technical-based culture, the kinds of viewpoints multicompetent learners bring to the table derive from diverse lived experiences and direct interaction with the distributed intelligence in their communities, physical and social world. The opportunities to interact with different kinds of people (e.g., engineers, parents, professors), in various cultural and linguistic settings (e.g., school, home, work) and through different discursive practices equip them with a wide range of valuable perspectives, repertoires of practices and various forms of acting and doing in the world (García & Wei, 2015; Gutiérrez & Rogoff, 2003).

Language practices

One of the means by which people draw on their strengths is through language. By looking at how language works, we can identify ways in which humans can tap the knowledge that resides in their differences from the dominant

 © ISLS

culture and language (Blommaert, 2013). The experiences people bring from living between languages and cultures equip them with the dexterity to navigate different contexts, such as engaging in specific ways of speaking and literacies (Gutiérrez & Rogoff, 2003). Researchers in translanguaging see language as associated with peoples' ways of "acting, being, knowing, and doing" (García & Wei, 2015). Thus, learning is enriched when it occurs within culturally and linguistically sustaining contexts that mobilize students' intellectual resources.

Translanguaging scholars have advocated for pedagogies that grant license for learners to draw on their full repertoire (García & Kano, 2014; Otheguy et al., 2015). However, the reality in learning environments is plagued with social norms that restrict students from drawing on their ways of speaking that feel authentic to them. For instance, industry settings tend to see languages other than English as unprofessional (Ruben, 2020). But linguistically-inclusive environments ensure students develop a deeper understanding and connection with ideas. In these contexts, students focus on cultivating ways of knowing instead of worrying about sounding right.

Cultural understandings

Learning is also cultural. Scholars have described cultural understandings as the plethora of practices developed through social interaction and the historicity and context of communities, which are ever-evolving for the purposes valued in these groups (Nasir et al., 2006). In thinking about the need for "dignity-conferring" interactions for belonging, Espinoza and Vossoughi (2014) invite us to think about how to open spaces for the multiplicity of voices in society to expand the discursive opportunities available to communities for the social futures they imagined to live (Costanza-Chock, 2020). For example, Lee (1995) described the role of wordplay characterized by "ironic, metaphoric, satirical, and figurative language" (p. 360) in learning as a practice from the African American community. Although African American students showed poor performance on standardized test assessments, Lee showed that the assessment instruments failed to capture the linguistic dexterity of these students and led to them not bringing the practices of their communities for learning. She argued for valuing students' cultural and linguistic multicompetences and welcoming them in the classroom as an asset for learning.

Cognitive resources

In her work with Latinx learners, Moschkovich (2012) focuses on the funds of cognitive resources that students bring to support their learning pathways. Instead of seeing their differences as deficits, she follows Vygotsky (1978) in centering the "potential for progress in what learners already know and do" (p.91). Summarizing scholarship in psycholinguistics related to mathematics, Moschkovich (2007) described bilinguals "selective attention" or the ability to focus on important information and reduce noise from non-relevant material. These multicompetent learners also have "translation skills" as they navigate the ways of speaking in their local contexts and those of the broader society (p.128). When engaging in different cognitive tasks, linguistically diverse students should be able to choose the ways of speaking that feel better to them for accomplishing the goals of the activity. The focus on students' backgrounds as a resource for learning transforms the power dynamics regarding who is heard and is allowed to contribute in the classroom (Bell, 2017).

Moving forward

Being a multicompetent learner in engineering and science today typically means having a predominantly monolingual teacher population whose cultural and linguistic backgrounds often differ from oneself. Students have teachers without the training to bridge community knowledge and practices into their pedagogies. And when students do bring the languages and experiences of their communities into making sense of scientific ideas and solving problems, they are seen as lacking objectivity and professionalism in the scientific and technical subjects, diminishing their sense of belonging. The lack of diversity in who teaches combined with assessments created without diverse populations in mind results in multicompetent learners with low academic performance scores.

Changing this dynamic and creating learning environments that see the potential in students as multicompetent learners involves considering their ways of speaking (language practices), what they know to be true in their communities (cultural understandings) and the knowledge and experiences associated with their lived realities (cognitive resources) as crucial for the world of engineering and science. A world that embraces this perspective requires seeing the communities where students come from not as discrete and essentialized groups in their language, culture and experience (e.g., Latinx people only as Spanish speakers). Instead, it involves embracing the nuances of how time and place influence their practices to incorporate who they are in the production of knowledge and problem-solving. It also dictates a teacher population that mirrors the student body, incorporates elements of students' lived realities in the education of future teachers, and investigates the role of the teacher's background and training in creating a culture of belonging in the disciplines. Educators in such a world would focus on developing conceptual understanding and practical experiences rather than grammar or

vocabulary (Warren et al., 1994) while acknowledging the multiple factors (e.g., audience, language boundaries, topics, places, social and political realities, time) that shape the opportunities available in learning environments. In short, there is no silver bullet that will address the needs of multicompetent learners to be welcomed into the science and engineering community, but there are concrete steps that can be taken to address this issue head-on.

