The findings indicate the importance of design elements that promote *accessibility*, *purposeful engagements*, and *meaningful learning experiences* in which students and their families participated and provided contributions back to the classroom for disciplinary specific use. Through the analysis we learned that family engagement was an essential component to supporting diverse and robust science discussions within the classroom as well as enabling children to receive feedback and engage in scientific practices both within and outside of the classroom walls. In designing for family engagement three key findings emerged, 1) Ongoing, relevant, and bidirectional communication supports the inclusion of families into disciplinary specific content, 2) Designing for activities which extend on everyday family events such as neighborhood walks and playground visits supports accessibility and inclusion, 3) Family science symposiums were designed for communicating information, investigations, celebration, and inclusion into their child's academic endeavors. This design framework afforded students and their families the opportunities to take advantage of a series of learning engagements where they could make diverse, intellectual connections between their ideas, experiences and scientific concepts. Designing for family engagements is important to highlight as our field continues to understand how to support children more equitably from diverse communities in engaging in meaningful science learning within elementary science classrooms.

Paper 3: Opening up or closing down space for equitable sensemaking during disciplinary engagement

Soo-Yean Shim, Christina Krist

This paper explores conditions that led an experienced science teacher to make space for equitable science sensemaking. The call for shifting science education from students "knowing about" content toward students "figuring out" how/why the natural world works has emphasized the importance of providing students with opportunities to engage in epistemic practices of science and take active roles in constructing knowledge (NGSS Lead States, 2013; Schwarz et al., 2017). One of the expectations is that this can promote equitable sensemaking in science classrooms, as students can build on their own ideas, personal experiences, and diverse ways of making sense of the world in the knowledge-building processes. However, disciplinary practices in science classrooms do not guarantee equitable sensemaking opportunities for students, especially if students' everyday ideas and experiences do not obviously align with teachers' disciplinary expectations.

Framework and methods

We observed that an experienced teacher, who had passion and capacity to be responsive to students' ideas, sometimes opened up, but other times unintentionally closed down space for students' equitable sensemaking while facilitating their disciplinary engagement. We explore the conditions and contexts that led this teacher to open up space for students' ideas, experiences, and ways of thinking, especially when she tried to support students' disciplinary engagement. The teacher, Nadine, was a middle school science teacher who had 15 years of teaching experience and multiple years of experience designing and enacting NGSS-aligned curricula and instruction. Her school, located in the US Midwest, served a population of ethnically and socioeconomically diverse students. We used data from point-of-view observations (Sherin et al., 2011) with Nadine over two instructional units. Nadine wore a GoPro camera and tagged moments while teaching in which she was making a decision in the moment about whether and how to pursue student ideas. Nadine was interviewed immediately after teaching to reflect on

 © ISLS

those moments. We identified episodes of equitable sensemaking—where students' everyday ideas and experiences were substantively taken up as part of the classroom community's disciplinary engagement—and qualitatively identified conditions (e.g., context of the lesson, what prompted Nadine's decision-making) that led Nadine to open up or close down space for equitable sensemaking. Due to space constraints, we present one such episode.

Findings

Episode: Pressing for mechanistic reasoning.

This episode occurred during a class discussion to design an experiment to investigate what yeast (as a model single-celled organism) needs to grow and reproduce. The curriculum materials explicitly noted that students would likely already know that water and salt are not "food" (carbohydrates, proteins, or fats), based on their learning in previous years. However, when Nadine asked her students to suggest what they thought yeast would need to reproduce, many of them said water. (Later, some students also said salt, but here, we focus on the class discussion about water.) In response, Nadine said, "So you're saying water," and students immediately responded with ideas and everyday experiences: "Because we need, that's why we drink a lot of water," "People die when they don't drink water for three days," "Our body has a lot of water." Instead of correcting students by saying that water is not food, Nadine decided to approach this by pressing for students' mechanistic reasoning about the role of water. She asked students what cells and water were made of, and students said, "molecules" and "atoms." This connection appeared to prompt an "a-ha" moment for many students. It reminded one student of her experience making bread and putting yeast in water as part of this process, which she shared eagerly ("Oh, that's why you put in like, the bread, the dough stuff, when you put in water, it goes up!"). Through discussion, the class co-constructed three mechanistic arguments specific to yeast: that 1) yeast makes gas through chemical reaction when it meets water, 2) yeast absorbs water like a sponge, and 3) the bread rising is evidence of the reproduction of yeast. The first two arguments in particular were mainly led by students, as they actively built on their personal experiences (e.g., "It *[the gas]* caught up in fresh bread, then all the steam comes out."). Importantly, this conversation also led to students' request to include an experimental condition that included yeast + water alone (in addition to yeast + sugar + water and yeast + salt + water).

Two conditions that led Nadine to make space.

In this episode, Nadine decided to make space for students' mechanistic reasoning, instead of foregrounding the authority of "canonical scientific knowledge" about what counts as food. This decision was a diversion from the curriculum, and based on her interview, was prompted by two major conditions. First, Nadine saw that students were highly engaged with the idea that yeast would need water for growth and reproduction based on their personal experiences. She said: "I felt pushed to change it *[spend more time on the discussion about water]*, because of the class's needs. They *[students]* were really set on water." Second, Nadine herself was not satisfied with the declarative knowledge that "water/salt is not food," and is therefore irrelevant to cell growth, as evidenced by own scientific wonderings during the interview: "And then I was thinking, 'Ok, well, water's made of molecules. If we go down that path of molecules, yeah, water molecules.' So, I asked that, and... oh, the salt, too. That was interesting, they were like, "Yeah, we need salt." ... Do I need to worry about kids figuring out that salt is not food? No, they can easily look at the food label. ... But then, sometimes, I'm tempted in my head to think, 'Well, it must just have something to do with how our body functions. We must need it.'" Here we see Nadine recognizing that students' intuition—that water is necessary for cell growth and reproduction—was not unreasonable, despite its contradiction with the information in the curriculum materials.

Implications

We argue that this space for expansive sensemaking provided students with richer opportunities for multifaceted disciplinary engagement than had she continued to press for "correct" knowledge. At the same time, these rich opportunities rest in the familiar tension between canonical correctness and responsive teaching. These tensions can oftentimes lead teachers to position disciplinary practices as *in opposition to* students' everyday reasoning and intuition: they are used to push back upon, diminish, redirect, or oppose students' everyday ideas. Instead, we saw Nadine use students' everyday ideas as the substance upon which disciplinary practices were deployed. First, Nadine's own continued sensemaking about water during her interview suggests that she recognized how students' everyday ideas were asking for a ***more complex accounting*** of what cells need to grow, rather than a misconceived one. Second, Nadine's continual presses for mechanisms in students' reasoning reflects her recognition of the ***disciplinary legitimacy of mechanistic reasoning*** as important scientific work in and of itself. Finally, we propose

that the fact that their reasoning about water could be ***empirically tested right away*** through the class experiment attenuated any worries about students eventually figuring out the scientifically correct explanation.

Paper 4: "We need to step it up—we are basically the future": Latinx young women doing chemistry

Jasmine Nation, Hosun Kang

This study explores three Mexican American girls' experiences mediated by a 10th grade chemistry curriculum co-designed by researchers and teachers in a long-term research-practice partnership. We show how the curricula and teacher's facilitation expanded students' opportunities to contribute in collective sense-making in a classroom community. Additionally, we uncover how these students constructed stories about themselves and science based on their interactions with peers and the teacher. The research questions that guide the analysis are: 1) In what ways did the Mexican American girls draw from their everyday experiences and ideas in relation to the focal phenomenon in high school chemistry? 2) How were their everyday experiences and ideas taken up and incorporated into the classroom learning context? 3) How were these students positioned by others in the classroom, and how did they position themselves in relation to science?

Framework

We draw upon the notion of 'figured world', a socially and culturally constructed space, that outlines what it means to participate, local definitions of science, and who is considered a science person (Calabrese Barton et al., 2012; Holland et al., 1998). Our analysis is rooted in classroom social encounters since relationships with others shaped learning opportunities, experiences, and perceptions of self for the three girls: Natalie, Juliana, and Briseida. Tuning into interactions helped us consider what experiences and types of knowledge ("history-in-person") were brought to the learning context, and how discourse was shaped by many factors beyond any individual.

Methods

This study employed qualitative case study methods (Merriam, 2009) and narrative analysis (Clandinin et al., 2007), to examine: (a) class session videos, (b) student artifacts (worksheets, models, assessments), student surveys, (c) interviews with the teacher about focal students, and (d) exit interviews with students. We analyzed each class session four times, approaching the video from four lenses (figured worlds of individual, small group, whole group, and intersection of storylines). We created event logs for each class, a unit event map, and interaction logs for each case student, recording every comment or question and whether the teacher or peers ignored, rejected, teased, or validated their experiences and ways of communicating. When we traced individual discourse over time, we paid attention to the interaction between the individual and collective storyline such as when a peer built on their ideas or their discourse shifted the focus of the class discussion.

Findings and Implications

Our analysis revealed how diverse modes of participation and opportunities to leverage cultural ways of being created **porous boundaries between everyday science and chemistry class.** We documented students drawing from *connections to loved ones; previous class knowledge; personal interests; local geographical and climate knowledge;* and *core values* such as climate activism. Additionally, the diverse activities including sharing stories, drawing models, and creating a PSA facilitated self-expression through *sense of humor, imagination/creativity,* and *home languages and informal discourses.* We also found the **students' discourse was taken up and incorporated in three consequential ways:** *1) epistemological recognition 2) cumulative contribution 3) across figured worlds (classroom and beyond)*.

Recognition within the rich disciplinary context, or epistemological recognition, was key to how students' ideas were incorporated into the class storyline. Rather than a general "thanks for sharing" or "great job", experiences were validated for their connection to the science content and how they propelled their unit forward in terms of answering the overall question of "Why are wildfires worse now than 100 years ago?" Contributions also occurred across time, creating a cumulative effect. The teacher referenced students' ideas from previous classes or other small groups, making connections and building out understanding. All three girls made connections based on their "history-in-person" that were sustained across multiple classes. These relevant experiences were almost always shared in their small group first, expanded by peers' ideas, and then presented in front of the whole class, where the teacher provided public validation and connected to previous content. The explanations articulated the importance of these ideas for all students and positioned students as authentic

 © ISLS

contributors through altering the direction or propelling the collective storyline forward. Opportunities to move between the figured worlds of the classroom (i.e. small group to whole class) were essential to formulating and refining complex ideas, and ultimately helped the girls develop agency in science.

Despite starting with different interests in and academic records in science, they all showed meaningful engagement with science and reported the unit as their favorite. Juliana, who was a "high achiever" in conventional science classrooms and expressed confidence in her science abilities, initially appeared uncomfortable with the format of this chemistry class. She did not participate much in either small group or whole class discussions until midway through the unit. In contrast, Natalie and Briseida, who had struggled more with previous science classes, immediately shared their fire stories and models with the whole group and continued to show high involvement throughout the unit based on the opportunities to integrate everyday science. Natalie leveraged her rich experiences from out-of-school science activities and childhood fascination with weather, while Briseida built new connections and interests and a commitment to "step it up" because "we have to-we are basically the future, you know...I think it really impacts me because it has to tell us that we have to step up and make a change to make our place better."

This work provides both practical and theoretical implications on how to support diverse Latinx students in high school science, through equitable enactment of the NGSS and recommendations for educators and policymakers (Cantu, 2012). Specifically, this study expands the knowledge base of culturally relevant pedagogy by articulating two critical dimensions—consequential ways of leveraging students' everyday experiences and recognizing their epistemological contributions. We advocate for more focus on how students leverage their cultural resources and on how teachers facilitate agentic collaborative sensemaking in science.

Abstract: What are pathways toward critical and just data literacies? Achieving critical and just data literacies is especially challenging in an ideologically polarizing "post-truth" world in which we confront a rising tide of misinformation and fake news, alongside discourse that denigrates politically conservative perspectives. Although reasoning with data is rooted in epistemic processes, the stances people take are—and should be—influenced by values, concerns about maintaining cultural group membership, and concerns about equity and justice.

 © ISLS

Through a range of approaches, contexts, and age groups, the papers seek to illuminate how to help learners become adept at employing data interpretation conventions, scrutinizing the reliability of data representations, and examining whether data representations render humans and more-than-humans visible or invisible, central, peripheral, unidimensional, or complex. Jointly, the papers examine how to cultivate publics who make use of consequential data representations to negotiate their everyday lives, and who identify and resist datafied injustice.

Keywords: data science education, data literacies, justice, epistemology, axiology, post-truth

Overview and significance

An increasing number of education scholars and practitioners are concerned with how we cope with the rising tide of misinformation (O'Connor & Weatherall, 2019) and fake news in our ideologically polarizing, "post-truth" world (e.g., Barzilai & Chinn, 2020; Kienhues et al., 2020; Lewandowsky et al., 2017; Tabak, 2020; Zummo, 2021). Efforts to address these challenges typically involve focus on epistemic issues and reasoning (Chinn et al. 2020a, 2020b; Kienhues et al., 2020; Sharon & Baram-Tsabari, 2020). Research in this vein often considers the effects of ideological group membership and identity, emphasizing the power of co-construction (Feinstein & Waddington, 2020), or the overshadowing of evidence (Jost et al., 2018). A growing body of research and development, including two sessions from ICLS 2020 that were cancelled due to the COVID-19 pandemic (Arastoopour Irgens et al., 2020; Matuk et al., 2020), focuses on the role that *critical data literacies* can play in creating not only more educated publics, but also a more just world (see also Hardy et al., 2020; Van Wart et al., 2020; Zummo et al., 2021). In this session, we propose examining *how people integrate data, and uses of data, in their reasoning about ideologically-tinged "post-truth" debates, and the stances and positions they take across the lifespan*. Although such reasoning is rooted in epistemic processes, the stances people take are—and should be—influenced by values, concerns about maintaining cultural group membership, and concerns about equity and justice (Arastoopour Irgens et al., 2020; Polman et al., 2020; Walsh & Tsurusaki, 2018).

In this session, we seek to heed the call by Lee, Wilkerson and Lanouette (2021) for a humanistic stance toward data science education. We seek to recognize that multiple ways of knowing and being should ethically be supported. This involves recognizing the problems of Western science's epistemic colonialism while also recognizing its potential; additionally, this involves seeking to avoid the traps of relativism. We therefore aim to recognize the role of power and politics, amid the severe and pressing social and ecological crises and injustices of our times, in which the histories, identities, and flourishing of certain humans and most more-than-humans (1) are marginalized, erased, and eradicated. At the same time, we recognize educational rhetoric focusing on "fake news" and misinformation often ends up denigrating politically conservative perspectives and those who hold them, creating dichotomies and increasing divisions without paving realistic ways forward. Therefore, we seek to answer the question: what are pathways toward critical and just data literacies?

All 9 posters share the grounding assumption that data representations are not simple or direct snapshots of states in the world, rather they are constituted by and they constitute ways of seeing and being in the world. This bi-directional process occurs through narrations of the data (Radinsky, 2020), an explicit or implicit theme in all of the posters. All posters also reflect a commitment to cultivating publics that feel able and entitled to engage in such interpretive processes, and that resist taking data representations at face value, investing instead in deliberative and critical processes (Tabak, 2020). Poster abstracts are listed below alphabetically by first author and referred to here by numbers in this sequence. Some of the posters, especially posters 2, 3, 5, 6, and 9 emphasize epistemic aspects: such as, what are conventions and means for reliable measurement and interpretation, how can alignment and misalignment with such conventions be discerned and assessed in consequential data representations. Some of the posters, especially posters 1, 4, 7, 8, and 9 emphasize axiomatic aspects, such as, how do data representations render humans and more-than-humans visible or invisible, central, peripheral, unidimensional, or complex; and how do representations serve or undermine justice. As a set, the posters integrate these aspects in considering what conventions should be adopted or taught, who should decide, and how can we productively balance conformity with contestation? By building on these shared assumptions and concerns but addressing a range of topics, disciplines, contexts and age groups, the session has potential to inform and appeal to a broad audience.

