International Society of the Learning Sciences

Preface

With its 16th edition, the International Conference of the Learning Sciences (ICLS) continues its now-annual convening in tandem with the International Conference of Computer-Supported Collaborative Learning (CSCL). ICLS is pleased to join with CSCL as a part the 2022 Annual Meeting of the International Society of the Learning Sciences.

ICLS 2022 was set to be the second ICLS meeting held in Asia, following the 2016 meeting in Singapore. Unfortunately, ongoing pandemic travel restrictions in Japan required that conference organizers move the conference online, like those of the past two years. Nonetheless, there will be local events held in Hiroshima to celebrate the conference and its setting, the city of Hiroshima along the beautiful Seto Inland Sea of Japan. Hiroshima is of course a worldwide symbol of peace as the first city ever to suffer an attack with an atomic bomb. The Hiroshima Peace Memorial Park stands to remind us of the urgent need to advance world peace in its many forms--a need only more urgent in the current worldwide climate of inequities and the eruption of war. Hiroshima University's School of Education is also the site of the second oldest teacher education professional school in Japan, established in 1902. The virtual setting of this year's conference is an inspiration to advance our work linking education with advancing peace and justice.

ICLS 2022 invited contributions and embraced multiple and diverse perspectives focusing on theoretical, conceptual, design-based and empirical work for advancing our understanding of learning and how it can be promoted. The conference called for papers on (a) promoting diversity, equity, and justice in educational settings, (b) investigating innovative pedagogies, technologies, and learning environments, (c) elucidating theories and processes of learning and teaching, and (d) connecting research, practice, and policy. ICLS received overwhelming interest from the Learning Sciences community and related fields, with a total of 735 submissions, which we believe to be record high in ICLS history. All submissions were blind reviewed by at least 2 reviewers (for papers and posters) or 3 reviewers (for symposia); a senior reviewer wrote a meta-review for each submission synthesizing the reviews and feedback. In total, 33% of long paper submissions (110 of 329) and 38% of short paper submissions (82 of 215) were accepted in the same category in which they were submitted. Other papers were accepted in a different category as space allowed. Most of the 27 symposium proposals were rated very highly by reviewers and senior reviewers; space permitted acceptance of 17. The final submissions are published in the ICLS Proceedings featuring 17 symposia, 110 long papers, 200 short papers, and 198 posters coming from six continents and 35 countries. We believe that the number of papers to be presented also represents a record number at ICLS.

The content of the LS track covers a number of exciting contemporaneous topics, including computational thinking, teacher practices, STEM education, design-based implementation research, game-based learning, data visualization, epistemic practices, learning in virtual environments, equity and justice, knowledge building, emotions, and much more. We are proud of the way that scholarship within the learning sciences community reflects and explores the realities of our everyday world with an eye on making it a better place to live.

Organizing a high-quality conference is contingent on the entire Learning Sciences community. With the largest number of proposals ever submitted and accepted in ICLS's history, we are indebted to the painstaking work and generosity of 747 reviewers and 115 senior reviewers for making this conference program possible.

It has been our honor to edit this year's conference proceedings for the Learning Sciences community in ISLS. We hope you enjoy the conference and are enriched by your participation.

Clark Chinn, Carol Chan, Yael Kali & Edna Tan, ICLS 2022 Conference Program Co-chairs

Acknowledgments

ISLS Annual Meeting 2022 conference organizers would like to give special thanks to the following committees and people for their support:

- International Society of the Learning Sciences (ISLS)
- ISLS Board of Directors and Executive Committee
- Hiroshima Convention & Visitors Bureau
- Wallace Foundation
- National Science Foundation (NSF)
- Taylor & Francis Asia Pacific
- EasyChair Support Team
- Whova Support Team
- Gather Support Team
- Gyomu Toko Center
- Conference Organizing Committee including
    - LS and CSCL Program Committees
    - Social Media Communications Co-Chairs
    - Doctoral Consortium Co-Chairs
    - Early Career Workshop Co-Chairs
    - Mid-Career Workshop Co-Chairs
    - Interactive Tools and Demos Co-Chairs
    - Pre-conference Workshops and Tutorials Co-Chairs
    - Technology Support Committee
    - Online Conference Committee
    - ISLS 2022 Advisory Board
- Reviewers and Sr. Reviewers
- Best Paper Award Committees
- Conference Proceeding Copy Editors

On-line designs for supporting teacher epistemic communities: A comparative analysis.....131
Etan Cohen, Gideon Dishon, Adam Lefstein

"Learning Experiences, Technology, and No Grades" – What Students Expect from a Non-Formal Learning Setting Outside of School.....139
Valentina Nachtigall, Nikol Rummel

Developing the Systems Thinking and Computational Thinking Identification Tool.....147
Jonathan Bowers, Namsoo Shin, Linsey Brennan, Emmanuel Emil Eidin, Lynn Stephens, Steve Roderick

Exploring Students' and Mathematics Teachers' Conceptions About the Work of Mathematical Scientists and Possible Relations to Mathematics Teaching.....155
Ramona Hagenkötter, Valentina Nachtigall, Katrin Rolka, Nikol Rummel

Making Sense of Integer Story-Interpretation Problems.....163
Mahtob Aqazade

The aRithmetic Discourse Profile as a tool for mapping students' subjectifying and mathematizing discourse.....171
Einat Heyd-Metzuyanim, Michal Tabach, Avital Elbaum-Cohen

Designs for Grounded and Embodied Mathematical Learning.....179
Mitchell Nathan, Candace Walkington, Michael Swart

Implicit and Explicit Emotion Regulation for Conflict Resolution: Narrative and Self-Compassion as Anti-Bullying Training.....187
Sheenyoung Park, Dimitra Tsovaltzi

Navigating the Conceptual and Critical Demands of Data Literacy in High School Spaces using Firsthand Data..195
Noora F Noushad, Jooeun Shim, Susan Yoon

"With You I'll be Able to Actually Learn Everything": Exploring Learner Experiences With a 'Study With Me' Video.....203
Rabia Ibtasar, Cecilia M. Heineke, Joseph E. Michaelis

Attenuation and Amplification of Agency through Goal Announcements in a Makerspace.....211
Megan Goeke, David DeLiema

"Bringing New Things to Light": Examining a Process of Insight-Driven Teacher Learning.....219
Ethan Rubin, Elizabeth van Es

Introducing Authentic Datasets into the Biology Classroom: Teachers' Considerations when Designing Digital Instruction Units.....227
Carmel Bar, Bat-Shahar Dorfman, Anat Yarden

Learning in Practice Space Games.....235
Matthew Gaydos, Yj Kim, Peter Samuelson Wardrip, Jason Colombino

How the Shape of the Earth is Argued into Being.....243
Shelly Reisner Vain, Ilana Dubovi, Iris Tabak

Mapping Visual Marginalia in Educational Contexts: A Model for New Types of Self-Regulation of Learning....250
Nadia Dario, Luca Tateo, Kristine Lund

Actor-Network Theory as a New Direction in Research on Educational Dialogues.....258
Ehud Tsemach, Baruch Schwarz

Solidarity in Shifting Lines of Practice: Learning in the Weave of Social Movements.....266
Tanner Vea, Joe Curnow

Effects of Uncertainty Markers on Metacognitive Group Awareness and Regulation.....274
Anna Radtke, Lenka Schnaubert

The Way to Better Learning Online: Using Online Discussions in College Classes During COVID-19.....282
Jaeseo Lim, Ji Won Yang, Junho Lee, Jooyong Park

How Higher Education Instructors Conceptualize Diversity: A Phenomenographic Study.....289
Nicole A.Suarez, Song Wang, Stacey Brydges, Stanley Lo

Using Epistemic Network Analysis to Explore Discourse Patterns across Design Iterations of a Teacher Dashboard.....297
Amy Adair, Jessica Owens, Janice Gobert

Dancing with Data: Embodying the Numerical and Humanistic Sides of Data.....305
Kayla Desportes, Ralph Vacca, Marian Tes, Peter Woods, Camillia Matuk, Anna Amato, Megan Silander

ReviewAid: A Scaffolded Approach to Supporting Readers' Evaluation of Health News.....313
Eunyoung Ko, Yeonsu Kim, Juho Kim

Learning science while caring for pets: Findings from a virtual workshop for teens.....321
Priyanka Parekh, Joseph L. Polman, Shaun K. Kane, R. Benjamin Shapiro

Supporting Teachers' Concept Development Through Aggregation.....329
Grace A. Chen, Elizabeth Metts, Ilana Horn, Katherine Schneeberger McGugan

Constructing an "Us" in Teacher Work Groups: Affordances and Limitations for Learning.....337
Nicole Louie, Mallika Scott

Mobile Augmented Reality Supporting Community-based Learning: Families' Exploration of Land-Water Interactions.....345
Heather Toomey Zimmerman, Susan M. Land, Lillyanna Faimon, Yu-Chen Chiu,

Infrastructuring for justice: Reframing scale through a rightful presence framework.....353
Angela Calabrese Barton, Edna Tan

Guided Epistemic Expansion in a Science Classroom.....361
Sugat Dabholkar, Joshua Danish, Uri Wilensky

Zoom School Diaries: Caregiver Insights from Listening In on Synchronous Instruction.....369
Rose K. Pozos, Brigid Barron, Caitlin K. Martin, April Ball, Flora Troy

"Keep it in the Village": A 25-Year Journey of Collective Concept Formation Transforming Financial Practices in a Rural Thai Village.....377
Luis Morales-Navarro, Deborah A. Fields, Paulo Blikstein

Conceptualizing Three Approaches for Integrating Criticality in K-12 Computing Education.....385
Luis Morales-Navarro, Yasmin Kafai

Using Synthetic Knowledge and Interaction Analysis to Investigate Learning in a Collaborative Digital Climate Learning Experience.....393
Lynne Zummo, Eliana Massey

Shifting from "broadening" to "empowering": One community's perspective on changing the learning sciences.....401

"Everything that's hard got harder": Preservice teachers' attempts at rigorous and responsive instruction during online pedagogical rehearsals in the Covid pandemic

David Stroupe, PhD., Julie Christensen
dstroupe@msu.edu, jacris@msu.edu, Michigan State University

Abstract: At the onset of the COVID-19 pandemic, our teacher preparation program shifted to an online setting, disrupting a key feature of practice-based teacher preparation: Preservice science teachers' (PSTs) approximation of rigorous and responsive instruction during extended pedagogical rehearsals called macroteaching. Given this unplanned shock to their preparation, we examined how PSTs viewed macroteaching and their evolving participation in the teaching rehearsal. Using a situative perspective, we collected multiple forms of data. We found that while PSTs wanted to enact rigorous and responsive instruction, their participation was deeply impacted by the sudden shift to an online setting. Our analysis of video-recorded lessons confirmed PSTs' observations that their instruction became less rigorous and responsive over time. We conclude with questions about teacher preparation during the pandemic.

The title of the paper is a quote from a preservice teacher (PST) describing her experience as an instructor for an extended pedagogical rehearsal during a practice-based secondary science methods course. Noting the difficulty of teacher preparation during a typical year, this PST succinctly summaries the herculean challenge of learning to teach during the COVID-19 pandemic when the teacher preparation program necessarily and abruptly ended in-person methods courses and shifted to online instruction in March 2020. In our secondary science method course, the shift from in-person to online participation immediately disrupted a key feature of practice-based teacher preparation: PSTs' approximation of rigorous and responsive instruction during pedagogical rehearsals (Grossman et al., 2009). In these rehearsals, dubbed "macroteaching" by a former student (Stroupe & Gotwals, 2018), PSTs learn to provide students with opportunities to examine puzzling phenomena and construct evidence-based explanations (rigor) while noticing and attending to student thinking as they build a classroom community with students (responsiveness) (Thompson et al., 2016, see Literature Review for further descriptions). At the start of the 2020 semester, macroteaching resembled previous instantiations. PSTs were divided into four content groups (biology, earth science, physics, chemistry). The first two groups – biology and earth science – each completed a round of in-person macroteaching, which included the use of 10-12 course instructional hours for the rehearsal of one unit of content instruction taught to peers in the methods course. The physics group completed one in-person lesson in March 2020. Then, as COVID-19 forced the shuttering of the university, the PSTs requested to continue macroteaching online.

As teacher educators, we wanted to support PST participation, and as a class, we decided to continue macroteaching with the remining physics unit and the entire chemistry unit using the Zoom™ video teleconferencing platform . However, given this unplanned and unwanted shift in the context of the practice-based teacher education methods course, we became curious about how the PSTs viewed maroteaching and their participation when COVID-19 forced them online. In addition, we wanted to understand how PSTs' participation around rigor and responsiveness during marcoteaching, both as instructors and students, might be shaped by the online setting. We asked:

- How did PSTs frame the purpose of macroteaching when COVID disrupted the practice-based methods course?
- How were PSTs' participation in macroteaching, and their attempts at rigorous and responsive instruction, shaped by the sudden disruption of practice-based methods course?

Background and framing

As Kang (in press) argues, the field of teacher education struggles to design professional learning opportunities for teachers to take up rigorous and responsive instruction. We extend this concern to teacher preparation, and claim that more research to examine the opportunities for PSTs to learn about, rehearse, and receive feedback about their attempts to enact rigorous and responsive instruction. While we hoped that macroteaching might provide such a learning opportunity for PSTs, moving the methods course online fundamentally changed the dynamic of the class and the instructional episodes that PSTs enacted during macroteaching (See table 1).

Rigor

 © ISLS

While some people may have an image of rigor as extensive content coverage and difficult tasks to complete, we claim rigor is an emergent property of discursive classroom interactions (Thompson et al., 2016). We frame rigor as a collaborative effort to construct and revise scientific explanations, which is a central practice across scientific disciplines (See Table 1).

Responsiveness

Like rigor, defining and understanding responsiveness in teaching is difficult. Broadly, from the perspectives of teachers, responsiveness involves noticing, attending to, interpreting, and using students' ideas and needs to shape pedagogical actions (Kang, in press; van Es et al., 2017). For this study, we focused on two dimensions of responsiveness: building on students' scientific ideas, and encouraging participation and building classroom community (See Tables 2 and 3).

Practice-based science teacher preparation

Given the need for a better understanding of preparing teachers for rigorous and responsive instruction, some researchers have focused on supporting PSTs through practice-based teacher preparation. By practice-based teacher preparation, we mean a framing of teacher education that focuses on disrupting preservice teachers' images of disciplinary work and teaching, reimagining teaching through a lens of equitable instruction, and learning core teaching practices through multiple opportunities to rehearse teaching, and building relationships with students and their communities (Stroupe, Hammerness, & McDonald, 2020). Through scaffolded work on interactive practices that encourage principled improvisation, preservice teachers can learn the more interactive relational judgments required by the teaching profession.

Macroteaching

While a practice-based approach to teacher preparation provide a framework for supporting PSTs, teacher educators must design learning opportunities for PSTs to approximate instructional practices. In our methods class, we use "macroteaching" as a learning opportunity for PSTs to approximate rigorous and responsive instruction. Macroteaching takes place at a large Midwestern university, where PSTs participate in a five-year teacher preparation program in which they major (and minor) in a science discipline while fulfilling requirements for a teaching certificate. During the PSTs' final year of coursework, they participate in two sequential four-hour per week secondary science methods courses. Macroteaching involves groups of PSTs planning, teaching, and reflecting on eleven to twelve consecutive hours of instruction to their peers (approximating a complete unit of instruction) during methods class. During macroteaching, PSTs engage in five learning opportunities:

- *In-the-moment consultations.* The teaching team gathers (often in a "huddle") to discuss their immediate and upcoming instructional decision.
- *"Time-out/time-in."* A pause during instruction—called a "time-out"—in order to engage in immediate reflection about a recent event.
- *"Rewind."* At times, following the time-out/time-in or instructional coaching, a teaching team member requests an immediate opportunity to retry an interactive episode.
- *Question-and-answer session at end of each lesson*. During the final five to ten minutes of each lesson taught by the teaching team, the PSTs serving as students and instructors ask the teaching team to decompose pedagogical decisions they made during class, and inquire about upcoming lessons.
- *Teaching team debrief at the end of the unit.* The preservice teacher "students" and instructors ask the teaching team to decompose pedagogical decisions made during the unit, and to reflect on instructional opportunities they might shift in the future.

Learning to teach in virtual settings

While macroteaching usually occurs in person during our methods class, the COVID-19 pandemic forced the PSTs to enter a virtual setting (Zoom™) to continue their preparation work. When investigating how to engage in teacher preparation online, we encountered a dearth of research about learning rigorous and responsive teaching practices in virtual settings (though studies do exist – see Cohen et al., 2019, and Watkins et al., 2020 for examples). This study, then, adds to literature by examining how PSTs' participation shifted when attempting to teach in a virtual environment.

Theoretical framing

We used situative theory to address the complexity of examining how and why PSTs' participation might be shaped moving into an online setting. Situative theory is a hybrid analytical lens framing individuals' learning through their participation in activities that occur through interactions with actors, tools, and discourses of a context (Greeno, 2006). A situative perspective on PSTs' participation helps focus researchers' analytical lens to make sense of why PSTs' participation might be shaped by an online setting given the new norms and expectations for participation (see Fairbanks et al., 2010; Peressini et al., 2004; Putnam & Borko, 2000).

Methods

Design Experiment

Given the conceptual framework and dual roles as instructors and researchers, we viewed this study as a forced design experiment. By forced design experiment, we mean that outside circumstances (i.e., the COVID-19 pandemic) required fundamental changes to the original design of the methods course. In turn, we rapidly and simultaneously engineered particular forms of participation for our PSTs while engaged in a systematic study of that participation within the new virtual methods class context (e.g., Penuel et al., 2011).

Participants and Methods Class Context

The 15 participants, all undergraduate students majoring in a science field, were peers in a secondary science methods course we co-taught and framed around rigorous and responsive instruction. The participants self-identified as: 9 women (1 East Asian, 1 Iraqi-American, 7 White Americans) and 6 men (White Americans). The methods course in this study was the second in a two-course sequence. We met for four hours per week, two hours per class.

Macroteaching

Importantly, the PSTs wanted to continue macroteaching online when the university shut down in-person instruction. As a classroom community, we co-designed an action plan given the impending closure, and the two macroteaching groups that did not teach in-person (physics and chemistry – see below) requested to continue macroteaching in order to have the opportunity for the extended pedagogical rehearsal. We constructed the teaching teams based on disciplinary major and teaching interests. In addition, we assigned each team a typical disciplinary topic that they would likely teach during their teaching career. Below, we list each team with participant pseudonyms, their science topic, and the time frame that participants enacted each unit:

- Biology (Human impact on ecosystems): Mallory, Kurt, Tom, Pam. Taught in person from January 21 – February 4, 2020).
- Earth Science (Tides): Victoria, Matt, Michael., Andi. Taught in person from February 11 – February 25.
- Physics (Sound and waves): Xuexue, Jay, Edna. Taught one lesson in person, and the remainder online from March 10 – March 26.
- Chemistry (Acids and bases): Phil, Zoe, Shirin, Raven. Taught online from April 2– April 16.

Data Collection

We collected and analyzed multiple forms of data from four different types of interactive episodes: (1) requested or informal planning communication, (2) observations/video recordings of macroteaching, (3) participant-generated artifacts, and (4) two types of interviews. We selected these data sources for three reasons. First, we wanted to collect an array of data to better understand how and why we and the PSTs learned over time. Second, we needed multiple forms of data to examine how the PSTs' pedagogical reasoning evolved during important episodes of professional work – planning, instructing, and reflecting. Third, given our situated theoretical framework, we thought that the data sources could better capture episodes of participation as the PSTs engaged in instructional practices.

Data Analysis

In this section, we describe four interacting phases of data analysis: (1) developing and applying codes to the initial round of interview coding, (2), using a priori codes about rigorous and responsive instruction to analyze macroteaching instruction in the online setting, and (3) pattern finding and triangulating data. The first phase of the data analyses focused on developing a coding scheme. The coding scheme was initially informed by the literature on rigorous and responsive teaching, approximations of practice, and later by emergent themes from the data. For interviews, the coding scheme was debated and iteratively revised in weekly research meetings until we reached a consensus. We each coded a sample of data using the final coding scheme, identified areas of disagreement and refined the coding process over time. For coding instructional episodes (see below), we used observation instruments validated in a prior study (see Stroupe & Gotwals, 2018)). We examined teaching episodes, or "small, socially shared scripted pieces of behavior" recognizable across most classrooms (Leinhardt & Steele, 2005). In total we coded 77 episodes within the 18 lessons.

Findings

In this section, we organize the findings around three assertions. First, while PSTs wanted to participate in rigorous and responsive instruction during online macroteaching, how they framed the purpose of macroteaching reflected the sudden shift in the medium of interaction and the timing of the rehearsals. Second, all participants observed that their participation was shaped by the rapid shift to a new classroom setting. The PSTs serving as instructors noticed that they altered their enactment of instruction, and the PSTs serving as students engaged with their instructors and peers differently than they hoped during macroteaching. Third, our analysis of video-recorded macroteaching observations aligned with the PSTs' stated observations during interviews: The PSTs' words and actions became less rigorous and responsive as macroteaching progressed. All

quotes are taken from whole class debriefing conversations, planning communication, class activities, or interviews. Note that our analysis and claims focus on macroteaching that occurred in the online setting after COVID forced a drastic shift in the practice-based teacher preparation program. We do not compare in-person macroteaching to online macroteaching. However, the PSTs used their experiences during in-person macroteahing to make sense of the dramatic shift in context, and this study aims to both share their stories based on their words and actions, and to examine their attempts at rigorous and responsive instruction as they navigated a terrible situation.

In terms of rigor, the physics and chemistry instruction decreased from focusing on how and why a phenomenon occurred, to asking students to describe what happened during a phenomenon. By the end of both units, the instructors' became focused on students citing facts and definitions about a phenomenon, the lowest rating on our coding scheme for rigor. For example, the physics group initially pressed students to determine *why* radio telescopes on Earth received fast radio bursts at regular intervals from space. During the first lessons, the physics group provided students with opportunities to consider how observable features of the phenomenon related to unobservable features, and to justify their thinking with initial evidence and life experiences. However, as the unit progressed, the physics group became more concerned with covering content and ensuring that students stated correct information. By the end of the unit, the physics group shifted from a focus on 'why" to a "what" focus in terms of rigor. The chemistry group followed the same pattern: Beginning the unit with high rigor by asking students to explain why chemicals might make people sick, but over time, decreasing the rigor and hoping that students might be able to recall information about chemical reactions.

Similarly, responsiveness (in terms of "Responding to and building on students' scientific ideas", BSI, and **"**Participation structures and the building of a community", PART) decreased after initial attempts to create online classroom communities in which students felt safe and valued to share and build on each other's science ideas. In both units, students' initial science ideas that could have become valuable resources for the classroom community were elicited and publicized, but never again used by the teaching team. For example, in the chemistry unit, the instructors asked students about a phenomenon of people becoming poisoned by mixing household cleaning products. One student, Edna, eagerly shared her story of a similar experience in the university chemistry laboratory in which she mixed chemicals, caused a potentially toxic gas to be created, and was decontaminated by the university fire patrol. This story triggered memories from other students who were in the chemistry building that day, recalled the evacuation, and wondered how a chemical reaction could clear out an entire campus building. Edna's story had the potential to shape the instructional team's unit, and during the first lessons, the PSTs engaged in features of responsiveness that rated highly on the coding scheme. By the end of the unit, however, the chemistry team "forgot about Edna story" (Phil), and instead focused on content coverage. Thus, our analysis of classroom videos aligned with PSTs' observations that their attempts at online macroteaching decreased in rigor and responsiveness over time.

Given the decline in rigor and responsiveness during macroteaching, PSTs also noticed that student talk decreased during macroteaching. Our analysis shows that instructional teams may have contributed to the decline by enacting instructional episodes that provided fewer opportunities for student talk. Specifically, we found that episodes that might promote talk, such as whole class conversations, became less frequent over time. In addition, episodes types that might limit possibilities for talk, such as content injection and seat work, increased in frequency during macroteaching Some episodes that might promote talk, such as small group conversations, were enacted across macroteaching lessons. While such episodes remained consistent in terms of frequency of enactment, the decrease in rigor and responsiveness of the episodes limited opportunities for talk, thus shaping student participation. Importantly, the PSTs' observations and instruction aligned: A decrease in rigor and responsiveness (especially in terms of BSI and PART) indicates that students had fewer opportunities to talk about science ideas, which is the phenomenon reported by the PSTs in interviews.

Discussion

This study occurred in the midst of a global pandemic that forced PSTs into an online setting, requiring them to make pedagogical decisions that they never anticipated, nor as they noted, ever wanted to make. As the course instructors, we wondered how the PSTs' participation in an extended pedagogical rehearsal – macroteaching – might be shaped by the new online setting. In this section, we make sense of the findings by noting that while the online setting constrained PSTs' participation, in another way, the online setting helped strengthen their desire to enact rigorous and responsive instruction because they experienced teaching episodes that limited their opportunities to learn with and from each other's ideas.

Rigor and responsiveness decreased

As noted in the findings, the rigor and responsiveness of instructional episodes decreased over the two macroteaching units taught online. Student talk became less frequent, teacher talk increasingly resembled Initiate-Response-Evaluate (IRE) discourse aimed at moving a conversation in the teacher's direction, and the

overall science talk became more focused on facts than on explanatory conversations about phenomena in the units. Thus, the cognitive demand of the class decreased (Michaels and O'Conner, 2012), even though the online setting was in place for half of the macroteaching units. While PSTs attempted to support conversations in which students might engage in rigorous and responsive activity, the reduction in participation constrained opportunities to hear and use students' ideas as resources to shape instruction. Subsequently, instruction resembled "delivery pedagogy" (Stroupe, 2016), in which the teachers are the sole knowledge authority their focus remains on controlling the classroom and covering curriculum (Duschl, 2008).

Using a situative perspective, we offer a two-pronged explanation that emerged from the data for the reduction in rigorous and responsive instruction over the course of macroteaching online. First, PSTs' engaged in pedagogical reasoning while simultaneously making sense of a new and rapidly changing setting. While the PSTs expressed disappointment that their participation dwindled and that their instruction drifted away from rigorous and responsive instruction, they understandably made participatory decisions that focused on surviving and accepting the online teaching rehearsal. The online setting required PSTs to question their initial instructional goals, and they subsequently made decisions based on their interpretation of possibilities. PSTs could simultaneously envision how they wanted to participate based on their experiences in-person, but still chose to think and act in ways that decreased rigor and responsiveness over time citing the online medium as the cause of their dual thinking.

Second, PSTs explicitly described how the online setting limited opportunities for using students' ideas and experiences as resources to shape instruction, which is a hallmark of rigorous and responsive instruction. PSTs lamented that the online setting limited how much time they could provide students to talk, engage in activities, and make sense of puzzling phenomena, and thus, they heard less from students over time. Without students' ideas available PSTs resorted to information delivery in the hopes of covering content deemed important during planning sessions. Even when students shared experiences that were immediately relevant to the unit (such as Edna's story about the chemistry lab evacuation), such ideas were rarely elevated to the public plane of talk at the whole-class level, or were lost in the chaos of online instruction. While online settings provide spaces for students' ideas to exist, PSTs often used such spaces as storage sites rather than inscriptions to be leveraged for later lessons. Again, PSTs frequently noted they wanted to use student thinking as they encountered during macroteaching in-person, but their reasoning about survival and enduring led them to make instructional decisions that limited the elicitation and use of students' ideas.

PSTs' participatory opportunities changed

Given PSTs' decisions to survive and accept the limitations of the context, their participatory opportunities changed for two reasons from a situative perspective. First, PSTs felt unable to use the learning opportunities embedded in macroteaching, such as time-outs and group consultations. Prior to moving online, PSTs serving as instructors witnessed the five learning opportunities embedded in macroteaching, and observed how their peers' participation was aided by the opportunities. In the online setting, however, PSTs expressed frustration because they felt limited in their learning opportunities in the online setting, especially after watching the biology and earth science groups engage in the reflective teaching during in-person macroteaching. PSTs, then, made decisions to survive and endure online macroteaching at the expense of more time-consuming but beneficial learning opportunities they observed in-person.

Second, as Philip et al. (2019) note, teaching practices are inherently relational. As the PSTs noted, the relational work of online instruction seems different than the possibilities for building and growing relationships in-person. In the online setting, PSTs serving as instructors could not engage in hallmarks of rigorous and responsive instructional practices that emphasize relational work such as providing daily opportunities for students to reason through productive talk and making student thinking public and subject to consideration by the classroom community (Engle & Conant, 2002; Lehrer & Schauble, 2006). Unlike in-person macroteaching, PSTs attempting online instruction did not prioritize relational work, which ultimately limited opportunities for students participation.

Tension between desired and enacted instruction

Given the decrease in rigorous and responsive instruction, and the reduction in PSTs' participatory opportunities, we worried that PSTs might begin to express an interest delivery pedagogies, or would become disenchanted with teaching. However, all PSTs reported that participating in an online setting helped strengthen their desire to enact rigorous and responsive instruction because they experienced teaching episodes that limited their opportunities to learn. Further, PSTs realized there was striking difference in their participation as instructors and students in-person or in online settings, and they vehemently expressed frustration that they could not enact instruction that aligned with their developing vision of from rigorous and responsive instruction.

The tension expressed by the PSTs between the instruction they wanted to enact and the instruction that occurred during online pedagogical episodes is not unique to this study. Teachers, regardless of setting, make

pedagogical decisions during planning and in-the-moment with students that reflect a constant conversation between a personal vision of instruction and learning and a context's implicit and explicit messages about what counts as success. The PSTs in this study made the decisions they felt necessary to "survive" and "cope" given the rapidly changing participatory circumstances. They balanced immediate needs of engaging in a pedagogical rehearsal in a drastically different setting with long term goals of learning to teach. Importantly, their vision of teaching that they wanted to enact remained unchanged, even as rigor and responsiveness of the instruction declined. The PSTs recognized that they could enact better instruction, and given a different setting that allowed for in-person interactions, they felt confident that they would make different pedagogical decisions that resulted in rigorous and responsive learning opportunities.

Conclusion

We are left with two lingering questions for the field to consider about practice-based teacher preparation and supporting PSTs as they learn about rigorous and responsive instruction. First, can online settings support practice-based teacher preparation? Second, will PSTs be more likely to push themselves to enact rigorous and responsive instruction during their first years of teaching? Will they be more attentive to student participation since they noticed how instruction and participatory structures are linked and can decline rigor and responsiveness in tandem?

Table 1. Forms of Explanatory Rigorous Talk.

1 **Definitions without epistemic features**	2	3	4 **Fully theorized science explanations**
Explicating definitions. Talk is about facts, procedures, equipment. Emphasis is on static entities (i.e. defining forces, evolution, etc.).	Offering descriptions or observations of a phenomenon – "what" you can see happening. OR talking about recording data about a phenomenon – what could be measured or recorded. When describing a correlation between variables – the emphasis is on "what" happens to X when Y is changed. Talk about unobservable ideas is in the form of vocabulary and is not specifically linked to the phenomenon under investigation.	Explaining "how" a phenomenon "works"—in one of 3 ways: 1) Talking about "how" a phenomenon is part of a larger process, 2) Talking about simple cause-effect relationships between two observable features of a phenomenon – simple correlation/ causation, or 3) Talking about what is happening on an unobservable (i.e. molecular) level but this is only tangentially linked to observable events.	Explaining theoretical underpinnings for "why" a phenomenon happens in the form of talking about scientific theories, models, laws [either standard ones or student-generated ones] that go beyond simple cause-and-effect relationships. Observable features of the phenomenon are broken down and underlying unobservable processes or entities are used as evidence for the theory or model.

Table 2. Dimension of Responsiveness: Responding to and building on students' scientific ideas

Features of Scientific Thinking/Talking in Classroom Discourse			
	Responding to individual's utterances (1.x)	*Responding to multiple students' answers (2.x)*	*Responding to multiple ideas in the community (3.x)*
Re-voicing ideas (x.1)	1.1. Teacher responds or re-voices students' science ideas, recognizing the students' contributions and providing feedback on students' ideas (1 student or multiple students) VERSION B: T. asks students to clarify their idea before doing the above moves (1.1b)	2.1. Teacher adopts a student word/idea as a part of the ongoing classroom discourse to build towards a scientific word/idea. Teacher might also show student work to the rest of the class.	3.1. Teacher and students re-voice ideas or use other students' ways of talking about science ideas.
Responding to content (x.2)	1.2. Teacher collects multiple students' ideas and stitches students' ideas together	2.2. Teacher encourages students to respond to one another's science ideas (i.e. juxtaposing or weaving students' ideas by clarifying which ideas need to be added to). T. adds "filler" (such as, "and", "because") words to support students in building on one another's ideas. Students do not just state ideas independently. Students use additive language in which they make arguments for claims that become more sophisticated over time, raise new questions, recognize a confusion, or made a new connection among ideas.	3.2. Teacher and students respond to partial understandings of others and both build on and critique the ideas.

Highlighting concepts (x.3)	1.3. Teacher highlights important contributions students make OR T. tacks on new pertinent content to s. idea toward the construction of an ideal/ normative scientific explanation	2.3. Teacher tracks and recounts to students their ideas that can be used to co-construct a scientific explanation (in small groups teacher tells students which of their ideas they need to stitch together, in whole class teacher tracks piece by piece students' contributions or draws attention to a part of an explanation students are struggling with).	3.3. Teacher tracks how students are formulating scientific ideas. Teacher encourages students to explore and build their own scientific ideas (explanatory flexibility). Non-normative forms of science talk are worked with on a public plane to elaborate and challenge known science ideas.
Reflecting on scientific practices (x.4)	1.4. Teacher tells students about conventional ways scientists represent ideas.	2.4 Teacher helps students distinguish characteristics of good scientific explanations and arguments from forms of talk in every-day language.	3.4. Students discuss what counts as good explanations and argumentation and distinguish from everyday talk. Students create hybrids between naturalistic ways of talking and following discursive norms in science.

3. Dimension of Responsiveness: Participation structures and the building of a community

Features of Scientific Thinking/Talking in Classroom Discourse			
	Responding to individual's utterances (1.x)	*Responding to multiple students' answers (2.x)*	*Responding to multiple ideas in the community (3.x)*
Soliciting student participation (x.1)	1.5. Teacher encourages student participation (teacher asks to hear multiple students' ideas, and asks students to listen to one another)	2.1 Teacher encourages students to respond to other students' ideas (generally, not science specific). Teacher (verbally or non-verbally) asks *each* student to contribute a thought or response to another student. Students make bids for other students to participate.	3.1 Students invite participation from classmates and refer to one another without intervention from the teacher (reversing authority).
Animating and reinforcing norms for participation (x.2)	1.2 Noticing the need for classroom participation norms	2.2 Teacher reflects with students on how classroom norms are being enacted in classroom conversations OR T. consistently reminds students of his/her high expectations for student participation ("I am expecting great things from this table").	3.2 Teacher and students reflect on how norms are supporting conversations.
Using status treatments for equitable participation (x.3)	1.3 Teacher attempting a status treatment (for example assigning participation roles, or using popsicle sticks to call on individual students for answers).	2.3 Teacher uses status treatments to invite more students to share/ hear ideas with one another (i.e. jig-saw activities that position students as knowledgeable when sharing information with classmates).	3.3 Teacher employs status treatments that change how dominating/not dominating students interact with one another by increasing the number of participants and the range of ideas up for discussion (i.e. structured turn-and-talks that elaborate students' causal hypotheses).
Labeling the purpose of participation as building a classroom and/or scientific community (x.4)	1.4 Teacher makes statements about being a good participant, listener.	2.4 Teacher draws parallels between classroom & places where scientists work; students are "like" scientists.	3.4 Students are recognized for legitimate participation in authentic science conversations or debates, critiquing one another's ideas and legitimized science ideas. Students' ideas and forms of participation are marked as contributions to science.

International Society of the Learning Sciences

From participants to creators: Considerations for community-led citizen science

Abstract: There is a plurality of opinions as to what citizen science looks like. We adopt a community-led approach and argue that enabling communities with no or limited science expertise to engage with designing their own scientific investigations is a means to democratising research. To understand the requirements for this form of community participation, we surveyed 150 participants of nQuire - a web-based solution that scaffolds the research design process - and identified factors that enabled and inhibited non-researchers from participating in research. Participants acknowledged the importance of taking part in scientific studies and reported learning benefits in terms of increased awareness and behavioural change. The majority of participants expressed interest in joining studies in the future, yet reported that they are rather unlikely to create their own investigations due to a lack of time, skills and support needed. Implications for the design of community-led citizen science are discussed.

Introduction

Researchers have been engaging the general public or non-researchers, with research activities for years. Many used to refer to, and treat research participants, as passive agents or "subjects" of research. In 1998, an advisory board from the National Health Service (NHS) in England moved away from the term "subjects" and replaced it with "participants", encouraging researchers to abide to a *"firm commitment to involving consumers in research—not as "subjects" of research, but as active participants in the process of deciding what research should take place, commissioning research, interpreting the results, and disseminating the findings"* (Boynton, 1998). Since then, the direct involvement of people with scientific or research activities is found to vary. Under the banner of Citizen Science (CS), we have seen the public collecting or processing data to support research activities led by scientists such as making or transcribing biodiversity observations. In other cases, it is involved in other aspects of the research processes like negotiating and deciding on what to study, how to collect and analyse data, or contribute to reports and publications (Shirk et al., 2012; Haklay, 2013).

Recently a further shift in terminology has been observed. Participation in CS is referred to as Community Citizen Science (CCS). There is a growing emphasis on bringing together communities to examine personally relevant and authentic topics and identify solutions that best match local needs (Audubon Center, 2018; Herodotou et al., 2021). The participation of the public in research has been viewed as a means to promote inquiry learning and critical thinking (Herodotou et al., 2017) and develop agency to solve global societal issues such as sustainability challenges (Sauermann et al., 2020). In this paper, we build on this definition to argue that CCS or community-led CS is a methodology that can *democratise research* by opening up all the stages of the scientific process to communities and individuals and allow the public to understand, get motivated and take part actively in these processes. This is not a straightforward endeavour; it requires capacity building in research institutions and organisations in order to change established perceptions and practices of how participants engage and support research, while at the same time, empower communities through, for example, appropriate training and technological tools, as to how to contribute or pursue their own research agendas in ways that are scientifically and ethically robust and thus acceptable by the research community.

Amongst the challenges reported when initiating or conducting a CCS project are the financial viability of the project, concerns about the quality of data, a lack of integration with learning, time demands to plan for such a project, and little appreciation in academia and policy (Hecker et al., 2018). There is often a lack of time and resources to design a project well, promote it and establish communication channels with participants, while technological skills are often needed for running it. On the other end of the spectrum, there are concerns about the accuracy of data collected and whether sampling is representative and sufficient. Technological development and innovation can be a means to overcome some of these challenges including having volunteers designing their own projects, communicating project findings during and after the project ends and sustaining engagement with participants, using web-based tools. In particular, at The Open University UK, we have developed a web-based platform - the nQuire platform (nquire.org.uk) - for managing the research process from start to end. Our intention is to enable non-researchers to become active creators of research and take control in defining and pursuing their own personally-relevant research agendas, with support from technology and research experts.

 © ISLS

In this study, we surveyed 150 nQuire participants who had taken part in at least one nQuire study in the past. None of them was involved in designing or managing their own study. Our motivation behind this work was twofold: the anecdotal observation that individuals with limited or no scientific background were less likely to show interest in setting up a study on nQuire, and the very low response-rates accompanying completion of online research (e.g., surveys). Therefore, in this study, we aimed to identify the factors that facilitate or inhibit (a) participation in scientific research as led by scientists and (b) intention of participants to create and lead their own research. In particular, we identified motivations of taking part in nQuire studies including any learning benefits, and sought participants' future intentions to participate and create their own studies. In the next section, we describe a learning-oriented theoretical framework this line of work is drawing from.

Theoretical background

Community Citizen science (CCS) shares similarities with Community-Based Participatory Research (Tremblay et al., 2018) in the sense that participants and researchers are perceived as equitable partners who are engaged in all the stages of scientific work with the aim to benefit communities and bring desirable change and development. What is unique in our approach to CCS are: (a) an emphasis on large-scale research, stemming from traditional conceptions of citizen science as a crowdsourcing activity, and (b) an explicit focus on facilitating participants' life-long learning and development. The former points to the engagement of the public with research at large-scale; this can be enabled by web-based technologies and tools that facilitate participation in research. Large scale research has the potential to engage more and diverse voices with research (especially when appropriate sampling processes are adopted), while it can be particularly suitable for pursuing research with communities that are not geographically bounded but defined by common problems or common interests. The latter refers to a learning-oriented approach to understanding and structuring engagement with research, which we coined as Community Inquiry (Herodotou et al., 2021). Community inquiry refers to participation in research through engagement with inquiry learning processes. Drawing from Bloom's taxonomy (Anderson et al., 2001), community inquiry can be structured upon the following learning objectives, through which participants can be guided to design their own investigations: (1) identify or recall an issue of interest or concern, (2) understand this issue through explanations and interpretations that result in defining specific and measurable research questions, (3) apply specific methods to answer these questions, (4) collect and analyse data emerging from these methods, (5) evaluate findings and the degree to which they answer given research questions and (6) create reports, publications, social media content for sharing findings. Scientists and technology are seen as an integral part of the process of design; scientists should scaffold communities to meet the above learning objectives, for example, by sharing expertise about the pros and cons of specific methods of data collection or discussing limitations of a given method of data analysis. Technology could help communities author their studies, collect and access data, and disseminate findings. In the next section, a technological solution designed to scaffold community-led research is described.

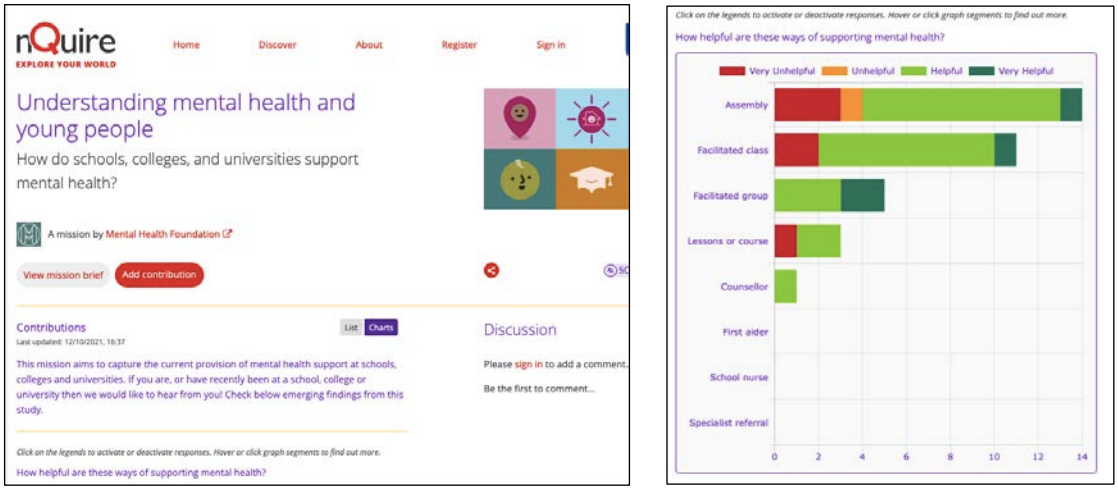
A technological solution for community-led citizen science

The nQuire platform (nquire.org.uk) has been designed with support from the Open University/BBC partnership in an effort to engage the general public with scientific work in ways that support their interests, learning and development. It has been iteratively designed by educational experts and in close consultation with end-users following principles of design-based, participatory research (Herodotou et al., 2018). nQuire enables communities or individuals to, either take part in scientific investigations designed by others, or be guided to design their own, personally relevant studies.

In terms of the former and as a means to support learning processes, participants receive *immediate* feedback: (a) after submitting their responses to an investigation (called a *mission*) in the form of narrative (text) informing them about issues related to the investigation they took part in and suggesting further relevant readings and studies. Also, they can receive *personalised* feedback based on their responses to specific questions, for example, the degree to which they can identify misinformation in news or get recommendations about how creative activities can improve their wellbeing, and (b) when visiting a mission in the form of data visualisations (interactive graphs of collected data) (See Figure 1) and reading, commenting and liking other people's actual responses to the mission questions. We perceive this as a means to open up the process of data analysis to the public and re-engage people with missions more than once, as they can revisit the mission at any time and observe how emerging findings are changing the more people take part in a study. In addition to this and following existing guidelines (Tweddle et al., 2012), the benefits from taking part in a mission are clearly communicated to participants and stated in the mission brief. Similarly, experiential learning or physical practice - shown to be effective in supporting learning processes (Alhajri et al., 2018) - is promoted by asking participants to complete

hands-on activities for data collection such as taking photos of nature, and measuring temperature and growth of trees.

Figure 1 A nQuire mission providing immediate access to data findings



Two mechanisms support participants in designing their own scientific investigations and taking control of the research process: (a) technology and (b) collaboration with scientists. The first mechanism is an authoring tool that guides the process of designing, testing and iterating a study through a series of steps including instructions about how to set up a "Big question", selecting different types of questions that enable the collection of text, image, map location and sensor data, enabling personalised feedback in the form of text or visualizations, piloting functionality (any data collected during piloting are deleted when the mission goes live), and downloading data collected after a mission goes live on nQuire (more details about the functionality of the authoring tool can be found in Herodotou et al., 2021). Participants can choose to create or take part in (i) confidential missions in the sense that all responses are private; anonymised data files can be accessed and downloaded by a mission author only, or (ii) social missions where all responses are open to the public to read, comment and like.

The second mechanism that scaffolds participants when creating their own investigations is a thorough process of review and approval led by Open University scientists that ensures the scientific and ethical quality of proposed studies (Herodotou et al., 2021). OU researchers communicate with mission authors to review, provide constructive feedback and suggest improvements to proposed investigations in ways that are scientifically valid and ethically correct. The process of approvals includes reviewing aspects of the mission such as the language and structure of the mission, ethical considerations, originality, copyrights, piloting and ensuring authors share interim and final reports with findings with their participants via nQuire (Herodotou et al., 2021).

The majority of missions on nQuire have been designed by academics or researchers affiliated with universities in the UK. Other missions have been designed by organisations such as the Mental Health Foundation, the Young Foundation, BBC Springwatch and BBC Weather, and the Royal Meteorological Society. One mission has been designed by an individual with research expertise and interest in engaging communities with research. These insights suggest that organisations with research expertise and/or interest in doing research and engaging with the public are those likely to use the nQuire authoring tool and initiate their own studies. The question raised is how we can engage individuals and communities with limited or no research expertise and interest in scientific investigations with the process of designing and implementing a scientific investigation.

Community-led research is timely; communities are better aware of where problems in their communities lie and have a vested interest in finding solutions (Whittle et al., 2012). Societal challenges such as sustainability transitions towards for example renewable energy use could be better addressed if communities were engaged in the problem definition and the framing and generation of potential solutions (Sauermann et al., 2020). Proposed solutions would be owned by communities and thus more likely to be adopted and applied in sustainable manners, as opposed to being imposed by research and policy experts. The online implementation of nQuire and the catering for large-scale research mean that concerns about sampling and reliance on small, atypical samples (Weigelhofer, & Pölz, 2016; Whittle et al., 2012) can be addressed as, with appropriate advertisement strategies, different populations can be reached. Also, nQuire visualisation tools enable awareness of the locations data are collected from that can inform promotion interventions to increase geographical sample representation. We acknowledge

that access to technology and the internet relate to persistent socioeconomic inequalities (Fiske et al., 2019) that may exclude certain populations from accessing the benefits of community-led research and these should be examined further and addressed. In this study, we consulted participants of nQuire missions in an effort to understand the factors that enable or inhibit this cohort of individuals from taking part, creating and pursuing their own scientific investigations.

Methodology

Survey questions were hosted in the JISC online survey platform. We asked participants to state the number and type of nQuire missions they took part in, their motivations for taking part in these missions including any learning benefits (to understand the reasons why people engage with scientific work) and their intention to take part and design their own study in the future. We emailed participants who took part in a scientific investigation or mission during the last year, and who had indicated at that time that they consented to be contacted about future studies. Closed questions were analysed using descriptive statistics (summary graphs and tables), while open-ended questions followed principles of thematic analysis (Kvale, 2007), capturing and reporting diverse voices and perceptions. We received responses from 150 participants. Participants were over 16 years old, as per the age limit for using nQuire. This research project has been reviewed by and received a favourable opinion from the Open University's Human Research Ethics Committee.

Results

The vast majority of respondents took part in one mission only (85%). Ten people (6.67%) indicated they had participated in two missions, six (4%) in three missions, a further six (4%) in 4-5 missions, and one person stated they had been involved in 11 or more missions. The topic of the missions participants took part in varied. As shown in Table 1 below, a majority took part in missions related to the environment including birds, pollinators and gardens. 20% of participants took part in literature-related missions and 12% in climate-related missions. Participation in missions was influenced by a number of factors including the range of mission topics available at a given time on nQuire as well as the degree of promotion of each mission. For example, the Gardenwatch missions were promoted by the BBC during the Springwatch 2019 TV series and reached more than 230K contributions.

Table 1
Number of participants and content of missions

Topic of mission participants took part in	Number and % mentioning (where 100% = 138)
Birds, pollinators (e.g., bees), mammals, worms	50
Therapeutic value of sounds of nature	7
	Total: 57 (41%)
Novels, literature, characters	27 (20%)
Climate related (heatwaves, climate anxiety)	17 (12%)
Covid-19 related	12 (9%)
Cognition/memory/sound	6 (4%)
Astrobiology	1
Chronotypes	1
Online teaching and learning	1
Others (participants could not recall or were unsure about the name of the mission)	14 (10%)

The main motivation for taking part in a scientific study on nQuire was to contribute to research and science (59%). A number of other participants participated because they believed that helping with science is

important (13%) or had an a priori personal interest in the topic of the investigation (11%). 10% wanted to learn more about the topic of the investigation, 5% wanted to experience what is like to participate in a CCS project and 3% stated other reasons.

In terms of learning in particular, a substantial number (43%) said that there was no change in their knowledge and explained that by (a) not remembering a lot about the mission they took part in and this inhibited them from being able to reflect on their learning, (b) previous knowledge about the topic: "*I'd already learned to recognise different species of bumblebee, but the project just wanted "bee" or "butterfly"*, and (c) not being informed about the findings of the study: *"Haven't heard any results"*. The latter stresses the important role of sharing findings with participants during and by the end of a project that can support their learning.

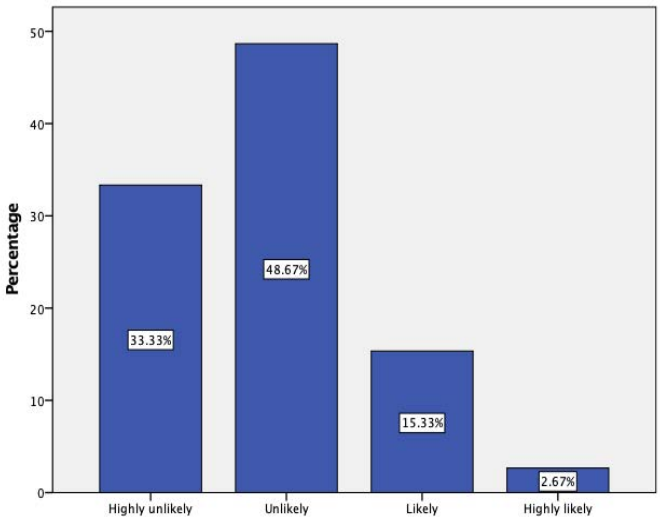
A majority of 48% said they know a little more about the topic of the mission, and 8% a lot more about it. Those participants reporting changes in their knowledge in terms of (a) increased awareness about the topic: *"I have become more aware of the diversity in my garden"* (Participant 1); *" questioning as to how a particular book has influenced/affected me on various levels, e.g., perception challenged, emotional response, escapement from the everyday, stimulated interests/new ideas, etc."* (Participant 2), *"Aware of what plants are likely to benefit insects and keen to make my garden more insect and pollinator friendly*" (Participant 71*).* (b) desire to learn more about the topic: *"The knowledge I gained has given me a desire to find out more through books. I would like to be involved with gaining practical knowledge especially with identification"* (Participant 13). (c) a change in everyday habits: *"To listen to more ambient sounds while out walking and not just plugging my headphones in. This has led to my walks making me feel more productive and calm." (Participant 32), "It was good to actively look at the environment of my garden and observe the insect life closely, I enjoyed the opportunity to slow down and take the time needed to identify then photograph the individual species...this is something I will do again. I actively garden for the benefit of wildlife anyway but this survey helped me understand the benefit of that on a more visceral level" (Participant, 20),* (d) taking action to support biodiversity: *"It led me to read up on helping pollinators and providing habitat in my garden"(Participants, 44), "I set up an Instagram account and posted photos on the [mission name] it encouraged me to take part in other surveys." (Participant, 83).*

A great majority of 89% expressed an intention to take part in future missions, stating that this is likely or highly likely to happen. 11% stated that this is unlikely. Their follow-up explanations showed that, such an action would depend on (a) a personally relevant research topic: *"If something was of interest to me I would participate" (Participant, 102)*, (b) time and effort required to take part: *"If I get invited and have time while the Mission is open then I probably would take part, especially if it's short and can be done at any time." (Participant, 54), "depending how many questions i need to answer" (Participant, 67),* (c) a general motive to help with science: *"If it helps with furthering scientific research"* (Participant, 134), (d) prior expertise in research: *"Volunteer entomologist, survey invertebrates. Volunteer in a research group at London NHM for many years. Record garden birds for BTO. Have MSc in Biological Recording." (Participant, 139),* (e) the possibility for unexpected discoveries: *"Finding something unusual would prompt me to take part unsolicited." (Participant, 87),* (f) having their voices heard: *"It is a way of having my understanding heard by someone relevant, rather than the rubbish from the media" (Participant*,103) (g) general interest in taking part in research: *"always happy to take part in surveys" (Participant, 122), "I love taking part in questionnaires and surveys. I am passionate about literature and reading" (Participant, 79).*

As shown in Fig. 2, only a small percentage of participants expressed an intention to design their own missions in the future and this was explained by (a) having the skills or competence to do so: *'I do this stuff off my own interest already' (Participant. 13), 'I'm a postgraduate social scientist, and I have a lot of interest in doing my own research. Some of it is unlikely to be properly funded through but it would still be interesting to do some surveys and have a go with it.' (Participant, 51),* and (b) having significant prior knowledge about the topic that can help them in designing a mission: *'Having expanded my knowledge on the importance of such a wide variety of pollinators I am wanting to survey a 1.75acre traditional hay meadow to establish how it is used by pollinators and other wildlife so decisions on future management and how it can be improved for wildlife can be made.' (Participant, 77).*

A large percentage of participants (83%) considered it unlikely or highly unlikely they would create their own study. Amongst the reasons given for this were (a) a lack of time: *"Lack of time to design, analyse and make useful use of the data" (Participant, 45),* (b) a lack of knowledge and skills: *"I would not have the knowledge of how to do this" (Participant, 61), "Not qualified" (Participant, 24), "I don't really have a suitable topic for inquiry" (Participant, 73), "I'm not that inventive to establish a project" (Participant, 81),* (c) a lack of support: *"I just don't have the type of work environment that would warrant me embarking on such a project" (Participant, 133)*, and (d) a lack of awareness that this is possible: *"I wasn't aware it was possible" (Participant, 101),* and (e) creating a project is not for the general public: *"why should I?"(Participant, 22), "There is no reason why I should (this is an odd question)" (Participant, 109).*

Figure 2 Likelihood of creating your own study in the future



Discussion

In this study, we surveyed 150 participants who took part in research studies or "missions" hosted on nQuire - a community citizen science (CCS) inquiry platform. The majority of participants participated in one mission, yet they reported an interest in taking part in more missions in the future. Half of them reported learning benefits after taking part in a mission expressed, as in other studies (Herodotou et al., 2020) in knowledge improvement, in particular increased topic awareness and a desire to learn more about the topic under study. Some responses revealed evidence of identity change or agency (Ballard et al., 2017) including changes in everyday habits and taking action to support biodiversity initiatives after taking part in a mission. Participants who did not report any learning benefits were either already knowledgeable about the mission topic or they had not been informed about the project findings, stressing the importance of sharing findings with participants and validating them as genuine contributors in research, as this could promote learning, and the value of accessing collected data and project findings (de Vries et al., 2019). Showing the personal and societal benefits of a study "constitute an effective informational nudge" that was shown to motivate further participation and increased awareness about environmentally-related topics (Cappa et al., 2020). Some nQuire missions related to literature, Covid-19 and pollinators have shared findings with participants, yet others have not done so yet and this may explain why some participants raised the need to access findings. These insights have informed the nQuire process of approvals which now requires authors to upload interim and final reports with findings to the platform as a means of providing feedback to participants and facilitating engagement. Participants receive email alerts when findings are available.

Aligning with existing studies (Jennett et al., 2016), the main motivations for taking part in a mission were to contribute to scientific research, the importance of helping with research, an *a priori* personal interest, and curiosity expressed in a desire to learn more about the topic. Participants' intention to participate in future missions was explained by multiple factors including (a) some of the aforementioned motives such as a desire to help with science and a personally relevant topic, (b) practical reasons including time and effort needed to take part in a mission, favouring short investigations, (c) prior research expertise that could help a mission, (d) the possibility for unexpected discoveries, and (e) to share personal opinions and have their voices heard.

As reported by participants, the transition from participating to creating scientific investigations is not a straightforward one; we observed a great majority of participants reporting that it is unlikely or highly unlikely that they would create their own mission. Amongst the factors explaining these perceptions were a lack of knowledge and skills for designing a study, a lack of support, and a lack of time. Of special interest is the fact that some participants were not aware that it is possible for them to design a study or could not see the value or benefit of having themselves doing so. These findings suggest that the shift from *participants* to *creators* necessitates concerted efforts in order to, first, raise awareness about the role communities and individuals can play in decision making and how their participation can contribute to solving societal problems in ways that best meet their needs. Second, training resources and tools are needed to support skills' development, scaffold the process of design, and lead to designing robust and ethical scientific investigations. Online platforms such as nQuire can support the process of designing personally meaningful projects by making explicit the design process through a series of steps and collaboration with scientists, whereas the provision of immediate feedback to participants after taking

part in a study and data visualisations allow for ongoing feedback that can support learning and motivate further participation.

Conclusions

One of the limitations of this study was the timing of the survey circulation as some participants had difficulties to recall the specific study they took part in and accurately report on its impact. Future studies should time such assessment close to when a study has been completed or embed questions assessing e.g., learning, motivation in the design of a study. Also, a single CCS platform, nQuire with specific design affordances has been studied. CCS platforms with different functionality are likely to promote other forms of community-led research, focusing on specific stages of the scientific work. For example, Zooniverse can scaffold the process of data analysis by enabling access to data collected by scientists, whereas iNaturalist supports the process of data collection and identification by enabling communities to record and upload species of biodiversity. As such, they are likely to support different forms of learning and engagement. In addition, the process of enabling non-researchers to design and implement their own studies necessitates further and more in-depth examinations. This study provided initial insights as to people's perceptions about community-led research and associated barriers. Further studies should engage with specific communities using e.g., interviews, focus groups, observations to understand specific requirements and trial interventions that can empower people to initiate their own studies and start thinking of themselves as scientists.

Careful consideration should be given to the time and effort needed for the general public to take part in CCS activities. In this study, survey participants valued the importance of helping science and expressed interest in taking part or initiating CCS activities, should time requirements be considered. Reflecting on these insights, bite-sized learning might be an appropriate approach to engaging the general public with CCS in ways that are not time consuming. Bite-sized learning (Manning et al., 2021) refers to activities that are short, focused on achieving one learning objective at a time, and less cognitively demanding. Taking as example the nQuire missions, a study could be divided into a series of separate, short missions, with few questions in each one and shared with participants at different points of time. For creating a community-led mission, this may mean that the different stages of scientific work become separated; for example, brainstorming ideas about a mission's big question could form a mission on its own. Similarly, identifying the most appropriate methods of data collection could be a separate voting mission.

In terms of pursuing community-led research, there is a need for researchers to communicate clearly the benefits of such activity for how decisions are made and how the voices of different people can be considered in the production of knowledge. Also, they should showcase ways such activities can be scaffolded through support from technology and scientists. Community-led research should be seen as an interdisciplinary activity where researchers and communities work closely together to share expertise and understanding and design studies that are inclusive and considerate of the specificities of a community.

Finally, the Open University/BBC partnership showcased the significant role large and well-known organisations can play in engaging the general public with CCS. The BBC has partnered with the Open University for over 50 years to provide access to learning at scale, at first via late night TV lectures, and recently through the co-production of content for TV, radio, podcasts, social and digital media. Encouraging the public to join or initiate CCS activities could be actively promoted as part of Open University/BBC social good agenda, bringing the public closer to science and supporting the development of scientific work. The development of CCS capacity in such organisations could be actively pursued through collaboration with institutions with expertise in CCS such as museums, charities and universities.

Interactive Transcription Techniques for Interaction Analysis

Arpit Mathur, Georgia Institute of Technology, arpitmathur19@gmail.com
Ben Rydal Shapiro, Georgia State University, ben@benrydal.com

Abstract: Interaction analysis is a valuable method and approach to study knowledge in use in the learning sciences and CSCL communities. Central to interaction analysis is the creation of transcripts to selectively encode and represent audio and video data. However, current transcription techniques used in interaction analysis, including multimodal transcription techniques, have yet to explore the strengths and weaknesses of interactive visualization to selectively encode and represent people's interaction in context. Drawing from recent efforts to amplify, not automate, transcription in qualitative research, this paper interactively visualizes one video dataset in five different ways using contemporary interactive visualization techniques. Findings and discussion characterize these visualizations as interactive transcripts that demonstrate techniques valuable to interaction analysis, but also highlight the need to expand how people, things, and context are represented through visualization mediums such as visualization programming languages to align with work more meaningfully in the learning sciences and CSCL communities.

Introduction

Interaction analysis is a valuable method and approach to study knowledge in use in the Learning Sciences and CSCL communities (Jordan & Henderson, 1995; also see Hall & Stevens, 2015). Interaction analysis relies on detailed analyses of audiovisual data to characterize interaction in ways that support analyses of learning or teaching, often from sociocultural or social practice perspectives. Central to interaction analysis is the creation of transcripts, which selectively encode and represent audio and video data to understand events from the perspective of participants and everyday people. However, current transcription techniques used in interaction analysis, including multimodal transcription techniques, derive primarily from the use of tools such as Microsoft Word or PowerPoint and have yet to explore the strengths and weaknesses of interactive visualization to selectively encode and represent people's interaction in context.

Drawing from recent efforts to amplify, not automate, transcription in qualitative research, this paper interactively visualizes one qualitative, video dataset in five different ways using contemporary interactive visualization techniques. Findings and discussion characterize these visualizations as interactive transcripts that demonstrate techniques valuable to interaction analysis, but also highlight the need to expand how people, things, and context are represented through visualization mediums such as visualization programming languages to align with learning sciences and CSCL research, including recent efforts to expand the methodological commitments of interaction analysis (see Krishnamoorthy et al., 2021; Marin et al., 2020; Silvis et al., 2022).

We begin by reviewing relevant work concerning transcription and interaction analysis as well as relevant visualization theories. Subsequently, we describe the video dataset we analyze in this paper. We then describe five different interactive visualizations of this dataset by unpacking the techniques, encoding decisions, and insights made visible in each visualization. These visualizations are web-based, open source, and made available in this paper. Findings and discussion summarize the contributions of these visualizations as interactive transcription techniques for interaction analysis but also highlight the need to expand how people, things, and context are represented through visualization mediums in future research.

Theoretical framework

Transcription and interaction analysis

Transcription is used to encode and translate various forms of unstructured data such as audio or video into a representation that aids in interpreting unstructured data (see Atkinson & Heritage, 1999; Erickson, 2004; Duranti, 2007; Jefferson, 1984; Gee, 1999; Goodwin, 1994; Hall & Stevens, 2015; Mondada, 2007). For learning sciences and CSCL researchers who use interaction analysis, transcription is central to selectively representing sequences of interaction in order to study learning or teaching (for recent examples see DeLiema, Enyedy & Danish, 2017; Keifert & Stevens, 2019; Kelton, 2021; Hennessy Elliott et al., 2020; Ma & Munter, 2014; Marin, 2020; Jung et al., 2020; Steier, 2014; Taylor, 2017; Vossoughi et al., 2020). Notably, transcription is viewed as a theory laden and selective practice of encoding data (Ochs, 1979; also see Hall, 2000; Derry et al., 2010). This means that any transcription method encodes and represents data in ways that are reflective of the assumptions, biases, and goals

 © ISLS

of the researcher (or computer) doing the transcribing. Likewise, qualitative researchers highlight the value of manual transcription (Lapadat & Lindsay, 1999; Erickson, 2004). While manual transcription is slow and tedious, the process provides ways to understand qualitative data that are fundamentally different than automated techniques emerging in fields such as computer vision and machine learning.

While transcription has evolved in many ways over the years, the mediums and tools used to produce transcripts have not changed considerably. Apart from a few examples (see Angus et al., 2012; Shapiro, Hall & Owens, 2017), transcripts are typically produced with language-based tools such as Microsoft word and PowerPoint that support static and typically text-focused transcripts. This is the case even as transcription has rapidly expanded in innovative ways from a focus only on language to multimodality (Bezemer & Mavers, 2011; Kress & van Leeuwen, 2006), with multimodal transcripts often using the same tools to characterize phenomena such as gesture. Put simply, while researchers continue to highlight how these tools are inadequate to characterize the complexity and layeredness inherent to studying interaction in settings such as classrooms, the potential strengths and weaknesses of interactive visualization to address some of these limitations remains unexplored.

Alternative visualization theories and integrative visualization

In response to broader arguments about how visualization can more meaningfully and intimately represent and communicate with people and communities, new theories of visualization have emerged that focus on alternative ways of knowing, non-binary approaches to data, and the contextual dimensions of data (e.g., D'Ignazio & Klein, 2016; Lupi, 2017). This paper draws from our developing efforts to connect these theories with qualitative research through the notion integrative visualization (Shapiro, 2019).

As we describe in prior work, integrative visualization is a human-centered process to interpret unstructured data such as audio or video typical of qualitative research in ways that support the development of grounded theory (Glaser & Strauss, 1967) and contextual computational tools. A key part of integrative visualization is the use of visualization mediums such as graphics editors or programming languages to support manual and iterative transcription of data collected in context. Such transcription amplified by visualization aims to further the grounded theory process (e.g., generation of categories, codes, units of analysis and questions) and lead to insights that can inform the development of contextual computational tools. Notably, integrative visualization extends the practice of "integrative diagramming" (Strauss, 1987) as used by qualitative researchers and is summarized as follows:

data context → transcription amplified by visualization → grounded theory & computational tools

This paper contributes to a deeper understanding about the strengths and weaknesses of visualization mediums such as graphics editors and programming languages to amplify manual transcription, specifically for interaction analysis as used in the learning sciences and CSCL communities.

Data sources

Our subsequent analysis draws from a video from a bilingual elementary classroom. This 2-minute video of classroom interaction shows the teaching of a key idea in the physics of matter—that matter occupies space—in a kindergarten-first grade classroom and is available at the following link: https://youtu.be/d8_pRUR-hmg. In the video, a teacher is seated with her students around her on the floor of a classroom and conducts a brief experiment involving a jar and marbles to illustrate how matter occupies space. The teacher also facilitates a discussion about the experiment with the class. This dataset was chosen because it was collected by and is well known to researchers who use interaction analysis in the learning sciences and CSCL communities. Notably, this video was central to a recent conference supported by the Spencer Foundation at Arizona State University where an interdisciplinary group of older and younger scholars gathered to document the basic patterns of visual and auditory attention employed by researchers who use video to study social interaction (Erickson et al., 2017: see: https://www.learninghowtolookandlisten.com).

Analysis

Our analysis uses an established visualization programming language called D3.js to interactively visualize this dataset in five ways. Figure 1 shows a static image of each of these five visualizations along with a screenshot from the video dataset introduced previously. Interactive visualizations of each of these images are open source and can be explored at the following link, and we encourage readers to explore each interactive visualization while reading our subsequent analysis: https://mrmathur.github.io/mos-visualizations/

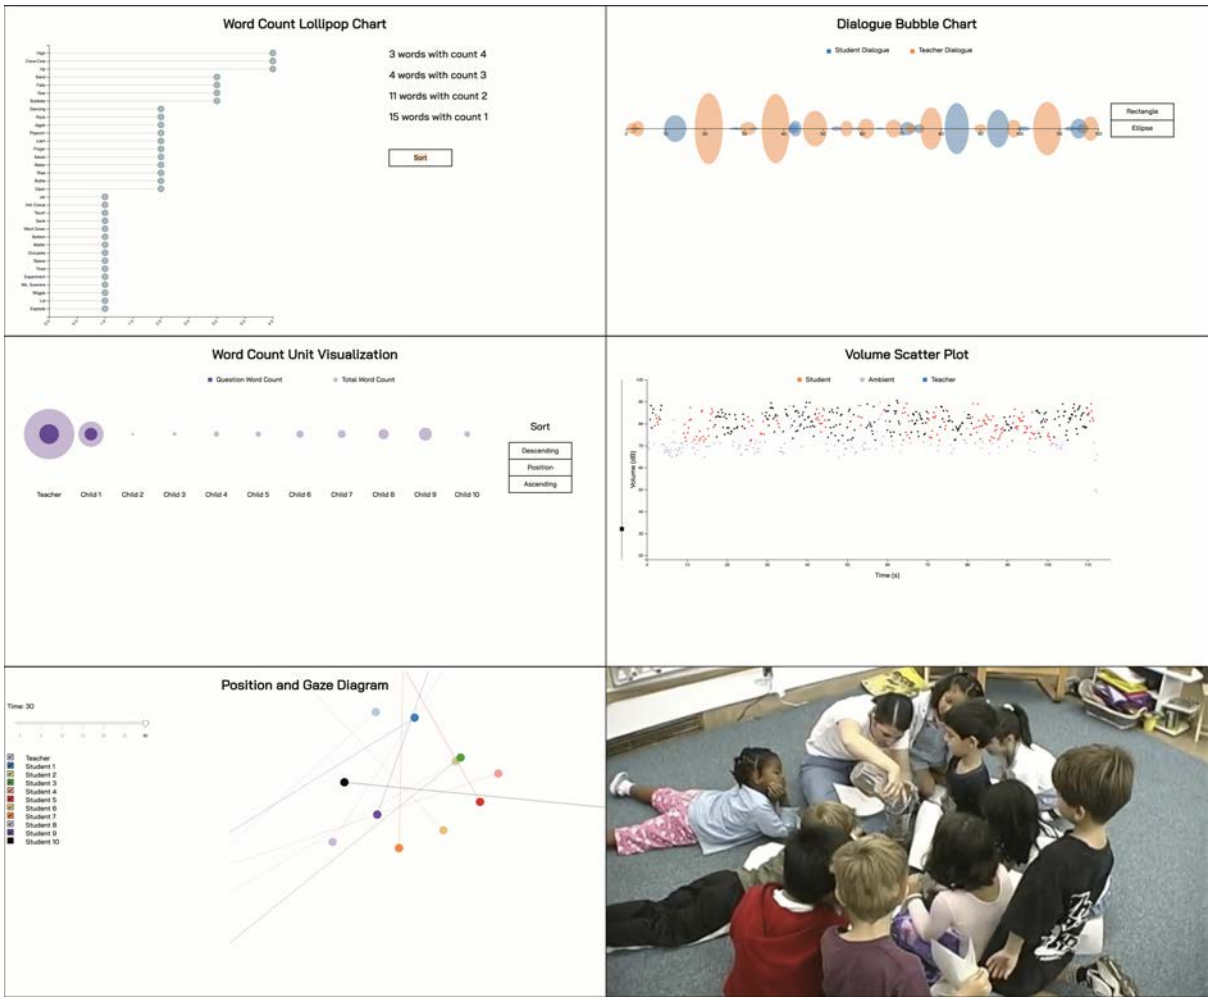

Figure 1. Screenshots from five different interactive visualizations of a two-minute video of classroom interaction. Interactive visualizations available at: https://mrmathur.github.io/mos-visualizations/

In the following we unpack each image and corresponding interactive visualization in this figure (from top left to bottom) by describing the a) specific representation and interaction techniques, b) encoding decisions and c) insights generated in each visualization. Our analysis aims to bridge language used by interaction analysts and visualization researchers in ways that help us discuss strengths and weaknesses of contemporary visualization techniques, including methodological commitments that are inherent to languages such as D3.js.

Visualization 1: Word count lollipop chart

Techniques

The first visualization is what is known as a lollipop chart, which is an extension of the more widely known bar chart. In this case, the length of each horizontal line across the X-axis encodes the number of times a word has been spoken during the 2-minute video of classroom interaction. Moreover, the chart supports standard forms of user interaction in two ways: Sorting and hovering (see Yi et al., 2007). Namely, the words can be sorted in ascending or descending order by using a button. Hovering over each circle also reveals the sentences in which the word was spoken and allows users to view and read these sentences.

Encoding Decisions

A database (i.e., a .csv file) was generated with each word, its frequency, and the sentences during which these words were spoken. Conversation spoken by teachers and students was occasionally in Spanish. The authors decided to only use the English translation of words in the video. Notably, articles and pronouns were also not included. With the database in place, a lollipop chart was made, by encoding the x position of the circle as the word length, and the y-axis as the rank (either ascending or descending, based on the user's selection). A lollipop

chart was used as opposed to a more standard bar chart because a lollipop chart affords more ways for users to interact with the data, in this case by reading sentences from which each word was derived.

Insights

Many basic insights are visible through this simple, standard representation. For example, while the central topic of this sequence of classroom interaction is the notion that "matter occupies space", those particular words are rarely spoken by the teacher or students. In contrast, metaphors such as CocaCola, Sand, Bubbles, and Dancing are repeatedly uttered. A few student names are also recurrent, however not all student names are spoken. Furthermore, the possibilities to interact with this visualization allow users to consider the context in which each utterance is spoken at a sentence level offering very different ways to read turns of talk in comparison to traditional, non-interactive transcription methods. However, many insights are also lost through this type of representation in comparison to a more traditional transcript. For example, coherence of participants' sense-making is difficult to recover even through interaction.

Visualization 2: Dialogue bubble chart

Techniques

The second visualization is a bubble chart, where each ellipse represents a conversation turn (i.e., in this case, uninterrupted speech that could span multiple sentences) spoken by either the teacher or a student. Ellipses are organized across a conventional timeline or time series display and the beginning and end (or left and right) of each ellipse marks the beginning and end of each conversation turn. Moreover, the visualization supports user interaction by allowing users to toggle between rectangles and ellipses to represent conversation turns, which allow users to explore subtly different aspects of conversation structure from this sequence of interaction. The users can also hover on a conversation turn (ellipse or rectangle), to display and read the dialogue spoken.

Encoding Decisions

A database was generated with each conversation turn, its content, and who spoke each conversation turn. Notably, each conversation turn was defined as a sequence of uninterrupted speech, which could span over multiple sentences. With the database in place, a bubble chart was made. The height of the ellipse indicates the number of words in each conversation turn. Thus, taller ellipses or rectangles (depending on the view selected by the user) indicate more words spoken during a conversation turn or a faster conversation turn. The left and right of each ellipse or rectangle indicate the beginning and end of each conversation turn. Thus, where ellipses or rectangles overlap indicates overlapping speech. The color of the bubbles represents who made each conversation turn. Hovering on a bubble reveals the content of the dialogue.

Insights

The bubble chart reveals several relevant insights. First, one can observe the general pacing of each conversation turn (i.e., length of conversation turns with respect to both the number of words and amount of time). This makes visible how the teacher speaks for much longer stretches of time and the parts of this interaction where students speak for long periods of time, often while asking a question. Likewise, the moments during this interaction when no one is speaking can be quickly identified. Moreover, overlapping ellipses (or rectangles depending on the view selected) are an interesting phenomenon. For example, these overlaps show that while students speak over one another they do not speak over or interrupt the teacher's speech. Furthermore, the teacher utters many more words per conversation turn in comparison to students, who generally speak fewer words and for shorter periods of time. Finally, the ability to quickly hover over each ellipse or rectangle and read conversation provides a fundamentally different way to compare conversation turns in comparison to existing transcription methods.

Visualization 3: Word count unit visualization

Techniques

The third visualization is what is known as a unit visualization. It is named so because every individual from the video is represented by a spherical unit. Different attributes of this unit encode different characteristics. Here, the area covered by the outer and inner circles represent the number of total words and also questions uttered by each student and the teacher during this sequence of interaction.

Encoding Decisions

A database was generated with each individual, the word count for each individual, and the question word count for each individual. Notably, expressions and exclamations were not included in word counts for each individual.

A distinction between a statement and question was made by judging the intonation of the dialogue, with the intent being to explore the role and significance of questioning in the classroom. With the database in place, a unit visualization was created. The area of the lighter circle indicates the total word count for each individual whereas the area of each darker circle indicates the question word count for each individual (as represented by the legend). Importantly, area (as opposed to the use of radius) was selected to encode total and question word counts because the consensus in the visualization community is to use area, as it is a more intuitive indicator of quantity. The x position of each individual is determined by one of three modes or orders selected by the user.

Insights

The visualization supports comparative analysis across individual speakers with respect to the number of words uttered and the number of questions posed. For example, the teacher speaks many more words and also a far larger number of questions whereas students have much lower word counts and fewer questions. The visualization makes evident differences in contributions between students. For example, the visualization highlights child 1 as a significant speaker in the classroom; Notably, she also asks the teacher the largest number of questions. Altogether, the visualization is quite useful to analyze conversational parity or whether there are equitable opportunities to talk. However, the coherence and meaning of conversation are backgrounded.

Visualization 4: Volume scatter plot

Techniques

The chart is a scatter plot, where each dot represents a 0.2s instant in the video. The x position of the dot encodes the timestamp of the instant, the y position encodes the volume of the video at that instant, and the color represents the volume contributor, which is indicative of the source of the volume at that instant of the video. The user can interact with the visualization by rescaling the y-axis through a vertical slider, which allows them to zoom into relevant parts of the graph.

Encoding Decisions

Using a free, mobile application, a database was generated that encoded the volume organized by contributors from the sequence of interaction at time intervals of 0.2s. Volume contributors (i.e., Student, Teacher and Ambient Noise) at every time stamp were manually encoded by the authors. Key decisions were made about how to allocate volume to individuals. For example, at times multiple individuals spoke, and in this encoding scheme, the individual with the longest conversation turn was chosen. Moreover, ambient noise reflects a general category that groups other types of noises during this sequence of interaction not related to speakers. From this data, a scatterplot was generated which encoded time on the x-axis, volume on the y-axis, and the contributor as color.

Insights

The scatterplot makes particular phenomena visible that are quite different than other visualizations reviewed thus far. For instance, stretches of ambient sound (when no one is speaking) correlate to when the teacher is conducting the demonstration that grounds the sequence of interaction. Moreover, the variety of intonations of different speakers are visible in ways quite different from how intonation is typically represented by textual conventions of current transcription methods. Furthermore, average volumes can be viewed and compared, for example, to understand how loudness or strength of projection by a speaker influences classroom interaction that in turn encourages or dissuades others to speak.

Visualization 5: Position and gaze diagram

Techniques

The chart is a position and gaze diagram, where each dot is positioned according to a person's pixel values in the video, and the line represents the gaze of the person, at any instant of time. Users can use the provided time slider to observe the positions and gaze at specific intervals of time while filtering capabilities via checkboxes allow users to selectively view everyone's position and gaze, simplifying the visualization.

Encoding Decisions

To deal with the complexity and size of data, 5 second intervals were chosen. Moreover, pixel values from the video were used to indicate the position of the person, as opposed to a bird's eye view of the room. Likewise, the gaze in the video is in 3D space. However, the gaze was mapped in 2D space, because of the two-dimensional nature of a video. The gaze was defined as the line between every student (and teacher), and the point at which the field of view intersected with the screen's boundary. A database was generated with 5 second intervals, the

pixel values for each person's head position, and the pixel values for the point at which their gaze intersects with the boundary of the screen. Circles were plotted at the pixel locations of each person's head positions, and a line was generated from the head to the gaze point. Each circle was color coded to identify the corresponding person.

Insights

The visualization indicates aspects of how the teacher, individual students, and the class collectively focus and manage their attention or, in other words, how gaze is recruited and allocated. Notably, it highlights the ebbs and flows of how gaze is collected and released during this sequence of interaction in ways that are different than traditional representations and conceptions of how gaze is recruited and allocated. In this case, ebbs and flows refer to moments when participants focus on a particular object or person simultaneously for a period of time or look at many different objects simultaneously. For example, around the 5s mark, it becomes clear that all the students begin looking at the center of the classroom or experiment, as opposed to many different directions observed earlier. Most students look at the teacher, whereas the teacher's gaze fluctuates between students. Those sitting away from the teacher seem to focus their gaze on the teacher, whereas those sitting next to her seem to look at other students. These interesting aspects of spatial noticing also expand traditional conceptions of gaze: Namely, it is typically assumed that all participants have equal affordances in a shared space, but this representation allows one to see how certain participants may have more or less affordances depending on where they are positioned within a shared space. This pattern repeats across the two-minute sequence of interaction in response to how the teacher gathers and releases attention through her gesture and talk.

Discussion

We characterize the previous visualizations as interactive transcripts and focus our discussion on how these transcripts, on one hand, highlight particular techniques valuable for interaction analysis but, on the other hand, demonstrate the need to expand how people and context are represented by visualization mediums such as visualization grammars and programming languages like D3.js. We unpack these statements in order.

The preceding interactive transcripts make use of standard visualization techniques to encourage analysis of new phenomena and questions about this dataset and classroom interaction. For example, as we demonstrated, conversation turns can be compared in ways that are very different than traditional transcription techniques. Such comparisons support new ways to study the pace of conversation, turn-taking patterns, instances of overlapping talk, and volume of conversation in ways quite relevant to situative studies of classroom interaction that view such phenomena as central to people's opportunities to learn. Likewise, as we highlighted, techniques such as the interactive unit visualization are quite useful to analyze conversational parity or whether there are equitable opportunities to talk—something that is challenging to show and study with traditional transcription techniques. Still further, techniques demonstrated through the positioning and gaze diagram challenge typical assumptions about how all participants have equal affordances in a shared space, showing how certain participants may have more or less affordances depending on where they are positioned within a shared space.

While we suggest such interactive transcription techniques are valuable to interaction analysis beyond the example discussed in this paper, like all transcripts, these techniques are theory laden. Notably, in comparison to traditional transcripts, the transcripts in this paper embody theories and methodological commitments inherent to contemporary interactive visualization techniques. Particularly, they highlight how such techniques were not designed to represent people and notions of context important to traditions of interaction analysis as used in the learning sciences and CSCL communities (see Matuk, DesPortes, & Hoadley, 2021). Indeed, as described by Bostock et al. (2011), the goals of D3.js are to make it easy to implement popular and conventional visualizations (such as bar charts, line charts, scatter plots) as well as custom visualizations on the web. Like many existing visualization programming languages or libraries, D3.js embodies visualization grammars or formal models of describing visualizations including data, transformations, scales, and visual marks. Such grammars were designed for data that is already structured (e.g., as a CSV file), typically characterized as raw or objective, and not focused on depicting people's interaction or complex learning ecologies such as classrooms or the natural world.

Extending ideas reviewed at the beginning of this paper, we suggest there is a need and opportunity to expand the notion of a "visualization grammar" to more deeply consider how people and context are represented in ways that align more meaningfully with work in the learning sciences and CSCL communities, including recent efforts to expand the methodological commitments of interaction analysis (Krishnamoorthy et al., 2021; Marin et al., 2020; Silvis et al., 2022). For example, such work might develop interactive glyphs for interaction analysis specific to different settings, new types of interaction techniques to take on the perspective of participants as they engage in interaction, or extend sketching metaphors and commitments to equity and accessibility foregrounded by programming languages such as p5.js that more meaningfully align with the iterative nature of qualitative traditions of interaction analysis (e.g., repeatedly watching video and iteratively developing transcripts).

Conclusion

We began this paper by reviewing how transcription is currently used in interaction analysis as well as our recent efforts to expand alternative visualization theories for qualitative research through integrative visualization. Subsequently, we illustrated and unpacked five different interactive transcripts that demonstrated visualization techniques to characterize types of classroom interaction in ways fundamentally different that traditional transcription approaches. We highlighted the value of such transcripts but also their weaknesses, emphasizing interactive transcripts provide another means to augment, not replace or automate, existing transcription practice for interaction analysis. Notably, we outlined the need and opportunity for researchers to explore how interactive transcription techniques can more deeply represent people and notions of context central to traditions of interaction analysis as used in the learning sciences and CSCL communities. Such work focuses on how visualization can expand qualitative traditions of interaction analysis in ways that are not focused solely on scaling research across contexts, but rather on studying the details of interaction within particular contexts from the perspective of everyday people, noting as others have that both lines of work can and should inform one another (Sherin, Kersting, & Berland, 2018; also see D'Angelo et al., 2020).

Why Feedback Literacy Matters for Learning Analytics

Yi-Shan Tsai, Monash University, yi-shan.tsai@monash.edu

Abstract: Learning analytics (LA) provides data-driven feedback that aims to improve learning and inform action. For learners, LA-based feedback may scaffold self-regulated learning skills, which are crucial to learning success. For teachers, LA-based feedback may help the evaluation of teaching effects and the need for interventions. However, the current development of LA has presented problems related to the cognitive, social-affective, and structural dimensions of feedback. In light of this, this position paper argues that attention needs to shift from the design of LA as a feedback product to one that facilitates a process in which both teachers and students play active roles in meaning-making. To this end, implications for feedback literacy in the context of LA are discussed.

Introduction

Learning analytics (LA) emerged as an interdisciplinary field a decade ago with a key mission to advance the understanding of learning and enhance this by using large datasets generated by learning processes. Early LA examples were largely motivated by the need to improve student retention in higher education, with a particularly common approach the application of predictive modelling to identify risks of failing (e.g., Arnold & Pistilli, 2012). Over the years, there has been growing awareness of the importance to ground LA in educational theories to identify meaningful metrics for the measurement of a learning phenomenon (Gašević et al., 2017). However, approaches to LA have been largely driven by behaviourism, in part due to constraints related to sources of data available; namely, commonly collectable data tend to focus on learner behaviour, such as log-ins and clicks. Despite this constraint, recent work in LA has made substantial break-throughs in inferring cognitive and meta-cognitive development among learners using LA (e.g., Jovanović et al., 2017; Uzir et al., 2020). However, the adoption of LA in real-world settings remains small in scale, thus limiting its expected impact on learning (Tsai et al., 2020; Viberg et al., 2018). Although there is abundant literature exploring social-technical issues that impede LA adoption (e.g., Macfadyen et al., 2014; Prinsloo & Slade, 2017; Tsai et al., 2021), there has been relatively little attention to key skills required for teachers and students to benefit from LA as a feedback process. A recent study by Gray and others (2021) proposed a framework for continuous professional development in LA for students, professional services, and teaching staff, focusing on three phases of skill development, including using and practicing feedback. However, the study has not explored skills that may be required for teachers and students to make sense of and use feedback generated by LA. This position paper is intended to bridge the gap by conceptualising feedback literacy in the context of LA for the purpose of enhancing the effectiveness and sustainability of LA and, more importantly, improving the overall feedback processes in higher education. To this end, I first conceptualise feedback and feedback literacy before outlining issues with LA-based feedback. Following that, I argue the importance of installing LA-specific feedback literacy among teachers and learners by highlighting three key dimensions required to make LA feedback effective.

Conceptualising feedback and feedback literacy

Feedback plays an important role in learning, and the main purpose is to bridge the gap between a desired learning goal and the current performance (Evans, 2013). According to Hattie and Timperley (2007), feedback serves to answer three broad questions: Where am I going (*feeding up* to learning goals or expected standards that a learner works towards)? How am I going (*feeding back* on a learner's actual level performance in relation to goals and standards)? Where to next (*feeding forward to* greater possibilities for learning)? Traditionally, feedback is perceived as *information* generated and delivered from teachers to students. This transmission model is based on a cognitive perspective, and teachers are considered the ones mainly responsible for the effectiveness of feedback (Boud & Molloy, 2013; Evans, 2013). This conceptualisation is still very much present in ways teaching quality and student experience are measured in higher education (Winstone & Carless, 2021), which to some extent have also influenced how teachers and students see feedback (Winstone et al., 2021). While not mutually exclusive, compared to the cognitive perspective, the social-constructivist paradigm highlights the importance of feedback as a *process* that requires teachers and students to work in tandem, i.e., to have shared responsibilities (Boud & Molloy, 2013; Evans, 2013). For example, Yang and Carless (2013) discussed three inter-related dimensions of feedback: *cognitive, social-affective, and structural*. At the *cognitive* level, feedback needs to help students narrow the gap between their current and desired performance in addition to increase their self-regulated learning (SRL) skills. However, activities that happen in the cognitive dimension can be subject to the *social-affective* dimension;

 © ISLS

that is, the power relationships between agents of feedback (e.g., teachers, students, and peers) and emotional reactions to feedback. As argued by Price et al. (2010, p. 280), "if the feedback is viewed as a product rather than part of a relational process, it is less likely to generate a response". In other words, a trust relationship between teachers and students is considered crucial to productive engagement with feedback, and treating feedback as a dialogic process may help offset power imbalance and cultivate trust (Yang & Carless, 2013).

The *structural* dimension is related to how feedback is organised and managed by the teacher and institution, e.g., timing, frequency, sequence, and modes of feedback. This dimension situates feedback in a wider learning context in which resources and policies can be determining factors of feedback effectiveness. When evaluations of feedback quality overemphasise this dimension, sustainability can become an issue because institutional resources are finite. In light of this, Boud and Molloy (2013) argue that for feedback to be sustainable, students need to be seen as active agents of change rather than passive recipients. Similarly, Winstone et al. (2021) suggest that a culture of responsibility sharing in feedback processes needs to be developed in order to move from feedback as telling to feedback as dialogue. On the other hand, Carless and Winstone (2020) suggest that in addition to *design* and *relational* dimensions, teacher feedback literacy has a *pragmatic* dimension; that is, a teacher's ability to be able to navigate tensions resulting from practical issues, such as resource and time constraints, by making inevitable compromises between the ideal, the defensible, and desirable feedback or leveraging technology for efficiency and timeliness.

Although both teacher-centred feedback and student-centred feedback highlight the importance of action in closing a feedback loop, the former assumes that learners depend on others to drive their learning and that learners would know what action to take when being provided with diagnostic information about their learning. In contrast, the latter emphasises the agency of learners who facilitate their own learning through active information seeking and sense-making (Boud & Molloy, 2013). Drawing on this student-centred view of feedback, Carless (2019) describes that feedback can take forms of *single, double*, and *spiral* loops. While feedback as a *single* loop focuses on short-term improvement of performance (predominantly task-driven), the *double*-loop process focuses on long-term impacts of feedback on the meta-cognition process, e.g., SRL, and the *spiral* process depicts learning as a complex, ongoing process in which learners continue to tackle some unresolved learning puzzles through continuous sense-making and the use of past feedback. In the core of this argument is the active role of learners who need to be able to *appreciate feedback*, *make judgement* based on feedback, *manage affect* resulted from feedback, and *take action* based on feedback – these are defined as key aspects of feedback literacy by Carless and Boud (2018). Building on this work, Molloy et al. (2020) further identified seven features of feedback literacy that emphasises feedback as an active, reciprocal process in which learners elicit information and enact outcomes of information processing, whereas Ryan et al (2021) proposed a model of eight feedback components that serve three functions: supporting future impact, enabling sensemaking, and supporting agency. In short, student-centred feedback processes requires feedback literacy to be present in both teachers and students, as have argued by Boud and Molloy (2013) that sustainable feedback depends on what learners bring and what the curriculum promotes in addition to what the environment affords. In this paper, feedback literacy for teachers is seen as *the ability to design and implement feedback not only as a piece of information that can help students achieve desired learning goals and personal development, but also as a process that serves pedagogical, social, and political purposes*; whereas feedback literacy for students is perceived as *the ability to seek feedback, decode and encode meanings of feedback relevant to their learning (thus resulting in beliefs and knowledge updates or action), and engage in feedback as a socio-cultural process*.

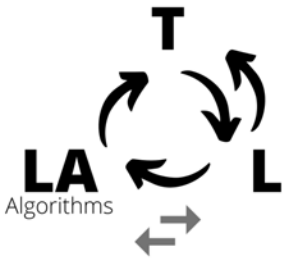
Learning analytics-based feedback

Learning analytics (LA) is commonly defined as "the measurement, collection, analysis and reporting of data about learners and their contexts, for purposes of understanding and optimizing learning and the environments in which it occurs" (Long et al., 2011, p. 3). A LA cycle is described with four key elements: learners, data, metrics, and interventions (Clow, 2012). As learners interact with learning activities and environments, a range of data such as clickstream, login, forum discussion, academic performance, and sensory data, can be processed into metrics or analytics, often visualised in forms of dashboards as feedback for teachers or learners. The intention is to provide information useful to inform interventions (e.g., curriculum updates) or conversation with students (Bennett & Folley, 2019; De Laet et al., 2020; Wise, 2014). In line with Winne and Butler (1994) who argue that feedback is an inherent catalyst of SRL, LA-based feedback serves to trigger an iterative cycle of self-monitoring (internal feedback), performance, evaluation, and external feedback. For learners, LA as external feedback may prompt them to assess their knowledge and beliefs, including domain knowledge, strategy knowledge, and learning motivations, based on which learners may devise learning plans. Similarly, for teachers, LA-based feedback may prompt them to assess their knowledge and beliefs about their domain knowledge, pedagogical

knowledge and strategy, and their current understanding of the learners, thereby reflecting on the effectiveness of teaching approaches and materials and the need to make change or provide interventions.

Unlike traditional feedback that typically involves teachers and learners, LA-based feedback includes the *algorithm* as a key agent that takes part in the process of measuring and evaluating learning outputs and communicating the results and feedback (Pardo, 2018). If feedback is directed to learners (student-facing LA), learners are expected to be able to make sense of the feedback and devise actions based on the presented data. In other words, there is an implied assumption that users have a functional level of feedback literacy and data literacy. If LA-based feedback is directed to teachers (teacher-facing LA), teachers act as a mediator between LA and students. In other words, teachers will be responsible for making sense of LA-based feedback and deciding whether and how to provide further feedback to learners as well as ways to incorporate LA into teaching practice. In this process, the direct interaction learners have is with the teacher. Thus, LA can facilitate two different loops of feedback, each highlighting the roles of learners and teachers differently in the sense-making process of LA-based feedback (Figure 1). In both loops, the outputs from learners (e.g., behaviour, performance, and emotional states after feedback is received) continue to feed back to LA, thus forming continuous feedback processes.

Figure 1
Two loops of learning analytics (LA) feedback directed at teachers (T) and learners (L) respectively



Problems with learning analytics-based feedback

Although students generally welcome timely feedback enabled by LA to keep them on track of their learning (Galaige et al., 2018; Tsai, Mello, et al., 2021), current practice has presented some issues threatening the effectiveness of feedback. In the following, I frame these issues within the feedback triangle proposed by Yang & Carless (2013): *cognitive, social-affective*, and *structural* dimensions.

Considering the *cognitive* dimension, LA appears to focus more on *feeding back* (learning progress) and *feeding up* (learning goals), but less on *feeding forwards* (where to next). For example, a systematic review by Matcha et al. (2019) on 29 LA dashboards found that 18 focus on presenting learning progress and the most common indicators are numbers of logins, posts, and tweets, followed by indicators of domain knowledge, e.g., exam marks. Similarly, a review on 95 articles about student-facing analytics system (Bodily & Verbert, 2017) found that when text feedback was provided, it tended to be descriptive about what happened in the past and how students were doing up to the point of the feedback. As the most referenced theoretical concepts of learning analytics dashboards (LADs) design are SRL, reference frames are common techniques adopted to raise awareness and prompt reflections on one's learning progress, such as through social comparison with peers, comparison between current achievement and goals (the *feeding up* element), and comparison with the earlier self (Jivet et al., 2017). Compared to *feeding back* and *feeding up*, the *feeding forward* element has been an area of weakness in LA as empirical studies continue to report issues about lacking actionable insights (Bennett & Folley, 2019; Jivet et al., 2020; Lim et al., 2019). For example, Corrin and de Barba (2015) found that students struggled to translate LA into learning strategies; Jivet et al. (2017) identified little support of LADs in scaffolding goal setting and planning; Cha and Park (2019) reported that students desire prescriptive tips and suggestions to help them achieve desired goals; and Li et al. (2021) found that teachers struggled to infer student learning or identify learning problems from analytics results. As such, aligning LA with pedagogical practices and learning sciences continues to be a focused area of development in the field (Knight et al., 2014, 2020; Wise, 2014).

The *social-affective* dimension of feedback emphasises the dialogic (Sutton, 2009) and relational (Price et al., 2010) nature of a feedback process, which requires trust and balanced power relationship between the provider and the recipient of feedback (Winstone et al., 2021). Although scholars have argued the value of LA in facilitating dialogue between teachers and students (De Laet et al., 2020; Wise, 2014), LA as a feedback process involves not only teachers and students, but also algorithms as a key feedback agent (Figure 1). As such, distrust in LA algorithms and data or facilitators of LA can hamper the dialogic and relational aspects of feedback. For example, Jones et al. (2020) argue that issues around data privacy can violate a trust relationship between students

and institutions; whereas Tsai et al. (2021) outline three areas of trust issues related to LA from perspectives of teachers and students: 1) numbers are subjective, 2) fear of power diminution, and 3) design and implementation. The first area includes issues about data accuracy, bias, and incomplete representation of learning. The second area includes negative impacts on professional and learner agency, unfair judgement on learning or teaching practice, the inability to remain in control of one's data. The third area is related to practical issues, including workload, the interpretability and usefulness of LA, equity of treatment, and demotivation to learn. Similarly, other studies that look into the social-affective dimension of feedback based on LA have identified students' fear of being treated as numbers (Roberts et al., 2016; Tsai, Mello, et al., 2021), and Lewis et al (2021) pointed out further that students who felt being noticed as individuals were more willing to seek support and engage with learning when LA is used.

The *structural* dimension of feedback focuses on how feedback is integrated into the instructional design and institutional processes. The rise of LA is in part a response to the growing pressure on higher education institutions to demonstrate quality (Ferguson, 2012; Tsai et al., 2020) and LA has demonstrated promising results in providing feedback at scale in a timely manner (Pardo et al., 2019). However, adoption and impacts of LA have been limited (Ferguson & Clow, 2017; Viberg et al., 2018) partly due to structural issues such as the complexity of educational systems (Macfadyen et al., 2014; Tsai et al., 2019) and the emphasis on analytics over learning (Guzmán-Valenzuela et al., 2021; Williamson et al., 2020), in addition to some of the trust issues mentioned above. A related issue to higher education's mounting pressure on boosting student satisfaction with timely feedback is that LA has been predominantly perceived as a technological tool to support this agenda rather than a process that requires proper integration into pedagogical practice (Wise, 2014). As a result, not only does LA-based feedback tend to be perceived as a product in line with the traditional feedback model – feedback as telling, but evaluations of LA also often focus on assessing its usability (e.g., acceptance, usefulness and ease-of-use) and impact on behavioural change to the extent that it is observable and the data is capturable (Jivet et al., 2018). This dominant conceptualisation of LA as feedback overlooks the cognitive and social-affective dimensions of feedback. It may also be argued that LA continues to promote a transmission model of feedback (Boud & Molloy, 2013), which considers a feedback loop closed in so far as action is taken by learners regardless of whether it is a passive response without learning actually taking place.

Learning analytics feedback literacy

Returning to the definition of LA as a process that aims to not only *understand*, but also *optimise* learning (Long et al., 2011), we need to move beyond evaluation to enhancement of learning. For example, before seeking better approaches to predict or measure learning results, ask first what learning gain can be expected by applying LA in teaching (Kitto et al., 2018). Before making algorithmic choices, ask first how the decisions align with human values (Chen & Zhu, 2019) and educational values (Wise et al., 2021). Before choosing what data to collect, ask first what metrics are meaningful to a teaching context (Brown, 2020). Before asking what students prefer for an LAD, ask what they need (Jivet et al., 2020). Important to all these questions is a thoughtful consideration of what teachers and learners offer. It is thus necessary to ask what feedback literacy means in a LA-based feedback process. In the following, I build on Carless and Boud (2018) and highlight three broad dimensions of feedback literacy that is important to effective feedback and the exertion of agency by both teachers and learners in the context of LA.

First, *appreciating LA-based feedback with critical awareness of its value and limitations*. To elicit a response from learners to feedback, it is crucial that learners recognise the value of feedback in learning so as to be receptive and proactive (Carless & Boud, 2018; Winstone et al., 2017). Similarly, the uptake of LA as data-driven feedback requires appreciation of data as computational representation of learners and learning, which can navigate attention to areas that may need intervention from the teacher or learners themselves (Gibson & Martinez-Maldonado, 2017; van Leeuwen et al., 2017). However, it is important to recognise that LA is valuable in so far as providing a snapshot of learning, the meaning of which is not complete until learners who generate the data and the teacher who facilitates learning activities bring in their interpretations drawing on their understanding of and experience in the learning or teaching situation. The knowledge of learners and teachers is particularly valuable in filling gaps of information that is not capturable by LA.

Second, *translating the computational representation of learning to psychological self or others and enacting the derived meanings*. As described earlier, LA-based feedback provides computational representations that describe what learners do or how they perform. Gibson and Martinez-Maldonado (2017) describe the sense-making process as an act of translation between the *computational epistemic domain* (computer) and the *psychosocial epistemic domain* (human). The former involves encoding what is observed from learners and processing it into a form (the computational representation) suitable for human interpretation. The latter involves a cognitive cycle of interpreting the computational representation in relation to the psychological *self* or *others*,

thereby constructing meanings and turning this into further products, such as action or the creation of an artefact or digital traces. Thus, a key dimension of feedback literacy in an LA-feedback process is the ability to move between the two domains. This requires both teachers and learners to actively interpret analytics in relation to their situations (e.g., learning and teaching approaches) and decide what action to take or not to take.

Third, *managing affect and negotiating power in the feedback loop*. Same as other forms of feedback, LA-based feedback can induce stress, anxiety, frustration, and other negative emotions especially when feedback continues to flag underperformance or when comparisons are made between individuals and peers (e.g., see Jivet et al. (2020) and Lim et al. (2019)). In addition, as data processing is not simply computational, but also inherently social and political, various decisions are made by a range of stakeholders (e.g., researchers, developers, managers, and service providers) involved in the overall LA cycle – from choosing data and algorithms to delivering downstream intervention. As such, both learners and teachers need to be proactive in questioning whose interests are being served when interacting with LA-based feedback. Moreover, depending on how data is collected, processed, shared, and presented, the process can cause discomfort when a sense of surveillance is experienced (Kwet & Prinsloo, 2020; Selwyn, 2020). It is thus necessary to engage in dialogue with decision makers to offset imbalanced power relationships and increase transparency, validity, and accountability. In other words, being LA literate is not only about being able to make sense of LA-based feedback productively, but also about having the ability to engage with LA in the wider social-political context, such as interrogating the ownership of one's own data or decisions made about or for an individual.

Conclusion

There is no doubt that LA has opened a door to a multitude of opportunities to understanding learning patterns and how learners interact with learning environments and others therein. It also has great potential to deal with one of the biggest feedback challenges – traceability (Malecka et al., 2020) – by iterating feedback loops through continuous data collection as shown in Figure 1. However, the effectiveness and sustainability of LA-based feedback are questionable if it does not support learners and teachers to exercise their agency or scaffold the development of LA-specific feedback literacy, which is conceptualised with three broad dimensions in this article:

- Appreciating LA-based feedback with critical awareness of its value and limitations
- Translating the computational representation of learning to psychological self or others and enacting the derived meanings
- Managing affect and negotiating power in the feedback loop

An important implication for practice is the need to scale training for both teachers and students. For the former, the training should focus not only on strengthening skills in the three aspects, but also related pedagogical skills including ways to enhance a feedback process with LA as part of the learning design and ways to support students to develop LA-feedback literacy. For students, such training may be the most effective if incorporated into their first-year curriculum so as to maximise their opportunities to benefit from LA-based feedback, as also suggested by Molloy et al. (2020) regarding feedback literacy development in higher education. There are also implications for LA design. Firstly, the design should prompt *dialogue*, such as showing reflective or even provocative questions to encourage thinking around important issues related to educational and human values, or embed communication channels for users to raise questions and express opinions to relevant stakeholders in an institution. Secondly, the design should *foreground sense-making*, such as providing mechanisms to guide interpretations in relation to where data comes from, what it means, and how it relates to oneself. Thirdly, the design should *support possibilities for further learning* (feeding forward)(Hattie & Timperley, 2007), such as providing recommendations based on inputs from teachers. In this way, LA may move away from a transmission feedback model to one that is student-centred, relational and process driven, with shared responsibilities between teachers and learners in making feedback effective.

Advancing the goals of problem-posing education in a Knowledge Building Community: An exploratory case study

Etan Cohen
etancohen@gmail.com
The University of Haifa & The Ben-Gurion University of the Negev

Abstract: Scholars of critical pedagogy have long argued for the transformation of schools from oppressive to emancipatory. Although Knowledge Building Communities (KBCs) were initially designed to achieve epistemic goals there exists a significant overlap between the theory underlying the KBC approach and Freire's notion of problem-posing education. Therefore, we asked how KBCs could mediate some key features of problem-posing. In this paper, we present qualitative findings from an exploratory case study of a KBC that was designed for the purpose of problem-posing. Our findings indicate that repurposing KBCs to achieve ethical aims holds promise, and we conclude with some specific question that we believe would be worthwhile to investigate in future studies.

Introduction

Paulo Freire is best known for his book *Pedagogy of the Oppressed* (Freire, 2005), in which he articulated a compelling critical social theory of education. Freire argued that education systems can be either oppressive or emancipatory, depending on how learners interact with teachers and content. Freire's impact has grown in recent years, especially in light of the "political turn" in the learning sciences (Philip et al., 2018). In addition, contemporary scholarship has identified similarities between Freire's work and some of the sociocultural learning theories that have become increasingly influential in the learning sciences (Vossoughi & Gutiérrez, 2017).

Knowledge Building Communities (KBCs) have long been recognized as a promising alternative to traditional learning environments (Scardamalia & Bereiter, 2014). The KBC approach fuses theory, pedagogy, and technology, and has been successfully applied in many educational contexts (Chen & Hong, 2016). Although individual KBCs differ from one another they share the goal of knowledge creation rather than internalization. Consequently, while KBCs typically aim to achieve epistemic aims, repositioning students as agentive subjects also realigns classroom power dynamics.

Notwithstanding clear differences between the KBC literature and Freire's vision, there is a substantial degree of overlap between them. Both approaches seek to reposition students as more agentive and to inspire open-ended knowledge-building trajectories that connect between students' real-world experiences and the content they engage with. This article begins by reviewing the theoretical overlap between Freire's vision and the KBC approach, and then presents findings from an exploratory case study intended to flesh out the connections between them. Ultimately, our aim is to open the door to a new avenue of KBC research that defines its aims in ethical terms in addition to epistemic ones.

Problem-posing education

Some goals of critical pedagogy

Widely recognized as the father of *critical pedagogy*, Freire (2005) maintained that many traditional learning environments are fundamentally oppressive, because they quell curiosity and creativity, thus denying learners the ability to think critically about the world around them and their place within it. In addition, they treat knowledge about the world as value-neutral, abstract, and static. Coupled together, these two features "create people who see no other serious possibility to the economic and cultural assemblage now extant" (Apple, 2004, p. 6).

Indeed, scholars of critical pedagogy have argued for the transformation of schools from oppressive to emancipatory, into institutions "where students can be educated to take their places in society from a position of empowerment rather than from a position of ideological and economic subordination" (Giroux, 1997, p. 120). In Freire's (2005) seminal work, emancipation is achieved through *praxis*, as learners combine reflection and action to assume the role of agentive subjects. Hence, one primary goal of critical pedagogy is to employ pedagogic means to empower students to rethink what they know about the world and their place within it, in a process that can promote equity and social justice.

From students-of-the-teacher to students-teachers

 © ISLS

At the heart of Freire's (2005) pedagogic vision is a contrast between *banking education* and *problem-posing education.* The former conceptualizes learning in terms of teachers depositing knowledge into students' minds, while the latter opens the door to more dynamic forms of learning (2005, p. 79). Shifting from banking to problem-posing repositions teachers, students, and knowledge vis-à-vis one another. When practicing *banking education*, teachers are active, learners are passive, and knowledge is value-neutral, objective, and static. Yet, in a *problem-posing* context, teacher, student, and knowledge dynamically co-constitute one another: "Through dialogue, the teacher-of-the-students and the students-of-the-teacher cease to exist and a new term emerges: teacher-student with students-teachers… People teach each other, mediated by the world". (Freire, 2005, p. 80).

How is problem-posing enacted? Freire outlines three unique features of the *students-teachers* who can be found in emancipatory learning environment. First, problem-posing aims to elevate students-teachers' awareness of reality and of themselves. This is achieved by transcending investigations that are mechanical and limited in scope, and by seeking out "the links between themes, a concern to pose these themes as problems, and a concern for their historical-cultural context" (p. 107). Second, students-teachers de-mythicize and problematize elements of their own world. Knowledge of real-world experiences (for instance, learners' own poverty) is no longer perceived as inevitable; rather, it is subject to change. Finally, teachers do not rely on claims of authority to motivate students. Instead, responsibility is distributed between the teacher-student and students-teachers.

Knowledge Building Communities

Theoretical underpinnings

The Knowledge Building Community (KBC) approach first emerged in the early 1990s (Scardamalia & Bereiter, 1991), and has been a central thrust of design-based research in the learning sciences ever since. KBCs are distinguishable by (1) their expectations from learners, (2) their ontological view of knowledge, and (3) the role played by discourse, dialog, and community (Chen & Hong, 2016).

Theoretically, these three points are all grounded in a distinction between *learning* and *knowledge building*, where learning is defined as "a change in [private and internal] mental state", and knowledge building as the "production of [out-in-the-world] designs, theories […] and the like" (Scardamalia & Bereiter, 2014, p. 397). In a KBC, learners' primary aim is *not* to internalize something that is already known to the teacher or to other students, but to produce and advance novel, out-in-the-world, ideas (cf. Popper, 1978) by engaging in productive knowledge building discourse (Bereiter & Scardamalia, 2016).

The Copernican shift that positions ideas – rather than learners – as the objects of change (cf. Sfard, 2015) means that KBCs afford learners higher levels of agency, so that they can collaborate to simultaneously advance many different ideas of their choice in myriad ways (e.g., Zhang et al., 2007). In addition, *humanistic* KBCs have also been shown to afford the co-construction of self and of ideas in humanistic learning environments that were inspired by the legacy of Carl Rogers (Hod & Ben-Zvi, 2018; Hod & Katz, 2020; Rogers, 1970).

Thus, notwithstanding the different theoretical underpinnings underlying problem-posing and KBCs, there exists a significant degree of overlap between them, most notably in how they view learners, knowledge, and the connection between the two. Both approaches value efforts to "rise above" (Scardamalia, 2002) specific real-world knowledge to inductively articulate broad and inclusive categories; both view knowledge and identity as dynamically and reflexively co-constituted; and both seek to transfer responsibility from teachers to learners.

KBC design principles: Socio-cognitive and technological dynamics

Scripted, procedure-based, pedagogical approaches provide detailed instructions for teachers and students to follow. In contrast, principle-based pedagogies define "core values and principles" (Zhang et al., 2011, p. 263), which teachers adapt to local contexts. The KBC approach is principle-based, offering teachers and researchers a set of twelve design principles that "serve an important regulative function for both teachers and students, helping to keep higher-level goals in mind" (Scardamalia & Bereiter, 2014, p. 403) (cf. author, 2021).

Each design principle comprises socio-cognitive and technological dynamics. Socio-cognitive dynamics are actualized through different types of participant structures; i.e., the "different norms and rights for speaking that different group arrangements[…] afford" (Michaels et al., 2004, p. 2355). Technological dynamics are embodied in the design of The Knowledge Forum (KF), an proprietary online tool designed to support KBCs (Scardamalia, 2017). Because it is principle-based, enacting the KBC approach in a given context is challenging. However, the existing set of principles and technology means that the KBC approach is more readily applicable than Freire's notion of problem-posing education, which is theoretical and abstract. The KBC design principles and much of the research surrounding them can be viewed as *Principled Practical Knowledge*, "which […] unlike formal theoretical knowledge, its main purpose is not explanation or prediction but practical guidance" (Bereiter, 2014, p. 6). Freire's work, in contrast, is theoretical and focused on explanation rather than on implementation.

Specifically, there are three KBC design principles that directly correspond with the features of students-teachers: *rise above*; *real ideas and authentic problems*; and *collective responsibility for community knowledge* (Table 1). While successfully enacting them is no small feat, embedding them into the learning environment does not require teachers to reinvent the wheel. Rather, teachers and researchers build on the design principles and existing literature to design learning environments that integrates the necessary participant structures and makes good use of KF, to mediate the desirable socio-cognitive and technological dynamics.

Table 1
Correspondence between the features of students-teachers and the KBC design principles

Feature of students-teachers (Freire, 2005)	**KB Socio-cognitive dynamics (Scardamalia, 2002)**	**KB Technological dynamics (Scardamalia, 2002)**
(1) *Elevated awareness*: "Thematic investigation thus becomes a common striving towards awareness of reality and towards self-awareness".	*Rise-Above*: "Creative knowledge building… means learning to work with diversity, complexity and messiness, and out of that achieve new syntheses".	Rise-above notes and views support unlimited embedding of ideas in increasingly advanced structures, and support emergent rather than fixed goals.
(2) *Knowledge and identity are co-constituted*: "students-teachers reflect simultaneously on themselves and the world without dichotomizing this reflection from action, and thus establish an authentic form of thought and action".	*Real ideas; authentic problems*: "Knowledge problems arise from efforts to understand the world… Problems are ones that learners really care about—usually very different from textbook problems and puzzles".	Knowledge Forum creates a culture for creative work with ideas. Notes and views serve as direct reflections of the core work of the organization and of the ideas of its creators.
(3) *Shared responsibility*: teachers and students "become jointly responsible for a process in which all grow. In this process, arguments based on 'authority' are no longer valid".	*Collective responsibility*: "Contributions to shared, top-level goals of the organization are prized and rewarded as much as individual achievements. Team members produce ideas of value to others and share responsibility for the overall advancement of knowledge in the community".	Knowledge Forum's open, collaborative workspace holds conceptual artifacts that are contributed by community members. Community membership is defined in terms of reading and building-on the notes of others, ensuring that views are informative and helpful for the community, linking views in ways that demonstrate view interrelationships.

Research focus

The purpose of KBCs has seldom been defined in terms of critical pedagogy. According to Scardamalia and Bereiter, the value of KBCs is primarily epistemic, in that they promote the type of design thinking required for "an 'innovation-driven' society" (Scardamalia & Bereiter, 2016, p. 3), or in their ability to mediate authentic scientific discourse (Bereiter et al., 1997). However, we conjectured that the KBC design could also be harnessed to achieve some of the goals of problem-posing education. Specifically, this article asks how the socio-cognitive and technological dynamics detailed in the KB design principles *rise above*, *real ideas and authentic problems*, and *collective responsibility for community knowledge*, can mediate the features of students-learners?

Method

General approach

The empirical data presented herein comes from an *exploratory case study* (Yin, 2009) intended to flesh out some of the ways in which the goals of critical pedagogy might be advanced by means of the KBC design. Given the lack of any existing theoretical or empirical work, the primary aim of our investigation was to pave the path for future research on how KBCs might be harnessed in support of the goals of critical pedagogy.

Context

Participants
We collaborated with a tenth-grade class in Central Israel comprising 25 students and their teacher, Amos (all names are pseudonyms). All the students identified as Jewish, and none were outwardly religious. Students came from diverse cultural, racial, and socioeconomic backgrounds. The school was publicly funded and belonged to the Jewish state-secular stream. Most of the students were unacquainted with each other or with the teacher.

Curricular content
Emancipation and oppression through learning are both tied to "everyday, informal, and popular culture and how the historical patterns of power that inform such cultures are imbricated in the formation of individual subjectivity and identity" (McLaren, 1994, p. 21). In Israel, the discourse surrounding race, nationality, religion, socioeconomic status, and other social categories is often dominated by the larger question of what it means to belong to the Jewish majority, or to a non-dominant minority, most notably Palestinian or Arab-Israeli. Israel is a Jewish state, but being Jewish means different things to different people, and can serve as a catch-all phrase that is unconsciously associated with the elements of one's identity that are most valued. Given the fluid definition of Jewish identity, its position at the crux of Israel's identity discourse, and its immediate ties to everyday life, we conjectured that exploring what it means in a KBC environment could offer students an emancipatory experience. The curriculum highlighted several points. First, that definitions of identity can overlap, complement, or contradict one another. Second, Jewish identity is not abstract; it shapes everyday life in Israel. Third, questions of identity are inescapable, but answers are always provisional. Finally, that identity discourse inevitably leads to marginalization. Students read op-eds and news articles, philosophical and legal texts, and additional resources.

Participant structures
Roughly a third of the time was dedicated to group meetings and the remaining two-thirds were spent in small groups. For *Group meetings* the students and teacher sat in a circle. Sometimes, participants discussed a new assignment or recent progress; and other times, group meetings were dedicated to personal conversations in which students reflected on their experiences and established trust and openness in the learning community. *Small groups*, usually numbering 2-4 students, typically gathered around one laptop as they read assignments, discussed various themes, and co-authored new notes that were added to KF.

Knowledge Forum
Our analysis requires explicating some basic functions of KF: *Notes* are the most basic type of contribution to KF. Notes include a title, co-authors and timestamp, scaffolds, and the note's content. *Scaffolds* are tags students select from a sidebar to bracket a segment of text in their note, which help ensure discourse is productive. *Build on* allows students to add a new note in response to an existing one. *Rise above notes* have all the functionality of standard notes, while also allowing users to drag-and-drop multiple existing notes into one space. *Views* are individual webpages, which begin as an empty canvas to which students can add notes, images, links, or files.

Data

Collection
Data included all notes from KF; students' end-of-year essays; video recordings of 25 lessons; and unstructured interviews with the teacher and students. The author attended all the lessons and took field notes throughout.

Selection and analysis
We drew on Sandoval (2014), who distinguished between the *embodiment* and *mediation* phases in DBR. To answer our research question, we sifted through the data, seeking out *rich points* (Agar, 1994, p. 232). For each rich point we selected, we conducted a detailed micro-analysis of what transpired in the *mediation* phase, asking what students did, wrote, or said; what motivated them; and what other alternatives were available. We then reflected on the mediating role of the curricular content, participant structures, and KF, which together constituted the essence of the *embodiment* phase, and asked how the design impacted the learning experience.

Findings

Elevated awareness
For the first assignment, the class was provided links to ten online news articles that illustrated how Jewish identity shapes everyday life in Israel. Articles touched on race, ethnicity, religion, and more. After splitting into groups and contributing ten notes to KF that summarized the articles, students were given the following instructions:

> [note title] Assignment #2: rising above
> [author] Amos [the teacher]
> [date] 11/12/2018
> [note body] One of the most crucial steps in knowledge building is called "rising above". Now that we have made some progress it's time to stop and think, so we can take the knowledge we've built to the next level… If you haven't done so already, read all the notes summarizing news articles. Each note discusses a different case, but some of them are connected. Join with another group or two whose notes' content is connected to yours. From 10 groups, you now must create no more than 4 groups in total. After creating a new group add a "rise above" note that takes our knowledge to the next level…

One group of students summarized an article about a controversy surrounding Ethiopian immigration to Israel. The Jewish community in Ethiopia is divided between Beta Israel, whose customs and rituals are outwardly Jewish, and the Falasha Mura, whose ancestry converted to Christianity. Because Israeli law grants automatic citizenship to all Jews except those who converted to a different religion, Beta Israel Ethiopians are typically allowed to immigrate to Israel and Falasha Mura are not. Another group read an article about Yoram Kaniuk, an Israeli author who won a heated court battle after demanding that he be identified as a "Jew of no religion". The four members of the two groups joined together and co-authored a new rise-above note (scaffolds *italicized*):

> [note title] Rise-above
> [authors] Ron, Eli, Zack, Shani
> [note body] *merging ideas* We decided to merge the articles "Falasha Mura" and "A religious-less man" because both talk about "who is a Jew" – under what circumstances someone is considered Jewish. In the first article, the Falasha Mura… are seeking recognition as Jews from the State. In the second article Yoram Kaniuk… is asking the court to be recognized as non-Jewish. Therefore, the articles are about the same principle of [recognizing] who is a Jew, yet each of them has an opposite view about the Jewish religion.

In this case, the move towards *elevated awareness* was significant. By seeking out the common denominator between the articles, the students were able to articulate a central theme in identity discourse – namely, *mutual recognition* (Ricoeur, 2005). This theme was new to them, but it became central to the class discourse especially as some students went on to explicitly demand recognition for themselves or for marginalized groups in Israeli society. This development was mediated by the tools and participant structures embodied in the KBC. KF allowed students to drag-and-drop their separate ideas into a shared space, while scaffolds indicated that this was a desirable knowledge building move [authors, 2020]. The participant structures (small groups that merged into larger ones) likewise mediated the process. Merging the groups, merging the notes, and merging the content, were three processes that were all embodied into the design of the KBC, and together they mediated an important facet of students-teachers.

Co-constructing knowledge and identity

The rise-above assignment generated a series of abstract questions that arose inductively from discussions of everyday life in Israel and marked a shift from news articles and op-eds to philosophical and legal texts. Amos uploaded eight texts to a new view on KF, and for each of the texts, provided some background information. Students were asked to form groups, select and read one text, and add a note to KF summarizing key takeaways. Each group then created a PowerPoint and presented their findings in a round of reciprocal teaching. One group chose segments from an article that juxtaposed *extreme* and *moderate* forms of Judaism. According to the author, moderate Judaism is grounded in a cultural definition of what it means to be Jewish, whereas extreme Judaism is dictated by religion and nationalism. Below is a segment from the conversation that ensued:

> Molly: …what's the difference between religion and culture? Religion is between you and God and culture is […] everyone together…
> Julie: About what Molly said, that culture brings people together – that's because it […isn't] black and white. You are free to design your culture as you wish and choose which [customs] to keep and which not to keep…

Noa: I think that in ultra-orthodox families, parents coerce their children… if they didn't do that then those who become secular wouldn't be alienated from their families. It comes from a very extreme place…

Shelly: I can give an example about myself. Our family keeps shabbat, we are traditional. Let's say, my sister, at some point she stopped keeping shabbat. At the beginning she didn't talk about it – not because she was afraid of what people would say but out of respect. She comes and keeps shabbat with us, she won't be on her phone around us, but she will outside… Now I also stopped keeping shabbat. Not because I don't like it or because I was coerced, it's just really hard for me [to keep shabbat] with [secular] friends, preparing for exams… I'm sure that when I grow up, I will go back to it…//

Amos: //[*turns to Noa*] you spoke about how rigid religion is… let me phrase this as a question. Is religion *really* so rigid? Shelly is suggesting something else, right?... [*turns to Shelly*] how would you characterize the relationship with religion in your family?

Shelly: My sister stopped keeping shabbat but she does celebrate holidays. My brother and father keep shabbat and attend synagogue. Me and my mother and my sister don't, but we won't drive on shabbat, out of respect…

Julie: [*Talking to Shelly*] that's a great example [of moderate Judaism]! Because [the author] says it's all about what you include and what you forgo… the flexibility in your family means that you can choose what you want to do and how you see Judaism…

Amos: Note the correspondence between Shelly's example and the article…

A close reading of this segment shows how Shelly's developing non-religious identity offered a new take on the curricular content. Molly suggested that religion is an individual experience, whereas Julie argued that religion offers no room for individual choice. Shelly's example refuted Molly's position and strengthened Julie's. In her experience, religion is a family affair, not an individual one; and her choices positioned her as someone who had left religion behind. For Noa, Shelly's story provided a moderate alternative to a specific form of religious extremism – she initially focused on ultra-orthodox Jews who abandon their family when they leave their religion. But Shelly described a more moderate approach whereby religious and non-religious family members can sustain an atmosphere of mutual respect. Julie and Amos both drew a direct line between Shelly's story and the article.

In this case, Shelly's real-world experience directly influenced the knowledge advancement in a process that was mediated by several elements of the KBC's design. Amos selected texts that were pertinent to students' lives; and when the connection emerged, he drew attention to it. In addition, participant structures intentionally created an atmosphere of trust where learners were willing to share intimate details about their own lives.

Shared responsibility

Roughly halfway through the enactment, Amos and [Author] invited several guests, including the school principal, teachers, university researchers, and the director of an educational non-profit, to see the KBC in action. Although they agreed the stakes were high, Amos decided to share responsibility with the students as much as possible. One week before the planned visit, the lesson began – as it usually did – with a group meeting. After a few minutes of chitchat, which Amos encouraged, he outlined the goals for today's lesson.

Amos: As always, we will do everything together, so what we'll do now is divide into pairs; each pair will take a laptop and think and suggest how you think the [visit] should look or how we should present things. What needs to happen [during the visit]? How should it be done? Who should do it? We're thinking together.

The next 50 minutes were dedicated to brainstorming as students contributed 23 new notes and build-ons to KF. After a short recess, students reconvened to discuss their ideas and move ahead with planning the visit.

Amos: What shall we do next? Let's go over the notes, and organize them according to theme, ok? Wandering through the groups and notes, I saw that there was a focus on how we work, so one group will present that [*trails off*].
[*two students arrive late*]

Amos: [*addresses late students in annoyed and frustrated tone*] Why are you late? I'm already in the middle of the lesson; this is not ok! Please don't be late. [*addresses class more coolly*] Let them sit down, [*indicates with finger*] there's a spot. [*resumes explanation*] We will quickly read all the notes, and divide into groups according to theme, so one

> group will present the technology we use… another will explain how our lessons work. In one note I saw a comparison to a regular class so one group can work on that…

Over the next 45 minutes, students read their notes aloud, and discussed various strategies for how best to present their KBC. One question that emerged in the following notes, and came up again in the discussion was whether it would be worthwhile to play a game to make the visit entertaining (scaffolds are *italicized*):

> [note title] Ideas for the sample lesson
> [authors] Lia and Amber
> [date] 1/7/2019
> [note body] *My idea is*… to teach the lesson in a more active way, not sitting down or in front of the laptops – this is something we should do more often...
>
> [build-on note title] Problem!!!
> [authors] Ella and Neta
> [note body] *The problem with this idea* In our opinion we [feel the] need to mention that if we have an active lesson, it could give the wrong impression that our lessons are more like a youth movement. Also, most of our lessons aren't like that, so it could misrepresent what we do.

This exchange transcended the question of how to present the KBC to outsiders. Lia and Amber were proposing to make *all the lessons* more active, apparently because they were unhappy with the rigorous text-based norm. But in another note, Ella and Neta expressed satisfaction with the KBC as-is:

> [note title] Presenting the learning community
> [Authors] Ella and Neta
> [note body] … *Something important I want to share* it is important to share with the guests the benefits of learning this way. For example: formulating and expressing opinions, presenting diverse points of view, improved literacy, and ability to analyze texts…

In this interaction, Amos used participant structures and KF to distribute the responsibility throughout the class – everyone was able to contribute, critique, and voice their opinions, whether on KF or in the group meeting. Indeed, Lia, Amber, Ella, Neta and others all felt comfortable voicing their opinions about the design of the KBC, regardless of whether they were happy with the norms or not. However, this episode also illuminates two challenges facing KBC designers who are oriented towards problem-posing. First, sharing responsibility with students is unlikely to mitigate disruptions. In this case, Amos felt compelled to assert himself as an authority figure despite the communal atmosphere and his opening comment "we do everything together". Second, shared responsibility also means various ideas that cannot necessarily be reconciled. Although their status was officially equal, Ella was a more central figure than the other three students, and as a result, her views were most influential. Revoking authority from the teacher created a power vacuum but did not necessarily mean that the environment was more equitable. The KBC ended up being emancipatory for Ella, but perhaps less so for Lia and Amber.

Discussion: Directions for future research

Our findings show how the design of a KBC mediated the features of Freire's conception of students-teachers. In each of the three episodes, the content, participant structures, and technological affordances of KF worked in concert to mediate some concrete goals of critical pedagogy among students.

Yet, although our study was informative, demonstrating the efficacy of the KBC approach as a means for accomplishing ethical aims, the rich points that we analyzed left us with a series of lingering questions that must be further explored. While Freire's model aspires for a form of praxis that combines reflection *and* action, our analysis of how rising above mediated elevated awareness was limited to reflection, begging the question of whether KBCs might mediate action as well, and if so, how?

Mediation of the co-construction of knowledge and identity through the principal *real ideas and authentic problems* was achieved by means of content and participant structures but was not supported by the technological affordances of KF. What new features might be introduced to future versions of KF to support this kind of identity work, which is crucial for problem-posing?

And finally, relinquishing authority and distributing responsibility evenly between teachers and students was partial and problematic. First, because although the teacher intended to "do everything together", he felt the need to assume an authoritative role as soon as two students disrupted the lesson by arriving late. And second,

because the power vacuum that he left behind was not filled by the students in an equitable way, but rather enabled one student to claim a leadership role based on her charisma and determination. Thus, the question of how to distribute power equitably in KBC remains open and requires further investigations and contemplation.

Conclusion

The "political turn" in the learning sciences has led increasingly more scholars to recognize that their work should take ethical considerations explicitly into account. Indeed, some have concluded that in addition to advancing learners' knowledge, skills, or expertise, their scholarship should also focus on achieving ethical aims. But doing so does not necessarily require them to go back to the drawing board to design new learning environments from scratch. On the contrary, this paper shows how existing scholarship can be modified or repurposed to design educational innovations that seek to promote social justice and other values.

Abstract: Scientific explanations rarely include all interactions and entities in a mechanism. Instead, some information is hidden in black boxes, keeping the focus on the explanation's essence. Studies show that navigating between black-box explanations and detailed mechanistic explanations perplexes students as they misunderstand the reasons for including or omitting mechanistic information. Therefore, we examined students' preference towards information allowing for the formation of either a black-box explanation or a detailed mechanistic explanation. Fifty-two 9th grade students read three scientific problems in three contexts. Students stated and justified their preference of information. Analysis revealed students based choices on problems' context and explanation's productivity. Students preferred black-box information when recognizing the need to make a prediction and detailed information when recognizing a need to control phenomena. Results suggest clear explanatory goals assist students' navigation between detailed and black-box explanations. This calls for a more explicit discussion around black boxes in the science classroom.

Introduction

The new mechanistic philosophy, explained by Machamer, Craver and Darden (2000; MDC), identifies mechanistic reasoning as a tool scientists can use to explain, predict and control phenomena. A mechanistic explanation is constructed first and foremost from a set of entities, the cogs and bolts of the mechanism. Each of these entities has its own activity, i.e., the thing the entity does and by that affects other entities in the mechanism. Furthermore, each entity has its own properties, i.e., essential characteristics of the entity, allowing it to perform its activity. As one describes the entities and their features (e.g. activities, properties), along with a description of how they are organized together, it can be shown that when they are organized together just so, they produce the phenomenon one is trying to explain (Craver & Darden, 2013, p. 65).

While mechanistic reasoning is an important part of the philosophy of science, it should not be considered a tool restricted to the use of scientists. Indeed, in the context of cognition, mechanistic reasoning has been described as a special case of causal reasoning, an inference about the causal relationship between two events, made in a manner that is not solely dependent on co-variation information (Ahn & Kalish, 2000). Research in the fields of cognitive and developmental psychology has taught us that this form of causal thinking is so natural to us that 4-years-old children are able to comprehend simple forms of mechanistic explanations (Lombrozo et al., 2018), that both young children and adults display a bias towards experts sharing mechanistic information (Lockhart et al., 2019) and that adults seek mechanistic explanations when trying to make sense of everyday events (Ahn et al., 1995).

While mechanistic reasoning seems to be performed at all ages, Perkins and Grotzer (2005) provide a review concerning the development of causal thinking, suggesting that mechanistic reasoning is a dimension of causal thinking that advances gradually. For example, while young students may provide surface level generalizations or token explanations when explaining a phenomenon (e.g. 'a trait is the result of a gene.'), more complex explanations, concerning underlying mechanisms are usually less common in such early ages. Following Russ et al.'s (2008) framework for analyzing classroom discussion, multiple studies have also highlighted the challenges students encounter while reasoning mechanistically in the classroom (e.g. Dickes et al., 2016; Duncan & Tseng, 2011; Haskel-Ittah & Yarden, 2017; van Mil et al., 2016). Furthermore, mechanistic reasoning has been included as one of the seven crosscutting concepts, listed as "Cause and effect: Mechanism and explanation", in the Next Generation Science Standards (NGSS) in the United States (NGSS Lead States, 2013). This inclusion contributed to the promotion of students' mechanistic reasoning as one of the goals of science education.

Although the ability to reason about mechanisms might be related to a person's age or developmental stage, research in biology education has taught us that students' ability to learn and reason about biological mechanisms also relies on disciplinary knowledge and specifically on students' familiarity with the entities in a mechanism. Such studies have also shown that students' mechanistic reasoning can be advanced by exposing students to information about these entities. For example, data suggest that third graders improve in their ability

 © ISLS

to reason about a mechanism in the context of ecology, as they iteratively conduct activities and are repeatedly exposed to the entities and entities' activities in the mechanism underlying a phenomenon (Dickes et al., 2016). In a similar manner, in the context of genetics, 7th grade students have been found to use proteins, the key entities in the learned mechanism, mainly when they are familiar with a protein's relevant activity (Haskel-Ittah et al., 2020). Likewise, undergraduate students' performance shows that they rely on their broader domain-specific knowledge of key entities to produce mechanistic explanations in novel contexts (Southard et al., 2017).

As studies focus on students' familiarity with entities in the mechanism, and as biological mechanisms tend to hold many entities, it becomes clear that the task of discussing all of these entities in the classroom becomes an immense one, to the teacher and students alike. Furthermore, considering the fact that some mechanisms can hold a vast number of entities and that every causal connection in a mechanism holds in itself a mechanism of its own, it can be argued that no mechanistic explanation is ever complete. Thus, we need to ask ourselves if we are paying as much attention as we need to the gaps in our mechanistic knowledge and mechanistic explanations.

It is not surprising to find out that most people work with partial understandings of mechanisms, as no human can actually hold in his mind the complete details of a complex mechanism (Keil, 2019). This means most mechanistic explanations intrinsically hold in them some knowledge gaps, points in which a causal connection in the mechanism is left unexplained. While knowledge gaps in a mechanistic explanation might make us question the correctness or completeness of the explanation, we must remember that mechanistic discourse acknowledges the existence of knowledge gaps, and has even objectified them by naming and focusing on them under the term of "black boxes". A black box, in the context of mechanistic reasoning, is a unit containing missing pieces, which we do not yet know how to fill in with entities and activities, in a way that it creates a gap between one step in the process to the next (Machamer et al., 2000). It should be emphasized that not every omitted or unknown detail in a phenomenon is a black box, just as black boxes are not simply forgotten details of a known mechanism. Black boxes are the parts of a mechanism for which we know the existence of a causal connection but are unable or indisposed to explain the nature of this causal connection. In other words, it is knowing that A causes B without explaining how exactly A causes B.

While it would seem like black boxes are the nemesis of any mechanistic philosophy, black boxes are regarded as a tool in scientific discourse. A good, well-known example of black boxes in biology would be the patterns and co-variation data produced by Gregory Mendel (1822-1884) in the 1860s, and rediscovered, during the beginning of 20th century, by Hugo de Vries (1848-1935), William Bateson (1861-1926) and others (Provine, 2001, p. 56). While Mendel was able to collect data in a precise, methodical manner, and use that data to detect inheritance patterns, he did not describe the underlying mechanisms of such patterns. The inherited factors of Mendel, later to be known as '*genes*', and gene variants, later to be known as '*allele'*, were never described in a mechanistic manner, but rather as part of a probabilistic model (Heim, 1991), meaning a model that allows for prediction, without explaining the underlying mechanisms, hence a black box. This black box knowledge, at the beginning of the 20th century, was enough to articulate several laws, such as the law of dominance and the law of segregation, allowing for the prediction of progeny population. Just as important, the acknowledgment of this probabilistic model as a black box (Morgan, 1909), which contains some unknown underlying mechanism that needs to be discovered, allowed scientists to focus their research on the entities inside this black box.

By the 1960's the scientific community was able to describe the entities and the entities' interactions within it (i.e., unpack the black box), a joint effort that has led to the accepted model of today's modern times, describing the activities of several entities such as the DNA, RNA and ribosomes (Cobb, 2015). In a similar manner, while the central dogma of molecular biology has been used a working model since the 1960s, the full structure of the ribosome, for which Ada Yonath was awarded the Nobel Prize for, was described only in the year 2000 (Weizmann Institute of Science, 2009). These examples go to show that scientists use and apply mechanistic explanations containing black boxes, in a productive manner, all the time. Furthermore, while this could be attributed to some kind of lack of choice (i.e., scientists have to make do with incomplete explanations), it should be made clear that even today, most mechanistic explanations concerning the central dogma would not benefit from the knowledge concerning the precise structure of the ribosome. Likewise, today, a genetic consultant can calculate, predict and explain the risk for the Tay-Sachs disease in one's family (an explanation containing the Mendelian black box) by considering the alleles in a family, without unpacking any details about the central dogma (i.e., the underlying mechanism). In summary, in scientific discourse, unpacking a black box when formulating a mechanistic explanation is dependent on the goal of the explanation, whether it is to explain the mechanism itself, predict the outcome of certain conditions or control a phenomenon by manipulating elements in its underlying mechanism (Machamer et al., 2000).

Although scientists accept and appreciate the existence of explanations containing black boxes, in the science classroom, science teachers usually hold the notion that while there might be different explanations using different amounts of detail and information, good explanations need to be as comprehensive as possible by

containing as many complex details as possible, in an effort to achieve a high a degree of similarity between the details in the explanation and the details in the phenomenon being explained (Justi & Gilbert, 2002). Furthermore, as demonstrated by a study in genetics education, students find it difficult to rationalize the co-existence of explanations including black boxes, alongside with explanations including that same unpacked black box. This has been specifically demonstrated in the context of genetics where black box explanations using information about Mendelian inheritance patterns co-exist alongside unpacked mechanism explanations using central dogma information (Gericke et al., 2013). While science appreciates the existence and productiveness of black box explanations, the focus, in the classroom, on an explanation's 'completeness', and the lack of attention to the productiveness of an explanation, is probably one of the reasons students often expect explanations to be 'complete' without any regard to their usefulness (Passmore et al., 2014). Accordingly, in the traditional biology classroom it might be difficult to find examples of students struggling with the idea of an explanation's productiveness, simply because they are usually required to give the most 'complete' explanation instead of choosing the most useful explanation or reason about the productiveness of their explanation.

While students' and teachers' tendency to search for the most 'complete' explanation can be attributed to a general bias towards detailed mechanistic explanations, it has been demonstrated that providing contextual cues concerning the goals of the explanation diminishes some of this bias. For example, Lockhart et al. (2019) demonstrated that while children and adults regard people providing mechanistic information about an object as more knowledgeable, they are more inclined to consult a non-mechanistic expert when they are informed that they need to sell an object. In a similar way, when adults are asked to rate the 'goodness' of mechanistic or teleological explanation, they prefer explanations that highlight the kinds of relationships that they expect to be useful for the task at hand (Vasilyeva et al., 2017). To make matters more complicated, it has been demonstrated that students reason about their choice of an explanation using several non-etiological reasons, such as the level of interest they find in the explanation and explanation complexity. For example, when students were asked to choose between a causal explanation or a teleological explanation to a phenomenon, some preferred a causal explanation because they viewed it as more 'interesting', while others preferred a teleological explanation because they viewed it as less 'complex' (Trommler et al., 2018).

Whereas the above-mentioned studies show that the choice between different explanations can be affected by contextual cues and that in some cases reasons for choosing an explanation can be non-etiological, all of them compare between epistemologically distinct explanations (e.g., mechanistic vs. teleological; mechanistic vs. functional). However, as previously discussed in this article, in some cases the difference between two mechanistic explanations can be the degree with which certain black boxes have been unpacked. While scientists determine whether to unpack a black box by evaluating the goal of the explanation, and specifically whether their aim is to explain, predict or control the phenomenon, it is not clear whether students can appreciate the existence of explanations containing black boxes when exposed to such goals.

In light of the above, it became of interest to examine whether students are able to appreciate the co-existence of explanations containing black boxes, alongside with explanations containing these same unpacked black boxes, when these explanations are presented in a context of different explanatory goals. To shed light on this problem, we strived to answer the following research question:

How do 9th grade students distinguish between the explanatory powers of black box explanations when faced with different contexts, containing different explanatory goals?

Methods

Research context and population

Ninth grade students in Israel are required to learn genetics. The mandatory curriculum includes chapters concerning the mechanism of meiosis, the mechanism of the central dogma and Mendel's principles. While Mendel's principles are essentially a black box which allows the prediction of traits in a progeny, the central dogma is the underlying mechanism which explains how exactly genes affect traits. Thus, while the appearance of traits can be predicted or explained by taking into account the existing alleles and using Mendel's principles, the unpacked central dogma mechanistic explanation allows detailing how entities, such as the DNA and RNA molecules, interact to produce such traits.

Fifty-two 9th grade students from two classes in the same school participated in this study. Both classes were taught by the same teacher, a science teacher with a M.Sc. in biology and on her 1st year of teaching. Students were taught about phenomenon and mechanisms in genetics, specifically the mechanism of meiosis, the mechanism of the central dogma of molecular biology and principles derived from the Mendelian black box, in that order. No explicit reference was made, in the classroom, to the term 'black box'. Furthermore, the teacher did

not pay any attention to the merits or constraints of using the Mendelian black box explanation vs. the unpacked central dogma mechanism.

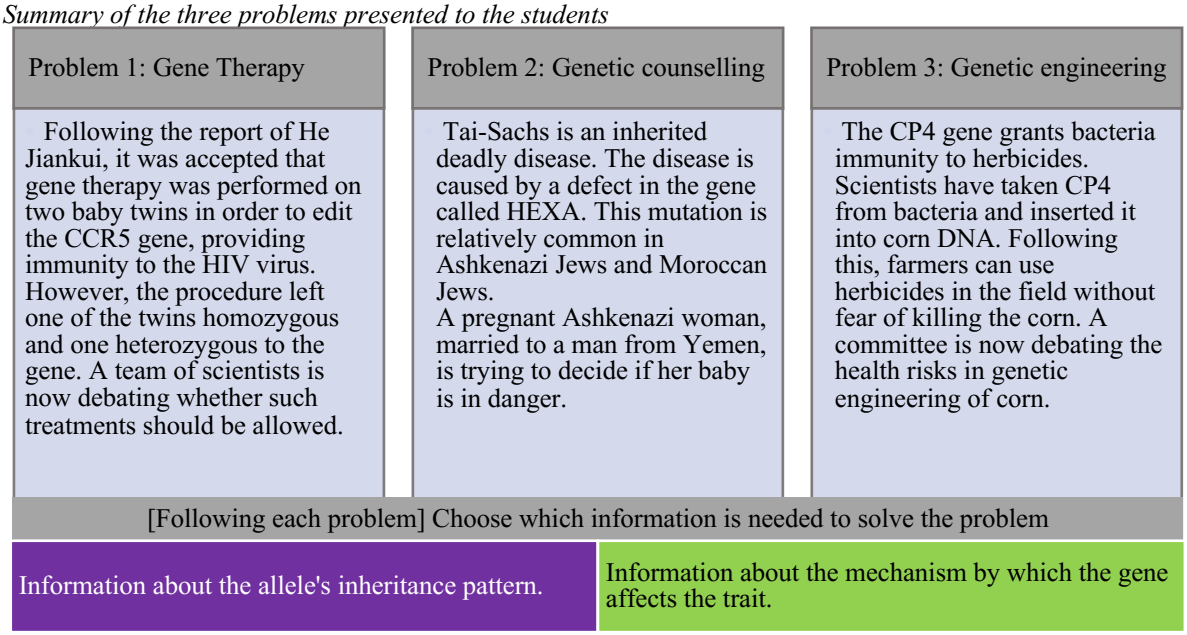
Research design

To examine students' preference of explanation in different contexts, each student read three scenarios in three different genetic contexts: gene therapy, genetic counseling and genetic engineering. Each scenario included a phenomenon in genetics lacking information about its underlying mechanism. The question at the end of each problem presented the students with a preference judgment task in which they were asked to choose which information is needed, in their eyes, to solve the problem at hand: a. information concerning the discussed alleles' Mendelian inheritance patterns or b. the mechanism by which the gene affects the trait. The three problems dealt with the issues of gene therapy, genetic concealing and genetic engineering as summarized in Figure 1.

We strived to minimize any effect derived from students' ability to use or come up with any explanations. Therefore, we asked students to choose which information they view as needed to solve the problem but did not ask them to solve it or even judge a written solution. We consider students' choice of option 'a' as a preference towards black box information and students' choice of option 'b' as a preference towards unpacked mechanism information. Thus, we use the term 'black box information' and 'unpacked mechanism information' to denote students' preference of either option 'a' or 'b', accordingly. This is not to suggest that students were aware of the type of information their answer is related to, but to classify students' choice of needed information to the type of explanation that can be constructed from that information.

Figure 1

Summary of the three problems presented to the students



After choosing an option, students were asked to justify their preference, before proceeding to the next problem. As each of the students provided three justifications, one to each problem, a total of 156 justifications were coded by two coders. Students' justifications were coded using an iterative bottom-up procedure, to reveal three categories: explain, predict and control. Justifications were coded as 'explain' when students wrote that the information they deemed as needed to solve the problem can be used to describe the phenomenon better or gain knowledge about it, without mentioning any other implications of this knowledge. For example, in the gene therapy problem, a student preferred to gain knowledge about the mechanism by which the allele leads to the discussed trait:

"Because I am interested in knowing how the defect in [the allele] CCR5 causes immunity."

The 'predict' code was used when students justified their choice by writing that the information achieved enables them to foresee the outcome of the conditions described. For example, in the genetic counseling problem, a student preferred to gain knowledge about the inheritance pattern of the discussed allele because:

"This will help the woman understand if her offspring will be sick."

The code 'control' was used when students claimed that the information can assist them in manipulating the outcome of the conditions described. For example, a student preferred to gain knowledge about the mechanism by which the allele leads to the discussed trait because:

 © ISLS

"Then we can make a cure."

Sixteen out of 156 justifications (10.3%) were coded as non-etiological or incoherent. Four justifications were omitted from analysis as they supported a rejection of both options (black box and unpacked mechanism). As a result, a total of 136 justifications were analyzed. Inter-rater agreement, between the two coders, concerning justification coding was 86% before peer discussion and 100% after peer discussion. Justifications were quantified and the rate of each category was calculated.

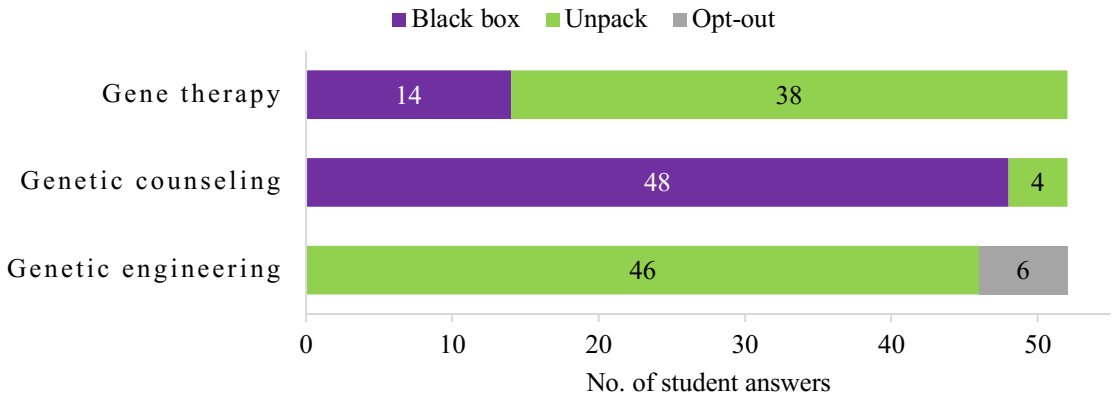
We wish to point out that as we focused on the contextual feature of productivity (predict, explain or control), our study did not include any analysis of other variables or discrepancies between the problems presented to the students. As such, we cannot determine whether other contexts, such as the organism in the problem, affected students' choices. It might be helpful to note that we were unable to identify justifications holding any reference to such variables.

Results

Choice of explanations was analyzed using a Chi Square test. As six students did not choose any of the options in the third problem and as an analysis of their justifications revealed they did not see any of the explanations as relevant to solving the problem, these students were excluded from the Chi Square test of the third problem.

Figure 2

Students' choices in preferance judgement task. n=52. Opt-out are students who did not write their choice.



Data analysis revealed a significant difference between the types of information chosen in the three different contexts (Figure 2). When faced with a problem in the genetic therapy context most students chose unpacked mechanistic information $X^2(1, N = 52) = 5.54$, $p<.01$. When faced with a problem in the context of genetic counseling most students chose black box information, $X^2(1, N = 52) = 18.62$, $p<.01$. Of the 46 students who made a choice when faced with a problem in the context of genetic engineering all students chose unpacked mechanistic information. Therefore, data suggest that students used the context of the problem to decide which type of information is needed, with a preference towards unpacked mechanistic information in the context of gene therapy and genetic engineering and black box information in the context of genetic counselling.

Distribution of students' justifications was analyzed using a Fisher's exact test. Data in Table 1 show that when students justified their preferences supporting black box information, 47 out of 57 were of the 'predict' kind, 7 were of the 'explain' kind and 3 were of the 'control' kind, revealing a significant relationship between the black box information choices and the type of justifications used by the students $X^2(2) = 28.3$, $p<0.05$. Examination of the residuals indicated that the 'predict' justification appeared in the black box category more often, while the 'control' justification appeared in this category significantly less (see 'Black box' row in Table 1). Therefore, it would seem that students associated black box information to its power of prediction. On the other hand, when students presented justifications coded as 'control', there was a significant association between this justification and the unpacked mechanism category (see 'Control' column in Table 1). Thus, it would seem that when students identified the problem as one that is linked with the need to control the phenomenon, they viewed the unpacked mechanistic information as needed in the context of the problem. It should also be noted that a relatively small number of justifications were of the 'explain' kind, 22 out of 136 justifications (16.2%). While Fisher's exact test did not reveal this low frequency as significant, it might be important to note that this can be the result of the context of the tasks, which did not merely require an explanation but posed problems that should be solved (evaluating a treatment, predicting and curing). Furthermore, while 15 out of 22 'explain' justifications (68.2%)

 © ISLS

were used to support unpacked mechanistic information, the difference between the two options (black box and unpacked) was not robust enough for drawing conclusions about differences between the choices.

Table 1

Distribution of students' justifications, sorted by justification type and the type of information the justification supported

	Explain	Predict	Control	Total
Black box	7	47	3	57
Unpacked mechanism	15	31	33	79
Total	22	78	36	136

Numbers indicate occurrence of each justification type.

Discussion

Scientists accept and appreciate the existence of explanations containing black boxes, as unpacking a black box when formulating a mechanistic explanation is dependent on the goal of the explanation: whether it is to explain the mechanism itself, predict the outcome of certain conditions or control a phenomenon by manipulating elements in its underlying mechanism (Machamer et al., 2000). However, in the classroom, teachers and students focus on an explanation's 'completeness' (Justi & Gilbert, 2002; Passmore et al., 2014). In the genetics classroom, students have access to both black box explanations and unpacked mechanism explanations. However, choosing to use the wrong type of explanation for the task at hand can lead students to incorrect conclusions (Gericke & El-Hani, 2018). Studies suggest that students struggle with understanding the differences between black box explanations and unpacked mechanism explanations (Gericke et al., 2013; Marbach-Ad & Stavy, 2000).

Our data points to a clear preference towards information needed for the construction of a detailed mechanistic explanation in the context of gene therapy and gene engineering. Furthermore, data points to a clear preference towards information needed for the construction of a black box explanation in the context of gene counselling. As students chose the type of information needed to solve the problem but were not asked to explicitly name each of the options, or even compare between them, it is impossible for us to determine whether they view each of the explanations as a black box explanation or a mechanistic explanation. However, our data does suggest that students were able to recognize some differences between the two explanations as they correlated each of them with different problems. Furthermore, students' justifications for choosing each type of information appear to point to their use of contextual cues embedded in the problems, a practice described in previous studies (e.g., Vasilyeva et al., 2017). Students referred to information concerning the underlying central-dogma-mechanism as one that allows control of the phenomenon, while referring to information concerning the Mendelian black box as one that allows for prediction. Therefore, our data hints at students' ability to classify each type of the offered information as different types of explanations, with different affordances towards their use in different problems. In that sense, it would seem that while previous research has demonstrated students' inability to rationalize the co-existence of central dogma explanations and Mendelian explanations (Gericke et al., 2013), providing students with contextual cues about the different goals achieved by using such explanations allows students to produce justified decisions in the context of this co-existence.

Although in this study students chose the content of information needed to solve a problem, they did not explicitly refer to the type of information (black box vs unpacked). However, we suggest that this is an important starting point to understand how students classify the information needed to formulate each type of explanation. According to our analysis, it would seem that students in this study perceived the provided black box explanations in a very distinct and consistent manner. When students faced a problem in the context of genetic counseling, almost all students in this study expressed a need for information about allele inheritance pattern, thereby taking a black box explanation approach. It should be noted, that the genetic counseling problem contained cues calling for the prediction of traits in the offspring population. The use of a black box explanation offers exactly this power. Therefore, students' preferences seem to reflect a very strong connection, made by the students, between the black box explanation and its application in explaining and predicting the distribution of phenotypes in a population of progeny. Supporting this claim are the students' justifications for their choices, as almost all students in this study expressed a wish to predict the outcome of the specified setup conditions. The above data suggest that students view black box explanations as explanations that are strongly connected to the ability to predict traits distribution in a progeny, and to predict the effect of an allele on a trait. While students acknowledged the black box explanation's power to offer prediction, it also became apparent that students perceived the unpacked mechanism explanation as one that allows manipulation of the scientific situation, in an exclusive manner (i.e., they did not view the black box explanation as one that offers a manipulation or explanation of traits).

Our analysis of students' justification to the use of each type of information leads to the conclusion that students judged the information presented to them in terms of productivity. Furthermore, while in a minority of

cases students presented justifications based on the need to explain phenomena, in most cases, students expressed a need to predict or control the outcomes of phenomena. We find this approach, towards the productivity of an explanation, concurrent with the way scientists view and use different types of information, as well as black box explanations (Machamer et al., 2000). Building on these students' intuitive understandings, in the classroom, may enhance students' distinction between different types of explanations and prevent conflation between a Mendelian black box perspective and a molecular mechanistic perspective, a known concern in the field of genetics education (Gericke et al., 2013).