Truly valuing these learners means creating spaces that send messages of belonging and reflect what they know to be true in their community while equipping students with the tools to navigate other realities without necessarily having as a goal to leave behind who they are. Students should be able to become proficient in the knowledge and discursive practices of the disciplines while also being able to communicate such expertise to the groups where they claim membership. They should be provided ample opportunities to make sense of scientific phenomena in their communities to understand the potential and limitations of scientific ideas in context (e.g., as shown in the scholarship of Morales-Doyle (2017) on chemistry in urban neighborhoods).

Multicompetent students should not have to pay the steep price of being seen as less knowledgeable or their contributions de-valued when using Spanish or speaking discursively. Ideas should be judged not on the sophistication of the vocabulary nor the language used to communicate them, but on students' conceptual understanding of real-world phenomena. If the goal is learning science and engineering, teachers must allow students to express their ideas in the ways that support their sense-making and honor those ways of speaking as valuable resources for communicating knowledge.

Conclusion

Up until now, much of the empirical and theoretical work on the role of language and cultural understandings has investigated the role of linguistic resources in discursive practices associated with science and engineering (Brown et al., 2005; Lee & Roth, 2002; Millar, 2006) or in social justice movements (without a focus on the disciplines) with the goal to liberate linguistically diverse learners from monoglossic expectations (Creese & Blackledge, 2015; García & Wei, 2015; Otheguy et al., 2015). Such studies have conceptualized language primarily as a medium for instruction. In contrast, this paper puts forward the idea of the multicompetent learners to shed light on how the diversity of experiences in Black and Brown communities (which are indexed through language) equip them to bring a different set of perspectives to learning. It challenges scholars to expand their understanding of bringing diverse perspectives into learning not simply as a matter of investigating the boundaries between languages but as an issue of whose linguistic practices are valued in society. As suggested by Moschkovich (2007), scholarship should focus not on comparing multicompetent learners with the dominant groups. Instead, the learning sciences should pay attention to the ways Black and Brown students make sense of, communicate and engage with different forms of knowledge within meaningful sociocultural and historical contexts.

This paper joins other calls to retire deficit-oriented perspectives toward culturally and linguistically diverse populations (González-Howard & Suárez, 2021), inviting us to embrace asset-based frameworks that see students as multicompetent learners, speakers and doers. The relevance of this work resides in understanding the nature of multicompetent individuals (Cook, 2016; Ortega, 2016) and how we could draw on the assets of these groups for equitable learning. This work advocates for expanding research endeavors that build on the creative insights diverse students bring to the scientific and engineering enterprise. Justice in science and engineering as well as in society demands we invite differences into learning environments and welcome individuals to come as their whole selves into the process of figuring out problems as well as producing, assessing, and creating new human realities (Calabrese Barton & Tan, 2020; Dym & Little, 2003; Sheppard, 2003).

Abstract: Epistemic practices are the goal- and norm-guided actions people use to develop knowledge within a domain, such as analyzing evidence to support scientific claims. Developing sound epistemic practices is critical considering the current rise in post-truth discourse that constrains society's abilities to make informed decisions. Learning scientists have increasingly offered frameworks and methodologies to support improved epistemic performance. However, there is a lack of consensus in the field about what epistemic practices are that students can take up, as well as strategies to best support teachers in this endeavor. This symposium brings together seven teams of researchers who have been working on developing epistemic practices in K-12 classrooms. In conversation with each other and the audience, we aim to understand how epistemic growth is conceptualized in its myriad forms across students and teachers in addition to the design characteristics and indicators of growth of learning environments that promote epistemic performance.

Keywords: epistemic practices, K-12 science education, reasoning and sensemaking, post-truth

 © ISLS

Symposium overview

With the recent rise in post-truth discourse, educators have been concerned with how to develop a citizenry capable of appropriately evaluating knowledge claims (Barzilai & Chinn, 2018; McIntyre, 2018). Recent publications have documented challenges in how citizens understand significant scientific issues. For example, Sloman and Fernbach (2017) discussed the tenacity of false beliefs about scientific matters, such as the causes of global warming; in one study, only 12% of respondents were even partially correct. Nichols (2017) revealed issues in the American educational system that do not enforce the habits of critical thinking to enable the evaluation of complex content to make informed decisions. Because many of the consequential issues are in the domain of science learning, such as climate change and vaccines, researchers have noted a pressing need to include a focus on epistemic practices in K-12 science classrooms (Chinn et al., 2021). Epistemic practices (EPs) are the goal- and norm-guided actions people engage in to develop knowledge within a particular domain. Some examples of EPs include constructing, critiquing, and revising models to fit patterns of evidence (Ford, 2008) and engaging in systematic research to develop patterns of evidence. Despite the growing efforts to promote epistemic education–education directed at promoting growth in students' ways of knowing–there is as yet too little clarity of what high-quality epistemic practices look like in classrooms (Rosman et al., 2016). Some research has focused on facets of reasoning practices without providing a more comprehensive picture. For example, research has focused more narrowly on reasoning strategies, such as checking the authenticity of sources or conducting controlled experiments without accounting for the aims or ideals (i.e., the standards) that are critical for establishing scientific knowledge (Chinn et al., 2020). There is a need for more systematic accounts of what high-quality epistemic practices involve. In particular, there is a need for improved theorizing as well as empirical research on the range of useful practices that students can master in classrooms.