We propose a 90-minute structured poster session. The session will open with a brief introduction, followed by highlights of each of the posters to orient the audience to the full set. There will be two rounds of free-form time during which the audience can engage with the different posters; in each round, only half of the poster-presenters will be at their posters, to allow presenters to engage with each others' posters as well. The session will conclude with two discussants, both with extensive research experience related to the ideas in the session— one discussant, Clark Chinn, will emphasize epistemic aspects, and another discussant, Thomas Philip,

will emphasize axiomatic aspects. There will be ample opportunity for audience active participation during the free-form segments, and following the commentaries.

1. "School. School. School. Home alone." Promoting students' critical media and data literacy through critique and design of narratives about teen time use.

Anna Amato, Megan Silander, Camillia Matuk, Jill Beale, Kayla DesPortes, Marian Tes, Ralph Vacca, and Peter J. Woods

Youth are often subjects, not producers of public data, which, as a result, can misrepresent their lived experiences (e.g., Lahusen & Kiess, 2020). How can ELA-integrated approaches to data literacy engage students in (1) identifying issues of youth representation in data and (2) in thinking critically about how data are produced and used (Gebre, 2018)? We collaborated with four urban public school teachers to design and implement an 8-day interdisciplinary unit investigating time use. Grade 7 students (N~80) examined arguments from news articles, documentary photography, social media, and the American Time Use Survey, and made inferences about how the (un)availability of time use data impacts representations of youth. Students then collected and analyzed data on their own time use. Qualitative analysis of participant interviews and artifacts showed how students reasoned about data and context, such as by reflecting on the impact of socioeconomic status and location on time use, making comparisons, and asking questions ("one kid might spend their time on the phone, another harvesting crop. Is one more valuable than the other?"). Students reasoned about the value of different data types for communicating meaning ("how would this [photographic] data look different if you presented it as numbers?"). They discussed sampling decisions and representation ("If we want a true and complete representation we would need more pictures"). They designed ways to sample their time use ("We can take photos of a teenager's day every hour and it can tell us a day in the life of a teenager."), attending to who produces data ("photos that teens take themselves") and to describing data patterns ("School.School.School.Home alone"). Findings suggest that integrated ELA-math instruction can expand students' ideas about data, support their critical reflection on data, and help them to generate ideas for representing their own experiences through data.

2. High School Students' Conceptions of Climate Change and COVID-19 Data Presented in Infographics

Daniel R. Pimentel, Emily Reigh, Victor R. Lee, and Bryan A. Brown

Recent concerns about science misinformation (e.g., Barzilai & Chinn, 2020) and the increased use of data infographics in media sources (Polman & Gebre, 2015) indicate a need to understand how young people conceptualize and reason about data presented to them as evidence. Drawing upon Hammer and colleagues' (2005) notion of epistemological frames and conceptual resources, our exploratory study examined the questions: 1) What epistemological frames are involved when students are asked to interpret and critique data from infographics about socioscientific issues? and 2) What conceptual resources do students use to engage in interpretation and critiquing tasks?

We conducted and recorded a think-aloud protocol using videoconferencing software. We observed 15 high school students while they interpreted and critiqued data in four different infographics; two about climate change and two about COVID vaccines. We then engaged in knowledge analysis (diSessa, Sherin, & Levin, 2015) to identify the frames and resources that students used to make sense of the data in each of these tasks. We illustrate that during interpretation tasks, most students primarily viewed data from a *representational* frame, positioning data as fixed and context-independent. When asked to critique, students tended to use a *relational* frame, viewing data as context-dependent and constructed (Leonelli, 2015). We argue that distinct resource sets and partial overlaps in conceptual resources determine whether students see the data represented in the infographics as authoritative or subject to critique. For instance, depending on the frame, students might treat data as correct and self-evident or as subject to error and personal bias. Further research should investigate how these frames might support critical data literacy practices.

3. Establishing trust relationships as a component of critical and just data literacies

Ilana Dubovi, Josh Radinsky, and Iris Tabak

We integrate findings from two studies examining how agency in everyday data practices is evinced not only through numeracy but through interpersonal experiences (Feinstein & Waddington, 2020; Tsatsou, 2018), mediated by trust relationships. These relationships can mitigate barriers to "the emancipatory process of

understanding and critically engaging with one's context" in a datafied society (Jansen, 2021). In highlighting trust as a target for research, we respond to calls for humanistic and relational approaches to data science literacy (Lee et al., 2021; Wilkerson & Polman, 2020).

Both studies focused on COVID19 information practices. One study surveyed 500 diverse (SES, education) Israeli adults; the other interviewed 6 adults (4 Israeli) about their data practices. STEM and social sciences [STEM+] survey participants were more likely than arts and humanities [AH] to reason with data about functional questions (e.g., should schools reopen). Trust (in science) was a significant contributing factor.

Similarly, STEM+ interviewees were versed in epistemic practices for approaching data with an air of "bending the representations to their inquiry will." Despite "following the lead" of the representations, AH interviewees critiqued data and took up new practices (e.g., attending to standardized ratios stating that they did so following the guidance of a trusted person). Trust relationships forged with friends, family and media personalities, who served as brokers of data literacy practices, supported taking up practices and feeling franchised to critique.

We cannot inoculate learners against fake news, but, like other educational responses to post-truth (Feinstein & Waddington, 2020), we suggest that a pathway toward fostering critical and just data literacies lies in helping learners to identify promising knowledge brokers and establish trust relationships.

4. Critical Data Practices within Community Infrastructuring for Survivance and Justice in the COVID-19 Multi-Pandemic

Day Greenberg, Angela Calabrese Barton, and Leslie Herrenkohl

In long-term research-practice partnerships, we investigated: How did youth engage in critical data practices (CDPs) in their out-of-school learning and action-taking related to COVID-19 and its intersections with in/justice?

We combine frameworks of critical data literacies and data justice to explore powered interactions among people and social structures that take shape through data. Data and data practices are never neutral nor independent of human thought systems. CDPs refer to data production, analysis, and sharing (Noble, 2018) to encounter/counter powered interactions and structures of harm (Philip et al., 2016) towards affecting lives, social relations and possibilities.

Using historicized and future-oriented participatory methodologies, we engaged in remote long-form dialogic interviews and experience sampling methods with 23 youth growing up in minoritized communities at three timepoints focused on: COVID-19 information accessed/applied towards decision-making; how efforts were situated within personal/community COVID-19 experiences/networks. We engaged in co-analysis with youth through practices of critical witnessing and being with, and oriented towards conscientization and social transformation of systemic inequities (Villenas, 2019).

We found that youths' CDPs involved efforts to recognize/leverage their intellectual power to engage, within community structures of support co-created in response to urgent shared need, including text and snapchat informational groups, grocery-redistribution networks, and extended family protection strategy sessions. These structures clustered and shifted dynamically in relation to data on the science of COVID-19 and health risks, safety, and social/emotional wellness. Youth also enacted alternative infrastructures for counter data production/aggregation towards community justice, amplifying community wisdom, and necessitating a reimagining of data sets and narratives as sites of struggle over what/who counts in COVID-19 data narratives. Youth navigated contentious spaces as data from different epistemological, social and political origins collided, necessitating new data engagement forms to navigate/transform spaces towards community survivance.

5. Data literacy and social design implications of algorithmic, socio-technical solutions to combating misinformation on social media

Eleni A. Kyza and Christiana Varda

In today's algorithmic-driven world, critical thinking is important for the evaluation of information on social media, where unvetted news abounds and potential misinformation lurks. Therefore, it is important to broaden our realm of inquiry to citizens and older adults and examine data citizenship perceptions and how artificial intelligence is being perceived and used (Hermes, 2006).

We conducted a quasi-experimental study with 80 adult participants to examine whether a socio-technical system — the Co-Inform co-created software browser plugin — supported misinformative-resilient actions, such as avoiding sharing or liking misinformation. We examined how participants reasoned about the big-data-driven interface, and the implications for the design of interventions to support evaluations of online information. We collected data on participants' actions and reflections when faced with misinformation on Twitter.

Analyses examined differences between the control and experimental groups (with/without the plugin) in terms of the participants' misinformation-resilient actions, as well as what prompted trust or distrust in the plugin.

Findings indicate that the experimental group (n=40) engaged in statistically fewer "likes" on misinformation; participants who trusted the software plugin were also less likely to share misinformation. Qualitative data analyses indicated that participants were critical towards the plugin, inquiring about dimensions of trustworthiness, such as transparency and explainability. Findings also point to insufficient understanding of the contemporary online mediascape, with participants overestimating their own abilities to evaluate the credibility of posts. These findings point to epistemic challenges relating to one's understanding of the digital world which should be addressed at multiple levels, and highlight the need for social design for addressing misinformation on social media (Pennycook & Rand, 2021). Such inquiries have implications for the design of sociotechnical systems and for school-based data literacy efforts.

6. Youth and the United Nations Sustainable Development Goals: Can Data Make the Global-Local Connection?

Andee Rubin

The seventeen UN Sustainable Development Goals (SDGs) (United Nations, 2021) are inspiring and far-reaching ambitions for a better world; they include no poverty, zero hunger, good health and well-being, and quality education. Youth (and adults) may feel these international goals are at a level they can't affect, yet middle school students often care deeply about such social issues. Perhaps data about how the countries of the world rate on SDGs can serve as a jumping-off point for youth to delve more deeply into local data around similar measures.

We document the design of NetApp Data Explorers, an out-of-school program whose goal is to support participants to move from a focus on international data on health and education to county-level data to more local and personal data and concerns. We describe both the particular design elements of the program whose purpose was to scaffold this journey and how participants navigated this narrowing and deepening of context. We focus on the influence of students' personal knowledge and experience in their interpretation the data and on the choices they made in "digging deeper" (Rubin, 2020, 2021; Lee & Wilkerson, 2018; Polman & Wilkerson, 2020). We also discuss data reasoning challenges that arose, including understanding how variability may be hidden when a rate is calculated for an entire country (e.g., in data such as "number of doctors per 100,000 people in a country") and untangling correlation and causation.

7. Developing Critical, Contextualized Data Agency through Educational Data Journalism

Stephen Sommer, Cynthia Graville, Joseph L. Polman, Andee Rubin, and Trang C. Tran

During a multi-year research partnership to cultivate data literacy amongst young people our team observed that in the course of doing journalistic work, many youth began to develop a critical consciousness about media, information, and data. Here we develop the concept of critical, contextualized data agency as a promising framework for an equity oriented approach to data education.

The concept of critical, contextualized data agency draws on a broad literature in the learning sciences related to individual and shared epistemic agency (Zimmerman & Weible, 2018) or learning agency (Barton & Tan, 2010; Damşa, et al., 2010). We build upon research related to learners' understanding and use of data actively contextualized and situated in their lives (Gebre & Polman, 2020; Lee & Wilkerson, 2018; Rubin, 2020; Wilkerson & Polman, 2020). We further add to these existing theoretical considerations an attention and emphasis on equity, social justice and critical or feminist data literacies (Arastoopour Irgens et al., 2020; D'Ignazio & Klein, 2020; Tygel & Kirsch, 2016)

We examine the development and manifestation of critical, contextualized data agency through two case studies. In a high school physical science class a student demonstrated a desire to communicate well-justified and actionable concerns to the public regarding growth hormones in livestock. In an after school program case, we document how another student took a global equity stance to argue for an expansive view of happiness beyond economics, and used data acumen to enhance and defend her arguments. Across these cases, we see the importance of cultivating agency to "speak truth to power," and how youth actively used data in contexts that emerged from their lives and contributed to imagining more just futures.

8. Forging Pathways from Computational Complex Systems Models to Current Socioscientific Issues Through Scientific Epistemic Practices

Susan Yoon, Clark Chinn, Amanda Cottone, Thomas Richman, Noora Noushad, and Huma Hussain-Abidi

The DeTECT project examines scientific epistemic practices of data use through computational complex systems models with a focus on transfer of those practices to evaluate controversial socioscientific issues. We are interested in the extent to which teachers and students are able to demonstrate adaptive epistemic practices (Chinn et al., 2020b). These include the ability to determine the veracity of claims based on fit with evidence and deciding which kinds of data are needed to construct accurate decisions in situated contexts. Scholars suggest that an education in epistemic practices requires expanded notions of disciplinary work (Brown, 2017) and highlight challenges in engaging teacher beliefs, improving skills and confidence in content enactments, and implementing pedagogies that afford student epistemic engagement (Buehl & Fives, 2016; Haverly et al., 2020).

We report on teachers' beliefs, enactments, and confidence levels with respect to teaching with curricula to improve student epistemic performance. Students worked with a computational model of gene regulation and examined variables (e.g., feedback loops) and data patterns that enable genes to be turned on and off due to environmental conditions. Students then applied this epistemic framing to current issues such as: data and research on CRISPR gene editing technologies and population disparities exacerbated by unequal access to them; or the intensification of climate change resulting from positive feedback loops and the disproportional impact on vulnerable groups. Preliminary results indicate that teachers hold strong beliefs about the importance of improving students' epistemic practices of data use and making broader connections to socioscientific issues. However, teachers also demonstrated challenges in translating those beliefs into practice, which are discussed in more detail in the presentation.

9. Storytelling with Data: A Syncretic Approach that Brings Together Social Justice with Middle School Science

Xinyu Wei, Cherise McBride, Michael Bakal, Collette Roberto, Emily Reigh, Puneet Bhargava, and Michelle Wilkerson

The Writing Data Stories project engages youth in learning activities that integrate computational data analysis and visualizations with personal testimony, interviews, and journalistic media stories. By facilitating middle school students to think more critically about social justice, the project encourages them to draw on evidence from their lived experience as a *syncretic approach* (Gutiérrez, 2008) whereby dataset exploration is deepened and contextualized through integration with personalized, multimodal "data stories" (Wilkerson et al., 2021).

We present evidence from a summer science camp on the U.S. west coast where grade 7-9 students explored the racially disproportionate impacts of COVID-19 and other health hazards. Reflecting on extended definitions of environmental racism (Holifield, 2001), students generated hypotheses through case studies, news stories, interviews with family members, and then explored publicly available datasets on the Common Online Data Analysis Platform (CODAP), a computational tool that helped them structure, calculate, filter, and transform data for scientific inquiry and argument (Erickson et al., 2019).

Through qualitative inquiry analysis, we found that students constructed oral and written presentations that contextualized data to highlight intersections of race, geography, health, and environment (Gutiérrez & Jurow, 2016). For example, several students reported the relationship between pollution burden and poverty level in the San Francisco Bay Area; others started advocating for social change after identifying particular communities most vulnerable to asthma. These findings illustrate emerging characteristics of sociocritical data literacy and center lived experience as valued sources of truth and axes for change. We propose that students' syncretic literacies enable them to publicly take a stance on urgent social issues by defining and debating environmental racism in and out of their science classrooms.

Endnotes

(1) "More-than-human" is used among others by indigenous communities and scholars to refer to other species and beings in nature with whom humans should be seen as having kinship relations (e.g., Kimmerer, 2013)

Abstract: Black, Brown, and Indigenous communities have long drawn upon storywork - the interrelated processes of storytelling and storylistening - as central strategies of wellness and thriving despite histories of dispossession and domination. This collection of papers theorizes with storywork and provides five contexts of storywork-in-praxis, where acts of creating, telling, and listening to stories feature centrally in critically re-designing spaces towards Black life, Indigenous futures, and the mutual flourishing of communities and lands. Through a syncretic approach, we bring together learning sciences research and perspectives from Black and Indigenous studies to further theorize the role that storywork plays within (1) sense-making activities, (2) the lives of communities that we have been a part of, and (3) our own lives as researchers-storylisteners. We consider the multiple roles of stories in research and design, the political/ethical nature of stories, and how storywork can re-organize power relations in ways that support individual and collective life.