In light of the above, our study supports the argument for explicitly teaching about the idea of black box explanations in the science classroom. We submit the idea that while classroom discussions tend to focus on the 'completeness' of explanations (Justi & Gilbert, 2002; Passmore et al., 2014), real life explanations are rarely complete. Rather than being complete, explanations can be productive and can be judged according to their productivity (Passmore et al., 2014). Our results suggest that students have the intuitive basis for gaining an understanding of the complex nature of various explanations. Therefore, explicitly pointing at different types of explanations and especially the presence of black boxes in explanations might be a way to help them establish a better understanding of the nature of different explanations. Namely, students understand that the need for unpacking black boxes is dependent on the contextual features of the problem. Thus, explicitly referring to black boxes in mechanistic explanations may help them understand what they can (and cannot) do with a given mechanistic explanation.

Lastly, this identified students' sensitivity to the relations between contextual features of the problem and the level of unpacking for a good-enough explanation calls for putting emphasis on the framing of questions and problems. It has been previously demonstrated that students who are unaware of the existence of a black box (e.g., the causal connection between genes and traits) find it harder to use new mechanistic information concerning the contents of that black box to construct a mechanistic understanding of the phenomena (Haskel-Ittah & Yarden, 2018). We submit that any mechanistic information discussed in the classroom should include not only an explicit discussion of the existence of the black box, but also a discussion of the reasons behind its unpacking. We view this framing as one that should include contextual hints on whether the problem requires an explanation, a prediction or a control of a phenomenon. As long as problems presented to students hold little or no contextual hints, discussion about the goodness of an explanation cannot be broader than the rote learning of details. However, once an explanation becomes a solution to a contextualized problem, other features of the explanation can be evaluated and a more authentic discussion can follow.

Relevance of Students' Goals for Learning Engagement and Knowledge Gains in an Online Learning Course

Martin Daumiller, Raven Rinas, & Markus Dresel

University of Augsburg, Germany

Abstract: Online courses are an important form of educational delivery worldwide, yet there are large differences in how well different participants learn from them. We strive to better understand these differences and investigate how they are related to participants' motivations and learning gains. Following an achievement goal approach, we distinguish between two mastery goals (task and learning goals) and performance approach and avoidance goals. We constructed an online course including 182 undergraduates and assessed their goals and prior knowledge before, and their knowledge gains after the course. Through learning analytics, we assessed learning engagement based on 9 indicators concerning usage, time, and clicks regarding the different course elements. Structural equation modelling showed that task goals were particularly beneficial for learning engagement, and in turn, learning gains. This paints a more nuanced picture of how mastery goals matter and illuminates how students' goals form a relevant premise for successful online learning.

Introduction

Online courses are a central element of educational systems and are becoming increasingly important. Over the last years, learning with online courses has rapidly increased and has been incorporated in all levels of educational systems (Castro & Tumibay, 2021; Lloyd et al., 2014). For example, in the USA in the academic year 2019-20, the percentage of students enrolled in distance education courses in postsecondary institutions was 51.8% (Hill, 2021)[1]. Adding to this, online learning is considered one of the most important forms of educational delivery in the world (e.g., Ng, 2016), and the recent shift to online teaching during COVID-19 provided a glimpse of what more is to come. However, this increasing trend of learning in online courses also comes with challenges, such as lower completion rates and participation (Ng, 2016; Simpson, 2013), making knowledge about how students differ in their engagement and learning within online courses crucial (see also Liu et al., 2009).

Despite the rising use and relevance of online learning, research on factors that drive students to learn successfully in such formats is still nascent. At the same time, knowledge about learning in traditional, face-to-face classroom settings cannot be readily transferred to online learning, as learning in classrooms and online courses systematically diverge: Besides format differences in terms of modes of interaction, accessible information, and (non-)linearity of design (Dettori et al., 2006), online learning is coined by more autonomy on the learner side and the requirement of high self-regulation in learning (Azevedo & Cromley, 2004; Kapp et al., 2015). While design and features of online courses such as social support are important for students' learning therein, learners' characteristics are also highly important and are considered as key competencies for successful online learning (Beaudoin et al., 2009). Within a given online course, there can be vast differences in the extent to which students engage. Consequently, to learn successfully in online courses, high levels of motivation and continuous learning engagement are required and need to be fostered (Simpson, 2008).

In the present research, we strive to better understand differences in learners' engagement in online courses and investigate how these are related to participants' motivations, as well as how they matter for learning performance. To this end, building on previous psychological and educational research, we conceptualize motivation using an achievement goal approach. Combining traditional data collection methods and learning analytics, we show that mastery goals are particularly beneficial for engagement, and in turn, learning gains.

Achievement goals and learning in online courses

Achievement motivation pertains to the energization and direction of competence-relevant behavior and describes why and how people strive toward competence and away from incompetence. As such, motivation is essential for how we experience and behave in achievement contexts, including learning in online courses. Moreover, motivation is dynamic and composed of personal as well as contextual aspects. Thus, for learning in an online course, it is especially important to consider the specific motivations regarding the upcoming course (opposed to general motivational characteristics). This does not (necessarily) reflect why individuals decide to participate in a given course, but rather differences in how they are motivated for this context. A prominent approach in educational psychology to describe such motivations is the achievement goal approach (Elliot & Hulleman, 2017).

 © ISLS

Achievement goals represent the "different ways of approaching, engaging in, and responding to achievement situations" (Ames, 1992, p. 261). They form cognitive representations of competence-related end states in achievement contexts that an individual is committed to approach or avoid (Elliot & Hulleman, 2017). Different types of achievement goals with which students approach a particular online course can be distinguished (de Barba et al., 2016). Given that these goals represent what individuals want to reach at the end of their learning, they act as a motivational basis for the interpretation of learning situations and self-regulation therein. Thus, close links with learning engagement and learning outcomes are to be expected. Indeed, previous research has shown that achievement goals are associated with self-regulated learning (Adesope et al. 2015; Zhou, 2013), learning engagement (Froiland & Worrell, 2016; Greene et al., 2004), and academic achievement (Church et al., 2001).

Following this approach, different types of goals have been suggested to matter in achievement contexts. While further distinctions have been discussed (for a contemporary overview see Daumiller et al., 2019), on a minimal level, three fundamental types of goals should be distinguished: mastery, performance approach, and performance avoidance goals. Mastery goals are characterized by a focus on task mastery and improvement. Based on their orientations, they can be distinguished further (see e.g., Daumiller & Zarrinabadi, 2020; Elliot et al., 2011; Hulleman et al., 2010; Korn et al., 2019), most notably depending on whether an individual is oriented at conducting tasks right (here termed *task goals*), or at the improvement of their own competencies (*learning goals*). Given these foci, mastery goals can be considered highly functional in learning contexts for engaged learning and learning gains, as they are focused on increasing levels of competence by acquiring the knowledge or skills that the task develops (Daumiller et al., 2021; Murayama et al., 2012; Payne et al., 2007; Wolters, 2004). It is worth noting that prior research typically assumes that mastery goals matter for learning outcomes through differences in students' engagement, but empirically, this proposed mediation has seldom been tested (Daumiller et al., 2021).

Opposed to mastery goals, *performance approach goals*[2] constitute a striving of wanting to be better than others, and *performance avoidance goals* are focused on avoiding doing worse than others. As such, performance approach goals combine a favorable approach-orientation with a focus on performance that serves to keep performance efforts channeled toward normative standards frequently eventuating in high levels of performance (Murayama et al., 2012). However, this might distract from deep learning, as reflected in a meta-analysis by Payne et al. (2007), where no associations with learning gains were found despite increased (adaptive as well as maladaptive) learning processes (e.g., Harackiewicz et al., 2000; Senko & Dawson, 2016). In contrast, performance avoidance goals combine two negative aspects (focus and valence), rendering clearly negative effects. Such goals are linked to anxiety, task distraction, and helpless engagement patterns (Elliot & Church, 1997) and have also been associated with reduced learning gains (Payne et al., 2007) and more maladaptive learning engagement of students in the form of more procrastination, surface processing and disorganization, and less deep processing (Diseth, 2011; Elliot et al., 1999; Elliot & McGregor, 2001; Wolters, 2004).

As described before, these general mechanisms of achievement goals may not readily transfer to online learning contexts (see de Barba et al., 2016). Regarding online learning, only few studies have yet investigated the relevance of achievement goals. However, accumulating evidence points to mastery goals mattering for online learning as well. For example, Xia and Huang (2014) investigated 132 students in a collaborative college-level online course and found that students pursuing strong mastery goals exhibited more frequent participation in online learning activities and reported to have learned a great deal from them. Yeh et al. (2019) found in a sample of 93 undergraduate and graduate students participating in various online courses that only mastery, but not performance goals, were positively related to supportive online learning behaviors and, by extension, expected grades mediated by an increased use of self-regulated learning strategies. Further, de Barba et al. (2016) found that for students participating in a MOOC (Massive Open Online Course), mastery approach goals assessed retrospectively after the course were associated with students' quiz attempts, and in turn, their final grades. In their study, de Barba et al. (2016) considered quiz attempts as one aspect of engagement, next to video hits.

Interpreting the current state of this line of research, three points should be considered. First, beyond research in the online learning context, mastery goals have typically been considered on a superordinate level in that they are not further distinguished into task and learning goals. Studies across different populations suggest different patterns of learning processes depending on whether individuals are focused on task or learning standards (Daumiller & Dresel, 2020; Elliot et al., 2011; Mascret et al., 2015b, 2015a; Yang et al., 2016). However, it is not yet clear how task and learning goals might specifically operate for such learning processes. As learning goals are focused on improving own competencies, they might be superior for learning processes compared to strivings focused on doing tasks right, as they may tie learning closer to one's self-worth. Conversely, task goals might be superior to learning goals in learning settings, as learning goals might distract learners from covering the full breadth of content to be learned (e.g., due to finding certain aspects particularly interesting and placing a focus on them), which might be especially the case in settings with high autonomy requirements (such as learning in online courses). As the research and practical implications drawn from these findings can differ substantially, further

investigations into the different facets of mastery goals are necessary. Adding to this, performance goals are still little understood in online learning contexts, where studies have either omitted them altogether (e.g., de Barba et al., 2016), or have not considered them relevant in remote learning contexts due to a lack of contact with peers (Sachs, 2001). More research is needed to determine their significance, especially as concerns about what others do may still be prevalent despite the actual presence of others. Lastly, in motivation research in general, self-reports are typically used to assess engagement. This can lead to a host of problems associated with same-source bias, desirable answering, and understandability (e.g., Karabenick et al., 2007), which need to be overcome by assessing engagement through other means. In the present work, we therefore consider learning engagement using a broad array of learning analytics indicators concerning how exactly students interacted with the online course.

Learning engagement and learning gains in online courses

Engagement can be defined as the time and energy students invest in educationally purposeful activities (Kuh et al., 2005). Research has consistently found engagement to be a key contributor to success in educational contexts. Importantly, learners who adopt a more engaged approach to learning are more likely to have increased learning gains (e.g., Froiland & Worrell, 2016). However, there is also variability in students' learning engagement, making it necessary to understand what individual factors might lead to different levels of engagement.

For examining learning engagement and outcomes in online contexts in particular, a unique opportunity to capture a more reliable understanding of these interrelations becomes apparent. Learning analytics paired with resulting log data from online courses represent a promising opportunity to measure and analyze how students engage with the different course materials in terms of specific interactions (e.g., views, clicks, posts, scrolls). Such objective indicators of engagement mark an important development within research on student learning, as they have the potential to overcome limitations from self-report measures and are minimally disruptive.

Indeed, several studies have found objective indicators of engagement within online courses to meaningfully represent students' learning involvement and persistence (e.g., Bonafini et al., 2017; de Barba et al., 2015; Phan et al., 2016; Pursel et al., 2016; Xiong et al., 2015). These objective forms of engagement have also been linked to different learning outcomes in theoretically sensible ways. For example, Bonafini et al. (2017) found that students who participated in a MOOC had a higher probability of course achievement when they completed more forum posts and watched more videos. Moreover, as previously noted, de Barba et al. (2016) defined students' engagement as their video hits and quiz attempts within a MOOC, which were positively linked to their interest and final grades. Adding to this, Xiong et al. (2015) assessed students' engagement in a MOOC as a latent variable through the indicators of: videos watched, forum posts, and number of assignments and quizzes completed—which was found to be positively predicted by motivation and resulted in higher student retention. To this end, construing engagement as a latent variable may be particularly advantageous to reflect the overarching psychological construct of engagement as opposed to only focusing on single indicators.

In terms of differentiating which objective indicators of learning engagement within online courses are better to investigate than others, a consensus within the literature has yet to be reached (see Agudo-Peregrina et al., 2014). Nevertheless, important criteria can be drawn from prior studies (e.g., Bonafini et al., 2017; de Barba et al., 2016; Xiong et al., 2015): To provide more comprehensive and reliable insights, several objective indicators of engagement should be simultaneously examined. Moreover, certain indicators—particularly page views, video views, and interactions with quizzes and assignments—have consistently been found to be meaningfully and significantly related to students' learning outcomes. These specific indicators are also commonly reported within studies investigating objective learning engagement in online courses and can therefore be more readily compared with existing research. Based on these considerations, in the present study, we considered the objective engagement indicators of page views (regarding core lessons, additional information, videos, and quizzes), clicks (within core lessons, additional information, assessments, and quizzes), and total time spent on the course.

The present research

As online learning continues to expand in higher education, the effects of pursuing different achievement goals on learners' engagement in online courses and the resulting learning gains need to be analyzed in more depth. In the present research, we aim to follow up on this research gap. Besides considering achievement goals in detail by distinguishing task and learning facets of mastery goals, we consider learning engagement based on multiple objective indicators. To test the relevance of achievement goals for learning engagement in online learning courses and how this consequently matters for learning gains, we put forth the following hypotheses based on the theoretical and empirical points previously discussed:

Hypothesis 1: Task and learning goals are positively associated with learning engagement.

Hypothesis 2: Performance avoidance goals are negatively associated with learning engagement.

Hypothesis 3: Learning engagement is positively associated with learning gains.

Given the unclear nature of performance approach goals, we did not formulate a directed hypothesis for this type of goal. Further, we presumed that both task and learning goals would result in positive effects, but tested for potential differences between these two facets of mastery goals on an explorative level.

Method

To answer our research questions, we constructed an online course on psychological research methods embedded in the curriculum of a psychology lecture and invited 182 students to participate in it over two weeks in November 2019. The study was conducted in full accordance with the Ethical Guidelines of the German Association of Psychologists and the American Psychological Association. Full anonymity of all participants was assured. We had no reason to assume that completing our survey would have any negative effects on the participants. We provide the online course used as an open educational resource and provide all data and code underlying this research in an open repository (https://osf.io/gp6h3/).

Participants and procedure

The participants of this study included students attending an introductory lecture on psychology. Typical for this population, participants were mostly women (135 identified as women, 45 as men, 2 as diverse), had an average age of 21.4 (SD = 2.6) years, and were in their first year of university. It should be noted that the students had not yet dealt with the topic of the online course (research methods) within their curriculum.

The online course contained 3 core lessons (including 10, 3, and 9 pages of learning content, respectively), 3 videos, 7 pages of additional helpful information, 16 quizzes, and 3 end-of-lesson assessments. It was constructed based on an earlier online course developed by Daumiller and Dresel (2019) and piloted regarding understandability, relevance of content, potential technological problems, and ease of use with five students. The average time spent on the online course was 122 minutes (SD = 70). When accessing the online course for the first time, participants were asked to complete a survey assessing their achievement goals and baseline knowledge. During the online course, we measured their learning engagement in the form of log data corresponding to the indicators of views, clicks, and total time. Directly after completing the online course, the students were required to participate in another knowledge test covering the topics within the course to gauge their learning gains.

Measures

We used the scale by Daumiller et al. (2019) to measure task approach (3 items; e.g., "… my goal is to fulfill the different requirements very well"; ω = .90), learning approach (4 items; e.g., "… my goal is to expand my knowledge as much as possible."; ω = .93), performance approach (4 items; e.g., "… my goal is to be better than the other students."; ω = .94), and performance avoidance (4 items; e.g., "… my goal is not to be worse than the other students"; ω = .94) goals. All items were directed at the online course (item stem: "In this online course…") and answered on a 8-point Likert-type scale ranging from 1 (*do not agree at all*) to 5 (*agree completely*).

As indicators of students' engagement during the course, we used log data concerning (a) the total amount of time students spent on the course, (b) how many times they viewed core lesson pages, (c) how many videos they viewed, (d) how many times they viewed additional information pages (containing supplemental information such as tips for reading research articles and a dictionary with key words), (e) how many times they viewed quizzes, (f) how active they were within the core lesson pages, (g) how active they were within the additional information pages, (h) how many answers they submitted within the assessments, and (i) how many answers they submitted within the quizzes. We modeled residual correlations between closely corresponding and partly dependent indicators (e.g., lesson views with lesson clicks). A CFA confirmed the presumed one-dimensional structure and supported modelling engagement as a latent factor (CFI = .97, TLI = .95, SRMR = .05).

We measured students' content knowledge concerning the online course by administering a slightly adapted and expanded multiple-choice test by Daumiller and Dresel (2019) containing 4 questions before the start of the course as well as the same questions along with 6 further, more difficult questions after the students finished the online course. Based on the proportion of correct items (pretest: M = .64, SD = .13, Min = .19, Max = .88; posttest: M = .65, SD = .11, Min = .38, Max = .90) we subsequently computed the residual change scores between these two knowledge test scores to describe students' learning gains during the course. Given that the post-test was more difficult than the pre-test, it should be noted that the change scores do not reflect the absolute amount of learning gains for each student (which we were not interested in), but instead allows us to quantify differences between the participating students with regard to their learning gains.

Analyses

We estimated a structural equation model in which learning gains were regressed on learning engagement (as a latent variable based on nine indicators) that was in turn regressed on the four achievement goals. We allowed for

direct effects from goals on learning gains. We estimated the direct effects as standardized partial regression coefficients and obtained indirect effects by combining the specified coefficients for direct effects; their statistical significance was tested with *z*-tests. The model was estimated in R version 4.1.1 (R Core Team, 2021) using the lavaan package version 0.6-9 and MLR as an estimator. There was no missing data.

Results

We present descriptive statistics as well as bivariate correlations between all variables in Table 1. In line with prior research on achievement goals, we found rather high levels of task and learning goals and lower levels of performance goals. All goals contained substantial amount of intra-individual variability, indicating that students started the course with different compositions of goals.

The results of the SEM (CFI = .96, TLI = .95, SRMR = .05) are visualized in Figure 1 and indicate that task approach goals had a positive, statistically significant effect on learning engagement, while learning approach goals and the two performance goals did not. Engagement in turn had a positive, statistically significant effect on learning gains. According to Acock (2014) both effects can be considered as moderate. Further, there was a small, statistically significant indirect effect from task goals via engagement on learning gains (β = .05, *SD* = .02).

Table 1

Descriptive Statistics and Bivariate Correlations

	M	*SD*	1	2	3	4	5	6	7	8	9	10	11	12	13
Achievement goals															
[1] Task approach goals	3.92	0.83													
[2] Learning approach goals	4.08	0.80	.69												
[3] Performance approach goals	2.15	1.00	.05	-.11											
[4] Performance avoidance goals	2.59	1.06	.15	.04	.74										
Learning engagement															
[5] Total time	122	70.3	.11	.04	-.02	.07

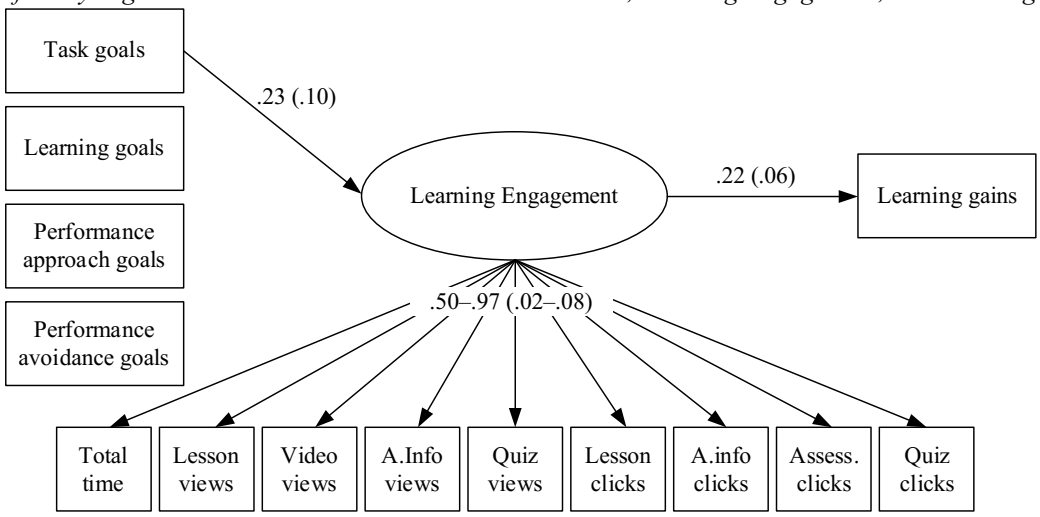
Results of Analyzing the Associations Between Achievement Goals, Learning Engagement, and Learning Gains



Note. Only statistically significant effects are visualized. Residuals and their correlations are not presented.

Discussion

As online courses are an important form of educational delivery worldwide, yet students vary substantially in how well they learn from them, we aimed to investigate differences in students' engagement and how they are related to participants' motivations and learning gains. Following an achievement goal approach, we distinguished between two mastery goals, namely task and learning goals, and included performance approach and avoidance goals. Besides this detailed view on students' goals, we expanded prior motivation research that primarily relied on self-reports by combining traditional data collection methods and novel learning analytics techniques, measuring learning engagement based on a broad variety of objective indicators. Our finding that especially task goals are beneficial for learning engagement, and in turn learning gains, paints a more nuanced picture of how mastery goals matter, and illuminates how students' goals form a relevant premise for successful online learning.

Confirming our expectations and in line with prior findings (e.g., Bonafini et al., 2017; de Barba et al., 2016), we found that learning engagement measured via objective indicators within the online course did indeed matter for students' learning gains. It should be borne in mind that our measure primarily focused on behavioral aspects of engagement; an increased relevance of engagement might have been found had we also considered cognitive and affective aspects more strongly. This highlights the importance of designing online courses in ways that spur engagement, as well as considering the role of personal learner characteristics that might impact learning engagement. Regarding the latter suggestion, our findings indicate that students' motivations expressed in the form of achievement goals constitute personal factors that impact their engagement within online courses.

In terms of the linkages with learning engagement, our findings support that across different types of learning environments, mastery approach goals are positively related to learning outcomes (see Belenky & Nokes-Malach, 2012). The finding that especially task goals (when compared with learning goals) matter for learning engagement and learning gains, requires a closer look into the relevance of mastery goals. Our findings imply that task and learning goals might indeed differ in how they matter for student learning (Daumiller & Dresel, 2020; Elliot et al., 2011; Mascret et al., 2015b, 2015a; Yang et al., 2016). Regarding learning processes, at least within clear learning contexts such as online courses, it might be the case that task goals are superior to learning goals, as learning goals might distract learners from covering the full breadth of content to be learned (e.g., due to finding certain aspects particularly interesting and focusing on them), which might especially be the case in settings with high autonomy requirements (such as learning in online courses). Here it should be considered that we designed the knowledge tests to operationalize learning gains by content-validly reflecting the full range of content within the course. This focus aligns with the notion that learning goals may foster deeper specialized knowledge gain, as opposed to an understanding of all relevant content to be learned. Future research might follow up on this by conducting interviews to inquire about students' learning processes in more detail. Another important take away is that although we also examined performance goals, no statistically significant effects were identified for this goal type with learning engagement or learning gains. This might be a function of the features of the online course, which included little opportunity for normative comparisons (e.g., no opportunity to compare quiz/assessment scores). Therefore, future research should consider a broad array of course features and how these might matter for the effects of performance goals.

When interpreting our findings, two key limitations need to be considered. Firstly, we considered a single online course with unique features, limiting generalizability and comparability of our findings. One way to address this could be extending the present study to courses with different designs. Second, we focused on engagement from an objective and behavioral perspective, however, additionally assessing emotional and cognitive facets of engagement would be an interesting and important direction for future research. Nevertheless, our findings already point to first practical implications. Specifically, task goals should be supported to allow for more successful online learning experiences. This may be facilitated through: (1) directly influencing these goals by stressing the importance of task mastery and putting the respective goals into writing; and (2) supporting these goal striving processes by an arrangement of contextual features emphasized in the online course (Lüftenegger et al., 2014).

In conclusion, our findings contribute to better understanding how established models of educational research can be applied to shed light on students' engagement and learning gains in the increasingly important context of online learning. While online courses may differ in design and support provided, personal learner characteristics such as their motivations should not be neglected. Our findings show that students' goals, and in particular, their task goals, are relevant for engaging more in online courses and taking more away from them.

Endnotes

(1) Given the aberrations of 2020 and 2021 data due to COVID-19, we rely on the data before COVID-19 as an indicator of how widespread the use of online learning courses has become (Hill, 2021).

(2) Similar to mastery goals, performance goals can be further distinguished based on whether they are directed at normative comparisons regarding performance (normative goals), or at competence demonstration (appearance

goals). For theoretical and conceptual clarity, we focus performance goals in the present work exclusively on normative comparisons (in line with Elliot & Murayama, 2008; Elliot et al., 2011).

Genres of Discussion-based Social Emotional Learning: Emotional Inquiry and Inclusive Emotional Dialogue

Abstract: Social and emotional learning (SEL) scholars advocate discussion as a promising instructional method yet rarely specify how such discussions should be conducted. Furthermore, SEL literature contains contradictory discursive imperatives and typically overlooks the ways emotional experience and expression are shaped by culture, class, and gender. We addressed these issues in analyses of two primary language arts lessons drawn from a two-year ethnographic study. Each case study lesson illustrated a different interactional genre for discussing emotions: (1) inclusive emotional dialogue, in which students shared emotions experienced in their everyday lives; (2) emotional inquiry, in which students explored emotions and their social meanings. Both types generated informative discussions about students' emotions but put the teacher and students in challenging positions as students publicly exposed their hardships. Both types were also, at times, limited by norms of hegemonic positivity, gender-based assumptions, and teachers' promotion of a white, middle-class emotional code.

Introduction: Promoting discussion through social emotional learning

Social emotional learning (SEL) is widely promoted as a means to improve students' well-being, academic achievement, mental health, and civic engagement (e.g., Domitrovich et al., 2017; Jones et al., 2017). One strategy for advancing SEL is to integrate social, emotional and academic development (Aspen Institute, 2019), for example, by 'enhancing' the language arts curriculum with SEL (Collaborative for Academic, Social, and Emotional Learning, 2017). A central method for advancing these aims is discussion-based instruction (e.g., Assor, 2020). However, scholars advocating classroom discussions for SEL rarely specify how they should be designed and facilitated.

We explore discussions about emotions in the analysis of two case study lessons drawn from a two-year ethnographic study of a dialogic pedagogy intervention designed to foster productive classroom dialogue in the language arts. The two lessons were conducted in a primary school in a mixed Arab-Jewish socio-economically disadvantaged Israeli city. Each case reflected a different interactional form for discussing emotions: (1) *inclusive emotional dialogue* – a form of dialogue in which participants are expected to share their own emotions and to support others' sharing of their emotions; and (2) *emotional inquiry* – a form of dialogue in which participants are encouraged to explore emotions and how they and others experience and express them.

Social emotional learning discursive imperatives

SEL, like other educational trends, emerged within a certain cultural and historical context and should be understood as part of a broader therapeutic turn in education (e.g., Ecclestone, 2012). For present purposes, we focus on how scholars envision SEL discussions. We identify three main discursive imperatives:

'Don't bottle things up'

SEL guidance emphasizes that pupils should learn how to express their emotions (Collaborative for Academic, Social, and Emotional Learning, 2013; Jones et al., 2017; Merrell & Gueldner, 2010) and advocates sharing emotions as a desired practice (Department for Education and Skills, 2005; Merrell & Gueldner, 2010). Cameron (2000) critiques the imperative 'don't bottle things up', noting that its goal is limited to venting bottled up feelings, and does not include reflecting on those feelings: 'to speak them so that they may subsequently be spoken *about'* (p. 157).

Inclusiveness

SEL programs place a strong emphasis on sharing emotions. Students are guided to share their emotions and teachers are expected to encourage such sharing, without restriction or direction (Gillies, 2011). Wilce and Fenigsen (2016) conclude that 'emotion pedagogies evince a need to recognize—and, often, fully accept—all emotions, including "bad" or "negative" ones such as anger or shame' (p. 84). The authors point out that the idea of emotional inclusiveness is historically recent, as many cultures have traditionally tended to direct people toward desired emotions, while avoiding and even condemning the expression of others.

Hegemonic positivity

SEL programs tend to promote what Stearns (2017) calls 'hegemonic positivity', based on 'an assumption that children should feel good in school and about school' (p. 265). Hegemonic positivity is expressed in SEL by proclaiming the primacy of joy and by putting a strong emphasis on training pupils to control anger and stay calm. Gillies (2011) calls it a '"feel good" language... that deflects argument and disarms criticism' (p. 188).

 © ISLS

Hegemonic positivity, however, has been criticized: for example, Dutro (2008) writes, 'if wounds are not welcome, children will correctly sense that what school wishes to hear is the banal, the safe, the bland, and they will leave what matters most muted beneath a sterile, clean bandage' (p. 18).

Hegemonic positivity is in tension with inclusiveness and the call to accept all emotions. For example, teachers in a classroom observed by Stearns (2017) explicitly told students that bad feelings 'should only last for a certain amount of time' (p. 277). Stearns asserts that the directive to focus on positive emotions made teachers overlook students' considerable interest in discussing 'bad', difficult, emotional states.

SEL in context

SEL not only expects and promotes a certain emotional code; it also assumes a cultural world in which it wishes to operate, addressing and ignoring other social identities and discursive genres. Following Stearns (2017), who identifies a gap between the rare explicit mentions of race, class, and gender during SEL discussions and their 'ineffable presence' in them (p.152), we discuss here how emotional dialogues interact with gender and socio-economic status.

Gender

Evans (2017) shows how perceptions of gender roles generate different expectations for boys' and girls' participation in SEL. Girls are invited to 'suspend affect, and to engage in the intellectual exercise of analysing and articulating emotions … In contrast, boys [are] … permitted to passively participate, with their docile bodies serving as a signifier of success' (Evans, 2017, p. 198). Similarly, Wood and Brownhill (2018) show how teachers evaluate pupils' needs vis-à-vis gender, depicting boys, mainly those with 'anger problems', as needing strong boundaries.

Socio-economic Class

Hoffman (2009) criticizes the common SEL demand that 'children in the elementary grades should be able to recognize and accurately label simple emotions', arguing that 'not all cultures interpret emotional experience in the same way, nor do they assign the same kinds of regulatory or expressive responses (such as talk) commonly shared by the White, American middle class' (p. 540). Gillies's (2011) ethnographic study exposes a multilayered gap between the everyday needs of underprivileged pupils and the values promoted by the influential Social and Emotional Aspects of Learning (SEAL) program. The students she studied often discussed difficult events, such as local teenage stabbings, in a 'seemingly emotionless manner' (2011, p. 200). From an SEL perspective, such a response is 'indicative of poor social skills and low emotional intelligence' (ibid). Yet Gillies suggests the students used this emotional code to cope with a reality they could not affect or escape, and it 'effectively worked to defuse difficult feelings while fostering supportive social bonds' (ibid).

In sum, scholars call on teachers to use discussions to promote SEL but prescribe different and often contradictory discursive imperatives. How are such discussions enacted in practice in classrooms in diverse cultural contexts?

Research context and methods

The data were collected as part of a design-based implementation research project designed to foster productive dialogue in primary language arts classrooms. Participating teachers aimed to facilitate discussions that afford students opportunities to express their thoughts, build on others' ideas, and reason about their own and others' perspectives (Alexander, 2020; Authors, 2021a).

During the 2019-2020 school year, the program included ten schools, most of which were in underprivileged neighborhoods, including the school at the center of this paper. This paper focuses on lessons in two fifth-grade classrooms, documented in March 2020. The two classes shared similar demographics: most of the 31-32 students in each class were Mizrahi Jews, several pupils recently emigrated from the former Soviet Union, each class contained one Arab student, and 4-5 students were identified as having special educational needs. Both classes had balanced distributions of boys and girls. Most students came from lower-middle-class families and, according to the teachers, some experienced financial difficulties and domestic violence. The two classroom teachers, whom we are calling 'Miriam' and 'Osnat', were both highly respected veterans.

The first author conducted weekly observations at the school, documenting teacher team meetings and Hebrew language arts lessons in Miriam's and Osnat's classrooms. Our two case study lessons, taught in the two fifth grade classes, were dedicated to a preparatory discussion conducted prior to reading the short story 'The King Who Could Not Cry'. The story tells of a king whose kingdom is extremely prosperous and whose subjects are wonderfully happy. Yet one problem vexes the king: he cannot cry. The story follows the king's futile attempts to cry, helped by his advisers who try to make him cry by showing him sad sights such as a black

clouds, dry thorns, and a lizard that lost its tail. These attempts fail one after another. Finally, after many years, upon reaching old age, the king sees a young couple in love; this reminds him of his youth and evokes his tears.

We chose to focus our analysis on the lessons dedicated to 'The King Who Could Not Cry' as the classroom discussions revolved around crying and emotional states related to crying, thus lending themselves particularly well to SEL topics and aims. We applied principles and methods of linguistic ethnographic micro-analysis (Rampton et al., 2015) in analyzing the cases.

Contrasting two forms of classroom emotional dialogue

We examined how two classroom discussions unfolded vis-à-vis teachers' anticipations and SEL goals, cultural assumptions, and contradictory imperatives. In our data we identified two types of discussion relevant to SEL: *inclusive emotional dialogue* and *emotional enquiry*. In inclusive emotional dialogue students share their experiences and feelings with the teacher's encouragement, support, empathy, and approval. In emotional inquiry, teachers and students investigate their emotional experiences and perspectives through the use of open-ended questions, probing one another's ideas, weighing evidence, and drawing connections.

Each form of dialogue sheds light on different aspects of the challenges facing classroom discussions about emotions. Yet both types of discussions require that students share personal emotional stories and associated ideas about emotions and their expression. In this way they may expose gaps between SEL-preferred white, middle-class emotional codes and how students from diverse backgrounds experience and express their own and others' emotions.

Inclusive emotional dialogue in Miriam's class

Miriam opened the discussion by asking the class: 'Ok, is there someone who is willing to share when he cried last? And why?' Thereby she set in motion a round robin discussion in which students shared in turn their personal experiences of crying. Each turn was followed either by clarification questions or empathetic approval.

Miriam's question aroused the class, generating much chatter and attention. The first four students shared short anecdotes to which Miriam replied with playful banter, thereby signaling that the students' contributions were welcome. During these short dialogues, a girl remarked that 'boys cry because, when they lose in something'. A boy commented, 'I've never seen a boy cry". John, a fairly tough and popular boy, said that he cried on his birthday, when he heard that his friend's mother had a baby.

The sixth student to take the floor said she cried yesterday, just to let things out. Here, Miriam built on the student's talk to express a general argument: "You say that you had something, that was kept inside, very, very much, and you did not let it out. Not by talking or by crying, and it just came out. Because it was night. I can understand what she's saying. At night, it's quieter around us and we slowly, slowly gather into ourselves towards – towards the night and sleep and dreams, and then many thoughts well up within us." Miriam then returned to John: 'Wait a minute I want to go back to what I heard John say earlier, you [plural] were at John's birthday party right? And Zohar was there too, right? And then they told Zohar his mother had given birth? So why did this make you cry?' 'It's moving,' he replied.

In these two interventions, while abiding with the inclusive norms of sharing and approving, Miriam accentuated ideas that aligned with the emotional code she wanted to promote. The conversation with John also demonstrated that while the conception that boys don't cry was present in the discussion, some boys, including tough and popular boys, talked about crying openly, even in the traditionally feminine context of a friend's significant life event.

About seven minutes into the discussion Miriam gave Liron the floor:

1	Miriam	Yes, Liron
2	Liron	<I cried this morning>
3	Miriam	Why?
4	Liron	I get up in the morning, it's my birthday and everything-
5	Miriam	Happy birthday, yes
6	Liron	Then, when I come out, my mother gets upset with my brother because he keeps asking her for money
7	Student	Exactly like me
8	Liron	Then my mother drove anxiously to work, and then I said to him ah .. 'Dean why are you annoying her', then h:::e grabbed me, and choked me and told me, 'You bug me again I'll cut you with a knife.' [Laughter, indistinct chatter] And then he told me, and then I told him, 'leave me alone already' and .. that's it.

As Liron talked about the violence directed toward him, many of the students reacted, talking to others around them but not to Liron, the teacher, or the entire class. Liron's story was, in our eyes, troubling. In class,

Rasoul was the only participant who explicitly signaled unease, gasping loudly to mark his bewilderment (during line 8, above, after Liron said 'choked me'). Rasoul then looked around the classroom for clues on how to act. Seeing no other student overtly express a similar reaction, he quickly went back to behaving 'regularly'. At this point, Miriam stepped in and probed Liron's emotional state:

9	Miriam	So, was it out of anger or out of …?
…	…	…
12	Miriam	So basically-
13	Student	I wouldn't back down [a tune pupils sing to fuel disputes and fights]
14	Student	Out of anger
15	Miriam	Hush [[makes a silencing movement with her hand; the noise continues]] So basically, what we saw here, really, thank you very much for sharing, first of all, but what we saw here is actually that [1] crying can come from many reasons, it can be a matter of physical pain
16	Yali	Miriam, I cry every day
17	Miriam	We got hit, it could be from excitement, enthusiasm, joy, frustration, nerves
18	Yali	From anxiety, out of anger
19	Miriam	Nerves, anger, there really are lots and lots,
20	Lucy	Or you can cry with joy.
21	Miriam	wide range of emotions, a wide range of emotions following which we can, ah, a person can ah, come to cry.

Miriam's response distanced the discussion from domestic violence through two discursive moves. First, she focused on Liron's emotional state. This echoes one of the key principles of SEL and emotional knowledge: focusing on naming emotions and reflecting on them. By so doing, Miriam turned Liron's story into a story about his internal emotions as opposed to the external events to which he was exposed. Moreover, Miriam suggested Liron was angry, and anger made him cry (line 9), without considering more passive emotional states, such as sadness, fear, anxiety, distress, or sorrow, which would reflect an innate helplessness Miriam's interpretation of Liron's emotional state as anger might have been affected by a gender-based perception of emotions and their expression (Evans, 2017; Wood & Brownhill, 2018) which sees anger as an active masculine emotional response to getting hurt (although we cannot know whether Miriam would have treated a female student differently).

Second, Miriam built on her focus on Liron's emotional state to conclude the entire discussion by pointing to the range of emotions that may bring people to cry, one of the main goals of the discussion. Turning a story about domestic violence into a discussion on the varied emotions that may evoke crying may be thought of as a form of defensive teaching (McNeil, 1982), aimed to defend the teacher, as well as the students, from public exposure of and discussion about students' hardships.

Similar dynamics have been identified in the sparse ethnographic literature on SEL in other classroom discussions. For example, Coe and Nastasi (2006) documented a classroom discussion in which a student told her class that her grandmother 'sometimes used a stick or cable wire' to beat her. The teacher replied by asking her if the situation was really stressful and if she was upset. Miriam was not trained for SEL, but she used the same 'name-your-emotional-state' practice and by using it, like the teachers documented by Coe and Nastasi, overlooked and perhaps normalized a story about domestic violence (see also Gillies, 2011; Stearns, 2017). To understand why this happens, we need to examine the structural conditions of emotional classroom discussions; we return to this issue in the Discussion.

Emotional inquiry in Osnat's lesson

Osnat initiated her classroom discussion with the question: 'Imagine that I have a magic wand and everyone I touch will never cry again. Who wants me to touch him?' The question yielded eight responses, with students saying they did not want to stop crying. The first student who answered the question explained that we can cry because of joy or happiness. While she spoke, several students offered additional examples of positive experiences that generate crying. One said 'laughter', which the speaking student embraced and repeated, and at least two others said '[out of] emotions'. The students in effect followed the logic of the dominant cultural code, according to which emotions and emotional expression are good and, since crying is the product of emotion, crying is also good.

Students also addressed crying as a means of communication. The first speaker who promoted this line of thought said that if she did not cry, others would not understand how she felt. A boy who spoke after her said that when he cries, 'everyone rushes to me and asks me what happened', thus attributing a specific message to crying: it calls for and generates positive attention. This was supported by other students. The next student (male) to speak said, 'If someone does something to you then… crying says, like, leave me alone. I did not do

anything to you, and… uff, crying saves us sometimes'. He emphasized a different message: crying is a socially legitimate way to stop a fight or a quarrel. Once again, other students expressed support.

Although the students did not respond to one another directly, their answers built on each other's content (Alexander, 2020), and they jointly portrayed possible communicative meanings crying may carry: it may generate caring attention, and it may signal to others that aggression has reached its limit and should be stopped. These answers indicate that children use crying in a unique way that adults rarely use.

After eight turns of students indicating they would not want to stop crying, Yotam, a student who often expressed provocative positions during classroom discussions, offered a heterodox response:

26	Yotam	I actually (*davka*) do want because-
27	Osnat	To touch you?
28	Yotam	Yes. Because
29	Osnat	Okay, why?
30	Yotam	I am more sensitive
31	Osnat	More what?
32	Yotam	Sensitive
33	Student	He is sensitive
34	Osnat	You are sense:::tive. Wait a minute, try, try explaining to me
35	Yotam	Like, when, when others insult me, I like
36	Student	I have never seen you cry
37	Osnat	Wait a minute, but I cannot hear Yotam
38	Yotam	Because let's say uh I'm just saying, let's say that when others insult me so hmmm.. I kind of take it to the heart, I think that maybe it is true
39	Osnat	And then?
40	Yotam	And then I cry

Yotam's answer, as we understand it, touches on a fundamental question about the relationship between emotions and expression. Yotam cries when two things happen: others insult him, and he takes it to heart and believes what they say about him to be true. For Yotam, crying appears to be a transformative act, part of an internalization process. If so, then it follows that *not* crying indicates not internalizing others' offending remarks, and thereby he is able to defend himself.

This echoes Gillies' (2011) discussion about emotions vis-à-vis social class (discussed previously), and the need of some lower-class students to suppress rather than express their emotions, as their structural position grants them limited power to affect their realities. Gillies asserts that they use this 'suppressive' talk to defuse difficult feelings. Yotam said his self-esteem was sometimes hurt when he was insulted, and the strategy he developed was trying not to cry. Perhaps this is why a student said that he had never seen Yotam cry (line 36).

Yotam first said he wanted Osnat to touch him with her magic wand. But by using the word *davka* (line 26), he indicated that his choice contradicted something - the atmosphere in the classroom or the generally expected answer (for an account of the 'inherent counter-expectation' nature of Hebrew *davka*, see Ariel & Katriel, 1977). Yotam also described himself as never crying 'from excitement or anything like that', referring to what previous speakers had said and thus performing, for the second time, a rare act in classroom discussions: expressing a position which opposed a teacher-approved answer. Osnat encouraged Yotam's voice, which differed from those of the other students, thereby bringing into the discussion a different understanding of crying

Iris, a student who tended to adopt Yotam's ideas and follow him when he spoke in class, particularly when he challenged Osnat, raised her hand as Yotam's turn ended. After getting the floor, she said: 'I do want you (Osnat) to touch me... because when you cry, I think it's not for good reasons, for example, for example, if you are shouted at, you cry, then it is something that also hurts you... and I do not want to be hurt.'

Anat, the fourteenth speaker, a student Iris often mocked during classroom discussions, asked to respond to Iris. This was the only instance when a student directly and critically addressed a previous speaker during this classroom discussion:

80	Anat	Can I address what Iris said?
81	Osnat	Yes
82	Anat	So, she said that if she would stop crying others would stop hurting her, but if she would stop crying then they would hurt her more because they would think she did not care.
83	Rona	Most of the time it is the other way around
84	Anat	She said-
85	Iris	Like, I will not get hurt

86	Anat	In my opinion if I would stop crying, people would hurt me and think that I do not care that they say things about me so they-
87	Osnat	So with the help of crying what does she do?
88	Anat	She's like, telling people 'stop hurting-
89	Student	Like, she drags attention (*goreret tsumi*)
90	Osnat	Attention maybe, maybe attention (*tsumet lev*), maybe this is how she manages to better express her emotions, in this way, with the help of crying

Anat built on an understanding of crying that was already established in the discussion – a signal to others to stop hurting you – to refute Iris's argument. We want to focus on lines 83 and 89, however. Rona turned to Anat and said, 'It is usually the other way around' (line 83), meaning that usually if you cry when others hurt you, they do not leave you alone but bother you more.

Anat continued her answer, treating crying as an action that signals to others to stop hurting you, but when Osnat asked her, 'So with the help of crying what does she do?', one of the boy students said, 'She drags *tsumi*' (line 89), a slang phrase that indicates something along the lines of pitifully asking for socially undeserved attention. Although he did not address Rona directly, his train of thought continued hers, thus establishing something similar to a counter script (Gutierrez et al., 1995), as they together produced a coherent line of answers that was overlooked or even blocked by the teacher. Osnat transformed *tsumi*, a derogatory phrase, into 'asking for *tsumet lev*', a neutral phrase (sharing the same root) meaning 'asking for attention'.

The discussion shows how emotional inquiry can produce valuable emotional knowledge. First, the students thought of crying as a means of communication, even a social request, but each student attributed a slightly different meaning to this request: making others react to how I feel, making everyone rush to me and ask me what happened, or signaling to others to leave me alone as 'crying saves us sometimes'. Second, students highlighted the relationship between expressing emotions and feeling them when they said they preferred not to cry so as not to get hurt. Third, the inquiry produced an opportunity to further discuss crying as communication while distinguishing legitimate and illegitimate social requests embedded in crying.

Discussion

Genres of classroom discussions about social and emotional issues

Discussion is seen as a favorable instructional method for SEL, but we found the term 'discussion' was too vague in the SEL literature. We identified in our data set two very different types of discussion, each with distinct goals, norms, affordances, constraints, and challenges.

In *inclusive emotional dialogue,* students were encouraged to narrate personal, sometimes difficult stories, thereby enabling the sharing of emotions as experienced in students' everyday lives. However, as indicated by Liron's story of how his brother choked him on his birthday, this genre can put teachers and students in a challenging position. On the one hand, sharing personal stories entails exposing fears and hardships in the class plenum, an environment in which it is hard to ensure that students receive the appropriate response to such exposure. On the other hand, if the teacher glosses over these issues, she implicitly conveys that such issues are either not important or unsuitable for discussion, should be kept secret, are not the school's business, and so on (Dutro, 2008).

Emotional inquiry promoted exploration of children's understandings and expressions of emotions. It generated informative discussions about emotional states related to crying and their diverse social meanings and may thus be considered especially compatible with SEL (as well as other pedagogic) goals. However, norms of hegemonic positivity can limit or silence the expression of emotions that deviate from official school expectations.

Faced with these challenges, the teachers we observed reacted in various ways. One reaction was to casually acknowledge the content of students' experiences by thanking them for sharing, indicating that what they shared was important, or by playfully bantering with them, thereby suggesting the sharing was in and of itself the end goal of the discussion. However, when sharing does not lead to reflection, SEL's effectiveness is questionable (Cameron, 2000; Nils & Rimé, 2012). A second reaction was to probe students' responses, figuring out together what made them cry or why they wished to continue or give up crying. A third reaction was to emphasize and generalize certain answers, thereby endorsing these answers as the teacher's and school's official position. Finally, in some cases, the teachers held back and chose not to discuss sensitive issues such as domestic or school violence.

SEL's cultural assumptions reflected in the classroom discussions

We found the *white, middle-class cultural code*, critically identified with SEL (Hoffman, 2009), conflicted with many students' cultural codes. For example, the SEL literature emphasizes inclusiveness (Wilce & Fenigsen,

2016). From this perspective, crying is encouraged. For Yotam, however, crying entailed internalizing bad things others had said about him, which gave him a solid reason to refrain from crying (see also Gillies' (2011) discussion of anger). Yotam was strong enough to insist on his perspective, and the classroom culture allowed him to take a critical stance on the teacher's position. In other instances, students may learn that their emotional code is inadequate, even when it serves important goals in their lives. This case thus serves as additional support for culturally relevant SEL (Mahfouz & Anthony-Stevens, 2020).

Our findings indicated *gender-based assumptions* can interact with classroom emotional dialogues. The conception that 'boys don't cry' was present in the classroom discussions and was even expressed directly. However, many boys actually reported having cried, and some even reported crying in stereotypically 'feminine' contexts, such as the birth of good friend's baby brother. The findings thus demonstrate that the classroom reality produces diverse manifestations of the relationship between gender, age, and the way emotions are talked about. Gender was also evident in the way Miriam constructed Liron's emotional state after he was attacked by his brother, calling it anger (a stereotypically masculine emotion), not sadness or helplessness.

We found the teachers were guided by *hegemonic positivity* (Stearns, 2017, 2018), in that they avoided talk about negative experiences and emotions and attempted to (re)interpret these as positive or neutral events or feelings. This phenomenon was manifested in several ways. First, a teacher's response to a student's story about domestic violence, while aligned with the SEL agenda of focusing on students' emotional responses, did not touch on some disturbing aspects of his story - his brother fighting with his mother over money and then choking the student for interfering. Second, in an instance of teacher-pupil miscommunication, a student's description of crying as 'asking for *tsumi*', a slang phrase that indicates pitifully asking for 'socially undeserved attention', was reframed by the teacher as 'asking for *tsumet lev*', a neutral phrase meaning 'asking for attention'.

The contradiction between hegemonic positivity and inclusiveness was reconciled by the general insistence that crying is essentially good. Teachers and students repeatedly addressed crying as desired using two main arguments: we also cry because of joy, and by crying, we 'let things out'. This may indicate a broader trend to affirm all emotions; if emotional states which initially seem bad are ultimately deemed positive, then naturally we need to accept and include them.

When hegemonic positivity and inclusiveness were disregarded, the teacher took a negative position on a student's stance (Osnat and Anat). This generated a classroom discussion in which students jointly inquired into the social meanings of crying. This finding suggests SEL could benefit from taking into consideration the pedagogic potential of encouraging conflicting voices when discussing emotions in the classroom (Authors, 2013; Authors, 2016).

Conclusion

Miriam and Osnat are both highly dedicated and experienced teachers who care deeply about their pupils. Why didn't Miriam develop the discussion on Liron's story of domestic violence (much like the teachers documented by previous ethnographers, such as Coe & Nastasi, 2006; Gillies, 2011; Stearns, 2017)? Why did Osnat miscommunicate with her students and transform *tsumi* into *tsumet-lev*?

Classroom discussions, particularly discussions in which pupils express original and unexpected ideas, complicate teaching. They increase uncertainty as the students' thoughts and ideas are expressed in them, not just the teacher's (Cohen, 2011). In emotional dialogue, which aims to discuss students' emotional codes, it is not only students' thoughts and ideas but also the content itself that is determined by students. In these discussions, almost any topic can emerge. The study shows that emotional dialogue requires teachers to facilitate extremely challenging discussions while encouraging students to share, supporting them when they share difficult stories, and defending them from exposure to criticism, threats to their status, and other social implications. To exploit the full potential of discussions, teachers also need to identify when students express emotional codes that differ from the teacher's and to encourage these expressions.

Overall, the findings indicate that integrating SEL into the 'regular' curriculum can enhance it (Collaborative for Academic, Social, and Emotional Learning, 2017. p. 2). They also shed light on some of SEL's blind spots and suggest that while SEL may enhance language arts, language arts instructional methods may also enhance SEL.

Locating as a Temporally-oriented Practice for Noticing Data for Improvement

Carlos Sandoval, WestEd, csandov2@wested.org
Elizabeth van Es, UC Irvine, evanes@uci.edu
Stephen Skoropad, UC Irvine, sskoropa@uci.edu

Abstract: This study examines how practitioners look at and make sense of improvement data through the lens of *noticing*. Conceptualizing noticing as a practice performed through talk, we examined data conversations in a teacher preparation networked improvement community and found that practitioners engaged in the noticing practice of *locating* data. In particular, we found that practitioners' noticing practice of locating was shaped by their temporal orientations, where attention to past, present, and/or future guided where and how they placed data within their own contexts and settings. We also found that practitioners located data either under their own or others' purviews or within the experiences of their students. One contribution theorizing noticing as a practice and applying noticing to improvement data as a material resource. Attending to how practitioners *notice* data can generate insight into the kinds of noticing practices that produce productive insight from improvement data.

Introduction

Networked improvement communities bring practitioners together around shared problems of practice to generate solutions that are usable in local contexts. In the context of improvement, the collection and analysis of data serves an important role. Unlike data for research that seeks to answer questions to advance a scholarly knowledge base, data for improvement intends to develop usable measures that provide real-time feedback that enable practitioners to take action (Bryk et al., 2015; Shah, 2019). When using data for improvement, the goal is to create a small number of measures that can be collected frequently and shared in data displays to allow the network to examine if it is improving over time and enable decisions to be made about how to improve. We focus on data use for improvement because of the increased interest in education research to examine how practitioners (e.g. leaders of schools, districts, and other educational organizations) can engage in systematic inquiry into the performance of their systems (Coburn & Stein, 2010; Datnow & Park, 2014). While data plays a central role in the improvement process and has emerged as a tool for facilitating improvement, we know little about how practitioners look at and make sense of data in the context of improvement efforts. In this study, we seek to understand how practitioners use data for improvement by conceptualizing the sensemaking of data as being expressed through *noticing practices.* The construct of noticing has been taken up to understand how teacher educators attend to and make sense of material resources (Amador, 2021; Kazemi et al., 2010). Traditionally, noticing has been taken up as a cognitive construct to examine how teachers look at and make sense of classroom video data (Sherin & Russ, 2015). We bring a noticing lens to help us understand how practitioners use improvement data, a different kind of material resource than classroom video. Additionally, we conceptualize noticing as a *practice* that is performed through action, of which talk is one kind. By examining practitioners' noticing *practice*, we focus our study on *how* practitioners engage with data, as opposed to *what* practitioners notice about data.

Our study takes place in the context of a teacher preparation networked improvement community. We study data use for improvement in this context for a few reasons. First, research in teacher education is often isolated to one course, in one context, limiting the field's ability to make progress in understanding whether and how particular pedagogies of teacher preparation prepare candidates for teaching (Cochran-Smith et al., 2015). In addition, current measures of teacher education are often used to make summative evaluations of program quality, such as meeting state credentialing or accreditation requirements (Bastian, 2018; Peck & McDonald, 2013). Such measures do not capture the process by which teacher education programs are designed over time to prepare candidates on particular aims.. Therefore, we know very little about how the organization of a program and the sequence of coursework and field experiences prepare candidates to learn the practice of teaching.

Though there is limited research on teacher education program data use, the limited body of work shows promise for using data to improve. Prior research on data use in teacher preparation shows how teacher education program stakeholders can use summative data, namely teaching performance assessments, to generate insight into program quality. For example, Peck and McDonald (2013) highlight how one program successfully used these summative data to learn about program quality via teacher education program staff's participation in scoring their candidates' teaching performance assessment portfolios. Further, Davis and Peck (2020), examined the various *organizational* practices that teacher education programs engaged in that enabled regular and productive data

 © ISLS

conversations. The authors found that programs that were successful in using data for program improvement held regular meeting times to discuss data and integrated data conversations into existing routines. While this line of research offers insight into the organization of data use conversations, questions remain about how teacher educators look at and make sense of data - what do they focus on, how do they engage with data, and how does their engagement with data inform improvement efforts. In this paper, we begin to explore these questions by illuminating teacher educators' *noticing practices* to understand *how* teacher educators look at and make sense of improvement data. To do this, we focus on one noticing practice that emerged as a dominant practice in our analysis: the noticing practice of *locating.* We illuminate how studying this particular noticing practice a) enabled teacher educators to make sense of data, and b) revealed the different places they located data.

Theoretical Framework

We draw on two broad lines of research to frame our inquiry into how teacher educators work with and make sense of data: noticing and practice theory. Together, these bodies of literature situate teacher educators' data use as a practice they enact to both attend to and reason about the problem of practice and the enactment of solutions. We elaborate on each framework below.

The construct of noticing captures what educators attend to, how they understand what they see, and the broad range of decisions they consider that inform the actions they take in practice (see Blomeke et al., 2015). In the context of teaching, researchers have sought to understand the nature of teacher noticing and how it can be developed to support more responsive, equitable instructional practice (Sherin et al., 2010; Schack et al., 2017). As this work has developed, researchers have argued for the active nature of teacher noticing. For example, van Es and Sherin (2021) propose a framework that defines teachers' noticing as three interrelated actions teachers take to gain deeper insight into student thinking in the context of classroom instruction. This is consistent with others who explain that noticing is driven by the activity system of which teachers are a part, where teachers are attending to and making sense of phenomena that is guiding their decision-making and thus provides new experiences for noticing (Erickson, 2011; Hand, 2012). Together, this line of research suggests that noticing is not passively observing, but rather, entails actively seeking out information and trying to understand the phenomenon under one's purview. We extend this research to propose that noticing is a practice that is being performed moment to moment through action, primarily discursive practices. Rather than conceptualizing noticing as a cognitive process, we position noticing as an action that is shaped by activity systems and in turn (re)shapes those activity systems.

To understand noticing as a practice, we draw on practice theory. Practice theory conceptualizes practice as simultaneously situated and situating action, where actions produce context and context constrains and enables action (Feldman & Orlikowski, 2011). We used practice theory to see how teacher educators performed noticing of improvement data in data conversations through talk. In our examination of how teacher educators looked at improvement data, the practice of *locating* emerged, where teacher educators placed data in temporally diverse ways. To understand this temporality in teacher educators' locating of data, we turned to Emirbayer and Mische's (1998) conception of agency to understand how teacher educators were *temporally oriented* as they engaged in locating data. Emirbayer and Mische view agency as a "process of social engagement" that is informed by orientations to the past, present, and future (p. 963). For Emirbayer and Mische, actions and the capacity to act are simultaneously influenced by past, present, and future, where actors may be more or less oriented to one over others at any given time. This view of agency helped us understand and see the varied ways temporality shaped teacher educators' data-locating practice.

Study Context and Research Methods

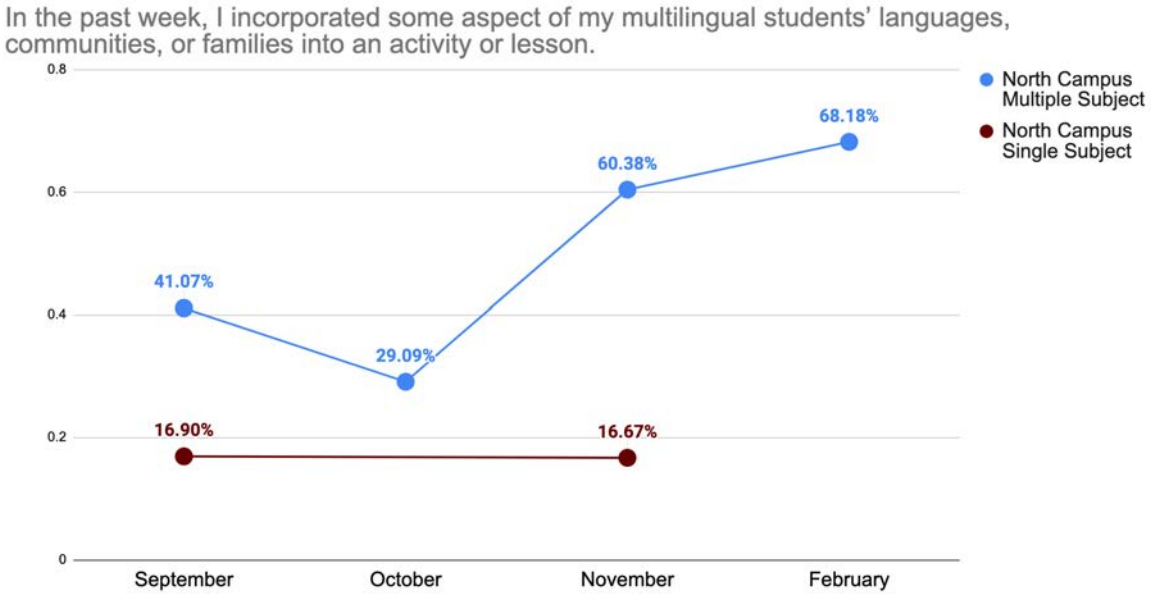
The study took place in the context of a broader research effort to understand the design and improvement of teacher education (cterin.ucop.edu). We developed a networked improvement community (NIC) consisting of eight teacher education programs, who are all part of a larger university system. The directors of these programs come together twice a year to share efforts to respond to state-wide policy mandates, to discuss local problems of practice and seek out support and advice on these issues, and to develop strategies to advocate for support for teacher preparation at their local campuses, across the university system, and within the state legislature. Because of their shared commitment to understanding and improving teacher preparation, this group became the site for launching a NIC.

The improvement project that is the focus of the study includes nine campuses in the NIC who collectively identified the preparation of candidates to support multilingual learners as the shared problem of practice (see Sandoval & van Es, 2021 for a description of launching the NIC). The measurement system the NIC developed included a survey consisting of 15 items that were both quantitative and qualitative in nature. These items asked questions about whether candidates learned about their multilingual students' backgrounds; whether

candidates considered multilingual students' experiences and backgrounds in their instruction; and whether candidates navigated school systems to advocate for their multilingual students. The network established a routine for making sense of these data across the network and within campuses. This routine included teacher educators administering the data to teacher candidates in their program coursework; improvement facilitators generating data displays from the data, typically in the form of line charts that showed the percent of candidates who said they engaged in particular activities in their placements (see Figure 1); and having teacher educators review and reflect on the displays.

Figure 1

Example of improvement data display



Data consist of audio and video recordings of data conversations with teacher educators. Additionally, data includes artifacts that were generated for and from these conversations, such as data displays, spreadsheets where data were stored and manipulated, drafts of and notes on the survey, and our memos about these data conversations that we generated in the moment. For this analysis, we selected six data conversations across five different teacher preparation programs and four different campuses over three academic years. Collectively, 12 teacher educators participated in these data conversations. We chose these six data conversations from the 17 data conversations we conducted in this network because they represented a variety of campuses, programs, and moments in time.

Data analysis was qualitative in nature. Informed by interaction analysis methodology (Jordan & Henderson, 1995) and research on noticing (van Es & Sherin, 2008; Sherin et al., 2011), we started by having the three authors collectively analyze one data conversation together, where we each highlighted what teacher educators noted in the data - what they thought was interesting or noteworthy in the data displays and in candidates' qualitative responses - as well as how they interpreted what they saw. As we reviewed the data, we observed that the teacher educators were engaging with the data displays in different ways, such as making requests to compare the displays to ones they viewed previously and talking with each other about how the displays reflected what was happening in their programs at different points in time. We then added an additional focus for our analysis that included capturing how teacher educators interacted with the data. We then viewed a second data conversation together, each capturing what teacher educators highlighted as noteworthy, how they reasoned about these highlighted elements of the data and how they interacted with each other and with the data. We each generated analytic memos that captured the noteworthy ways they engaged with the data and summarized key observations and insights they generated from the analysis of data. We then compared our individual memos and discussed any discrepancies in our analyses. Using this same process, we each analyzed one additional data conversation—with the exception of the first author, who analyzed two conversations—along the three broad categories, generating analytic memos for each one. We then conducted a cross case discussion, among all the conversations we analyzed. At this point, we identified the practice of locating as something that all the teacher educators were doing as they

interacted with the data. In the final round of analysis, we returned to the data to generate evidence for locating and to characterize the various ways teachers engaged in this noticing practice in data conversations. We now turn to present our findings.

Findings

Examining teacher educators' noticing practices revealed that teacher educators engaged in the practice of *locating.* Locating refers to how teacher educators' situated improvement data within a range of contexts to make sense of it. TEs located improvement data within their own program and within their own or others' purview. This practice of locating improvement data within varied contexts was also influenced by teacher educators' varied temporal orientations, where some TEs were more oriented towards the past while others were more oriented towards the future or present.

We begin by describing how teacher educators located improvement data within their teacher preparation programs, such as program structures and activities in which teacher candidates engaged. We surface a series of exchanges in February 2020 among teacher educators at a teacher preparation program around improvement data from an item that read: "In the past week, I incorporated some aspect of my multilingual students' languages, communities, or families into an activity or lesson." The data display had shown that 29 percent of candidates had responded affirmatively ("Yes, in my fieldwork" or "Yes, in my coursework and fieldwork") in October 2019; 60 percent responded affirmatively in November 2019; and 68 percent responded affirmatively in February 2020. The facilitator prompted teacher educators about the increase:

> Facilitator: I'm curious what you all think, because it seems to be—it went up to 60 percent. It went from 29 to 60 percent, which is a huge jump, and then it went to 68 percent.
>
> Oscar: They're also taking two language courses. During that time during the fall, they're taking the Language for the Chicano Child [course]. And then in the winter quarter, they're taking a course on [English Language Development].
>
> Rachel: Well, and then for us, there also may have been the pulse-off thing going on. So if it was given in October in the second week of a pulse-off, then anyone who was pulsing off would say no. If given in the first week of a pulse-off, those people would have been in their classrooms the prior week. This has to do with "in the past week" language. So just "the past week" part could account for some of that difference as well.

Both Rachel and Oscar located the data within what program activities and structures candidates were experiencing as they completed the survey, evidence for what we argue is a pronounced orientation to the past. For example, when asked about the changes in data from October to November and February, Rachel points to the "pulse-off" program structure; TEs would later explain that "pulse-off" referred to a routine that occurred throughout the winter and spring quarters where candidates worked in their student-teaching placements for two weeks before taking a two-week break. Rachel explained how candidates may not have had opportunities to incorporate multilingual students' families, communities, or languages into an activity or lesson if they were "pulsing-off," or taking a two-week break from their student-teaching placement at the time the survey was administered. Rachel's locating of data was influenced by her orientation to past program structures, evidenced by her recollection of what candidates were experiencing at the time that may have influenced the data.

TEs' locating of improvement data within program structures and activities were not always influenced by an orientation to the past, however. TEs also located data within program activities and structures in ways that were influenced by a closer attention to the present and future. During the same meeting, Oscar suggested adding follow-up questions to the survey to gain insight into how candidates responded relative to particular program structures, while another TE in the room, Maria, built on Oscar's suggestion.

> Oscar: Or even at the end of this, like, [can we ask a] follow up that shows the graph and ask them, to what to what do you attribute this growth in your opinion? They can say I attribute it to Lisa's class. And we can kind of see how many folks attribute it to Lisa's class. How many folks attributed it to their resident teacher?
>
> Maria: Could it be a menu? Like, coursework, and then we can list the classes? Or resident teachers, and we can list the supervisors?

> Oscar: Or, you know, we can call it like [student-teaching placement]? Your classes? I don't know.

Oscar and Maria located the data within program structures and activities—in this case, coursework, resident teachers, and student-teaching placements—but with more of an orientation to present and future than past as was surfaced in the previous exchanges. This time, Oscar and Maria were *imagining* how candidates might respond and generating ideas for new follow-up items to understand what program structures were influencing how they might respond. We note that, in alignment with Emirbayer and Mische (1998), Oscar and Maria's exchanges were at once temporally oriented to the past, present, and future. However, we argue that their exchanges are evidence of a more resonant orientation to a) the future, where TEs are imagining the possibilities for candidates' responses, and b) the present, where TEs are generating ideas for items that can be added to the survey to gain insight into candidates' responses. In this meeting, TEs engaged in the practice of locating primarily to situate data within program activities, and their temporal orientation shaped how they made sense of data and the ways in which they responded to data. How TEs located data within program activities and structures changed drastically based on whether they were oriented more towards past, present, or future. In this case, TEs moved from finding explanations for why improvement data looked the way they do to ideating new items to gather more information about improvement data.

We turn to describe how TEs located data within their own or others' purview, situating improvement data as someone's responsibility to look at and respond. We argue that this particular way of locating was also influenced by TEs' orientations to past, present, and future. We illustrate this first by examining segments from a data conversation with Alicia, a teacher educator primarily responsible for leading the single-subject program at her campus. During this conversation, Alicia located the data under her own purview, viewing data as something she was responsible for and could control. In April of 2021, Alicia reviewed improvement data and noted that 45 percent of candidates responded affirmatively to the item "In the past week, I incorporated some aspect of my multilingual students' languages, communities, or families into an activity or lesson," remarking that she "expected more" candidates to respond affirmatively. Following this remark, Acacia began to generate ideas for how she wanted to respond to the data and landed on changing a form teacher candidates are required to use and complete when preparing for observations from supervisors.

> I got this thing where I'm just like… the long term goals are just not working with me. Lately, I've been thinking, okay, Alicia. What can you do now? Right, like I'm thinking of like immediate changes… It doesn't have to be voted on by the steering committee. We don't have to analyze all this data. Like I could just do it now, right? And so, because they have 12 observations, this is something that I could change. I can add, you know something about, "How do you incorporate? Like, what was the question? I can add, "I am incorporating some aspect of my multilingual students' languages, communities, or families by doing the following."

Alicia's comment that the "long term goals are just not working with me" and that she asked herself what she can "do now" suggest that Alicia's temporal orientation foregrounds the present by locating the improvement data as something she is capable of acting on and responding to "immediately." Her focus on "something that [she] could change" was evidence that she located improvement data by placing it under her purview as something to which she ought to respond. We also argue that Alicia's orientation to the future and past were simultaneously influencing how she located improvement data. Alicia's comment that changes do not "have to be voted on by the steering committee," and that she could make these changes immediately suggest that Alicia was attending to the *future* by imagining the trajectory of a "change" would be, while drawing on her *past* experiences with the process of making changes in the program. While Alicia was at once simultaneously oriented towards the past, present, and future, we viewed her comment as having a tone that was more aligned with a present orientation, with an emphasis on making a decision about what she can do immediately.

We contrast this noticing practice of locating data within one's own purview with an instance where a teacher educator located improvement data under someone else's purview. We surface a data conversation that occurred in January 2019 with Janice, a teacher educator in the multiple-subject program at Alicia's campus. We highlight here how Janice located the data as being under someone else's purview, primarily because, at the moment, Janice was teaching a class on teacher inquiry. During this data conversation, the facilitator first showed Janice descriptive info about how many candidates responded and how long it took them to complete the survey. The facilitator then asked Janice to review the data displays. Janice reviewed and commented on each display. Halfway through, Janice reviewed an item in the survey that read, "In the past week, I reflected on how schools enforce the use of Standard English." Teacher candidates were asked to choose one of four responses: "Yes, in

my program coursework," "Yes, in my fieldwork," "Yes, in my program coursework and fieldwork," or "No." Janice was presented with a bar chart that displayed that twenty-one of the 53 candidates who responded answered "No," one candidate responded "Yes, in my program coursework," 23 candidates responded "Yes, in my fieldwork," and eight candidates responded "Yes, in both my coursework and fieldwork." After pausing to review these displays, Janice responded:

> Janice: I keep going back and forth with these, like, I'm wondering like in this middle one here, I reflected on how schools enforce the use of standard English. Why are some things... do we do it [in my class]? Because that would fall into a particular class. I don't see myself doing that in [my inquiry class] necessarily. Like, only if it was a discussion. Like I wouldn't necessarily... like I see that as…
>
> Facilitator: Like, really specialized?
>
> Janice: Yeah, like it wouldn't necessarily fit in my content. I can see there are other courses that it would totally fit into, right.
>
> Facilitator: This seems like you're saying… like oh, that actually is sort of course dependent, right. That's not something that we necessarily have to talk about throughout. Whereas some of these are important to sort of bring up sort of—
>
> Janice: Yeah, or if it's different. Schools enforce the use of standard English—so I could see that. Well. I guess I'm having a harder time of how I would connect to that in [my inquiry class], but maybe because I'm just thinking about it from that lens. But having taught math methods, I think that's a huge one that we would talk about.

In these exchanges, Janice is locating improvement data as something that does not exist under her purview given that her class is focused on inquiry. Janice's comment that she did not "see myself doing that in [my inquiry class]" illustrates how she located improvement data as something over which she had no control. For Janice, data from this item is relevant to "other courses" and not something she would talk about in her course. We viewed these exchanges as being influenced by Janice's pronounced orientation to the past, drawing on her past experiences of what her class does and does not emphasize. By orienting to how her class on inquiry has been conducted, Janice is locating data on candidates' reflection on the enforcement of Standard English outside of her purview. While Janice is locating specific improvement data outside of her own purview, we are not making the claim that Janice is absolving herself of responsibility for the data broadly. In these exchanges, Janice mentions that the topic of enforcing the use of Standard English would be a "huge" point of discussion in her teacher preparation program course on math methods. Additionally, in prior exchanges during this meeting, Janice reflected back on whether she led any activities related to the items and wondered why she did or did not do so, indicating she viewed improvement data as something for which she holds some responsibility. What we argue, instead, is that TEs engaging in the noticing practice of locating improvement data served to place data within some people's purview at particular times, and thus shaped how they looked at and responded to improvement data.

Our findings illuminate how teacher educators performed noticing of improvement data and focused on one specific noticing practice that emerged as prominent as TEs looked at improvement data: locating. Teacher educators engaged in the practice of noticing in a range of ways, namely locating improvement data within program structures and activities and locating data under some teacher educator's purview and outside of others' purview. Additionally, we argue that the practice of locating data was influenced by the temporal orientations of teacher educators, where orientations to the past, present, and future shaped where and how teacher educators located data and what teacher educators did once they located data. Having illuminated how TEs located data and how that was influenced by TEs' orientation to past, present, and future, we turn to discuss implications for teacher preparation and improvement data use.

Discussion and Conclusion

This study is significant in three ways. First, our study stretches conceptualizations of noticing by viewing it as a practice that is performed through discursive moves and in relation to artifacts under one's purview. Second, we contend that examining how practitioners *notice* data can enable those leading and studying improvement science-driven efforts to examine how data conversations can be led to engage in noticing practices that are productive

for doing improvement. Finally, our study examines the use of data for improvement in teacher preparation, a field where data use, and improvement data use in particular, are not well-understood.

Our findings build on prior research to propose that noticing is not only a cognitive process, but also a practice that is enacted as educators work with and analyze artifacts of practice. Elsewhere, van Es and Sherin (2021) describe how teachers actively work with students' ideas to shape interactions in order to gain deeper insight into students' mathematical thinking. In doing so, they position noticing as a process that is mediated through interaction in classroom activity. Here, we extend this research to conceptualize noticing as a practice that is performed, through talk, as teacher educators interact with artifacts of practice, in this case, data displays. By characterizing the ways teacher educators enact *locating* we see that noticing not only entails what and how individuals and communities attend to and reason representations of practices (e.g. video, student work) but also involves how individuals and communities interact with these artifacts in order to attend to and understand their meaning. By shifting our lens to how teacher educators engage with artifacts, we begin to expand theory of construct of noticing in educational contexts.

We also contribute to improvement-focused research by examining how practitioners make sense of and use improvement data. Although there exists numerous studies examining practitioners' data use and sensemaking (e.g., Datnow & Hubbard, 2015; Horn et al., 2015), our study focuses on how practitioners use data designed specifically for continuous improvement and situated within an improvement effort. Because improvement data differ from data for research or accountability (Bryk et al., 2015), we argue that understanding how practitioners make sense of improvement data is critical for enabling productive data conversations. Unpacking the noticing practice of locating helped to unveil how and where practitioners place data temporally and specific to their own contexts and settings. Understanding how teacher educators located data helped us to see that improvement data were enabling particular acts of locating. For example, for some teacher educators, reviewing improvement data enabled them to locate the data as being something for which they are responsible for, while enabling other teacher educators to locate data as someone else's responsibility. We argue that attending to the varied performances of locating can help those leading improvement efforts design data conversation activities and protocols that enable certain kinds of locating.

Finally, our study adds to a small but growing body of research on data use in teacher preparation. To date, very few studies have examined the use and sensemaking of data in the context of teacher preparation. Those that do examine data use in teacher preparation focus on how teacher preparation programs can organize themselves to enable the collection and use of data for program improvement (e.g., Davis & Peck, 2020). Our study gets inside data conversations to reveal how teacher educators engaged in the noticing practice of locating to situate improvement data within program activities, coursework, student-teaching placements, and instruction. Unveiling the varied ways that teacher educators located improvement data help reveal teacher educators' conjectures about what program activities are pertinent to improvement efforts. Additionally, understanding how teacher educators make sense of improvement data can help to conceptualize efforts to make improvement data more useful relative to specific improvement efforts.

We conclude by arguing for closer examinations of how practitioners notice improvement data. We argue that doing so can enable those leading improvement efforts to examine how they organize improvement data conversations to make them more productive. Taking a noticing lens enables improvement-focused researchers to get inside data conversations to inform how they organize data-driven improvement efforts. We argue that examining how data conversations unfold is a critical step in improving how improvement work is carried out.

Modeling-based Learning in Pre-School Science: Affordances of Different Types of Children-Constructed Models

Loucas T. Louca, European University Cyprus, L.Louca@euc.ac.cy

Abstract: Despite its proven added value, Modeling-based Learning(MbL) in science is not commonly incorporated into early grades science education. Following a growing body of research on using MbL in early grades, this multi-case study seeks to provide detailed descriptions of the implementation of MbL with 3 groups of pre-K children engaged in the study of three different phenomena, taught by 3 different teachers participating in a professional development program of pre-school science education. Findings across the different cases suggest that participating pre-school children were successfully engaged in authentic MbL activities and developed several different types of models using knowledge and experiences, as well as a variety of features of both analogical and mechanistic reasoning. I use this evidence to argue that (a)different MbL tools may afford different learning opportunities; (b)pre-school children have modeling resources that can use to utilize different tools using MbL in natural ways of young children learning (e.g.,playing).

Introduction

Within the larger context of inquiry-based learning, models and the process of modeling are considered integral parts of science learning, providing students opportunities to understand and explain natural phenomena (e.g., Gilbert & Justi, 2016). The authors of the Next Generation Science Standards (NGSS Lead States, 2013) define modeling as a practice that involves the development, revision, use, and evaluation of models aiming at predicting and explaining physical phenomena (Appendix F, p. 6). Externalized through various means and representation tools, a student-generated model along with the process of its development becomes a learning tool enabling students to understand the mechanism underlying natural phenomena (Schwarz et al., 2009). This helps students develop concrete representations of their understanding of a structure, a process, or a natural system, as well as to use models as tools for engaging in scientific reasoning. Recognizing the process of modeling as a key component of learning in science, NGSS Lead States (2013) suggests that learning science should include developing an understanding of natural phenomena through the construction and refinement of models (Louca & Zacharia, 2015), as well as learning the processes of developing and refining those models (White & Frederiksen, 1998). In this respect, models and modeling are considered integral parts of science learning, primarily because they provide the means for students to represent, describe, examine, understand, predict and explain natural phenomena (e.g., Justi & Gilbert, 2016).

Theoretical framework

Modeling-based Learning (MbL) has been widely advocated as an approach that meaningfully engages students in authentic practices of learning of and about science (e.g., Louca et al, 2011; Louca & Zacharia, 2015). Despite this emphasis, only a limited number of studies have investigated MbL among K-6 students (e.g., Louca, 2021). As part of their efforts to enhance our understanding of MbL with young learners, Louca et al (2011) developed a framework for analyzing student-constructed models of natural phenomena. Aligned with other research on MbL in science (e.g., Clement, 1989; Gilbert, 1995; Glynn & Duit, 1995; Ingham & Gilbert, 1991; Penner et al, 1997; Penner, 2001), the Louca et al framework includes five elements of student-constructed models: representation of (i) the phenomenon's physical objects, (ii) the phenomenon's physical entities, (iii) the physical processes, (iv) the interactions among physical objects, entities, and processes, and (v) the accuracy of the phenomenon depiction. This framework provides a coherent system for analyzing and evaluating student-constructed models based on their structural components, it can capture the model's sophistication across the 5 structural components, and it may provide a picture of model progress over time during instruction.

Louca et al's (2011) application of their framework suggested, for example, that the students in the study tended to move from simplistic representations of physical entities to more sophisticated ones. Further, in the case of the representation of object behavior(s) elements, the findings suggested that students' initial models used more non-causal or semi-causal representations of the objects' behavior, as opposed to their final models, in which they used more causal representation of the objects' behavior. Such a framework is particularly useful for providing a picture of how students' models, as well as their learning, progress (e.g., Lehrer & Schauble, 2006; Lesh et al., 2000; Metcalf et al., 2000; Windschitl et al. 2008). Moreover, the framework reveals

 © ISLS

differences among different modeling tools, which could enable teachers and curriculum developers to select the more appropriate environment for the construction of models for a specific physical phenomenon.

Models as student representations of their understanding of a structure, process, or system in science, are directly related to the representation of causal, coherent explanations of the target phenomenon, that is, causal mechanisms. Ke and Schwarz (2019) explain that "developing and revising models that address the mechanism of phenomena lies at the core of the scientific endeavor" (p. 183). In this respect, successful modeling should result in models that include the underlying mechanism of the phenomenon or system. Russ et al (2008) developed a scheme of 7 components of mechanistic reasoning. Those components include (i) descriptions of the target phenomenon (what we see happening), (ii) identification of the set-up conditions that are necessary for the phenomenon to happen, (iii) identification of entities (conceptual or real objects that play a particular role in the phenomenon, (iv) identification of the entities activities, (v) identification of the entities properties, (vi) identification of the entities organization, and (vii) chaining (talking about what had happened prior to a phenomenon and what will happen). Limited research on MbL with young learners, however, has highlighted that they are able to engage in MbL, develop a number of different types of models, using various features of analogical and mechanistic reasoning (Louca, 2020).

MbL also involves analogical reasoning, namely a way of thinking that relies upon an analogy (May et al., 2006). Individuals use analogical reasoning to present commonalities between two phenomena or systems to support predictions or explanations for one of the systems while drawing information from the second system, which usually is more familiar to them. In this sense, analogical reasoning is an important ingredient for causal and scientific thinking because it supports the transfer of knowledge from a well-known or better-known phenomenon or system to a less well-known one. For example, in an attempt to explain how the heart works, individuals may use as an analogy a pump. In this view, expert mechanistic reasoning (Ke & Schwarz, 2019; Russ et al., 2008) involves the generation, use, and evaluation of analogies (May et al, 2006) because analogies can be valuable tools for constructing one's own understanding in a variety of contexts. Unlike most of the research about analogies (focused almost exclusively on their pedagogical value in curriculum materials and teacher explanations for promoting conceptual change in students (May et al, 2006)), we are interested in students' abilities for analogical reasoning that includes (i) the generation of analogies (that includes a target case (unknown), a base case (known) and a relation that maps elements from one case to the other), (ii) the evaluation of the validity of an analogy and subsequent refinement (that includes identification of the key features of an analogy and its limitations), (iii) the use of analogies to create new knowledge by making new inferences about the target case and creating abstract generalizations and (iv) the use of analogies to communicate ideas in science to others (Clement, 1998; May et al, 2006).

Purpose

This is a qualitative multi-case research study seeking to provide detailed descriptions of the different ways pre-K children may engage in MbL using a variety of modeling tools and representation media as well as the types and characteristics of the models they constructed. With an emphasis on the representation of the mechanism of natural phenomena, in this study, I analyze evidence from 3 case studies to comparatively describe the different ways that pre-school children may use different modeling and representation tools while learning in science through MbL. I use this evidence to argue that (a) different modeling/representation tools may afford different learning opportunities; (b) pre-school children have modeling resources (Louca & Zacharia, 2019; Louca, 2020) that can use in order to utilize different modeling/representation tools using MbL in natural ways of young children learning (e.g., playing); and (c) educators may find it productive to choose among these tools depending on children's prior modeling experiences and the mechanism(s) to be represented.

Methods, data sources, and analyses

Following a multi-case study approach (Yin, 2017), this study involved the analysis of data from 3 different groups of pre-school children (age range: 4,5-6) in Cyprus taught by 3 different teachers. All 3 teachers participated in the same professional development (PD) program organized by the author over the duration of a school year. The cases selected for this study were the teachers' first attempt to implement an MbL-in-science unit. Teachers developed their modeling unit from scratch after they participated in PD sessions about inquiry-based learning and teaching science in preschool, and MbL in pre-school science. For the purpose of this study, all lessons (about 40-minute duration) in each case study were videotaped and transcribed for analysis. Children's work (models) was also collected for analysis. Table 1 presents an overview of the data collected.

Since this study involved children aged 5-6, I adopted the approach of drawing-based modeling as used by various researchers in the field (Ainsworth, Prain, & Tytler, 2011; Brooks, 2009) in which children use annotated drawings to represent their models. Thus, when in this study children created drawings, 3-D structures

or used gestural/bodily representations as their representations of the phenomenon under study (Gilbert, 2004), they also accompanied their models with oral descriptions or annotations of their model.

Table 1
Overview of data collection.

Case	Number of children	Number of meetings	Rounds of MbL cycles	Types of model representation		
				Paper & Pencil	3-D structure	Physical representation
Case 1. Plant parts & functions	20	5	4	X	X	
Case 2. Solution of substances in water	18	3	2	X		
Case 3. Shadow formation	25	5	3	X		X

Modeling discourse Analysis: Derived from the videos, transcripts of student conversations served as the primary source of data. The analysis of modeling discourse builds on analyses of children's conversations in science (e.g., Ball, 1993; Gallas, 1995) focusing on the interest of the science education community in classroom discourse (e.g., Kurth et al., 2002; van Zee et al., 2001). This analysis uses transcribed children's conversations as a gateway to children thinking and learning experiences (Edwards & Mercer, 1995). From the videos, I selected and transcribed all conversations that included children's presentations and discussions of their models. These discourse data were coded along with the artifact data (see below) using a coding scheme developed in a previous study (Louca et al, 2011), which codes student talk for: physical objects, physical entities, physical processes, and physical interactions. Then, I used the discourse findings to develop detailed accounts of the context and the content of the modeling conversation describing the student contributions towards MbL. Lastly, I also carried out a coding in terms of the representation of the mechanism in children models and their descriptions, using the Russ et al (2008) coding scheme (see theoretical framework).

Artifact Analysis: To support the discourse analyses above, I also analyzed student-constructed models using artifact analysis adopted from Louca et al (2011). Codes from this analysis included the ways that children represented different elements in their models: physical objects, physical entities, physical processes, and physical interactions.

Findings

Below I briefly present an overview of each of the three cases and then turn into a discussion about common emerging themes from all the 3 case studies.

Case study 1: Plant parts and their functions

For the first lesson, children working in 4 groups identified similarities and differences among several wild plants they collected. In a whole classroom discussion that followed, they agreed that all their collected plants shared the same 4 parts: roots, stem, leaves, and flowers. They also identified that despite those similarities, their plants were different in the type of roots they carried, the shape and the size of their leaves, and the color, the size, and the petal shape of the flowers. In the second lesson, the teacher asked children to draw their findings in order to show them to the children of the next-door classroom. Each group chose a different part of the plants, which they drew independently and put together at the end, making a large poster (model 1) as depicted in Figure 1a. At the end of the session, children compared their poster with one of the real wild plants they collected, identifying a series of disadvantages, mostly related to the way they depicted the information they knew about all the plants into a single drawing. This, children suggested was helpful for letting others know about that information provided, but on the other hand, it was misleading in terms of what a single plant looked like. Thus, children spent lesson 3 revising their first model. Their teacher, however, proposed to work on a 3-dimensional structure as their second representation, using materials that they were familiar with (Figure 1b). This time, each child developed their own model. The comparative evaluation of their models identified a different number of limitations, this time focused on the ways they represented each part of the wild plant and the selection of the materials used for the representation of the plant's parts. In lesson 4, each child worked on a revision of their model, still using 3-dimensional materials. The lesson took place after an investigation of the process of transpiration, using experiences and collecting evidence from an experiment carried out in their schoolyard. This time, their models were substantially revised (see Figure 1c) utilizing materials for their representations that had implications for the plant part functions such as roots showing uptake of water, leaves represented in a way that implied the process of water retention and transpiration, and the stem as a vehicle for water transportation from roots to the leaves. During the evaluation of their models, children agreed that despite their models' revised representation of the plants' parts, their representations contained little information about

the process that takes place inside the plants' parts. Thus, they collectively decided to develop a new model, that would contain information about those processes (e.g., water uptake, water transportation, transpiration), and they discussed how 3-dimensional models had limitations in representing this information. Thus, during lesson 5 they decided to revert to a single, collective paper-and-pencil model, having their teacher noting in words their explanations about their drawings of the processes (Figure 1d).

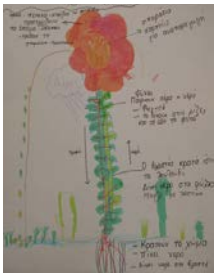
1c. Example of Model 3



1d. Model 4

Table 2 presents artifact analysis findings regarding the models developed by children in case study 1. Findings suggest that the first two models were of similar nature, with the second model having a better representation of the physical objects involved in the phenomenon. For instance, in model 1 children included multiple representations of the same physical objects (e.g., roots), whereas in model 2 they represent only one type of root which was similar to each child's plant. In model 3 the root representation gets better with children choosing particular materials to represent the root, which they thought were related to the functions of the root, and in model 4 they were fully depicted (e.g., water is also presented) and orally discussed how the different objects involved in the phenomenon. In terms of physical entities, processes, and interactions, these were more-or-less absent in models 1 and 2, whereas in model 3 children started making connections to the physical entities, related to the fact that the representation of the physical objects took into consideration the objects functions (processes and interactions). The representation for physical entities, processes, and interactions got better in model 4, with physical processes involved in the phenomenon coded as fully represented.

Table 2
Artifact analysis of Case 1 children models

	Model 1 (one for all)			Model 2 (individual children)			Model 3 (individual children)			Model 4 (one for all)		
	L. 1*	L. 2*	L. 3*	L. 1	L. 2	L. 3	L. 1	L. 2	L. 3	L. 1	L. 2	L. 3
Physical objects	100%				100%				100%			100%
Physical entities	100%			100%			80%	20%			100%	
Physical processes	100%			100%			65%	35%				100%
Physical interactions	100%			100%			55%	45%			100%	

*Level 1 - Limited representation, *Level 2 - Partly represented, *Level 3 -Fully represented

Case study 1 children started addressing the mechanism underlying the phenomenon in model 3, possibly, possibly due to the investigation of the process of transpiration that preceded this modeling round, as well as the 3-D materials that they were using to develop their model 3. Based on the Russ et al (2008) scheme, children's 3rd model and their descriptions included descriptions of the target phenomenon and identification of entities. In their fourth model, students also discussed the identification of the entities' activities, the entities' properties, and their organization possibly due, among others, to the change of the modeling medium.

Case study 2: Solution of substances in water

The first lesson of case study 2 focused on describing how different substances behave in water in an attempt to operationally define the phenomenon: some substances dissolved in the water (e.g., instant coffee, flour), while others did not (e.g., small rocks, beans). In the second lesson, children collected data from the following experiment: In a clear glass of water, they placed a drop of brown food color at the bottom of the glass. Every 2 minutes, children recorded on a piece of paper what they observed in the glass. After collecting the observations, they gathered into the whole class setting, and the teacher displayed children's drawings in the sequence they

were recorded on the whiteboard to talk about what they had recorded, specifically focusing the discussion on the changes in the water. Through this discussion, children reached a consensus that by the last drawing, the water became brownish, although it was not as brown as the initial drop of the food color that they had recorded in their first drawing. The teacher decided that this drawing could play the role of children's first model and used it to ask for interpretations of the data collected to be incorporated in a revised model by asking: "Suppose you are in the water. What would you see happening?" Children went back to their group tables, were provided a clean sheet of paper, and asked to draw that story. This drawing was the children's model of the phenomenon under study. In the third lesson, children presented their 18 models to the rest of the class, talked about them, and discussed their differences and similarities. Figure 2 presents 3 examples of children's models that differ in the way they represented the phenomenon. The first one is a sequential approach, in which children focused on presenting in their paper-and-pencil model a sequence of drawings in an effort to represent sequential scenes of the phenomenon. A second type of model depiction included all these scenes of the phenomenon happening over time in a single drawing. A third type of depiction simply provided the final scene of the phenomenon, with the brown "pieces" randomly distributed in the water. This third type of model does not include or refer to any mechanism of the phenomenon under study. More details about this case can be found in Louca (2020). Due to time limitations, children in this case study did not work on further revisions of their models. They simply talked about the similarities and differences of their models, in an effort to identify the advantages and disadvantages of their representations.

Figure 2

Examples of representations developed by the children

2a 2b 2c

The artifact analysis of model 1 (Table 3)suggested limited representation of all components of the model - physical entities, processes, and interactions were completely absent from the model. The artifact analysis of their revised models (model 2) suggests that children presented and talked about physical objects represented in their models (e.g., the water, the dye drop, the water and the dye pieces (aka molecules)), physical entities (e.g., "pieces" being the smallest possible unit of the substance, the "pieces" having the same color properties as the substance), physical processes (e.g., molecules moving, each molecule being able to behave independently of the rest of molecules; the random movement of the colored molecules), and interactions among physical objects and physical entities. Table 3 provides an overview of the artifact analysis of the models. These findings suggest that although all of the children-constructed models included all the physical objects of the phenomenon under study, only 58% of them had fully represented the various interactions between physical objects, entities, and processes. In terms of physical entities, only 32% of the models fully included them. 68% of the models had fully represented the physical processes involved.

Based on the Russ et al (2008) mechanistic reasoning scheme, for their second model children used a number of elements of mechanistic reasoning. 82% of the models presented were accompanied by mechanistic explanations. The data suggest that level 1 representation (limited representation) for all components had a mean of 7%, level 2 (partly represented) 38%, and level 3 (fully represented) 55%. All the children provided a full description of the target phenomenon. 68% of the models also included a level 3 identification of the set-up conditions necessary for the phenomenon to take place; 66% fully identified the entities (conceptual or real objects) that played a particular role in the phenomenon. 65% of the children models included entities' activities, whereas 10% of the total models had limited representations of the entities' activities; I have found a similar picture regarding the description of the entities' properties. The last 2 components were much less addressed in children's descriptions: no fully described the identification of the entities' organization (19% level 1, and 81% level 2); only 30% of the models fully included chaining, whereas 60% of the models had chaining represented as level 2.

Table 3
Artifact analysis of Case 2 children model 2

	Model 1			Model 2		
	L. 1*	L. 2*	L. 3*	L. 1	L. 2	L. 3
Physical objects	100%					100%
Physical entities	100%				68%	32%
Physical processes	100%			10%	22%	68%
Physical interactions	100%			10%	32%	58%

*Level 1 - Limited representation, *Level 2 - Partly represented, *Level 3 -Fully represented

Case study 3: Shadow formation

Case study's 3 lesson 1 started with children investigating the conditions under which a shadow is created. To resolve this, children designed an experiment during which they found that in order to create a shadow they needed a light source, an object, and a screen to get the shadow on, in that order. In the following lesson, children worked on figuring out how to increase the size of a shadow. They experimented with materials and identified 2 different ways to change the size of a shadow. In the 3rd lesson, the teacher asked the children to develop a representation of how they thought the shadow is created, asking them to reflect on their experiences from experimenting with shadow in the last two lessons. This resulted in their first model (Figure 3a). During the comparative evaluation of their models, one common issue identified was the ways children used the light rays as a conceptual idea playing a critical role in the process of creating a shadow, as well as the characteristics of the shadow produced. These were extensively discussed and revised in most of the drawings/models 2 during lesson 4 (Figure 3b). In lesson 5, the children along with their teacher got outside their classroom, into an open-air patio, which was always windy. The teacher asked children to think about ways to represent the shadow formation, as they represented it through their previous models. Children had to think/invent ways to represent the various physical objects taking place in the phenomenon, the physical entities (such as light rays) that are involved, and the interactions between them that resulted in the physical processes of the phenomenon. This discussion resulted in their collective model 3 (figure 3c and 3d) in which some children function as the "light-production cells", holding long paper stripes as the light rays. One child was the object for creating the shadow (wearing a red piece of cloth) and a child wearing a black piece of cloth represented the shadow created. Figure 3c represents the lights-off situation and Figure 3d represents the lights-on situation.

Figure 3
Examples of representations developed by the children

3a. Model 1 3b. Model 2 3c. Model 3 3d. Model 3

Table 4
Artifact analysis of Case 1 children models

	Model 1 (individual children)			Model 2 (individual children)			Model 3 (one model for all)		
	L. 1	L. 2	L. 3	L. 1	L. 2	L. 3	L. 1	L. 2	L. 3
Physical objects		100%			100%				100%
Physical entities	40%	60%		20%	80%			100%	
Physical processes	32%	58%		16%	68%	16%		100%	
Physical interactions	16%	68%	16%		84%	16%		100%	

*Level 1 - Limited representation, *Level 2 - Partly represented, *Level 3 -Fully represented

The artifact analysis (Table 4) suggests that the representation of the physical objects was partial for Model 1 and model 2, whereas model 3 had a full representation. For the rest of the model components, there was an increase in the quality of representation from model 1 to model 2 and then to model 3, although the level 3 representations of physical processes and interactions were lost in model 3 possibly due to the change of the modeling medium and the fact that children worked together to develop a single model.

In terms of mechanistic reasoning, children in case study 3 started addressing the mechanism of the phenomenon from their model 1 by providing descriptions of the target phenomenon, identification of the set-up

conditions that are necessary for the phenomenon to happen, and identification of entities (conceptual or real objects that play a particular role in the phenomenon, even though the entities activities and properties were never fully represented. With the improvement of the representation of model components from model 1 to model 2 and then to model 3, there was an improvement in the children's description of the mechanism of the phenomenon. All the children described the target phenomenon and some identification of the set-up conditions necessary for the phenomenon to take place; they also identified the entities (conceptual or real objects) that played a particular role in the phenomenon as well as the entities' activities, and their properties. The same applies to the last 2 components of the mechanism in children's descriptions: although no full description was provided, children were able to describe the entities' organization as well as the chaining.

Discussion

My purpose in this multi-case study was to provide detailed descriptions of the different ways pre-K children may engage in MbL focusing on the variety of the modeling tools and representation media used by children. Agreeing with prior studies suggesting that pre-school children are able to represent mechanisms underlying natural phenomena (e.g., Louca, 2020), data from this study suggest that, overall, pre-school children are also able to use a variety of modeling representation media such as paper-and-pencil, 3-dimensional materials or physical/body representations to represent that mechanism. In at least 2 of the cases presented, children in the study were able to talk about the possible different ways of representing their models, engaged in a conversation about different ways' affordances in terms of their representational power, and collaboratively decide which way better suited their representational needs. Thus, I contend that some evidence suggests that children as young as pre-school may be able to move from one type of representation to another, with the possibility to invoke what Louca & Zacharia (2019) have suggested as modeling resources in order to utilize different modeling/representation tools. While I do not suggest that these children were experts in MbL, these findings may further suggest that educators may find it productive to choose among these tools, depending on children's prior modeling experiences and the types of mechanism(s) to be represented. Future research should further investigate this direction.

Towards this direction, it is also important to highlight children's abilities not only to use different modeling media, but also to choose among different modeling media, in terms of enabling them to show aspects of the mechanism underlying the phenomenon. Although this needs further investigation, I suggest, it might be related to epistemological implications of the MbL as described by Schwartz (2019) in terms of epistemic considerations within the disciplinary norms of the scientific community, which includes the nature of the knowledge provided by the model, the justification of that knowledge, its generalization and the audience of the model. Lastly, I contend that the findings I describe in this study may prove useful for educators seeking to engage pre-school children to MbL in science by helping them choose among different modeling/representation media depending on children's prior modeling experiences and the mechanism(s) to be represented.

Illuminating Supports for Representations of Science through Examining Modes of Reproduction

Laura Zeller, University of Illinois Chicago, lzelle2@uic.edu

Abstract: Knowing how to move towards scientific literacy for all requires an understanding of how science is represented within classrooms. Patterns in science representation range across a continuum from science as isolated truths to an integration of knowledge, practice, and conceptualization that creates holistic science representations. This action research case study examines science representations across this continuum within a science course for elementary education majors at a minority serving institution and how these practices of representation are supported across multiple levels of the educational system. Findings presented summarize overall course patterns and supports and give details of a pattern that leads to suggestions for reform efforts towards the goal of scientific literacy for all. The need to look beyond single-level changes is evidenced by how supports acted at a multitude of levels and how supports that sustained holistic representations of science interplayed with those that supported non-holistic representations.

Introduction

As science education works towards the goal of scientific literacy for all, it is important to examine how science is represented in classrooms, but simply characterizing science representations within a classroom is insufficient. There is a need to understand how and why science classroom practices beneficial to student learning are or are not implemented (Gardner et al., 2021). It is only by understanding how content is represented within a web of systematic supports that lasting change can be enacted (Cobb et al., 2009). This requires knowing how those representations are supported both within the classroom and across the complex, multi-leveled education system that situates the classroom.

In this study, I examine science representations within a science content course for future elementary educators studying at a minority serving institution and preparing to teach in urban schools. I ask two questions: (1) How did practices of science representation manifest in this course, and (2) how are patterns in these practices supported in a way that sustains them across the course? To do this, I use methods based on the MoRe Institutional Framework to engage in a multi-leveled analysis of the supports that sustain both ideal and non-ideal practices (Anderson & Colyvas, 2021; Zeller, Under Review).

Parts of Science

Lederman and Lederman (2020) discuss that there are three parts of science that are integral to developing scientific literacy: scientific knowledge (SK), scientific inquiry (SI), and the nature of scientific knowledge (NOSK). SK is the facts and knowledge that have resulted from science (e.g. Newton's Laws, the Big Bang Theory, and the density of water). SI is the practices of scientists, the process by which SK is created (e.g. experimentation, data analysis, and analyzing claims). NOSK is characteristics that are inherent to SK and set SK apart from opinions and unsubstantiated claims (e.g. empirically based, tied to human creativity and culture, and changing/tentative). In order for someone to be scientifically literate, they need to have an understanding of all three parts of science.

In this study, I operationalize "holistic science representation" to mean a collection of representations that showcase all three parts of science. This holistic representation is one end of a continuum, the other end of which has science as isolated facts that are taken as total truth. Along this continuum are various gradations of non-holistic representations that combine parts of science, such as SK and SI coupled together but not showing NOSK within classroom materials and activities.

It is important to note that looking at science representations in the classroom is only an initial step towards creating learning environments that develop scientific literacy. Specifically, research shows that students do not learn NOSK through simple exposure and that learning NOSK requires explicit instruction (Lederman & Abell, 2014; Marchlewicz & Wink, 2011). Looking at representations, however, lays the groundwork by looking at how NOSK is present within classrooms before specific efforts have been made to implement explicit instruction on NOSK.

 © ISLS

MoRe Institutional Framework

In order to expand my view beyond simply what is happening in the classroom, I utilized the MoRe Institutional Framework (Anderson & Colyvas, 2021). This framework is rooted in institutional theory, starting with Jepperson's (1991) definition of institutions as continually reproduced "social patterns" that are sustained by "self-activating social processes" (pp. 144-145). Anderson and Colyvas (2021) discuss these self-activating processes as modes of reproduction and how they manifest in observable ways at multiple levels of complex systems. They present categories of modes of reproduction that the literature shows are prominent in education, including policy, framing, stakeholder interests, learner identities, roles, assessment, routines, and professional norms. Modes of reproduction are the key to understanding why a pattern of practice continually occurs within a classroom.

What makes the MoRe Institutional Framework powerful for investigating classroom practice is looking beyond a single, idealized pattern of practice by examining modes of reproduction supporting both ideal and non-ideal practices. These practices are often conflicting. Practices do not often manifest in binaries, one practice or the other. Rather, it is better to conceptualize the range of these practices as a continuum that creates space to investigate complexity. Looking at how institutionalized patterns of practice manifest along a continuum illuminates the interplay between opposing practices. It is possible that one practice may even act to support the very practice it is trying to replace (Anderson, 2017).

Methods

This work is part of a larger study conducted within the methodologies of case study and action research (Zeller, Under Review). Case study effectively allowed me to look in depth into the patterns of practice within a single classroom and develop rich, detailed descriptions (Yin, 2006). Utilizing action research, through having the author as part of the instructional team, afforded access and insider understanding of situated processes and evidence that are not available within observational studies (Roth, 2001). Case study and action research methodologies require specific tools for data analysis. In this study, the MoRe Institutional Framework provides those methodological tools, including categories and coding strategies that were used to create the case descriptions. Within this paper, I pay attention to the particular ways that the MoRe Institutional Framework facilitates description of practices of science representation and how these practices were supported.

Context and participants

The course examined in this study was a science content course for elementary education majors during the Fall 2020 semester. The course ran a single lecture section of 72 students and three lab sub-sections synchronously online. The course is a required class for the major in elementary education, which focuses on preparing students to teach in urban schools, at a large, R1 university in the Midwestern United States. The university is classified as a minority serving institution. The course covered physics, space, and earth sciences topics and is one of two required science content courses.

The course team consisted of two co-instructors and two teaching assistants (TAs) and is traditionally taught by one professor from the physics department and one from the earth sciences department. In the semester of the study, the earth sciences instructor was the professor who had taught the class in years past, and the author, a graduate student in learning sciences with six years' experience teaching high school physics, filled the role of physics instructor of the course. For clarity within this paper, I refer to myself in the first person as a researcher and in third person as an instructor. A graduate student from the physics department was the TA for one of the lab sections while a graduate student from earth sciences was the TA for the other two sections.

The course is unique within the university as it is taught by staff from two separate departments of the College of Liberal Arts and Sciences and is a required course for undergraduate students within the College of Education. Each co-instructor earns a full course teaching credit for the course, regardless of co-instructing. It is extremely unusual for a course to be co-taught like this, especially across departments at the university. The TAs for the course are regularly hand-picked, before other appointments are made in the departments, to select graduate students who are interested in teaching and fit the role of working with education majors. One artifact of these special conditions is that the instructors have more freedom and flexibility, which leads to the instructors regularly using the course as a place for innovation.

Data collection and analysis

Data analyzed for this study included course materials as well as reflections and interviews from the course team members. The course materials included the slide decks for both lecture and lab, activity documents and poll questions used during lecture, lab assignment documents (prelab assignments, instructions, activities, and conclusion questions), and summative portfolio assessments. Interviews were semi-structured and focused on

individuals' experiences within the semester. The course team reflections were completed before each interview and used to inform some of the interview conversation. I conducted three rounds of reflection/interview with each other team member. A separate research associate conducted two rounds of reflection/interview with me, as the physics instructor. The data was initially grouped into two strands: practices data and supports data. Utilizing the structure of the MoRe Institutional Framework to illuminate the complex web of supports and patterns in the classroom, I empirically investigated both patterns of practice and modes of reproduction (Zeller, Under Review).

The analysis of the data for practices focused on patterns of science representation in the course. Codes were developed out of Lederman and Lederman's (2020) descriptions of the three parts of science. Table 1 details the codes and sub codes. Heatmap tables of codes within and across documents were used to identify patterns along the continuum between representing science as isolated facts and holistically representing SK, SI, and NOSK. I then used the coded data to build descriptions of how these patterns manifested.

Table 1

Definitions of sub-codes within each part of science

Sub-Code	***Definition***	***Example from Case***
Scientific Knowledge (SK)		
Truth Statement	Statements of how things are or what something is (e.g. scientific law, definition).	Presenting the definition of force and various types of forces.
Mechanistic Explanation	Statements of why things are the way they are (e.g. scientific theory, cause/effect).	Presenting how igneous, metamorphic, and sedimentary rocks are formed.
Applying SK	Use of knowledge within a scenario or phenomenon (e.g. solving problems).	Completing practice questions by creating energy bar charts for given scenarios.
Scientific Inquiry (SI)		
Doing Science	Students are engaged in scientific inquiry/practices.	Creating a model of the earth and sun showing the causes of eclipses and moon phases.
How to Do Science	Teaching about how to engage in scientific inquiry/practices.	Presentation of how to analyze a model, such as a motion graph.
Doing Science to Teach	Using scientific inquiry as a demonstration tool within instruction of content.	Demonstrating how to use equations for energy to understand different types of energy.
Inquiry as Pedagogy	Students doing science as learning tool (with learning outcomes other than doing/understanding inquiry).	Students building understanding of circuits through guided exploration of a simulation.
Nature of Scientific Knowledge (NOSK)		
Human Creativity	The human part of science (e.g. starting with a question, choice, creativity, collaboration, or inference making).	Labs asking students to write questions about phenomena before knowing what the outcome should be.
Empirical	Discussion of data/observations that back up scientific knowledge or the use of data/observations in scientific thinking.	Discussion of the evidence that shows that the solar system is heliocentric, not geocentric.
Changing/ Tentative	Discussing scientific knowledge changing over time, acknowledging skepticism within science, or considering multiple theories for the same phenomenon.	Discussion of the recent shift in acceptance from continental drift theory to plate tectonics theory.
Socially Embedded	Connections between science and everyday life, especially where one seems to directly affect the other, including discussing diversity in science.	Presenting the history behind the adoption of alternating current over direct current and its connection to the world's fair.
Subjective/ Theory-laden	How scientific theory shapes how we do science and how we explain scientific knowledge.	Discussing the direction of conventional current and how it is still used even through electrons move the other direction.

The analysis of the data for supports focused on the categories of modes of reproduction from Anderson and Colyvas (2021). First, the broad, category codes of policy, stakeholder interests, framing, learner identity, roles, assessment, routine, and professional norms were applied. I then reviewed how the categories occurred within each segment and developed codes for specific supports within each category.

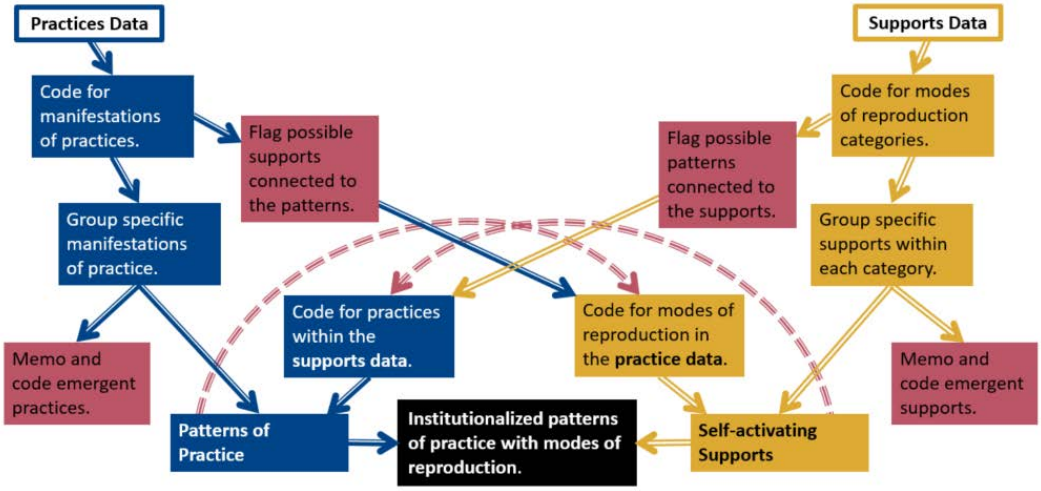
 © ISLS

Once the practices and supports data were coded for practices and modes of reproduction, respectively, I went back and cross-coded to capture more detail. Through micro-rounds of iteration and focusing on specific practices in turn, I created groupings of modes of reproduction that supported each pattern of practice.

The flow of the analysis process is summarized in Figure 1. The blue boxes and arrows in Figure 1 show the analysis of practices data, looking for patterns across the continuum. The yellow boxes and arrows show the analysis of supports data using the categories of modes of reproduction. The pink boxes and arrows show the iteration of cross-coding that occurred between the two sets of data to form complete account of patterns and supports that were assembled into groupings of institutionalized patterns of practice with modes of reproduction.

Figure 1

Flowchart of data analysis



Findings

The data showed both overall and nuanced patterns across the continuum of science representations within the course. Figure 2 shows heatmap tables of SK, SI, and NOSK within the lecture, lab, and summative assessment for each unit, shown in order of instruction. The scales for each lecture, lab, and summative assessment indicate the frequency of each part of science within each unit. The gradient scales for lecture and lab were each normalized based on the number of meetings per unit. The included numerical scale matches the color gradients to make the data more accessible. The darkest boxes of each color scale (1.00) indicate the unit-part of science combination that had the highest frequency. White boxes (0.00) indicate coding for that the part of science did not appear within that unit.

Figure 2

Heatmap tables of science representations of SK, SI, and NOSK within lecture, labs, and summative assessments (portfolios) by unit of the course

	Lecture			Lab			Summative Assessment		
Course Unit	**SK**	**SI**	**NOSK**	**SK**	**SI**	**NOSK**	**SK**	**SI**	**NOSK**
Physics: Motion	0.78	0.59	0.03	0.45	0.41	0.19	0.82	0.73	0.09
Space	0.85	0.36	0.81	0.53	0.33	0.22	0.91	0.55	0.18
Earth: Geology	0.73	0.25	0.51	0.78	0.44	0.28	0.64	0.55	0.36
Physics: Electricity	1.00	0.32	0.21	0.55	0.19	0.16	1.00	0.27	0.18
Earth: Climate	0.45	0.26	0.30	1.00	0.47	0.34	0.64	0.36	0.36
Physics: Waves	0.53	0.18	0.00	*no lab this unit*			0.36	0.27	0.09

As evidenced in Figure 2, all three parts of science were represented within each part of the course, but NOSK was less prevalent and sometimes missing within units. Some units are strongly holistic, while others only weakly represented some parts. No units, however, appeared at the end of the continuum of representing science as isolated facts as they all included representation of both SK and SI. When looking between units, there is a distinct difference in the amount of NOSK representation within the physics units versus the earth and space units.

 © ISLS

The supports for the overall pattern and variation by discipline patterns are presented in Table 2, grouped by mode of reproduction category. The first pattern describes the science representation of the course in general and is provided to give the reader a brief idea about how the course was shaped as a whole. I present the details of the pattern of variation of science representation between disciplines below, exploring both how this was seen within the course and how it was supported at various levels. I first describe the patterns of practice and then the supports.

Table 2
Patterns of practice of science representations and their corresponding supports

Patterns of Practice	Support Category	Specific Supports within Categories
SK and SI representation with limited NOSK representation.	Policy	The university offered this course specifically for urban education majors. The college specified this as a lab course. State standards shaped what is included in a course for future teachers.
	Routine	The course lab structure included NOSK across whole semester.
	Stakeholder	There was interest in preparing the students to be educators.
	Identity	The students were identified as future educators.
	Assessment	The assessments used in the class created opportunity for rich inclusion of SI.
	Framing	The course team thought scientific literacy was important.
	Roles	Neither instructor had training in teaching NOSK.
Science representation variation by discipline.	Roles	The physics instructor was trained in and valued Modeling Instruction. The earth sciences instructor saw the goal of general education science courses to be building general appreciation and understanding of science.
	Framing	The physics instructor thought learning goals should focus on the integration of scientific knowledge and practices. The earth sciences teaching assistant thought of science as understanding mechanisms.
	Professional Norms	Earth and space sciences have theory shifts accessible to this course. Physics courses traditionally focus on algorithmic solving.
	Policy	The university set the contact hours for the course.

Patterns of science representation variation by discipline

Here, I give a detailed account of how science representation varied by discipline within the course structures of lecture, lab, and assessment. The earth and space science units included more NOSK than physics units. In lecture, physics units mostly presented science as just SK and SI while the earth and space units represented science more holistically through the additional inclusion of NOSK. All units included representations of SK and SI, but two of the three physics units lacked representations of NOSK in lecture. Only the electricity physics unit represented NOSK significantly, by discussing electricity within the socially-embedded context of how electricity is embedded within everyday life and the theory-laden way historical decisions (e.g. the direction of conventional current flow) affect how we interact with and study electricity. The earth and space units, in contrast, all represented NOSK. Earth and space units consistently made ties to the history of science and the human aspect of theory development. This represented science as including human creativity and being theory-laden. The space and geology units also strongly represented science as changing/tentative and empirical because they discussed historical shifts in theory: heliocentric to geocentric and continental drift to plate tectonics. Overall, the earth and space unit lectures provided more holistic science representations by including more representations of NOSK along with the SK and SI that was well represented across all units, while physics had fewer NOSK representations.

For the labs, all units, across earth, space, and physics, represented NOSK. This was directly tied to the routine lab structure. Labs that specifically represented NOSK the most were the labs on plate tectonics (in the geology unit) and climate. The plate tectonics lab repeatedly represented science as changing/tentative, theory-laden, and empirical through the discussion of the shift from continental drift theory to plate tectonic theory. The climate lab represented science as empirical through the analysis of longitudinal data sets to identify changes in

atmospheric carbon and global temperatures. Overall, the labs more consistently represented NOSK across units than lecture, but the earth and space units still had more representations than the physics units.

For the summative unit assessments, SK and SI were generally well represented but NOSK was minimally represented across units in both disciplines. The earth and space assessments still had a slightly higher representation of NOSK through socially embedded questions and empirical data sets provided for interpretation. The first two physics assessments included unspecific connections to everyday life and analysis of a provided data set, providing weaker, but still present NOSK representations. The last physics assessment, however, completely lacked representations of NOSK and included the least SK and SI of any unit assessment. This assessment covered the shortest unit and focused more on reflection on learning over the whole semester than the content of the final unit. Even with the general lack of NOSK representation across all summative assessments, the earth and space assessments still generally represented it more than the physics assessments, matching the pattern seen across lecture and lab.

Supports for science representation variation by discipline

To understand why the difference in science representations between disciplines persisted across the semester, I developed an account of the supports that reproduced this pattern. More holistic science representation in earth and space units than in physics units was supported by modes of reproduction at the individual, course, and scientific-field levels. At the individual level, the framing and roles assumed by members of the instructional team shaped the focus of various units. Disciplinary professional norms drove different practices within each unit, and course-level policy in the form of learning goals further connected course practices to professional norms.

The general lack of NOSK in physics was connected to a strong focus on SK and SI. This focus was supported at the individual level by how the physics instructor's training in Modeling Instruction (Wells et al., 1995) for high school physics permeated their teaching of this course. This pedagogy focuses on students learning through developing and using scientific models and shaped the physics instructor's framing of student learning goals. The physics instructor reflected on how Modeling Instruction shaped their instructional choices:

> I really felt strongly that, um, the tools of modeling that I've learned from Modeling Instruction and using visual models to help build conceptual understanding of the concepts is more important than 'plug and chug and get an answer'… So I tried really hard to focus on these models, using graphs and force diagrams and bar charts and different semi quantitative models, to talk about the concepts of motion force and energy (Physics Instructor, Interview 1).

This meant that the physics units, especially the motion unit, were more focused on the integration SK and SI, which is evidenced by the strong SK and SI representation across the first unit. Although Modeling Instruction does not specifically exclude NOSK, it caused the physics instructor to focus more specifically on inclusion of SI. This focus also likely contributed to the absence of socio-cultural connections because of the difficulty students had in mastering the graphical and mathematical models of motion, leaving less space for NOSK representation through rich, socially embedded context. The way the physics instructor implemented Modeling Instruction supported rich representations SK and SI, to the neglect of NOSK.

Supports for the inclusion of NOSK in earth and space units came from the individual level through the earth sciences instructor seeing their role as a general education instructor as helping students build a general appreciation and understanding of science. They talked about this in an interview:

> A lot of [the goal of the course] for me is just passing on interests in science and excitement about science and being able to share that with their students… I think [this course] is trying to cultivate interest and feeling more confident in their science skills (Earth Science Instructor, Interview 1).

This understanding of their role helped reproduce the inclusion of NOSK representation through connecting with students' interests with highly contextualized examples in the earth and space units, including the assessments. This supported socially embedded science representations across earth and space units.

The earth sciences TA's individual-level framing of science as focused on understanding the mechanistic explanations for phenomena supported inclusion of NOSK. This TA helped design the earth and space labs and therefore had more impact on those units than the physics units. They said that for lab redesign and instruction they, "wanted to communicate these mechanisms and such, and that being a big point, but the practice of actually trying to get them to understand and check-in with them as we go" (Earth Science Teaching Assistant, Interview 2). The earth sciences TA also had a background in planetary science and was a guest lecturer during the space

unit. Therefore, their framing especially reproduced the NOSK representation of science as empirical in the space unit's discussion of helio- vs. geocentrism through the focus on evidence that supports each theory.

The specific content of this course, which created the base structure for inclusion of SK, SI, and/or NOSK, was reproduced by the semi-formal policy of course learning goals. These goals, however, are tied to higher-level traditions of what is taught in introductory earth science and physics courses. Although the specific content of this course is also influenced by state-level, K-12 science teaching standards, these too are descended from the field-level traditions of Physics and Earth Sciences. The professional norms of each discipline reproduced variation in how each unit represented science. These norms include both field-knowledge development and traditions of what is included in introductory courses.

Within the earth and space units of the course, professional norms reproduced representations of NOSK through the examination of theory change and the examination of large, longitudinal data sets. The pervasive focus on theory shifts in the earth and space units was supported by professional norms at the scientific-field level, reproducing representations of science as changing/tentative. Classic introductory earth and space topics, include models of the solar system and the earth's crust. These two topics are imbued with NOSK representation because of the major historical shifts in theory related to them. This is especially true for the earth's crust since the shift from continual drift theory to plate tectonics theory happened quite recently. Science was also represented as empirical through the traditions of using large, longitudinal data sets to analyze climate change. The nature of the content traditional to earth sciences courses supported pervasive representation of NOSK.

Introductory physics courses traditionally focus on motion (including kinematics, dynamics, and energy). Within the scope of an introductory course, the theory for motion has not recently changed. Additionally, this content is often taught in an algorithmic, fact-based fashion, which focuses on computing the correct answer to a question. These traditional approaches are SK forward, neglecting the SI and NOSK opportunities. The physics instructor's framing through the lens of Modeling Instruction contributed to more representation of SI, but as previously discussed, not NOSK. Although many reforms (e.g. Modeling Instruction) try to disrupt these patterns, field-level professional norms are inherently institutionalized and taken for granted as something that just is, which makes them strong modes of reproduction.

Discussion and Implications

Examination of the findings in this study illuminates information about how holistic and non-holistic science representations are reproduced within this classroom and points towards efforts that could help reforms aiming for scientific literacy. The interplay between modes of reproduction for holistic representations and those that only reproduced inclusion of SK and SI and how these supports manifest at many levels show that reform efforts need to look beyond just what the teacher is doing, or other single-level changes.

Within the overall course findings summarized in Figure 2 and Table 2, NOSK is the part of science that was least represented and reproduced. Modes of reproduction influencing how science was represented in the course spanned levels from individual to scientific field, emphasizing the need to consider action beyond teachers. However, at the individual level, framing and role based modes of reproduction acted through the course team, emphasizing that although there is a need to consider the wider system, the instructors are still central to classroom practice.

The findings also show examples of how this course uniquely involves cross-department and college collaboration which affects what policies and professional norms reproduce classroom practices. Specifically, the freedom and flexibility within this course for instructors to innovate creates a diverse web of modes of reproduction that affect practice.

When looking at the specific example of NOSK being represented more within earth and space units than within physics units, more detailed conclusions emerge. The specific background and training of the physics instructor provided the example of a specific past reform effort, in the form of Modeling Instruction, permeating into a space other than the original intended setting based on instructor transfer. This transfer, however, was constricted by the new classroom environment, causing the instructor to focus narrowly on specific goals. In this case, the focus on integrating SI and SK meant that NOSK was not supported within the physics units, especially the motion unit.

The split between earth and space and physics units' representation of NOSK also brought to light the deep institutionalization of professional norms from the different science fields. Things that are most taken for granted can most stand in the way of reform. For example, one implication of this study is that, after the investigated semester was over, I discussed possible changes in the motion unit with the regular physics instructor of the course and we decided to cut some very traditional content in order to be able to make other content more accessible. This challenged the professional norms of introductory physics content and opened the door for changes in classroom practice.

The variation between the science disciplines also exemplifies that the specific classroom context and goals must be considered when formulating plans for implementing reforms. What comes easily in one discipline may be difficult in another. This pairs with the difficulty in transferring Modeling Instruction pedagogy between educational settings (i.e. high school physics to an undergraduate, interdisciplinary science course) to show how influential the specifics of the classroom and surrounding system are to classroom practice. This shows how important it is to use research methods, such as the ones used in this study, to deeply look at what is supporting classroom practice and understand the complexity of implementing change.

Together, the findings suggest that, in order for this course to implement reforms towards the goal of scientific literacy for all, particular attention is needed towards consistency in the representation of NOSK across disciplines. Possible actions include writing formal course goals and learning objectives that connect to NOSK, especially in the physics units by showcasing how historical work by scientists exemplifies NOSK, then examining content coverage and how this aligns with course goals. These actions would attempt to establish course-level policies that balance out the lack of higher-level policy support of NOSK inclusion and create space for challenging taken-for-granted field-level professional norms.

These findings also have important implications for wider study of the complex, interlacing web that institutionalizes practices in the classroom. The current findings provide insight into supports of science representations manifesting on the timescale of a semester, but can also inform conceptualization and investigation of issues outside of the single course or semester. Changing the unit of analysis from within one semester to looking at change across school years would provide a different view with different affordances towards wider change. What is considered unchanging or transient depends on the timescale of analysis (Lemke, 2000). Therefore, within a longer-term study, multiple snapshots of a longitudinal reform effort focusing on patterns and modes of reproduction could result in better understanding of the process of constructing and deconstructing modes of reproduction in service of lasting change.

High School Science Education in a "Post-truth" Society: Confronting Confirmation Bias with Students and Teachers

Abstract: Incorporating the goals of a comprehensive epistemic education into K12 curricula is increasingly critical. In this study, we worked with high school biology students and teachers to evaluate how to enact strategies to counter confirmation bias while engaging in scientific modeling. We used a video-cued method in interviews with participants and then applied the AIR model to analyze responses. Findings show that most could identify biased epistemic processes. Additionally, teachers listened to some of their students' evaluations and were surprised by what they heard. This suggests noticing students' epistemic cognition in the classroom is difficult and engaging students in video-cued discussions about reliable scientific practices around a familiar activity may allow for learners' thinking to become more visible.

Keywords: Epistemic Cognition, Metacognition, Scientific Modeling, Biology Education

Introduction

Science denialism has become increasingly prevalent, with the internet allowing for the exponential spread of misinformation on important socioscientific issues, such as vaccine safety and climate change (Sharon & Baram-Tsabari, 2020). Individuals' tendency towards *confirmation bias* is likely one important underlying cause of this worrying trend (Gorman & Gorman, 2021). One manifestation of confirmation bias is the evaluation of evidence to favor one's prior beliefs, as when evidence supporting one's beliefs is considered accurate and reliable, whereas equally relevant and sound evidence against one's beliefs is dismissed as false or erroneous (Nickerson, 1998). As a result, processing new information with an open-mind and demonstrating the ability to change a belief in light of contradictory evidence can be extremely difficult (Gorman & Gorman, 2021). Thus, the repercussions of unconfronted confirmation bias and its effects in propagating anti-science beliefs will continue to have detrimental effects on global public health and safety (Gorman & Gorman, 2021).

Given the gravity of current socioscientific issues, it is imperative that science educators improve students' abilities to critically evaluate evidence and distinguish well-justified and accurate information from false and misleading claims (Chinn et al., 2021). This involves emphasizing epistemic educational goals for students, among which, include increasing their awareness of cognitive biases, as well as helping them to develop and implement strategies that can counteract those biases (Barzilai & Chinn, 2018; Hofer, 2016). Such educational goals have emerged from research on *epistemic cognition*, which can be defined as people's ways of knowing—including cognitions and practices used to establish, critique, and use knowledge within disciplines (Greene et al., 2016). Research has revealed that teachers need support in developing the best ways to cultivate a comprehensive epistemic education given the complexity of the topic; however, we are still limited in our understanding of the best ways to design and enact such supports (Fives et al., 2017; Sandoval et al., 2016).

In this study, we investigate how students and teachers are working with well-developed modeling curricula from the perspective of their epistemic performance, specifically as it relates to confronting confirmation bias in evaluating evidence. Using a video-cued interview method (Tobin, 2019), we identified a case of confirmation bias occurring in previously collected video footage of past high school biology students engaging in a modeling unit and then asked current students and their teachers to evaluate the epistemic performance of the students in the clip. In an effort to contribute to research and design that promotes effective epistemic education in science classrooms, we addressed the following research questions: 1) How did current students and their teachers evaluate the epistemic performance of past students working with the modeling curriculum? 2) How did teachers respond and react to hearing some of their own students' evaluation of the epistemic performance exhibited in the video clip?

Supporting teachers in promoting an epistemic education

The complexity and relevance of epistemic cognition in science teaching is critical to address, yet current instructional practices tend to fall short of developing students' capacities in this way (Chinn et al., 2020; Elby et

 © ISLS

al., 2016). Indeed, multiple contextual factors are likely to affect teachers' abilities to focus on epistemic performance goals in the classroom, as teachers are likely to hold a multitude of goals for their students (both epistemic and non-epistemic) simultaneously (Fives et al., 2017; Buehl & Fives, 2016). Furthermore, the contextualized nature of epistemic cognition demands that teachers attend to the specific tasks and learning environment of a given activity, as well as to become proficient in teaching across various knowledge domains (e.g., biology and scientific modeling) (Sandoval, 2014). This means that teachers must be able to notice and assess their students' epistemic cognition to better understand how to support it; yet the development of such an awareness and assessment requires significant time (Fives et al., 2017).

Indeed, the best ways to support teachers in promoting a successful epistemic education have not yet been clearly defined (Muis et al., 2016). For example, more research examining the links between various aspects of teacher practice (e.g., specific instructional designs, pedagogy, student agency in the classroom) and how they can lead to successful epistemic performance when learning science is needed (Sandoval, 2014). As a start, science classrooms need to incorporate activities that allow students to engage in the real practices of scientists (Gorman & Gorman, 2021). In addition, teachers must also be able to identify and assess their students' knowledge about these scientific practices and then use this information to improve instruction (Fives et al., 2017). In the next section, we describe a pathway (situated within the context of scientific modeling in high school biology) that would allow teachers to begin investigating ways of noticing and assessing their students' epistemic cognition.

Epistemic performance within the domain of scientific modeling

To promote the goals of an epistemic education (Barzilai & Chinn, 2018) in high school science classrooms, we adopted the AIR model of epistemic cognition as a framework to evaluate learners' epistemic performance as they engaged in scientific modeling (Chinn et al., 2014). The AIR model establishes three main components of epistemic cognition as being: Aims, Ideals, and Reliable processes. Aims refer to the specific goal of inquiry, whereas Ideals are the standards or criteria that an individual uses to determine whether epistemic aims have been met. Reliable processes denote the strategies (individual or collective) that people use to successfully achieve their aims. Because this study focuses on participants evaluating how past students engaged in modeling during their science class, we emphasize identifying only the ideals and reliable processes related to this particular learning activity. Therefore, for the purposes of this study we analyze learners' *epistemic performance* in terms of the reliability of the epistemic processes used, and the appropriateness of the ideals applied, to the modeling task being evaluated. Indeed, previous research has shown that students need support in understanding both how to think like scientists and why scientific processes are reliable (Elby et al., 2016).

Table 1.
A Selection of Ideals and Reliable Processes to Promote Successful Epistemic Performance During Modeling

Epistemic Performance to Promote in the Complex Systems Modeling Curriculum	
Ideal 1 •Rigorous fit with evidence that is relevant, ample, systematic, and conclusive	
Reliable Processes (RPs)	• Multiple hypotheses. Consider multiple hypotheses (even if it is just a hypothesis and its negation). Make predictions based on these alternative hypotheses and test them together. • Multiple trials. Run multiple simulations to establish average phenomena under the same starting conditions. • Revise explanatory models when there are small or large discrepancies with evidence.
Ideal 2 • Has plausible, well-established underlying biological process (or mechanism)	
RPs	• Incorporate underlying biological processes into models to explain phenomena. • Examine interactions of elements in simulations carefully and systematically to grasp underlying processes.
Ideal 3 • Fit with prior (well-established) knowledge	
RPs	• Use previous science to evaluate and understand phenomena being modeled. • Evaluate whether ideas are consistent with well-established prior knowledge.

The AIR model can be used as a lens to examine the thinking strategies within a domain and to analyze various reasoning problems in the public sphere, such as those associated with confirmation biases (Chinn et al., 2014). As an example, biased epistemic performance could involve aiming to preserve one's prior beliefs. The biased ideals associated with this aim could include aligning beliefs with flawed or limited evidence. The biased processes associated with this ideal could then include cherry-picking data, dismissing contradictory evidence, or only seeking out supportive information. In contrast, unbiased epistemic ideals and processes could include aligning beliefs with evidence that is ample and conclusive and then using the reliable process of fairly weighing evidence on multiple sides of a question and developing arguments with thorough evidence-based reasons. This general example using the AIR model to understand how to mitigate against cognitive biases can be applied towards evaluating students' epistemic performance as it relates to the modeling curricula being studied here. Table 1 consists of a (non-exhaustive) list of ideals and reliable processes that can be applied while

engaging in scientific modeling that can lead to successful epistemic performance. This list emerged from two main sources: 1) a review of the literature on the epistemology of scientific modeling (e.g., Schwarz et al., 2009) and 2) a previously validated coding manual that emerged from the analysis of past student groups engaging in the modeling units. Next, we describe how Table 1 guided this analysis, as it includes strategies that can support an individual in learning to reason in rigorous, unbiased ways.

Methods

Context and participants

In this exploratory study we used previously collected video footage from students working with complex systems modeling curricula that combine experimentation with data analysis to generate discussion about epistemic performance with current students and their teachers. We asked students and teachers to evaluate a clip of a pair of students engaging in a modeling unit where they were investigating the effects of enzymes on the breakdown of starch to sugar (see Table 2).

Table 2

Transcript and the Research Team's Analysis of Video Clip Shown to Study Participants

Dialogue between Student A and B (regular font) with contextual descriptions of the scene (italics)	**Epistemic Processes Identified by the Research Team**
The clip begins with Student A reading the worksheet instructions aloud to partner, Student B. The students are trying to understand how varying the starting amount of substrate (starch) will affect the amount of product (sugar) produced in the absence of enzymes. **Student A:** Hypothesize: If you started with 60 starch molecules, how many sugar molecules would you expect to form? Use your graph to help make a prediction. Use the simulation to test your prediction...Group prediction I'm gonna say about like 50…50… **Student B:** 55? **Student A:** 55. Alright now we have to run it. Ready? Are you ready? *Student A then runs the simulation.* **Student B:** Why does is say hashtag? Oh wait, it says number of sugar molecules. **Student A:** *Laughing at her partner's comment. Once the simulation is finished running Student A points to the counter indicating the number of sugar molecules formed and says,* "It only produced 31!" **Student B:** That's fake. **Student A:** Can we do it again? **Student B:** Yeah. *They run the simulation a second time without speaking. The output after this run again reads 31.* **Student B:** That's so fake! **Student A:** *Laughing as speaks.* We said 55….We're doing it one more time. (*The student then runs the simulation a third time using the same starting conditions).* **Student B:** It was the same number every time, it's obviously going to be the same number. **Student A:** No, see (*pointing to the sugar output counter on the simulation)*, look, no. It's 49! This is cray. **Student B:** F-a-a-a-k-e. **Student A:** Can we do it again? **Student B:** No, just do 49. It's fine. *This student chooses to report the number that is closest to their initial prediction.* **Student A:** *Pointing to the sugar output counter in the simulation, student says,* **"**Hold on, I'm doing it one more time." *The simulation runs as in previous trials but the output from this run reads, "34".* **Student B**: The simulation result was 49! **Student A:** Relax, relax. I'm doing it one more. *And student runs the simulation with the same initial conditions for the 5th time. At the end of the run the sugar output counter reads, "43".* **Student A:** This is so inaccurate. **Student B:** It's called randomizer [sic].	• Did not appear to use prior knowledge (e.g., data from previous runs to justify their prediction) to better understand the experiment (less reliable) • Did not articulate multiple hypotheses, only considered one prediction (less reliable) • Believed contradictory evidence to be "fake" and "inaccurate"; could have been more open-minded (less reliable) • Ran multiple trials using the same starting condition (more reliable) • Could have looked to see what was going on in the simulation (e.g., did not observe how the molecules were moving and interacting during the runs) (less reliable) • Did not compute averages of data points collected, tried to cherry pick the result that matched their prediction most closely (less reliable) • Could have addressed whether their initial prediction, or overall understanding, was correct (i.e., did not try to understand why their results were different from prediction) (less reliable) • Student B eventually seemed to recognize that randomness/ stochasticity could be contributing to their results (more reliable)

While the clip in Table 2 was filmed in 2013, the unit used has remained largely unchanged since, and was therefore familiar to the participants. The clip was chosen because it demonstrated a clear case of confirmation bias. We employed a video-cued ethnographic method (Tobin, 2019) with the intention of eliciting participants' metacognition to gain contextualized insight into the learning practices they enact during modeling. This allowed us to measure aspects of their *metacognitive knowledge* (or the knowledge about how to perform an activity that will result in knowing) of the modeling task and the strategies used (Barzilai & Zohar, 2014). Table 2 also details our a priori analysis of the epistemic processes observed in the clip and whether we considered them less or more reliable. Our identification of these processes and assessment of their quality is directly aligned with the selected list of the more general ideals and reliable processes outlined in Table 1. Of the 8 processes identified, 6 were categorized as less reliable, while the remaining two were considered more reliable.

Table 3

Coding Examples Illustrating the Less and More Reliable Processes Noted in Student and Teacher Responses

RPs Observed in Clip	Coding Examples
Making Only One Prediction- Did not articulate multiple hypotheses, only made one prediction (less)	"Only one approach was considered." (Teacher Hanna, 4 Aug 2021) "Didn't consider another hypothesis." (Teacher Rachel, 4 Aug 2021)
Cherry Picking Data- Picking one specific result that matched their prediction most closely (less)	"If you're looking for a specific result, you can make the data match that. For example, as soon as they saw the result that there's 49, they went with that." (Focus Group with Cindy's students, 10 May 2021)
Dismissing Opposing Evidence- Believed contradictory evidence to be "fake" and "inaccurate"; could have been more open-minded (less)	"When they got answer that they thought didn't make sense, they freak out a little bit…not freak out, but they just kind of dismiss it in way." (Focus Group with Lindsay's students, 21 May 2021)
Not Reconsidering Mental Model- Could have addressed whether their prediction (or mental model) was correct; did not try to understand why the results were different (less)	"I think they should've thought about why they were getting 31 or whatever instead of the 55. Maybe put some thought into why it was incorrect." (Focus Group with Cindy's Students, 10 May 2021) "Students are unwilling to adjust their initial beliefs even when the same evidence arises multiple times." (Teacher, Cindy, 4 Aug 2021)
Not Observing the Interactions of Agents within the Model- Could have examined the model more closely; did not observe how the agents were interacting (less)	"I also think it would be important for them to possibly look at how the things are moving in there a little more too. Because I know sometimes in the ones we've done, we've had things disappear. We've had things bounce off and things and it might just be interesting to see if it does any of that in this." (Focus Group with Catherine's students, 13 May 2021)
Not Applying Prior Knowledge- Did not appear to use prior knowledge (e.g., data from previous runs to justify their prediction) to better understand the experiment (less)	"I don't know how they came up with the number 55 [as their prediction] at all, so I think they should've talked it over more, use more of the experiment's data." (Focus Group with Elizabeth's students, 11 May 2021) "Student makes argument that 55 starch molecules will occur, based on no evidence-based reasons (that they articulate)." (Teacher Catherine, 4 Aug 2021)
Running Multiple Trials- Ran multiple trials using the same starting conditions (more)	"I think their strategy was decent because they ran the simulation many times to see, does [sic] the numbers change." (Focus Group with Rachel's students, 15 Jun 2021)
Noting Randomness Occurs in Biological Systems- Student B eventually seemed to recognize that randomness/stochasticity could be contributing to their results (more)	"They attempt to explain the different numbers by hinting that there is a touch of randomness." (Teacher Elizabeth, 4 Aug 2021) "Well, I think they didn't understand that it was randomized at first. And then they found out that it was randomized and they were like, 'Oh, it's randomized, it's not fake.'" (Focus Group with Rachel's students, 15 Jun 2021)

In the 2020-2021 academic year, we interviewed 37 ninth grade biology students and eight of their teachers. Participation in student focus groups was voluntary, so only self-selecting students participated; however, teachers indicated that the participating students represented a broad range of students with respect to performance level. Half of the students interviewed attended private, college preparatory schools and the other half attended large suburban public schools in the north or southeastern U.S. The eight teachers were selected for this study as they represented teacher experts with respect to the modeling curricula being studied (i.e., they had implemented the curricula multiple times already and helped to facilitate other teachers' uptake of it). These teachers participated in a virtual professional development (PD) summer workshop with the larger goal of becoming design collaborators in modifying the existing curricula to better promote epistemic performance. The teachers, on average, had 10 years of teaching experience, with a range of 5–18 years at the time the workshop occurred.

Data sources and analysis

To address research question #1, students and teachers were prompted to examine and reflect on the epistemic performance demonstrated in the video clip. Student data was collected in end-of-school-year focus groups (April-July 2021). We conducted 11 semi-structured focus groups consisting of 2 to 4 students, each lasting approximately 60 minutes. As part of the interview, students were shown the video clip, asked to describe the strategies they observed the students in the clip enacting, and then asked to evaluate whether they thought these were good strategies in terms of better understanding the scientific phenomenon being modeled. Teacher data was collected as part of an activity in a summer PD workshop (August 2021). Evaluation of the video clip by teachers occurred once they had already been explicitly introduced to Ideal 1 (rigorous fit with evidence) and its associated processes (see Table 1) and were ready to begin exploring its applications in the modeling units (this occurred on Day 3 of the ten-day workshop). Once teachers viewed the clip, they responded to similar questions as the students; however, teachers first engaged in individual reflection and then participated in a large group discussion about their reflections. To address research question #2, teachers next listened to select audio clips of some of the students' responses to the clip. Teacher data regarding their responses on hearing their students' evaluations of the clip was collected via asynchronous group discussion posts on Canvas as part of the PD. In their posts, teachers were prompted to identify and react to the more—or less—reliable epistemic processes they heard their current students articulating in their evaluations.

To guide this analysis, we used the 8 epistemic process codes previously identified in relation to the video clip (see Table 3, column 1) and recorded them as being mentioned or not within any single focus group response of students or within any individual teacher response upon viewing the video clip. This list of epistemic processes related to this modeling curriculum were generated by a modified method of interaction analysis (IA) by all the authors (Jordan & Henderson, 1995). Author 1 then initially coded the student and teacher responses and then conducted interrater reliability analysis on 20% of the coded enactments with Authors 4 and 5; this returned a Cohen's kappa = 0.94. Regarding the analysis aimed at addressing research question 2, we identified and summarized the salient themes that emerged in the teachers' Canvas discussion posts as they reacted to hearing some of their own students evaluate the video clip. Here we used a constant comparative method of analysis, where the first author read the first discussion post and recorded overall emergent themes, and that information was then compared to and triangulated with each subsequent discussion post to validate that a particular response emerged from multiple teachers (Glaser, 2008).

Results

Below we first present the percent presence (scored as being noted in any of the 11 student focus groups or in any 8 teacher responses) of the focal reliable processes for students and teachers and elaborate on key ideas from their responses. Second, we include teachers' reflections upon hearing the audio clips of some of their own students responding to the video clip. In asking teachers to evaluate their current students' scientific epistemologies in this way, we gain insight into how teachers understand their level of epistemic performance.

Table 4

Presence of 8 Epistemic Processes in Student and Teacher Responses

Less and More Reliable Processes Coded As Present Within the Video Clip	Student % Presence	Teacher % Presence
Making Only One Prediction	0%	50%
Cherry Picking Data	91%	88%
Dismissing Opposing Evidence	82%	88%
Not Reconsidering Mental Model	82%	50%
Not Observing the Interaction of Agents within the Model	36%	0%
Not Applying Prior Knowledge	73%	63%
Running Multiple Trials	100%	100%
Noting Randomness Occurs in Biological Systems	27%	63%

Students' and teachers' evaluation of epistemic performance in the video clip

Table 4 shows that student groups at some point noted almost all (7 of 8) of the epistemic processes that had been used to code their responses. However, students more rarely identified several reliable processes, such as *Noting Randomness Occurs in Biological Systems* and *Making Only One Prediction.* In addition, the fact that students frequently identified the processes *Cherry Picking*, *Dismissing Opposing Evidence* and *Not Reconsidering Mental Model* demonstrates that many of them readily recognized some of the less reliable processes underlying the confirmation bias evident in the clip (although no one labeled it as such). For example, a student in Catherine's class noted that "one thing that…people do a lot is when they…want to be right and think that they're right, they

just disregard other things." Another student in Elizabeth's class pointed out that "after running it three times, they actually ran it more than three times. But instead of averaging their data, they cherry pick the one that was closest to their prediction, which is just not being a good scientist."

However, in one instance a student in Catherine's class seemed to articulate the value in the tendency to want to stick to one's original hypothesis, "I think that it shows the trust they have in their predictions and their hypothesis. It's kind of a good thing how much they trust it." To which a classmate responded, "I feel like they need to realize that…at a certain point, you have to realize that the simulation might be right, and your prediction might be wrong. And instead of…saying it's fake, or whatever, just say maybe our prediction's not quite accurate and…why is it not accurate." In this example with Catherine's students, one student indicated that trusting in your original hypothesis is a "good thing", whereas another cautioned that at some point it is important to consider that you could be wrong. In fact, most students regarded the students in the clip as displaying less reliable strategies in continuing to believe their prediction was correct despite mounting evidence.

Beyond recognizing the pitfalls of disregarding or cherry-picking data, some students pointed out that falsification of hypotheses happens often in science and is something you "shouldn't be upset about." One student in Elizabeth's class astutely noted that falsification should be discussed more explicitly in classrooms: "I think in general, more of what needs to be done in…science classrooms…is that it's fine for the data to negate your predictions. Because I think so often students are discouraged by data that disproves what they previously thought, but I think it should be more normalized." Therefore, this student not only evaluated the clip but further suggested an instructional strategy that could improve students' epistemic performance in science class. These findings show that student groups were able to articulate their metacognitive knowledge of working with the modeling units and demonstrated a solid understanding of some of the more reliable epistemic processes related to it.

Teachers' individual responses to the clip also aligned closely with the epistemic processes that the authors had previously identified (see Table 4). Teachers noted almost all the pre-identified epistemic processes (7 of 8) with high frequency (50% or greater), with the exception of *Not Observing the Interaction of Agents within the Model* (0% noted this). Also, the frequent mention of the processes *Dismissing Opposing Evidence* and *Not Reconsidering Mental Model* (88% or 7 of 8 teachers noted these) in their responses demonstrated that, like students, most teachers readily recognized the biased processes evident in the clip. Moreover, while *these* students overall demonstrated the metacognitive awareness of the need to correct for confirmation bias, many teachers (4 of 8) pointed out that while when implementing the modeling units in their classroom, they have also experienced similar situations to what they saw on the clip. For example, Linda recalled, "Doing this the first time with my students, this exact simulation, and I had a group of girls that were like in a panic, calling me over, 'it's broken, it's broken, it's not working.' And I said, 'What's broken?' They [said], 'we keep getting different numbers.' And they were so adamant it was broken, and since it was the very first time that I was doing it, it hadn't really occurred to me that they would have that immediate response." Hanna also mentioned that her students "struggled a lot with the idea of not getting the same results again and again." These responses show that current teachers are indeed noticing instances of confirmation bias during modeling. Many students seem to doubt the probabilistic nature of the simulation and whether it is "right" because they have yet to learn about the authenticity of such scientific processes firsthand. Therefore, these modeling curricula could be an important tool needed in science classrooms to redress the misconception that scientific knowledge is absolute.

Teachers' reflections on hearing students' evaluation of the video clip

After evaluating the clip, teachers then listened and reacted to some of their students' evaluation of the epistemic processes they had observed. Overall, teachers were surprised at how thoughtfully students commented on the reliability of the epistemic processes they noticed, and they noted some contextual variables (e.g., performance goals, societal pressures) that can influence students' epistemic performance. When teachers listened to a clip from Elizabeth's class, which included the observation a student made about "cherry picking" data and another that made a point about normalizing falsification in science class as described above, they mentioned being "really surprised," "astounded," and "completely blown away" at how "insightful" these students were in assessing epistemic performance. In fact, Elizabeth recognized her students' voices and described her amazement in hearing their evaluation of the clip: "One of the speakers who identified several apt practices completely threw me! She was struggling all year, was very quiet, and often seemed to lose focus. I found it very interesting that she was still able to glean some of these practices (I was pretty shocked)! This was very interesting for me to hear."

In addition to being surprised, teachers agreed that their students' insights were "extremely thoughtful" and that "encouraging acceptance of being wrong in your hypothesis was great!" Linda further elaborated that "it always interests me how [students] can have such great understanding of the right practices to use, but in the classroom, they often get focused on that 'task completion' and don't follow through!" This comment suggests that while this video-cued method might elicit some surprisingly insightful reflections, these may be more difficult

for students to enact during science class, when performance goals (e.g., task completion, or getting a good grade) may affect the processes students use. The second audio clip teachers listened to was from Catherine's class and included the observation a student made about how it is good to "trust in your prediction," as described above. Teachers identified this response as less reliable, and Julie even suggested it was "possibly a reflection of being a teenager in this country—it seems like there's a lot of messaging about being confident and trusting in yourself and your ideas. So, in a way [this student] seemed to reflect that cultural idea." Catherine agreed adding that "I think that it is likely that societal ideas about confidence and trusting yourself are seeping in."

Finally, after engaging in this activity, teachers were intrigued by what they heard and eager to hear more from their students regarding their focus group responses. Lindsay elaborated, "Listening to the student samples was insightful. As a teacher…we hear from the student groups we are working with at a particular moment, but often their dialogue is biased towards what they think we, the teacher, want to hear. It was nice to hear their candid conversations." Teachers also agreed that having *all* of their students evaluate the epistemic performance of other students working with the same models (as their focus group students did) as a classroom activity would be beneficial in promoting more reliable scientific modeling processes in the classroom. Lindsay added that this activity "would be a great way to spark the conversations about [more and less reliable processes] and how students can identify when they are putting less productive strategies in play and how to correct them." Taken together, these teacher reflections on some of their students' responses to the video clip demonstrated that they uncovered some very surprising and otherwise hidden aspects of epistemic performance that they were not seemingly unaware of prior to this activity. This revelation underscores the prevalence of a major barrier towards teachers' ability to promote the goals of an epistemic education in their practice: being positioned to notice and accurately assess their students' epistemic cognition.

Discussion

In this study, we used video-cued discussions with students and teachers to uncover their metacognitive knowledge regarding scientific modeling. All participants noticed and discussed at least some of the 8 previously identified epistemic processes at work in the video clip. Many of the biased processes observed in the clip included some hallmarks of confirmation bias (e.g., cherry-picking); thus, students and teachers were aware of confirmation bias and were able to accurately identify some aspects of it in practice. However, engaging students with effective curricular tools, such as the modeling curricula investigated here, is likely only one of many important factors leading to the development of more sophisticated epistemic cognition (Muis et al., 2016). While these modeling units probably contributed to the successful epistemic performance exhibited by students in focus groups, more explicit instruction regarding ideals and the justification of reliable scientific processes could also improve student outcomes, as teachers pointed out that they had seen these kinds of biased processes playing out in their classroom.

The second part of the study, when teachers listened to students identify the epistemic processes from the video clip, revealed that teachers were not necessarily attuned to their students' epistemic cognition. Teachers were "astounded" and "surprised" by the metacognitive knowledge their students articulated regarding modeling. This is problematic because perceiving this and then using it to inform future instruction is a critical aspect involved in promoting an epistemic education (Fives et al., 2017). Furthermore, teachers also accurately pointed out that students' epistemic cognition is shaped not only by cognitive biases, but also by factors such as social and cultural influences, performance goals, and attitude towards learning (Elby et al., 2016); therefore, the video-cued method used to invoke metacognition around a familiar activity was powerful in revealing this kind of thinking. In fact, multiple teachers agreed that showing their students a clip such as this would be a fruitful classroom activity. Because we know teachers need better supports for incorporating epistemic educational goals in instruction (Muis et al., 2016) and more activities that elicit metacognitive thinking are needed to address this (e.g., Chinn et al., 2020), we suggest using this type of method directly in the classroom. Our findings here indicate making this kind of metacognitive knowledge explicit in science class could contribute positively to the epistemic climate of the classroom (Muis et al., 2016). Future studies might then address how an intervention like this might affect epistemic performance across knowledge domains and/or compared to other better-known interventions, such as those that involve reading and responding to persuasive texts (e.g., Porsch & Bromme, 2011).

In conclusion, even though it is well established that teachers need to notice their students' epistemic performance, this is difficult to achieve, and it is likely there are biased processes going unnoticed and perhaps inadvertently being reinforced in science classrooms. Incorporating more metacognitive thinking into science classrooms to redress this is not a new suggestion (e.g., Barzilai & Chinn, 2018; Hofer, 2004) but this study provides support for the value of using a video-cued evaluation of familiar classroom practices as a method to help elevate learners' thinking into the metacognitive realm. Additionally, it seems necessary to make these types of ideals and reliable processes more explicit to students, as this could provide a mechanism for transfer of the

more domain-general aspects of successful epistemic performance towards everyday decision-making regarding current socioscientific issues.

An Assessment Framework for Complex Systems Understanding

Hala Khodr, Aditi Kothiyal, Barbara Bruno, Pierre Dillenbourg

Abstract: Complex systems understanding is crucial for understanding the sciences of the twenty-first century. Helping students with the principles of complex systems is thus both a challenge and an opportunity. In order to investigate the effectiveness of complex systems learning activities, we would like to have an assessment instrument which we can ultimately use as pre and post-test to assess the learning gain. In this paper, we developed an assessment instrument as a questionnaire containing five scenarios related to key concepts of complex systems understanding. After validating the understandability of the questions, we collected answers from 37 participants including experts as well as non-experts. We finally propose a scoring scheme based on fuzzy logic. This approach results in a general procedure which is compact, automatic and human legible to quantify expertise in complex systems concepts.

Introduction

Order, regularities, and patterns are ubiquitous around us. A flock of birds winging in the sky, the self-organization of social insects, or the synchronized blinking of fireflies are examples of natural complex systems where "macro" patterns arise from the interaction of "micro" agents. Complex systems can be defined as "an interdisciplinary field of research that seeks to explain how large numbers of relatively simple entities organize themselves, without the benefit of any central controller, into a collective whole that creates patterns, uses information, and, in some cases, evolves and learns" (Mitchell, 2009, p. 4).