In addition to a lack of consensus or clarity on what epistemic practices are that students can take up, we know very little about how best to support teachers in this endeavor. We know that when implemented well in classrooms, pedagogical practices that engage students in epistemic work can disrupt traditional hierarchies of power in science education (Barton & Tan, 2009; Hand, 2012). Epistemic positioning of students also propels a shift in instructional practices from those that engage students in mimicking "correct" canonical science information to adopting strategies that empower students to develop their own ideas (Haverly et al., 2020; Stroupe et al., 2018). Most schools, especially within formal environments, struggle to engage students' epistemic practices (Erikson & Lindberg, 2016). Supporting students' epistemic practices within science classrooms is a challenge for teachers because of the tensions that arise from maintaining authoritative control over the content while attempting to create authentic opportunities for students to engage with and construct knowledge that is meaningful to them (Braaten & Sheth, 2017). This kind of teaching requires tools and processes that are distinctly designed to leverage students' ideas for an active knowledge production process within classrooms while adhering to structural limitations of formal science classrooms (Brown, 2018). Hence, there is a need to investigate innovative professional development (PD) pedagogies and environments that support teachers to engage in epistemic teaching practices. We also need a concentrated effort to understand what PD supports should look like and, importantly, what PD features help to overcome the structural tensions between the epistemic instructional practices and traditional power dynamics between students and teachers.

With an international group of scholars, in this session we seek to investigate frameworks and methodologies that support students' and teachers' epistemic performance by asking the following questions: 1) How is epistemic growth conceptualized in its myriad forms across students and teachers? 2) What are the design characteristics of the processes, tools, and learning environments that promote epistemic performance in science classrooms? and 3) How are epistemic learning gains measured and what can be agreed upon as successful indicators of epistemic growth?

Structure of symposium

To demonstrate the range of applications, symposium presenters will present both theoretical and empirical research and early and late-stage work that addresses post-truth issues. The symposium will be structured to allow conversations between presenters and the audience about the collective emerging scholarly work, with the ultimate goal of mapping current and future possibilities for advancing the field of educational epistemic performance. We will begin with a 5-minute introduction from each of the 7 posters followed by 40 minutes of participant rotations to each poster. Our discussant Dr, Toshio Mochizuki will offer 10 minutes of remarks on the collective scholarship and then we will open up the discussion to both presenters and participants.

Designing for growth in apt source evaluation performance

Sarit Barzilai, Shiri Mor-Hagani, Fayez Abed, & Danna Tal-Savir

Being able to evaluate the trustworthiness of information providers is vital for navigating "post-truth" information landscapes. Current approaches to source evaluation instruction often focus on teaching students how to apply a set of heuristics or a criteria checklist. There are several limitations to such conceptions of sourcing instruction. First, instruction is often divorced from students' science learning and inquiry. Consequently, the importance of source evaluation for reaching sound conclusions can be under-appreciated (Paul et al., 2017). Second, simple sourcing rules underestimate the complexity of evaluating sources. This requires discerning and evaluating multiple epistemic criteria that students can find hard to grasp (Allchin, 2021). Third, students may have little agency to evaluate sources and determine who *they* trust. Consequently, disagreements about who to trust between students from different social and cultural backgrounds, and between students and teachers, are usually ignored. We use the Apt-AIR framework (Barzilai & Chinn, 2018) to inform our efforts to design instruction that addresses some of these challenges. The Apt-AIR framework posits that epistemic growth means increasing competence to successfully achieve epistemic aims. Further, epistemic growth involves five intertwined aspects: (1) increased practical abilities to employ reliable processes and apply appropriate ideals in order to achieve epistemic aims (2) in an adaptive manner across diverse tasks and contexts; as well as increased (3) metacognitive understanding and regulation of epistemic aims, criteria, and processes, (4) dispositions to value and pursue these, and (5) grasp of their fundamentally social nature and uses.

Through ongoing collaborations with teachers, we developed several principles for designing learning environments to support growth in apt source evaluation performance. One principle is *making sources meaningful*. This means integrating sources with diverse trustworthiness levels in engaging inquiry activities, so that students have opportunities to grapple with diverse sources [Apt-AIR aspects 1&2] and experience the risks of relying on unreliable sources [aspect 4]. A second principle is *making sources visible.* We have developed a scaffold for visualizing sources and mapping how sources relate to competing claims (Barzilai et al., 2020, 2021). We found that visualization helps support growth in practical abilities to evaluate sources [aspect 1]; and that it facilitates individual and collaborative regulation of sourcing as well as understanding of the impact of sources on knowledge construction and evaluation [aspects 3&5]. A third principle is providing *meta-epistemic discourse prompts* that encourage students to explain their source evaluations, describe their criteria, and discuss their disagreements about source trustworthiness [aspects 3&5]. Such discussions become meaningful when students have *epistemic agency to decide who to trust* [aspects 4&5]. We will illustrate the affordances and challenges of implementing these principles using examples and artifacts from inquiry units in which Israeli ninth grade students conducted investigations using diverse authentic information sources. These findings contribute to the design of learning environments that can prepare students for reasoning in a “post-truth” world.