Keywords: storywork, becoming collectives, Black and Indigenous studies, nature-culture relations, politics and ethics of learning

Focus of symposium

Throughout human history stories have been an organizing technology in intergenerational strategies of resurgence and coming to know who we are and who we could become together across difference. Building with these histories, this symposium is grounded in the experiences, epistemologies, and story-theories of Black, Brown and Indigenous communities and collectives. We choose to center our symposium on the interrelated processes of storytelling and storylistening, or what Jo-Ann Archibald (2008) has called *storywork*. Reaffirming that stories are central to human learning and becoming (Marin et al., 2020; Brayboy, 2005), we extend lines of thought and forms of inquiry to more robustly understand the forms, places, and processes of storying and restor(y)ing our relationships to each other and who we seek to become as educators, teachers, researchers, relatives, and human people within this vast web of life.

Which stories are told, by whom, and how we listen to stories matters and has consequences for how people experience the ethical, powered, and political dimensions of learning. In many schooling contexts, claims of objectivity permeate and control the permissible bounds of sense-making within disciplines, shaping what counts as science or knowing more broadly (e.g. Bang., et al, 2012; Lee, 2001). The act of living and listening with stories can help with navigating the epistemological and axiological tensions that arise from engaging with settled expectations based in whiteness (Bang et al., 2012). Stories resonate realities and importantly ground-truth and make place for our felt theories (Million, 2008). In this way, stories and storytelling are methods for refusing ongoing ontological erasure and epistemic violence (Marker, 2006). They also provide a representational infrastructure (or conditions, Hall & Jurow, 2015) for continually enacting intergenerational healing, community wellness, and regeneration.

The papers within this symposium hold a broad definition of stories, including songs, *platicas*, *dichos*, proverbs, and other artistic traditions held by humans and more-than-humans. These story-forms engage the

 © ISLS

multiple senses and ways humans come to know the world, our relations, and the peaceful social order, or what is known as *omenàlà* in Igbo society (Penfield & Duru, 1988; Kopano, 2002). As a collective, we theorize with storywork and riff on the personal, collective, ethical, and political possibilities that emerge from participating in storytelling and storylistening. Together, we pay attention to how stories might sensitize us to each other, the relations of others, and provide forms to bear witness to trauma. We also foreground efforts to reclaim stories that have often been stolen from many of our communities and repackaged towards settler aims through hungry listening (Robinson, 2020).

As researchers of human learning and becoming, we are particularly interested in how stories may surface in the (re)membering of felt experiences in our own lives within intergenerational and inter-ontological (e.g. across humans, waters, plants, animals, and other more-than-human beings) thought and ongoing activity. Through this dialogue, we are interested in how the interrelated processes of storytelling and storylistening connect our whole beings to other kin-relations - human, plants, animal, spirits, and ancestors across multiple timescales where the act of listening is also an act of creation, health, and healing. Malian writer Hampaté Bâ (1981) suggests that the health of a community's social relations depends on how well their stories circulate and continue. Given these responsibilities and possibilities, we continue to ask:

- How does storywork ethically guide our processes of knowledge production (as teachers/learners/ researchers)?
- What does storylistening, an under-theorized dimension in the field of learning sciences, teach us about the design of learning environments in which relational knowledge can emerge?
- How are stories learned, taken up, circulated, listened with, and brought forward across human and more-than-human interlocutors in learning environments - and towards what ends?
- What methodological approaches might help us to better understand storywork across human and more-than-human interlocutors?
- What kinds of visions of wellness, joint orientations and collective pursuits are possible with stories?

Relevance and Contribution

The collection of papers within this symposium speaks to the multiplicity of ways that humans make meaning, dream with, and become story-ready with each other and the rest of the living world. This session holds two main threads, theorizing with stories-as-theories and stories-in-praxis. First, we theorize with stories and becoming story-ready as humans. Being story-ready refers to the ways we humans prepare our hearts and spirits to learn and listen with stories and find meaning from that story within our own lives (Archibald, 2008). It signals an openness and vulnerability to allow another being's stories to guide what we ought to do or how we should act. For us, being story-ready is core to supporting relational becoming - the attuning of ourselves to the rhythm and resonance of others and their relations (Meixi, in press; Nzinga, in press). Second, we turn to design and practice-based implications for the building and sustaining of relational or subject-subject focused designs within and across learning environments (e.g. Bang and Vossoughi, 2016; Booker, 2016; 2019; Marin & Bang, 2015).

Across the papers, we make visible the work of stories within five distinct contexts: as professional and emerging artists that became community during the pandemic; as scholars and community members who recognize the capacity of Indigenous intellectual traditions to shape and expand possible futures, particularly during widespread crisis; as mothers and community members on traditional lands and waters, within e-textiles quiltmaking and the strengthening of Black futures; and as educators committed to offering more liberatory mathematical possibilities for children in elementary classrooms, imagining possible selves among elementary mathematics educators through collective storying. Each of the papers comes from within particular contexts of power and historicity at multiple scales - histories of settler colonialism, systemic anti-Blackness, public schooling and institutionalized norms, and narrow notions of mathematics and science. As a field, we need more scholarship on the roles of storywork in critically re-designing spaces of disequilibrium, negation, and harm for Black and Indigenous young people to ones that further our relational responsibilities to each other and a more just and thriving living for all people and lands. We suggest that centering one of human's oldest technologies - our stories as felt theories - (Brayboy, 2005; Million, 2008) can facilitate the conditions necessary for collaboration and educational innovation. This symposium offers a deep dive into stories, with theoretical, methodological, analytical and practice-based implications for our designs and our relational becoming.

Organization of symposium

This symposium will consist of five featured papers and two discussants. We intend to begin with inviting the audience to consider their own forms of storywork, axiologies, and relational becoming. We will then present each paper as a story, with time at the end of the session for a dialogue and discussion among our two discussants.

Paper 1: Wellness Belongs to Us: Reimagining intergenerational knowledge and embodied wisdom through Hip-Hop arts storytelling

Kalonji Nzinga and Marlene Palomar

Researchers in the learning sciences have noted ways in which storytelling and storylistening in communities of color provide ways for youth to build counternarratives to resist mainstream narratives (Delgado, 1989; Solórzano & Yosso 2002). One such mainstream narrative is that wellness practices are lacking within marginalized communities. The current design-based research study was constructed to analyze how a storytelling intervention introducing the essential elements of hip-hop arts (Knowledge, Djing, Breakdancing, Graffiti, Emceeing) could provide space for adolescents to redefine wellness and articulate healing practices endogenous to their own communities. We were rooted in the following questions: (1) how do youth redefine wellness through art and through their senses, and (2) where do narratives live and how do they circulate through the learning environment and in their communities.

Our intervention centered youth from Latinx, African-American, AAPI, and Indigenous communities with deep histories in the Greater Denver area who are vulnerable to cultural displacement and gentrification. The communities we worked with are both underserved by mainstream mental health care institutions and have seen their cultural practices historically marginalized. The intervention took place within a hybrid (remote/in-person) Ethnic Studies classroom at North High School in the midst of global pandemic. A design team consisting of artists, activists, scholars, students, teachers, and emcees engaged in the creation of a hip-hop based education learning environment that nurtured the exploration of wellness and resistance storytelling in digital form. Storytelling and storylistening was conceived of as reactivating knowledge systems that have been rendered useless by colonial and neoliberal conditions (Abebe, 2021). Our online learning environment weaved narrative, song, art, and intergenerational knowledge as a form of cultural preservation through the circulation of stories (Lambert, 2010; Iseke & Moore, 2011; Cunsolo Willox et al., 2013; Kitchenham, 2013) engaging multiple generations in meaningful engagement with storytelling/storylistening (Hausknecht et al., 2021).

We take a case study approach, focusing on 8 learners and their stories (6 youth and 2 instructors). Using multimodal discourse analysis we analyze a single artistic story produced by these 8 individuals (song, visual art, playlist, interactive website) as well as an artist statement that they produced. Using open and closed coding techniques a team of artist-researchers investigated the ways in which each of these community members defined wellness, incorporated their senses, and also how their stories reflected relationships to community members.

Our analysis produced various conclusions about the process by which stories circulated in the learning environment. First, the vulnerable artistic process that the instructors went through (both while designing the curriculum and while presenting it to learners) modeled techniques of healing expression for the youth. There was evidence of storylistening by the youth, elements of the instructors wellness and artistic forms of expression were seen weaved through the artistic element and statement. In their art youth also reconceptualized wellness as something that was already a part of who they were, and their commitment to transformational resistance in the context of their self, community, diaspora. Youth often reimagined everyday cultural practices that they were already engaged in as worthy, valuable, and connected to wellness.

Paper 2: Stories of (Re)creation and (Re)emergence: Engaging land-based approaches to education and wellbeing

Emma Elliott, Sabrina Elliott, Meixi, and Alayna Eagle Shield

Human survival is predicated upon ethical and sustainable relationships with the land and all living beings. The ethical foundations of our intellectual traditions are best understood as a reflection of our deep sense of interconnectedness, characterized by relational reciprocities, both of which informs how we make sense and move about in the world. These axiological commitments shape our identities, our reciprocal relations with plant and animal nations, and natural world relations, as well as our education, health, and political systems. By drawing on Indigenous stories as the crux of theory development and knowledge co-creation, as well as Indigenous concepts

of relationality, this study identifies social and psychological dimensions of wellbeing from a Cowichan perspective.

This study drew on principles of community-based design research (Bang, et al, 2015), and was a part of a larger study that took place within the context of Cowichan Tribes on Vancouver Island, British Columbia. To consider how Indigenous intellectual traditions and related ethical commitments can help illuminate strategies that facilitate overall wellbeing (e.g., education and health) of all peoples, this study engaged the power of Indigenous creation and land-based stories. With the expertise of a community-based research assistant and a graduate student researcher, we conducted 25 land-based interviews with elders and other cultural knowledge keepers. At each site, the researcher engaged each participant in Coast Salish storytelling and storylistening (Archibald, 2008) to document the stories that emerged from each place, and recorded each interview using GoPro cameras to capture land-based methodologies including "walking, reading, and storying the land" (Marin & Bang, 2018). Four researchers, including the community-based research assistant, analyzed each interview using a constant comparative process consistent with grounded theory methodology (Glaser & Strauss, 2017) to identify local social and psychological dimensions of health and wellbeing.

By engaging land-based and Indigenous approaches to research, we found that embedded within local, land-based stories are the frameworks to teach science, technology, engineering, math, medicine, and environmental sustainability, as well as culture, language, and arts. The stories gathered in this study provided considerations about context and conditions, collective and intergenerational contributions, cross-cultural relations, and directions forward toward a just and sustainable future for all. In particular, our study documented stories, both historical and contemporary, that provided Cowichan people with 1) connections to their land and territory, as well as to animal and plant nations; 2) land-based and Indigenous teaching and learning strategies, 3) a deep commitment to Indigenous relationality; and 4) theories and practices that included sustainable frameworks to teach all learners what it means to be a human being and how to "walk in a good way."

Throughout the course of this study, the world experienced (and continues to experience) multiple pandemics, including the novel coronavirus, police violence against Black people and anti-Black racism, and a widespread climate crisis (Ladson-Billings, 2021). As educators, we continue to imagine our contribution to education and wellbeing, and frankly to humanity, throughout this challenging time. As scholars, we recognize that through widespread crisis or chaos, creativity and imagination can emerge. We have the opportunity to recreate and re-imagine another way of educating and caring for our children. As Indigenous peoples, we recognize the strength of our relational onto-epistemologies and axiological commitments, and offer Indigenous relationality as a framework for addressing widespread crises across humans, plant and animal nations, and natural world entities. Indigenous intellectual traditions are rooted in our ancestral territories and expressed as "an ecology of relationships in the absence of coercion, hierarchy, or authoritarian power…, relationships based on deep reciprocity, respect, noninterference, self-determination, and freedom" (Simpson, 2017, p. 8). These systems of relationships have been put in place to ensure human collective survival. We must not only understand the theoretical underpinnings of our stories, we must also strive to engage these theories in the process of re-imagining our collective futures. The answers to the social and psychological predicaments faced by our communities are embedded within the intellectual traditions of each community, and more specifically, within land-based local stories that serve as theories of learning and wellbeing (Brayboy, 2005).

Paper 3: Restorying STEM Learning Communities through E-textiles Quiltmaking

Mia S. Shaw

The purpose of this study was to design an inclusive STEM learning community with minoritized youth from an informal STEM program at a local science museum. I conceptualize youth's STEM learning through this four-year program as "legitimate peripheral participation in communities of practice" (Lave & Wenger, 1991, p. 31). In other words, youth deepen their knowledge of STEM practices and careers through deepening their membership into the STEM community in the form of hands-on workshops, field trips, and internships. However, dominant narratives about who or what are considered "legitimate" STEM identities, practices, and goals have resulted in the historical and institutional exclusion of communities across various social locations (i.e., race/ethnicity, gender, class, and ability). I ask: How do we design for creating inclusive STEM learning communities that reimagine dominant narratives surrounding what STEM is and who belongs? One of the ways the learning sciences have considered reimagining or "restorying" narratives surrounding STEM learning—particularly those endorsing "narrowly defined hegemonic science practices steeped in material culture" (p. 409)—has been to frame the

heterogeneity of cultural practices and experiences as central to learning and designing learning environments (Rahm, 2019).

This study engages in heterogeneity through the sharing of diverse STEM stories and experiences, for exchanging stories can create learning communities through providing a "cohering feeling of shared concerns, values, and investigations" (hooks, 2010, p. 52). In order to design for heterogeneous STEM identities and practices through the sharing and listening to stories, I developed and facilitated a two-part, 45-hour workshop in which youth designed electronic textile (hereafter, e-textiles) quilt patches that "restor(y)ed" dominant narratives about computing technology. An analytical perspective used in narrative and literacy studies, restorying describes how minoritized youth "narrate the word and the world, [analyze] their lived experiences and then [synthesize] and [recontextualize] a multiplicity of stories in order to form new narratives" (Thomas & Stornaiuolo, 2016, p. 318). E-textiles are fabrics embedded with microcomputers, lights, and sensors stitched together with conductive thread and programmed to perform various actions (Buechley, Peppler, Eisenberg, & Kafai, 2013). Furthermore, minoritized groups have used quilting as both an art form and sociopolitical tool to resist oppression and collectively reconstruct their cultural histories through sharing stories of their lived experiences (Cash, 1995; Stull, 2001). Through the integration of historically-feminized practices of crafting (and quilting) with historically-masculinized practices of engineering and design (Buechley, Peppler, Eisenberg, & Kafai, 2013), e-textiles quiltmaking serves as a novel approach for creating inclusive STEM learning communities.

Through analyzing field notes and video observations of community-building activities, participants' exit tickets, and researcher memos, narratives surrounding the culture of STEM learning (particularly in formal schools) emerged. Through collaborating to design a collective quilt including all their patches of restor(y)ed narratives, youth and adults present were able to reimagine and create a STEM learning community rooted in empathy-building and psychological safety, as well as play and authentic friendships. Implications for this study include the design of collective narrative-based artifacts as a context for developing inclusive STEM learning communities.