Not only is this an important domain to learn about on its own, but it actually consists of a "powerful idea" (Papert, 1980) that cuts across disciplines and can lead to the understanding of a large class of physical and social phenomena taught as conceptually different subjects. Researchers argue that different complex systems in nature, such as insect colonies, brain activity, immune systems, economies, the atmosphere, and human social interactions, have much in common. In fact, understanding complex systems is fundamental to understanding science, and it is becoming one of the essential cognitive skills needed for the twenty-first century (Reed, 2020). It is therefore not surprising that the Nobel Prize in physics in 2021 was awarded for groundbreaking contributions to our understanding of complex physical systems.

An active research area within the teaching and learning of complex systems is that of developing computational tools and resources for facilitating the learning of complex systems concepts. These are mostly based on agent-based modeling environments such as StartLogo or NetLogo that help students construct a connection between the interactions of micro-level particles/agents and the emergent complex macro behaviors. These learning environments are based on the assumption that whenever students have the opportunity to take the point of view of an atom, an electron, a sheep, a fish, an ant, or a trader, they are more ready to conceive complex systems (Wilensky & Rand, 2015). Repenning et al. (2010) developed "Collective Simulations" that help students to learn about the intricacies of interdependent complex systems by engaging them through social learning techniques in the classroom along with networked computers. Similarly, participatory simulations, such as Hubnet (Wilensky et al., 2006), were developed as a type of role-playing activity used in classrooms to explore how complex dynamic systems evolve over time through individual elements acting. In order to evaluate the effectiveness of these resources, it is necessary to assess the learners' complex systems knowledge, which is challenging given its cross-disciplinary nature and vastness of its underlying concepts. Therefore, an important area of research consists of developing instruments to assess complex systems understanding.

In this paper, we focus on this second research goal. We develop a general assessment instrument, freely publicly available, assessing the five essential complex systems ontological concepts, discuss its validation and provide an automatic, human legible general scheme to classify expertise in complex systems concepts.

Theoretical Background

Complex systems are present everywhere in nature, and many are commonly observed or experienced by all of us during our daily life. However, experts and novices think and build their knowledge about complexity in significantly different ways. Hmelo-Silver (2007) found that novices focus on the visible and static structures of the subsystems involved while experts incorporate structures, causal behaviors, and functions. Similarly, Jacobson (2001) documented that the differences between experts and novices lie in the cognitive and ontological ways of

 © ISLS

thinking. Novices were committed to believe that systems work in a centralized, predictable and reductive ways, while experts tend more to describe systems as decentralized, nonlinear, and nonreductive.

Learning about complex systems is challenging (Hmelo-Silver, 2006), and many studies investigate the difficulty that humans have in understanding and grasping complex systems, alongside common misconceptions about them. Resnick (1994) discusses students' bias to generally assume that the behavior of a system is controlled by lead - a leader orchestrating the system's patterns, or by seed - a single pre-existing entity in the environment, rather than resulting from decentralized interactions. This inclination toward centralization is referred to as Deterministic-Centralized Mindset. Moreover, probabilistic non-deterministic behavior in systems is also found to be a challenging concept to comprehend (Wilkerson-Jerde, 2015). Similarly, people tend to assume immediate effects instead of indirect cascading effects (Grotzer et al., 2015). Chi et al. (2005) have also shown that a process is generally thought of as a direct static phenomenon rather than emergent. An assessment instrument for complex systems understanding should therefore be designed to detect the presence of these misconceptions.

Yoon et al. conducted a study where they analyzed students' responses to one open-ended question in an ecology context concerning the effects of the arrival of geese on a park ecosystem. Results showed that the most difficult ideas to grasp are those related to the decentralized organization of the system and the unpredictable or non-deterministic nature of effects. They then proposed a learning progression to systematize the pathways students undertake to enhance their conceptual competence in complex systems. In another context, Wilensky and Abrahamson (2006) studied the student learning of the spread of diseases in a participatory simulation activity. Their findings identified several reasons for students' incorrect interpretation when explaining the agent-to-aggregate (i.e. micro to macro) relationship. These include proportional and linear reasoning, randomness-determinism confusions, disregarding feedback loop effects, and anticipating emergence from agents' rule-based interactions. Their assessment was composed of questionnaires and interviews where the situations, modeling, and representation tools relate thematically to the disease spread context. The students were provided with a modeling kit (stationery, Lego, strings, etc.) and data-charting tools to give them a choice between either modeling the process itself with concluding their response based on this, or directly charting quantitative data without thinking through the process. The key items in the questions were the spread of a mold on a moldy piece of bread, the scattering of people in a gym class, the spread of a rumor in a class, and the disease spread.

Hmelo-Silver et al. (2007) suggested a framework based on structure-behavior-function theory to represent how people think about complex systems, in particular, in a biological context. Structures refer to the elements, functions to the role of an element, behaviors to mechanisms of how the structures achieve their function. The case study included two biological complex systems: the human respiratory system and an aquarium ecosystem. To assess complex systems understanding, interviews were conducted, including drawing and open-ended questions. These were then coded by the presence and absence of the target concepts (structures, behaviors, functions). Jacobson (2001) developed another framework depicting multiple categories of complex systems concepts based on ontological and epistemological "component beliefs". Multiple studies then followed and adapted this framework (Jacobson et al., 2011; Yoon, 2011, 2019). Jacobson et al. (2011) refined this framework to focus on five main concepts that we also rely on in this work (more details later). They developed a hypermedia learning environment consisting of five NetLogo agent-based models: foraging of ants, traffic jams, self-organization of slime molds, social segregation, and wolf-sheep predation. Interactive scaffolding was introduced related to declarative knowledge of the complex ontologies as well as problem-solving exercises to compare and contrast the different aspects. Ontological shifts were observed, which further confirms and validates earlier results concerning the main concepts comprising complex systems.

In the literature discussed above, many studies explored the importance of as well as the difficulties encountered when learning about complex systems, and defined and validated its main concepts. However, there is no instrument available to objectively score a learner's understanding across different concepts of complex systems, in addition to different contexts. The contribution of our paper is motivated by this limitation. Based on and inspired by the findings above, in this paper, we compose a general assessment instrument that can be used to assess expertise within complex systems. The instrument requires participants to answer questions related to five different scenarios which are then scored to extract their competence in five ontological concepts required for complex systems understanding. More specifically, our research question is: can we quantify the expertise in complex systems based on answering questions targeting related ontological concepts?

Method

Materials

The instrument is designed as a questionnaire consisting of five scenarios related to key concepts of complex systems understanding. These concepts, identified as core complex systems characteristics, used and validated in

prior research (Jacobson, 2001, Jacobson et al. 2011, Yoon et al, 2019) are the five ontological categories of complex systems understanding — Order (Centralized, Decentralized), Causes (Single, Multiple), Actions effect (Linear, Nonlinear), Agents effect (Predictable, Random), and Processes (Static, Emergent). The scenarios draw inspiration from literature and are: Traffic Jam (Resnick, 1994), Scattering (Wilensky and Abrahamson, 2006), Flock of Birds (Jacobson, 2001), Butterfly Effect (Jacobson, 2001), and Robots and Gold (Resnick, 1994). For each scenario, the questions were formulated with a mix of Multiple Choice Questions (MCQs) and open-ended questions. They were written in an appropriate way to be answered by both experts and novices alike. No formal declarative concepts were used. The detailed questions can be found here. Whereas the last two scenarios (butterfly effect and robots and gold) are thought experiments, the first three scenarios include familiar (scattering, traffic jam) or naturally observed behaviors (flocks of birds). Moreover, we distinguish two types of questions: whether it involves explaining the behavior of a system (e.g. *How is it that the birds fly in a flock?* in the third scenario) or defining rules to enact it (e.g. *How should the robots move in order to find the gold?* in the last scenario). Finally, the questions, even in the same scenario, can tackle different perspectives: local (agent perspective, e.g. *What does each person need to do in order to scatter?* in the second scenario) and global (external observers, e.g. *If you were up really high, and could watch your class scatter, what would you see from above when they're scattering?* in the second scenario).

Procedure

An iterative approach was followed to refine the questions and validate the instrument. A first version of the questionnaire was sent out to 11 participants of varying ages and educational backgrounds. The goal of this first validation was to evaluate the understandability of the scenarios and questions and to obtain a range of the possible answers from our target population in order to develop a coding scheme. Based on this first feedback, the questions were refined, and confusing statements were clarified. The first draft of the coding scheme was also developed. Our goal in the second iteration was to validate that the chosen questions assessed the set of complex systems concepts, further validate the understandability of the questions and refine the coding scheme. The second validation phase included two steps. First, we discussed and validated the questions and coding scheme with an expert in complex systems education to ensure that the five scenarios and accompanying questions were representative of all the complex systems concepts. Second, we followed a verbal cognitive methodology in which three novices (undergraduate students) and three experts (graduates/post graduates in swarm robotics) were asked to read the questions and describe verbally what they understood from the question and how they would answer the questions. Then they wrote the answers in the questionnaire. Based on this second validation, final refinements were done to the questions and coding scheme.

Subjects

The final version of the questionnaire was administered to two groups of participants:

- An ***expert*** group including eight subjects who responded to a personal request for participation sent by email. They were purposively sampled to include PhD students or holders in a related domain (mainly in swarm robotics, physics, and computer science). They self-rated their expertise in complex systems with an average of 5/7 and confidence in answers with an average of 5.625/7. The mean age of the group was 33.88 years (SD = 3.59), with six males and two females. Classified by ISCED Majors, 3 are in Engineering and 5 are in Science.
- A ***non-expert*** group including 29 subjects. They were recruited from requests diffused online and among students in university and high school. The mean age of the group was 24.21 years old (SD = 6.31) with 16 females (55%) and 13 males (45%). These included five students from high school, 25 in Bachelor, 7 in Masters, and 2 PhD students. Classified by ISCED Majors, 15 are in Science, 3 in Health, 4 in Engineering, 1 in Education, 2 in Social Science, and 4 in General Knowledge (high school students).

Scoring and Coding Scheme

The responses were scored based on the five key concepts mentioned previously. We consider 3 levels of understanding: a clockwork (corresponding to a centralized mindset) mental model, a complex systems mental model, and an intermediate or in-between level. Table 1 provides the concepts, focus, and the difference between

clockwork and complex responses (Jacobson et al. 2011, Yoon et al, 2019). Based on these concepts a detailed coding manual was developed for each of the questions (can be found here).

Table 1

General coding scheme: concepts, focus, and the difference between clockwork and complex responses.

Concept	Focus	Clockwork Mental Model	Complex Systems Mental Model
Control	The control is centralized or decentralized	Response indicates that the system is controlled by a leader (order is top-down)	Response indicates that the system is decentralized (order is bottom-up)
Causes	The number of causes that contribute to the outcome	Response attributes the outcome to one primary cause/factor	Response attributes the outcome to multiple causes/factors
Action Effect	Interaction between agents are linear/proportional or not	Small action→ small effect Large action→ large effect	Small action →large effects Effects of actions may not be repeatable
Agents Effect	Predictability of actions of agents	Actions of agents may be predictable	Actions are not predictable, random
Process	How the system works	System is an event defined by its global behavior	System is a dynamic process, self-organizes through agent interactions

The inter-rater reliability of the coding scheme was assessed with three raters coding 25% of the responses. The interrater agreement was measured using Cohen's Kappa and was found to be 0.66 which denotes a substantial agreement. The discrepancies were discussed and related details were added to the coding scheme to make it clearer. The remainder of the responses were subsequently split among the three raters to code.

Below we describe the traffic jam scenario and its coding scheme as an example. The instruction is:

On the road, each car followed only three rules: 1) If there is a car close ahead of you, slow down
2) If there aren't any cars close ahead of you, speed up (unless you are already moving at the speed limit)
3) Comply with driving regulations concerning all other elements on the road, such as: slow down if you detect a radar trap, traffic lights, accidents, entry ramps… (we attach a gif)
Question 1: What is causing this traffic jam? Select all applicable choices (radar trap, broken bridge, entry ramp with merging traffic, accident, nothing, other)
Question 2: Explain in your own words how your choice(s) is (are) causing the traffic jam.
Question 3: The radar trap is removed, and there are no accidents on the road, no broken bridge, no entry ramp or any other external events. Can a traffic jam still form? (Yes, No)
Question 4: If yes, why do you think a traffic jam can still form? If No, explain in your own words, how the cars will behave on the road.

We target three main complexity concepts with this scenario: causes, control, and action effects. Examples of responses and scores are given in Table 2.

Table 2

Scores of 3 participants for the first scenario: Traffic Jam

ID	Q.1	Q.2	Q.3	Q.4	Scores
P1	Radar trap, Broken Bridge, Entry Ramp with merging traffic, Accident, Nothing	Slow down compounds resulting in a complete halt. Netlogo has this model and explains it well too.	Yes	As one car's behavior is dependent on others, the speeds and behaviors become nondeterministic. Even a slight slowdown to avoid bumping into the car in front can compound as the reaction time may have a slight delay as well.	Control (1) Causes (1) Action (1)
P2	Radar trap	Cars are driving slower after they stopped suddenly	No	They will behave freely with no stops or jams	Control (0) Causes (0) Action (0)

 © ISLS

P3	Broken Bridge, Accident	They basically cause a blockage to traffic, so that vehicles 'pile up'	Yes	It also depends on the amount of cars on the street	Control (1) Causes (0.5) Action (0)

Results

For each participant, we summed up all the scores per concept, as well as per scenario. Each raw score was divided by the total possible score, to have standardized scores for the different concepts and scenarios. The total score was calculated as the average over all the concepts. A significant difference was found between the scores of experts and the non-expert over all concepts, except the concept "Causes" where the non-expert also scored high (see Figure 1). Considering scenarios, significant differences were found between the experts and non-expert participants in all scenarios except in the second (scatter) scenario (see Figure 2). In the robots and gold scenario, the difference was larger with a huge effect size (Cohen's d = 2.2).

Figure 1

*Comparison of experts and non-experts over the concepts. * (**) indicates a significant difference with p-value<0.05 (<0.005) with a Mann-Whitney Test.*

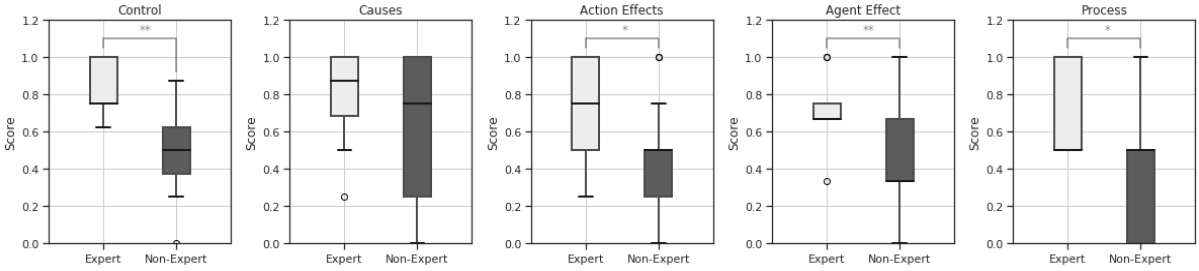

Figure 2

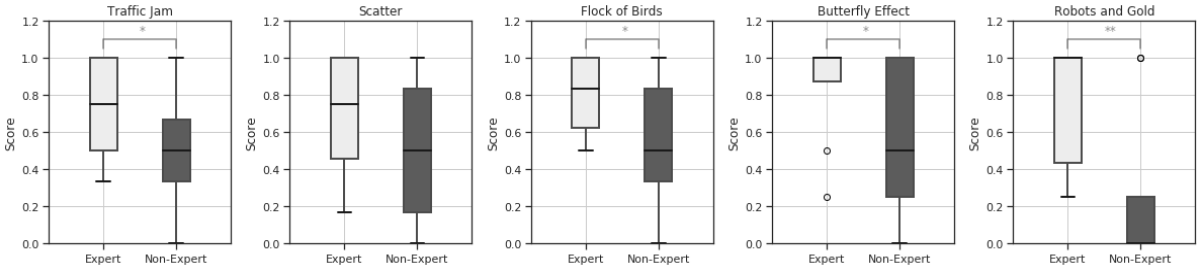
Differences per scenario among the experts versus the non-experts.

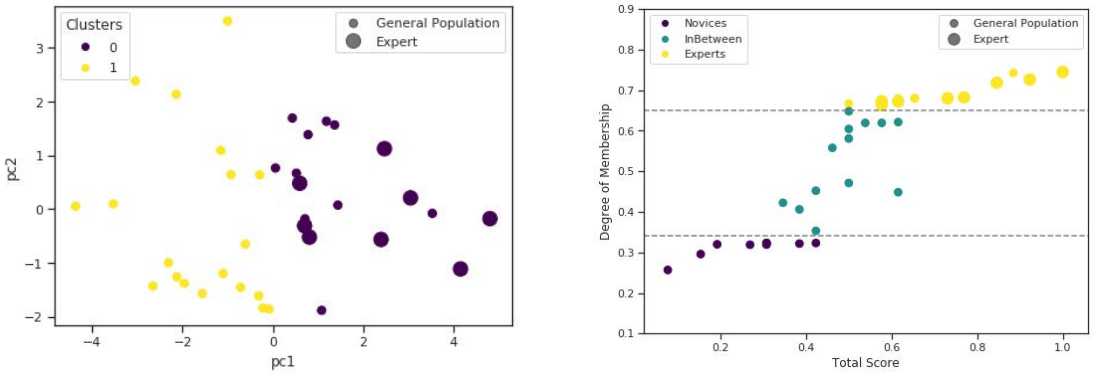


To verify that our mapping of concepts to questions was complete, we investigate the correlation between concepts. A strong significant correlation exists between total score and each of the respective concepts (spearman correlation with control = 0.75, action effects = 0.72, agent effects = 0.68, process = 0.66) and a moderate correlation with the causes concept (0.46). A moderate significant correlation also exists between the control concept and each of action effects (0.44) and agent effects (0.62) concepts and between action effects and process (0.48) concepts. A weak significant correlation (0.34) also exists between the concept action effects and agent effects. Furthermore, we investigate the correlation between scenarios. We only found weak significant correlation between scenarios 1 and 3 (0.35), as well as scenarios 2 and 4 (0.37).

While experts are expected to be knowledgeable on the concepts (and this assumption is supported by their high scores), participants belonging to the non-expert group can have varying degrees of understanding of complex systems, lying at different points on the continuum from novices to experts. Therefore, to verify whether the population can be divided into two groups, namely the novices and the experts, we conduct a clustering on the whole dataset involving the 37 participants on the basis of 10 features taken into account: the scores of each concept, as well as the scores of each scenario. A principal component analysis (PCA) is conducted to extract the 6 most significant principal components, explaining 95% of the variance. The purpose is to make groups which are hardly separable in the space by the original features, but better separable in the new space spanned by the Principal Components (PCs). To verify the separability of our population, we perform a C-means clustering for the association of each participant to a cluster. The number of clusters is fixed to 2 to verify whether the expert participants indeed cluster together when all features are considered together. The results, shown in Figure 3a, revealed that all the experts belong to the same cluster, as well as some of the participants from the non-experts. An extended discussion of this finding is reported in the Discussion section.

Figure 3

(a) Clustering results (b) fuzzy system output vs total score and division into 3 classes



(a) (b)

Figure 4

Differences per concept among the three groups.

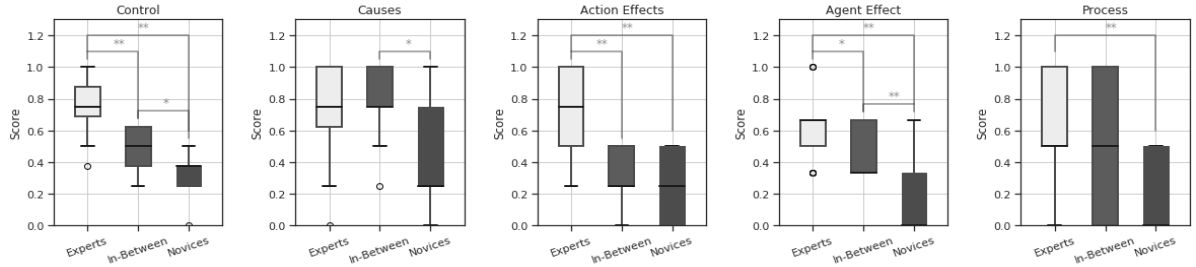


Figure 5

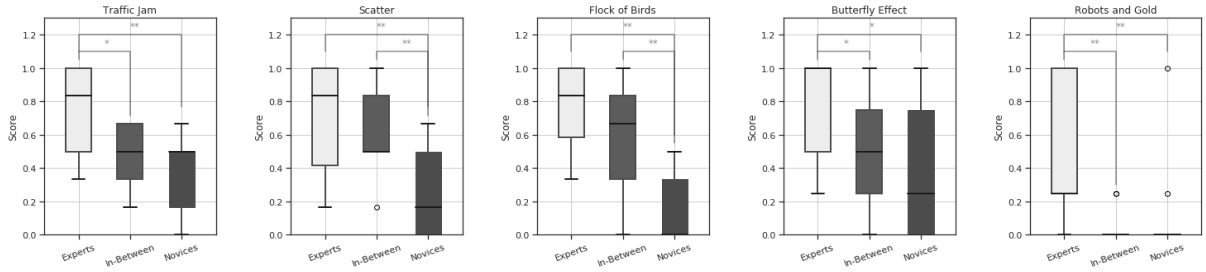
Differences per scenario among the three groups.



So far, we have analyzed our participants' responses either over single concepts/scenarios, or over the dimensions returned by PCA, which are a combination of these scores. What would be interesting is to have a global complex systems expertise score, which makes it immediate to evaluate a person's complex systems understanding. More concretely, our goal is to define a mapping between the concepts/scenarios and a global score of expertise. One approach is to sum and average over all the concepts; however, with this method, the distribution over all concepts is blended. We address the above challenges by using techniques from fuzzy logic systems. Fuzzy logic allows us to encode qualitative relations among multiple variables (fuzzy rules) in a unifying formalism (Driankov, 2001). In our case, the relation to describe is the one between a given vector of values for the complex systems' scores (concepts and scenarios), and the corresponding global level of expertise. The fuzzy rules are encoded as if-then rules underlying the qualitative fact that an expert level should have a high level in all the input variables; conversely, a novice level should have a low level in all the input variables. Each input membership function is modeled as a logistic sigmoidal function. The parameters of a sigmoid are fitted after applying a 1D clustering on each of the dimensions. The output membership function is modeled as a trapezoidal function with cut-off limits set between 0.35 and 0.65. Figure 3.b shows the relation between the total score and the output fuzzy logic score. We notice that the relation is sigmoidal rather than linear. Again, we verify that the group that we already know are experts actually score high on the degree of membership of the expert level. We also can identify a separation of three classes: experts scoring higher than 0.65, novices scoring lower than 0.35 and an average in-between group. We recomputed the differences per concepts and scenarios between the populations of three identified classes. Results are shown in Figures 4 and 5.

Discussions and Implications

In this paper, we propose a tool that can be used to assess a person's expertise in complex systems which requires solving five different scenarios and relies on a coding scheme to extract their competence in five ontological concepts required for complex systems understanding. A study with 37 participants including experts and non-experts was conducted to validate our instrument. Significant differences were found in the scores of the two groups. Finally, an automatic approach based on fuzzy logic for getting a general score is proposed and analyzed.

In our first analysis, we found a significant difference between the scores of experts and the non-experts over different concepts and scenarios, which is in line with previous literature (Jacobson, 2001). One exception is the concept of "Causes" where the non-experts scored high too (see Figure 1). While it may be possible that this concept is easier to grasp than others, an alternative explanation is that in our instrument the questions measuring causes were mainly MCQs, which possibly led respondents to select more than one option. Conversely, in the last scenario (robots and gold), the difference in scores was much larger: a possible explanation is that in this scenario, participants were asked to enact/design rules in a novel scenario, rather than explaining an observed phenomenon. Given the ubiquitousness of centrally controlled systems in the world around us and novices' inclination towards the centralized mindset (Resnick, 1994), it is likely that novices believe in the superiority of centralized over decentralized systems and so chose to enact centralized rules.

Subsequently, we designed a Fuzzy System to compute a global score of expertise in complex systems understanding. The score computed by the Fuzzy Inference System (FIS) is not always equal to the average score, since the FIS takes into account the combination of scoring high on the different features, rather than having more skewed scores by one high value. For example, a participant with very high scores on the *causes* concept and scenario 4 (both 1) but very low scores on the *control* concept, and scenario 5 (0.25, and 0 respectively), had the final score pushed down with comparison to the average score (0.44 instead of 0.61). Similarly, a participant with very low scores on the *causes* concepts, and scenario 2 (0.25 and 0.33) but high scores on the *control* concept, and scenario 5 (0.75, and 1 respectively), had the final score pushed up with comparison to the average score (0.67 instead of 0.58). Moreover, in our total score analysis, the results indicate a separation between 3 groups of expertise. The subjects already known to be experts all belong to the expert cluster. Few participants from the non-experts also belonged to the same expert group. By looking at their major, they were a group of students doing their masters in biology, so they perhaps have a background knowledge in biological complex systems, which could explain their performance. The other two groups had populations of mixed educational backgrounds. Although not significant, looking at the mean age of the clusters, the novice group had the lowest mean (22.0), then the in-between group (26.5), then the experts group had the highest (28.7).

To better understand the differences between the three groups, we look again at the difference between the concepts. Significant differences were found for the concepts: control, causes, and agent effects between the novices and in-between groups; and for the concepts: control, action effects and agent effects between the expert and in-between groups. For the scenarios, it was scatter and flock of birds between the novices and the in-between groups, and traffic jam, butterfly effect and robots and gold between the expert and the in-between groups. Looking back to the theoretical background, we observe similar trends to link difficulties related complex ideas. Yoon et al (2019), reported that order and deterministic effects (which link to control and agent and action effects in our definitions) constitute the hardest concept to grasp. Similarly, Resnick (1994) suggested that the commitment to centralized mindset constitutes a strong misconception for learners. Lastly, Grotzer et al. (2015) focused on the difficulty of understanding non-linear effects in a system.

Finally, although through our questionnaire we only target the implicit knowledge of complex systems, the use of declarative knowledge (emphasis in italics) was observed in the experts' responses (Jacobson et al., 2011). An example is the explanation of the butterfly effect given by an expert:

> In a system with *nonlinear dynamics* such as with *positive feedback* loops, small changes in certain periods or locations can have large effects. Collective decision-making for a new nest in ant groups is one example, where the number of insects recruited to go to a specific new nest depends on how many are recruiting […]

On the other hand, an answer to the same question, given by a participant from the non-experts and which also display implicit but lacks declarative knowledge is:

> I think those effects are the norm rather than an exception. For example, teachers influence the future life of students in small ways every day, and therefore also influence the lives of those they interact with.

In conclusion, the assessment, coding scheme and scoring approach proposed in this paper advance our understanding of people's understanding of complex systems. Moreover, our instrument contributes to the design of learning activities to engage students about complex systems and helps investigate the effectiveness of such activities. The differences per concepts and scenarios between three different groups observed in our study suggest to follow a learning progression moving from less to more advanced concepts, as well as following a learning process based on the conceptual change approach to trap existing conceptions from a clockwork mental model to a complex systems mental model, which will be part of our future work (Khodr, et al, 2022).

Investigating experts' and middle school learners' uncertainty management during collaborative engineering design tasks

Navneet Kaur, Indian Institute of Technology Bombay, navneetkaur@iitb.ac.in
Chandan Dasgupta, Indian Institute of Technology Bombay, cdasgupta@iitb.ac.in

Abstract: Young learners are increasingly engaging in engineering design activities in their classrooms. However, limited research exists regarding uncertainty management practices in engineering design, what experts do, and how to scaffold the process for novice learners. To address this gap, we investigated uncertainty management practices in engineering design of experts and beginner designers at the middle school level. We interviewed five design experts and identified six prominent uncertainty management practices in engineering design. We also analyzed data from five groups of middle school learners working on ill-structured design problems to understand their uncertainty management processes and identified learner difficulties in productively engaging in uncertainty management practices.

Introduction and Background

Managing uncertainties is an integral part of solving engineering design problems. While there has been a growing emphasis on teaching young students about design thinking and productively engaging them in engineering design practices (Crismond & Adams, 2012), the focus lacks on how to help them tackle the inherent uncertainty. Engineering design problems require learners to tackle uncertainties at every stage of the design process, choose from multiple alternatives, and deal with incomplete information and unclear objectives while collaborating with multiple team members (Dym, Little, Orwin, & Spjut, 2009; Ullman, 2001). Prior research acknowledges that learning how to deal with uncertainties productively is crucial and young learners can and should engage in the process at the school level itself to further develop their reasoning and sense-making (Dasgupta, 2019; Dym et al., 2009; M. E. Jordan & McDaniel, 2014). However, prior work sheds limited light on how learners' subjective experiences of uncertainty affect their actions and design approach, how it is different or similar to expert designers, and how we can help learners manage uncertainties productively.

Amongst the limited literature available on this topic, seminal contributions by Jordan et al. (2014) highlight the important role of peer responses for collaboratively tackling uncertainty faced by middle school learners during a robotics engineering activity. The authors concluded that learners respond to uncertainties in both supportive and unsupportive ways, shaping the trajectory of their uncertainty management processes. Other researchers focusing on K-12 learners have highlighted how uncertainty affects learners' engagement in science practices (e.g., Metz, 2016; Radinsky, 2008), scientific argumentation (e.g., Chen, 2020), and how can we engage learners in "productive uncertainty" (Manz, 2018) in the context of science learning. We take these relevant and valuable research into consideration as we investigate the following research questions: (a) What are uncertainty management practices in the context of engineering design as defined and practiced by experts? (b) What challenges do middle school learners encounter while productively engaging in engineering design practices?

Cognitive and learning scientists have favored contrasting expert and novice processes for understanding disciplinary practices in a domain and identifying scaffolds required for supporting novices' processes (e.g., Crismond & Adams, 2012). We interviewed five design experts to identify and describe uncertainty management practices in engineering design. The experts in our study have eight to twelve years of experience in solving engineering design problems in different capacities like - participant in large projects, mentor, and project manager. These experts are at the "Informed Designer" level (Crismond & Adams, 2012). Expertise at this level maps well to "a generic model of design expertise that corresponds to ways of perceiving, interpreting, structuring, and solving complex problems" and is considered appropriate for contrasting and interpreting learners' behaviors at the "beginner designer" level (Crismond & Adams, 2012). We also referred to literature on design expertise to inform and validate our findings. Then, we analyzed middle school learners' behaviors and interactions during their attempts to resolve uncertainties to help us unpack learner processes and problem areas that hinder their productive engagement in uncertainty management practices.

Method

Participants and Setting

We interviewed five professionals (four males and one female) specializing in the fields of engineering, architecture and design to answer our first research question i.e. what are uncertainty management practices in the

context of solving engineering design problems? All the professionals have experience of eight to twelve years working on various engineering design projects. The projects range from devising solutions for bio-medical problems to developing tools for assessing environment friendly and sustainable designs. Two of the male experts (Expert ND and Expert KG) are currently working as design entrepreneur. Expert SA (female) is an assistant professor at a technical institute in India. Expert AK (male) is a Senior Project Manager at a Medical Device Development Unit at a technical institute in India and Expert AR (male) is a Senior Interaction Designer and Design Expert at a multinational company.

The interviews were semi-structured in nature and conducted by the first author of the paper, in online mode using the Google Meet platform. Each interview lasted for sixty to ninety minutes and the medium of communication was English. The experts were informed about the broad goals of the research and provided with the sample questions that would guide the interview. The questions probed them to talk about different situations and scenarios where they experienced uncertainty, reflect on how they dealt with them, the role of team members in the uncertainty management process, and how different uncertainty situations and management strategies relate to the engineering design process. All the experts also have teaching and mentoring experience, therefore we also asked them about their views on teaching and learning of uncertainty management and kind of support that learners might need in this regard.

To identify what difficulties and challenges learners face in productively engaging in uncertainty management, we analyzed data of five groups of sixth and seventh grade learners. Data came from two studies that were conducted with the broader aim of understanding middle school learners' uncertainty management processes in collaborative settings. The first study was a four-hour study conducted in a one-day workshop mode with five seventh grade learners from multiple schools in an Indian metropolitan city. Learners had to design a cleaning robot using the LEGO Mindstorms™ kit that could accomplish certain tasks efficiently while optimizing the design cost (Kaur & Dasgupta, 2019; Kaur, Patel, & Dasgupta, 2019). We grouped learners into two teams randomly for working on the design problem. First team (Group A) consisted of two students (one boy and one girl) and the other team (Group B) consisted of three students (two girls and one boy).

The second study was a four-day study (approximately one hour each day) conducted in a middle school classroom setting in a large public school in an Indian metropolitan city. A total of 44 students participated who were randomly divided into 12 teams (groups of 3 or 4) by the researchers. We analyzed data from three teams who were the most vocal (hence had clear audio). Group A consisted of four participants (three males and one female), Group B also consisted of four participants (two males and two females), and Group C consisted of three participants (two females and one male). We gave students a design task of building a balloon powered toy by maximizing the distance traveled in a straight line (Kaur & Dasgupta, 2021). We collected both audio and video recordings of the teams for the entire course of the activity in both the studies. The authors of the paper were present in the class as observers. Teaching assistants (T.A.s) from the same department (two T.A.'s for first study and three T.A.'s for the second study) were also present. They handled the audio and video data collection and also mentored groups from time to time.

Data analysis

We analyzed interview data from the five experts using thematic analysis (Braun & Clarke, 2012) to identify themes related to uncertainty management practices of experts. We also reviewed literature on design expertise to support this analysis process. Thematic analysis is an appropriate method for our goal since we wanted to explore the range of ways experts experience and deal with uncertainties. Following the methods of inductive thematic analysis, we first familiarized ourselves with the data by listening to the audio recordings of interviews and transcribing them. Then we generated initial codes from three interviews from our data set. Refer to Table 1 for an example of how initial codes emerged from transcript. The next step was to review the literature on design expertise to find if more codes emerge related to experts' uncertainty management. Then we collated the related codes into categories and themes (See Table 2 for an example), which was followed by reviewing the themes against the remaining two interviews to ensure consistency. Finally, we refined our themes by repeated discussions where we examined their descriptions.

Table 1

Initial codes emerging from the transcript of expert interviews during thematic analysis

Transcript	Initial Coding
[00:16:45.26] Interviewer: Can you tell me about the uncertainties that you experienced with respect to these projects (Projects mentioned by expert earlier to this question)?	

[00:17:10.15] *Expert ND:* Yeah, so uncertainties are part and parcel of this whole process. And earlier it used to be a little scary. This was I think 4-5 years ago but then after NIT and after working on these projects, it was clear that **uncertainty is going to be part of this process** and **they have to just be accepted so that we keep moving forward**. So uncertainty, yeah it is part of the process and it **has to be acknowledged** in the process.	- *Acknowledging uncertainty* - *Accept uncertainty to keep moving*

Table 2
Themes emerging by combining codes during thematic analysis of expert interviews

Combining Codes		Theme
- Collect more information - Talk to multiple experts for different perspectives - Clarify with industry, clinical partners, technology partners and relevant stakeholders in initial phase - Literature and existing patents - Weekly meetings	- Involve experts and team-members to understand the breadth and depth of the problem - Seek advice from experts and team-members for evaluating and revising ideas, and planning next steps - Analyze and evaluate gathered knowledge in the problem context (List is not exhaustive)	*Taking feedback from relevant sources*

Themes emerging from analysis of expert data were then used as a guiding framework to identify learner difficulties and challenges in productively engaging in uncertainty management practices during the collaborative engineering design task. For the learners' data, we first used a coding scheme by Jordan et al. (2014) to identify all the episodes where uncertainties were expressed by the team members. This coding scheme uses indicators like hedges (e.g., 'maybe,' 'sort of,' 'perhaps'), probabilistic statements (e.g., 'likely,' 'probably'), and non-verbal cues (e.g., use of gaps like 'mmm…') to identify expressions of uncertainty. These indicators marked the start of an uncertainty episode for the team. The episode ended when the conversation or the physical activity of the team members no longer focused on the specific uncertainty the group was dealing with. A total of ninety-four episodes were analyzed from the two learners' data sets combined. We analyzed these episodes following inductive and interpretive approach and using methods of interaction analysis (Jordan & Henderson, 1995). Our unit of analysis was "individual in a group" (Hogan & Fisherkeller, 2005) and we paid attention to both verbal and non-verbal learner behaviors during their interaction. By analyzing learner interactions against the uncertainty management practices identified from the experts' data, we identified difficulties and challenges that the learners encountered during the uncertainty management practices.

Findings

We identified six prevalent uncertainty management practices that experts engage in during the engineering design process. The following section will define these six practices (P1 to P6) and simultaneously discuss middle school learners' uncertainty management behaviors concerning these practices.

Acknowledge and proactively respond to uncertainty (P1)

The experts who participated in our study partially agreed that ignoring uncertainty is a common practice in their design practice. They reported that ignoring is not a 'good' way of dealing with certain types of uncertainty. According to the experts, some uncertainties cannot be dealt with immediately because of reasons like dependence on other tasks or situations that cannot be controlled in the present. Experts suggest that instead of completely ignoring uncertainty in such situations, one should proactively discuss them and plan immediate and future steps that would help in addressing them. For example, expert ND mentioned that his strategy of dealing with such uncertainties is a combination of *"proactive" and "ignorance."* He says, *"proactive is the first immediate future, first two stages or something and the rest, I am ignorant about it because it is too early to think about it."* Experts also mentioned that strategies like *"categorizing"* and *"prioritizing"* uncertainty helps in planning how to manage them. Experts prioritize uncertainties based on aspects like - their relevance to the current design phase, dependence on other uncertainties or tasks, and which uncertainties are critical for making progress.

In contrast, beginner learners usually ignore uncertainties expressed by their team-members at various instances. Learners from our study dismissed uncertainty expressed by others by either explicitly declaring it as irrelevant, delaying it without any discussion or by choosing not to respond. For example, consider the excerpt below from Team A's episode in Study 1. Aditi expressed the uncertainty regarding whether they should design

their robot to clean the eraser dust (one of the trash materials) as she considered it to be a difficult task. However, the other team member (Sneha) completely ignored this uncertainty by calling it *"unimportant."*

Sneha: Our robot will clean everything.
Aditi: Should we use Eraser dust? Won't it be difficult to clean it? It kind of…sticks to the floor.
Sneha: This is not important right now; we will be able to do it.

One of the factors contributing to learners ignoring uncertainty was the way they position themselves and other team members. For example, in study 2, group B (See Table 3), Anu and Anmol ignored Krish when he raised his concern about Anu's decision (line 9). Instead of responding to his concern, Anmol reminded him of the task he had asked him to do and instructed him to concentrate on that (lines 9, 10). Even Krish did not confront Anmol; instead, he updated him about his work and asked what he should do next (lines 11, 12). Both Anmol's and Krish's behavior indicates that they positioned each other in a supervisor and assistant kind of relationship. This kind of relationship between Anmol and Krish persistently existed in other uncertainty episodes also. Anmol's behavior of ignoring Krish's uncertainty and Krish's behavior of not confronting Anmol and following his instructions seemed to stem from their positioning dynamics.

Summary. Expert designers acknowledge and proactively plan mitigation steps to address uncertainties at appropriate design stages. However, learners may not acknowledge every uncertainty and usually respond by delaying them without a plan or completely ignoring them.

Maintaining uncertainty (P2)

It is the tendency to increase uncertainty by going into the depth of knowledge required to resolve it. The following excerpt from Expert KG's interview where he talks about expanding on ideas in the ideation phase of design interview speaks to this practice: *"So I had to think three-four ways of cleaning the membrane. For all of them, I had sketched down ways in which I could do it and these sketches, what I did was, I had taken to the expert from the 'X' institute….but I let that uncertainty be in the ideation phase so that it does not affect my ideation….So if I kill this stupid idea right now, I will not get those two brilliant ideas later and I would have never learned what all right or wrong cold happen with them."*

There are episodes where beginner learners engage in deep discussions for understanding and resolving uncertainty. These situations provide learners opportunity to share and discuss alternative perspectives, negotiate ideas, and collaboratively build knowledge to make progress in the design process. However, in most cases such productive discussions do not sustain. One of the reasons is the tendency to prematurely converge on ideas and make quick decisions instead of expanding uncertainty further. For example, consider the excerpt from an episode from group B (Study 2) in Table 3, Anmol asks his team-mates to remind him of the straw that they decided to use as nozzle (line 1 and line 3). Anu picks up a 10mm straw to answer him (line 4). When Anmol asked for Anu's reasoning for choosing the 10mm straw, she randomly pointed to the other team saying, *"they are also using the large straw, so we can use it too."* Anu tried to defend her decision without providing a logical explanation. The other team-member, Krish, also confronted her (line 9) but both Anu and Anmol ignored his concern. In this episode, Anu's actions of ignoring the disagreement expressed by her team-mates (lines 5 & 9) and providing superficial rationales for her decision indicated that she expected to manage uncertainty by making a quick decision, without engaging in any sense-making discussion. She was concerned about moving ahead and complete the task *"fast"* instead of making an informed decision (line 14). Even the other team members – Pooja and Krish did not persist on resolving their uncertainty and agreed to the decision made by Anu and Anmol who were primarily making all the other decisions in the design process.

Table 3

Excerpt from an episode of group B, Study 2

	Verbal Transcript	***Nonverbal Transcript***
1	*Anmol: Ae which nozzle had we thought of?*	*Anmol picks the 8mm nozzle straw, which is tied to the balloon.*
2	*Anu: On your mark, get set*	*Anu rolls the wheels on the desk.*
3	*Anmol: Hey which one we had to take from these?*	*Anmol places his hand over the chin and speaks louder than before.*
4	*Anu: This*	*Anu takes the 10mm nozzle straw in her hand and raises it high.*
5	*Pooja: No the smaller one*	*Pooja directs her gaze to the 8mm nozzle straw in Anmol's hand and lifts her eyebrow to point to it.*

6	*Anmol: why this one?*	*Anmol is looking at Anu. Anu is looking around in the room.*
7	*Anmol: Tell*	*Anmol raises his voice.*
8	*Anu: They are also using the large straw, so we can use it too*	*Anu points to the team sitting next to them.*
9	*Krish: But those people are using white ones*	*Krish points to another team in the class.*
10	*Anmol: You first complete this. Do it carefully.*	*Anmol turns towards Krish.*
11	*Krish: Yes, it's almost done. What should I do after this?*	*Krish starts collecting the cardboard pieces.*
12	*Anmol: Wait, I will tell you*	*Anmol uses hand gesture asking Krish to wait*
13	*Anmol: Then tell what should we do?*	*Anmol turns his face towards Anu.*
14	*Anu: Let's use red one. We have to do this fast and complete it. Otherwise, we will be left behind*	*Anu is looking at Anmol as she speaks.*

*Summary***.** Experts expand uncertainty for clarifying different aspects of uncertainty and logically converge to informed decisions. But learners prematurely converge to decisions with intentions to reduce uncertainty quickly.

Taking feedback from relevant sources (P3)

When uncertainty is experienced, one common practice is identifying and approaching the appropriate source of knowledge. This can help reduce the uncertainty by clarifying doubts and confusions and introducing more uncertainties that would further guide the knowledge seeking path, or act as an anchor for deciding next steps. Experts emphasized that this practice is particularly essential during the initial stage of design when they are defining problem as it helps in *"planning"* what to do next *"better"*. For instance, Expert AK said - *"You get it clarified with your industry, your clinical partners, your technology partners, whoever it is, the stakeholders who are there, that's where your prior art becomes really important in clearing the uncertainties. May be reading up literature on that, may be reading existing patents regarding the same. So all of this helps in clearing up these uncertainties, the unknowns which are there in the project. So once the ground up work is done, we plan accordingly, at least some part of the unknowns become known to us and then planning becomes better."*

A crucial aspect of clarifying uncertainty is assessing and evaluating the gathered information in the context of problem that is being solved. For example, Expert ND says, "*After doing certain experiments, we saw some observations. So if I were to interpret those observations, I would interpret it in a certain way but if I give the same experiment results to an academic person, they would see it in a very different way. I have to consider both perspectives and see how they serve the purpose of resolving my uncertainties."*

On the other hand, some learners usually ask for direct solutions and answers from authority figures to resolve uncertainty instead of asking relevant questions that could guide their uncertainty management processes. Some learners do attempt to engage in collaborative discussions and reasoning with fellow team-members, however in most cases, there is problem of unequal participation. Learners usually approach only specific team-members to discuss their uncertainties, as was the case with Anmol from group B, study 2 (see Table 3). Anmol only approached Anu for discussing which nozzle straw to use. This was clearly evident as Anmol was turning towards her and maintaining eye contact only with her during the discussion of the uncertainty (lines 6, 7, 13). These behaviors usually produce knowledge that lacks sound reasoning and is biased due to limited perspectives.

Learners also faced difficulty in framing their uncertainty into relevant questions that could trigger constructive discussion or feedback and usually do not persist on asking questions or expressing uncertainty to elicit responses. They even do not assess the information received from other sources, and usually accept it especially if it comes from a person considered as a higher source of knowledge authority.

Summary. Similar to experts, learners do engage in taking feedback. However, they struggle in articulating their uncertainty and lack critical assessment of gathered information.

Using engineering design specific tools and techniques (P4)

There is evidence that experts use conceptual and technical tools and techniques for resolving uncertainties. Experts from our interviews used tools such as *"usability goal setting"* (Joshi, 2009), *"sketches and drawings",* and *"standard project management tools"* which help resolve uncertainties at different design phases.

The beginner designers do not have awareness about the existing engineering design tools and techniques. Although, they do intuitively engage in tactics like brainstorming and making drawings and sketches for different purposes during uncertainty management. However, learners lack knowledge about how to use these tools

effectively. For example, sketches made by learners in our study lacked details like labeling of parts and mention of specifications like dimensions, size, and materials. Leaners miss out on important details when they use these sketches during design phases like creating prototypes, causing problems later.

Summary. Experts effectively use standardized design tools and techniques to manage uncertainties, while beginners lack apriori knowledge about these tools and their application.

Keep track of micro and macro progress (P5)

All the experts in the interviews had a view that continuous progress in the uncertainty management and the overall design process is an important indicator of productive uncertainty management. For example, Expert ND when asked about how they judge if their students are managing uncertainty productively during a design project, says, *"the biggest, the first marker is - Are they moving forward? If I am looking at them every half an hour or 2 hours, when I come back, if they are still solving the same problem, that means there is something wrong, they are not moving forward ..... so basically it is the progress of whatever they are doing. Are they stuck at the same point? if yes, why are they stuck? Why are they not able to resolve that uncertainty? That is the question."* Experts monitor the micro progress made on sub-tasks within a bigger problem and consider it essential for tackling uncertainty. They frequently reflect on the state of uncertainty and accordingly prioritize them to decide how and when to address them. They simultaneously keep track of the overall progress (or macro progress) of the design life cycle which helps them regulate tactics and strategies for resolving uncertainties. For example, in the excerpt below, Expert AK emphasize the need to *"track progress"* by ways like setting *"milestones"* for managing uncertainty and regularly checking if the team is progressing towards them. Similarly, Expert AR talks about tactic of using *"weekly reports"* to *"capture all the uncertainties, all the dependencies"* and use it an anchor for discussion with the teammates and for tracking progress.

In our learner data, we came across only a few instances where learners reflect on their state of uncertainty and regulate their uncertainty management strategies and this was not a regular practice for any of the groups. The teams reflected on the state of their progress only towards the end when they were left with limited time to complete the task and when they were unable to resolve a critical uncertainty. For example, consider the excerpt from Team B, study 1. After failing to figure out where and how to place the EV3 brick for a long time, Team B participants reflect back on ideas that did not work for them earlier. However, they finally decided to copy what the other team had done, realizing that they do not have enough time left to complete the task.

1	*Shilpa: What should we do? We have not attached it (EV3 brick) yet. We also have to try it then*
	[Kartika and Shilpa discuss about different ideas for keeping the EV3 and contrasting them with orientations that did not work for them before]
6	*Kartika: See, they have used the cage (structure to hold the EV3 brick).*
7	*B2: Yeah I think we should also just do it and start testing, we have no time left.*

Also, learners do not explicitly discuss and prioritize uncertainties. In episodes where teams struggle with multiple uncertainties at the same time, they find it challenging to break uncertainty into relevant questions and smaller tasks, and often do not reflect on the interdependencies among different uncertainties which is required for planning next steps in the uncertainty management process.

*Summary***.** Experts track their micro and macro level progress; reflecting on their uncertainty management process regularly. But learners do not engage in such processes regularly, likely leading to poor uncertainty management.

Maintaining positive attitude (P6)

Experts emphasize the importance of maintaining a positive attitude when dealing with uncertainties. For example, while reflecting on his earlier experiences of managing uncertainty, Expert ND says: *"You are working on a project, and you want it to succeed, so all the uncertainties have to be resolved. Now you can do it with a positive attitude or a negative attitude. Negative attitude will not lead you anywhere, so positive attitude is must to resolve all those uncertainties. And I think I learned this from the funding application process long back where a lot of experts are sitting in a room, and they are just throwing questions at you. Is it going to be safe? How is it going to work? What percentage? And all of that."* Similarly, while talking about her teaching experience with undergraduate students, Expert SA says that learners generally start panicking if they cannot resolve uncertainties. In such cases, her approach is to intently listen to their concerns and encourage them to look at the uncertainties as *"opportunity for learning"* instead of feeling "*demotivated."*

We observed that learners in our study also get demotivated when they felt stuck in a situation or experience multiple uncertainties simultaneously. For example, in one of the episodes from Study 2, Team C participants used phrases like "*let us go die*" (figuratively speaking) and "*we will be disqualified*" when all their efforts failed to figure out why their toy vehicle was not moving. Their tone was anxious and indicated disappointment. Also, after this episode of repeated failures, the team members changed their uncertainty management approach. Earlier, they were engaged in systematic experimentation and logical reasoning to troubleshoot the problem. However, afterward, they blindly took decisions with the focus to somehow complete the task instead of making sense of their actions.

Summary. Experts emphasize on keeping a positive attitude for effective uncertainty management. Learners often panic in difficult situations and hence needs support for staying positive to ensure progress.

Discussion

Findings from the analysis of experts' interviews advance our understanding of how uncertainties are managed in authentic scenarios of solving ill-structured engineering design problems. Comparative analysis of learners' uncertainty management behaviors with respect to experts' uncertainty management help identify potential learner difficulties and challenges while managing uncertainties. These challenges could throw light on the key problem areas where learners need support.

Our findings revealed that learners' response to the uncertainty of their team-member(s) is not very supportive (refer P1). This is aligned with the findings of Jordan et al. (2014) regarding the supportive and unsupportive role of peers during a robotics engineering activity. We found that in our study, the learners ridicule, ignore or delay uncertainties expressed by their team members. One of the reasons leading to these behaviors was found to be learners' positioning of themselves and their team members during the uncertainty management process (P1). Therefore, to ensure that learners acknowledge uncertainty expressed by their team members and learn from their experiences to resolve it, they should *consider themselves and other team members as equal collaborators* and *equally participate in discussions and decision-making*. These findings thus indicate towards the possible need to *help learners build team rapport and enable equal participation* so that they acknowledge each other's uncertainty and collectively engage in its management process.

Prior research suggests "ignoring uncertainty" as one of the uncertainty management strategies of designers (Lipshitz & Strauss, 1997). However, experts suggest that instead of completely dismissing or ignoring uncertainty, one must acknowledge it and proactively plan mitigation steps to address the uncertainty (P1). Furthermore, experts frequently expand uncertainty and then logically converge to a decision (P2). This aligns with prior research that suggests that instead of converging to decisions early, problem-solvers need to indulge in divergent thinking, especially during the initial phases of design, where they break down uncertainty further, ask more questions, explore various ideas and seek as much information. This helps in clarifying uncertainty, expanding knowledge repertoire, and ensuring that decisions are logical and sound (Dym et al., 2009). Thus, based on these findings, we suggest that learners need support to *build tolerance to uncertainty* so that they feel comfortable with its existence, acknowledge it, and also allow it to persist till they have adequate knowledge to make informed decisions.

Another finding was that learners often ask questions that demand direct answers or information when seeking feedback and usually accept the information without assessing or evaluating them (P3). In contrast, experts seek information from multiple reliable sources before taking a decision (Dym et al., 2009). Experts engage in practices like critical thinking, analytic discussions, argumentation and systematic experimentation for assessing information, evaluating it and applying it in the relevant context in order to make design decisions (Crismond & Adams, 2012). This suggest that learners will *likely require support for articulating uncertainty better and posing relevant questions* that guide their uncertainty management process. Learners may also benefit from *support for making judgments and decisions about the credibility, relevance, and application of information received from various knowledge authorities.* These supports could be in the form of *tools along with instructions regarding their applicability to various uncertain situations.* Tools serve as a medium for asking questions and finding answers as the design process unfolds (Dym et al., 2009) and are frequently used by experts (P4). Such scaffolds are part of an expert's repertoire and often help them keep track of micro and macro progress (P5).

Uncertainties can be overwhelming and lead to a state of *'paralysis'* (Ullman, 2001). To overcome these situations, maintaining a positive attitude and persevering in the face of adversity become imperative (P6). Hence learners may benefit from *environments that foster positive attitudes and behavior*s.

Limitations, Implications, and Conclusion

A limitation of this study is the relatively small sample size of experts and learner groups to make claims about the generalizability of the findings. Although the large number of episodes analyzed from the data of five

groups provides sufficient breadth for analysis, including more heterogeneous groups would ensure diversity amongst participants. Similarly, interviewing more experts and conducting an ethnographic study of experts resolving uncertainties in their workplace setting could help in validating and refining the findings.

This paper looks at engineering design practices from the lens of uncertainty management and highlights six practices that are essential for managing uncertainty effectively. These findings provide new insights for informing teaching and learning of engineering design at the K-12 level. Uncertainty is an inherent part of the engineering design process and findings from this study can inform the design of learning environments to support productive engagement in disciplinary practices of engineering design. For example, our study highlighted how experiencing certain uncertainties at specific design stages triggers negative emotions like feeling anxious and demotivated, and how it affects learners' uncertainty management processes. These findings can be leveraged by the Learning Sciences research community for creating robust scaffolds for supporting uncertainty management in classrooms. Future research could further elaborate on key problem issues that hinders learners' engagement in engineering design practices and identify relevant pedagogical and technological solutions to address them. Simultaneously, we need to keep advancing our knowledge regarding underlying processes that affect learners' uncertainty management.

University Students' Conceptions of Reflective Learning in Education Courses

Addisu Leyew Bailie and Engida H. Gebre
abailie@sfu.ca, egebre@sfu.ca
Simon Fraser University

Abstract: Reflective learning experience has been considered crucial in higher education. Accordingly, most programs have embedded reflective learning experiences into the curriculum. However, there is a dearth of research on students' conceptions of reflective learning and how they perceive the value of their experience. This study aimed to explore how university students taking education courses understand reflective learning. A qualitative analysis of data collected from 12 student interviews and 161 open-ended survey responses revealed four different ways of understanding reflective learning: engaging with content, evaluating learning, relating learning to other experiences, and reframing understandings and perspectives. The findings have implications for design of learning environments for reflective learning.

Introduction

Reflective learning experience has been considered crucial because of its importance both in formal and informal learning environments. In formal learning environments, reflective learning experiences provide students with opportunities to engage in high quality dialogue (Brockbank et al., 2002; Dukewich & Vossen, 2015), develop learner agency (Lin & Schwartz, 2003), and examine the effectiveness of their learning strategies (Ertmer & Newby, 1996). Reflection has also the potential to cultivate lifelong and transformative learning that go beyond the context of classrooms (Brockbank et al., 2002; Tan, 2021). In informal learning environments such as social media and the Internet, for instance, students are often presented with a great deal of misinformation and disinformation. Thus, developing reflective skills and mindset helps them question and challenge the source and validity of the information rather than readily consume it. In the context of workplace learning, reflection can serve as a tool for dealing with uncertain and complex issues (Chan & Lee, 2021) and coping with the demands of multiple expectations (Ryan & Barton, 2020). It is also argued that reflection is central in the concept of graduateness as it underpins the skills and attributes that are valued by employers (Wharton, 2017).

Because of the above-mentioned potential benefits, there has been widespread calls for integrating reflective learning into courses and experiences in higher education. As a result, reflection has become a requirement of many university courses (Ertmer & Newby, 1996; Quinton & Smallbone, 2010; Rivers et al., 2014). However, little is understood about how to develop reflective skills (Clara, 2015; Ertmer & Newby, 1996). Besides, reports indicate that students' engagement in reflective learning is minimal (Mair, 2012; Power, 2016). Mair (2012) argued that the value of reflective learning in higher education is seldom realized as students' engagement is very unsatisfactory.

Students' minimal engagement in reflective learning can be attributed to the various elements of learning environments. Among these elements is students' own conceptions of what reflective learning entails. Research on students' conceptions of learning has generally gained considerable attention because of its association with learning strategies, approaches to learning, and effective learning (Loyens et al., 2009). Conceptions are often adopted based on perceived learning contexts (Trigwell & Ashwin, 2006) and develop and change through educational experience (Entwistle & Peterson, 2004; Loyens et al., 2009). Thus, purposes and underlying values of reflective learning that are conveyed either implicitly or explicitly by instructors or their educational programs determine the forms and focuses of reflection (Ecclestone, 1996). Understanding students' conceptions provides insights about the nature of learning environments designed to foster reflective learning and student engagement.

Research on reflective learning employed an array of approaches to examine students' reflective learning experiences and/or develop frameworks for the purpose. Some researchers have relied on learning artifacts such as journals, portfolios, and reflective assignments to gauge levels of students' reflection (e.g., Fund et al., 2002; Kember et al., 2008). Others employed structured surveys and conducted quantitative analysis to determine students' reflective skills and to compare the levels across certain demographic variables (e.g., Kember et al., 2000). Both approaches provide insights into the nature and level of students' reflective skills and experiences. However, more evidence of and insights into the why and how of students' approaches to reflective tasks can be obtained by looking into their conceptions of what reflective learning entails. This paper therefore aimed to explore students' conceptions of reflective learning. The study was guided by the research question, "What are students' conceptions of reflective learning in the context of education courses?"

 © ISLS

Conceptions of Reflective learning

Conceptions refer to the different ways people understand a particular phenomenon (Marton & Pong, 2005) that mediate their reactions to situations involving the phenomenon (Pratt, 1992). In the literature, there exist a variety of conceptualizations of reflective learning ranging from a simple awareness of events and thoughts to critique and transformation of assumptions and hegemonic practices. Dewey's (1933) conceptualization of reflective learning relates to a rational and systematic process of problem solving. Building on Dewey's work, Clara (2015) emphasized the notion of transformation of an incoherent situation to a coherent one as central to the concept of reflection. In his transformative view of learning, Merizow (1991) understood reflection as critique of assumptions and taken-for-granted beliefs. Others considered self-examination and inquiry as central in the reflective learning process (Boyd & Fales,1983; Mortari, 2012).

These diverse interpretations of reflective learning allow educators to adopt or develop perspectives that align with the purposes they pursue in their courses. These perspectives have the potential to influence students' conceptions of reflective learning. This is because conceptions are situational and exposure to different learning contexts impacts how students adopt and develop them (Smith & Blake, 2009). For instance, research showed that constructivist conceptions of learning were reflected by students who experienced a learner-centered learning environment compared to students who were enrolled in a conventional curriculum (Loyens et al., 2009).

Students' conceptions, which are adopted based on perceived learning contexts, would influence their approaches to and engagement in the task (Trigwell & Ashwin, 2006). Cognizant of such relationships, we believe that efforts to foster reflective learning in higher education would benefit from an understanding of students' conceptions. This paper therefore aimed to explore the different ways students understand reflective learning in the context of education courses.

Method

This is part of a larger study on perspectives and practices of reflective learning in higher education. The purpose of this paper is to understand and describe students' conceptions of reflective learning using data from interviews and open-ended survey at a western Canadian university. To achieve our purpose, we adopted a phenomenographic research approach. At the heart of phenomenographic research is participants' conceptions of the phenomena of interest. The underlying theoretical assumption is that there are only a limited number of ways of understanding a given phenomenon (Entwistle, 1997; Richardson, 1999; Tight, 2016). In this study, the phenomenon of interest is students' conceptions of reflective learning.

Data were collected from students in the Faculty of Education in 2020. Although reflective learning is expected to be incorporated in different programs and disciplines, we focused on students taking education courses because they are expected to have a more nuanced view of reflective learning. Thus, education courses that were scheduled to be offered in the academic year were first identified. Then, the brief course descriptions that were posted online to assist student enrollment were examined pertaining to inclusion of reflective learning experiences. Accordingly, 22 courses that included reflection in the course descriptions, learning outcomes, and/or assessment strategies were selected as sources of data. Such preliminary assessment was important to ensure that participants who had the experiences of the phenomena of interest are included which is considered important in phenomenographic studies (González, 2011). Then, students were accessed via their professors and invited to complete a survey and to volunteer for interview.

A total of 274 students participated in the survey. Students were comprised from undergraduate, graduate and professional development programs. Graduate students are MA/MSc/MEd students who were enrolled in different programs such as mathematics education, curriculum studies, educational leadership, and equity studies in education. Undergraduate students are comprised from different faculties of the university, but they were all taking education courses. Students of the professional development program (PDP) are teacher education students who were admitted to the program after completing a bachelor's degree in different disciplinary areas and were preparing to become elementary or secondary school teachers.

Data were collected through interview and open-ended survey. Interviewing is considered in phenomenography a primary method to understand participants' conceptions of phenomena (Åkerlind, 2005; Marton, 1986) because of its capability for eliciting detailed and rich account of participants' lifeworld (Ashworth & Lucas, 2000). We employed a semi-structured approach to interviewing that involved improvising questions and probes when appropriate. The general purpose of the interview was to explore students' understanding of reflective learning, the kind of opportunities they were provided to engage in reflective learning and their perceptions of barriers to engage in the processes. However, the data used for this study focuses on their conceptions of reflective learning. Examples of interview questions that helped to elicit participants' understanding include: How do you describe reflective learning? In what ways do you think you have been engaged in reflective learning in this course? How did you go about reflection in the course? How is being

reflective important in higher education? Interviews were conducted both in-person and virtually. Since most of the data were collected during the COVID-19 pandemic, phone and zoom interviews were used depending on the participants' choice. Among the interviews we conducted for the larger study, the analysis for this paper is based on data from twelve participants. Interviews were audio-recorded and transcribed verbatim.

The survey included both close-ended and open-ended items that were intended to answer the research questions we formulated in the larger project. However, in this paper we used responses to one open-ended item, i.e., How do you define reflective learning? Among the 274 students who completed the general survey, 161 students responded to this question. Of these, 51.6% were taking professional development courses, 29.8% undergraduate courses, and 18.6% graduate courses.

In phenomenography, data analysis is a recursive process in which transcripts are read several times, pertinent data are identified and segmented, and then the underlying meanings of the sorted data are compared (Åkerlind, 2005; Forster, 2016; Tight, 2016). Accordingly, we sorted, segmented, organized, and examined data from the responses to the open-ended item in the survey and the interview transcripts. Then, we read the transcripts multiple times to explore similarities and differences in participants' conceptions. The process resulted in the development of categories of descriptions, which are the main outcomes of phenomenographic analysis (Åkerlind, 2005; Entwistle, 1997; Svensson, 1997).

Results

Analysis of data indicate four qualitatively different conceptions of reflective learning by students: engaging with content, evaluating learning process, making connections to experiences, and reframing understandings and experiences. Descriptions of each category are presented with examples of excerpts from the data.

Table 1

Categories of students' conceptions of reflective learning

Category	Description	Example Excerpts
Engaging with Content	Reflective learning is seen as engaging with course content and involves an in-depth examination and analysis rather than merely memorizing the information	"I think it's more about taking what you learn and not just memorizing facts and then spitting them out on a test, but learning it and then kind of processing it more deeply and showing it in a paper or some kind of project that you can really think about it and critically think about it" (UGs1)
Evaluating Learning process	Reflective learning looking back and reviewing learning goals, activities and strategies and determining their effectiveness	"It is about learning strategies, thinking about effective strategies, what works, what does not work, etc. . . . I think it's, at this point, the only way that I know to actually like how to do well in my classes. These are the methods that I use for every single class. And this course is no exception" (UGs6)
Relating learning to experiences	Reflective learning is about making connections among course concepts, prior knowledge, past personal experiences and anticipated practices and experiences	"I think [reflective learning] encourages the student to come out of their comfort zone and then they're sharing their stories as well, because each thing . . . can be tied to something in the real life and that's why we're studying it because you want to take to the job sector, real life sector or home life." (UGs7)
Reframing understandings and perspectives	Reflective learning is seen as developing new knowledge, modifying, or reconstructing beliefs, experiences, and practices	"It's that the reflective piece is the goal and is the learning and when you kind of spiral in your learning, so I find that I revisit certain themes that's to do with my inner landscape. And it's changing the perspective that I once had on something that was a truth" (GRs16)

Reflective learning as engaging with content

In this category, reflective learning is understood as a process of critically engaging with disciplinary concepts, principles, and ideas that students are presented with. Participants used an array of expressions that denote the thought processes and activities involved while engaging with the subject matter content which include thinking deeply, critically assessing, contemplating, taking a moment/time to think, looking back, mulling over, pondering, and understanding. Despite the variations in expression, they refer to mental activities applied to content that go beyond surface level. The following excerpts demonstrate the processes involved while engaging with content:

UGs25: Deep thinking about the course material that can be reflected in interesting engaging group discussions, written assignments, or any other opportunity for critical thinking. Not pure fact memorization.

PDs104: Going beyond just surface level to explore and develop new ideas.

UGs72: Reflective learning is learning that occurs when given a chance or moment to stop and think. It is the deeper understanding of thoughts and ideas, rather than the mere memorization of them.

PDs159 Taking time to think about and contemplate on ideas, readings and discussions related to education.

In the above excerpts, one can notice words and phrases such as 'deep thinking', 'stop and think' and 'contemplate' that illustrate the thought processes involved when engaging with contents and reading materials. These descriptions imply that reflective learning entails going beyond rote memorization and learning and rather focus on engaging in higher order thinking processes pertaining to the content being learned. When asked about how they understand reflective learning, one interviewee replied, "I think just generally it's not blindly following and consuming the material that we are given but taking time to almost like digest this, and have it make sense in for a personalized understanding of whatever it may be" (GDs22). So, the main facet of this category of conception is that reflection targets content with the aim of developing an in-depth understanding of what they are learning.

Reflective learning as evaluating learning process

In this category, reflective learning is understood as looking back to learning goals, strategies, activities, and outcomes. This category is different from the previous as reflection mainly targets the "how" than the "what" of learning. The following excerpts from four participants' responses to the question on what reflective learning is clearly demonstrates this conception.

UGs01: From a student perspective, looking deeply at study habits, strategies, and skills; and motivations for learning. Analyzing these areas and deciding whether they are effective and serving goals, and how improvements can be made in the future.

PDs134: Reflective learning is understanding both how you learn and the influences that allow you or disallow you to learn.

GRs56: I would think about how engaged I was, what my circumstances were at the time, what factors contributed to or detracted from my learning or non-learning, and the result of those factors on my learning.

UGs13: You complete the task and then you reflect on it - how you approached the task, what strategies, what went well etc.

Here, students reflect on learning activities and processes that they were engaged in. An important facet of this conception is that reflection targets not only the goals they set, the learning strategies they chose and employed, or the activities they performed, but also the factors that are associated with the way they approach the tasks. Such a reflection often aims to identify what worked well and what did not in the learning process and thereby inform future learning. UGs20's definition of reflective learning succinctly describes this aim. The participant defined it as "looking back on your own learning/studying to think about how it went, how it could have been better, and what you can do to make it better."

Reflective learning as relating learning to past and future experiences

In this category, reflective learning is seen as making connections between learning and personal life experiences and anticipated future practices. Key terms such as relating, connecting, and reconciling are emphasized in participants' responses that are coded in this category. The connections can be of different kinds with different purposes; however, participants viewed it as a key characteristic of reflective learning that makes it distinct from

non-reflective activities. One of the common types of connection evident from participants' responses is between course contents and personal experiences. That is, reflective learning is viewed as relating concepts and ideas encountered in the courses to personal life experiences. The following excerpts illustrate the point:

PDs146: The ability to make connections with what you are learning to your personal experiences and values.

UGs02: Taking a step back after readings or assignments to see how it would manifest in my own life in order to better understand concepts and create a deeper connection with the material

UGs58: Reflective learning involves students thinking about what they have read, done, or learned, relating the lesson at hand to their own lives and making meaning out of the material.

PDs179: A style of learning in which students are encouraged to think about concepts introduced in seminars/readings/assignments and how the ideas are related to their own values and experiences.

Reflective learning as relating entails connecting course concepts not only to personal lives but also to previously learned concepts and anticipated professional practice situations. The following excerpt from a participant illustrates the importance of making connections between contents over time:

> Reflective learning (or at least the process of reflective assignments in this course) combines summation of topics and encourage extension of presented ideas and philosophies into previously covered topics/information as well as whether the topics/information agree or disagree with personal, currently existing values. (PDs153)

Another facet of connection is expressed in terms of applying learning and/or personal experiences to other situations. Participants illustrated various forms and directions of transfer of learning and experience which include applying concepts or theories learned in courses to practice situations, or future practice; applying personal experiences to the understanding of the course experience; or use learning strategies that are found effective in future learning. Among these variety of applications, the most common one entails the use of course based knowledge and skill in personal and professional lives. UGs59's response to the question of what reflective learning is typifies this conception. The participant stated, "reflective learning is applying what you learn in class to your daily life. Applying it can take the form of thinking about the material, discussing it with someone else or creating beneficial activities for your family's development." The notion of application is not only from contents to personal and professional life but also from personal and professional experience to course experiences. UGs40's response indicates the bidirectional nature of application between content and personal experiences. The participant stated, "applying own experiences on what is being taught and what things I learn apply to my own life." Another participant also described reflective learning as "using past experience to contemplate current issues and guide future actions."

In general, this category is different from the previous categories in its focus on examining current learning experiences in relation to past and anticipated future experiences. The purpose could be simply to facilitate understanding of what they are learning or consider the relevance of what they are learning by examining its applicability.

Reflective learning as reframing understandings and experiences

In this category, reflective learning is considered as changes in ideas, understandings, practices, or personal perspectives. Although experiences based on the previous three categories would ultimately lead to such kinds of changes, what differentiates this category of conception is its prime focus on the outcomes of the reflective learning process. As such, it entails acquiring new ideas pertaining to subject matter content; reframing prior assumptions and perspectives; and adopting new ways of doing things like learning or teaching.

One of the outcomes is questioning personal perspectives and biases. That is, participants understood the outcomes of reflective learning in terms of reframing preconceived ideas and beliefs. One participant, for example, described reflective learning as: "critically thinking of your internalized attitudes, assumptions, beliefs, and experiences and how we can shift our views to better consider the experiences and contexts of others" (PDs188). In a similar way, the following response emphasizes the notion of reflective learning as reconstructing perspectives and experiences:

> [Reflective learning] is kind of see where you yourself as an individual have come from. So, for example, when I left the country [Canada], and I began teaching in Korea, and where I was, as a teacher, and, as a beginning, like a new educator in a new environment is a very different person from where I am now. So, it's like you have to self-reflect not only on new pedagogies that you've learned and how you can implement them, but also how you as person has to have changed over time. (GTs17)

When asked about the importance of reflective learning, another interviewee illustrated how change and growth is key by saying, "I wanted to say, I don't think you can grow without reflection.… I think change is inevitable, but to kind of create authority in your growth, yeah, I don't know that's possible without being able to reflect" (PDs23). A related aspect of reframing focuses on modifying, adding to, or correcting previously acquired knowledge or just acquiring new knowledge. The following excerpts indicate changes related to knowledge:

UGs47:	Learn things you didn't know before or things knew already but others may hold different ideas.
UGs57:	Acquiring new knowledge with self-reflection during or after that new learning.
GRs76:	Being able to revisit concepts in order to further improve and cement them.
PDs191:	The idea of coming back to previously owned knowledge to challenge, complete, correct it.

In general, this conception emphasizes the changes achieved as a result of reflective learning experiences. Participants' responses may include both the processes and objects of reflection; however, seeing things anew and/or reframing existing understandings, beliefs and assumptions are seen as central to the concept of reflective learning.

Discussion

Our findings indicate that students understood reflective learning in four qualitatively different ways: engaging with content, evaluating learning, relating learning to other experiences, and reframing one's own understandings and beliefs. Scholars contend that students' conceptions are situational and are influenced by the nature of learning environments they experience (Loyens et al., 2009; Smith & Blake, 2009). Thus, the four categories we identified in this study provide insights into the kind of reflective learning experiences and tasks that students have been engaged with. These experiences vary in their focus ranging from disciplinary concepts to personal beliefs and life experiences.

The goals of engaging with content at greater depth; evaluating one's own learning strategies; and exploring concepts and theories in relation to one's prior experiences and assumptions are all relevant. However, considering the uncertainties and complexities of the contemporary world as well as the abundance and pervasive influence of digital information on students' formal and informal learning, the focus of reflective tasks on content, learning strategies and personal experiences may not suffice. Gorski and Dalton (2020) question the adequacy of achieving personal transformation through reflection on one's experiences and biases, albeit an important goal by itself. We concur with their call for the need to provide students with opportunities of examining hegemonic practices and taken-for-granted assumptions and thereby transforming structures and systems to pursue justice in the wider society. In addition, explicit instruction of conceptualizations of reflective learning that go beyond content and personal reflection would provide students opportunities to explore alternative possibilities and aim towards the larger goal of social justice.

Teachers' and principals' views of interdisciplinary learning

Abstract: Little is known about how teachers and principals view interdisciplinarity at the K-12 level. In recent years, we have been working with Israel's Ministry of Education and ten secondary schools to develop and enact interdisciplinary curricula in the humanities. During this partnership, we conducted a series of twenty-four interviews with teachers and principals, to glean their views of interdisciplinarity. We found that they understood interdisciplinarity as a broad reform with the potential to impact school life in myriad ways. Moreover, their views on the definitions, potential benefits, and ways to enact interdisciplinarity at the K-12 level extended beyond a cognitive lens, to include sociocultural and critical interpretations as well. Ultimately, we believe that teachers and principals are uniquely situated, and that their points of view could contribute to a grounded theory of interdisciplinarity at the K-12 level, which is currently lacking.

Over the past century, interdisciplinary learning at the K-12 level has often been seen as a promising innovation. Yet, notwithstanding many efforts at interdisciplinary reform, there is scant unbiased theoretical and empirical research explicating what it is, why it may be worthwhile, or how best to implement it (for a brief historical review see Grossman et al., 2000). Indeed, not much has changed since Applebee et al. (2007, p. 1004) noted that "scholarship in the field is remarkably underconceptualized".

With an eye towards understanding the meaning of interdisciplinary learning at the K-12 level, its potential value, and how it is best enacted, this paper presents teachers' and principals' views on these questions. The data we analyzed was drawn from an ongoing research-practice partnership (RPP) between our group from the University of [blinded] and Israel's Ministry of Education, which may pave the path towards a large-scale shift to interdisciplinarity in the humanities across Israeli middle schools.

During the first phase of our study, we conducted twenty-four interviews with twenty teachers and principals representing ten schools, to glean their views on what interdisciplinarity means in a school context. Most of the existing research on interdisciplinarity at the K-12 level is rooted in three approaches – cognitive, sociocultural and critical – which we describe briefly in the Background section. In the subsequent sections, we show how our interviewees simultaneously adopted all three approaches, leading us to conclude that they ought to be viewed as coalescing; and setting the stage for future efforts to generate a grounded theory of interdisciplinarity at school that takes all three approaches into account.

Background

Underlying any definition of interdisciplinarity is a particular view of what constitutes a discipline. Three central ways of conceptualizing disciplines can be found in the literature and each bear on interdisciplinarity differently. The cognitive approach, which is focused primarily on knowledge, understanding, and ways of thinking (e.g., Hirst, 2010), views disciplinarity in terms of content and expertise. Bruner, for instance, argued that at the core of each discipline are some fundamental concepts, such as *tragedy* in literature or *number*, *measure*, and *probability* in science (Bruner, 1960/1999; cf. Schwab, 1964). In another notable example, Wineburg (2001) identified and articulated professional historians' disciplinary heuristics and unique disposition towards far-removed objects of knowing (cf. Herrenkohl & Polman, 2018). From a cognitive perspective, an interdisciplinary curriculum could entail investigating complex phenomena that are better understood when viewed simultaneously through multiple disciplinary lenses (e.g. Boix Mansilla et al., 2000).

While the sociocultural approach recognizes that disciplines are marked by identifiable bodies of knowledge and ways of thinking, it views them as part of a complex system: "mind, culture, history, and the social world [are] interrelated processes that constitute each other." (Lave, 1991, p. 63) This view considers disciplinary knowledge in light of the identities of the people who create and use it and the human contexts within which it is applied. Viewed in this way, interdisciplinarity would manifest itself first and foremost in the creation of a new community whose members hail from diverse disciplinary ones, which in a K-12 context could comprise teachers of different subjects. Forming the community would require new routines, a shared history and a collective sense of purpose, in addition to intellectual innovation (Grossman et al., 2001).

Finally, the critical approach views the disciplines primarily as hierarchical structures that regulate discourse by determining how people are allowed to use language. Most notably, it was Foucault who argued that

 © ISLS

to partake in a disciplinary discourse, one must "fulfil certain conditions, in a sense stricter and more complex than pure and simple truth… in order to part of a discipline, a proposition has to be able to be inscribed on a certain type of theoretical horizon" (Foucault, 1981, p. 60; cf. Apple, 2004). By extension, disciplinarity can also determine how financial resources are allocated and which activities are valued by the institutions that allocate them (Weingart, 2010). Thus, interdisciplinarity would mark an opportunity to unveil and undermine institutional power structures and empower individuals to engage in activities previously considered illegitimate (Fish, 1989) (1).

Several empirical studies have fleshed out these theoretical approaches. Applebee et al. (2007) adopted a cognitive lens, distinguishing between different levels of conceptual integration that form an "interdisciplinary continuum." They found a correlation between the degree of integration and the likelihood that teachers incorporate discussions and "envisionment-building" into their instruction; but they also warned that there are additional factors at play (p. 1035). Grossman et al. (2001) established an interdisciplinary community of English and History teachers and studied it through a sociocultural lens, to show how the evolution of the community's integrative epistemic discourse was intertwined with interpersonal dynamics and additional cultural dimensions. Brandes and Seixas (2000) used a critical lens to explore how a group of teachers navigated the institutional tensions and inconsistencies between school and university contexts, when studying at an interdisciplinary program in the humanities. Yet lacking from the existing scholarship is an in-depth view of teachers' and principals' own perspectives on interdisciplinarity at school – what they understand it to mean, why they are drawn to it, or how they think it is best to implement it. To address this gap in the literature, we asked:

1. How do teachers and principals understand interdisciplinarity?
2. What motivates them to implement interdisciplinary curricula?
3. How do they believe interdisciplinarity should be enacted in school contexts?

Method

Context

In 2019, we partnered with Israel's Ministry of Education for a four-year Research-Practice Partnership (Coburn & Penuel, 2016) with two goals in mind. First, we set out to develop, implement and test new interdisciplinary curricula in the humanities at Israeli middle schools. Second, we were interested in further conceptualizing interdisciplinary learning, understanding its unique features, and perhaps most importantly, articulating its affordances and constraints in educational contexts. Because we hope to make contributions to practice and theory in an iterative process, a Design-Based Implementation Research (DBIR) approach was selected (Fishman et al., 2013). We commenced by recruiting ten middle schools, which had already begun implementing interdisciplinary programs or were intent on doing so soon. For the first iteration of our study, each school sent several representatives to a professional development (PD) course in which we discussed some theoretical background; provided scaffolds for each team to develop a concrete plan of action to implement in 2021/2; and encouraged each team to experiment with a small-scale pilot implementation (2).

Participants

In this paper, we present findings from twenty-four interviews conducted in two rounds, with representatives of each of the ten schools in our project. The schools represented a variety of sizes, socioeconomic levels, and academic achievement levels. The practitioners we interviewed ranged from second-year teachers to seasoned principals.

Data collection and analysis

Our data sources included recordings and fieldnotes from all PD sessions; artifacts produced by participants, including a set of lesson plans and a summative poster by each school team; and interviews, which provided the bulk of the data for this paper. For each of the ten schools, we interviewed either the principal or vice-principal, and one teacher. The first interview focused on interdisciplinarity in K-12 in general, whereas the second round, which only included the teachers, focused on their experiences at the PD course, and how their views and plans had developed throughout the year (3). Interviews were semi-structured and were conducted via ZOOM, recorded, and transcribed. We used a thematic approach (Braun & Clarke, 2006) to analyze the transcripts, generating a detailed portrait of their views of interdisciplinarity, their motivations for implementing it, and the changes to school life that they think it might entail. Where possible, the interview data was triangulated with other data sources to increase validity and broaden our interpretive horizons.

Findings

For our interviewees, interdisciplinarity extends beyond the walls of the classroom and can impact life at school in myriad ways. Our analysis culminated in a distinction between three spaces that serve as metaphors for the kinds of dynamics that were described: the classroom, the teachers' room, and the principal's office.

Inside the classroom

How do teachers and practitioners perceive what goes on in class during an interdisciplinary lesson? In a traditional disciplinary setting, the content of a curriculum is often organized around the big ideas that shape a specific discipline's discourse. But in lieu of the typical disciplinary structure, how are interdisciplinary curricula organized? Our interviewees described three interdisciplinary foci: historical, topical, and identity-centered. Describing the historical focus, one teacher explained that "for every grade we choose three disciplines, and the central discipline is always history… [the others] could be literature and civics, [or] geography and literature" (Esti) (4). The topical focus invites learners to investigate a single topic from multiple disciplinary perspectives; for instance: "We discussed nature, the connection between humankind and nature. Really nice. We learned a poem […] and the Jewish attitude towards nature and the environment. We also learned about social activism in Jerusalem" (Adelle). Another teacher described a unit that was organized around an investigation of students' identities: "each day we ask a specific question about identity, and then all of the disciplines are learned through the prism of that identity-focused question" (Neta).

Integrating the disciplines in these three ways – which are not mutually exclusive – is intended to highlight the connections across knowledge that would otherwise remain fragmented, rendering it more meaningful. One interviewee explained: "[interdisciplinarity is] when the students get the coherence of the whole story, [when] they understand that now we're talking about racism and they find it in the story we're reading, [*and*] in human history, *and* understand what Judaism's attitude towards it is." (Adelle) For another interviewee – an experienced principal – the difference between fragmented bits of information and interconnected knowledge is equivalent to the difference between rote learning and learning for understanding: "shifting from a student who knows s/he needs to memorize the material to one who understands, who really understands the topic and sees it from multiple perspectives. That, from my point of view, is the [interdisciplinary] approach." (Sivan)

In addition to content, the practitioners we interviewed also described other ways in which a shift to interdisciplinarity could impact classroom dynamics. By default, abandoning disciplinarity in Israel means departing from the mandatory curricula, which are overseen by the Ministry of Education's Pedagogical Secretariat. This comes with a renewed sense of freedom, which Ari, an experienced principal, called "complete autonomy", allowing teachers to do "whatever they want." While this principal wasn't happy with all his teachers' choices, he still called this aspect of interdisciplinary learning "a huge success." Another principal explained how this sense of freedom that derives from the lack of oversight inherent to interdisciplinarity affords a practice that he called "to flow," allowing the lesson to develop in unpredictable ways that aren't constrained by disciplinary boundaries: "all of my pedagogical sensors light up when a discussion in class flows and flows… looking back, […] these [interdisciplinary] lessons were much more interesting and instructive." (Amir) Another teacher reiterated this:

> We start talking about refugees in Israel [but] according to the curriculum we designed, next lesson is meant to be about the French Revolution… dammit, there is no matriculation, we just had an amazing discussion about immigrants' children, which is important from an ethical perspective, I go with it, happily! So, it will take some time, OK… fourteen-year-old's finally express their opinion about something… you want me to interrupt that? It's anti-democratic (Alex).

Some interviewees also tied interdisciplinarity to other pedagogical reforms that they hoped to implement. For example, one teacher explained how the interdisciplinary curriculum they designed was primarily intended to grant students more agency: "For us, interdisciplinarity came after we decided to focus on student proactivity as a pedagogical goal." (Neta) Another principal explained that "interdisciplinary learning at its best is something that is very, very independent for students. They know how to do it on their own and in groups. The teacher is a mediator not a lecturer…" (Sivan). One teacher explained that while inquiry learning was not necessarily contingent upon interdisciplinarity, the latter is "much more inviting, because it opens things up." (Jen) Some examples of project-based alternatives to traditional forms of teaching and learning that interviewees associated with interdisciplinarity included field trips, creative art projects, recording a podcast, and producing books.

A final feature of the classroom dynamics that our interviewees tied to interdisciplinary curricula is that it affords more meaningful learning for students. This can manifest itself in (a) a focus on skills rather than content;

(b) teaching content that is relevant to students' everyday lives; (c) improved emotional wellbeing; and (d) a deeper relationship between the teacher and the class. Several interviewees perceived interdisciplinary learning as an opportunity to focus on age-appropriate transferable skills, at the expense of discipline-specific content. One principal explained that there is not enough correspondence between the official disciplinary curricula overseen by the Ministry and students' stage of cognitive development; whereas "when we're talking about interdisciplinary pedagogy it means we aren't looking at each subject, we are looking at what skills the learner needs in the middle school." (Dvir) Ron explained that while interdisciplinary settings afford an opportunity to focus on skills, the nature of these skills is similar to those taught in traditional disciplinary lessons: "it's the same skills: reading, writing, comparing texts." In contrast, Neta described a unique skill that is inherently interdisciplinary:

> Once you connect the [multiple] disciplines, you understand complexity. If you bring a literary work that illuminates the aspects of dealing with a particular issue, then history will gain depth […] the connectedness allows us to deepen students' perspectives. A lot of times at the year's end [students] themselves tell us that they acquired diverse perspectives on events or phenomena, they tell us that they learned to look at the world in a more complex way.

For some educators, the main reason for adopting an interdisciplinary approach is because students are bored with disciplinary content or unable to relate to it: "I [also] teach history, and the student can't connect with that." (Esti) Along the same lines, one principal explained that the primary motivator for an interdisciplinary curriculum is to make learning more relevant to students' lives: "for it to annoy them, make them happy, do something to them… they may not remember the details, but they will remember the values that derive from it, the things that are relevant to their lives." (Sivan) Another principal explained that interdisciplinary learning is more relevant *and* more interesting, because "reality is interdisciplinary. You look at the Supreme Court [for example]; understanding what happens there at any given moment requires an understanding of civics, history, and sociology." (Amir)

Some teachers and principals identified interdisciplinarity as a setting that can also contribute to students' emotional wellbeing. According to one principal, "the main benefit is that it will be good for kids to come to school. It's considered almost taboo or rude to talk about the enjoyment of learning, the pleasure that Socrates talks about." From his perspective, "connecting learning to kids' lives will make it more interesting and by extension more pleasurable." (Amir) This idea related to another theme that emerged from our analysis. Some of the interviewees explained that interdisciplinarity enables teachers to forge deeper, more meaningful, relationships with their students, due to the greater number of teaching hours dedicated to interdisciplinary curricula, which essentially pools resources from multiple subjects: "…I get to see these students for all their difficulties, complexities, successes… these connections forged over time transform me into a meaningful figure for them." (Esti)

Teachers' room

Being a teacher extends beyond the classroom. The practitioners that we interviewed described various ways in which enacting a new interdisciplinary curriculum might relate more broadly to a teacher's professional identity and daily routines. For instance, one interviewee discussed how teacher training programs cultivate a disciplinary identity among trainees, which can be difficult to apply in an interdisciplinary setting. Others also identified a similar tension – when they assume a disciplinary identity, teachers have a sense of confidence grounded in their expertise; but at the same time, this limits opportunities to learn new content:

> This year I began teaching literature, which is something I've never done [because I am a history teacher], and I really enjoyed it. On the other hand, this raises the question of professionalism… I am the only person at school with an MA in history and I think I'm a good history teacher [so why should others teach history?]. There is a tension here. (Jason)

What characterizes the professional identity of interdisciplinary teachers? Given the requirement to teach content outside their realm of expertise, a teacher must be "open to learn, an autodidact, creative, think outside the box… there needs to be openness and desire, it won't work with everyone. For a teacher who's been in the system for thirty years it could cause an identity crisis." (Esti) Others mentioned a sense of professional loneliness that accompanies interdisciplinarity, which isn't backed by any formal body in the Ministry of Education: "I am doing something so lonely… When I talk about it with the head of History or Literature [at the Ministry] they are

shocked, so who's backing me?" (Adelle) Another teacher explained that the interdisciplinary approach requires a different disposition towards students:

> For my professional identity the success of the interdisciplinary program is a dream… if there are teachers that think that children, teens […] don't have a deep inner world or well-formed or interesting views, a teacher who believes that is unsuited for interdisciplinary teaching. Really. Interdisciplinary teaching is for teachers who believe that each student has depth, curiosity, an opinion […] whoever believes that is suited for interdisciplinarity. (Alex)

Almost all the practitioners we interviewed discussed the process of *developing* the interdisciplinary curriculum at length, identifying it as a unique experience that had an impact on their day-to-day lives at school. One teacher with three years' experience teaching interdisciplinary curricula described the norm at her school:

> We sit and build the curriculum; each teacher in the community comes from a different discipline, and then according to the topic we choose, everyone brings content from their own world… no year is like the previous one, because the curriculum is always being updated, and if there are new teachers I believe everyone needs to leave their mark, because otherwise it's like "let's find a lesson plan online and teach it", which is worthless… (Esti)

Designing the new curricula requires effort on behalf of the teachers, who don't always feel they've received adequate training: "no one taught me how to design an integrated curriculum." (Adelle) Indeed, one principal identified curriculum design as a major hurdle for enacting a new interdisciplinary curriculum: "[it] requires intense collaboration between teachers… how do you indicate that they're doing something amazing that not everyone can do?" (Amir) Given that the content in the humanities can be controversial, designing the curricula also generates an ethical discourse among teachers, who need to decide what's worth teaching and what is off-limits: "[the conflict with the] Palestinians is an explosive topic… we're not going to agree, as colleagues, we're not going to agree; we won't form a clear message on this issue […], which is fine, I love it!" (Alex) With regards to this tension, another interviewee suggested that teachers be allowed to choose their own path: "not everything will be dictated [to teachers]; there will be suggestions, but they won't be dictated." (Ron)

Designing the curriculum is typically done collaboratively, meaning that enacting an interdisciplinary curriculum requires intense teamwork, which tends to revolve around a weekly meeting that is seen as essential: "there is no such thing as cancelling the [interdisciplinary] staff meeting, it's our 'holy of holies.'" (Noam) Sometimes, collaboration can lead to power struggles between teachers of different subjects, which one principal called "the discipline wars." (Ari) Some of the teachers also drew a parallel between the collaboration among the teachers on the team and the ways in which students interact in class: "I do the same with the teachers as I demand from students. Meaning I form a group, make sure there is all kinds of enrichment and camaraderie, and that it is experiential… meetings are significant, not just coming together to chat." (Noam)

What purpose do interdisciplinary staff meetings serve? One of the teachers discussed emotional support, explaining that at a certain point "it really feels like family, you can share, everything said there stays there, I feel safe to vent… it's totally open." (Alex) Other teachers pointed out that they sometimes need their colleagues' professional guidance: "if I am a language arts teacher I will teach history if need be, but I will first sit with someone who is more professional." (Sarah) Others pointed out that collaboration affords an equal distribution of the workload: "in the end it pays off, because I wrote a [lesson] plan, and six others each wrote one, so we already have seven lesson plans." (Esti) Finally, one principal described how collaboration offers "a new group to belong to. I no longer belong to the literature staff, or bible, or history, I am part of a development staff… everyone contributes something that the others don't have" (Dvir).

Principal's office

A third realm of influence that interviewees tied to interdisciplinarity touched on the school's institutional structure and organizational culture. This category included strategies for implementation and potential organizational hurdles and benefits, timetables and schedules, and external partnerships. Several interviewees described who they think is best suited to lead the implementation of an interdisciplinary approach. One teacher said that to successfully enact an interdisciplinary curriculum, "you mainly need a brave principal," explaining how parents tend to challenge new initiatives. In her view, only the principal can stand up to parents, "and say 'listen, there is a cutting-edge program here, it's different, it's fresh, but it really connects learners to the content.'" (Esti) Another principal noted: "Parents today say, 'you need to give so and so [teaching] hours in a certain subject and suddenly you're making it interdisciplinary, are you giving less hours [in total]?'" (Natalie) What does

enactment look like? In some cases, our interviewees described an extended process led by a small group of "gung ho" teachers, for instance:

> We began with a curriculum that we built […] about topics we thought would interest the students… we always feel like we need to edit it, change it, add to it, move things around. In the first years, the curriculum was criticized a lot at school, the students were also baffled, and a lot of the teachers didn't know their role, it created a lot of confusion and we, a group of gung-ho teachers, kept developing it… by the second or third year we had a curriculum that was more organized and precise in terms of its goals, which was less confusing for students. (Sivan)

Most experienced interviewees described the first years of enactment as challenging; one principal went as far as declaring that "the chances of failure [in the first year] are almost 100%". (Dvir) Some schools enacted their interdisciplinary curricula gradually, while others did so only partially. One principal explained: "I am opposed to doing the whole school and prefer taking one grade, which will be a success. The kids will enjoy. We'll see some results. That's what I am after." (Sarah)

Organizationally, Israeli schools face several acute challenges that can be tied to interdisciplinarity. The interviewees identified three specific organizational problems that might be overcome by enacting an interdisciplinary curriculum: a surplus of subjects, a lack of teachers, and a lack of facetime for each teacher per class. One principal in a school with a well-established interdisciplinary curriculum explained: "if I teach disciplinarily, I am talking about twelve subjects for each Israeli student… so I ask myself, how is meaningful learning possible [with so many subjects]?" (Ari) Another teacher suggested that her principal chose interdisciplinarity because he thought: "I don't have enough literature teachers, so I can do humanities [instead] and the history teacher can teach literature too." (Adelle) Another principal also noted that "initially our goal was organizational, to give humanities teachers six hours [in each class] instead of the normal two." (Sivan) She explained: "Two hours a week isn't enough; a cancellation here, a field trip there, another event, and there is no connection [between the teacher and the class] … That was the need at the beginning."

Leveraging the interdisciplinary curriculum to overcome these challenges can require changes to the schedule, such as shifting from single-period to double-period lessons, yet along with the excitement about the organizational affordances of implementing a new interdisciplinary curriculum, interviewees noted challenges to planning a new schedule: I, right now, have no idea how I'm going to do it, really… I have teachers who supposedly have blank hours in their timetables, or I give some classes too many hours. This is where I am stuck." (Natalie)

Another problem that one teacher identified was that interdisciplinarity might serve as an instrument to accelerate the decline of the humanities in Israel's education system: "the school has to be very honest not to take teaching hours intended for Literature and History and allocate them to Math and English." (Adelle) Yet another challenge was the increase in workload that worried some of the interviewees. In response, most of them suggested freeing interdisciplinary teachers from some of their normal responsibilities and compensating them for developing the new curricula. In two cases, we were told about teachers who are paid the equivalent of a weekly teaching hour, which they dedicate to staff meetings and curriculum design. One teacher had another idea: "in my opinion… [they should] give us two days off [every year] so we can write lesson plans and develop new ideas, because there is no textbook, and usually it's on our own time. You need to fund [the work we do]." (Alex)

One principal with a well-established interdisciplinary curriculum discussed how "these are the places we can enjoy some freedom" from the rigorous oversight on the part of the Ministry of Education. However, he also bemoaned the lack of support and backing that are the result of being alienated from a system that is inherently disciplinary: "as far as I'm concerned, any cooperation with elements at the Ministry or the Municipality are a blessing… [I need] people to back us up." (Ari) (See Table 1 for a summary of the findings).

Table 1
Summary of findings: The potential impact of interdisciplinarity throughout school

	Classroom	**Teachers' room**	**Principal's office**
How is inter-disciplinarity enacted?	Content from multiple subjects is organized historically, topically, or by identity.	Teachers act as content developers, teamwork is essential.	Enactment can be partial or take years to implement; principal and teachers play leadership roles.

Potential benefits of inter-disciplinarity	*Students*: increased understanding, meaningful learning; emotional wellbeing. *Teachers*: sense of freedom. *Both*: better connections with each other.	Teachers develop a sense of belonging to a new group that provides emotional support; workload is distributed.	Better timetable organization; freedom from institutional oversight.
Hurdles to implementation		Teachers' training is less relevant; disconnect from broad professional community; teams may experience "discipline wars."	Difficulty organizing teachers' timetables; lack of institutional backing.

Discussion and conclusion

The teachers and principals we interviewed understood interdisciplinarity broadly, as an innovation that could have a major impact on life at school. And while we distinguished between the classroom, the teachers' room, and the principal's office for analytic purposes, our interviewees described intricate ways in which they overlap with one another. For instance, the lack of institutional supervision was viewed from the principal's office as an advantage (less restrictions) and a drawback (less backing). In the classroom, it crucially allows teachers to "flow"; whereas in the teachers' room, it was tied to feelings of loneliness and disempowerment. Based on this example and others like it, one key takeaway was that teachers and principals view interdisciplinarity as a broad and complex reform that cannot be contained within a single part of school life.

We also found that teachers and principals view interdisciplinarity simultaneously through all three theoretical lenses introduced in the background section. For instance, consider how teachers pool their hours when teaching interdisciplinarily. This shift in teachers' timetables has profound implications that extend across all three approaches. Cognitively, interdisciplinarity in this context affords drawing connections between subjects typically learned separately (Stevens et al., 2005), which interviewees saw as an opportunity to cultivate students' understanding. Socioculturally, it lays the foundation for new types of interactions between teachers and students that afford deeper, more meaningful relationships. Finally, viewed through a critical lens, changing teachers' timetables in this way is nearly impossible, due to pressure from parents, teachers' unions or government supervision. This example, and several others that emerged in our analysis, indicated that the three theoretical lenses of interdisciplinarity actually overlapped and interacted in educators' views. In future, this could form the basis of a grounded theory of interdisciplinarity at school, which is currently lacking.

Almost three decades ago, Lytle and Cochran-Smith (1994, p. 24) argued that "Missing from the field of research on teaching, then, are the voices of teachers themselves, the questions teachers ask, and the interpretive frames that teachers use to understand and improve their own classroom practices." This paper shows that teachers and principals understand interdisciplinarity in multiple ways, which overlap, complement, and contradict one another. It follows that the benefits they associate with interdisciplinarity extend across school, touching on content, students' wellbeing, teachers' professional identity, and even their terms of employment. Finally, enactment requires meticulous planning, and must overcome many hurdles.

Endnotes

(1) Another potential theoretical framing derives from Isaiah Berlin's distinction between "Enlightenment" and "Counter-Enlightenment" and its applications to curricular philosophy. The Enlightenment view corresponds with the cognitive lens, whereas Counter-Enlightenment corresponds with the sociocultural and critical lenses (cf. Mali et al., 2003).
(2) One of the scaffolds distinguished between multidisciplinary, cross-disciplinary, interdisciplinary, and transdisciplinary (cf. Julie Thompson Klein, 2010), and operationalized each term for curricular design.
(3) Interview protocols are available upon request. Please contact the corresponding author for more details.
(4) We used pseudonyms to protect the privacy of interviewees.

On-line designs for supporting teacher epistemic communities: A comparative analysis

Etan Cohen, Gideon Dishon, & Adam Lefstein
etancohen@gmail.com, gidi.dishon@gmail.com, alefstein@gmail.com
The Ben-Gurion University of the Negev

Abstract: Over the past four decades, various types of epistemic resources required for teaching, and alternative infrastructures for creating and disseminating them, have been proposed. Today's proliferation of online tools for teachers means that there are infinitely more possibilities, setting the stage for a reinvigorated discussion surrounding what teachers are expected to do, and how best to support them in their work. In this essay, we offer a comparative analysis of three online platforms for teachers, to identify contemporary conceptions of teaching and to highlight some of the considerations and tradeoffs that should be taken into account when designing such a platform.

Introduction

Over half a century ago, Derrida (1967/1997) foresaw "The end of the book and the beginning of writing" in the history of ideas. Contrary to the traditional philosophical view that sees language as a means to express an eternal truth – an undertaking he thought was epitomized by the book – Derrida argued that the meaning of a text is transient and contingent upon its readers. "The end of the book" thus acknowledges the limitations of language and ushers in a new era of philosophical inquiry, which Derrida called "the beginning of writing".

In a similar vein, we are currently witnessing a major shift in the history of teaching, driven in part by the emergence of online platforms for teachers that offer viable alternatives to textbooks. Like Derrida's notion of "the book", textbooks symbolize a definitive, finalized version of the curriculum, content, and means of its transmission to students. But contemporary information and communication technologies (ICTs) offer infinitely more design choices than traditional textbooks. As a result, questions pertaining to what teachers are expected to do, and how best to support their work, can be reevaluated in a new light. Like "the end of the book" – which is a precursor to "the beginning of writing" – the "end" of the textbook might bring about a "beginning" of teaching; a revitalized conversation about what teaching is, and what resources and infrastructures can best support it.

In this essay, we offer a comparative analysis of three online platforms for teachers. Our intention is to highlight possibilities afforded by emerging ICTs and discuss the ways in which they can position teachers vis-à-vis their students, the curriculum, and the teaching profession. For instance, should social networking technologies support teachers in sharing their work with one another? How much agency should teachers have in determining what, and how, to teach? What communities should teachers engage with in their work, and to what ends?

Resources for teaching

Epistemic infrastructure

With the goal of elevating teaching from "mere craft" (Shulman, 1986, p. 13) to full-fledged profession, Shulman identified and articulated several types of knowledge that master teachers display in their work, including content knowledge, general pedagogic knowledge, curriculum knowledge, pedagogical content knowledge, knowledge of learners, knowledge of educational contexts, and knowledge of educational ends. Shulman maintained that the study of best practice could enable researchers to articulate this knowledge, so that it might be disseminated to teachers as part of their training, through professional development, and by other means, thereby contributing to the improvement of teaching across the board.

In the years since, efforts to develop epistemic resources for teachers, and the means for their creation and dissemination, have advanced in several directions. Ball and Cohen (1996) suggested redesigning curricular materials so that they might also be used to disseminate epistemic resources pertaining to content, pedagogy, the curriculum itself, and more, to teachers. Davis and Krajcik (2005) envisioned "educative curricular materials" that help teachers anticipate and interpret learners' responses; enhance teachers' own knowledge of the subject matter; draw connections between different curricular units; understand the pedagogical considerations that drive curriculum designers; and promote teachers' ability to adapt existing curricula to their own particular needs. Hiebert et al. (2002) advocated a "knowledge base for the teaching profession". Notably, they detailed some characteristics required to ensure that resources for teachers would be useful and reliable. According to Hiebert et al., ensuring that resources are detailed, concrete, and specific, helps link them to practice. Organizing these

 © ISLS

resources according to problems of practice (not according to the theoretical distinctions favored by researchers) interconnects different types of knowledge. Making resources publicly accessible means they can be openly examined and widely consumed by colleagues. And finally, sound mechanisms for quality control ensure that the resources are accurate, verifiable, and continually improving. What might such a repository look like? Hiebert et al. call on readers to "imagine large digital libraries linking video examples of teaching, images of students' work, and commentary by teachers and researchers, all integrated around shared topics, and even shared lessons" (p. 8).

Epistemic Communities (ECs) offer another approach to creating and disseminating epistemic resources for teachers. ECs "consist of individuals with identical or similar 'frames of reference' and cognitive 'orientation systems'" (Hakanson, 2010, p. 1807). Underlying an EC is a triad of theory, codes, and tools shared by community members. A *theory* is any frame of reference shared by community members that provides the context required for sensemaking, be it an evidence-based scientific theory, a normative view of what is good or right, or a ubiquitous rule of thumb. *Codes* are the "symbolic means" (p. 1810) by which community members communicate with one another, including both ordinary and specialized language such as formulae, diagrams, etc. Finally, *tools* are tangible artifacts such as hardware and software that community members use to accomplish their work, to communicate with one another, and to store their communal memory. According to Hakanson (2010), the epistemic infrastructure provided by ECs streamlines knowledge transactions – namely articulation of new knowledge and replication of existing knowledge in new contexts – within the community (cf. Nonaka, 1991).

Glazer and Peurach (2015) offered two concrete examples of well-developed ECs that functioned as an infrastructure for creating and sharing knowledge within a professional community of teachers and other educational practitioners. In their own words, "shared tools, theories, and codes served as the thread connecting classrooms and schools" (p. 192) and led to the success of *Success for America* and *America's Choice*. Their analysis showed how the community's epistemic and social infrastructures enabled *Success for America* to draw on the shared experiences of teachers to inform the design of the curriculum. Similarly, they observed numerous cases in their study of *America's Choice*, where individual teachers' insights were integrated into the design of formal tools that were then disseminated, shaping activity throughout the community.

Communal infrastructure

In recent decades, sociocultural theories demonstrating how knowledge and other aspects of belonging to a particular community are interdependent have gained traction (e.g., Lave, 1991). Therefore, the expectation that teachers will simply draw on a public repository of epistemic resources may be unrealistic. While access to epistemic resources is crucial for supporting teachers in their work, a communal infrastructure is also likely vital.

Indeed, Shulman was ultimately dissatisfied with his earlier work because it focused on individual teachers and overlooked the communal infrastructure mediating their growth and activity. The alternative model that Shulman & Shulman (2004) proposed integrated two levels of analysis – individual *and* communal – and argued that the two co-constitute each other. Specifically, they posited that the individual teacher's vision, skills, understandings, and motivations were supported by the communal ideology, community of practice, knowledge base, and mutual support within which they were situated (and vice-versa: the communal is also shaped by the individual). In a similar vein, Lampert, Boerst, and Graziani (2011) showed how access to a shared knowledge base supported ambitious forms of teaching at scale when it was coupled with a robust social infrastructure. Their study showed how (a) teachers with students in common regularly shared their experiences and insights with their colleagues; (b) lesson plans were neatly organized and easily accessible to everyone; and (c) the entire staff was well-versed in a shared theory that served as a basis for the shared enterprise of planning and evaluating learning.

ECs similarly highlight the social infrastructure that can support effective knowledge work among teachers. In addition to the cognitive work they afford, shared theories, codes, and tools also lay the groundwork for *communication* and *collaboration* among colleagues. Moreover, belonging to an EC provides members with a sense of *identity*, which is mediated by their participation in the community. Finally, the "irreducible tension" (Wertsch, 1997, p. 6) between individuals and communities' cultural tools determines members' sense of *agency*. The measure of agency can increase or decrease, depending on the design of the tool: "in some cases the cultural tool dominates the picture… in other cases the cultural tool presents a wide range of possibilities for improvisation and the mediated action that emerges is more heavily shaped by the agent" (ibid.).

Mediating tools

Cognition can be viewed as a process that is distributed across agents' minds and their surroundings, including the tools that they employ (Brown et al., 1989). To ensure that tools are useful, their designers imagine how they will be used, and build into them a consequent set of affordances and constraints. A tool's *affordances* are the ways in which it can be used, which are "jointly determined by the qualities of the object and the abilities of the agent that is interacting" with it (Norman, 2013, p. 11); whereas *constraints* limit the ways in which one can

interact with a tool. For example, glass *affords* vision and *constrains* passage (Norman, 2013). Therefore, glass can be useful for designing a barrier that people are meant to see through, but not pass through. Importantly, affordances and constraints are not contradictory, but complementary. Together, they shape how a tool is used. To communicate a tool's intended use and affordances or constraints, designers use *signifiers*: "any mark or sound, any perceivable indicator that communicates appropriate behavior to a person" (Norman, 2013, p. 14).

The proliferation of ICTs in recent decades has led to an influx of educational technologies and online tools for teachers. These tools can be imbued with new types of affordances, constraints, and signifiers unavailable in traditional textbooks. They can include large amounts content; can be interactive and customizable; and can function as social networks for disseminating user-generated content and supporting teacher collaboration and mutual learning. Thus, ICTs can support novel forms of teaching, and can reflect evolving conceptions of what teaching is or what it ought to become. These emerging possibilities and views are reflected in the affordances and constraints embedded into the specific design of each tool.

Some concrete examples

To advance our understanding of how online platforms can support different forms of teaching, we offer a comparative analysis of three platforms: *The Lesson Planner*, recently launched by Israel's Ministry of Education; *Reading Like a Historian* (RLH), of Stanford's History Education Group; and *Sefaria*, a virtual Jewish library. These online platforms were chosen based on a purposive sampling that highlights maximum variation in terms of their epistemic and communal infrastructures (Patton, 1990). Specifically, we asked three questions. First, what epistemic and communal infrastructures does each platform provide? Second, how are the epistemic and communal infrastructures mediated by the online platforms, in terms of each platform's affordances, constraints, and signifiers? And finally, what vision of teaching and teachers does each platform reflect and support?

For the sake of clarity and coherence, we adopted ECs as an analytic lens, focusing on the epistemic and social infrastructures provided by each platform, as well as their intended uses. Specifically, we analyzed each of the websites (i.e., *tools*), asking what *theories* of teaching underlie them; what *codes* they use to talk about teaching; how they afford and constrain *creative knowledge work* by teachers; how they afford and constrain *communication and collaboration* among teachers; what sense of *belonging* and *identity* they seek to inspire and support; and how each site affords and constrains teacher *agency*.

The Lesson Planner

Design

The Lesson Planner offers Israeli teachers access to thematic units and lesson plans in math, science, language arts, humanities, and more, organized according to the official curricula for grades 1-10. For instance, a unit intended to support eighth grade history teachers includes three lessons on the Enlightenment. The first lesson focuses on Enlightenment epistemology, exemplified by Kant's dictum *Sapere aude!* ("have courage to use your own reason!"). The second lesson shifts to a discussion of society and governance, introducing the terms *social contract*, *separation of powers*, and *enlightened absolutism*. The final lesson surveys Diderot and d'Alembert's Encyclopedia, and its significance to the history of ideas. The unit's landing page includes a paragraph with some background information, followed by three buttons labelled "knowledge and big ideas", "skills", and "values". Underneath, there are three more buttons linking to the individual lesson plans. Links to the lesson plans also appear in a sidebar as well as a drop-down menu at the top of the page.

"Knowledge and big ideas" leads to a 1200-word essay on the Enlightenment that includes references to academic works. It articulates three big ideas that are the crux of the unit: "anything can be achieved through the power of mind", "the growth of knowledge advances human progress", and "ideas breed political change". "Skills" leads to a list of nine generic skills, such as "digital literacy" and "critical thinking," that the unit mediates. Each skill is briefly defined, and a table details the various components in the unit that are connected to each skill. Finally, "values" leads to a list of three virtues: "passion for learning", "respect for humankind and family members," and "commitment to Israel as a Jewish and democratic state," which are all supposedly strengthened by studying the Enlightenment unit. Here too there is a table with links, but there are no definitions or explanations.

Each individual lesson has its own landing page, with four tabs: "Knowledge in the lesson", "Skills in the lesson", "Values in the lesson", and "Proposals for building a lesson". Again, the knowledge tab offers a comprehensive essay, whereas skills and values are more telegraphic, offering titles (in the case of skills also brief definitions) and a table linking to relevant components of the lesson. The fourth tab leads to an interactive interface that assists users in constructing lesson plans based the unit's themes and resources. On the left is an empty lesson plan template, titled "my lesson", which is divided into three sections labeled *introduction*, *body*, and *conclusion*. The right side of the screen is similarly divided into the same three sections, including several proposals for

activities and assignments in each section. For instance, for the first lesson on the Enlightenment, there are three proposed introductions. The first suggests asking students to share what comes to mind in association with the word "light"; the second suggests writing "2+2=5" on the board and discussing with students what they know and how they know it; and finally, the third suggests contrasting epochs and events in the study of history.

Some of the assignments that appear on the right are interactive, allowing students to contribute by answering open-ended questions, commenting on a forum, highlighting text, etc. Some are collaborative, so that students can see each other's contributions, whereas others collect individual student answers and present them to the teacher in an LMS interface. As they scroll through, teachers can either drag and drop individual suggestions from the right to populate the empty sections of the lesson plan on the left, or they can create new assignments of various types (open question, highlight the correct answer, add comments to a thread, etc.). Once the lesson plan is complete, it is automatically saved to the teacher's profile pages, and s/he can share it with students via a link for distance learning, project it to a screen for face-to-face sessions, or print it.

Epistemic infrastructure: Theories and codes

The theories about teaching that are embedded into *The Lesson Planner* touch on content and structure. In terms of content, the site calls for a triple focus on knowledge, skills, and values. In the Israeli context, this is part of a broader effort to realign pedagogic practice with a view that assigns the education system responsibility to promote social values and cultivate learners' 21st century skills. Along these lines, Israel's principal education law was redrafted in 2000 to highlight educational goals that include love and respect for others; cultivating learners' personalities, creativity, and talent; and a set of skills and dispositions including intellectual curiosity, critical thinking, and ingenuity. In 2020, Israel's Ministry of Education drafted a strategic document entitled "Skills of the [ideal] graduate," calling for a greater focus on preparing graduates for the innovation age. Yet notwithstanding these frameworks, which are reflected in the general design of *The Lesson Planner*, the areas dedicated to knowledge, and the tools offered therein, are far more developed than those dedicated to skills and values.

As for structure, the platform assumes that individual lessons are insufficient for exploring big ideas, but that entire curricula are too broad. The middle ground – thematic series' of up to five lessons – is considered best. The platform requires any lesson, regardless of subject and age-level, to be structured similarly, with intro, body, and conclusion sections. Thus, the designers of *The Lesson Planner* view teachers of various subjects such as mathematics, science, and history, similarly. The codes throughout the site's interface reflect these two foci as well. The landing page for each unit and each lesson features multiple buttons and tabs labelled "knowledge and big ideas", "skills", and "values"; lesson plans are divided into "intro", "body", and "conclusion".

Communal infrastructure: Communication/collaboration, identity, and agency

The Lesson Planner allows teachers to easily share links to lesson plans with students. However, it does not afford collaboration among teachers: they cannot co-create new lessons, nor can they share their lessons with one another. By being open to *all* teachers, and to teachers *only*, the platform demarcates a professional identity that is determined by one's status as teacher and is uninfluenced by specialization or focus (e.g., subject matter). Teachers are encouraged to be agentive, abandon textbooks, and innovate by creating original lesson plans. Yet, the role of teachers is also heavily constrained. Though in theory teachers could rely on the platform to plan their own lessons, the platform's organization according to the existing curricula, the ease of drawing from available predetermined activities rather than creating new ones, and the requirement that all lessons be structured according to a general template, imply that teachers are encouraged to mostly stay within the vetted lesson plans.

Reading like a historian

Design

Stanford's *Reading Like a Historian* (RLH) platform offers teachers free access to over 150 lesson plans. According to the site, "each lesson revolves around a central historical question and features a set of primary documents designed for groups of students with a range of reading skills." For each individual lesson plan, there is a landing page with a brief introduction, an image, and links to downloadable materials at the bottom of the page. For instance, in *The battle of Lexington* lesson "students practice sourcing, corroboration, and contextualization as they weigh competing accounts of who fired the first shots of the Revolutionary War" (sheg.stanford.edu/history-lessons/battle-lexington). The landing page features downloadable teacher materials, student materials in English and Spanish, original documents (all three in PDF), and a PowerPoint file. Teacher materials detail specific instructions, scripted questions, and points to highlight for each PowerPoint slide.

Once teachers establish some basic facts about the battle, they are instructed to pose two questions: "What happened at the battle of Lexington? And who fired the first shot?". These questions are first addressed by

comparing two images depicting the battle, one by Canadian artist Henry Sendham in 1886 and the second by Thomas Doolittle, a silversmith who spoke with veterans of the battle, in 1775. Teachers are instructed to "make sure to highlight how each painting might be considered both trustworthy and untrustworthy" before moving on to a comparison of two additional accounts of the battle: a diary entry by a British soldier, and the testimony of 34 colonists. Ultimately, "students should note that evidence about who fired the first shot is contradictory" as they summarize what they have learned about the Battle of Lexington and about historical inquiry more broadly.

Epistemic infrastructure: Theories and codes

The theory underlying RLH touches on the purpose of history education, and on the role of teachers in realizing it. In his research, Wineburg (2001) has shown that professional historians ask a unique set of foundational questions when engaging with historical documents as they attempt to reconstruct and understand the past. However, the ultimate aim of history education in Wineburg's (2016) view is not historical at all, but rather to cultivate historical thinking among learners, with an eye on transferring and applying it to contemporary contexts.

This goal is achieved by means of four key heuristics, which are also codes that describe the authentic work done by historians as well as by students in the RLH class: *sourcing*, i.e., considering the document's source and purpose; *contextualization*, i.e., placing the document in a temporal and cultural context; *corroboration*, i.e., comparing the accounts of multiple sources against each other; and *close reading*, i.e., carefully considering an author's use of language and word choice (Riesman, 2012).

Communal infrastructure: Communication, collaboration, identity, and agency

The files that are available on the RLH platform are ready for use, and do not require any preparation. The site uses the PDF file format, which affords ease of use and consistent appearance in multiple interfaces, but is difficult to edit, thereby constraining modification. The implicit message to teachers is that designing the lessons does not fall under their auspices. The site does not afford any communication or collaboration between teachers, who are viewed as end users, not contributors. In terms of identity, history teachers are positioned as a bridge between expert historians and history students. They understand the purpose of history education and the codes that historians use; and they can make them accessible to learners by simulating historical inquiry. However, they are not expected to sift through archives seeking out primary documents that can shed light on the past. Teachers do not select which primary sources to teach, what questions to ask, or how to structure lessons in ways that are conducive to advancing learners' historical thinking skills.

Sefaria

Design

According to its *About* page, "*Sefaria* is a non-profit organization dedicated to building the future of Jewish learning in an open and participatory way". The site has two primary interfaces for interacting with hundreds of Jewish texts originating from across the globe and spanning thousands of years of authorship. The library interface allows users to search the entire corpus in various ways, such as a search bar, navigating to a particular passage (e.g., Genesis, 11, 4), or by topic (e.g., Yom Kippur). Selecting any passage in any work reveals a sidebar with links to all other passages throughout the entire corpus that cite it (or are cited by it), so that users can open multiple sources that are in conversation with one another, side-by-side. The sidebar includes additional functions, such as "chavruta" (=dyad), which provides a link to a video-chat room that users can share to learn a text together.

In addition to the interactive library, *Sefaria* also includes a *source sheet* function. Source sheets are blank documents that users can populate with texts, images, and videos that they upload or link to. In addition, users can search or navigate the library from within the source sheet interface and add select passages to their sheet. Alternatively, when a passage is selected from the library interface, it can be added to a user's source sheet through a dedicated "add to sheet" button on the sidebar. Source sheets are an invitation to users to articulate new meanings by placing existing passages from various sources side-by-side. Like other contemporary cloud-based word-processing software, *Sefaria*'s source sheets are collaborative, and can be edited simultaneously by multiple users. Source sheets have unique URLs, are attributed to their creators and saved to their profile pages, and are also published on a curated "community" page that is regularly updated. In addition to the platform's native functionality, *Sefaria* also actively maintains Facebook and WhatsApp groups for teachers. For instance, a *Sefaria* employee recently posted the following to a private Facebook group called "The *Sefaria* Classroom: Where Educators Share, Ask, and Think Together":

> Pop culture is definitely not my strong suit these days, but […] I find it's a nice way to engage students. I've put together a sheet of clips from *Ha-Yehudim Ba'im* ("The Jews are Coming"), a

> satirical (and irreverent) Israeli [TV] show, with some of the texts they reference or comment on. The sheet is collaborative, so you are all invited to add your own texts and clips you know of to this sheet. No need to restrict to The Jews are Coming, though! Any and all shows/movie clips are welcome!
>
> (https://www.facebook.com/groups/*Sefaria*.classroom/permalink/3927401540676757)

Attached to this post was a link to a source sheet on *Sefaria*, extending 25 pages long, which started off with the following explanation: "This sheet is a work in progress and collaborative, which means that anyone with a *Sefaria* account can add their own links and sources to this very sheet. Please contribute ...!"

Epistemic infrastructure: Theories and codes

According to one Jewish tradition, the Jewish canon contains infinite meanings that come to light as individuals engage with it over time (Hartman, 2002). Indeed, a hallmark of Jewish culture is that the same canonical texts have served as the foundation for contemporary discourses throughout the ages, resulting in a vast and interconnected web of texts that are in dialogue with one another, in which the same words and expressions have taken on many meanings when interpreted from within different socio-historical contexts (cf. Bakhtin, 1981). Along these lines, *Sefaria* embodies a theory of teaching that fuses together four key ideas: (a) intertextual (b) meaning making, that is (c) mediated through discourse and (d) pluralistic in nature.

The codes that *Sefaria* employs reflect how it combines two distinct worlds: Torah study and contemporary ICTs. For example, the source sheet interface is reminiscent of modern word processors, with "file", "format", and "insert" menus and a "share" button at the top. But the library's sidebar includes buttons such as "manuscripts", "Torah readings", and "Chavruta" – words drawn from the discourse of the Yeshiva world.

Communal infrastructure: Communication, collaboration, identity, and agency

Sefaria's design affords many forms of communication and collaboration among users. *Source sheets* can be collaboratively co-created; they are available through users' profile pages; and they have unique URLs that can be shared. *Sefaria*'s homepage also includes a "community" button linking to a curated collection of recently published source sheets. Finally, source sheets are indexed by the site, and are searchable according to lexical content, tags, and topic, which essentially makes them part of the Jewish canon. The *virtual library* interface also affords communication, by means of the "Chavruta" video chat function.

While *Sefaria* maintains separate Facebook and WhatsApp groups for teachers to share ideas and lesson plans, the platform does not distinguish between teachers and other users. In terms of identity, *Sefaria* positions teachers as members of an intellectual community that extends beyond formal education and seeks to blur the boundaries between school and the outside world. Because this intellectual community values novel contributions to an ongoing open-ended conversation, teachers are encouraged to be agentive in their engagement with sources. The site does not preselect what to teach or how to teach it, but rather affords opportunities to easily navigate a large corpus of data and to offer novel contributions by selecting specific passages to focus on.

Designing ICTs for teachers in a post-textbook age

Resources and infrastructure

In the previous section, we identified several key differences between the epistemic resources available on each of the platforms we surveyed. This comparison highlights the degree to which the theories, codes, and tools provided by each site cohere with one another. RLH's platform is markedly coherent. The site's codes all derive directly from the corresponding theory of history education, and the tools (e.g., PDFs and PowerPoints that serve as handouts, presentations, and lesson plans) are appropriate resources for mediating the types of interactions this theory calls for: a learning environment in which students can read "like historians".

Because it is trying to create a new type of learning experience that situates traditional Jewish texts within a contemporary digital context, *Sefaria*'s interface must bridge two distinct cultural worlds. The theory underlying it and the codes and tools featured on the site are complex and may not always cohere with one another. For instance, seasoned Torah scholars might easily navigate the traditional texts, yet still not comprehend the purpose of digitizing the library. Likewise, digitally literate individuals will quickly grasp the site's hyper-textual, collaborative, interface; but they may not identify with the goal of intertextual discourse-based meaning-making.

Finally, *The Lesson Planner*'s interface features a different type of tension. The platform's infrastructure outwardly embodies the view that teaching ought to focus simultaneously on knowledge, skills, and values. Yet, in practice, the resources it provides are almost exclusively focused on knowledge. This incongruence reflects the different forces at play within the Ministry of Education, whose influence is apparent in the design of the site. The

Ministry's leadership – responsible for outlining the *infrastructure* – is primarily political, and thus focused on the changing role of the education system in Israeli society, which is expressed in the emerging focus on skills and values. Yet the *resources* provided on the site were drafted by teachers and curriculum designers, whose perspective is shaped by their real-world classroom experiences, which tend to be knowledge focused.

Identity and agency

So, who *are* teachers and what are they expected *to do*? One crucial insight that emerged from our analysis touches on the communities that teachers are expected to belong to, which shape their professional identity. According to *The Lesson Planner*, all teachers – regardless of the subjects they teach or the age of their students – belong to a single professional community.

In contrast, RLH is geared specifically towards history teachers and designed to cater to the unique aims of history education. RLH recognizes the value of the unique thinking skills that professional historians apply when investigating the past and sees history teachers as central to translating and importing them into K-12 settings. Yet notwithstanding the overlap between the two communities, professional historians and history teachers do essentially different things. For historians, sourcing, contextualizing, corroborating, and close reading are a means to interpreting and understanding the past. Yet for teachers, the equation is reversed. Historical inquiry is a means that serves the purpose of developing learners' thinking skills, which they require to successfully navigate current affairs. Finally, *Sefaria* also recognizes a distinction between two communities of learners: everyday people, and teachers. But contrary to RLH, *Sefaria*'s aim is to blur the lines between the two communities, to the point where what goes on inside the classroom and what goes on outside of it are in direct conversation with one another and essentially part of the same project.

Different views of what teaching is, what teachers do, and what they need, also entail different measures of agency. History teachers are not historians and cannot be expected to curate the primary sources for their lessons, because they do not have the expertise or means required to do so. Therefore, the resources that RLH provides are intended for use as-is; they are packaged in a format that is not intended to be edited (e.g., PDFs). In contrast, *The Lesson Planner* sees lessons as flexible, and so long as teachers adhere to the basic guidelines for content and structure, they are encouraged to design individualized lessons. However, while it provides a proprietary drag-and-drop technology to support the design of new lesson plans, *The Lesson Planner* does not allow teachers to share their original work with colleagues. This may be due to quality control concerns, or because the government is unwilling to relinquish control over content, especially in light of the politically-charged public scrutiny of curricular materials that address controversial issues ([blinded], 2017). Finally, *Sefaria* affords creation *and* dissemination of resources created by teachers, because its purpose is to democratize meaning making and undermine existing power structures so that more people will partake in an ongoing conversation they may previously have been marginalized from.

Design tradeoffs

When resources are packaged in a ready-to-use format, as on RLH, they do not require much time or expertise to deploy; teachers can print PDFs and download PowerPoints in a matter of minutes. In contrast, navigating *The Lesson Planner* requires more time and expertise. Beyond the expectation that they will master its new drag-and-drop interface, teachers are also expected to choose from multiple suggested activities and resources, which is also time-consuming and expertise-dependent. Finally, using *Sefaria* to plan and teach a lesson requires even greater time, effort, and expertise, due to the requirement to curate different resources within a coherent theme.

Another important tradeoff concerns the interplay between quality assurance and teacher agency. The more agency teachers have in creating and disseminating content, the less oversight and control moderators have. This means that while a view of teacher-generated resources might seem appealing at first, there can be no guarantee that the resources they produce will be in line with the worldview the site is intended to advance. For instance, *Sefaria*'s moderators have no way of ensuring that teachers do not use the platform to create spurious connections or advance anti-democratic interpretations. *The Lesson Planner* can similarly be abused, but because lesson plans cannot be shared among teachers, the potential damage is relatively limited by the sites design constraints. And finally, RLH's approach means that quality of the materials on the site is assured.

Conclusion

How might the emergence of new ICTs reshape teaching? Replacing textbooks with online platforms does not in and of itself ensure qualitative shifts in expectations from teachers or in the types of resources they are provided. Indeed, educational innovation can result "in even more old-fashioned, traditional forms of teaching and learning – instructionism on steroids" (Sawyer, 2014, p. 729).

However, the mere presence of online platforms alongside textbooks brings the inevitability of the content-delivery approach into question and requires curriculum designers to justify their choices. For instance, social networking technologies potentially afford a bottom-up approach to curriculum design, whereby teachers are actively engaged in creating and sharing – not just delivering – educational content. But as we have seen, there are tradeoffs inherent to such a model. More teacher agency means less quality control and might require teachers to engage in a new line of work they may not be prepared for. In light of emerging ICTs, these are tensions that should be addressed either way.

Like other professions that have undergone fundamental changes in the information age, teaching may eventually adapt to new technologies. The multitude of platforms that already exist online offer diverse possibilities, requiring practitioners, policymakers, researchers, and others to stake their ground, and clearly articulate what types of infrastructures and resources they believe contemporary teachers need, and why.

"Learning Experiences, Technology, and No Grades" – What Students Expect from a Non-Formal Learning Setting Outside of School

Valentina Nachtigall, Nikol Rummel
valentina.nachtigall@rub.de, nikol.rummel@rub.de
Ruhr-Universität Bochum

Abstract: The present study investigates the expectations of 88 students towards their visit of an out-of-school lab (OSL) for social sciences and humanities and how these expectations relate to both their actual experiences of the visit and their situational interest in the project contents. OSLs are non-formal learning settings which are usually visited by whole classes and aim at authentically communicating scientific ways of thinking and working. In contrast to this goal, our findings suggest that the least students expect from an OSL visit is to get authentic insights into scientific research. They rather expect to have a nice time with their classmates and without pressure to perform. Our findings also point to the need to change these expectations, as especially the expectation to get authentic insights into scientific research positively correlated with students' reported experience of having acquired knowledge during their visit and their situational interest in the project contents.

Introduction

"Well, we'll see whether I'll do better or worse on the next exam [pause/interruption] but the teacher couldn't care less about what we're doing here anyway.[1] These thoughts were stated by a secondary school student at the beginning of a collaborative problem-solving activity that took place in an out-of-school lab (OSL) for social sciences and humanities during one of our previous studies (Nachtigall et al., 2020). The student visited the lab together with his whole educational science course and attended a one-day project which focused on principles of experimental design in educational science research. Similar to other non-formal learning settings outside of school (such as museums, science centers, science outreach programs, etc.), OSLs pursue the goal of fostering students' interest in and knowledge about scientific ways of thinking and working by providing them authentic insights into scientific endeavors (e.g., Scharfenberg & Bogner, 2014). These goals are partly in line with the expectations that students hold when visiting OSLs for *natural sciences*. As the findings by Garner and Eilks (2015) and Schwarzer and Parchmann (2015) demonstrate, students who visit those labs for natural sciences especially hope to conduct experiments (which is a typical scientific practice of natural scientists) and to have access to authentic scientific tools (Schwarzer & Parchmann, 2015) or at least to better laboratory equipment than in school (Garner & Eilks, 2015). In OSLs for *social sciences and humanities*, students usually cannot conduct hands-on experiments by applying, for instance, high-tech laboratory equipment. Instead, these labs implement problem- or inquiry-based learning activities in order to emulate core features of scientific inquiry and to provide students with authentic experiences of scientific ways of thinking and working (Pauly, 2012).

The effectiveness of OSLs for students' knowledge about and interest in scientific ways of thinking and working could be affected by students' expectations towards visiting an OSL. Findings from research on museum learning indeed demonstrate that the visitors' expectations (especially the expectation to learn something) affect the impacts of a museum visit on student learning (e.g., Falk, 2006). According to the contextual model of learning developed by Falk and Dierking (2004), the visitors' motivations and expectations represent one factor that affects the quality of a museum experience, and as Falk and Dierking (2004) state "When expectations are fulfilled, learning is facilitated. When expectations are unmet learning suffers." (p. 141).

In contrast to research on museum learning, research on OSLs has not yet focused on investigating students' expectations and the role that these expectations may play for the effectiveness of OSLs. But knowledge about students' expectations could be helpful in order to enhance the intended effectiveness of OSLs. One outcome variable that has been particularly focused on by previous research on the effectiveness of OSLs relates to students' situational interest. Situational interest is defined as "the psychological state of engaging or the predisposition to reengage with particular […] content" (Hidi & Renninger, 2006, p. 112), and is assumed to be first triggered and then maintained by (usually but not exclusively) external features, such as learning materials and activities, of the learning setting (Hidi & Renninger, 2006). However, so far, empirical evidence barely supports the intended effects of OSLs on students' development of (situational) interest or their acquisition of knowledge. For instance, large-scale studies conducted by Itzek-Greulich and colleagues (e.g., 2017)

 © ISLS

demonstrated no (partly even negative) effects of OSLs on both students' situational interest and achievement in chemistry. Thus, uncovering the expectations of students visiting an OSL may be helpful or even necessary in order to get a better understanding of the potentials and boundaries of OSLs for fostering students' knowledge about and interest in scientific ways of thinking and working.

Investigating the expectations of students who visit an OSL *for social sciences and humanities* may be particularly interesting and necessary as students tend to associate the work of scientists within the social sciences and humanities – in contrast to the work of natural scientists – with activities, such as teaching and helping others, but not with scientific research (e.g., Nachtigall & Rummel, 2020). Thus, one could assume that students' expectations with regard to their visit of an OSL for social sciences and humanities are not in line with the goal of OSLs, namely to provide students with authentic insights into *scientific* ways of thinking and working. This assumption is further supported by the student's statement above suggesting that students may hope to improve their achievement in school by visiting an OSL for social sciences and humanities or, at the same time, to just have a day off from school on which they do not have to meet any expectations from their teachers.

Against this background, the present study first explores the expectations of students who visit an OSL for social sciences and humanities (Research Question 1). For this purpose, we developed and tested a respective questionnaire. We then examine how students' expectations at the beginning of their visit relate to their actual experiences of the OSL (Research Question 2). Thereby, we aim to investigate whether or not students' initial expectations have been met during their OSL visit. Finally, we examine the relation of students' initial expectations to their (triggered and maintained) situational interest in the contents of the project (Research Question 3), whereby we investigate whether students' initial expectations are associated with an outcome variable that has been focused on in previous OSL research, and that is assumed to be linked to student learning.

Method

We developed a one-day project for an OSL for social sciences and humanities at a large German university. The project, entitled "*Media and its impacts – critical interpretation of study results and reflection on one's own media use*", primarily aimed at communicating social science research methods to students and consisted of two parts. While the first part of the project focused on the differences between correlative and causal evidence exemplified by studies investigating different impacts of media usage, the second part of the project tried to sensitize students for some actual risks while using media, or more specifically, while sharing personal data in social media. It should be noted that we designed our OSL project primarily as a project for educational science courses. However, after our first data collection with an educational science course and after the first COVID-19 regulations, we opened our OSL project for all interested courses in order to increase our sample size.

Participants

Participants were 88 high school students (Age: $M = 16.49$, $SD = 0.78$; 60% female) who visited the OSL as whole classes and with their teachers. In total, four classes from three schools attended the OSL. See Table 1 for an overview of the sample characteristics per class.

Table 1
Descriptive statistics of the sample separated by class

Course	School	Month of data collection	Number of students			Age
			Total	Female	Male	*M* (*SD*)
Educational sciences / 11th grade	A	March 2020	30	18	12	16.63 (0.81)
Mixed course / 10th grade	B	September 2020	23	10	13	16.35 (0.49)
Mixed course / 10th grade	B	September 2020	17	10	7	16.24 (0.44)
Psychology / 11th grade	C	November 2020	18	15	3	16.73 (1.22)

Measures

To investigate our research questions, we administered two online questionnaires that the students completed on laptops during their visit in the OSL: (1) A pre-questionnaire at the beginning of students' OSL visit and (2) a post-questionnaire at the end of the OSL project. The pre-questionnaire assessed students' expectations related to the OSL visit. The post-questionnaire measured students' experiences of their OSL visit and their situational interest in the contents of the OSL project.

The pre-questionnaire assessed students' *expectations* related to the OSL project by using two open-ended questions and eight scales with, in total, 24 items. We adapted the following *two open-ended questions* from Garner and Eilks (2015): (1) What do you expect from today's out-of-school lab visit? (2) Does the work in the out-of-school lab differ from regular lessons in school? – What do you think, what are the differences? Through a bottom-up process and, thus, grounded in the actual data, we developed six categories that classify the student answers to the first open-ended question (see Table 2), and ten categories for the student answers to the second open-ended question (see Table 3). Two raters coded 100% of the dataset and reached mostly satisfying agreements (see Tables 2 and 3). Prior to analysis, disagreements were resolved by discussion.

Table 2
Codebook for the student answers to the open-ended question #1

Category/ code name	**Description** Students expect …	**Example**	**κ**
INFORMATION ABOUT THE TOPIC	… to receive information about the topic of the project (i.e., media, its impacts, risks, and/or usage).	"Information about the correct usage of media"; "To learn a lot about the impacts of media"	.93
NEW (LEARNING) EXPERIENCES	… to gain (new) experiences more generally and/or to learn something (new).	"to gain experiences"; "to learn something new"; "new knowledge"; "to gain more knowledge"	.62
RESEARCH & UNIVERSITY	… to get insights into scientific ways of working and/or the university context.	"To get impressions of scientific work at the university"; "to gain more knowledge about the university and the things one can learn at the university";	.94
PERSONAL SURPLUS VALUE	… to make personally meaningful experiences.	"To learn more about me"; "To learn something for my future or for my life in general"	.61
INTERESTING CONTENTS	… interesting topics or an interesting project more generally.	"I hope it will be interesting"; "Interesting new insights"	.82
OTHERS	… nothing specific or exceptional things.	"I will let myself be surprised"; "to have fun and good collaboration"	.44

Table 3
Codebook for the student answers to the open-ended question #2

Category/ code name	**Description** Students think/describe …	**Example**	**κ**
MORE TECHNOLOGY	… that an OSL provides access to more/better technology and/or more innovative (modern) materials.	"maybe more work on computers and with technology more generally"; "regular instruction is not as modern as instruction in an OSL"	.86
NO PRESSURE AND GRADES	… learning in an OSL as being more relaxed than in school as they get no grades and have no pressure to perform.	"no grades → nor pressure to perform"; "the OSL is freer than regular instruction, there are no grades, less pressure, no compulsion"	.85
MORE COLLABO-RATION AND AUTONOMY	… that learning in an OSL offers more opportunities for self-directed and/or collaborative learning.	"More collaboration and personal decision-making"; "more collaboration"; "I think that one can perform more independently"	.97
MORE PRACTICE-ORIENTATION	… learning and the learning contents in an OSL as being more practice-oriented.	"the work in an OSL is possibly more practical than in regular instruction in school"; "more illustrative things"	.89
DIFFERENT CONTENTS AND TASKS	… that the contents and tasks in an OSL are different.	"I think that one works on more meaningful and modern topics than in regular instruction"	.75
SCIENTIFIC PRACTICES	… that OSLs employ certain research methods and/or that the	"the administration and analysis of surveys"; "maybe there are more	1.00

	learning activities are featured by elements of scientific practices.	experiments"; "one engages more with analysis and interpretation"	
DIFFERENT LEARNING ACTIVITIES	… that various features of the learning activities in an OSL differ from school.	"one works with more different methods and media"; "longer duration"; "the way how information is provided is different"	.51
MORE PROFESSIONAL	… features of OSLs that point to more professionalism.	"they know how one learns"; "the instructor will be more open to our criticism"; "It is more reputable here"	.88
MORE KNOWLEDGE AND INTEREST	… that learning leads to more knowledge than in school and/or is featured by higher motivation, fun, or interest.	"participating in the activities of the OSL is more driven by fun and interest"; "one becomes smarter"	.79
NO DIFFERENCES	… that there are no differences.	"Similar structure, almost no differences"; "no differences at all"	.65

We developed and partly adapted eight scales with *24 items* from previous OSL research (i.e., Garner & Eilks, 2015; Schwarzer & Parchmann, 2015) as well as from previous museum research (i.e., Phelan et al., 2017). The scales referred to the following expectations each measured through three items (all items started as follows: "During today's out-of-school lab visit it is important for me …"):

(1) Knowledge acquisition (e.g., "to extend my knowledge of educational science theories/concepts/topics.");
(2) Interest development (e.g., "to deepen my interest in educational science themes.");
(3) Reference to everyday life (e.g., "that the topics of the OSL project are related to my everyday life.");
(4) Social experience (e.g., "to spend time with my classmates.");
(5) Career orientation (e.g., "to get an impression of what it means to study at a university.");
(6) Scientific authenticity (e.g., "to work with contents, materials, or methods that are also used by real scientists.");
(7) Autonomy (e.g., "that the activities allow me to implement my own ideas.");
(8) Insights into research methods (e.g., "to learn something about research methods.").

Students responded to all items on a Likert scale ranging from 1 (*not true at all*) to 5 (*absolutely true*). As our OSL project was initially developed for educational science courses only, some of the items referred to the school subject/the discipline of educational sciences. However, as we opened our OSL project for all interested courses after the first COVID-19 regulations and our first data collection, we excluded four items that referred to expectations with regard to students' educational science classes in school (e.g., "to understand the relevance of topics from my educational science classes for my everyday life").

We included the remaining 20 items in a principal component analysis with varimax rotation in order to examine whether the eight theoretically assumed factors for assessing students' expectations could be found in our data. Using an eigenvalue of 1 or greater led to the extraction of five factors that explained 66% of variance. The first factor unified eight items from four different (initially assumed) dimensions (i.e., interest development: 3 items; knowledge acquisition: 1 item; career orientation: 2 items; insights into research methods: 2 items) that all somehow referred to the educational science discipline. Hence, we named this factor as KNOWLEDGE ABOUT & INTEREST IN EDUCATIONAL SCIENCES (*Cronbachs's* $\alpha = .88$). The second factor combined all three items of the dimension *scientific authenticity* and one item of the dimension *insights into research methods*, which did not refer to educational science research methods in particular but to research methods in general. We named this factor as AUTHENTIC INSIGHTS INTO SCIENTIFIC RESEARCH (*Cronbachs's* $\alpha = .78$). The third factor unified all three items of the autonomy scale, one item from the "reference to everyday life" dimension (see example item above), and the following item of the *social experience* dimension: "to have a nice time". We named this factor as NICE AND FREE TIME (*Cronbachs's* $\alpha = .74$). The two remaining items of the social experience scale, which both referred to the expectation to spend (a nice) time with one's classmates, loaded on the fourth factor, which is why we stuck with the original name SOCIAL EXPERIENCE (*Cronbachs's* $\alpha = .77$). One last item of the CAREER ORIENTATION scale (see example item above) loaded on the fifth factor. We will use these five dimensions for our present analysis of students' OLS expectations.

The post-questionnaire measured students' *experiences* of the OSL project by using the same, but slightly rephrased, items as in the pre-questionnaire for assessing students' expectations (e.g., "During today's out-of-school lab visit, I learned something about research methods"). We again excluded the four items that referred to educational science classes in school, and conducted an exploratory factor analysis. The results revealed a factor solution that differed from the solution for the dataset of the pre-questionnaire. Moreover, the extracted factors could not be comprehensibly interpreted. As we, moreover, aimed to compare students' initial expectations with their actual experiences, we decided to form the same five scales as for the dataset of the pre-questionnaire, namely: KNOWLEDGE ABOUT & INTEREST IN EDUCATIONAL SCIENCES (8 items: *Cronbachs's* α = .89), AUTHENTIC INSIGHTS INTO SCIENTIFIC RESEARCH (4 items: *Cronbachs's* α = .67), NICE AND FREE TIME (5 items: *Cronbachs's* α = .84), SOCIAL EXPERIENCE (2 items: *Cronbachs's* α = .81), and CAREER ORIENTATION (1 item).

For assessing students' *situational interest*, we used the scale from Lewalter and Willems (2009). Building on the assumption that situational interest is first triggered and then maintained (e.g., Hidi & Renninger, 2006), the scale consists of six items (e.g., "To what extent was the engagement with the contents of this project exciting for you?") that assess *triggered* situational interest (catch dimension) and of further six items (e.g., "To what extend would you like to learn more about certain topics of the project?") that measure *maintained* situational interest (hold dimension). Students replied to all items on a scale from 1 (*strongly disagree*) to 5 (*strongly agree*). The internal consistencies of the catch (*Cronbachs's* α = .95) and hold items (*Cronbachs's* α = .86) are satisfying.

Procedure

Table 4 shows the procedure. It should be mentioned that we conducted the OSL project in collaboration with social psychologists from another university who were responsible for the second part of the project and who administered a questionnaire assessing students' usage of media which is not the focus of the present paper.

Table 4
Procedure of the present study

Pre-questionnaire (duration: 15. Min.)	
Part 1: Critical Interpretation of study results (2.5 hours)	Collaborative problem solving & presentation of results in whole class
	Short break
	Instruction + collaborative problem solving
Lunch break (1 hour)	
Part 2: Reflection on own media usage (2 hours)	Questionnaire assessing students' usage of media (not focused on in this paper)
	Interactive workshop with small-group activities and whole-class discussions
Post-questionnaire (duration: 15. Min.)	

During the first part of the project day (after filling in the pre-questionnaire), students were asked to collaboratively analyze the design of one out of three published studies on the relation between the use of different media (i.e., social media or media with violent content) on the one hand and different personal characteristics (i.e., mental and physical well-being, empathy, or aggressive behavior) on the other hand. Specifically, students were asked to think about the possible results that could be revealed by the study at hand and whether the study could test a causal hypothesis. The student groups created posters summarizing their thoughts and presented them to the whole class. Afterwards, they received an instruction on why correlation studies cannot yield causal evidence, which is a typical misconception of students and usually part of their solution generated during the initial collaborative problem-solving activity. Finally, students were asked to collaboratively develop a study design which would allow for testing a causal hypothesis. Afterwards, their ideas were discussed in the whole class and the instructor presented an ideal solution, namely the conduction of a controlled experiment.

During the second part of the project (after a lunch break), students first reflected on their own use and perception of different internet applications by filling in a questionnaire. Afterwards, they discussed (in small groups and the whole class) potential benefits and risks of sharing personal information on social media and the opportunities to improve one's internet privacy. They also received brief instructions on these topics. After the second part of the project and, thus, at the end of their OSL visit, students completed the post-questionnaire.

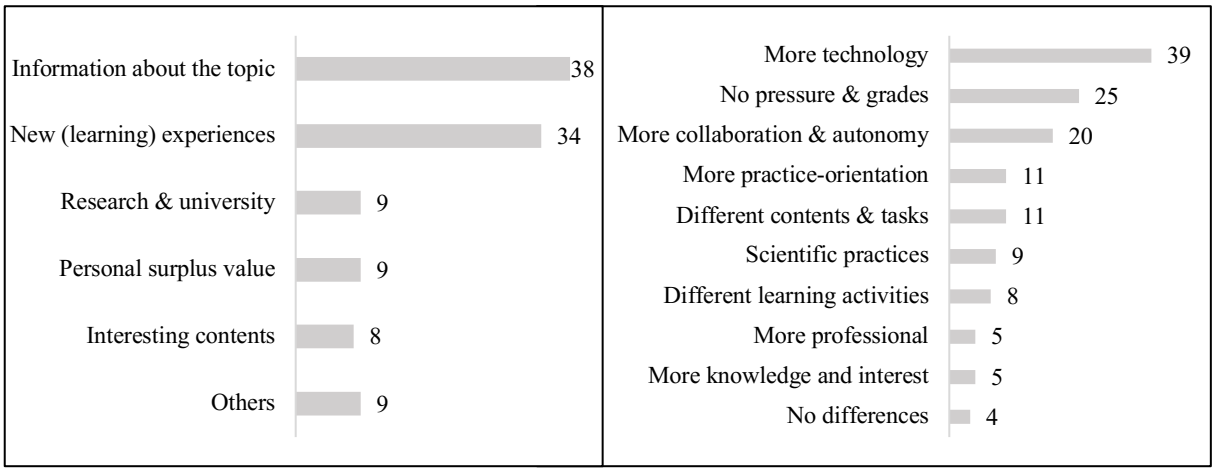
Results

Research question 1: Expectations

With respect to our first research question (i.e., what do students expect from their visit of an OSL for social sciences and humanities?), the analysis of the student answers to the two open-ended questions reveals that

students especially expect to get INFORMATION ABOUT THE TOPIC of the project (here: media) and/or to gain NEW (LEARNING) EXPERIENCES more generally. This may be exemplified by the following two student answers to the first open-ended question: "I expect that we will learn something new, e.g., how to better deal with media." or "Getting to know new things, maybe about the negative impacts of media.". Students, moreover, think that their work in the OSL differs from their regular instruction in school in particular with regard to their access to materials and tools that are featured by MORE TECHNOLOGY. Students further think that learning in an OSL, in contrast to learning in school, is featured by NO PRESSURE AND GRADES and/or MORE COLLABORATION AND AUTONOMY. One student, for instance, gave the following answer to the second open-ended question: "more relaxed atmosphere, no pressure to perform, better technology". Other students stated: "The work with technical devices and more work in groups could be a difference to school." or "more digital, more independent work". Figure 1 shows the descriptive statistics of the coded student answers to the two open-ended questions.

Figure 1
Absolute frequencies of the coded answers to the open-ended question #1 (left diagram) and #2 (right diagram)



Students' responses to the close-ended items further show that they especially expect to have a NICE AND FREE TIME (M = 3.79; SD = 0.71) in which they are enabled to work in a self-directed way on contents that are related to their everyday life. What they expect the least is to get AUTHENTIC INSIGHTS INTO SCIENTIFIC RESEARCH (M = 3.22; SD = 0.96). Students' expectations with regard to SOCIAL EXPERIENCES (M = 3.51; SD = 1.13), CAREER ORIENTATION (M = 3.48; SD = 1.41), and KNOWLEDGE ABOUT AND INTEREST IN EDUCATIONAL SCIENCES (M = 3.47; SD = 0.85) are almost equally high and range between the two former described expectations.

Research question 2: Experiences

The descriptive statistics show that students had high SOCIAL EXPERIENCES (M = 3.99; SD = 1.05) during their OSL visit. They, moreover, experienced their visit as a NICE AND FREE TIME (M = 3.84; SD = 0.89). Compared to these rather social and emotional experiences, students experienced their OSL visit as less beneficial for both their KNOWLEDGE ABOUT AND INTEREST IN EDUCATIONAL SCIENCES (M = 3.13; SD = 0.86) as well as their CAREER ORIENTATION (M = 2.74; SD = 1.18). Their experiences with regard to gaining AUTHENTIC INSIGHTS INTO SCIENTIFIC RESEARCH (M = 3.46; SD = 0.88) ranges in the upper middle of the previous four types of experiences.

To investigate our second research question (i.e., how are students' expectations regarding their OSL visit related to their experiences of their OSL visit?), we first conducted a Wilcoxon signed-rank test (as most of the data deviated from normality) in order to examine the differences between students' initial expectations at the beginning of their OSL visit and their actual experiences at the end of their visit. We then calculated the correlations between the two sets of variables. For CAREER ORIENTATION (z = -3.63, p < .001) and KNOWLEDGE ABOUT AND INTEREST IN EDUCATIONAL SCIENCES (z = -3.96, p < .001), the results of the Wilcoxon test demonstrate that students' expectations were significantly higher at the beginning of their OSL visit than their respective experiences at the end of their visit. For SOCIAL EXPERIENCES (z = -3.41, p = .001) and AUTHENTIC INSIGHTS INTO SCIENTIFIC RESEARCH (z = -2.09, p = .037), the results show that students expectations were significantly lower at the beginning of the OSL project than their experiences of the project at the end of their visit. We found no significant difference with regard to the variable NICE AND FREE TIME (z = -1.23, p = .22). For the correlational analyses, we calculated spearman rho and used an alpha level of .05. The results are depicted in Table 5.

 © ISLS

Table 5
*Correlations between initial expectations and actual experiences (Note. **p < .01 and *p < .05)*

	Initial expectations				
Actual experiences	Knowledge & interest	Authentic insights	Nice and free time	Social experiences	Career orientation
Knowledge & interest	r_s = .51**	r_s = .31**	r_s = .15	r_s = .13	r_s = .35**
Authentic insights	r_s = .17	r_s = .24*	r_s = .07	r_s = .11	r_s = .11
Nice and free time	r_s = .29**	r_s = .30**	r_s = .35**	r_s = .25*	r_s = .19
Social experiences	r_s = .21	r_s = .08	r_s = .18	r_s = .36**	r_s = .15
Career orientation	r_s = .28**	r_s = .32**	r_s = .14	r_s = .17	r_s = .13

As these results demonstrate, except for career orientation, all variables of the same dimension significantly and positively correlate with each other. For instance, if the expectation to increase one's knowledge about and interest in educational sciences is high at the beginning of the OSL visit, the respective experience of having increased one's knowledge and interest is also high at the end of the OSL visit. The correlational analyses further suggest differentiated experiences of the OSL visit depending on the initial expectations. For instance, the higher students expected to get authentic insights into scientific research at the beginning of their visit, the higher did they experience the OSL project as one that (1) promoted their knowledge about and interest in educational sciences, (2) provided them authentic insights into scientific research, (3) enabled them to have a nice and free time, and (4) offered career orientation. On the contrary, the initial expectation to have a nice and free time during the OSL visit is only positively associated with the experience of the OSL visit as nice and free time.

Research question 3: Situational interest

To investigate our third research question (i.e., are students' expectations towards their OSL visit associated with their situational interest in the contents of the OSL project?), we again conducted correlational analyses and calculated spearman rho. The results reveal that both students' triggered and maintained situational interest at the end of the OSL visit positively and significantly correlate with their initial expectations to (1) increase one's knowledge about and interest in educational sciences (catch: r_s = .38, p < .001; hold: r_s = .31, p = .003), (2) get authentic insights into scientific research (catch: r_s = .29, p = .007; hold: r_s = .22, p = .04), and (3) get impressions helpful for one's career orientation (catch: r_s = .27, p = .01; hold: r_s = .22, p = .04). The expectations to have a nice and free time as well as to make social experiences during the OSL visit do neither correlate with students' triggered situational interest (nice and free time: r_s = .20, p = .06; social experiences: r_s = .12, p = .27) nor with their maintained situational interest (nice and free time: r_s = .14, p = .19; social experiences: r_s = .07, p = .52).

Discussion

The findings of the present study on students' expectations towards their visit of an OSL (out-of-school lab) for social sciences and humanities (Research question 1) demonstrate that secondary school students have rather unspecific and broad expectations (e.g., "making new learning experiences" or "more technology") and especially hope to have a nice and relaxed time without pressure to perform and in which they can work independently and collaborate with their classmates. Students expect the least to get authentic insights into scientific research, which is, however, generally a goal of OSLs and was indeed the primary goal of the OSL project in which the present study took place. A possible explanation for this result may relate to the fact that the social sciences and humanities as well as scientists within these disciplines are barely associated with science and research (Nachtigall & Rummel, 2020). Thus, our findings point to the need to foster students' beliefs and conceptions about social sciences and humanities, and (maybe even thereby) their expectations towards visiting an OSL for social sciences and humanities. However, our findings also suggest that OSLs may have the potential to change these beliefs, as students experienced the OSL project at the end of their visit (Research Question 2) as one that provided them with insights into scientific research (i.e., this experience was significantly higher as the respective initial expectation). Consequently, to enhance the effectiveness of OSLs, one could assume that students have to visit an OSL multiple times: first to adjust their expectations, and then to increase their knowledge about and interest in scientific research. Our findings further support the assumption developed and tested in the context of museum research that the visitors' expectations affect the quality and experiences of their actual visit of a museum (Falk

& Dierking, 2004). Specifically, our correlational analyses suggest that the more students expected to increase their knowledge about and interest in educational sciences or to get authentic insights into scientific research at the beginning of their OSL visit, the more did they experience the OSL project as one that (1) promoted their knowledge about and interest in educational sciences, (2) provided them authentic insights into scientific research (correlated only with the respective initial expectation), (3) enabled them to have a nice and free time, and (4) offered career orientation. On the contrary, the initial expectation of having a nice and free time – what the students in the present study expected the most – correlated only with the experience of the OSL project as one that enabled them to have a nice and free time. The same is true for students' situational interest (Research Question 3). That is, while the expectations to increase one's knowledge and interest related to educational science, to get authentic insights into scientific research, and to receive information helpful for one's career orientation positively correlated with students' situational interest in the contents of the OSL project, the initial expectations of making social experiences and having a nice and free time did not correlate with students' situational interest. To conclude, although more research is required to further investigate students' expectations towards visiting non-formal learning settings, such as OSLs, and the role that these expectations play for different learning outcomes, the present study indicates that students' expectations relate to both their actual experiences of the OSL visit and their situational interest in the contents of the OSL project. With a better and deeper understanding of students' expectations towards visiting an OSL (for social sciences and humanities), future research could investigate ways for adjusting students' expectations and, in turn, for improving their actual experiences and learning outcomes.