Toward “truth”: Scientific sensemaking through epistemic and social negotiations

Emily Adah & Leema Berland

To address the call for equity, science teachers position students to collaboratively make sense of a phenomenon by using scientific practices and applying science ideas in small groups. Simultaneously, they must negotiate implicit understandings about whose scientific ideas are valued, what scientific ideas count, and how they should be communicated—they must negotiate multiple epistemological perspectives (Bang & Medin, 2006). These epistemic judgments are part of the sense they make of the scientific phenomenon under study—the “truth” they discern. Thus, students must practice addressing and evaluating implicit and embedded claims about the identities of the speaker and the audience, the students’ relationships to science and to knowledge, and bids for what language, culture, and norms belong in science discourse, all while making sense of a scientific phenomenon (Brown, 2004). In this study, we view epistemic growth as change in epistemic practices and ideas (Herrenkohl, 2006), from traditional and fixed, exclusionary understandings and ideas, to flexible and responsive to the situation (Berland & Crucet, 2015). We present our analyses of instances in which students engage in sensemaking as a complex and multi-layered negotiation where the “truth” encompasses more than resolution of scientific ideas.

As part of a larger design-based research project, we gathered data from videotaped transcriptions of 3 small groups’ interactions during an 8-week project-based unit on animal adaptations. We reviewed video and transcripts to identify moments in which students made bids to introduce different ways of engaging in the collaborative sensemaking work. We employed discourse analysis to describe the decision-making criteria being employed, how bids to change it were made and responded to, power dynamics associated with these moments, and finally, the “truth” students constructed (i.e., the sense they made). Through these analyses, we explore the growth of scientific sensemaking as epistemic and relational negotiations. For example, consider an interaction between two Latine, 4th graders making sense of a bird’s life cycle. One student began the discussion in formal English and affected posture, suggesting that science ideas should be communicated in ways that align with historical and institutional scientific norms. With unsuccessful take-up by others, the student introduced

 © ISLS

alternative epistemic criteria (i.e., he spoke conspiratorially in Spanish, using an informal posture suggesting that science ideas come from non-privileged sources). This stance was curtailed by the partner as non-credible. However, when the same student switched modalities and offered ideas with informal English and a gesture for center stage, the partner attended. Hence, scientific sensemaking enabled and coordinated, and was enabled and coordinated by, epistemic negotiations.

This brief interaction underscores the epistemic negotiations that determine "truth" during sensemaking. In our poster, we explore the claim that a key aspect of growth in epistemic practice in the post-truth era is this multilayered negotiation.

Tools to support thinking and regulating scientific inquiry

M. Anne Britt, Steven McGee, Randi McGee-Tekula, Kathryn Rupp, Karyn Higgs, Kathleen Easley, & Amanda M. Durik

The scientific practices students are expected to learn from inquiry units in science classes are the same ones that students need to develop to evaluate scientific claims outside the classroom. Many students, however, struggle to coordinate these skills to create a scientific argument (Osborne et al., 2004). Some challenges for middle school students are: including providing reasoning to demonstrate why the evidence supports a claim and/or why the evidence refutes an opposing claim. Previous research with middle school students has found that students place less emphasis on engaging in scientific practices, as compared to understanding specific scientific phenomena (Rupp et al., 2020). One potential support for students is to help teachers support students' reflection on and development of these scientific practices (Herrenkohl et al., 2011) to improve epistemic competence (Chinn et al., 2014). Our team approaches epistemic cognition as the development of a regulatory task model which includes understanding the goal state (purpose) of each subtask, understanding how to accomplish each subtask (subgoals, tools, and strategies), and valuing the goals of the primary task and the subgoals of each subtask (Britt et al., 2018). A discipline-appropriate task model instantiates epistemic aims and value, epistemic ideals or criteria, and epistemic processes to achieve those aims.

We will describe the development of two tools designed to help teachers guide students through a multi-session inquiry unit that required engagement in and reflection on epistemic practices within the discipline of science. The first tool, *Investigation Steps Chart***,** is a class-level regulatory structure to help students develop epistemic practice of figuring out how the unit and lesson investigation questions will be explored through scientific inquiry, what was found, and what still needs to be done to answer each of the questions. This is intended to help students develop a task model to organize multiple days of inquiry to support writing of a unit culminating with a scientific argument. The *Investigation Steps Chart* uses key NGSS storyline routines (i.e., exploration, navigation, investigation, problematization, "putting the pieces together") to guide inquiry (Reiser, 2017). The second tool, *The Evidence Sorter***,** supports student synthesizing notes taken across the multi-day inquiry to help students construct argumentation by: (a) organizing all evidence collected during the unit, (b) determining which claim is best supported, (c) engaging in reasoning to connect evidence to the chosen claim. These tools were improved upon over the course of two academic years in the context of middle-school science classes in the Chicago Public Schools. Iterations were informed systematically by: teacher feedback provided during workshops, analysis of student written work, classroom observations (pre-pandemic only), and analysis of teacher and student surveys. The key changes to the *Investigation Steps Chart* included reordering the questions so that students did not consider materials not available, improved emphasis on the student's role in scientific practices as they consider how the material that is provided will be used, encouraging separately the connections with the overall goal (unit question) and subgoals (investigation question), and including a prompt for making deliberative connections to the key concepts as a scaffold or a lens for creating reasoning statements. The key change in the *Evidence Sorter* was a revision to decrease cognitive load. Through the use of tools that bring students into the discussion about the process of scientific inquiry, students should develop appropriate epistemic cognition and practices that can be used when they encounter scientific claims.