Paper 4: Co-constructed Anti-Deficit Storytelling in Mathematics Education

Mallika Scott

Justice-oriented teacher preparation programs aim to prepare novice teachers to create more humanizing learning communities in which each student can bring their full selves to learning (e.g. Andrews et al., 2019). Creating these types of caring and rigorous communities in the mathematics classroom requires grappling with and disrupting deficit discourses about students from currently and historically marginalized communities that remain prevalent in K-12 schools (Adiredja & Louie, 2020; McDermott et al., 2006). The stories teachers tell about children often function to reinforce narrow conceptions of ways of knowing and being in the mathematics classroom and to reproduce existing hierarchies (Horn, 2007; Louie, 2019). However, stories also have the potential to support teachers toward more liberatory and expansive views of children and of mathematical learning (Battey & Franke, 2015). Here, I present an analysis of a learning community of beginning teachers who co-constructed a form of storywork – storytelling and storylistening about children that disrupted deficit discourses rampant in their school contexts.

This study was informed by social approaches to design that emphasize designing activity systems intended to afford new forms of activity (Gutiérrez & Jurow, 2016; Gutiérrez & Vossoughi, 2010). The author served as facilitator, co-designer, and researcher of a learning community of six first-year elementary school teachers from the same preparation program. Teachers participated in monthly meetings in which they told stories of successes and dilemmas from their classroom teaching. Data sources include video recordings of meetings and audio recordings of interviews with participants. Data were analyzed to examine how teacher stories from the classroom were co-constructed and functioned to reproduce or disrupt deficit discourse about mathematics teaching and learning.

Findings indicate that participants co-constructed a new joint activity of telling stories about children that reinterpreted student behavior from an anti-deficit perspective. This activity grew out of an emergent need in the community for teachers to support each other to expand their own limited views of the children in their classrooms by collectively investigating why student behavior might be considered sensible within the classroom learning ecology. As teachers listened to each other's stories, examined classroom artifacts, and thought together about the experiences of individual children in their classrooms, they supported each other to open their hearts and spirits to connect with children in the experience of learning mathematics. In describing how this activity supported her learning, first-grade teacher Selina reflected, "I don't think I would have gotten to that point if I

didn't have everybody looking at the same work with me. Because I was such in a box. [...] So asking for an outside perspective and not limiting yourself to a deficit view, like what are they not getting. It's like what are they getting, and what is it about this that is confusing." Through this activity, participants collectively constructed new stories of mathematical learning that pushed back on individual, deficit-oriented interpretations and honored children's dignity as learners and as human beings (Espinoza et al., 2020; Espinoza & Vossoughi, 2014).

Paper 5: Becoming Maestras Matemáticas through Pláticando

Sandra Zuniga-Ruiz

I grew up listening to my abuelita's historias about being raised en el rancho and navigating the struggles of migrating to the United States. I bear witness to her memories, memories that would be intertwined with dichos and consejos of becoming buena gente. I begin with the stories of my abuelita because storytelling is interconnected with who we are in history, intergenerational knowledge and connetion that is passed on, and storytelling provides a groundwork for the future. These stories were of the form of pláticas, critical conversations. In this work, pláticas are a cultural practice of storytelling embedded in the design of transformative learning communities (Gutierrez & Jurow, 2016) that I argue is central to learning and becoming. This paper centers *pláticas* as stories that create opportunities for prospective teachers of color, Mexicanas, to engage with the complexity of issues related to social justice and mathematics.

Becoming a mathematics social justice educator entails understanding and engaging with multiple literacies: racial, critical and mathematical literacy (Freire, 1996; Sealy-Ruiz, 2011; Schoenfeld, 2014). While such literacies are central and never an outcome, very little is known how one grapples and develops such literacies with mathematics while centering the experiences of marginalized communities. One such way to center the experiences of prospective teachers of color (PCTs) is through the creation of a counterspace, a "safe space" created by marginalized people in response to the daily barrage of racial microaggressions (Solorzano, Ceja, & Yosso, 2000). This study merged the need to create spaces for us and with us while paying close attention to designing a transformative learning community.

The purpose of this project was to co-construct a learning community where PTCs had opportunities to grapple with issues of race, justice and mathematics. Such opportunities came from the use of tools and artifacts to spark conversation. The women had all taken the same math content course so they had a shared experience that allowed them to talk with one another about their math experiences. The co-participants in this study are a researcher and 4 PTCs who self-identify as Mexicanas. Even though the participants are in the same ethnic group, there is a lot of diversity within the group. PTCs are all college graduates who attended a Hispanic Serving Institution in a predominantly immigrant Latinx community. At the time of the study, all co-participants had yet to begin a credential program and intended to continue to work in the community they grew up in. The participants were selected by their willingness to engage in conversations about social justice and mathematics. Data sources include video recordings of zoom meetings and interviews with co-participants.

Through analyzing the video data, findings suggest that the stories that the mujeres shared about their families served to both construct new meanings with one another and with mathematics itself. For instance, the developmental stories of parents doing math in their everyday life pushed on the mujeres' understandings of who does math and what is math. The storytelling about family helped build a collective community where they were vulnerable and were able to relate to struggles of their multifaceted identities as women of color. Furthermore, their experiences in the pláticas served as a foundation for the women to co-construct a vision of a mathematics learning community grounded on community, historicity and dignity (Espinoza et. al, 2020; Espinoza & Vossoughi, 2014).

International Society of the Learning Sciences

Developing Accessible and Sustainable Computational Modeling Tools in Learning Science: What is Next?

Chairs: Tamar Fuhrmann, TC Columbia University; Sharona T Levy, Faculty of Education, University of Haifa
Discussant: Uri Wilensky, Learning Sciences & Computer Science, Northwestern University

Introduction

In this symposium, we address two issues that extend the body of research on students' computational modeling: enabling greater access to computational modeling activities and sustaining such activities within educational settings. Modeling has become an essential part of many scientific disciplines -- a core element in professional scientific practice for formulating and testing hypotheses, justifying new claims, and explaining natural and artificial phenomena (Pluta et al., 2011; Halloun, 2011). The involvement of students in developing a scientific model has been shown to have many pedagogical affordances: models can be used as inquiry tools, creating meaningful learning opportunities (Gilbert et al., 2016; Passmore et al., 2014; Schwarz et al., 2012); additionally, models enhance students' disciplinary knowledge (Passmore et al., 2014) and help develop their understanding of the epistemology behind constructing scientific models (Lehrer et al., 2006; Schwarz et al., 2005). In addition, it has been found that students who engage in designing their models also develop a critical perspective about models and metamodeling knowledge (Wagh et al., 2018; Fuhrmann et al., 2018). The last few years have seen modeling activities gradually take root as part of science education. Incorporating modeling has become a key goal in many countries' national standards in the past decade and a core component of school curricula (Gilbert et al., 2016), as evidenced by the fact that national policy documents have centered modeling activities in the curriculum (National Research Council, 2007; NGSS, 2013) and by the fact that modeling is woven throughout the Next Generation Science Standards (NGSS).

With the realization that constructing models is essential and computational modeling should be learned in schools, new computer modeling environments and designs have proliferated. As a result, today, a wider range of robust, mature, and carefully designed software and hardware tools are available for modeling in K-12. Nevertheless, several issues remain to be addressed before students engage in meaningful modeling activities, create their models based on data, and share them and discuss them with others, thus participating in activities aligned with authentic scientific practices.

The papers in this symposium focus on the big question of what is next in domain-specific computational modeling languages/environments for K-12 students. To this end, we address two relevant issues, namely accessible and sustainable development. Here, we define *accessible* development as development that enables students with different interests, contexts, and abilities to begin interacting with the learning materials. This can be done by lowering the threshold to begin using the tools and/or by catering to different forms of expression to motivate students to begin engaging with the tools. Increasing accessibility to a learning environment is necessary when considering schools with teachers who may or may not have the skills to support a class of students constructing computational models. Students' need for support in constructing a computational model is significant, and learning design needs to consider how to offload some of this responsibility from the teacher to the computational toolkits themselves.

We define *sustainable* development as creating learning materials that can continue generating new activities over time, be it for additional content, for higher ability levels, or for other extensions. Ensuring the sustainability of innovative and expressive activities such as computational modeling in schools is an important endeavor that has been undertaken by several leaders and researchers (Horn et al., 2011; Kelter et al., 2021). Building upon these efforts, there is a need to continue developing and diversifying the strategies for supporting the continued use of computational modeling in science learning. In the process of variation and selection in different contexts, this would advance the broader vision of democratizing people's use of computation as a tool to express their assumptions regarding phenomena in the world and of generating dynamic representations that can be compared with these assumptions.

Paper 1 presents a nuanced framework that differentially integrates divergent data sources with modeling activities and labs. Paper 2 introduces the Much.Matter.in.Motion platform for modeling, which unifies computation across systems in chemistry and physics. It demonstrates the idea with research into learning about electricity through computational modeling. Paper 3 presents research with a novel extension to the Scratch environment that enables topical computational modeling. Further, this paper looks at related research that highlights how students' ideas are expressed visually and evolved through the programs they construct. Paper 4 presents work and research with the StarLogo Nova platform. It looks at how programming blocks might be used for learning a variety of scientific phenomena across the curriculum while enabling the opening of these blocks

 © ISLS

to get a deeper understanding of the computational constructs. Finally, Paper 5 presents a framework for making computational modeling in science a sustainable activity in middle schools.

Each of the papers in the symposium addresses accessibility and sustainability in different ways. Regarding accessibility, common to all the papers is the use of functional computational blocks that are limited to a subset of phenomena and form a library of concepts that students can use to construct their models. By limiting the library of concepts and aligning them with a variety of intuitive concepts, it is made possible for the students to immediately begin constructing with relatively little support. In Paper 4, these blocks can be opened up during the learning process, supporting students as they gradually come to understand the more basic computational constructs the blocks are built from.

As to sustainability, the papers provide an array of strategies. Paper 5 specifically addresses sustainability and presents a framework with several components that could support the continued use of modeling in schools. Papers 1 and 3 both employ Bifocal Modeling, an approach that combines the use of labs and models to facilitate easy comparison. In this way, additional practices common in science education are integrated with modeling, thus strengthening the holding power of those practices.

Similarly, Paper 2 intersperses physical experiments into the learning unit, with the express goal of helping students transition back and forth between experience and representation. Integrating standard science education practices into learning units that engage with modeling can also be seen in Paper 1, where a framework for integrating data practices with modeling is presented. In Paper 4, using the mature StarLogo Nova platform and beginning with a more limited library of blocks enables the gradual transition to a full-blown modeling toolkit by gradually unpacking these blocks, providing for an extended developmental learning process that can continue even over several years. Another strategy used in paper 4 to increase sustainability is creating several libraries, each of which addresses different curriculum topics so that modeling can be integrated into learning throughout the school year. Finally, in Papers 2, 3 and 4, the limited set of blocks enables modeling a broader range of phenomena — systems in chemistry and physics — by capturing the computational similarities among diverse phenomena; this supports the vision of continued use of the same platform as students progress in their studies and learn new topics in these sciences.

The session will open with introductory words. Five paper contributions will then follow. Our discussant, Prof. Uri Wilensky, will draw upon the various strategies developed to increase accessibility and sustainability to interrogate some of their implicit assumptions underlying the learning designs and the related research presented in the papers. The symposium intends to integrate and focus our efforts on furthering scientific computational modeling in schools, streamlining it to the burning issues we have addressed. To summarize, the papers comprising this symposium acknowledge several essential issues regarding computational modeling in science. The more we know about this topic, the more we are driven to further explore and extend our understanding. We hope that the symposium helps democratize this important science learning component by addressing key issues that can make modeling more widely available for all learners and relevant throughout their studies.

Paper 1: Comparing and Contrasting Real-World Data and Models: Cognition, Pedagogy, and Implementation

Engin Bumbacher, Tamar Fuhrmann & Paulo Blikstein

Empirical data plays a crucial role in scientific modeling: scientists use such data to construct, refine or decide between possible models (Passmore et al., 2009), and assess the adequacy of a given model by the degree to which that model is able to explain the data (Passmore & Svoboda, 2012). However, approaches to model-based learning (MBL) have predominantly focused on model-based and data-based practices separately (Bumbacher et al., 2018). While these reductive approaches have helped students improve in the respective practices (Zimmerman, 2000), they have yet to prove successful in helping students develop a deeper grasp of the practices and epistemic understanding of the scientific endeavor (Berland et al., 2016; Chinn & Malhotra, 2002).

Recent technological advances hold the promise to support more integrative approaches that interweave models and data. For example, the Bifocal Modeling framework (Blikstein, 2014, 2016) suggests integrating technologies for real-world data collection with technologies for computational modeling to enable real-time comparisons of simulated and real data. Studies have shown that activities designed according to this framework can develop students' conceptual understanding and meta-modeling competences (Blikstein, 2014; Fuhrmann et al., 2018), but more work is needed to examine the types of learning opportunities that arise from comparing real-world data and computational models, as well as the conditions under which they arise.

Integrating real-world data in the modeling process provides learning opportunities that would not arise if students just focused on the models. For example, real-world data might encourage students to explore more deeply the

 © ISLS

underlying features of a phenomenon (Schwarz, Akcaoglu, Ke, & Zhan, 2013) in order to decide on criteria of model-fit. Similarly, real-world data might also inform the evaluation of models, when students have to decide how well a model fits the data, and what conclusions are justified by the data (Holmes, Wieman, & Bonn, 2015). But there is not just one type of data source, and there is not just one way of comparing models and data. We argue that the type and quality of learning opportunities arising from comparing models and data are dependent on the type of data source being used, and the way models and data are brought together. For example, juxtaposing a model-based simulation of bacterial growth with time lapse recordings of an actual experiment might encourage students to engage differently in the comparison of models and data than merely contrasting the growth curves of the simulated and real bacteria.

Thus, developing technologies and pedagogical approaches that productively integrate data and models necessitates a better understanding of the types of data sources and types of comparisons of models and data. This is particularly relevant today, as the past decade has seen an explosion of novel empirical data sources and means of collecting data (Lee & Wilkerson, 2018). Novel technologies like probeware, wearable sensor technologies or remote laboratories enable individuals to collect quantitative data continuously and in real-time. The internet provides access to large, publicly-available datasets in the form of spatial data, quantitative data tables, or qualitative data such as videos. Further, computer vision algorithms can even turn non-quantitative data like videos and images into quantified datasets (e.g. Hossain et al., 2016). Depending on the data source, real data might be produced and compared to models in real-time or asynchronously. And depending on the data source, real and simulated data can be compared in side-by-side visualizations or overlaid in the same visualizations; they can be compared across multiple dynamically linked visualizations, or quantitatively by means of analysis tools, and so on. Each of the data sources necessitates different data-related skills, and each of the types of comparisons has different implications for what students might focus on and how they might reason when using models and data. In this presentation, we present a taxonomy of these types of data sources and types of comparisons, and elaborate on how they might impact possible learning opportunities. This work is necessary to guide the development of technologies and activities for rich scientific inquiry through the integration of computational models with real-world data.

Paper 2: Eighth-Grade Students Learn Electricity through Constructing Computational Models with Much.Matter.in.Motion

Janan Saba, Elon Langbeheim, Hagit Hel-Or & Sharona T. Levy

This study focuses on students' learning of the concept of electric current through the lens of complex systems by constructing computational models with an iconic interface. We focus on how students develop mental models that associate properties of a circuit at the macro-level, such as the magnitude and direction of the electric current, with entities at the micro-level, such as electrons and their motion (Eylon, & Ganiel, 1990). We examine the students' development of mental models as they construct computational models with an early widget-based version of the Much.Matter.in.Motion platform (MMM; Levy et al., 2018). One of MMM's main affordances is sustainability, which enables modeling of many physics and chemistry phenomena.

Learners rely on cognitive constructs termed "mental models" when explaining the world around them (Norman, 1983). They develop these mental models through interactions with natural or human-made systems; yet, these models are often partial, unstable, and inaccurate. It is important to support students' expression of these mental models and to follow their transformations through learning. This process is facilitated by having this expression take the visual form of drawing, on the one hand, and become animated through the generative power of computation, on the other hand.