Endnotes

Abstract: We developed the Systems Thinking (ST) and Computational Thinking (CT) Identification Tool (ID Tool) to identify student involvement in ST and CT as they construct and revise computational models. Our ID Tool builds off the ST and CT Through Modeling Framework, emphasizing the synergistic relationship between ST and CT and demonstrating how both can be supported through computational modeling. This paper describes the process of designing and validating the ID Tool with special emphasis on the observable indicators of testing and debugging computational models. We collected 75 hours of students' interactions with a computational modeling tool and analyzed them using the ID Tool to characterize students' use of ST and CT when involved in modeling. The results suggest that the ID Tool has the potential to allow researchers and practitioners to identify student involvement in various aspects of ST and CT as they construct and revise computational models.

Introduction

Many of our current societal and ecological challenges involve complex systems composed of interconnected elements. From global pandemics to climate change, these challenges require systems thinking (ST) to identify how various elements contribute to emergent effects in large-scale systems. ST enables individuals to investigate how a single part of a system can have broader impacts on the whole system (Meadows, 2008). Given the complexity of most systems, computational thinking (CT) is often required to approach these problems. CT is a sensemaking process where one decomposes a problem in a systematic way, translates it into an algorithm that can be interpreted by an information processing agent, and iteratively refines it based on new observations and new data inputs (Grover & Pea, 2018; Wing, 2006). Because both ST and CT are important for addressing problems involving complex systems, it is fruitful to consider their synergies for investigating phenomena (Shin et al., in press; Weintrop, 2016). ST and CT are also increasingly being emphasized as important elements of science education on a global scale, being incorporated into official policy documents in many countries including the U.S., the U.K., and Taiwan (Csizmadia et al., 2015; NGSS Lead States, 2013; So et al., 2020).

These efforts to include ST and CT as key aspects of science education create a need for developing new research tools for characterizing and monitoring student use of these types of thinking (Grover & Pea, 2018). One framework that recognizes the interconnected relationship between ST and CT is the "ST and CT Through Modeling Framework," which describes how student use of ST and CT can be supported through the construction of computational models (Bowers et al., 2022; Shin et al., in press). This framework seeks to clarify and expand the conceptualizations of ST and CT as proposed by the NGSS as well as demonstrate the synergy between ST, CT, and modeling (NGSS Lead States, 2013; Shin et al., in press). Given its focus on the interconnectedness of ST and CT, this framework provides a foundation for developing an instrument for observing student use of ST and CT as they construct and revise computational models. Such a tool may facilitate researchers in recognizing instances of and patterns in students' use of specific ST and CT aspects as they construct and revise models. In this paper, we first summarize our conceptualization of the three main components of our framework (ST, CT, and modeling) and how these components combine to form five computational modeling practices. We then describe how we developed a research tool based on this framework to explore student use of ST and CT as they constructed and revised computational models using a semi-quantitative computational modeling tool. Finally, we provide examples of how this tool can be used to identify and categorize student use of ST and CT.

Theoretical Approach

Systems thinking is an approach to exploring a phenomenon as a network of elements that work together to create a system with emergent behavior that is more than the sum of its constituent parts (Arnold & Wade, 2015; Forrester, 1971; Meadows, 2008). We define an "element" as a key part of a system that can be independently described yet interacts with other aspects of the system to impact the overall behavior of that system. Many

 © ISLS

complex phenomena can be described as a series of interacting elements with feedback relationships and informational delays that often generate counterintuitive behaviors (Booth-Sweeney & Sterman, 2007; Cronin et al., 2009). To fully engage in ST, students need to move beyond simple linear causal reasoning to a system behavior perspective so that they can identify common structural patterns found within and across systems. Our framework identifies five major aspects of ST: (1) defining a system's structure and boundaries, (2) engaging in causal reasoning, (3) recognizing interconnections and identifying feedback, (4) framing problems or phenomena in terms of behavior over time, and (5) predicting system behavior based on system structure (Shin et al., in press).

Computational thinking has many definitions ranging from being grounded in mathematics and data analysis (NRC, 2012) to being an aspect of sensemaking centered on formulating questions through testing models and simulations (Schwarz et al., 2017; Weintrop et al., 2016) to thinking like a computer scientist (Grover & Pea, 2018; Wing, 2006). Synthesizing these approaches, we define CT as a form of sensemaking that uses an iterative and quantitative approach to decompose a phenomenon or problem to explore, explain, and predict the behavior of that phenomenon or to find a solution to a problem through the creation and iterative revision of algorithms (Shin et al., in press). Our framework identifies five major aspects of CT: (1) decomposing problems such that they are computationally solvable, (2) creating computational artifacts using algorithmic thinking, (3) generating, organizing, and interpreting data, (4) testing and debugging, and (5) making iterative refinements.

In addition to ST and CT, modeling forms the third component of our framework. Modeling is the process of creating a representation of a phenomenon such that the representation can be used to explain or predict the behavior of that phenomenon (Harrison & Treagust, 2000; Schwarz et al., 2009). From this perspective, models are viewed not just as the product of scientific inquiry but as essential tools for supporting scientific reasoning and sensemaking (Schwarz et al., 2009). Additionally, analyzing existing models can help one gain insight into different aspects of a phenomenon and predict its future behavior (zu Belzen & Krüger, 2010). Scientists and students often use models to represent their conceptualization of a phenomenon so that they can synthesize and communicate their ideas to others (Gilbert & Justi, 2016). Within our framework, students utilize both ST and CT approaches as they engage in the process of modeling.

While researchers (Berland & Wilensky, 2015; Wing, 2017) claim that CT and ST are intertwined and support each other, we view CT and ST as co-equal, yet distinct in the context of modeling because of their unique ways of approaching problems. CT focuses on designing solutions through computation while ST analyzes the various relationships among elements in a system (Shute et al., 2017). Our framework thus defines CT and ST as separate entities and identifies five computational modeling practices that combine aspects of ST and CT: (M1) characterize problem or phenomenon to model, (M2) define the boundaries of the system, (M3) design and construct model structure, (M4) test, evaluate, and debug model behavior, and (M5) use model to explain and predict behavior of phenomenon or design solution to a problem (Bowers et al., 2022). Students engage in these modeling practices as they construct, test, revise, and use their computational models. Students characterize the phenomenon (M1) as they discuss and unpack key elements of the phenomenon under study and as they learn about new elements of the phenomenon. Students define the boundaries of the system (M2) and design/construct model structure (M3) as they discuss which variables to add to their models and set relationships between these variables respectively. Once students have built their initial models, they can analyze the model output and should compare this output to real-world data or their emerging understanding of the phenomenon to identify and modify flaws in their model, thus testing and debugging of model behavior (M4). Finally, students use their models to construct explanations of the phenomenon or predict how the system will behave under different circumstances (M5). Each of these practices are supported by a combination of aspects of ST and CT (Table 1).

Table 1
The computational modeling practices and associated ST and CT aspects

Computational Modeling Practice	Associated ST and CT Aspects
M1. Characterize Problem or Phenomenon	ST: Define a System CT: Decompose Problems
M2. Define System Boundaries	ST: Define a System, Frame Phenomena in Terms of Behavior over Time CT: Decompose Problems, Create Algorithmic Artifacts
M3. Design and Construct Model Structure	ST: Engage in Causal Reasoning, Recognize Interconnections and Feedback, Frame Phenomena in Terms of Behavior over Time

 © ISLS

	CT: Create Algorithmic Artifacts
M4. Test, Evaluate, and Debug Model Behavior	ST: Define a System, Predicting System Behavior Based on System Structure CT: Generate and Interpret Data, Test and Debug, Make Iterative Refinements
M5. Use Model to Explain and Predict Behavior of Phenomenon	ST: Predict System Behavior Based on System Structure, Engage in Causal Reasoning CT: Generate and Interpret Data, Test and Debug, Make Iterative Refinements

Although the science education community has established ST, CT, and modeling as key learning goals, we know relatively little about how to support students in these practices. We used the ST and CT Through Modeling Framework to develop a research tool that could help researchers investigate student use of ST and CT as they build, test, and revise models. We hypothesize that such a tool could help researchers identify which aspects of ST and CT students use more frequently or find challenging. Therefore, we investigate these research questions: How can one characterize patterns of student use of specific aspects of ST and CT as they construct and revise models? Which aspects seem to be more challenging for learners? To address these questions, we developed the ST and CT Identification Tool (ID Tool) to classify instances of students using aspects of ST and CT as they build, test, and revise models.

Methods

Study context and data sources

The data used to develop and evaluate our ID Tool came from a high school chemistry unit on evaporative cooling designed to meet NGSS learning goals and enacted at a Midwestern U.S. STEM school. We designed this unit around Project-Based Learning (PBL) principles (Krajcik & Shin, 2022) in which students explore the phenomenon of evaporative cooling, use a driving question and a driving question board and conduct investigations to address the driving question. This unit also centered on students building and revising models of phenomena using an open-source semi-quantitative computational modeling tool called SageModeler (Figure 1). SageModeler is a modeling tool that allows students to construct semi-quantitative models without using formal programming language (https://sagemodeler.concord.org). Students can test these models using a simulation function to generate model output and using graphs constructed from the output or imported from real-world data. To collect data on students building and revising their models, we used 15 hours of screencasts from five pairs of students for a total of 75 hours. Screencasts record the students' actions on their laptop screens and record student audio while they are building and manipulating their computational models.

Instrument development

Content validity refers to the extent all aspects of our framework align with the literature. For content validity, we conducted an extensive literature review of CT, ST, and modeling, and deconstructed each practice into smaller aspects and sub-aspects (Shin et al., in press). We examined specific aspects of ST and CT to define how students should be able to use their knowledge through five modeling practices. During the development processes, our research team – including experts in science, learning sciences, learning technology, and science education – defined, reviewed, and revised the modeling process and specified aspects of ST and CT in the context of modeling through discussing disagreements and ambiguities, continuing (or updating) our literature review, and teachers' and students' data collected from implementation. Our research team expanded on this work, developing a theoretical framework describing how specific aspects of ST and CT are applied through five distinct modeling practices. These processes confirmed the theory-based modeling process outlined in the framework, ensuring that the ST and CT aspects were operationalized to monitor student involvement in these aspects while modeling.

Construct validity is the extent to which the indicators of our ID Tool measure our intended constructs. To accomplish construct validity, our approach focuses on defining indicators (evidence) clearly and comprehensively and describing measurable (observable) behaviors that are present when learners are utilizing the desired ST and CT aspects through modeling. We first decomposed the various aspects of ST and CT associated with each modeling practice into smaller sub-aspects. For example, the computational modeling practice of "test, evaluate, and debug model behavior" (M4) is supported by the ST aspects of "defining a system" and "predicting system behavior based on system structure" along with the CT aspects of "generating, organizing, and interpreting data," "testing and debugging," and "making iterative refinements" (Table 1). These ST and CT aspects can in turn be broken down into more specialized sub-aspects. Within the CT aspect of "testing and

debugging" we identified three key sub-aspects associated with the modeling practice of "test, evaluate, and debug model behavior": "detecting issues in an inappropriate solution," "fixing issues based on the behavior of the artifact," and "confirming the solution using multiple starting conditions."

We then identified specific learner-generated behaviors or knowledge products that can be associated with one or more of these sub-aspects of ST and CT. These behaviors were operationalized as indicators. In this study, we are specifically focusing on indicators associated with "testing and debugging" as the literature strongly suggests that students often have difficulty fully participating in its associated ST and CT aspects (Grover & Pea, 2018). The six indicators associated with the (M4) modeling practice behavior are listed below, along with their respective ST and CT aspects and sub-aspects.

- **4A**. *Analyzing and Sensemaking through Discourse*. ST: defining a system (redefining model structure) and predicting system behavior. CT: testing and debugging (detecting faults and fixing faults)
- **4B**. *Analyzing Model Output: Simulations*. ST: Not applicable (NA). CT: interpreting data (generating data, analyzing data), testing and debugging (detecting faults, confirming solutions), and iterative refinement (verifying solutions)
- **4C**. *Analyzing Model Output: Graphs*. ST: NA. CT: interpreting data (generating data, analyzing data), testing and debugging (detecting faults, confirming solutions), and iterative refinement (verifying solutions)
- **4D**. *Analyzing and Using External Data*. ST: NA. CT: interpreting data (generating data, analyzing data) and iterative refinement (verifying solutions)
- **4E**. *Using Feedback*. ST: defining a system (redefining model structure). CT: testing and debugging (fixing issues) and iterative refinement (making modifications and verifying solutions)
- **4F**. *Reflecting upon Iterative Refinement*. ST: defining a system (redefining model structure). CT: testing and debugging (fixing issues) and iterative refinement (making modifications and verifying solutions).

The modeling research team also reviewed the indicators to determine if they plausibly indicated student use of individual aspects of ST and CT. Once these indicators were reviewed, we further refined and developed them into a four-part classification system (ranging in ascending order from Level 1 to Level 4) to explore the sophistication of student use of these aspects. We then conducted an interrater reliability test for these indicators, which demonstrated a 91.7% agreement (Cohen's Kappa, .87) between two independent coders.

Data analysis and findings

To code students' collaborative interactions as they built a computational model with SageModeler, we analyzed screencast data using Atlas.ti to organize the data according to the four levels of the ID Tool and to determine the relative frequency of each of these six indicators. The patterns of each group as well as among groups were analyzed to characterize how students used ST and CT aspects during modeling and which aspects seemed challenging for learners. Below we summarize how student behaviors served as evidence for ST and CT by matching indicators from the ID tool with observations from our study.

The computational modeling practice of "test, evaluate, and debug model behavior" occurs as students evaluate their models and consider changes they need to make so that their models more accurately reflect their understanding of the phenomenon. Given the various approaches students can take to evaluating and revising their models, we have identified six observable indicators as evidence that students are involved in different aspects of this modeling practice as listed above as 4A-4F. As students worked on refining their models with their partners, they often discussed specific model relationships and/or broader model behavior. For example, when evaluating their early model, two students had this conversation regarding relationships between variables:

> "Student 1: As the molecular energy increases, that makes the molecular spacing of the substance increase. That's good. And then the spacing of the air molecules increases, this [molecular spacing] stays the same until it [spacing of the air molecules] gets small as there's not a lot of space. Student 2: Makes sense. Student 1: We can change this [the relationship between spacing of air molecules and molecular spacing]. Student 2: Yeah, I don't think that makes sense. Student 1: Is it the other way then? Student 2: Maybe?"

This conversation is an example of indicator 4A, students participating in analyzing and sensemaking of model structure through discourse. At Level 1, students verbalize the changes they made to their model or describe the area of their model they believe needed further revisions, but do not provide reasoning for making these changes or why an area of their model needs improvement. If a student verbalizes reasoning but does not participate in a mutual dialogue with their partner, they are considered performing at Level 2. To progress to Level 3 requires that students engage in a back-and-forth dialogue by providing reasoning for making key changes to

their model. Evidence for Level 4 would be a student exchange in which they consider how changes to their model would impact the behavior of the model. Because the students in this example provide a brief amount of reasoning as they are trying to justify the relationship between the spacing of air molecules and molecular spacing and both students contribute to the discourse (although Student 2 does so in a minimalist manner), we consider this to be evidence of students participating at Level 3 for Indicator 4A.

In addition to listening to student discourse, we observe students using model output features to test their model's behavior. SageModeler offers two ways of generating and analyzing model output: manipulating variables using the simulation tool and generating graphs. Both actions produce observable indicators (4B and 4C, respectively). The simulation tool allows students to manipulate the relative amount of each input to test its impact on model behavior (Figure 1A). If students adjust the relative amount of one or more input variables, but do not verbalize their interpretation of this process, we consider this evidence of some attempt to interpret data, even if only at Level 1. Once students begin verbalizing their interpretation of the testing process (either by identifying specific flaws in their model or by stating that their model is functioning in accordance with their expectations), we can map their progress to Level 2. Identifying Levels 3 and 4 requires that students participate in a meaningful back and forth dialogue with either their partner, one or more peers, or a teacher. If the conversation focuses on the smaller aspects of model behavior (centering on a single causal chain), we consider this evidence of Level 3 for interpreting data using the simulation tool, while evidence of Level 4 would require a more holistic discussion of the model (e.g., focusing on how multiple causal chains impact each other).

Students can also use SageModeler to generate graphs that analyze the relationships between two variables from their model (Figure 1B). If students unsuccessfully attempt to make a graph of two variables from the model output, we consider this evidence of Level 1 for indicator 4C. If students successfully make a graph of two variables, but do not discuss their interpretation of this graph, their behavior can be categorized as Level 2. Evidence for Level 3 requires students to participate in a dialogue where they discuss their interpretation of the graph and its implications for those two variables in isolation from the broader context of the model. If students consider the implications this graph has for both these two variables and broader model behavior, this is considered evidence for Level 4 for generating and analyzing data, detecting faults, and confirming and verifying a solution. In Figure 1A, these students used the simulate feature to look at their model output, but neither student verbalized this process in a meaningful way, so we inferred that the students were performing at Level 1 for indicator 4B. The students who made the graph in Figure 1B verbalized their interpretation of the graph, stating, "This graph shows that as IMF increases the potential energy increases but then plateaus. That makes sense to me." This is evidence of Level 3 performance for indicator 4C.

Figure 1A
Student use of "Simulate" feature in SageModeler.

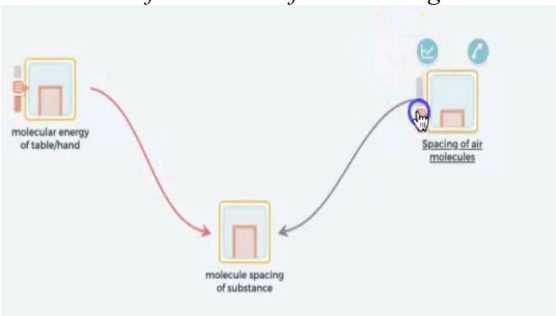

Figure 1B
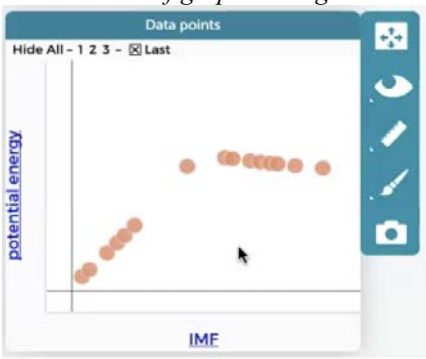
Student use of graphs in SageModeler.



Just as students can analyze their model output to see if their model behaves according to their understanding of the phenomenon, students can also examine external data sources to verify if their models accurately describe the phenomenon as evidenced by indicator 4D. When students superficially refer to the existence of data or loosely reference dubious data sources, they are at Level 1. At Level 2, students reference external data (from real-world observation or specific information provided by instruction or readings) to inform or justify changes made to their models, but do not actively compare these data to their model output. Once students progress to comparing specific pieces of real-world data to their model output, they can be said to be engaging at Level 3. This is particularly evident if they input quantitative external data into the modeling program and directly compare it to their model output (Figure 2). Finally, if students compare and contrast their external data to model output and discuss the validity of the external data, this is evidence of Level 4 performance. In

Figure 2, the students input real-world data from an experiment into SageModeler but did not actively compare these data to their model output, indicating a Level 2 performance.

Figure 2
Students inputting external data

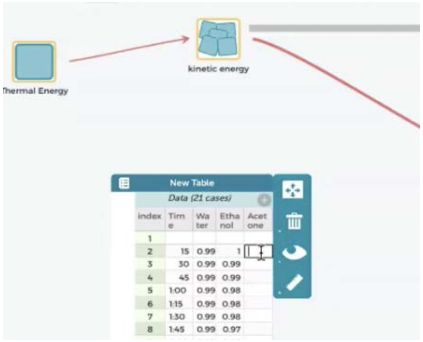


Figure 3
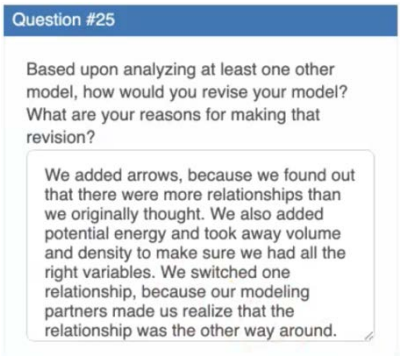
Student's written reflections on iterative refinement



Another important way students can receive feedback on their models is through discussions with peers or a teacher, which can inform further revisions, allowing students to engage in using feedback to inform model revisions (Indicator 4E). If the feedback students receive does not inform any changes to their model or prompt further analytical discourse, they are at Level 1. Note that if the feedback they receive is inappropriate and students do not discuss why this feedback was inappropriate their behavior would still be indicative of a Level 1 performance. Students who use this feedback to make changes to their models but have neither a discussion with their partner before making these changes nor test their models after making these changes are at Level 2. Once students use this feedback to either spark an analytical discussion or analyze their model's behavior after making recommended changes, they are operating at Level 3. If students then address the originator of the feedback or have a conversation with another student group about why they made these changes or what new insights have emerged from their testing and debugging of these changes, their behavior can be categorized as being at Level 4. For instance, one of their peers asked another pair to remove "density" as a variable from their model, arguing that it was not necessary to explain the phenomenon. This pair of students then removed the density variable but did not discuss why they were removing this variable. We classify this performing at Level 2.

Finally, students should be given opportunities to reflect on the changes they have made to their models. Students can participate in the process of reflecting upon iterative refinement (4F) through discussion or through writing as seen in Figure 3. Student level of expertise is suggested by the depth and richness of the insights they exhibit into their own revision process. When students give surface-level feedback on the quality of their models at a given point in time, without considering the changes they have made or the reasons for making these changes, they are performing at Level 1. To infer Level 2 performance, students list specific changes that they have made to their models, but do not provide any detailed reasons for making these changes. Evidence for Level 3 performance requires that students reflect upon specific changes to their models and explain their reasoning behind these changes. Finally, students performing at Level 4 emphasize broader changes that have occurred to their models over a longer period (often across multiple revisions) and provide an explanation as to how their model has evolved. In Figure 3, a pair of students list the changes they have recently made to their models and give specific reasons for making these changes (peer feedback and changes in conceptual understanding). As this reflection focuses on more immediate changes and not broader patterns, it is evidence of Level 3 performance. Overall, these results support Research Question 1 (How can one characterize patterns of student use of specific aspects of ST and CT as they construct and revise models?) as they demonstrate how our ID Tool can be used to identify and classify specific instances of students using ST and CT as they are testing and debugging their models.

Using our ID Tool, we examined the screencasts of five student groups during an evaporative cooling unit. We then compared the relative amount of time (as determined by the number of 10-minute intervals where students were involved in at least once in a respective indicator) these students spent participating in each of the six sets of behaviors we viewed as indicators of involvement with the modeling practice of testing and debugging (Table 2). Incidents were recorded for each 10-minute block and data from all five groups were aggregated to compare the relative amount of time coded for the presence of each indicator. Time points where students were not exhibiting any indicators were excluded from this data set and students could exhibit multiple indicators within one 10-minute block. The results suggest that students spent a large portion of their time using discourse-based strategies to analyze their models (as seen by their high use of Analyzing and Sensemaking of Models through

Discourse [4A], 59.5%) and often utilized the simulation features present within the modeling program. However, these students seem less likely to use external data sources to drive their revision process ([Indicator 4D], 15.1%) and even more hesitant to use graphs to analyze their model output ([Indicator 4C], 3.2%). This suggests that additional scaffolds are likely needed to support student participation in these activities. It is important to note that although students were more likely to participate in Analyzing and Sensemaking of Models through Discourse (Indicator 4A), many exhibited performance only at Level 1 and Level 2 behaviors, which might indicate that performing at higher levels for these indicators were more challenging for them. For instance, we observed several instances where the student in charge of the cursor dominated the sensemaking discussion, while their partner provided minimal feedback or verbal sensemaking support. Overall, these results address Research Question 2 (Which aspects seem to be more challenging for learners?) by suggesting that aspects associated with Indicator 4C are more challenging for students or are less supported by either the curriculum or their teachers compared to aspects associated with Indicators 4A or 4B.

Table 2
Relative time spent participating in each indicator for all five groups

Indicator	Total time Spent*	Relative Percentage
4A. Analyzing models: Discourse	75 (G1:13, G2: 24, G3: 16, G4: 9, G5: 13)	59.5
4B. Analyzing Model Output: Simulations	48 (G1: 4, G2: 15, G3: 12, G4: 5, G5: 12)	38.1
4C. Analyzing Model Output: Graphs	4 (G1: 0, G2: 0, G3: 4, G4: 0, G5: 0)	3.2
4D. Analyzing External Data	19 (G1: 6, G2: 6, G3: 3, G4: 2, G5: 2)	15.1
4E. Using Feedback	36 (G1: 11, G2: 5, G3: 3, G4: 11, G5: 6)	28.6
4F. Reflecting upon Iterative Refinement	41 (G1: 3, G2: 12, G3: 11, G4: 5, G5: 10)	32.5
Total	223 (G1:37, G2:62, G3: 49; G4:32 G5:43)	

Note: * Total number of 10-minute coding blocks where indicator is present at least once. G: group. GX: total coding blocks where indicator is present. Due to students often participating in multiple indicators in a single 10-minute block and the "relative percentage" referring to the percentage of coding blocks where this indicator is present, the sum of the relative percentages does not add up to 100%.

Conclusions and implications

These results demonstrate how the ID Tool can be used to characterize patterns and challenges of student use of specific aspects of ST and CT as they construct and revise models. While the instrument described in this paper focuses on aspects of ST and CT used during model revision, we have also developed other indicators for ST and CT that need to be validated. A draft of these additional indicators can be found at https://tinyurl.com/2ft6rkza**.** Building off the ST and CT Through Modeling Framework, our ID Tool seeks to connect abstract ideas of student cognition with concrete indicators that can be observed through screencasts, classroom videos, or direct observation of students in classrooms. As each indicator is grounded in specific aspects and sub-aspects of ST and CT, it can be used to track how students are using ST and CT in various learning activities across disciplines. Therefore, this tool can be used to develop future research instruments such as teacher and student interview protocols and classroom observation instruments as well as assist with creating ST and CT integrated learning activities. While the ID tool is primarily designed for research use, it can be modified to be used by teachers to help them identify moments where students are using ST and CT. Overall, our ID Tool represents an important step in developing a meaningful instrument for monitoring student use of ST and CT while constructing and revising models in realistic classroom settings. Further validity studies based on students' data in various learning contexts are needed to iteratively revise this ID Tool as an evidence-based principled tool to observe student use of ST and CT as they construct and revise computational models. We are also in the process of utilizing this tool to further investigate how students utilize ST and CT aspects within a computational modeling context. Given the increased need and benefits to incorporate ST, CT, and modeling into science education, there is a growing demand for tools that can support researchers, curriculum developers, and teachers in classifying instances of

 © ISLS

students use of these practices. Our research efforts on the ID Tool seek to further research in ST, CT, and computational modeling and promote the integration of these three research fields to support student learning.

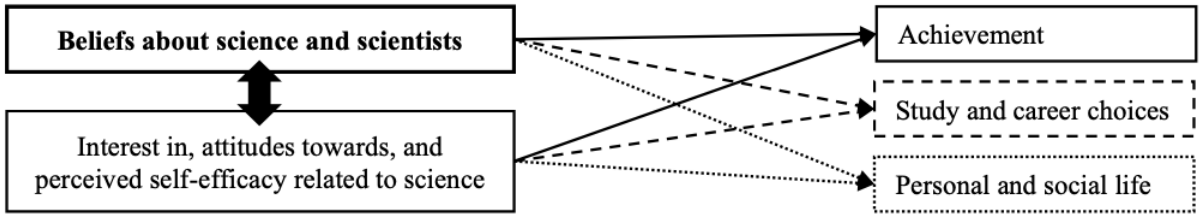
Abstract: The aim of this paper is to investigate students' and teachers' conceptions about the work of mathematical scientists, and to explore possible relations to mathematics teaching. Therefore, we conducted an exploratory interview study with 14 9th graders and 5 mathematics teachers. The results show that students have inadequate and limited conceptions about the work of mathematical scientists. The belief that mathematical scientists do the same kind of mathematics as students do in the classroom – namely calculating – but on a higher level supports the assumption that students' conceptions of the work of mathematical scientists are also based on their experiences in the classroom. We discuss the findings in light of previous research on images of mathematics, naïve epistemological beliefs about mathematics and conceptions about mathematicians. We further derive ideas for fostering more accurate conceptions in students.

Introduction

Several researchers (e.g., Christidou, 2011; Finson, 2002; Nachtigall & Rummel, 2020) have assumed that students' conceptions about science and scientists – especially in the field of STEM – are interrelated with their interest in and their attitudes towards science, and, therefore, affect their achievement as well as their study and career choices (see also Figure 1).

Figure 1
Model on the effects of students' beliefs about science and scientists (Nachtigall & Rummel, 2020, p.641)



Students' who have incomplete or negative conceptions of science and scientists are, for example, less likely to pursue science courses and enter a science-related career (Stamer, Kubsch et al., 2019). Consequently, it is necessary to explore and understand students' conceptions. Only if educators have some understanding of students' conceptions, they will be able to effectively and positively impact these conceptions through instruction (Finson, 2002).

Previous studies have shown that students often have limited, inaccurate, and stereotypical conceptions about science and scientists. For example, the results of the study by Newton and Newton (1992) show that the majority of students conceptualize science as the processing of substances for making new materials (a kind of applied chemistry) or as the study of living things, especially of animals. Research on students' images of scientists further demonstrates that many students picture scientists as older or middle-aged Caucasian men who wear lab coats, glasses and/or beards, and work in laboratories surrounded by symbols of research, knowledge, and technology, such as test tubes, Bunsen burners, flasks, and bottles (see Christidou, 2011; Finson, 2002). Especially with regard to mathematics Barbeau (1990, p. 42, as quoted in Picker & Berry, 2000) concludes that there is "probably no area of human activity […] as afflicted as mathematics with a gap between the public perception of its nature and what its practitioners believe it to be." Furthermore, Furinghetti (1993, p. 34) argues that mathematics "is a discipline that enjoys a peculiar property: it may be loved or hated, understood or misunderstood, but everybody has some mental image of it." Inaccurate or stereotypical conceptions about mathematics and mathematical scientists may hinder students' study of mathematics (Picker & Berry, 2000). The results of a study by Köller et al. (2000), for instance, show that students' beliefs about the nature of knowledge

 © ISLS

and the process of knowledge acquisition in mathematics influence their interest, their learning, and, consequently, their achievement in mathematics. It is likely to assume that students' conceptions about typical activities of mathematical scientists may also influence their interest, their learning, and, thus, their achievement as well as their study and career choices in mathematics (see Figure 1). However, in contrast to students' beliefs about the nature of knowledge and the process of knowledge acquisition, little research has been focused on students' perceptions about mathematical scientists until now. Especially, so far, students' conceptions about the work of mathematical scientists have not been explicitly investigated in detail.

Against this background, it appears essential to investigate students' conceptions about the work of mathematical scientists. Therefore, the aim of this paper is to investigate students' perceptions about typical activities of mathematical scientists. Subsequently, students' conceptions can be changed and, as a result, their thinking about their roles as future mathematicians can be facilitated and extended (Rock & Shaw, 2000). However, if inadequate and stereotypic conceptions can be found, it is important to explore where these perceptions arise from to then be able to derive specific interventions to foster more adequate conceptions. Obviously, students' perceptions about the work of mathematical scientists are likely mainly based on their classroom experiences. Thus, additionally, teachers' perceptions about typical activities of mathematical scientists are also investigated, in order to explore possible relations to mathematics teaching.

Students' conceptions about mathematics and the work of mathematicians

Students often have a negative image of mathematics (e.g., Furinghetti, 1993; Howson & Kahane, 1990; National Research Council, 1989) and naïve epistemological beliefs about mathematics (e.g., Köller et al., 2000; Schoenfeld, 1988) as well as limited conceptions about mathematicians and their work (Malkevitch, 1997; Picker & Berry, 2000; Rock & Shaw, 2000).

With respect to *images of mathematics*, several researchers (e.g., Furinghetti, 1993; Howson & Kahane, 1990; National Research Council, 1989) have shown that many people have a negative image of mathematics. The National Research Council (1989, p. 43) portrayed the following picture of mathematics:

> Unfortunately, as children become socialised by school and society, they begin to view mathematics as a rigid system of externally dictated rules governed by standards of accuracy, speed and memory. Their view of mathematics shifts gradually from enthusiasm to apprehension, from confidence to fear. Eventually, most students leave mathematics under duress, convinced that only geniuses can learn it.

Consequently, Howson and Kahane (1990) talk about the "mathematics' image problem".

A comparable picture was found in previous studies with regard to *epistemological beliefs about mathematics* (e.g., Köller et al., 2000; Schoenfeld, 1988). Epistemological beliefs are individuals' representations about the nature of knowledge and the process of knowledge acquisition (Hofer & Pintrich, 1997). Focusing on mathematics, Schoenfeld (1988) first investigated epistemological beliefs of students in a qualitative study. The results show that students believed that finding the right answer and expressing it in the right form is what matters. Moreover, students viewed themselves as passive consumers of others' mathematics. Schoenfeld assumes that these perceptions are largely affected by the experiences that students make in mathematics classes. In the mathematics classroom – according to Schoenfeld – the subject matter is presented, explained, and rehearsed; there is little sense of exploration or of the importance of understanding. He concludes that through such mathematics teaching, students learn only to master algorithmic procedures, but not to think mathematically. The results of the study by Köller et al. (2000) also show that students primarily emphasize the schematic-algorithmic orientation of mathematics and of mathematics teaching. The majority of the students agreed with the following statements: "Mathematics is the retention and application of definitions, formulas, mathematical facts, and procedures.", and "Doing mathematics means: applying general rules and procedures to specific tasks." Moreover, students seem unfamiliar with a relativistic scientific-theoretical position that emphasizes the constructive and processual character of mathematics. Furthermore, the results by Köller et al. (2000) show that students' epistemological beliefs about mathematics influence their interest, their learning, and, thus, their achievement: Students with the belief that mathematics is simply the application of solution algorithms to given tasks are less interested and obtain lower achievement, whereas students with a relativistic conception of mathematics demonstrate higher interest in mathematics and, as a likely consequence, gain higher achievement.

But not only the images of mathematics and students' epistemological beliefs about mathematics are inadequate. Many people also lack knowledge *about what it is that mathematicians actually do* (e.g., Malkevitch, 1997; Picker & Berry, 2000). From mathematicians' point of view, important mathematical activities of mathematicians mainly relate to participating in original research, conjecturing, generalizing, and exploring as

well as communicating, proving, and making connections (Brandt et al., 2016). Malkevitch (1997, p. 93) pointed out that students "can not connect the value of the study of mathematics with what mathematicians really do. […] students have learned when to 'call' or hire a doctor, electrician, geologist, or plumber, but not when to 'call' or hire a mathematician." Students' beliefs about the work of mathematicians probably constitute a part of their epistemological beliefs about mathematics. However, these beliefs about the work of mathematicians or scientists more generally are of particular interest with respect to students' study and career choices "because many young people base their occupational choices on these simplified conceptions" (Stamer, Kubsch et al., 2019, p. 85; see also Figure 1). However, so far, research has not focused on explicitly investigating students' conceptions about typical activities of mathematicians in detail. To our knowledge, there are only two studies conducted by Rock and Shaw (2000) and Picker and Berry (2000) that focused primarily on students' conceptions about mathematicians. These studies offer first insights into students' conceptions about the work of mathematicians: Students believe that mathematicians do applications similar to those they have seen in their own mathematics classes (e.g., arithmetic computation, area and perimeter, and measurement). Both Rock and Shaw (2000) and Picker and Berry (2000) attribute the inadequate and limited conceptions about mathematicians (and their work) to the experiences that students made in mathematics classes. Mathematics classes, in turn, are influenced by teachers' beliefs related to mathematics. For example, the results of a study by Stipek et al. (2001) show that teachers with more traditional beliefs about the nature of mathematics, the teaching, and learning of mathematics, i.e., who believe that mathematics is a static body of knowledge involving a set of rules and procedures that they have to transmit to the students, are less likely to implement inquiry-based mathematics instruction. Presumably, teachers' conceptions about typical activities of mathematical scientists may also influence their classroom teaching.

Research questions

As introduced before, the results of the study by Köller et al. (2000) show that students' *epistemological beliefs about mathematics* influence their interest, their learning, and, thus, their achievement. Similar impacts may be assumed for students' *conceptions about the work of scientists* in general (see Figure 1) or of mathematicians in particular. Students' conceptions about typical activities of mathematicians may particularly influence their study and career choices (Stamer, Kubsch et al., 2019). Against this background, the present study aims to explicitly investigate students' conceptions about typical activities of mathematical scientists (research question 1). Given that these conceptions are likely rooted in students' experiences in mathematics classrooms – which in turn are influenced by teachers' beliefs related to mathematics (Stipek et al., 2001) – the present study also aims to investigate teachers' conceptions about the work of mathematical scientists (research question 2). The purpose of the present study is then to uncover possible relations between students' conceptions about the work of mathematical scientists and the experiences they are given in mathematics classes (research question 3).

Method

To investigate our research questions, we conducted an exploratory interview study with 14 9th graders (age: $M = 14.86$, $SD = 0.66$; 78.6% male; interest in mathematics between 1 = no interest and 6 = high interest: $M = 4.14$, $SD = 1.23$; school grade in mathematics between 1 = very good and 6 = unsatisfactory: $M = 2.14$, $SD = 0.86$) and 5 mathematics teachers (one male; teaching experience in mathematics: 2 to 13 years) who taught in grades 9 or 10 from urban schools in Germany. Both students and teachers volunteered to participate in our interview study by responding to a written inquiry that we had sent to local schools. We interviewed the students as well as the mathematics teachers in June and July 2021 using semi-structured interviews. The interviews with the students lasted between 9 and 17 minutes and with the teachers between 16 and 34 minutes. The interview protocol contained the following three parts: (1) View on mathematics and doing mathematics, (2) Typical mathematical activities of mathematical scientists, (3) Typical mathematical activities during mathematical experimentation. The interview protocol for the mathematics teachers included additional questions about their teaching of mathematics in all three aforementioned parts of the protocol. We used the questions of the first part as an introduction to the interview and the topic. The third part was used to finally illustrate typical mathematical activities by using a specific classroom example and to enable the students and teachers to relate these activities to the work of mathematical scientists. To investigate the research questions of the present study, we look at the students' and teachers' responses to the questions of the second part of the interview.

In the second part of the interview, we asked the students and teachers the following question: "What do you think are typical activities of mathematical scientists who work, for example, at universities?" We also asked for similarities and differences between what mathematical scientists do and what students do. In addition, we asked the teachers: "To what extent do you teach typical mathematical activities of mathematical scientists in your 9th or 10th grade mathematics classes?" We systematically analyzed the students' and teachers' responses through

different coding procedures that were guided by the analysis process of constructivist grounded theory methodology (e.g., Charmaz, 2006). Charmaz's constructivist grounded theory methodology is particular suitable for exploratory investigations of little-known phenomena due to the largely exclusion of prior knowledge. It focuses on analytically capturing and interpretively understanding the characteristics and contexts of the phenomenon. For this purpose, we first analyzed fragments of data (i.e., words, lines, and segments) to assess their relevance for answering the research questions (initial coding; e.g., Charmaz, 2006). This process allowed us to remain open for exploring any conceptions about typical activities of mathematical scientists that can be detected in the data. In doing so, terms used by students and teachers were adopted as in vivo codes. For example, the following segment from a statement of T4 "that they [mathematical scientists] […] make assertions which they then perhaps try to prove somehow with the help of given theorems or somehow deduce things themselves, so that they can then somehow prove their assertions or relations which they want to show […]" was first coded with the in vivo codes *proving* and *deducing*. This first step of coding led us to a collection of various individual activities of mathematical scientists from the students' and teachers' point of view. In a second step (focused coding; e.g., Charmaz, 2006), we selected what we thought were the most useful in vivo codes and tested them against extensive data. Specifically, we compared data with data and then data with codes. Thus, we obtained core conceptual categories. These categories no longer included only individual activities, but rather represented more general and abstract conceptions. For instance, the statement of T4 above was assigned to the more general and abstract conception *doing research*. Throughout the whole coding process, the authors collaboratively negotiated the coding of the data. For this purpose, we repeatedly compared our understanding of the data to achieve greater precision and consistency (see, e.g., Corbin & Strauss, 1990). In addition, we used, for example, a clear protocol of codes and memoing to improve reliability through transparency.

Results

Students' conceptions about the work of mathematical scientists

Based on the coding procedure described above, we identified the following conceptions of students (research question 1): Students believe mathematical scientists …

- do the same kind of mathematics as the students in the classroom but on a higher level,
- optimize existing procedures,
- teach mathematics,
- conduct didactic research, and
- carry out professions that require mathematical calculations.

The majority of the 14 students ($n = 11$) believe that mathematical scientists *do the same kind of mathematics* as they do in their mathematics classroom but *on a higher level*. When asked for similarities and differences between what mathematical scientists do and what students do, S4, for example, answered on a rather general level: "[…] of course, we do something slightly different, but somehow also the same." S6 responded more concretely: "[…] [mathematical scientists] also calculate like we do. But I think they get much more difficult tasks and have to solve much more complex things with their heads." Another example for the conception that mathematical scientists do the same kind of mathematics as school students do but on a higher level, can be found in the following statement from S8: "[…] they [mathematical scientists] also convert formulas, do calculations and, yes, they also simply look at things like triangles […]. So of course, it's much more complicated what they do at universities than here in schools." S3 added that mathematical scientists "also have to figure things out and also do math with their heads and with calculators and with computers maybe even." S6 also mentioned, in addition to mental arithmetic, the use of the calculator, the set square, and various shapes as other similarities between what mathematical scientists do and what students do. Moreover, from the perspective of students, mathematical scientists often use "things that we don't even know here at school yet" (S5), because the students "still do the somewhat simple things and try to figure them out. They [the mathematical scientists] do the difficult ones one step above" (S12). Furthermore, mathematical scientists apply mathematical knowledge, whereas students learn mathematics: "[…] we [students] sit to many in a room and learn there, but I think […] [in] science, there they sit alone and already calculate, so they don't learn, but already apply the knowledge" (S5).

Some of the students ($n = 4$) also revealed the conception that mathematical scientists *optimize existing procedures*. For example, from the perspective of S1, mathematical scientists deal with "how to calculate something or how to make something simpler than it really is now. […] And mathematicians […] also try to bring their own way in or find a simpler variant." S10 also believes that mathematical scientists try to "simplify new or the mathematical rules students have […] [and] find new ways to solve something."

In addition, from the perspective of some students ($n = 3$), mathematical scientists *teach mathematics*: "I think teaching. […] Yes, teach other people and instruct them" (S4). Also for S1, mathematical scientists "must also be able to explain things to people or also represent things in a simplified way." Furthermore, S2 even focuses on *didactic research* as mathematical scientists conduct interviews and test different (teaching) materials – similar to the present study.

Some of the students ($n = 3$) referred rather to other *professions or areas in which mathematical calculations are required*, for instance, to the application of mathematics in economics or in handcraft. When asked for typical activities of mathematical scientists S7 answered: "I would imagine now, with business I would imagine just something, with numbers, with orders."

Teachers' conceptions about the work of mathematical scientists

With regard to research question 2, we observed the following conceptions of mathematics teachers: Mathematics teachers believe mathematical scientists …

- do mathematical research,
- teach mathematics,
- solve abstract problems, and
- provide bases for models.

Most of the teachers ($n = 4$) named "*mathematical research*" (e.g., T1) as a typical activity of mathematical scientists. From the perspective of T3, mathematical scientists conduct research in order to develop new or to optimize existing procedures: "[…] research, connect any theorems and find something new or a faster way somewhere […]." A similar conception was also shown by T4 who considers mathematical research mainly in the context of deducing and proving: "that they [mathematical scientists] want to explore various relations in more detail and make assertions which they then perhaps try to prove somehow with the help of given theorems or somehow deduce things themselves, so that they can then somehow prove their assertions or relations which they want to show […]." Moreover, T4 added that mathematical scientists actually find out new things, whereas students find out what has already been found out: "that what the students can discover […] has already been discovered, […] and they have to think about it, […] to understand it […]. And what an applied mathematician does, for me, is to find out something new." T3 also mentioned that a goal of mathematical research is to find out what is actually new through deducing and proving, which is a difference between what mathematical scientists do and what students do. In contrast, according to T3, students only use mathematical knowledge: "[mathematical scientist] apply what they already know and try to prove things and the students […] only use, but don't get anywhere with it, but are always confronted with the same tasks." There is also a large discrepancy from the other teachers' perspective between what mathematical scientists do and what students do. For instance, T2 differentiates as follows: "So I would say at school, you don't learn mathematics at all, you learn calculation. You actually learn calculation."

In addition, a few teachers ($n = 2$) identified *teaching* as a typical activity of mathematical scientists. For example, T5: "Mathematics teaching in science […] [for the] respective students […]." Furthermore, T1 named *solving abstract problems* as a typical activity of mathematical scientists: "[…] a lot of dealing with abstract problems." T2 mentioned *creating the basis for models* "in order to be able to use them in the real world."

Possible relations to mathematics teaching

With respect to possible relations to mathematics teaching (research question 3), the teachers' answers show that the teaching of typical activities of mathematical scientists plays rather a subordinate role in their classes. In the mathematics lessons of T3, for instance, typical activities of mathematical scientists are taught "rather seldom". If anything, the teachers try to teach deducing or proving as typical activities of mathematical scientists, as evidenced by the following statements: "[…] so one tries to proceed very logically and to conclude things deductively again and again […]" (T1) or "Now, classic example: Pythagorean theorem. You just let them prove it" (T2).

From the perspective of the teachers, the following reasons often prevent the teaching of typical activities of mathematical scientists in mathematic classes:

- the requirements in graduation,
- the lack of time,
- the abilities of the students, and
- their own distance from the university context.

The majority of teachers ($n = 3$) are hindered from teaching typical activities of mathematical scientists mainly by the *requirements in graduation* and the *lack of time*. For instance, T3 said that typical activities of mathematical scientists are not required in the curriculum and, consequently, not required in the final exams: "since it is not really intended by the curriculum, it's of course always difficult with regard to any final exams, where only pure calculation is required or the same standard formulations are somehow tested, to take time and say: 'We will do it anyway.', because you actually know that they don't need it at least for this exam and most of them don't need it later either." T1 also emphasizes – besides the lack of time – that class tests often do not require typical activities of mathematical scientists: "But what is required in class tests, for example, is a completely different matter. So, the whole system is a bit ambivalent."

Another reason for T1 and T3 why the teaching of typical activities of mathematical scientists plays a rather minor role in the classroom are the *abilities of the students*. Among others, T1 emphasizes the "discrepancy between the level at which one has to work in school in some cases […] and what is required later in the university context […] or what would be needed for exact mathematical work." T3 also stresses that there is seldom the opportunity to teach typical activities of mathematical scientists and that then often the majority of students are not able to follow: "[…] from time to time, you try to tickle out a little bit, especially when you notice that the attention is there and that a setting arises where you can think a little further and one or the other is perhaps at a point where it is also possible. But the majority can't follow and at this point it is always difficult to promote this [typical activities of mathematical scientists] in a larger group […]."

In addition, T3 also considered their *own distance from the university context* as a further reason: "The longer you are away from university work, I would say, the more insecure you feel about being able to pass on such activities."

Discussion and implications

To conclude, the results of our exploratory interview study show that students have inadequate and limited conceptions about the work of mathematical scientists. The majority of the students believe that mathematical scientists mainly calculate – as they also do in their own mathematics classes – but on a higher level. Rock and Shaw (2000) as well as Picker and Berry (2000) found similar conceptions about mathematicians in students. Our results are, moreover, in line with previous findings on students' epistemological beliefs about mathematics (e.g., Köller et al., 2000; Schoenfeld, 1988). Specifically, we found that the schematic-algorithmic orientation of mathematics is also present in students' conceptions about the work of mathematical scientists. However, in everyday life as well as professional contexts, challenges are increasingly posed that cannot be met by the schematic application of mathematical rules. Rather, mastering these challenges requires the use of mathematical tools to process and evaluate them, such as problem solving, reasoning or modeling (Hammer et al., 2016). Our results are especially critical in light of the fact that we surveyed mainly students with a high interest and good grades in mathematics. These students may also be interested in studying mathematics at a university after having graduated from school. But their limited conceptions focusing on the schematic-algorithmic orientation of mathematics may be particularly problematic in the university context: The mathematics curriculum at a university initially focuses on the scientific character of mathematics and, especially, mathematical proving, and not on the performance of calculations. Students' limited conceptions about typical activities of mathematical scientists may lead to unrealistic expectations about the requirements of mathematics studies which, in turn, may hinder the effectiveness of individual learning processes (see Rach et al., 2014). If already students with a high interest and good grades in mathematics have inadequate and limited conceptions, it raises the question what conceptions students with low interest and/or poor grades in mathematics have about typical activities of mathematical scientists. Further research should therefore also investigate the conceptions of students with low interest and/or poor grades in mathematics.

Consequently, the results of the present study highlight the need to change students' conceptions about typical activities of mathematical scientists and to foster more adequate conceptions. As mentioned above, it is therefore essential to know where these conceptions arise from in order to be able to derive specific interventions for fostering more adequate conceptions. The present study suggests that students' conceptions are based on their classroom experiences. Mathematics classes, in turn, are influenced by teachers' beliefs related to mathematics (Stipek et al., 2001). Our results additionally show that teachers have limited conceptions about the work of mathematical scientists, too, as the teachers who participated in our study named only some of the important activities of mathematical scientists, usually remaining rather vague about the concrete activities. Although the majority of the teachers identified doing mathematical research – often in connection with deducing and proving – as typical activities of mathematical scientists, they did not describe it in more detail and did not name further activities mathematicians consider as important, such as conjecturing, generalizing, and exploring or communicating (see Brandt et al., 2016). This result may be attributed to the teachers' own classroom experiences

as students, too, and also to their experiences from studying mathematics at university. During studying mathematics at university, the teachers probably gained only a few insights into the work of mathematical scientists. In lectures, mathematics is "formal, precise, ordered and abstract" and is often presented only "in 'finished' form" (Hersh, 1991, p. 128), but not the way mathematical scientists actually work and figure things out, for example, by conjecturing, generalizing, and exploring or communicating. Therefore, it is also necessary to broaden teachers' conceptions about typical activities of mathematical scientists.

One promising opportunity to foster more adequate conceptions about typical activities of mathematical scientists in both students and teachers relates to offering insights into the work of mathematical scientists. This could be achieved, for example, by cooperating with mathematical scientists as role models or mentors who tell students and teachers about their work or by using narratives written by and about mathematical scientists. Another possibility to promote more adequate conceptions about typical activities of mathematical scientists is to carry out these activities by oneself. One potentially promising approach could relate to the authentic contextualization of learning settings. Authentic learning contexts try to provide authentic activities that reflect the way the knowledge will be used in real life (Herrington & Oliver, 2000). With regard to mathematics teaching, an authentic learning activity may include mathematical modeling with hands-on experimental tasks (see Carreira & Baioa, 2018). However, both such visits of mathematical scientists and such tasks are always very time consuming. As the findings of our interviews with mathematics teachers show, there is a lack of time in school to teach typical activities of mathematical scientists. Therefore, it would be useful to teach typical activities of mathematical scientists outside the classroom. One possibly fruitful opportunity may be offered by out-of-school labs. Projects in out-of-school labs aim to promote adequate conceptions about science and scientists by enabling students to authentically experience scientific ways of thinking and working (Scharfenberg & Bogner, 2014). As part of such projects, students could, for instance, also collaborate with real mathematical scientists. Unfortunately, real mathematical scientists often do not have the time to work with students. For this reason, Stamer, Pönicke et al. (2019), for example, used videos as part of a project in an out-of-school lab in which scientists could be observed at work. The results showed that students recognized all explicitly intended authentic scientific activities in the videos. Given this finding, observing mathematical scientists at work also appears as a beneficial way to foster more accurate conceptions about mathematical scientists and their work in students. For future research, it would additionally be interesting to examine the effect of those authentic insights on students' interest in and their attitudes towards mathematics.

Making Sense of Integer Story-Interpretation Problems

Mahtob Aqazade, Rice University, Mahtob.aqazade@rice.edu

Abstract: Exploring students' conceptions of integers is more complex than simply explaining the elements of integer knowledge and certainly is challenging to describe how those elements are structured. In this paper, I highlight how fifth graders restructured their whole-number knowledge elements to establish an integer knowledge structure by exploring their interpretations of two integer story-interpretation problems. Students with correct integer order and value interpretations were most successful in solving these problems. Students who knew negative numbers are less than positive numbers but had difficulties interpreting integers' values were more successful than those who relied on numbers' absolute value. However, they attempted to use the negative signs in their number-sentences. This study informs the importance of triangulating students' integer knowledge elements, the process of forming an integer knowledge structure, and further highlights the significance of using problem-solving situations that allow for eliciting diverse mathematical thinking and learning processes.

With introducing negative numbers, the knowledge elements around order and value, minus sign interpretations, addition and subtraction, and associated mathematical language requires restructuring to form a coherently structured integer knowledge system. From whole-number knowledge to integer knowledge, students need to make sense of multiple meanings of the minus sign (i.e., unary, symmetric, and binary; Vlassis, 2004, 2008), distinguish between absolute value ($|-5| > |-3|$) versus linear value ($-5 < -3$), and interpret the meanings of addition and subtraction while accompanying them with the mathematical language (i.e., directed magnitude language; e.g., adding a negative number is getting *more negative*; Aqazade & Bofferding, 2021; Bofferding, 2014, 2019). These knowledge elements may seem mutually inclusive. However, some students may have developed one or more of their whole-number knowledge elements into integer knowledge elements without framing a coherent structure of integer knowledge among them. For example, one can distinguish the linear values versus absolute values by connecting to the directed magnitude language (e.g., -5 is more negative than -3) but may not integrate the directional aspects of more and less with values when adding and subtracting with negative integers (Aqazade, 2021; Aqazade & Bofferding, 2021). To develop a coherently structured integer knowledge system, the knowledge elements need to be reorganized into a theory or schema (Aqazade & Bofferding, 2021). Thus, it is crucial to provide problem-solving situations that allow for students to exhibit their interpretations of knowledge elements individually and collectively within the knowledge system. Such problem-solving situations can depict a more holistic view of students' knowledge development and open space for their diverse mathematical thinking. By drawing from and building on prior research around students' integer knowledge (e.g., Bishop et al., 2014; Bofferding, 2014; Whitacre et al., 2017), in this paper, I aim to illustrate a more holistic picture of how students' integer knowledge elements were in formation towards establishing a coherent integer knowledge structure using a particular problem-solving situation (i.e., story-interpretation problems). I argue that using story-interpretation problems challenged students to rethink their integer knowledge elements and revise or restructure them for forming a cohesive integer knowledge structure. Thus, this work provides perspectives on learning processes and problem-solving situations within domain-specific knowledge.

From whole-number to integer knowledge

To develop integer order and value knowledge elements, students need to make sense of the numbers' order and how it relates to their values. When introducing negative numbers, integer values can be represented as absolute value ($|-7| > |-2|$) or linear value ($-7 < -2$) perspectives (e.g., Bofferding, 2014). Prior studies have explored students' interpretations of integer order and values when comparing or ordering integers (e.g., Whitacre et al., 2017). For example, Whitacre et al. (2017) investigated students' reasoning about integer comparison by having them find the *larger* number between a pair of integers. They found comparing two positive numbers was the easiest and comparing two negative numbers was the most difficult. Bofferding and Farmer (2019) used temperature context to explore how students responded to different integer comparison question phrasing (e.g., most hot, least cold). Students performed better on *most cold* than *least hot* comparisons. They also did better with *most hot* for positive-number-only comparisons and *least cold* for negative-number-only comparisons.

With negative numbers, not only does the minus sign take different meanings (i.e., binary, unary, symmetric) but also adding or subtracting integers involves a directional movement (e.g., Bofferding, 2014;

 © ISLS

Vlassis, 2004, 2008). For example, adding a negative integer no longer relates to getting more or larger rather it represents *more* in the negative direction or downwards on a vertical number line (Bruno & Martinon, 1999). Previous related work focused on detailing students' addition or subtraction solution strategies and their understanding of minus sign meanings for open number-sentence or story problems (e.g., Aqazade & Bofferding, 2021; Bishop et al., 2014; Whitacre et al., 2014). For instance, Murray (1985) found students' correct responses to integer addition or subtraction problems often happened when they could ignore the negative signs, operate as numbers were positive, and append the negative signs to their answers (e.g., -9 – -4 → 9 – 4 = 5 → -5 or -3 + -5 → 3 + 5 = 8 → -8), which refers to *add or subtract make negative* strategy leveraging the symmetric meaning of the minus sign (see Aqazade & Bofferding, 2021; Bofferding et al., 2017; Vlassis, 2004, 2008). Using *counting up or down from a negative number* strategy (e.g., 8 + -3 is -3, -2, …, 5) representing the unary meaning of the minus sign was a less common strategy (Aqazade & Bofferding, 2021; Bishop et al., 2014; Bofferding et al., 2017; Vlassis, 2004, 2008). Often, students who did not know about numbers below zero ignored the negative signs and add or subtract the numbers' absolute values (e.g., 4 + -6 = 10; i.e., *absolute value* strategy) or treated the negative signs as subtraction signs showing the binary meaning of the minus sign (e.g., 4 + -6 → 6 – 4 = 2; Aqazade & Bofferding, 2021; Bofferding et al., 2017; Vlassis, 2004, 2008).

Although several integer knowledge elements were implicitly involved in the prior research, this work explicitly unfolds students' interpretations of integer knowledge elements and the extent to which they represent a structured knowledge system. Thus, the purpose of this paper is to describe the triangulation among students' integer order and value interpretations, integer addition and subtraction and minus sign interpretations, and associated directed magnitude language. I used integer story-interpretation problems involving temperature and directed magnitude language and sought to explore the following research questions: When solving integer story-interpretation problems, how did fifth-grade students' order and value knowledge elements relate to (a) their knowledge elements of the directed magnitude language and addition or subtraction as represented in their number-sentences? and (b) their drawn thermometers?

Methods

Participants and setting

Forty fifth-grade students (24 girls and 16 boys) participated in this study from an intermediate school in the Midwest, United States with 73% economically disadvantaged and 12% English-Language-Learners.

Data sources and analysis

I used task-based interviews involving a problem-solver (student) who interacts with one or more problem-solving situations and an interviewer (researcher) who follows up with nondirective questions (e.g., "can you tell me more about that?"). The goal of task-based interviews is to delve into students' complex problem-solving processes (Goldin, 2000; Maher & Sigley, 2014). In this study, students individually solved and explained integer-related test items: order and value items (e.g., circle the temperature that is most cold? 15, -27, 10); directed magnitude language items (e.g., when it gets 5 degrees more hot, where does the arrow on the thermometer change to?); story-interpretation items (see Table 2); and integer addition and subtraction items (e.g., 8 – 12 =).

To answer the research questions, I first classified students' responses to integer order and value items into *whole-number, transitional,* and *integer* categories that describe their interpretations of order and value knowledge elements (see Table 1). Second, using these categories, I aimed to explain students' responses to the story-interpretation items, which contained three parts: (a) directed magnitude language terms, (b) writing a number-sentence, and (c) drawing a thermometer. In this paper, I only focused on two story-interpretation problems (see Table 2). I chose items that target the temperature change from a positive to a negative number and crossing zero (item 1) and within negative numbers (item 2).

Table 1
Categories of Students' Responses on Integer Order and Value Items (see Bofferding, 2014)

Interpretation of order and value	Description	Example(s)
Whole-number	Ignoring the negative signs, comparing, and ordering negative numbers based on their absolute value or in reversed order.	Ordering based on absolute value 0, -1, 2, -5, -7, 10. Reversed ordering -1, -5, -7, 0, 2, 10. Choosing -20 as the most hot temperature among -20, 12, and 0.

 © ISLS

Transitional	Distinguishing the positive and negative numbers as negative numbers being smaller than positive numbers. Ordering negative numbers as below zero and correctly. Comparing the negative numbers sometimes based on their absolute values and sometimes correctly based on their linear values.	Choosing 12 as the most hot temperature among -20, 12, and 0. Choosing -19 as the most hot temperature among -14, 0, and -19.
Integer	Ordering the integers correctly. Comparing integers correctly based on their linear values.	Ordering -7, -5, -1, 0, 2, 10. Choosing 12 as the most hot temperature among -20, 12, and 0. Choosing 0 as the most hot temperature among -14, 0, and -19.

Table 2
Two Story-Interpretation Items

Item #	Story-interpretation
1	If South Bend's temperature changes from -20 to 15, which of these terms can explain this change? The temperature got _____. Circle all the terms here that would work. *more hot, more cold, less hot, less cold* How did you decide? Write a number sentence that shows this change. Draw a thermometer that shows how this change happens?
2	If West Lafayette's temperature changes from -33 to -22, which of these terms can explain this change? The temperature got _____. Circle all the terms here that would work. *more hot, more cold, less hot, less cold* How did you decide? Write a number-sentence that shows this change. Draw a thermometer that shows how this change happens?

In the analysis of students' responses to each story-interpretation item, for the directed magnitude language terms, I identified whether they relied on only one term (e.g., less or cold for less cold) or the compound terms. For writing a number-sentence, I marked whether it was with or without negative signs and whether it represented a correct temperature change (see Table 3). Further, I categorized students' solution strategies for their written number-sentences. If students did not use any negative signs in their written number-sentences, I classified their strategies as *whole-number*. Among students who made use of the negative signs in their written number-sentences, I characterized their strategies as *absolute value* (i.e., adding or subtracting integers' absolute values), *add or subtract make negative* (i.e., adding or subtracting integers' absolute values and appending the negative sign to the answer), or *counting up or down from a negative number* (i.e., starting at a negative number and counting towards a positive or negative direction) (e.g., Aqazade, 2017; Aqazade & Bofferding, 2021; Bishop et al., 2014; Bofferding et al., 2017; Murray, 1985). Finally, for drawing thermometers, I identified numbers' placements and orders on the thermometers and the directional movement for the temperature change based on students' explanations and drawings.

Table 3
Written Number-Sentence Categories

Number-sentence		Description	Examples
Without negative signs	Incorrect change	Not including negative signs and not showing the correct temperature change.	Item 1: 20 – 5 = 15 or 20 – 15 = 5 Item 2: 33 – 11 = 22 or 33 – 22 = 11
	Correct change	Not including negative signs but correctly showing the appropriate temperature change.	Item 1: 20 + 15 = 35 Item 2: Not applicable
With negative signs	Incorrect change	Including negative signs but not showing the correct temperature change[a].	Item 1: -20 – 5 = 15, -20 – -5 = 15, -20 – 15 = 35, -20 + 15 = 35, -20 + 15 = -35, -20 – 35 = 15, or 15 – 35 = -20 Item 2: 33 – 22 = -11, -33 – 11 = 22, -33 – 22 = 11, -33 – 22 = -11, -33 – -22 = -11, -33 + -11 = -22, or -22 + 11 = -33

	Correct change	Including negative signs and correctly showing the temperature change.	Item 1: 15 – -20 = 35 or -20 + 35 = 15 Item 2: -33 + 11 = -22, -33 – -11 = -22, or -22 – -33 = 11

[a] Some of the written number-sentences in this category are mathematically correct but do not fit with what the item was asking in terms of showing the temperature change.

Findings

Based on the responses on integer order and value items, 10 (26%), 18 (46%), and 11 (28%) students were classified in the whole-number, transitional, and integer categories, respectively.

Directed magnitude language terms

Temperature change from -20 to 15

Two, ten, and all students from the whole-number, transitional, and integer categories respectively chose both "more hot" and "less cold" correctly. Mina(whole-number)(1) chose "more cold" and by relying on numbers' absolute values explained, "Because twenty is like going less and then to fifteen, it got more cold." However, by knowing negative numbers are smaller than positive numbers, students' choices in the transitional category were correct. For instance, June(transitional) said, "I decided that by thinking because it's negative twenty and this [15] doesn't have a negative, even though it's a small number, it's not a negative so it's a bigger number." Students' incorrect choice of directed magnitude language was due to focusing on one term of the compound terms; relating them to numbers; choosing only one of the two correct compound terms; relying on numbers' absolute values; or a mix of these reasons.

Temperature change from -33 to -22

None of the students in the whole-number category correctly chose both "more hot" and "less cold." Seven students from the transitional category and all students from the integer category correctly chose both of them. For example, Jane(integer) said, "Because thirty-three is a bigger negative number and bigger negative numbers are colder in temperature-wise, and since twenty-two is less than thirty-three, it made thirty-three to twenty-two, you know we got hotter." Reasons for students' incorrect choice was similar to the temperature change from -20 to 15. For example, Cruz(whole-number) chose "more cold" and "less cold" by relating terms to numbers, pointed at -33 saying, "This is more cold" and then at -22 saying, "This is less cold." Lane(transitional) chose "more cold" and "less hot" by relying on numbers' absolute value, "So if it's thirty-three…and if it goes to twenty-two, then the temperature is dropping down. That means it's like going to get colder."

Written number-sentence without negative signs

Students' number-sentences varied depending on how they interpreted the integers' order and values and whether they attempted to make use of the negative signs (see Tables 4 and 5). For the incorrect temperature change from -20 to 15, both 20 – 15 = 5 or 20 – 5 = 15 demonstrated students' *whole-number* strategy. Similarly, for the incorrect temperature change from -33 to -22, 33 – 22 = 11 or 33 – 11 = 22 both represented the *whole-number* strategy. For the correct temperature change from -20 to 15, several students from the whole-number and transitional categories wrote 15 + 20 = 35. For instance, Jasmin(transitional) said:

> I went from negative twenty at this one all the way down to zero. And then I counted how many positive degrees there were with how many negative degrees there were, and I added them together to get thirty-five degrees. So that would be how many there would be to get to fifteen.

Written number sentences with negative signs

Temperature change from -20 to 15

Negative signs in students' number-sentences were used differently (see Table 4). For the incorrect temperature change, students often solved their written number-sentences by relying on the *absolute value* strategy. A few students like Mila(transitional) (-20 + 15 = -35) used the negative sign with its symmetric meaning and applied the *add make negative* strategy. Choosing correct numbers but not writing the operation correctly, Joshua(transitional) (-20 – 15 = 35) explained "because it's getting more hot," he needed to subtract the numbers, "So basically, you'd have to subtract twenty. Then that would equal zero and then it'd be fifteen. So, you have to do the twenty plus the fifteen, and it equals thirty-five." Similarly, Bob(integer) (-20 – 35 = 15) added 15 and 20

to find 35 but was not sure whether to subtract 35 from -20 or add it. Many students like Bob seemed to know the distance between -20 and 15 but were not successful in representing it in a number-sentence.

Liv(transitional) wrote a mathematically correct number-sentence, 15 – 35 = -20, but did not represent an appropriate temperature change from -20 to 15:

> Since it's a negative number again, how you would normally do it is five minus five equals zero. Then you have one minus three which you can't do. So, you have to go to the negatives. If you do minus three, it'll be negative two – so negative twenty.

For the correct temperature change, some students like Ariana(transitional) (-20 + 36 = 15) miscounted or Landon(transitional) (15 – -20 = -15) who wrote a correct number-sentence showing the change but applied the *subtract make negative* strategy, miscounted, and answered the number-sentence incorrectly. Another example is Cody(integer) (15 – -20 = -5) with a correct number-sentence but and an incorrect answer. He explained, "Because you can just take away subtraction symbol and do fifteen minus twenty." Thus, Cody actually ignored the negative sign and solved 15 – -20 as if it was 15 – 20. Several students wrote a correct addition number-sentence involving a negative number (i.e., -20 + 35 = 15). For example, Corbin(transitional) explained, "Because if you add these two, you would get thirty-five. So, then you would add thirty-five to twenty which would get you positive fifteen."

Table 4

Categories of Students' Written Number-Sentence on Temperature Change from -20 to 15

Written number-sentence category		Order & value interpretation category	Number-sentence
Without negative signs	Incorrect change (n = 8)	Whole-number (n = 4)	20 – 15 = 5
		Transitional (n = 4)	20 – 15 = 15, 20 – 5 = 15, 20 – 15 = 5
	Correct change (n = 4)	Whole-number (n = 2)	20 + 15 = 35
		Transitional (n = 2)	20 + 15 = 35
With negative signs	Incorrect change (n = 13)	Whole-number (n = 4)	-20 + 15 = 35, -20 – 5 = 15, 15 + -20 = __
		Transitional (n = 6)	-20 + 15 = 35, -20 + 15 = -35, -20 + 15 = 15, -20 – 15 = 35, -20 – 15 = 15, 15 – 35 = -20
		Integer (n = 3)	-20 – 35 = 15, 15 – 35 = -20, 15 – 25 = -20
	Correct change (n = 14)	Transitional (n = 6)	-20 + 35 = 15, -20 + 36 = 15, 15 – -20 = -15
		Integer (n = 8)	-20 + 35 = 15, 15 – -20 = -5

Temperature change from -33 to -22

For the incorrect temperature change, students often applied the *absolute value* or *add/subtract make negative* strategies (see Table 5). For example, Kori(whole-number) wrote -33 – 11 = 22 using the *absolute value* strategy, "You subtract thirty-three from eleven that makes twenty-two." Greta(integer) wrote 33 – 22 = -11 and said, "All I had to do was to subtract thirty-three by twenty-two and add the negative sign," which illustrated the *subtract make negative* strategy. Anna(integer) wrote -33 + -11 = -22, "Because minus twenty-two is technically more than minus thirty-three because minus twenty-two is closer to zero" but she was not sure whether to write -11 or 11. Some students wrote a mathematically correct number-sentence (i.e., -33 – -22 = -11) without showing a correct temperature change. For example, Jessica(whole-number) said, "Since it got lower, you subtract to get the actual lowest number," showing the *subtract make negative* strategy. For the correct temperature change, for example, Liv(transitional) wrote -33 + 11 = -22 demonstrating the *counting up from negative* strategy:

> If you were adding negative thirty-three to eleven, it's like minusing, but instead, it's a negative. It's flipped. It would be negative twenty-two…It will get higher up to negative twenty-two. So, you would have to add because that's getting higher.

Cody(integer) with writing -22 – -33 = 11 represented a more sophisticated strategy. He explained, "Because I would take away minuses and you switch the numbers so it would be negative thirty-three minus negative twenty-two that would be negative eleven [but wrote eleven]."

Table 5

Categories of Students' Written Number-Sentence on Temperature Change from -33 to -22

Written number-sentence category		Order & value interpretation category	Number-sentence
Without negative signs	Incorrect change (n = 11)	Whole-number (n = 6)	33 – 11 = 22, 33 – 22 = 11, 33 + 22 = 55, 22 + __ = 33
		Transitional (n = 5)	33 – 11 = 22, 33 – 22 = 11
With negative signs	Incorrect change (n = 22)	Whole-number (n = 4)	-33 – 11 = 22, -33 – -22 = -11
		Transitional (n = 9)	33 – 22 = -11, -33 – 22 = 11, -33 – 11 = 22, -33 – -22 = -11, -33 + -22 = -11
		Integer (n = 9)	33 – 22 = -11, -33 – 22 = -11, -33 – 11 = -22, -33 – -22 = -11, -22 + 11 = -33, -33 + -11 = -22
	Correct change (n = 6)	Transitional (n = 4)	-33 + 11 = -22, -33 – -11 = -22
		Integer (n = 2)	-33 + 11 = -22, -22 – -33 = 11

Drawn thermometers

Temperature change from -20 to 15

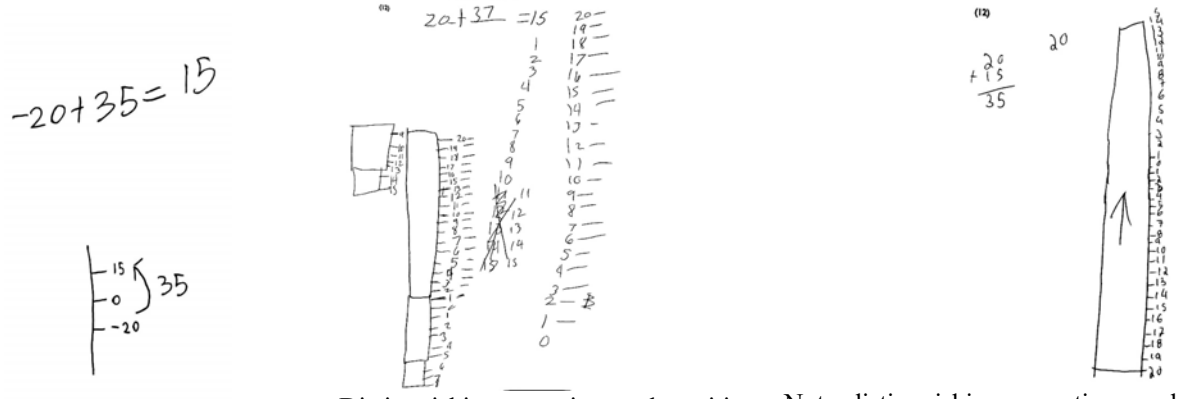
Because of ignoring the negative sign and relying on numbers' absolute value, four students from the whole-number category and five students from the transitional category put the -20 on top and 15 on the bottom of their thermometers and indicated the downward movement to show the temperature change. Among these students, even those who included the negative signs in their number-sentences, all except for Mila(transitional) (-20 + 15 = -35) solved them using the *absolute value* strategy. All these students' number-sentences were aligned with their directional movements on their thermometers (e.g., subtraction is moving downward; see Figure 1). Overall, even students who could distinguish positive and negative numbers—but could not differentiate the linear versus absolute value—often indicated the temperature is "going down."

Temperature change from -33 to -22

Similar to the temperature change from -20 to 15, students who relied on the numbers' absolute value or ignored the negatives did not correctly demonstrate the temperature change from -33 to -22. They placed the temperatures on the thermometers as if they were all positive numbers. For example, Jade(whole-number) put -33 on the top of her thermometer and said, "So it's thirty-three right here and it goes down." Overall, four students from the whole-number category, eight students from the transitional category, and two students from the integer category put the -33 on top and -22 on the bottom of their thermometers and indicated the downward movement to show the change from -33 to -22 (see Figure 1).

Figure 1

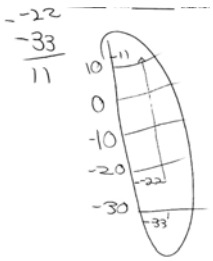
Examples of Students' Drawn Thermometer



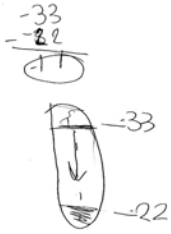
-20 at the bottom and 15 at the top: Kristen(transitional)

Distinguishing negative and positive numbers; -20 at the top and 15 at the bottom: Lucy(transitional)

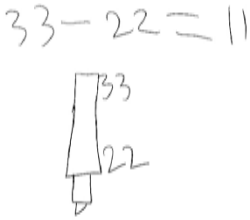
Not distinguishing negative and positive numbers; -20 at the top and 15 at the bottom: June(transitional)



-33 at the bottom and -22 at the top: Cody(integer)



Distinguishing negative and positive numbers; -33 at the top and -22 at the bottom: Kate(whole-number)



Not distinguishing negative and positive numbers; -33 at the top and -22 at the bottom: Max(whole-number)

Significance, contribution, and implications

In attempts to promote better learning, it is essential to understand what processes are involved in one's learning. Understanding these processes helps develop learning environments that support more effective learning experiences. In this study, using story-interpretation problems provided a space to unfold such processes of fifth-grade students and their problem-solving approaches. These story-interpretation problems allowed for eliciting students' conceptions in a problem-solving situation. By focusing on the concept of integers, I explored how students made meaning of different elements within the integer knowledge system and the extent to which these elements represent a structured system.

Overall, because students from the whole-number and transitional categories were still making sense of integers' order and values, it was not surprising to see a looser structure among their knowledge elements when solving the story-interpretation items. Consequently, having a more robust structure for order and value knowledge elements among students in the integer category led them to interpret the story-interpretation items more accurately. Although students in the whole-number category often ignored negatives when interpreting integers' values and had difficulties making sense of the directed magnitude language terms, some of them wrote number-sentences with negative signs, illuminating their attempts in extending the minus sign meanings by using the *add/subtract make negative* or *count up/down from negative* strategies. Students in the transitional category were more successful than those in the whole-number category when interpreting the numbers' values but some of them still reversed the negatives on their drawn thermometer and had difficulties writing a number-sentence, suggesting their integer knowledge structure was still in formation.

The results of this study contributed and added to the research on understanding students' integer knowledge development (e.g., Bofferding & Farmer, 2019; Whitacre et al., 2017). For example, although Bofferding and Farmer (2019) detailed students' different responses based on numbers and language involved in the comparison items, they did not provide evidence into the connection between their integer value knowledge and their interpretation of directed magnitude language. In this paper, students' choice of directed magnitude language terms for a temperature change provides such evidence and shows how using directed magnitude language could draw students' attention to both direction and the absolute value of which the temperature changes (e.g., the temperature change from -33 to -22 reflects a decrease from the absolute value perspective but shows an upward movement on the thermometer; see Bofferding, 2014, 2019). Further, students' drawn thermometers were additional evidence to describe their consistency between integer values and directed magnitude language interpretation, which suggests the importance of using an instructional model in determining the coordination between value and directed magnitude elements. Overall, the combination of asking students to choose the correct directed magnitude language term and drawing thermometers could potentially draw their attention to the differences between numbers' absolute value versus linear value. Unlike other studies (e.g., Whitacre et al., 2014), in the story-interpretation items, writing a number-sentence to "show the temperature change" highlighted how numbers' type and direction that temperature changes influence students to write an addition versus subtraction problem. Further, despite presenting the temperatures with their formal notations, the story-interpretation items still represented a realistic contextual problem because of asking to "show the temperature change." Thus, the results of students' responses to story-interpretation items opened a new window into ways in which students can generate a number-sentence relevant to story problems.

Together, the implications of this study highlight the importance of mathematical language as represented in students' choice of directed magnitude language terms. Students' directed magnitude language interpretations not only influenced their term choice, but also in some cases, was reflected in their written number-sentences and drawn thermometers. Perhaps, ways in which students make sense of mathematical language could tell a more cohesive story about how they think mathematically, rather than just their work with numbers and operations. Thus, mathematical language should become one of the central knowledge elements in

mathematics instruction. In addition to using mathematical language in the story problems, asking students to demonstrate their thinking in a different way by drawing a thermometer is essential to extend their access to mathematics and exhibit diverse ways of knowing and doing mathematics.

Endnotes

(1) I included students' categories for interpretation of order and value knowledge elements (whole-number, transitional, integer) in the parentheses after their pseudonym.

The aRithmetic Discourse Profile as a tool for mapping students' subjectifying and mathematizing discourse

Abstract: We present a new tool for mapping students' arithmetic discourse, named the aRithmetic Discourse Profile (RDP). The tool was developed based on the commognitive theory (Sfard, 2008). Its main goal is mapping students' mastery of arithmetic routines on a continuum between ritual (procedure based) and explorative (goal-based) participation. In addition, the tool maps the subjectifying statements of students (statements constructing their identity in action) to assess the affective aspects of the student's performance. We exemplify the tool on 3 tasks performed by 12 7th grade students. The findings show various possible relations between subjectifying and ritual/explorative performance.

Introduction

By the time students finish elementary school, they are supposed to have mastered the arithmetic discourse – the discourse on whole numbers, fractions, and the four operations that are used to manipulate these mathematical objects. Yet the learning of arithmetic often fails at certain points, and students arrive with insufficient skills to middle school and the demands of algebra, which is built on arithmetic. Moreover, students often develop, during the process of getting initiated into the mathematical discourse (through the gate of arithmetic) identities of failure. They come to endorse narratives about themselves such as "I am no good with numbers" or "I don't understand fractions" (Heyd-Metzuyanim, 2015). These identity narratives constrain their participation in mathematical activities and may often lead to disengagement, thus harming not just the learning of arithmetic but the learning of more advanced topics too.

Currently, there are little tools that can assess, holistically, the mastery that students have achieved of the arithmetic discourse. By "holistically", we mean that the tools relate both to the mathematical aspects of the discourse (often termed the "cognitive" elements) and the identity-related aspects of this discourse (often termed "affective"). Tests that assess mathematical disabilities or difficulties (e.g. Chinn, 2020; Dowker, 2019) are useful for determining which specific mathematical skills students may be lacking, yet they do not relate to the affective aspects of their participation. In contrast, tests that assess anxiety or attitudes towards mathematics (e.g. Hopko, 2003), do not relate to the mathematical skills of the student. Moreover, most tests of mathematical "knowledge" are built on paper and pencil techniques and focus on the end-result: whether the student's answer to a task is correct or not. Yet much information about the processes of participation, procedures employed and identity narratives produced along the way are lost this way. For this, a more processual approach for assessing students' mastery is needed – one which is based on examining their talk, not just their writing. In this work, we propose a novel tool, named the aRithmetic Discourse Profile, whose aim is to assess the extent to which a student mastered the arithmetic discourse, as well as their subjectifications – the identity stories that they produce while engaged in this discourse. Our aim in this paper is to introduce the tool, demonstrate its application and examine the results that can be obtained from applying it to a set of 12 students whose discourse was examined with it.

Theoretical Background

The theoretical framework employed for this study is the commognitive one (Sfard, 2008). This theory is used for several reasons: first, it has established a useful explanation of students' learning of mathematics as progression from ritual to explorative participation (Lavie et al., 2019; Sfard & Lavie, 2005). Ritual participation is characterized by rigid rule-following and reliance on external authority of experts. For example, imitating the teacher who is saying "fifteen" and writing "15" by writing the numerals 1 next to 5 without being able to name the "1" as a "ten". In accordance with the view of learning as becoming a participant in a community of discourse, Sfard and Lavie (2005) show how such participation is an unavoidable stage of learning, since at the initial phases of getting introduced to a certain discourse, learners are so unfamiliar with the objects on which this discourse is about, that they can only thoughtfully imitate others. Gradually, as they come to *objectify* the signs and symbols introduced to them, for example, as they come to see "15" as an object made up of certain parts (1 ten, 5 units), they become more explorative in their production of narratives about these objects. That is, they employ routines to manipulate these objects in flexible ways, and based on their own authority, or agency. Most importantly, their

 © ISLS

participation is *goal oriented*, that is, they employ certain procedures with the goal of the task in mind, rather than being satisfied with following the steps of an imitated procedure.

Previous works within the commognitive framework showed that the location of a student on the ritual-explorative continuum may be tightly related to their identity narratives – namely, those endorsable stories a student tells about herself (and others tell about her) that are reifying (talk about attributes of a person rather than about her actions) and significant to the storyteller (Sfard & Prusak, 2005). The relation between ritual participation and identity could be seen, for example, in the case of a student who described herself as "good in math" but "not good in fractions" and who indeed performed relatively exploratively in the discourse on whole numbers yet ritually in tasks that included rational numbers (Heyd-Metzuyanim, 2015). This student managed to achieve high grades in middle school due to diligent and hard work of following teacher-authored rules in algebra. Yet towards high-school, her ritual participation in the mathematical discourse widened so much that she failed her exams and ended up in a low achieving group. This case illustrated the need for early assessment and profiling of students "ritual pockets" of mathematical performance, even those students who achieve good grades, so that such "pockets" of ritual participation do not widen and lead to the development of a general identity of failure. The conclusions from this reported study, however, were based only on a single case-study. There is thus need of more rigorous examination of the relation between students' mathematizing and their concomitant subjectifications, namely those utterances that they communicate about themselves. Other studies of subjectifying activity (e.g. Heyd-Metzuyanim & Sfard, 2012) have also pointed to the importance of examining *implicit* subjectifying actions, namely those actions that are not expressed explicitly (such as "I'm not sure") but non-verbally or indirectly (e.g. by making a statement and waiting for the teacher to approve, ending the utterance with a questioning intonation, etc.). These implicit subjectifications are often even more potent in forming a story of a student as incompetent than the stories told explicitly out loud.

The idea to use a discursive lens to profile students' discourse has been employed and tested almost two decades ago, in one of the earliest commognitive works, by Ben-Yehuda (Ben-Yehuda, 2003; Ben-Yehuda et al., 2005). In her dissertation, Ben-Yehuda examined the discourse of 14 7th grade students, attempting to capture the unique characteristics of discourse of students with low achievements. This work showed the rich utility of the discursive framework and established the initial format of the tool, namely a "think aloud" interview where the student is given a set of arithmetic tasks aligned with the standard arithmetic curriculum. In addition, it showed evidence that students experiencing difficulties often did not talk about mathematical objects as existing of themselves but as symbols to be syntactically manipulated on the paper using memorized and meaningless procedures. However, since the theory of learning as progressing from ritual to explorative participation did not yet exist at that time, the characteristics found in Ben-Yehuda's study were still rather scattered. Moreover, the work did not result in a systematic coding scheme for analyzing students' discourse and did not enable placing a certain students' profile on a continuum (or several axes of continua) between ritual and explorative performance.

A much more recent work (Lavie et al., 2019) provided the missing conceptualization of operationalizing exactly what it means to participate ritually, or enact a ritual routine. This work followed the development of the numerical discourse of a 2.5 years old boy, over two years. It defined a routine as a pair of task (a situation that requires a certain action) and a procedure (a sequence of steps for achieving the goal). Lavie and colleagues showed through extraordinary detail how the young boy's routine of answering the task "where there is more?" *de-ritualized* according to the following characteristics: (a) it became more *flexible*, that is, more procedures were employed, alternately, to achieve the same task; (b) it became *bonded*, namely, sub-procedures became linked to each other in a way that the output of a step served as the input of the next step; (c) it became more *agentive* in the sense that the boy initiated the procedures and sub-procedures on his own, rather than looking for guidance from the adult who interacted with him; (d) the focus of the child, in enacting the routine, turned *from the procedure* to *the goal* of the task, where the importance lay in what it is that is to be achieved through the procedure In the current work, we add to these characteristics some additional ones, taken from other works that examined ritual participation and were more tailored to the discourse of older students: *objectification* (discussed earlier) and *mediation* (important when seeking to see to what extent the task is performed with the aid of a teacher). Finally, since we are dealing with issues of mastery of a school-discourse we are also interested whether the procedures employed by the students and the narratives derived from these procedures are *canonical* or not (or "mathematically correct").

With relation to the above characteristics of ritual/explorative participation, and seeking to understand the relations between them and subjectifying utterances, we ask in this paper:

1. What is the profile of students' participation on an axis between ritual and exploration, as obtained from the RDP?
2. To what extent does the ritual/explorative participation of students, as captured by the RDP tool, cohere with students' subjectifications?

Method

Our analytical tool was developed as a secondary data analysis, on data collected by the first author (Heyd-Metzuyanim, 2011). The data consists of arithmetic interviews conducted with 12 7th graders. The interviews were conducted as part of a larger study where the author taught the 12 students in groups over a period of 5 months, in an out of school "course". The course was broadly defined as "mathematics enrichment" and the original study was aimed at examining interactions between emotional and cognitive aspects of learning. The students were placed in three groups (each of 4): Low achieving, middle-high achieving, and excelling. The excelling group consisted of 4 boys who came from an accelerated mathematics and science classroom (to which entrance was based on very high grades in elementary school mathematics and other subjects). Placement in the low and middle-high achieving group was based on reports coming from the school and the students' parents.

The arithmetic discourse interviews were originally conducted to serve as a form of baseline, to examine the progress of the students during the course. However, they were never systematically analyzed. All the interviews were conducted by the first author, in a one-on-one setting. Students were asked to think out loud as they solved the problems (Young, 2005). When they were not successful and asked for help, the interviewer attempted to scaffold the task, yet mostly she refrained from giving feedback on the correctness of the results. Interviews were videotaped with two cameras, one pointing at the student's face and one on his writing. Written artifacts were collected too.

The interview protocol was based on Ben-Yehuda's study (Ben-Yehuda, 2003) and consisted of 24 tasks (some of them very short) that had potential to illuminate various aspects of students' arithmetic discourse. For the present study we chose three tasks for analysis (the full protocol appears in (Heyd-Metzuyanim, 2011)). These tasks were (1) A word problem which asked students to calculate how much would cost a shirt and a pair of pants if two shirts cost 200 Shekels (local currency) and 3 pair of pants cost 300 Shekels ; (2) the task Multiply in your head 25×99; and (3) calculate $\frac{1}{2} + \frac{1}{10}$. We chose these three tasks as they spanned a relatively large domain of arithmetic skills, namely – solving word problems (using addition and multiplication), multiplying whole numbers and manipulating fractions.

Method of analysis

The first stage of analysis consisted of marking verbs, nouns and pronouns, which would highlight the subjectifying and mathematizing talk. Pronouns and verbs usually indicate subjectifying ("I think", "I don't know", etc.) whereas mathematical nouns indicated objectification ("two thirds of nine *is* six"). The second stage consisted of mapping the routines enacted by the student into the structure of task-procedure, including the sub-tasks and sub-procedures involved (examples will be shown in the findings section). The third stage, which is the main stage of analysis, is coding the routine according to the criteria given in table 1.

Table 1 - Criteria of analysis for ritual-explorative routines

	Criterion (X, X)		Analytical actions	Characteristics of an explorative routine	Characteristics of a ritual routine
	Explorative	Ritual			
	X = 0/1	X = 0/1			
1	Objectified /syntactic mediation. Note: Can receive (1, 0) for objectified mediation or (0, 1) for syntactic mediation		Searching for evidence that the nouns signify numbers/quantities and not just the signifier of the number	In whole numbers, relating to the place value of the numeral. In fractions: relating to different realizations of the fraction as the same, including fraction as operator, part of whole, part of quantity, etc.	In whole numbers: relating to operations as signaling procedures on digits rather than on the whole number. In fractions, relating separately to the numerator and denominator.
2	Flexibility Note: can also receive (0, 0) if no conclusive evidence is found		Look for multiple procedures that are associated with the same task.	More than one procedure is associated with the main task OR a non-standard procedure is applied to the task.	Relying on only one procedure while showing rigidity and reluctance to use any other procedure.
3	Agency/External authority Note: coding is done on procedures and sub-procedures.		Look for subjectifying discourse; examine verbs/pronouns and non-verbal signals	Mathematizing with high confidence (no hesitations, question marks, no looking for approval).	Talking with question marks; Verbally or Non-verbally seeking approval from the interviewer; Relating to external

	Possible codes: (1, 0); (0, 1) and (1, 1)	that indicate the confidence.	Spontaneously articulating mathematical narratives	authority for justification (e.g. "that's what I learned in school")
4	Focus on goal or on procedure Note: coding is determined according to main procedure. Therefore, can only receive (1, 0) or (0, 1)	Look for verbs indicating doing (e.g. "I add") vs. being verbs indicating the result ("it is…");	Talking about the result, checking it, or explaining it spontaneously	Talking about the actions of the procedure. Ending the procedure without relating to the reasonableness of the result.
5	Bondedness Note: considered in relation to the full task. Therefore, can only receive (1, 0) or (0, 1)	Examine the procedure; sub-procedures and the bonds between them.	Each sub-procedure feeds the next sub-procedure. The narrative of the result of sub-procedure N serves as the input of sub-procedure N+1.	There is a disconnect between a certain sub-procedure and its following one OR sub-procedures using different realizations are not treated as the same.

The final three characteristics were coded in a binary fashion, getting either a score of (1, 0) for explorative, or (0,1) for ritual performance. *Canonical procedures* were coded as explorative if all the steps in the procedure aligned with standard mathematical procedures. *Canonical narratives* were coded as explorative if the end result of a procedure (e.g. the end result for the task "two thirds of 9" was "six") was canonical. *Mediation* was coded as (1, 0) if the procedure was fully initiated and enacted by the student, and (0, 1) if some parts of it were mediated by the interviewer.

Subjectifying was coded in the following way: statements that included direct reference to the self and one's actions or mental states (but not just descriptions of mathematical actions), were coded as "explicit subjectifying". These were coded as negative (-) if they included a negative statement about oneself (such as "I don't know" or "I don't think I can do this") and (+) if they were positive ("I can do this" or "this is fun"). Notice that "this is fun" was coded as explicit subjectification since the assumption was that a reference to oneself is implied in the statement ("this is fun *for me*"). Non-verbal emotional expressions and statements that communicated lack of confidence (such as smiling embarrassedly or asking "is this right?") were coded as *implicit negative subjectifications*. Although lack of negative subjectifications (implicit or explicit) could be interpreted as implicitly subjectifying confidence, we did not code for positive implicit subjectifications, since it was impossible to discern between "neutral" affective communication and "confidence". There were thus only three codes for subjectifying: two for negative (explicit and implicit) and one for explicit positive.

Reliability was assured through the following procedures: Two coders developed the coding criteria (the 1st and 2nd author), and then trained the third author on 20% of the data. Following that, the third author blind-coded an additional 20% of the data achieving sufficient agreement. Next, the third author coded the full set of 5 tasks, while the two other authors monitored reliability by double coding (blindly) 25% of each task. The overall Kappa of these blind codings was 0.85.

Findings

Overall findings from three tasks

Table 2 - overall codings of 12 students' on three tasks. Numbers indicate the difference between exploration and ritual elements of the routine.

Task/Student		Shirts&Pants	Subjectifying Exp	Subjectifying Implct	$\frac{1}{2}+\frac{1}{10}$	Subjectifying Exp	Subjectifying Implct	25×99	Subjectifying		Total
Dana	LA	-8	-	-	-4	+		-6	-	-	-18
Hili	LA	6		-	N/A	-	-	N/A	-		N/A
Hila	LA	4	-	-	-4			-6	-		-6
Naor	LA	6		-	-4		-	-5	-		3
Edna	MA	4		-	3	-	-	2	-	-	9
Idit	MA	8			-3		-	-1	-	-	4
Dan	MA	7			8	+		-1		-	14
Ziv	MA	6		-	5		-	5		-	16
Ram	EA	7			7	-		8	-		22
Gabi	EA	7			7			8			22

Yoram	EA	7			8			8			23
Amir	EA	7			8			7			22

Legend: LA = Low achieving group; MA = middle/high achieving group; EA = excelling group; Exp = Explicit; Implct = Implicit; + indicates positive subjectifications; - indicates negative subjectifications

Regarding the first RQ, we see high variance in students' performance on the three tasks. While some students performed almost fully exploratively (e.g. Yoram, Gabi and Amir), some students enacted the routines ritually (Dana , Hila), or completely disengaged (Hili). Some students (e.g. Edna, Idit) showed mixed performance, with mostly explorative participation in the "shirts and pants" word problem, along mixed routines or ritual routines in the adding fractions and multiplying two-digit numbers tasks. We see in these results evidence for the validity of the RDP since the performance was mostly in agreement with students' general achievements in school (as operationalized through their placement in the three achievement groups).
Regarding the second RQ, we see general coherence between the placement of students in achievement groups, and negative subjectifications: the lower the group, the more negative subjectifications (more "-" in the top part of the table). We also see consistency within students with relation to subjectifying, which hints at the stable mathematical identities (reified stories about oneself) that students have developed by this age. Thus, some students, such as Gabi, Yoram and Amir, never subjectified (neither negatively or explicitly positively), while others subjectified negatively very often (Hili, Edna). Yet others (such as Dana) subjectified both negatively and positively. Indicating much attention to oneself and one own's performance in the process of mathematizing. Another observation coming from Table 2 is that students in the low achieving group tended to subjectify negatively even when performing relatively exploratively (e.g. Hila in the word problem; Edna in $\frac{1}{2}+\frac{1}{10}$). Finally, when comparing the three tasks, the word problem was overall performed most exploratively, while the other two tasks (multiplication and adding fractions) were quite similar in the indexes of ritual and explorative participation. However, even in the word problem where almost all the students showed mastery, some students still subjectified negatively, communicating lack of confidence, or negative evaluations of their performance. Thus, in conclusion, we saw general coherence between ritual performance and negative subjectifications, with a tendency of overly-negative subjectifying in some students' discourse. We now move to exemplify some instances of coherence and incoherence between ritual/explorative performance and negative/positive subjectifications.

Example of coherence between ritual/explorative and subjectifications

	Speaker	**What is said (what is done) – *Explicit subjectifications marked in italics.* Implicit subjectifications marked in shadow.**	Written product 1	Edna	(Reads the task "calculate in your head 25×99", mumbles) *I don't think I can do it* (…) you can do two times nine and then five times nine and then add it up? Or is that actually.. You can subtract from this (unclear what "this" refers to)	
2	Interv.	Umm you can… but I think there's a more effective way. Because the 99.. it's very close to something	
3	Edna	Do like 100 and then take away one?	
4	Interv.	OK	
5	Edna	I.. I know, but *I don't know* how much to take away from this (smiles shily, fumbles with her pencil) … *I don't know*	
6	Interv.	If you call this 25 times, or actually 99 times 25 (Edna: OK) Will that help you?	
7	Edna	No (giggles) (Interv: No?) Take away from this 25?	
8	Interv.	OK so try it	
9	Edna	A hundred, umm like.. it's simply 2500 (Interv. OK). I think.. and then take away 25 that's… two thousands.. four hundred.. seventy five	
10	Interv.	Good	
11	Edna	Is it right?	
12	Interv.	A-ha	

The routine Edna employed for the task of multiplying 25×99 was coded as follows: Regarding *Objectification*: her routine was coded as explorative (1, 0) since she related to the product of the multiplication (2500) as an object ("it's simply 2500") [9], and since she saw the multiplication by 99 as meaning that one 25 needs to be "taken

away" from the 2500. The criterion of *flexibility* received a mark both on the explorative and the ritual columns (1, 1). The reason for "rigidity" (ritual) was that, initially, Edna did not show signs of employing spontaneously more than one procedure for the task. The first procedure she suggested ("you can do two times nine and then five times nine and then add it up" [1]) led her to a dead end ("I don't think I can do it" [1]). However, when the interviewer suggested another procedure (signaling it with "calling it 99 times 25") Edna picked up this prompt and associated with the task the procedure of multiplying 25 by 100 and taking away 25, a procedure that she completed successfully. This was taken as an indicator of flexibility since although the procedure was suggested by the interviewer, Edna saw the "sameness" in both her suggested (yet unperformed) procedures, and the one suggested by the interviewer. *Agency* also received a mixed code (1, 1). Evidence of agency were seen in deciding to employ the 25X100×=2500 sub-procedure, as well as the decision to take away 25 from 2500. Evidence of reliance on external authority were found in relying on the interviewer for hinting which procedure to use, as well as asking for confirmation at the end [11]. The criterion of *focus on goal/procedure* received only a mark of exploration (1, 0), as there were no indications of focus on the procedure. The whole performance was tailored towards reaching the narrative of what the product of 25×99 is. Moreover, Edna even envisioned initially two alternative procedures for accomplishing the goal [1], but discarded them as impossible (or difficult) for her to perform. The focus was thus never on simply enacting a certain procedure, but on choosing a procedure that would both fit for the task at hand, and be doable. With relation to *Bondedness*, the whole procedure and sub-procedures were bonded with each other. We found no indication of disconnect between the sub-procedures. Therefore, the criterion was marked as explorative (1, 0). In addition to these criteria, the criteria of *canonical procedures* and *canonical narratives* both received an exploration mark (1,0). Finally, the criterion of *mediation* received a ritual score (0, 1) since the choice of procedure was mediated, as well as its monitoring. Thus, in summary, the routine received 7 marks for exploration, 5 for ritual, and the difference mark was 2, which marks a "mixed performance" routine, with some tendency towards exploration. However, Edna's subjectifications are negative. She communicates both explicit [1, 5] and implicit subjectifications of lack of confidence [5, 7, 11]. Thus, Edna's subjectifications give hardly any hint of the explorative, or agentive parts of her routine.

Example of incoherence: ritual performance, positive subjectification

	Speaker	**What is said (what is done) – *Explicit subjectifications marked in italics.* Implicit subjectifications marked in shadow.** Written product: $\frac{1}{10}+\frac{1}{2}=\frac{2}{12}$
1	Dana	Oh, great! This, this- oh, *this is fun*. You do one plus one equals.. ah (writes) two
2	Interviewer	Umhm
3	Dana	Like this, and then ten and two, twelve (with confidence)
4	Interviewer	OK

The routine Dana employs for the task of adding $\frac{1}{2}+\frac{1}{10}$ was coded as follows: Regarding *Objectification*: her routine was coded as syntactic (ritual) (0, 1), since she treats the nominator and denominator as two whole numbers with no relation between them ("you do one plus one" [1], "and then ten and two" [3]). The criterion of *flexibility* received a mark of rigidity (ritual) (0, 1) because there was no indication that Dana had any other procedure to employ, and because of the deterministic "you do" declaration. *Agency* received an explorative code (1, 0) since Dana showed no hesitation, talked with confidence and came up with the procedure on her own. The criterion of *focus on goal/procedure* received a ritual mark (0, 1) since Dana only talked about steps in the procedure (adding the top numerals and bottom numerals), talked about actions ("you do") and showed no interest in the result (she did not even name the $\frac{2}{12}$ as "two twelfths"). With relation to *Bondedness*, the routine was coded as ritual (0, 1) since the two sub-procedures were not bonded (adding 1+1 and adding 2+10), neither was there any bondedness between these two sub-procedures and the task of adding half and a tenth. The criteria of *canonical procedures* and *canonical narratives* both received a ritual mark (0, 1). Finally, the criterion of *mediation* received an explorative score (1, 0) since the choice of procedure was not mediated and there was no intervention on the part of the interviewer. Thus, in summary, the routine received 2 marks for exploration, 6 for ritual, and the difference mark was -4, which marks a ritual routine.

Yet, despite this ritual performance Dana's subjectifications were positive. She communicates both explicit subjectifications of feeling confident "this is fun" [1] and implicit subjectifications of confidence [1, 3]. Thus, Dana's subjectifications give hardly any hint of the ritual nature of her performance.

Example of coherence: explorative performance, positive subjectification

The last example is taken from Dan's interview. Here is how he solved the task of adding $\frac{1}{2}+\frac{1}{10}$.

	Speaker	What is said (what is done) – ***Explicit subjectifications marked in italics.*** **Implicit subjectifications marked in shadow.** Written product 1	Dan	(Reads from the sheet) "Solve the exercises", um calculate this?
2	Interviewer	Uh yes you need to solve, yeah. You can do it in writing
3	Dan	No, *I don't need to calculate, I don't have to calculate*
4	Interviewer	How?
5	Dan	Oh *I can do it quickly* (Interviewer: OK). So this equals uh.. 6 divided by 10.

The routine Dan employs for the task of adding $\frac{1}{2}+\frac{1}{10}$ was coded as follows: *Objectification*: his routine was coded as objectified (explorative) (1, 0), since he effortlessly samed $\frac{1}{2}$ and $\frac{5}{10}$ and since he talked about "six divided by ten" which is not the standard way of calling the fraction (standard would be "six tenths"). The criterion of *flexibility* received a mark of exploration (1, 0) because he chose a non-standard procedure (naming $\frac{1}{2}$ as $\frac{5}{10}$ and then adding the two fractions in his head). *Agency* received an explorative code (1, 0) since he showed no hesitation and came up with procedure on his own. The criterion of *focus on goal/procedure* received an explorative mark (1, 0) since Dan's focus was on the result, and he even explicitly said that he can "do it without calculation", referring to being able to come up with an answer without following the standard procedure taught in school. With relation to *Bondedness*, the routine was coded as explorative (1, 0) since there were two sub-procedures (realizing $\frac{1}{2}$ as $\frac{5}{10}$ and then adding $\frac{1}{10}$ and $\frac{5}{10}$) and they fed one into the other. The criteria of *canonical procedures* and *canonical narratives* both received an explorative mark (1, 0). Finally, the criterion of *mediation* received an explorative score (1, 0) since the choice of procedure was not mediated and there was no intervention on the part of the interviewer. Thus, in summary, the routine received 8 marks for exploration, 0 for ritual, and the difference mark was 8, which marks a highly explorative routine. Dan's subjectifications cohered with the explorative nature of his routine. He communicated both explicit subjectifications of feeling confident "I don't need to calculate" [1] and "I can do it quickly" [3] and showed no subjectifications of hesitation.

Discussion

Our goal in this research was to develop a holistic tool for mapping students' arithmetic discourse along the ritual-explorative axis, as well as to map their subjectifying (identity construction) discourse. We asked what the application of this tool to the discourse of 12 students, solving 3 tasks, would reveal. We also wished to examine to what extent the ritual or explorative performance of students is in coherence with their subjectifications – namely their evaluations of themselves as they work on the tasks. Our findings revealed that the students' ritual/explorative performance was highly varied and it was generally consistent with their placement in the different achievement groups. Low achieving students generally performed more ritually than their high achieving peers. These findings add credibility to the theory of learning as advancing from ritual to explorative participation, as it shows that students who have mastered the arithmetic discourse (and are thus probably achieving highly on school mathematics tasks) perform mostly exploratively on the given tasks, while low achieving students have not mastered the discourse and thus perform ritually.

In relation to the question of coherence between subjectifications and performance, our findings showed that the students' subjectifications generally agreed with students' ritual/explorative performance, with ritual enactments of routines accompanied more by negative subjectifications than explorative enactments. There was also coherence between the identity of the student as low, middle/high achieving or excelling (as seen in the placement of students in groups) and their subjectifications: the lower achieving students subjectified more negatively than the high-achieving students. However, there were also interesting inconsistencies. One was where students subjectified negatively, but their performance was relatively explorative. The other (rarer) occurrences were when students evaluated their performance positively but their performance was highly ritual.

These findings strengthen the validity and utility of the RDP tool. The validity can be derived from the agreement between the scores on ritual/explorative performance on the three tasks and the general achievement and mathematical identities of the students. The utility of the tool can be found in the nuanced view of students' performance, which, for example, can reveal certain students' over-tendency to negatively evaluate their performance, as well as certain tasks (such as adding fractions) that may be susceptible to over-confidence (students' subjectifying positively despite their ritual performance).

This report has been concerned with only three tasks out of the 24 that are included in the RDP. Future work should examine if other tasks significantly change the picture obtained by the analysis of these tasks. Thus, this work is limited in the ability to generalize from the findings to the general arithmetic discourse of students. It is also limited by the small number of participants, a regular limitation in highly work-intensive methods such as discourse analysis. Finally, the RDP mostly contains standard calculation tasks, not complex problems that involve modeling or literacy, nor does it include non-arithmetic parts of the mathematics curriculum such as geometry or statistics (data analysis). Thus, one should be careful in deriving from its results conclusions about the general mathematics discourse of students.

Nevertheless, the RDP has multiple avenues for future development and utility. First, the main utility of this tool is in examining interventions aimed at increasing explorative participation. Current paper-and-pencil tools are not sufficiently discriminative to examine such minute developments. Second, the RDP can function as a diagnostical tool for examining "pockets of ritual participation" that need to be attended to. As reviewed earlier, such "pockets" may widen over time and lead to generalized failure, despite students' effort and aspirations (Heyd-Metzuyanim, 2015). Finally, learning to use the tool and analyze students' discourse with it, may teach teachers to turn their attention towards processes of ritual and explorative participation. Although it is highly improbable that a teacher could expend the effort of analyzing each of their students with this tool, some experience with it may still go a long way. As shown in professional development efforts in the past (e.g. the CGI professional development program, (Franke et al., 1998)), when teachers become familiar with a certain theoretical lens that helps them better understand their students' learning processes, this can, by itself, change their teaching practices to be more attuned to their students' needs.

Designs for Grounded and Embodied Mathematical Learning

Mitchell J. Nathan, University of Wisconsin-Madison, MNathan@wisc.edu
Candace Walkington, Southern Methodist University, CWalkington@smu.edu
Michael Swart, University of Wisconsin-Madison, MSwart@wisc.edu

Abstract: Findings synthesized across five empirical, laboratory- and classroom-based studies of high school and college students engaged in geometric reasoning and proof production during single and multi-session investigations (346 participants overall) are presented. The findings converge on several design principles for embodied mathematical thinking and learning. *The Hidden Village* is presented as an instance of an embodied learning environment that uses the narrative context of a visual novel to instantiate these design principles and investigate their influences on mathematical thinking and learning, and to inform a broader theoretical framework of grounded and embodied learning. The interplay of theoretical, empirical, and design considerations of grounded and embodied learning reframes learning, transfer, and assessment, offering promising new pathways for an emerging class of learning environments.

Grounded and embodied learning

Grounded and embodied learning (GEL) offers a framework for understanding and designing for meaning making based on body-based processes. These GEL processes include actions, gestures, operative speech, and collaborative movements, as well as processes for supporting simulated action and imagination. Evidence is mounting that GEL is also activated during interventions, such as when learners are prompted to perform directed actions or are prompted to engage in simulated actions. This paper summarizes a set of interwoven empirical, theoretical, and design advancements for mathematical reasoning and their implications for teaching, learning, learning environment design, and assessment.

The **theoretical contributions** offer hypothesis-driven inquiry into the nature of learning and meaning making through body-based experiences, and principled guidance for the design of learning technology and educational experiences. **Empirical** contributions span several laboratory- and classroom-based studies of high school and college students and high school teachers; in all, some 346 participants who engaged in 5 single and multi-session investigations. These investigations provide evidence of the role of embodied processes for meaning making in support of mathematical reasoning and theoretically guided design principles to promote learning.

Design advancements to technologies for embodied thinking and learning serve as essential instantiations of theoretically derived hypotheses, as well as vital spaces in which embodied behaviors are elicited and data collected. Empirical findings and theoretical progress inform improvements in learning environment design that then make possible further theoretical and empirical advancements. In the final section, we explore how the interplay of evidence, theory, and design offer pathways for progress on complex issues facing GEL, such as generalizing research, bridging research and practice, and the emergence of designs and design principles.

Theoretical Frame: Grounded and Embodied Mathematical Cognition

Assumptions About Cognition

Memories, experiences, and meaning are constructed through the continuous *interactions* among environmental, social, cognitive, motoric, and perceptual processes of a highly dynamic, self-regulating organism, via a *perception-action loop* (Neisser, 1976; Varela et al., 1991). The cognitive system is a *predictive architecture*, continually anticipating responses to sensorial input from the environment and from within (Clark, 2013; Glenberg, 1997). People engage in cognitive processes that *extend* beyond the individual actor. Task-relevant knowledge is *embedded* in the situations in which activity unfolds and is *distributed* across actors, objects, and space (Clark & Chalmers, 1998). People can regulate distributed resources through cognitive *offloading* (Hutchins, 1995; Wilson, 2002). Finally, to be meaningful, new ideas, abstractions, and symbolic representations must be *grounded* in one's lived, sensorimotor experiences (Harnad, 1990; Glenberg et al., 2004).

Several scholars have synthesized evidence-based design principles for fostering embodied learning (Abrahamson et al., 2020; Lindgren & Johnson-Glenberg, 2013; Johnson-Glenberg et al., 2014; Skulmowski & Rey, 2018), with considerable overlap on these considerations: Motoric engagement; cognitive relevance of actions (aka "action-concept congruency"); and presence, including virtual, sensorial, and social immersion.

Integrating Linguistic and Body-Based Processes

Mathematical cognition emerges from the interplay of symbolic, verbal, and sensorimotor knowledge and processes. Symbol systems are important disciplinary representations that codify formal knowledge, yet their arbitrary, abstract, and amodal (i.e., ungrounded) nature poses challenges for learners (Nathan, 2012). Oral language serves as a source for consciously grounding symbol systems, expressing meaning, and representing abstract relations (Koedinger, Alibali & Nathan, 2008). Sensorimotor processes offer a complement, through nonverbal and nonsymbolic forms of knowing based on one's lived experiences. Through the cognitive mechanism of conceptual metaphor, bodily processes can be the basis for grounding foundational mathematical concepts, such as number, as well as the means to *link* to more advanced topics (Lakoff & Núñez, 2000).

Gestures are spontaneous acts of the body—most typically the hands and arms—used during mathematical learning and teaching that integrate naturally with public speech (social communication) and inner speech (verbalizable thinking) to make direct indexical reference to the world (deixis), depict worldly objects (iconics), and represent abstract relations (metaphorics) (Alibali & Nathan, 2012). Gesture has three special qualities relevant for embodied mathematical cognition. First, it can manifest simulated actions (Hostetter & Alibali, 2008). As an example, one does not merely imagine *100* as a symbol, but as a location along a mental number line, with a corresponding gesture that may sweep to the right of the body's central axis. Second, gestures can add abstract as well as sensorimotor information from actions into the cognitive encoding of a task. In effect, gestures help to *schematize* the most important qualities of task-relevant actions—physical and simulated actions—that can facilitate the formation and generalization of task-relevant cognitive processes for future use (Kita et al., 2017). As such, gestures "provide a bridge between concrete actions and more abstract representation" (Goldin-Meadow & Beilock, 2010, p. 672). Third, gestures express multimodal knowledge that cannot be verbalized, and which may be unconscious or as yet linguistically and symbolically unformed.

Action-Cognition Transduction: How Actions Produce Ideas

Cognitive processes have historically been framed using computer-based metaphors. Within this metaphor, a "central processing unit" governs the behaviors of "peripherals" such as perceptual systems, and output devices in the form of actuators such as our hands, that act upon the world (Eisenberg, 2002). We readily accept that our thoughts can (often) control our actions. *Action–cognition transduction* (ACT) explains how, in reciprocal fashion, body movement can induce mental states and actions through the complex coupling of feedforward and feedback interactions (Nathan, 2017). This alternative cognitive architecture places the function of peripherals as also central to cognition, through means such as gestures, eye gaze patterns, epistemic actions, and cognitive offloading (Kirsch & Maglio, 1994; Wilson, 2002). Actions, in this view, literally change our minds.

Geometric Reasoning and Mathematical Proof Production

Embodied approaches to thinking and learning confront some unique challenges regarding mathematical proof. Proof is a central disciplinary practice among mathematicians, serving as the primary method for testing claims, constructing knowledge, and disseminating research (Lakatos, 2015). Geometry is the primary scholastic content area for k-12 students learning to produce mathematically valid proofs and is used to explore properties of space and shape (Lehrer & Chazan, 2012; NCTM, 2000; Stylianides, 2007). As a topic of advanced mathematics, it is steeped in abstractions and formalizations to make universal claims that go well beyond personal experiences. Formulating proofs does not rest on well-rehearsed procedures. It requires the development of mathematical intuition along with logical, generalizable, and goal-directed, operational thought (Harel & Sowder, 2005).

Despite its importance, educational systems struggle to cultivate proof practices (Dreyfus, 1999). As examples, students rely on tautological claims without cultivating true insights about the phenomena of interest and tend to overgeneralize claims derived from specific examples (e.g., Healy & Hoyles, 2000). This prompted our inquiry about ways to promote GEL of proof practices.

Theoretically Guided Research Questions

We report on the findings from several empirical studies designed to explore the following questions: (1) What are the emerging cognitive principles for GEL of geometry proof? (2) How can these principles inform the design of computer-based embodied learning experiences?

Empirical Support for GEL of Mathematical Reasoning

Dynamic Gestures Enact Simulated Actions to Facilitate Geometric Reasoning

This first study (Nathan et al., 2020) asked: *Is geometric reasoning associated with participants' gesture production?* Secondarily, we wanted to know: *Does the strength of the relationship between geometric reasoning*

and gesture production depend on participants' mathematical expertise? We analyzed video recordings of 46 mathematics experts and 44 non-experts recruited from a large US midwestern university who evaluated the truth of conjectures about geometric properties (Table 1). We used logistic regression for binary outcomes (0/1) to model accuracy of intuition (snap judgments), insight (gist), and proof. A valid proof had to show reasoning that is logical, operational, and generalizable across the class of mathematical objects under consideration.

Table 1
Truth value, insights, and proof for example mathematical conjectures.

Conjecture Text	Truth	Insight	Proof	Cognitively Relevant Directed Actions
The area of a parallelogram is the same as the area of a rectangle with the same length and height	True	(1) States a parallelogram is a rectangle tilted or pushed over. (2) States area of a parallelogram and a rectangle have the same formula.	(1) Shows cutting off a triangle from the parallelogram, or rearranging the area makes them congruent. (2) State all rectangles are parallelograms thus the formula for area is the same.	
Given that you know the measure of all three angles of a triangle, there is only one unique triangle that can be formed with these three angle measurements	False	States similar triangles or infinite/many triangles	(1) Gives specific counterexample (2) Visually shows scaling or discusses scaling and similar triangles	

Analyses provide empirical support for claims that geometry proof production is an embodied activity, even when controlling for math expertise, language use, and spatial ability. We coded for *dynamic depictive gestures* that portray generalizable properties of shape and space through enactment of transformational operations (e.g., dilation, skewing; Garcia & Infante, 2012; Nathan & Walkington, 2017). *Dynamic depictive gestures* (Figure 1) are contrasted with non-dynamic depictive gestures that may trace or merely refer to mathematical objects and their transformations. Non-dynamic depictive gestures were associated with correct mathematical intuitions (p = .004). Dynamic depictive gestures were more likely to be associated with correct insights (p = 0.042) and mathematically valid proofs (p < .0001) than when no such gestures were made. Furthermore, experts significantly out-performed non-experts and were more likely to produce dynamic gestures (79%) than non-experts (52%).

The benefits of dynamic gestures were replicated among undergraduates from a large, southwestern university (N = 108). There, production of dynamic gestures was associated with mathematical insights (d = 0.45, p < .05) and mathematically valid proof (d = 0.74, p < 0.001), but production of any gesture was not (Walkington et al., 2019). Dynamic gestures may allow participants to explore generalized properties of shapes and space, thus supporting their geometric reasoning. This suggests that gestures, as simulated actions, provide an alternative account of mathematical reasoning than that of symbolic cognition. This raises questions of whether and how to design learning experiences that elicit gestures in service of mathematical thinking and learning.

Directed Actions Foster Reasoning and Performance Benefits Through Video Game Play: The Importance of Cognitive Relevance

To explore how eliciting gestures impacts mathematical reasoning, we developed *The Hidden Village* (THV), an embodied video game that uses the *visual novel* genre (Cavallaro, 2009). We explored to questions: *Can we use directed actions to elicit dynamic gestures that will enhance geometry proof performance?* And *Does the cognitive relevance of the directed actions used in the game matter?*

A player mimics movements of in-game "villagers" doing activities such as dance and play (Figure 2). THV uses 3D motion-capture technology via the Kinect™ sensor array to track player motion in real time to determine if the player has performed the intended directed action. *Directed actions* are carefully chosen movements curated from prior sessions of successful mathematical reasoning. Once the directed actions are repeatedly matched, the player reads a geometry conjecture (Table 1), decides if it always true or ever false, provides an explanation in speech and gesture (which is recorded), and then chooses a multiple-choice response.

 © ISLS

Completing each conjecture cycle earns a knowledge token and reveals a bit more of the map of THV.

In this experiment (Walkington et al., 2021), 85 high school students (65 female) from a program for soon-to-be first-generation college students were recruited. Forty-eight identified as Hispanic, 26 as African American, 5 as Asian, 3 as Caucasian, 2 as other race/ethnicity, and 1 had race/ethnicity data missing. Each student played eight conjectures. Cognitive relevance of the directed actions to each conjecture was manipulated within-subjects (4 relevant, 4 irrelevant). For example, a conjecture poses "The area of a parallelogram is the same as the area of a rectangle with the same length and height." The cognitively relevant directed actions in Table 1 schematize the conjecture's mathematical relations (Nathan & Walkington, 2017). The *irrelevant* directed actions are recycled actions from other conjectures to vary relevance while controlling for physical complexity. Conjecture order was counterbalanced using an 8-item Latin square factorial design. Participants were not informed that any of their directed actions were relevant to the conjectures they were being asked to prove.

Data were analyzed using mixed effects logistic regression models with repeated observations of students solving conjectures nested within student. Participant ID was made a random effect with an additional random effect for conjecture. Condition (relevant v. irrelevant) was not a reliable predictor of gesture usage on its own. Still, when participants were cued with relevant actions, they showed superior proof performance compared to times when cued to make irrelevant actions, *provided* they made any gestures ($d = 1.13$, $p < 0.01$), or, more strongly, when they made dynamic depictive gestures ($d = 1.56$, $p < 0.01$). Similar advantages for cognitive relevance were observed for performance on mathematical insight ($d = 1.02$, $p < .01$) and intuition ($d = 1.00$, $p < .01$), *so long as* students produced dynamic gestures during their explanations.

The results suggest that cognitively relevant directed actions contribute to superior mathematical reasoning. This beneficial influence is not direct, however, but appears to be *moderated* by the role of dynamic gestures during students' multimodal explanations. This may be because explanatory gestures help to schematize relevant mathematical information (Kita et al., 2017), thus enabling students to make better use of the conceptual information they obtain via action-cognition transduction when they perform directed actions that are cognitively relevant. Comparable actions that are not cognitively relevant offer fewer benefits to mathematical reasoning.

Collaborative Gestures Enhance Geometric Reasoning Via Extended Cognition

Collaboration offers another potential way to increase students' production of dynamic gestures during mathematical reasoning, supporting enhanced performance. When high school students (N = 51) from a school district in the Southwestern US were observed playing *The Hidden Village* in groups, they operated as a form of distributed system, with mathematical thinking extended across multiple members of the group in speech as well as gestures. Walkington and colleagues (2019, 2021) documented several types of *collaborative gestures,* defined as "gestures that are physically and gesturally taken up by multiple learners, holding a meaning that is explicitly dependent upon the gestures of interactional partners." Forms of collaborative gesture that students exhibited included (Figure 3): echoing (55.5%), as when a gesture was repeated; mirroring (24.4%), as when an observer matches the speaker's gestures at the same time; alternating (20%), as when an observer proposes an alternate gesture to advance the group's mathematical line of thinking without copying (as in echoing); and joint gestures (15.5%), as when multiple learners use their hands conjointly to form a single mathematical object or idea.

They found that gestures--especially collaborative gesture production--contributed significantly to student performance. When group members did not gesture, students generated the correct insight 12% of the time. In comparison, the correct insight was produced more often with non-collaborative gestures (39%) and far more often with collaborative gestures (72%). Extending body-based resources across multiple participants, as well as other resources, reveals additional ways embodiment facilitates cognition.

Embodied Knowledge Transfer and the Travel of Ideas

One of the hallmarks of learning is to foster transfer, the conditions in which prior experiences facilitate learning and extend its reach to novel, but related areas of performance. Goldstone, Landy, and Son (2008) demonstrate how perceptual learning transfers "not through acquiring and applying symbolic formalisms but rather through modifying automatically perceived similarities between scenarios by training one's perceptual interpretations" (p. 329). In this small-scale study (Kirankumar et al., 2021), 12 students in a Title I high school played THV in small groups during Day 1. On Day 2 they used the THV-Conjecture Editor (Figure 4) to co-create new game content for their classmates. In so doing, they had to create cognitively relevant directed actions that would foster mathematical learning among their peers for Day 3, but without telling them—only through game play.

Group A chose to create the *ABC Reflection* conjecture (which is false)*: Given three points A, B, and C, and their reflected images about a line, A', B', and C', then ∠ ABC and ∠ A'B'C' are not equal.* Within-group analyses of their collaborative co-design (Day 2) showed that students regularly produced dynamic depictive gestures while investigating which directed actions would assist new players in forming the proper geometric

relations relevant to proving their conjecture. Between-group analyses (Day 3) showed that students in Groups B and D learned some insights and proof elements by playing the *ABC Reflection* conjecture from Group A.

The spontaneous gestures produced by students in Group D following Group A's directed actions demonstrated that game play provided an embodied conceptualization of reflection. The gesture made by a student in Group B reveals an understanding of reflection based on the directed actions performed by their teammate. This is demonstrated using a hand flip rather than whole arm/torso flip, showing how the student tracked the key invariant relation (angular measure), mapping that relation across contexts and bodies through the student's own body movement. The action (hand flip) performed in the new context can activate common cognitive states through transduction, which highlights the invariant relation in its new setting. This highlight helps establish the mapping by preserving what must remain invariant as it travels across contexts and physical settings.

These two cases provide preliminary insights into how ideas can "travel" via embodied engagement through game content creation and game play. It illustrates how "transfer is an embedded process, situated in a particular physical and sociocultural learning context" (Nathan & Alibali, 2021, p. 52).

Discussion

With these empirical findings in mind, we revisit the research questions. For the first question, we highlight several emerging design principles for GEL of geometry proof. One principle is the apparent cognitive benefits of *integrating linguistic and body-based processes*: Gestures are multimodal linguistic forms that both express and influence students' mathematical reasoning in ways that are both nonverbal (intuition) and verbal (insight and proofs), even when controlling for spatial ability and prior math education. Dynamic gestures in particular are shown to support the simulated actions (Hostetter & Alibali, 2008, 2019) needed for hypothesizing and generalizing universal truths about space and shape, which is central to geometry proof practices.

A second principle is that the *cognitive relevance of directed actions* is critical for designing effective interventions to enhance the quality of students' proofs. This builds on the notion that decentralizes cognition by recognizing that cognition and goal-directed actions mutually and reciprocally influence one another through transduction (Nathan, 2017). The mapping of concepts to relevant actions is, however, not a simple one-to-one relationship, which illustrates its complexity while also inviting tremendous variety for the designer. This design constraint appears to rest on the degree to which learners use explanatory gesture (again, integrating linguistic and bodily processes) to schematize the key mathematical relationships through movement (Walkington et al., 2021).

Creating collaborative contexts is a third principle shown to foster the kinds of gestures that are beneficial to mathematical reasoning (Walkington et al., 2019). In addition, the collaborative interactions that arise in these contexts support the formation of distributed knowledge exhibited by students' collaborative gestures, and the tightly coupled interactions that foster shared meaning. The final principle is *designing for embodied transfer by supporting production of prior actions*. Transfer emerges from the embodied nature of learning and the natural tendency of learners to predict the world and build cohesion across their learning experiences (Nathan & Alibali, 2021). In this sense, transfer is the default mode for engaged learners. Recurrent action sequences can bridge the travel of ideas across contexts, and educational environments need to be designed with this in mind. It also underscores how transfer is inherently embedded in socially mediated interactions among learners with teachers, peers, and technologies, allowing ideas to "travel" among groups and across contexts.

The second research question asks how these principles inform the design of computer-based embodied learning experiences. We explored these design principles in the context of *The Hidden Village* (THV), a visual novel used to engage players in embodied mathematical reasoning. THV is designed to integrate linguistic- and body-based processes during learning and performance assessment. It does this by eliciting from players the movements that were curated from prior sessions of successful mathematical reasoning. Following this, THV collects data on players' nonverbal intuitions (i.e., snap judgments) about the truth of the mathematical conjectures of interest. It then elicits these movements during players' multimodal explanations and justifications. In this way, it strives to bridge the chasm between exemplar-based concrete thinking and generalized abstractions that are central to mathematically valid proof production.

THV draws on the power of collaboration to engage players in the formation of distributed knowledge. Collaborators are shown to do far more than share knowledge verbally and symbolically. In addition, people come to recognize the representational power and expressiveness of both their own bodies and that of their collaborators. These interactions require establishing a shared understanding as well as offering ways to extend their own embodied thoughts onto the world around them. THV also explores the power of collaborative co-creation of new mathematical content to share with others. Creators come to recognize some of the ways their novel mathematical ideas become grounded in movement. They can then use movement as a means for transmitting generalizable concepts to others, who demonstrate them through their own movements. By recognizing transfer as an inherently embodied process, THV offers alternative ways to build shared knowledge. This raises considerations about the

role of the body in assessment, as learners may exhibit understanding through movements before they are aware of new emergent meanings or before they can verbalize new ways of thinking (Church & Goldin-Meadow, 1986).

Here, we have looked at the close relationship among empirical evidence, theory building, and design to investigate pathways for progress on complex issues facing GEL. We believe this work starts to establish an empirical basis for theorizing how linguistic and bodily knowledge among individuals and groups serve advanced mathematical reasoning, and the technological designs to support these types of social and embodied interactions. Still, this work has several limitations. One is the provisional nature of many of these empirical findings, which must face replication using larger and more varied samples, conducted with less direct input from the original research team. Another is that the principles themselves need to be tested with other digital platforms and using a broad array of student outcome measures before they can be really regarded as well established and generalizable. Our interest is to foster this additional research and the scrutiny it offers for theory and design. We take these initial steps as promising forays into a new class of theories and technologies for grounded and embodied learning.

Implicit and Explicit Emotion Regulation for Conflict Resolution: Narrative and Self-Compassion as Anti-Bullying Training

Sheenyoung Park, Daegu Metropolitan Office of Education (DMOE), babosky@gmail.com
Dimitra Tsovaltzi, German Institute for Artificial Intelligence (DFKI), dimitra.tsovaltzi@dfki.de

Abstract: Bullying poses a risk for equity and justice in learning. It can compromise learning achievement and hinter task performance. Emotions are key to handling bullying, thus need to be understood for the development of anti-bullying technological supports. We investigate effects of combining implicit and explicit emotion regulation strategies on empathy and conflict resolution styles among adolescents in a school bullying context. Based on dual-process framework of emotion regulation (Gyurak et al., 2011), the experimental group engaged in self-compassion induction as explicit regulation in combination with narrative construction as implicit regulation whereas the control group completed narrative construction only. The combination of implicit and explicit regulation was associated with significant increases in self-compassion subscales of self-kindness and mindfulness. It also elicited indicators of prosocial conflict resolution style: namely other-inclusion behavior and a tendency to inclusive choice of beneficiary from the bystander perspective. Effects on empathy were not larger with additional explicit support.

Theoretical background

Bullying can take forms of direct physical or verbal aggression, indirect manipulations of social relational structures (Björkqvist et al., 1992), or even recently emerging forms of aggression through digital media (H. J. Thomas et al., 2014). Recent findings support that bullying does not only concern those who are directly involved in an incident (e. g., Dodge & Price, 1994; Hodges et al., 1997), but is rather a socially grounded group process through which even seemingly less involved members of a peer group, so called bystanders, can contribute to reinforce, moderate, or prevent incidents of bullying (Peets et al., 2015; Salmivalli et al., 1996). Bystander behaviors affect adolescents' perception of the victimized (Gini et al., 2008) and such social contexts can determine how they behave in bullying incidents (Salmivalli et al, 1998). Targeting the group as a whole and enhancing general levels of empathy of its members are, thus, regarded as crucial aspects of systemic intervention/prevention measures against bullying (Kärnä et al., 2011).

Bullying poses a risk for equity and justice in learning contexts as it compromises learning achievement, especially for the unsupported and repeatedly bullied students (Juvonen, Wang, & Espinoza, 2011) and diminishes performance due to attentional deficits related to processing negative emotions (Dolcos et al., 2020). Bullying is a source of socio-emotional conflict, which often leaves bystanders, especially, at an emotional limbo (Hilt et al., 2019). It may thus render them unable to take vital anti-bullying actions. Therefore, emotions in bullying situations and their regulation need to be understood to develop anti-bullying technological supports. *Empathy,* as a commonly investigated emotional compound in the context of bullying, refers to one's reactions to the observed experiences of another (Davis, 1983). It is widely accepted that empathy consists of cognitive understanding of mental states of others (*perspective taking*) and emotional responses to perceived emotional states of others (Davis, 1983). Other-oriented emotional responses (*empathic concern*) signify concern for others, altruistic motivations (Batson et al., 1987), and regulation of one's own negative emotions (e.g., *personal distress*) (Eisenberg & Fabes, 1995; Panfile & Laible, 2012). Previous research has shown positive associations between empathy and defending behaviors of bystanders in bullying incidents (see van Noorden et al., 2014 for a review), who may become catalysts in conflict resolution and whose situational behaviors may depend on the regulation of their own negative emotions.

Emotions arise when one recognizes personal relevance in social contexts and assigns meaning to the experience. Thus emotions are malleable recursive processes where an emotional response to a situation can change the meaning assigned to the emotion-provoking situation (Gross & Thompson, 2007). Through such iterative emotion generative processes, we may influence which emotions we experience, when and how we experience and express them (Gross, 1998b). According to the dual-process model, emotional responses are modulated by the interplay of two ways of *emotion regulation* (ER): *explicit* processes, which require conscious effort, some level of metacognitive monitoring, and awareness, and *implicit* processes, which are evoked automatically by the stimuli and do not necessarily involve metacognitive processes (Gyurak et al., 2011). One might benefit from explicitly learning and using strategies (e.g., reappraisal or detachment) by assigning different meanings to emotion-provoking situations or maintaining a distant observer perspective (Gross, 1998a, 2002;

 © ISLS

Kalisch et al., 2005). At the same time, engaging in such explicit regulation processes may routinize and trigger these strategies automatically, making them implicit in the long run (Gyurak et al., 2011). Hence, explicit ER seems to interact with implicit ER. While conscious effortful explicit processes might not be possible or advisable at all times, e. g. when attention needs to be focused on the learning tasks, implicit processes are activated automatically (Dolcos et al., 2020). However, helpful implicit processes might not be cultivated without support. Thus, the interaction of implicit and explicit ER needs to be examined and compared to only implicit processes.

Using narratives to implicitly induce reliable emotions in realistic conditions has enhanced scientific understanding of human emotions (Jääskeläinen et al., 2021; Kanske et al., 2015). Numerous studies of bullying have also used narratives in the form of fictional characters or hypothetical episodes to elicit relevant responses from young people allowing for interpretations of their perspectives and attitudes (e.g., Bosacki et al., 2006; Jeniffer et al., 2006). In addition, *narrative construction* is suggested as a strategy to down-regulate negative emotions as it allows for expression of emotions, coherent restructuring of the events (Pasupathi et al., 2017), and active meaning-making based on one's experiences (Plowman et al., 1999), thereby attenuating intensity of emotional impact. Therefore, it can be considered as an implicit ER without the need of conscious effortful processes and yet reflecting automatic emotional responses to a situation that may become transparent to oneself.

Self-compassion (SC) is conceptualized as being kind and understanding to oneself rather than judgmental (*self-kindness*), interpreting one's personal experiences as part of human experience (*common humanity*), and being aware of one's painful thoughts and feelings without over-identifying with them (*mindfulness*) (Neff, 2003). Dispositional SC is positively correlated with ER (Finlay-Jones et al., 2015), empathy (Neff & Pommier, 2013) and prosocial behavior (Welp & Brown, 2014). Explicit long-term training of SC increases levels of dispositional SC among adolescents (Bluth et al., 2016) and supporting SC through simple instructions mediates effects of situation-specific self-related negative emotions (Leary et al., 2007).

Following the dual-process framework of emotion regulation, we explore the potential of narrative as implicit ER strategy that can reveal one's own emotional responses, and self-compassion as explicit ER strategy that may shift attention to these emotional responses. The two together, may influence how one experiences the bullying situation and one's own role in it, and increase empathy and prosocial behavior. We investigate the following research questions: Is conflict resolution promoted through SC induction and narrative construction? Do the positive effects of SC induction transfer to bystanders in conflict situations like bullying? Can inducing SC in combination with narrative construction promote empathy and prosocial behavior beyond what narrative construction alone can promote? We hypothesize that additional SC induction will have stronger effects than narrative construction alone, when assuming the bystander role in bullying situations and will:

H1: increase levels of self-compassion,
H2: increase levels of empathy, and
H3: increase prosocial conflict resolution: other-inclusion behaviors and inclusive choice of beneficiary.

Method

Participants

We recruited 30 female participants, aged 15-16 from two classes of a girls high school in Korea, to control for gender differences with females showing higher use of ER strategies (McRae et al., 2008), empathy and prosocial behavior (Barr & Higgins-D'Alessandro, 2007) than males. They were all first-year students, randomly assigned to each class upon admission to the school. They had not acquainted their new classmates and the school staff when the experiment started since the school had been closed due to pandemic. 16 students were in experimental group and 14 students were in control group. To avoid confounding effects from class or teacher, each group was invited to Google classroom respectively two weeks before school opening and completed all the tasks online.

Procedure

Dispositional self-compassion and empathy were first measured before the intervention. After two weeks, subjects all engaged in implicit ER task (narrative construction) to avoid prompting effects. The experimental group completed additional explicit ER task (SC induction) prior to implicit regulation, to set the scene for more empathic reactions during implicit ER task. Right after the intervention, dispositional self-compassion and empathy were measured again. Self-constructed narratives of subjects were analyzed for behavioral responses.

Explicit emotion regulation

Instructed SC induction was adapted from Leary and colleagues (2007). It consisted of one trigger question and three self-compassion questions. We referred to the Revised Cyber Bullying Inventory (Topcu & Erdur-Baker, 2010) to compose the trigger question to reflect the predominance of online interactions as a means of

communication among adolescents. Subjects in experimental group were asked to recall their unpleasant online communication experiences with the details of the situation and their emotions and behaviors evoked by the incident. After that, they were to answer three open questions implementing subcomponents of SC: a) Try to think of ways that other people would also experience similar events and feelings like what you experienced (common humanity), b) Imagine your friend who is always supportive and understanding, who knows your strengths and weaknesses, wrote a message to you and that made you feel much better and comfortable. What would have the friend written? (self-kindness) c) Try to describe your feelings about the experience in an objective and unemotional way (mindfulness). Upon completion of this task, they proceeded to implicit ER task.

Implicit emotion regulation

Implicit ER task consisted of a video clip and subsequent narrative construction. We prepared an edited excerpt from the movie *Bang Bang You're Dead* directed by Guy Ferland (2002). A diagram introducing three main characters with their pre-existing relational conflicts was presented prior to watching the excerpt. The video starts with the *protagonist*(P) arriving at school, shows him getting verbally and physically teased by the *antagonist*(A) and his friends, practicing a play script with his *friend*(F), and ends where he almost physically gets into a fight when a rehearsal with the theater team was interrupted by the *antagonist*. Narrative construction was operationalized as follows. Subjects were told to imagine as if they were the screenwriter and continue to write the story by answering open questions about the characters and the conflict. Subjects were to describe what decisions or behaviors each of the three characters would make and the reasons behind them. Finally, subjects were to describe how the story should end, in other words, how the conflict should be resolved.

Measurements

Self-compassion

The Self-Compassion Scale for Youth (Neff et al., 2020) was used to measure dispositional SC before and after intervention. It consists of 17 items, three subscales for compassionate (self-kindness, common humanity, mindfulness) and three for uncompassionate responding (self-judgement, isolation, over-identification). Subjects rated how they act towards themselves in difficult times on a 5-point scale ranging from 1 (almost never) to 5 (almost always). The uncompassionate subscales were reverse coded. Item analysis showed marginal to high internal consistency across subscales and time (pre: α = .436~.840, post: α = .488~.839). The total scores for pre- (α = .842) and post-measurement (α = .828) indicate high internal consistency.

Empathy

Interpersonal Reactivity Index (Davis, 1983) was used to measure empathy traits. Three subscales of IRI were included: *perspective taking* (PT), *empathic concern* (EC), and *personal distress* (PD). Subjects rated how well an item describes themselves on a 5-point scale ranging from 1 (does not describe me well) to 5 (describe very well). An item from EC had a negative value in item discriminatory power at post-measurement, therefore was not included in the analysis. The item analysis indicates marginal to acceptable internal consistency (pre: α = .547~.781, post: α = .638~.803).

Table 1

Coding scheme description and example responses for other-inclusion behavior

Category	Description	Example response
Self-oriented	Behaviors or decisions intended to relieve one's own safety, feelings, desires, or concerns	F refuses to help P because she doesn't want to get involved in his trouble.
Close-vicinity	Behaviors or decisions intended to care for, or affected by understanding of people in close vicinity, compromising the intention to alleviate one's own safety, feelings, desires, or concerns to support for theirs	P stops confronting A and football team because he doesn't want to cause any problems to the theater team
Distant	Behaviors or decisions intended to care for, or affected by understanding of not only those in close vicinity but also distant party (opponent party), taking into account safety, feelings, desires, or concerns of the distant party	A recognizes he shouldn't have pranked on P. He apologizes to P and asks for forgiveness.

Conflict resolution style: Other-inclusion behavior and choice of beneficiary

Two types of CRS were measured as indicators of prosocial behaviors using directed content analysis (Hsieh & Shannon, 2005) of subjects' self-constructed narratives: *other-inclusion behavior* and *choice of beneficiary*. *Other-inclusion behavior* was operationalized as descriptions of character behavior that allow inferring how subjects may behave themselves in reality. We devised a coding scheme (see Table 1) to represent self-other interaction in conflict situations based on previous works on conflict resolution (Kurdek, 1994; Neff & Harter, 2002). *Choice of beneficiary* was measured as predictions of the story ending. The coding scheme was based on the two-dimensional taxonomy of the conflict handling mode (Thomas & Kilman, 1974, cited in K. W. Thomas, 1992). We borrowed the concept of one's *choice of beneficiary* referring to the extent to whose welfare is optimized among the conflicting parties (see Table 2) (K. W. Thomas, 1992). Two independent raters annotated participants' narratives separately for statistical analysis. After the first iteration, the coding schemes were reviewed and modified. The second iteration reached the alpha value of .81 ~ .86 across characters for other-inclusion behavior and .86 for choice of beneficiary (Hayes & Krippendorff, 2007). The remaining differences were resolved upon consensus.

Table 2
Coding scheme description and example responses for choice of beneficiary

Category	Description	Example response
Avoidance	No resolution of the conflict. Conflicting parties are at stalemate, no improvement or change in the conflict situation	Despite efforts of F, P goes on to seek his own revenge on football team.
Partisan	Optimize the welfare of one of the conflicting parties, while the other party yielding	What A did to P gets discovered by school authority and A gets dispelled from school.
Joint-welfare	Concerns of both conflicting parties are dealt with by a certain extent of improvements or compromise from both sides	A stops bullying because he knows what he did was wrong while P focuses on theater play.
Systemic	Extension of conflict resolution to the general population in the group or establishing constructive relationship between conflicting parties	After A apologizes and P accepts the apology, the three become good friends.

Figure 1
Means of IRI and SCS-Y between conditions after intervention

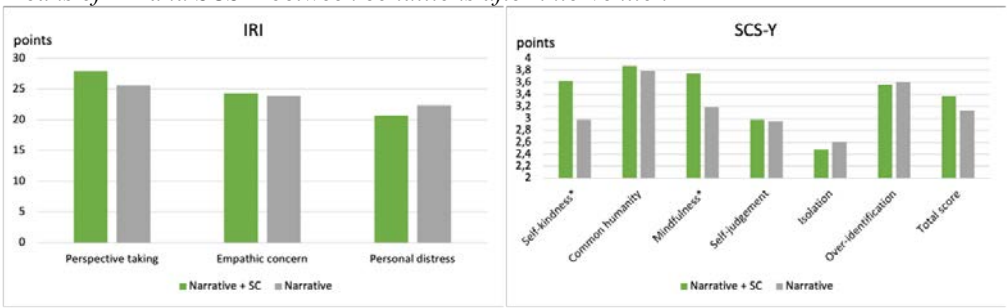

Figure 2
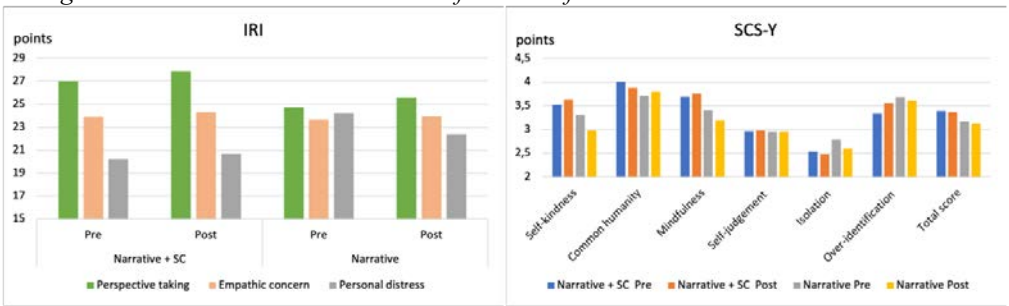
Changes in IRI and SCS-Y mean scores before and after intervention within each condition



Results

Self-compassion and empathy

Levels of SC showed no significant differences between the two groups before intervention. We performed independent *t*-test with posttest results to see if SC induction elicited significant differences in SC. Significant differences were found in subscales of SC ($t(28) = 2.293$, $p = .03$, *Cohen's d* = 0.839) and mindfulness ($t(28) = 2.813$, $p = .009$, *Cohen's d* = 1.03), but not in the total score ($t(28) = 1.242$, $p = .225$, *Cohen's d* = 0.454), partially confirming *H1* (see Figure 1). SC induction greatly affected subscales of self-kindness and mindfulness, but not overall dispositional SC.

Levels of PT and EC increased in both groups (Figure 2). However, there was no significant difference between the two groups after intervention (PT: $t(28) = 1.793$, $p = .084$, *Cohen's d* = 0.656; EC: $t(28) = 0.32$, $p = .751$, $d = 0.117$; PD: $t(28) = -0.997$, $p = .328$, *Cohen's d* = -0.354). Before intervention, a significant difference was observed in the levels of PD between the two groups ($t(28) = -2.476$, $p = .02$, *Cohen's d = -0.906*), but not after intervention. PD decreased with narrative construction only ($t(13) = -1.97$, $p = .07$, *Cohen's d* = -0.49), but increased with additional SC induction ($t(15) = 0.465$, $p = .649$, *Cohen's d* = 0.13). Other than expected, narrative only decreased the levels of PD but in combination with SC induction, increased it. *H2* is rejected.

Table 3

Frequencies and estimates of binary regression of other-inclusion behavior with condition as predictor

	Category	Narrative + SC (n = 16)	Narrative (n = 14)	*B (SE)*	*OR (95% CI)*	*p*
Protagonist	Self-oriented	8	10	.916 (.775)	2.50 (0.548, 11.41)	.237
	Close-vicinity	8	4			
	Distant	0	0			
Antagonist	Self-oriented	13	13	1.099 (1.219)	3.00 (0.275, 32.746)	.368
	Close-vicinity	1	0			
	Distant	2	1			
Friend	Self-oriented	1	6	2.42 (1.165)	11.25 (1.146, 110.461)	.038
	Close-vicinity	15	8			
	Distant	0	0			

Table 4

Frequencies and estimates of multinomial regression of choice of beneficiary with condition as predictor

Category	Narrative + SC (n = 16)	Narrative (n = 14)	*B (SE)*	*OR (95% CI)*	*p*
Avoiding	2	8	Reference		
Partisan	8	4	2.079 (1.00)	8.00 (1.127, 56.793)	.038

Systemic	3	1	2.485 (12.00)	12.00 (0.773, 186.362)	.076

Other-inclusion behavior and choice of beneficiary

Logistic regression was used to analyze behavioral responses represented in self-constructed narratives. EPV (event per variable) number of 10 suffices to run the logistic regression (Peduzzi et al., 1996) and the 95% confidence interval for odds ratio measured above 1 suffices to say that an association can be assumed from the model (Field, 2013). For the ease of comparing with other character behavior assessment, the responses for scales

of *close-vicinity* and *distant* of *antagonist* behavior assessment were merged to run binary logistic regression. *Other-inclusion behaviors* showed a large variance across three characters in the video (see Table 3). The variance can be attributed to differences in *close-vicinity* between the two conditions. The behavior of the *friend* was assessed as more caring for or being affected by other people in *close vicinity* (protagonist, in this case) in the experimental group, which we expected to be the effect of SC support. *Choice of beneficiary* represented in the narratives missed significance between the two groups ($\chi^2 = 7.714$, $p = .067$), in accordance with H3. As shown in Table 4, significant variance of the regression model stems from the contrast between *avoiding* and *partisan*. The experimental group were more likely to resolve the conflict in favor of one of the conflicting parties than to avoid the conflict situation, as expected for SC support.

Discussion

Combining *SC induction,* as explicit ER support, with *narrative construction,* as implicit ER support, showed expected changes in adolescents' self-compassion and prosocial behavior, although not all hypotheses were supported. The combination of explicit and implicit regulation showed significant increases in SC subscales of *self-kindness* and *mindfulness*, and more constructive conflict regulation. For conflict regulation, *other-inclusion behavior* from the bystander perspective was more frequent in the constructed narratives with additional SC support. There was also a tendency for *inclusive choice of beneficiary*. The combination tended to report resolving the conflict of bullying in favor of the victimized, than avoiding the conflict situation. Differences in empathy were not significant: *perspective taking* and *empathic concern* increased for both, whereas *personal distress* decreased for narrative construction, as expected, but surprisingly increased with additional SC support.

Significant differences in the subscales of *self-kindness* and *mindfulness* align with previous work that suggests training in SC facilitates a transition towards a more compassionate balance of SC components (Bluth et al., 2016; Phillips, 2019). By combining explicit and implicit strategies, we found supportive evidence after only a short SC-based intervention. SC support increased PD, possibly because it enabled adolescents to attend to and become more aware of the suffering of others, having soothed themselves first. The role of awareness in how explicit SC supports ER processes needs to be examined further, to provide a differential account of its effects, based on kinds and levels (implicit - explicit) of promoted awareness, and its reflection processes that are triggered.

Lack of significant differences in PT and in EC between conditions can be attributed to the metacognitive elements of SC which entails acting with awareness (Solem et al., 2015). Explicit SC support may have increased both the understanding of the mental states of the protagonist and subjects' self-oriented emotional responding alike, especially in combination with narrative-based support. This might have prohibited expected implicit other-oriented emotional responding. However, we also found that prosocial behavior, important for the defender bystander role, was induced without significant increases in PT and EC. This aligns with previous results that would predict that SC results in active prosocial responses with less empathy (Welp & Brown, 2014), after having dealt with socio-cognitive conflict through self-soothing. SC support elicited a tendency to resolve the bullying situation in favor of the victimized which may suggest that SC can contribute to create a supportive social environment for the victimized. This aligns with systemic approaches on bullying with an emphasis on an ecological entity (Cowie & Jennifer, 2008). Thus providing technological anti-bullying supports for bystanders may create a new social context and foster equity and justice at school.

These results point to differential effects of implicit narrative-based and explicit SC instruction. They thus contribute to the discussion of the interplay between socio-emotional and cognitive aspects, particularly with regard to implicit vs. explicit support and socio-cognitive conflict resolution. Both implicit and explicit strategies evoke PT and EC, but only additional explicit SC support increases self-oriented PD and prosocial behavior. A possible mediating effect of SC on PD through soothing needs to be tested. This study shows important first results on how self-compassion induction in addition to standard narrative can promote constructive conflict resolution and a transition to healthy compassionate mindsets among adolescents. Since narrative has been associated with the development of the self, it is worth testing its long-term effects. These effects, however, should be tested in vivo in relation with other factors that can account for one's behavior in bullying contexts, such as sociometric status, needs, and expectancies of social network of a peer group (Salmivalli et al., 1998). Since this study tested a female population to control for gender effects, transfer to a mixed-gender population also needs to be tested.

Abstract: Curriculum efforts to promote data literacy continue to evolve in K-12 spaces to meet the larger need of developing data-informed citizens. The learning objectives of these efforts tend to shift from conceptual data literacy objectives such as demonstration of adequate statistical reasoning to critical data literacy objectives such as empowering students to design, collect and analyze data to serve their needs. However, most studies do not delineate between these objectives, often giving an incomplete picture of student understanding of data, and the effectiveness of the curriculum in meeting these two data literacy objectives. In this paper, we study the outcomes that emerged from a curriculum unit designed to empower students to collect, analyze and present data from their neighborhood. We specifically evaluate the conceptual and critical data objectives of 14 high school students. Our findings indicate that students struggled to demonstrate equal competence in conceptual and critical data literacy goals.

Introduction

Among the many needs to make educational content relevant for application in the knowledge economy, there is a growing effort to develop teaching and learning practices that promote data literacy in K-12 classrooms (Frank et al., 2016; Gebre, 2018; Wilkerson & Polman, 2020). In the current knowledge economy, big data is ubiquitous, with corporations and governments using data from individual's everyday behaviors (e.g., shopping habits, social media interactions, and voting preferences) —a development that is only going to increase in coming years (Borges-Rey, 2016; Deahl, 2014; Pangrazio & Selwyn, 2019). However, individuals continue to be limited in their ability to understand the nature of data and often perceive it as an objective statistical measure, rather than understanding how data is collected, manipulated, and used, often without their permission (Borges-Rey, 2016; Pangrazio & Selwyn, 2019). This effort to develop a data-informed citizenry has ignited heightened interest in educational research to curate curricula that enable students to actively engage, reason, and critique activities and products involving data (Wilkerson & Polman, 2020; Wolff et al., 2016; Lee et al., 2021). This is evident in emerging standards and coordinated curricular efforts to promote "data science for everyone" (Lee et al., 2021; Ridgway, 2016; Wilkerson & Polman, 2020).

However, current curricular efforts often fail to capture the conceptual data objectives (e.g., ability to draw accurate inferences, interpret central tendencies, read graphs) and critical data perspectives (e.g., ability to engage in data production process, critique inherent bias in data) needed to develop data informed citizenry - often simplifying the objectives or measuring one over the other, as opposed to both (Irgens et al., 2020; Philip et al., 2018; Lee et al., 2021). Consider for example, the use of mobile sensors and firsthand data. Most data literacy curricula that use sensors and firsthand data value activities that involve learners posing questions for data analysis, designing experiments and visiting sites for data collection (Hardy et al., 2020; Manz, 2012). These studies measure students' ability to engage meaningfully in data literacy practices such as sampling and measurement, developing a sense of agency and ownership over data, and drawing inferences based on their knowledge of the context, which data literacy objectives that are largely critical in nature (Hardy et al., 2020; Stornaiuolo et al., 2020). Conversely, less emphasis is provided in these studies to evaluate students' ability to statistically or quantitatively reason with data which includes traditional statistical skills such as reading a graph, identifying variability, boundaries of drawing inference (Lee & Wilkerson, 2018; Rubin, 2020; Irgens et al., 2020). Importantly, there exists conflicting evidence on the effectiveness and the value addition of using firsthand data. Studies have shown that student's proximity with data sets interferes with their ability to draw accurate inferences, often discounting the variability they observe during the data collection process (Hug & McNiell, 2008; Konold, 2015; Lee & Wilkerson, 2018). There are very limited studies that have evaluated both conceptual objectives and critical data literacy perspectives in K-12 interventions (Irgens et al., 2020; Philip et al., 2018; Pfannkuch et al, 2018).