It did not fly but it would outside: Pushback and purpose in investigation practice

Eve Manz & Chris Georgen

We conceptualize science practice, including empirical investigation, as model alignment, involving representational practice, model-based reasoning, and pushback from people, representations, and the world (Manz et al., 2020; Nersessian, 2008; 2012; Rouse, 2015). We ask how children can engage in iterative investigative work where they seek to make progress on understanding some aspect of the world by modeling it: representing it, playing the model out, making sense of the implications, and then refining their understanding and, sometimes, the investigative model itself. In doing so, we seek to shift current instructional approaches and

pedagogical strategies for classroom investigations, which rely on investigations demonstrating general principles (plants need light; water can shape earth, a magnet's force decreases with distance) and, almost invariably, lead to materials dictating investigation procedures and teachers stepping in to correct children's ways of measuring, interpreting, or making connections so that they will conclude what they need to. These approaches oversimplify scientific activity, omit opportunities for children to engage in critical evaluation of models and their relations, and introduce investigation as a school game that involves following rules, letting go of what you know of the more complex world, and trusting the teacher's authority.

We engaged in co-design and design-based research with teachers to develop, implement, collect video data on, analyze, and revise investigations into seed travel. Second grade (7 and 8 year-old) students plan, conduct, and make sense of how well particular seeds travel by water, wind, and sticking, using the wind tests as a focal case. In the first instantiation, the team focused on children's choice and agency in designing their investigations, providing an array of materials to use (paper fans, straws, an electric fan). We experienced substantial difficulty helping students reason about the results of the investigation and make connections to the form/function and ecological relationships involved in seed travel. In the redesigned investigation, students (1) examined video of seeds travel by wind, beginning to focus on particular mechanisms, (2) argued over what counted as "flying," (3) conducted a shared test and collected data, (4) rejected the test as providing useful information about the maple seed, which needs to be dropped from a high enough height that it will twirl, and (4) re-tested the maple seed by dropping it from a window.

We highlight several design features and aspects of young children's thinking across these two instantiations, using it as a case to invite discussion. First, we found that children's framing of the purpose of their investigative work including, and often laminated, frames for *representing the world, making something happen, and figuring out.* These were dynamic and context-dependent, and further were consequential for the conceptual resources that were called on and refined and children's evaluative and iterative practices. Bringing together representational and figuring-out frames appeared important for allowing children to develop and iterate tests that allowed them to make and evaluate claims about seed travel. Features of the environment that supported these framings included shared experiences with the phenomenon, support to play out and evaluate the implications of investigation choices, focusing uncertainty and discussion on choices that have conceptual import (here the height of the maple seed), and designing pushback into children's work with investigations. We will further share the assessment foci and practices we and our teacher partners are building to consider epistemic growth in children's framings and related practices for evaluating investigative choices.

Students' understanding and caring about placing trust in the time of corona

Jessica Shuk Ching Leung

In a world increasingly shaped by science, there is a pressing need for citizens to be able to make informed judgment about knowledge claims in socioscientific issues. These are ill-structured problems that are inextricably linked with science and require both scientific and ethical reasoning for decision-making. Laypeople's limited understanding of science often predisposes them to placing trust on science experts about these issues. To avoid misplacing trust, students need to learn the nature of science (NOS) – How does science work? What happens when scientists disagree? When should we be skeptical about science? (Höttecke & Allchin, 2020). This is not merely about understanding NOS. It is also about the use of such understanding (Ford, 2008). This may include: (1) identifying whether recognition from peer reviewers has been obtained; (2) examining the credentials of those who claim expertise; (3) determining the level of expert consensus; and (4) identifying possible sources of bias (Leung & Cheng, 2021). Developing students' understanding of NOS as a form of practice, rather than strictly a form of knowledge, has been shown to play a productive role in their evaluation of socioscientific issues (Leung, 2020). This practice-oriented approach to learning NOS was informed by the Apt-AIR framework of epistemic growth (Barzilai & Chinn, 2018), which conceives epistemic growth as increasing competence to successfully achieve epistemic aims. Developing such competence does not only involve the practical abilities of employing reliable epistemic processes and epistemic ideals to achieve epistemic aims, but also entails students' metacognitive understanding and regulation as well as their motivation-affective disposition to value and pursue epistemic aims.

Contextualized within the Covid-19 pandemic, this qualitative case study examines students' growth in understanding and caring about placing trust in a lesson unit guided by a practice-oriented approach to NOS. Seventy-three undergraduate students enrolled in a general education course on making sense of socioscientific issues participated in this study. Reflective journals were used to capture participants' growth in epistemic performance. Findings revealed: (1) an increased awareness on the need and reasons for laypeople to place informed trust on knowledge claims; (2) consideration of a broader range of reliable epistemic processes; (3)

increased consciousness about these epistemic processes; and (4) increased concern, inclination and self-efficacy in assigning epistemic trust. Participants expressing increased understanding about reliable epistemic processes often showed appreciation for these processes. This suggests an association between participants' understanding and caring about reliable epistemic processes, offering empirical support for the intertwining of aspects in the Apt-AIR framework.