Most computational platforms that were designed to support teaching of electricity are based on a macro-level representation of circuits (e.g. Roll et al., 2018), with only a few environments attempting to introduce electric circuits from a micro-level perspective (Sengupta & Wilensky, 2009). In our study, we developed the MMM modeling platform (created with NetLogo [Wilensky, 1999]) for building and running computational models. MMM enables model construction at the micro-level without coding, by using pre-built model features that can be added and modified. To increase the accessibility of MMM, it is set up in such a way that users first draw the boundaries of their model conductor, and then add particles for which they define size, initial speed, heading, and interactions. After constructing the model, students can run the model and observe the resulting behavior. Figure 1 shows a screenshot of the MMM platform with a constructed model. The brown particles represent the atoms, and the red particles represent electrons.

 © ISLS

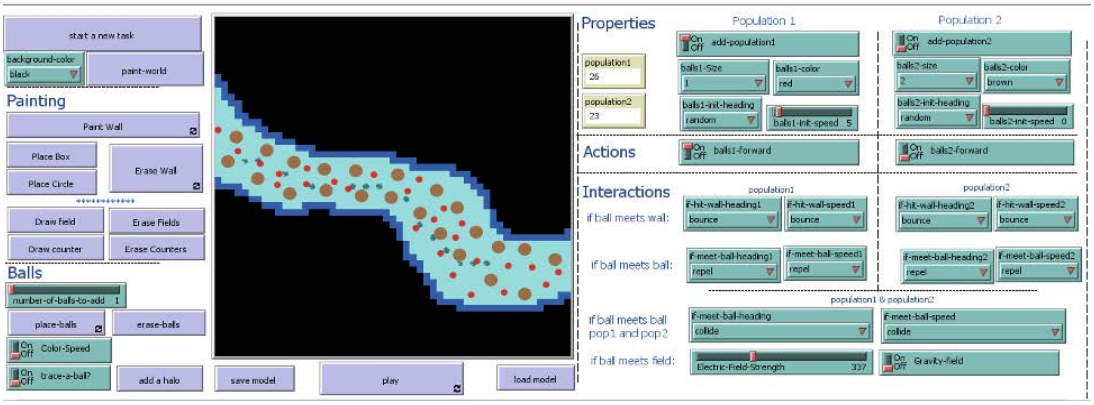

Figure 1. The Much.Matter.in.Motion (MMM) interface

Thirty-three eighth-grade students' learning by constructing models is compared with 23 students' learning with a normative curriculum, during six 1.5-hour sessions. The learning process included physical experiments and modeling activities. Students completed pre-and-post-test questionnaires and four students were interviewed. Activities were logged and screen-captured.

The interaction between time and group ($F(1,54)=6.67$, $p<0.05$) shows the superior learning of the experimental group. The specific component that contributes to this significance is the micro-level reasoning on the systems. A two-step cluster analysis was conducted on the students' responses to the open-ended items in the questionnaires regarding simple electric circuits. Five mental models were revealed that differed across several features: the balance between physical macro-level components and micro-level descriptions and the degree of integration between the micro and macro levels. Comparing the magnitude of the transitions between mental models across the two groups shows a significant transition magnitude for the experimental group between pre- and post-testing compared to the comparison group.

Our study shows that constructing micro-level models of electric conductors advances micro-level conceptualization of the electric circuit, and does not diminish the overall macro-level understanding. In addition, cluster analysis is an important methodological advancement compared to prior studies that examined individual responses without an integrated approach that combines all of the knowledge elements expressed by each student. Results indicate that enabling students to construct computational models using MMM promotes progress in thinking about electric circuits: from simpler mental models that are focused at the macro-level in the beginning of the learning process to more sophisticated ones at the end that include the micro-level entities and interactions. This approach to learning science is now being extended to additional topics. We are now studying the sustainability of these ideas over time and across topics.

Paper 3: Unpacking Students' Reasoning Using Computational Models With Domain-Specific Blocks

Cassia Fernandez, Tamar Fuhrmann, Paulo Blikstein & Roseli de Deus Lopes

Engaging students in modeling practices to make sense of scientific phenomena and the nature of science is the focus of recent reforms in science education (NGSS, 2013; NRC, 2012). Creating a computational model can be a valuable way for students to create and test their own hypotheses and refine their understanding of natural phenomena (Gilbert et al., 2016; Passmore et al., 2014; Schwarz et al., 2012). Although the constructivist idea that students are not "blank slates" but rather possess a wide range of previous knowledge on natural phenomena is well established (diSessa, 2018), there is, still, less research than needed about what students already know in specific domains of science. Thus, often, educators and designers (by no fault of their own) are not completely aware of preconceptions that students might bring to classrooms, what they are confused about, or how their ideas about the world fit with what they are attempting to learn. This paper aims to analyze students' conceptual trajectories while programming a computational model, in order to understand their initial, nonstandard, ideas about diffusion and how those ideas evolve. We are interested in learning how interaction with a constrained model can reveal students' thinking and, thus, inform designers on how to design tools and languages that acknowledge students' ideas and sensemaking (Wilkerson-Jerde et al., 2010; Wagh et al., 2017).

 © ISLS

Our preliminary findings are drawn from a pilot study conducted through individual online sessions with seven 5th-grade students. Each session lasted one hour and involved model creating and comparison with data (Fuhrmann et al., 2018). Students observed a diffusion experiment and designed a model to explain the phenomenon at the particle level, using their experimental observations to validate and refine the model. For these sessions, we designed an initial version of nine domain-specific programming blocks integrated into Scratch as an extension. By combining our blocks with the original Scratch blocks, we expected students to test and refine their own ideas about diffusion, using scaffolding tasks and questions from the researchers.

The use of block-based modeling tools has many affordances for young students. For example, it allows them to develop their own scientific models without being overwhelmed by text programming in a dynamic process (Gouvea et al., 2017). By doing so, students can revise their ideas and make changes through many iterations. According to our findings (see Figure 2), designing computational models in this way helped students externalize scientific ideas that would otherwise remain tacit. Through coding their models, students revealed unexpected concepts such as molecule "transmutation," atoms that would simply disappear or "melt," and particles with volition. Being able to express those ideas in code was crucial for students to be able to then reflect on those ideas, understand their possible flaws, and refine their initial ideas.

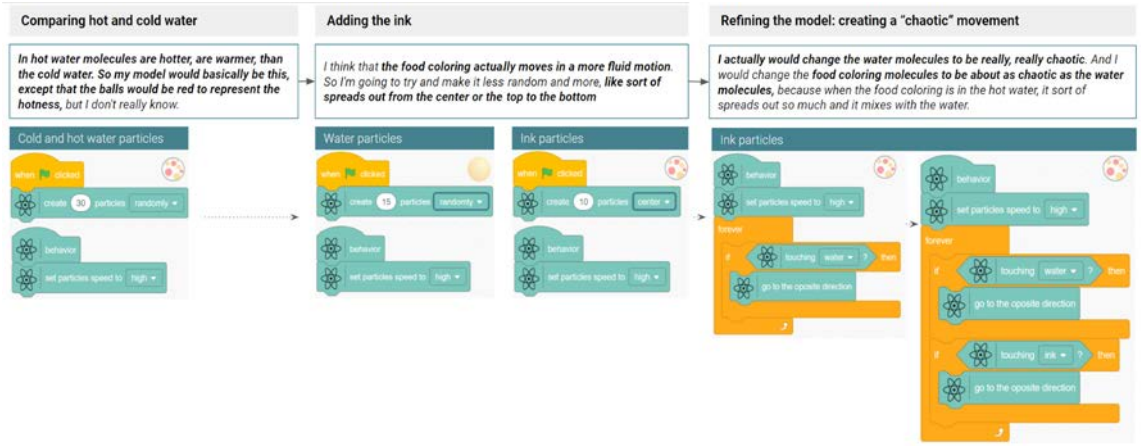

Figure 2. An example of student initial ideas and the evolvement process illustrated with blocks

The use of blocks can be a valuable strategy to explore students' reasoning processes: the translation of ideas into code unpacks students' thinking. It reveals inadequate conceptions since it forces students to make their thinking visible. By being aware of students' prior knowledge and identifying possible sources of confusion, science educators can mediate the scientific knowledge-building process for learners; help them make sense of how scientific models are generated and validated; and scaffold learners' conceptual understandings rather than merely giving them the "correct answer." While learning how students reason about a phenomenon, designers and researchers can create more domain-specific blocks that acknowledge students' initial ideas and sensemaking processes.

Paper 4: Custom Blocks in StarLogo Nova: Lowering Barriers and Providing Pathways to Further Learning

Daniel Wendel & Eric Klopfer

Agent-based computational modeling (ABM) has been shown to help students reason about the parts and interactions in systems that give rise to observed scientific phenomena at the system level (Klopfer, 2003; Resnick, 1994; Sengupta & Wilensky, 2009; Wilensky, 1999). Using models has shown some benefit (Yoon et al., 2016), and modifying and creating models provides a rich opportunity to engage in both the practice of modeling and in computational thinking (Sengupta et al., 2013; Wagh, Cook-Whitt, & Wilensky, 2017; Weintrop et al., 2016), both of which are essential skills for modern scientists (Foster, 2006). However, our experience and the experience of many other researchers in computational modeling is that teachers are often reluctant to incorporate modeling due to its high startup costs, particularly the cost of learning to "code" (Ertmer & Ottenbreit-Leftwich, 2013; Guzdial 1994; Hsiao et al. 2019).

In a current research project, working with our partners at NYU, we found that students — including English language learners — in a 5th grade classroom were able to use our online ABM tool, StarLogo Nova (www.slnova.org), to create models of microbes breaking down solid food into waste products and gas, conserving the overall mass of the system to match their "landfill bottle" physical models. In post interviews, these students demonstrated systems thinking as they explained the process of modeling the phenomena. They were able to reason more effectively about aspects included in their models than about hypothetical scenarios they had not modeled (Haas et al., 2020), which underscores how important having created the model is to students' ability to make sense of the phenomenon. In this full-year curriculum, the costs can be amortized across a whole year, but many teachers need activities that can be integrated into existing curricula within a more constrained time frame.

We have reconciled the need to address particulars of the curriculum with the desire to build student modeling skills across the year by making changes to the StarLogo Nova platform in the form of "custom blocks." We developed StarLogo Nova to be beginner-friendly, using a blocks-based programming language to reduce the barriers of syntax faced by novices (Klopfer et al., 2009). However, the process of modeling concepts or phenomena from a set of domain-general programming primitives remains challenging (Anderson & Wendel, 2020). Recently, domain-specific modeling languages/environments (DSMLs/DSMEs) have attempted to narrow the conceptual gap between programming language semantics and scientific phenomena (Hasan & Biswas, 2017). For example, whereas StarLogo Nova's modeling language may represent a predator's "hunt" behavior as "face toward nearest prey agent; move forward 1 space; on collision, delete prey and increase my energy trait," a DSML for ecosystems may simply use "chase prey; if I catch prey, eat it".

In science education, these DSMLs are typically implemented as sets of "custom blocks" layered on top of existing primitives in a modeling environment. These blocks are carefully designed by educators to be beginner-friendly, but are typically treated as "black boxes" to shield students from the underlying implementation (e.g. Basu et al., 2013; Wilkerson-Jerde, Wagh et al., 2015). In contrast, in computational thinking/computer science education, blocks-based programming environments engage learners themselves in the process of creating and modifying custom blocks as an introduction to procedural abstraction; Snap!'s previous version was even named "BYOB: Build Your Own Blocks" (Harvey, 2020).

StarLogo Nova's new custom blocks feature aims to combine these ideas. Rather than viewing the custom blocks of a DSML as black boxes to hide underlying complexity, we have intentionally designed StarLogo Nova's new custom blocks feature to capitalize on StarLogo Nova's "blocks all the way down" language architecture, hoping to transform a custom block's underlying implementation from a liability into an opportunity. Because custom blocks can themselves contain custom blocks, we envision and are beginning to investigate a layered abstraction approach, with DSML blocks providing not only a seamless introduction to computational modeling, but also a path to deeper understanding by allowing students to "look inside," reading and modifying code at successively more domain-general (and therefore more flexible and powerful) layers of abstraction as their computational modeling skill grows.

Paper 5: Towards Sustained Computational Modeling: Exploring Strategies to Support Extended Investigations in Middle School Classrooms

Aditi Wagh, Tamar Fuhrmann, Michelle Wilkerson, Engin Bumbacher & Paulo Blikstein

There is now a considerable amount of research exploring how, through design and pedagogy, educators can lower the barrier to computational modeling for young learners. For example, modeling environments that make use of accessible media like block-based (e.g., Klopfer, Yoon & Um, 2005) and/or domain-specific (e.g., Repenning & Summer, 2005; Wilkerson, Wagh & Wilensky, 2017) toolkits ease the technical aspects of programming, whilst pedagogical approaches such as embodied (e.g., Wilensky & Reisman, 2006) and bifocal modeling (Blikstein et al., 2016; Fuhrmann et al., 2018) support conceptual aspects of computational modeling. This research has contributed to our understanding of how to make computational modeling an accessible practice in science classrooms. However, less is known about how to make computational modeling a *sustained* practice in classrooms. By "sustained", we mean engaging in extended investigations using computational modeling.

In this paper, we will describe how our research aims to foster sustained engagement in modeling using data from co-design sessions with teachers and classroom implementations. We draw on two design strategies from the broader scientific modeling literature (Lehrer & Schauble, 2012; Manz, 2015) in which extended investigations with modeling and iterative refinement are part of what students do. We use these strategies in the design of the computational modeling toolkit and the curriculum. The first strategy involves building uncertainty into student investigations through experimental data to create resistances for students to consider, tackle, and

 © ISLS

possibly resolve (Manz, 2015). Tackling such uncertainties together with the use of data can amplify disciplinary ideas while supporting progress along a modeling trajectory. In related work, the authors of this paper have integrated computational modeling with data in order to highlight — rather than dismiss — discrepancies between models and data, bringing noise, uncertainty, and intrinsic differences between them to the forefront (Blikstein et al., 2016). This bifocal modeling approach has been successful in several domains, but for relatively shorter interventions (Fuhrmann et al., 2020). The second strategy we draw on is repeatedly revisiting a small set of disciplinary ideas from multiple perspectives to pursue extended investigations (Lehrer & Schauble, 2012). We envision this as enabling students to construct, deconstruct, and recombine models of related phenomena as well as unpacking blocks and chunking them in ways that can be meaningful for students. We see this as a way to deepen engagement in modeling so as to develop an epistemologically rich perspective on the role of computational modeling in understanding a phenomenon.

In our paper, we report on co-design sessions with three middle school science teachers as they provide feedback on the computational modeling toolkit and refine two curricular activities. Our analysis describes the role that teachers expect the data to play in supporting students' computational modeling activities, and how to support students in coordinating data analysis and model refinement. We also describe how teachers suggest linking across curricular topics, particularly through model construction, deconstruction, and recombination. Finally, we share challenges teachers anticipate in this work.

Shirin Vossoughi, Northwestern University (USA), shirin.vossoughi@northwestern.edu

Abstract: In this symposium, we will reconceptualize our methodologies and research design centering histories in places, bodies, and disciplinary learning. We re-engage in qualitative methodologies that guided us so far yet limited us in fully accounting for the sociopolitical and sociohistorical nature of our research and analyses. This symposium challenges individualized knowledge production and invites the field of the learning sciences to bring forth collective and dialogic figuring and refiguring, co-thinking, and community/solidarity building. Four sets of paired dialogues will defamiliarize familiar methodologies in the learning sciences (e.g., video-based research, interaction analysis, ethnography) toward fuller consideration of power and radical transformation. These paired dialogues will also open new horizons on the role of arts and affect in research from the perspectives of histories in places and in bodies. Collectively, we will revisit the epistemological assumptions that shaped what were rendered visible and invisible in our research process.