To meet the larger goal of developing data-informed citizens, it is imperative that studies on data literacy evaluate both conceptual and critical data objectives (Irgens et al., 2020). If both objectives are not attended to with equal emphasis, there is a risk of developing student knowledge and skills of statistics alone without the ability to critically assess the purposes of data use that can preserve individual agency and well-being. Likewise, without a core understanding of how to access or read data products, being able to make accurate critiques of data applications will be sacrificed (Irgens et al., 2020; Lee et al., 20201; Philip et al., 2018). This study aims to address the above concerns. We first present the design of a curriculum and instruction intervention on the topic of bioinformatics that has one of its central aims as promoting students' conceptual

and critical competencies in data literacy using firsthand data. We then evaluate the conceptual and critical data objectives of 14 high school students who engaged with the curriculum. We analyze students' conceptual and critical understanding of data literacy using Rubin's (2020) data literacy framework and Hardy et al.'s (2020) data production framework asking the following research questions 1) In what ways did students demonstrate an accurate understanding of conceptual objective and critical data perspectives? 2) What constructs of conceptual objectives and critical perspectives did they struggle to demonstrate accurately?

Theoretical framework

Learning scientists have defined data literacy in multiple ways, often with the primary objectives fluctuating between the conceptual and critical focus (Hardy et al., 2020; Kjelvik & Schultheis, 2020; Rubin, 2020). For example, Rubin (2020) conceptualizes data literacy as the ability to work with statistical elements of data that include computing aggregates, accounting for variability, and drawing accurate inferences among others. Notice that the primary objective of data literacy with the conceptual focus here is on quantitative reasoning which is the ability to engage with numerical information found in graphs, equations, and descriptive statistics to critically engage with data collected from real-world phenomena. On the other hand, Hardy et al. (2020) define data literacy as the ability for students to understand data as produced, which is through the interaction between human intent, disciplinary tools such as sensors, and the limitations of the context within which data is collected. Here, a critical focus of data literacy is on student's ability to engage with data production practices, i.e., to be able to make active decisions in the design, collection, analysis and communication of data with the broader intent of turning data into knowledge that benefits the student or their larger community. While there is overlap across both definitions on the ability to read data critically and use authentic data sets, they differ in the granular focus of their primary objectives. These objectives, if taken separately, would reflect different learning goals when translated into classroom settings. (Irgens et al., 2020; Lee et al., 2021; Wolff et al., 2016).

Defining conceptual and critical data objectives

While multiple frameworks that speak to conceptual needs of data literacy exist (Kjelvik & Schultheis, 2020; Rubin, 2020), in this paper, we use Rubin (2020)'s five parameters to study the conceptual understanding of students' data literacy because of the framework's focus on the contextual factors that shape and influence the nature of data. The framework includes five critical objectives on working with data, which can be briefly explained as follows: 1) *context,* the "who, where, what, why and how" of data collection that shows its purpose and surrounding circumstances; 2) *variability,* the nature of data that varies in value over time and space; 3) *aggregate*, summarizing data as a set of values and understanding what it does and doesn't reflect about its distribution; 4) *visualization,* visual displays of data, deciding how the data is displayed and understanding what choices are made in the process; and 5) *inference*, drawing conclusions based only on the data without using outside assumptions. These are the constructs we measure as a parameter of conceptual understanding of data literacy in this study.

There exist three interconnected views of critical data literacy: 1) data literacy as comprehension; 2) data literacy as critique; and 3) data literacy as participation (Irgens et al., 2020). The first two views conceptualize critical understanding of data as the ability to not only comprehend the variability and human bias within the data production process but also critique how data is inherently politically, socially, and racially constructed. In this paper, we focus on the third perspective of critical data literacy which is data literacy as participation. The primary focus here is to actively engage with data production practices, which include making active decisions about the design, collection, analysis, and communication of data with the broader intent of turning data into knowledge that benefits the student or their larger community (Hardy et al., 2020; Irgens et al., 2020). Hardy et al. 's (2020) data production framework provides a lens to study student's engagement as data agents by analyzing three core data perspectives; a) *material:* the ability to understand that data is produced as a result of negotiations between instruments such as sensors and the material world, b) *disciplinary:* an understanding of the disciplinary nature of tools and inquiry practices, and c) *human*: an understanding that data products cannot be delineated from human intentions that drive the production and design of data. In this paper, critical data literacy is measured by analyzing the degree to which students developed these perspectives. Combining these two lenses, which speak to both conceptual and critical data objectives, helps us measure student outcomes that speak to both their statistical reasoning abilities and their ability to critically engage with data production practices.

Methodology

Context

In this section, we provide a brief overview of the NSF-funded project within which this smaller study was housed. The larger project focused on developing a curriculum and instruction for teaching bioinformatics in high school biology classrooms. The curriculum spanned approximately 16 lessons, or about 20 hours of instruction, and guided students in

problem-based learning (PBL) investigation on the topic of air quality and asthma in urban environments. For this smaller study, we focused on the data literacy components of the broader bioinformatics unit. We mapped the data literacy unit activities onto the instructional recommendations of Rubin (2020) and Hardy et al. (2020) to ensure the conceptual and critical data objectives were being met (Table 1). These activities were introduced across three phases intended to build student familiarity with 1) data tools, 2) data collection and analysis, and 3) real-world data production. Students collected air quality measures (carbon monoxide (CO) and particulate matter (PM)) with portable sensors and phones in different neighborhood locations. Students then analyzed the class dataset to compute averages and compared their findings to Environmental Protection Agency (EPA) data that was stored on a project-constructed website. This website allowed students to make visualizations of their own data and view visualizations of air quality data around the U.S. for comparison. Based on their data analyses students presented solutions to address the disparities that they saw in their urban areas as compared to other urban, suburban, or rural areas.

Table 1

Curricular activities that align with recommendations from Rubin (2020) and Hardy (2020)

Curricular Recommendations	Curricular Activities
Variability: Use data sources that are likely to vary both in space and time (R).	- Students collect air quality data from four different locations or from some location at four different times of the day and discuss how the measured data changes over time/location.
Aggregate: Engage in discussions about the intent of computing aggregates in statistics and reflect on what aggregate values communicate and what it doesn't (R).	- Reflect on the rationale of computing mean and median. - Debate if mean or median is a better representative of a sample and why? - Conduct a t-test to compare averages between two locations.
Visualization: Engage in self-expression and revealing patterns (R).	- Visualize data using bar graphs. - Discuss alternate visualizations such as infographics and pie charts.
Inference: Discuss what we have learned applies beyond this particular dataset? (R).	- Teacher engages in-class discussion on how generalizable the data collected from their specific data sample is. - Students report findings, their analysis, and possible recommendations.
Material: Provide students with the opportunity to manipulate data collection and analysis tools (H).	- Follow procedures to operate the mobile sensor for data collection and accumulate data on Google Sheets. - Practice collecting data using mobile sensors in and outside school. - Analyze the data accumulated from the sensors and compute the mean of all readings collected using data analysis tools.
Humanistic: Provide students choices in setting purposes for data production (H).	- Select the problem they want to explore using data on the issue of asthma. - Select a variety of neighborhood areas to investigate the issue of asthma.
Disciplinary: Provide students with the opportunity to design data collection and analysis in a goal-directed manner reflective of most science-inquiry processes (H).	- Set research questions for the data investigation process and present rationale for expert (teacher) approval. - Conduct rehearsals of data collection planning for contingencies. - Revise the data collection plan based on the trials with the sensors. - Students report findings, their analysis, and possible recommendations.

Participants

For this study, we report the findings from one biology teacher, Sam, who had 17 years of teaching experience and taught at a public high school in the northeastern U.S. He was nominated as a desirable teacher by the director of science in the school district to select an ideal population (IES & NSF, 2013) and designated a model teacher. This study reports on data collected from 14 students from his class. There were 11 11th graders and 3 12th graders of which, 10 were female and 4 were male students, who self-reported to be 42.86% Asian or Pacific Islander, 35.71% White, 7.14% for African American, Hispanic, and others respectively. Most of the students did not have prior experience working with data.

Data Sources and analysis

We collected and analyzed data from three sources: 1) students' final project reports, 2) student focus group interviews, and 3) classroom observation notes. *Students' final project reports* included detailed write-ups on the data inquiry process. Students were provided with a project template and a rubric to include their group's research questions, their description of the data collection sites, the inferences they made about the data, and the rationale behind their reasoning. They worked in groups to complete the project. There were five project reports in total. *Student's focus group interviews* included student reflections captured from two student groups. The interviews probed insights into the data collection and design process where students discussed the problems they encountered while using the sensors and Google Sheets. Finally, the *classroom*

observation notes captured detailed descriptions of the classroom interaction and teachers' instructional practices, activities taking place including materials distributed to students, and conversations that occurred during the data collection process.

Students' final projects and interview transcripts were used as the primary data source for our analysis, while observation notes provided additional evidence to triangulate our claims. To address the research questions, we reviewed students' final projects and interview transcripts to identify parts that illustrated an understanding of data. These segments of data were then extracted to a spreadsheet and analyzed for instances that demonstrated critical and conceptual data objectives using an internally developed coding manual. The coding manual included eight categories, five reflective of conceptual and three reflective of critical data literacy. The definitions which were derived from our two theoretical frameworks. After reviewing the segments of data, we adapted the coding manual to better capture students' understanding of data as demonstrated in the curriculum. There were 182 segments of data that emerged from this process. The interrater reliability test from the larger study was conducted by two raters with 38 of the 182 segments (21% of the data) yielding an alpha score of .85 which is an acceptable level of agreement.

From these segments, for this paper, we extracted 41 segments from Sam's students and categorized the segments of data across the eight categories of data literacy using the coding manual. In addition, the segments of data were further examined by first and second authors to determine if they were reflective of an accurate understanding of the category it was coded for. For example, the following segment of data "This place is very important to this project because every day this chemical plant would let out pollution, 386,000 tons of hazardous air pollutants into the atmosphere each year." was coded as evidence of an accurate understanding of 'context' because students' choice of data sites reflected intentionality and alignment with their larger research question. We coded segments of data as inaccurate understanding of the 'context' if it did not include detailed information of data collection site, description of the sites is random information that does not align with the research question. Table 2 shows accurate and inaccurate categorization manuals for critical data literacy.

Table 2
Categorization manual for conceptual and critical data literacy (Category and Definition)

Accurate	Inaccurate
Context: When student descriptions of data collection sites reflect intentionality and alignment with the research question for their projects.	**Context:** Student description of data collection sites are random information that does not align with the research question.
Variability: Student reflections refer to interferences caused by context, sensor etc. to the data collection process.	**Variability:** Student does not report any fluctuations experienced during the data collection process
Aggregate: When making references to central tendencies students compare results to a universal standard in order to draw conclusions. They refer to and explain outliers.	**Aggregate:** Reports only indicate the mean and median values pooled from different data collection sites.
Inferences: When drawing conclusions, students refrain from generalizing their findings beyond the scope of data and refrain from using "always" or "never." The reports mention the variability they observed during the data collection.	**Inferences:** The student reports draw conclusions without accounting for the variability observed during the data collection process.
Material: Students discuss the troubleshooting strategies employed during the data collection process.	**Material:** Students only refer to issues faced during the process of data collection or analysis.
Humanistic: Students refer to the factors that pertain to community or personally relevant factors that motivated them to pursue certain data questions and sites over others.	**Humanistic:** Students make no reference to community or personally relevant factors that motivated the design of the data production process. The description appears generic.
Disciplinary: By referring to the research questions, parameters of data collection site etc. These are often instances laid out during the planning stage.	**Disciplinary:** There is no reference to the steps that went into planning for the data collection or analysis.

Findings

Across the five final projects, the segments of data that were coded for accurate critical data perspective were slightly more than those coded for accurate conceptual data objectives. Out of 41 segments of data coded as accurate, 40.74% were assigned to conceptual objectives while 59.26% reflected critical data objectives (Table 3). The findings are organized to report accurate and inaccurate demonstrations of conceptual and critical data.

Table 3
Summary of data coded as accurate or inaccurate

	Con* # (%)	Var* # (%)	Agg* # (%)	Vis* # (%)	Inf* # (%)	Total # (%)	Mat** # (%)	Dis** # (%)	Hum** # (%)	Total # (%)

Accurate	7 (63.64)	0 (0)	3 (27.27)	1 (9.09)	0 (0)	11 (100)	1 (5.88)	10 (58.82)	6 (35.29)	17 (100)
Inaccurate	0 (0)	3 (23.08)	2 (15.38)	4 (30.77)	4 (30.77)	13 (100)	0 (0)	0 (0)	0 (0)	0 (0)

*Conceptual perspectives: Con = Context, Var = Variability, Agg = Aggregate, Vis = Visualization;
**Critical objectives: Inf = Inference, Mat = Material, Dis = Disciplinary, Hum = Human nature of data

Students' accurate and inaccurate demonstration of conceptual data objectives

Out of the total 11 accurate references made to conceptual objectives, 68.29% references were made to context, and 31.71% were made to aggregate. This is indicative of the fact that students understood the context-dependent nature of data - choosing to be intentional in aligning the selection of the data sites to the research questions they wanted to answer and exhibited confidence in being able to curate, analyze and present data that serve their personal interests and community needs.

Among the five conceptual data literacy concepts, the most frequently and accurately referenced construct was the concept of 'context'. These included rich descriptions of data collection sites communicating the intentional selection of these sites. These descriptions indicated that students understood the context-dependent nature of data, often communicating in the final report important details that shaped their data collection and analysis process. For example, in the excerpt below, students describe the three data sites from where data was collected, providing details of the site that could influence the research question they were investigating which was whether the air quality is better in areas that were less crowded and had more greenery such as the example below,

> Using the sensor and the app on our phone we collected data at five locations around [School]: 1) 17th and [Blue] St.: There were no cars passing by [...], 2) Community College Underpass: There were a few smokers nearby [...] There was also a bus docking and lots of cars passing by, 3) Outside Dunkin Donuts: [...] but there were a lot of cars passing by [...]

In the above excerpt, students signal to context-related information such as the number of people, the number of cars, and the quality of greenery at the sites which were present during the process of data collection. This reveals that students understood the need to capture and provide as much information present across data sites that may be relevant to the nature of inquiry the data collection process was being conducted for.

The second category of conceptual data literacy that appeared more frequently in the student's final data reports was the 'aggregate' code. An 'aggregate' view of data signals a conceptual understanding where students are able to view aggregate values as numbers that summarize trends as opposed to individual data values that are an exact representation of the population (Rubin, 2020). 'aggregate' code was assigned to segments of data where students made references to outliers in their data while reporting the mean scores of the data collected from various sites or when students compared their mean score of Air Quality Index (AQI) to the standards mentioned in the National AQI table while interpreting the data. For example, in the excerpt below, students reference how they interpreted the average calculated across three data sites while referencing the standards of the National AQI table and accounting for an outlier.

> Our PM 2.5 data, in comparison to the AQI, is good, with average levels of 11[...] Our CO data, in comparison to the Air Quality Index, is very poor, at an average of about 18. However, if you leave out one of the data points that is very high in comparison to the others, the CO level average is just 12.84, which falls into the poor section.

In the above excerpt, students not only point to an outlier in the data set but also detail how the omission of the datapoint could change the inference drawn from the data set of the AQI being average to poor. This indicates that students have a nuanced understanding of central tendencies that go beyond just the ability to calculate the mean or median.

The conceptual constructs of 'variability,' 'visualization,' and 'inference' were not referenced accurately in the student's final data reports. Out of 13 inaccurate references, 23.08% was referenced to 'variability,' while 30.77% was referenced to 'visualization' and 'inference' respectively. Errors included the absence of visual representation of data, overgeneralization of inferences beyond the data collected by students, and the omission of variance in the reports. Despite the use of mobile sensors in the curriculum, the segments of data that referred to the 'variability' and 'inference' construct accurately were 0. The low scores indicate that students struggled to critically account for the fluctuations that arose during the data collection process caused by sensors, and the data collection sites in their findings or analysis. For example, when reflecting on the data collection process, a group in their focus group interview referred to how the malfunctioning mobile air sensors posed a problem,

> We were nervous at times that we didn't actually get some data points with the sensors. The Bluetooth connection sometimes would go on and off. So, when we weren't sure, we ended up leaving some sites and collected 7 data points from some sites to make up for the sites we couldn't collect data from.

However, in the same group's final report the students did not mention how the interference caused by the erroneous functioning of sensors or the omission of data points from some sites and the addition of data sources from other sites, influenced the conclusion they drew about the air quality near food trucks. Their final report stated the following finding conclusively, "Our data shows that all of the food distributors have good PM 2.5 levels, but the CO levels are not so good [...] Using the averages of CO and PM 2.5 levels, it is shown that halal trucks have the best air quality." This excerpt indicates that while students experienced material resistance during the process of data collection, they did not account for how these interferences shaped the conclusions they drew about the air quality near food trucks. In their final report, the group did not reference the omission of data sites. This is indicative of the fact that students found it challenging to account for the interferences that may have arisen from the variance in context or sensors. In the final inferences, they made about the data students chose to draw general inferences about the data instead of using a language of uncertainty to communicate the findings or state the limitations of their data collection process. It may also be the case that students may not have had the conceptual understanding of data to understand that the omission of specific data sites cannot be compensated with additional data collected from other sites.

Students accurate and inaccurate demonstration of critical data objectives

Out of the 17 total references made to critical data perspectives, 35.29% was coded as 'human perspective,' 58.82% was given to 'disciplinary,' while only 5.88% was given to 'material perspective.' This is indicative of the fact that students understood the inherently personal nature of data production process and also understood the inquiry driven nature of data production. However, they struggled with troubleshooting the issues that came up during the process of data collection.

Out of the total 17 references made to 'critical perspective, 35.29% was given the 'human perspective' code. This is indicative of students' confidence in being able to curate, analyze and present data that serve their needs. The presence of 'human perspective' indicated that students understood that one can collect, use and analyze data for purposes that may vary from being personally relevant to self or to others. The segments of data coded for 'human perspective' included students' reflections on the personal relevance of the data production process. These reflections varied from broader impacts of community such as clean air, more green space to more personally relevant issues such as quality of air in places that students frequented after school or investigating the correlation between unconventional smoking mediums such as hookah bars and vaping to educate their peers on harmful effects of smoking. For example, a group from Sam's class mentioned their rationale to design their data production process to study the quality of air in a hookah bar as follows.

> But people (peers) think vaping is not as harmful as smoking, and hookah too. They just think smoking is more harmful, but in reality, they are all kind of related to each other. They have the same effect [...] So, we were just thinking of something that would be kind of unique but also have the same idea. So, we came up with hookah […] Going to a hookah lounge is important for our experiment as this place is relevant to our community because it has become a popular hangout spot for our friends.

In this excerpt, students chose to investigate research questions that helped answer a question that was relevant to people in their immediate community. The group chose to investigate a question that would help improve a problem (i.e., increase awareness about the harmful effects of Hookah). As opposed to the narrow belief that data is produced primarily as evidence in evaluating claims, the human perspective promotes the idea that goals and purposes of data production can vary from being conceptual, playful, personally relevant to self or others (Hardy et al., 2020). These segments of data, therefore, demonstrate students' understanding of a human perspective or the variant nature of goals of data produced for humans. We know the more students personalize the goals for producing data, the higher the likelihood that students adopt the mindsets of being able to produce and critically engage with data (Stornaiuolo et al., 2020; Wilkerson & Polman, 2020).

Another code that appeared more frequently in the student reports and interviews were 'disciplinary perspectives' (58.82%). These codes included references that indicated a systematically designed goal-directed inquiry. For example, references made to research questions, the number of trials planned for data collection and use of mobile sensors. The disciplinary codes largely captured the degree to which students systematically planned their data production process prior to stepping out in the field. For instance, in the excerpt below students' detail methods and procedures they engaged in to plan their data collection process.

> How does a chemical plant affect air pollution in the environment surrounding it? Chemical plant Honeywell in Philadelphia, Procedure: First we will test the air in three different locations (School A, B and Chemical Plant Honeywell in [City]). Next, we will record the data (CO, temperature, PM 2.5, and the Humidity) for all locations. The data will be recorded three times for each location for about 30 seconds. Later, we will take all the data and compare the results for all three locations. This experiment will be performed on October 15, 2019.

Here, the group intentionally selected three data collection sites; one site that was closest to a chemical plant and two school sites that were located at a safe distance from chemical plants, to specifically investigate how the chemical plants shape the quality of air in their neighborhood. This is indicative of the fact that students understood the goal-directed nature of the data production process, choosing to be intentional in aligning the selection of the data sites to the question they wanted to answer. They also refer to the number of times and the duration of data collection at each site.

The critical perspective code that appeared the least in the student reports were 'material perspectives.' These included instances from student interviews and reports where students discussed ways in which they troubleshooted the issues they faced during the data collection process. For instance, in the below excerpt,

> Student A: I stayed in the same place and when we were back there, the door was open, but I asked her if she could close it for the experiment, and I did it every five minutes to give it some time. [...] There was no one that was coming in at the time, because I didn't want the air to get out, to affect it. So, I did it when everyone was seated, and people were smoking hookah.

In the above excerpt students refer to the issue of changing conditions at their data collection site and how they troubleshooted this variability by trying to time the collection of air quality data only when the doors were closed. These instances, however, were low. While there were references made to issues of malfunctioning sensors or contextual variance in the student interviews, there were less references made to how these issues were troubleshooted. Also, these variances reported in the student interviews were not referenced during the reporting of the data which explained the low score on accurate 'inferences' discussed earlier in the conceptual data section. The low scores on material perspective indicates that while students were able to note aspects of material setting (e.g., sensors and details of data collecting sites) that would influence the data production process they weren't able to troubleshoot or account for the fluctuations they noted during the data collection process when making inferences about the data.

Discussion

In this study, we examined how conceptual and critical data literacy objectives manifested in a curriculum that used firsthand data to promote both. Our findings indicate that if we want to broaden data literacy from its traditional focus on quantitative reasoning and statistical literacy to include critical reasoning with data production practices, we need to ensure that the rigor of conceptual understanding is also measured. Despite the use of firsthand data students struggled to demonstrate equal competence in conceptual and critical data literacy goals, with most students demonstrating an understanding of critical perspectives of data literacy over conceptual goals.

Our findings on students' conceptual outcomes replicate observations from earlier studies that have shown that student's proximity with data sets interferes with their ability to draw accurate inferences, often discounting the variability they observe during the data collection process (Hug & McNeill, 2008; Knold, 2015; Lee & Wilkerson, 2018). Our findings on critical outcomes also align with previous studies have shown that giving students the agency to decide the nature of data production and investigation is more likely to promote an understanding of data as produced (Hardy, 2020; Stornaiuolo et al., 2020). This variance in student understanding of conceptual and critical elements of data literacy is problematic as the primary goal of critical data literacy is to actively engage with data production practices, i.e., to empower students to make active decisions in the design, collection, analysis, and communication of data with the broader intent of turning data into knowledge that benefits the student or their larger community (Hardy et al., 2020; Irgens et al., 2020). However, in order for students to be empowered as critical agents of data, they need to demonstrate an accurate understanding of the conceptual aspects of data. The lack of competence in conceptual data literacy concepts is more likely to lead to a critical understanding that is not conceptually sound (Jiang & Khan, 2019). The inaccurate understanding of conceptual concepts such as 'variability' and 'inference' is more likely to lead to overgeneralization of data and the drawing of inaccurate inferences (Rubin, 2020), a trend we observed in our findings. Despite the inaccurate conceptualization of 'variability,' in our study, the student groups scored high on critical perspectives aspects of data. This means that students demonstrated the intention to produce data for themselves or for others while being unaware of their misconception of core conceptual data literacy principles. As demonstrated in the result section, while students accurately made note of the variables in the data collection sites during the data collection process, most groups did not make the connection between the variance they noticed during the data collection process and the inferences they drew about the data instead choosing to draw conclusive inferences. Therefore, the efficiency of enactments of critical data literacy is called into question due to the incomplete or inaccurate conceptual understanding of the student groups. Our study adds value to the current debates about teaching data literacy from either a conceptual or critical perspective. We suggest that in order for students to become completely data literate, curriculum and instruction should focus on knowledge and skills that combine both perspectives.

"With You I'll be Able to Actually Learn Everything": Exploring Learner Experiences With a 'Study With Me' Video

Rabia Ibtasar, Cecilia M. Heineke, and Joseph E. Michaelis
ribtas2@uic.edu, cheine3@uic.edu, jmich@uic.edu
University of Illinois-Chicago

Abstract: Study With Me (SWM) videos are recordings of individuals silently studying for hours with minimal interaction with the viewers. Despite the lack of any instructional and conversational elements, these unique virtual spaces continue to attract millions of viewers. In this paper, we conducted a Thematic Analysis on the comments generated by viewers for one popular SWM video to understand why viewers engaged with the video and what benefits they may be getting from their engagement. Our analysis revealed four themes: (1) the SWM video provided social support for studying, (2) the SWM video created an idealized structured study experience, (3) the video content creator was seen as a relatable role model and, (4) viewers found the SWM video benefitted short-term and long-term goals. We discuss the theoretical implications on social learning processes and practical implications for designing social aspects of learning environments.

Introduction

Online learning platforms have gained popularity over the years as an important resource for learners. Recently, the Covid-19 pandemic forced learners around the globe to quickly adapt to online spaces as a dominant part of their learning and studying routines. A new phenomenon in online learning is Study With Me (SWM) videos that show a prerecorded video of a person, the *content creator*, studying silently for hours without any direct interaction with an asynchronous audience of *viewers*. Despite the lack of any instructional and conversational elements, these unique videos continue to attract millions of viewers who exhibit a high level of interactivity and engagement through comments posted on these virtual spaces. These public, informal, generally unmoderated, and self-organized online affinity spaces (Gee, 2004) serve a sizeable collection of viewers who seem to receive educational benefits from the experience of observing another person studying. Yet, little work exists to examine how these SWM videos may be supporting viewers during studying activities that are usually done in isolation. To address this gap, we investigated this unique form of social learning by examining an SWM video as a naturally occurring, self-sustaining online affinity space, to expand our current theories of learning and incorporate this understanding into our practice. In this paper, **our goal is to examine the authentic viewer interactions in an online Study With Me video** to understand the learning experience of engaging in these affinity spaces, including why people come to these virtual spaces and what benefits they feel they receive from their visits.

Theoretical background

The need for social interaction during learning may be a strong impetus behind the formation of educational affinity spaces, where people seek out others who share similar interests, activities, or goals. Gee's conceptualization of affinity spaces (2004) provides a useful lens to investigate online asynchronous learning spaces, such as SWM videos, and the interactions taking place around them. Rather than 'communities' to which people 'belong' or of which they are 'members', Gee suggests that we talk of affinity spaces to capture contemporary forms of social affiliation. Affinity spaces are loosely organized social and cultural settings in which participants are connected by some *common endeavor*. Gee's framework allows us to examine the configurations of virtual spaces that characteristically have fluid participation patterns by shifting our attention away from notions of membership in communities towards focusing on people's interactions within these spaces. As such, SWM video sites represent affinity spaces for people studying remotely and asynchronously across the globe.

The role of affinity spaces as a space for interaction where people can engage socially with others in an informal context around a common endeavor is consistent with situated views of learning or learning in authentic contexts. This perspective emphasizes the role of social interactions to deepen learning when participants engage with each other in the learning experience. Social learning theory proposes social interaction, including observing and imitating others, can lead to the acquisition of new understanding and behaviors, because learning is an emergent and co-created social process (Cress & Kimmerle, 2018). The importance of social influences on learning can be seen in modern movements towards collaborative learning spaces where co-creating knowledge happens within the structure of collective problem solving (Miyake & Kirschner, 2014).

 © ISLS

A unique form of social learning exists, where the social interaction occurs passively rather than actively, as in the case of learning in the presence of others. For example, students get together to study in shared spaces, such as libraries, without necessarily sharing any materials or interacting with each other directly. Researchers have shown that some students prefer studying with their friends at libraries because they enjoy their companionship and because simply being in the proximity of others helps their concentration (Bersani et al., 2013). Similarly, research on co-working office spaces such as WeWork, suggests that the passive social presence of others and watching other people working, may lead to increased productivity by improving motivation to work and by providing a sense of energy (Swezey & Vertesi, 2019). In this way, passive social experiences can positively influence learning by supporting motivation or self-regulation, where the structure of a learning space, modeling of good habits, and the implicit and explicit encouragement from others can influence activity (Winne 1995). While some research has been done to establish these passive social influences on learning and behavior, few studies examine why people choose to engage in these behaviors and what benefits they feel they receive.

Online learning platforms are a unique educational medium that provide opportunities for 'anytime/anywhere' learning. Videos as instructional tools have become a prominent approach to online learning, particularly during the Covid-19 pandemic, where videos can be quickly delivered as educational content to millions of viewers on an impressive array of topics. For example, Khan Academy is a leading free online resource that offers instructional videos and materials on hundreds of topics, from math to history, to over 48 million users in over 190 countries (Khan Academy, 2021). These sites can act as a resource for student's self-directed learning, including goal-setting, creating strategies to achieve those goals, and then evaluating those goals (Suciu, 2020).

YouTube represents the most prominent site for hosting educational videos, covering topics from cooking, home improvement and language learning, to geometry, rocketry, and physical education. Commonly these videos include instructors who discuss a topic or demonstrate a skill or technique. YouTube's platform also offers social networking features (Ellison & Boyd, 2007), where its text-commenting facility introduces a resource beyond the content in the videos. YouTube comments provide a space for coherent textual interaction around each video where multiple viewers can engage in asynchronous conversations (Boyd, 2014; Burgess & Green, 2009). These viewer interactions about and around the videos make YouTube an important online space where content is continuously bring transformed through people's ongoing social interactions through reading or posting comments. The use of YouTube as a *social* networking site has implications for how studying with SWM videos may be transformed into a social activity, even though it is at face a passive activity.

Research has shown that the design of environmental and structural features impacts learning and behavior (Taylor, 2009). SWM videos vary widely in their designs including synchronous or asynchronous sessions, the number of people present in the video, length of the videos, background features and whether the video creator speaks out loud or faces the camera. Often SWM content creators make a series of videos over time that are hosted at a YouTube *channel* that presents a curated list of studying videos. The use of these SWM videos as studying tools has exploded over the past few years with many content creators routinely attracting millions of views per video. Thus, SWM videos have emerged as a common learning resource and affinity space for students across the globe that warrants examination within the larger context of learning sciences and educational research.

We have found two early studies of SWM in the literature that have utilized interview data from the viewers and content creators to offer some insight into how people use the videos and the content creator's perspective in making these videos. This early research on SWM studying suggests that viewers are able to personalize ambience at a low cost through their selection of specific SWM videos and get emotional support during their studying (Lee et al., 2021). Additionally, the content creators were motivated to produce content because they sought supervision and connection with others during their studying activities (Wang & Zhang, 2021). However, as research on SWM is limited, we believe an in-depth examination of the content creator's and the viewers' authentic interaction via comments further inform our understanding of SWM as a learning environment and offer insights about theory and practice of learning in affinity spaces and of socially situated learning more generally. These *interactions* within the SWM affinity space, constantly modify and transform the content and space providing a rich source of people's perspectives and social interaction. Through examining these interactions, our goal is to explore *why* users are drawn to studying with these videos, *how* they interact with each other, and *what* outcomes viewers achieve with their studying. Specifically, we ask the Research Question: **Why do viewers view, study, and engage with SWM videos, and what benefits do they believe they get from interacting within this space?**

Method

For this study, we selected a single YouTube SWM video, posted in 2017, from a popular video content creator who has posted dozens of videos on their YouTube channel. This video was chosen as representative of highly regarded SWM, because it has over 7 million views, a significant number of likes (104,667), relatively few dislikes

(2,178) and a large number of comments (4,350) that provide a rich set of viewer responses and interactions within the video space. In this video, the video content creator engages in structured studying, their gaze turned away from the camera, accompanied by a curated music playlist in the background. The video is structured utilizing the pomodoro technique, a time management strategy that breaks down a large task into a series of smaller tasks. This video is 2 hours and 32 minutes long, with timed pomodoro study segments of 25 minutes followed by a 5-minute break. The content creator has a simple study space with minimal décor (See Figure 1). During the video, the content creator can be seen highlighting a book, taking handwritten notes, and reading on her laptop. While the angle of the video switches throughout the video, from the side of her desk to the upper corner of her desk, the content creator never engages in any direct interaction with viewers.

Figure 1
Image from Study With Me video

Our analysis began by downloading all 4,350 comments verbatim from the SWM video post. Next, we removed any indecipherable or irrelevant comments, such as advertising or random symbols. We then conducted a Thematic Analysis (Braun et al., 2016) to analyze the content of the comments. We began with a process of open semantic coding on a subset (20%) of the data and used the semantic codes to generate a series of latent axial codes. The final set of axial codes was defined and reviewed by the three authors and one additional research assistant to resolve conflicts, and then applied to the entire dataset. All four researchers used these codes to iteratively propose and refine emergent themes, and finally reached consensus on four themes that reflect the viewers beliefs and interactions within this SWM affinity space. We present each theme, along with evidence from viewer comments, as quotes, to support those themes below. Quotes are attributed to the comment number from that post, and abbreviations and misspellings left unedited to capture the poster's actual comment accurately.

We reviewed the video and YouTube comments according to the Ethics of Using Social Media Data in Research Framework (Townsend & Wallace, 2017). Based on this framework, we determined that the video and comments were reasonably expected to be observed by strangers, that the participants were typically university students who do not represent a vulnerable population, and that contents of the video and comments did not contain sensitive subject matter. Based on recommendations from Townsend and Wallace, we chose to anonymize the viewer usernames by attributing quotes to the comment number rather than usernames and blur the content creator's face in our illustration of the SWM video.

Results

We found that viewers seemed to build a robust social environment in the SWM affinity space where they often described their feelings, reported their achievements, and engaged in a form of social connection making with the video creator and other viewers through the posting of comments. For example, one viewer explained the many benefits they felt they received from engaging with the SWM video over a period of several years:

> After 4.5 years, I have finally graduated with my bachelors degree. I finished finals a week ago and I wanted to come back by and thank you for making this video. I watched this video countless times and studied "with" you when I didn't think I could possibly get it all done by the deadline. Endless cramming and work on assignments can be lonely stuff, so it was nice to have it feel like someone was there working hard alongside me. Thank you for studying with me all those times ❤️ (#2969).

Detailed comments like this were frequent and demonstrate that the SWM video deeply impacted viewers' studying experiences to the extent that they felt compelled to return to the affinity space and express their appreciation towards the video creator. Our analysis of the video comments resulted in four major themes that help us understand why viewers engaged with this SWM video: (1) the SWM video provided social support for

studying, (2) the SWM video created an idealized structured study experience, (3) the video creator was seen as a relatable role model and, (4) viewers found the SWM video benefitted short-term and long-term goals. We describe each theme below supported by direct quotes from the SWM video comments.

Theme 1: The SWM video provided social support for studying

Our analysis showed that viewers felt the SWM video provided social support to viewers in three main ways, including: (1) the video made viewers feel less lonely, (2) the video site provided a space for social connection making, and (3) the digital presence of the content creator felt like they were actively studying with someone.

First, viewers directly described their experiences with using the SWM video as making them feel less lonely while studying. Viewers often explicitly stated that they were dealing with loneliness while studying such as saying, "This video has been so helpful in keeping me motivated and on track (and not dying of loneliness. I haven't actually spoken to anyone all day)" (#0053). Viewers indicated how watching the video helped them get through emotional or difficult phases in their school life when they felt "extremely alone" and "feeling like I had no friends" (#2299) or through particularly challenging personal times during Covid such as, "I'm watching this as I'm trying to get use to uni life and coping with my mental health… it helped so much especially during quarantine times where no one is around." (#2596). Specifically, viewers wrote they experienced feelings of togetherness during their viewing experience, saying "even though we are studying separately we are all in this together" (#1372) and "love the we're in this together vibe." (#0198).

Second, these feelings of togetherness appeared to be directly supported by the way viewers used the SWM space for social interactions with other viewers. These interactions were often similar to what you might observe in an in-person physical study session or study group, and sometimes included responses to comments from the content creator or led to detailed exchanges between viewers. Viewers asked questions, such as, "Would you mind if i ask you to tell me the name of the song at the very beginning (~04:11)?" (#0218), made suggestions, such as, "would you mind putting in a tiny bell or something at the end of each session?" (#0333), or added compliments, like the "music is superb" (#0276). Some viewers even added humor, for example, "Who's working to exams and drinking coffee like water like i do?" (#0117) that would draw responses, like "This is barely the first week of the term and i am already doing this hahaha" (#0117-3). Many times, viewers stated they spent time reading other people's comments, "Spending my 3-5 minutes reading YouTube comments LOL" (#0643), indicating that the comment section played a social role for viewers. These types of comments demonstrate a way that viewers were reminded they were not the only ones using the video to study making them feel less isolated. These social comments may have provided viewers a break from focusing on their activity and played a role like the conversational snippets people experience in an in-person study session. Additionally, viewers connected through reflections of their own cultures and their opinions and beliefs about school systems and studying patterns. For instance, one viewer responded to a comment that elaborated on studying habits in a viewer's home country, South Korea, by saying, "I am from Nigeria and I can say it's almost similar. You're to study without failing. I'm in uni now and it's by far the hardest task to survive especially when you have lecturers who are not willing to be merciful and make it harder for you" (#0058-19). Overall, viewers engaged socially through comments and this likely helped foster a sense of community and togetherness in the SWM affinity space.

Third, viewer comments suggested that they felt like they were actively studying with the content creator and with other viewers who were watching the video. For example, one viewer commented about studying with other viewers when they said, "It's really nice to be streaming and knowing others are watching or to watch others working. It's like having a friend study with you :)" (#0210). Similarly, a viewer elaborated that they had difficulty studying alone but because of the SWM video they had access to social support remotely, and finished by saying, "studying 'with' someone helps so much" (#1362). Furthermore, viewers brought up the issue of struggling with concentration and described how the digital presence of the video creator provided a support mechanism in terms of monitoring behaviors. For example, one viewer explained that their ADHD condition made it difficult to concentrate but they were able to receive support through the SWM space as they "need some one to monitor me or some to work with" (#1239-1).

Viewers referred to the content creator as their "study buddy" (#008) and described how the content creator helps avoid distraction and instilling beliefs that they could accomplish their tasks. For example, one viewer said, "studied "with" you when I didn't think I could possibly get it all done by the deadline" (#2969), and another said, "When I study, i would usually get distracted very easily. But when i study with you i am able to finish revising so many things in a day" (#2336). Additionally, viewers felt the content creator's digital presence provided social and mental support to help with loneliness. Viewers said, the content creator helped them "get through the toughest and hardest times … you made me feel that someone is here and struggling too"(#2545) and made them "feel like I am not alone and like someone else is making sure that I am studying" (#0400). Thus, the asynchronous nature of the SWM space seems to allow a unique type of controlled and passive social interaction

where viewers can feel socially connected to others and experience a sense of actively studying with someone without distraction.

Theme 2: The SWM environment created an idealized structured study experience

In addition to the social supports, viewers found the SWM video was helpful in generating an ideal mood for studying in two ways, by creating (1) a structured studying experience using the pomodoro technique, and (2) an idealized setting through different environmental features.

The Pomodoro technique utilized by the content creator was lauded as providing necessary structure to the studying process leading to increased levels of productivity. The viewers found that the structure helped them to "work much more efficiently" (#1291) and that the technique is a "great choice for me, because I'm this type of person, who needs to have many little breakes" (#0596). Viewers commented that the length of the pomodoro sessions helped them to remain focused, such as, "First time in my life - studied for 2.5 hrs" (#0382), create a routine where they could "study regularly"(#0399), and effectively incorporate breaks into their study sessions, such as, "The day before tests I'm always in let me get all I can get info mode, so I always forget to take breaks, but this reminds me to take breaks so I absorb the information and not feel overwhelmed" (#0435).

Viewers frequently credited environmental elements, such as the music, movements the content creator makes during studying, the soft lighting in the video and the content creator's cat, as creating the ideal setting for studying, but these were not all universally liked. Often viewers would refer generally to the calming nature of the environmental features, such as one viewer who said, "having a low work ethic and anxiety means that it's always been quite difficult for me to focus. These helped so so much to calm my nerves and keep me on track" (#0708). For others, they specifically mention features, including the music that was often credited as setting the right mood for viewers who commented that the music "is so calm yet give you the push" (#1384), "switches my mind and mood to study" (#0836), and "makes homework enjoyable" (#1154). One viewer said, "I really felt alone when studying by myself but hearing the music and knowing you were studying too gave me motivation," (#1340) indicating that the music enhanced the motivating feeling of working with someone. Music was such a significant element in the video that comments commonly referred to the precise point in the video that helped them study, such as comments that said, "suddenly at 58:18, it was like my books hypnotized me to study more" (#0671), and "at 35:45 the music really helped my studying" (#0606).

Viewers credited small movements of the content creator as supporting a studying atmosphere. For example, "the paper turning or the book flipping that just put you in the studying mode" (#0045). For some, the content creators' pet cat added to the setting, being referred to as "a great supervisor" (#1004) and described as giving "me so much motivation!" (#0906). The lighting in the video was described as creating the right mood as one viewer pointed out, "think the environment and the lighting she study in makes these videos perfect" (#1836). Moreover, these environmental elements induced feelings of calmness in viewers who said the video was "the most peaceful and calm study session" (#2601), helped to "wash away the anxiety" (#0285) and "calm my nervous distraction attacks" (#0361). These comments suggest that rather than the novelty of the video scene, it was the sense of calm and focus supported by the environmental elements in the video that led viewers to repeatedly return to this video during studying, as viewers indicated they "watched this video countless times" (#2969).

Finally, while most viewers felt that the video environment played a positive role by enhancing their studying experience, some described the same features as having a negative effect on them. For instance, viewers pointed out that the music choice was "a little too intensive for studying" (#0274) and the "music and the rhythm is distracting me from concentrating" (#0386). Similarly, some viewers felt the presence of the cat in the video was a source of distraction for them, and they "literally cant stop looking at the cat and not studying" (#0023-1).

Theme 3: The content creator was seen as a relatable role model in the affinity space

We found that video comments frequently referred to the content creator as a relatable role model in two ways, including: (1) she was inspiring and motivational because she embodied the characteristics of the ideal study partner, and (2) she was viewed as a study expert to that could offer studying advice.

First, viewers described in detail how the content creator's studying habits inspired and motivated them. For example, one viewer said, "you seem so focused, that is good and inspiring some how" (#0059) and "seeing you study for that long motivates me to study extra" (#0246). They often described the content creator as someone who embodied the characteristics of the ideal study partner. For example, one viewer said, "sometimes it's great to have someone as motivated as you to keep you going and help you stay disciplined" (#0216). Viewers frequently pointed out the content creators' specific positive study behaviors such as her ability "to study like this without even touching your phone or spacing out while in pomodoro" (#1173), to have "no distraction, no texting, no messages" (#1334), and displaying exemplary behaviors such as, "reading and typing on the laptop at the same time" (#0783) and "if you can keep going so can I!"(#0613). Viewers who identified themselves as students in

medical disciplines in the comments found the content creator particularly relatable. For example, one viewer said, “The process of becoming a doctor is the hardest thing I've ever done and I just keep wanting to give up. You are about 3 years ahead of me but watching you go through the process (and your struggles along the way) make me feel less alone now that I see where you are” (#1183).

Second, viewers saw the content creator as a study expert and sought advice from her on general study questions. For example, viewers asked for “some study tips and tricks that will help during exam time"(#0081) and “any tips with textbook use?” (#0110). They also sought elaboration on particular techniques such as “a specific method for retaining information” (#0083) or dealing with issues while studying such as “I don't how to deal with my studying if i got problem in life, in that case, I have no idea to concentrate on my study. Hope to get advice” (#0196). These comments suggest that the content creator took on a role that is more significant than a silent study partner. The posted comments showed evidence that viewers perceived the content creators’ discipline and good study habits as something to be modelled. For instance, one viewer said “I wish I have the same discipline that you have” (#1936) and another shared, “I have huge problems with discipline and concentration…whenever I start to look around and procrastinate I see you and I'm like "Uhh, I really should be studying" and “get back to it” (#1429). These comments help us recognize that the content creator was seen as a role model who motivated the emulation of similar behaviors in the viewers.

Theme 4: Viewers found the SWM video benefitted short-term and long-term goals

Our final theme demonstrates how the SWM video was used by viewers as a tool to: (1) provide focus and motivation while studying in the short-term, and (2) help them accomplish measurable short and long-term achievements.

Our analysis suggests that the SWM video helped viewers self-regulate as the content creator’s presence, albeit in an asynchronous video, played a role in engaging with the video. They explained that seeing the video creator studying hard and concentrating had a positive effect on the amount of time they studied. For example, one viewer said, “For 21 years i could not study. Now for 2 days i'm studying with you and time flies!”(#0168). Others felt the video broke their “procrastination cycle ”(#1053) to improve their productivity, such as comment #2601 that stated, “Math would normally take me about 3.5- 4 hours to solve 95 questions but today I finished 95 questions in 1 hour!!!”. Moreover, viewers expressed that the SWM video made them feel accountable such as, “it's nice to study "with" someone so i feel like i'm being held accountable when i get off track” (#0292). In these ways, viewers express short-term benefits of improving concentration, productivity, and accountability.

Viewers also attributed visits to the SWM video as helping them in accomplishing specific measurable achievements in the short and long term. Describing the benefits for short-term achievements typically including exams and course work, including “finishing my general chem 1 lab report” (#0302) and “passed my Organic chemistry exam” (#0596). These comments illustrate that viewers turned to the SWM video as a support for their learning in particularly stressful times for high stakes exams and assignments. Additionally, viewers credited the SWM video in helping them achieve more long-term objectives such as completing classes, medical school, or graduating from college. For example, one viewer had used the SWM video to “get through about two months of my EMT class and still going!” (#0655). Another viewer shared they had graduated from business school and “if it wasnt for ur videos at 5am, or midnight or 4 pm, I wouldn’t have been able to study for those exams.” (#0896). Similarly, another viewer said, “I just finished my bachelor degree. I would like to come back to your channel and thank you. Your videos contribute a lot to my success” (#0913). Here, these comments demonstrate how users felt the repeated and prolonged use of the SWM videos benefitted their long-term goals.

Discussion

In this paper, we set out to explore how and why viewers use SWM videos, an online asynchronous version of studying in the presence of others. We examined one YouTube SWM video to see how this virtual affinity space provides social support and opportunities for social interaction during studying activities usually done in isolation.

Our findings suggest that viewers are drawn to the SWM video to achieve short-term and long-term goals, because their studying experiences are transformed by indirect and passive social interactions, the structured studying and idealized video environment, and the positive influence of the content creator as a studying role model. Viewers found the presence of the content creator motivated them to engage in efficient, focused, and prolonged studying behavior, and described the comment space as a way of feeling connected to the content creator and other viewers who were potentially engaged in the same studying experience. We believe these findings provide important insights into the learning experiences of people as they engage in an online, asynchronous studying environment including: (1) the impact of indirect and controlled social interaction on learning, motivation and studying behavior, and (2) the importance and affordances of environmental and

structural features in these learning environments. Here we discuss how our results support and expand on prior work and explore the practical implications of these findings.

First, our findings suggest that social engagement was critical to many of the viewers of the SWM videos, and that people participated in these asynchronous online spaces to find a social space to study. This indirect social interaction took two forms, one as a feeling of collective activity with other viewers, and the other as a passive studying experience with the content creator. Viewers made connections to others across the globe by posting about specific goals and outcomes and sharing their study habits, such as their difficulty in studying for long stretches of time or being easily distracted when studying by themselves. As in prior work, these goal-stating comments and sharing of practices, as self-reflections, can help viewers practice metacognitive skills that are beneficial to self-regulation during their learning experience (Winne, 1995). The results also indicate that the SWM affinity space filled an important gap in viewer's studying experiences by allowing them to access this social space at any time of the day or night, where feeling connected to others despite odd hours helped people stay motivated and focused. This on-demand social experience helped solidify the communal feeling of working with others, as seen in library study groups (Bersani et al., 2013) and towards a common endeavor, as is common in affinity spaces (Gee, 2004), but further provides flexible access to the space and social activity.

We believe that the viewers' perception of the content creator as a role model is unique in that viewers seemed to find the content creator's simple act of studying as inspirational. Viewers often commented on her exemplary studying skills, where the content creator displayed complete focus and attention by keeping her gaze on the computer screen and textbook throughout the video session. Observing the modeling of such positive behaviors by the content creator seemed to have a significant motivational effect on the viewers who wanted to emulate her. This response to the content creator's modeling may represent an important social influence on the viewers behavior. Comments that indicated the feeling of studying with someone and the benefits of seeing the content creator actively working, such as "if you can keep going so can I!" (#0613) demonstrate a type of companionship and camaraderie in the experience similar to research on in-person co-studying (Bersani et al., 2013). We were struck by how much viewers found that this modeling effect works even through a pre-recorded video, and that one well modeled studying session could benefit millions of others. These findings show the importance of co-studying and that it can be accomplished remotely and asynchronously. We believe these findings demonstrate the strength of student needs for social connections, even in passive forms, as motivation and positive social influences during learning activities.

Our second main finding shows that viewers frequently attended to environmental features, beyond the content creator's presence, in the SWM video. These environmental features included the structure of the pomodoro technique, the presence of the content creator's cat, the curated music playlist, the dim lighting, and the video creator's movements (such as highlighting text and concentrating on the computer screen) as creating an ideal ambiance for their studying experience. The elements of the video seemed to be instrumental in drawing people into this space and bringing them back repeatedly because the experience of studying with the content creator evoked feelings of calmness, motivation, and focus, as one viewer said the video "helped so so much to calm my nerves and keep me on track" (#0708). Empirical evidence in research has illustrated the importance of environmental and structural features for the design of learning environments (Taylor, 2009), and our findings help illustrate how this effect holds for asynchronous online learning environments as well. This study has practical implications for improving students learning and studying experiences and suggest that learners may benefit from the design of informal and formal learning environments that include designing for specific environmental features to evoke positive affective responses. Our findings suggest that details, such as lighting, can be influential, and should be carefully considered when creating online learning materials, such as video tutorials, but also for in-person learning spaces, particularly when students are asked to work independently.

These two findings help build on existing theory on social learning in affinity spaces by examining a uniquely passive social learning experience, the SWM video, to understand the naturally occurring, self-sustaining interactions within this space. We used Gee's framework to conceptualize affinity driven interaction in the SWM video to inform our understanding of why these spaces exist and continue to grow. Further investigations into the social interactions of viewers outside of one SWM affinity space, such as in other SWM sites, can help us understand how these affinity spaces connect, and how the movement of viewers across these spaces allows additional opportunities for connection making that support viewers studying and learning experiences. These SWM videos also inform our understanding of social learning, more generally, in demonstrating the strength of passive social influences on studying and learning, where we expand our understanding of shared learning activities (Cress & Kimmerle, 2018) to include asynchronous interaction and passive influences. The practical implications of the study point towards changing our current practices of asking and expecting students to study alone. This study shows that people have a strong social need to feel connected to others and that co-located studying, even when it's in the form of a digital presence, is beneficial to people's learning experiences.

Conclusion

In this study, we demonstrate that asynchronous online affinity spaces such as SWM videos may have emerged to meet the need for learners to experience social connections and positive environmental influences while they engage in otherwise isolated studying activities. We believe this further strengthens arguments for social engagement during all forms of learning, in and out of formal classrooms. We recognize this study is limited in examining one SWM video, and by analyzing only viewer comments as evidence of the activity in the affinity space. We plan future studies to broaden this examination to include multiple videos from multiple content creators, and to look at how individual viewers may interact with different content creators and different videos over time. Future studies may also include interviews or survey-based research of content creators and viewers to include their retrospective perspectives or may include experience sampling or think-aloud studies to examine the actual process of studying with SWM. We also recognize that our study is limited in only examining asynchronous SWM, and suggest additional work to explore how newer platforms, such as Twitch, support synchronous forms of SWM. In summary, the rapid prominence of SWM videos as studying tools demonstrates how valuable social companionship is during learning, and this should impact the way we design all forms of learning. We hope to build on these insights to improve learning experiences for all students.

Attenuation and Amplification of Agency through Goal Announcements in a Makerspace

Megan Goeke, University of Minnesota – Twin Cities, goeke018@umn.edu
David DeLiema, University of Minnesota – Twin Cities, ddeliema@umn.edu

Abstract: Agency in makerspaces is frequently in flux, amplified or attenuated through interactions between the maker and individuals around them. Looking at goal announcements in a makerspace designed to provide no predetermined goals, we see that these moments tend to follow triadic dialog patterns and that makers orient to the potential evaluation through hedging and multimodal demonstration. We argue that maker educators need to carefully attend to how interaction shapes maker agency without assuming that open-endedness alone will suffice.

Introduction

Educators who embrace the 21st century "maker movement" often emphasize the pedagogical values of promoting maker agency, designing to support persistence across moments of failure, and addressing the perceived divide between producers and consumers (Doughtery, 2013; Bevan, 2017). However, recent ethnographic studies of makerspaces have shown that they fall short of these larger promises. Maker activities often take the form of prescriptive assembly kits (Blikstein & Worsley, 2016) and place undue value on high-tech versus cultural making practices (Vossoughi, Hooper, & Escudé, 2016). Moreover, youth deeply engaged in making are frequently required to push against dominant narratives of neoliberal entrepreneurship (Greenberg et. al., 2020) and individualism (Vossoughi et. al., 2021). In particular, these works highlight how educative maker programs can reproduce societal inequities (Ryoo & Kekelis, 2018; Elliot, 2021) unless those inequities are intentionally addressed (Buchholz et al., 2014; Calabrese Barton & Tan, 2019; Lee et al., 2021). Taking inspiration from recent efforts that attend to the microgenetic processes of learning in makerspaces, we focus on how maker ideals are realized or subverted on a moment-to-moment basis.

Focusing on the value of maker agency, this study identifies patterns of intrafamily interaction concerning a critical moment for amplifying and attenuating agency: the public announcement of a goal. Goal announcements - including statements of goals such as "I'm making a house" and statements of lacking goals such as "I don't know what I'm making" - are critical because they mark a point in time in which the maker's intention (which is often studied as a private psychological and cognitive experience) become available to others in the makerspace through verbal and embodied pronouncements. Once a goal has been announced, it becomes a public substrate (Goodwin, 2017) that others can assess, question, or ignore (Pomerantz, 1984). In this way, the statement of the goal has social consequences and represents one kind of moment where a maker's agency is at stake. To this end, we draw on key tenets of discursive psychology to investigate interaction patterns structuring goal announcements in a museum-based maker setting with minimal activity prompts. Building on Shah & Lewis' (2019) examination of the moment-by-moment *amplification* and *attenuation* of power in pair programming contexts, this analysis examines conversational dynamics of amplification and attenuation with respect to maker agency. More specifically, the study focuses on goal announcements in a makerspace to understand how maker agency is attenuated or amplified during intrafamily interactions.

Based on the existing literature concerning maker agency, goals in education, and power in conversation (Philip & Gupta, 2020), we focus on when goal announcements arise, who initiates the goal announcement, the conversational content, and resistance to announcing. To this end, we center the following research question: As a site of potential maker agency, how do public announcements of maker goals unfold in interaction?

Literature review

This work is grounded in three theoretical spaces: student agency, goal announcement, and power as embedded in moment-to-moment interaction. Agency is often conceptualized as the socioculturally mediated capacity to make independent choices and actions (Schlosser, 2019). In this operationalization, the sociocultural emphasis refers to societal and cultural structures – ever-present in individual lives – that shape where individuals are able to exert agency. People in social interaction mediate these sociocultural structures by endorsing, resisting, and revising them at the moment-to-moment scale of conversation (Philip & Gupta, 2020; Shah & Lewis, 2019). From this perspective, we see individual agency as a fluid achievement of the microgenetic structure of a social context. In conversational moments, agency is amplified or attenuated: increased or decreased in a given situation from an ever-present baseline that assumes tensions around agency. In makerspaces, the decision of what to make – the

 © ISLS

maker's goal – is a key opportunity for the enactment of agency, and thus conversations around maker goal announcements provide a window through which to examine these social dynamics. Goals can occupy the space of private psychological experience, or they can be shared outwardly within the course of a making activity, creating a shared focal point in collaborative work or simply a point of departure for understanding the independent actions of others (Strivers & Sidnell, 2016). Because the public presentation of an otherwise private goal might fundamentally change what the interlocutors discuss, what they critique, etc., we would anticipate a degree of tension between withholding and providing public goal announcements. This tension brings maker agency to the foreground of these social encounters.

To even further sharpen our focus on maker agency during goal announcements, we layer into our analysis considerations of interactional power. In particular, we examine power in terms of known structural patterns of conversation. Human conversation is structured around interlocutors taking turns speaking; overlapping speech is rare (Sacks, Schegloff, & Jefferson, 1974). Turns are sequentially organized with immediate next-turns responding to immediately prior turns, known as conditional relevancy. How interlocutors accept or resist the conversational themes set by their interlocutor in the immediately preceding turn throws light on microgenetic exertions of power (Heritage, 2003). For the purposes of our study, we additionally focus on triadic dialog and hedging as lenses through which power plays out. In triadic dialog, such as initiate-respond-feedback sequences frequently documented in classroom settings (Cazden, 2001), the individual who initiates a conversation or topic change holds greater power than the second speaker based on both setting the conversational agenda and later reacting to the second speaker's contribution (Esmonde & Langer-Osuna, 2013; Hutchby, 1996). In turn, the second speaker might resist the conversational agenda of triadic dialog in the contours of their response (Stivers & Hayashi, 2010), including through hedging. Verbal hedges are defined as "downtoning expressions or expressions of tentativeness or possibility" (Johansen, 2020, p 1), functioning as a mitigation strategy to withhold the speaker's full commitment to what they are saying (Hyland, 1996). Hedging allows for full acceptance in the first speaker's conversational agenda but resistance to potential critiques of their contribution.

Makerspace context

The video data used in our analysis were collected in an open-ended makerspace designed and hosted at a large midwestern science museum between October and December 2016. Overall, the designers envisioned a makerspace focused on cardboard boxes as the primary material resource. The designers selected cardboard for its perceived familiarity for families, ability to be manipulated with low tech tools such as scissors, and possibility for post-visit family learning, specifically that families would continue making at home with their own cardboard supplies. Just inside the entrance doors, a single sign provided general rules: "Rules of play: Please do: Build, construct, stack, and mine with the boxes. Please don't: Climb, Throw, Stand On, or Kick the boxes." To the left of this sign, a large pile of employee-donated cardboard materials - including a variety of sizes, thicknesses, and colors - provided source material for visitor making. The only example cardboard creations in the space were pieces left behind by previous visitors. In October 2016, a museum employee wrote "Be Creative" in masking tape on the black wall of the makerspace; from then on, the space included visitor-generated tape graffiti as a prominent visual feature. In terms of design ethos, the designers strived for unlimited material resources (cardboard and tape), easy to use tools (scissors and safety boxcutters), and no predetermined directions in order to foster the maker's agency and imagination.

Method

The above-described data set was originally collected to investigate youth (aged 9 to 15 years old) experiences of failure in makerspaces. We selected this dataset for secondary analysis because the maker educators who designed the space placed high value on maker agency. Additionally, the video data collection procedures involved minimal intervention in participant's authentic maker interaction within a family group. Eight family groups participated in video data collection, resulting in 4.5 total hours of video. Family groups were recruited as they entered the makerspace upon their own accord, meaning the participants all self-selected to engage with this particular museum experience. Only families with at least one child between 9 and 15 years old were invited to participate in the video data collection. Unfortunately, no demographic data was collected beyond the inclusion question during this stage of the original project's data collection.

Data collection

Video was collected with chest-mounted GoPro cameras, allowing groups to move through the makerspace without needing to manage the camera. All video camera placements foreground and background particular features of the environment (Hall, 2000); chest-mounted GoPros capture the wearer's hands and forward facing context along with the audio record of near interlocutors, approximating that individual's experience of the

unfolding moment (Burris, 2017). Based on the interests of the original study, the 9 to 15 year old child wore one chest-mounted camera, and in five cases, an additional family member wore a second chest-mounted camera. Participating families were asked to spend as much or as little time as they wanted in the space and to return to the researcher when ready to leave in order to complete a short interview. For our analysis, we only include the first question of the interview - "What did you make today?" - because it directly related to goal announcements.

Analytic methods

This study uses interaction analysis and draws on the tenets of discursive psychology. Interaction analysis (IA; Jordan & Henderson, 1995) is concerned with microgenetic processes and focused on routine patterns of human action - including verbal, multimodal, and tool-based actions. IA is concerned with the situated nature of knowledge and action, highlighting how people use aspects of the social and material world around them to sequentially and simultaneously understand one another and engage with an activity (Hall & Stevens, 2015). Analytic attention is directed to social and material resources that hold relevance for interlocutors: participants engaged in interaction/conversation. Where interlocutors place their attention is where researchers place theirs. We focus our IA on the identification of patterns in goal announcements across the data set, highlighting the temporal, material, and social aspects of these patterns. Discursive psychology (DP; Wiggins, 2017) is an approach that examines how people reference psychological phenomena in conversation and what social purpose those conversational moves accomplish. For example, a student may respond to a teacher's question with "I don't remember the answer"; a DP analysis would identify what social action the claim of not recalling performs - such as inviting teacher support - setting aside questions about the statement's accuracy (e.g., whether the student actually remembers). We engage with DP to understand the organization of goal announcements, attending to how the interactions shape who has agency over which decisions in the makerspace context.

Initial exploratory analysis

While content logging the data (at 2 min intervals), we noticed a pattern where some youth makers proclaimed, "I don't know what I'm making," while simultaneously engaging in physical making actions such as cutting, taping, or folding. Exploring the content logs further, we noticed that makers seemed to make this statement after being asked by another person about what their creation was, drawing our attention to goal announcements.

We identified clips from the content logs related to goal announcements to conduct an initial exploratory interaction analysis. We selected for diversity in this initial set of clips, specifically choosing examples of goal announcements from different families, points in the making process, ages of interlocutors, and announcement type (e.g., naming a goal or saying "I don't know"). In an effort to capture all relevant context, we segmented clips to include significant time before and after the goal announcement. We then transcribed each clip using Mondada's (2018) transcription system that blends Conversation Analysis conventions with precise multimodal representations. Multimodal transcription also allows us to document how individuals engage with physical objects, particularly important for understanding interaction in making contexts (Fasulo & Monzoni, 2009).

We iteratively analyzed this set of goal announcement clips through multiple viewings, individually and in group data sessions with other researchers (Jordan & Henderson, 1995). Our viewings focused on the turn by turn unfolding of goal announcements, meaning we explored how these moments were initiated and closed, how they differed from one another, and how they were connected longitudinally within a family's making session. Early in this exploratory IA phase, we began articulating interaction conjectures to describe patterns in unfolding goal announcements that were common across clips (Hoey & Kendrick, 2017). To sharpen these interaction conjectures, additional disconfirming cases were identified, segmented, and transcribed.

Data selection: Freezing the analytic frame

After examining 10 total clips during the initial exploratory IA phase, we wanted to investigate how common these moments were across the data set. We froze the two interaction conjectures developed in the exploratory IA phase and developed inclusion criteria, specifically that clips needed to include a) at least two interlocutors in order to be considered an announcement, b) (at least) one interlocutor claiming that the object being discussed was their creation, c) the object and the maker's hands (typically) visible in the video frame, and d) interlocutors focusing on object identification (e.g., naming it). To develop a complete clip corpus, we re-watched every video collected, tagging all moments which met the inclusion criteria. These moments were segmented from the larger video; each clip was bound by a change in the conversational topic or a substantial break in conversation. This process resulted in 88 clips (mean per family group = 11; SD = 5). We then coded features related to our interaction conjectures, including who initiates the discussion about the maker's goal, whether the goal is announced or withheld, use of a hedging word (Johansen, 2020), and physical engagement with the creation. We recognize that coding interaction data requires deep understanding of the phenomena and clear definitions (DeLiema et. al.,

2021; Hammer & Berland, 2014); we are currently engaged in such a concerted effort. For now, we present this coding of the total video corpus to demonstrate the ubiquity of goal announcement interactions in this makerspace.

Results

Our analysis uncovered two consistent interaction conjectures present across goal announcements:

1. Goal announcements in this makerspace follow an overall initiate-respond-feedback (IRF) sequence.
2. Makers orient to the interaction as evaluative, evidenced by hedging and multimodal demonstration in goal announcements.

For the sake of space, we detail two illustrative cases from a single family and then summarize basic spoken elements of goal announcements from the total video corpus.

"Cute dog thing": Announced goals and lack of goals

We begin with an example of two youth makers – Emma and Lily – from the same family. The sole adult in their group – Sara – asks each maker to publicly announce their making goals. This interaction occurred less than a minute into the family's time in the makerspace, just after both youth makers had gathered materials and tools but prior to active construction moves such as cutting, taping, stacking, etc. Transcription conventions include bold font for verbal actions, non-bold font for physical actions, degree signs to note the beginning and end of Emma's physical actions, and asterisks to note the beginning and end of Lily's physical actions.

Lack of goal announced

Our analysis begins at the point that Emma walks over and drops their cardboard materials on the ground near Sara, who is sitting in a chair. Emma begins manipulating the roll of tape as Sara initiates the interaction:

Figure 1

Transcript of Emma's Goal Announcement

1	**Sara:** Emma:	**Do you have something in mind° that you are going to make?°** °Pull tape ----------->°
2	**Emma:**	**(1.6)** **I don know**
3	Emma:	°**(2.8)** ° °Kneels on ground°
4	**Sara:**	**Well why don't you come up with somethin**
5		**(6.0)**

Sara *initiates* the interaction with a question. The structure of a question – such as standard Wh-questions, polar questions, "or" elliptical alternative questions, and declarative questions (Hobbs, 2012) – constrains response possibilities, though resistance to the interactional agenda is always a possibility. The question structure in this case requests a statement from the recipient about the presence (polar yes/no, "do you") of an internal ("something in mind") goal for subsequent and presumed planned actions ("are going to make"). By asking this question, Sara generates a discursive climate in which Emma is asked to provide a polar response to the possibility that they have an intention in their mind that will drive what they make.

Instead of adhering to the yes/no response format, Emma responds with the statement "I don know." In the space of public discourse, this response is relatively ambiguous. Emma could be saying that she lacks a goal or Emma could be saying that she does not know the answer to Sara's questions. With this analysis, we are not attempting to make a claim about whether Emma did or did not have a goal at this point in the activity. The social implications of outwardly stating a lack of goal are the focus of our analysis. Looking at the structure of their *response*, Emma delays their response significantly beyond the 1 second conversational threshold typical of responses (Jefferson, 1989). When they do speak, Emma moves beyond the "required" response of a polar question, indicating they interpreted the question as a request for an actual goal, not just its presence (Stivers & Hayashi, 2010). "I don't know" as a question response can serve many functions beyond a truthful announcement of lacking information, including avoiding the conversational agenda, avoiding assessment, avoiding explicit disagreement, or hedging (Tsui, 1991). We cannot glean Emma's individual agenda with their "I don't know," but we can point to its situated social action of avoiding further pursuit of Sara's question about the goal.

After another substantial 2.8 second pause between conversational turns, Sara gives Emma *feedback* related to the lack of goal, specifically that Emma should establish a goal (line 4). "Well" at the front of turn indicates contrast or rejection of the previous speaker's stance (Schegloff & Lerner, 2009). While the grammatical structure of Sara's feedback is a question, her prosody reflects a statement tone, and neither Sara nor Emma treat the utterance as a question in need of response (line 5). Sara's feedback acts as a directive to Emma, positioning their lack of a goal as something to be repaired.

Goal announced

Just 6 seconds later, Lily, who had been traversing the makerspace to retrieve materials, enters the scene. Lily had been out of earshot during the previous interaction about Emma's goal. The following interaction plays out here:

Figure 2

Transcript of Lily's Goal Announcement

6	**Sara:** Lily: **Sara:** Emma:	***Lily, do you have something in mind *** *sits down, grabs scissors---------->* **that you are going to °make?** °Grabbing tape, Looks at tape->
7	**Lily:** Emma:	**I want to make it have cute eyes ° °and eye lashes** -------------------------------->° °Looks at Lily->
8	**Sara:** Emma: **Sara:** Lily:	**A°°:Oh so you're making a human°°out of it?** ->°°Looks at Sara-------------->°°Looks at Lily----->**or a like a* cardboard person?** *grabs box, flips over--->
9	**Lily:** Lily: **Lily:** Lily:	**No a cardboard (.) cute* (.) dog thing.** ---------------------->****(1.0) * You *know *** *sets down* *picks up tape roll*
10	**Emma:** Lily:	***Lily I can help you with that** *manipulating tape roll------>
11	Lily:	--->* *Pulls tape*

In this short transcript, we see Sara *initiate* the interaction with the same question they previously directed to Emma (line 6). Lily *responds* with a description (line 2), reflecting an interpretation of the initial question as not polar but a request for the goal itself. Specifically, their description highlights two attributes ("cute eyes and eye lashes") and an intention ("want to make it"). Notably, Lily's response has no evidence of hesitation or hedging, indicating full commitment to "cute eyes and eye lashes" as their goal. Sara provides *feedback* via reframing Lily's goal response from attributes to a single thing (line 3; "human", "cardboard person"). The questioning prosody signals Sara's positioning as not knowing, aligning with IRF literature concerning continuation of IRF sequences that lead learners to particular outcomes (Skiveland, Solem, & Skovholt, 2021). Sara's subsequent request for clarification reveals firmer parameters in this moment around what constitutes a goal, namely a bounded thing, not just an attribute. This process of reframing a response parallels research on IRF sequences in formal classrooms, where teachers will guide students to anticipated responses through various re-initiation and feedback mechanisms (Zemel & Koschmann, 2011).

In response to Sara's reframing of their announced goal, Lily *responds* again (line 9), this time crafting a response oriented to the *feedback* from Sara. First, Lily quickly states "No," rejecting the specific potential goal stated by Sara. Lily then states their goal of making a "cardboard cute dog" with a micropause separating each word. While micropauses can indicate the opportunity to end a conversational turn (Sacks, Schegloff, & Jefferson, 1974), Lily's lack of closing prosody and simultaneous physical engagement with the cardboard box act as turn continuations, giving Lily a longer conversational turn in order to construct a response. Lily's word choices – specifically pulling forward the words "cute" and "cardboard" – create a blend between their original goal announcement and Sara's reframing. Lily also meets Sara's request to provide a description of a bounded thing with the addition of "dog" in their goal announcement. Finally, Lily ends their second response with a hedge – "thing" – which moderates their commitment to the entire goal announcement (Johanson, 2020).

After finishing their second goal announcement, Lily waits for a next turn from Sara, indicated by the significant pause after the word "thing" (line 9; Jefferson, 1989). Sara does not perform the anticipated next turn,

so Lily repairs the interactional hole with "You know." Emma further repairs the lack of next-turn from Sara with her own offer of assistance (line 10). However, Lily does not respond to this offer, nor does Emma pursue such a response. However, such offers of assistance provide another type of feedback, signaling that the announced goal is worth pursuing with additional resources.

Analytical synthesis

In both cases, we see maker agency amplified by the deferment to the youth to name their making goal and attenuated by Sara's feedback on those announcements. Following an IRF structure, Sara initiates each sequence with a question, and the sequence is closed with a feedback statement without questioning prosody. Emma announced a lack of goal, an exertion of agency relative to how to approach making, and Sara established the expectation that Emma would need to resolve this omission, attenuating Emma's agency over that decision. This also left open the possibility for Sara to reinitiate the IRF sequence in the future. In contrast, Lily announced a goal based on attributes, which Sara framed as an incomplete response in her continuation of the IRF sequence. Lily's second goal announcement reflected a new orientation to Sara's feedback, shaping the response to include aspects of Sara's reframing and hedging the entire announcement with the word "thing." Both of these moves reflect Lily's orientation towards Sara's feedback as constraining their field of choices, an attenuation of agency. While Sara did not close the IRF sequence with Lily, Emma stepped in and provided a positive feedback turn. These two conversation sequences exemplify our interaction conjectures and demonstrate how they relate to amplification and attenuation of maker agency in small-scale interactions.

Summary of video corpus

To demonstrate the ubiquity of goal announcements and the contours of attenuation and amplification of agency within them, we present an initial summary (see Table 1) of some core verbal features of goal announcement interactions across the eight families in this study.

Table 1

Summary of Goal Announcement Interaction clips (n=96).

Family	Number of Adults	Number of Children	Total Time Making (mm:ss)	Clips			
				Total	Preceding Question	Lack of Goal	Announced Goal with Hedge
A	1	2	18:36	11	6	2	4

G	1	4	17:45	7	4	1	0
H	2	2	44:28	17	7	4	3

Discussion

Power is infused in social interaction, including moments like naming a goal in a makerspace (Philip & Gupta, 2020). Looking across goal announcements in this makerspace, we see maker agency as frequently in flux, constructed by small but impactful moments of amplification and attenuation. Goal announcements typically begin with a question from the non-maker. As seen in Sara's phrasing, the structure of the question may amplify maker agency by framing the maker as the person choosing the goal. However, the questioner also places themselves in the powerful position of first and third speaker in triadic dialog, both setting the conversational agenda and critiquing the second speaker's response. That feedback turn can attenuate maker agency, as we see in Sara's shaping of both Emma's and Lily's goal formulation. The makers orient to the evaluative nature of the triadic dialogue, using hedges to buffer critique and shaping their response to meet the expectations of the non-maker. Announcements of lack of goals – such as Emma's "I don't know" response – are forms of resistance to immediate conversational agendas, preventing the immediate opportunity to evaluate, but from single interactions alone, we cannot see how amplification or attenuation of agency shapes making across goal announcements.

Our next analysis steps aim to examine additional factors influencing agency in goal announcements, including temporal arrangement, interlocutor ages, and individual or collaborative making projects. Since 2016, the museum designers for the makerspace have iterated on the design of the space to include intentional exemplars

and activity prompts ranging from assembly style making to open-ended tinkering (Bevan, 2017) in order to support a wider variety of family engagement preferences. We will compare findings from across makerspace designs to understand how the educational design contributes to attenuation and amplification of maker agency.

Just because a makerspace is designed to support agency does not mean it is experienced this way. When applying these findings to maker practice, we do not advocate for settings in which people never ask makers what they are working towards. Such a directive would likely constrain collaboration, limit joint learning, and undermine other maker values (Vossoughi et al., 2021). We argue instead that supporting maker agency needs to be more intentional than simply not providing goals, which was the design intention in this makerspace. By attending to when a goal announcement is made, who has the power to prompt for that announcement, and perhaps what alternative interaction structures could be used to move away from immediate feedback, maker educators may develop norms that consistently amplify maker agency.

"Bringing New Things to Light": Examining a Process of Insight-Driven Teacher Learning

Ethan Rubin, Elizabeth A. van Es
ebrubin@uci.edu, evanes@uci.edu
University of California, Irvine

Abstract: Effective teaching relies on practices of reflection and inquiry that must be cultivated throughout teachers' careers. Professional development (PD) can support those practices by positioning participants to develop and build on insights. Using data from a PD program focused on teacher noticing for equity, we draw on practice theory to identify the process and associated practices that emerged through participation in collaborative inquiry. Analysis reveals three phases of activity, consisting of interrelated practices that drove insight-based learning: building awareness, collaborative exploration, and learning through design. Through engaging in this process, participants made unconscious aspects of teaching visible that allowed participants to deepen and expand their insights, and through design, articulated new insights and situated their learning back in the context of their teaching. These findings have implications for designing PD that prioritizes participants' agency to cultivate practices of reflection and inquiry.

Introduction

Teaching has been widely theorized as a dynamic, relational, and responsive discipline that requires practitioners to develop ways of seeing and interpreting that can unveil and support learning processes (Erickson, 2011; Mason, 2002). In this sense, effective teaching relies on practices of reflection, inquiry, and continuous improvement that must be intentionally cultivated throughout a teacher's career (Cochran-Smith & Lytle, 2009; Lampert, 2001). This dimension of teaching, which we refer to as *learning-for-teaching*, consists of adopting and adapting practices, in contrast to propositional knowledge about content or strategies (Ball & Cohen, 1999; Kennedy, 2016). Consequently, we propose that professional development (PD) programs to support learning-for-teaching must elicit and build on participant inquiry and insight to *enable them to develop and implement relevant practices*. This need for a dynamic and participatory PD model presents a challenge for PD designers, who must consider how to create the conditions for participants' insights to emerge and facilitate a process of development that is ultimately teacher-driven (Kennedy, 2016). Doing so requires a deep understanding of the practices and processes of insight-based learning, particularly in the context of developing the ambiguous and contextual aspects of teaching.

We draw on participatory and collaborative research models that position practitioners as both experts and learners. Through collaboration with colleagues and facilitators, practitioners apply, explore, and develop their knowledge of their discipline and contexts to produce insights that support continuous improvement (Bang & Vossoughi, 2016; Engeström, 2011). These models point to prioritizing teacher agency in the context of improving teaching, as we recognize that positioning teachers as experts engaged in practices of continuous improvement entails allowing them to guide the practices and processes of their own learning (Cochran-Smith & Lytle, 2009). In our study, we are concerned with understanding the practices that support the development of learning-for-teaching when PD participants engage in collaborative inquiry. Therefore, we ask the research questions: How do teacher-participants experience insight-driven professional development as a generative process for developing learning-for-teaching? What practices emerge in the process of collaborative inquiry?

Theoretical framing

Teacher agency in professional development

Teacher agency has been theorized as an important dimension of teacher learning (Imants & Van der Wal, 2019; Sancar et al, 2021), which indicates that efforts to support teacher learning in professional development can be characterized by the degree of teacher agency they afford. Kennedy (2016) situates PD programs on a spectrum that begins with prescriptive approaches that instruct teachers how to teach and moves toward programs that position participants to generate their own insights. These insight-driven approaches lie at the opposite end of the spectrum, focusing on generative practices that elicit and leverage participants' insights to articulate and refine concepts for improving teaching (Cochran-Smith & Lytle, 2009; Kennedy, 2016). Borko et al (2011) describe a similar spectrum, moving from highly specified PD programs to highly adaptive programs. Highly specified programs define the goals and the mechanisms that will be employed to produce pre-selected desired outcomes.

 © ISLS

Adaptive programs, on the other hand, respond to the needs and interests of participants to determine the goals and foci of PD. The spectrum of teacher agency to which these authors refer does not indicate that more teacher agency is preferable or more effective. Rather, they suggest that different approaches to PD support different forms of teacher learning.

Developing learning-for-teaching practices

We situate this study in the context of insight-driven PD because we theorize that the practices of learning-for-teaching develop through experiences of co-constructing, adapting, and engaging in relevant practices. For teachers to internalize learning-for-teaching, PD must provide opportunities for participants to develop their own practices of inquiry and building on insight. An extensive body of literature on teacher learning identifies developing practices for ongoing inquiry and reflection as the foundation for continuous learning (Grossman et al, 2019; Lampert, 2001; Mason, 2011). This focus on developing practices is particularly important for supporting teachers enacting responsive, equitable, empathetic pedagogies that require ongoing reflection and insight (Lampert, 2010). In this sense, learning-for-teaching refers to a set of diverse, variable, and evolving practices that drive toward continuous learning and improvement. A PD program to learning-for-teaching must therefore be dynamic and responsive, allowing participants the agency to adopt an inquiry stance toward their own teaching and drive the learning process through insight (Cochran-Smith & Lytle, 2009; Mason, 2009).

In this study, we draw on practice theory to investigate how learning-for-teaching can emerge and develop in the context of an insight-driven PD program. Research on teaching has used the term "practice" to refer to replicable and socially recognized routines, e.g. five practices for orchestrating productive discussions (Stein et al, 2008) or high-leverage practices for beginning teaching (Ball & Forzani, 2011). In contrast, Gherardi (2009) cautions against conflating practices with routines, instead defining practice as "a knowledgeable collective action that forges relations and connections among all the resources available and all the constraints present" (p. 117). It is this sense of practice that characterizes learning-for-teaching: teachers apply and develop their knowledge, in collaboration with both colleagues and students, to forge relations and connections in the process of teaching and learning. Gherardi (2009) adds that "acting as a competent practitioner is synonymous with knowing how to connect successfully with the field of practices thus activated" (p. 118). Accordingly, insight-driven PD aims to develop teachers' ability to forge those relations and connections by positioning them as expert practitioners with the agency to develop their own practices of inquiry and insight. By collaborating to explore, co-construct, and engage in learning-for-teaching practices, participants can activate those practices and embed them in their teaching.

Noticing for equity as an instance of learning-for-teaching

To learn how participants in insight-driven PD programs develop and adopt the practices of inquiry that characterize learning-for-teaching, we examine the case of an insight-driven PD focused on developing teacher noticing for equity. Teacher noticing has been identified as a core construct for teaching that prioritizes the practices of inquiry and reflection we associate with learning-for-teaching. Mason (2002, 2009) calls for developing the discipline to notice in order to support teachers' ongoing learning and insight, while Erickson (2011) draws attention to the highly personal and variable character of teacher noticing. Santagata & Guarino (2011) identify developing teachers' noticing as a core area for teacher education, and van Es & Sherin (2021) argue that adopting an inquiry stance is central to teacher noticing because it positions teachers to be curious about learners in the moment. More recent research reveals the role noticing plays for teachers who are seeking to develop more equity-focused classrooms. Specifically, this work recognizes that teachers develop insight into the ways their own personal histories, the histories of learners, and the histories of schooling shape teachers' noticing in classroom interactions (Kalinec-Craig, 2017; Louie, 2017; Mendoza et al., 2021). Given that this fits with our construct of learning-for-teaching, noticing for equity provides an ideal context to examine how relevant practices emerge and come to be adopted.

Methods

Study Context

This study examines a professional development program called **Co**mmunity **A**nd **T**eacher **T**eams Investigate **E**quitable **N**oticing & **D**ispositions, abbreviated as CoATTEND. This three-year program applied a strengths-based lens to developing teacher noticing for equity in mathematics through participatory action research. CoATTEND began with a series of meetings in which participants discussed key concepts, engaged in thought-provoking activities and reflections, and discussed the nature of inequity and its manifestations in local schools. UCI researchers then conducted a series of classroom observations and used video recordings of these

observations to conduct a noticing interview related to each observation. The noticing interview is like a clinical interview (Hunting, 1997), in which the teacher and a researcher came together to watch and discuss key classroom moments. The observations and noticing interviews were interspersed with additional full team meetings to reflect on the process and discuss emerging themes and insights. During the following year, participants stepped into a co-designer role to create a learning experience for a second cohort of teachers based on the insights and practices that had emerged. This design work involved creating lists of essential topics and concepts, planning a progression of workshops, and identifying formative experiences that could engage and support a new cohort of PD participants.

In addition to developing knowledge about noticing for equity, CoATTEND prioritized "provoking and sustaining an expansive transformation process led and owned by the practitioners" (Engeström, 2011, p. 606). In this program, the subject matter *and* the practices of inquiry were negotiated and co-constructed with participants. Participants assumed increasing agency over the shape of the process to develop new concepts that emerged through their activity and built on their insights, needs, and goals. Rather than aiming to control the process and produce predetermined outcomes, we approach this case with a mindset of curiosity. Having provided participants with opportunities for insight-driven learning and improvement, we seek to learn *what they did with them.* What practices did the participants gravitate to and experience as generative? How did those practices support the emergence or articulation of insights, and how did they position those insights to drive improvement?

Participants and data sources

CoATTEND began with a group of four secondary mathematics teachers and three community educators. Because the involvement of community educators differed from that of teacher participants (e.g. community educators did not participate in noticing interviews), this analysis focuses on the experiences of the four secondary math teachers who participated. All four taught in the same public school district and were identified for recruitment by mathematics teacher educators and their district colleagues on the basis of their demonstrated commitment to equitable teaching. Participants are referred to in this paper by the pseudonyms Jose, Susan, Leah, and Kate.

The primary data source for this analysis is a set of reflective interviews that were conducted with each participant after three years of program activities. Each interview was roughly an hour in duration. Interview questions focused on their retrospective impressions of the program, their memories of impactful experiences and interactions, and their understanding of how program activities supported their learning and development. Developing our analysis of the reflective interviews also relied on artifacts produced during co-design activities in the final year of the project. In the process of designing a program for teacher learning based on their collaboration in CoATTEND, participants identified various impactful and generative components of *their* experience and used their insights to develop a plan for a professional development program. These components, represented in the planning artifacts they produced, provide an outline of their learning process from their perspective.

Analytic Approach

Because participant insight and inquiry are at the center of this PD model, the practices of teacher learning in this context emerged during the course of the program. Gherardi notes that "before action takes place, plans serve only a predictive or organizational purpose" (Gherardi, 2009, p. 122). Centering and building from participant insights means the practices and process cannot be entirely under the designers' control; learning through insight comes to life through the actions that take place in participants' activity and interaction (Ball & Cohen, 1999; Kennedy, 2016). Understanding the practices and processes that generate and drive teacher learning therefore requires a phenomenological lens: how did the participants experience the process? How did they understand the practices involved? How did the practices emerge and interact to drive a process of learning? Regarding similar analyses of emerging processes, Coles (2019) advises researchers to begin with the *last* data collected, arguing that "the final piece of data should exhibit the most stable (meta)patterns" (p. 6). By identifying patterns that became stable and recognizable by the *end* of a phase of research, as opposed to looking for the patterns that researchers sought to enact at the start, analysis remains "grounded rather than evaluative…i.e. the pattern is observable in the data and not based on an evaluation of values or virtues" (p. 6). Consequently, we bracket the theories of learning and the design that informed the professional development program at the start and focus instead on participants' retrospective impressions to map the process and practices of learning to notice. In Gherardi's terms, this is an analysis "conducted 'from within', that is, from the point of view of the practitioners and the activity that is being performed, with its temporality and processuality, as well as the emergent and negotiated order of the action being done" (Gherardi, 2009, p. 117). By centering how the practices in this PD emerged, evolved, and interacted over time from the participants' perspective, we aim to represent a process of teacher learning that was driven and shaped by their knowledge, experiences, needs, and insights.

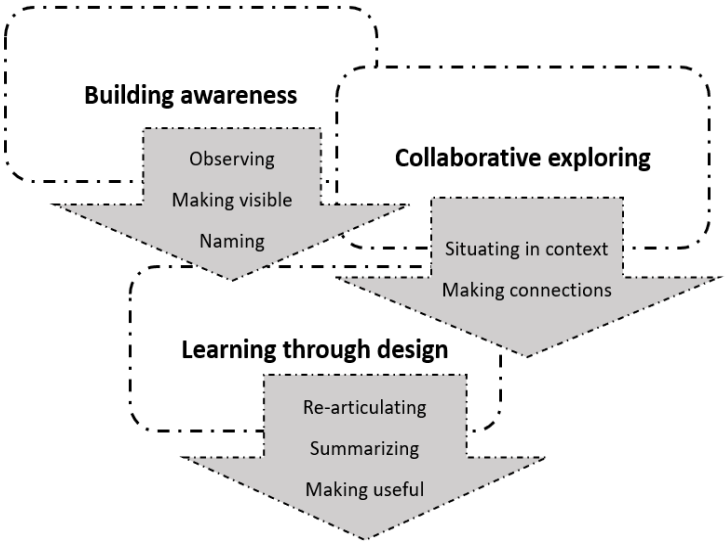
In line with Coles' suggestion, we began with an analysis of reflective interviews to center participants' perspectives on the practices and process that unfolded. We first analyzed these interviews at the word and phrase level with an *in vivo* coding approach (Saldaña, 2011), highlighting terms that participants used to describe essential practices, components, and effects from their experiences in the program. As a primarily inductive technique, *in vivo* coding acts as a "grounding strategy" to develop theory from process data**.** Because we designed the program according to our conjectures about teacher learning, we do not claim this analysis as a fully inductive grounded theory (Charmaz, 2006). Through *in vivo* coding, however, we prioritize induction over deduction and root our claims in empirical data in accord with our research questions; Langley (1999) recommends induction as a means to "explore the interpretations and emotions of different individuals or groups living through the same processes" (p. 700). Our *in vivo* analysis identified over 300 relevant words and phrases, which we reduced to create a set of 54 terms that occurred across the reflective interviews. Based on chronology, patterns, and conceptual links, we organized those terms into categories and used them to produce a visual model of the process that participants described. Langley characterizes visual mapping as an "organizing strategy": it uses the products of the inductive analysis, which grounds the analysis in empirical data, to "descriptively represent process data in a systematic organized form" (Langley, 1999, p. 707). Developing the visual model is therefore both an approach to sensemaking about process data and a way to represent findings.

Findings

Participants' reflections on the CoATTEND PD program indicated three sets of interrelated practices. Although these practices iterated and overlapped throughout the program, participants indicated a sense of sequence that led to representing these practices as phases of activity. These phases lead into each other to drive a process of learning, modeled in Figure 1. Below, we describe each phase of the model and the practices that emerged. Rather than making rigid or deterministic claims about teacher learning, this model is akin to a map of ocean currents - it represents a process in which the elements are in motion and are not strictly separated, but instead intermix and entangle in complex and non-linear ways. At the same time, participants' accounts indicate a sequence and a sense of progress that was consistent across interviews, allowing us to treat the process as a recognizable and reliable pattern of developing activity.

Figure 1

Process model of teacher learning practices in the CoATTEND program



Building awareness

The PD began with a phase of building awareness, in which participants focused on their teaching practices, the contexts of their schools and communities, and the personal and social histories that influence their noticing. Participants voiced an initial impression that the purpose of the program was primarily to observe. Leah described the initial activities as "just always let's look at the interactions, let's look at, you know, and so it was kept really at a level of 'this is what I'm looking at'". By attending to their practice of observing, however, participants came to appreciate the complexity and importance of noticing. To that point, Kate commented that "I thought noticing was simply some kind of just being very, very observant. But I think, as the meetings went on, I realized it was

way more complicated than that and that there was so much more involved with how we see ourselves in the classroom from our historical side and how that changes how we view our students and I think vice versa." In this phase, the group arrived at the insight that observing consists of nuanced practices that must be learned and developed in their own right. Moreover, they found that observing opened up opportunities to engage in deeper practices of reflection and inquiry regarding their teaching.

Engaging in the practice of observation supported a complementary practice of making unconscious aspects of teaching visible. Intentionally observing improved participants' awareness and ability to notice, thereby making unconscious aspects of their teaching and noticing visible to themselves. Kate articulated her sense that observing gave rise to a more complex practices, saying that "I forget all the inner workings of what [teaching] takes because it's just natural now that I don't think about all the little steps to do exactly what I do and I didn't realize I'm multitasking and thinking about kids on so many levels all the time. Which is why I think the noticing took on so many more layers than what I thought it was. It's not just being observant. I think it's more than that." This "layered" dimension of noticing only became visible when participants consciously set their attention to the practice of observing. Leah described the practices of this phase as "bringing new things to light", explaining that "you had done what you did for years and it just became, I guess, internalized. What I think this process did was externalize it, like, bring it out. I think all of us have said, 'Oh, I didn't know I was doing that.'" Likewise, Jose noted that "it was just a little bit of an eye-opener to realize that most teachers are actually doing things that we're looking into, but we don't realize we're doing them. And so that started the process of me thinking about those things." For Jose, making unconscious aspects of teaching visible was the starting point for a larger process of inquiry. Through all these comments, participants emphasized the importance of externalizing unconscious aspects of practice, including habits, assumptions, interpretations, and internalized routines.

That increasing ability to notice, which participants experienced as increasing visibility of the phenomena, also developed in tandem with a practice of naming relevant phenomena and concepts. Lisa commented that "you guys always put into words what I'm thinking but I can't put it into words." Jose described the same naming practice by pointing out that "once everything got integrated and once we got in the know, once we saw what we were doing and we could put labels on everything, everything got laid out in a way that makes sense." This practice of naming enabled participants to refer to their insights clearly, which made it possible to take stock of their progress and made the insights produced through building awareness available as the basis for a new phase of practices. Having names for the concepts and insights that were emerging enabled participants to move forward with exploring their ideas more deeply in the next phase.

Collaborative exploring

The practices of building awareness made the results of observation available for a phase of collaborative exploring; having externalized and named unconscious aspects of teaching allowed for them to be explored, questioned, and connected. In this phase, participants described both deepening and broadening their insights. Susan pointed out that "our activities help to really distill those things out where I had to pinpoint, yeah, this is the moment, or this is the way that I felt." These references to "pinpointing" and "distilling" indicate a practice of focusing in on an observation and refining it to produce a clearer or more detailed conception. At the same time, participants also referred to connecting and contextualizing insights. Susan highlighted these practices by saying that "there's some, like, threads that just all have come together in this project for me of things that were kind of already there, but they're clarified now. It's like everything's coming into focus and now I see how they relate to each other. Whereas before they were just sort of these things that were like floating around out there and they were influencing me, but I talked about them very, as separate entities, not as parts of the whole." In this sense, collaborative exploring involved situating ideas in context and drawing connections that allowed participants to understand their knowledge and practices as a cohesive network.

Across these accounts, participants pointed out that collaboration was a crucial component of the practices in this phase. Kate identified a contrast between collaborating in CoATTEND and the typical collaboration she experienced as a teacher, pointing out that "I don't usually go into other teachers' classrooms and I don't really talk about teaching practices with others like that in that way. I think we talk about, like, 'Oh, where are you in chapter seven?' Or 'How did you do this one thing?' We talk about very simple things to discuss, but nothing this deep." While discussion and collaboration occur in the normal course of teaching, Kate argues that the norms of collaboration in that context do not activate the practices of learning-for-teaching that CoATTEND prioritized. Leah also emphasized the value of collaborative exploring, saying that "I absolutely love having the whole group at the big table and just hearing, and everybody had input and bouncing ideas off each other. I think what we create as a group is big because it's this person's idea and that person, and we come together and create something that obviously you couldn't create alone." This sense that the results of collaborative

exploring were deeper and more expansive than individual reflection could have produced appears in several teachers' reflections.

Learning through design

At this point, the research team and the participants agreed to design a new PD program on the basis of the insights they had developed. This design phase motivated participants to re-articulate and summarize their insights for the sake of making participants' insights useful as the basis of future PD programs. In this phase, participants were motivated to make their insights useful for teacher learning. This sense of purpose was ostensibly aimed at supporting other teachers, but designing also rendered participants' own understanding in more concrete and actionable forms by pushing them to situate their insights back in the context of teaching. Kate described this phase as "trying to create a new language [and] putting what we're doing into a practice that is digestible for people.", adding that "it felt more practical and it was easier for me to see what we're doing based on how are we going to show this to someone else." By working to frame and express their insights in terms that appeal to other teachers, participants returned to an examination of teaching in context and strengthened the connections between their insights and their teaching.

The practice of summarizing helped participants articulate the purposes and the outcomes of the program. Leah described the design phase as "just this big summary of what we'd been through" and emphasized the value of the summarizing practice: "it's a big confidence thing because I don't know, you know, you're thinking 'am I good enough to help with that, did I have enough experience?' But it was neat to see the different things we had done, and then I could kind of join with 'okay, that's, I'm good with that, and I'm not so good with that.'" The practice of summarizing enabled Leah to take stock of her own developing knowledge, leading to increased confidence in the knowledge she had built and a sense for areas of growth that deserved further attention. Susan expressed a similar sense that the concrete character of designing was beneficial, saying that "once we had some headings, then things really started to hum, clicking happened. It wasn't that we were disagreeing before, it was just this like, well, there wasn't a clear goal. So there was a whole lot of talking, which wasn't bad because it deepened our understanding of other things, but this process has felt fun because we see an outcome." Ambiguity regarding the goals and process of the work was a consequence of allowing room for teacher agency. Because the outcomes and practices were not predetermined, participants had to navigate through the uncertainty of building on their own insights without a "clear" goal. While that aspect of the process was valuable and necessary, participants found that these practices of articulating and summarizing the insights they had explored enabled them to make sense of the progress they had made. Susan summed up her impressions with the comment, "I think all of that stuff was really, really important to getting to this place, but now being able to put all of those things together feels good."

Discussion

This analysis reveals the messy process of insight-driven teacher learning, as well as the practices this process entailed. We contend that the dynamic, open character of the process positioned participants to develop new insights, grounded in their knowledge and experience of their teaching contexts, and use them as the basis for improving their practices of learning-for-teaching. In short, we see participants developing the practices of learning-for-teaching by engaging in those same practices of inquiry and reflection in the context of the PD.

Prior research demonstrates the importance of developing these learning-for-teaching practices (Cochran-Smith & Lytle, 2009; Lampert, 2010; Mason, 2009). Moreover, the personal, contextual, and ambiguous dimension of learning-for-teaching practices is central to their enactment (Kalinec-Craig, 2017; Louie, 2017; Mendoza et al, 2021). Because this approach to teacher learning emphasizes practices that build on participant insights instead of focusing on predetermined content, we hold insight-driven PD models are especially suited to responsive needs of developing learning-for-teaching. By centering this PD on the practices and processes of inquiry in addition to the content addressed, teachers were positioned to engage in the generative process of building on the insights they developed based on their own understanding and experiences. This characteristic makes insight-driven PD responsive to teachers' learning trajectories, thereby supporting the development of their learning-for-teaching practices through a different process than would be afforded by one-size-fits-all content (Kennedy, 2016). While many of the patterns we describe here align with the theories and conjectures that informed the design of the program, some aspects stood out as unexpected, participant-directed elements. For instance, the noticing interviews were initially conceived as an instrument for data collection, but participants found them to be impactful for their own learning and development. Consequently, we reconceptualized the noticing interview as a central learning activity in the PD and are planning to include it as a pedagogical structure in future PD and teacher preparation programs. Moving into the third stage, learning through design, was similarly participant-directed. The original plan involved the participants collaborating with researchers on data analysis in

a more typical "academic" fashion. Upon reaching that point, however, participants voiced a strong desire to design PD for pre-service and early career teachers and had comparatively little interest in data analysis or academic writing. As a result, the research team chose to follow participants' energy and pursue the design phase as a set of practices that the *participants* expected to be generative. These changes in emphasis and direction on the basis of participants' engagement highlight the opportunities for reciprocal learning afforded by an adaptive, insight-based approach to professional development.

As an effort to map a fluid and dynamic process of learning, the process model we provide appears more static and straightforward than the network of practices it represents; recall the comparison above to a map of ocean currents. Consistent with the processual lens of our analysis, our model represents the evolving practices of the PD in phases to render the *patterns* and *trajectories* of participants' activity visible (Gherardi, 2009; Langley, 1999). The challenge in applying this model, therefore, is to design with the "current" of insight-driven learning in mind without forcing participants to follow a particular course. Our findings suggest that beginning with building awareness, providing opportunities for multiple forms of collaboration, and applying insights through co-design work can together encourage practices of inquiry that at the same time prioritize participants' insights and preserve their agency. We recognize, however, the limitations of investigating this process on the basis of a single case. Future work could improve and complicate our understanding of insight-driven PD by modeling the emergence of practices in additional cases and contexts of teacher learning (Langley, 1999; Saldaña, 2011). With a clearer picture of designing for and facilitating the process of insight-driven learning, PD stands to support teachers in cultivating a deep, personal, and lasting orientation to reflective, responsive, and equitable teaching practices.

Introducing Authentic Datasets into the Biology Classroom: Teachers' Considerations when Designing Digital Instruction Units

Carmel Bar, Bat-Shahar Dorfman, Anat Yarden

Weizmann Institute of Science, Israel

Abstract: Introducing datasets into the science classroom may facilitate developing scientific practices and epistemic thinking. However, authentic datasets are rarely used in high school, and little is known about biology teachers' knowledge considerations regarding dataset-driven instruction. Here we investigated these knowledge considerations in high-school biology teachers. Forty teachers designed dataset-driven instruction units and completed open-ended questionnaires during a professional development workshop. Our analysis, based on the PISA framework of scientific literacy, indicated that although epistemic considerations were the most prominent of teachers' perceived benefits of dataset-driven instruction, they were less pronounced than content and procedural considerations in the instruction units that they designed. This suggests that although teachers recognize the value of epistemic thinking and see authentic datasets as a means to facilitate scientific literacy, further effort is needed to assist teachers in designing instruction units which better reflect these goals.

Introduction

Biology as a discipline has a long history of engaging with large datasets (Leonelli, 2014). Using authentic datasets in the science classroom enables students and teachers to engage in, and assist in developing scientific practices (Kjelvik & Schultheis, 2019; Wyner, 2013). However, most current use of data in the biology classroom is highly simplified, as authentic datasets are messy and complicated. Indeed, selection and curation of datasets require expertise and application of domain knowledge (Duncan et al., 2018). This notable gap between biology as a data-based science and high-school biology could be mediated by the biology teacher. However, little is known about teachers' perceptions of the challenges and benefits of data-driven instruction, or their design considerations, in general and in biology in particular. Therefore, we examined the knowledge considerations expressed in biology teachers' views of data-driven instruction, and in the goals that they set when designing data-driven activities tailored to their students. Our research focuses on teachers' epistemic considerations in using and designing data-driven instruction, and offers insights that can be further used to design better learning materials, teachers' professional development (PD) programs and teacher education. This may be a step toward promoting the use of authentic datasets in the high-school biology classroom, thus contributing to students' scientific data literacy.

Theoretical framework

Promoting scientific data literacy by using authentic data and the teacher's role

To gain scientific literacy, one should understand not only basic scientific information, but also the process by which science is carried out, and its epistemic backbone (NRC, 2012). Here we followed the OECD PISA framework (OECD, 2019), which defines scientific literacy as the ability to participate in science-related issues. This framework defines three components of scientific literacy: (a) content knowledge – knowledge of the theoretical concepts and ideas of the discipline; (b) procedural knowledge – knowledge of the standard procedures that underlie the methods and practices used to establish scientific knowledge; and (c) epistemic knowledge – understanding the rationale of scientific inquiry, and how scientific knowledge is derived; and the degree to which such knowledge is justified by evidence or theoretical explanations. The competency-based perspective described in the PISA framework also recognizes an affective element in the student's display of these competencies (OECD, 2019).

The recent strategic vision proposal for the PISA 2024 framework anchors the importance of data literacy, and states that understanding global challenges, such as pandemics, requires evaluating statistical data and probabilistic thinking (OECD, 2020). Data literacy can be developed by asking students to use authentic datasets, establish and justify interpretations, and consider potential sources of error, such as limited data (Osborne, 2014). Use of authentic datasets in the science classroom provides a broader range of science practices in which students and teachers can engage, and assists in developing these competencies (Kjelvik & Schultheis, 2019; Wyner, 2013), while applying biological knowledge (Yarden & Levkovich, 2021, p. 72). Although datasets do not permit the full scope of scientific inquiry, because students do not collect the data first-hand, datasets can provide a rich,

 © ISLS

multifaceted set of information that requires highly complex reasoning (Chinn & Malhotra, 2002), various research questions, and data-analysis approaches (Wyner, 2013). To support data literacy among students, teachers must first be aware of its importance, gain familiarity with data-rich environments and be able to mediate these practices to their students. Previous research has shown that curriculum materials alone, without teacher-mediated norms that enable scientific sense-making and epistemic talk, are not sufficient to promote students' understanding of scientific knowledge (e.g., Berland et al., 2016). Thus, effectively teaching scientific reasoning requires holding a body of epistemic knowledge (Kind & Osborne, 2017) and applying epistemic considerations (Ke & Schwarz, 2019). When designing data-rich activities for their students, teachers use a variety of goals and considerations. Understanding teachers' considerations in general, and epistemic considerations in particular, is important because they shed light on what teachers notice, value, and see as important for students to learn (Ariely et al., 2021). Therefore, here we focus on teachers' epistemic considerations regarding the use and design of data-driven activities for their students.

Science teachers' PD

Implementing instructional approaches that involve authentic scientific practices and technologies requires first introducing them to the teachers. Providing teachers with opportunities to experience the technology first-hand, to observe its pedagogical benefits and gain an awareness of its associated challenges may affect their approach to applying the technology in their classroom (Dorfman et al., 2019; Mishra et al., 2019). Referring specifically to working with authentic data, research has shown that following PD courses, teachers changed their views toward using authentic data and toward the way they use data in their classes. For example, following a PD course which included the implementation of a data-rich ecology curriculum, ninth-grade biology teachers were more positively disposed to including authentic scientific data in their lesson plans (Wyner, 2013). Another recent study showed that at the end of a PD course, teachers were able to integrate computational thinking into their teaching, emphasizing the important role of teachers as co-designers of activities for their students (Wu et al., 2020).

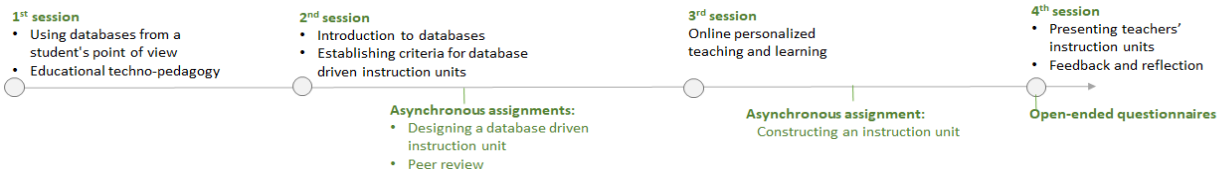
PD courses in which teachers design and adapt instructional units can support different modes of use by the teachers, while meeting their instructional goals and their students' needs (Brown, 2011). Supporting teachers' design process in the form of co-design can enhance teacher understanding of the technology being used, foster professional growth and improve outcomes in the classroom (Peel et al., 2020). Even in the context of integrating advanced educational technology, co-design processes that involve teachers have been shown to be a useful approach to designing solutions that address teachers' needs, and to gaining the teachers' trust (Holstein et al., 2019).

The context of the study

Description of PD workshop

In light of the above, a PD workshop was designed to help high-school biology teachers incorporate authentic digital datasets into their instruction, and to identify their knowledge considerations toward using datasets and while designing digital instruction units. We followed the Eylon and Bagno (2006) three-stage model of teachers' PD. In the first stage—*teachers as learners*, they experience data-driven instruction units as students. In the second stage—*teachers as curriculum developers*, they design an instruction unit based on their own pedagogical expertise, consultations with experts and critique by their peers. In the third stage—*reflection*, teachers report on their designed units and reflect on their design process (Eylon & Bagno, 2006). Similarly, in the current workshop, teachers first experienced an online data-driven activity as students. Then they were presented with authentic taxonomy datasets. Based on those datasets, while relying on their pedagogical expertise, the teachers developed different instruction units. Following the workshop, teachers' views and considerations of data-driven instruction were assessed through an open-ended questionnaire and their written instruction units (Figure 1). The workshop was designed and taught by the researchers and took place during the summer break (July–August 2020), in the context of the activities carried out by the National Center for High-School Biology Teachers in Israel. Due to the restrictions following the COVID-19 outbreak, the PD workshop was designed and carried out as a 30-hour online workshop, using the Personalized Teaching and Learning (PeTeL) platform. As a result, the rate of registration and participation was higher than expected (n = 52), and participants included teachers who do not usually participate in the face-to-face activities of the National Center for High-School Biology Teachers in Israel due to distance and time considerations. In addition, the COVID-19 restrictions created a need for teachers to access online activities for their students, which may also have contributed to the relatively high number of participants (Sun et al., 2020).

Figure 1
Professional development timeline



The datasets used in the activities

The teachers were presented with several authentic taxonomic datasets of various species that were curated in natural history museums, with different contents and volumes. The following datasets were available to the teachers: (a) mammal dataset (16,139 cases over 17 measurements); (b) gazelle dataset (1,175 cases over 14 measurements)—this was a subset of the bigger mammalian dataset; (c) bird dataset (5,653 cases over 19 measurements), and (d) brown bear dataset (1,339 cases over 13 measurements).

The first three datasets (a–c) were constructed in collaboration with the Steinhardt Museum of Natural History (https://smnh.tau.ac.il/en/); the fourth dataset (d) was based on the Arctos museum collectors' database (https://arctos.database.museum/home.cfm). All datasets were cleaned to remove duplicates and irrelevant data, and formats and units were standardized. Variability and biological outliers were maintained. Each dataset included variables such as weight, body length, and time of collection. The datasets were introduced to the teachers using the Common Online Data Analysis Platform – CODAP (Finzer, 2016). In addition, the teachers were told that they could use other public or personal datasets. However, 85% of the teachers who completed all of the assignments (n = 34/40) chose to use one of the four ready-made datasets (or subsets of those datasets) for their instruction units.

Research questions

Teachers have a key role in promoting data literacy and epistemic thinking in the biology classroom. Since little is known about high-school biology teachers' views regarding dataset-driven instruction, we sought to answer the following research questions: (1) How are high-school biology teachers' knowledge considerations expressed in their perceptions of the challenges and benefits of using authentic datasets in their classroom? (2) How are knowledge considerations in general, and epistemic considerations in particular, expressed in teachers' data-driven instruction units?

Methods

Participants

Participants were high-school biology teachers in the above-described PD workshop focusing on dataset-driven instruction. Of the 52 teachers who started the workshop, 40 completed all of the assignments. Herein, we present the findings based on those 40 teachers. All of the teachers teach biology in high schools across Israel, and have teaching experience ranging from 1–44 years (avg 13.7 ± 9). Only eight teachers had previous experience working or teaching with datasets. The teachers voluntarily chose to participate in the PD workshop and in the accompanying research.

Data collection and analysis

Teachers' views and considerations regarding the use of authentic datasets in the classroom were assessed by:

a) An open-ended questionnaire, which asked the teachers to "describe the challenges and benefits of dataset-driven instruction (i) for you as a teacher and (ii) for your students." The questionnaires were voluntarily filled at the closing session on the last day of the workshop. Each participant wrote freely, with a total of 66 benefits and 58 challenges.

b) Written instruction units: during the workshop, the teachers designed dataset-driven digital instruction units, and documented their design considerations. Due to space limitations, in the current paper we focus on the design considerations expressed in their teaching goals (a total of 140 considerations).

The data from the questionnaires and instruction units were analyzed according to the PISA framework (2019). In addition to these predetermined categories, we identified subcategories using the deductive–inductive procedure approach (Srnka & Koeszegi, 2007). Two science-education researchers independently analyzed the

data, and the categorization was discussed until an acceptance rate of 100% between researchers was reached. Pearson's chi-square test was performed to assess whether the distribution of the teachers' perceived benefits and design considerations were consistent. A case study was chosen from the instruction units. A comprehensive analysis of that case study is beyond the scope of the current paper and therefore, it is presented here only to demonstrate the translation of epistemic considerations into an instructional sequence. To provide a rich illustration, we chose the instruction units with the most detailed epistemic considerations.

Results

The challenges of using authentic datasets in the biology classroom

In the open-ended questionnaire, teachers related to different challenges of data-driven instruction, with a total of 58 references. The knowledge considerations expressed in their answers are summarized in Table 1, in the order of their appearance in the PISA framework (OECD, 2019). Teachers' responses included considerations along the four dimensions: teaching content, procedural knowledge, epistemic knowledge, and affective aspects (coherent with the PISA framework—OECD, 2019). Eight teachers related to conflicts between teaching the required *content* knowledge and teaching with datasets, as the latter is often time-consuming. Some mentioned that contemplating the datasets may distract the students from the content knowledge. Most of the answers (n = 28/58, 48%) related to *procedural* challenges. They referred to difficulties derived from working with technology, which are not specific to working with datasets (n = 11, 19%), such as getting used to a new platform, user interface of the website, remembering a new password, etc. The rest of the procedural considerations (n = 17, 29%) related to data-driven instruction, such as the size of the databases potentially hindering students' orientation or operation throughout the activity. Some teachers stated the need for a lot of preparation work on their part, i.e., finding a quality dataset, editing, and cleaning it for their students.

Ten teachers (17%) related to the *epistemic* challenges of dataset-driven instruction, such as its "messy" nature, and questioned the reliability of authentic data, as well as of detaching the database from the way in which the data were collected, making the data meaningless for the students. Finally, twelve teachers also stated the affective influences of the large datasets, as being intimidating and/or frustrating, and potentially hindering students' approaching or completing their tasks (Table 1).

Table 1

Teachers' knowledge considerations expressed in the challenges of using dataset-driven instruction

Knowledge considerations	Challenges	Examples and number of references	
Content knowledge	Data-driven instruction conflicts with the curriculum	"Not part of the curriculum" "The main disadvantage is the time that such an activity takes, and which in the meantime can divert attention from the logical sequence of content teaching"	8
Procedural knowledge	Challenges specific to data-driven instruction (e.g., orientation difficulties, need for adaptations)	"The databases are too overloaded with data. They sometimes need adaptations to be made accessible to students"	17
	General technological challenges (e.g., the website, the platform, the user interface)	"The work on the website is not simple" "Students will have difficulty using the dataset because the environment is new, it will take them time to get used to it"	11
Epistemic knowledge	Messy and unreliable data	"The dataset is not 'clean' and sometimes includes incorrect or inaccurate information. There is educational value in seeing that in science, there are sometimes strange results, but from a teaching point of view, it also creates challenges"	10
Affect and engagement	Dataset sizes may be intimidating	"At first it can seem scary and intimidating" "The students will see the large dataset and will despair, without trying to use it"	12

The benefits of using authentic datasets in the biology classroom

In the open-ended questionnaire, teachers related to different benefits of data-driven instruction, with a total of 66 responses. The knowledge considerations expressed in their answers are summarized in Table 2, in the order of

their appearance in the PISA framework (OECD, 2019). Teachers' responses included considerations along the four dimensions: teaching content, procedural knowledge, epistemic knowledge, and affective aspects (coherent with the PISA framework—OECD, 2019). Nine answers (14%) related to the benefits of using datasets for teaching and learning *content* knowledge, to authentically exemplify phenomena instead of teaching them in theory. Seventeen teachers (26%) addressed *procedural* knowledge and stated that datasets can enable the development and practice of inquiry skills, such as constructing graphs and other means of data visualization. It can allow students to explore first-hand the connection between variables, and distinguish between correlation and causality. The most popular answer (n = 24/66, 36%, Table 2) referred to the advantage of using datasets for teaching *epistemic* knowledge. The teachers wrote that using authentic datasets provides an opportunity to expose their students to an authentic scientific practice as it is done in the real world. The encounter with authentic data evokes critical thinking (for example, regarding inconsistent results) and enables discussions about the nature of science. Furthermore, the teachers stated that using datasets in the classroom can improve students' interest and curiosity and contribute to diverse teaching methods (n = 16/66, 24%).

Table 2
Teachers' knowledge considerations expressed in the benefits of using dataset-driven instruction

Knowledge considerations	Benefits	Examples and number of references	
Content knowledge	Enables learning biological content knowledge	"A lot of information can be extracted and taught based on datasets" "Gives a lot of knowledge...allows thinking about various factors"	9
Procedural knowledge	Enables developing and practicing inquiry skills	"Students learn to build graphs themselves, and experience the difference between dependent and independent variables, etc."	17
Epistemic knowledge	Using authentic data	"The most important benefit is exposure to how research is really done, where the graphs are imperfect and require critical thinking"	9
	Nature of science	"Opportunity to discuss views based on data from different periods"	7
	Higher-order thinking	"Teaches critical thinking"	8
Affect and engagement	Affective aspects – interest and curiosity	"It's really interesting"	8
	Diverse teaching methods	"A new learning environment that is different from what the students are used to"	8

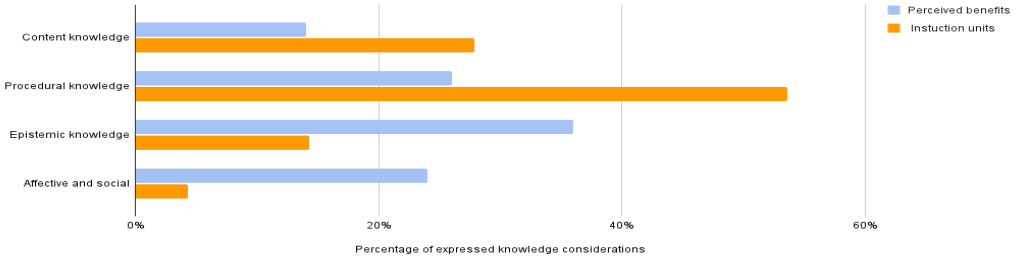
Teachers' knowledge considerations expressed in their instruction units

To answer the second research question, how knowledge considerations in general, and epistemic considerations in particular, are expressed in teachers' data-driven instruction units, we analyzed the instruction units according to the PISA framework (OECD, 2019). In the current paper, we focus on the considerations expressed in their stated teaching goals. Out of a total of 140 considerations, 31 focused on biological *content* knowledge, such as "The students will learn about the characteristics and risks of radon gas." The majority focused on *procedural* knowledge (n = 75/140). The teachers' aim was for their students to "identify the scientific inquiry components" or "identify measurements that deviate from the trend of most of the data and will explain the anomalies and how to analyze general trends despite the anomalous examples." *Epistemic* considerations (n = 20/140) included references such as "the students will gain knowledge regarding science and scientific research: critical thinking, research planning, problem definition and using suitable graphs" or "Students will recognize and understand the issue of dataset reliability." All but one of the teachers who highlighted epistemic design considerations also addressed procedural knowledge. Only six design considerations took into account affect and engagement aspects ("Creating a 'sense of discovery' of ecological rules," "Emphasize the individual's commitment to the population in following the rules"). To further investigate how knowledge considerations are expressed in teachers' data-driven instruction units (research question 2), we explored the extent to which the knowledge considerations stated

by teachers as benefits of data-driven instruction were manifested in their units. Although all knowledge components were expressed as considerations in both the perceived benefits and the instruction units, there was a significant difference ($p < .001$) between the distribution of those knowledge considerations in each case. Pearson chi-square test revealed a significant difference between knowledge considerations in teachers' perceived benefits and instruction units ($X^2(4, n = 206) = 38.63, p < .001$). Figure 2 illustrates 40 teachers' general considerations (blue) and their actual designing considerations (orange) as expressed in the dataset-driven instruction units. When generally discussing data-driven instruction, the most prominent consideration was epistemic knowledge (36% of considerations, Figure 2). However, when designing units in practice, 54% of the considerations related to procedural knowledge, 28% to content knowledge, and epistemic considerations dropped to 14%.

Figure 2

Knowledge considerations expressed in teachers' instruction units (n = 140) and perceived benefits (n = 66)



The case of teacher AS: students as inquirers

The following case study was chosen to depict teachers' epistemic considerations when designing data-driven instruction units in biology (italics have been added to emphasize epistemic considerations). Teacher AS has 20 years of teaching experience. She teaches biology in a Jewish religious school in the central part of Israel. Her instructional unit made use of the brown bear dataset, aimed at students' "acquaintance with the term dataset; *understanding that in order to understand and evaluate the data*, a way must be found to categorize the vast amount of data in the dataset; and carrying out a data-driven investigation – from 'dry' data we can draw conclusions and *support or refute our assumptions*" (AS written instruction unit). Note that content knowledge, although popular among other participants, was not one of her explicit goals. Her unit starts by showing a video of bears, and then the bear dataset is introduced to students accompanied by a series of questions aimed at "familiarizing the students with the dataset and the *investigation possibilities on the one hand, and its limitations on the other*." She asks her students "*What questions arise around the dataset? Which information is lacking?*" The activity includes questions referring to the *data source and data collection*, taking into account ethical considerations, "to evoke curiosity, thinking and interest...Were the data collected from bears that were hunted and killed? Or captured, fitted with a transmitter and re-released?" AS proposes scaffolding for her students and her instruction unit includes an in-class demonstration of visualizations and written instructions for independent work. In the last part of the instruction unit, the *students choose their own research question*, define variables, create graphs and draw conclusions. AS states that "*there is an immense amount of data and the students as inquirers should decide what is relevant and right for them.*" The AS case study demonstrates how this teacher's instruction unit highlights epistemic thinking through authentic dataset inquiry, from thinking about the way in which the data were obtained, to considering the dataset's limitations and merits.

Discussion and implications

In this study, we provide an analysis of knowledge considerations expressed in biology teachers' perceptions of the challenges and benefits of dataset-driven instruction, as well as of their considerations when deciding on their design of a dataset-driven instruction unit. The conclusions of this study leverage the PISA framework for scientific literacy, and further refine it by identifying subcategories, in the context of scientific data literacy. Our conclusions have implications for the use of datasets for biology teaching and for science teacher education, particularly as science teachers face the challenge of engaging in debates around the epistemic nature of science, for which dataset instruction can serve as one of many possible instructional strategies.

Our analysis shows that although some teachers perceived dataset-driven instruction as a possible way of teaching content knowledge, content considerations were the least pronounced of the knowledge components when they considered the benefits and challenges of dataset-driven instruction. This may be because the teachers perceive dataset-driven instruction as conflicting with the curriculum. Indeed, it has been shown that when designing non-mandatory curriculum instruction units, most science teachers' decisions are related to contextual

factors, such as work overload (Kaplan Mintz et al., 2021). However, when designing their instruction units, content considerations were expressed significantly more often in the teachers' goals. The teachers found ways to connect the databases to the curriculum, possibly minimizing the aforementioned conflict.

Procedural considerations made up a major fraction of the perceived benefits and challenges. Teachers often related to dataset-driven instruction as beneficial for teaching and practicing scientific practices and inquiry (both guided and open), which are a part of the mandatory Israeli biology curriculum. Perhaps that contributed to procedural considerations being the most pronounced component in the instruction units, considering the influence of their connection to the curriculum on teachers' practice (Kaplan Mintz et al., 2021). Chinn and Malhotra (2002) stated that database tasks have the potential to simulate most features of authentic reasoning in the context of interpreting existing data. They studied database-driven activities in which students conducted investigations using a database containing information about dozens of birds (Reiser et al., 2001). However, they concluded that those database tasks do not allow students to design and carry out their own studies and do not permit new investigations. Our results indicated that our much larger datasets (thousands of cases) may allow teachers to prompt their students to ask novel research questions, and seek answers in the dataset. As teacher AS explained, the volume of the data enables the students to become "inquirers, [who] should decide what is relevant and right for them." The procedural challenges were both dataset-specific and related to technology in general, and were attributed similarly to students and teachers. The teachers addressed these in their instruction units, providing scaffolds and leading their students step by step through the datasets, as demonstrated in the case study.

As for epistemic considerations, the most popular benefit of authentic dataset-driven instruction referred to the opportunity afforded to teach epistemic knowledge, exposing students "to how research is really done, when the graphs are imperfect and require critical thinking." The epistemic considerations were also demonstrated through the case study. Teachers' epistemic considerations while designing dataset-driven instruction indicated that they: (a) recognize the value of epistemic thinking for students' scientific literacy and (b) see authentic datasets as means of teaching epistemic thinking.

However, in the instruction units, the fraction of epistemic considerations decreased significantly, becoming the least pronounced amongst the knowledge components. One possible explanation for this gap is that epistemic knowledge (although declared as important) is not expressed in practice, in the biology curriculum. As discussed above, the curriculum affects teachers' practices. Another possible explanation lies in the challenges. As teachers noted, there are epistemic-related challenges in dataset-driven instruction, such as explaining the messy nature and reliability of the data, and data-collection procedures (which are not always available to teachers). Overcoming these challenges is even harder when procedural-related challenges are still very pronounced, as our analysis revealed. Research has suggested that there is a hierarchy for the use of knowledge components during learning, according to which procedural knowledge is needed to promote epistemic knowledge (Levkovich & Yarden, 2021). Therefore, it is possible that because the teachers are new to dataset-driven instruction, they still struggle with the procedural knowledge involved in engaging with datasets; although they did see authentic datasets as a means of teaching epistemic thinking, they are still limited in their ability to incorporate these ideas into practice. The gap between teachers' knowledge considerations in the perceived benefits and in the units they designed is not surprising. Research has shown the difficulty in inducing in-service teachers to change, and in their translating new approaches and ideas into practice (reviewed in Luft & Hewson, 2014). The PD workshop presented here was only 30 hours long, and although the participating teachers already deemed dataset instruction as valuable (as they chose to participate in the workshop), it could only have a limited effect on teacher change. Nevertheless, increasing instructors' access to high-quality, data-intensive resources, alongside the necessary training to effectively implement them, might increase the use of authentic data in the science classroom (Kjelvik & Schultheis, 2019). Further effort is needed to assist teachers in designing instruction units that better represent these goals. For example, future PD courses might explicitly discuss the way epistemic knowledge and considerations can be expressed in dataset-driven instruction.

Abstract: Classroom-based assessment is essential to good teaching and learning. Nevertheless, pre-service and in-service teacher's assessment professional development (PD) has been slow to change and the research supporting good assessment PD is still nascent. In this paper, we report the investigation of a relatively new approach to assessment PD, a game-based intervention, *MetaRubric*, a game designed to provide teachers with a playful experience that supports critical examination of rubrics, including their design and use. Games - and in particular practice space games - have been suggested to be potentially useful for teacher professional development, however little has been written about their design, practical application to teacher professional development, especially in the context of assessment, or mechanisms of action. The data presented here provide preliminary empirical support for and detail the design of one such intervention.

Rubrics for Improving Teacher Assessment Literacy

Teacher's assessment practices are widely acknowledged to be an important influence on student learning. Black and Wiliam (1998), for example, in their widely circulated meta-analysis, reported that classroom assessment can improve student performance on large-scale assessments with effect sizes between 0.4 and 0.7, which are "amongst the largest ever reported for educational interventions" (p.61). Despite its importance in education, assessment has a decades-long history of being a challenging area of teacher preparation (Pastore & Andrade, 2019). In the early 1990s, top education associations in the U.S. collaborated to publish the Standards for Teacher Competence in the Educational Assessment of Students (American Federation of Teachers et al., 1990). A decade after the Standards publication, assessment continued to be a critical issue, with authors citing "unacceptably low levels of assessment literacy among practicing teachers and administrators in our schools" (Stiggins, 1991) and surveys suggesting that pre-service and in-service teachers held inadequate levels of assessment literacy across the same period (Campbell et al., 2002; Plake, 1993). Despite the longstanding support of classroom assessment for improving learning, professional development programs have not significantly improved in preparing teachers to practice in-class assessment (DeLuca et al., 2016).

Rubrics, or scoring tools typically presented as a matrix split into levels that describe expectations for an assignment's evaluation, are one type of in-class assessment tool that may be useful for addressing this need; they are a tool that is both effective and that can be reasonably introduced through typical teacher professional development. Research supporting classroom-based rubric use has grown massively over the past two decades - from 100 papers in 1997 to 1000 in 2005, to 5000 in 2013 (Dawson, 2015) - making a review of rubrics literature beyond the scope of this paper. Two points are worth noting from other reviews of the literature, however. First, empirical evidence supporting the benefits of rubric use has grown while evidence showing negative effects of their use is not supported (Brookhart & Chen, 2015; Dawson, 2015; Jonsson & Svingby, 2007; Panadero & Jonsson, 2013, 2020). Such studies have shown that rubrics can be useful in assessing higher order cognitive skills, performance skills and complex skills (Arter & Chappuis, 2006; Mertler, 2004), in supporting student self- and peer-assessment, and for communicating with learners how they can improve their work (Andrade, 2005). In addition to improving assessment and learning, rubrics are used by teachers to communicate expectations for an assignment, provide focused feedback on works in progress, and grade final products (Andrade, 1997, 2000; Popham, 1997).

Second, because effective rubric design and use is a professional, on-going process, training for both students and teachers is recommended (Brookhart & Chen, 2015; Reddy & Andrade, 2010). Rubrics by themselves are not entirely self-explanatory (e.g. Andrade, 2005) and require interpretation by the students in order to be used effectively, particularly with open-ended authentic tasks. Additionally, while there is strong evidence that rubrics can be used as a regulatory device that ensures consistency, rubrics alone do not necessarily lead to better assessment validity (Jonsson & Svingby, 2007). Thus, how a rubric is designed and used matters, and to be effective, professional development programs may need to help teachers shift rubrics away from a focus on products or content and toward what rubrics do best - make expectations and criteria explicit (Jonsson & Svingby, 2007). This paper and project focused on this latter point of professional

 © ISLS

development. Specifically, it explored the design and use of a game intended to improve how teachers thought about and used rubrics in their classrooms. Based on teachers' use of the game, *MetaRubric*, we suggest that one way to create games for teacher professional development is to create artifacts that support 1) in-game, playful opportunities for players to connect prior professional experience and knowledge with local practices, problems, and solutions, and that 2) encourage opportunities for reflection and sharing amongst their colleagues.

Games for Teacher Professional Development

Games have been seen as a useful means of professional development (PD) in diverse domains, such as architecture (Agapiou, 2006), engineering (Baker et al., 2005; Deshpande & Huang, 2011), construction management (Pariafsai, 2016), entrepreneurship (Kriz & Auchter, 2016), nursing (Tan et al., 2017), medical surgery (Sabri et al., 2010), and journalism (Hatfield & Shaffer, 2006). However, game-based learning applications are still nascent for teacher PD (Pozzi et al., 2016). More attention devoted toward teacher professional development for effective game use (e.g., Annetta & Shapiro, 2019; Foster & Shah, 2020; Stieler-Hunt & Jones, 2019) than toward using games as tools for teacher professional development (Meredith, 2016; though see Markauskaite & Goodyear, 2017; Vrasidas & Solomou, 2013). This new field of games for teacher professional development has only recently begun to organize and theorize how such games should be designed, how their designs tend to lead to particular learning outcomes, and how such games should best be used.

Given the variety of contexts and learning goals of teacher professional development, an educational PD game's design could vary widely, making it paramount at the outset to be clear about the game's intended effects, its relationship to other aspects of PD, and theorized mechanisms for learning (Gaydos, 2015). For example, a teacher PD game may be designed to provide a context in which players may develop an improved understanding of subject matter content (e.g., statistics; Dayal & Sharma, 2020) or more directly to help players understand and practice particular ways of *knowing* and *being* that are based on teacher professional standards and practices (e.g. lesson design; Markauskaite & Goodyear, 2017). In this paper, we detail the game *MetaRubric's* design and intended learning goals, present data from its use, and then situate our findings and the game in the context of epistemic games in order to theorize the role of games in teacher PD.

MetaRubric, a Teacher Professional Development Game-Based Activity

MetaRubric is a card game-based activity designed to be played by groups of 3 - 5 players in education professional development settings. The game consists of a set of numbered cards, each containing instructions for the players to follow. To play *MetaRubric,* one player flips through the deck of cards, reading aloud the instructions on each card for all of the players to complete. Cards are flipped over and read until the deck is complete. The game is divided into two rounds. Cards #1-12 are around 1, and cards #13-20 are round two. There is a recommended break in between the rounds, which are expected to take about one hour each. During the first round, players are instructed to create a movie poster based on a film all players are familiar with, create a rubric to evaluate that poster, and then evaluate one another's' posters using the rubric. During the second phase, players are instructed to create a rubric to evaluate the rubrics that they created during the first phase - a "*meta-rubric*". The players then evaluate each other's rubrics using the *meta-rubric.*

The broad aim of the activity is to provide players with a playful, creative experience that they can evaluate with a rubric and a *meta-rubric* that they use to evaluate the rubric they just created. In this completing the *meta-rubric* creation process, the hope is that participants will reflect on the advantages and disadvantages of rubrics, especially for open-ended, creative activities like the one they just completed. The activity is creative and game-like (e.g., it includes scoring) though it may not be a "game" per se, as it does not tend to support typical game activities. For example, the design relies on the emotional affordances that are provoked by the purposeful ordering of activities –the movie poster is deliberately created before the rubric used to evaluate it. Re-doing the activity or doing the events out of order would presumably provoke different reflections from the players, making *MetaRubric's* re-playability more like narrative-based games that are typically played only once, and less like games that support strategizing and replayability. Given the familial nature of games and difficulty in clearly defined borders (e.g., Gee, 2011)

MetaRubric's design sought to integrate design principles from previous research on teacher professional development. In particular, three design principles that were primary in this work were:

1) Teacher professional learning as social - Research on teacher professional development has demonstrated the value of teachers learning from each other as they take on new instructional reforms (e.g. Grossman, Wineburg & Woolworth, 2001). *MetaRubric* is played in a group of colleagues or other professionals (e.g., rather than as a single player game at a PC).

2) Teacher professional learning should de-privatize practice - In general, this collective work of teacher learning serves to de-privatize the teachers' practice (Bryk et al, 2001; Wardrip & Herman, 2018). Too often, teachers' work has been characterized as isolated without allowing colleagues to see each other's work (Lortie, 2002). In *MetaRubric*, rubric creation and interpretation – an often-isolated activity – is carried out in real-time and discussed in groups.
3) Teacher professional development should supports sense making - *MetaRubric* creates opportunities for teachers' sense-making of what new forms of instruction might look like, particularly through providing a concrete example (the rubric creation process) (Rosebery & Puttick, 1998). Teachers can observe other professionals' sense-making processes and through the guided discussion, share with others what they're thinking (e.g., their justifications and rationale). These discussions create opportunities for teachers to learn new practices (Horn et al, 2015)

Prior to this study, *MetaRubric* had been used as an educational experience at conferences and as a part of teacher PD workshops. Participants, through self-report, were generally positive about the game experience reporting a range of educational take-aways (Kim & Rosenheck, 2020). *MetaRubric* is a teacher professional practice space game (Reich et al., 2018), meaning that it is designed to provide an opportunity for teachers to rehearse and reflect on their instructional practices, particularly through playful activities that help to surface problems they might encounter during design and enactment. Teacher professional practice space games are theorized to compel teachers to change their use of rubrics due to greater empathy with how students experience the rubrics and a deeper recognition of the tensions faced during rubric design and use (Reich et al., 2018). This study sought to gather more direct data supporting this theorized process, connecting the particularities of its design to teacher learning and professional development. To do so, this study focused on educators' meaning making through examining their discussion before, during, and after game play (Horn & Kane, 2015), seeking to draw connections between how it is that teachers talked about the game and their teaching practices.

Methods

Eight high school teachers were recruited to participate in this study. All were from the same high school where one of the author's worked as a principal. The recruited teachers had been teaching for 2 - 12 years, taught at least one English class in general, advanced, or special education classes for students from 9 - 12 grade. The teachers were asked to bring rubric materials that they currently or previously used in their classes for discussion. At the start of the first session, all of the teachers were briefly told about the game, its design, and the structure of the research. Then, they were split into two groups of four based on their professional learning community and colleagues they work with on a regular basis. In these groups, they were 1) interviewed, 2) played *MetaRubric,* and 3) were interviewed again, with each group led by one of the paper authors. The following prompts were used to guide the interviews, which lasted between 30 minutes and 1 hour: What kinds of formative assessments do you currently use in your teaching? What are your views on rubrics and how have you used them? How do you think about designing assessments to support student-centered learning? Can you share some examples of assessment tools that you use? Researchers were present in each group during game play to answer questions and provide additional moderation, such as keeping track of time and explaining unclear instructions. Teachers' interviews and their discussions during game play were audio recorded and transcribed. Additional researcher field notes from the observations were also included in the corpus of data.

Analysis

To understand teachers' views of rubrics going into game play, two researchers independently reviewed the pre-interview, game, and post-interview transcripts, and created descriptive codes to answer the following research questions: 1) "How do teachers view rubrics?" 2) "How do teachers talk about the game?" and 3) "How do teachers talk about rubrics relative to the game experience?" Working independently, the descriptive codes were then grouped into themes. To maximize coverage and coherence of the research question results, the researchers then shared their generated themes in order to create a combined theme set. They then reviewed their descriptive codes to either combine codes, generate new themes, or to reassess whether a new code might need to be applied to the original data.

Utterances used to answer the first two research questions were found by looking for explicit references to the game or to rubrics in the transcripts. Utterances used to answer the third question (making sense of the game in terms of their professional experience related to rubrics) were inherently less clear, as such reasoning would likely be internal rather than explicit. For example, ideal data would include a teacher saying something like, "Based on the game, I think that rubrics..." or "Based on my experience using rubrics, I think that the game..."

Therefore, in order to answer this question, we looked for utterances about rubrics that occurred *during* game play. This data allows us to characterize the game-based, rubric-oriented discussion.

We sought credibility in our analysis through several means (Lincoln & Guba, 1985). Specifically, we sought to maintain methodological consistency through our data collection and analysis (Morse et al., 2002). By this, we mean that our data and analysis were aligned with our research questions and the theoretical framework guiding the study. This was not meant to constrain our process of analysis. Rather, this alignment was intended to ensure "trustworthiness" (Lincoln, 1995) in that our point of inquiry, our analytic approach and our analyses were carried out systematically and as we designed. Also, we conducted regular critical discussions of our analysis among the research team. This permitted us to compare each other's interpretations, challenge one another's analyses and refine our own coding definitions to maintain a common understanding among the group. When consensus was not reached, additional examples from the data were brought to the discussion and the coding definitions were refined until consensus was reached. Finally, having a principal as part of the research team allowed the team a built-in way for the researchers to check interpretations.

Results

How did the teachers view rubrics?

With regards to student learning, the teachers described rubrics as providing a backdrop against which they and their students could evaluate work, "setting the tone" for feedback on how the student could improve. For example, one teacher described rubrics as a tool that provides a space within which students' work could fall (e.g., a 3 out of 4 for clarity), and teachers, students themselves, or peers could perform such an assessment. In addition to being used by students for formatively evaluating their work, the teachers saw rubrics as a means for communicating with students, helping them students to internalize the values along which their work is judged (e.g., good papers are clearly written). Ideally, the teachers expressed, rubrics provided both a scale and descriptive text that students would use repeatedly as they edited and improved their work.

Another function of rubrics the teachers discussed was as tools to communicate their evaluations to students, to other teachers, to parents, and to administrators. Two communication examples were emphasized, communication with colleagues, so that different teachers within department were "on the same page" with regards to evaluation, and communication with administration and parents, so that teachers could explain (e.g., during parent-teacher conferences) why a student paper received a particular score. The rubric, in this way, served as both a means for professional communication amongst teachers, and as an assessment tool that provided transparent and justifiable rationale for student grades.

The teachers also cited challenges to using rubrics to help students learn. They expressed concerns that the students might not understand what a rubric's component means (e.g., what does it mean for a paper to show originality?), what the difference between rubric scores means (a 3 or a 4 on clarity), or how a student might change their work, given the feedback they get through the rubric (e.g., how can a sentence be changed to become clearer?). They pointed out that creating longer, more verbose versions of rubrics could provide more examples, hopefully communicating the evaluation metric in more detail, but were concerned about students not reading the rubrics, especially if the rubric was long or had a lot of dense text. Applying a rubric can also be difficult because interpreting student work relative to a rubric is inherently subjective, and different teachers within the department can use the same rubric but end up with a different score for the student's work, a problem that is amplified the more diverse or creative student submissions are. Additionally, different parts of student writing may fall into different levels of quality, leading to problems like "circling between the [levels]" for an overall evaluation. Finally, teachers noted that rubrics are not often used in real-world settings, and so while students may find them useful during school, the skill needed to use a rubric well might not have application once students graduate.

How did teachers talk about the game?

During the post interview, teachers described positive and problematic aspects of the game, *MetaRubric*. They pointed out that the game highlighted the way that rubrics don't always support a level of creativity in student work, rather, rubrics can limit what students create from the onset. *MetaRubric*, they said, helped to highlight this difference - between trying to come up with creative solutions versus more narrowly aiming to fulfill assignment criteria.

Reflecting on *MetaRubric* as a professional development tool, the teachers pointed out that the game very quickly helped them to talk about professional practices while also avoiding personal aspects of professional work that can get "dicey," such as when two teachers might critically discuss the merits of a rubric that one of them had developed. By providing a playful, neutral activity, *MetaRubric* provided an experience where teachers

felt they could more easily talk amongst one another about the professional challenges of rubric use, "getting on the same page" especially with colleagues who don't normally work closely together.

With regards to drawbacks to *MetaRubric*, they pointed out that the game did not seem to teach them anything particular (e.g., a significantly new way to view rubrics, a new method for rubric creation or use). This was especially notable for these teachers when they encountered and reflected on the parting words of the game, which states that players should have gained "a new perspective on what is and isn't helpful in evaluating students' open-ended work."

How do teachers talk about rubrics in terms of the game experience?

We categorized how teachers talked about rubrics in terms of the rubrics generated through the game as well as how teachers talked about rubrics relative to the game and in their professional work. With regards to the game-based rubrics, the teachers' discussions were based around the use of the rubrics, such as "what [score] did you give that? I gave that an 8." As they used the rubrics in the game to grade one another's movie posters, they also asked one another for clarifications (e.g., "What did you mean by that?").

With regards to talking about the game-based rubrics and their own rubrics, the teachers pointed out that they had a different definition of "rubric" than the game seemed to use. Three of the teachers said that, within the past year they had taken a professional development course that was explicitly oriented toward creating good rubrics, and that based on that course, they understood rubrics to be different from what the game was focused on. As a result of that prior PD, they'd consider the game-generated rubric to be more akin to a checklist than a rubric, as it did not go into sufficient detail regarding the assignment's grading criteria.

Prior to this study, informal observations of how *MetaRubric* was played suggested that the target experience was being achieved, with participants making and thinking about rubrics more deeply, reflecting on their own prior understanding of rubrics, and their use of rubrics in classrooms. Results from this study support that, showing first-hand how *MetaRubric* provokes rich discussion around the problems that teachers face, including their understanding of what rubrics are and what role rubrics play within their profession. These discussions, including the teachers views and the problems they face with rubrics, were extremely context-dependent, relating to both the teachers' personal experiences and training with rubrics, the goals for teaching and learning they have in their classrooms, and the school environment in which they work.

Discussion

Design and Use of *MetaRubric* – Is surfacing problems enough?

MetaRubric was originally designed as a professional practice space game that could provide a play-based experience through which teachers create rubrics, and then reflect on the rubrics and their own rubric-based practices (Kim & Rosenheck, 2020; Reich et al., 2018). Observations from this study suggests that *MetaRubric* was successful in this regard – it created a collaborative playful experience that was a short enough to play during an hours-long PD workshops, it simplified rubric creation, and it served as a shared experience that was reflected on relative to professional notions of rubric design and use.

MetaRubric and other similar professional practice space games, by design, use the games' rules and mechanics to allow for teachers to playfully engage with these professional practices, surfacing problems rather scaffolding particular teaching practices (Reich et al., 2018). That is, the game does not embed, for example, "how to make rubrics better" in its core design or in the post-game reflection. Instead, the game's intended experience ends once an issue is raised, and at this point, relies on teachers' prior professional knowledge and experience to make the experience educational and beneficial moving forward. As a result, players may walk away from a game play session not necessarily knowing how to improve their own rubrics. In this study, for example, teachers raised the challenge of creating rubrics that provide verbose descriptions that attempt to provide students with clarity against the risk of creating rubrics that were too long and that students did not read at all. The problem was one that many had struggled with and none new how to resolve effectively. So, while the teachers were generally positive about the PD experience and the way that the game created a space where they could quickly and easily discuss rubric-related issues, they also expressed that the artifacts generated through game play were neither rubrics (by their understanding) nor did the experience significantly change their view of rubric design and use. Further design work is therefore needed if the game experience is to achieve its intended goal of helping participants impact their own rubric design and use.

Learning in a practice space game

The work of teaching has long been characterized as taking place in isolation (Lortie, 2002), however educational reformers have begun to emphasize the importance of professional practice learning opportunities that

intentionally bring teachers together to reflect upon and shift teaching practice (Wardrip et al., 2015). As the data from this study suggests, PD games like *MetaRubric* may be particularly useful tools for this community-oriented reflection, as the game tends to achieve its intended design goal of helping participant raise issues of practice that they faced. In order to move forward with *MetaRubric's* design and differentiate between individual and community-oriented learning that can occur beyond raising issues of practice, we believe it's necessary to further specify what and how learning might occur, especially relative to the particularities of the game's design.

To do, we turn to Markauskaite, Goodyear, and Bachfischer (2014)'s typology of epistemic games, which differentiates between epistemic games that are *formal*, in which disciplinary epistemologies are conveyed to the player and those that are *functional*, pertaining to the epistemic knowledge used to make sense of the world, especially in professional contexts. In formal epistemic games, the epistemologies adopted by players are new and knowledge is associated with a particular discipline. In functional epistemic games, players are concerned with determining how disciplinary knowledge is situated and applied to their professional actions. Markauskaite, Goodyear, and Bachfischer (2014) go on to categorize different epistemic game types based on 1) their review of five different fields' professional development course material and 2) interviews with relevant faculty. The game types they describe are: propositional games, situated problem-solving games, meta-professional games and trans-professional games, translational public discourse games, and weaving games. *MetaRubric,* though it was not intended to be designed with the taxonomy in mind, can be interpreted as a *(functional) meta-professional game,* or a game that does not aim to convey *new* disciplinary knowledge to the players, rather is designed with the intention to "*enhance joint knowledgeable action"* (p. 1291) especially through re-describing the activity from a shared professional view with intentions of applying disciplinary knowledge to local professional contexts. Identifying *MetaRubric* as a functional meta-professional game is helpful for specifying design aims, identifying shortcomings in achieving those aims, and for guiding the development of supplementary and supporting learning activities to address such shortcomings.

For example, teacher professional development practice space games like *MetaRubric* are characterized by at least two parts, a playful experience that models a component of teaching and the post-game reflection activity (Reich et al., 2018). The playful experience is used as a foil for reflection; the reflection is presumably to help teachers relate their game experience to their own actual professional practices (though its role is not clearly specified in prior literature). In *MetaRubric,* in particular, five reflection questions are provided: Did this activity make you think differently about rubrics? Next time you make a rubric for a class, what will you keep in mind? How did you feel about the format of this rubric? Did it work well or was it constraining? How would you modify it to better meet your needs? Revisiting the design intention of the game, we can see how these questions might change – from questions that are intended to provoke individual conceptual and practical change, toward a change in the local professional community through sharing of expertise, connecting with one another, and finding local solutions.

Advancing Games for Teacher Professional Development

Practice space games are a relatively new approach to teacher PD, and more work is needed to both understand how such games can be designed and used effectively, especially across different audiences and environments. Given the complex landscape of teacher PD, different models of game and play-based learning will need to be explored. For example, games designed for professional environments with participating experts might be designed with less focus less on directly affecting individuals' practice through novel understanding and more on helping teachers sharing expertise with one another. Such games could better support players through dialog - talking about current practices, the professional problems the face, and then coming up with solutions to solve these problems. Learning in such a game activity is less like knowledge acquisition from game play, and more like participation in a professional learning community; the role of the game is to support professional community development. Nevertheless, given the rapidly changing landscape of education technology and the way that in-class assessment skills and associated professional development have long been critiqued (e.g., Brookhart, 2001; Campbell et al. 2002), practice space PD games research is especially timely (Timmis et al., 2016; Will et al., 2019).

How the Shape of the Earth is Argued into Being

Shelly Reisner Vain, Ben Gurion University, vains@post.bgu.ac.il
Ilana Dubovi, Tel-Aviv University, ilanadubovi@tauex.tau.ac.il
Iris Tabak, Ben-Gurion University of the Negev, itabak@bgu.ac.il

Abstract: Claims that depart from Western scientific consensus, such as the relationship between vaccines and autism or the flat shape of the earth are often disparaged. We aim to cultivate greater convergence with scientific consensus, from a stance that rejects attributing alternative explanations to heedless partisanship or emotional susceptibility. We focus on the 'flat earth' explanation, and examine argumentative moves, attention to evidence and knowledge co-construction in YouTube discussions between supporters and critics of 'flat earth.' We found that Flat Earth supporters engage in argumentation and meta-talk about evidence, even at least as frequently as the critics. These findings suggest that cultivating greater convergence on scientific consensus requires deep and nuanced approaches, because alternative explanations can be couched in scientific, deliberative, and argumentative structures.

Introduction

"We're not just fighting an epidemic; we're fighting an infodemic" said the WHO Director at a conference on the COVID-19 outbreak (WHO, 2020). Indeed, scientific misinformation and disinformation on well established scientific topics such as climate change, vaccinations, and the shape of earth are being challenged and disputed. Specifically, in contrast to Western scientific canon, the Flat Earth movement argues that the earth's shape is planar, doubting government agencies' evidence that the earth is spherical (Garwood, 2008). In light of declining trust in science and institutional providers of information (Barzilai & Chinn, 2020), the proliferation of alternative theories (Landrum & Olshansky, 2019), such flat earth, foretell increasing divergence from scientific consensus, some to detrimental effects (Sinatra & Lombardi, 2020). Although ultimately our aim is to encourage public engagement with science, and to support greater convergence with scientific convention, we reject approaches that attribute the adoption of alternative explanations to deficit, heedless partisanship or emotional susceptibility. Instead, we contend that a deeper understanding of the internal logic of such theories can provide more productive avenues for deepening belief and trust in Western science (Kienhues et al., 2020), and increasing the convergence between publicly held beliefs and scientific convention. Therefore, the current study proposes to elucidate how alternative theories are communicated and maintained by discourse practices on social media.

We focus on discourse in post-video comments on YouTube that appear following videos in support of Flat Earth. Unlike other alternative theories, such as concerns over specific vaccines or schedules of vaccinations, where there is controversy within the scientific community, there is a strong consensus over the spherical shape of the Earth, and the idea that the Earth is flat is a radical departure from scientific canon. We chose YouTube as the medium for our analysis due to its key role in the Flat Earth movement. A Flat Earth Conference in Raleigh, North Carolina, November 2017, revealed that many of the participants came to accept the alternative theory of Flat Earth after watching videos about it on YouTube (Olshansky et al., 2020).

Theoretical background

Discursive approaches to knowledge

A discursive approach to knowledge and knowing assumes that social groups and cultures develop shared meanings that are ascribed to practices, artifacts, and systems of signs (Gee, 1990; Kelly & Green, 1998) and that these shared meanings are reflected in interaction and communication. Argumentation is a specific form of discourse in which participants make claims, support these claims with evidence, or try to refute or discount claims raised by others (van Eemeren et al., 2015). Argumentation can be disputational in which participants have persuasion goals, or it can be a form of knowledge construction, referred to as deliberative argumentation (Asterhan & Schwarz, 2016) or collaborative argumentation (Chinn & Clark, 2013) in which participants are mainly driven to understand an issue. In this study, we focus on scientific knowledge and understanding from a community and discursive perspective (Mason, 2007). That is, rather than examine the declarative conceptions of specific individuals through interviews, written tests or tasks, the study examines naturalistic discussions concerning the shape of the earth as these discussions occur spontaneously in the comments section of YouTube videos. This approach may limit our ability to understand individual cognition, but it provides insight into the ways in which knowledge is used in practice in the world. Specifically, by examining arguments between those

 © ISLS

that advocate that the earth is flat and those that advocate that the earth is round, we can examine the ways in which each of these groups engages with the practices and theories of formal western science.

Alternative conceptions and public engagement with science

Science education has a long history of examining learners' conceptions and the ways in which they align with or depart from scientific conventions, variably referred to as misconceptions or alternative conceptions (Chi et al., 1994; DiSessa, 2014; Duschl & Jiménez-Aleixandre, 2012; Linn & Eylon, 2006; Linn, 2008). Examining public engagement with science, there are increasing concerns over the proliferation of alternative conceptions that depart from canonical scientific explanations of natural phenomena or that cast doubt over scientific innovations such as vaccines (Sinatra et al., 2014; Sinatra & Lombardi, 2020). The advent of the Internet and social media has brought about greater access to both conventional science information as well as to alternative positions, and people struggle with reconciling these conflicting resources (Tabak, 2016). One approach to alternative conceptions sees these alternative conceptions as a deficit on the part of those who hold these alternative conceptions (Brossard & Lewenstein, 2010; Seakin & Hobson, 2017; Stocklmayer & Bryant, 2012), implying that if the public were less ignorant of science they would not maintain such conceptions. These approaches may be more pronounced as research on post-truth suggests that people are highly susceptible to adopting misinformation online, and that they tend to engage in immediate surface processing of information (Barzilai & Chinn, 2020; Brashier & Marsh, 2020; Kahan et al., 2017) rather than engage in deeper deliberation (Bago et al., 2020; Sinatra & Lombardi, 2020; Tabak, 2020). In recent years, the deficit model has been critized as an inaccurate and denegrating protrayal of public understanding of science (Brossard & Lewenstein, 2010; Sturgis & Allum, 2004), and there are increasing calls for gaining a better understanding of the nature of the public's scientific knowledge and skills and of how they are used in everyday contexts.

The Flat Earth community

In contrast to current scientific convention that the Earth is spherical, there are those that maintain that the earth is flat (Olshansky et al., 2020). Within the community that adopts a flat earth position, referred to by some as Flat Earthers', there are different perspectives over how gravity works, whether the earth is surrounded by a sheet of ice, and other ideas concerning celestial bodies beyond the earth (Garwood, 2008; York, 2017). Although Flat Earthers have existed for at least as long as spherical earth theories emerged, there has been a resurgence and expansion of this community in the last few decades, considerably influenced by videos posted on YouTube promoting the flat earth perspective (Brazil, 2020; Olshansky et al., 2020). Dating back to at least the 1970's and continuing today, members of the flat earth community offer justifications for their position that include references to religious scripture as well as those that are based on observation, measurement and experimentation (Vogt, 1979; York, 2017). The relationship between conventional Western science views and religious views and their role in adopting flat earth perspectives is an area of study and of mixed results, where religiosity, sensitivity to conspiracy ideology and science literacy were all implicated in a tendency to adopt alternative theories, and a flat earth perspective (Landrum & Olshansky, 2019). In this study, we seek to better understand the foundation of flat earth perspectives by focusing on how flat earth ideas are constituted through the discourse and argumentation that takes place within the flat earth community and between Flat Earthers' and their critics in post-video comments on YouTube.

Methods

We used several search and filtering strategies in order to obtain the YouTube videos that were used in our analysis of post-video comments on videos advocating a flat earth approach. We initially searched for "flat earth" on YouTube and selected the top 20 by number of views. Afterwards, we extended our search using information we obtained from other sources such as documentaries about the Flat Earth community, search trends and popular sites as shown on Google Trends. We searched YouTube for videos based on names of leaders in the community, and on the use of experimentation in support of the flat earth theory. We collected a database of 20-30 videos. Our first filter criteria was videos that advocate for the flat earth theory, next we eliminated videos that had comments that consisted mostly of derogatory interchange. Finally, we selected 4 videos published on the "YouTube" platform that advocated for flat earth, had extensive comments and "likes," and that represented two types of videos typically found in the database we collected, as described below.