Supporting students' development of a "grasp of modeling"

Na'ama Av-Shalom, Ravit Golan Duncan, Clark Chinn, Joshua Danish, Cindy Hmelo-Silver, Danielle Murphy, Christina Stiso, Zachary Ryan & Jinzhi Zhou

Science is a social knowledge-building process, in which scientists collaborate to construct knowledge and ratify it through a process of social critique (Ford, 2008). For example, scientists refine their ideas through a social process of receiving critique from the scientific community (e.g., through peer review or at conferences) and refining their ideas based on these critiques with the aim that the knowledge will eventually be taken up by the community. Often, these knowledge building practices are foregrounded in science instruction with little attention to social critique (Ford, 2008). But, to navigate information in an epistemically complicated post-truth world, students need to develop a robust understanding not only of how science is done, but also how these practices lead to reliable knowledge. For this, students need opportunities to engage in evaluation and critique (Ford, 2008). One context for knowledge construction and critique is modeling (NRC, 2013). An important aspect of modeling practice are the norms that scientists use as they engage in modeling--particularly reliable epistemic processes and epistemic ideals (see AIR framework: Chinn & Rinehart, 2016). Reliable epistemic processes are practices involved in doing modeling, such as defining components and processes in a mechanism. Epistemic ideals are the criteria that scientists use to evaluate models, such as "models are good when they explain a mechanism." A key ideal, fit with evidence, and the associated reliable evidentiary processes (e.g., integrating bodies of evidence; see Duncan et al., 2018) form the foundation for establishing the veracity of models in science (NRC, 2013). Extending work by Ford (2008) and Duncan et al. (2018), we suggest that a "grasp of modeling" involves understanding how models are constructed and critiqued, and how the norms guiding this process are themselves constructed and ratified through social critique processes.

In the Scaffolding Explanations and Epistemic Development for Systems (SEEDS) project, we explore how students develop such a grasp of modeling practice. We designed a fifth-grade model-based science intervention focused on constructing and critiquing models using epistemic criteria. Classes collaboratively developed and revised criteria for evaluating models. Students worked together in small groups using the computer-based Model and Evidence Mapping Environment (MEME) to construct and critique evidence-based models of a phenomenon using different kinds of evidence. In prior and ongoing analyses of written artifacts, pair interviews, and classroom videos of groups, we focused on students' use and metacognitive understanding of reliable processes and ideals for modeling. For instance, in interviews students were asked to rank the importance of each of their class criteria. In their justifications for their ranking, students were able to reason about the nature of different criteria (e.g., redundancies) and their relationships to the aims of the model (e.g., communicating ideas) (Murphy et al., 2021). Although the students did not consistently prioritize evidentiary criteria, they did offer justifications regarding the role of evidence (e.g., supporting accuracy), showing a growing metaepistemic understanding of the relationship of evidentiary norms to modeling. Our analysis indicates that supporting students in developing a sophisticated grasp of modeling—a central aspect of scientific knowledge-building—can equip them to engage with science as they encounter it in the post-truth world.

Epistemic practices that advance learning of complex scientific models

Noora F. Noushad, Amanda Cottone, Huma Hussain-Abidi, Clark Chinn & Susan A. Yoon

With the recent rise in post-truth discourse, educators have been concerned with how to develop a citizenry capable of critically evaluating knowledge claims (Barzilai & Chinn, 2018; McIntyre, 2018). Since many of the issues are consequential to the domain of science learning, such as climate change and vaccines, researchers have noted pressing needs to include a focus on epistemic practices in K12 science classrooms (Chinn et al., 2020). Our project addresses the implications for designing for post-truth reasoning by examining productive epistemic practices (the practices used to establish, critique, and use knowledge within a domain) that occur when students reason with biological models in science classrooms. With the eventual goal of using these practices when evaluating science-related real-world issues, in this poster, we articulate efforts in the first phase of the project, which was to establish a baseline understanding of what epistemic practices students already use. We were also interested in identifying those epistemic practices that are most appropriate for establishing knowledge claims with our complex systems biology curricula. To address these research goals, we use the AIR framework found

in Barzilai and Chinn (2018), who argue that the goal of epistemic education is *apt epistemic performance,* which refers to successfully achieving epistemic goals (such as accurate beliefs or a good understanding) through competence. Epistemic competence involves use of: 1) *Epistemic **A**ims and values*: the goals that people have, such as developing explanations, and the value that people place on these aims; 2) *Epistemic **I**deals*: the criteria that are used to evaluate whether the epistemic aims have been met (e.g., fit with evidence) and 3) ***R**eliable epistemic processes*: the procedures, strategies, and methods that have a high probability of achieving epistemic aims (e.g., selecting representative samples in a study).

We analyzed an archived video dataset of students interacting with the biological models from a previous research project that occurred between 2012 and 2014. The curriculum requires students to run the models, collect and analyze data, and make inferences about the scientific phenomena, e.g., how to create a sustainable ecological system. Using Interactional Analysis (Jordan & Henderson, 1995) to analyze the five videos of student pairs, we identified ten AIR codes related to our modeling curriculum. They comprised six epistemic processes and four epistemic ideals. We inferred that the observed processes were typically governed by an ideal that students were applying in the background. For example, the process, *Inferencing,* was always coded together with the ideal, *Fit with Evidence,* because all instances of making inferences involved students citing evidence from the simulation to fit their mental model. The categories of processes and ideals that emerged with the greatest frequencies were: *Run and Observe* (process), *Describe Trends* (process), and *Fit with Evidence* (ideal). However, we noted that students often drew conclusions based on insufficient evidence (such as single runs of the model rather than averaging multiple runs). Furthermore, we found that there were a number of other processes and ideals not present in student reasoning, such as *Planning an Experiment* (process), *Making Data-Informed Revisions* (process), *Check Plausibility* (process), *Making Sense* (ideal), and *Having a Mechanism* (ideal). We used these findings to modify the curriculum to develop greater epistemic performance in the subsequent summer PD workshop. We also worked with teachers to relate these EPs to issues that are current in the public domain to demonstrate adaptive epistemic practices, e.g., the complexity of global warming. We are currently collecting data to see how the modified curricula worked in classrooms. We further report on these experiences in the poster.