The overall focus of the symposium: Historicizing methodologies

Background

The International Society of the Learning Sciences Annual Meeting in 2022 will be held in Hiroshima, Japan – where histories of militarism, war, and colonial violence are still vividly inscribed within people, buildings, and ecosystems even after 76 years since the atomic bomb was dropped. Disciplinary learning, which is at the core of our inquiry in the learning sciences field, is never in a historical vacuum. Learning is "fundamentally cultural, unfolding through multiple pathways that occur in relation to shifting social and contextual conditions, to which humans are constantly adapting" (Lee, et al., 2020, p. xvii). STEM disciplines carry histories of colonialism and militarism and have directly contributed to destroying bodies and places (Philip et al., 2018; Takeuchi et al., 2020; Vossoughi & Vakil, 2018). As we center historicity in our conceptualization of disciplinary learning, we are grappling with a question: How can we account for the ghosts that haunt our historic present (Gordon, 1997). What will the ghosts in Hiroshima speak to us as we reconfigure the portraits of learning, learners, and disciplines in the post-pandemic world?

In our recent scholarship and panel discussions, we have collectively been pushing the field of the learning sciences to interrogate ahistorical epistemological assumptions on bodies, places, and disciplinary learning and calling for fuller accounts on historicity, coloniality and power (Ali, 2018, 2019; Avraamidou, 2020; Davis & Schaeffer, 2019; Marin, 2020; Martins, 2020, Philip et al., 2018, Philip & Sengupta, 2021; Takeuchi, 2021; Vossoughi et al., 2021). Our ISLS 2021 panel, *Expanding Conceptions of Learning: Colonialism, Social Movements, and Possible Futures*, identified some of the edges in our field: a) colonial histories and materiality/notability, b) racialization and discipline across countries (beyond the US), c) learning, freedom and agency, and d) criticality, ethical relations and possible worlds. In one of our dialogues, Audrey Msimanga reminded us of colonial narratives around learning and learners perpetuated upon people in the Global South:

> This local, national, continental and even global narrative that "something is not there" in the African child is often what shapes thinking about education in the Sub-Saharan Africa contexts that I have worked in. It is not unusual for a whole systemic reform or a review of the curriculum, a rethink of pedagogical approaches and/or assessment practices to be framed around just addressing "what is missing" in the learner. What is more, this broader narrative then filters

 © ISLS

> down and bears nasty stubborn babies in the heads of teachers and learners themselves (A. Msimanga, Personal Communication, May, 2021).

How can we, as the field of the learning sciences, shift away from this damaging narrative of deficiency, incompleteness, and insufficiency imposed upon learners under the guise of development and learning?

The field of the learning sciences is dynamically shifting to center learning that happens in the forms of collective resistance and protest (e.g., Special Issue organized by Curnow & Jurow, 2021), of prefigurative relationship-building processes (Uttamchandani, 2021), of multigenerational alliances (Tivaringe & Kirshner, 2021). Despite these shifts, the methodologies we draw from in our field remain largely devoid of full consideration of histories of places and bodies. The taken-for-granted White gaze (Toni Morrison quoted in Paris, 2019) assumed in "ethnography" has largely remained unquestioned. Colonial assumptions that separate human and more-than-human behind interactional analysis (Jordan & Henderson, 1995) have just recently begun to be questioned (Krishnamoorthy et al., 2021; Marin, 2020). How can we reimagine histories of surveillance and inherent power (Ali, 2018) reproduced through video-based fieldworks? Taking account of what is shifting and what remains unchallenged in the field, in our symposium, we aim for critical accounts of histories inscribed in places and bodies by reimagining our methodology. We will collectively re-figure ways in which we might reconceptualize our methodologies and research design as we take histories in places, bodies, and disciplinary learning seriously. Through our symposium, we pose questions to ourselves and to the field of the learning sciences: What kinds of questions do we have to ask for (and of) ourselves to deeply engage in historicity through our analyses and design? How do we re-engage in classic qualitative methodologies that have guided us so far, yet limited us in other ways? How could we reconceptualize our methodologies while accounting for sociopoliticalness and sociohistoricalness in our research and analyses?

In line with learning sciences scholarship focused on communality, justice and design (e.g., Davis & Schaeffer, 2019; Gutiérrez, & Vossoughi, 2010; Special Issue organized by Curnow & Jurow, 2021), we propose this symposium as an intentional shift away from methodological approaches that privilege individualized knowledge production and those that treat disciplines and methods in the field of the learning sciences as settled. In our call to deepen and historicize methodologies, we are drawn to interrogate the meaning and purposes of researcher reflexivity. Traditionally, the notion of researcher reflexivity calls for scholars to name intersectional identities and describe what we see as proximal histories (e.g., to characterize recent interactions and relationships to places and participants). Positionality statements, now a gold standard of qualitative research, may be contextualized by entries in fieldwork journals that are seldom (and never fully) represented in reports of research findings. While this attention to reflexivity represents an important departure from the positivist research stance, this notion of reflexivity does not necessarily invite or demand inquiries into collective histories of experience. Our methodologies may demonstrate an awareness of inter-subjectivity but inadvertently obscure the long and complicated histories that stretch across places, bodies, and time. At the same time, we recognize that important forms of reflection and insights into the relationships cultivated between learning scientists and research participants are sometimes intentionally withheld. We question what counts as disclosable and relevant to the study of learning, when and for whom accounts of identities and methodologies may fall short in capturing the richness of human experience (Bang & Vossoughi, 2016; Philip et al, 2018). Consequently, we seek to analyze, together, methodological efforts to "resist and navigate potentially disempowering social systems" (Lee, 2017, p.x) to include reflections on how our own vulnerabilities (Behar, 1996; Howard, 2020), knowledge, histories (Gutiérrez et al, 2017) and commitments inform what we notice and interpret.

Our ISLS 2021 symposium challenged individualized knowledge production and moved us to collective and dialogic refiguring of the field of the learning sciences. Unlike a traditional symposium that is formed by a set of related yet independent research papers, our symposium will result from our ongoing dialogues as pairs and as a whole group. In preparation for this symposium, we will continue this process of co-thinking and co-figuring by engaging in shared textual reading and paired and group analyses of data. During the symposium, we will extend this co-thinking and co-figuring to the audiences and participants by sharing our unfinished thoughts, our embodied tensions and dilemmas as learning sciences researchers, and inviting contemplations and questions from the audiences.

Description of Each Paired Paper

The first paper critically reflects on the collection and analysis of video data from an ongoing project on land-based disciplinary learning with refugee children. Highlighting moments of youth agentic selection (Ali, 2018), authors explore the subtle agentic moves that children use to communicate what should not or cannot be captured by the camera, in light of the geopolitical configuration of identities (Takeuchi, 2021). Paper two pursues questions about Interaction Analysis (IA) and ethnography by co-analyzing key moments from a community-

based summer program and a collective of improvisational jazz artists and musicians. Findings consider if/how IA can function as a tool for radical transformation and facilitate generative forms of relational praxis (Gutiérrez & Vossoughi, 2010) and accountability. Paper 3 invites a reimagining of the study of affect in the Learning Sciences that includes attention to emotional configurations (Vea, 2020) that emerge over time. Drawing examples from two projects that investigated students' layered sensemaking in STEM, the authors analyze how the felt dimensions of learning can also be viewed as embedded within longer, racialized histories of power. Finally, Paper 4 considers the role of arts-based methods as tools for disrupting narrow, exclusionary conceptualizations of science. Taking examples from projects situated in Brazil and the Netherlands, the authors describe the relationship between the methodological design, youth participation and longstanding issues of colonialism and power in science.

Format of the Symposium

For the symposium, each pair will present methodological insights developed through analyzing empirical data to explore histories in bodies, in places, and in disciplines. Each pair will share portions of their shared analyses salient for rethinking social research methodologies from sociohistorical and sociopolitical perspectives. Each pair will analyze (or reanalyze) data from our ongoing and previous works. In this process, we will defamiliarize familiar methodologies and methods of analyses, and revisit some of the epistemological assumptions that shaped what were rendered visible and invisible in our research process. As a group, we collectively identify some areas where our field may further develop its tools and insights in order to account for histories in places, bodies and disciplines — through research methodology. This session will last ninety minutes, beginning with a five-minute introduction by the session co-chairs. Following, four papers will be presented (15 minutes each). The co-chairs will then facilitate a conversation across the papers for five to ten minutes. We will conclude this session with a fifteen-minute reflection and response on audience comments on the digital white board. We will also allow participants to engage in reflection or ask questions during these concluding fifteen minutes. Recognizing the limitations and opportunities of an online conference symposium, we have decided to utilize a digital white board to allow participants to engage in reflection and response, in real time. A digital white board allows for multiple streams of conversation to happen parallel, as opposed to utilizing a chat window. The whiteboard will include a guiding question developed for each paper as well as an overall guiding question. An example question is: 1) how we might more fully account for, and attend to, what constitutes post-Cartesian "rigor" in data collection and analysis as we attempt to shift away from Eurocentric, Western epistemologies? Over the course of the symposium, participants will be reminded to engage in conversation and response on the digital white board.

Off camera scripts in video research: Histories and politics of visibility

Arshad Ali, Miwa Aoki Takeuchi

Video-based research has been one of the primary research methods being used in the learning sciences (Derry et al., 2010). Video cameras are never neutral records of human activity. Rather, cameras are directed in particular directions to capture specific events, and more importantly, to not capture activity beyond the frame. Be it human, motion detection or algorithmic, the directionality of cameras is not without context, meaning and purpose (Ferguson, 2019). Beyond directionality, cameras themselves often represent a manifestation of the carceral state in the lives and experiences of poor and youth of color (Gregory, 2020). This is especially true for the communities that are under the threat of police surveillance. The presence of video cameras can inscribe traumatic relationships and panopticonic gazes (Foucault, 1980, p. 39) of being seen in public spaces (Ali, 2019). The field of the learning sciences has not fully articulated the histories of construction of Other (Said, 1978) through video-based research, and explored the material and epistemological limitations of this tool. Our dialogue critically reflects on what our research tools, including video cameras, produce and reproduce in the process of the learning sciences research.

We engaged in collective viewing of video data collected by an ongoing research project with refugee families and children's intergenerational wisdom sharing and land-based disciplinary learning in urban farms. The project was conducted in urban farms in the land of Treaty 7 regions during the COVID-19 pandemic and we analyzed video data and fieldnotes collected over 11 visits from August 2020 to September 2021 (each visit lasted 60 to 150 minutes). Video data were collected using a hand-held camera (worn by a researcher and participants), a wearable camera (worn by a researcher and participants), and a smartphone camera of a researcher. In this paper, the authors engage in shared analyses of what becomes visible and invisible in the video data and fieldnotes to each of us, who come with different histories and ontologies.

Our dialogue highlights moments of youth's agentic selection (Ali, 2018) of what should be presented and erased as data in the presence of a video camera. Recognizing the right and potential of participant refusal (Tuck & Yang, 2014), we, together, unpacked subtle agentic moves by young children to show what should and should not be documented in the video data, as well as what cannot be documented, in light of the geopolitical configuration of identities (Takeuchi, 2021). Our dialogue directed us to comparatively look at what was unveiled and hidden between when a video camera was on and off. For example, in the face of racism experienced on historically predominantly white farmlands after colonization, a refugee child from Syria only shared their experiences of racism and verbal and physical attack in the process of shared walks (Lee & Ingold, 2006; Marin & Bang, 2018), without a video camera. Children used a still camera to take photos that euphemistically reflect their racialized experiences, without explicitly explaining them verbally. In contrast, when the video camera was on, children shared the experiences partially, without explicitly naming the details of their experiences. We interpreted these moments of youth's agentic selection as key to interpreting macro carceral contexts and panoptical white gazes (Morrison, in Paris, 2019) and refusal (Tuck & Yang, 2014) for dignity (Espinoza et al, 2020).

Our dialogue through shared analyses raises questions to the field about the role of the learning sciences research in reproduction of surveillance and racialized gaze through video-based research. Our dialogue also identifies moments of youth's reappropriation of video and still cameras to challenge hierarchical relationships on seeing and being seen.

We will conclude our presentation by engaging the panelists and audience in a conversation exploring the significance of off-the-record (Ali, 2018) scripts for learning, and ask how we might more fully account for, and attend to, what constitutes post-Cartesian "rigor" in data collection and analysis as we attempt to shift away from Eurocentric, Western epistemologies.

Relational Ethics, Researchers as Learners and Methodological Futurities

Ananda Marin, Shirin Vossoughi

In what ways can Interaction Analysis (IA) and related ethnographic methodologies seed radical transformation? What role does deep engagement with the histories of bodies, places and disciplines play in such possibilities? We pursue these questions through close engagement with two settings where we participated in co-design relations that preceded and spilled out beyond "researcher" in ways that matter for how we understand the roles of research. We co-analyze key moments from one another's settings to consider how our training in IA and ethnography served as axiologies that shape everyday relations, particularly when shared political and educational work are leading activities and research is reconfigured as a form of learning towards those evolving ends.

In the first setting, ethnographic and interactional methodologies (McDermott & Raley, 2011) were utilized to scaffold teacher learning through careful attunement to pedagogical interactions. Within a teacher residency program that combined university courses on learning and educational justice with guided participation in a community-based summer program serving Black and Latinx middle school youth, the broader study considers the pedagogies and forms of co-teaching that supported teachers to attune to the histories of bodies, places and disciplines in ways that nurtured deep shifts in their ways of being with children. We draw on teacher fieldnotes as well as the dialogic feedback they received from researchers/teacher educators to examine how a novice teacher shifted their own talk and embodied interaction with a student in ways that reached towards an ethic of relationality, racial justice and holistic personhood. This empirical story helps us consider how criticality becomes necessary but insufficient for supporting educators to perceive and construct possible futures in here and now activity (Bang, 2020; Bang & Vossoughi, 2016).

In the second setting, co-design (Ishimaru et al., 2018) and conversational methods (Kovach, 2010; Wilson, 2008) were used as tools to explore how collaborative and improvisational performances become contexts for the microgenetic and ontogenetic development of skills, knowledge, and capacities across time, space, and social relationships. This project invited a collective of five Chicago-based improvisational jazz artists and musicians that routinely perform together and apart in various combinations of ensembles to use the tools of research to engage in and reflect upon their routine activities (i.e., designing and enacting a conversational concert and listening session). We draw on video and transcript data from co-design sessions to examine how genealogy and kinship (Janke & Gilles, 2012) were evoked to create contexts for participants to mobilize research toward their own desired ends — engaging in processes of relationship building through historicizing their own embodied and geographical stories of artistic creation. We consider how material relations (i.e., instruments and artistic tools) not present in the scene are made relevant through processes of remembering and storying, troubling tendencies towards relational dehistoricizing in IA.

 © ISLS

Both studies consider what it can mean to understand researchers as learners who observe to participate and participate to observe in ways that can facilitate a relational praxis (Gutiérrez & Vossoughi, 2010). We consider interactional and ethnographic sensibilities as both scaffolded and endogenous to life (people are always already reading bodies, place, race, gender etc.) in ways that highlight the complex, sedimented layers of everyday activity. We work together to articulate how the growing attention to criticality in the learning sciences might reimagine and reorganize research towards transformative ends, raising questions about anchoring a critical politic (only) in the deconstruction of research as power. Here we draw on Indigenous and Māori centered work on the centrality of kinship and genealogy (Jahnke & Gillies, 2012), as well as ideas of "worthy witnessing" (Winn & Ubiles, 2011) to support relational accountabilities and the co-creation of possible futures.