We sampled 1278 post-video comments out of these 4 videos. Each video represents a stance supporting the Flat Earth theory, from a different perspective: two videos explain and discuss common questions regarding the theory, and two videos present experiments. We assessed each comment as a unit of analysis using a four-fold coding system:

1. Supporters vs. critics. We coded statements for being expressed to support or to oppose to Flat Earth theory.
2. *Argumentative Discourse Moves.* A coding system was developed based on Lu, Chiu, and Law (2011). Comments were coded along three main dimensions for argumentative discourse moves. The first dimension of the code considered how the present comment evaluates previous comments; namely, whether it expresses disagreement, a counter claim, agreement, or a question. The second, classified each comment as having grounds to warrant their comments. Third, classified each ground for its type (e.g., religious, or scientific).
3. *Meta-talk about evidence*. A coding scheme developed by Shi (2020) to examine changes in use of evidence-based claims during argumentative discourse. This scheme conceptualizes three categories: solicit evidence (e.g., "what is your evidence?"), evaluate source of evidence (e.g., "tell us where you get that evidence", and evaluate content of evidence (e.g., judgment of evidence quality and evidence comparison).
4. *Collaborative knowledge construction (CKC).* We used Gunawardena, Lowe, and Anderson's (1997) coding scheme which assesses the process of knowledge construction in a series of successive (though not necessarily strictly sequential) phases that are viewed as moving from lower to higher levels of group collaborative interaction: (1) Sharing/Adding (e.g., a statement of observation or opinion; definition, description, identification of a problem); (2) Negotiating meaning (agreement or disagreement by providing restatements, by identifying inconsistencies, or by asking for clarification); (3) Elaborating (building on and expanding previous statements and meanings); (4) Proposing synthesis (synthesis of the discussion with the prospect of testing it and finalizing it); and (5) Consensus/Applying constructed knowledge (stating a summary of agreements, application of new knowledge, metacognitive statements of changes in knowledge or ways of thinking).

Findings

From the resulting data, one detail that stood out was that even though the videos support the Flat Earth theory, most of the comments were made by those opposing it 679 (60.2%).

Argumentative Discourse moves. Overall, the most common discourse move was expression of disagreement (630; 61%). As apparent from Table 1, critics expressed significantly more statements of disagreement than Flat Earth supporters (76.2 % versus 38.8%, accordingly; $X_2 = 146.798$, $p<.001$); in contrast, Flat Earth supporters expressed significantly more statements of agreement than critics (39.2% versus 7.2%, accordingly; $X_2 = 158.923$, $p<.001$). Posting direct disagreements was also more prominent at experiment-based videos discussions than discussions that followed theory only based videos (72.8% versus 48.9%, accordingly; $X_2 = 62.115$, $p<.001$).

Overall, 31.7% of *argumentative discourse moves* also included grounds. While there was no significant difference in number of grounds incorporated by supporters compared to critics ($X_2 = 0.435$, $p=.510$), there was a significant difference in type of grounds that were used. Particularly, Flat Earth critics grounded their claims using science-based information significantly more than Flat Earth supporters (98.6% versus 56.0%); while Flat Earth supporters tended to warrant their claims using religious based evidence (44% versus 3.2%, accordingly; $X_2 = 101.134$, $p<.001$).

There was also a significant difference between videos that only discussed the Flat Earth theory and videos that incorporated experiments (Table 1). Particularly, videos with experiments tended to incorporate more grounds in their comments than theory only videos (34.7% versus 28.5%, accordingly, Table 1).

TABLE 1.
Argumentative Discourse Moves count and percentage by participant position or type of videos

		Participants position		Video type	
	Subtypes	Supporters	Critics	Theory only	Experiment
Evaluation:					
	Claim	54 (12.9%)	45 (7.3%)	79 (15.5%)	20 (3.8%)
	Agree	164 (39.2%)	44 (7.2%)	110 (21.6%)	98 (18.7%)
	Disagree	162 (38.8%)	468 (76.2%)	249 (48.9%)	381 (72.8%)
	Question	38 (9.1%)	57 (9.3%)	71 (13.9%)	24 (4.6%)

 © ISLS

Statistics (X_2)	$X_2 = 192.185$, $p < 0.001$		$X_2 = 86.590$, $p < 0.001$	
Grounds:	137 (30.6%)	220 (32.4%)	157 (28.5%)	200 (34.7%)
Statistics (X_2)	$X_2 = 0.435$, $p = 0.510$		$X_2 = 4.957$, $p < 0.05$	

Meta-talk about evidence took place in about 24.1 % of comments. Meta-talk analysis revealed a significant difference between supporters and critics (Table 2). A post-hoc analysis showed that Flat Earth supporters tended to evaluate source of evidence significantly more than critics (12.8% versus 4.5%, accordingly; $X_2 = 6.178$, $p<.05$); while Flat Earth critics tended to judge the quality of evidence significantly more than supporters (36% versus 19.1%; $X_2 = 8.251$, $p<.01$).

Meta-talk about evidence also evolved differently throughout the different types of videos (Table 2). Videos that involved experiments tended to raise more judgment of evidence quality comments (41.8% versus 18.8%, accordingly, $X_2 = 17.005$, $p<.001$); and evidence comprehension (37.3% versus 21.7%, accordingly; $X_2 = 7.943$, $p<.01$). Discussions following videos that only involved theory tended to incorporate more source of evidence evaluation comments than videos with experiments (11.6 % versus 3%, accordingly; $X_2 = 7.397$, $p<.01$).

TABLE 2.
Meta-talk evidence analysis by participant position or type of videos

	Participants' position		Type of videos	
Meta-talk about evidence	Supporters	Critics	Theory only	Experiment
Solicit evidence	7 (7.4%)	21 (11.8%)	20.3%	0%
Evaluate source of evidence	12 (12.8%)	8 (4.5%)	11.6%	3.0%
Evaluate content of evidence:				
Comprehension	20 (21.3%)	60 (33.7%)	30 (21.7%)	50 (37.3%)
Judgment of Evidence Quality	18 (19.1%)	64 (36.0%)	26 (18.8%)	56 (41.8%)
Multiple Interpretation	14 (14.9%)	6 (3.4%)	18 (13%)	2 (1.5%)
Evidence Comparison	23 (24.5%)	19 (10.7%)	20 (14.5%)	22 (16.4%)
Statistics (X_2)	$X_2 = 34.539$, $p < 0.001$		$X_2 = 64.026$, $p < 0.001$	

Finally, *Collaborative knowledge construction (CKC)* analysis revealed that a bigger proportion of comments posted by Flat Earth supporters achieved higher levels of group collaborative knowledge co-construction (level 3 of elaborating; Table 3) than critics (18% versus 10.1% accordingly, $X_2 = 15.191$, $p<.001$). Interestingly, there were no significant differences at the CKC higher levels (level 3 to level 5) that were achieved by the theory videos and experimental videos (Table 3).

TABLE 3.
Collaborative knowledge construction (CKC) analysis by participant position or type of videos

	Level 1	Level 2	Level 3	Level 4	Level 5
CKC levels:	Sharing/ Adding	Negotiating meaning	Elaborating	Proposing synthesis	Consensus/ Applying
Participants' position:					
Supporters	182 (41 %)	172 (38.7%)	80 (18%)	6 (1.4%)	4 (0.9%)
Critics	304 (45.6%)	282 (42.3%)	67 (10.1%)	11 (1.7%)	2 (0.3%)
Type of videos:					
Theory only	279 (51.4%)	183 (33.7%)	69 (12.7%)	10 (1.8%)	2 (0.4%)
Experiment	207 (36.5%)	271 (47.8%)	78 (13.8%)	7 (1.2%)	4 (0.7%)

Discussion

The broader research program in which this study is embedded aims to understand how people reason about science in everyday contexts to inform formal and community-oriented science education. We further aim to advance greater trust in, and alignment with formal (Western) scientific practices and knowledge. However, we work from a grounding assumption that alternative perspectives arise from a conceptual ecology and reflect an internal logic (Chinn et al., 2020; Demastes et al., 1995; diSessa, 2018). Therefore, we aim to uncover and understand the internal logic underlying alternative theories, as they are "talked into being" (Caronia & Chieregato, 2016) and constituted through naturalistic discourse (Kelly & Chen, 1999). In the present study, we examined the Flat Earth community as a test case, analyzing and characterizing the discourse moves of YouTube post-video comments.

Our findings reveal that in open public discussion venues, theoretical and ideological commitments are shaped and sustained not only through supportive and co-constructed discussion within the community but also through defense of these ideas against critics. The YouTube information ecosystem attracted and gave voice to Flat Earth theory supporters and to its critics. Ironically, critics, who seem to have the goal of eradicating flat earth ideas, may in fact contribute to perpetuating these ideas by providing supporters a need to "close ranks" and defend their perspective (White et al., 2018). In our analysis, Flat Earth supporters achieved higher collaborative knowledge construction levels than critics.

Moreover, the patterns that we found in these pro/con flat earth debates in YouTube post-video comments differed from patterns we found in other, less charged, science-related post-video discussions. The Flat Earth debates included (among supporters) higher levels of collaborative knowledge construction and of expressions of disagreement than those found in less charged discussions, which were predominantly characterized by neutral claims (Dubovi & Tabak, 2020). This supports the notion that Flat Earth supporters are driven toward Flat Earth preserving argumentative moves. In addition, it suggests that research examining scientific discussions on social media should pay closer attention to the social-emotional weight of the issues that are discussed (Dubovi & Tabak, 2021), because differences along these dimensions could affect argumentative patterns.

If we consider the flat earth critic participants as reflecting a stance more aligned with formal science, then we see that Flat Earth'ers are more similar than different, discursively, to "scientifically aligned" speakers. Both Flat Earth supporters and critics engaged in argumentative discourse and meta-talk dialogue about evidence. However, there were two main patterns that distinguished supporters from critics, which could inform education. Flat Earth critics and supporters incorporated warrants for their claims with similar frequency, but they based these claims on different grounds. Flat Earth supporters tended to call on religious evidence, while critics relied more on scientific warrants.

The similarities in argumentative moves between supporters and critics point to the difficulty in resisting alternative scientific explanations. Prior research demonstrates that people are sensitive to texts and discourse that connote "scientificality," and consider the more scientific-seeming texts to be more reliable (Bromme et al., 2015; Thomm & Bromme, 2012). The discussions following videos that presented experiments in support of a flat earth are especially pertinent, because of the combined effect of the use of experiments and the higher proportion of argumentative moves. Therefore, through their "scientificality," alternative theory presentations on social media may seem reliable and convincing. The similarities in argumentative structures and moves between supporters and critics suggests that extending experiences with scientific argumentation may not be sufficient for supporting greater alignment with scientific consensus. The differences in warrants suggest that developing a deeper understanding of the nature of evidence and what constitutes scientific evidence versus other forms of evidence (Chinn et al., 2020; Duncan et al., 2018) may be a step in the right direction.

Conclusion

People who maintain alternative scientific beliefs are often cast as adopting these positions from unreasoned responses to emotional manipulation or to group affiliations. The Flat Earth discussions that we analyze suggest that at least those members of the Flath Earth community who participated in the discussion were reasoned and deliberative, and that much of their argumentative moves were aligned with scientific moves. These findings suggest that cultivating greater convergence on scientific consensus requires deep and nuanced approaches, because alternative explanations can be couched in scientific, deliberative, and argumentative structures.

Mapping Visual Marginalia in Educational Contexts: A Model for New Types of Self-Regulation of Learning

Nadia Dario, CNRS, École Normale Supérieure de Lyon, Université de Lyon 2, nadia.dario@ens-lyon.fr
Kristine Lund, CNRS, École Normale Supérieure de Lyon, Université de Lyon 2, kristine.lund@ens-lyon.fr
Luca Tateo, University of Oslo, luca.tateo@isp.uio.no

Abstract: Visual Marginalia (VM) are a common phenomenon in school, but they hold untapped potentials. We aim to understand their nature and role in learning and thinking. Marginalia are described as making annotations in book margins. In this paper, we extend this concept to include visual self-expressions such as para-writings and para-drawings, creative drawings and writings at the margin of books or notebooks, modification of book pictures, titles or texts, squiggling and doodling. VM are part of students' self-regulatory processes but are frowned upon by teachers. Thus, VM are *marginal* but also *marginalized*. We present a theoretical discussion of the topic, a new semiotic methodology that maps visual marginalia in a real classroom, and a model that reveals unstudied ways that students self-regulate.

Visual Marginalia, visible thought in the margins

Marginalia are the production of graphical and textual elements in the margins of written texts. The Latin term "*marginalia"*, meaning "on the margin", refers to a praxis as old as books themselves and a way to overcome physical and temporal borders. Notes and drawings written in a book or manuscript (Jackson, 2001), allow authors and readers to challenge the text. Jackson (2001; 2010) and Golick (2004) identified two aims of marginalia. The first is a public use where authors of marginalia respond to significant works or to a historical accounting of social and cultural rituals by leaving messages for posterity. The second holds a private function where authors use marginalia to create self-awareness, "tracing the development of reader self-definition in and by relation to the text" (Jackson, 2010, p.10; McHatton & May, 2013). Our work led us to extend marginalia to visual marginalia (VM) in order to study their impact on cognition, motivation, emotions, and regulation of learning.

Marginalia in the educational field: Visual Marginalia

According to social and cognitive constructivism, learners' thoughts and actions are influenced by external elements and by context (Hadwin & Oshige, 2011), but teachers tend to consider external elements in ontological isolation from context and culture. Science teachers typically downplay students' personal experience, artifacts and practices, positioning schooling as potentially disconnected from and not necessarily relevant to students' everyday lives and interests (Darling-Hammond et al. 2020). Yet, individual goals and self-efficacy influence motivation (Bandura,1999) and motivation and goals are expressed in collateral processes and productions (1). According to Reid (2018) marginalia are studied in the development of reading and writing skills with adults where a reader or student, relates to a written text to be understood, modified, or reflected on (Jackson, 2001; Stoddard, 2005). However, we are not aware of studies that consider marginalia as an expression of students' experience and emotional world while they are reading, listening and participating *in class*.

If Schott (2011) claims that marginalia are related to the prevailing state of mind of the author (2), VM 's definition (Dario & Tateo, in press) include the marginalia's author who is interacting in the educational context. Furthermore, VM include all collateral productions such as para-writings and para-drawings, creative drawings and writings at the margin of books or notebooks, modifications of book pictures, titles or texts, squiggling and doodling (the former being less organized and more unconscious), made by students in interaction with the lesson and *not* directly requested by the teacher. Thus, such products are both marginal and marginalized by teachers who may neglect their educational value. VM's main characteristics are as follows (Dario & Tateo, in press):

- They are collateral, literally "located at the margin of the lesson", of the printed book or hand-written notes. Depending on the type of cognitive-emotional involvement stemming from the context or from the lesson, VM assume different positions, locations and forms. First, they may have no relationship to the lesson. Second, they may relate both to the lesson text and the context of the lesson. Third, they may not be related to the lesson context, but reveal the cognitive-emotional state of the student. Thus, writing on the margins is a cognitive-emotional dialogue with the lesson text and context, in which internalization (e.g. thinking and memorizing) and externalization (structuring and expressing cognitive and emotional states) feed into one another (Vygotsky, 1997). VM play a role in structuring,

 © ISLS

understanding, articulating and extending individual experiences because these signs are manifestations of people's uniqueness in relation to socio-cultural context (Vygotsky, 1997).

- They are carried out on support using an exosomatic tool such as a pencil, a pen, or mouse on a screen. Tools change the nature and value of marginalia and Visual Marginalia.
- Marginalia embody affects, meaning they capture how a body acts when it is embedded in a collective that encompasses not just other individuals, but entangled material and discursive elements that constantly co-produce each other (Barad, 2007; MacLure, 2013). In addition, they can reduce tensions generated by negative emotions and be a relaxation strategy to foster learning, a tool for emotion awareness and emotion regulation (Polo, Lund, Platin & Niccolai, 2016).

In summary, marginalia have been studied in contexts where individuals read and annotate material on their own. Based on their marginalia, connections have been made to these readers' learning and thinking. However, in educational contexts where students are interacting in class with their peers and a teacher, there is a significant potential in developing more comprehensive theoretical and empirical approaches to grasp the role of Visual Marginalia in the teaching/learning process. We use a semiotic cultural psychology approach to study Visual Marginalia, to create a qualitative methodology to explore their phenomenology, and to propose a descriptive model that places VM within a two-axis space, from spontaneous to deliberate and from marginalized to normative, allowing us to discuss their impact in self-regulation (Järvelä, Hadwin, Malmberg, & Miller, 2018).

A semiotic approach to marginalia

Educational phenomena are complex and a classroom is a sociocultural environment, providing meanings and resources for human beings to act and stabilize the world they experience through the semiotic mediation of sign-systems and systems of activity (Valsiner, 2007). Visual Marginalia are particular types of signs that play a role both in the internalization and in the externalization of meanings at school. Once meanings are internalized and the developing person has learned to master signs, they will be able to use them to externalize meanings back into social relationships. This process occurs through an active production of meanings by the developing person, in a constant negotiation between social interpretations and personal meaning-making.

Furthermore, the scaffolding role of drawing in the ontogenetic development of sign-mediated higher psychological functions is clearly acknowledged (Papandreou, 2014). It is thus reasonable that Visual Marginalia continue to play a role of external mediator in the elaboration of meaning in the course of development. The marginal spaces become the arena where students can elaborate meaning through the production of particular signs. However, in accordance with the developmental approach of cultural psychology of education, we must observe the process *in its making, in its historical unfolding*, in order to really grasp the developmental role of Visual Marginalia. Thus, Visual Marginalia are studied in their development and the methodology used allows us to "specify precisely both where the development happens and where interventions into development are located" (Valsiner & van der Veer, 2017, p. 152). This requires being able to capture the moving horizon of the developmental process, thus observing the production of Visual Marginalia in the classroom's ecological context.

Accordingly, we present our innovative methodology used to map Visual Marginalia in an authentic school context. Through interviews, we co-construct with the participants the development of their VM and the links with the lesson and the written or printed page. Our aim was to access the first-person subjective experience of students inside the classroom context. This gave us a window into how their emotions led to self-regulation.

A qualitative methodology to study Visual Marginalia

Study Design

To our knowledge, no study exists on VM in the classroom. We approach VM as a developmental process, through the perspectives of semiotic cultural psychology (Anderson & Larson, 2013) that respects phenomenological and interpretive epistemology (Giorgi et al., 1975). In other words, we aimed to describe the who, what, why, when and where of Visual Marginalia. We were also sensitive to personal meaning-making, considering the different voices involved in the process (e.g. students, teachers, and researchers). The protocol is based on a design that employs a teachers' questionnaire, video-recorded lessons (two for each class) and "auto-confrontation" interviews (Theureau, 2003; Clot, 2005). Due to the pandemic, the lesson was conducted at a distance for secondary schools, but face-to-face for primary schools.

Participants

Data came from three classes (42 students, 6-12 years; from primary (15 students, 7 males, 2nd grade; 12 students, 6 males, 5th grade) and secondary school (15 students, 7 males, 6th grade). All three teachers were female. Lessons

took place at *Istituto Comprensivo* in Northern Italy during the 2021 lockdown. Not all participants were Italian native speakers but all had been schooled in Italy for 4 years. No one had behavioral or learning difficulties. Each teacher and student participated voluntarily and parents authorized their children. Three students opted out.

Materials/Tools

The tools used were the:

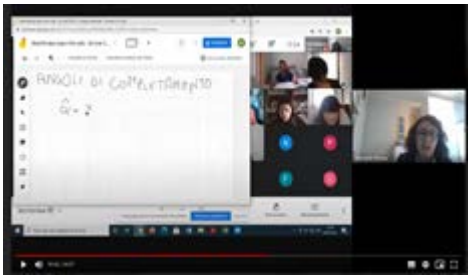
- Google Meet Platform where teachers and students interact, video-record lessons and conduct interviews;
- Interactive Whiteboard (IWB), where researchers interact with Primary School Students via the above;
- Wide-angle lens camera on the IWB to video-record face to face lessons at Primary School;
- Google Jamboard where students move a pointer on Visual Marginalia to explain how they made them.

Procedure

- Phase 0: The researcher established a collaboration with the school and kick-off meetings were organized with the principal and the teachers who participated. Classes were identified and parental assent acquired.
- Phase 1: The teachers filled in a questionnaire on lesson organization: time, activities, task. A researcher gave teachers instructions on how to activate Google Meet and record the lesson. Primary school teachers activated Google Meet so a researcher could participate (cf. Figure1a). Classes in secondary school were virtual and the teacher, students, and researchers were connected through Google Meet (cf. Figure1b).
- Phase 2: The researcher re-informed students that their work would be recorded due to interest in their activities. No further information was provided. The video-recording was set for 40 minutes. Students were trained for 10 minutes on the presence of the camera. At the end, we asked the children to hand in any Visual Marginalia. Some VM were collected by screenshot within Google Meet by photo. Other students sent in photos of their VM with a smartphone. One author viewed all three classroom videos.

Figure 1 (a,b)

The video-recorded lesson in the primary school is on the left (2a) and the secondary school lesson in the Google Meet Platform is on the right (2b).

a)


b)

- Phase 3: Researchers carried out auto-confrontation interviews (15-20 minutes in Google Meet) where students revealed how they produced Visual Marginalia from start to finish. Interviews took place within two hours from the end of the recorded lesson and were conducted in parallel by a researcher and by two Master Degree students. The interviewer shared two screens. The first contained the student's marginalia (first column) and the second contained the lesson (third column). The student could move a pointer and explain the different phases of her elaboration (Table 1). Students are designated by "P" for pupil; "T" is for teacher, and "I" is for interviewer. Participants are numbered.

Table 1

Example of Mapping the developmental Visual Marginalia productions during a lesson

 a)	P.1: "I meant to take notes and so, as instructed by the teacher, I made a complementary angle".	 b)	T1: "You have to write that alpha and beta are complementary".

Results and Interpretation

We give six canonical examples of Visual Marginalia (scribbling, ornaments, modifications of images, doodling, and drawing). Due to space and interest, we do not present labels or annotations. Interviews reveal how students produced VM. They all appear in Dario & Tateo (in press) and we discovered no new forms of VM. We illustrate how particular instances of Visual Marginalia have an impact on cognition, emotion, and self-regulation in the classroom. This allows us to propose an initial model that reveals unstudied ways that students self-regulate.

Scribbling

This type of VM consists of lines and scrawls. It is positioned at the margin and it corresponds to a rapid movement of the student's hand and often only makes sense to the student at the end of the action. In Figure 2, the student says he is bored and unmotivated in math class and so continues to work on the art concept of *chiaroscuro*. In Figure 3, the student also recounts how she gradually attributed meaning to her scribble while doing it.

Figure 2

A student during math class uses a scribble to reflect upon an art concept studied in the previous period

1: How did you feel before you started scribbling?
P.31: Bored, I had finished the exercise and did not know what to do
I1: and how did scribbling make you feel?
P.31: less bored
I1: Do you also remember what you were thinking?
P.31: About the art lesson I had done earlier
I1: And why?
P.31: Because we had done the chiaroscuro and I wanted to see if I could do it
I1: So it is not connected to the arithmetic lesson but to that of art?
P.31: Yes
[…]
F: Was it born spontaneously or did you decide to make it with intention?
P.31: Spontaneously
I1: That is, did you find yourself doing it without thinking about it?
P.31 Yes

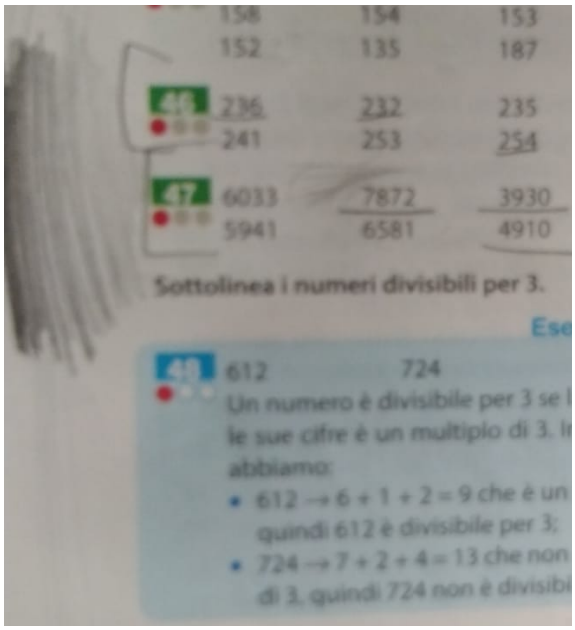


Figure 3

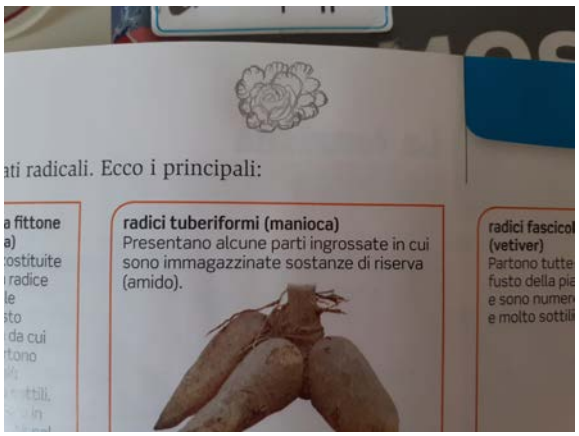
In science class, a student uses a scribble of a flower to conceptualize a metaphor for inner and outer beauty

I: Can you explain it to me?
P.40: There are two flowers, on the outside it is an ugly flower, while on the inside it is a rose that I tried to make look real
I: and what does it mean for you?
P.40: its meaning is not to judge from appearances but to see what that person is like from within, a butterfly is first a caterpillar and then becomes a butterfly
[…]
P.40: We were talking about plants
[…]
P.40: First, I did a scrawl then I realized that…It was a science lesson. I wanted to simply draw a flower because it was science time but then I thought I could draw a rose with a message of inner beauty

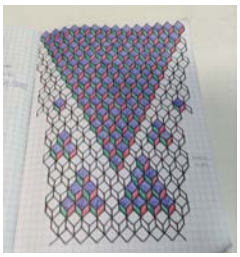


Ornaments

In this VM (cf. Figure 4) students repetitively produce the same simple form (e.g. flower, cube...) but there is a pattern. The student is concentrated on the lesson in the same way as for labels, and reproduces the same element. This particular example is from Dario & Tateo (in press).

Figure 4
In middle school art class, this student produced this detailed ornament that helped her to concentrate

I1 Then when you did this, did your emotion change?
P.2: Yes, I became calm. Let's say that I'm myself again...not because I have many other thoughts but boredom simply disappears and becomes concentration!
I1: Were you getting bored when you made it?
P.2: Yes, a little but it helped me reason and eliminate boredom.



Modifications of images

In this VM, the student modifies the pictures that are printed in the book, for example by inserting decorative/drawn elements (e.g. moustaches, new clothes, noses, etc). In **Figure 5**, the student expresses a state of being connected with the context; he was laughing with his peers during the English lesson on actions. When a scene of happiness appears in a cartoon in the book page, he produces the marginalia, retracing the main characters' mouth and putting crosses on their eyes. In this manner, he creates his prevailing emotion: happiness.

Figure 5
Pupil 25 modified the image on the right during an English lesson on actions to express his emotion

P.25: Yes, the things done with the red pen (.) I made the outlines of the mouths
I1: the crosses on the eyes
P.25: ((chuckle))
I1: I wanted to ask you why did you decide to do this?
P.25: Ehh ... because maybe I had seen some things in cartoons or things came to mind and made me laugh

A student may also use modification of images when he is angry and unmotivated. In **Figure 6**, the student had failed in the first class, and considered that his history teacher was responsible. Thus, during the lesson he often emphasizes his state of being.

Figure 6
Participant 25 modified the picture during an English lesson on actions

P.25 It depends if we are talking about history, in this case it is like if a war was taking place in my head and many times, I draw war pictures on the school images.
I1. What happens in the image?
P.25 "Well, if it is already in the book…maybe I change the character's eyes. I make him meaner. If he has a gun, I add a sword, so I give him a fighting spirit

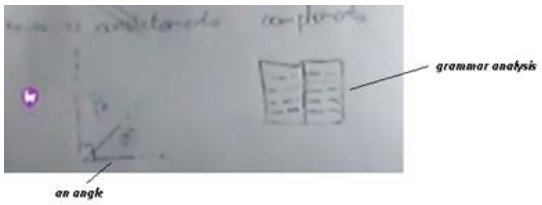
A Doodling Medley

In a doodling medley, the student produces elements that do not have a meaning individually, but have a student-constructed collective meaning (cf. Figure 7). Here, the student thinks of the word "complement" in its mathematical context because two angles that add up to 90° are complementary angles. In addition, the dots on the end of the angle rays represent infinity. But, he also relates these two concepts (complement and dots) to Italian grammar. A sentence with a subject, verb, and complement, is complete, in a similar sense to completing

a 90° angle. Secondly, this student's grammar teacher also always forgot to dot the "i's" and the student was reminded of this when his math teacher said "Please, put the dots that I have forgotten on the sides of the angles".

Figure 7
The student shares the value of marginalia as a tool to reflect on the language of math and grammar.

P1: Here I thought of 'complement', a term used in the grammar analysis that I did with my primary school teacher
I2. "So, is there a relationship with what is happening here"?
P1. "Yup…the connection here is that the teacher said: "Remember to put the dots at the end of the sides of the angles" and so I remembered that my primary school teacher never dotted the "i's" and we used to say: "Teacher, the dots! "



Drawing

Figure 8 shows realistic representations of a scene that condenses the teacher's lecture and page content. The drawing is done at the margin of a hand-written story. The student draws a picture as the teacher reads.

Figure 8
The drawing done by a primary school student to sustain her comprehension and memory during the lesson.

I1: Why did you choose to draw it?
P.8: because it was like the story the teacher read to us
I1: Did it help you understand the story better?
P.8: yes
I1: and what does it represent?
P.8: A little dog and a little girl playing together.
I1: Did the teacher ask you to draw it?
P.8: No, I felt like doing it

A model for new types of self-regulation of learning

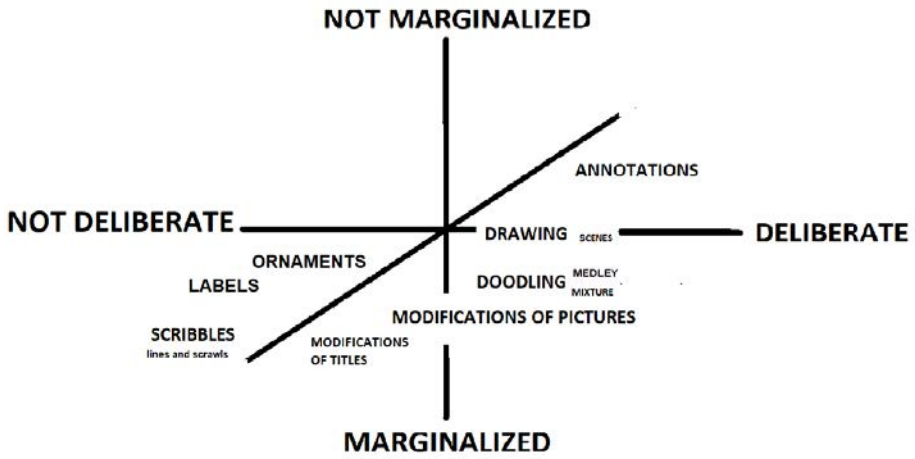
Our analysis allows us to generate an initial model that reveals unstudied ways of how students self-regulate in the classroom (cf. Figure 9). The correlation between the lesson and Visual Marginalia functions as an intermediate space of signification where the student relates his VM to the lesson and enhances the value of both. VM acquire value as they move from being spontaneous to deliberate. Specifically, if the students in our corpus find parts of the lesson boring, their Visual Marginalia are spontaneous products that take the form of scribbles, labels or ornaments, corresponding to automatic writings that the student produces when she has a pen in her hand. They help her to maintain attention during the lesson and awareness of the classroom around her, and limit inappropriate body movements (P.11 "At school I often end up drawing when theoretical subjects are being discussed and teachers could be distracted by my movements). VM can also be deliberate. Modifications of images, doodles and drawings are more deliberate forms and they sustain students' ability to explain, recall prior knowledge, information and experiences about a lesson (Andrade, 2010; Brown, 2014) as well as remember a printed text or their notes, and as we have seen, help students recognize their self-facilitation of understanding.

Often, students' VM change from a spontaneous, repetitive and hardly understandable form (squiggling, labels and ornaments) to a deliberate and meaningful one (drawing and annotations). That said, the entire trial and error process remains mainly marginalized (e.g. generally thought by teachers to be childish) and we argue that this is a missed opportunity. We present the diagonal line moving up to the right as a potential for creative productions. We have observed that students' unstructured drawing and writing (e.g. scribbles, loops or curls) has accompanied the generation of new concepts or creative productions. There is support for this idea from Winnicott (Berger, 1980) who discovered that when children play the squiggle Game, they manifest the necessity to start with a circular line before producing a new drawing.

Certain types of VM (scribbles, labels and ornaments) can also be an escape from stressful situations or they can contain the expression of feelings connected with the ongoing lesson. Thus, Visual Marginalia could reinforce an internal feeling or repress it. VM increase students' self-awareness of their feelings and their state of

being (See P.25 in Figure 5 and Figure 6) and their skill in recognizing and manifesting them. VM are an emotional regulator. When students feel unmotivated or disengaged, they draw and consequently they reduce their tendency to mind-wander while increasing their concentration.

Figure 9
Visual Marginalia occur along two continua: spontaneous to deliberate and marginalized to not marginalized.



In the case of doodling (mixture and medley), Visual Marginalia becomes a powerful tool in elaborating the learning experience when there is high-level content-based interaction (cf. Figure 9). Through the connections between elements, we can reconstruct the elaboration of student thought. When retrieving information immediately after the teacher's talk or reading, a student may have access to a highly active mental network and, according to Fletcher, van den Broek, & Arthur, (1996) meta-comprehension can be facilitated (Thiede et al., 2018). Doodles are multimodal summaries of knowledge at the margin without being time consuming practices.

Conclusions

We illustrated the concept of Visual Marginalia, a ubiquitous phenomenon, to which little attention is paid in the educational field. We presented a qualitative methodology, implemented at two school levels in order to explore VM in an authentic teaching-learning context. We showed how video-recorded lessons and "*auto-confrontation*" interviews with students *revealed* how and why VM were produced during class, giving the interviewer insight into the reasons for emotions it produced, or what emotions caused it, and how these emotions were linked to the lesson. We then proposed a model illustrating heretofore unstudied ways in which students self-regulate.

In this sense, VM are not regressive and childish, but can be a valuable visual support for teachers to understand how students self-regulate their socio-cognitive-emotional processes. Given the visual nature of VM, our perspectives for teacher training modules include 1) STEAM (Science, Technologies, Engineering, Art and Mathematics), where art can be used to express scientific concepts and 2) collaborative settings, where students can use marginalia to engage in transactive discourses such as critique, challenges, and synthesis.

Endnotes

(1) We use the term collateral to indicate all the processes at the margin or marginalized by teachers and students and that are considered to have little or no educational value.
(2) According to Schott (2011) doodles provide a window into the personality and the psychology of authors. They can be a symbol of mental disorders such as schizophrenia and they recall surrealist automatic drawings.

Actor-Network Theory as a New Direction in Research on Educational Dialogues

Abstract: The analysis of educational dialogues has been traditionally undertaken according to pre-given coding schemes, which are often teacher-centered, and in which multiple time scales are not considered. In this paper, we consider the use of Actor-Network Theory (ANT) methodology. While ANT has already been used in education, its application for analyzing the deployment of educational dialogues over time is novel. We analyze some educational dialogues in a program dedicated to dialogic pedagogy. We show that ANT enables us to consider the observation of educational dialogues as the formation and dissolution of networks between humans and non-humans, where roles are not pre-determined but translated in interactions, and the educational design of instructions is black-boxed.

The gaps between dialogism and dialogic teaching

Dialogism is a vast domain that has inspired scholars from various traditions (Marxism, semiotics, structuralism, religious criticism) and disciplines such as history, philosophy, sociology, anthropology, and psychology. It has also revolutionized the world of education. This revolution is firstly linked to Bakhtin's communication legacy. According to Bakhtin, every utterance is related to another utterance, true to turn-taking. The conversational norms are followed for a discourse to have a cohesive flow in which individuals respond to one another (Bakhtin, 1935). Bakhtin's enterprise critiques the monologization of the human experience that he perceived in the dominant linguistic, literary, philosophical, and political theories of his time (Baxter, 2006).

While dialogism breaks the monology of humanism, it is still bound by its Humanist threads: it focuses on the human as the instrument of knowledge-making. Dialogists focus on 'culture', sociolinguistics, classroom interactions, and communication patterns, which are all human-centered. This is evidenced, for example, by take-up 'the utterance' as the basic unit of analysis in dialogical research (Bakhtin, 1935). Davies and Renshaw (2019) stretch the notion of human beyond the unfinalisability of dialogism and its humanist legacies; they adopt a *posthumanist* political approach that 'dislocates the foundations of the humanist worldview' (Braidotti, 2006, p. 203). For them, human is neither a biological nor sociological category, but an interface, a field of intersecting material and symbolic forces; a surface where multiple codes (sex, class, age, race, etc.) are inscribed'.

Dialogic education is a pedagogical movement based on dialogism. Its implementation is constrained by the educational structures, practices, and norms in place in schools, though. Consequently, the major ideas of dialogism – the interrelation of voices and their uniqueness and the polyglossy of communication – do not fit classroom talk ruled by traditional pedagogies. The fact that voices should be aligned to what is recognized as correct, the centrality of the teacher as the authority of official knowledge, the attainment of clear learning outcomes, are few phenomena that make it difficult to implement dialogic education. The term Educational Dialogues points at a change, which envisions classroom talk as more fit to dialogism. The recent volume Research Methods for Educational Dialogues (Kershner et al., 2020), which is aimed at presenting various methodologies for observing the quality of educational dialogues, stresses in fact the passage from old to new practices. In the

volume, the Scheme for Educational Dialogue Analysis or SEDA elaborated by Sara Hennessy and her colleagues is presented. It transcribes the dialogue, divides and classifies it according to pre-given code schemes (Hennessy et al. 2016). SEDA served as a tool for showing that Dialogic Teaching improves learning outcomes (Howe et al., 2019) which provides an important answer to the detractors of Dialogic Education. However, SEDA does not enable us to look at the development of dialogues over time. Also, it is anthropocentric and does not relate to non-human actors and how they shape classroom dialogue.

Actor Network-Theory

Actor-Network-Theory (ANT) seeks to give an account of how the social world endlessly disassembles and reassembles itself through the complex interactions of its actors, which may be animate or inanimate. ANT spurns traditional social 'forces' as determinate of actions, seeking to account for social structure by analyzing the processes and connections through which networks are assembled. Latour and Woolgar's (1979) ethnography of a biomedical laboratory draws on citational data, and research reports from the lab supplemented with fieldwork and interviews. They turned the lab into a place where facts are 'secreted' through processes that involve researchers as actors assemble and interpret data.

A key assumption in ANT is *symmetry* (Latour &Woolgar, 1979). ANT researchers oppose approaches that concentrate only on humans, while objects, machines, and materials remain often overlooked. According to the ANT approach, all things, human and non-human, can assemble, exert force, change, and be changed. According to ANT researchers, nothing is given or *a priori* defined. Entities, human and non-human, are transformed through to process of becoming part of a collective network (Fenwick & Edwards 2010). The title of an actor does not convey a pre-given role; it is translated by his/her/its actions, connections, and the change he makes in a specific network. Agency, power, identity, and knowledge are relational effects of a certain network and not pre-given attributes. For example, McGregor (2004) shows how a science teacher becomes a knowing location through the interaction of materials, routines, texts, and people. She describes how laboratory artifacts, instructional practices, and teacher traits are assembled into a network and create knowledge and agency.

Certain assemblages stabilize and move about from one network to another network and extend its original network's power. When these assemblages move to new networks, they can be taken for granted. Fenwick and Edwards (2010) bring an example of the Black Boxing in education and describe how curricula become Black Boxes. A curriculum is an effect of a heterogeneous network of people and things, and historical and political networks, which often solidify and become durable. Then it spreads and shapes the learning in classes. The teachers (and the students) might take the curriculum for granted, leaving behind the ongoing discussion and interaction that led to its creation.

In this paper, we exemplify the use of Actor-Network Theory (ANT), a methodology that has not been used to analyze educational dialogues. Educational dialogues are viewed through networks of teachers, students, and actants that exert power on each other. The roles in the networks are not pre-determined but translated in interactions (e.g., the teacher may become a discussant whose status is comparable to that of the students). Educational activities designed to promote dialogue are often black-boxed, and the original process and circumstances of their creation might be ignored. Still, this black-boxing is possibly reversed in further educational

dialogues. We show then that the adoption of ANT for analyzing educational dialogues uncovers the shifts from less dialogic to more dialogic and explains the mechanisms that lead to these shifts. Shifts from one network to other convey the change of power relations between the different actors and the determining role of non-human actors (instructions, pictures, etc.). ANT emphasizes how these actants shape the dynamics of networks in which educational dialogues lay. We draw from ANT's analysis implications both for research and educational practice in dialogic education.

The educational context

In September 2019, we initiated a multidisciplinary, dialogic instruction program in four schools in a mid-size town in Israel. A school professional development (PD) program was implemented in which teachers that taught in Grade 7 in mathematics, humanities, and science. The school principals encouraged the teachers to participate in the program in order to enact dialogic practices in their classes. We negotiated the program with all the stakeholders involved. The teachers and superintendents responsible for schools pointed at the need for a program that would raise strong interest and engagement. We preconized the enactment of a dialogic pedagogy for enabling interdisciplinary processes among students. We and the stakeholders decided to instigate an out-of-school series of interdisciplinary activities to foster dialogic argumentation. 130 Grade 7 students participated in a series of activities organized in "climax days". Each climax day focused on a different societal issue, and included disciplinary sessions (in mathematics, science and philosophy) during which students learned about ideas relevant to the societal issue, preceded an interdisciplinary session in which a joint product (e.g. a presentation, a clip, a written story, a petition) was produced. Deliberations around texts that invited inquiry and dialogic argumentation were conducted in all disciplines and all sessions.

1st example: Revealing with ANT the complex role of design in educational dialogues

The teacher begins the lesson by giving explicit instructions for a small group activity: "This activity summarizes everything you have been through today... I will distribute a board with an axis to each group, representing the degree to which arguments support or oppose the issue we discuss today [Would it be right for the government to mandate parents to vaccinate their children?]. You will be provided the cards you already produced in the previous sessions in the different disciplines. We will discuss this question in this summary section using all the information you gathered along the different sections. You should already have two cards of reasons and arguments pro or against vaccination… so you should pinpoint your card somewhere on this axis. In addition, I will give you cards with new arguments, and you should decide as a group where to place them on the axis." The instructions conveyed a meticulous design. Then the teacher arranged the students into different groups. We present an excerpt from one group of five girls. After clarifying the instructions, the group discussed how to design the board:

Table 1

Excerpt 1

55	s1	Just one minute, so we need to [design the board] with one side opposing, and the other side supporting.

56	s4	Let's split it into halves, and then we will know.
58	s4	Right. It is [designed that way] so we can put [the cards] here and here in the plus-minus axis.
60	s3	Axis. Look, I and Yuval thought [abrupted].
61	s4	Don't make dots; make them lines. That way.
62	s2	Yuval, should I write it this way?

In this excerpt, the human actors are the teacher and the students. They explicitly refer to the Bristol board or point at it in all turns. It is a non-human actor; it is an actant. This reference to the Bristol board exemplifies the methodological concept of symmetry (Fenwick & Edwards 2010), in the interaction between human and non-human actors. In this example we can see how the Bristol exerts agency and shapes the interaction as an actant: The teacher's instructions referred to the board; the "we need to design the board" in turn 55 shows that the students interact with the instructions just given by the teacher. The Bristol board is translated to become a performing part of the network, which almost "gives orders" to the human actors, like in line 56 as if the board 'says' "split me in two halves and then you will know". In this interaction, the non-human actor, the Bristol board, becomes the center of the network instead of the group of students. It exerts force upon them and subordinates them. The students are busy with making a material product, which alienates their actions. We define such a network in which some human actors are subordinated as a non-dialogic network. After five minutes of designing the board, a student suddenly asked her friends' opinion on mandatory vaccination. This discussion went on for a few minutes only, as another student interrupted it to request the group to focus on an organizational task.

Table 2

Excerpt 2

76	s5	Girls, do you support mandatory vaccination?
77	s4	No
78	s1	No
79	s2	Yes
84	s5	I support vaccinations, but I don't think it should be mandatory.
85	s4	I don't think it should be mandatory because in the end, come on, someone that doesn't want to [be vaccinated] it is his problem.
86	s5	No, it is not only his problem.
87	s6	All the people with cancer and babies [that cannot get vaccinated]. **[88-146] the argumentative discussion continues**
147	s2	In the end, [he has a choice] about his health, and I understand that he can infect someone by accident. But the majority of the population, as Lea said, is vaccinated so [abrupted].
148	s1	As you said, who does not get vaccinated, it is his problem; he will get sick.
150	s5	If someone doesn't take care when he has lice, others get infected.

158	s3	First thing, I wanted to say that we have to start working as Rachel [the teacher] said. Stop! You wrinkle it!
181	s2	We should. Let's organize it [the cards on the board].
184	s4	I wanted to say we have to start working and don't say our opinions; otherwise, we will not work.
185	s5	Because our opinions do not matter, just joking.
186	s2	So, let's finish [with saying] the opinions
205	s2	First, we read [the card], and then we need to decide if it is supports or opposes.
206	s5	We don't care about your opinions. Read already!
209	s3	"The Israeli Ministry of Health. Vaccinations are considered a medical breakthrough. They defend against disease…"
210	s1	OK, we got the message. It's pro.

This excerpt demonstrates how easily a network can be dissolved. Students examine the issue and constitute the main actors of a dialogic network up to line 150 (and in fact to line 157, which is not displayed). In line 158, S3 calls her peers to "start working", namely classifying text cards on the axis on the board (158). The board, and the text cards exert their power upon the students, who decide to end their argumentative dialogue: In line 184, s4 suggests to "stop saying their opinions because otherwise, we will not work." In line 185, s5 sarcastically says that "our opinions do not matter." The students obediently read the reasons on text cards and decide if they support or oppose compulsory vaccination. Students' decisions are immediate and do not lead to further discussion. This exposes what Latour termed "a Black Box" - a process when dynamic events and negotiations freeze and become durable. Then it can extend itself to other networks and contexts where it conceals the dynamics and circumstances where it was produced. Paradoxically, when the researchers designed this activity, they intended to promote a dialogue. They assumed reading the text cards would enrich the students' dialogue and open it into new directions. However, this complex process was frozen into compliance to a set of instructions that dissolved the small group network. The classification of the text cards black-box the network, into a material product used in further activities without reference to the network that preceded its production. Therefore, instead of promoting a richer dialogue, the students' interpretation of instructions undermined it and replaced it with a different network where instructions and boards ruled interactions.

2nd example: The contextual character of the formation and dissolution of networks

Like in the first example, the teacher gives instructions in a small class before splitting it into two small groups. The teacher asks one of the students to read a text, which describes a futurist scenario about Genetically altered embryos and its possible consequences, and then says: "What I ask you right now is to split into two groups: supporting and opposing [genetically altered embryos]. You can use the futurist scenario [text to support your position]. Think about what kinds of reasons, supporting and opposing it provides. There are things here that can help you. What I ask you to do is to split into two different groups and write arguments supporting and opposing [genetically altered embryos]". The beginning of the discussion in the group assigned to support genetic

modifications deploys in a dialogic network, in which the students present different reasons, weigh them, and challenge each other.

Table 3

Excerpt 3

4	s1	So, let's think about the reasons. Wait, [are we] support or oppose?
5	s2	support.
15	s2	I have something really good. We can genetically modify children. I am talking about health here. They will not have diseases, so the government will not have to invest in vaccinations and have much more money. Think that one genetic modification [is needed] instead of eighty years of medical treatment.
17	s3	It is written here that it costs a few million dollars.
27	s3	On the one hand, it is good, but on the other hand [disrupted]
28	s4	Many people will lose their jobs.
30	s1	We don't know what will happen fifteen years from now. Maybe many other medications will be found, and perhaps the doctors' community will change. Perhaps we will not need so many doctors and robots will take their place.

The teacher functions as a facilitator of the dialogue (not shown in the protocol). After 15 minutes, a second teacher (T2) joins the conversation and changes its direction:

Table 4

Excerpt 4

130	t2	OK, I would like to ask you something: Who eats fruits? All the fruits we eat today, all food engineering is based on genetic modifications. Wild bananas don’t look like the ones you eat.
144	t2	So, I gave you a piece of information. How does it help you to argue in favor [of genetically altered embryos]?
145	s1	It does not.
146	s2	It really does. If genetically modified fruits come out so tasty. Why shouldn't we?
147	s4	They are so pretty and healthy and good - so we also want to be pretty and smart.
153	t2	You know that one of the opposers' arguments is the fear of technology. Their fear will affect other things. But we can say: it is not frightening; we use it and we even - (interrupted)
154	s1	But we never tried it on humans! Vegetables, fruits, and humans have different genetic structures.
155	t2	Noa, you support [your group is supposed to support genetically altered embryos].

 © ISLS

156 s1 I am against it!

157 t2 You should [interrupted].

158 s3 Noa, write that all fruits are [genetically] modified yet we eat them.

159 s1 I wrote [it].

This excerpt demonstrates the unexpectedness of a network in educational dialogues. T2's interventions in lines 130 and 144 were intended to refute critiques about genetic engineering based on a comparison of human and food genetic engineering, ineluctably leading the students to conclude that people should not fear genetic engineering. One might expect that this move would reduce student agency. However, S1's interventions in lines 145, 154 and 156 change power relations: In line 154, S1 challenges T2's position according to which genetic modifications were never experienced on humans' fetuses because humans have a different genetic code than vegetables. She put herself as an equal contributor as the teacher by doing so. Before the teacher joined the discussion, the students constantly examined and challenged each other ideas, and their agency was salient. The students' agency conveyed in their dialectical activity was not altered when T1 appeared (not shown in the excerpt): S1 criticized T1's statement the same way her other students challenged S1's position several minutes earlier. Nevertheless, despite her criticism of T1's statement, she eventually writes T1's challenge on the Bristol board. Her acceptance shows that agency and power should be seen as dynamic effects of relations.

This example shows that roles cannot be prescribed in advance in educational dialogues. Entities, human and non-human, are translated in specific contexts, e.g., changed through to the process of becoming part of a collective network (Latour & Wooglar 1979; Fenwick & Edwards 2010). The role of the teacher, of the students, and other objects emerge from their interactions and assemble in specific networks. The title 'teacher' or 'student' does not convey a pre-given role; it is translated by actions, connections, and changes in a specific network. The second example demonstrates the tension in the process of translation. The teacher acted as an authority that wished to transfer knowledge; however, as she joined an existing discussion where the agency was in the hands of students, S1 did not see her as a source of knowledge but as an interlocutor whose position could be challenged.

Discussion

The use of ANT is not new in educational research. ANT has been used for investigating curricula, policy analysis, and the relations between technology and education (Hamilton, 2012; Wright & Parchoma, 2011). Yet ANT has not been used for contexts of learning in social interaction. The present paper focuses on educational dialogues and capitalizes on ANT to consider dialogues as networks of human and non-human actors who constantly assemble, dissolve and reassemble, and exert force and agency on each other.

Although the analysis of several protocols is not sufficient to validate the usefulness of the ANT methodology in research on educational dialogues, it points at several phenomena that we recurred in further analyses. First, the maintenance of educational dialogues is fragile: They may assemble due to instructional designs and paradoxically dissolve because of these very designs. We showed that the documents, instructions, etc., that these designs generate might play as actors whose agency interrupts the deployment of educational dialogues. More generally, the ANT methodology stresses the central role of inanimate things – Bristol, instructions, texts, and various tools in inhibiting or catalyzing the deployment of dialogues. The ANT

methodology suggests that designers should plan meticulously settings to not impair the flow of educational dialogues. Moreover, we saw that ANT helps identifying black-boxed networks, that are solidify and exert power in further activities as the original process and circumstances of their creation might be ignored.

The use of the ANT methodology enabled us to exemplify how actors do not have fixed pre-determined roles. Instead, this role emerges in specific networks that assemble or dissolve: The role of the teacher or the students varied in the protocols we presented from a peremptory figure to a facilitator of dialogues; students alternatively complied with instructions or opposed the injections of the teacher. We claim that the context of educational dialogues, which is a context of educational change, is characterized by frequent passages, back and forth, between traditional and novel roles. The insights we reached should be backed up in further research, but the examples we presented point at an important role that ANT should play: when the term "dialogue" is overused, this methodology enables to distinguish between dialogic and the non-dialogic in the classroom discourse.

Solidarity in Shifting Lines of Practice: Learning in the Weave of Social Movements

Tanner Vea, Pennsylvania State University, tvea@psu.edu
Joe Curnow, University of Manitoba, joe.curnow@umanitoba.ca

Abstract: While learning sciences researchers have explored forms of solidarity underpinning learning and relations across powered forms of social difference, they have largely not integrated insights from social movements literature. Building with lines of practice theory (Azevedo, 2011, 2013), we analyze ethnographic interviews with animal rights activists to understand how power relations and the felt obligations of privilege shape how individual lines of practice develop within the collective pursuit of justice. We find that individual learners feel the implications of their place in the "weave," as one thread among many, shaping their practice in ways that are neither internal nor external, but fundamentally relational.

As the learning sciences have embraced questions of power, politics, and ethics in recent years, a theme around relationships of solidarity has organically emerged. In analysis of classrooms, of social movements, of extra-curricular activities, and other spaces, we have seen the significance of relationships of solidarity across diverse contexts. This is a promising field of analysis, with much to offer our understandings of who is learning, when, and how, and the emergent work actively addresses racialization and gender as significant relations that must be accounted for. However, across the different analyses, scholars have theorized the relations differently and inconsistently, generating descriptive terminologies steeped in specific contexts. As social movement-attentive/immersed researchers, we read all of these examples as residing under the umbrella of solidarity, yet without attending to the social movement usage or the academic treatments of solidarity that underpin their use.

This additional literature productively supplements learning sciences theorization of relational enactments of solidarity. The learning sciences have long been sensitive to accounts of learning as an interpersonal phenomenon (Vygotsky, 1978), but have often left power relations under-examined (Esmonde, 2017; The Politics of Learning Writing Collective, 2017). Learning research in movements helps correct this, enabling new analyses of collective learning in the form of larger transformation in social structures that movements effect. There is also value in examining how learning transforms individuals within movements and how power inflects that process.

Theories of learning in out-of-school spaces, such as "lines of practice" (Azevedo, 2011, 2013) and "cultural learning pathways" (Bell et al., 2012) can help us bridge these theoretical conversations. We revisit these ideas in the context of more recent work on relationships in politicized learning contexts to build on what they offer for our accounts of individual learning within solidary relations. We seek to orient learning sciences researchers to theories of solidarity in order to anchor the emergent work on relationality in the broader theory and praxis of social movements. We then use the conceptual tools from solidarity studies to analyze the relations of solidarity that show up in our own research in social movements to articulate the messiness of learning in and from relations of solidarity and the contradictions that are inherent to those relationships. We argue that when we examine the learning of individuals as they act on the basis of solidarity in social movements, we can see how their learning is constrained and opened up not only in relation to their own constraints and scopes of possibility, but in the deeply affective ways in which they understand the constraints and scopes of possibility of *others*.

In the sections that follow, we briefly highlight work in the learning sciences that fits under the umbrella of solidarity, and then review social movement theories of solidarity to ground learning sciences work in larger conversations around political organizing across difference. We also bring to bear insights from out-of-school learning and how people develop increasingly sophisticated practice. We then provide an overview of the animal rights activist group Direct Action Everywhere, our data collection, and our methods for analyzing these shifting pathways and possibilities as activists mobilized solidarity frames. We analyze the data from activists reflecting on the solidarity tactics they attempted, tying them to both the theories of solidarity we review, and reading them through the lens of lines of practice. We conclude by arguing that learning in solidarity reveals important insights about the relational and collective nature of individual development.

Solidarity in the learning sciences

Recent work in the learning sciences that has focused on relationships in explicitly politicized learning contexts demonstrates the value of shared experiences in developing solidarity relationships. The Politics of Learning Writing Collective (2017) call to action asked the learning sciences to be in solidarity with community, using research partnerships as an avenue for social change, and sharing the fight against nationalist racial capitalism.

As a call to action, the paper did not articulate what solidarity is or how it enables learning relations, but it emphasized solidarity as an emergent concept that can—and should—underlie learning sciences approaches.

We see evidence of solidarity across many examples of recent work. Uttamchandani's (2021) work on educational intimacy theorizes the relational practices of queer youth as they prefigure spaces of radical inclusion that embody queer politics. Using humor, teasing, self-deprecation, and other interactional practices, these young people focused on building relationships of care which both expressed and enabled their political work. Key to this perspective is the ability of LGBTQ+ youth with a shared basis of experience to prefigure together the relations of justice they wanted to see more broadly. Teeters and Jurow (2018) describe relations of confianza, signifying "commitment, trust, and reliability" forged in intimate spaces. In their work with promotoras in a mostly low-income and Mexican immigrant neighborhood, they examined how relations of confianza enabled expansive forms of learning by laying a relational foundation on which community change could be built. Vea (2020a) examined how friendship forged in shared experiences of community enjoyment in an animal rights collective helped make learning possible through emotional configurations that enabled and sustained new forms of politics. Curnow et al. (2020) argued that relationships based in shared experiences of gendered marginalization within a social movement organization created spaces where snarky critiques of masculinity and mainstream environmentalism led to stronger relationships and stronger political analysis through dialectical and iterative processes. In each of these cases, shared experience was a foundation for political learning and change.

The work of McKinney de Royston, Vakil, and colleagues (McKinney de Royston et al., 2017; Vakil & McKinney de Royston, 2019) both demonstrates the importance of explicitly race-conscious solidarity and the consequences of its absence. McKinney de Royston et al. (2017) found that in a program for Black middle school boys taught by Black men, educators developed an explicitly politicized notion of caring in which academic success and addressing systemic racial inequities was seen as preconditioned on the social-emotional wellbeing of the Black youth and the intentional cultivation of strong instructor-student relationships. Vakil and McKinney de Royston (2019) developed the idea of "politicized trust" as encompassing mutual understanding, respect, and solidarity. Focusing on solidarity as an interactional accomplishment, they found that a lack of politicized trust between a Black/Eritrean student and a white student ultimately limited the possibilities for equity-oriented learning in a multiracial classroom. While in one case, relationships based in shared racialized experience supported an explicitly politicized form of learning, in the other case, a lack of racial and political solidarity interrupted opportunities for learning.

These contributions demonstrate the significance of relationality for shaping learning, and they put politics at the center of those relationships. In attending to marginalized communities, they highlight learning that happens in and through struggle, along with the joy, intimacy, and trust that emerge from those spaces. But these analyses do not draw on the larger body of scholarship around solidarity and the complicated, and often contradictory, relations of power that emerge when people work and learn across difference, especially in cases where people in positions of relative power and privilege are working for and alongside those with less power, while contesting those very power relations they seek to leverage. These messy politics and relationships across difference push learning scientists to bring stronger theories of solidarity into focus alongside conceptual tools for understanding learning, finding new points of synthesis that can strengthen our understandings of both solidarity and learning. To do this, we now turn to the social movement and scholar activist literatures of solidarity to expand the discussion and anchor it in social movement praxis.

Social movement perspectives on solidarity

We focus on theories of solidarity rooted in social movement contexts, many of which are written by scholar-activists embedded in solidarity campaigns, and we note that these applications that stem from the ground are significantly different than the political theories that circulate (Curnow & Helferty 2017). Solidarity is defined as activism in one location—geographical, socio-economic, political—that works to "defend the interests, rights, and identities" of people in other locations (Olesen, 2005; Sundberg, 2007). The central premise of solidarity, from activist perspectives, is that solidarity is defined by its attention to work on behalf of others (Finley-Brook & Hoyt, 2009), though many stress that solidarity is not done on behalf of others—it is not charity. Koopman (2012) argues that the difference between charity and solidarity is foundational: where charity makes no effort to disrupt systems or imbalances of power (it is oriented to helping people navigate existing systems) solidarity is constructed as a process of amplifying voices of marginalized people (Koopman, 2012; Mahrouse, 2014) or standing alongside the oppressed (Brown & Yaffe, 2014; Shohat, 2001). These campaigns are based in shared vision of collective liberation (Finley-Brook & Hoyt, 2009; Hussey & Curnow, 2016; Mahrouse, 2014).

Across the strategies for solidarity, the distinguishing features are a recognition of inequitable power relations and an attempt to prefigure different kinds of relationships. This means that solidarity strategies explicitly attempt to use disparate access to power and privilege as part of their strategic interventions (Koopman 2012;

Mahrouse, 2014). Solidarity campaigns often rely on the participation of people who benefit from structural privilege in current systems working within their own communities to spread understanding of privilege and grow the base of people working to unmake systems of oppression (Finley-Brook & Hoyt, 2009; Hussey & Curnow, 2016; Koopman, 2012), or to strategically focus on advocacy work within their own countries in support of campaigns elsewhere in the world (Finley-Brook & Hoyt, 2009). The research and campaigns framed around solidarity stress that mutual solidarity is possible and is built on resisting systemic power imbalances (Sundberg, 2007). Reviewing this work on various theorizations of solidarity, Curnow and Helferty (2018) argue that the contradictions of solidarity are significant, and that the ideas about using racialized power and privilege to counteract it ultimately rely on and reinforce those very positions of power. They argue that ideas of solidarity are often incommensurable, and that the tensions embedded within solidarity relations, while not resolving anything in a tidy or satisfying way, do work to "remain unreconciled" (Whetung, 2017) and create opportunities for new political formations, both structurally and in practice and consciousness.

For a learning sciences perspective, this body of work demands attention to how individual learners within movements make sense of their own locations relative to power and relative to others alongside whom they are learning. It also suggests the importance of looking closely at how these personalized and other-oriented analyses of power are felt and translated into political and moral obligations to act in specific ways within the overall collective. In order to achieve group goals, individuals acting in solidarity must learn to interpret what the power arrangement means for how their own trajectories of learning *ought to* take shape.

Building on the navigation of "lines" and "pathways"

Learning scientists have demonstrated how power arrangements shape individual learning in out-of-school pursuits. For example, Azevedo's (2011, 2013) concept of "lines of practice" suggests how patterns of interest-driven activity cluster at intersections between individuals' "preferences" and "conditions of practice" in their environment. "Preferences" refer to the "variety of long-term goals, values, and beliefs" that shape a learner's pursuits (Azevedo, 2011, p. 162). They are conceived in individualized and interiorized ways, as "elements in a person's psychology" (p. 163). "Conditions of practice" involve constraints and affordances that shape practice:

> the material infrastructure available to the practitioner (e.g., rocket kits of varied assembly complexity), the immediate circumstances of the hobbyist's life (e.g., the person's socioeconomic status and whether or not he/she has easy access to practice sites), the larger social, cultural and institutional spaces in which the hobby exists (e.g., the availability of hobby stores), and so forth. (p. 163)

Azevedo's research revealed that preferences and conditions of practice were in dynamic interrelationship with one another. They seemed to "cluster" into particular expressions of activity, or "lines of practice" along which the constraints and affordances external to the learner could be attuned in ways that satisfied and extended their preferences. In this way, lines of practice represent "the deep patterns of engagement" of an individual learner's activity over time (p. 163). A line of practice is a particularized and developing form of life that an individual navigates in value-driven and pragmatic ways.

A second navigational metaphor from the literature is "cultural learning pathways," defined as "connected chains of personally consequential activity and sense-making" (Bell et al., 2012, p. 270). These pathways develop over the life course, span diverse settings, and reflect the values that guide the activity of individuals and social groups. Like lines of practice theory, Bell et al. specify that cultural learning pathways are a way to account for the "opportunities and impediments faced by learners" (p. 271). They draw attention to the ways that "individuals and groups arrange or transform the conditions of their own learning in relation to their expectations, interests, concerns, and available resources" (p. 271). Bell et al. focus on acts of coordination that people make between their concerns and the arrangements available to them. As acts of coordination accrete over time, analysis reveals how "people come to participate in specific forms of social practices in increasingly sophisticated and socially coordinated ways" (p. 274). The authors present the notion of "scopes of possibility" to describe the dynamic interplay between learner's actions, the social and material dimensions of place, and the social positions available within settings (p. 277).

In this paper, we build on these ideas by putting them into conversation with social movement theorizations of solidarity and learning sciences literature examining the politicized contexts in which relationships across difference shape the possibilities for learning and social transformation. Learning to be in solidarity entails undertaking personal and other-oriented analyses of power. Learners must conceptually understand how differential access to power, along racialized, class-based, or even species-based lines condition the practices they and others can engage in on the way to social transformation. This conceptual understanding

must be combined with an axiological commitment, involving an emotionally rooted regard for the other, to act in ways that others may not be able. In this way, an individual's line of practice or learning pathway in the context of solidarity, while individually articulated, is always perforated by social others—by what we know and feel of their positions in relations of power, and what we know and feel about how we ought to practice as a result. A solidarity relationship marks the connection between at least two lines of practice, and the ways in which ethical and political commitments shape their trajectories in tandem. Working together in solidarity may counterintuitively require lines of practice to diverge.

Context: Direct Action Everywhere

This research was conducted with Direct Action Everywhere's (DxE) San Francisco Bay Area chapter, the original chapter of an international animal rights network founded in 2012. Organizers reported that by 2017, the chapter had approximately 150 active members. Activists in DxE SF Bay Area were mostly White, though many Asian, Latinx, and Black activists also participated. The group aimed to shift social norms around the use of more-than-human animals through direct action, ultimately working to achieve "total animal liberation." For example, the activists held protests in restaurants and grocery stores. They also conducted "open rescues," using video to document conditions in farm facilities and leaving with sick and injured animals. For DxE, shifting social norms also required politicizing existing vegans within the organization so that they were prepared to take direct action.

While many social movement organizations use solidarity as a coordinating frame, animal rights activism attend to these ideas in a distinctive way. For many of the tactics, motivational frames, and emotional configurations (Vea, 2020b) deployed in animal rights, solidarity is mobilized unconventionally, in that it relies on ideas of cross-species help, rather than a collective liberation approach. However, there are places where mainstream solidarity discourses are visible, as we will explore in the data below. In these places we see solidarity emerge as a strategy and tactic between participants within the DxE community.

Methods

The larger study on which this analysis is based used participant observation and ethnographic interviews to understand how people learned to become animal rights activists and participate in the valued practices of the group. Vea engaged in participant observation with DxE SF Bay Area between December 2014 and May 2015 and between October 2016 and July 2017. Settings included protests, social events, trainings, outreach events, working meetings, and more. Vea wrote fieldnotes (Emerson et al., 2011) which became a primary data source. While analysis of fieldnotes inform the analytical claims, here we focus primarily on ethnographic interviews with current and former DxE activists. Interview participants included 10 women and 10 men, ranging from early-adulthood to middle-age and were majority White, with two identified as Latinx, one as Asian, and one as biracial. Vea asked about personal stories of changing involvement with respect to vegetarianism, veganism, animal rights, and activism activities. Interviews were audio-recorded and transcribed.

To analyze the data, Vea coded the transcripts for privilege, risk, danger, and other concepts that relate to the idea of speakers using their relative power and position to enact change. A parallel track of coding focused on emotion, and how emotion was articulated, made sense of, and cultivated (see Vea, 2020b). These parallel processes of coding help illuminate the ways in which individuals' developing lines of practice were shaped both by a political analysis of where vulnerability resides—and their own position relative to it—and by constructed emotional meanings that attached to their analysis. The coding was conducted iteratively, and the instances from the transcripts shared below are selected for their ability to illustrate the multiple ways solidarity showed up in the data, along with learning around power, emotion, and risk that supported those axiological and tactical choices.

Findings: Lines of practice as threads in the weave

Unlike some other forms of interest-driven learning in out-of-school settings, participation in the practices of DxE carried some embodied and legal risks. In preparation for protests, DxE organizers always reviewed the principles of nonviolence with activists. In addition to being sound strategy, they believed, nonviolence could also help prevent potential confrontations with bystanders from escalating to violence. DxE also assigned police liaisons at most actions. These people were trained to interface with law enforcement, if they were to show up, and all other activists were instructed not to speak with police under any circumstances. Other tactics, such as open rescue—a civil disobedience tactic that included breaking into farms to collect information, bear witness, and remove animals for placement at sanctuaries—involved even more risk. To be trained to take part in open rescue, activists needed to sign a non-disclosure agreement, a measure DxE used to prevent infiltrators from industry groups. Risks were also mitigated through workshops on digital security and how to handle potential police interrogation, for

example, and DxE had a Legal Working Group who examined legal issues behind upcoming actions and who could be called up in case of arrest.

Taking on these risky strategies was often framed through a lens of solidarity. Activists explained that the open rescues and confrontational tactics with people they assumed would not be supportive were a critical way for them to build awareness of the conditions facing more-than-human animals. As with the literature on solidarity, they believed that they had a responsibility to use their relative positions of power in service to the political struggle they engaged. Even as they contested the injustice of these systems (whether it be white supremacy or human supremacy), they intended to leverage those power imbalances strategically. This tension created opportunities to learn and shift their scopes of possibility that are not easily explained in terms of "preferences" and "conditions of practice."

In this section, we introduce excerpts from interviews with three White DxE activists, each of whom were grappling with what their privilege meant for how they should pursue their activist practice. Yet each of them articulated their understanding of privilege and solidarity in different ways. In our analysis, we attend to how each activist developed a line of activist practice in relation to other lines of existence—both human and more-than-human. If a movement was made up of many individuals' developing lines of practice, the movement itself can be seen as a woven fabric that uses all threads within it to reach toward justice.

Daniel: Practicing community protection

In some cases, DxE activists foregrounded human-human power relations in explaining why they were developing their activist practice in particular directions. For example, a young White woman named Daniel explained why she was training to be a police liaison:

> One of the reasons that I want to be a police liaison is to contribute to my community but also because I AM White. I have more privilege, and I feel like, okay, this is a way that I can really exercise my privilege in a way that is going to protect my community. I can physically put my body between police and demonstrators.

In her discussion, Daniel drew on the social-movement-rooted theories of solidarity that demand that people use relative racial privilege to provide safety to other people and to advance political goals through consciously using racial privilege to undermine white supremacy. She centers her racial position as the rationale for her tactical choice and her specific role as a police liaison—the rationale being that police are less likely to brutalize a White person than someone racialized as a person of color.

> It's very stressful, [laugh] and it's scary. It's not something that I ENJOY doing. I don't WANT to talk to police, but it's a role that's needed, and it's one that I can use my privilege to do.

Daniel's line of practice in the role of police liaison is shaped by a sense of duty that emerges from her concern for the conditions of precarity affecting others in her community. She was good friends with many other activists, some of whom were members of communities she understood to be marginalized, and those relationships meant that her understanding of privilege was not just intellectual but deeply felt in her day-to-day work with the group. Daniel acknowledged that emotion could have pushed her in ways that constrained her participation as a police liaison. She found it "stressful" and "scary," but it was nonetheless an obligation for her to take up the role and its practices. In this sense, Daniel's felt freedom, a recognition of her privilege as allowing her range of motion in her activist practice that was not afforded to others, also entailed its own feeling of constraint.

In this example, we see Daniel's "preferences" (Azevedo, 2011) come into direct conflict with other considerations that guide her line of practice as a developing activist. In particular, we see Daniel grappling with how her position within racialized power relations requires her morally and politically to step up to meet the overall needs of DxE's cause. Central to this reasoning is the fact that others in the community cannot practice in the ways she can, due to her privilege, so she feels an obligation to "protect [her] community." Daniel intentionally leveraged whiteness to insulate others from police violence—a strategy rooted in activist solidarity. In performing solidarity in this way, her ethical and tactical choices reflect an understanding of whiteness and white supremacy that is imbued with emotional meaning from her friendships and community ties. Her talk in the interview also demonstrates some of her mixed feelings about this ethical obligation. Her preference would clearly be *not* to develop a line of practice as police liaison. However, in the weave of the movement, some threads have to be on the outer edges. Taking up a position of vulnerability is something, she says, "I can use my privilege to do."

Tamar: Caring enough?

Questions of solidarity, privilege, and responsibility also shaped Tamar's involvement in the campaign, though they reoriented away from Daniel's focus on human-human solidarity across power difference to instead focus on human/more-than-human animal relations. Tamar reflected on her own choices around which tactics she had not engaged in. She focused in particular on open rescue, a tactic that was valued in the community, but which came at higher risk to participants because of the illegal activity. Tamar said:

> I would say I'm definitely still very uncomfortable with the idea of being arrested, for a lot of reasons... both short-term and long-term consequences. And I think there's a lot of pressure in spaces like this where ... I would say I'm probably—out of the most involved people in DxE, I would say I'm probably the only one who has never done an open rescue. I don't know if that's true or not, but—I can think of someone as involved as me who hasn't done open rescue. But in that core circle of people, I'm one of the few people who hasn't, and that's definitely made me feel a lot of pressure, not that anyone is putting on me specifically, but just like, does this mean I don't care about the issue as much as those people who are willing to risk their lives? Am I weak? *Am I not giving up some of my privilege that I should be*? I don't know. It just makes me think a lot of these questions, I guess.

In particular we note how the question of privilege (emphasis ours) animated Tamar's sense-making about what tactics she should be using. The suggestion that to be a good activist, to prove one's dedication, a person had to leverage their privilege and risk arrest on behalf of more-than-human animals is something that Tamar sensed was circulating in DxE, even though she specified that no one "is putting [this pressure] on me specifically." Still, she "fe[lt] a lot of pressure" to develop her line of practice to include open rescue as a moral duty and as a choice that said something about her character and strength of commitment to the cause of animal liberation ("does this mean I don't care about the issue as much as those people who were willing to risk their lives?"). She compared the thread of her practice to others in the weave "in that core circle of people" who were as active as her in DxE. In Tamar's case, we draw attention to the way an axiological commitment to the protection of more-than-human animals was "socially coordinated" (Bell et al., 2012). Tamar was acutely aware of the developing lines of practice of the activists around her in the fabric of DxE, and the normative pressure to use her privilege as human and as a White person served as a condition of practice shaping her development in strongly felt ways.

Tyler: Grateful to go into "hell"

In another interview, Tyler, a White man, also talked about his privilege, explaining how his status made it possible for him to adopt particular tactical repertoires that were considered higher risk, but also higher impact. Like Daniel, he stressed how his positionality made it possible for him to take on tactics with a higher risk of arrest, and he suggested that his privilege shaped his political choices. He said:

> For one it's like a really big privilege to just be able to go and see these places like firsthand? And like I can do it... because I'm a citizen you know, and able-bodied and all those other things that kind of give me this opportunity. And so I feel just like grateful for the chance to go, which it's kind of an odd thing to feel grateful for because it's hell, you know? It's horrible. And I personally don't feel like I've really suffered from what I've seen, you know? But some people have, so I've been lucky to not.

First, we see Tyler adopting the mainstream-in-movements ideas of solidarity, where power and privilege are considered a rationale for taking up specific actions in service to less-powerful others, and in the process implicitly troubling the power relationship even as he relies on it. In particular, he references his citizenship status and ability as factors that give him the "privilege" of seeing farming facilities firsthand. However, we also see Tyler mobilizing the discourse of solidarity in relation to other-than-human animals. It was a privilege in part because drawing close to the embodied site of suffering was valued in this group as a way to uncover and communicate the ethical truth of their cause (Vea, 2019). For Tyler and other DxE activists, farming facilities were "hell," which made the privilege to bear witness to them "an odd thing to feel grateful for." Tyler referenced another form of privilege as well, the privilege to witness and not to suffer "from what [he has] seen." He knew other people who had developed their lines of practice in similar ways to him, also participating in open rescue actions, but who experienced what they regarded as secondary trauma from what they had witnessed. Tyler was aware of how the thread of his practice stood out in relation to the threads of those others, and it allowed him to feel he could make a particularly important contribution to the movement.

There is a distinctive cross-species solidarity being articulated in emergent ways that are specific to animal rights activism, and that extend the frame, which we argue reflects a significant learning accomplishment. Later in the interview, Tyler again expressed his willingness to take on risks of violence and punishment in service to protecting more-than-human lives:

> After watching *Earthlings* [a documentary] and just getting involved I feel like I really appreciated the injustice that animals go through and would be willing to suffer whether that's like go to jail or whatever—risk my life? But— But— So I had that like in me, but I just didn't have an opportunity to like make those risks.

Tyler's politicization exemplifies learning around power and solidarity. In making his choices to engage in tactical repertoires that risk arrest (or even bodily harm), he explicitly troubled dominant power relations where human lives were valued more highly than more-than-human animal lives. He made an axiological commitment to solidarity, in which he used his positionality to work toward animal liberation—and he did this through potentially jeopardizing his privilege. Informing the development of Tyler's line of practice was a felt appreciation of "the injustice that animals go through," a moral and emotional impingement that helped thread his line of practice through the fibers of others in the movement, human and more-than-human.

Conclusions and significance

For members of DxE, practicing solidarity by using their privilege in service to the protection of less structurally-empowered others was an animating tactic and ethic. The idea of taking on risk to serve both human and more-than-human partners drove the tactical decisions, the motivational frames, the emotional configurations, and the ethical foundation of these activists. We see the social movement idea of solidarity extended across forms of human difference such as race and ability, and we can also see the activists grappling with what those forms of difference mean in relation to the species line as a powered form of social difference understudied in the solidarity literature. DxE members wrestled in multiple complex ways with the personal costs of solidarity and their theories of change as they related to power, privilege, and risk.

For the learning sciences, this analysis shifts the focus of solidarity work. Where others in the field have productively considered how relationships of trust, intimacy, and shared politics enable particular learning ecologies, this work elucidates learning processes that at once draw members' individual cognition toward power relations, while also shifting their collective lines of practice. Expanding the analytical power of lines of practice theory through solidarity highlights the ways that individual development of practice is shaped by complex awareness of collective goals for social change (the more just future toward which the collective weave of lines is reaching) and of what other lines of practice in the collective are best positioned to do, according to their place in powered relations such as race, gender, or ability. We see this theoretical intervention as an expansion of lines of practice theory, toward a more rigorous accounting of how individuals' lines of learning and development are always being navigated among the thickly woven lines of others. In our analysis, the understanding activists expressed about their place in the weave was more than a form of declarative knowledge. It was deeply felt as an emotional and axiological obligation to do right, according to the privilege one has. If "preferences" are seen as internal factors and "conditions of practice" are understood as external factors shaping an individual's developing line of practice, the notion of the weave draws our attention to the ultimate impossibility of separating what is internal and external in learning in solidarity. In fact, it is the powered relation between self and others that defined how these activists understood how and why to develop their practice in the ways they did.

There's a clear move from learning scientists to study the learning that is made possible in spaces shaped by solidarity. This move entails an interest in studying the solidarity made possible through learning as well as how people learn about and practice solidarity. Actualizing just social futures is not just about speculation or design work. It requires the right relations between people to carry out the work of acting in solidarity, even when it is difficult, long, and may conflict with some individuals' supposed self-interest. For learning settings beyond social movements, educators and designers should consider whether learning settings make space for relational accountability and solidarity to emerge, or whether they foreclose those possibilities. Researchers should consider whether and how the felt freedom of privilege or the moral impingement of obligation shape individuals' learning and participation. Though the embodied risks may be less severe, all learning is done with others. It matters whether our theorizations are sensitized to what it means to learn amid the weave, or whether they reify the supposedly stable boundaries between individuals. Combining social movement theorizations of solidarity with learning sciences theorizations of interest-driven practice in out-of-school settings helps reveal what people understand about how they are in relation with others in their learning activity, and how those understandings bear on what they can do together in the future. If the learning sciences want to concern themselves with the making

of more just social futures, then we need to understand how people know and feel the obligations of their practice according to their place in the weave of the collective.

Effects of Uncertainty Markers on Metacognitive Group Awareness and Regulation

Anna Radtke, University of Duisburg-Essen, anna.radtke@stud.uni-due.de
Lenka Schnaubert, University of Duisburg-Essen, lenka.schnaubert@uni-due.de

Abstract: Social platforms provide a vast amount of resources for sharing, discussing, and searching for information. Thereby, learners need to monitor their understanding to metacognitively regulate their learning. Awareness of peers' metacognitions can affect individual regulation processes and such information may be communicated through language characteristics. Thus, in our experimental study (N = 214), we examined the effects of uncertainty markers in a social media forum setting on perceptions of uncertainty within the group as well as changes in learners' content-related assumptions, certainty, and learning intention. Results confirmed the influence of uncertainty markers on perceived uncertainty within the group, which in turn affected the learners' changes in assumptions and learning intention via changes in certainty. Further exploratory analyses showed that the effect of perceived group uncertainty on own certainty was stronger for men than for women. This study confirms the intricate nature of individual and social metacognitive processes in online learning.

Metacognitive awareness and learning regulation

Digital learning environments enable location- and time-independent accessibility as well as interactive, individualized, and adaptive learning. Online environments also provide a digital space for collaborative learning, in which learners can work collectively on authentic learning problems and their solutions (e.g., Mäkitalo et al., 2005). Additionally, social media platforms provide a vast amount of resources for sharing, discussing, and searching for information. This extends to wikis and discussion forums (e.g., Heimbuch et al., 2018) or social networking sites (e.g., Tsovaltzi et al., 2015), where users potentially interact with a large number of often unknown users. In these contexts, individual and collaborative learning activities alternate with some learners actively contributing and others mostly consuming the externalized learning processes of others. Thus, like in other individual learning contexts, learners need to make various relevant learning decisions and metacognitively regulate their learning. However, they are also influenced by their social context.

Metacognition is essential for regulating individual and collaborative learning processes (e.g., Salonen et al., 2005) and is understood as "knowledge and cognition about cognitive phenomena" (Flavell, 1979, p. 906). Metacognitive planning, monitoring, and regulation enable learners to productively and reflectively use adequate learning strategies to achieve learning goals. Thereby, metacognitive monitoring of own knowledge and learning plays a central role in metacognitive models of self-regulated learning (e.g., Winne & Hadwin, 1998), as it forms the basis for controlling learning activities (Nelson & Narens, 1990; Thiede et al., 2003) and thus study success (e.g., Thiede, 1999). A learner's assessment of how well they have understood a topic influences whether they consider further learning necessary and this thus may affect their intention to learn (Renner & Renner, 2001; Von der Linden & Roebers, 2006). Metacognitive monitoring of own knowledge may result in experiences of certainty or uncertainty with regard to specific assumptions. Uncertainty can have a motivational effect (Anselme, 2010) and leads to an increase in engagement in learning (Howard-Jones & Demetriou, 2009; Ozcelik et al., 2013). Uncertainty can further increase and guide information-seeking behavior and when learners close perceived gaps within their knowledge, uncertainty is reduced (e.g., Schnaubert & Bodemer, 2016, 2017). Additionally, uncertainty is related to a lack of supporting evidence for specific assumptions (e.g., Gigerenzer et al., 1991; McGarty et al., 1993) and has thus been linked to an increase in changes in assumptions (Schnaubert et al., 2021). From a metacognitive perspective, it thus seems logical that learners may use uncertainty as an indicator for gaps in knowledge and may thus increase their intention to seek further information and learn when uncertain, but that learners uncertain are also more prone to change their assumptions regarding the learning content.

While even in individual digital learning environments, social processes may play an important role for learning (see Schneider et al., 2022), social platforms additionally provide a context for learners to communicate and interact. Awareness information about the social context may severely affect individual learning and also metacognitive regulation (Schnaubert & Bodemer, 2016; Schnaubert et al., 2021). Thus, in addition to individual metacognitions formed through metacognitive monitoring, there are also social metacognitions, which are based on monitoring of knowledge, emotions, and actions of other learning group members (Chiu, 2008). Social metacognitions convey what beliefs the other learners have, what mental and emotional state they are in, and how they envision effective collaboration (Jost et al., 1998). Being aware of others' metacognitions can facilitate

 © ISLS

collaboration processes during collaborative learning (e.g., Dehler et al., 2011; Schnaubert & Bodemer, 2019). Active social metacognitive monitoring may additionally help learners to identify their own cognitive and metacognitive mistakes. By actively engaging with others' metacognitive views and strategies, learners get the opportunity to adjust their own metacognitions (Schnaubert et al., 2021). Because of this, own metacognitive experiences can also be strongly influenced by social processes (Carr & Jessup, 1997). For example, Karabenick (1996) found that the more questions peer-students ask about the learning material, the greater becomes the learners' reported confusion about the content of that material because of perceived uncertainty in a classroom. Thus, monitoring other learners' metacognitions may provide information relevant to judge other learners, their assumptions, or the task at hand and may thus lead to changes in own metacognitive judgments (e.g., Schnaubert et al., 2021). These adjusted judgments may then be used as a basis for metacognitive regulation as frequently observed in individual learning (e.g., Thiede et al., 2003).

To test how awareness of others' metacognitions influences individual metacognitive monitoring and self-regulation, Schnaubert and colleagues presented metacognitive group awareness information to learners in the form of uncertainty ratings of their peers and found learners to converge towards these peers and regulate their learning processes accordingly (Schnaubert & Bodemer, 2016; Schnaubert et al., 2021). While it seems reasonable that learners take their social context into account when regulating learning in digital and social learning environments, these studies presented peer awareness information explicitly and it remains unclear, if the results found may be transferred to learning scenarios void of group awareness tools. In real-life learning contexts, learners rarely judge their certainty and present the information to their peers, but metacognitive processes may be communicated through words, actions, or facial expressions. Thus, it is assumed that learners can build group awareness (i.e., the salient perception of group characteristics; Bodemer & Dehler, 2011) by monitoring social interaction and extracting partner- or group-related information (e.g., Engelmann et al., 2009).

In digital learning environments, uncertainty in own assumptions can be conveyed in textual messages through the use of the co-called uncertainty markers (e.g., Jordan & McDaniel, 2014). These include, for example, interjections used as fillers (e.g., "well…", "so…"), hedges (e.g., "somehow", "perhaps"), but also self-referential phrases (e.g., "as far as I know") and sentences that report mental states reflecting metacognitive awareness of uncertainty like "I am not quite sure" (e.g., Durik et al., 2008; Jordan & McDaniel, 2014). The use of uncertainty markers may thus convey a lack of internal uncertainty associated with lack of knowledge (e.g., Juanchich et al., 2017) and leads to a weakening of the persuasiveness of the presented assumption (e.g., Blankenship & Holtgraves, 2005; Hosman et al., 2002), as uncertainty affects how speakers as sources of information are perceived (e.g., Price & Stone, 2004; Tenney et al., 2011). According to Green (1984), the interlocutor's uncertainty can be identified by three categories of particular expressions: (1) certain frequency adverbs (e.g., "often" or "rarely"), (2) adverbs that convey the psychological uncertainty of the person speaking (e.g., "expected" or "desperate"), and (3) modal verbs and linguistic devices that represent ambiguous uncertainty (e.g., "could" or "maybe"). Further speech or text characteristics (e.g., ellipses ("...") at the end of a sentence) may indicate missing information and be associated with incomplete knowledge or uncertainty. Uncertainty markers that occur in both spoken and written language include also tag questions as well as hypotheticals (if-sentences; e.g., Bernstein, 1962). It can thus be concluded, that various language characteristics may be associated with uncertainty as metacognitive characteristic of the speaker and may influence metacognitive group awareness (i.e., the salient perception of metacognitions of other learners or the group; Schnaubert & Bodemer, 2019).

Based on the above described literature, we assume uncertainty markers in social media posts to affect metacognitive group awareness and thus increase the perceived uncertainty that learners attribute to the social group (H1). It was further established that uncertainty within a group may affect own metacognitive evaluations of certainty (see also Schnaubert et al., 2021) and we thus assume perceived uncertainty within social media posts to reduce the level of certainty of social media consumers (H2). As uncertain learners are more likely to change their assumptions about the learning content (e.g., Schnaubert et al., 2021), we assume perceived uncertainty within a social group to positively affect changes in assumptions via an increase in individual uncertainty (H3). Following the argumentation above, perceived uncertainty within social media posts is further assumed to positively affect the intention to learn by promoting individual uncertainty via an increase in perceived group uncertainty (H4).

While the assumed processes are based on theory and empirical findings concerning general mechanisms of metacognition, differential effects are largely unknown. One characteristic frequently associated with differences in certainty and social perception is gender. While there are several empirical findings that reveal gender-specific differences in metacognitive processes in learning and self-regulation (e.g., Bidjerano, 2005; Zimmerman & Martinez-Pons, 1990), how they are influenced by social aspects of metacognition is unclear. Thus, as a first step, we will additionally exploratively analyze if gender affects how perceptions of uncertainty within a social group affect own metacognitive assumptions (E1).

Methods

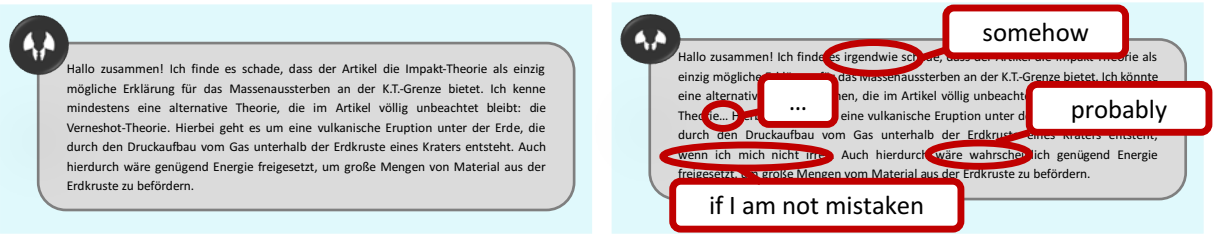
N = 220 participants initially completed the online study (ID: psychmeth_2020_MCSM_06), which was approved by the local ethics committee (vote: 2005PFSA4986). We excluded four participants with a reading speed above 600 words per minute as it can be assumed that they did not engage attentively and with full comprehension of the study content (e.g., Carver, 1990). We also excluded two participants who took a considerably long time to complete the study (> 1h) as this indicates interruptions or off-screen periods. The remaining sample thus consisted of *N* = 214 participants (*n* = 107 in each experimental group). The average completion time of these participants was 14 minutes and 37 seconds (*SD* = 7.35; range: 03:43–36:43 minutes). 133 of the remaining participants (62.1%) were women and 81 men (37.9%). Their age ranged from 18 to 68 years (*M* = 26.88, *SD* = 9.15), 104 had completed secondary school as their highest degree (high school or equivalent: 94 / 43.9%; lower secondary school: 10 / 4%) and 110 had an additional university degree (bachelor: 86 / 40.2%; master: 24 / 11.2%).

Design and procedure

At the beginning of the study, participants were randomly assigned to one of two experimental conditions. The conditions differed in the wording of the forum messages they received during the second reading phase, in which they read a discussion in a forum. One group received text messages with uncertainty markers during the study (UM+) and the other received text messages without markers (UM-) (cf. figure 1). Uncertainty markers were taken from the above described categories and we ensured that the text messages still read natural.

Figure 1

Examples for the uncertainty markers in text massages without UM (left) and with UM (right)



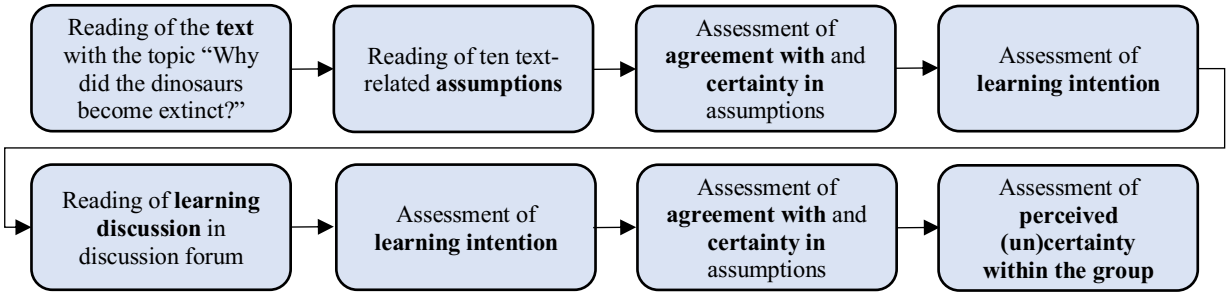
After giving informed consent and answering a number of questionnaires (e.g., self-efficacy, self-monitoring), all participants read a text with the topic "Why did the dinosaurs become extinct?". The text was based on materials from Heimbuch and Bodemer's (2017) adaptation of Buder and Bodemer's (2011) learning material on the extinction of dinosaurs, who used it to study group awareness in wiki-based learning. Subsequently, the participants read ten text-related assumptions (e.g., "The glass spherules around the Chicxulub crater are clear evidence that there was a meteorite impact 65 million years ago.") and expressed their agreement or disagreement with each assumption ("Do you agree with this assumption?"; *yes* vs. *no*). After each of the ten assumptions, the participants were asked about the certainty in their assessment ("How certain are you that your assumption is correct?") on six-point scale from 1 (*not certain at all*) to 6 (*completely certain*) (cf. Schnaubert & Bodemer, 2019). Afterwards, the participants' learning intention was recorded ("Would you like to look at further learning materials on this topic in the future?"). Participants were offered a six-point scale to answer, from 1 (*definitely not*) to 6 (*definitely*). Afterwards, the participants read the discussion in the online forum. The discussion threads each consisted of 14 posts with either 602 (UM-) or 719 (UM+) words. The content of the discussions between the experimental groups was identical, but the messages in the forum of UM+ contained uncertainty markers to convey uncertainty, while the messages in UM- did not (cf. figure 1). Subsequently, the participants were asked again whether they would look at further learning materials on this topic in the future to determine possible changes in their learning intention. Following, the participants had to express their (dis)agreement with the same ten text-related assumptions in the same order again and had to judge their certainty in their assessment. We further assessed the perceived (un)certainty within the learning group by having all participants rate the certainty of the contributors in the discussion forum on a scale from 1 (*not certain at all*) to 6 (*completely certain*) (this measure was later recoded; see below). The procedure is shown in figure 2.

Dependent variables

The dependent variables were calculated as follows: The number of *changes in learning assumptions* was determined by counting the number of assumptions (0 to 10) participants changed from "yes" to "no" or vice versa after reading the forum discussion. A higher value thus indicates more changes. *Changes in learning intention* was operationalized as the difference between learning intention before and after reading the discussion

(-5 to +5). A positive value indicates an increase in learning intention from pre to post while a negative value indicates a decrease. *Changes in own certainty* were calculated as the difference between the average certainty in own assumptions before and after reading the learning discussion (-5 to +5). Positive values indicate participants gaining certainty in their assumptions while negative values indicate losing certainty from pre to post. *Perceived uncertainty within the group* was determined by recoding the perceived certainty score (1 to 6) so that higher numbers indicate perceiving the group as more uncertain while lower numbers indicate perceiving it as certain.

Figure 2
Procedure



Results

Table 1 provides an overview over descriptive statistics of the dependent variables and their intercorrelations. We first tested if uncertainty markers in text messages caused learners to perceive their learning group as more uncertain (H1). A *t*-test for independent samples showed that there was a significant difference in the perceived certainty of the learning group between both experimental groups ($t(212) = 7.58$, $p < .001$, $d = 1.04$), with participants in UM- (without uncertainty markers) perceiving their learning group to be less uncertain and thus more certain ($M = 3.00$, $SD = 1.41$) than participants in UM+ ($M = 4.42$, $SD = 1.33$), supporting H1.

Using the SPSS software PROCESS macro (version 3.5) by Hayes (2017), we conducted simple mediation analyses (PROCESS model 4) to test the direct effect (H2) as well as the mediation hypotheses (H3 and H4). We found a significant total effect of *perceived uncertainty within the group* on *changes in learning assumptions* (ß = 0.22, $p < .001$, 95% CI [.09, .35]; cf. figure 3, left). We also found a significant negative effect of *perceived uncertainty within the group* on *changes in own certainty* (ß = -0.42, $p < .001$, 95% CI [-.55, -.30]), supporting hypothesis H2. Further, we founded a significant negative effect of *changes in own certainty* on *changes in learning assumptions* (ß = 0.32, $p < .001$, 95% CI [.46, .18]). As assumed in hypothesis H3, the analysis thereby revealed a significant indirect effect of *perceived uncertainty within the group* on *changes in learning assumptions* mediated by *changes in own certainty* (effect = 0.13, 95% CI [0.07, 0.22]). We founded no direct effect of *perceived uncertainty within the group* on *changes in learning assumptions* (ß = 0.08, $p = .235$, 95% CI [-.06, .22]) after controlling for the indirect effect. Taking together, the link between *perceived uncertainty within the group* and *changes in learning assumptions* is mediated by *changes in own certainty*.

In order to test the hypothesis H4, we calculated simple mediation analysis with *changes in learning intention* as dependent variable (cf. figure 3, right). We found a significant total effect of *perceived uncertainty within the group* on *changes in learning intention* (ß = 0.29, $p < .001$, 95% CI [.16, .42]). *Changes in own certainty* thereby significantly affected *changes in learning intention* (ß = -.43, $p <. 001$, 95% CI [-.56, -.30]) and there was a significant indirect effect of *perceived uncertainty within the group* on *changes in learning intention* mediated by *changes in own certainty* (effect = 0.18, 95% CI [0.09, 0.29]). *Perceived uncertainty within the group* had no direct effect on *changes in learning intention* after controlling for the indirect effect (ß = .11, $p = .114$, 95% CI [-.03, .24]). Thus, the effect of *perceived uncertainty within the group* on *changes in learning intention* is mediated by the participants' *changes in own certainty*, supporting H4.

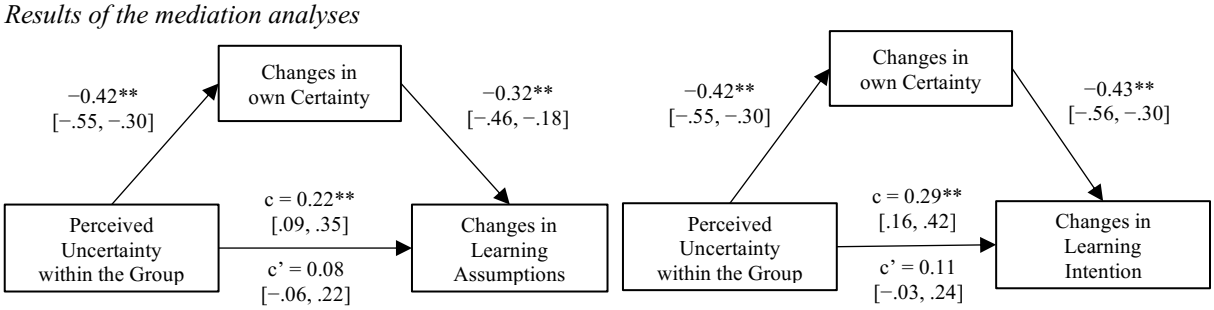
Table 1
Means, standard deviations, and correlations with confidence intervals

Variable	*M*	*SD*	1	2	3
1. Perceived Uncertainty within the Group	3.71	1.54			
2. Changes in own Certainty	-0.03	0.66	-.423** [-.52, -.31]	(−)	
3. Changes in Learning Assumptions	2.14	1.79	.219** [.08, .36]	-.353** [-.47, -.21]	(−)
4. Changes in Learning Intention	-0.11	1.11	.288** [.13, .43]	-.476** [-.62, -.32]	.325** [.18, .46]

Note. $N = 214$; values in square brackets indicate the 95% confidence interval for each coefficient. Two-tailed significance: ** $p < .01$

 © ISLS

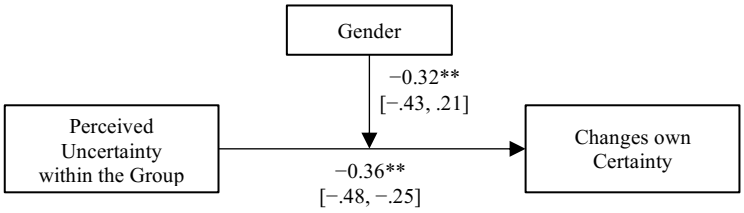
Figure 3
Results of the mediation analyses



Note. c = total effect; c' = direct effect; values in square brackets indicate the 95% confidence interval. Two-tailed significance: ** $p < .01$

Exploratively, the moderating effect of gender on the relationship between the *perceived uncertainty within the group* and *changes in own certainty* was investigated (E1). The moderation analysis showed a significant moderation effect: ß = -0.32, $p < .001$, 95% CI [-.43, -.21] (cf. figure 4). This means that *perceived uncertainty within the group* leads to significantly greater reductions in the men's certainty compared to women's.

Figure 4
Results of the moderation analysis of gender effect



Note. values in square brackets indicate 95% confidence interval. Two-tailed significance: ** $p < .01$.

Table 2 shows gender-specific differences in the *changes in own certainty* depending on different levels of *perceived uncertainty in the group*. For men, being confronted with uncertainty in the group led to a rapid decrease in own certainty, whereas women's certainty remained relatively stable even when perceiving high uncertainty in the group. It thus seems that the dampening effect of uncertainty in a learning group is stronger for men, leading to an overall decrease in certainty when perceiving the group to be uncertain only for men.

Table 2
Gender-specific changes in own certainty depending on perceived uncertainty within the group

perceived uncertainty within the group	changes in own certainty	
	female	male
low	0.281	0.528
neutral	0.166	-0.244
high	0.052	-1.016

Discussion

Taken together, we found uncertainty markers in social media posts to affect how learners perceive the certainty within the learning group. While this seems not surprising, it does mean learners are aware of the textual features and sensitive towards these markers. Further, it seems to have clear implications for the self-regulation of learning as perceived uncertainty within the social group seems to "rub off" on learners. While one would assume learners to become more confident during learning due to actual knowledge gained, overall, confidence seemed to be rather stable overall. However, the higher the perceived uncertainty, the lower this gain was. Furthermore, while women seemed to rather gain confidence under all conditions of perceived uncertainty within the group and rather less affected by the latter, men gained confidence when group uncertainty was judged low, but severely lost confidence in their assumptions when they perceived high uncertainty within the group. Thus, men seem to react stronger to social stimuli than women. This is surprising, as women are traditionally assumed to be more susceptible to social influence (Eagly & Carli, 1981) and better to perceive social stimuli (e.g., Bai et al., 2015), although scientific

results paint a much more pronounced picture. For example, there are indications that men may be more susceptible to social learning (Abdullahi et al., 2019) while other studies found not such effect but personality traits to be the important determinants (Oyibo & Vassileva, 2019). As sample characteristics may be one influencing factor and sample sized did vary between both gender groups in our study, further research needs to replicate found effects to unveil the mechanisms leading to these differences.

As expected, perceived uncertainty within the group also led to more changes in own assumptions and an increase in learning intention. Both effects were mediated by changes in own certainty. The results show that effects found regarding explicitly presented metacognitive awareness information (e.g., Schnaubert & Bodemer, 2016; Schnaubert et al., 2021) are transferable to more implicit markers in communication. This stresses the relevance of understanding the effects social contexts have on metacognitive self-regulation in digital and social learning environments. Further, it shows that language characteristics affect metacognitive group awareness. Linguistic markers are important to understand online communication and knowledge exchange even in anonymous online groups as communication not only contains content-information, but contextual cues used to generate group awareness (see Engelmann et al., 2009), which is also relevant for individual learning processes in digital and social learning environments (e.g., Heimbuch & Bodemer, 2017). While we focused our study on individual effects in social contexts, a logical next step seems to be the transfer to collaborative interaction processes. Apart from effects on metacognitive self-regulation and usage of the information about social metacognition for evaluating and regulating own learning processes, linguistic markers may provide valuable awareness information to appropriately interact with learning partners, for example by focusing on uncertain content (Schnaubert & Bodemer, 2019) or providing explanations to peers (Dehler et al., 2011). The correct interpretation of the metacognitive messages is crucial, as an incorrect interpretation may lead to misunderstandings and emotional conflicts, which could have a counterproductive effect on the learning process (Chiu & Kuo, 2008). Especially on large online learning platforms, when learners often do not know their peers and many communication-related aspects relevant to building group awareness may be unavailable, group awareness tools may be used to support collaboration and knowledge exchange (e.g., Janssen & Bodemer, 2013). However, without such tools, learners need to look for other cues to judge their social context and it is vital to understand how learners gain group awareness in unsupported learning settings (Schnaubert & Bodemer, 2022).

As we used a number of uncertainty markers, further research should look into more subtle differences in linguistic or speech characteristics and may use real online communication to determine the effects of uncertainty markers on metacognitive group awareness and subsequent effects on metacognitive monitoring and learning regulation in real online learning scenarios. Integrating this research with language technology to detect further uncertainty markers and estimate their effect on uncertainty perception (e.g., Pon-Barry & Shieber, 2011) would provide further insights into (social) metacognitive processes in digital and social learning environments.

The Way to Better Learning Online: Using Online Discussions in College Classes During COVID-19

Jaeseo Lim, Ji Won Yang, Junho Lee, and Jooyong Park
jaeseolim, yangji921, smbslt3, jooypark@snu.ac.kr
Seoul National University

Abstract: In recent years, a large body of evidence demonstrates that active learning through engaging college students in a discussion leads to increased learning outcomes. However, more empirical studies are needed to understand its effectiveness in online classes. In Experiment 1, students majoring in veterinary medicine were randomly assigned to three conditions: Lecture and Review, Lecture and Discussion, and Self-study and Discussion. Post-test results showed that the two discussion groups achieved significantly higher scores than the review group. Moreover, among the two discussion groups, the self-study group performed better than the lecture group. To reconsider the reliability and generalizability of our study we conducted Experiment 2 in which, we compared the performance of the two discussion conditions again for students majoring in social science. Our findings indicate that not only online discussions but active learning activities such as self-studying before the discussion is also crucial for students' learning.

Introduction

COVID-19 caused substantial confusion around the world, and education was no exception. As a result, educational institutions and schools in many countries have opted for online education (Rose, 2020; Kogan et al., 2020; Daniel, 2020). While the concept of online learning differs within researchers, it exists in various formats, such as, e-learning, web-based learning, cyber learning, distance learning, or mobile learning (Jacobson, 2004; Khan, 2005). Nevertheless, most online education consists of pre-recorded one-way style lectures shared by the instructors.

Growing bodies of studies show that the benefits of active learning move beyond those of one-way traditional lectures (Yannier et al., 2021). In particular, interacting with peers through discussions facilitates students' learning. According to the ICAP theory of cognitive engagement, collaborative dialogue through discussions often promotes greater learning than studying alone (Chi, 2009, 2021). However, although there is ample evidence that discussion facilitates students' learning, giving a lecture is a commonly used instructional method throughout the undergraduate curriculum (Lim et al., 2018; Stains et al., 2018). It is also difficult to find research comparing activities that come before and after the discussion, and even, the effect of active online learning activities has not been examined enough.

The present study compared the learning effects of reviewing study materials with those of discussions. We also compared two different pre-discussion activities, watching a lecture and self-studying. Additionally, through two experiments from two different majors, we can also pave the way for instructors who practice online discussions to promote better active learning online during and after COVID-19.

Literature Review

Pedagogical framework

Passive learning often refers to a teacher-centered instructional method. An example of passive learning is where students listen and watch teachers' didactic lectures. Chi (2009) posits that when students watch a lecture without any manipulation of the learning material, this is regarded passive (learning). Traditional lectures are lectures that are not effective in encouraging learners' discussions and acquiring deeper comprehension (Bligh, 1998). Therefore, it is possible that teachers wrongly believe that their lectures can draw students' attention, promote their motivation, and increase learning outcomes.

Although there is ample research on the limitation of passive learning, most classes are still composed of didactic lecturing (Stains et al., 2018). Wieman and Perkins (2005) emphasize that lectures deliver too much information and knowledge to students, while they do not understand much of it. In particular, STEM subjects still seem to be predominated by lectures (Stains et al., 2018). Stains and colleagues analyzed observation data

 © ISLS

from about 2,000 classes taught by more than 500 STEM faculty members. Their findings indicate that lecturing (i.e., teacher-centered learning) is pervasive in STEM courses. Likewise, Freeman et al. (2014) conducted a meta-analysis comparing students' academic performances in traditional lecture-centered classes to those who took active learning classes in the field of STEM. The results showed that active classes bring about higher scores and lower drop and failure rates compared to traditional lectures.

In accordance with previous studies indicating the limitations of lectures and passive learning, various alternative instructional methods have been explored (Mayer & Alexander, 2017; Chi & Wyle, 2014). Among the various definitions of active learning, Chi and Wyle (2014) classified active learning using Interactive-Constructive-Active-Passive (ICAP) modes. The ICAP framework is based on students' behaviors of engagement. Not surprisingly, the order of the modes (I > C > A > P) matches the order of students' learning outcomes. In detail, the *P mode* includes learning that happens when students sit in traditional lectures. The *A mode* involve activities in which students physically manipulate learning materials such as highlighting. The *C mode* refers to situations where students add new information to the given learning materials on their own, such as drawing a concept-map, or asking a question. Lastly, the *I mode* occurs when two or more students in *C mode* collaborate with each other. A representative example would be discussions that occur among students in class.

Schwartz and Bransford (1998) focused on preliminary activities that comes before lectures. Schwartz and Bransford showed that the learning effect of lectures differs depending on what learning activities were conducted in advance. They experimented three groups to prove their point. Group 1 simply summarized the learning materials and then listened to the lectures; group 2 analyzed the learning materials twice; finally, group 3 analyzed the learning materials and listened to the lectures. As a result, there were no significant differences in the recognition test, but group 3 had the highest score on the transfer test. Thus, even if instructors give a lecture, the learning effect varies depending on what and how students do before and after learning.

Therefore, we adopted the framework of Schwartz and Bransford (1999) and Chi and Wyle (2014). We conducted an experiment to compare the learning outcomes between a group that simply reviews the material after a lecture, a group that discusses the material with each other after the lecture, and a group that discusses after self-studying.

Peer discussions in classes

As an alternative to traditional lectures, researchers have claimed discussion as a promising instructional method (Almasi & Garas-York, 2014). Although students learn better or best when they are active, and engaged (Yannier et al., 2021), discussions are still rarely used in most classes (Walsh & Sattes, 2015). Specifically, even though students who participated in the discussion recognize that it helps themlearn and understand, discussions are rarely used in educational settings (Alvermann et al., 1996; Almasi et al., 2001). What is worse, discussion occurs as merely a post-reading event in which the teacher assists and intervenes students' interactions. This type of discussion is referred to as a teacher-led discussion or structured discussion. In a teacher-led discussion, teachers play a central role by starting the discussion, by asking a question and putting their opinions forward. In other words, the Initiate-Response-Evaluate (IRE) structure of discourse is dominantly used by the teacher in a teacher-led classroom (Cazden, 1986; Mehan 1979). Many teachers in teacher-led discussions wait less for students to respond and provide feedback authoritatively. Thus, students in teacher-led discussions often choose to remain passive (Good et al., 1987).

However, not all teacher-led discussions have only negative effects. Wolf et al. (2005) investigated the relationship between the quality of talk and reading comprehension. Twenty-one reading comprehension lessons in ten schools were examined. Results showed that student talk was predictors of knowledge sharing during the lessons. Also, the type of teacher's question was important for students' learning, where open-ended questions and follow-up probes were most effective.

McIntyre et al. (2006) also investigated the effect of teacher's scaffolding during students' discussions. They analyzed data from classroom observations, videos, and interviews. Their results indicated that teacher discourse can lead to students' engagement in interaction, facilitate students' participation and help bring them into the discussions.

Even still many researchers posit that student-centered discussion (i.e., peer discussion or unstructured discussion) are more effective than teacher-led discussion (Almasi, 1995; Hogan et al. 1999; Many & Wisman, 1992). Wilson et al. (1984) contended that discussions occur when a student deliberately initiate a talk with peers with a definite topic or goal in mind. For example, Almasi (1995) compared the effects of teacher-led discussions and those of student-led discussions. As a result, students in peer discussion were able to internalize their ability to recognize and resolve conflicts better than students in teacher-led discussions. Students in students-led discussion were also able to learn to think critically and retrieve argument-relevant information as they learn the principles of argumentative reasoning during peer discussions.

However, related research above has mainly focused on young children's literacy skills generalized in expository text. In the present study, we expanded on previous works and observed various aspects of unstructured discussions in college students. In particular, we investigated college students' academic achievements when they learned the contents of the textbook through discussions in actual classroom settings.

We conducted our research in online classes. With the demands of the times due to COVID-19 and the advent of online learning methodologies and technologies, educational stakeholders are actively utilizing effective e-learning methods. In this study, we investigated whether online discussion has a greater learning effect than other traditional instructions, and what pre-discussion activities maximize the effect of peer discussions. All in all, we compared the learning effects of three learning (experimental) conditions: Lecture Review (LR); Lecture Discussion (LD); and Self-study Discussion (SD), representing the combination of learning activities conducted by students, respectively. Based on the ICAP framework, we predicted that students in the two discussion groups would show greater learning achievement than those in the review group (LD, and SD > LR). In addition, compared to those who listened to a lecture, which is a relatively passive learning activity, we expected that the students who self-studied prior to the discussion would also show higher learning gains (SD > LD).

Experiment 1

Experiment 1 investigated the learning effect of the peer discussion activity itself, and the effect of different prior learning activities before the discussion. In this experiment, veterinary medical students were randomly assigned to three groups: LR, LD, and SD conditions.

Participants

All experiments were reviewed and approved by the university Institutional Review Board. Eighty-five undergraduate students majoring in veterinary medicine participated in this experiment (N = 85, female = 39). Students were randomly assigned to three groups: LR (n = 7), LD (n = 20), and SD (n = 18) conditions. There were no significant differences in age and gender between groups.

Materials

A monologue-style video clip was used as the lecture video in this experiment. The lecture video was from an actual lecture clip uploaded on the Internet for open use. The learning topic covered in this experiment was chemistry, specifically sections concerning covalent bonds. The topic was basic knowledge for veterinary medical students. We tried to secure the ecological validity of the learning material and made sure all veterinary students learned chemistry in their undergraduate curricula. A six-page lecture note was written based on the video clip which was used for self-study during the experiment.

The final test was comprised of transfer type items. Transfer type items were designed to test participants' improvement in transfer of learning which refers to applying learned knowledge from the materials (i.e., lectures and textbooks) to new situations. A total of 12 transfer type items worth 33 points were used.

Procedure

Students filled out a consent form and were given an explanation regarding the procedures. The LR group watched the lecture video for 20 minutes and then studied the six-paged text for 15 minutes. The text was not provided when watching the lecture. The LD group watched the lecture for 20 minutes, and then discussed about what they learned in groups of three for 15 minutes. The SD group studied the text by themselves for 20 minutes, and then had a group discussion of three for 15 minutes. All three groups had the same total amount of learning time. After completing the entire learning process, a 20-minute test was taken.

Results and discussions

The mean values and standard deviations of test scores for transfer type items (i.e., total score) are presented in **Table 1**. We conducted an analysis of covariates (ANCOVA) to examine the difference among the three groups. Age and gender were controlled as covariates. Significant differences were found between the three groups, $F(2, 40) = 7.72$, $P = .001$, partial eta-squared = .279. There were no significant effects of gender and age.

In detail, the LR group (M = 13.86, SD = 4.22) had the lowest score, Ps <.05, but the LD group (M = 18.90, SD = 4.33) and the SD group (M = 20.83, SD = 3.85) showed no significant difference, P = .317.

Table 1

Descriptive statistics of Experiment 1

	LR group (n = 7)	LD group (n = 20)	SD group (n = 18)
Transfer type items	13.86 (4.22)	18.90 (4.33)	20.83 (3.85)

Note. Data are shown as values of mean (standard deviation). LR refers to lecture and review; LD refers to lecture and discussion; and SD refers to self-study and discussion.

In line with our prediction that discussions would enhance students' learning, the results showed the LD group scored significantly higher than the LR group. Therefore, our findings supported the findings from the ICAP framework by Chi and Wylie (2014).

However, although there was a trend between the scores, there was no significant difference between the two discussion groups as expected. The result may be due to a small number of participants. Moreover, the results may be due to the topic of learning which was too familiar to veterinary medical students. Therefore, in Experiment 2, participants were recruited from the college of social sciences who were not familiar to, and had no prior knowledge on the learning contents. We conducted Experiment 2 with only the LD group and the SD group, which did not show a significant difference in Experiment 1.

Experiment 2

Experiment 2 examined the learning effects of having a discussion after different prior learning activities. In this experiment, students from the college of social sciences were recruited and randomly assigned to different two discussion groups (i.e., LD and SD groups).

Participants, learning materials, and procedure

Undergraduate students from the college of social sciences participated in this experiment for course credits. A total of sixty-two students were randomly assigned to two different groups: LD (n = 30) and SD (n = 32) conditions (N = 62, female = 32). There were no significant differences in age and gender between the groups.

Learning materials and experimental procedures were identical to Experiment 1.

Results and discussions

The mean values and standard deviations of final test scores for transfer type items are presented in **Table 2**. We conducted orthogonal planned comparison to examine the difference between the two discussion groups. The results showed that the SD group (M = 17.03, SD = 3.09) scored significantly higher than the LD group (M = 10.67, SD = 3.40), $t(60) = 7.731$, $P < .001$.

Table 2

Descriptive statistics of Experiment 2

	LD group (n = 30)	SD group (n = 32)
Transfer type items	10.67 (3.40)	17.03 (3.09)
Comparison	*t*	*P*
	7.731	< .001

Note. Data are shown as values of mean (standard deviation). LD refers to lecture and discussion; and SD refers to self-study and discussion.

In line with our prediction, the results showed that the SD group outperformed the LD group. Therefore, students' learning achievements varied depending on the type of learning activities before the discussion. The more active the learning activities before the discussion, the greater the outcome students gain through the discussion.

Comparison of Experiment 1 and Experiment 2

 © ISLS

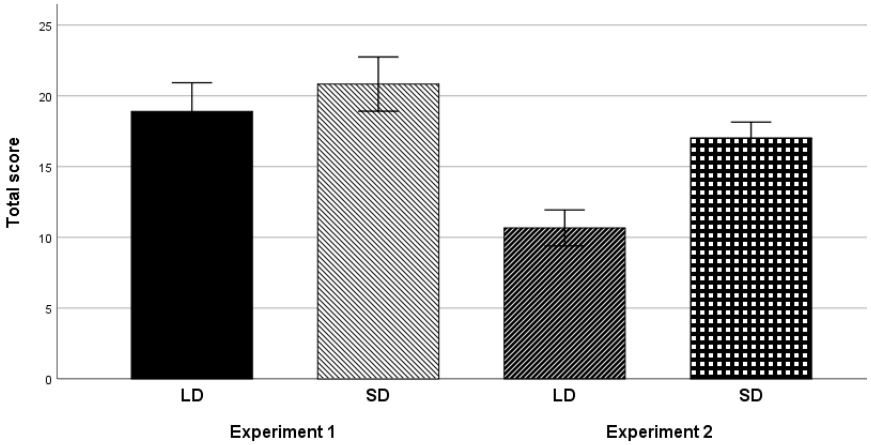
A summary of the results of both experiments is presented in **Figure 1**. In Experiment 1, there was no significant difference between the LD group and the SD group. On the other hand, in Experiment 2, the two discussion groups showed a significant difference.

Specifically, scores of the LD group of Experiment 1 had no significant difference with those of the SD group of Experiment 2, $P = .426$, while the scores were higher than those of the LD group of Experiment 2, $P < .001$. The SD group of Experiment 1 scored significantly higher than the SD group of Experiment 2, $P = .003$. Finally, the LD group of Experiment 2 scored significantly lower than the other three groups, Ps $< .001$.

Therefore, considering that there was no significant difference between the two SD groups across the two experiments, while no significant difference was also observed between the two discussion groups (i.e. LD and SD groups) in Experiment 1, the results may have been affected by the topic of the learning material. Participants in Experiment 1 already had basic understanding in chemistry, a fundamental subject needed to learn veterinary medicine, resulting in no significant difference between the two discussion conditions. However, with participants in Experiment 2 all majoring in social science with no background knowledge on the given topic, experimental results better revealed the effects of different prior activities each conducted by the two discussion groups.

Figure 1

Summary of Experiment 1 and Experiment 2



Note. Data are shown as values of mean (standard deviation). LD refers to lecture and discussion; and SD refers to self-study and discussion. The total score corresponds to scores for transfer type items. Error bars show +/- 2 standard error.

General discussion

The present study investigated whether discussions could be used as an effective instructional method in online learning. Our predictionswere that discussions would promote students' learning than reviewing, which is a more familiar and traditional learning method. Based on Chi and Wyle (2014)'s ICAP framework that showed active learning activities enhanced students' learning outcomes over passive learning, we predicted that self-studying before the discussion would be more effective than listening to a lecture. In other words, we expected that self-study, a relatively more active activity, would increase students' engagement in discussion and its learning effects.

In Experiment 1, we compared students' learning gains between the three learning conditions: Lecture Review (LR), Lecture Discussion (LD), and Self-study Discussion (SD). In line with our prediction based on the proposal by Chi and Wylie and other theoretical frameworks on active learning, discussions increased students' learning gains. The LD group had significantly higher scores than the LR group. However, unlike our initial prediction, there was no significant difference between the two discussion groups, the LD group and the SD group. This result was probably because veterinary medical students had prior knowledge of the contents related to the learning materials. Therefore, in order to increase the reliability and validity of the experiment, we conducted Experiment 2 with students majoring in social science.

In Experiment 2, the LD group and the SD group were compared with other participants majoring in social science. The learning materials and experimental procedures were the same as Experiment 1. The results showed that the scores of the SD group were significantly higher than those of the LD group. Thus, students' learning gains varied depending on the type of learning activities before the discussion. The SD group who self-studied the material before the discussion were involved in a more active learning activity than listening to a lecture as the LD group did, leading to greater achievements.

Our findings denote that discussions indeed enhance students' learning. In addition, its effect on learning varies depending on the type of activities before the discussion. Therefore, educational stakeholders, including teachers, should actively use discussion as a learning tool and provide opportunities and time for students to fully explore the learning materials before the discussion.

Finally, the result of this study suggests that effective online discussions are also possible. As Daniel (2020) suggested, we need to prepare for the upcoming disaster by applying the existing instrumental method to various types of classes (e.g., from offline discussion to online discussion). Now as we reconsider the effectiveness of online education due to COVID-19, our results show the potential and applicability of online discussions in student learning.

Limitations and suggestions

This study is early research for verifying the effect of online discussions, and more research is required in the future. First, the discussions in this study are unstructured, whereas our experiment can be repeated for structured discussions that involve teachers' interventions or for other semi-structured discussions. For example, Lim et al. (2019) used students' questions and summary notes of learning materials during the discussion that(and) added more structure. Therefore, future research should validate the effect of various forms of discussions used for learning.

Second, it is necessary to analyze the contents of the discussion. Future studies need to check how students changed their discussion patterns and contents according to their pre-discussion learning activities. Through more sophisticated dialogue analysis and topic modeling, researchers should be able to find additional evidence on the effectiveness of discussions that differs by what learning activity comes in advance.

Lastly, the long-term effects of discussions must be investigated. This study was conducted as a one-time study, and ended in an hour, but future studies may consider changes and trajectories of learning during discussions through a longer study up to one week or one semester.

How Higher Education Instructors Conceptualize Diversity: A Phenomenographic Study

Nicole A. Suarez, Song Wang, Stacey Brydges, Stanley M. Lo
nasuarez@ucsd.edu, sow004@ucsd.edu, sbrydges@ucsd.edu, smlo@ucsd.edu
University of California San Diego

Abstract: Higher education institutions around the globe have increasingly made the commitment to diversity. Instructors play an integral role in creating inclusive learning environments. Guided by sociopolitical perspectives on learning, we ask: How do higher education instructors conceptualize diversity? How do these conceptions inform curriculum and instruction? Interview data from 30 instructors teaching at minority-serving institutions in the United States revealed three distinct conceptions of diversity defined by variations in five aspects: student identities, intelligence mindset, pedagogical motivation, learning environment, and legitimized membership. The essentialist conception is based on students having inherently determinate traits described by preexisting universal categories. The functionalist conception differentiates students by academic performance. The existentialist conception acknowledges that students have unique experiences that impact the learning process. Our results indicate that while instructors acknowledge different student features and have varying understanding for why diversity is important, some conceptions of diversity do not necessarily suggest an inclusive culture.

Introduction

The United Nations Educational, Scientific and Cultural Organization (UNESCO) has called for higher education institutions around the world to make the commitment to diversity. In an effort to promote inclusion and equity within education systems around the world, UNESCO (2020) called for the recognition and support of all learners who are diverse in "race, social class, ethnicity, religion, gender, sexual orientation, migrant status, and ability" (p. 24). Instructors serve an important role in the diffusion of diversity efforts through their design and implementation of transformed curriculum and cultivation of equitable teaching and learning environments (Kezar et al, 2008). Building the capabilities of and commitment from instructors to do this work often comes in the form of professional development (PD) (Macdonald et al., 2019). Though positive outcomes from such initiatives have been observed (Booker et al., 2016; Dewsbury & Brame, 2019), research continues to document chilly classroom climates and students' negative experiences (Harrison & Tanner, 2018; Súarez-Orozco et al., 2015). A reason for such inconsistencies may be the assumption that instructor participation in PD programs is the solution to improving classroom climate. Professional learning does not take place in a vacuum, and the usual focus of PD programs on instructor teaching practices overlooks the importance of the meaning instructors ascribe to student diversity (Amundsen & Wilson, 2012).

The need to investigate how instructors conceptualize diversity rests on the assumption that how one conceives of the world informs the approaches they take and the practices they employ (Pratt, 1992). Previous literature has demonstrated that instructors' conceptions of teaching are likely aligned with the approaches they adopt and the practices they implement; thus, any changes in conceptions will lead to observable changes in approaches and practice (Ho et al., 2001). Empirical research spanning decades has reported on different approaches and practices instructors have used in response to student diversity. Three pedagogical approaches have been broadly described: (a) the *ignore* approach, where instructors do not respond to student diversity; (b) the *compensate* approach, where instructors accommodate for students' diversity; and (c) the *utilize* approach, where instructors recognize student diversity as an enhancement to the learning environment (Boelens, 2018; Gordon et al., 2010). The most notable practice described in the literature is microaggressions (e.g. derogatory statements and invalidations (Sue et al., 2007)) perpetrated by instructors towards students. These often racial and gendered comments are a main contributing factor to the unwelcoming climate experienced by students in higher education (Harrison & Tanner, 2018). There still remains a dearth of literature on how instructors conceptualize diversity. Previous publications have discussed diversity as conceptualized through group and individual differences (Gordon, 2010; Jokikokko, 2005) or through external attributes and invisible characteristics (Jokikokko, 2005). Yet, there is also a lack of studies who attempt to connect conceptions of diversity and instructor approaches and practices. Leveraging the newfound traction and discourse surrounding critical consciousness (Freire, 1970) and the social and political ways of understanding education, teaching, and learning

 © ISLS

(Barton & Tan, 2020; González & Moll, 2002; Gutiérrez, 2013; Yosso, 2005), we sought to answer the following research questions: (a) how do instructors conceptualize diversity in higher education? and (b) how do these conceptions inform curriculum and instruction?

Conceptual framework

Phenomenography focuses on the qualitatively different ways that individuals experience, understand, and think about the same phenomenon (Marton, 1981). It is a common theoretical orientation used when examining conceptions (Åkerlind, 2005). The aim of phenomenography is to identify a range of conceptions, rather than describe correct or incorrect ways of thinking (Marton, 1981). Because conceptions are internal constructs, a phenomenon is assumed to be inseparable from an individual's experience. Therefore, phenomenography adopts a subjectivist and relative view of the nature of knowledge, where internal knowledge such as conceptions is dependent on the external reality and ultimately created through human thinking and activity (Svennson, 1997).

This relational nature between conceptions and reality means that a conception, when expressed, emphasizes parts of reality that have been more deeply experienced and thought about by an individual (Lamb et al., 2011). A fundamental assumption of phenomenography is that while conceptions holistically represent characteristics of a phenomenon, they can also be described compartmentally in terms of their reduced parts (Svennson, 1997). These reduced parts represent specific features of the phenomenon and are known as aspects (Marton & Booth, 1997). Variation theory within phenomenography further formalizes such awareness and relationship into an outcome space, which organizes the set of descriptions that are logically related to one another and reveals the distinctive ways in which individuals conceptualize a phenomenon (Marton et al., 2004).

Methods

Participants

Our study was conducted across multiple two-year and four-year minority-serving institutions (MSI) in California, United States. The instructors who served as participants were recruited from three PD programs. All instructors in our study engaged in their respective PD programs for at least one year. While this convenience sample through the PD programs was likely not representative of faculty at large in higher education, the sampling was also purposeful for the following reasons (Patton, 1990). Instructors who teach at MSIs are more likely to have interacted extensively with students from diverse backgrounds in their classrooms. The instructors also sought support and resources to develop pedagogical knowledge and improve their instructional practices. These specific contextual factors potentially provide information-rich experiences in relation to the phenomenon of diversity.

The sample included 30 instructors: 16 were full-time faculty at four-year MSIs, eight were part-time faculty at four-year MSIs, and six were full-time faculty at two-year MSIs. In terms of racial and ethnic backgrounds,19 instructors identified as White or Caucasian; five as Hispanic, Latina/o/x, or Chicana/o/x; two as Asian or Asian American; two with multiple racial and ethnic identities; and two unknown. In terms of gender, 17 instructors identified as women, 12 as men, and one unknown. In terms of disciplines, 19 instructors were in the natural sciences, eight in the humanities, and three in the social sciences. Each instructor taught a range of courses with a variety in class size and subject matter within their respective disciplines. The inclusion of instructors from different institution types and disciplines provides a more complete sample to draw from in making the outcome space, leading to informative and robust findings.

Data collection and analysis

Instructors were interviewed using a semi-structured protocol designed to explore their conceptions of diversity in relation to teaching and learning in the classroom. The semi-structured interview format allowed instructors the freedom to expand their views while maintaining a focus (Bernard, 1988). Interviews lasted approximately 60 minutes each, and the protocol consisted of six main questions: (1) When you hear the word diversity in relation to higher education, what comes to mind? (2) Was there ever a time in your academic career when you thought about diversity in a different way? How did you think about diversity then? (3) Are there other words that your campus or department use to describe ideas related to diversity? (4) Does student diversity influence how you teach? (5) Does student diversity influence how your students learn? (6) What do students who excel in your course or discipline have in common? What do students who are struggling in your course or discipline have in common? Interviews were audio-recorded, transcribed verbatim, and de-identified before analysis.

The analytical process was organized into three steps. First, two members of the research team developed preliminary codes using contact summary forms and close readings of the transcripts. Conceptual labels were created to describe what each instructor appeared to be attending to when discussing their experiences. At this

time, the research team consisting of all four authors also drew parallels between ideas identified in the interviews and existing constructs in the literature. This comparison served as an iterative process in which the investigative findings influenced the literature reviewed by the researchers, which in turn informed the refinement of data analysis. Second, these initial codes were transformed into conceptual categories by drawing relationships among the different aspects and variations emerging from the data. A constant comparative method (Glaser & Strauss, 1967) was employed to compare descriptions and definitions for each category with those from previously analyzed transcripts. This allowed for the confirmation or disconfirmation of previous conjectures, the guarding against biases, and the maintenance of consistency. Finally, data for each aspect were revisited to further refine and delineate the outcome space, resulting in different conceptions of diversity held by the instructors.

Our research team consisted of diverse perspectives including different nationalities and varying intersections of race, ethnicity, and gender. We used a process of argumentation at all three stages of the analytical process (Schoenfeld, 1992) to come to a consensus regarding the development of the codes, aspects, conceptions, and outcome space. Any disagreements were debated and fully resolved in research team meetings. Engagement in this activity provided a check against personal biases and aided with reliability. Åkerlind (2005) described this process as dialogic reliability in phenomenography, where researchers reach agreement "through discussion and mutual critique of the data and of each researcher's interpretive hypotheses" (p.331).

Findings

Instructors in this study attended to five aspects when conceptualizing diversity: (a) student identities, (b) intelligence mindset, (c) student engagement, (d) pedagogical motivation, and (e) legitimized membership. Based on the variations within each of these aspects, we identified three qualitatively distinct conceptions. The first conception maintains a focus on fixed qualities about groups of students and standards for higher education. Borrowing from the field of philosophy, we term the first conception *essentialist,* as essentialism defines the nature of entities in the world by a set of immutable traits. The second conception centers on student achievement, with students divorced from their context. We call the second conception *functionalist* because the functionalism ideology in philosophy asserts that entities in the world are defined by how well they function within their environments. The third conception, which we designate *existentialist,* foregrounds individual student experiences. In existentialism, individuals are not merely thinking subjects but are acting, feeling, and living humans with stories that extend beyond their immediate environments. We describe how instructors with these three conceptions interpret and enact each of the five aspects in a phenomenographic outcome space (Table 1).

Table 1

Outcome Space for Instructor Conceptions of Diversity

	Essentialist	Functionalist	Existentialist
Student Identities: How an instructor interprets student characteristics	Static: Student traits are permanent	Malleable: Student attributes can adapt to the learning environment	Experiential: Students' lived experiences are inseparable from them as learners
Intelligence mindset: How an instructor perceives student intelligence	Fixed: Intelligence is an innate quality that cannot be changed	Deficit: Expertise in a discipline can be developed over time with resources	Asset: Different experiences can be leveraged as intelligence in learning
Student engagement: How an instructor perceives the impact student diversity has on student engagement	Irrelevant: Student diversity does not contribute to learning	Supporting weaknesses: Students who are more successful can help students who are struggling	Reciprocity: Students can learn from one another's perspectives and unique experiences
Pedagogical motivation: How an instructor perceives their role in teaching diverse students	Equal treatment: Students are regarded equally to maintain fairness	Accommodation: Student deficits should be attended to	Intentional implementation: Student diversity should be engaged in the course
Legitimized membership: How an instructor positions students relative to the implicit classroom norms and structures	Outsiders: Students who cannot conform to instructor expectations do not belong	Guests: An instructor scaffolds learning environment to help students meet expectations	Rightful presence: An instructor centers student knowledge, experiences, and stories

Student identities

Student identities describes how an instructor interprets the characteristics that make students diverse. In the essentialist conception, an instructor views student characteristics as permanent and unchanging or, in other words, *static*. In the functionalist conception, an instructor perceives student characteristics as *malleable* and acknowledges that student differences position certain students better for success than others. In the existentialist conception, an instructor foregrounds the origins of student identities and recognizes these identities as outputs of the *experiential* lived histories of each student.

> *Static (essentialist):* "Linguistic diversity, well, some of my Chinese students have been great in terms of effort. Some of them, I think, never understood a word I said. And I don't know why they're here. So there's diversity of background in that respect."

> *Malleable (functionalist):* "I went, 'Here's a bunch of readings. Let's read and talk about them.' They didn't know what to do. Some had good high school backgrounds, some not up to that. That's always been a challenge. I've always been sympathetic to students. I've tried to make things as accessible as I can."

> *Experiential (existentialist):* "I'm not going to be able to sit with all 200 students and find out what it is about their background that resonate with what they're trying to learn. By background, it might mean the stories their family told, the way they were taught to approach an assignment in high school (…) The fact that they come from different backgrounds and have had different educational opportunities until they walked in the door affects how they learn and whether or not they feel confident or a bit imposter-ish on campus."

Intelligence mindset

Intelligence mindset describes how an instructor perceives student intelligence. In the essentialist conception, an instructor views intelligence as a *fixed*, innate quality of a student that defines their ability to succeed. In the functionalist conception, an instructor views intelligence from a *deficit* perspective as a characteristic that can be developed over time. In the existentialist conception, an instructor values students' *assets* as forms of intelligence.

> *Fixed (essentialist)*: "I was a person who told my students if they did poorly on the test, 'Maybe you should consider changing your major.' I'm basically telling that student, 'You cannot get better than this' and 'You will always do bad on the exams no matter what you do.'"

> *Deficit (functionalist)*: [Referring to students at a two-year institution] "Sometimes I tell my students, 'When I look at you, a lot of you are as motivated and as intelligent as my class at [four-year institution]. But all of you lack the background from age 13 to 18 to study harder. It's the discipline to solve problems.'"

> *Asset (existentialist)*: "You don't want to feel, 'Everyone seems to be getting it but I'm not. I must be dumb.' It's like, 'No, wait. What's your major? A music major? What can you tell us about this?' Including and trying to figure out how everyone can participate, feel like they belong, and are helping."

Student engagement

Student engagement describes how an instructor perceives the impact diversity has on students' interaction with the course content and with one another. In the essentialist conception, an instructor considers student diversity as *irrelevant* to student learning and engagement. In the functionalist conception, student engagement is oriented around how the learning environment can be organized to *support the weaknesses* of certain groups of students. In the existentialist conception, student engagement is characterized by the interpretation that every student possesses a unique combination of knowledge, experiences, and skills; thus, the learning environment should facilitate *reciprocity*, or a sharing of these individual characteristics.

> *Irrelevant (essentialist):* "You're saying that from the student's point of view, does their own diversity influence the way they learn? I wouldn't think so. I think we all learn in similar ways."

Supporting weaknesses (functionalist): "If I give my students group work, that means that there's a group of four but only two people work because the smart kids do all the problems (…) I say, 'After you're done, I'll pick one random person to do the problem.' So then, everybody needs to know it. They need to talk to each other."

Reciprocity (existentialist): "More experiences that students have in and out of the classroom—in terms of working with a diverse student population—is going to help them in the long run. Whether they go to academia or another job, they're going to work with diverse employees. The more they understand how to work with different personalities, mindsets, the more prepared they're going to be to help make a change for the world. (…) It will really benefit them in creating a more meaningful existence in their work or personal life."

Pedagogical motivation

Pedagogical motivation describes how an instructor perceives their role in teaching students from diverse backgrounds. In the essentialist conception, an instructor views a responsibility to attend to the idea of fairness and employ instructional strategies based on *equality*. In the functionalist conception, an instructor recognizes that diversity impacts student circumstances and affects student performance; thus, an instructor should alter instructional strategies to *accommodate* student diversity. In the existentialist conception, an instructor attends to the importance of diversity within the classroom and *intentionally implements* pedagogical strategies and curriculum that fosters thinking and conversations centered around diversity and social justice issues.

Equal treatment (essentialist): "I treat everyone the same. I grade everybody the same. I'm grading based on the quality of their work."

Accommodations (functionalist): "I try my best to have policies in class that make it clear to students that it's okay for them to have other things going on in their lives. I do that by dropping a homework and a quiz without any penalty."

Intentional implementation (existentialist): "I thought, 'Who cares if this class is about mechanics and materials? This is still about humans.' Bringing in some of these conversations into my class. I feel like it's my duty. The first female crash test dummy was just designed. Because we've always used the standard male crash test dummy, women are more likely to be injured and die in car accidents. (…) I showed them this picture, 'Here's the first female crash test dummy. Why is this important? Why do we need to create different crash test dummies?'"

Legitimized membership

Legitimized membership describes how an instructor positions students relative to implicit classroom norms and structures. In the essentialist conception, an instructor considers students as *outsiders* and attends to the lack of skills and abilities that students have. In the functionalist conception, an instructor positions students as *guests* and holds a sense of responsibility to help students navigate the rigorous expectations of higher education. In the existentialist conception, an instructor attends to the *rightful presence* of students in higher education and values the knowledge and experiences that students bring, even if it does not align with existing norms and practices.

Outsiders (essentialist): "My first semester ever, I would teach, then give a midterm, and say, 'We did all these problems and lectures. How come they don't know how to do this?' The first expectation when you teach is everything you say, students should know how to do."

Guests (functionalist): "I put in a ton of scaffolds. (…) I'm like, 'Here's the homework. It's really important you do it every week. Here are the applications, activities, and quizzes.' I do all of that because I think it helps the student diversity—the students that don't know that they need to study every week, right? They might not know how to really do that."

Rightful presence (existentialist): "For an instructor, it should be productively humbling to say, 'I can't know everything about your experiences.' I felt it was important to invite the students into the exploration process and make them feel like they could be experts about it. There's so much about the discourse of academic English and the discourse of higher education that is still couched in a really WASP [White Anglo-Saxon Protestant] way. And if we presume that's the

only way people will display or perform knowledge, then we're cutting people out automatically who don't want to present or speak that way."

Outcome space

All of the instructors interviewed in our study recognized diversity, yet as our findings have shown, there is a wide range of how diversity is understood and manifested (Table 1). The five aspects (student identities, intelligence mindset, student engagement, pedagogical motivation, and legitimized membership) are organized into rows and represent the compartmental characteristics of diversity that instructors attended to. Represented by the columns, we identified the three conceptions (essentialist, functionalist, and existentialist) based on a holistic integration of the aspects around similar philosophical assumptions (Table 1).

In the essentialist conception, an instructor perceives students as having static characteristics and fixed intelligence. Diversity is irrelevant to student learning and engagement. An instructor adopts pedagogical strategies based on equal treatment and meritocracy and positions students as outsiders to higher education. In the functionalist conception, an instructor holds the understanding that students can be functional in higher education with support and resources. Student characteristics are viewed as malleable and student intelligence is perceived from a deficit perspective. An instructor accommodates students' diversity and learning environments are organized so that accomplished students can support those with weaknesses. Students are guests since their presence still requires affirmation and assistance from the structures and authority in higher education. In the existentialist conception, an instructor views individual experiences as the origin for student characteristics and as assets in building upon knowledge and skills. An instructor facilitates reciprocity or exchange between students and takes responsibility for engaging them in discussions about how their experiences and the experiences of others impact their work as scholars in their disciplines. Students are rightfully present and belong in higher education spaces.

Implications

Table 1 can serve as a tool for instructors to reflect on their own beliefs. Such processing offers ways to consider new dimensions of diversity and how it impacts the classroom from both instructor and student perspectives. While the existing literature describes a handful of PD interventions aimed at transforming instructional practices, our outcome space offers a framework to support conceptual change. Given the relationship between conceptions and practices, we argue that PD that incorporates conceptual change can promote the adoption of more targeted practices to foster inclusive classroom climates. While the findings we have articulated from our study do not directly suggest any modes or mechanisms for conceptual change, existing literature has several suggestions.

The first mechanism for conceptual change is based in Relational Cultural Theory (RCT), a paradigm in which individuals grow through their relationships with others (Schwartz, 2019). RCT asserts that meaning and empowerment can be derived by instructors as they connect authentically with their students. In developing greater awareness and understanding of their students' backgrounds, instructors are positioned to recognize aspects of diversity during interactions and curriculum design. Eastman et al. (2019) conducted a case study of an engineering professor and documented the professor's changing understanding of race, privilege, and equity. They noted that the professor's interactions with minoritized students were essential experiences that promoted a change in perspective. While building relationships with students may be an informal practice undertaken by individual instructors, formal interventions can facilitate these interactions. For example, Carballo et al. (2019) reported on a training intervention in which faculty conceptions of disability and inclusive education were transformed towards a more positive understanding of how they could support their students with disabilities. They noted that an important feature of their intervention was that students with disabilities were invited to speak about their experiences at each session.

The second mechanism for conceptual change utilizes the phenomenographic lens. The emphasis on levels of awareness in phenomenography provides a pedagogical framework known as the Pedagogy of Learning (Marton et al. 2004), which allows for "the object of learning to serve as a starting point to explore the conditions that make learning possible" (Wright & Osman, 2018, p. 264). If the goal is for instructors to have and enact upon a deeper understanding of the diversity that exists in their classroom, they must be familiarized with the range of conceptions in order to reflect on their own level of awareness and current conceptions and approaches to diversity (Trigwell et al., 2005; Wright & Osman, 2018). The aspects and conceptions we have outlined in our outcome space should be explicitly presented to instructors as the object of learning. This presentation of contrasting conceptions may enable instructors to reflect on what conception of diversity they currently hold and what conception of diversity they desire to hold. The aspects provide instructors with different angles of diversity to which they should attend. These in turn can be connected to specific approaches and practices. Whether it is

through individual reflection or a formalized PD opportunity, we invite instructors to recognize the power and impact their beliefs and actions have on students.

Using Epistemic Network Analysis to Explore Discourse Patterns across Design Iterations of a Teacher Dashboard

Abstract: Providing high-level support to students on NGSS inquiry practices can be challenging; however, teacher dashboards can help teachers provide just-in-time instruction to students, both in-person and online. Prior work has shown some success with a dashboard that alerts teachers in real time on students' science inquiry difficulties, but teachers differed in their use of the alerts. To further support teachers, we designed a second iteration, in which the alerts included actionable, evidence-based Teacher Inquiry Practice Supports (TIPS), a series of suggested scaffolds that teachers can use to support students on the practices with which they are struggling. In this study, we investigate how the discursive support patterns from one teacher differed when using the dashboard alerts *without* TIPS followed by *with* TIPS. Findings suggest that TIPS influenced how the teacher incorporated different types of support for her students, and further, that the support given varied across different virtual lab stages.

Introduction

With increased efforts to boost national science achievement, 44 states and D.C. have adopted the Next Generation Science Standards (NGSS Lead States 2013; NGSS, henceforth), which outlines core science inquiry practices that, when richly integrated with content, reflect competencies that students need for future success in STEM careers (National Research Council, 2018). However, teachers have found inquiry to be difficult to implement in their science classrooms for many reasons, including: time, space, or material constraints (Lo et al., 2014; Zinger et al., 2020); the lack of authentic, empirically tested resources (Krajcik, et al., 2000; Schneider, et al., 2005); the time-intensive, subjective nature of grading inquiry (Deters, 2005); the arduous burden of grading multiple authentic inquiry assignments (Gobert et al., 2018); and the lack of immediate actionable data for identifying student difficulties (Kuhn, 2005).

Due to these difficulties in teaching *and* assessing inquiry, teachers need real-time, fine-grained data about their students' inquiry competencies that are typically not visible within the constraints of the class (Martinez-Maldonado, et al., 2015). One technological development that can address this need is a dashboard, a monitoring tool that provides data on student performance and progress (Dillenbourg, 2013; Holstein et al., 2019). Alerting dashboards can provide detailed, contextual information to teachers to identify and diagnose students' difficulties and to support students' learning in real time (Roschelle et al., 2017).

Although a number of dashboards consider students' content understanding or collaborative interactions in science (e.g., CK Biology curriculum dashboard; Acosta & Slotta, 2018; WISE dashboard, Matuk et al., 2016; SAIL Smart Space's tablet tool, Tissenbaum & Slotta, 2019), these tools are not designed or technologically-instrumented to gather and analyze students' science inquiry practice competencies emphasized as critical by policy documents such as the Next Generation Science Standards (NGSS, 2013). Furthermore, these science dashboards either do not provide alerts (e.g., Acosta & Slotta, 2018; Matuk et al., 2016) or only provide alerts about activity completion (e.g., Tissenbaum & Slotta, 2019), rather than providing real-time alerts about student difficulties. Thus, for NGSS to be realized, there is a need for alerting dashboards that provide teachers with actionable data about their students' inquiry competencies so that teachers can provide instruction on inquiry practices to students as they work in real-time, when deep learning is optimal (Koedinger & Corbett, 2006).

About Inq-ITS and Inq-Blotter

The Inquiry Intelligent Tutoring System (Inq-ITS) is an intelligent tutoring system platform that uses patented, educational data-mined and knowledge-engineered algorithms (Gobert et al., 2013) to assess students' competencies on key scientific inquiry practices outlined in the Next Generation Science Standards (NGSS, 2013). To better help teachers provide support to students as they are conducting inquiry within the virtual labs in the Inq-ITS environment, a teacher dashboard, called Inq-Blotter, was developed (Gobert et al., 2018). With Inq-Blotter, teachers receive real-time alerts based on the data gathered from the fine-grained automated assessments built into Inq-ITS. In the original design iteration of Inq-Blotter, these alerts provided textual descriptions and visualizations about both individual and whole-class student performance, including information on the activities students completed, progress bars with scores on each of the inquiry practices, and fine-grained data about

 © ISLS

students' difficulties on each of the practices (Gobert et al., 2018). To our knowledge, this is the only dashboard that provides alerts based on rigorous, fine-grained assessment of students' scientific inquiry competencies.

To test this first design iteration of the alerts in Inq-Blotter, Sao Pedro et al. (2019) conducted a randomized controlled study comparing the effects of teacher support elicited by Inq-Blotter with alerts versus without alerts (i.e., no performance data) and found that students supported by a teacher using alerts improved more than students helped by a teacher without alerts. While these alerts were helpful in notifying teachers about the specific ways in which individual students were struggling, additional studies have shown that, when provided with the basic alerts alone, teachers may tend to deliver lower levels of support to students (e.g., telling students which variables to hold constant in an investigation; Dickler et al., 2019, 2021). Although the lower levels of support may help students in the short term, the students who received more sophisticated combinations of high-level inquiry support (e.g., explaining what controlled variables are and why they are important) showed more robust improvement in their inquiry practice performances over time (Dickler et al., 2019, 2021).

Therefore, for the second design iteration of the alerts, we used high-level exemplars of teacher support that were associated with student improvement (Dickler et al., 2019) to develop Teacher Inquiry Practice Supports (TIPS; Adair et al., 2020). Embedded directly into the alerts, TIPS offers suggestions on *how* teachers can provide inquiry support to a student for the specific practice with which they are struggling. Due to its importance for teachers' instruction of NGSS practices, more in-depth research is needed to determine how TIPS influence the types of support that teachers provide when guiding their students' scientific inquiry.

In the present case study, we build on our prior work that used Epistemic Network Analysis (ENA; Shaffer et al., 2016) to examine teacher discourse when using Inq-Blotter (Dickler et al., 2019, 2021). Specifically, we use these same methods to deeply examine the discursive support patterns of one teacher, Mrs. A, and compare the ways in which those patterns change when the Inq-Blotter alerts contain TIPS versus when they do not. In short, we seek to understand: *How do the discursive patterns of support differ when Mrs. A uses the teacher dashboard alerts with TIPS versus without TIPS?*

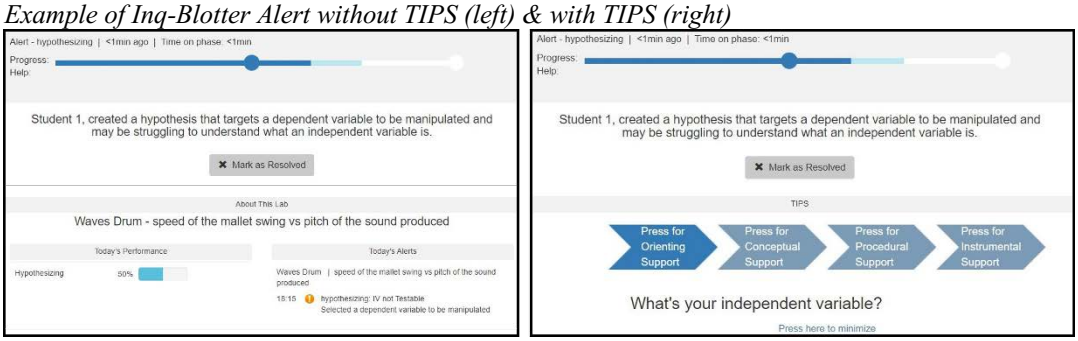
Method

Participants include one teacher, Mrs. A, and her eighth-grade physical science students from a Title 1 middle school located in the Northwestern United States. Mrs. A reported that, of her 157 students, 97% receive free/reduced lunch, 74% are English Language Learners, and 83% identify as students of color. Mrs. A has six years of teaching experience, including five years using Inq-ITS in her classroom. However, she had no experience with Inq-Blotter prior to the data collection days.

Data was collected over two days in January 2021, during which Mrs. A was conducting synchronous classes fully remotely via Zoom due to the COVID-19 pandemic. The school followed an alternating A/B schedule, in which students on "Schedule A" had class with Mrs. A on Tuesdays and Thursdays, while students on "Schedule B" had class with Mrs. A on Wednesdays and Fridays. In total, 65 students logged in and worked on at least one stage of the virtual lab during the two data collection days – 30 students on Day 1 (Tuesday) and 35 *different* students on Day 2 (Wednesday).

Figure 1

Example of Inq-Blotter Alert without TIPS (left) & with TIPS (right)



Materials

The students used Inq-ITS to conduct an NGSS-aligned virtual inquiry investigations on the topic of waves, related to NGSS Performance Expectation MS-PS4-2. The goal of the investigation was to determine how the speed of a mallet striking a drum influences the pitch of the sound produced. As part of the inquiry investigation, the students complete four stages: (1) asking questions/hypothesizing, (2) carrying out investigations/collecting data, (3) analyzing/interpreting data, and (4) constructing explanations/communicating findings. For the first three

stages, students are automatically assessed in real time through algorithms built into Inq-ITS, which then trigger fine-grained alerts for the teacher to view on Inq-Blotter (Gobert et al., 2013, 2018). Development of the automated scoring and dashboard alerts, for the communicating findings stage is still on-going (Li et al., 2017).

On both data collection days, Mrs. A used Inq-Blotter (Gobert et al., 2018) to receive real-time alerts about her students' difficulties on specific inquiry practices as they were working on the lab. Specifically, on Day 1, the teacher used the original version of Inq-Blotter *without* the instructional support of TIPS, and on Day 2, the teacher used the iterated design version of Inq-Blotter *with* the instructional support of TIPS embedded into the alerts (see Figure 1). The TIPS (Teacher Inquiry Practice Supports; Adair et al., 2020) are a series of suggested scaffolds, which were modeled from the supports (Adair et al., 2020) that teachers had generated in real time when responding to the first design iteration of Inq-Blotter alerts and that were shown to improve student inquiry performance in prior studies (Dickler et al., 2019, 2021).

Measures

All teacher-student interactions during the designated class times over the two data collection days were audio-recorded via the video conferencing platform Zoom. Audio recordings were transcribed, and 211 teacher-spoken segments were identified from across the class sessions. A segment was considered a new segment if the teacher: (a) shifted from addressing one individual student to another, or (b) shifted to addressing the whole class rather than an individual student or vice versa. Two researchers coded all teacher-spoken segments, with 86% agreement initially between the researchers. Disagreements were discussed and clarifications to the codebook were made until 100% agreement was reached. The agreed-upon codes were used for analyses.

The codebook included seven types of support (see Table 1) developed and used in prior studies with Inq-Blotter (Dickler et al., 2019, 2021). The first four types of support (orienting, conceptual, procedural, and instrumental) are scaffolds that are implemented specifically in supporting students on inquiry practices, whereas the last three types (scientific content, evaluative, and technical) are not directly related to inquiry support. Codes were not considered mutually exclusive and could co-occur within teacher-spoken segments. Each teacher-spoken segment was also labeled according to the inquiry stage on which the student was being helped. Of the 211 teacher-spoken segments, 113 segments occurred on Day 1 and 98 on Day 2.

Table 1
Types of Teacher Support

Type	Description	Example
Orienting	Direct student attention to components of inquiry practice	"Let's look at your goal"
Conceptual	Explain key terms and components of inquiry practice	"The dependent variable is the thing we're going to measure."
Procedural	Provide guidance on the steps involved with an inquiry practice	"You need to be changing one thing at a time."
Instrumental	Tell exact actions needed to move forward on an inquiry practice	"So, we need to pick the one that says, 'does not support my hypothesis.'"
Scientific Content	Explain information about a scientific concept or phenomenon	"Pitch has to do with how high or low the note sounds to you."
Evaluative	Provide comments on the quality/accuracy of student work	"It looks like you're having some trouble…"
Technical	Help with online challenges (scrolling, screensharing, etc.)	"Oh, will you scroll up a little bit?"