Session Abstract: Over the past decade, science education has been pushed to an inflection point. What was once a given of scalable standards-based science education is now being reimagined as adaptable models for teaching science through collaborative student-led sensemaking. This tension of supporting individual students' ways of knowing and being in coordination with canonical STEM practices has teachers caught between a paradigmatic binary. The field of the Learning Sciences provides comprehensive knowledge about the need for opening up diverse learning pathways in the classroom, yet little is discussed about what to do once those learning pathways are made visible. In this symposium, the authors consider how teachers "make space" for student contributions in classroom-based science education, and consequently, analyze what happens after it is made.

Focus of the symposium

This symposium seeks to put in conversation learning designs that "make space" (Haverly et al., 2018); or open up opportunities for students to make visible, share, and enact their own "culturally organized learning pathways" (Nasir et al., 2020) for collaborative sensemaking in classroom-based learning. However, given the pervasive pressures teachers face to implement canonical, standards-based STEM practices (cf., Horn & Campbell, 2015),

 © ISLS

opportunities to encourage students to participate using their own cultural resources (Gutiérrez & Rogoff, 2003)—that open up diverse connected learning pathways—continues to be a challenge.

Significance and contribution

The works collected here highlight multimodal practices in which teachers use representations (Ainsworth et al., 2020), scaffolds (e.g., Tabak, 2004), and other mediated actions (Wertsch, 1993) to support meaningful learning experiences (Schwartz et al., 2020) wherein students' culturally relevant (Ladson-Billings, 2014) knowledge, skills, and dispositions lead collaborative sense-making about science phenomena. These acts of "making space" redistribute epistemic authority and agency (Miller et al., 2018) towards diverse ways of knowing and being in ways that move beyond the constraints and expectations of a narrow, standards-based STEM pipeline (Cannady et al., 2014). With a goal of supporting the inclusion—and the growth—of diverse ways of knowing and being in classroom sense-making, this symposium explores multiple approaches to teaching in which educators worked to bring out and validate students' ideas and prior experiences for collective problem-solving and context-relevant learning experiences. Since teachers are navigating complex interactions and relationships with students, we also consider moments where teachers' moves missed making-space opportunities as a way to implicate future professional development and science teaching; especially within pedagogical moments that present a greater potential for students to make visible, share, and enact their prior experiences. In our different analytic viewpoints, we offer examples of approaches, tools, and activities where teachers trusted students (and their families) to lead sense-making experiences. When teachers acknowledged that students offered important ideas with which to work, they challenged the singular STEM pipeline narrative and set up emergent trajectories for transforming how learners "do science."

Organization of the symposium

Following an introductory talk that frames the session, each author or authors will describe their work and explain how it expands the paradigm of *making space*. Our discussant will synthesize the works and connect these pieces to the field in a broader sense, then conclude with questions for the audience to consider. This session will use 90 minutes accordingly: (1) 7-minute introduction and framing (Chairs); (2) four 12-minute talks from author(s); (3) 15-minute synthesis of the work and connection to the field (Discussant); and (4) 20-minute conversation with the attendees based on discussant-posed questions.

Paper 1: Making space for heterogeneity in phenomenon-centered science learning

Ashlyn Pierson, Danielle Keifert, Sarah Lee, Heather Johnson, Adam Bell

In the past decade, the call to start "from [students'] curiosity about what they see around them" (NRC, 2012, p. 11) has led to the development of phenomenon-centered science curricula (e.g., Edelson et al., 2021; Krajick et al., 2011; Reiser et al., 2021) that encourage students to co-construct knowledge by asking questions about a phenomenon, then exploring a subset of questions that align with a pre-determined "storyline." Through this process, students develop shared understandings and "knowledge products" (Berland et al., 2016, p. 8). These curricula foreground an image of science-as-convergence, bringing together students' diverse ideas to create a shared explanation. While convergence represents important aspects of disciplinary science, it backgrounds other (messy, nonlinear) images of science. Moreover, it creates tensions between accountability to standards and fully empowering students to engage in "felt" inquiry—feeling puzzled and exploring questions of interest to them (Keifert & Stevens, 2019). For instance, in these convergence-seeking curricula, "it is likely that not all students' questions can be fully taken up" (Reiser et al., 2021, p. 818). In response, we ask instead: how can foregrounding an image of science-as-heterogeneity make space for students to genuinely lead inquiry?