Studying Affect and Learning through Lenses of Collective Memory, Histories, and Imagination

Natalie R. Davis, Thomas Philip

Research on teaching and learning has long focused on the role of emotions and affect (Boler, 1999; Fredricks et al, 2004; Vygotsky, 1987). Much of this work has explored how emotions serve as a conduit for learning by shaping motivations to learn and participate within communities of practice (Vea, 2020). More recently, scholars have advanced research that (re)considers emotion as a target of learning, and that recognizes the collective, political and ideological understandings represented through affective stancetaking (e.g. Boler & Zembylas, 2016; Curnow et al, 2021; Vea, 2020). While the Learning Sciences has demonstrated a growing interest in examining the affective dimensions of learning, there has been less focus on the methodological frameworks and tools needed to deepen understandings of emotion as situated in collective memory, histories, and imagination.

One of our primary concerns lies in the methodological tendency to overemphasize researcher-observed, individualized, universal and/or discrete constructs for emotion. An exclusive focus on an individual's affective experiences through this lens may obscure the complex relationships between affect, sociopolitical histories and contexts. For example, traditional ethnographic methods and discourse analysis are less likely to provide insight into affective experiences of learning that are not overtly expressed in the body at present or articulated aloud (Parks, 2020). Outbursts are documented but more subtle felt understandings tied to histories of power and race often drop out of our analyses. This may inadvertently suggest that learning only carries emotional valence at particular moments in time and in direct response to recent stimuli. Classical methodological approaches may also de-emphasize the racialized, gendered and/or aged experiences of learning to negotiate, subdue or internalize emotions in educational contexts. How do we account for the felt dimensions of learning that may be discerned in interaction while also interrogating if/how/when full emotional expression is constrained or otherwise less visible? As an alternative to decontextualized and individual assessments, the lens of emotional configurations helps us name and study the "situated and reciprocal interrelationships between feeling, conceptual sense-making, and practice that give emotion social meaning in the learning of individuals and collectives" over time (Vea, 2020).

In this paper, we revisit comparative cases from our individual work focused on ethics, historicity, politics and STEM learning. The first case draws data from a project that investigated Black children's layered meaning making during a classroom unit on water (Davis & Schaeffer, 2019). This work centered analyses of the socioscientific and felt dimensions of learning about water justice, a topic which can also be viewed as layered and embedded in longer, racialized histories of power. The second case explores undergraduate students' sensemaking in an engineering ethics class focused on militarized drones (Philip et al., 2018). The re-analysis presented here situates the localized manifestations of affect within the broader historical memories and ideologies of colonialism, imperialism, and nationalism. Looking across our own research, we consider the methodological openings and tensions inherent to work focused on affect, learning and justice. Applying the lens of emotional configurations and Gordon's (1997) notion of haunting, we look closely at textual and visual data to determine if/how they might serve as a window into collective histories of sociopolitical striving and human suffering.

Our findings raise questions about how we represent and study affective experiences in spaces of learning. Where the learning sciences has in large part focused on how individuals feel, our analyses suggest that collective longings for justice, imagination and shared felt experiences also co-construct learning in important ways. In the case of the water justice example, Black children's strong emotional responses to and learning about the Flint water crisis were also connected to their layered understandings and awareness of racism. We conclude with ideas for how researchers might become more methodologically attuned to collectivity and histories while also attending to the nuances of affect in moment-to-moment activity.

Arts-based methods in exploring issues related to power and colonialism in science participation

Lucy Avraamidou, Isabel Martins

Our purpose in this paper is to argue about both the need and the value for disrupting specific conceptualizations of the nature of science (i.e., white, heterosexual, middle-class men with superior intellect producing absolute knowledge in an isolated, culture-free, and methodical way) through capitalizing on ethos: scientific knowledge should be accessible to all members of the scientific and social communities to use. Toward this goal, we will engage with the following questions: a) How have understandings of the nature of science contributed to conceptualizations of who can be a scientist and who is recognized as a scientist? b) How are these understandings tied to issues related to power and colonialism in science education, c) How have these conceptualizations contributed to producing exclusionary narratives and perpetuating inequalities in science? d) How might arts-based methods be used to explore issues related to power and colonialism in science participation?

In exploring these questions, we draw from research projects carried out in the context of the Netherlands and Brazil and provide empirical evidence of how various arts-based methods (e.g., narrative production, life stories, photovoice products, writing and poetry) were used to explore issues related to power and colonialism in science participation in the context of after-school science programs with young children.

The first research project is situated in the Netherlands and examines the ways in which out-of-school, STEM community-based programs might serve as a means for disrupting monolithic conceptualizations of the nature of science and existing exclusionary narratives of who is considered a legitimate producer of scientific knowledge (Avraamidou, 2021). This is especially important in former colonial contexts, such as the Netherlands, which, unlike other European countries lags behind in processing its colonial past across educational institutions (Wekker, 2016). Hence, the out-of-school program, theoretically framed in Culturally-Relevant/Sustaining Pedagogies, aims to serve a group of young children with a migration background. The project comes as a response to the urgency and value of engaging with a set of underexplored questions that relate to issues of colonialism, power, and racism, in science education in the Netherlands.

The Netherlands is used as an example of a country with a colonial past, in order to make the case for the urgency and value of addressing goals related to social justice in education. This interest is rooted within the fact that the community of educational researchers, especially in the area of STEM education, have remained largely uninvolved with research that examines issues related to access, inequality, colonization and equity.

The second research project is set in Brazil, a country where race relations have been shaped along almost four centuries of slavery of Black populations who were brought by force from Africa. For Gomes (2003), one of the challenges faced by Black populations in Brazil is "to build a positive Black identity in a society that, historically, has taught black people from very early on that in order to be [socially] accepted, it's necessary to deny their own identity" (p. 171). In 2003, following years of claims by social movements, a federal bill made the teaching of Afro-Brazilian and African History and Culture compulsory in Brazilian Basic Education. Although authors like Santos and Neto (2011) acknowledge that the school alone will not be capable of reversing years of disqualification of the black population and consequent social injustices, several efforts have been made to reinforce the role of schooling in fighting against racism and overcoming prejudice (Verrangia 2014). The project analyses the efforts of a community of learning which gathers university researchers, pre-service and in-service teachers, and research students in order to develop contents for a website that explore approaches to racism in the science curriculum. Contents are organized as Questions & Answers which address issues such as: social media algorithms that select and erase images of people according to phenotypic aspects; ways through which structural racism in Brazil shapes social and professional relations in science; expressions of scientific racism concerning health rights of the Black population, amongst others. Analyses explore transdisciplinary contributions to the understanding of racism and its curriculum representations as well as ways to fight it.

Abstract: This double symposium brings together activity-theoretical formative intervention research conducted in six continents. The aim is to illuminate and examine the common threads, important differences, and new challenges of formative intervention studies to address "wicked problems" in different cultural, political, and economic contexts. Formative interventions facilitate expansive learning and systemic transformation led by local stakeholders in organizations and social movements. The formative intervention methodology is based on the principles of double stimulation and ascending from the abstract to the concrete. Its most well-known application is the Change Laboratory method. Formative interventions generate and support expansive learning and transformative agency. The current global crises of climate change, poverty and deepening inequalities are giving rise to what is called fourth generation activity theory for tackling fateful challenges by building heterogenous multi-activity coalitions. The symposium will present the theoretical and pedagogical challenges and possibilities in Change Laboratories and other formative interventions to develop just and sustainable solutions to global crises.

Symposium Overview

This double symposium brings together activity-theoretical formative intervention research conducted in six continents. The aim is to illuminate and examine the common threads, important differences, and new challenges of formative intervention studies in different cultural, political, and economic contexts. The methodology of formative interventions is based on the principles of double stimulation and ascending from the abstract to the concrete (Engeström, Sannino & Virkkunen, 2014; Sannino, Engeström & Lemos, 2016). Its most well-known application is the Change Laboratory method that has been used in more than 30 countries since its inception in Finland in the 1990s (Engeström & al., 1996; Sannino & Engeström, 2017; Virkkunen & Newnham, 2013). Formative interventions generate and support expansive learning (Engeström, 2015) and transformative agency (Sannino, 2020b). The current global crises of climate change, poverty, and racial inequality are giving rise to what is called fourth generation activity theory for tackling fateful challenges by building heterogenous multi-activity coalitions. This is reflected in recent developments in Change Laboratories and other formative interventions. The symposium will present and discuss these developments and seek ways to conceptualize them.

In learning sciences, it has been suggested that formative interventions might be a way to overcome the limitations of the linear interventions and expand design-based research regarding engaging local stakeholders in the design, implementation, and analysis of interventions (Gutierrez, Engeström, & Sannino, 2016; Penuel, 2014; Sannino & Engeström, 2017). Change Laboratories and other formative interventions offer new possibilities for rigorous analyses of intensive processes of collective learning, agency formation and design. Methods developed for systematic analyses of formative intervention processes allow for comparisons between interventions conducted in different circumstances. The symposium presentations will examine a range of methods used in such analyses.

The six papers of the double symposium are those of (1) Yrjö Engeström (Europe), (2) Annalisa Sannino (Europe), (3) Aydin Bal (North America), (4) Marco Pereira Querol (South America), (5) Heila Lotz-Sisitka (Africa), (6) Ge Wei (Asia), and (7) Nick Hopwood (Australia). Together the papers offer a rich set of detailed case analyses of Change Laboratories and other formative interventions from the six continents.

 © ISLS

The authors of the papers will elaborate specifically on the following questions from the perspective of their own continents:

- What are the challenges and needs for which formative interventions pursuing fourth generation activity theory might be particularly useful and relevant?
- What theoretical and pedagogical challenges and possible new developments might be identified in the methodology of formative interventions?

Paper 1: Formative Interventions in Theory and Practice: Change Laboratories across the Globe

Yrjö Engeström, University of Helsinki, Finland

This introductory paper of the symposium reviews and discusses the basic theoretical and methodological tenets of formative interventions. It presents the preliminary results of a comprehensive literature review of studies on Change Laboratory interventions conducted in different parts of the world. The Change Laboratory is a formative intervention method based on cultural-historical activity theory and the theory of expansive learning. Committed to serving struggles for equity, social justice and sustainability, the Change Laboratory was developed and first implemented in 1995 in Finland. Grounded in dialectics and the Vygotskian theoretical tradition, its uptake has been demanding and only quite recently it has reached the point of accelerated international adoption. By now the Change Laboratory has been used in over 30 countries in educational institutions, workplaces, and communities to generate bottom-up solutions to challenging problems and complex transformations. At this point, about 250 publications on Change Laboratories have been identified. This growing body of research s warrants a careful and comprehensive review.

Paper 2: Change Laboratories of the Fourth Generation: Interconnected Interventions for Eradicating Homelessness in Finland

Annalisa Sannino, Tampere University, Finland

Fourth generation activity theory (Engeström & Sannino, 2021) emerges largely through formative interventions that support the creation and development of heterogenous coalitions focused on critical societal challenges and "wicked problems." Whereas the early implementations of the Change Laboratory method were focused on contradictions and transformations in single relatively well-bounded activity systems (Engeström et al., 1996), fourth generation Change Laboratories bring together actors from different activity systems, from grassroots practitioners and activists to administrators and decision-makers across sectors and levels of governance.

The first full-scale effort at this type of Change Laboratory intervention was conducted in 2018 and 2019 in Finland, to support the effort to eradicate homelessness in the country. Three interconnected Change Laboratories were conducted, the first one in a supported housing unit for formerly homeless young people, the second one in the city of Tampere, and the third one at the national level. A large number of NGOs, public sector service providers and agencies, cities, and ministries participated in the city level and national level Change Laboratories. However, the first intervention in the housing unit became a reference point and source of energy for the subsequent city level and national level laboratories (Sannino, 2020a; 2020b).

In fourth generation activity theory studies, multiple coalescing expansive learning cycles need to be nurtured and analyzed. In this paper, we will examine connections and interactions between the expansive learning cycles of three Change Laboratories. All the six sessions of each Change Laboratory were video-recorded and transcribed. We also recorded a number of interviews with participants and homelessness experts. In addition, each Change Laboratory produced a document detailing the solutions and suggestions designed in the intervention. This extensive dataset will be analyzed to answer the following questions:

1. What kinds of connections and interactions may be identified between the expansive learning cycles induced by the three Change Laboratories?
2. How were these connections and interactions related to the different expansive learning actions (Engeström, Rantavuori & Kerosuo, 2013) and to the different steps in the formation of transformative agency by double stimulation (Sannino, 2015; 2020a; 2020b; Morselli & Sannino, 2021)?

Paper 3: Inclusive Future Making to Address the Racialization of Behavioral Problems in Schools

Aydin Bal, University of Wisconsin-Madison, USA

This paper presents the Culturally Responsive Behavioral Interventions and Supports (CRPBIS) Project and a multisite longitudinal formative intervention study, Learning Lab, that aims to examine and disrupt the

racialization of behavioral problems with local stakeholders, especially those from racially minoritized communities who have been historically excluded from schools' knowledge-production and decision-making activities.

Disproportionality in behavioral outcomes is a historically accumulated systemic contradiction that requires systemic solutions led and owned by local stakeholders (Bal, 2018). The CRPBIS Project was initiated in 2011 in the state of Wisconsin as a strategic family-school-community-university coalition and funded by the state's education agency, districts, civic organizations. An inclusive knowledge-production and systemic design process, Learning Lab, has been implemented in public schools in the United States (U.S.) and Brazil facing racial disparities in school discipline. Learning Lab is informed by Cultural-Historical Activity Theory (CHAT), critical pedagogies, and decolonizing epistemologies (Cole, 1996; Engeström, 2016; Freire, 2000; Ladson-Billings & Tate, 2006; Smith, 2021). Learning Lab is a formative intervention in which local stakeholders work collectively to transform their systems through articulation, examination, and resolution of contradictions. The role of the interventionists in formative interventions is to stimulate a transformation process (Gutierrez et al., 2016).

Learning Lab has been implemented at 12 schools: Two elementary, seven middle, and two high schools in four districts in Florida and Wisconsin in U.S. and one K-12 special education school in Rio, Brazil (Bal, 2016; Bal et al., 2018; Bal et al., 2021). Leaning Labs informed each other. Learning Labs included 10-15 stakeholders, especially those who were historically excluded from schools' problem solving and decision-making activities. Learning Lab united students, parents, community members, teachers, support staff (e.g., social workers, and playground attendants), administrators, representatives of civic organizations (e.g., Urban League, Centro Hispano) and the university researchers. Following a cycle of expansive actions (Engeström, 2016), members started identifying daily manifestations of the contradictions in their schools related to discipline and analyzed their existing discipline systems and its outcomes. Then, they designed new behavioral support systems to address those contradictions. The new systems were culturally responsive to their school communities' diverse experiences, resources, interests, and goals. The new systems are implemented in the next academic year.

Data were generated through video recordings of meetings, interviews, and document analysis. The method of analysis of expansive actions (Engeström et al., 2013) and the emergence of transformative agency (Sannino, 2015) were utilized.

This paper presents the design principles of the Learning Lab as an example of fourth generation CHAT (Engeström & Sannino, 2021). The session will contribute to the learning sciences by demonstrating how local stakeholders and organizations with diverse and often opposing interests and histories built heterogenous coalitions that collectively generated knowledge about racial disproportionality and designed the future of their schools for justice, joy, and expansive learning for *all*.

Paper 4: Formative Interventions for Re-integration of Adolescents in Conflict with the Law

Luciana Pena Morgado, Rodolfo Andrade de Gouveia Vilela, Marco Antonio Pereira Querol

Change Laboratory has been increasingly used in Brazil as a method for developing work in multiple activities (Vilela et al. 2020). For instance, it has been applied in developing the activity of children labor prevention (Donatelli et al. 2020), public health (Masiero, 2018), education (Cenci et al. 2016; Silva-Macaia et al. 2020), railway transport (Lopes et al. 2020), urban cleaning service (Bobadilha, 2020), waste management (Cassandre et al. 2018), agroforestry (Francisco Junior, 2018), airport construction (Lopes et al. 2018), and labor inspection (Vilela et al. 2018) among others.