Analysis

First, we addressed whether there were differences in the patterns of support provided by Mrs. A throughout all teacher-spoken segments on Day 1 (when the Inq-Blotter alerts did not include TIPS) versus Day 2 (when the alerts included TIPS). To do so, we compared the proportions of the types of support across the two conditions and conducted chi-squared tests to determine the significance of the associations between the condition (i.e., the presence of TIPS) and the occurrences of the types of support.

Additionally, we conducted an epistemic network analysis (ENA; Shaffer et al., 2016) for all 211 teacher-spoken segments (see "Comprehensive Epistemic Network Analysis" in the Results section). To further understand if and how the discourse patterns differed across the different inquiry stages with TIPS versus no TIPS,

we conducted additional epistemic network analyses to compare how Mrs. A's support patterns differed for each condition on each inquiry stage (i.e., Hypothesizing, Collecting Data, and Analyzing Data).

We created the epistemic network graphs using an online graphical tool (Marquart et al., 2018). In the graphs, the nodes represent the types of teacher support (see Table 1), and the thickness, or strength, of the lines connecting the nodes represents the frequency of co-occurrence between the two types of support. We evaluated the differences between the networks quantitatively using t-tests on the mean centroid values, which are determined by the average strengths of the connections between the types of teacher support in the network, as well as qualitatively by visually comparing the strengths of the connections in the subtracted networks.

Results

Overall, we found that Mrs. A provided her students with different types of support (see Table 1) when TIPS were embedded in the alerts versus when they were not. In particular, the proportions of all four types of inquiry support (orienting, conceptual, procedural, and instrumental) that occurred in the teacher-spoken segments with TIPS (Day 2) *increased* from the proportions of inquiry support that occurred without TIPS (Day 1). A chi-squared test showed that there were significant relationships between the presence of TIPS and the occurrences of the orienting, conceptual, and procedural supports, but not between TIPS conditions and instrumental support. These results suggest that the availability of different types of inquiry support embedded directly into an alert (see Figure 1) helped the teacher to include these supports more frequently in the guidance she provided to her students.

Additionally, there was a significant relationship between the presence of TIPS and the occurrence of evaluative support. One explanation for the increase in evaluative remarks with TIPS (Day 2) is that the teacher referenced the dashboard more, and, as a result, she more often led conversations with individual students by directly commenting on a particular aspect of the practice with which they were struggling (e.g., "It looks like you've been changing a lot of variables") rather than asking the student about their general progress (e.g., "How is it going?"). Although she had access to alerts both days, TIPS may have lessened the acute complexity inherent in addressing frequent and on-going student needs, and in turn, provided pedagogical support for assessment conversations at the boundaries of curriculum, instruction, and assessment (Duschl & Gitomer, 1997).

However, we found no significant association between the condition and the occurrence of scientific content support or technical support. A Fisher's exact test was used to test the relationship between the condition and scientific content support due to the limited number of instances in which the teacher used this type of support. These results are not surprising since the TIPS embedded in the alerts provide suggestions for *inquiry*, rather than scientific content support and are categorized into the four types of inquiry-related support. Also, Mrs. A had five years of teaching experience with Inq-ITS, and the very few instances of scientific content support may have been due to her familiarity with the system and her understanding that the NGSS (2013) emphasizes competencies with the practices that can be transferred across science domains.

Table 2

Proportions of Each Type of Support Occurring in Teacher-Spoken Segments

Type of Support	Without TIPS (N = 113)	With TIPS (N = 98)	Statistics
Orienting	19.5%	35.7%	$X^2(1) = 7.025$, $p = .008$*
Conceptual	8.0%	21.4%	$X^2(1) = 7.801$, $p = .005$*
Procedural	25.7%	46.9%	$X^2(1) = 10.369$, $p = .001$*
Instrumental	23.9%	31.6%	$X^2(1) = 1.577$, $p = .209$
Scientific Content	2.7%	0.0%	$p = .250$, Fisher's exact test
Evaluative	22.1%	40.8%	$X^2(1) = 8.603$, $p = .003$*
Technical	48.7%	51.0%	$X^2(1) = 0.116$, $p = .734$

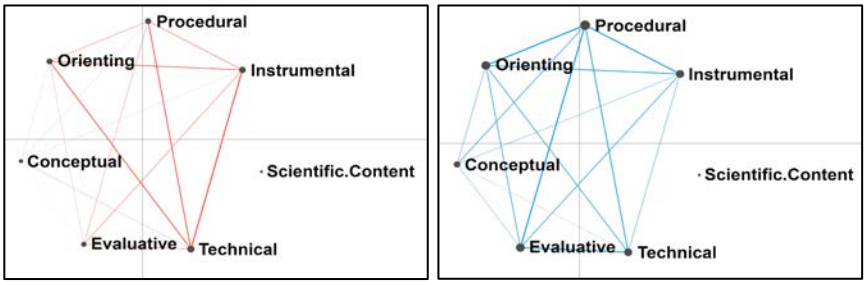
Findings from the Comprehensive Epistemic Network Analysis

We conducted an ENA (Shaffer et al., 2016) to compare how the 112 teacher-spoken segments that occurred on Day 1 (without TIPS) differed from the 98 teacher-spoken segments that occurred on Day 2 (with TIPS) in terms of the types of support provided. When comparing the mean centroid values of the networks (see Figure 2), the ENA revealed a significant difference in Mrs. A's support patterns when she used the alerting dashboard with TIPS ($M = -0.12$, $SD = 0.40$) versus without TIPS ($M = 0.10$, $SD = 0.27$; $t(164.39) = -4.58$, $p < 0.00$, $d = 0.65$).

Moreover, the subtracted networks show that conceptual and procedural supports co-occurred more often with the other types of inquiry support on Day 2 than on Day 1. That is, when responding to alerts with TIPS, the teacher used and integrated more of the different types of *inquiry* support than she did when responding to alerts without TIPS, demonstrating greater complexity of support appropriate for the sophistication of the practices.

Figure 2

Comprehensive Support Networks Day 1 (Without TIPS; red; left) vs. Day 2 (With TIPS; blue; right)



Findings from the Epistemic Network Analyses for Each Inquiry Stage

We also sought to understand how the teacher's support patterns changed depending on the inquiry stage with which the student was being helped. To do this, we identified the teacher-spoken segments associated with each of the four inquiry stages and used the same ENA technique, comparing the teacher-spoken segments that occurred on Day 1 (without TIPS) to the ones that occurred on Day 2 (with TIPS) for each of the four inquiry stages.

For the first three inquiry stages (i.e., Hypothesizing, Collecting Data, and Analyzing Data), the ENA revealed significant differences in the patterns of support provided by the teacher when she had access to alerts with TIPS versus without TIPS (see Table 3) when comparing mean centroid values of the networks (see Figures 3, 4, and 5), indicating that TIPS influenced Mrs. A's pedagogical discourse on Day 2. However, for the last stage (i.e., Communicating Findings), there was *not* a significant difference in the patterns of support provided by the teacher on Day 2 versus Day 1 when comparing the mean centroid values of the networks. Because automated scoring for the Communicating Findings stage is still in development, alerts were not available for this stage. Nonetheless, the teacher may have used a combination of her pedagogical content knowledge for both inquiry (Magnusson et al., 1999) and for communicating findings (McNeill & Knight, 2013) as well as knowledge of the alerts and TIPS from the previous stages to inform the kind of support that she would provide her students on this last stage. Though we do not see a significant difference between the two conditions here, future work is needed to determine if and how the alerting dashboard could further augment teacher support on communicating findings during inquiry, especially given the importance of this inquiry competency.

Table 3

Epistemic Network Analysis on Discursive Support Patterns for each Inquiry Stage

	No TIPS			TIPS			
Inquiry Stage	Mean	SD	N	Mean	SD	N	Statistics
1. Hypothesizing	0.52	0.53	22	-0.45	0.81	25	$t(41.80) = -4.90$, $p = 0$*, $d = 1.39$
2. Collecting Data	0.92	0.37	8	-0.57	1.15	13	$t(15.60) = -4.31$, $p = 0.00$*, $d = 1.58$
3. Analyzing Data	-0.77	1.63	7	1.08	0.92	5	$t(9.67) = 2.50$, $p = 0.03$*, $d = 1.33$
4. Comm. Findings	0.37	0.79	10	-0.28	0.82	13	$t(19.89) = -1.92$, $p = 0.07$, $d = 0.80$

ENA for Inquiry Stage 1: Hypothesizing

For the first inquiry stage (Hypothesizing), an examination of the subtracted networks (see Figure 3) shows a similar change in Mrs. A's discursive patterns as we had seen in the overall networks (see Figure 2), which showed stronger connections between more types of inquiry support when TIPS were embedded in the alerts. For example, when helping a student on the first inquiry stage *without* TIPS in the alerts, Mrs. A said:

> Will you scroll up…so we can see the goal on your screen? [Technical; Orienting] Okay…it says determine how the mallet speed influences the pitch of the sound produced. So first, we're going to look at the mallet speed. And then second, we're going to look at the pitch. [Orienting] So in the first box where it says, "What I Will Change," you're gonna find...the option that says mallet speed [Instrumental]...And then we're gonna see how it influences the pitch of the sound. [Procedural] So then…in the box [where] it says, "What Will Happen," you're gonna find the one that says pitch of the sound. [Instrumental] There you go…Perfect [Evaluative].

In this example, the teacher employs both non-inquiry supports (evaluative and technical) as well as inquiry supports (orienting, procedural, and instrumental). However, the inquiry support focuses on low-level

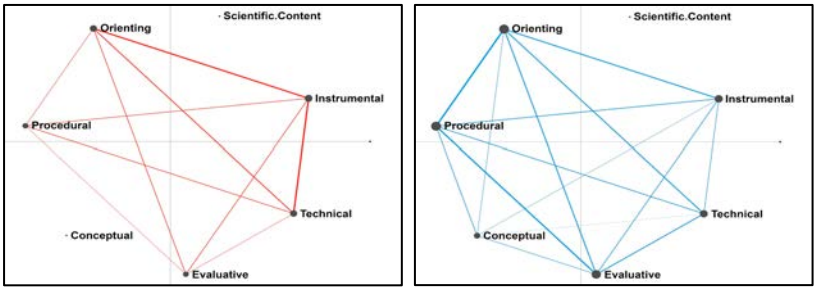
instrumental support, in which the teacher is telling the student exactly what to select in the virtual lab. In contrast, when helping a different student on the same stage but *with* TIPS, Mrs. A said:

> Okay, so let's start by looking at your goal. [Orienting] The goal says determine how the mallet speed influences the pitch of the sound produced. So, in that goal is where you are going to get your independent and your dependent variable. [Procedural] So the independent variable is the thing that you're going to change. [Conceptual] So that's what you're going to click in that "What I Will Change" box [Instrumental]. If you're not sure what's supposed to change, you can look at the goal [Orienting]…usually, the independent variable is listed first. [Procedural]

Instead of telling the student the exact answer as she did in the previous segment, Mrs. A provides a combination of targeted inquiry supports (i.e., orienting, procedural, and conceptual). Moreover, through explaining what an independent variable is, Mrs. A implements a high-level *conceptual* support, which is typically associated with greater student improvement (Dickler et al., 2021).

Figure 3

Stage 1 Support Networks Day 1 (Without TIPS; red; left) vs. Day 2 (With TIPS; blue; right)

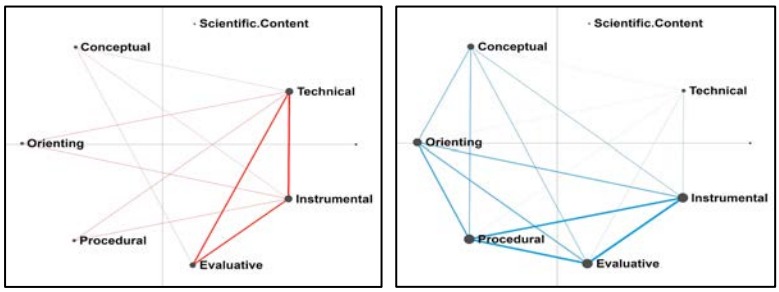


ENA for Inquiry Stage 2: Collecting Data

For the second inquiry stage (i.e., Collecting Data), an examination of the networks (see Figure 4) shows that, on Day 1 (without TIPS), Mrs. A mainly provided support with technical, evaluative, and instrumental components. On Day 2 (with TIPS), we see stronger connections between evaluative, instrumental, and procedural supports, as well as some increased strength in the connections to orienting and conceptual supports. The stronger connections toward the other inquiry support types on Day 2 show that Mrs. A shifted to include more elaborate supports to help students *notice* aspects involved in conducting investigations (i.e., orienting support) and piece together *how* (i.e., procedural support) and *why* (i.e., conceptual support) they should conduct investigations, without providing direct instruction of exactly what to do in the virtual lab (i.e., instrumental support).

Figure 4

Stage 2 Support Networks Day 1 (Without TIPS; red; left) vs. Day 2 (With TIPS; blue; right)

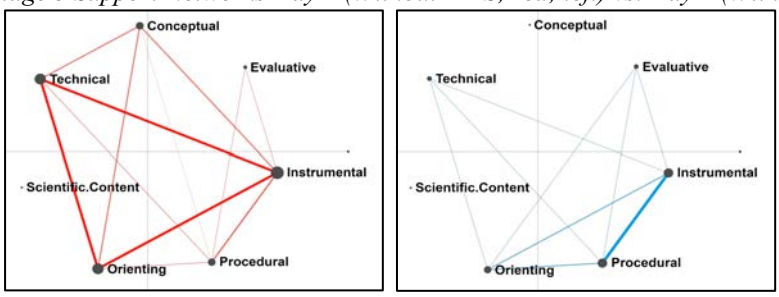


ENA for Inquiry Stage 3: Analyzing Data

Lastly, for the third inquiry stage (i.e., Analyzing Data), an examination of the subtracted networks (see Figure 5) shows that, on Day 1 (without TIPS), Mrs. A mainly provided support with technical, instrumental, and orienting components (similar to the types of support she provided on the previous stages), but she also combined conceptual support into the guidance she provided to her students as well. However, Mrs. A focused primarily on instrumental and procedural support on the analyzing data stage on Day 2 (with TIPS).

Figure 5

Stage 3 Support Networks Day 1 (Without TIPS; red; left) vs. Day 2 (With TIPS; blue; right)



While the shift to include more procedural support when using TIPS is consistent with the shifts that we see in the previous stages (i.e., Hypothesizing and Collecting Data), it is perhaps surprising that no conceptual support occurred in the teacher-spoken segments on Day 2 since we would expect that Mrs. A would use TIPS to implement conceptual support more often for the Analyzing Data stage as she had done for the previous inquiry stages. One explanation is that the teacher had fewer opportunities to provide conceptual support on this stage because several students (approximately 13% of the students on Day 1 and 26% on Day 2) did not reach this stage of the virtual lab. Moreover, the complexity involved with the data analysis stage may have led the teacher to choose certain types of support over others. Further work is needed to determine why a teacher chooses to use certain supports, whether some supports are more effective than others on different inquiry stages, and if and how teachers would incorporate the conceptual support suggestions offered in TIPS when given more opportunities.

Discussion

With the rollout of the NGSS (2013), there is a need for resources that help teachers in assessing and supporting their students' competencies with science inquiry practices (Kuhn, 2005; Pruitt, 2014). Alerting dashboards, when paired with a system like Inq-ITS that is instrumented to provide fine-grained data in real time on students' inquiry difficulties (Gobert et al., 2018), can be helpful to teachers' instruction of NGSS and, in turn, to students' learning of these competencies (Dickler et al., 2019). However, even with fine-grained data about students' difficulties, teachers still may not provide support at the level of sophistication needed to help students improve on the practices (Dickler et al., 2021) without pedagogical guidance in the form of TIPS (Adair et al., 2020).

In this study, we addressed how instructional guidance in the form of TIPS could influence a teacher's pedagogical discourse practices related to science inquiry. We found that, for Mrs. A, a teacher with five years of experience teaching with the virtual lab investigations in Inq-ITS, there was significant evidence of her pedagogical content knowledge for inquiry (Magnusson et al., 1999), since, even without TIPS, she prioritized inquiry support. Nevertheless, she still benefitted from TIPS, as they allowed her to more frequently blend high-level inquiry supports (i.e., conceptual and procedural), which tend to be associated with student improvement on inquiry practices (Dickler et al., 2021). As revealed through the ENA, the more frequent co-occurrences of the high-level supports in the *with*-TIPS condition demonstrates that TIPS helped Mrs. A in growing the sophistication and complexity in her informal formative assessment practices, which are essential for fostering effective scientific inquiry learning (Ruiz-Primo & Furtak, 2006).

This research not only provides a rich example of how iterative design and research-based improvements can improve alerting dashboards, but also furthers understanding of how to support and optimize teachers' use of alerting dashboards. These findings suggest that alerting dashboards, like Inq-Blotter, that include actionable data through real-time alerts as well as instructional support for teachers (such as, in the form of TIPS), have great potential for helping teachers in realizing the vision of the NGSS (2013).

Lastly, since TIPS were modeled from the supports (Adair et al., 2020) that were generated by real teachers in real-time when responding to first design iteration of Inq-Blotter alerts and that were shown to improve student inquiry performance (Dickler et al., 2019, 2021), future work will address if and how teachers' continued usage of TIPS over time supports student improvement on the inquiry practices.

Abstract: Data literacy is important for supporting individuals to incorporate information from research studies into their own perspectives and decision-making processes. However, it can be challenging for students to read, understand, and relate to data. Students have to be able to traverse the representational forms that data takes on (i.e., numerical, graphical, etc.) and connect it to their understanding of a topic. We explore the implementation of a co-designed data-dance unit in which middle school students created their own embodied metaphors to represent and communicate about graphs through dance. In analyzing dance artifacts and post-study interviews with the learners and teachers, we demonstrate how the creation of embodied metaphors in dance led to new ways of exploring the data as learners reflected on different perspectives on topics across numerical values, contexts, and implications.

Introduction

Dance encompasses technical and creative problem-solving practices that center the body. Dance education supports non-verbal expression that packs and unpacks meaning through movement (Hanna, 2008; Koff, 2000). Dance is not just a practice meant for professionals, but a discipline that offers everyone a way of developing "self-expression and interpretation through motion" (Koff, 2000). The unique embodied practices of dance create opportunities to expand the ways that learners can explore and build understanding with and about data. We co-designed a unit that combines math and contemporary dance practices in which learners explored a set of graphs about chosen topics, and developed dances to represent and communicate about their data. We present findings from this experience answering the following research question: ***How did learners engage in embodied meaning-making around data in a contemporary dance and data unit?***

Background Literature

Data Literacy and Data Art

Data literacy has been critiqued for focusing mostly on technical skills with disregard for broader concepts like *citizenship* and *empowerment,* which can exacerbate educational and social inequities (D'Ignazio, 2017). A creative data literacy framing that incorporates art production with data practices can attend to these issues (D'Ignazio, 2017) and help students achieve the same rigor in learning as traditional curricula (Bhargava et al., 2016). In particular, creative data literacy can support students in developing their identities in relation to data (Stornaiuolo, 2019) and seeing themselves as able to "speak data" through creative practices (D'Ignazio, 2017). Bhargava & D'Ignazio (2017), for instance, show that creating data sculptures helped students overcome initial barriers while attending to their complex ideas. Data art has helped students explore the social-situativity of data through developing narratives, argumentation, and perspective taking (Viégas & Wattenberg, 2007). Data sculptures, for example, have helped students develop their contextual understanding of data, connecting data sets to the social setting where it lives (Sauvé et al., 2020) and facilitated students' data interpretation in relation to the social context through the sculptures' ability to embody data using metaphors (Zhao & Moere, 2008).

Embodiment of Mathematical Concepts

Our work takes a grounded cognitive approach (Barsalou, 2010) to explore ways to promote engagement with data. Specifically, we examine how a data-dance context provides opportunities for learners to create embodied metaphors to think about, represent, and communicate about data. Research suggests that the embodiment of mathematical concepts can benefit students' learning of abstract ideas in math (Moerman, 2016; Mickelson & Ju, 2010). Several studies have found a positive link between physical movement and cognitive skills associated with mathematical concepts (Fenyvesi et al., 2019; Namukasa et al., 2007). For instance, work by Rosenfeld (2013)

 © ISLS

supported children in understanding mathematical concepts by building original choreographies. Similarly, Helsa and Hartono (2011) found that traditional dance could support students' understanding of symmetry. Embodied metaphors with dance have the potential to center the body, movement, improvisation and play within our reflective practices (Petsilas et al., 2019). Divergent approaches to data literacy education embrace context-bound inquiry and encourage the challenging of neutral, objective representations of data. In this study, we explore how dancing with and about data can support the understanding of mathematical concepts such as number sense, contextualization of data, and making meaning with data.

Methods

We engaged in co-design with one math and one dance teacher in a public charter school in the Midwestern United States. The teachers taught the data-dance unit to eleven 7th grade students who were in both the math and dance classes. The middle school student population is 65% White, 19% Hispanic, and 6% Black—46% of the student population qualifies for free or reduced lunch. A team of four researchers met every other week with the two teachers for a semester prior to implementation. They created activities to frame different concepts and determine how best to support students in creating a final dance performance integrating data. In the unit, students: (1) picked a topic of interest, (2) interpreted and analyzed data sources on that topic provided by the co-design team, and (3) created a dance in response to the data and their questions grounded in the data. Students performed these dances and presented an artist statement explaining them at an exhibition attended by other students, teachers, parents, and community members.

In the math classroom, students met over three weeks, for a total of six sessions. Topics of these lessons included statistical questions, data visualizations, measures of central tendency, and recognizing/interpreting trends in data. In the dance classroom, students met over 18 weeks (4 sessions per week), with the sessions starting prior to the math sessions. The teacher dedicated the first seven weeks of the semester to introducing contemporary dance and developing contemporary dance techniques with students. In Weeks 8 and 9, students created a smaller scale, collective version of the larger project (interpreting data, creating questions, and developing dances in response). In Weeks 11-18, students independently created, presented, and reflected on their dances developed through an analysis of their graphs. We collected data from five separate project groups that engaged with data on: (1) *Women's Rights*—Emily, Gabby, Amber, Cameron, (2) *Minecraft*—Cory, (3) *Animal Populations*—Irene, Debbie, (4) *Mental Health*—Margaret, and (5) *Social Media and Mental Health*—Will, Brooke, Ashley. Student names used in the analysis are pseudonyms.

Our data include: student group interviews, dance planning materials, and a paired teacher interview. The student group interviews were conducted with each of the five student teams. The dance planning materials were created by each of the student teams and made them connect *claims/supports* from the data to *movements* in their dance. The paired teacher interview was conducted after unit implementation with both the art and math teachers. We engaged in an iterative coding process beginning with open descriptive coding (Saldaña, 2015) that was refined through social moderation (Frederiksen, 1998). For each iteration, conflicts and differences in interpretation were discussed and codes were refined. The codebook was reviewed and checked for clarity with researchers outside of the project team, who discussed the coding of a subset of data.

Findings

In this paper, we focus on one of our analytic themes, ***embodied data characteristics***—*characteristics of the data that students used to create embodied metaphors*. We identified three data characteristics that students used to create embodied metaphors: graph shape & numerical value, data context, and data implications (Table 1).

Table 1
Embodied Data Characteristics Codebook

Graph Shape & Numerical Values	Movements representative of the physical appearance of the graph or the data patterns within the graphs (rate, percentage, or summary of data)
Context	Movements that provide an example of the data points, categories, or attributes.
Implications	Movements representative of what happens as a result of the data

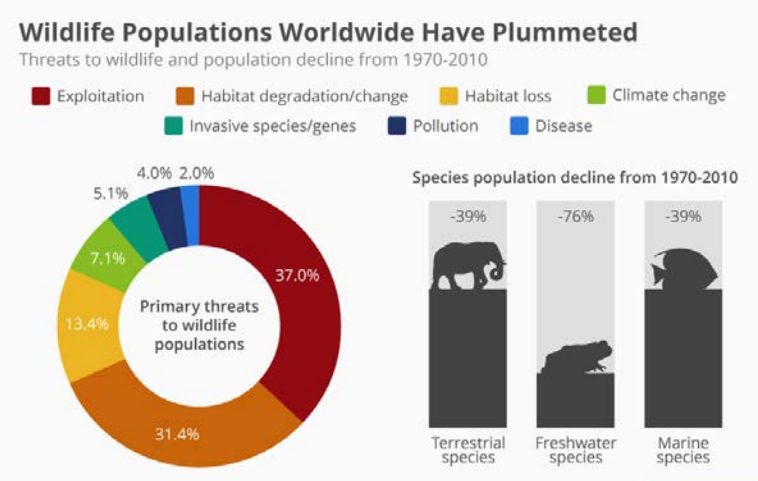
Embodying Graph Shape & Numerical Value

One of the initial activities, students engaged in with their graphs was to explore the shape of a graph through movement, "Like for one day, we would like physically shape out the graphs, like actually show the ups and

downs of it." One student in the animal populations group (Figure 1), explained how this was a useful exercise, "looking at [the graph] at different angles and like even just making its actual shape…really helped us understand how it was going down or up and in what ways we can help fix this...It made us look at the graphs in a different way. Like at all angles to figure out what is the best view we can get of this graph to make movements to help others understand what is happening."

Figure 1

Graph used by the Animal Populations Group (Statista, 2014)



Through examination of the shape the students began thinking about why the graph was the way it was. While this was a starter activity, the final performances often also had some movements where learners were embodying the graph shape or numerical values within the graph. Students would often transpose a dance dynamic, such as levels or body position, onto the value of a data descriptor of a categorical variable that they would embody within the movement. Emily in the women's rights group, for example, describes how her group embodied the different countries (Figure 2) in order to communicate the percentage of women and men who agree that "A woman's most important role is to take care of her home and children" (data in Figure 3): "[They] all came from a sitting position and rise up…representing certain countries…to show like how high the percentage was on the graph…I went from a higher position downward, [to] a really low percentage…we're trying to take the image of the graph into our dancing." Illustrated in Figure 2 are three dancers from the women's rights group (representing the majority from the graph data) rising up from a sitting position, while another dancer (representing North America) goes from standing to sitting. This movement drew the student's attention to what the data values were as well as the differences across categories, as well as changes over time. For example, in the Minecraft dance the student did a dance move where his forearm traced the shape of the data over time, "It is meant to represent the main change in the number of hours watched of Minecraft on Twitch and shape of the graph" (Figure 4).

Embodying the Context of the Data

Most of the movements that students discussed and performed embedded data into a context. At the high level, learners created movements that were literal relationships to their topic, such as Cory doing the robot walk to represent Minecraft. However, the majority of these movements embodied some trait or feature of a categorical variable or data point outside of the numerical value represented in the graph. For example, in the case of Debbie and Irene who created dance sequences that were graceful like a bird or representative of a fish's swimming movements, learners had to examine some aspect of the category beyond what was represented in the graph to create their movement. For example, Debbie and Irene also depicted exploitation:

> **Claim/Support**: One of the first things we noticed on this graph was that exploitation is one of the biggest causes of all of this. Exploitation is in this case when humans take advantage of animals and almost use them, giving nothing in return...
> **Movements**: In our dance we do a trust fall [deliberately falling and trusting someone to catch them] with a very narrow and low drop. This is showing how humans are taking animals for granted

Figure 2
Women's Rights Group performing a routine captured in three frames over time

Figure 3
Graph used by the Women's Rights Group (Facebook, 2021)

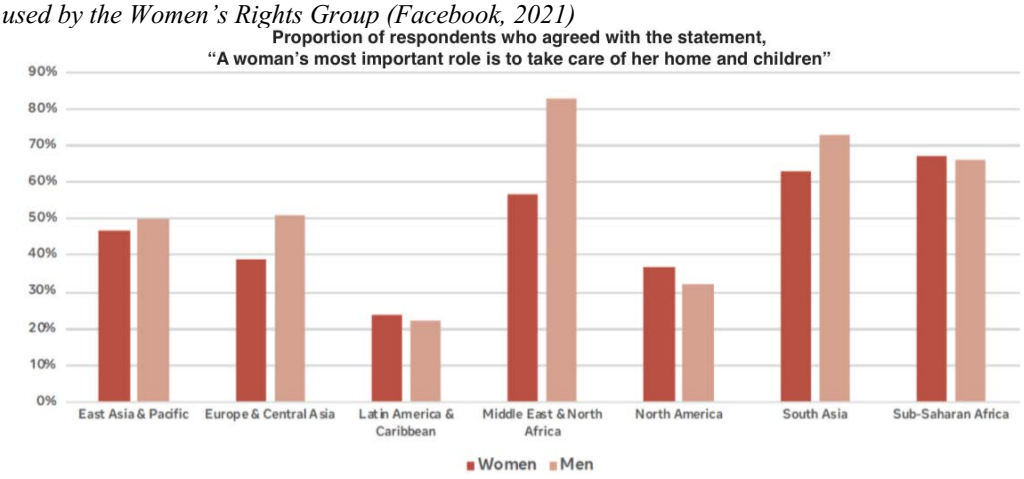


Figure 4
Graph used by Cory focusing on Minecraft (Statista, 2020)

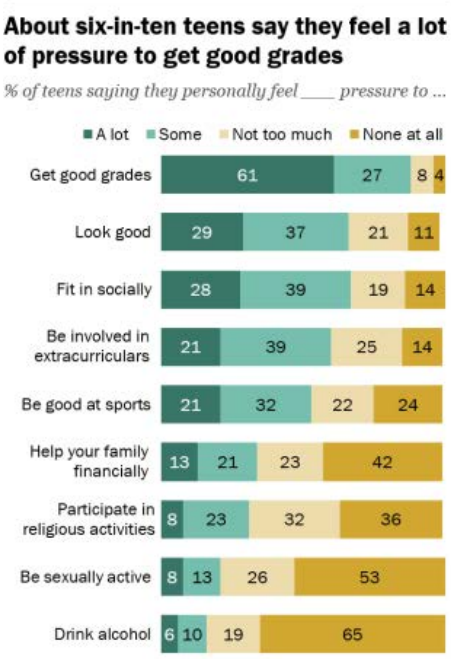
 © ISLS

Similarly, Margaret highlighted how there was a higher percentage of girls receiving treatment for depression than boys. At one point in her dance, she "was looking more through the viewpoint of a girl. And doing those reaching movements helps me like show I was able to get help" (Figure 5b). Students also constructed narratives around the data illustrating how scenarios might play out around the data. For example, the Social Media and Mental Health group outlined a movement using the graph in Figure 5a:

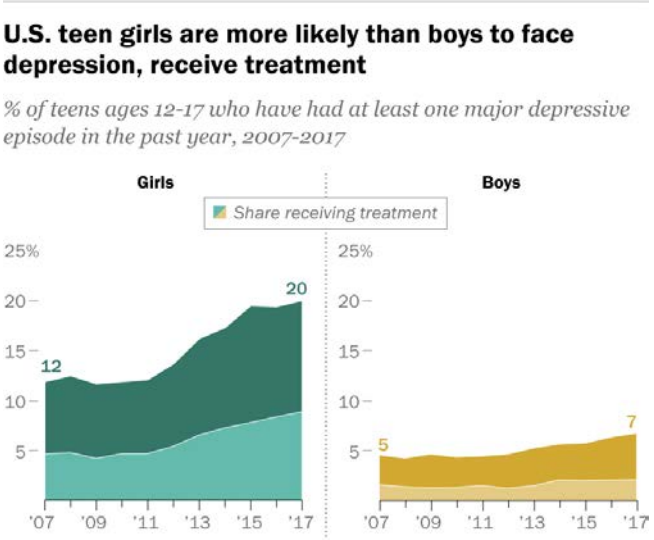
> **Claim/Support**: The main stressor that teens face is related to getting good grades in school. 88% of teens reported feeling at least some stress to get good grades.
> **Movements**: I fall down to represent struggling in school, then I pull back up the rope to represent getting back on track. I do this three times to show the ups and downs that teens face with getting [good grades].

Figure 5

(a) Graph used by the Mental Health and the Social Media and Mental Health group (Pew Research Center, 2018)



(b) Graph used by the Mental Health group (Pew Research Center, 2017)



Embodying Implications of the Data

In some of the movements, students began to explore the implications of the data through their choreography. In the Women's Rights group, their dance highlights what can happen if perceptions of a woman's role are changed,

> **Claim/Support**: While some regions have not changed their perception of what women can do, there are regions who have changed their perception. (The lower bars in North America/Latin America vs the higher bars in the middle east/asia) In those regions, women now take on different careers and have more freedom to work toward what they want to accomplish.
> **Movements**: All four dancers are representing females. We start by doing movements lower and work toward higher levels to show women working up toward their goals over time. All dancers then walk in circles to show different roles women can take if the perception is changed like it has been in…North America and Latin America.

Additionally, students created movements about what an attribute implied about a variable, such as Maragret in the mental health group showing the implications of lgbt youth who were not able to get mental health care,

 © ISLS

Claim/Support: 16% of lgbt youth did not get mental health care because their parents did not allow them to go
Movements: "Shampoo" to express the feeling of being caged in, unable to move

Discussion: Evolving Data Practices with Dance

Dance practices fundamentally changed how learners built knowledge with data, including how they examined, reasoned around, related to, and represented the data. We focus on creation practices and performance practices.

Creation Practices: Data Reasoning through Embodied Metaphors

Learners needed to understand the data in order to translate it into a metaphor with bodily movements. The embodied metaphors covered the spectrum of what Zhao & Moore (2008) describe as the metaphorical distance from the data: these metaphors both drew attention to certain aspects of the data, while also *hiding* other aspects of the data. Part of learners' examination of their data involved embodied exploration of the numerical values and physical characteristics of the graph and the variables represented. They had to think through the values and angles within the graph then translate them into body positions and movements that they then experienced. This process helped students notice particular trends and compare values of categorical variables. This finding aligns with Goldin and Kaput's (2013) assertion that multimodal sensory imagery can help facilitate a *number sense,* which involves understanding the meaning and size of numbers as well as equivalent representations and expressions (McIntosh et al., 1992). In our work, learners were able to draw on the grounded kinesthetic and embodied modalities of dance to experience the data. This has implications for how the learners' number sense of the data is shifted by having to embody the data.

The learners also engaged in what Hanna (2008) calls "concretization" in which dancers reflect outward aspects of a concept through movement. Learners explored different aspects of the variables within the data and characteristics surrounding the data in the real world in order to create movements around it. This was evidenced by their exploration of how a fish moves, roles that women take on, or what exploitation means. *Concretizing* the data encouraged learners to think about and convey the broader context of the data, including the people, actors, environmental context, and emotions. At times they embodied the cases within the variables and other times they embodied things that were implicated within the cases in order to convey meaning. In Eisner's (1997) reflection on alternative forms of data representation in research, he highlights how examining different forms are necessary to cultivate data representations that stimulate empathy, connect to individuals in the data, and increase the types of questions that we ask about the data. As we try to humanize data for learners (Lee et al., 2021), examining artistic representational forms like dance show promise in the ways they facilitate a contextual grounding and reflection on people and the environment in ways that stimulate personal, cultural, and societal exploration.

The collaborative dances also stimulated learners to reason about data via each other's movement and body positions. The collaborative work expanded their potential region of focus on the data as they could now simultaneously represent multiple categorical variables or multiple actors in their metaphorical representations. This enabled them to portray relationships and interactions across the dancers and thus the data and actors they were representing. Through this process they reflected across the similarities and connections and the differences and departures in their representations. This was done in both the numerical sense—i.e. differences in value—and the characteristic sense—i.e. a woman's role versus a man's role. The representations conveyed a meaning that was dependent on the dancers coordinated movement together. The dance created opportunities for what Ma and Hall (2018) have termed *ensemble learning* wherein learners engage in collaborative activity that cannot be done alone and results in a performance. This type of learning stimulates engagement in the representations, learner agency over sections of a routine, and distributes mathematical concepts across learners. We observed ensemble learning as learners distributed roles within their danced metaphors to communicate through a "*sequence of unfolding movement,* including who does what to whom and how" (Hanna, 2008).

Performative Practices: Audience and Interpretation

The performances engaged the audience in cognitive sensemaking with data and in kinesthetic empathy—feeling as though their bodies are participating in the movements they see as well as experiencing the feelings that the performance evokes (Carlson, et al., 2019). For instance, in the Women's rights dance, the raised fist movement not only serves to communicate the role of power in data on perceptions of the role of women in society, but also, as described by one of the learners, seeks to generate an affective state that is "powerful." The consideration of music—i.e., the tempo and cultural references—were also forms of embodying affect to elicit certain audience responses, or what one learner referred to as "actual feelings." While meaning was made through the movements and dance phrases, the students' dances came together in a locus of meaning that was centered around the "*whole pattern of performance,* emphasizing structure, style, feeling, or drama" (Hanna, 2008, p. 493). This involved

creating new meaning of the data through the coordination between music, movements (individual and collaborative), performance, and experience of the audience.

This tension of balancing data representations with affective and aesthetic considerations speaks to a broader dialogue in the field of data literacy education and data visualization around humanistic data literacy (Lee, et al. 2021) that challenges claims of data as objective, neutral, and universal. In work by Klein and D'gnazio (2020) that connects feminist theory to data visualization, the authors note how embodiment and affect are too often not situated on par with more more quantitative methods of knowing and experiencing the world. In providing principles that encapsulate 'data feminism' the authors write, "the third principle of data feminism, is to elevate emotion and embodiment" (p. 95). Increasingly, data visualization approaches are exploring activating emotion, leveraging embodiment, and creating novel presentation forms to help people grasp and learn more from data-driven arguments (e.g., Rust, 2014). Learning experiences, such as creating and performing data dances from both a math and art disciplinary perspective has potential to center tensions on the role of affect in making claims about how the data should feel, how audiences engage in embodied and affective forms of sense-making through kinesthetic empathy, and the use of artistic dance practices that center this affective communication in data visualizations (e.g., music, gestures).

Conclusion & Limitations

The case study of dance and data demonstrated the potential of the embodied processes to develop learners' sensemaking of the data. Embodiment provided learners with an opportunity to develop a number sense as they deconstructed an understanding of the graphical representations. Further, their movements concretized their ideas about the data which grounded their numerical understanding in the real-world context of the data. Last, learners' creation of distributed representations across multiple learners facilitated collaborative sense-making about the data. In addition to embodiment, the performative practice had learners attempting to engage the audience to develop their own understanding of the data through their dynamic performances that were explicitly not neutral or objective. Although this study alludes to a number of important connections between data literacy and embodied learning, there were some limitations. First, the study was situated in the context of contemporary dance, limiting the range of embodied practices. Second, we ran into challenges in understanding learners' affective responses relying mostly on their verbal descriptions instead of embodied emotional responses during the curricular unit due to our limited ability to observe during classroom activities. Future research could more deeply attend to the contextualized instantiation of the data and dance practices. Additionally, we should continue to explore additional forms of dance to understand the breadth of embodied learning that can support data literacy while expanding the types of practices that can support learners in contextualizing and humanizing their data investigations.

Abstract: As health news stories affect the audiences' decision and behavior, readers need to understand and evaluate the information. However, assessing the quality of health news stories is challenging for non-expert readers, as it requires both media and scientific literacy. In this paper, we design a web interface, ReviewAid, that guides online readers' evaluation of health news stories with the evaluation criteria designed for non-experts. ReviewAid scaffolds readers' evaluation process by providing 1) explicit guidance that asks readers to distinguish the quality of media and scientific findings and 2) example comments for each criterion. Results from our study with 44 participants show that ReviewAid helps readers better connect the evaluation criteria to the specific news story. ReviewAid also enabled participants to conduct a more grounded and accurate evaluation of the content of scientific research.

Introduction

The media coverage of scientific research has been an important channel of scientific information for the public, and health is among the most preferred topics for both science journalists and their audience. As health news affects audiences' decision or behavior (Pew Research Center, 2017), health news should deliver accurate information on the scientific findings and discuss its implication for readers. However, health news stories are often criticized for being oversimplified, inaccurate, or biased (Dudo, 2015), and social media worsens the situation by accelerating the spread of sensational and clickbait stories (Waszak et al., 2018). Recent COVID-19 misinformation scandals (e.g., the effectiveness of Hydroxychloroquine in COVID-19 treatment) show how the inappropriate dissemination of scientific research can actually harm public health (Wong, 2020).

Modern science education has been focusing on nurturing the public's ability to understand and evaluate scientific information in their everyday life (NRC, 2012). However, it is known that the public, even those who are scientifically literate, tends to take news stories at face value by deferring the evaluation to the science journalists or relying on their gut feeling (Shah et al., 2017). In fact, assessing health news stories is a complex task for readers, as it necessitates the use of both scientific and media literacy. One needs to gauge the quality of scientific evidence and evaluate how properly the information is delivered and interpreted at the same time.

The most widely used strategy is to use explicit evaluation criteria (see Table 1 for examples) that question the quality of media and scientific research. Evaluation criteria can provide conceptual knowledge on the required inquiry steps and, at the same time, can serve as a basis for quantifying the quality of news stories. Unfortunately, previous research showed that understanding and applying evaluation criteria itself is a challenging task, and people easily make a superficial or incorrect evaluation (Nicolaidou et al., 2011; Zhang et al., 2018). Therefore, in the classroom setting, instructors provide additional guidance on how to apply criteria and correct students' inappropriate assessments. In this paper, we bring this strategy of using evaluation criteria to support readers' assessment of health news stories in an informal, everyday reading context.

However, as there is no such instructor who can guide readers' evaluation process in the informal reading context, it is important to understand the potential misuse of evaluation criteria and provide preventive measures. We conducted a series of observations in which participants were asked to evaluate a health news story following the evaluation criteria by themselves. We found that readers confuse the quality of news stories with the quality of scientific research and fail to apply the evaluation criteria in the context of a specific news story.

Based on the observation, we designed a web interface, ReviewAid, that guides readers' assessment of health news stories. ReviewAid uses criteria designed for non-expert readers and guides readers to evaluate the level of information coverage, the validity of the research, and the quality of the interpretation of the research separately. ReviewAid presents example questions for each evaluation step to help readers understand and apply each criterion to the specific news story. We conducted a between-subjects study with 44 participants to understand the effect of ReviewAid on the quality of readers' assessment and self-efficacy in assessing health news stories. The result shows that participants in the ReviewAid condition better connected the criteria to the specific news story and conducted a more grounded and accurate evaluation of the content of scientific findings. Also, participants in the ReviewAid condition reported a higher level of self-efficacy in explaining how the news story can be improved than participants in the baseline condition.

Background

We first provide background on what makes public communication of scientific research challenging. Then we review existing evaluation criteria developed by scholars and practitioners and discuss differences between the criteria used in science education and journalism.

Challenges in public communication of scientific research

Health news stories are a result of the sequential effort of multiple players (e.g., scientists, PR team, and science journalists) in the production pathway. While there exist many factors that make the public communication of scientific research challenging, the most important and inevitable challenges are those raised by the complex nature of scientific research. Scientific research consists of components such as theoretical background, experiment design, and analysis, and this innate complexity of scientific research makes it hard for journalists to accurately deliver the information (Dunwoody, 1982). Another factor that complicates the public communication of science is the tentativeness of scientific research. The complex and conditional nature of scientific research sometimes limits the scientists' knowledge and control of a subject matter, making some studies have limited validity (Bromme et al., 2014; Peters & Dunwoody, 2016). Health-related research has an especially high level of tentativeness as it often involves human or living subjects, whereas researchers have less control over the condition (Sumner et al., 2014). Therefore, the certainty of the finding is not determined solely by single research but can be only established from a number of studies that align with it (Lee et al., 2012). Communicating the tentativeness of the finding is a very demanding task for journalists as it requires a huge amount of time and effort and sometimes costs readers' engagement and trust in scientific research and the media (Stocking, 1999).

Evaluation criteria for health news stories

Researchers and practitioners in science education have developed sets of evaluation criteria to teach students how to conduct a scientific inquiry when reading media reports on scientific findings. They aim to teach what to consider in evaluating a scientific claim and what can threaten the validity of the claim delivered through the media (Jarman & McClune, 2007). They guide students to question the *content* of scientific research, such as participants, procedure, measures, or who the researchers are (Oliveras et al., 2013; Tsai et al., 2013). However, previous research showed that students tend to make a superficial or incorrect evaluation of the content of research and have to practice the evaluation multiple times to understand the evaluation criteria and use them appropriately (Nicolaidou et al. 2011; Donnelly et al., 2014).

While criteria developed for students are focused on the *content* of the research, criteria developed for the general public put more emphasis on the *context* of the research. Criteria developed by journalists (e.g., Health News Review.org) or public organizations (e.g., NCCIH (n.d.)) guide readers to ask questions on how news stories deliver scientific research, interpret it, and discuss it in a broader context. They include questions on cost and potential side effects of interventions studied (e.g., new medicine or doing a specific exercise), how strong the study findings are, or how certain and novel the finding is. However, it is difficult to assess the context of research without prior knowledge in the research delivered, and this remains a question as to how well an average health news reader can use these guidelines to evaluate health news stories.

It is important to assess the health news story regarding both *content* and *context* of the research. With evaluation criteria on the content of the research, readers can judge the validity and reliability of the research conducted. On the other hand, the evaluation criteria on the context of the research help readers understand the certainty of the research finding and appropriate application or consequences. In this paper, we design a system that guides readers to evaluate a health news story on both content and context of the research.

Formative Study: Readers' challenges in evaluating health news stories

To better understand the challenges that readers face while evaluating health news stories, we conducted a series of observations and semi-structured interviews. Specifically, we sought to identify readers' difficulties in understanding and applying given evaluation criteria in the online reading environment, where no additional guidance and support from an expert or instructor is expected.

Method

We recruited eight participants (6 male, 2 female) from an online community of a technical university in South Korea. Participation was limited to those who are fluent in English and have no prior research experience. Five participants were undergraduate students, two were entering graduate students, and one was a first-year graduate student. We prepared two news stories titled "How Your Morning Coffee Might Slow Down Aging" (Park, 2017) and "Weight-loss pills can help. So why don't more people use them?" (Carroll, 2018), from stories with low

expert ratings (less than 3 out of 5) in HealthNewsReview.org. Participants were asked to choose a news story they are more interested in, evaluate the story by following evaluation criteria provided, and explain rationales for their assessment. After the session, we conducted a short interview on their overall experience and difficulties they faced during the evaluation process. All of the sessions were conducted individually. Each participant was paid KRW 10,000 (approx. $8) for their hour-long participation.

We asked participants to evaluate one health news story following two sets of criteria, Always Ask (AA) (Jarman & McClune, 2007) and HeathNewsReview.org (HNR). AA is evaluation criteria designed to teach scientific inquiry steps for students and has more focus on the content of research. AA comes with detailed and explicit subcriteria for each high-level criterion. On the other hand, HNR is criteria developed by groups of journalists and scientists and has more focus on the context of research and how the story frames and discusses the scientific research. We used both sets of criteria to observe readers' difficulties in applying criteria on the content and context of the research. Table 1 shows example criteria from AA and HNR. Four participants were guided to follow AA first, and the other four were guided to follow HNR first.

Table 1

Example evaluation criteria used in Always Ask and Health News Review

Source	Always Ask	Health News Review
Example criteria	How was the research conducted? - What were the subjects of the study? - What was the sample size? - How was the experiment carried out?	Does the story adequately explain the harms of the intervention? Does the story establish the true novelty of the approach?

Findings

First of all, seven (out of eight) participants said that the evaluation criteria helped them to learn what to consider. Four participants explicitly mentioned that they could realize that some questions are very important only after seeing them. Despite their positive comments on having evaluation criteria, participants had difficulties across various steps, from understanding each criterion to applying the criteria to evaluate the news story.

Providing a rationale for their evaluation

Participants often failed to provide a rationale for their evaluation. This happened a lot when participants were evaluating the news story with HNR, which does not give explicit subcriteria for each criterion. P8 said, "I think I understood what each (HNR) criterion is asking for, but this does not mean I know what to consider. I can give a score based on my impression, but I cannot explain why I gave that score." Most participants said they are more confident with their evaluation given to AA than HNR as the subcriteria helped them understand concrete questions that they can ask and develop their thoughts. To prevent readers assessing health news stories by their gut feeling or impression, it is important to guide them with detailed and explicit criteria.

Facing evaluation criteria that require prior knowledge or external information

Criteria that ask about the value (e.g., novelty or implication) of the delivered research require external information or expert knowledge. To answer questions such as "Does this story establish the true novelty of the approach?" (HNR) or "What is the importance of this study?" (AA), readers need to have prior knowledge in the topic or even knowledge of previous research in the domain. Participants said that they feel helpless when they are asked to evaluate such criteria. P4 said, "It seems that I need to conduct an extensive investigation to really judge the novelty of this research, and I don't think I can correctly answer the question even after the investigation." P2 said that "Some criteria were meaningless to me as there was nothing that I could do."

This does not mean, however, that those criteria should not be given to readers. Having such criteria is still valuable as they suggest and teach readers what to consider with health news stories. Rather, the benefits of such criteria can be maintained without discouraging the readers by adjusting the scope and target of the evaluation. For example, rather than asking readers to evaluate the novelty of the research, readers can still check whether the news story has explained or discussed how novel the research is.

Distinguishing the quality of news story and the quality of scientific research covered

The quality of research and how it is delivered affect the quality of health news stories. However, participants failed to distinguish the quality of the story from the quality of the research. Six participants mistook the lack of information for lack of validity in the research. For example, there were three participants who concluded the research has limited validity by making a wrong assumption that researchers did not control potential confounding variables. Only two participants said that there is not enough information to evaluate the validity of the research.

It is important for readers to clearly distinguish the source of the problem because the consequences of evaluation can differ a lot. For example, suppose a patient reads a low-quality health news story on a potentially effective intervention. If the patient concludes that the finding is insignificant or invalid, the consequence can be just ignoring the information. On the other hand, if the patient concludes that the media did a poor job delivering the research, the patient can find more information about the research or consult with his doctor.

Applying evaluation criteria to the context of an individual news story

As scientific research varies in its topic and methodology, specific information that is critical for readers can also vary for each health news story. In our observation, participants expressed difficulties in applying criteria to the specific health news story being evaluated. This happens even when participants think they conceptually understand what the evaluation criteria are asking for. Participants said they could point out that some criteria are not met, but they could not explicitly say what should be included or improved in the news story. For example, regarding the criterion "What data were collected" (AA), P5 noted that "I can see that there exists limited information on the data collected but cannot think of what it is specifically."

ReviewAid

Based on our observations, we designed a web interface called ReviewAid that scaffolds online readers' evaluation of health news. In ReviewAid, readers review a health news story by following the evaluation criteria designed for non-expert readers. For each subcriterion, ReviewAid provides explicit guidance on medium-research distinction and helps readers connect the evaluation criteria and the target news article with examples.

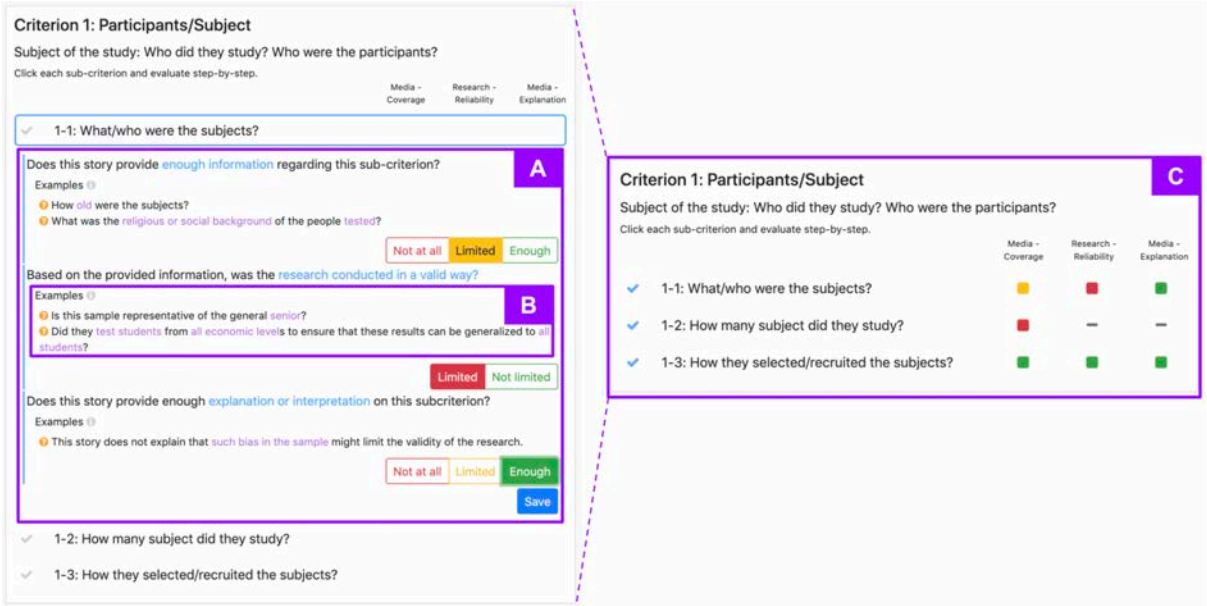
In ReviewAid, readers evaluate a health news story by following seven evaluation criteria that we developed by restructuring existing criteria, namely AA, HNR, and the criteria based on the taxonomy developed in Korpan et al. (1997) (e.g., Zimmerman et al., 2001). Criteria were chosen and designed so that they support scientific inquiry on both the *content* and *context* of the research. Criteria 1-5 are introduced to scaffold the scientific inquiry process explicitly. Criterion 6 is on its connection with other research or theory, and criterion 7 asks about its application and implication to the real world. To help readers better understand each criterion, ReviewAid provides two to four subcriteria (see Figure1-(C), for example) for each criterion. When a reader selects a criterion to review, corresponding subcriteria are prompted. Readers evaluate the story for each subcriterion and then assess the high-level criterion based on it.

1. Participants/Subject: Who did the research study? Who were the participants?
2. Research Design: How and why is this research designed, and how is it done?
3. Measure: How were the factor (putative cause) and effect defined and measured?
4. Data & Statistics: How were the raw data and statistical results?
5. Social Context: Is there any social factor that may have influenced the research? Who did the research, funded it, or who is advertising it?
6. Theory & Related Research: Does the finding align with other research? Is there a theory that can explain the observed effect?
7. Application & Implication: What is the implication of this study finding, and how should I relate this finding to the real world?

When a reader selects a subcriterion to evaluate, ReviewAid provides procedural support to prevent them from confusing the quality of media and research. ReviewAid guides readers to evaluate the news article on 1) how well the story provides information (coverage), 2) how reliable the research is (reliability), and 3) how well the story explains or interprets the reliability of the research (explanation). The system prompts the evaluations of these aspects in order of coverage, reliability, and explanation. To prevent potential confusion between the media coverage and research validity, the step for research reliability is skipped if the reader answers there is no information. For the criteria on the contextual information (6 and 7) that require prior knowledge or external information, readers are not asked to assess them by themselves but to assess how the news story discusses them (explanation). Figure 1-(A) shows the evaluation steps ordered by the aspects.

For evaluating coverage, reliability, and explanation, ReviewAid shows example questions or comments related to each aspect. While each criterion comes in a general form that can be applied to any news story on health-related research, examples serve as concrete instantiations of each criterion that readers can refer to understand the criterion and apply it to their context. We constructed the example pool based on students' questions raised on scientific news briefs collected in Korpan et al. (1994) and questions and comments left in expert reviews in HealthNewsReview.org. Phrases that are specific to the news stories that each question or comment is raised on were indicated separately (in purple color), as shown in Figure 1-(B).

Figure 1
Overview of the scaffolded evaluation process in ReviewAid. (A) For each subcriterion, the user evaluates the story for each of media coverage, research validity, and media interpretation (B) Example comments raised in other news stories are shown. Terms that are specific to the source news story are colored in purple. (C) Evaluations on the subcriteria are summarized.



Evaluation

ReviewAid system scaffolds readers' assessment with 1) explicit and detailed evaluation criteria, 2) explicit procedural support to distinguish media and the research, and 3) examples that instantiate each criterion to a specific news story. We conducted a study to assess the effect of ReviewAid on the readers' evaluation of health news stories. As the benefits of having explicit and detailed criteria are well studied in previous research (e.g., Reiser et al., 2001), we focus on the effect of explicit guidance on medium-research distinction and examples. Specifically, we aim to understand readers' experience in evaluating health news stories with ReviewAid and the quality of assessment that they make.

Method

We conducted a between-subjects study with two conditions: Baseline and ReviewAid. In both conditions, participants were asked to evaluate a health news story with seven criteria with 2-4 subcriteria for each. In the ReviewAid condition, participants were asked to follow the designed evaluation process for each subcriterion before giving a score to the story. In the Baseline condition, participants were shown the subcriteria, but the scaffolded evaluation process in ReviewAid was not presented.

Participants and procedure

As ReviewAid is designed to support health news readers in their informal reading context, we tried to recruit participants from the general population. Previous research (Berinsky et al., 2012) showed that population samples recruited in Amazon Mechanical Turk (MTurk) tend to be more representative of the U.S. population than samples from in-person recruitment. We recruited 44 participants (20 male, 24 female) from MTurk and randomly assigned them to one of the two conditions. We had 21 and 23 participants for the Baseline and ReviewAid conditions, respectively. For their 40-60 minutes-long participation, participants were paid $8. The average age was 36.5 (SD: 8.69). A total of 35 participants had tertiary education, and three among them had postgraduate education.

In the pre-survey, we asked questions on factors that may affect their experience and outcome of the main task, such as education level, prior experience in research-related activities, perceived media literacy, and how they prefer cognitive work (NFC scales in REI-10). In the main task, each participant evaluated a health news story titled "Tofu might harm memory in elderly." (Kahn, 2008) (adapted from Leung et al. (2015)) with seven criteria. For each criterion, participants were asked to rate the story in a 1-5 scale and explain their rationale for the score. In the post-survey, participants were asked to describe how the evaluation criteria and scaffolded evaluation process affected their evaluation. Also, we asked participants to rate how confident they are about 1)

judging the quality of a health news story, 2) pointing out inadequacies of a health news story, and 3) suggesting ways to improve a health news story in a 7-points Likert scale.

Measuring the quality of assessment

To measure the quality of participants' assessment, we conducted a discourse analysis of the evaluation comment written by each participant. We measured the number of rationales provided in each comment, the number of rationales specific to the news story, and the number of incorrect rationales. The analysis was conducted with 88 comments on criterion #1 (participants/subject) and criterion #6 (theory and related research). These two criteria were chosen so that we can analyze comments on both content and context of research.

The analysis was done in three steps. One of the authors and one external coder (Ph.D. student in biology) worked together in every step. In the first step, we split each comment into multiple arguments so that each argument contains a single intention or meaning, and a total of 88 comments were divided into 417 arguments. In the second step, we marked whether each argument contains a rationale. To ensure consistency between coders, the two coders divided the first 10% of comments together and then divided the next 10% independently, compared the result, and discussed to reach an agreement. After the consistency building session, each coder independently coded the remaining arguments, and the inter-coder agreement was 0.79 (Cohen's Kappa). The two coders finalized the result by discussion. Out of 417 arguments, 318 (76.3%) were of rationale-type. In the last step, we labeled whether each rational-type argument is specific to the news story (binary) and correct (binary). The inter-coder agreements (Cohen's Kappa) were 0.86 and 0.83 for specificity and accuracy, respectively.

Results

Overall, participants showed a moderate to high level of confidence in their media literacy (Mdn=5). There were no between-group differences in media literacy, as well as in the perception of health news and need for cognition. The average time spent on the reviewing task was 19 minutes (longest: 45 mins, shortest: 7 mins). The average completion times for the Baseline and ReviewAid conditions were 17.3 and 21.0 minutes, respectively.

Table 2

The numbers of participants who provided rationale, specific rationale, and incorrect rationale and the number of arguments provided respectively with median.

		Criterion #1		Criterion #6	
		Baseline	ReviewAid	Baseline	ReviewAid
Participants	(1) Total	21	23	21	23
	(2) Rationale	17 (81.0%)	22 (95.7%)	21 (100.0%)	23 (100.0%)
	(3) Specific rationale	9 (42.9%)	19 (82.6%)	10 (47.6%)	18 (78.3%)
	(4) Incorrect rationale	10 (47.6%)	5 (21.7%)	3 (14.3%)	4 (17.4%)
Arguments	(5) Total	97, Mdn=4	149, Mdn=7	81, Mdn=3	90, Mdn=3
	(6) Rationale	60, Mdn=3	116, Mdn=5	66, Mdn=3	76, Mdn=3
	(7) Specific rationale	32, Mdn=0	89, Mdn=4	20, Mdn=0	28, Mdn=1
	(8) Incorrect rationale	14, Mdn=0	7, Mdn=0	5, Mdn=0	5, Mdn=0

Table 2 shows 1) the number of participants who provided rationale, specific rationale, and incorrect rationale and 2) the number of arguments with a rational, specific rationale, and incorrect rationale in each condition and criterion. Participants in ReviewAid condition provided significantly more rationales (Mdn=5) than the Baseline participants (Mdn=3) for criterion #1 (Mann-Whitney (MW) Test, U=139.5, $p < .005$). However, there was no significant difference in the number of rationales for criterion #6 (Mdn=3 in both conditions), which is about the context of the research (MW Test, U=226.5, $p > .05$).

The proportion of participants who provided rationale that is specific to the news story (see Table 2, row (3)) was higher in the ReviewAid condition, for both criteria (χ^2 Test, $\chi^2(1, N=44)=7.50$, $p<0.01$ and $\chi^2(1, N=44)=4.45$, $p<.05$, for criteria #1 and #6 respectively). The median number of specific rationale provided in each review was 0 and 4 for criterion #1, 0 and 1 for criterion #6 for Baseline and ReviewAid, respectively. The difference was statistically significant for criterion #1 but not for criterion #6 (MW Test, U=122, $p<.005$ and U=187.5, $p=0.184$, respectively).

Regarding the accuracy of evaluation, for criterion #1, ten and five participants provided incorrect rationales in the Baseline and ReviewAid conditions, respectively. Among those who provided at least one rationale, 58.7% (10 out of 17) in Baseline and 22.7% (5 out of 22) in ReviewAid made incorrect arguments in their comments and the difference between the conditions is statistically significant (χ^2 Test, $\chi^2(1, N=44)=5.27$, $p<0.05$). For criterion #6, 3 (out of 21) and 4 (out of 23) participants provided incorrect rationales in Baseline

and ReviewAid conditions (χ^2 Test, $\chi^2(1, N=44)=0.12$, $p=0.720$). The median number of incorrect rationale in each comment was 0 for both conditions and both criteria.

Overall, participants showed a high level of self-efficacy with median score 5 for questions on how confident they are with 1) judging the quality of a health news story, 2) pointing out inadequacies of a health news story, and median score 6 for question on 3) suggesting ways to improve a health news story. There was no difference between the conditions for the first (Mdn=5 in both conditions) and second (Mdn=6 in both conditions). For the third question on suggesting ways to improve, participants in the ReviewAid condition (Mdn=6) gave significantly higher scores than participants in the Baseline (Mdn=5) (MW Test, $U=172$, $p<0.05$).

In both conditions, participants said that having detailed evaluation criteria helped them conduct a grounded evaluation. P19 in the Baseline said, "The subcriteria were very helpful in that it made it simple to know which direction to go in my evaluation." Participants said that the scaffolded evaluation process in ReviewAid helped them conduct detailed and accurate assessments. P21 noted, "I think it (distinguishing media and research) added to my ability to see piece by piece what was affecting my opinion and better articulate my thoughts in my reviews. It helped me notice what was missing." Also, P14 said, "Examples helped me fully understand what was being asked and how it applied to this specific article."

Discussion and future work

In our evaluation, ReviewAid had different effects on the type of evaluation criteria. For criterion #1, which is on the content of the research, participants in the ReviewAid condition provided more rationales and more specific rationales than those in the Baseline condition. Also, compared to the Baseline, the proportion of participants who provided wrong rationale was significantly smaller in the ReviewAid condition. For criterion #6, however, there was no difference between conditions in the number of rationales and the ratio of participants with incorrect rationales. As criterion #6 is on the context of research, ReviewAid does not present the guidance on medium-research distinction and the only difference between the Baseline and ReviewAid condition was the presence of examples. Our results illustrate that the examples given for criterion #6 helped participants better connect the criteria to the specific news story but not in providing more ground or accurately assessing the news story.

In our study, participants in the Baseline condition showed a moderate to high level of self-efficacy in assessing health news stories and said that having detailed evaluation criteria helped their assessment. However, we saw that such confidence does not guarantee the accuracy of their assessment. As readers are confident in their evaluation, it is hard for them to realize that their evaluation is incorrect. This illustrates how simply adapting tools from formal learning can result in undesired outcomes in the informal learning context. It is important to understand the differences between the two learning conditions and specific challenges in the informal setting.

Although our study results show the benefits of having the scaffolded evaluation process, we note that the observed effect needs to be further verified in future studies. The effect of having the ReviewAid system should be further evaluated in studies with large numbers of participants and on various health news stories. Another limitation of this study is the lack of consideration of readers' prior knowledge and beliefs on the subject matter. Prior research showed that prior knowledge and beliefs on the subject matter could significantly affect one's reasoning process, especially with socio-scientific issues such as climate change and genetic engineering (Christenson et al., 2014). Future studies can investigate online readers' challenges in relation to their prior knowledge or belief and design a system that supports their evaluation of health news stories.

We also emphasize the need for designing a system that guides online readers' evaluation of health news stories that is more practical to be used by online readers. In our study, participants spent 20 minutes evaluating a single news story on average. This questions the practicality and impact of the ReviewAid system. In our future work, we will investigate a more practical use of the ReviewAid system by supporting collaborative and shared evaluation of health news stories among readers.

Lastly, while this work focuses on the health news stories, the idea of supporting non-expert readers to distinguish media and the source information and conduct contextualized evaluation can be transferred to other domains where expert knowledge is disseminated and communicated to the public, such as economy or policy. We envision a future where non-experts can actively engage in a structured evaluation process with various types of information.

Learning science while caring for pets: Findings from a virtual workshop for teens

Priyanka Parekh, Joseph Polman, Shaun Kane, R. Benjamin Shapiro
priyanka.parekh@colorado.edu, joseph.polman@colorado.edu, shaun.kane@colorado.edu, dude@colorado.edu
University of Colorado Boulder

Abstract: Pets are beloved family members in many cultures. Companionship with pets motivates and positions humans as inquirers as they find out their pets' experiences with them. With the need to advance science education from dualist notions of the world and the learner as separate entities, our research team conducted a two-week online summer camp to engage teens and their pets in investigations around pets' senses. Following a qualitative analysis of participants' talk and projects at the workshop, we found that teens engaged in science learning practices while investigating aspects of their pets' lives and designing experiences for them. Additionally, participants adopted an ecological and relational approach to science learning that positioned themselves and their pets as subjects. We discuss implications for future work with pets, and for the design of other STEM learning environments that engage perspective-taking, empathy, and care.

Introduction

The field of K-12 science education values science content and scientific practices and endeavors to reach learners across socioeconomic boundaries to create a just and equitable society (National Research Council, 2007). Although most agree that science education is crucial to an informed citizenry, the field's view of what constitutes science learning is often restricted to thinking, acting, and practicing like a certain kind of a scientist. In the historically dominant view, a scientist represents a positivist objective view of the world and treats and studies nature in isolation using valuable skills such as conducting controlled studies while maintaining objectivity. Based on this view of what constitutes scientific work, K-12 science education typically encourages learners to use an emotion-free, impersonal approach to study the world independent of their lives and contexts. Although such a view of science education has produced promising outcomes for some science learners, its relevance and appeal to many others remain limited. There are other, less acknowledged soft skills such as a meaningful relationship with nature on which scientists rely that positions them as members of an ecosystem and affects the very depth and breadth of scientific knowledge. For example, Barbara McClintock's cultivation of a close relationship with the corn maize she studied that led to the discovery of transposable genetic elements (Keller, 1984) and primatologist Jane Goodall's research among families of chimpanzees in Tanzania is the basis of modern-day primatology research (Peterson, 2015).

As individuals, learners exist in relation to the world. To fully appreciate these relationships as rich contexts for science learning, we need knowledge and appreciation of contexts and inquiry skills where relationships are central. Engaging in inquiry with pets at home affords us this unique opportunity. We conjecture that humans' nurturing relationships with pets in a familiar ecology encourage teens to engage in holistic science practice. Based on this motivation, we infused a group of teens' home settings with Augmented Reality (AR) technologies to understand the sensory experiences of pets. Following this, we studied the teens' use of soft skills such as perspective-taking, care, and empathy in shaping their inquiry into the pets' lives. We designed our study as a two-week virtual workshop where teens engaged in tool use, investigations to understand their pets' preferences and behaviors, and experience design. In the following sections, we elaborate a theoretical framework, detail the study design and analytical methods, highlight a few initial findings and consider the implications of our work to the field of science education.

Theoretical Framework

Western scientific methods are founded on the principles of control, isolating study subjects and variables from their contexts, among others. These methods have led to scientific discovery and innovation in modern times, but have fallen short in solving some problems, such as environmental pollution. Such failures are noteworthy because products and methods of Western science are, at least in part, responsible for these problems. The lack of a viable solution indicates that a shift in thinking about and doing science is necessary.

The *Framework for K-12 Science Education* (National Research Council, 2012) and the Next Generation Science Standards (NGSS Lead States, 2013) aim to prepare students to learn particular science practices. However, there exist other holistic scientific methodologies from which learners could benefit. Overall, these

 © ISLS

methods rely on what we know of the world in relation to the mutual, structural, and social interconnectedness of life where agency of all elements and multiple ways of knowing are key. For example, naturalistic methods rely on observing phenomena with minimum intervention (Boyd, 1980). Indigenous knowledge derives from the ecological interconnectedness of nature of which humans are but a member (Bang et al., 2013; Brayboy et al., 2008; Cajete, 2000). The principle of agency of all non-human elements of nature is instrumental to so-called posthuman (Pickering, 1995) and new materialist (Latour, 1987) methods. Common to these ways of knowing and doing science are at least two principles. First, nature and culture are inseparable (Haraway, 2003; Fuentes, 2010); an integrated, multispecies, contextual knowledge of nature benefits all. Second, there are methods, ways of knowing, and skills that privilege such intimate knowledge.

Donna Haraway's notion of naturecultures stresses the entanglement of the natural and the cultural, the bodily and the mind, the material and the semiotic. The reduction of the boundary between humans and nature, especially between humans and pets as companion species, is foundational to our study. As elements of natureculture, humans and companion species like dogs live in close association and the agency of both species is important; therefore, our interconnectedness rather than seeing other animals as objects of study is essential. However, any species of animals, including humans, are limited in perceptive capacities. Therefore, to inquire into animal sensory experiences, we must understand that sensory experiences are not uniform across the living world - each creature has its own "umwelt" (von Uexküll, 2001), a German term usually translated as "the world as experienced by a particular creature." Animal umwelts are unique in each of the five senses and are not accessible to us humans to a great extent, leading to various misconceptions and misunderstandings. Technology, especially AR, can broaden the window of sensory perception for users to better understand the natural world by overcoming the cognitive and biological challenges first by creating unique experiences and second by inquiring into those experiences. Doing so might allow us to adopt a relational and ecological understanding of animals' lives with humans by adopting the animals' perspective. Perspective-taking is the cognitive ability to consider the world from another individual's viewpoint (Galinsky et al, 2008) and has both perceptual and conceptual aspects. Perspective-taking based on direct observation and experience forms the background for empathy (the ability to connect emotionally with another individual) and care (the motivation to attentively rehabilitate through companionship and commitment).

The use of technologies in this way has implications for our understanding of human actions within the ecosystem as well. We need to move beyond the traditional conceptualization of learning ecology that recognizes a range of factors that affect the learner (for example, Bronfenbrenner, 1979) to include the learner and animals as active agents and in certain positionalities within the web of coexistence. Learning in this context implies valuing human-animal coexistence as a mutually reciprocal, dynamic, ever-evolving web of relationships. In our view, a workshop designed with such a goal could be the site where teen participants come to understand and define nature-culture relationships in their local contexts. Consequently, the workshop could help us understand how teens' soft skills such as perspective-taking, empathy, and care help them redefine science learning and related practices.

With this motivation, we answer two research questions:

1. How do teens at the workshop engage in the science learning practices of questioning, planning and carrying out investigations, and constructing explanations and designing solutions?
2. How do perspective-taking, empathy, and care shape the teens' science learning practices?

Methods

Overview of study

We structured this study as a two-week virtual summer camp that situated scientific inquiry and design work within adolescents' home environments with their pets. We designed this virtual camp with a mixture of synchronous and asynchronous at-home activities because of the COVID-19 pandemic. We shipped a box of materials to each participant that contained pet toys, treats, and craft materials to support their remote participation. During camp, we met with participants as a group for an hour each morning over Zoom to orient the participants to the tools and their use, and later asked participants to share their work from the previous day's at-home activities.

Recruitment

We recruited middle school and high school aged adolescents through a university-run STEM mailing list for youth who had previously engaged in STEM summer programs and were looking for similar experiences. The participants were between the ages of 13-18, had at least one dog or cat at home, and had internet and computer

access for the two weeks. Thirteen adolescents joined the program, along with 9 dogs and 5 cats. We examine the participation of the 11 participants who completed the study. All names used in this paper are pseudonyms. Each participant chose either one cat or one dog to be their main companion for the camp, with the exception of one participant, Riley, who participated with both of her dogs.

Camp activity design

Overall, we used research in the fields of human- and animal-computer-interaction, to develop the above-mentioned tools and the workshop plan. We designed the **first week of camp** to investigate their pet's senses and behaviors through the use of two tools - one, a set of two Snapchat filters called DoggyVision (DV) and KittyVision (KV; Authors, Year) that mimic the selective blindness of dogs and cats, two, a paper pinna modeled after canine and feline external ears and worn as human ear-accessories. The filters (the tools relevant to this paper) show the camera's view with an approximation of a pet's dichromatic vision making the images appear brown and dull, muted (Figure 1). At the workshop, participants were prompted to use the filter to photograph familiar objects and environments and to interpret how those images look relative to their own experience of it. Based on this observation, participants then planned their own investigations. In the **second week of camp**, participants worked on experience design projects that enriched some aspects of their pets' lives. Participants tested and evaluated their pets' interactions with their projects and conducted multiple iterations of their investigations and shared these to the entire group. In addition to these activities, we assigned a "Blog Prompt of the Day" which included prompts to write narrative journal entries from their pet's perspective, with the goal of connecting learning outcomes to perspective-taking and empathetic practices.

Figure 1
Images captured by a participant.
(a) A cat's food and water bowl on a tray using a regular camera, (b) and the KV filter.

Data Analysis

To begin the analysis, we observed five out of the ten workshop session recordings closely. We then created content logs detailing the participants' plans and actions as captured in their talk and photographic details of their investigations. Next, we analyzed the content logs for three specific Science and Engineering Practices (SEPs) as detailed in the Next Generation Science Standards (NGSS) for middle and high school-age learners. We chose three SEPs (Questioning; Planning and carrying out investigations; and Constructing explanations and designing solutions) to focus on in this preliminary analysis. In doing so, we explored these practices in depth while compromising the breadth of all eight SEPs. In parallel to this, we analyzed the content logs to identify instances of perspective-taking, empathy, and care. In the second round of analysis, we looked for SEPs informed by perspective-taking, empathy, and care and identified how they were connected.

Findings

We report two main findings. **First,** the camp design encouraged participants to engage in science learning practices, specifically, questioning, planning and carrying out investigations, and constructing explanations and designing solutions. **Second,** these science learning practices were rooted in perspective-taking, empathy, and care that serve the goals of science education.

Perspective-taking using tools

"I wonder why my dog's favorite toys are, like, not red." Wade (male, fifteen) wanted to find out why his dog Popper played with a select few toys. On what basis was the dog choosing these toys over the many others? As he photographed objects in and around the house using the DV filter, Wade noticed that red appears as green to dogs, which would mean that the red toys blend in with the grass when he plays fetch with the dog on the grass.

Surprisingly, despite not liking red-colored toys, the dog seems to like a red, white, and blue volleyball. Wade wondered how Popper perceived this tricolored volleyball differently from other solid red toys. Using the DV filter helped Wade understand why the dog does not play with red-colored toys on the grass, he thought aloud why can't dogs see red and green? By extension, what are the colors that would pop out in a dog's perspective and why? Further, if this is what his dog's vision constitutes, how might vision affect his dog's choice of toys? Wade's words indicate the direction of his inquiry - he wanted to find out the basis of the animal's selective colorblindness and how this unique sensory ability affects the dog. Wade's inquiry is situated in the careful observation of his dog's behavior and his willingness to enhance his dog's playtime experience. The empathy that he feels for the animal becomes relevant in light of what he has observed using the filter tool. When Wade compared what he observed in his dog's behavior every day with what the DV filter revealed to him, the pet's choices seemed obviously connected to the animal's sensory experiences. His attentive companionship shaped his questions. Siobhan's (female, fifteen) inquiry, like Wade's, is situated in close companionship, empathy, and care for her cat, Tigger. When Tigger rejects toys, Siobhan interprets the cat's response as different from a human rejection of a toy, i.e. not liking the toy for one or more reasons. Tigger's rejection of a toy could mean many things, from a lack of visibility in the current environment to a lack of suitability for play, rather than just dislike or a different preference. Wade concluded that if Popper could see a toy, especially as a ball, he would play with it, implying that Popper liked the ball as a toy. The only way for Siobhan and Wade to learn more about the pets is to interact with the pets intentionally and in close association and study the animals' behavior in different microenvironments within their home.

As the participants and facilitators continued to use and inquire with the DV/KV filters and what selective color blindness implies for their pets, Siobhan observed that her cat Tigger saw colors, primary and secondary, differently. For example, using the KV filter, she found that her purple sweatshirt looks closer to blue to her cat because Tigger cannot see the red in the purple. As Siobhan adopted the cat's perspective using the KV filter, she examined objects and colors of objects that are not immediately interesting to the pet, unlike a toy. Like Wade, she too examined her understanding of selective color blindness in the context of her cat's behavior and observed that her cat could not distinguish well between some shades of blue and purple, leading her to pay close attention to the colors her cat does prefer. Later, she wondered if the right color was enough for Tigger to like a toy. What if a toy was the right color, but not a suitable toy for play? The design and materials of the toys could be important factors too. What if Tigger could not play with it like he wanted to by batting it on the floor? Siobhan wanted to examine the texture of the cat toy materials to understand the cat's playtime as an experience that is affected by selective color blindness but constituted of many more factors including the sensory modalities of touch and movement. Using the filter gave them access into an area of inquiry. Using pet toys in slightly varying settings such as playing outside versus playing inside the home, and playing with different toys, and observing the pet's response, they extended their inquiry. Such a systematic inquiry initiated by tool use and intentionally extended in an everyday setting is a promising sign of science learning.

For both Siobhan and Wade, investigating pet vision through the filters led to an inquiry into pet vision in the context of play with toys where vision has a particular role. For example, if pets cannot see a toy such as a ball, if they cannot use the toy in a particular way, such as bat it or track it and chase it, they find it challenging to play with it. In this respect, playing with toys served as a meaningful context for inquiry into the sensory experience of vision, the animals' umwelt, and the unique natural, material, and social ecosystem. Finally, Siobhan and Wade's inquiry was not just about pets' vision, but the pets' sensory experiences in an ecosystem they share with humans and interact with them.

Conducting investigations with pets

As the workshop progressed to the second week, the participants planned and conducted investigations to inquire how their pets would behave in a particular setting designed to understand their preferences and behaviors based on what they could see. Adrianna (female, thirteen) considered finding out her dog's favorite color, specifically, a favorite lacrosse ball color since her family buys packs of assorted lacrosse balls to play with the dogs. Adrianna was not sure that her dog, Wally, would choose the balls at all if he was not in the mood to play. Hence, she planned to smear all the balls with peanut butter and place them at an equal distance from Wally. Adrianna based her plan on the knowledge of her pet - the animal does not play with all toys equally, might not play on command, might need to be rewarded for following instructions from time to time, and has favorite incentives. She recognized that smearing all the balls with Wally's favorite treat, peanut butter, might result in Wally eating all the peanut butter negating the influence of a favorite color on the dog's choice. Upon recognizing this limitation in the setup, Adrianna sought to refine it or use a control rather than force Wally to act on command or take away the incentive. Although she wants to find out more about her dog's behavior, Adrianna is mindful of the animal's likes and dislikes in planning and carrying out her investigation. She recognizes that her investigation is not going

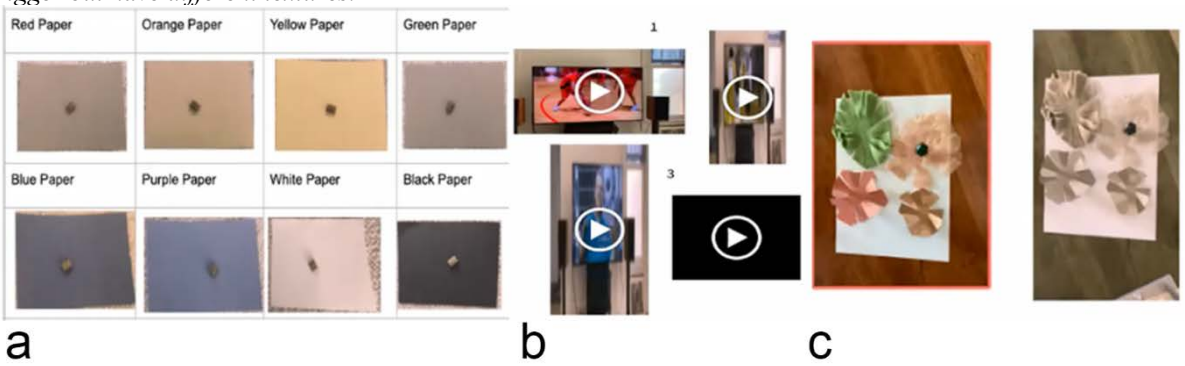
to be successful because of the use of peanut butter as a treat for the dog and she is open to considering other alternatives. Here, Adrianna's knowledge of her pet informed the design of her investigation, her understanding of dog behavior in general helped her evaluate and reflect on it. Her willingness to find out more about the animal and her desire to conduct a successful investigation motivate future refinements.

Evee's (female, sixteen) cat Saskia has a favorite treat. The treat is reddish-brown in color and Evee offers treats to Saskia on the light-brown wood-paneled floors. Using the KV filter, Evee has observed two things, first, that the treats appear as brown rather than reddish-brown to the cat, and second, they are close in color to the brown floor. Evee wonders if this is the reason her cat cannot see the treats very well. To find out a way to make the treat more visible to Saskia, Evee conducted an investigation (Figure 2a). She cut out small squares of construction paper in all colors of the rainbow, white, and black, and placed one piece of the favorite treat on each cutout. She placed the cutout-treat combination in an array and waited for the cat to choose one for each of the two iterations of the investigation. To her surprise, the cat chose the orange cutout-treat combination and consistently chose from the reg-orange-yellow-green row rather than the blue-purple-white-black row on both iterations of the investigation. Evee captured an image of the investigational setup using the KV filter to investigate the setting from the cat's perspective. Based on what she observed, Saskia's choice intrigued Evee. Evee expected the cat to choose the white cutout-treat combination because it appeared very close in color to the orange and yellow cutout-treat combinations. The treat stood out equally well against the yellow and orange, and moderately against the green and red. The treat stood out very well against the white cutout and yet, Saskia ignored it. Unable to explain Saskia's choice, Evee concluded that there could be other factors involved that influenced the outcome of her investigation. For example, was something other than visibility of the treat by virtue of color and contrast guiding Saskia's choice? Could smell be a factor? Evee recalled that often she needed to tempt Saskia with a sniff of a treat to lead her to her food and treats and once at the location, Saskia sniffed further before eating her food. She often missed treats that were farther away and Evee wondered if Saskia was acting out of habit as well as. Despite her meticulously planned investigation and an initial conjecture that the cat relied on smell only to guide her because she could not see her food well against the floor, Evee cannot accept Saskia's omission of the white paper-treat unit as the cat simply overlooking the treat. She felt the need for further inquiry into the combined effect of visibility, smell, and habit in Saskia's treat eating habits.

Figure 2

Investigations conducted by participants at the workshop.

(a) Evee's treat contrast investigation with treats placed on colored construction paper cutouts; (b) Luna's TV show investigation where she observed Rocco's reaction to different TV shows with and without sound; (c) Siobhan's color and texture investigation with Tigger where she chose colors that would appear the same to Tigger but have different textures.



Evee designed her investigation to make Saskia's experience of living in her home better for the animal. She wondered if it might be inconvenient for the animal to not be able to see her food and to not be able to seek food independently at home. This close observation of her cat and the commitment and affection she has for the pet drive her inquiry. In her narration of the investigation and its outcome, Evee was reluctant to call her cat disobedient or her investigation a failure; she accepted the cat's behavior and perception as factors she had to design her investigation around. Evee attentively observed Saskia and used the animal's response to the investigation to shape and elaborate her understanding of feline perception and related behavior. The investigation answered some of Evee's questions about Saskia's behavior and partially solved the cat's problem of not being able to see her food. Yet, new questions emerged and Evee demonstrated willingness to inquire further into Saskia's sensory experience.

Luna's (female, fourteen) dog Rocco likes to watch TV, and Luna wondered what aspects of the TV shows the dog liked the most. Using the DV filter, she rejected her preliminary hypothesis that the dog likes very colorful scenes; the scenes that appear colorful to Luna's human eyes appear pretty dull to the dog. Luna then considered that the dog probably likes scenes that include barking dogs and moving objects. To examine the effect of sounds versus sight on her dog's behavior, she muted the TV (Figure 2b). She observed a less enthusiastic response from Rocco - the dog did not jump onto the TV but still paid attention to moving objects such as basketballs. However, the dog was less willing to watch TV when the news was on, indicating that only certain sounds appealed to him. In a discussion during a group synchronous Zoom, another participant related how her cat refused to watch TV even when she turned on the nature channel and specifically pointed at birds. Luna shared that her dog had favorite TV shows. Siobhan added that her cat liked her iPad, especially when she played Minecraft on it. They wondered if moving objects and sounds attracted pets to TV shows and if all cats and dogs were attracted to these in the same way and to the same extent. These participants were surprised to learn that the color on the television screen made no difference to the pet – they learned using the filters that their pets' world was quite visually dull.

In her investigation, Luna carefully manipulated one variable at a time to understand what Rocco was responding to - sights, sounds or both. She found that her dog, and her friends' pets, had very particular tastes; they like certain sounds and sights and not others. In the context of this observation of Rocco's preferences and the findings of her investigation, Luna concluded that Rocco perhaps likes watching basketball and baseball because he liked balls. Rocco also liked playing with other dogs which explained why he got excited when other dogs appeared on the TV screen. Her experiment was carefully designed and implemented, and Luna relied on the findings of the investigation and her knowledge of Rocco's preferences to better understand why Rocco liked to watch TV. However, Luna's investigation did not require Rocco to do anything new in a controlled study condition, rather, Luna used a situation Rocco already was familiar with and liked to learn more about the animal. The findings of the investigation help Luna refine her understanding of Rocco's behavior, in turn, it makes Rocco's TV time more enjoyable as Luna knew what he liked best. The careful observation of the dog's everyday actions helped her design the investigation; the close companionship and commitment with her dog gave Luna a thorough understanding of the factors that were in play in the investigation and led to the outcome.

Siobhan's cat Tigger is full of energy and likes to play with toys, and at times, Siobhan finds it difficult to keep up with the energetic kitten. Her plan was to design a toy Tigger could independently play with leaving Siobhan enough time to attend to her schoolwork. Tigger liked toys that are visible to him and are easy to move across the floor so he can bat them. Siobhan noticed that the toys' visibility and movement across wooden floors contribute to the cat's willingness to play with the toy. So, she conducted an investigation to test the effects of textures on the cat's choice of toys by choosing fabrics that would appear close in color to Tigger but feel different to him (Figure 2c). To ensure that she would be studying the effect of texture only in her investigation, she examined several fabric pieces through KV to ensure that these would appear similar to the cat and ensured that the toys were similar in design. Siobhan designed her investigation specifically to test her hypothesis - her cat liked certain textures over others and needed to see the toy against a background. She controlled for the color of the fabric swatches in her investigation because using the KV filter she saw that most colors appeared quite dull to cats implying that contrast and visibility were more important than any particular color. She assumed that most toys looked quite dull to her cat and hence, other toy features must be attractive to Tigger and other animals. Her choice of toy design was evidence of her close observation of her pet, his tendencies and preferences, and her caring relationship with him. Although she wanted to conduct an investigation with the cat, the purpose of the investigation, the processes that the cat has to go through are incentives for the animal.

Overall, in this section we observed that the teen participants engaged in the following science learning practices (further details are in Table 1.). In the context of an AR-mediated tool use, they asked and refined questions about their pets' behavior (For example, Popper choosing some toys over others), they planned and carried out investigations to illuminate pets' everyday choices and habits (for example, Saskia needing to be hand-fed treats) and constructed explanations and designing solutions (for example, Rocco preferring some TV shows over others). The ways in which they carried out their inquiry revealed a strong sense of care and empathy towards their pet companions. In their investigations, the teens strived to be mindful of and uphold the animals' agency and living conditions.

Table 1

An example of science practices enacted by a participant with perspective-taking, empathy, and care.

Science practices	Enactment of practice	Enactment of perspective-taking, empathy, and care

 © ISLS

Questioning [Careful observation; Seeking clarity; Examining understanding; Determine relationships; Clarify and refine understanding] Planning and carrying out investigations [Plan and design to produce data; Produce evidence; Select appropriate tools; Manipulate variables and collect data] Constructing explanations and designing solutions [Make a claim; Construct an evidence-based explanation; Reason scientifically]	Luna: I was wondering why Rocco liked watching TV shows, so I filmed some of his favorite scenes from movies and shows. They did not have a lot of vibrant colors in DV but had a lot of dogs barking or a lot of motion. I muted the TV a few times and he ran up to the TV only when there were dogs running around. His favorite toy seems to be balls. When my mom turned on the news he went away.	Luna tried to understand her pet's preference for some TV shows. Understanding this helps her support a better life for the pet rather than assuming their likes and dislikes based on one factor. Using the DV filter she observed that most TV shows appeared very dull to the animal and she wondered if there were other aspects of the shows that attracted Rocco. She planned an investigation to find out what the pet likes to watch on TV and why. Luna had a thorough understanding of her pet's likes and dislikes and relied on this knowledge to plan her investigation. Most TV shows she uses for the investigation are those that the dog already likes. The pet's enjoyment is paramount and Luna does not force the dog to participate in the investigation when he walks away.

Discussion

Ecological perspectives privilege our knowledge of nature as the function of at least two key factors - our interactions with the world and our positionality as just one element of nature. On the other hand, as users and practitioners of Western science, we presume a divide between the world as an object of study and the learner as the outsider individual manipulating the world for the sole purpose of gaining knowledge (Bang & Marin, 2015; Hecht & Crowley, 2019). Knowing about the world around us requires more than factual knowledge to include relationships within the ecosystem involving us and those with which we interact. Although such an undertaking might seem challenging, approaches such as the one adopted in this study can shape a change in a promising new direction.

Tools like the AR filters we describe here permit participants to experience the world as experienced by another species and serve as an invitation into another species' sensory experience. In doing so, these tools support a more profound, relational science learning, one that makes room for inquiry through perspective-taking, empathy, and care and builds on the learner's familiarity with and knowledge of their environment. In the above-mentioned instances, the human participants positioned themselves as equals to their animal companions, respecting and valuing their agency. When the animals choose to respond to some investigations and conditions and not others, the participants found ways to work with the animals rather than coercing them to act against their own interests. In fact, in the above examples, the animals were co-participants rather than research subjects. The human participants exercised their agency and so did the animals, making them co-participants and their relationship a subject-subject relationship. Further, the participants saw the animals' unexpected response to conditions and environments as relevant information that shaped their understanding of the animals as research subjects rather than an unexpected factor that negatively influenced their investigation and needed to be controlled. We wonder if the close relationship between the participants and their pet companions infused these investigations with affect and in doing so, contributed to rather than detracted from their success.

Conclusion

Overall, the findings above indicate that intimate knowledge of a pet at home is an excellent starting point for learning science. Further, as participants questioned the form, function, and scale of pet sensory experience, they situated themselves in an empathetic and caring relationship with the pet where the pet's agency was just as important as theirs. Their inquiry was situated in and motivated by this relationship. Such motivations and the soft skills of relating to them became relevant to learning science at the workshop. These observations lead us to the following refinement of what the science education community values as successful science learning. First, successful science learning experiences can take many forms rather than just one, stringently structured form of a closely controlled investigation involving defined variables. Evee, Luna, and Siobhan's investigations did not resemble standard science investigations and yet, were rich contexts for learning, and relevant and meaningful to them as learners. Second, we need to broaden our understanding of what science learning constitutes. We see that

in the context of the workshop, adopting the perspective of another species, learning to be in an ecosystem by sharing agency are important aspects of learning that shape how and what we know as learners.

Supporting Teachers' Concept Development Through Aggregation

Abstract: This study analyzes transcripts of conversations in which mathematics teachers and researchers debrief videotaped lessons by, in part, examining aggregated classroom data from the videotaped lesson. We conclude that aggregating data in debrief conversations can support teachers' concept development when the aggregation a) demonstrates internal contrasts and b) is underscored by participants' discursive moves. Consequently, we recommend that facilitators seeking to prompt teacher learning use lesson-level aggregations to identify and press on comparisons and distinctions in teaching practice. This study can inform research on teacher learning by unpacking how a common practice—aggregating data—contributes to teachers' concept development and has implications both for practitioners and for the emerging field of classroom data visualization.

Introduction

To summarize information about how teaching unfolds throughout a lesson, practitioners—administrators, evaluators, and teachers themselves—often aggregate data from observing teachers' classrooms, such as tallying teacher or student behaviors or quantifying time-on-task (e.g., Mason et al., 2019; Simonsen et al., 2013). A growing body of work on data visualization aims to make such aggregations accessible to teachers, with researchers developing software that illustrates which students are asked which types of questions or which solicitation methods teachers use to ask questions (Herbel-Eisenmann & Shah, 2019) or how class time is spent on different activities or in different configurations (Nagro et al., 2020). Such research, whether rooted in coaching, teacher evaluation, or data visualization, often claims that aggregating data can lead to teacher improvement, but rarely reports how teachers perceive or use such data. In a notable exception, Chen and colleagues (2020) demonstrated that seeing and discussing aggregated evidence of academically productive talk increased teachers' use of academically productive talk but did not investigate how or why it did so. Without understanding how or why aggregating classroom data contributes to teacher learning, aggregators risk the co-optation of powerful tools for problematic purposes, such as teacher or student surveillance under the guise of accountability (Webb, 2005). At best, introducing new data collection practices may increase demands on teachers' time and resources with little benefit for teachers and students. Therefore, this study investigates *how the aggregation of classroom data can support teachers' concept development in lesson debrief conversations.*

Conceptual framework

To do so, we draw on situative theories of teacher learning that take knowledge, and therefore concepts, to be both shared and distributed among actors and artifacts (Hall & Horn, 2012; Hall & Jurow, 2015). Rather than being individually held and carried from situation to situation, the concepts in circulation in any given situation depend on context. This context may include teachers' values, beliefs, and goals (Aguirre & Speer, 1999); the available representational infrastructure (Hall & Jurow, 2015); and the conversational routines, frames, and stories that are common in a particular community (Bannister, 2015; Yoon, 2016); among other things. Concepts serve explanatory purposes in that they help teachers coordinate and "ge[t] information from the world" (diSessa & Sherin, 1998, p. 1171; see also, Philip, 2011) and in doing so, enable pedagogical judgment (Horn, 2020). For this paper, we operationalize a concept as something—a topic, word, phrase, or idea—that 1) carries local meaning; 2) is related to beliefs, values, explanations, definitions, and other concepts in articulable ways; and 3) make interpretation, decision-making, and action possible.

To understand concept *development*, then, we draw on the conceptual change literature. Instead of treating concepts as purely additive (see diSessa [2006] for the limitations to additive conceptualizations of concept development), we take concepts to be pre-existing and gradually transformed through social interaction. In other words, the set of associated definitions, explanations, values, and beliefs that are attached to a concept shift as teachers engage in—among other social practices—conversations about teaching. Shifts in these associations become evident through shifts in teachers' activity patterns (Hall & Jurow, 2015) or, sometimes and more immediately, shifting narratives and mobilizations for future work (Horn et al., 2017; Kane, 2020).

Research methods

Context and data collection

Data for this study was collected as part of a larger research-practice partnership where the research team and the leaders of a professional development organization (PDO) collaborated to understand and improve their support of veteran mathematics teachers' growth (Horn & Garner, 2021). In this partnership, we engaged in video-based formative feedback (VFF) cycles with school-based teams of teachers. In each VFF cycle, teachers identified inquiry questions about their own practice and selected student groups to record; researchers filmed the teachers' classes using a point-of-view camera worn by the teacher, a whole-class camera mounted on a rotating tripod, and four audio recorders, one for each selected student group; researchers reviewed the collected video and audio to identify clips that would support co-inquiry around teachers' inquiry questions; and the teachers, their school-based colleagues, and researchers engaged in a lesson debrief conversation centered on the selected clips. For timely feedback, each VFF cycle took place within two to four days. We collected the aforementioned classroom video and audio recordings, classroom observation fieldnotes, video recordings and transcriptions of the VFF debriefs, researcher memos, and artifacts from the classroom observations and debrief conversations.

Over two years of data collection, we worked with 13 teachers across six school teams. These teachers had between 5-25 years of teaching experience, and most had obtained or were nearing completion of National Board Certification. We conducted 32 VFF cycles and aggregated lesson-level patterns in 15 of them; in three of those VFF cycles, researchers did not share the aggregated data with teachers during the debriefs. In three of the remaining 12 VFF cycles, multiple types of data were aggregated and shared (e.g., teachers' use of class time and strategies used in students' boardwork). From the 12 VFF cycles, then, there were 15 total instances where lesson-level patterns were aggregated and discussed with teachers during the debrief.

Phase 1 data analysis: Identifying instances of concept development

To select focal and comparative cases, we created analytic memos and tables (Miles et al., 2020) to summarize each instance where lesson-level patterns were aggregated, classified the data aggregated, and identified why the data was aggregated. The most common aggregated data included instances of a particular pedagogical move in a lesson (e.g., list of times teacher tried to get the whole class's attention), teachers' uses of class time (e.g., minutes per activity), and students' boardwork (e.g., list of strategies represented). Aggregation was roughly equally prompted by researchers' hunches (eight instances) and teachers' requests (seven instances). Next, three researchers independently coded each instance for the concepts evident in the debrief and how associated concepts shifted over the course of the debrief. Through discussion, we reached consensus on two instances where aggregation clearly contributed to concept development. Then, we wrote narrative memos tracing the evidence for concept development across each instance. Discussing these memos across the broader research team, in conjunction with reviewing relevant literature, led us to two hypotheses about the mechanisms that contributed to concept development: H1) concept development depends on the aggregated data presenting a clear contrast between what teachers expected to see in their classrooms and what actually happened and H2) concept development depends on participants' use of strong discursive moves to introduce and shift associated concepts.

Phase 2 data analysis: Comparative case analyses

To explore these hypotheses, we conducted comparative case analyses (Yin, 2014). Through open, concept-driven coding, we identified three relevant comparative cases that had similar surface characteristics as the two focal concept development cases but that did not result in clear concept development (see Table 1). Next, we used MAXQDA qualitative analysis software to inductively code the focal and comparative case debrief transcripts (Miles et al., 2020) and visualize the coded data over time.

Table 1
Cases coded in Phase 2 analysis

Case (* denotes focal case)	What was aggregated	Participating teachers
* Including Students	How teachers included students during small group work	Abigail, Clark, Veronica, Franck
* Goes Into	Students' uses of "goes into"	Lizette, Julie
Questions	Teacher questions during small group work	Lee, Doha
Boardwork Creativity	Students' solutions to a particular problem	Clark, Franck
Class Time	Minutes per activity	Clark, Franck

We operationalized H1 by identifying contrasts in aggregated data and then coding debrief transcripts for associated concepts. Visualizing these codes revealed clusters of associated concepts, shifts in associated concepts, when these shifts happened, and what prompted the shifts, which we summarized in analytic memos. For H2, we coded researchers' and teachers' discursive moves with deductive codes drawn from research on activities that support teachers' conceptual change (e.g., proposing solutions [Hall & Jurow, 2015]; asking clarifying questions, offering different interpretations [Horn et al., 2017]) and inductive codes developed for additional moves that were common (e.g., elaboration, affirmation). We examined instances of the most frequent codes using techniques from discourse analysis to determine the meanings, accomplishments, and significance of these moves (Gee, 2014). For example, if a researcher offered a differing interpretation of a problem, we considered whether and how this interpretation was taken up, and by whom, in subsequent turns of talk; if a teacher asked a clarifying question, we considered whether the question served to fact-check what had happened in the videotaped lesson and/or to establish common ground among participants, etc. Finally, we articulated connections between contrasts in the aggregated data, shifts in concepts, and participants' discursive moves.

Findings

We found that although a contrast between teachers' expectations and the aggregated data was neither necessary nor sufficient for concept development (H1), internal contrasts within the aggregated data did seem to be necessary, if also not sufficient, for concept development. For example, in the Including Students Case, teachers did not demonstrate any surprise after seeing an aggregation of their strategies for including an excluded student in small group work. However, the aggregated strategies highlighted a contrast between the intention of supporting students' equal participation as a proxy for equity and supporting individual students' participation as a way of meeting their emotional, social, and agentic needs. Conversely, the Boardwork Creativity Case did not show concept development despite internal contrasts within the aggregated data. Teachers continued to rue the homogeneity of students' solutions even though researchers—and in some cases, the teachers themselves—pointed out instances where students demonstrated unexpected and creative solutions, perhaps because researchers accepted teachers' initial dismissals of the surprising solutions without following up.

Findings from H1 confirmed the importance of participants' discursive moves in prompting concept development, but contrary to H2, we found that researchers' strong moves were neither necessary nor sufficient for concept development. Instead, concept development occurred when either researchers or teachers *offered different interpretations* and then *elaborated* on concepts in ways that diverged from what had been taken as shared. For example, in the Goes Into Case, the teacher initially attributed students' interchangeable uses of "goes into" for exponentiation and multiplication to latency and to her leniency in allowing imprecise language. The lead researcher repeatedly proposed students' unclear conceptual understanding as a factor instead, but the teacher did not take up this interpretation and associate different concepts with it until a second researcher elaborated on how to assess students' conceptual understanding. In the Lee Questions Case, the researcher also repeatedly queried the teacher's interpretations of his questioning strategies, asking about his intentions and how else he could have accomplished them. However, neither the researcher nor teacher elaborated on, say, why his questions did not accomplish his intentions. Although the teacher acknowledged the researcher's queries, even indicating agreement with her concerns, he elaborated extensively on his own pre-existing interpretations and brainstormed how he might revise his future questioning strategies without taking up the researcher's ideas.

In brief, our findings suggest that aggregating patterns supports teachers' concept development when multiple possible interpretations of internal contrasts within the aggregated data are unspooled by participants' discursive moves. Next, we illustrate this finding by describing the aggregated contrasts, shifts in associated concepts, and how both researchers and teachers elaborated on differing interpretations in our focal cases.

Case 1: Including Students

Context and aggregation

In the Including Students case, four Algebra 1 teachers at Banneker High School—Abigail, Clark, Franck, and Veronica—were filmed teaching similar lessons in which students worked at whiteboards in randomly-assigned groups of 2-3 students to write and solve series to find the number of blocks in various towers. Abigail had asked to see examples of how each teacher had promoted discussion or equity, so the research team, led in this VFF by Grace, aggregated a series of six videoclips in which one student in a small group appeared to be left out and a teacher had done something to bring that student into the small group conversation. For example, in one clip, Franck lightheartedly asked a student to talk to another student "because he looks lonely." In another, Veronica directed a follow-up question at a student who had not been participating in the conversation. Taken together, these clips highlighted contrasting strategies for supporting students' participation in small groups.

 © ISLS

Shifts in associated concepts

In the first third of the debrief, Grace showed the video clips in rapid succession and teachers engaged in mostly binary assessments of students' participation and of the efficiency and effectiveness of intervention strategies for supporting student participation (e.g., "that's it, quick;" "she looks like she's thinking;" "success"). Then, Grace prompted teachers to share their pedagogical reasoning around the aggregated clips. In the second third of the debrief, teachers named forms of student participation other than discussing solutions and analyzed the aggregated intervention strategies in more detail. For example, Clark wondered whether he should create more opportunities for students to ask their group members for help when they do not do so "naturally:"

> Franck: A problem I have with that is that one kid will definitely always be the asker.
> Veronica: The asker?
> Franck: Yeah.
> Veronica: Or the person being asked.
> Franck: Yes, all the time. Especially in a certain makeup of that group, and I don't know how comfortable that would feel to a kid, being the asker or the askee or whatever, you know? So I just wonder, I don't know.
> Abigail: […] I tell them when who's talking. So that's part of the equity thing that I think is important is that like [students assigned to] reds talk first. There's red and yellow, reds talk first. All reds have to talk and so then all yellows have to talk…

In this portion of the VFF debrief, teachers discussed the associated concepts of *equal participation as a proxy for equity*, *mitigating status differentials across students*, and *participation as an opportunity for academic learning*. These associated concepts represented a shift from the binary assessments demonstrated in the first third of the debrief and contrasted participation for participation's sake with participation for learning's sake and were made salient by teachers' further discussion of the strategies shown in the aggregated videoclips.

Differing interpretations and elaborations generate further contrasts

Then, Grace invited Franck to introduce Roberto, a student who Franck had described as having a substantially different skillset compared to other students in the class. Teachers viewed a clip in which Franck tried to include Roberto in his small group's conversation, and the final third of the VFF debrief became substantially more complex. Continuing to frame *participation as an opportunity for student learning*, Clark initially interpreted the dilemma as one of preserving Roberto's learning opportunities while maintaining the status-equalizing advantage of randomly-assigned and thus heterogeneous groups. He proposed strategically assigning Roberto and a partner to just work on the first problem while other students moved on, and then added:

> It's kind of sad to me that [the first problem is] still sitting there probably unsolved for him and very solvable, and [it would be] a nice accomplishment for him. And he doesn't get to do it because we're already moving on to this other thing. So I'm just wondering how we could make it without, honestly, tracking your grouping…

Franck asked how he could assign Roberto and a partner to work just on the first problem "without singling [Roberto] out." In response, Clark and Veronica brainstormed another strategy: still using random groups but then assigning Roberto to write his groupmates' ideas on the whiteboard. They surmised that Roberto could still have learning opportunities from writing mathematical solutions, even if he did not contribute to figuring them out.

Franck offered a differing interpretation: "But maybe that's like you forcing him to do something he doesn't want to. I mean, is that agency?" Teachers did not immediately take up the concept of *student participation as a reflection of agency*; Veronica and Clark elaborated further on Clark's original interpretation, generating and troubleshooting additional strategies that could elicit Roberto's participation while preserving his learning opportunities. After several minutes, Franck re-introduced his question more directly.

> Franck: Do you think he's getting something from standing up there with those two?
> Clark: I personally would say no.
> Veronica: You say no?
> Clark: Very little. Not—
> Franck: More than if he sat by himself.
> Veronica: There's more to school though.
> Clark: Abigail?

 © ISLS

Abigail:	Yeah, I do think he's probably getting some, I mean, I don't know. I don't know the student, but I think that he is.
Franck:	[turns to his aide] Do you think he's getting something?
Aide:	Roberto? I don't think so.
Veronica:	But you have to think about the social context, too. It looks like he's participating, his body language is "hey, I'm doing this thing that I'm supposed to be doing" and so maybe we're meeting a different need, which is allowing him to be near and participate in a low-risk way.
Abigail:	Participate in school.

In this exchange, Franck prompted his colleagues to reconsider his differing interpretation: that participating in small groups might be meeting students' needs beyond learning mathematics. This time, Veronica picked up and elaborated on this interpretation, suggesting that Roberto's current form of participation may be serving social needs. Abigail and Clark followed up with additional ways that students' social and emotional needs might be met by listening quietly to their groupmates rather than actively figuring out solutions. Finally, Franck asked what would happen if he simply told Roberto's group that "when I come back, I want Roberto to be explaining number one. Now how does that make Roberto feel? That's my question." In contrast to teachers' earlier discussions of strategies for supporting student participation, Franck identified a proposal with the potential to address both Roberto's mathematical learning and his social need to perform participation in a low-risk way, and solicited his colleagues' feedback on how this strategy would make Roberto feel, as opposed to simply whether it might "work" in the sense of compelling Roberto to talk.

In the final third of this debrief, the concepts associated with supporting student participation shifted from *participation as a proxy for equity* and *participation as an opportunity for academic learning*—both of which suggest that teachers' primary goal is to increase student talk and thereby student learning—to *participation as meeting students' social, emotional, and agentic needs*. These shifts occurred when teachers shared differing interpretations of pedagogical dilemmas illustrated by the aggregated videoclips—specifically, questioning how intervention strategies might affect students' agency and their needs other than academic learning—and then elaborated on these differing interpretations. Doing so led to concept development and mobilization for future work by expanding what teachers considered when assessing intervention strategies.

Case 2: Goes Into

Context and aggregation

In the Goes Into case, Lizette had taught an Algebra 2 lesson in which students engaged in small group work to practice evaluating logarithms. Lizette asked researchers (Brette and Lani) to attend to how students were thinking about logarithms. While reviewing video, Brette and Lani noticed that students were using the phrase "goes into" to describe both multiplication (e.g., "two goes into 128 sixty-four times") and exponentiation (e.g., "three goes into nine twice"). This pattern appeared across multiple student groups and throughout the lesson. To highlight the contrast, Brette and Lani selected two videoclips of the same student group using "goes into" in different ways. Brette introduced the data by saying, "there's also the issue of 'goes into' and the way that students were using that. This group, which was the blue group, they were using 'goes into' in both ways." Lizette initially interpreted Brette's observation as an issue of *imprecise language risking miscommunication*:

> So then, if someone is talking to a person who's using it both ways, they don't necessarily know—maybe the kid who's saying it has it in their head straight, but the people who are listening might not. And also maybe the one who's saying it might not.

Brette, however, suggested that "it was interesting that some students were using it both ways to mean both things at different points." By highlighting internal inconsistencies within the same students, rather than inconsistencies between how different students were using the phrase, she gestured towards *imprecise language as an indicator of students' conceptual understanding*.

Shifts in associated concepts

Lizette then explained that she had originally taught logarithms using a number line representation to conceptually illustrate the difference between multiplication and exponentiation, but she had done a long time ago and students may have forgotten in the intervening months. In doing so, she attributed students' *imprecise language to be a reflection of latency* rather than an indicator of their (potentially unclear) conceptual understanding.

Lizette: But when it's so far separated from when we did that—'cuz that was in the beginning of the semester or the end of last semester, I can't even remember. It was like months ago either way, right? […] It's been so long that then, especially when the vocabulary stuff comes up, makes sense that it's all over the place.

Brette: But there were also things like the $log_b b = 1$. A lot of kids were like, "Oh that is clearly one." And [student] back here was like, "Yeah, y'all, that's one."

In identifying a similarly-aged concept that students appeared to remember clearly, Brette contradicted Lizette's interpretation that latency was the primary cause of students' imprecise language. Lizette, however, continued to elaborate on the pedagogical dilemmas that latency presented. She noted that her Calculus students still struggled with logarithms even though some had also learned the number line representation and wondered whether she ought to be reteaching logarithms to them too. In doing so, Lizette recognized that the number line representation alone could not ensure students' conceptual understanding but continued to attribute student confusion to latency.

Later in the VFF debrief, Brette took a different approach to probing students' uses of "goes into:"

Brette: I got the sense that maybe [students] came up with the 'goes into' language and you were rolling with it?

Lizette: […] I just wasn't intentionally trying to go with it but I also wasn't as strict about—like when we did the warm up, I probably wasn't very strict about it. […] I should have said something. […] Sometimes in my head maybe I'm like, "Yeah okay now we've got it revoiced the way I wanted it." But I didn't articulate why that was the way I wanted us to go. And so then they don't see that one way is going to be better for them to use than another when it comes to later stuff.

Lizette's elaborations suggested that she interpreted Brette's prompt as associating *imprecise language with teacher leniency*. She said she should have been stricter about monitoring students' language and more explicit about explaining why precise language mattered. Although she shifted her associated concepts, attributing latency to teacher leniency instead of latency, this was not the shift that Brette had hoped for.

The importance of elaboration

Brette made another bid for her interpretation of students' understanding by positing that students might not have understood that there *were* multiple meanings of "goes into:"

Brette: I didn't get a sense that kids who were using the "goes into" phrasing knew—

Lizette: —not to

Brette: Or were like clearly aware that there were two different uses of "goes into."

This time, Lani jumped in to elaborate on Brette's interpretation.

Lani: We listened to a bunch of these last night, the "goes into" examples, and we were just listening to a lot of their talk. And I was trying to see if I thought there was a kind of shared understanding of that inverse relationship between exponentiation and logarithms. Like if they saw it as a process or if they saw it as a procedure.

Brette: Yeah, it felt like sort of a translation thing?

Lizette: Yeah, that makes sense.

Brette: Like log whatever of whatever is a language that I'm not familiar with, and so I'm going to rewrite it into words that I know.

Lizette: Yeah, instead of understanding conceptually that it undoes.

Lani's elaboration, and Brette's further elaboration, seemed to finally cement for Lizette the differing interpretation that Brette had been trying to present throughout the VFF debrief, and she articulated in her own words that students' imprecise language likely indicated the extent of their conceptual understanding. Next, Brette and Lizette reviewed some of the specific examples that Lizette had used in her activity and how they may have contributed to students' confusion. As Lizette began to identify changes she wanted to make to this lesson for next year, Lani pressed Lizette to continue thinking about her current class of students and the state of their conceptual understanding of logarithms:

> With how they're talking about it, if they forgot the procedure a month from now, could they recreate it with the words they're saying about what's going on? And I didn't think so. I think that they were kind of like going through the number line and doing things with it and they were kind of powering through that one calculation.

Lani provided a concrete model for how Lizette could treat students' talk as evidence of their conceptual understanding; this elaboration framed students' imprecise language as a useful source of formative assessment rather than merely an inevitability due to latency or a consequence of teacher leniency.

After researchers' persistence in offering an interpretation of students' imprecise language that differed from Lizette's initial interpretations, and more importantly, elaborating on it, Lizette incorporated their interpretations by planning how she would revisit students' conceptual understanding of logarithms on Monday:

> So I think I want to just do just generally solving equations, and kind of like scaffold it and end with logs maybe? […] So looking at a lot of those inverses. That's kind of where my head is at currently so we can kind of go through inverses again and then throw in an exponential. […] So reintroduce it again as "this is the tool that we need to be able to undo."

The solution that Lizette proposed, reintroducing logarithms as a type of inverse, took *imprecise language as an indicator of students' conceptual understanding* instead of reflecting her previous interpretations of imprecise language as a reflection of *latency* or *teacher leniency*. This demonstrated a shift in the concepts that she associated with students' imprecise language. Although the aggregated videoclips made clear the contrast between students' different uses of "goes into," and although Brette had repeatedly offered an interpretation of the contrast focused on conceptual understanding, Lizette did not fully take up this interpretation until Lani (and then Brette) elaborated on this interpretation, suggesting that *elaboration* as a discursive move is critical to concept development.

Discussion

Examining the highlighted contrasts, associated concepts, and key discursive moves in the Including Students and Goes Into cases suggests that teachers' concept development can be supported by 1) the aggregation of patterns in classroom teaching that reveal internal contrasts and 2) elaboration, whether by teacher colleagues or researchers, on different interpretations of those patterns.

Aggregating patterns across student groups, across the minutes of a lesson, across instances of a particular routine or pedagogical move, or other things, collapses an otherwise-disperse set of data points to a more manageable scale, making comparisons and distinctions more obvious and easier for teachers to make sense of. Lampert writes that zooming in and out between scales—what happens in an interaction compared to what happens over multiple interactions, for example—"enrich[es] our understanding not only of different levels of phenomena but also their relationships to one another" (2001, p. 44). In other words, aggregating data coordinates processes that occur at different scales, highlighting what is typical and where there are possibilities for change (Lemke, 2000; Taylor & Hall, 2013). By doing so, aggregation supports shifts in the beliefs, values, and ideas that teachers associate with particular concepts about teaching, thereby developing their intuitions and ability to make in-the-moment decisions (Horn, 2020; Lampert, 2001).

This study brings research on teacher learning into conversation with the growing research on classroom data visualizations, identifying mechanisms by which aggregating data can support teacher learning. We suggest that researchers designing data visualization tools consider how their tools illuminate contrasts at different levels of scale and also attend to the types of conversations about teaching that might be sparked by their tools. Our findings recommend that facilitators who aim to support teacher learning (and/or instructional improvement by way of teacher learning) may find it useful to aggregate lesson-level data and share the aggregations with teachers not because the aggregations themselves necessarily prompt conceptual change but because aggregations can often make visible internal contrasts, whether between teachers' intentions or expectations and observed classroom practice or between their initial assumptions or interpretations and alternate possibilities. This internal contrast, in turn, can provide fodder for the types of discursive moves that lead to concept development, especially if facilitators are able to attend to and even introduce differing interpretations and to prompt elaborations on these different interpretations. Furthermore, classroom observations should be extended beyond the limited "pop ins" that administrators often employ; our research shows the promise of aggregating data and identifying patterns across full lessons instead of focusing on short episodes. Finally, we hope that future research can examine whether aggregating data across lessons and/or across teachers supports learning in similar ways.

Constructing an "Us" in Teacher Work Groups: Affordances and Limitations for Learning

Nicole Louie, University of Wisconsin–Madison, nlouie@wisc.edu
Mallika Scott, California State University, Fullerton, mhscott@fullerton.edu

Abstract: Research on teacher collaboration suggests that shared values and a sense of solidarity are important resources for generative discourse and robust teacher learning. Drawing on data from two groups of elementary mathematics teachers, this paper examines how teachers construct identities as "us" and the effects of these processes on teachers' opportunities to engage in equity- and justice-oriented sensemaking and learning. The analysis demonstrates that constructions of "them" sometimes accompany constructions of "us" and shows how this inhibits teachers' opportunities to learn. Strategies for building solidarity without sparking us/them dynamics, grounded in data, are discussed.

Background and purpose

Studies of teachers' collaborative work groups often point to shared values and a sense of being "in it together" as important for the kinds of critical, reflective discourse that support robust teacher learning, suggesting that these groups benefit from developing a collective identity or sense of "us" (Baldinger, 2018; see also Lefstein et al., 2020; Bolam et al., 2005; Louis et al., 1996). A sense of "us" appears to be especially salient for groups with shared commitments to centering students and advancing equity and justice (e.g., Benitez et al., 2009; McCotter, 2001; Picower, 2011). Yet constructions of "us" may define what is bad, deficient, and wrong as well as what is normal, valued, and good. In this paper, we examine how teacher groups construct identities as "us," what values anchor these group identities, who may be constructed as "them," and the effects of these dynamics on teachers' opportunities to engage in equity- and justice-oriented sense-making and learning.

Prior research

While many studies highlight the potential of teacher collaboration to support teacher learning (e.g., Bolam et al., 2005; Darling-Hammond et al., 2017), others indicate that such collaboration may fall short of producing the intended learning or change (e.g., Author, 2016; Stokes, 2001). Little (1990) has gone so far as to observe that teacher collaboration is often "contrived, inauthentic, grafted on, [and] perched precariously … on the margins of real work" (p. 510). One reason for this is that collaboration is inherently laden with the risk of others' judgment, particularly when it involves opening one's practice for the kind of examination and reflection that is needed to foster learning. As one teacher explained to Le Fevre (2014), "It is hard to show what you do to the others, because … you just do what you think is best for your kids, what you feel in your heart but then it might not match up as good enough against someone else's way of teaching" (pp. 59–60). Vedder-Weiss and colleagues (2019) have further found that teachers work to avoid "face threats" not only to their own public image, but also to colleagues' images. For example, various studies have shown that teachers may focus their collaboration on administrative tasks, limit themselves to swapping classroom activities and practices in a superficial way, actively silence critical perspectives, or cancel meetings altogether, all of which can be understood at least partially in terms of managing the threat of unfavorable judgment from peers (Louie, 2016; Vedder-Weiss et al., 2019).

Trust, shared values, and a sense of safety for intellectual risk-taking can support teachers to manage the risks of collaboration more productively (Bolam et al., 2005; Vescio, 2008; Lefstein et al., 2020). However, little is known about how groups of teachers develop these characteristics. Some studies suggest that convening groups based on core values that are already shared (such as a commitment to social justice) allows teachers to exist in a "sacred space" of support, honest dialogue, reflection, and critique (McCotter, 2001, pp. 690-691). Yet this obscures the moment-to-moment work that goes into co-constructing any learning environment, as well as the ongoing negotiation of meaning that is required to make abstractions (e.g., social justice) concrete and actionable.

In this paper, we add to the small body of research investigating the dynamics of teachers' efforts to navigate the risks of professional collaboration, particularly equity- and justice-oriented collaboration, focusing on how teachers construct "us" and "them" in moment-to-moment interaction and the effects on their opportunities to learn.

Theoretical perspective

A conceptual starting point for our inquiry is the awareness that all teacher learning is situated in what Horn and Garner (in press) term the "baggage of the binary," the culturally pervasive tendency to think of both specific

 © ISLS

teaching practices and individual teachers as either "good" or "bad." This good/bad binary imposes an evaluative frame that suggests that a good teacher should be skilled in applying "best practices" to deliver lessons that run smoothly and reliably produce measurable gains in student achievement. In this context, grappling with multiple perspectives and uncertainty exposes teachers to the risk of appearing bad at their jobs (the "face threat" described above; Vedder-Weiss et al., 2019). Moreover, when beliefs about students are on the table, particularly beliefs linked to racism and other systems of oppression, there is the additional risk of appearing to be a bad person as well as an incompetent professional (Stokes, 2001).

Teaching is much more complicated than a good/bad binary indicates. What counts as "good" practice depends on context. Furthermore, teachers must often juggle competing priorities, such as building on what their students know, can do, and are interested in learning and following externally mandated scope, sequence, and pacing (two priorities that are often in tension even when they are not directly opposed). For teachers working toward a vision for mathematics classrooms that is not yet widely practiced (e.g., equity- and justice-oriented visions), tensions and contradictions between various goals and obligations can be constant. Research on teacher learning that focuses on the mastery of particular practices or the acquisition of specific types of knowledge along a linear trajectory miss these tensions and contradictions. Here, we emphasize an understudied aspect of teacher learning: the ongoing grappling that teachers engage in as they attempt to re-solve "fundamentally unsolvable problems" (Philip, 2019, p. 5) in their everyday teaching. This grappling is necessarily social, in that local communities of practice make available certain ways of understanding young people, mathematics, and learning. When these communities are formed around a shared vision for mathematics teaching, they can provide teachers with collective resources to engage in the ongoing grappling of how to live up to their commitments in daily classroom teaching.

For teachers who are committed to anti-deficit mathematics teaching, living up to one's commitments can present an even greater need for ongoing grappling. Deficit ideologies remain widespread and are embedded within systems and structures that overemphasize what students cannot or do not do. These ideologies further locate some students as intellectually deficient and inferior to others in ways that intersect with existing social hierarchies based on race, class, gender, cultural or linguistic background, and (dis)ability, thereby functioning to reproduce these same hierarchies (Adiredja & Louie, 2020; Martin, 2009). Because deficit ideologies are culturally dominant (at least in the United States), they influence teachers' sense-making about their daily practice, no matter how committed teachers might be to working for justice (Louie, 2018). Philip (2019) has described the work involved in disrupting deficit ideologies and practices as "principled improvisation," highlighting both the unpredictable and ever evolving nature of teaching and the necessity of constantly maintaining a principled orientation toward justice when making moment-to-moment decisions. This conception of teaching acknowledges that "each moment of teaching and learning is consequential as teachers and students continually and jointly renegotiate power and possibility in every interaction" (Philip, 2019, p. 5). In this paper, we investigate teacher learning from the perspective of seeking to learn more about how teacher workgroups can be co-constructed to support the type of grappling that is necessary in equitable, student-centered mathematics teaching, especially teaching that challenges deficit ideologies (i.e., anti-deficit teaching).

Methods

The two of us, Nicole and Mallika, are united by our experiences as former teachers who have ourselves grappled with the challenges of realizing strengths-based, anti-deficit goals in our classrooms. We continued to engage in this grappling as graduate students at the University of California, Berkeley (where we first met) and still engage in it today, in our roles as teacher educators and researchers. We thus approach our research with a sense of the challenges many teachers face and an interest in understanding and supporting their ongoing learning, which contrasts with approaches that seem to blame teachers for their shortcomings. This relates to our shared goal of complexifying research on teacher learning by attending to the entanglement of this learning with political and ideological contexts and its messy, non-linear character.

In this paper, our analysis draws from two research projects, which we initially conducted independent of one another. Mallika's study was a social design-based research project of a teacher learning community that she co-designed with six first-year teachers from the same K-8 teacher preparation cohort. These teachers were all Mallika's students in a math methods course and were selected because they would be teaching elementary school locally and had voiced a shared commitment which they articulated in the first community meeting as "creating a math community where everyone meaningfully contributes to the mathematical work of the classroom." This overarching commitment grew out of shared experiences in the math methods course of seeking to disrupt processes of marginalization within the mathematics classroom which function to uphold racialized hierarchies of mathematical ability (Martin, 2009). The learning community (named Math Crew by participants) was intended to support teachers to work toward their shared commitments while navigating the tensions and contradictions of

working within deficit-oriented systems of schooling. The support structure consisted of monthly community meetings and periodic classroom visits from Mallika.

Nicole's project involved groups of teachers at four schools, all participating in a professional development program called the Elementary Mathematics Collaborative (EMC; a pseudonym, like all school and teacher names in this paper). Situated in a large American city, EMC focused on "high-need" schools in economically and politically marginalized neighborhoods, with the goal of supporting "ALL students [to] engage in mathematical sense-making leading to deep mathematical understanding" and "to develop a sense of mathematical agency and authority" (according to EMC materials). EMC's mission was thus connected to equity concerns, but in ways that did not explicitly name or interrogate systems of oppression in mathematics education. "Cycles of collaborative practice" were an important component of EMC activities. Similar to lesson study (Lewis et al., 2006), these cycles involved teachers in collaboratively planning a lesson, observing one teacher enact the lesson, then sharing what they had observed and planning next steps together. Each cycle was facilitated by an EMC coach. Nicole was involved as a participant-observer (not as a coach or PD leader).

To analyze our data, we examined the values around which solidarity was organized. What values did participants claim as their own? Relatedly, what did they characterize as qualities of "good" teaching/teachers or "bad" teaching/teachers? Because we were also concerned with whether teachers' constructions of "us" set up a dynamic of "us versus them," we asked: who was included (implicitly or explicitly) in the solidarity being constructed? Connected to our interest in teachers' opportunities to learn in these episodes, we also investigated how teachers framed grappling and struggle (e.g., as an important and necessary part of learning, or as an indication of failure) and what ideas they did or did not set themselves up to grapple with together.

We selected five episodes for close analysis, aiming for variety with respect to the answers to the questions outlined above. Two episodes were drawn from EMC's School 53, involving the EMC coach and three teachers and the other three episodes are from community meetings in Math Crew.

Findings

We use five episodes across the work groups from our two studies to elaborate how constructions of "us" and "them" are not stable characteristics of groups but instead are constructed from moment to moment in ways that shape opportunities for learning. In both Math Crew and School 53 there were moments when teachers and coaches/facilitators co-constructed "us" as a group in which teachers could struggle and grapple together toward their shared commitments, as illustrated with episodes 1 and 2 (Math Crew) and episode 4 (School 53). While in Math Crew these constructions of "us" were explicitly anti-deficit and supported teachers to grapple with deficit ideologies, the construction of "us" in School 53 focused more broadly on student-centered mathematics teaching, illustrating the ways that solidarity in teacher work groups is co-constructed toward particular goals. In both teacher work groups, when constructions of "us" also included constructions of "them," this tended to lead to binaries of "right" or "wrong" answers and "good" or "bad" teachers, which closed down opportunities for grappling and deeper reasoning about teaching as illustrated in episode 3 (Math Crew) and episode 5 (School 53). Across these five episodes we emphasize the in the moment construction of "us" and "them" as affording and constraining opportunities for teachers to grapple with teaching toward their commitments.

Math Crew

Math Crew was formed with an explicit commitment to working toward anti-deficit mathematics teaching. The community was voluntary, and all six teachers who chose to participate did so because they wanted to receive support in trying to live up to their commitment to disrupting deficit ideologies in their everyday teaching. We selected three episodes to elaborate the ways constructions of "us" and "them" afford and constrained teacher learning toward grappling with deficit ideologies. The first two episodes illustrate how constructions of "us" fostered moments of solidarity in the struggle of maintaining a strengths-based lens in everyday teaching and created opportunities for teachers to think more deeply about deficit ideologies. The third episode illustrates how, even with an anti-deficit construction of "us", moment to moment constructions of "them" can close opportunities for deeper reasoning and grappling about teaching.

Episode 1: Constructing an "us" that supports collective anti-deficit learning

To illustrate constructing an "us" with anti-deficit goals, we use an episode from Math Crew during the learning community meeting in November. In this episode, one teacher, Maritza, shared a story from her 4th grade classroom. She told the community about how, during a classroom visit, [Author 2] had helped Maritza notice a mathematical strength of one of the students in her classroom who had been labeled as "struggling" in math by school administrators. Maritza described how she had not initially noticed what the child was doing but that, once Mallika had pointed it out, she was able to highlight this strength both in the student's small group and in a whole

group discussion. She then described how this action shifted status dynamics and seemed to positively impact the student's math participation during subsequent math lessons. Right after Maritza finished sharing this story of a "success" in her commitment to working toward anti-deficit math teaching, Kara jumped in to share, "I have a connection. It was so helpful to have [Author 2] in the classroom just cause I was so scattered when Mallika came." After explaining more about why she was scattered, she went on to say, "[Author 2] was like 'it would just be nice for you to be able to take notes on strengths.' Literally the only thing I had on my notepad at the end of that session was (drawing a box in the air) a rectangle." At this, the other teachers erupt in loud, exuberant laughter, with lots of head nodding and signals of agreement. Kara further explained, "One kid asked 'what's a rectangle?' and it was a little blue rectangle. I was like 'this is a rectangle.' That's all I had taken (using air quotes) 'note' of." At this, Maritza laughed loudly, Marie put her head in her hands laughing, and Selina commented, "Oh my god, that is amazing."

While Maritza's story had focused on a positive moment in her teaching, Kara chose to draw out and connect with the struggle that Maritza mentioned about how hard it was to notice strengths on her own. With her rectangle story, Kara built on this acknowledgement of struggle to share a moment of total failure in being able to live up to her commitment to noting strengths in the day-to-day intensity of classroom teaching. The laughter in the responses from other teachers seemed to indicate a form of solidarity (Takeuchi, 2016) in the shared struggle to enact their commitments, and provides evidence of the co-construction of an "us" committed to taking an antideficit stance AND an "us" of human beings who sometimes fail in their attempts to embody that stance in their everyday teaching. In the intense reactions to Kara's story, there was a palpable sense of relief in being able to hold that failure collectively, as a community.

Episode 2: Drawing on a co-constructed anti-deficit "us" to grapple with deficit ideologies

The co-construction of an anti-deficit "us" that included struggle helped to create a space in Math Crew for beginning teachers to grapple with deficit ideologies and the ways those ideologies are embedded within structures and systems. With this episode, we show the type of grappling that teachers were able to engage in, and how that grappling connected to an anti-deficit "us" that includes struggle and imperfection. Toward the beginning of the final meeting as a learning community, Kara shared a recent tension she had experienced at her school site where she was asked "to fill out these classification cards for next year and we have to rate each of our students like high, medium, or low in math." Kara went on to describe the tension this caused for her:

> And I was like, 'oh no, that's terrible.' It felt sad that that's how the school wants to think about students and that they would think about distributing kids based on that, like 'oh we don't want to give this teachers too many "low" (air quotes with fingers) kids' to ease the burden but it also made me think about how I see my students, and the kids who I feel anxious about in math are the kids who do have trouble persevering or kids who have low self-esteem. It's not low based on any score, I'm looking more at their relationship to math and the way they see themselves as a math learner and that just makes me even more driven to set up my culture next year even more enforcing the expectation and the value that everyone is a math learner and has something to contribute. I also felt kind of like, moral, do I stand up to the system and say 'I will not fill out these classification cards' or is it like, what do I look at to fill these out, what are you asking for?

In talking through her dilemma, Kara explicitly indexed an anti-deficit "us" by using the same language that had been co-constructed in Math Crew of everyone having something to contribute to a math community. In this story, deficit ideologies were located within systems and structures, which was evident when Kara raised the question "do I stand up to the system?" (emphasis added). By bringing this "moral" dilemma to Math Crew, she was treating the constructed "us" as a resource to help her reflect on and grapple with how she was hoping to see the children in her classroom. Here, Kara interrogated the category of "low" by considering which students she felt "anxious about in math" instead of treating these categories as taken-for-granted and static, as the classification cards suggested.

Kara then talked out loud about what she might do, describing in detail her thinking about one of her students who "at the beginning of the year for addition and subtraction used his fingers and would do it under the table but felt super insecure about math." She went on to describe how this student now "is just like an awesome partner to have in math and is seen as someone who has cool strategies and is seen as someone who participates in full group math thinking and is able to ask questions and get help." She concluded by saying, "I can't see putting him high, medium, low. Where would I? I don't know, none of the above. He's just a cool kid." Throughout this storytelling, the co-constructed "us" of Math Crew was a place where deficit ideologies could be

questioned and grappled with, and where the point was not to find the "right" answer to the dilemma of the classification card, but instead to reflect and reason about how to navigate it in a way that was consistent with their shared commitment to disrupting deficit ideologies.

Episode 3: Constructing a "them" that inhibits anti-deficit collective learning

During the same conversation in Math Crew, another teacher, Selina, who taught at the same school site as Kara, told another story that also involved constructing an explicitly anti-deficit "us" (Kara and Selina had discussed these stories in the car on the way to the meeting). While Selina's construction of "us" was similar to Kara's construction, when Selina spoke about deficit ideologies, she located these ideologies in individuals rather than in systems, thus constructing "them" in contrast to the anti-deficit "us" of Math Crew.

The story Selina told involved an inquiry project about language and mathematics across different schools in her district. She described a moment during the collaborative planning process when she suggested randomly selecting a student to share and another teacher questioned that choice:

> One of the teachers was like 'well what if you choose somebody that has it completely wrong and they're totally lost and don't know what's going on?' Aaand that just felt so negative to me, like, 'what do you do with this kid that doesn't get it?' So I said, 'you know what, everybody has some kind of math thinking so we're going to tease out whatever it is that they're bringing and just talk about it. And, you know, at least in my classroom everyone has something to contribute.' And I think in that moment is really when I saw that clear division between my thinking and other people's thinking, which is crazy to realize that not everybody thinks like we do.

As in Kara's story, Selina used the shared language of Math Crew ("everyone has something to contribute") to refer to a co-constructed "us." This "us" provided a resource for her to push on the deficit ideologies she encountered during the project. However, in contrast to Kara's story, Selina also constructed "them" when she emphasized what she tried to do in "my classroom" (in contrast to other teachers' classrooms) and when she described the "clear division between my thinking and other people's thinking." When Selina concluded by saying "not everybody thinks like we do," the "us" that she constructed was in contrast to "them" as other educators who do not hold the same anti-deficit stance.

During her story-telling, Selina focused on "right" and "wrong" approaches to teaching associated with the "us" and "them" that she had constructed. We argue that this sense of "them" and of "right" and "wrong" is not supportive of anti-deficit teacher learning in that the quick offering of solutions interferes with the type of grappling that is essential for trying to engage in the ongoing task of living up to one's commitments in everyday teaching. In this instance, for example, the group might have instead engaged with the problem of practice that her colleague had raised of how to respond to children when they have an incorrect answer—a genuine dilemma in anti-deficit instruction. In addition, when "them" is constructed as other educators, the potential exists for an undermining of trust, solidarity, and risk-taking because any teacher could at some point become "them" if they do not say or do the "right" thing. Selina's and Kara's stories, which were shared during the same conversation, highlight the dynamic, moment-to-moment nature of constructions of "us" and "them." While Kara's construction of "us" made space for deeper thinking about her own practice, Selina's construction of an "us" that included "them" seemed to inhibit grappling with the everyday challenges of living up to her commitments.

School 53

We now turn to two episodes at School 53. Episode 4 reinforces our finding from Math Crew that constructions of "us" can open up opportunities for teachers to learn—i.e., to collaboratively grapple with the challenges of reconciling commitments to equitable, student-centered instruction with competing ways of understanding their own work. Episode 5 shows how even a subtle construction of "them" may close down opportunities to learn, similar to Episode 3 in Math Crew but with a "them" that is present in the room. Together, the two School 53 episodes show that "us" and "them" are not stable; rather, they are constructed from moment to moment and in relation to particular goals and values. Both of these episodes are drawn from a single lesson debrief. Ms. Scott had just taught a lesson that did not go according to plan. She is joined by two of her colleagues at School 53 (Ms. Ortiz and Ms. Edmond) and the EMC coach (Ms. Koets).

Episode 4: Constructing an "us" that supports collective learning

Coming out of the lesson, Ms. Scott was quite flustered. She was clearly aware that she had not followed the plan of allowing students' ideas to drive the lesson, explaining that she had seen them making mistakes and "being a

mother hen, I don't want them to struggle or get frustrated." Yet her efforts to guide students "in my direction," to her solution strategy, had lost many students. Ms. Koets (the coach) immediately positioned herself in solidarity with Ms. Scott, saying, "It's very hard. This is not how we were taught as children. This is not how we were taught when we went to teacher school, right? So it's hard sometimes to, like let the class kind of go free." She further noted that leading students to "the answer" is oftentimes "what [students] want, and what we kind of feel like we have to do," framing what Ms. Scott did as fulfilling an obligation for which teachers are often made to feel responsible. Ms. Ortiz also hinted at ways that their shared project of engaging students with challenging, open-ended tasks ran counter to customary instruction, noting that open-ended tasks could be "scary": "I can understand where I think you're coming from, because I would think that. You have less control because there's so much freedom." The group went on to examine the work students had done before Ms. Scott pulled them together. They focused their discussion on student strategies and insights that Ms. Scott could build on when she returned to the task the next day, as well as "good teacher move[s]" (in Ms. Koets's words) through which Ms. Scott had actually supported students to generate those strategies and insights, despite her perception that she had made a mess of the lesson.

Members of the group thus participated in constructing an "us" united around centering students' mathematical thinking, in explicit contrast to teacher-centered traditions in U.S. schooling. They made repeated use of the pronoun "we," especially Ms. Koets, and positioned themselves as sharing in Ms. Scott's struggles with giving students enough "freedom" to exercise mathematical agency (similar to how teachers in Math Crew positioned themselves as sharing Kara's and Maritza's struggles to notice strengths in Episode 1). Notably, Ms. Koets also explicitly disrupted interpretations of herself as an expert, saying, "We, in this, safe environment right now, I'm not evaluating you in any way. I will never evaluate any of you." She thus rejected the common framing of coaching as evaluative and hierarchical in favor of a collective "we." This developing solidarity went beyond empathizing with struggles to open opportunities for group members to learn together in service of their shared project, specifically, to grapple with the feelings of discomfort and fear that the shift in "control" from teachers to students brought out. The group framed this as a shared challenge that could and should be raised for discussion and collective sense-making in their meetings.

Episode 5: Constructing a "them" that hinders collective learning

One might assume that the solidarity Ms. Scott, Ms. Ortiz, Ms. Edmond, and Ms. Koets constructed around supporting students to engage with open-ended challenges would extend to "ALL students," in accordance with the PD program's stated vision. Approximately 30 minutes into the conversation, however, Ms. Edmond remarked that she had been looking for ways to support "higher-order thinking" and give students opportunities to "take more charge," musing that she could use an activity similar to the one Ms. Scott had just taught—but "maybe I would only do it for my higher-level groups, and not everyone." Ms. Scott picked up this idea, starting to say, "I really believe, if I took some of my higher learners and, put them in a small group—" before being interrupted by Ms. Koets, who placed her hand in front of her chest, palm toward the group, and said, "I gotta, here's, here's my pushback. I want it for everybody." A flood of overlapping talk ensued. Ms. Ortiz nodded and echoed, "Not only higher learners, yeah." Ms. Scott repeated, "For everybody," and shifted awkwardly in her seat. Three times, Ms. Edmond unsuccessfully attempted to break into the conversation to clarify her intent. Ms. Ortiz asserted, "There's an entry point for everyone," then qualified this statement, gesturing at the student work on the table and saying, "at least for this one. I've watched some other ones that have been very abstract." On her fourth attempt, Ms. Edmond gained the floor and clarified, "So my small groups are more like centers. So each student gets a chance to visit a center." Ms. Koets responded by briefly elaborating on her concern that "kids at this [low] level may never get such fun wonderful tasks, and they can do it," then quickly moving on to "teacher moves that have to happen" and cannot be done by students at centers if they work totally independently.

Instead of building an "us" around the challenge of disrupting the deficit thinking that "we were taught as children … [and] taught when we went to teacher school" (as Ms. Koets did earlier in the conversation), the group momentarily fractured. Ms. Koets interrupted Ms. Scott, limiting the group's access to Ms. Scott's sensemaking (and resources it might have contained for collective sense-making) and shifting the conversation to Ms. Koets's ideas. Furthermore, the coach framed her perspective as "pushback" and emphasized "I," not "we," putting Ms. Edmond and Ms. Scott on the defensive, physically on the other side of the small wall of her hand. Ms. Ortiz aligned herself with Ms. Koets, contributing to the construction of an "us" who believe in making rich, challenging tasks accessible to "everybody" and "everyone," in contrast to a "them" who thinks such tasks might be appropriate only for "higher-level" students. Notably, they worked to repair this rift in their solidarity. Ms. Ortiz's hedge, "at least for this one," left open the possibility that there might be other tasks where they would all agree on restricting access to "higher learners," and Ms. Koets responded with, "Yeah. Yeah." And when Ms.

Edmond finally got to speak, she aligned herself with the "everyone" camp, as though she had never considered "higher-level groups, and not everyone."

In some ways, the group's work in this lesson debrief might be considered successful. At a cross-school PD meeting a few days later, Ms. Scott shared her story of learning to give students more space to generate their own ideas, saying that she had returned to the task with her whole class and was "proud of my babies" for their breakthroughs. Collaborative coaching cycles continued at the school with all three teachers' involvement, and Ms. Koets reported that she did not hear any of them mention "higher learners" again. Yet the opportunities for teachers to engage in anti-deficit learning were quite limited and abstract. They were not able to grapple with the meaning of "high" and "low" as conceptual categories, or with the potential disconnect between specific experiences and observations that might seem to indicate that these categories capture important distinctions between students (in contrast to the Math Crew episode in which Kara opened a space to "think about how I see my students"). Indeed, the fact that these labels did not come up again in their conversations might indicate less that teachers learned something about the harm those labels could do than that the us/them dynamics in this episode—with the intense risk they presented of being cast as "them"—discouraged participants from using this group as a space for such grappling.

Discussion and implications

The episodes we have shared show that a sense of solidarity as "us" can be an important resource for teacher learning in collaborative work groups. In both Math Crew and School 53 conversations, participants invoked shared values and goals in ways that supported them to then grapple with the difficulty of enacting those values to achieve their goals in the context of systemic ways of thinking that emphasized competing values and goals and which continued to influence them, making it hard for them to see students' strengths (in Math Crew, Episode 1) and to give students more freedom to explore their own ideas and strategies (in the first episode at School 53).

We have also shown, however, that constructing an "us" that is defined by opposition to a concrete "them" can backfire. This opposition may momentarily unify (some) members of the group, but us/them dynamics can close opportunities for sense-making by emphasizing "right" and "wrong" answers, and create the potential for members of the group to slide from "us" to "them" at any time. This interferes with learning because it is difficult to reveal one's struggles when faced with the risk of being judged a bad teacher or worse, a bad person. Further research and practice could productively explore how teacher groups can be supported to build solidarity without constructing someone else as "bad." Our data suggest several strategies. First, groups might be guided to focus on the ways that deficit ideologies are embedded in institutions, structures, cultural traditions, and social practices rather than focusing on "bad" individuals. This appeared in our data when Kara referenced school as a system that operated by classifying students as "high, medium, or low," and when Ms. Koets referenced "how we were taught as children" as an obstacle to student-centered instruction.

A second strategy teacher groups might use to build an "us" without a "them" is to deliberately blur the line between "good" and "bad" teachers, allowing "good" teachers to make "bad" mistakes without becoming "bad" people. This was especially evident in the episode in which Maritza and Kara shared their failures to notice their students' strengths. Instead of responding with judgment or censure, their colleagues laughed in genuine solidarity. Together with the first strategy we described (focusing on deficit ideologies as embedded in institutions, structures, cultural traditions, and social practices instead of in "bad" individuals), blurring the good/bad binary recognizes that all of us are socialized into oppressive systems, so it is not a personal fault when those systems are reflected in our thoughts and actions—although we are responsible for repairing harm and for engaging in ongoing learning to do better.

A third strategy that may be vital for building solidarity as "us" without constructing an opposing "them" is for teachers and teacher educators to deliberately invite one another to grapple with the messiness of realizing anti-deficit goals in everyday practice. This goes beyond the first two strategies, which may be employed in ways that teachers experience as supportive (because they may foster a sense of belonging, camaraderie, and empathy, for example) but which may fall short of engendering anti-deficit learning. This strategy also clarifies that antideficit learning is not linear or something that can ever be accomplished once and for all. Such learning is not a matter of excising certain terms (like "high" and "low") from our vocabulary but of continuing to wrestle with the ways that oppressive ideologies persistently shape how we think and act.

Fulfilling the responsibility for ongoing anti-deficit learning in a world that remains strongly shaped by deficit ideologies is nontrivial. We have shown how participants in our studies created opportunities to grapple with the challenges of realizing their ideals, without having to fear that their struggles made them "bad teachers." We have also shown how constructions of "them" shrank rather than opened space for such grappling. If participants had built up an "us" without creating a "them" in those instances, using the strategies we have outlined here and which we saw them use on other occasions, they might have been able to engage in more meaningful

learning in those episodes and perhaps in subsequent interactions as well. More research is needed to further explore this possibility, but in the meantime, we hope that these strategies will be useful to other teacher groups, as they work to harness the power of collaboration to transform deficit ideologies and contribute to dismantling systems of domination, through daily teaching and (teacher) learning.

Mobile Augmented Reality Supporting Community-based Learning: Families' Exploration of Land-Water Interactions

Heather Toomey Zimmerman, Susan M. Land, Lillyanna Faimon, Yu-Chen Chiu
heather@psu.edu, sland@psu.edu, lkf5240@psu.edu, yxc599@psu.edu
Penn State University

Abstract: From a design-based research study investigating rural families' science learning with mobile devices, we share findings related to the intergenerational exploration of geological time concepts at a children's garden at a university arboretum. The team developed a mobile augmented reality app, *Time Explorers*, focused on how millions of years of rock-water interactions shaped Appalachia. Data are recorded videos of app usage and interviews from 17 families (51 people); videos were transcribed, coded, and developed into qualitative case studies. We present results related to design elements that supported sensory engagement (e.g., observation, touch) through AR visualizations related to geological history. This analysis contributes to the literature on informal learning environments, theory related to learning-on-the-move, and the role of sensory engagement with AR experiences in outdoor learning.

Understanding the scale of earth sciences scientific phenomena, such as geological time, is often difficult for learners (Cervato & Frodeman, 2012; McDonald et al., 2019). Geosciences educational researchers and educators (e.g., Orion & Ault, 2013; Resnick et al, 2017; Tretter et al, 2006) have used pedagogical techniques such as analogies, walking or moving through a scaled version of a time or space, or time-lapsed videos to address these challenging concepts. Additionally, the environmental crises that overlap the earth sciences, such as water quality and freshwater access, are complex— requiring understanding and solutions that integrate information across various geographic, geological, and time scales. To address these difficulties in learning earth sciences concepts, our team has been developing mobile, augmented reality (MAR) apps deployed on handheld computers (iPads, iPhones) to support rural families to learn these complex topics in outdoor spaces in their communities. This analysis focuses on one app, *Time Explorers*, that addresses geological time with an immersive MAR experience that illustrates how millions of years of rock-water interactions shaped one Appalachian community.

MAR layers digital material into outdoor spaces via devices' screens to expand opportunities for learning (Ryokai & Agogino, 2013; Zimmerman et al, 2020). MAR relies on digital resources to reveal scientific meanings not directly visible to learners (Dunleavy & Dede, 2014) in parks, gardens, and forests (Georgiou & Kyza, 2017; Kamarainen et al., 2013; Land & Zimmerman, 2015). Our immersive MAR designs focus on developing *micro-sites* (Sharples & Pea, 2014) for families' learning —drawing upon planned and emergent experiences to create science learning opportunities related to geological topics. In this paper, we ask the research question:

- How does a MAR app influence families' sensory engagement related to understandings of geological time in an informal learning environment as they participate in an immersive learning-on-the-move experience to understand the effects of millions of years of land-water interactions?

Conceptual Framework: Learning-on-the-Move and Sensory Engagement

Geological time is foundational to understanding the geosciences as it "highlights the way geoscientists tell time – a coarse time scale in which millions of years are the most common coins of currency" (Cervato & Frodeman, 2012, p. 3). Earth's geological time can be determined by observations and analyses of rock strata and the fossils the strata contain. Cervato and Frodeman (2012) point out numerous reasons that learning geological time is difficult for learners including that learners mistake the timing of key geological events (e.g., formation of mountains, landform movements), confuse the timing and distance between geological periods, and have limited understanding of the rate of erosion, deposition, and landform movements. Our research and development efforts on a MAR app influence brought together two key concepts to first design for and then analyze families' sensemaking about geological time: a) learning-on-the-move to illuminate the change in time metaphor of the app and b) sensory engagement (e.g., visual, tactile) to observe evidence of the past in the rocks and the simulated cave and rock strata on-site.

Learning-on-the-Move to Support the Understanding of Scale

Researchers study the use of mobile technologies in and around communities via the concept of learning-on-the-move (LOTM) (Marin, 2020; Silvis et al., 2018; Taylor, 2017; Zimmerman, & Land, 2022). LOTM describes a social learning process where people collaboratively learn as they move their bodies within and through spaces.

 © ISLS

Movement, especially gesture, has been found to be a supportive sensemaking approach in science and mathematics education (e.g., Alibali & Nathan, 2012) —including with technology (Kang, et al., 2021). Looking at movements within and across spaces, Silvis et al. (2018) investigated families' technology practices and found that mobile computers and other technologies were integrated as learning tools across sites. Taylor (2017) used ethnographic methods to explore how youths used mobile technologies, on foot and by bicycle, to understand their community as a designed, complex system.

In our case, we designed for LOTM, where people's movement enhanced our immersive time travel narrative and encouraged sensory engagement with the specimens and sculptures in a garden. Drawing from Ma (2017) who considered large-scale "multi-party, whole-body interactions" as critical in learning geometry, we designed learning experiences for families, whereby moving their bodies through a children's garden together, leveraged multiple body-place interactions to make sense of geological time. Relatedly, we built our research and design efforts from Marin's (2020) assertions that " walking and lands/waters have always been and continue to be central to human learning, development, and activity (p. 282)." Marin and Bang (2018) found questioning, directing, and narrating were key learning practices that families used to make sense of the natural world, and as such, in our designs, the team left space for families' conversations to allow for learning practices to emerge.

Sensory Engagement to Support Scientific Observations

Beery and Jørgensen (2018) note that when children play outside, their physical play includes body movement and sensory engagement. Ballantyne and Packer (2009) argue that sensory engagement is an essential part of learning in environmental education experiences. From McClain and Zimmerman (2016), we define sensory engagement as gestures and movements that foster visual, auditory, and tactile observations and gestures that create joint attention (i.e., pointing) and discussions.

Sensory engagement (through visual and tactile means) supports scientific observation (Eberbach & Crowley, 2009). Mogk and Goodwin (2012) argue that learning to observe is critical for the geosciences: "Observations in the field allow us to interpret and explain what has happened in the past (postdiction) in order to show us what is possible regarding present and future Earth phenomena (prediction)" (p. 141). We focus on sensory engagement in our study, as primarily tactile and visual observations. This includes the learners comparing the texture of sandstone and limestone rocks, feeling for marks of erosions, and observing rock layers and how they can move over time.

Method: Two Iterations of Design-Based Research

We use the iterative, qualitative approach of design-based research (DBR) approach (Sandoval & Bell, 2004). DBR advances theory related to LOTM and sensory engagement as it enhances practice related to the design of informal learning environments.

Participants and setting

Our study focused on rural families visiting the children's garden at the Arboretum at Penn State. We utilized our community partners' websites, social media sites, and listservs for recruiting. All participating families required internet access to complete online consent and participate in our Zoom interviews. We acknowledge that we only reached rural families with ample technological resources during COVID-19.

In Iteration 1, seven families living in two rural counties participated (8 adults, 12 youths). Guardians self-reported their families' racial affiliations as White (100%); two children were also guardian-reported as Other (10%). Children (female: 25%, male 75%, non-binary: 0%) were primarily 5-12 years old (92%). Two guardians were scientists; two were administrative staff. Other occupations were writer, farmer, and educator. One family homeschooled their children. In Iteration 2, ten families living in one rural county participated in the research (15 adults, 16 youths). Guardians self-reported their families' racial affiliations as mostly White (White: 97%, Black or African American: 3%, Hispanic or Latinx Origin: 3%). Children (female: 50%, male 50%, non-binary: 0%) were primarily 5-12 years old (94%). Four guardians were educators (e.g., teachers, instructors, professors); three were unemployed; and others' occupations were researcher, program specialist, homemaker, human resources staff, illustrator, CFO, self-employed, and military. Two families homeschooled their children.

Time Explorers app features and technology

The *Time Explorers* MAR experience was approximately 20-40 minutes as families completed a narrative time travel journey through the geological history of Appalachia in the children's garden. *Time Explorers* was divided into eight micro-sites organized by geological time (starting at prehistory). Guided by the GPS map, learners moved forward in time to understand how vital landforms of the area were formed in Appalachia: (a) Time Spiral (Ordovician Period), (b) Coral Sculpture, (c) Limestone Boulders, (d) Sandstone Boulders, (e) Arched Rock Wall,

(f) In-and-Out Creek, (g) Cave, and (h) Spring Basin (Figure 1). In Iteration 2, the MAR elements were the same; however, we added an AR filter family selfie at the end of the experience, a back button, made simple text edits for clarity, fine-tuned the GPS for the cave micro-site, and added a pre-interview task.