Framework

Research provides countless examples of science as a messy, non-linear process that is shaped by human and material agency, offering an image of science-as-heterogeneity (Gooding, 2006; Latour, 1993; 1999; Pickering, 1995). Rosebery et al. (2010) argue that such heterogeneity is fundamental to K-12 science learning, showing that words like "heat" can take on multiple meanings. Building on this work, we see heterogeneity not only as a starting point for asking questions, but also as an opportunity to empower students to lead inquiry that is deeply felt (Keifert & Stevens, 2019). By valuing the multiple co-existing ideas that students see in a phenomenon, researchers and educators can attend to the generative and disciplined questions that students propose.

 © ISLS

Methods

We present a case (Yin, 2014) that illustrates how a third-grade teacher, Jack, used a heterogeneity-seeking approach to make space for students' questions and ideas in a phenomenon-centered unit about magnets. Data include video-recorded lesson observations and post-observation interviews (to triangulate observations with Jack's intentions and reflections). We used interaction analysis (Jordan & Henderson, 1995) to analyze how Jack made space for students' questions and ideas, and we used co-operative action (Goodwin 2018) as a lens to understand how he brought together multimodal representations and materials in service of these goals.

Findings and Implications

We describe how Jack used a heterogeneity-seeking approach to make space for students' questions and ideas. We focus on a unit anchored with a video: a reporter showed that a car parked at the bottom of "Magnetic Hill" would roll backward uphill in neutral (in fact, an optical illusion). Though the phenomenon is *not* caused by magnets, Jack explained in an interview that investigating these (false) claims could allow students to explore concepts like magnetic fields, attraction, and repulsion. Jack encouraged each student to create and test their own theory about what happened. He provided students with materials to model their theory, and he used questioning to help students refine their theories. In this way, though the unit was centered on a single phenomenon, Jack invited students to bring new phenomena to the group and relate these phenomena to ongoing inquiry (Could a strong, underground magnet from an asteroid pull the car? Could the Earth's core and magnetic field pull the car?). Rather than choosing one or two ideas for the students to investigate as a class, Jack encouraged each student to test the theory that "is most true to you." Through questioning, Jack gave voice to the material agency that pushed back on their theories—he repeatedly asked students "what do [the materials] represent?" and "how does that help you prove your theory?" For example, when a student claimed the asteroid theory worked because he could hold a magnet above a toy car to pull it up a ramp, Jack responded, "but the asteroid is under the road." Jack's case offers one example of how a heterogeneity-seeking approach can allow students to genuinely lead inquiry in their classrooms. With this case, we offer a new paradigm for phenomenon-centered instruction that foregrounds heterogeneity (and epistemic authority) rather than convergence. We propose that reframing phenomenon-centered instruction in this way is one step toward valuing and leveraging students' affective experience in science (e.g., Keifert et al., 2018; Jaber & Hammer, 2016) to support generative disciplined science learning.

Paper 2: Family Engagement and the Kindergarten Classroom

Michelle Salgado

Research has continued to call for family engagement in science education, particularly from culturally and linguistically diverse families (Barton et al., 2004; NRC, 2012; Schwartz et al., 2017). Family engagement is well supported by research which indicates the positive impact on student achievement and influence over gaps in opportunities afforded to children in school settings (Sheridan & Kim, 2015; Henderson & Mapp, 2002). Further, family engagement is not only possible but essential to young children's engagement in science and engineering disciplines (NRC, 2021). The purpose for this study will be aiming to contribute research to the field of science education as it relates to designing learning environments that support family engagement in scientific practices of observation and obtaining, evaluating and communicating information. Research Questions: 1. How do families engage in school direct scientific activities that support scientific practices? 2. What are the design elements of such activities that promote meaningful engagement by families?

Framework

In this study I attended to a situative perspective (Gresfali & Greeno, 2008) where learning occurs within the activity systems utilized by social worlds and actively provides opportunities for families to engage and participate. Authority figures in the classroom, actively problematized the assumption that participation and understanding are solely attributes of the student occurring in school (Gresfali et al., 2008) and instead, views students and families as epistemic agents capable of co-creating a collaborative classroom culture (Stroupe, 2014). Using this perspective allows for a shift in how this teacher-researcher partnership opens spaces where we consider how we view, frame, and design with children and families for disciplinary specific learning.

Methods

A collaborative design study (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003) was conducted with kindergarten students over the course of four years. In this paper I present the two cases from year two and year four cohort and examine a set of family engagement activities which were selected using purposeful sampling

(Merriam, 2009; Patton 2015). This video-based research study was conducted in a title one elementary school. The school's demographic composition: 80% Free and Reduced Lunch; 23.3% Special Education; 42.4% Transitional Bilingual; 46.4% Hispanic/Latino, 19.6% Asian, 4.4% Pacific Islander, 8.2% African American, 9.8% white. The selected multilingual classrooms had 24 and 27 students respectively, with over half of the students coming from immigrant or refugee families. Families regularly brought lunch to their children and ate with them in the classroom.

Building off of previous scholarship on family engagement and scientific practices in elementary grades, I analyzed how families engaged with the activities which occurred both at the school and outside of the school in the neighborhoods. I drew out emergent codes to provide additional explanatory significance for the design elements of the family engagement activities and the responses of the families within those activities. After coding transcripts I looked for themes and patterns in the coded data that corresponded to specific designed elements present during particular activities. Particular combinations of conditions generated by the coding scheme and emergent themes led to opportunities that were more likely to result in meaningful family engagement with scientific practices.

Findings and Implications