Figure 1

Data sources and analysis

Due to COVID-19, our data were collected with a social distancing protocol. Data include 16 families' iPad screen recordings and GoPro videos that captured their talk interactions in the MAR learning experience. One family's GoPro video and four families' screen recordings were not fully captured due to technical difficulties. Families borrowed one iPad with the *Time Explorers* app, which recorded their app interactions and talk throughout the experience. One family member wore a hat-mounted GoPro camera to record the experience in the first-person view. The screen recordings and GoPro videos were displayed side-by-side for data analysis. Additional data included 17 pre- and post-experience interviews via Zoom and 17 online demographic survey responses. In Iteration 1, the pre-experience interview included questions on how ridges, valleys, and caves formed and if the family had prior experience with caves. The post-experience interview included a) the same two questions, b) a drawing task which asked the oldest child to draw how ridges, valleys, and caves formed, and c) the family's overall impression of the app. In Iteration 2, we also included a) the drawing task in the pre-experience interview, b) questions related to how caves formed and how water shaped the landscape, and c) one question on whether the family had ever seen similar landforms. The drawing task was completed by the families' eldest child (with

any younger children having the option to also complete a drawing). The eldest child explained the drawings first, followed by a family discussion.

To analyze how families used sensory engagement and learning-on-the-move to make sense of the geological prehistory, we conducted a qualitative analysis of the screen recordings (thirteen whole and two partial) and GoPro videos (sixteen full) at the unit of analysis of the family (defined for our study as at least one guardian and one child aged 5 to 12). To conduct interaction analysis (Jordan & Henderson, 1995), the authors held co-viewing sessions to watch all screen recording and GoPro videos together (after the videos were professionally transcribed). Codes were applied to the video records by two authors to compare and contrast the families' experiences. Based on the IA session notes and coding spreadsheet, we selected three cases on how the MAR app influenced sensory engagement for this manuscript. To further analyze the three focal cases, a line-by-line analysis of the transcripts occurred, which highlighted how families' sensory engagement (verbal or tactile) was connected to verbally stated observation of hydrogeological phenomena or explanation of geological history at each micro-site. To understand the three case study families' learning outcomes, the drawing tasks from each family were analyzed to understand any changes in learning of water-rock interactions over geological history. Finally, to enhance our data analyses' trustworthiness, the team conducted co-viewing sessions, shared notes, and multiple researchers double-checking transcripts and codes.

Results

Overall, the families who engaged with *Time Explorers* successfully navigated through the learning-on-the-move time travel metaphor to move their family through the garden on a time walk from the Ordovician period to the present day. Families started at the time spiral and had an app image that moved them through key landforms that represented different periods of geological time, used the app resources to place the landforms in their appropriate geological time, and engaged in sensory engagement (primarily tactile and visual observations) to support their understanding of the formation of the Appalachian landscape.

Case study 1: MAR app supported sensory engagement without being a distraction

Given the digital technology, our team examined if our MAR materials supported geosciences-related observational engagement in the children's garden without distracting the families. We found the mobile computers did not dissuade families from engaging with sensory exploration in the outdoor learning space. During the AR experience, Tanya (Mother) and Oliver (11-year-old boy) engaged in sensory observations of the features representing the landforms. For example, at the Sandstone Boulders, following the display of a prompt, the family walked closer to the rock and touched it:

Tanya: What do you see? ((touches sandstone))
Oliver: It's smoother, and it's flatter than the other one [refers to Limestone micro-site] ((touches sandstone)). It has little dents in it. (Figure 3)
Tanya: They are picked apart in some areas ((moves a finger to an indent)). Feels bumpy and almost like sand a little bit, right?
Oliver: Mhmmm (affirmative). ((touches the indent))

Figure 3
Screenshot of the Sandstone Boulders (left); Tanya and Oliver observing the rock

Tanya and Oliver actively engaged in a visual and tactile exploration of the rock's appearance and texture caused by erosion as they moved their fingers across its surface. Tanya used her body to guide Oliver where to touch the rock and look for the evidence of erosion. Additionally, Oliver compared the last limestone micro-site to the current sandstone micro-site as he compared the rocks that formed in different geological times.

Comparing Oliver's pre- and post-experience drawings (Figure 4) and responses in the interviews, Oliver adopted scientific vocabulary related to changes in the Appalachian area over millions of year (e.g., his language moving from terms such as "jagged" rocks and mountains to terms such as limestone, sandstone, ridges, and valleys). For example, in the pre-experience interview, he included a local mountain, a river, and some houses in his drawing (Figure 4, left), and when asked how caves were formed, he said tectonic plates formed caves; whereas, in the post-experience drawing (Figure 4, right), he noted a cave was eroded by water over millions of years. Oliver demonstrated a clearer understanding of what and how natural forces (i.e., water eroding rocks over a long time) shaped his community's present-day landforms.

Figure 4

Oliver's pre-experience (left: long ago and now) and post-experience drawings (right: long ago and now)

Case Study 2: Learning-on-the-move allowed families to integrate complex information about geological historic periods across the micro-sites of learning

Our team designed for LOTM to allow for the geological time walk, anchored by MAR elements within the app. As they moved through the children's garden, families built knowledge about how Appalachia changed over geological time, as they connected information from different micro-sites of learning to see that Pennsylvania was under water millions of years ago. One example of this comes from one family, Jennifer (Mother), Amanda (Mother), Izzy (11-year-old girl), and Ethan (7-year-old boy):

Izzy: Look at this photo about ridges flowing. ((reads)) "Talk about what you learned." Let's talk about what we've learned. Sandstone. ((gestures toward Arched Rock Wall micro-site)) It's made of sandstone and limestone.
Amanda: Sandstone is made of sand and silica.
Izzy: Quartz and silica. [connects to Sandstone MAR micro-site content]
Amanda: Oh. Quartz and silica. Thank you. (…)
Jennifer: Ethan, do you remember what limestone is made from?
Ethan: Sand. ((touches arched rock wall))
Jennifer: Nope. Close. It has to do with the sea. [references Coral Sculpture micro-site content]
Izzy: Carbon — no
Ethan: Coral!
Izzy: What is coral made of?
Jennifer: It's sea creatures.
Amanda: Calcium. [connects to Limestone MAR micro-site content]

This case illustrates how the LOTM experience encouraged the family to connect information across the garden — synthesizing information from four MAR micro-sites together at the (human-created) Arched Wall, which simulated the strata of limestone, sandstone, and other rocks. Izzy, Amanda, Jennifer and Ethan discussed the connection of the sandstone and limestone in their community today (that makes up the visible ridges and valleys) to the prehistoric oceans (with coral) that covered Pennsylvania millions of years ago.

Similarly, Izzy's understanding of how Appalachia changed over geological time also shifted from the pre- to post-experience interview, illustrating her connecting multiple micro-sites and times from the immersive experience. Describing her pre-experience drawing (which both contained mountains, trees, and a river (Figure 5, left)), she said: "I would say that the land hasn't changed too much, except for the humanity that has come to, um, destroy everything in its path." Her post-experience drawings, however, show her understanding of how the land has changed over geological time as shown through multiple micro-sites in *Time Explorers*: "mountains from plates pushing the other, and trees, and rivers from erosion" (Figure 5, right). The difference in her descriptions and drawings of how Pennsylvania has changed over geological time demonstrates that she gained an understanding of how water, rock, and tectonic plates influenced Appalachia over millions of years.

Figure 5

Izzy's pre-experience (left: long ago and now) and post-experience drawings (right: long ago and now)

Case Study 3: Discussion prompts and photographic features of the MAR app encouraged talk about how geological history changed the community landscape

The discussion prompts and photo-taking activities in *Time Explorers* facilitated families' in-situ science observation. For instance, in response to the discussion prompt "*Look closer at limestone boulders and talk about what you see*," Helen (Mother), Noah (11-year-old boy), and Jesse (9-year-old boy) collaboratively observed the limestone rocks.

Jesse: ((kneels and touches the rocks)) I sort of see... Is that rust? (Figure 6a)
Noah: Yeah. It looks like some.
Jesse: It looks like rust or copper.
Helen: I think there's something growing, don't you think, Jesse? It just happens to be that color.
Noah: Yeah. It looks like this is probably what—maybe calcium? Something that definitely has hardened over time.

Later, Helen walked and pointed out another rock that had cracks on it (Figure 6b), which gathered the boys closer and led them to discuss the hypothesis of water and rock interaction in the past created the cracks in the present time:

Helen: Okay. ((walks to the right)) What do you think these things are? ((points at another rock)) (Figure 6c)
Noah: I think those were pools of water.
Helen: Are these fossils?
Noah: ((walks to the right side of Helen)) No, I think those are pools of water. Just like really like — grew.
Jesse: Yeah, because pools of water make cracks like that ((points at another rock and walks around the rock)). (Figure 6d)

Figure 6

Helen, Jesse, and Noah use the family discussion prompts embedded in the app to notice cracks in rocks to understand that water and rock, together shape how Appalachia has developed over millions of year.

(6a) **(6b)** **(6c)** **(6d)**

In the process of discussing the prompt, the family shared their observations of the limestone rocks on-the-move. Walking to different spots around the Limestone Boulders, they first shared their observations of interesting rock textures aloud then collaboratively built different hypotheses of how the cracks on the rocks might form over geological time by drawing upon each other's observation.

In addition to the discussion prompts, the photo-taking activities embedded in the app also supported families to apply the augmented information to their observation in-situ. For instance, while Jesse was taking photographs at the In-and-Out Creek at another micro-site, Noah walked around a simulated stream to find evidence that represented water eroding limestone rocks to create water gaps:

Noah: Come over here! There's something you got to see. Look, you can see how there — it's very eroded. ((Helen and Jesse walk to Noah))
Helen: Isn't that cool?
Noah: It's very eroded in that area. ((points to the rock))
Jesse: It looks like it has three layers. ((takes a photo))

The photograph-taking activity supported the family in noticing and observing rock features that matched what they learned about water gaps from the app earlier. Through taking photos, the family made collaborative observations. Though Noah was not holding the device to take photographs, he was actively participating in the learning process as he constantly moved around, looked for evidence, and shared his observations aloud with Jesse and Helen. This pattern was commonly seen across families with more than one child, where parents and siblings took turns taking photographs and helping each other locate interesting, picturesque spots.

Discussion

Theoretically, our work further conceptualizes the role of the LOTM social learning process in an outdoor learning environment. Prior work sought to understand naturalistic perspectives on LOTM with technology (Silvis et al., 2018; Taylor, 2017) and without (Ma, 2017; Marin, 2020). In our study, we designed the *Time Explorers* app with LOTM principles, so LOTM became a pedagogical tool used to advance the geological time narrative. By moving through eight micro-sites representing eight different geological times in a children's garden, families relied on a time travel narrative to support their temporal understandings of complex geosciences concepts. Both the families' talk in situ and the families' pre- and post-experience drawings (e.g., Figures 4 and 5) provide evidence of the LOTM experience allowing participants to understand how water-rock interactions shaped community landforms over millions of years.

The case study analyses illustrated how MAR can support family conversations that integrate complex hydrogeological concepts throughout the learning experiences. The prior research (e.g., Cervato & Frodeman, 2012) has shown that developing geosciences understanding can be challenging; however, families in our study nonetheless connected multiple MAR micro-sites (i.e., Jennifer, Amanda, Izzy, and Ethan) to build complex understandings of how water, sandstone, and limestone interacted to create their community's present landscape.

Given the importance of sensory observations in outdoor learning (Ballantyne & Packer, 2009; Beery & Jørgensen, 2018), we found evidence that using the MAR app encouraged sensory observation in the children's garden with the digital content supporting, not distracting, families' outdoor explorations (i.e., Tanya and Oliver). The app's prompts suggested that families compare and contrast textures of limestone and sandstone rocks and find and discuss the visual evidence of water gaps, patterns in rock strata, and erosion. All the families in the study engaged in tactile and visual sensory engagement during the observation of concepts related to Appalachian geological time in response to the *Time Explorers* prompts and activities.

Finally, our analyses elucidate how the MAR app's photo-taking activities and discussion prompts could be successful tools in an app designed for rural families' outdoor learning (e.g., Figure 2 and Noah, Jesse, and Helen). While photo-taking and discussion prompts have been used in informal spaces in prior work, our research adds to the utility of these tools while LOTM during outdoor education experiences and to support geosciences observations. Prior literature reviews (Eberbach & Crowley, 2009) found little evidence of people recording and referring to observational notes when engaging in out-of-school-time science. Here, the families used photographs to capture and conversations to reflect on their observations as they moved through a children's garden; these tools were easy to deploy on a MAR app and quickly taken up by families.

Infrastructuring for justice: Reframing scale through a rightful presence framework

Angela Calabrese Barton, University of Michigan, angiecb@umich.edu
Edna Tan, University of North Carolina at Greensboro, e_tan@uncg.edu

Abstract: A challenge inherent in infrastructuring for justice lies in how existing structures and foundations that anchor education and educational reform enterprises are rooted in White Supremacy and heteropatriarchy, given their historical dominance in the disciplines, schooling and society. Drawing from justice-oriented studies of reform, and rightful presence centered participatory design-based research in long-term research+practice partnerships (RPP), we argue that infrastructuring for justice-oriented reform is contingent on scaling allied, sociopolitical activity systems in schools. Infrastructuring for justice requires on-going resistances, disruptions and transformations of existing structures and foundations that anchor educational research and reform. The objects of reform need to shift to the scalability of new relationalities from the scalability of products, tools, and ideas. Such new relationalities should be viewed as the new foundations for infrastructuring reform, with attention paid to the political clarity necessary for the conditions that make such justice-oriented reform possible.

Introduction

Justice-oriented studies of educational reform critique how current organization of educational infrastructures erase the experiences and practices of children/youth and communities in favor of schooling and disciplinary knowledge. A challenge inherent in infrastructuring for justice lies in how existing structures and foundations that anchor educational research/reform enterprises are rooted in White Supremacy and hetero-patriarchy, given their historical dominance in the disciplines, schooling and society. While it might be possible to infrastructure by building on technologies and practices that already exist (Bødker et al., 2017), the work entailed in infrastructuring for justice lies in the "redesign of components, relations, and routines" (Penuel, 2019, p. 659) towards disrupting injustices reproduced by existing systems and structures. We contend that systemic injustices are widespread, historical and enduring. Systemic injustices are not homogenous but rather, are made manifest via contextualized, local practices normalized as benign. Before we can infrastructure for justice, identifying such normalized unjust practices and structures – what they are, how they work, how they might be disrupted, who needs to be involved and in what ways – is necessary. Building on theories of critical justice and the rightful presence framework for teaching and learning (Calabrese Barton & Tan, 2020), *in this paper we argue that infrastructuring for justice is contingent on engaging in sustained, allied, sociopolitical activity systems in schools.*

Infrastructuring Educational Innovation

What and when is infrastructure?

Infrastructuring for educational innovation has become an important focus of reform efforts. As a theory useful for helping the field make sense of educational innovations – including their design, enactments, spread and scale – infrastructuring has become a useful lens for designing for conditions necessary for reform to take hold (Penuel, 2019). Penuel (2019), drawing upon Star (1999), describes infrastructuring in education as the coordination of the components of systems of practice, such as standards, curriculum, assessment, policies and organizational routines, that educators, school leaders and researchers collaboratively use to accomplish their work. Such coordination brings these varied components into relation with each other with directionality or intention. Thus, it accounts for the systems that are already in place that shape practice, and the possibilities for sustaining it. Infrastructuring, or a lack thereof, also helps to explain why, even when innovations are successful, they often do not last beyond the "hothouse" conditions under which they are typically introduced (Penuel, 2019).

A critical part of infrastructuring for sustained innovation involves redesigning infrastructure in ways that support the goals of innovation. For example, Hall et al. (2021), in their efforts to design for coherence in the implementation of the Next Generation Science Standards, across three crucial networks – mentor teachers, district specialists and assessment specialists – show that infrastructuring redesign involved not only identifying useful resources and frameworks related to the NGSS, but also fostering collegial workspaces for sharing experiences, challenges and needs as forms of productive professional learning. Such redesign work can be fraught with tensions, however, especially when innovations seek to disrupt inequalities. Studies have shown that this friction often results from both the efforts to design for and insert missing components of infrastructures,

 © ISLS

especially in contexts historically underserved by society's social structures, and also in the negotiation how these new components work within coordination with other components. Equitable implementation of innovation requires a more "proactive stance toward infrastructure redesign," by "allocating more and targeted resources to schools and teachers than might be provided to schools with more privileged students" (Penuel, 2019, p. 670).

Prost et al. (2019) report on one community-university partnership sought to infrastructure for food democracy. They demonstrate how the partnerships efforts initially focused on designing a food hub, a missing components of the local food infrastructure, then shifted to redesigning how the food hub worked in coordination with other structures, through establishing new coalitions and new spaces for connecting with community around the food hub, and designing new practices for how the food hub use could expand in the community. Like Hall et al., (2021), relationship building across networks, including spaces for doing so, were critical to integrating new components into existing structures. However, integration efforts were disrupted when differences arose over the direction of the project between the baker, who wished to focus on expanding their food hubs, versus the community center, who wished to improve the prototypes' operation through engaging the local community more deeply. These differences reflected different priorities and social positionings within the infrastructuring efforts.

This kind of tension is similar to the challenges that teachers in a participating school faced when their reform-oriented science lessons were observed by district leaders using a routine observation framework (Penuel, 2019). This framework did not recognize the inquiry work required of such reform, and some participating teachers received low scores. This friction made visible the different priorities of different stakeholders as they sought to integrate educational innovation into existing structures. RPP members redesigned the infrastructure to make space for new visions of what classroom teaching could look like, for example, by creating new resources that linked the routine observation framework to inquiry and by creating new routines involving district leaders to leverage these resources in coaching science teachers. Such negotiations involved developing new components of infrastructure, such as the new tools, as well as practices for when/how such components are enacted within a coordinated ensemble, such as how district leaders leveraged these tools in support of instructional improvement.

Thus, infrastructuring is also about asking "*when*", in tandem with asking "*what*" in the sense that infrastructures are dynamic interactions (Penuel, 2019). Of concern is how these components serve educators and students well more so than only whether such components exist. When infrastructures are working well, they largely go unnoticed (Hall et al., 2021). *However, since existing western schooling infrastructure is built to work for students of the dominant culture, there has been little need historically to trouble existing, foundational infrastructure, even as minoritized students have simultaneously been historically underserved by said infrastructure.* While the limited resourcing that make up the components of an infrastructure may be critical, the nature of the infrastructure itself should be called into question. *We thus further conjecture that a central question should be "who" is infrastructure, and to whom is infrastructuring useful? Whose interests does it serve?*

Who is infrastructure?

Asking the question of "who" calls into focus how infrastructuring is both embodied and historical. What we mean is that teachers and students experience how systems of practice are coordinated toward particular goals and outcomes in the present, with the materials, tools and approaches legitimized by a system that is rooted in Whiteness and heteropatriarchy. Justice-oriented reform cannot succeed if the very structures in which such reforms are enactment are themselves not called into question.

We find urgently important that infrastructuring shifts attention from the portability of materials, tools and ideas for the sustainability and scale of innovation to "a kind of mangling of innovations within varied educational contexts." Yet, mangling of innovations within entrenched structures, even when such efforts seek to redesign components of these structures, do not explicitly or even necessarily call into question the histories of practice and of people that live within, sustain and benefit from existing structures. To seek social innovation without the transformation of existing structures leads to bounded justice (Creary, 2021).

We came to ask this question of *who is infrastructure,* through our decades-long RPP involving schools, community organizations, and universities. As we sought to infrastructure for social innovation in classrooms and schools, we were confronted with the same kind of fraught tensions noted by Penuel and others, making visible fundamental differences not only in the priorities of the social innovations and the existing schooling structures, but also in the underpinning ideologies. Competing priorities tied to differentially powered stakeholders produced injustices that unfolded in micro-moments, played out through normalized school practices. Surfacing such root causes of injustices is challenging because they are hidden as the supposed benign structures of schooling. To make visible such structurally normed, unjust practices, we turn to the rightful presence framework.

The rightful presence framework was informed by empirical data from long-term research-practice-partnerships (RPPs) in middle schools and local communities across two states. We sought to have a different way to make sense of when and why innovation led to more just and sustained outcomes, and when it did not.

Three, imbricating tenets undergird this framework: 1) Political struggle is integral to disciplinary learning through asserting the right to reauthor existing rights (mired in injustices that are normalized); 2) Exposing injustices and imagining new, just, possibilities are germane to rightfulness; 3) A collective disruption of norms are necessary and contingent on allied political struggle demanding engagement from the powered and oppressed. In short, we learned that new sociopolitical activity systems are needed in order to infrastructure for justice. They involve a range of stakeholders who collectively acknowledge unjust powered dynamics that have always been at work in schooling, who work together to perturb such dynamics towards more just ends.

With the rightful presence framework, infrastructuring for justice brings into focus not only the *when of infrastructuring*, but the *who of infrastructuring*, as related to troubling established practices in schools related to teaching, learning and being. Such modes of transformation necessitate taking up new practices, with stakeholders (teachers, students, school staff, administrators, community members) taking on new roles, that has implications for how existing roles and practices might shift to transform who and what schooling is for.

Infrastructuring for justice

Justice-oriented infrastructuring seeks to redress injustice by creating new conditions to support innovative and political organizations, resistances, and transformations within systems (Bang, 2020). Deepening the definition of infrastructure in this way questions the dominance of the power-holders who built structures of practice and interaction (Dantec & DiSalvo, 2013). Infrastructuring to redress injustice must create new conditions to support innovative and political organization and disruptions within systems (Bødker et al., 2017). To take seriously a political view of infrastructuring questions the dominance of the power-holders who built structures of practice and interaction. It opens up possibilities for considering porosity, movement, and transformation to allow for democratized actions and redistributions towards ideals of justice. Infrastructuring, thus, does more than mangle new innovations with existing infrastructure of systems. It offers new tools and access points into the system for critiquing foundational systemic assumptions and designs. Infrastructuring for justice provides key insights into how scale can be sought for with justice-oriented reform interventions. We present two key points.

1. A focus on the sustainability and scalability of new relationalities

New relationalities

Infrastructuring for justice, with its focus on conditions necessary for scale and sustainability, calls into question the object of reform. Infrastructuring for justice requires on-going resistances, disruptions and transformations of existing structures and foundations that anchor educational research and reform. We suggest that sustainability and scalability should focus on *new relationalities – anchored in the Who and When of infrastructure* – rather than on products, tools, or even ideas. Such new relationalities should be viewed as the new foundations for infrastructuring education innovation, with attention paid to the ethical and political clarity necessary for the conditions that make such justice-oriented reform possible. By new relationalities we mean a practice of how we understand ourselves, others, and things, such as structures, in relationship to each other and to context, in the present and historically, as mediated through power and possibility.

This work requires careful attention to the power-mediated tensions that arise as people, ideas, and histories come into contact, along with the critical awareness and reorganization of power relations that necessarily results. It is a kind of political work imbued with political clarity and relationship building for cultivating critical awareness on racial and social injustice (Madkins & McKinney de Royston, 2019), but also oriented towards action and accountability. This kind of justice-oriented praxis of infrustructuring refuses separation of the past from the present and the possible future (Tuck, 2009). It also demands the kind of critically aware action taking that is linked to accountability in the sense that local actions make history, and have social and political consequence (Calabrese Barton & Tan, 2019).

New relationalities, anchored in rightful presence seeking allied sociopolitical struggles, are critical to re-imagining how infrastructuring for justice shapes the trajectories of reform. Such a mode of engagement reframes the work of infrastructuring away from the scalability of ideas, tools or products towards relationalities, which form the new foundations for building justice-oriented infrastructures. Scalability often hinges on "something" – a tool, model, product (e.g., recommended "best practices") – rather than on the interactions and relationships these products mediate among people and the broader organizational, political and social contexts in which reform happens. What goes to scale is designed to be flexible enough to translate across settings with the goal of broad reach. Scalability is deemed successful when such products are taken up by large numbers with fidelity. However, when a product is streamlined for transferability and scale, even when replicability is the goal, some features are reduced while others are amplified. What gets amplified inadvertently hews to the established norms operating in society, across institutions, as teachers are inclined to approaches most familiar to their

established practices, foregoing deeper and disruptive pedagogical shifts for surface enactments (e.g., bounded activities, classroom materials) of reform (Coburn, 2003). In school settings, such established norms are typically undergirded in White Supremacy and heteropatriarchy. Given the systemic nature of these norms, the "common denominator" to which scalability goals adhere are the established powered norms across settings. When scalability is dependent on maintaining unjust power dynamics across settings, scalability becomes a means by which unjust power dynamics are maintained and reproduced. We build on Coburn's (2003) notion of the depth of scaling reform. We echo her assertation that beyond taking up discrete reform products, belief systems that inform norms and practices need to be likewise shifted. When lensed with rightful presence, we contend that such deeper shifts occur via allied sociopolitical struggles as legitimate classroom and school activity systems.

Infrastructuring is a long-term and future-oriented process. It needs to account for the relational work that unfolds in participatory processes, as projects shift in direction, involve new people, and develop over time, as new power dynamics are struggled for collectively through the reauthoring of rights that amplify community voices and foster community agencies. Relational work takes shape in efforts to disrupt and transform institutional relations and practices, where the locus of power/ownership shifts towards community. This happens, in part, through evolving and expanding involvement of stakeholder in an RPP partnership, especially participants who have typically not been included, such as parents, staff from community partner institutions, youth, teachers, and the range of roles undertaken. Widening the range of stakeholders and expanding the roles within stakeholder profiles are the processes through which unjust power dynamics that have historically been at work in society and across institutions can begin to be disrupted. To identify such, researcher-embedded research practice partnership work is a robust way to unearth the forms and functions of normalized (and thus hidden) unjust practices.

Enacting in practice: Vignette from our RPP

Consider how middle school science teachers learned how to become critical witnesses of youths' STEM-related lives outside of the classroom, thus forming new relationalities with youth and with STEM. A design decision we made as an RPP at the beginning of a 5-year project focused on designing tools for middle grades engineering, and that built groundwork for new infrastructuring work, was engaging in co-design of reform-based classroom teaching and learning tools with teachers, youth and community educators in community spaces, using pedagogies of *being with* (Villenas, 2019). As we developed a teaching framework for engineering for sustainable communities with engineering design challenges, we spent time together, being with, weekly, after school, in STEM club spaces at partnering community centers. We foreground *being with* as justice-driven embodiments of mutualism and trust that occur along the powered-boundaries of race, class, gender, education, age, and geopolitical locations. *Being with* is conceptualized as intentional social activity, involving critical relationalities and practices of witnessing that seek to understand/disrupt normative power hierarchies that precipitate inequitable processes of partnering, both in the here-and-now and towards imagined futures.

Sessions took place 2-hour blocks, weekly, after school at the participating clubs, and involved activity structures that supported teachers, youth, community educators, and researchers in engaging STEM together, sharing ideas/stories, giving critical witness to others' experiences, expertise, and hopes for STEM in their lives and communities, especially across difference, and co-designing teaching and learning tools that drew upon insights from dialogues. We spent time collaboratively enacting and reflecting on co-designed tools, with stretched out enactments in these afterschool spaces, allowing for maximal time for in-the-moment and ongoing refinement of tools from multiple perspectives. This process supported collaborative construction of teaching tools that were co-owned by teachers, youth, and community, and created new spaces for teachers and researchers to build relationships with youth and community members, over time and through shared activities, hosted on community turf, thereby engaging in a version of intergenerational relations and learning.

Two teachers, Ms. D and Ms. L, reflected on how they saw their students "in their element" at a community-based STEM club instead of in their school classrooms. Both teachers spent time as community members participating with youth at a community-based STEM club that focuses using STEM as a tool and resource to address injustices in youths' everyday lives. Examples of prototypes included a 3 foot, 50 piece geodesic playdome with solar-powered LED "reading lights" that two middle school girls built for their friends in response to the lack of play structures at the community center. The teachers were "blown away" by the sophistication their students displayed through in building engineering prototypes to address community identified challenges. Ms. D marveled at "how creative the students are when they have time" and their understanding of community issues, which she opined she "would have never seen or known from interacting with them just in the classroom". Both teachers asked, "How do we do this in the classroom?" Explicitly inviting social concerns as legitimate school-science concerns was not the norm in Ms. D and Ms. L's middle school. The lack of play structures at a community club serving children as a STEM issue, a community issue and a justice-related issue (one youth said, "kids need to play, kids need to move!") became apparent to the teachers as the project unfolded.

This kind of infrastructuring builds critical groundwork for scalability that works *from and within community histories and experiences with schooling/STEM*. It emphasizes teacher and youth participants as people who contribute to reform by bringing concerns to bear, situates knowledge production and practice within local contexts in ways that give witness to teachers' and youth's experiences, and contributes to the improvement of conditions for teachers and youth. By integrating the ideas and experiences of school and community educators and researchers with youth, more relevant and sustainable results arise for research, practice and local communities. Oliver (2001) writes, "We are obligated to witness beyond recognition, to testify and to listen to testimony, to encounter each other, because subjectivity and humanity are the result of witnessing" (p. 90).

Critical witnessing is a kind of being with that demanded a critical openness to multiple perspectives that disrupted and repositioned taken-for-granted binaries such as expert/novice and insider/outsider. Ms. D and Ms. L learnt through direct observation, youth and communities' "live and current" justice-related concerns that were integrally tied to the nature of STEM engagement. What STEM is, to whom, the reach of STEM, what STEM can be and the outcomes of STEM, in short, the nature of STEM along its epistemological, ontological and axiological axes, were called into question and reconsidered. Engaging in critical witnessing broadened the horizon of the teachers regarding the boundaries of where, who, when, youth live STEM-engaged moments in their everyday lives. The community club, during after-school hours, with stakeholders that include various community members such as friends, club staff, parents, after-school teachers, were all key players in STEM. On the literal turf of the community STEM club, rightful presence allied political struggles were practices stakeholders were engaging in.

2. New political allyship towards rightful presence

Political allyship

Infrastructuring for justice requires attention be paid to how innovations support new political allyship towards rightful presence through making visible particular local injustices and possibilities. Infrastructuring work, then, is about making potential futures visible, debated, and acted upon. This includes focusing on how participants at various organizational and political levels (youth, parents, teachers, school leaders) are afforded ever expanding opportunities to act both in the present and in future activities, across spaces and scales of activity.

From a rightful presence framing, scalability needs to be twinned with sustainability, not replicability, given the very local and contextualized nature of unjust practices that require disruption and reimagination. By sustainable we mean how insights and processes, as well as design results, may be continually activated and expanded across scales of activity – time, settings (horizontal) and levels of power (vertical). If we consider how, in a justice-oriented RPP, sustainability needs to rest on communities, once justice-oriented infrastructuring is put into place, then communities should be sustainably supported to solidify new hybrid practices that center community voice and desires. For example, when parents and teachers find a way of collaborating productively together (with solidified logistical and activity-based infrastructure), the "new practices" the RPP have seeded have a higher probability of becoming the new norms that are more justice-oriented and locally-grounded.

Sustaining social innovation relates not only to how the intervention itself is appropriated in use, but also how participants at various organizational and political levels (youth, parents, teachers, school leaders) are afforded opportunities to act both in the present and in future activities. As new people work together, across communities, and intergenerationally, and people not ordinarily involved in reform design work together, they expand their understanding and opportunities for action in relation to both people (e.g., the experiences, resources and understandings others bring and how they relate to them) as well as the design context itself (e.g., what the problem space is, how we work together to address it). Penuel notes, "Interventions themselves are contested spaces, filled with tensions and resistance from a range of stakeholders" (Penuel, 2019, p. 21). Foregrounding relational design work as integral to scalability is important because it centers the messy, political, and sometimes contentious work of participatory reform processes, especially those processes meant to disrupt systemic forms of power. We see such relational design work – another form of allied political struggle between researchers, teachers and youth – as equivalent to building new justice-oriented foundations as a part of infrastructuring that disrupts White Supremacy. It is through such struggles that ownership of the more just and new practices is cultivated and deepened within the insiders of the community with power (e.g., teachers, school staff and administrators) that sustainability of the reform might develop and settle.

Enacting in practice: Vignette from our RPP

In the next example, which took place five years into the design work described in the previous example, we focus on one teacher, Ms. B. She was in her third year enacting pedagogical tools focused on community ethnography as pedagogy in her 6th grade classroom. In a unit focused on engineering for sustainable communities, Ms. B's students had opportunities to engage defining authentic problems that they felt their classroom communities faced in relation to sustainability. They were learning to use engineering practices and core

disciplinary ideas focused on energy systems to design solutions to these problems. Integrated into the design process was explorations of the needs and expertise of their local community as students sought to design and build solutions that could actually make a difference in fostering a "happy, health and just classroom" (Ms. B). Students were given the challenge of designing for a sustainable classroom in ways that leveraged their developing STEM knowledge (energy transformation, sources, and environmental impacts), community knowledge (issues that matter, to whom, how and why). The class spent 3 weeks on the design investigations, prototyping, testing and refining process.

During the design process, students used community ethnography to identify several key challenges to sustainability they felt their classroom faced, including students being tired and cranky in school, the need for more opportunities to celebrate and value each other, and a need for more fun and joy in learning. Student groups designed a wide-range of solutions that could be integrated into the routines of their classroom: a light-up interactive art board, where students could draw and pin their art for others to enjoy, light-up games to be used during free time or when the class is feeling stressed, and a light-up joy box group to be used in the school's social workers office as another tool to support students navigating hard emotional times, and Marble Drop engineering design, an innovative one-person game that supported players in completing a marble maze and lighting up the board to celebrate. All projects used either handcrank generators or solar panels to power them.

By several key accounts, the implementation was successful. Students expressed enjoyment. Authentic projects were successfully completed. Students exhibited mastery of the science and engineering learning goals (Tan, Calabrese Barton & Benavides, 2019). However, several weeks after implementing this unit, Ms. B discovered that some of her students were frustrated that their designs were not actually being used to address their community concerns. Students' designs were meant to make their school happier, healthier and more just, while also leveraging green technologies in support of the environment. Mrs. B was an expert in teaching this unit she helped co-develop, and had taught it during three consecutive academic years.

Consider for example, two groups who shared with Mrs. B and their classmates that their designs were not being used as they hoped. The Joy Box group created their original design to be used in the school's social workers office as tool to support students navigating hard emotional times. The students worried their design was "useless" when they realized the school social worker could not use it because her office was too small. Another group wanted to support other students in having chances to have more ways to calm down when they created the Marble Drop game. This design was an innovative one-person game that supported players in completing a marble maze and lighting up the board to celebrate. The boys who made this design knew that having opportunities to take their mind off whatever was triggering their anger was a calming coping mechanism for them. However, the students noticed that it was not kept in the common library space like they imagined but was in a closet instead.

While Ms. B could have considered the engineering design unit a success if she only evaluated the designs based on the required STEM goals, she instead gave critical witness to their concerns. She hosted a conversation in STEM class on why the projects were not working, and what they students wanted to do about that. Bringing ideas back to the RPP, she worked with researchers, partner teachers, and school personnel, to design and enact new structures to support students in further optimizing their designs to better meet their goals for classroom sustainability. First, she supported students in defining *what the success criteria would be* for their engineering designs by asking questions such as: "How can you tell if your engineering design is meeting your goal?", "Who should be using the design?", and "How often should the engineering design be used?". She then supported students in using tools such as *observations and community interviews to evaluate their engineering design's success and make plans to improve their designs to address the issues that mattered to them*. Ms. B extended the unit so that students could refine their goals and designs. She also engaged students in considering the social contracts that might be required to organize for new school routines around their designs.

Ms. B also created space for students to connect with a range of stakeholders to discuss ideas on why their projects were not working and possibilities for revision. The creators of the Marble Drop game interviewed the school's administrative assistant to get permission to store the game next to her desk and encourage students who were sent out of their classrooms for "disrupting" class to play the game as a way to calm down. In response to their conversations, they created written directions for students to follow which included these two tips: "Fact: Hand crank can go both ways." and "Fact: Do not take marbles."

For the Joy Box, Mrs. B supported the group to collaborate with school personnel to better address their goals. Students worked with the social worker to develop a social contract on how and when the joy box would be used. The students sent letters to each teacher in the school explaining how the Joy Box works. They went to each classroom to present the Joy Box and answer questions. The school community put the Joy Box to use as a result. Both students and staff placed positive messages in the hand crank-powered light-up Joy box weekly. While in use, the group delivered the messages to each classroom while lighting the Joy Box. Students described having their "hearts feel warm" as the schoolwide positive message delivery system was used by the community.

Ms. B. recognized students' assessment of their under-utilized engineering designs as a bid for rightful presence. As Ms. B described, it was that the youth were disappointed that their initial designs to address issues that mattered to their school communities fell short of *their* desired outcomes, which were to feel joy, to warm hearts, and to care for each other, although this was important to her. It was also that she began to question what authentic designs really were: "We actually had to change things. To say, you know, this isn't working here. There is something wrong. If school has taken away the joy because you can't get recognized or whatever a kid might be feeling, then there is something deeper that needs to change. More than just the project itself." The tools and approaches to following up on students' experiences with designs became a part of the unit moving forward.

Infrastructuring efforts caused friction when students expressed disappointment their designs did not work. Ms. B engaged the friction as a productive space of learning, not just for herself, but for her RPP and her students. She created space to give witness to students' frustrations with the sociopolitics of school life as an act of allied political struggle. Her acts humanized the youths' participation and valued them as cultural and whole people. They also opened up opportunities for new forms of science learning, reframing what counts as just, learning outcomes and who, beyond the science teacher and students of this class, are involved in realizing such.

Ms. B, along with members of her RPP and school community, furthered the goals of infrastructuring for justice – continuing to foster new modes of being, new relationalities that disrupt established power-dynamics between who are experts, who are novices, whose ideas matter, why and for whom, ultimately reflecting what the RPP values in a) the classroom enactments, b) the RPP efforts, and c) the tool/products produced. This example points towards new orientations for what sustainability in reform may mean. Insights and processes, as well as design results, may be continually activated and expanded across scales of activity – time, settings (horizontal) and levels of power (vertical) – as seen in: Tracing multiple pathways, new metrics for success, new spaces of engagement of reform. This kind of infrastructuring is not just infrastructuring for educational innovation, but also for just, happy and healthy communities.

Discussion

Engaging in longitudinal, community-based RPP work has led us to three insights on infrastructuring for justice, imbricated with one another, and anchored in and contingent upon allied political struggles as core practices.

First, we suggest there is a need to reconsider the nature of infrastructure connectivity. Western schooling practices have artificially siloed what counts as legitimate school epistemologies and ontologies, reflecting White male, heteropatriarchal axiologies. Even when positively regarded by the field of STEM education, community-based STEM experiences are positioned as adjacent to school STEM teaching and learning, in a supportive role to students where positive outcomes from these out-of-school experiences might be "supplementary" to students of color but the gains from such out-of-school STEM experiences, whether epistemological or axiological, fail to accrue mobility between the out of school infrastructure into the school STEM infrastructure because of conflicting axiologies. While "alternative" infrastructures, such as out-of-school STEM programs housed in community clubs, are necessary for seeding new relationalities between youth, STEM and communities, infrastructuring symbiotic connections between youths' STEM experiences out of school and in school itself, requires allied political struggle. Ms. D and Ms. L were compelled by the expansive STEM epistemologies and ontologies they witnessed at the community STEM program. They were simultaneously concerned about how differently school STEM is set up. What was most apparent to the teachers were the incommensurability, as they perceived, between in school and out of school STEM. This calls into question the nature of STEM education infrastructure pertaining to what is valued and sanctioned in which activity systems that youth engage in STEM; and discerning the kinds of allied political struggles, involving which stakeholders, where and when, need to take place to support mobilities of resources and gains made between in school and out of school STEM infrastructure.

Second, friction serves as indicators of progress when infrastructuring for justice. Aligning with the rightful presence framework, infrastructuring for justice through allied political struggles is necessarily disruptive. When students are reauthoring rights with the support of more powerful allies like teachers, they are disrupting normalized practices, replacing them with new ones that shift the epistemological, ontological and axiological nature of school STEM. As described earlier, dissatisfied with the mere completion and tested functionality of their engineering prototypes, students' insistence on buy in from the school to put their prototypes to use as they intended necessitated Ms. B's recognition that she needed to do more to advocate for students' hoped-for outcomes with their projects. Such friction made visible the limitations of redesign, since "infrastructuring efforts must always wrestle with what is already there in place in systems—that is, existing infrastructures and practices that are products of past design efforts and that persist in their influence on practice" (Penuel, 2019, p. 662). At Ms. B's school, none of the prior reform efforts were concerned with student projects that impact community identified problems, nor prioritized the potential of shifting social interactions as a result of the afterlife of these projects, as an important STEM learning outcome. The friction manifested in students' frustrations to Ms. B, made

visible such limitations and lent directionality and impetus to Ms. B to engage in further allied political struggle with the students that involved other adult stakeholders in the school and her RPP.

Understanding that systemic oppressions in schools operate through local practices calls into question the feasibility of scaling context-independent products. Traditional notions of scaling such supposedly applicable and thus highly mobile products therefore becomes antithetical to the justice reform agenda and in fact, most likely works to reproduce injustices. Infrastructuring for justice flips the script on scale in its grassroots origins – when local, unjust, normalized practices are collectively identified and interrogated via allied political struggle through new activity systems as inherent to reform, the possibilities of enacting new, more just practices are higher and become an accountability measure of justice-oriented scale. Such a grassroots mechanism of scale has a higher and more authentic potential to "build in" ownership and therefore, sustainability.

Conclusions

Infrastructuring work takes place in the complex interactions arising from resistance and accommodation, disruption and revision that make up the relational work of design. This relational work does not focus on the design of the intervention itself, but on the conditions that make possible the sustainability of outcomes tied to the intervention, such as the very kinds of transformations of institutional relations and practices mentioned above. Time spent, in both quality and quantity, building new foundations is necessary for the political clarity needed for the relational work of sustained reform. Our stance on justice-oriented infrastructuring with communities described here is informed by our decades of entrenched, empirical participatory design work. Being embedded thickly in context across time is a robust and ethical way of making sense of the necessary infrastructuring work at the different vertical and horizontal levels of power/political authority in schools/communities.

Guided Epistemic Expansion in a Science Classroom

Sugat Dabholkar, Northwestern University, sugat@u.northwestern.edu
Joshua Danish, Indiana University, jdanish@indiana.edu
Uri Wilensky, Northwestern University, uri@northwestern.edu

Abstract: In this paper, we study students' epistemic engagement in a learning environment that uses Emergent Systems Microworlds (ESMs). ESMs are agent-based computational models that are designed as constructionist microworlds. We use Engeström's theory of expansive learning for analyzing how agent-based restructurations and constructionist design features of a learning environment facilitate the epistemic expansion of an activity system in a science classroom. We analyze three design features of an ESM-based learning environment that created generative contradictions, which allowed students to devise epistemically expansive ways using the same features to address those contradictions. We discuss how these features facilitated student learning as the students used the ESM as a computational experimental system to test and establish evidence-based claims and collectively shape epistemic practices. This work provides an approach for designing learning environments that foreground students' epistemic engagement in shaping science practices to learn about disciplinary ideas.

Introduction

In his 1991 paper, Engeström discussed approaches to overcome the encapsulation of schooling, which he defined as the artificial separation of school learning from experience, cognition, practices, and values from outside the school (Engeström, 1991). Engeström's framing of this issue goes beyond the concerns regarding designing for out-of-school learning experiences. He draws attention to the lack of direct connections between ideas that one learns in school and their relevance to everyday learning and lived experiences out of school including potential disciplinary practices. From the communities of practice (CoP) standpoint (Lave & Wenger, 1991), which Engeström discusses as one of the approaches to overcome this separation, learning is defined as the legitimate peripheral participation in a community of practice. So, what would such legitimate peripheral participation be for science students in a school?

Science educators and researchers have advocated for decades that science learning should involve meaningful participation in scientific inquiry or sense-making practices to learn about disciplinary ideas (Abd-El-Khalick et al., 2004; Duschl, 2008; Schwarz et al., 2017). Such participation in science practices is intended to serve two purposes – (1) when students construct knowledge by experiencing and investigating natural phenomena in the world, they learn deeply about the science content, and (2) the engagement in the practices of scientific knowledge construction also allows students to learn about the practices themselves. Such meaningful participation in science practices requires reimagining the roles of students and teachers in the science classroom such that students become *doers of science* and not *receivers of facts* (Miller et al., 2018; Schwartz et al., 2004). For example, biology students can participate in the same practices as professional biologists, such as using agent-based computational models to investigate a biological phenomenon such as prey-predation population fluctuations or synchronization of flashing of fireflies (e.g., Wilensky & Reisman, 2006).

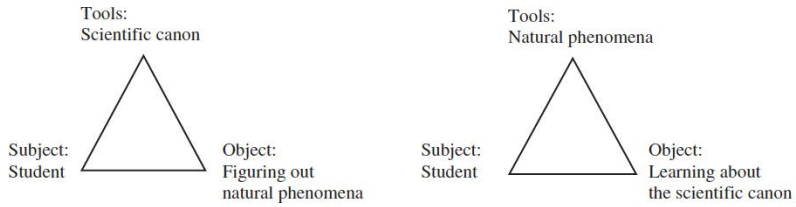
Having agency in shaping the community's shared knowledge construction work is an important aspect of science researcher practice (Latour, 1987). Engaging students in similar ways in knowledge construction processes requires designing learning environments that support students' epistemic agency. The term epistemic agency was introduced into education literature in relation to the research on knowledge-building communities conducted by Scardamalia and Bereiter (1991). Epistemic agency refers to students' ability to shape and evaluate knowledge and knowledge-building practices in the classroom (Scardamalia & Bereiter, 1991; Stroupe, 2014). The Next Generation Science Standards (NGSS) has recommended a set of science practices that are epistemically equivalent to those practices of scientists (NGSS Lead States, 2013). However, this framing of epistemic equivalence creates a contradiction for *doing science* using the NGSS framework (Miller et al., 2018) because encouraging students to appropriate a set of practices chosen by others does not position students with epistemic agency: the power to shape the knowledge production and practices of a community. In a classroom setting there is often a tension between teaching established disciplinary ideas and authentically participating in practices to construct knowledge (Russ & Berland, 2019; Schwarz et al., 2017). What Russ & Beland (2019) refer to as a problem of practice arises because of this tension between learning established ideas and constructing one's own ideas. The authors highlight a dichotomy between two intended objects or goals of students' activity in a science classroom using the activity theory framework (See Figure 1). This dichotomy is between "Figuring it out" vs

 © ISLS

"Learning about" activity systems, where the former is focused on using the scientific canon to figure out a natural phenomenon and the latter is focused on using a natural phenomenon as a tool to learn about the scientific cannon.

Figure 1

Mediational activity triangles in a science classroom (From: Russ & Berland, 2019, p. 286)



a. "Figuring It Out" activity system b. "Learning About" activity system

In this paper, we propose a different way, an epistemically expansive way, to frame students' classroom participation based on Engeström's framework of expansive learning (Engeström, 1991, 2001) to address the problem of practice. We use expansive learning framework because it is intended to promote and capture participation in constructing a new activity system, which is what students do when they, like scientists, identify the questions that will guide their work, and the methods that will help them answer those questions most efficaciously. Using this framework, we analyze student learning in a classroom learning environment which was designed to support students' agentic participation by providing them with tools to engage in epistemic practices. We refer to this learning environment as Emergent Systems Microworld (ESM)-based learning environment. An ESM is a computational microworld designed using constructionist and agent-based modeling principles (Dabholkar et al., 2018; Dabholkar & Wilensky, 2019). Our goal in developing this curriculum was to not simply have students use the model, but to have them refine their own practice so that the kinds of agent-based computational models we provided would have value in helping them pursue their own epistemic goals. Thus, we wanted to support and guide them in engaging in epistemically expansive learning. We used the term guided because in contrast with traditional approaches to expansive learning where participants solely identify their need for and direction of change, our goal was to help encourage a specific new direction of socially constructing knowledge using scientific inquiry practices. We investigate the following research questions in this paper:

What design features of an ESM supported a guided epistemic expansion? How did these features mediate students' epistemically expansive learning?

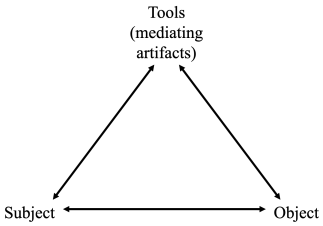
Theoretical Framework

Activity theory and expansive learning

In this paper, we analyze how an ESM-based curriculum supports the transformation of a classroom activity such that students take more agentic roles as they construct and evaluate knowledge using Cultural Historical Activity Theory (CHAT) and its extension, the theory of expansive learning by Engeström (2001). Activity theory provides a lens to design and investigate learning environments that support student engagement in social knowledge-building activities in specific domain areas such as complex systems (e.g., Danish, 2013, 2014; DeLiema, Enyedy, & Danish, 2019). The focus of such analysis is to investigate how different *tools* in a learning environment mediate individual and social transformation (Engeström, 1999).

Figure 2

Vygotsky's mediational triangle (from (Cole, 1998), p. 119)



The original activity triangle or mediational triangle, proposed by Vygotsky, explains the relationships between subject, object, and a mediating tool (Vygotsky, 1978) (Figure 2). The mediational triangle helps in understanding the object-directed nature of human action. While Engeström has since expanded the triangle to include the community, rules, and division of labor (Engeström, 2001), we find that focusing primarily on the designed mediational tools can provide clarity in our design efforts and avoid some of the challenges that arise

from attempting to categorize all of the mediators in play (Witte, 2005). In a classroom setting, an object for a student is not necessarily the same as the object that is intended by a teacher for the student. The intended object is the purpose for which the activity is designed, and the enacted object is the object that a subject (student) uses a tool to achieve. This distinction becomes even more crucial when one intends to use activity theory to design and analyze a learning environment. For example, when an ESM-based learning environment is designed for students to socially construct knowledge, the object 'to socially construct knowledge' is an intended object for the students by the designer of the ESM-based curriculum. So, how can designers' intended object for students become the enacted object in a classroom activity system?

In the theory of expansive learning, Engeström (2001) discusses the possibility of expansive transformation of an activity system, in which the Object (goal/purpose) of Activity gets reimagined as subjects engage with a mediational tool. In the context of science education, such expansive transformations mean a shift in the role of students in a science class from listening and understanding to actively engaging in knowledge-building practices. In this paper, we analyze how design features of a learning environment guide such epistemic expansion such that designers' intended object becomes the enacted object.

Design Framework

ESMs and ESM-based curricula

Over the years, scientific communities across the globe have developed experimental model systems that have affordances to investigate specific aspects of natural phenomena. For example, fruitflies' (*Drosophila*) chromosomal organization and their short life span have made them a model system to study genetics. We argue that using principles of Learning Sciences computational models can be designed to be pedagogically effective model systems that support students' self-driven investigations and therefore their epistemically agentic learning within the constraints of a classroom. In this work, we designed Emergent Systems Microworlds (ESMs) as computational model systems embedded in ESM-based curricula for students to investigate a modeled emergent phenomenon in agentic ways.

ESM design combines two design approaches in Learning Sciences, namely agent-based modeling of emergent systems and constructionism (Papert, 1980; Wilensky, 2001). Agent-based representations in ESMs create affordances for learners to engage deeply with a complex emergent phenomenon (Goldstone & Wilensky, 2008; Wilensky & Reisman, 2006). An ESM is designed as a microworld using constructionist design principles to mediate students' self-driven explorations to investigate various aspects of the represented disciplinary ideas (Edwards, 1995; Papert, 1980). An ESM-based curriculum and accompanying pedagogical practices are intended facilitate such student engagement in self-directed, interest-driven explorations and investigations using an ESM. Students are encouraged to share their findings and participate in teacher-guided reflections to collaboratively construct knowledge about the modeled complex phenomenon in an ESM. Our design goal for the ESM-based learning environment was to support students in seeing their participation in epistemically agentic ways – as producers, consumers and evaluators of knowledge.

ESM-mediated Guided Epistemic Expansion

As we discussed before in a learning environment designed for epistemically expansive learning, the intended object 'social construction of disciplinary knowledge' must become the enacted object of classroom activity. Though this framing is inspired by Engeström's theory of expansive learning, there is an important distinction in our framing and Engeström's. Engeström focuses on inherent contradictions creating a driving force for change such that new cultural patterns are produced in the activity system, which are often previously unimagined (Engeström, 1991, 1999); whereas an ESM-based curriculum is designed to *guide* a transformation of an activity system to make its enacted object to be 'social construction of disciplinary knowledge'. To underscore this distinction, we use the term *guided epistemic expansion* to refer to the ESM-mediated transformation of a classroom activity system.

Cole (1998) expanded the concept of mediational tools to include representations that communicate the community's norms, beliefs, and understandings, as well as cognitive structures that guide action and thought (Cole, 1998). This extended concept of mediational tools becomes important in the context of designing a learning environment. Different features of a learning environment can be considered as tools to analyze how they support different intermediate activities that build towards change in an activity system. These features can act as tools to mediate student activity by supporting or constraining an action. Analysis of these features as mediational tools allows deeper insights into learning activities in an environment designed to support certain forms of learning. The mediational tools in our work are the design features of an ESM, which is a constructionist agent-based computational model. The theory of constructionism has always foregrounded such students' epistemically

meaningful participation in constructing knowledge (Papert, 1980; Turkle & Papert, 1992; Wilensky, 2003; Wagh et al., 2017).

This kind of intended epistemic expansive learning in a science classroom addresses the *problem of practice* (Russ & Berland, 2019) by building on the idea of Invented Science. The authors argue that children invent 'science' to satisfy their curiosity about why and how a phenomenon occurs. However, to achieve the object of satisfying curiosity, children need to have the appropriate cognitive resources to act as mediational tools (Elby & Hammer, 2010; Piaget, 1970; Smith III et al., 1994). In a classroom setting where teachers try to balance their time between "Figuring it out" vs "Learning about" activity systems, external tools that would provide students objects-to-think-with can serve to engage in epistemic pursuits to 'invent science' (Papert, 1980; Turkle & Papert, 1992). Analysis of such mediational tools in a learning environment using activity theory can provide insights into how students socially construct knowledge of a complex phenomenon (Danish, 2013, 2014). In this paper, we discuss how a computational model system in the form of an ESM provides students with such tools to collectively support the social construction of knowledge of the modeled phenomenon.

Methods

Participants and Setting

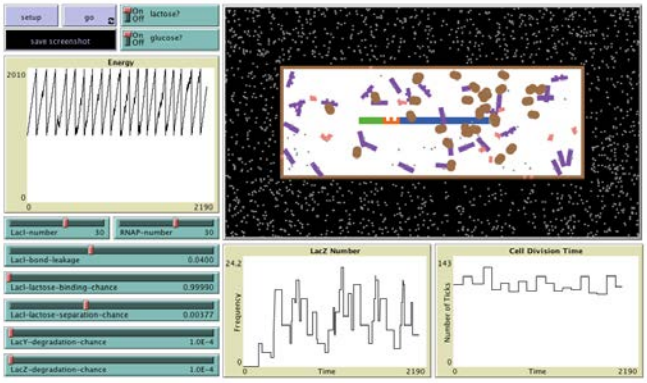
The first author was the lead designer and the lead teacher of the ESM, and the ESM-based curriculum discussed in this paper. From the methodological perspective, this made him an "unusually observant participant" and a designer (Erickson, 2006). The first author conducted these courses in two locations: twice during a weekend extra-school program for middle school students conducted by a talent-development center in a midwestern university in the United States, and twice in residential summer camps in a western city in India. The data presented in this paper is from the fourth iteration in India in which 12 students participated, of which 5 were female and 7 were male. All the students were of Asian Indian origin. We collected data in various forms, namely videos of student discussions (around 150 hours), fieldnotes, workbooks in which students wrote their observations and explanations, the computational artifacts (models, screenshots, and presentations) that students created, pre- and post-tests, and pre- and post-interviews.

GenEvo an ESM based curriculum

To engage students in constructing knowledge of disciplinary ideas regarding gene-regulatory mechanisms and evolution, we created an ESM-based curriculum, GenEvo (Dabholkar et al., 2018; Dabholkar & Wilensky, 2016). In this paper, we study students' epistemically expansive learning with the GenEvo curriculum (Dabholkar & Wilensky, 2016). This curriculum incorporates a series of four interconnected computational models designed using Wilensky's agent-based programmable modeling environment NetLogo (Wilensky, 1999). NetLogo was designed for both constructionist learning experiences and for use in scientific research. Since these four NetLogo models are strongly interconnected, they form an ESM because the underlying rules for agent behavior are consistent across the models. Using this curriculum, students can investigate the emergent properties of biological systems, including gene regulation, carrying capacity, genetic drift, and natural selection.

Figure 3

A screenshot of the first model (Genetic Switch) of the GenEvo ESM which allows students to manipulate and observe molecular interactions inside a bacterial cell



The curricular activities were designed to guide student investigations and engage students in discussing and evolving epistemic practices to establish and evaluate knowledge claims. These discussions included topics such as - *What counts evidence for a particular claim*? *What are various ways to collect, analyze and present*

evidence? *How does one establish a claim using evidence*? Since students were using an ESM to investigate specific aspects of a phenomenon, these discussions were strongly grounded in concrete aspects regarding the biological system under investigation. Throughout the curriculum, students iteratively explored specific aspects of the phenomenon, investigated specific questions, collected evidence, and presented how their evidence supported their claims regarding the research questions.

Microethnographic analysis

To investigate students learning using the ESM-based curriculum, we conducted microethnographic analysis (Erickson, 1986, 2006) of classroom videos, specifically focusing on the dynamics of students' shifting participation in the activity and their shaping of the sociocultural practices of knowledge construction and evaluation in the classroom. Using a top-down approach, we identified instances in the field notes that indicated student engagement in knowledge construction. We performed a micro-ethnographic analysis of videos of these instances to investigate how restructuration properties of the ESM instantiated through ESM design features (mediators) and how complementing pedagogical moves by the teacher (mediation) supported student engagement in knowledge construction.

All episodes related to knowledge construction and evaluation (n = 92) were further coded using a bottom-up approach to identify the objects (the intended goals of the activity), the design features as mediating tools (mediators), and accompanying pedagogical moves (mediation). Even though the ESM is a primary mediating tool for all the activities, we coded for specific design features of the ESM to further investigate how those design features mediated different aspects of knowledge construction. We identified how these design features mediated specific intermediate objects as the activity system underwent transformation.

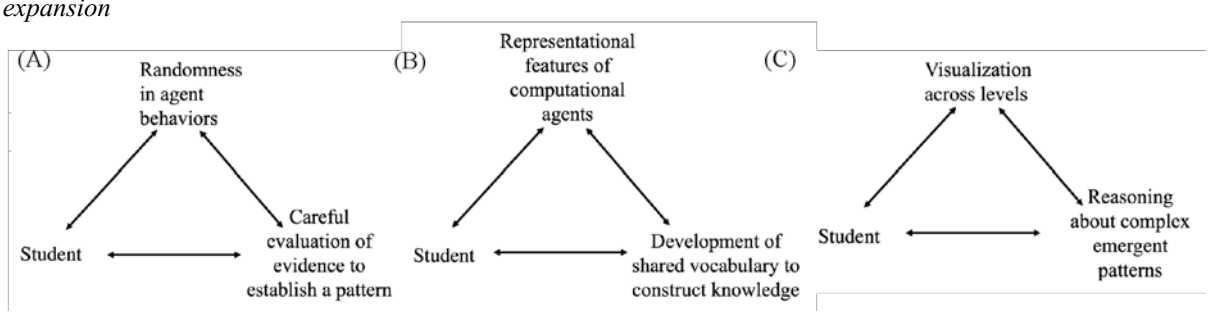
Findings

In the previous work, we have demonstrated students' learning gains regarding disciplinary ideas and shifts in their perceptions regarding their roles in a science classroom from the perspective of epistemic agency (Dabholkar et al., 2018; Dabholkar & Wilensky, 2019). In this paper, we focus on identifying and analyzing design features that mediated students' epistemically learning expansive learning. In the GenEvo ESM-based learning environment, students constructed their shared knowledge about how genetic regulation takes place in a bacterial cell as an emergent phenomenon by conducting experiments with the ESM, developing, and evaluating evidence-based claims and establishing practices to evaluate the claims.

Internal contradictions in an activity system act as a driving force for change as it undergoes expansive transformation (Engeström, 2001). We microethnographically analyzed three design features focusing on how contradictions arose because of those design features of the ESM and how the same features allowed students to find ways to address those contradictions. Our analysis helps in understanding how these internal contradictions acted as a driving force for epistemic expansion in the classroom. These design features mediated students' engagement in intermediate objects in the activity systems as they progressed with constructing knowledge of disciplinary ideas and evolving scientific practices (see Figure 3). The three objects of intermediate activity systems were (1) careful evaluation of evidence to establish a pattern, (2) development of shared vocabulary to construct knowledge, and (3) reasoning about complex emergent patterns. These objects are intermediate steps that are essential to construct knowledge about the complex phenomenon modeled in the ESM. Student enactment towards achieving these objects, in turn, mediated the transformation of the classroom activity system. The object of the classroom activity system became the social construction of knowledge about complex disciplinary ideas.

Figure 4

Intermediate activity systems in an ESM-based learning environment as the activity system underwent epistemic expansion



Randomness in encoded agent behaviors in the ESM caused slight differences in experimental outcomes, even when an experiment was repeated with identical conditions (Figure 4A). This design feature of the ESM

makes the behavior of the ESM as a system close to the behavior of the real-world system (a bacterial cell, in this case) it models. Despite such stochasticity in agent behaviors, those behaviors produce consistent emergent patterns at the system level. This feature created contradictions when students tried to evaluate each other's claims. When asked for their conclusions after a curricular activity, a student, Shaurin said, "*Even with the same parameters, you won't get the same results every single time…But there is some pattern*". This was after students had investigated the effects of sugar availability in the environment on the energy of a bacterial cell. When asked further about the pattern, Shaurin and other students shared their observations and concluded that cell division time was shorter when glucose is present than other conditions, even though the observed cell division times were slightly different for all the students. In this exercise, students collectively developed an important insight regarding a practice of science, which is that there can be variability in observed data within the same experimental conditions and multiple trials need to be conducted to verify the validity of observed patterns. This led to the classroom community evolving two practices for carefully evaluating evidence: conducting multiple trials and carefully observing the mechanistic details by slowing down a model. More rigorous forms of these practices are prevalent in modern biological research: statistical analysis and time-lapse microscopy.

Another set of contradicting observations arose when students attempted to establish claims regarding the properties of specific agents and their interactions with each other because of the lack of established identities for computational agents (proteins and parts of DNA) in the microworld. These contradictions required students to develop shared vocabulary to construct knowledge (Figure 4B). While in a traditional model, a teacher might give a key or legend for the biological names of proteins and parts of DNA, in this classroom the teacher encouraged students to develop and use their naming conventions for identifying agents in the model. Students used representational features (shapes and colors) to develop a shared vocabulary for creating naming conventions for computational agents. This vocabulary evolved from "pink and purple stuff" to "pink triangles, pink rectangles, purple keys, and potato-shaped things". This incidental design feature served to engage students in an important scientific practice. Since students were investigating how molecular interactions resulted in genetic regulation at the cellular level, establishing the clarity about the identities of computational agents, their properties, and their interactions with each other was crucial. Such development of shared vocabulary is an important aspect of science practice. For example, naming conventions of organisms such as SARS-CoV-2, allows scientists across the world to easily share their findings. Representational features of computational agents in the ESM, though initially created contractions, also allowed students to devise ways to address those contradictions.

The GenEvo ESM was designed for students to visualize agent behaviors at the level of biomolecules and reason about how genetic regulation takes place at the cellular level. Students could visualize properties and interactions between biomolecules and system-level parameters such as the energy of the cell and cell division time. Discussions based on these visualizations created contradictions regarding a fundamental aspect of emergent systems: who is controlling all this – the cell, specific control molecules in the cell, or the genetic control is an emergent property of a cell. These contradictions served as a driving force for students to reason about how behaviors and interactions at micro-level result into emergent patterns at the system level (Figure 4C). Since students had designed and conducted various experiments to investigate agent-level properties, and interactions of biomolecules in different environmental conditions (presence or absence of specific sugars, glucose, and lactose) and system-level outcomes, they argued using the mechanistic details of molecular interactions to address the contradiction by reasoning how this emergent behavior at the cellular level can be manifested through interactions of biomolecules.

Discussion

In this paper, we developed a theoretical construct, *guided epistemic expansion* to name a design outcome that is intended to address the problem of practice. Our analysis of an ESM-based learning environment demonstrates how design features of an ESM mediated the *guided epistemic expansion* in the GenEvo learning environment. The findings show that three design features supported shifts towards student engagement in the social construction of knowledge about a complex phenomenon. The learning outcomes for the students were three-fold, (a) they developed knowledge about disciplinary ideas about genetics and evolution, (b) they developed knowledge about *doing science* by evolving practices to investigate a phenomenon, (c) they shifted their perceptions about their agency in the process of knowledge construction. The third learning outcome is about their *epistemic consciousness,* the realization that they can participate in constructing knowledge and devising ways to construct knowledge. One student reflected on her learning in post-interview, "*We sort of learned like how scientists would learn about the world. We do not have as much knowledge as scientists do. We formed groups, we shared ideas, we got ideas, we combined them*."

The three analyzed design features - (1) randomness in agent behaviors, (2) representational features of computational agents, and (3) visualization across levels of the ESM mediated students' engagement in specific

intermediate learning goals (objects of the activity system) as they progressed with constructing knowledge of disciplinary ideas and evolving scientific practices. These three design features created contradictions as students tried to make sense of the modeled phenomenon in the ESM. These contradictions served as a driving force for the classroom community, guided by the teacher, to use the same features for addressing those contradictions. Students' enactment towards achieving these objects, in turn, mediated the transformation of the classroom activity system through epistemic expansion. The object of the classroom activity system became the social construction of knowledge about complex disciplinary ideas, which resulted in the outcome of students' expanded ideas about their participation in learning science in the classroom in epistemically agentic ways.

This work demonstrates how the design of learning environments and allied pedagogical practices to support students' epistemic agency in a science classroom can result in epistemically expansive learning. Through this work, we provide a way to address the problem of practice by providing students a computational experimental system or a playground to test and establish evidence-based claims and collectively shape practices for doing so. As students use such computational microworlds to make sense of a modeled phenomenon, contradictions created by certain design features of the ESM-based learning environment led to guided epistemic expansive learning. In the future, we would like to investigate how students make sense of their learning trajectories in such learning environments and whether they see shifts in their epistemic agency as the classroom activity systems undergo epistemic expansion.

Abstract: Continuing schooling during the Covid-19 pandemic dramatically changed the way students, families, and teachers engaged with school and academic content. Remote instructional methods utilized by schools to reach students in their homes often relied on internet-based communication tools and individualized learning platforms, and divided instructional time into two categories: synchronous and asynchronous. We consider how synchronous learning moments, defined as live interaction between the focal children and their teachers via video or phone calls, were experienced by 109 families of elementary school children across the U.S. Specifically, we examine who had access to synchronous lessons, what happened during those lessons, and what parents and other caregivers noticed given their proximity and ability to observe the lessons first hand. We discuss how the sense of connection to peers and teachers that the synchronous interactions provided was critical to engaging students with school during the transition to distance learning.

Introduction

Few events have shocked the U.S. education system as much as the sudden shift to distance learning during the onset of the Covid-19 pandemic in the spring of 2020. The situation presented challenges for educators and caregivers for which there was little guidance. School personnel did their best to sustain learning and provide for students' basic needs, leading to a patchwork of approaches that depended on the resources of each family, school, and district (Anderson & Hirra, 2020; Reich et al., 2020). Caregivers were expected to help their children keep up their academics, motivation, and social-emotional learning, as well as balance competing demands from work and existing responsibilities (Fontenelle-Tereshchuk, 2021; Garbe et al., 2021). Across the developed world, caregivers struggled to access distance learning due to a lack of digital resources, lack of communication with the teachers, child learning differences, and limits of their own content and pedagogical knowledge (Bhamani et al., 2020; Dong et al., 2020). Large scale data from the Household Pulse survey indicates that overall in the U.S., parents were doing what they could to help their children continue with their academics during distance learning and that the number of "live" contact hours with teachers correlated with the amount of time children spent on schoolwork (Bansak & Star, 2021). However, low-income families were less likely to have regular, synchronous contact with their teachers during remote learning in addition to less access to computers and high-speed internet, critically impacting the quality and quantity of instruction these students were able to receive (Bansak & Star, 2021; Katz & Rideout, 2021). Although analyses based on large scale data are critical for beginning to specify the resources that contributed to resilience, to understand how and why synchronous sessions supported learning we need documentation of the interactions that took place. Qualitative work has begun to explore how caregivers supported their children's learning (e.g., Barron et al, 2021; Bhamani et al., 2020; Sonnenschein et al, 2021). This paper contributes to that line of work.

We present findings from a remote diary study conducted with families across the U.S. focused on understanding how families were adapting to remote learning. Our analysis explores examples of synchronous moments that caregivers reported. We examine what happened in these learning moments (e.g., content, structure, engagement) and what caregivers noticed through observing their children engaged in synchronous learning. We define a "synchronous activity" as a learning moment that includes live interaction between the focal children and their school teachers facilitated via video conferencing or phone calls. While many other kinds of synchronous learning took place in the moments that caregivers described in the study (e.g., reading to younger cousins over FaceTime), we have deliberately limited the scope of the activities in this analysis because of the novelty of the medium of instruction at this scale, weight placed on synchronous instruction for students during the pandemic, and the lack of equity of access. Our findings complicate the story of synchronous school-based remote learning during the pandemic, highlighting the social and emotional benefits the live communication with their teachers and peers provided for the children during a time when social activity was restricted. We also describe how caregivers and teachers played complimentary roles in fostering a sense of connection between home and school for the children through synchronous learning moments.

Theoretical framing

Coordination across spaces in children's learning ecologies (Barron, 2006) and the creation of systems of support for children's social, emotional, academic, cognitive, and physical wellbeing (Darling-Hammond et al., 2019) are critical for healthy child development. One aspect of that is caregiver involvement with schooling, which is known to be positively associated with children's academic success in the U.S., both for in-person schooling (Smith et al., 2020) and virtual school environments (Garbe et al., 2021). Positive home-school relationships shape children's sense of belonging in school environments. Yet crossing the boundary between home and school to advocate for their children's individual needs requires caregivers to develop and maintain working relationships with their children's teachers (Lawrence-Lightfoot, 2004). This amount of time and effort is often out of reach for caregivers who do not have work flexibility or may face a language barrier (Valdez, 1996). When the pandemic forced home and school to be co-located, although many of these factors remained challenging, new opportunities emerged for caregivers and teachers to cooperate and establish multifaceted systems of support to foster healthy learning environments for the children under adverse circumstances.

During synchronous sessions caregivers were often actively engaged, providing technical assistance, supervising or simply keeping their child company, and taking the opportunity to observe interactions and listen in on classroom discussions. Observing and listening in on activities and events are modes of active learning that Rogoff et al (2003) describe as learning through "intent participation." Much of the previous research on intent participation has come from examining how children learn to participate in everyday practice that shapes community life (Rogoff et al, 2003; Rogoff, 2014) as well as in more structured learning environments (e.g., Jocuns, 2008). However, intent participation could also be used to describe how caregivers of young children learn to shape their interactions with their children based on their noticings of their children in different settings. Caregivers regularly take on new responsibilities and roles to meet the needs of their children (Barron et al., 2009), gathering information on how to do so through formal and informal sources (e.g., family networks or child-rearing classes; Radey & Randolph, 2009). Rarely do they need to do so under such unusual conditions as a global pandemic. Given the enormous challenge for maintaining motivation during school closures, we focus on what parents noticed about what facilitated their child's positive engagement with school during video-mediated classroom interactions. Our analysis draws on situated views of learning that conceptualizes engagement as dynamic, multidimensional, and often connected to idiosyncratic social or activity-based preferences (Azevedo, 2013). We foreground how caregivers described the relational, material, participatory, and content-related resources that contributed to their children's enjoyment of synchronous sessions.

Methods

In May and June 2020, we collected over 700 reflections, including 668 diary entries of learning moments, from 109 families with children aged 5-10 using *dscout*, a smartphone-based remote qualitative research platform (Barron et al., 2021). Using a smartphone-based app allowed us to collect multimodal in-the-moment data from busy caregivers as they went through their days and observed their children learning. Our method foregrounds the perspectives of caregivers which gives us unique insights into the roles caregivers were playing during the stressful months early in the pandemic where they were forced to balance competing priorities of work, child care, and schooling. We recruited from *dscout's* participant panel. Our criteria for participation were: (a) having a child between ages of 5-10 living at home, (b) the child's school had moved to remote instruction and was in session for the entire duration of the study, and (c) the applicant had given consent for their responses to be used for research. Over 1,000 people applied to be part of the study. We sorted applicants into low ($0-49K), middle ($50-99K), and high ($100K+) income groups and randomly selected 37 participants from each group to ensure a diversity of socioeconomic status in the sample. In total 109 caregivers completed the study. They were from 28 states and were mostly women (67%) with children in public elementary schools (84%). Racially, 55% self-identified as white, 16% as Black, and 15% as Latinx, 9% as Asian, and 4% as Middle Eastern or North African. Slightly over half (55%) of the caregivers reported an annual household income of at or above the national median income of $75k. Participants were paid $75 at the end of the study.

Data collection was organized around five themes: (1) relationship to school pre-pandemic, (2) relationship to school during distance learning, (3) daily learning moments, (4) how the family learned about Covid-19, and (5) reflections. For each theme, participants answered a series of questions using short videos, photographs, survey questions, and direct messages to the researchers. Theme #3, daily learning moments, is where we draw data for this analysis. Data for these moments included a 2-minute video, transcribed, of the caregiver explaining and reflecting on a learning moment they observed that day, a photo of the activity, as well as multiple-choice survey style items where the caregivers reported the subject of the activity (e.g., art, writing, math), how much learning they perceived to be happening in the moment, and how engaged the child was with the activity (e.g., how much fun they were having.) For this part of the study, we asked caregivers to share six

learning moments they observed over the course of a week. Of the 668 learning moments we received, 128 (18%) were identified as examples of synchronous video or phone-enabled interactions with teachers through multiple rounds of qualitative coding.

Next, we employed a mixed-methods analysis to explore the following questions: (1) Across the whole sample, how did access to and the content of synchronous learning experiences vary by family demographics? (2) How engaging were synchronous learning moments for the children and what did they look like? (3) What do caregivers learn about their children's experience in distance learning as a result of listening in, observing, supervising, and assisting with instruction? To understand the distribution of synchronous moments across our sample, we used statistics to analyze caregiver responses to survey items about what their child's school provided for remote instruction, including communication channels with the teacher. Next, using iterative rounds of inductive and deductive coding, our team developed a codebook for a thematic analysis of the structure, challenges, benefits, and caregiver insights present in the caregiver descriptions of the events (Saldaña, 2011) and applied the codebook to the sample. Additionally, to deepen our interpretation of what was happening in the learning moments and what caregivers were attending to, we looked at our coding of the synchronous activities in relation to the standardized data the caregivers reported about the details of the learning moments, including child engagement.

Findings

In the sections below, we utilize descriptive statistics to explore the question of equitable access (research question #1) and show the variety of content and structure of the synchronous activities (research question #2). We further illustrate the aspects of synchronous learning moments that facilitated positive student engagement (research question #2) and how caregivers acted as partners in supporting that engagement (research question #3) with representative qualitative examples.

Access to synchronous lessons

In the overall sample of participants (n=109) higher-income families (annual incomes above the national median of $75k) were more likely than lower-income families (annual incomes less than $75k) to indicate having access to synchronous classes, other types of family-teacher communication such as individualized messages from teachers, and access to teacher-recorded video content (Table 1).

Table 1. Reported access to synchronous opportunities by income group

		Median income groups			
	N	Higher	Lower	X^2	p
Synchronous classes	109	92%	72%	6.48	0.01
Individualized messages from teachers	109	90%	67%	8.6	.003
Teacher-recorded video content	109	68%	47%	5.1	0.02

The sub-set of 128 examples of synchronous learning we identified through iterative rounds of coding came from 71 families (65.1%). The caregivers who submitted these moments did not differ significantly from the rest of the whole sample (n=109) by income (54% above $75k annual income).

Positive engagement in synchronous lessons

In the diary entries of learning moments, caregivers reported their children's positive engagement on a Likert scale item with rating options from 0-10. A one-way ANOVA revealed a significant difference in caregiver perceptions of synchronous and non-synchronous moments ($F(1,666) = 9.49$, $p = .002$). Overall, caregivers rated synchronous learning moments as more engaging ($M = 7.73$, $SE = .240$) than non-synchronous moments ($M=6.90$, $SE = .117$). About 60% of synchronous moments (77 of the 128) were rated as highly engaging , meaning they were higher than the median engagement score across all learning activities documented. Through parent ratings and descriptions of the moments, we were able to explore what caregivers noticed that might have made these synchronous learning moments engaging.

Structure and content of engaging lessons

Whole class meetings were the most common (55%) of several ways that caregivers reported their children participating in synchronous lessons. Children also participated in small groups (12%), had one-on-one meetings

with teachers (9%), and received special education pull-out instruction (4%). Over three quarters of these meetings were structured in some way (82%) while a minority were unstructured (9%). There were no meaningful differences in caregiver ratings of engagement by the structure of the synchronous moments.

The most commonly covered academic content in synchronous lessons was reading (32%), followed by mathematics (27%), science (15%), and writing (15%). The activities that were more likely to be rated as highly engaging, however, were either art or music (X^2 = 5.7, p=0.02), and the ones less likely to be highly engaging were math lessons (X^2 = 8.17, p= 0.004) and writing lessons (X^2 = 10.66, p = 0.001). Alice described how her kindergartener's weekly Zoom music class provides "A little bit of normalcy and all this crazy times":

> Her music teacher comes on and then she can see her teacher as well as all the other children in her class. So it lasts about a half an hour and my daughter absolutely loves it. She loves doing it. She loves music. They play games, they play songs, and do little dance moves and everything like that. [...]The teacher is able to mute them and unmute them and sing along and call on people and things like that. So my daughter really enjoys it.

Alice's attention to the positive experience her daughter has in music class encourages her to keep logging on to the class each week. Indeed, this attention to the importance of social, emotional, and content-related interactions emerged across the synchronous sample as was made evident by what aspects of the synchronous moments caregivers highlighted in their documentation.

Engagement fostered through teachers caring and connecting

Caregivers noted the importance of synchronous sessions for supporting a sense of connection to peers and for providing opportunities for teachers to communicate their caring for students' well-being. For example, Dillon reflected, "this one was pretty cool for the teacher to make the time to keep my child feeling cared for. [...] my daughter was doing a one-on-one check-in with her teacher and they were just talking about various things catching up on what was going on in her life and a few other things." The emotional benefit for his fourth-grade daughter of having a one-on-one check-in with her teacher was great since she had liked her teacher and "was sad when the school year got cut drastically short. [...] The interaction went really well and she was pretty happy to get that one-on-one attention which my child tends to thrive on."

In another example, Ida, mother to second-grader Lani shared her observations of a whole class Zoom:

> [I]t's a good thing that they do this [...] twice a week, to kind of like you know, talk about the book they're reading, learning about vocabularies, or either you know, just kind of keep track of what they are working on this week. And I like the idea of doing this because they get to see their friends, their classmates and their teacher and say hi, and what have they been doing for the past few days or weeks. And it's very engaging, and I like when my daughter is able to share her... whatever she's been doing for the past few days, and [...] check in. So they [are] kind of like, slowly, [...] making sure that the kids stay on track as far as their grade level.

Ida describes a Zoom meeting in which the class is reviewing the content they have been working on and has an opportunity to connect face-to-face. The purpose of the time together is not necessarily to learn new content or complete an assignment. However, these twice-weekly meetings keep Lani engaged with her class and reflect care and attention from her teacher.

Engagement fostered through teachers welcoming children's interests and identities

Caregivers also noticed their children enjoying synchronous lessons when they had the opportunity to share their interests and aspects of their identities with their classmates. Being given more agency over what they brought to class was motivating for the students. Some examples caregivers shared were times where the children brought items to Show and Tell, dressed up as superheroes, or had open sharing time to talk about things on their minds. Other moments tied more directly to the content of the class. For example, Billy's second-grade son was disappointed when schools closed, and "he could not have science class in person anymore." However, his teacher organized a virtual lab for the class, and "when he learned he was going to have a virtual lab he became really excited." Billy commented on how his son was "intrigued the whole time. And he was telling me about the different stages of a scientific experiment, and how he was making observations about what he was seeing. So overall, it went really well, and he seemed to love it."

School routines that were transferred to Zoom were also opportunities for student agency in some schools. Layla shared how her kindergarten daughter "was glowing" when she was chosen by the school principal to

display the Israeli flag and lead the school in the Israeli national anthem. She explained, “ever since Israel had its 72nd birthday [...] my daughter wanted to make a flag for that country”. She went on to describe how the school met every morning to say the pledge of allegiance to the US flag, but then also included flags and anthems from different countries when students express interest in sharing their own.

Caregivers as partners in supporting positive engagement

Through leading synchronous sessions for their students to be together virtually, or connect one-on-one with students, teachers enabled opportunities for social and emotional connections that would not have been possible otherwise under the shelter-in-place orders and social distancing guidance. Teachers facilitating these learning moments for students provided an opportunity for caregivers to take a step back and watch how their children reacted to the sessions, and come up with strategies to support their children from home.

Synchronous lessons reveal complicated emotions

Throughout the reflections from caregivers on their children’s positive engagement in synchronous lessons, caregivers highlight the value of maintaining a social connection to peers and teachers for their children’s emotional well-being. During a difficult time filled with fear and uncertainty, synchronous class meetings and activities provided caregivers insights into how their children were handling the situation. For Maggie, a poetry assignment helped her understand what her fourth-grade son was thinking and feeling:

> So I'd say it was successful but not necessarily for the academic purpose of it. But we're not really using Zoom at the elementary level for instructional purposes anyway so it was just kind of a bonus educational activity today that a couple of kids shared poems but was far more social and importantly so. [...] I think it was a really good activity just because you know it kind of let me see the things that were on his mind that he hasn't necessarily been expressing [...] I think it was you know it's definitely something I'm going to save to kind of earmark this time in his life. So I'm glad it was an assignment we had. [...] I do think it proved a good exercise in emotional wellness.

The poem Maggie’s son wrote was titled, “Empty Soccer Field,” and expressed the sadness he felt not being able to play soccer with his friends at the time.

When teachers provided forums for students to share and express their identities, parents noticed engagement but that engagement was often complex. Brie gave an example of how her first-grade son’s teacher opened their thrice-weekly morning meetings with “Does anybody want to share?” Students would read to each other and show off their pets, and Brie’s son “enjoyed showing his ladybugs and his roly-polys [laughs] and his other bug pets.” While Brie notes that “when he goes, he’s always wanting to share, and listening to his friends share,” she also says that he reports that he does not like the class meetings. She reflects, “So, it's kind of funny to me that he doesn't like them. I just think he doesn't really like the online-- He has not enjoyed like, online play dates or any of the online interactions with friends. It's been really difficult for him. He misses actually being with friends and really playing.” Through listening in on her son’s class meetings, Brie was able to see her son’s continued reticence to socialize online, even if there are aspects of it that he did enjoy.

Caregiver strategies for supporting positive engagement in synchronous lessons

From the other side of the camera from the teachers, caregivers took up multiple roles for supporting their children’s engagement during the synchronous lessons. Some encouraged hesitant children to attend, such as Connie who reports she and her husband encourage their fifth-grade daughter to participate so that she “stays connected with her teacher and classmates. I think it helps keep her engaged in doing the online E-learning classwork.” While children were logged on to their video classes, caregivers were often close by listening in on what was happening (e.g., actively attending to the child’s actions or interactions with the teacher or their peers), actively supervising (e.g., assisting in time and task management), or taking on a teaching role to modify instruction live to meet their children’s needs.

Modifying instruction often occurred when the children were confused during the lesson and did not have a good way to get their questions answered by the teacher. For example, Arielle’s fourth-grade daughter Cami got lost during a math lesson, and Arielle, who was listening in next to her, stepped in to help Cami get back on track. She explained:

> So [Cami’s] teacher was going a little fast, because they are learning-- they're learning at a fast pace, because school is now wrapping up, so she's trying to squeeze a lot of stuff in. So [Cami]

> was getting very, very confused, and I had to mute her and turn off the camera and kind of re-explain the concepts to her. I also did it in the traditional math way instead of the Common Core, which has 10 steps. And she got that way better, so I would like to think that I am a secondary teacher for her.

In this moment, Arielle was supervising Cami because after the previous class was over, "she turned her camera off and muted herself. So she had thought that she could just hang out on her phone. So I just sit there, do my work right next to her, and make sure that she took notes and did the assignment and asked questions and just participated." Arielle's insistence that Cami participate fully in the synchronous lesson ended up not being fully realized in that she effectively pulled Cami out of the classroom for private instruction using different pedagogical strategies than the teacher. However, by engaging with the content, they did surface an area of confusion for Cami and addressed it immediately.

Jade also kept a careful eye on her fifth-grade grandson Henry, who had an IEP, and stepped in to advocate for his learning and help manage social interactions. For example, when Henry was put in a small group with classmates to write a collaborative report on the U.S. "Founding Fathers," his classmates ignored him. Jade noticed the negative dynamic and shared that, "I'm not gonna have the other kids close him out and him trying to work on it on its own. I'm trying to figure out a way if maybe he can do a report on a founding father on his own, and I need to check with the teacher maybe do it that way." Synchronous classes were hard for Henry to keep up with, and sometimes he would switch to listening to audiobooks or working on a personalized learning platform instead of following along with the class. Jade supported these activities and ran interference to try to make Henry's live interactions with teachers and peers a positive experience.

Helping children manage their emotions, stress, and anxiety was also a responsibility that some caregivers took up explicitly. Ramira, for example, shared how her fifth-grade daughter came to her to ask questions instead of asking the teacher because she wanted to finish her work before the end of the lesson since it was the start of a holiday weekend. "During the event she Was getting anxious about finishing her Work due the holiday weekend" shared Ramira, "She was engaged by asking me questions and muting and not wanting to finish, and finally after some coaching, she was able to focus and concentrate."

Caregivers also attended to the physical arrangements that their children set up for themselves to be comfortable during synchronous lessons. This view into their children's preferred working environment was possible due to the caregiver's observing and supporting their children to experience synchronous instruction as positively as possible given the constraints of the time. For example, Matt, caregiver of third-grade Oliver, noted that Oliver "likes to snuggle up with the dog and blankets. Been doing it, and I think it gives him comfort when he's online with his classmates." One day during the morning meeting the class was sharing who they admire most and Oliver said he admired the dog. Matt reflected "it is true because that dog does give him comfort, and he likes to be the class clown- [...] teacher didn't yell at him. I don't know that I thought it was super appropriate, but it seemed to work for him." Mariah also noted where her fifth-grade daughter was comfortable taking calls: from her bed but dressed up "so she can kind of show off her classmates and to make sure she looks the best :-)." Mariah takes a hands off approach to give her daughter space to connect with the teacher and classmates on her own. "When she does her zoom calls I pretty much kind of stay out of it," Mariah shared, "I want her to have that time away from me to be with her teachers and to be with her classmates so that she can have the slightest bit of normalcy."

Discussion

Given the rapid transition to remote learning, the varied responses and capacity by districts across the US, and the widespread utilization of technology tools for school-to-student communication and lesson delivery, we set out to understand how families experienced school-driven synchronous moments. We found that caregivers whose household income was below the national average reported less access to synchronous classes as well as other family-teacher technology-mediated interactions, and shared fewer synchronous moments in their learning diaries. This is especially critical in light of our other findings that highlight the benefits of synchronous moments that reach far beyond just being academic content delivery mechanisms. Synchronous sessions tended to be recognized by caregivers as highly engaging for their children. Encountering and fostering positive social interactions and emotional connections to school during the difficult transition to distance learning was important to caregivers. Our finding aligns with Katz and Rideout (2021) who conducted a nationally representative study of underconnected, lower-income families (less than $75k annual income) and found that top priorities for their children upon returning to school in the fall of 2020 were social or emotional (50%). Their study also underscores the inequity of lower-income families not having access to synchronous opportunities which we found to provide generative moments of social and emotional support.

Additionally, we found that as caregivers attended to their children's reactions and engagement with synchronous lessons, they reflected on how the content, structure, and relational components of the sessions contributed to their children's experiences. These findings also align with Katz and Rideout (2021) who found that parents of 3-13 year-olds felt that they knew more about their child as a learner (66%) and more about the content and structure of school (62%). In some cases, especially when student engagement or focus was a challenge, caregivers used what they knew about the activity and their child and took an active role in mediating their children's engagement with the lessons to support a positive outcome for them. This action was typically not possible before the pandemic. While teachers and schools scaffolded synchronous opportunities, parents were on the other side of the camera with their kids providing a supporting role using a variety of strategies. They mediated moments of potential meltdown by stepping in to turn off the camera and providing extra coaching about the material or letting them skip a session altogether, they gave reassurance and coaching for anxious learners, and they helped create the physical conditions that offered comfort and security for engaging in synchronous learning moments.

Together, these findings suggest a more complex picture of online learning during the pandemic. Synchronous sessions were not always just a re-creation of school lessons; many engaged young people through supporting peer-to-peer and student-to-teacher connections and opportunities for personal expression and agency. The live interaction with teachers and peers provided by synchronous learning moments fostered a sense of connection and stability that was critical for well-being during the uncertainty that marked the beginning of the pandemic. Yet in our data, the incidental partnership between teachers and caregivers made it clear how caregivers were playing a supporting role for their children during these synchronous moments, adapting and reacting in the moment depending on what they noticed, often bolstering engagement. More research is needed to understand how a sense of connection with peers and teachers was maintained for the families who did not have that live interaction with school during critical points in the pandemic. In our sample, caregivers who worked during the day did find ways to connect with schools, despite being unable to connect synchronously. These included caregivers who watched previously recorded zoom sessions with their children and others who found other ways to communicate with teachers and peers

Further, our qualitative findings are consistent with larger studies showing relationships between online synchronous connections and metrics of engagement in learning (e.g., Aguilar et al., 2021). This convergence between studies warrants future research that can offer deeper explanations for how and why synchronous connections may support engagement in the moment and over time. Experiments and broader ethnographic studies that include a more diverse set of family situations can offer theoretically rich and design-relevant data. In addition to new research designs, multiple measures of engagement will be useful in advancing this work. Our parent rating of engagement in activities is novel and future work can be designed to validate such ratings through designs that include children's views or interactional metrics of participation in learning moments.

Conclusion

Nearly two years later, Covid-19 continues to have a lasting impact on families and schools. Large-scale reports detailing the "learning loss" shown through standardized testing data devalue the efforts by teachers and caregivers to attend to children's well-being during the pandemic, and the learning partnerships that emerged in response to the disruption of the pandemic. Findings from our analysis have implications for emerging models of schooling for the rest of the pandemic and beyond, fostering positive engagement with school and child well-being, as well as for future educational research centered on families. With regards to the former, the experiences of our families in this study highlight the importance of having real-time interactions with peers and teachers for academic and social purposes. Future models of home-based learning in the "new normal" must capture those benefits while also taking into account the additional burden placed on caregivers by the technical and pedagogical challenges introduced by synchronous remote learning. However, our results point to promising directions for increased communication and coordination between teachers and caregivers allowing for students to engage in more personalized and interest-driven learning as part of academic instruction. Additionally, the data suggest that having synchronous interactions within a virtual school context helps learners and caregivers feel connected to teachers and peers. Synchronous connections may be an important source of educational resilience, allowing parents and children to cope with the challenges presented by distance learning and sustain or increase their enjoyment while learning.

"Keep it in the Village": A 25-Year Journey of Collective Concept Formation Transforming Financial Practices in a Rural Thai Village

Luis Morales-Navarro, University of Pennsylvania, luismn@upenn.edu
Deborah A. Fields, Utah State University, deborah.fields@usu.edu
Paulo Blikstein, Columbia University, paulob@tc.columbia.edu

Abstract: Community-generated concepts, namely "germ cells," can be productive to address problem situations. Yet most literature on germ cells accounts for the initial development of concepts and how these create opportunities for learning and concrete application. This taps into only a small part of the potential power of a germ cell to be generative. In this paper we consider the ongoing development and application of a germ cell in a rural Thai village over 24 years, showing how through a series of learning intraventions, each involving self-analysis and reflection alongside concrete community actions, a germ cell slowly evolved, continuing to orient the village's transformative work. In this process, the villagers' family and community financial practices underwent dramatic, productive change. The ongoing unfolding and expanding concrete manifestations of the germ cell shed light on their generative capacity in community learning and transformation.
Keywords: germ cell, formative intervention, intravention, activity theory, concept formation

Introduction

Supporting collective community learning through concrete changes in practice is an underlying challenge in the learning sciences (Gutiérrez & Vossoughi, 2010) that requires forming collective concepts that catalyze change. One way to approach concept formation is through the analysis of germ cells: powerful, underlying ideas (i.e., abstract concepts) developed through experimentation and self-analysis by a group of people to orient their actions toward productive, collective learning. In other words, a germ cell is a simple explanatory concept that people construct to transform their community practices in concrete ways to learn expansively (Engeström & Sannino, 2012; Gutiérrez & Penuel, 2014). In this paper we explore the community development of a germ cell that helped to orient dramatic improvement in community financial practices in one rural Thai village over 24 years.

In the late 1990's, like many subsistence agricultural villages, the northern Thai village of Ban Samkha faced crippling financial conditions that threatened its survival. They were collectively buried under unsustainable debt at high interest rates and, according to their own descriptions, had no understanding of the mathematics of compound interest (or its influence on their debt) or how they accumulated such debt in the first place. Problematic practices added to their expenses, for instance, selling all their crops at low prices and purchasing food from outside vendors at higher costs. While various government and nonprofit organizations initiated development programs in prior years to help Ban Samkha and other villages, for instance providing an influx of cash with a "village fund" or group lending initiative (Coleman, 1999), without a means to comprehend the underlying issues behind their financial problems these interventions worsened the village's problems. Villagers expressed feeling incapable of understanding, much less tackling the concerns that overwhelmed them.

The challenges Ban Samkha faced were not unique; they were (and are) common in villages throughout Thailand and the world (Chichaibelu, 2018). Although transformative social change in villages and rural communities is a valued ideal, supporting it is nontrivial. Villages face multiple, interrelated obstacles, from a lack of financial literacy to unsustainable agricultural practices, to local ecologies actively being reshaped by climate change (e.g., Sayizonga et al., 2016). In the face of these challenges, community participation and leadership are necessary for initiatives to succeed, yet most development initiatives in Thailand and across the world are designed with scant understanding of local contexts, community interests, or the histories and power structures in which problems are rooted (Gutiérrez & Vossoughi, 2010; Nuttavuthisit, 2014). Further, the participatory practices necessary for community empowerment and transformation (Freire & Macedo, 1987), as well as the understanding of larger schemes of exploitation (Freire, 1974), are usually absent from financial literacy education programs (Blue & Pinto, 2017). However, the development of local agency is essential for community members to become "agents of change" and take action together (e.g., Gutiérrez & Jurow, 2016). Such agency requires conceptual development on the part of communities: the ability to analyze their specific, local challenges and develop means of organizing and acting toward transformation (Vossoughi & Gutiérrez, 2016). In these contexts, community formative interventions, which include the development of germ cells, can provide a means for expansive learning and transformative agency (Sannino et al., 2016). Yet most literature on germ cells addresses only their initial development and application over the first few years of an intervention (e.g.,

 © ISLS

Ivaldi & Scaratti, 2016), tapping merely a small bit of the potential power of germ cells to be generative for years and across multiple areas of community life.

In this paper we consider how Ban Samkha developed a germ cell— "keeping it in the village"—and how this germ cell helped spur the village's learning through a truly remarkable series of intraventions over 24 years. The germ cell emerged through collective analysis of their financial problems and supported the development of many concrete actions in the village. Further, what began in the financial domain slowly expanded to other domains as the germ cell was incrementally developed over time. To study this, we drew on 37 hours of interviews across four visits over as many years in addition to over 350 pages of documentation by the village and a supporting foundation. We employ an iterative case study approach, using chronological sequencing and thematic analysis, and apply Engeström and colleagues' (2012) framework of learning actions for ascending from the abstract to the concrete to address the following research questions: (1) How did the village develop a germ cell? and (2) How did that germ cell evolve over time through multiple, concrete village-led intraventions? In the discussion we consider implications of this work for community development alongside theoretical insights from the village's markedly longitudinal and generative development of the germ cell.

Background

Village learning, like other community learning, can be observed in changes in practices, as conceptual thinking occurs in action (Davydov, 1990). Davydov (2008) proposes that when learners engage on a particular task, they "complete a sort of microcycle of the ascent from the abstract to the concrete" (p. 124) in order to assimilate, in a Vygotskian sense, theoretical knowledge and form concepts. In these sequences of learning actions, which consist of operations that occur within the context of a learning task, germ cells emerge as general concepts or activity units. Germ cells are abstract concepts created through iterative experimental and analytical examination of one's own community's practices (Gutiérrez & Penuel, 2014). The abstraction of the germ cell is developed in the process of modeling a solution to a problem situation and captures the genetic unit capable of creating new and concrete change (Falmagne, 1995; Davydov, 1990). For Davydov, the proponent of the term, these conceptual cells work like biological cells in the sense that "a cell is what everything stems from and is reduced to" (Davydov, 1999, p.47). To wit, germ cells reproduce like biological cells, generating new implementations and extensions of a concept as learners "ascend to the concrete" (Falmagne, 1995; Davydov, 1990) of concept formation by mastering conceptual understanding through concrete changes in practices—further constructing the abstract idea by applying it in everyday situations.

Engeström and colleagues (2012) have a long history of studying the development of germ cells in formative interventions where communities address challenges with the support of researchers. Building on Davydov, they argue that concepts are formed as learners ascend from the abstract to the concrete where, starting with a problem situation, they model an abstract concept that is developed and becomes concrete when applied in practice. This process occurs in a sequence of epistemic actions that include (1) questioning, (2) analyzing, (3) modeling, (4) examining, (5) implementing, (6) reflecting, and (7) evaluating. In such a sequence, the germ cell itself is discovered, modeled, and examined experimentally and analytically by learners as they investigate and transform their activities. Germ cells play an important role as the smallest unit of the complex totality of all the analysis and changes in practice, they carry the contradictions of the whole, and in practice can be ubiquitous to a point that they may go unnoticed (*Ibid.*). More importantly, germ cells are generative and can be extended in multiple applications and future developments. Yet while the generativity of germ cells is well argued for, most research on germ cells takes place in researcher-led formative interventions where the time limitations of research projects (i.e., 3-5 years) often curtail the evidence for the longevity and "multiple applications" of germ cells.

In the learning sciences, most research on germ cells has focused on single learning sequences to study how germ cells are formed. For instance, Engeström and colleagues (2012) studied how care workers at an elderly home alongside elderly people at risk of losing physical mobility collectively formed a new concept of mobility over a period of two years. Through the simple idea of "standing up" they included regular mobility exercises in home visits and daily life. This was generative in framing physical mobility in terms of sustainability and in generating innovative ways of using household objects to support mobility and autonomy. Other work has addressed the emergence of the "walk the talk" germ cell in a formative intervention among volunteers at a nonprofit as a concept that in practice can help align volunteer work with organizational values (Ivaldi & Scaratti, 2016) or the "tighten knots" germ cell as a concept that through concrete practices helped an interdisciplinary health promotion team come together and work towards common goals when providing health services from complementary disciplines (*Ibid.*). These examples focus on germ cell emergence without addressing germ cell generativity over time and domains.

This is not to say that there is no research that has focused on generativity beyond the initial conception and application of a germ cell. As an example, Sannino and colleagues (2016) describe how in a *series* of learning

sequences over many years, a community in an urban Brazilian informal settlement developed, sustained and expanded a germ cell. The germ cell, that trash has value and "trash is life," emerged as the community was dealing with flooding where trash in the river affected its members' health and safety. The community's questioning and analysis led to an *intra*vention on waste management, where the germ cell "trash is life" emerged. Yet the generativity of the idea continued far beyond this initial development, and the community continued to learn, as evidenced in their changing practices over 3 years in related areas: waste management and policies, flooding prevention, community safety, and even policy advocacy at a city level. Further, through the concept of "trash is life", the community became aware of its rights and its power to transform and improve itself (Sannino et al., 2016). We find this work particularly inspiring because it was not researcher-driven, but primarily community-driven (illustrated with the term *intra*ventions), in a sense a social design experiment (Gutiérrez & Jurow, 2016) generated by and iterated on by the community itself. This is also a provocative example of a germ cell that the community applied in multiple ways, providing evidence of the promised generativity of germ cells. Building on this work, we analyze the community-led formation and generativity of a germ cell in Ban Samkha across a series of learning sequences in community-led financial intraventions over a period of 24 years. We consider how the germ cell developed over time—evolving through iterative experimentation, practice, analysis, and reflection—and briefly describe how it became generative in other domains of village life through environmental, health, and educational initiatives.

Methods

Context

Ban Samkha is a rural village in northern Thailand (~600 people) that today is known as a "model village" in the country (Bruneau, 2009) for its financial, environmental, and agricultural sustainability initiatives, including a community bank, a successful homestay program (~3000 tourists a year), and a ban against herbicides and pesticides. By internalizing the learning philosophy of Thai Constructionism (see Blikstein & Fields, 2021; Fields & Blikstein, under review), the village developed an established sense of agency with a learning process they applied iteratively with perseverance. This paper is part of a larger study on the development and pursuit of a unique implementation of Papert's constructionism (1980) in Thailand (see also Cavallo, 2000), which over two decades was reshaped through local internalization into Thai Constructionism (Fields & Blikstein, under review). Elsewhere we have documented the transformative story of Ban Samkha's journey to become "a village that learns" (Fields et al., under review). Here we focus on the development and role of the germ cell—"keeping it in the village"—that helped drive their communal work in finances.

Participants, data collection and analysis

We collected data during four research visits to Thailand from 2017-2020, including three extended research visits to the village. We interviewed 14 villagers and 6 people from other institutions that mentored and/or learned from villagers, totaling more than 37 hours of interviews, in addition to gathering over 350 pages of scanned project documentation, including a book published by the village (Ban Samkha, 2005). Interviews focused on participants' personal and collective narratives of struggle and change, as well as experiences learning with constructionism (the original topic of the broader study). Later interviews built on early analysis, soliciting specific details about what led to significant events and projects. Overall, we spent 1-5 hours with each participant, individually and/or in focus groups. Further, to develop a common understanding of research interests and IRB concepts of privacy and research protections, we spoke with translators extensively before interviews to support more meaningful translation and interpretation. Of note, the native language of Ban Samkha villagers is Lanna, and interviews were conducted in Thai, English, or a blend, depending on villager preference. We clarified meanings whenever greater understanding was needed.

The 14 participants interviewed, while a small sample, represented a range of people who participated in the constructionist efforts over the course of 24 years in different ways. Some were children at the time of the first intraventions and as of our last visit led various village committees. Others joined in very peripheral ways in the early years and became more involved 5-10 years later but are not considered core leaders of initiatives. Still others did not even begin to be involved until 10 years after early intraventions in the village. Some were the original core leaders. The villagers chose who we interviewed. We began with a few contacts in the village, networked through a foundation that worked with them since 2001. We requested to meet a range of people involved in different ways, and our contacts chose people from a variety of ages, professions, and gender, including local farmers, teachers, parents, homestay hosts, local monks, village committee leaders, etc. We were invited into homes as well as the village meeting hall and participants showed us their accounting forms, reflective documents, farm products, crops, fruit trees, check dams, etc. The villagers we interviewed represent only a

fraction of those involved in constructionist efforts in Ban Samkha and of the village population at large (~600 people). While interviews were primarily based on memories, some 20+ years old, these were checked by villagers' meticulous written records and reflections, for instance of every visit by mentors over 24 years (into the hundreds), records of village and family farm finances, and contributions (knowledge and monetary) by outside organizations. Most notable is a publicly available, village-authored book covering 1999-2003, including detailed explanations of the historical origins of village problems and sequences of early intraventions (Ban Samkha, 2005). To honor and reference Ban Samkha's own written history as well as other native Thai authors who have researched the village (e.g., Koanantakool, 2004; Sipitakiat, 2020), we identify the village by name. Consequently, we seek to protect the identity of participants by keeping names and identifiers of individuals as anonymous as possible. This serves to protect villagers who could be easily identified by gender, age, or profession.

In developing the case study, we conducted chronological sequencing, and thematic analysis (Merriam, 1988) to organize villagers' accounts of events. Before our third data collection visit to the village, we created a comprehensive timeline of key events. Then, during this visit, using an 8-foot-long version of the timeline with movable post-it notes for events, we invited villagers in four different focus groups to help fill in missing events and confirm the order. Villagers checked each other's accounts, and together we created a firm order of key events important to villagers which further prompted reflective, insightful conversations. Once we had a clear understanding of the intraventions conducted in the village we conducted thematic analysis (Yin, 2018) of initiatives in five key domains of village life (financial, environmental, educational, agricultural, entrepreneurial) across all interviews. Through this process we recognized that villagers engaged with a germ cell that we summarize in English as "keeping it in the village". Further the meaning of this germ cell changed over time—evident in villagers' explanations of their initiatives, reflections, and changed thinking. Following this insight, we applied Engeström and colleagues' (2012) framework of learning actions for ascending from the abstract to the concrete as an analytical grid to investigate how the germ cell was developed and identify the sequence of learning actions within each intravention. Then we compared how the model of the germ cell changed and evolved in practice to analyze its development and generativity over time.

For external validity we engaged in "member checking" with feedback sessions at several stages of analysis and writing, including follow-up interviews, focus group interviews, and the timeline construction. In addition, two long-term Thai Constructionists with 15-20 years of experience with the village provided feedback on our findings to support analytical rigor as well as political and cultural sensitivity.

Findings

To situate Ban Samkha's challenges historically (Gutiérrez & Vossoughi, 2010), we begin where the village itself placed the origins of its current financial struggles. In the mid-1900's, as modern farming technologies were advertised and better roads connected the village to the provincial capital, farmers bought "iron buffalos" or walking tractors, started selling rice and produce to middle-people from outside the village, and began utilizing chemical fertilizers, pesticides, and herbicides (Ban Sam Kha, 2005). Villagers took out high-interest loans for farming, vehicles, and secondary education for children (*Ibid.*). But it was the 2540/1997 crash of Asian markets, which started in Thailand, that took village debt to unprecedented levels. That year, the country's economy contracted 11%, and the cost of living increased by 40% (Hewison, 2000). Villagers returned from the cities looking for work and the collective debt of all families summed more than 18 million baht (31 million baht or 1 million USD adjusted for inflation, ~12,000,000 USD converted per purchasing power parity) gathering interest at high rates (Koanantakool, 2004). Something had to be done. As one villager explained, they had to find ways to survive because "the entire village was in bad debt" (interview, 2018). Debt was a common problem across Thailand, as were government interventions to try to resolve it, including the 2512/1969 "village fund" (Coleman, 1999). However, in Ban Samkha and other villages, this initiative failed. As a villager explained, "because of our lack of knowledge, we used [the] money the wrong way… we actually used it for our daily expenses" (interview, 2020). However, in 2540/1997, the villagers approached their financial issues with a new and different resolve: to understand them and seek knowledge. Thus began a series of initiatives—or intraventions—by the villagers to learn ways to address their financial problems, a process that led to rich financial literacy and further developments that the village could not have predicted at the time.

Keeping it in the Village: Forming the Germ Cell

In pursuing financial health, villagers eventually created a new concept: "keeping it in the village." This germ cell developed across successive and iterative intraventions. Here, we analyze how the germ cell was formed through a sequence of learning actions taken by the village. In 2540/1997, villagers began by **questioning** the nature of their debt. Unlike prior efforts, they rejected the idea that they could not understand their finances, sought help to learn about debt and organized to find solutions. In a second learning action, with the support of a Japanese

nonprofit, "fourteen smart people studied debt in depth" (interview, 2020), spending 3-4 hours daily over an entire year to inquire into the origin of villagers' debt and **analyzed** it using spreadsheets to keep track of income, payments and debt owed. A village leader explained:

> We looked back to try to figure out how all the debt was accumulated and how the problem might be solved. We realized that the villagers didn't have savings, only debt. Saving is hard if the amount of money is small, it's difficult to deposit it to the bank (interview, 2020).

This initiative, which they called the Debt Research Group, was not a complete sequence of ascension to the concrete as described by Engeström and colleagues (2012) and did not yet model a new concept or germ cell. However, after the debt analysis villagers realized they needed to find a way of "creating savings within the village" (interview, 2020). The questioning and analysis conducted during this intravention led to the first model of a plausible solution that same year (2540/1997), an intravention they called the Honesty Savings Group.

The village council decided to mandate participation in the Honesty Savings Group, with 40 families each contributing 30 baht/month (~1 USD/month in 2021 rates) to a collective fund that was then used to make payments on the most urgent loans (like that described by Martin, Goldman & Jiménez, 2009). It was here that the first iteration of the idea of "keeping money in the village" appeared: villagers engaged in **modeling** the new idea, or germ cell, which provided the beginnings of a plausible solution to their financial problems—saving money, paying off debt and working collectively. They **reflected** and **evaluated** their work looking for possibilities to expand it: "we learned from creating the savings group. When we took out loans, the interest was high. So, we said to each other, let's stop getting loans from the bank. Let's use our own savings for the loans" (interview, 2020). In other words, villagers began to conceptualize the need to save money, pay off debt (even a little), and not take out further loans to pay off earlier loans. Villagers' learning actions in these two initiatives set the stage for later work that evolved around the emergent germ cell "keeping it in the village".

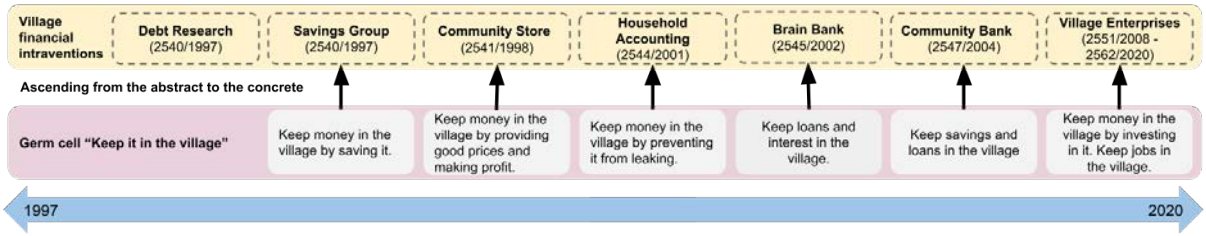
Generativity of the germ cell

The germ cell of "keeping it in the village" was core in the development of several more concrete financial initiatives that also helped to further refine the idea, leading to a cycle of generativity (see Figure 1) where the village went from saving money with the Honesty Savings Group, to keeping it from "leaking", to investing it.

In 2544/2001, villagers extended their research into the nature of their debt in the Household Accounting Program, shifting from a village-level analysis of how much debt existed to family-level analysis of how debt was created. Support came from a Thai foundation that invited a janitor from a nearby industrial plant to share how he kept track of his finances using a simple spreadsheet that laid out income and expenses. After formal discussion, including opposition from some villagers, the village council decided to make the Household Accounting Program mandatory. Small groups of 6 households, each with a leader (usually a woman) completed household spreadsheets and met monthly to share insights from their accounting and identify how their debt was created. The village decided to use the funding the foundation provided for snacks to pay each household leader (30 baht/month, ~1 USD in 2021 rates) for the effort of accounting, adding to the potential to save money. Thus, research on village debt evolved into research on family debt, which led to insights about over-expenditures that allowed for changes in family financial practices, namely, to keep money from "leaking" out and encourage saving within families. The Household Accounting Program was credited for many behavioral changes in people's lives. For example, one man, who had been contemplating suicide because he did not understand why his debt grew the more and harder he worked, learned through his analysis of daily expenses that instant coffee purchases were beyond his means; further, the more he worked, the more he spent on coffee packets (interview, 2017). Understanding his income and expenses helped him change his habits and decrease coffee consumption (*Ibid.*). Villagers shared many other stories of how the insights from accounting research helped change their spending habits. The Household Accounting Program provides the first example of how the germ cell "keeping it in the village" began to expand beyond its initial conception to include preventing money from "leaking out," made concrete through the new layers of self-research and changed family practices.

Figure 1

Visualization of the generativity of the germ cell and its development over time.



Other intraventions further developed the germ cell by creating a cooperative store and banking systems within the village that could keep profits, financial transactions, debt, interest, and savings in the village. The cooperative community store, opened in 2541/1998, provided reasonable prices for villagers, creating beneficial competition with the other stores in the village and allowing families to save more. At the same time a portion of revenue from the store went directly into village coffers, enabling the village itself to invest in community initiatives and infrastructure. Here, "keeping it in the village" included price competition and profits. A second intravention was the Brain Bank, a youth-led bank that issued loans to villagers. It started in 2545/2002 when children used savings from a fundraising event at an English language camp to provide a small loan to a cherished elder. In this bank individual villagers themselves chose what interest they could pay, including unusual forms such as providing expertise on raising crops or animals. Not all loans were paid back in a timely manner, leading to some difficult learning, but slowly profits built up. This was the first time that interest from loans (even in the form of animals or expertise) was kept in the village rather than paid to an outside financial institution. This success, along with a growing understanding of interest and loans, led to the later development of a Community Bank (2545/2004) in partnership with a commercial bank in the provincial capital. One villager reflected on how one initiative led to another and to the creation of the community bank:

> Every family had debt and paid interest. We never talked about it, villagers just paid whatever interest the outside banks calculated. We saw the data, and the bigger picture: we were really getting taken advantage of. We told the villagers that we were going to build our own bank. We created our dream. (interview, 2020)

Some villagers attended a year of classes to learn how to manage the bank. Now, villagers earned more interest on their savings, paid less interest on loans, and the village itself benefited from loan payments.

Other financial initiatives over the past 15 years focused on keeping money in the village by investing in small enterprises (see Figure 1). A younger generation of villagers, that were children and teens while the germ cell emerged, have recently started several enterprises including a rice paper plant, a dried mushroom factory, and a local tourism program. All the enterprises capitalize on the village's resources (leftover rice leaves, foraged mushrooms, native knowledge, and people) at the same time as they prioritize hiring and paying people from their village and others nearby communities, keeping money and jobs in the region.

The germ cell of "keeping it in the village" became so important that the village now teaches its children about savings and interest through a savings program in the primary school. All children entering the school get a savings spreadsheet to track how much money they save during primary school with interest calculated monthly. Every week children bring in allowance or earnings from small jobs like traditional dance performances at the village homestay. "It's become a tradition of saving, everyone has to bring their own cash to school, it's like creating a discipline and habit of saving for the kids," (interview, 2020) a teacher explained. Over the course of 7 years (K-6), some children even save enough to pay for secondary school expenses.

Generativity in other domains

Over the past two decades the germ cell, "keeping it in the village," has further developed as villagers implemented concrete intraventions beyond financial initiatives. After six years of work on debt and financial management (with parallel efforts in education and computers), the village sought to study (and then invest in) their *environment* as a source of income:

> After the research of 2544 [2001], we knew that our income mostly came from the forests and mountains. When we knew where the money came from, we became interested in the environment. It started after the research; the research told us to do so. (interview, 2020)

This led to the development of sustainable water and fire management intraventions (see Fields et al., under review) which extended the germ cell to literally keeping water in the village as well as protecting the natural resources the village had. Other intraventions extended the germ cell to keep *health* in the village by banning pesticides and herbicides and promoting organic farming. In more recent years, village leaders have recruited young people (pursuing education and careers in cities around Thailand) to return to the village. Young people have filled positions leading the savings and loans programs, managing the homestay program, teaching in the school, managing dam maintenance, and running fire prevention initiatives. The village is quite literally seeking to keep their *young people* in the village, embodied most fully in a young people's branch of the village council. Though space prevents us from exploring these examples in more depth, the germ cell which the village developed through iterative learning sequences of ascending to concrete change has become extremely generative in the multiple intraventions the village has conducted over more than two decades, beginning in the domain of finances but stretching to the environment, health, and urban/rural migration.

Discussion

In this paper, we documented how the germ cell "keeping it in the village" emerged through Ban Samkha's collective analysis of financial problems. Before their transformative series of intraventions, villagers struggled financially even when provided with outside support such as the early "village fund" program sponsored by the government. They did not understand their financial problems and their causes. Through iterative analysis and collective reflection, villagers developed the germ cell: a concept they could comprehend and apply across different initiatives. Indeed, the germ cell gave them the means to understand the underlying issues of their problems, organize and transform their reality over 24 years, becoming a "model village" in the country (Bruneau, 2009). Our analysis demonstrates that the germ cell played an important role in community-driven learning and formative interventions as members used it to communicate concepts in practice with each other as well as with outsiders, explaining and modeling plausible solutions to problem situations. Like the Brazilian community discussed by Sannino and colleagues (2016), intraventions in Ban Samkha and the development of the germ cell were not researcher-led, but community-driven, with support from outside organizations, resulting in multiple generative, practical, and transformative intraventions by the community for the community. Iteratively modeling the germ cell was key as villagers developed empowering abilities (Freire & Macedo, 1987) to study and understand their problems, think critically, and enact change. The community-driven learning and decades of work of Ban Samkha provides an alternative to the large (and often unsuccessful) efforts of other more top-down development initiatives that do not focus on local understanding and leadership.

While iteratively developing the germ cell "keeping it in the village", the villagers transformed the social and material settings of their community. They applied means of collective analysis and reflection, locally adapting methods (e.g., the philosophy of Thai Constructionism) and tools (e.g., spreadsheets, notational forms of household accounting, models of a community bank) that they learned from other people and organizations. One crucial element was the creation of village-wide policies that mandated that everyone participated in initiatives such as the Household Accounting Program or later banning all herbicides and pesticides from village farms. These tools and policies (mandated or otherwise) bring up the role of infrastructures in the village's work. Engeström and colleagues (2012) recognize the importance of infrastructure in ascending from the abstract to the concrete by calling for "further analysis of the roles and potentials of mediational artifacts in actions and activities" (p. 304). Elsewhere we have begun to explore the series of policies that the village established that supported collective change even if some members were resistant (Fields et al., under review). While it is beyond the scope of this paper to fully account for and explore the role of representational and social infrastructures (Ma & Hall, 2018) that supported the village's generative work, we note this as an area for further research. Studying how germ cells, or conceptual practices, evolve over long periods and how, in the process of ascending from the abstract to the concrete, learners transform representational and social infrastructures that can support the generativity of germ cells themselves, is important for better understanding and supporting community-led transformative change.

Our analysis complements studies that focus in more detail on the first years of germ cell development, providing insights into how a community can evolve, adapt, and iteratively apply a germ cell over time and in practice. The "it" of "keeping *it* in the village" came to mean not just leaked out money, but investments, interest, loans, expertise, water, environmental resources, and people. The longitudinal lens of the study (achieved in large part through the detailed record keeping and collective memory of the villagers) provides insights into the generativity of the germ cell and was essential in seeing its continued, iterative development.

Ban Samkha constitutes an existence proof of the power of emancipatory collective action (Gutierrez, & Jurow, 2016; Freire, 1973) in which communities solve complex problems by learning, collaborating, and getting to the bottom of long-established oppression schemes. By reading and writing the world with a new and expanding lens— keeping it in the village—they transformed the village and transformed themselves.

Conceptualizing Three Approaches for Integrating Criticality in K-12 Computing Education

Luis Morales-Navarro & Yasmin B. Kafai
University of Pennsylvania
luismn@upenn.edu & kafai@upenn.edu

Abstract: As several critical issues in computing such as algorithmic bias, discriminatory practices, techno-solutionism have become more visible, numerous approaches are being proposed to integrate criticality in K-12 computing education. Yet, how exactly these approaches address criticality and translate it into classroom practice is not clear. In this conceptual paper, we first historicize how current approaches in critical computing education draw on previous work which has promoted learner empowerment through critical analysis and production. We then identify three emergent framings: (1) inquiry, (2) design and (3) reimagination that build on and expand these critical traditions in todays' K-12 computing education. Finally, we discuss how these framings highlight issues to be addressed and provide directions for further learning sciences research and design.
Keywords: critical computing, computing education, literacies, empowerment, criticality

Introduction

As CS education has gained an unprecedented momentum, becoming part of the K-12 curriculum over the past ten years (Halvorson, 2020), several critical issues in computing as a discipline have become more visible: (1) algorithmic bias is pervasive and reinforcing historical inequities and damaging minoritized communities, (2) discrimination in industry against minoritized peoples in hiring and management practices continues, and (3) computing continues to be taught and learned as a value neutral subject (Gebru, 2020). Today we recognize that code is not neutral, computing technologies reflect the values and biases of their creators and computing alone is not the solution to all problems, it often perpetuates existing concerns, causes new problems or deepens existing ones (Costanza-Chock, 2020). In K-12 classrooms, computing is commonly introduced and experienced as a "value-neutral tool independent from society" (Ko et al., 2020, p.31) without considering its societal and ethical implications (Vakil, 2018). Yet learning computing with disciplinary authenticity requires attending to its critical and political dimensions (Philip & Sengupta, 2020).

More recently, efforts to foreground criticality in K-12 computing have addressed this lack of concern for societal and ethical implications and limitations of the discipline through numerous approaches, among them: justice-centered efforts (Vakil, 2018; Costanza-Chock, 2020; Lin, 2021), critical computational empowerment (Tissenbaum et al., 2017), critical computational literacy (Lee & Soep, 2016), critical computing literacy (Scharber et al., 2021), responsible computing (Mozilla, 2021), computational action (Tissenbaum et al., 2019), critical algorithmic literacy (Dasgupta & Hill, 2021) abolitionist computing (Jones & araujo melo, 2021), computational empowerment (Iversen et al., 2018), and counter-hegemonic computing (Eglash et al., 2021). While this proliferation of proposals highlights the growing importance given to critical issues in computing education, it is unclear what each approach means by criticality in computing, who is participating in these efforts, and how students and teachers are engaged in critical computing activities.

In this conceptual paper, we take a step back from individual approaches by identifying their historical roots in human computer interaction (HCI) and in language arts and literacy (LAL) studies and how these perspectives foreshadowed today's critical computing education (CCE) efforts. We then identify and describe how three emergent framings— (1) inquiry, (2) design, and (3) reimagination— address criticality in K-12 computing education. Finally, we discuss how these framings highlight issues to be addressed and provide directions for future learning sciences research and design.

Historicizing criticality

Recent calls for considering the political dimensions of learning sciences in design and research (see Booker et al., 2020; Philip et al., 2017) have been followed by efforts in critical science literacy (Ryu et al., 2020), critical history and social studies (Jackson, 2020; Hostetler et al., 2018), critical data literacies (Irgens et al., 2020; Stornaiuolo, 2020), and also in computer science education (Ko et al., 2020; Kafai & Proctor, 2021). Yet critical perspectives in computing and how computing is learned and taught have been present from the early days. For instance, Weizenbaum (1976) argued that the technical innovation of computers did not necessarily promote social progress. Most importantly, he distinguished the differences in human and machine decision making, noting that

 © ISLS

computers lacked compassion in their calculations. From the education side, Papert (1987) pointed towards the fallacy of seeing the computer (or software program) as the agent of change in student learning, considering people and culture as the driving forces of learning. Discussions in computing and education about criticality have developed in HCI around the Aarhus conferences community (Bertelsen et al., 2005) and in the new literacies movement around the New London meetings (New London Group, 1996). These two perspectives combined can be helpful to situate current efforts in CCE and better understand the development of different pedagogical approaches.

Many learning science researchers are familiar with work from language arts and literacy (LAL) studies where critical literacies are seen as ways of being and doing through which learners participate in the world. Central here is Freire's work on critical consciousness and literacy. Freire (1970) proposed an emancipatory model of literacy based on a dialectical relationship between the human beings and the world, where literacy is not seen as a collection of skills but rather a precondition for freedom, participation in the world and social empowerment within a wider project of social and political reconstruction. These ideas were further developed in the New London Group meetings where the multimodality of literacies and pedagogy were considered to propose that literacies must have a critical framing for learners to grow in their practice while consciously engaging with historical, social, and political contexts (see Cope & Kalantzis, 2000). Today, critical literacies bring together ideas from marxist, queer, feminist, postcolonial, and critical race theories to inquire on the dymanics of power present in the world and the learning process. In a recent review, Vasquez and colleagues (2019) argue that such a framework does not always involve taking a negative stance, but rather looking at issues from different perspectives, analyzing, suggesting and creating possibilities for change and improvement. The vast literature in critical literacies can be helpful in bringing CCE to K-12 classrooms. In fact, thinking about computing by applying frameworks from literacies is not new. The relationship between reading and writing code as extensions of literacies has been extensively discussed (see DiSessa, 2001; Vee, 2017) by emphasizing how learning computing is necessary to fully participate in the world.

Lesser known is that in HCI the term "critical computing" has a long history that dates to 1975 when the first Aarhus conference convened to discuss the development of computing systems in context. These conversations at Aarhus emerged through dialogues on how computing could support workers with a particular interest in marxist approaches for understanding the design and use of technology in relation to class and power struggles (Nygaard, 1992). Over time, these discussions have evolved, expanding critical computing to "critical action, not only as workplace actionism, but also by integrating a broader scope of critical analysis and critical practice" (p. 3)—grounded in political, economic, and aesthetic theories—in how computing systems are designed and used in the workplace, education, and at home (Bertelsen et al., 2005). The contributions of the Aarhus community and their perspectives on computing challenge many of the everyday practices of computing professionals and the ways we introduce learners to the field. For instance, within the Aarhus community, Burstall (1992) reflected that computing education that prioritizes technical concepts at the expense of critical awareness of other people and the environment loses the ability to accomplish the goals of the field.

Empowerment

Even though these critical perspectives in computing and education are products of different communities, contexts, and conversations, taken together they provide useful underpinnings for CCE. Indeed, the agency of learners, and the analysis as well as production of texts and code have been conceptualized as foundations for critical engagement in both traditions. To begin with, both HCI and LAL emphasize the need for empowerment or agency of learners. For instance, in Freire and Macedo's (1987) emancipatory model of literacy, literacy is a precondition for empowerment and participation in the world. Recently, critical literacies have been framed as a way of being and doing (Pandya & Ávila, 2014), extending literacies beyond an orientation for teaching and learning. This with the goal that learners can analyze and interrogate the micro features of texts and their macro—institutional, political, societal—conditions while focusing on how relations of power work, design and produce texts beyond classroom assignments (Vasquez et. al., 2019). The goal of literacy here is also one of empowerment, for learners to critically engage with the world to design social futures (New London Group, 1996). From the HCI perspective, Aarhus' "critical computing" proposes that computing is a process of reality construction and transformation of the world (Floyd, 1992). This opens possibilities to reframe the development of computing applications from designing for requirements to designing for the opportunities of creating better, more just, and equitable worlds (Floyd, 2002). In this sense, novice learners must be empowered to use their curiosity and creativity to critically interrogate the history, implications and limitations of computing and create for the possibility of more equitable futures. How do these perspectives envision to promote agency or empowerment of learners? Two approaches stand out: one being reading or analysis, the other being writing or production of "texts" or "code".

Analysis

In both LAL and HCI analysis plays an important role in critical empowerment. For instance, in literacies, critical reading engages learners in reading beyond the words of the page. Indeed, for Freire "reading the world precedes reading the word" (Freire & Macedo, 1987) as learners can use critical literacy to make sense of their reality. Critical reading involves deconstructing texts (e.g., media, discourse, technologies) to question how these are constructed (Vasquez et al., 2019). This kind of reading generates opportunities for "unpacking myths and distortions and building new ways of knowing and acting upon the world" (Luke, 2014, p. 22) by consciously investigating relationships of power, ideologies, and values in the process of reading (New London Group, 1996). As learners critique texts, they deconstruct and reconstruct them creating opportunities to disrupt, examine and sometimes dismantle problematic practices as well as to imagine alternatives, hypothesize how to change things and even take action (Vasquez et al., 2019). Similarly, in the Aarhus community technological criticism also plays an important role for understanding the impact of computing and how computers are used. Indeed, here reflection on the unconscious values embedded in computing applications and practices is central as well as investigating the ways in which technologies perpetuate oppression (Sengers et al., 2005).

Production

To promote agency, writing or production are important. The New London Group (1996), in reframing literacy studies, foregrounds the key role of designing new texts and redesigning existing texts for learners to participate in designing the future. This process of production requires that learners understand the positions from which they design so that they too read their own creations critically. This perspective resonates with Freire's (1985) idea that "reading the word is not only preceded by reading the world, but also by a certain form of writing it or rewriting" (p. 18). In this context, critical literacies are not only critical reading but also critical writing where writing means designing and redesigning texts in ways that aspire towards justice and can be socially transformative. Likewise, Christiane Floyd (2005), who played a key role in shaping the critical computing agenda within the Aarhus conferences, argues that in critical computing, understanding the impact of computing and how computers are used is not enough. She claims that critical computing is intertwined with the development of computing applications and the goal that these applications should have a positive impact in society. Furthermore, Floyd argues that there is a difference between being critical in computing and being critical on computing. Being critical in computing is concerned with design and production of critical computing applications. This is distinct from being critical on computing, which centers technological criticism over the design of applications that can address critical issues. Critical computing involves considering that in producing computing applications social and technical factors are intertwined (Andelfinger, 2002). From this perspective the idea of computer programming must be widened to take the social context of software and its development into account (Nygaard 1986). Programming is framed as the means for non-technical ends or goals (Andelfinger, 2002) which require investigating how the decisions taken when coding have social and environmental implications (Nygaard, 1992).

Integrating criticality in K-12 computing education

Reviewing the historical roots of criticality in both computing and education provides a backdrop to examine how current research promotes CCE. From this review of HCI and LAL it emerges that CCE must empower learners to critically analyze computing, examine power and values, and interrogate the implications and limitations of computing applications. Likewise, CCE should include creating computing applications that aspire towards justice and that reflectively consider the limitations and implications of computing for people and the environment. In this section, we propose that out of these two traditions, three different pedagogical operationalizations or framings CCE emerge: (1) critical inquiry, (2) critical design, and (3) critical reimagination. Each of these approaches promotes the empowerment of learners through critique (reading), production (writing), or combinations thereof.

Critical Inquiry

One approach to CCE, which we call "critical inquiry" involves students inquiring on the implications of computing. Here Lin (2021) argues that affordance analysis can be used in computing education to examine how algorithms and abstractions such as data structures have political implications. For instance, the use of binary trees in hiring decisions, autocomplete for search engines, and shortest paths for navigation can have problematic unintended consequences that reproduce systemic injustice. According to Lin, comparative analysis of data structures and algorithms can enable students to critique the dominant approaches that address social good without design justice and problematize power in computing. Having students be critical on computing in the same courses where they are learning technical concepts and skills can situate conversations and applications of technical concepts in their social context. Other initiatives have addressed how in computing inequities are not just

reproduced but amplified in new ways. For instance, in a design experiment conducted by Vakil (Irgens et al., 2020), students examined surveillance technologies in their communities and created infographics to explain the implications of these technologies. Through this experience students explored the ethical tensions of how the surveillance technologies they use in their everyday lives reproduce practices that disproportionately target and impact minoritized communities.

The "critical inquiry" approach centers on critique—that is looking at issues from multiple perspectives, analyzing dynamics of power, and suggesting possibilities for change (Vasquez et al., 2019), drawing on the tradition of LAL. This approach can be productive when integrated across introductory computing curricula in order to have learners consider how the decisions made while programming have social and environmental implications. That way as novices learn technical concepts and programming skills these can be grounded in critical socio-technical conversations on computing (Nygaard, 1992). When engaging in critique, learning activities can connect to the lived experiences of students, like in Vakil's experiment, by having them investigate the implications and limitations of the technologies they use. Critique can be empowering, giving students the rightful presence—that is legitimized membership and participation, where the community works towards justice by making injustice and social change visible (Calabrese Barton & Tan, 2019)—to interrogate systems of oppression and question what computing is and how computing is enacted in the world. At the same time, learners can have agency to decide what issues they want to investigate. Yet CCE has the potential to go beyond inquiry by engaging learners in the production of critical computing applications.

Critical Design

A second approach to CCE, which we call "critical design", centers on designing and redesigning with computing in ways that aspire towards justice and change. In this approach learners critically design applications that address the needs of communities. For instance, Lee and Soep (2016) argue that when young people design applications to address their own community problems, they create opportunities for themselves and their communities, and that "only through production of these digital tools will youth develop the agency required to make the changes they want to see" (p. 481). Through their experiences at Youth Radio, they have documented how youth create mobile and web applications for their communities, including, for example, an app called "Know Your Queer Rights" that provided resources to support LGBTQ+ youth (Soep et al., 2021) or an app to track and raise awareness of gentrification (Lee & Soep, 2016). Other approaches to critical design have students design for communities other than their own. Bar-El and Worsley (2021) discuss a course, centered around accessibility, designed to encourage students to explore computing as a field that promotes democratization by having learners design tools and activities to broaden participation in CS. In this intervention students were embedded in the spaces for which they designed and were in dialogue with community members. They argue that by creating real-life projects for real communities, learners can benefit from interrogating the history and assumptions of computing and its applications (Bar-El & Worsley, 2020). Overall, Tissenbaum and colleagues (2017) propose that empowerment comes from creating interventions in the real and physical world in which learners analyze the problems of their communities and create real solutions. For them, learners must have opportunities to create applications that have an impact on their communities from the moment they begin to learn how to code (Tissenbaum et al., 2019). This contrasts with common approaches to computing education that prioritize learning technical skills first and working on real-world applications later.

While engaging in critical design, learners have the opportunity to participate in critiquing and producing computing applications. Critical design aligns well with the ideas from the Aarhus conferences particularly seeing programming as a social activity where writing code is the means for non-technical ends or goals (Andelfinger, 2002). It also addresses coding, in a similar fashion to how critical literacies theorize writing, as the process in which learners design and redesign in ways that aspire towards justice while reading their own creations critically (Vasquez et al., 2019). Critical design is also an opportunity to design computing applications beyond requirements, thinking about the opportunities (Floyd, 2002) that computing gives creators and users to make more equitable worlds and to inquire into the sociopolitical values and purposes of making with computational technologies (Vossoughi et al., 2016). Furthermore, analyzing problems in their communities and designing computing applications to address these problems can support the development of learners' rightful presence, empowering students to be and do critical computing in authentic and meaningful ways. But empowering students also means giving them the creative power and freedom to pursue their own interests and projects. These design activities can connect to learner lives beyond deficit views of their experiences (Jones & araujo melo, 2021) recognizing how the cultural wealth of their communities can have a positive impact in the learning environment and the computing applications youth create. This requires thinking about cultural context beyond making superficial connections to computing concepts so that learners can participate in their culture while computing,

draw from their own culture and even remake it by investigating authentic problems and concerns they can engage with in their designs (Blikstein, 2008; Hooper, 2008).

Critical Reimagination

A third approach involves "critical reimagination"—rethinking the present and the past to critically reimagine computing and technology and create more equitable and just futures. Holbert and colleagues, for instance, created the 'Remixing Wakanda' project (2020) in which Black female youth used their personal stories to design speculative artifacts that address social and environmental injustice. Bringing together Afrofuturist and constructionist ideas participants imagined and created possible futures where their communities thrived and where technology helped create a more equitable and sustainable world. They reimagined how technology could be used proactively to improve their communities. They created speculative computing projects such as a cloak that expressed information about the health, wellness, mood and identity of its wearer or a trash can that converted waste into energy. Other efforts have focused on having students reimagine computing cultures that are equitable where female, Black and brown youth can fully participate. Efforts employing restorying (Shaw et al., 2021) build on Black feminist perspectives for youth to imagine and build the worlds and computing cultures they want to live and participate in. Shaw and colleagues (2021) describe how youth engaged in interrogating dominant narratives about CS and crafted computational artifacts that reimagined CS, its values, who can participate and how it is done.

Critical reimagination engages learners with the social and political reconstruction discussed by Giroux (1987) that requires critique, production, and empowerment. As bell hooks (1991) argues imagination is emancipatory because thinking of possible futures involves critical thinking, analysis, and reflection of the present as well as a desire to build better worlds. In this approach when learners engage in production, they design beyond requirements for the opportunity of creating better worlds. Learners address critical computing as emancipation (Dearden et al., 2005) and through their speculative computational artifacts transform the world by constructing and proposing new realities (Floyd, 1992). Here learners are empowered to reimagine what can be done with computing and what computing can be, having the rightful presence to question and rethink the discipline. Yet in critical reimagination activities it is important to provide space for student agency so that they develop their own voices while accomplishing their desired computational goals. Reimagination connects the past, present and future, understanding that technology is not created in a void but builds on previous traditions. With critical reimagination the future is not pre-established but rather learners engage in what Freire (1970) calls hopeful "revolutionary futurity," looking at the past to understand themselves and addressing how the present must change in order to imagine and build the future.

From our analysis, we see that some of these current efforts in CCE align with the three proposed framings while others engage with more than one. For instance, justice efforts (Lin, 2021) align with critical inquiry while critical computational empowerment (Tissenbaum et al., 2017), critical computational literacy (Lee & Soep, 2016) and computational action (Tissenbaum et al., 2019) prioritize critical design. Abolitionist computing (Jones & araujo melo, 2021), counter-hegemonic computing (Eglash et al., 2021), and restorying (Shaw et al., 2021) tend to align better with critical reimagination. Other justice-centered efforts (Vakil, 2018), responsible computing (Mozilla, 2021), critical computing literacy (Scharber et al., 2021), and critical algorithmic literacy (Dasgupta & Hill, 2021) engage both critical inquiry and design. Computational empowerment (Iversen et al., 2018) and justice-centered efforts such as Costanza-Chock's (2020) design justice address critical inquiry, action and reimagination.

Considerations for the Learning Sciences Design and Research

As the learning sciences turn their attention to the political and critical dimensions of learning (Philipps et al., 2017) so is K-12 computing education. By historicizing how criticality has been approached in computing and education we situate CCE in both fields. The three approaches we discussed as framings for learning and instruction emerged from our analysis of efforts to design and research criticality in computing.

In identifying the different directions criticality assumes in each of the framings, we also noticed several issues that require special attention in designing and researching learning tools, activities, and environments: (1) who is involved in addressing critical issues in computing, (2) how to avoid the pitfalls of techno-solutionism, (3) how learners engage creatively with criticality, and (4) how do we connect learning disciplinary skills and concepts with criticality. First, criticality in computing should be addressed by all. In reviewing the various efforts in critical inquiry, design and reimagination we noticed that these involved mostly students from racialized and minoritized communities. While this was probably done with the best intentions, to broaden participation, we

should also be aware that such efforts could put a double "burden" on learners of minoritized communities (Jones & araujo melo, 2021), first as those who predominantly experience marginalization and discrimination when using technologies and participating in computing, and then as those tasked to identify challenges, develop new solutions, fix problems, and reimagine alternate futures. This is important work, but it is essential that *all* learners are engaged in CCE.

Second, while having students create computing applications that address real world problems is beneficial, it is equally important to consider what already exists in the communities that learners engage with, encourage them to be critical towards their own work and avoid the pitfalls of techno-chauvinism and techno-solutionism—the beliefs that technology is always the solution (Costanza-Chock, 2020). Indeed, the critical design and reimagination approaches must acknowledge the limitations of computational solutions, questioning the possible implications of using computing to "fix the world."

Furthermore, we must consider how learners engage creatively with criticality. In inquiry, design and reimagination learners can connect to their personal interests and their lived experiences, to think, create and share their ideas with their peers. To do this, learners' agency must be authentic, giving space for students to decide what issues to investigate and what kind of artifacts they want to create. This with the goal that they can engage in what Freire (1970) calls the "creative transformation" of understanding, coding and participating in the world. Ultimately, while we want learners to "have the opportunity to experience the full conceptual and expressive powers of coding" (Resnick & Rusk, 2020, p. 121), we also see a need to connect criticality back to creativity and curiosity.

Finally, we should also consider how we join criticality with efforts for developing technical coding skills rather than seeing them as separate enterprises. We take note that efforts in CCE predominantly take place in out-of-school settings. This is partly because current curricular frameworks and standards are very much focused on teaching and learning of computational skills and concepts, often relegating criticality to the sidelines. Yet alternatives are possible. In Denmark, for instance, the national K-12 computing curriculum framework (Caspersen, 2022) inherited many of the ideas of the Aarhus conferences (Iversen et al., 2018) giving computational empowerment the same importance as computational thinking. Here empowerment is approached as the concern for learners to understand how computing affects their lives and society to creatively and critically participate in the construction of computing applications.

Conclusions

Our goal in this conceptual paper is not pit approaches against one another but to recognize that inquiry, design and reimagination are each valuable ways to create learning activities that can engage with criticality in K-12 computing research. Indeed, as Vakil and Higgs (2019) write, the goal is that learners "can understand, analyze, critique, and reimagine the technologies that shape everyday lives" (p.31). The approaches, in fact, offer partial but complimentary ways for addressing criticality. Inquiry focuses on understanding the underpinning of technologies and power structures. Design promotes understanding criticality while making computing applications, creating a relevant context for learning technical skills and concepts, and reimagination centers on rethinking the present and the past to critically reimagine computing for the future. We hope our proposed framings may serve as tools for learning scientists to further design, investigate, and harness their potential in driving disciplinary critical engagement not only in computing but also in other fields.

In conceptualizing the suggested operationalizations of CCE, we are reminded that being critical involves both understanding the role of computing in society and of society in computing (Kafai & Proctor, 2021). This requires not only discussing critical issues but deeply inquiring, designing, and reimagining how computing can be transformed to be more just and equitable and to positively impact the lives of communities. Ultimately, as we saw in our historization of CCE, the goal is to empower learners to fully participate in computing through critique and production. We hope that our conceptualization of three emerging operationalizations contributes to advance our understanding of criticality in learning sciences.

Using Synthetic Knowledge and Interaction Analysis to Investigate Learning in a Collaborative Digital Climate Learning Experience

Lynne M. Zummo, University of Utah, lynne.zummo@utah.edu
Eliana Massey, University of Utah, u1375812@utah.edu

Abstract: This paper presents a theoretical argument for investigating moment-to-moment learning processes around socio-scientific issues (SSIs), or complex, often ambiguous issues that intertwine science and society. It argues that prior theories of learning are not sufficient to explain learning that takes place through engagement with SSIs because of the characteristically modern nature of such issues. We argue that applying synthetic knowledge and interaction analysis can advance theory in this area. In particular, we pay close attention to the science learning that unfolds around SSIs, and we argue that designing effective science learning experiences around such issues first merits thorough investigation of moment-to-moment learning processes. We present empirical evidence from a study of a museum-based collaborative learning experience via a digital simulation about climate change to show the complexities of learning about SSIs and, in doing so, take initial steps towards advancing learning theory around SSIs.

Introduction

In a time of rapid climatic change, global pandemic, and social unrest catalyzed by these far-reaching socio-scientific issues (SSIs), the need for well-designed learning experiences about such issues is great. Places of science education, in particular, from K-12 classrooms to informal learning centers, are seeking to implement learning experiences about climate change, COVID-19, and other modern SSIs (e.g. Owens et al., 2017). However, while research in science education has examined instructional approaches for SSIs, few have investigated the moment-to-moment learning processes that take place as learners participate in such instructional experiences (Christodoulou et al., 2021). Yet, we argue that attention to these processes is critical when considering the design of new experiences. Furthermore, we argue that given the nature of characteristically modern SSIs like climate change, existing theories of learning fall short in explaining learning around them, particularly when considering *science* learning, because such issues create a novel intersection of science knowledge, identity, values, and risk assessment not previously accounted for with learning theory. Thus, this paper draws together multiple theories to argue for new research in this field. We then take a step towards advancing such theory through an empirical investigation of an experience in an informal science education center in which participants collaboratively engage in a digital climate simulation to learn about climate change.

Background: Learning through socio-scientific issues

Science education scholars have argued for instruction centered on socio-scientific issues (SSIs)—complex and often ambiguous issues that bridge science and society and demand moral consideration in addition to scientific reasoning (e.g. Sadler, 2009; Zeidler et al., 2005)—such as climate change and genetic engineering. Research has shown that SSI instruction can support science knowledge gains (Klosterman & Sadler, 2010), engagement in science practices, such as modeling (Ke et al., 2021), in concert with moral development (Fowler et al., 2009).

From this work have emerged important pedagogical models for SSIs, as well as cogent claims about the need to adapt science instruction to take up SSIs. Yet, missing is empirically grounded theory to explain the learning processes that occur when students engage with SSIs. Studies in the SSI genre tend to measure gains in knowledge and in other indicators of reasoning through pre- and post-instruction assessments (e.g., Romine et al., 2017). While this work has established clear ideas about what *can* change within learners through SSI instruction, there is little understanding of *how* that learning process unfolds (Christodoulou et al., 2021). What knowledge and resources students draw on and how various changes in context might influence learning trajectories remain largely unexamined; theory to explain the learning taking place within SSI-oriented learning experiences remain underdeveloped. This dearth of theory is particularly concerning given the nature of SSIs. They are not traditional science topics, around which an array of explanatory learning theories exists. Rather, SSIs often reflect "unfinished" contemporary science, or science in the making. Such issues are often touchpoints of controversy, eliciting strong emotional responses and triggering aspects of identity (e.g., Druckman & McGrath, 2019). Furthermore, recent worked has hinted at the complexity of SSI learning processes, showing that learning outcomes are influenced by much more than knowledge gains, and that other factors, such as cultural worldview can interact with knowledge gains in surprising ways (Author et al., 2021). Drawing on this idea, we argue that

 © ISLS

existing theory cannot adequately explain the complexity of learning involved when students confront SSIs. Thus, with this study, we offer an investigation into the moment-to-moment processes of learning involved when confronting these issues with the aim of advancing and deepening theory related to learning through SSIs.

However, this is not to say that no work progressing towards learning theory has been done. Walsh and Tsurusaki (2018) drew on sociocultural theories of identity to show how students' negotiation of their dissonant political and classroom identities influenced learning during an instructional unit on climate change over several weeks. Investigating on a much finer timescale, Philip and colleagues (2018) drew on theories of ideology and positioning to document how ideology, as made material through social interactions, influenced learning within one session of a university-level engineering class studying drone warfare. Taken together, these studies suggest that learning about SSIs is highly complex and involves a large number of likely intertwined variables, such as identity and ideology, more than perhaps can be captured through traditional knowledge assessments.

Theoretical Framework

To advance theories of learning around SSIs, we approach this study with a multifaceted theoretical framework. This framework aims to capture nuances of why learning of SSIs is likely inexplicable fully by current theories. Additionally, in illuminating the theoretical underpinnings with which we approach this study, the following framework guides the methodology and analysis presented here.

Modernity & risk

SSIs are complex and often ambiguous, holding different implications for diverse stakeholders (e.g. Sadler, 2009; Zeidler et al., 2019). Our argument adds that such issues are products of late modernity (Giddens, 1991), which is characterized by abstract knowledge systems typically inaccessible to most people. These abstract systems allow for the creation of territories of future possibilities, or in Giddens' words, the "colonization of the future" (p. 111). For example, transforming fossil fuels into the sorts of energy that power our homes, vehicles, and buildings relies on a complex network of abstract knowledge systems, from petroleum geology to electrical engineering. It is this very network of knowledge systems that then mediates our long-term creation of future possibilities. These systems and associated colonization of the future bring both heightened security and risk. Daily lives are relatively safe, compared to history, yet the risks that do exist are high consequence. For example, with reliable energy sources made possible through knowledge systems related to fossil fuels also comes potentially catastrophic shifts in climate. Such high consequence risks, and individuals' navigation of them, is intertwined with identity negotiation in the modern age, Giddens argued.

We argue for the development of new theories of learning around SSIs characteristic of late modernity, such as climate change. Climate change embodies the sort of high consequence risk inherent to colonizing the future, precipitated by decades of fossil fuel combustion in attempts to secure and stabilize daily life. Furthermore, like typical issues of late modernity, in Giddens' view, climate change is characterized by shifting knowledge claims from experts. Expert knowledge about modern issues is tenuous, as the issues themselves are emergent and fluid. Expert claims around such emergent issues and within related knowledge systems are often shifting and unstable. Therefore, connecting non-experts to such fluid and uncertain knowledge is inherently fraught. Recent sociopolitical history of climate change epitomizes this nature of modern knowledge, with persistent conflict around climate change within US news media (e.g. Bolin & Hamilton, 2018). Shifting claims from the scientific community (albeit some deliberately manufactured via funding from the fossil fuel industry, see Oreskes & Conway, 2011) have made public actions controversial and identity provoking.

The fluid nature of expert-produced scientific knowledge around climate change has real implications for the ways in which learners make sense of such an issue. How people draw on scientific knowledge and practices in conjunction with other resources when learning about climate change is likely not able to be captured by current theories of learning. Predictably, prior work on climate change education has shown that an often complex set of factors influence the learning process, including cultural worldview (Author et al., 2021), social norms (Busch et al., 2019), political identity (Walsh & Tsurusaki, 2018), in addition to science knowledge (Stevenson et al., 2014), with research only beginning to parse these influences. Investigating learning around climate change can provide new insight into how learners draw on science within characteristically modern issues.

Synthetic knowledge & interaction analysis

To understand learning, this study uses an approach that integrates theoretical underpinnings of both knowledge analysis (KA) and interaction analysis (IA), as called for by scholars in these previously disparate traditions (Brown et al., 2016). Undergirding KA is the theory of knowledge in pieces (KiP; diSessa, 1993), which suggests that individuals' knowledge systems are composed of various "pieces", also referred to as resources (Hammer, 2000), or knowledge elements that learners used to make sense of various situations and compose larger

knowledge systems. Knowledge pieces are highly dependent on context, activated by some contexts but not by others. The varied and dynamic nature of these elements leads to complex reasoning that can shift quickly moment-to-moment, as learners draw on a multitude of knowledge resources in sensemaking.

In parallel, undergirding IA are theories that emphasize the significance of the social space in the emergence of knowledge (e.g. Hall & Stevens, 2016). Various contexts created through the constantly shifting social space allow for certain ideas or pieces of knowledge to emerge. And, the emergence of various knowledge pieces and consequent responses to them influence the course of social interaction. Taking up ideas of scholars seeking to integrate KA and IA (e.g. Azevedo & Lee, 2016), this study recognizes the importance of an individual's knowledge resources (and, by extension, the influence of context on emergence of different elements) while also recognizing that the bounds of knowledge extend into the social space and the practices encountered socially. An individual is not a solitary being functioning on their own; rather, the contexts and social situations surrounding them influence their cognitive work. So, this study adopts the view that learners draw on knowledge elements in context-dependent ways within a learning experience, yet also that the social situation of that learner deeply influences that process.

Applied here, this theoretical view suggests that learning about characteristically modern SSIs will likely involve knowledge pieces traditionally seen as "scientific" about relevant science concepts (e.g. the greenhouse effect), as well as knowledge pieces about societal aspects of the particular issue. Furthermore, within the context of learning in a social space, various social positionings, practices, and resources will influence what knowledge elements emerge, are treated as valid, and consequently get taken up and use by others in a group.

Ideology

An ideology is a shared system of representation through which humans act, speak, and participate in the social and material world (Althusser, 1971; Hall, 1985). Such a system guides the assumptions that people use to make meaning; the ideology in place influences the meaning made from an experience. Ideology comes to have "material" existence through human action and speech; an ideology exists to the extent that it is inscribed in practices. Recent work in learning sciences has taken up ideology as a theoretical lens, demonstrating that the making material of ideology by students in classroom discourse influences learning that ensues (Philip et al., 2018). To understand ideology, this work has applied a KiP approach (diSessa, 1993), showing that naturalized axioms, or "pieces" of ideology emerge in context-dependent ways to influence learning (Philip, 2011). As with an integrated KA-IA views, context is critical to the emergence of such pieces—certain contexts make salient certain pieces of ideology, or naturalized axioms, while others do not.

Given the focus of this study on modern issues at the interface of science and society, we are particularly interested ideologies about the distribution of goods in society related to our colonization of the future, such as energy resources. We argue that these ideologies likely influence the meaning making that surrounds such goods, and, further, that this influence extends to the scientific meaning making scaffolded by particular learning opportunities around such issues. Prior research supports this argument, showing that the discourse students used for scientific sensemaking in a US science classroom was at the same time ideological and served in reproducing ideologies about the distribution of goods in society (Author, 2021; Author, in review). Thus, to this study, we bring a theoretical lens that integrates a KA-IA approach with notions of ideology to understand learning around characteristic modern, risk-laden issues. We argue that this novel approach can expand theories of learning to offer fuller explanatory accounts of the learning that takes place of characteristically modern SSIs.

Research questions

1. What knowledge, social, and ideological resources do learners draw on while participating in a climate change digital simulation learning experience?
2. What patterns exist among learners' drawing on of these resources?

Methods

Stemming from the theoretical commitments described above, this study employed methods from KA and IA (e.g. diSessa et al., 2016; Hall & Stevens, 2016) to understand moment-to-moment processes within a collaborative digital learning experience about climate change.

Context, participants, & data collection

Data were collected at a science museum affiliated with a large, public university in the US. Data collection occurred within one of the museum's galleries, where a digital climate simulation is installed. Visitors interact with this simulation in a partially closed room, with up to five visitors participating at once. Each player sits at a console with an individual touchscreen. One big screen is projected onto the wall in front of the players. The

projection shows the simulated city and the overall progress of the simulation, including when and where each player chooses to build or demolish something. The simulated city is made to resemble the local landscape of the museum, and its name references the region.

The simulation includes six rounds of 90 seconds each. During each round, each player is given four options for actions and can pick two actions to enact. Specific options are unique to each player and are randomized. Potential options include constructing various energy sources (e.g. coal plant, solar farm), agricultural sources (e.g. alfalfa farm, bison farm), or recreational opportunities (e.g. amusement park). Options could also include demolishing structures or installing geoengineering devices, such as artificial trees. At the end of each round, players are directed to look up at the projection to see how their city has changed. After each player's decisions are pointed out, the projection shows whether the group achieved a set of goals for the round, including goals for: 1) energy production, 2) food production, and 3) recreation opportunities ("fun produced"). Then, it shows how the group's actions affected the climate by using a bar indicator that ranges from 0 to 10, with 10 indicating extreme climate change. At the end of some rounds, depending on the degree to which the climate has changed, there are catastrophic natural disasters, such as drought, wildfire, dust storms, or sudden snowpack melt. As climate change increases, so does the likelihood of a disaster. When a disaster occurs, it destroys some structures built by the group, which then impacts energy and food production. After a group finishes playing, the simulated world does not automatically reset. Rather, the next group "inherits" the developed world, including the state of its climate. However, a group can choose to reset the world entirely at any point.