The study presents a Change Laboratory intervention implemented for developing activities involved in the re-integration of Adolescents in conflict with the law (Morgado, 2018; Morgado et al. 2020). The initial problem that led to the demand of the intervention presented in this study was the recurring episodes of violence in which security guards and adolescents were involved in a cycle of violence. The intervention took place in a Re-integration Center located in Campinas, Sao Paulo State, Brazil. In the study, we will present how the method of double stimulation was used to produce transformative agency and expansive learning. The data is composed by 30 hours of transcription of videos of 14 sessions, lasting two hours each, which took place between August 30, 2018, and April 30, 2019. During the sessions, with the use of double stimulation, practitioners expanded their conception of the problem and causes of violence, formulating a hypothesis of the main contradiction between the object of social workers (to re-integrate by education and psychological assistance) and the object of the security guards (to imprison using violence). With the help of models as second

stimulus, workers designed, tested, and implemented a germ-cell - a new model for the activity that integrated both objects. They developed a boundary crossing tool, what they called an "Qualified Case Discussion", in which the family of the adolescent, the security guard, the social workers, psychologists and pedagogues jointly constructed the trajectory of a young. The main developmental challenge now is how to expand the new model to other units of the institutions and to the high management.

Paper 5: @River Commons Formative Intervention: Scaling Citizen-based Water Quality Monitoring in South Africa

Heila Lotz-Sisitka, Rhodes University, South Africa

Fourth generation CHAT research and its concern for poverty and climate change responsiveness via expansive learning and transformative agency (Engeström & Sannino, in Yamazumi, 2020) is immanently necessary in South Africa, the 30th driest country in the world where we are experiencing a persistent crisis in water resources supply and quality management which affect the poor most severely. This crisis intersects with a historicity of apartheid state infrastructure marginalization, and contemporary mass failure of wastewater treatment plants and associated monitoring capacity. Coupled with regular climate change induced droughts, this manifests as a cultural-historical-ecological wicked '@RiverCommons' problem of long durée. It induces an urgency to learn and act in and for equity and sustainability in a context where a history of racism and exclusion has left up to 60% young people unemployed. Involved in the '@River Commons' 4th generation CHAT inspired formative intervention processes (Engeström & Sannino, 2021) are policy actors, intermediary institutions, and citizen-based water quality monitoring (CBWQM) groups operating in an intersecting, multi-levelled system of heterogeneous coalitions (HCs). Currently this is involving the following HCs:

A tertiary form of heterogenous coalition (HC) involving: the Department of Science and Innovation, the Water Research Commission, Ecological Infrastructure for Water Security coalitions, business partners, major NGOs, national educational institutions, and the Presidential Employment Stimulus Programme

Secondary form HCs - Hosting organizations and graduates: River Rovers (supporting the Enviro-Champs) and Data Detectives (translating the data from the mobile data monitoring application into tools for 'management into action' and 'agency for river health' activity, amongst others), all working in support of CBWQM river monitoring activity.

Primary HCs involving unemployed youth and their communities, community organizations, traditional leaders and local government partners who monitor and report on river health at local levels in and across catchments.

All are engaged in expansive learning cycles that seek to address a pernicious policy-praxis contradiction that promotes CBWQM, but which fails to support it pro-actively on all fronts.

The '@RiverCommons' formative intervention is taking place as we speak – to date over the past four years, continuing into the present. Led by a coalition of active partner organizations operating within and between diverse HCs; expansive learning cycle(s) and transformative agency via double stimulation processes have been catalyzed along HC learning pathways that focus on different aspects of generatively 'scaling' CBWQM activity along a differentiated CBWQM value chain. Mirror data and double stimulation tools have been generated through historical and ethnographic data that includes reviews of CBWQM practice, survey data involving 60 CBWQM HCs, analysis of research and evaluation reports, questionnaire data, and in-depth policy contradictions analysis as well as workshop data.

Four adapted change laboratory interventions or 'national workshops', involving intersecting actors from the 3 HCs, with smaller scale less formal Change Laboratories involving multi-actors (at times online due to COVID-19) in-between the 3 main CLs, were catalyzed and documented, with more emerging. Diverse aspects of generative forms of 'scaling' CBWQM activity have, so far, been advanced with different HCs along expansive learning pathways, and via cross over Change Laboratories involving all HCs. The 'old' activity of voluntary CBWQM using a limited scope of tools has been extended to a youth employment initiative developing a 'work for the common good and learn for the future' approach to CBWQM that embraces equity and sustainability principles *at the same time*, using a wider range of tools, but which still needs to be more fully institutionalized and embedded in national systems of education, training and work. The '@RiverCommons' formative intervention work is therefore still in progress but is shaping emergence of ethico-politically inspired emancipatory agency from below for scaling of CBWQM '@River Commons' in settings where equity and sustainability must be engaged at the same time. Elaboration of the focus on emergent ethico-political emancipatory agency across HCs offers a new perspective on CHAT research, especially in its emergent fourth generation.

Paper 6: Developing Pre-service Teachers' Practical Knowledge through Formative Interventions

Ge Wei, Capital Normal University, Beijing, China

Practical knowledge is critical for the professional development of teachers, and the development of such knowledge in advance is important in initial teacher education (ITE). However, very little research has so far been undertaken to uncover the evolutionary process through which the components of such practical knowledge are acquired. By conducting a longitudinal interventionist study in a Chinese Normal university during the 2017-2018 academic year, this paper helps improve the understanding of how pre-service teachers (PSTs) develop their practical knowledge through interventions made by more experienced external parties (e.g., school and university mentors). Through the 13-month period of formative interventions, we examined a series of changes in PSTs' practical knowledge through their performance in a mandatory learning module, *Curriculum and Instruction* (which includes two courses and seven credits), in a bachelor-level ITE program.

Drawing on expansive learning theory (Engeström, 2015), we explored a multi-cyclical learning trajectory of theory and practice during the interventions. The results showed that the seven expansive learning actions functioned as analytical tools to map the PSTs' learning, while several deviations, disruptions, and practical actions of design during the process were revealed as well. Moreover, knowledge components of PSTs' practical knowledge have various manifestations in different sessions of intervention.

This study is a response to the historical crisis of the theory–practice schism in teacher education. In contrast to a linear input-output teacher training method, formative interventions facilitate the development of PSTs' practical knowledge through active engagement, self-inquiry, and a 'heterogeneous coalition' (Engeström & Sannino, 2020) between PSTs, teacher educators, and potential knowledgeable others. This study proposes a new research agenda for the transformation of ITE program through the activation of PSTs' professional agency in formative interventions. Meanwhile, it contributes Asian experiences and reflection to the methodology of interventionist studies in an uncertain times.

Paper 7: Developing Equitable and Engaging Pedagogies in Nepalese Classrooms through a Cross-national Pragmatic Formative Intervention

Nick Hopwood, University of Technology Sydney, Australia

This paper addresses the questions of this symposium with reference to a collaboration between education researchers in Australia and teachers and teacher educators in Nepal. What are the current challenges and needs for which Change Laboratories and other formative interventions pursuing fourth generation activity theory might be particularly useful and relevant? What theoretical and pedagogical challenges and possible new developments might be identified in the methodology of formative interventions? In this case, challenges related to (1) aiming to deliver long-term change but having only limited time for direct collaboration; and (2) constraints in the Nepali education system that created contradictions between participants' desired pedagogies and those that seemed possible. The formative intervention needed to develop means to enact high quality pedagogies that cost little or nothing in money and time. The paper reveals how pragmatic variations to Change Laboratories can uphold foundational principles while also adapting to contingencies of complex international collaborations and challenging pedagogical environments.

Starting points: frustrated pedagogical ideals

Many teachers and teacher educators share a common frustration: that the pedagogies that wish to see enacted in classrooms do not materialize. We need to identify historically accumulated contradictions in activity systems that lie at the roots of these difficulties. In countries such as Nepal, these contradictions originate in colonial influences on formal education, and continued inequalities of wealth. Today, teachers are charged with delivering a curriculum that is heavy with content, often in crowded classrooms, often in a language (English) that is not the language students speak at home. Cultural values and norms also shape what teachers do in the classroom, and thus may contribute both to the development of contradictions, but also ways of breaking away from them.

The intervention

A formative intervention study was conducted that resulted in a significant change in pedagogies across a whole school in Kathmandu. It was part of a collaboration between the University of Technology Sydney, Kathmandu University and Tribhuvan University in Nepal, The Royal University of Bhutan, a Nepalese

 © ISLS

educational NGO, and teachers from schools in Nepal and Bhutan. A group of 14 teacher educators and teachers spent two weeks in Sydney, and then continued the process of change upon return home. Inspired by the Change Laboratory (Engeström et al., 2014), mirror data were collected to enable participants to gain reflective distance and see themselves as agentic actors (Virkkunen & Newnham, 2013): closely discussing practice and using artefacts to identify problems and question the status quo (Bal et al., 2021; Morris et al., 2021). A key contradiction was identified: a desire to engage learners more, more interactively with each other, and more equitably (particularly concerning female and less high-achieving students) vs didactic approaches that became a default for teachers concerned to deliver content in a short amount of time (where student engagement tended to be limited to higher-achieving boys who would volunteer to answer teacher questions, and there was otherwise little student-student interaction).

The outcomes

Participants developed a suite of eight principles: new mediating artefacts to reshape classroom practice. Crucially these were viewed as being low-or-no cost materially and in terms of time. These were: growth, playfulness, liveliness, designing for praise and appreciation, setting up for success, inclusiveness, journeys between concrete and abstract, and stories. Two teacher educators from Kathmandu University applied these principles through the idea of micro-projects. They took this idea back and worked over several years with a nearby school – Creative Academy. Micro-projects began as a germ cell, a compressed idea that ascended and expanded into diverse concrete forms (Engeström, 2020). It was a practical idea that could embody the eight principles. Over time, a micro-projects group formed in the school, and their use spread across curriculum areas and grades, first across the primary school and then into the secondary school.

Insights

Micro-projects became firmly embedded in pedagogies in Creative Academy, representing a significant transformation. This became possible through expansive learning, prompted by the formative intervention. However, tracing ways in which the object expanded reveals how this process relied on principles that have long underpinned Change Laboratories, but which diverge significantly in their concrete, pragmatic manifestation. This suggests a helpful openness in CHAT-inspired formative interventions, showing their adaptability in the face of distinctive challenges presented by contextual needs and constraints.

Abstract: This symposium questions a basic assumption in the research and design of embodied learning environments: that the embodied forms of participation we design for will always be taken up as good and desired by participants. Across five papers, we reflect on our own design work across various contexts to think about how embodied learning spaces have and can invite embodied forms of participation that engage learners in meaningful participation while also affirming their dignity and human becoming. Across our work we seek to understand how learners' dignity intersects with embodiment. Together our research offers new directions in embodied methodologies and the design of embodied technologies and activities.

In the last decade, researchers and practitioners in the Learning Sciences have championed the embodied foundations of learning (e.g., McDermott & Pea, 2020; Nathan, 2022), leading to improved understandings of the role of embodiment in various settings (e.g., Vossoughi et al., 2020), the development of frameworks and technology-mediated learning environments that leverage learners' embodied actions to foster new learning (Abrahamson & Lindgren, 2014; Danish et al., 2020), and the description of embodied pedagogies that can broaden learners' pathways for understanding complicated concepts, particularly topics in STEM (DeSutter & Stieff, 2017). However, a tacit assumption in the majority of this work is that learners are willing and desire to participate in such physical and visible ways. While the affordances of leveraging embodied resources for sense-making are well documented, designing embodied learning environments without attending to the lived embodied experiences of learners and their "linguistic and cultural-historical repertoires" (Gutiérrez & Rogoff, 2003, p. 22) can reiterate deficit perspectives of learning and diminish opportunities for dignity affirming educational experiences. By dignity affirming educational experiences we are referring to the ways we position learners to have meaningful and substantive interactions with learning materials that also affirm their personal identity and cultural and moral sensibilities (Espinoza et al., 2020). Dignity and learning are inextricably linked. The ways that educational environments sanction certain forms of participation within them can either legitimize or delegitimize learners' sense of worth. This is particularly important to attend to in embodied learning environments because the body is not just a source of intellectual activity, the humanizing and dehumanizing experiences of the lived body also impact cognition (Bustamante et al., 2019). Therefore, as educators designing for embodiment, we must attend to learners' repertoires of practice in order to honor learners' participation rights and affirm their educational dignity (Espinoza et al., 2020).

The goal of this symposium is to initiate dialogue on how we currently create embodied learning environments, and how we might do so in ways that increasingly honor learners' repertoires of practice and offer them dignity-affirming educational experiences. To explore this issue, this symposium brings together researchers involved in designing embodied learning environments to present a range of examples in which they have asked the following question of their work: *How can we invite learners to participate in embodied learning experiences in dignity-affirming ways?*

 © ISLS

The first two papers discuss the use of embodied pedagogies in classrooms showing ways to honor learner dignity through movement. The next two papers discuss the design and implementation of embodied Mixed Reality platforms providing methodological guidance for future designs. The fifth paper draws from trauma-sensitive instruction and offers principles for developing inclusive instruction in embodied activity. Taken together, these papers take a critical look at embodied learning and offer suggestions for revising research methodologies and technology design that can move us forward toward building dignity affirming embodied learning environments.

The symposium will be organized as follows: (1) Co-chairs will share a brief introduction introducing the themes and issues to be discussed (3 min); (2) each project will present (10 min); (3) the discussant Molly Kelton will examine themes and juxtapositions across the papers with an eye toward how affirmations of dignity require us to re-consider common assumptions made in the field about learners' bodies and their experiences of embodied designs; (12 min); (4) we will take questions from the audience (10 min).

The Relationality of Theatre Games: How Undergraduates "Warm-Up" to Embodied Learning

Lindsay Lindberg, Ananda Marin, Andrea Kern, Marjorie Faulstich Orellana

Despite movement being beneficial for learning (Nathan, 2021), the majority of learning experiences in the academy are sedentary (Barbour, 2004). In order to combat this sedentary bias, learning activities must be designed carefully to accomplish engaging embodied learning practices. This paper describes the importance of allowing university students the opportunity to physically engage with "warm-up" activities as preparation for the physical and cognitive practices of embodied learning.

Leading work in the Learning Sciences has called for research that values new forms of relationality as outcomes of learning (DiGiacomo & Gutiérrez, 2016; Vossoughi et al., 2020), expanding what it means to take changes in participation as evidence of learning (Lave & Wenger, 1991). Warm-up activities provide an analytic opportunity in which this change in participation is visible over a short period of time as participants move from seated and still, to moving and active. Warm-ups in the performing arts are often used for participants to attune to both themselves and to the rest of the group. A warm-up invites participants to attend to themselves and move in a way that is safe and comfortable for them, and also begin to shift their attention to a learning community that is larger than themselves. As learners gain an intrinsic perspective of the group they constitute together, we are able to see the ways that moving becomes consequential for their learning (Hall & Jurrow, 2015). This shift in attention is both conceptual and physical, and can be brought about in part through a series of warm-up exercises.

We present data from one multi-year ethnographic project attending to undergraduates in a college course and a student-centered after school program for K-5th grade students. Using video data from three lessons in which a theatre artist guided a group of 30 undergraduates through warm-up exercises, we highlight one warm-up activity: "pass the clap." This activity consists of participants working together to "pass" a "clap" around a circle (person 1 makes eye contact with person 2 on their left before clapping simultaneously; person 2 then turns to their left and claps with person 3, and so on). We present examples of how a theatre warm-up provided the opportunity to guide participants from an "I" centric view to a "we" experience of a learning environment.

Within "pass the clap," new relations emerged as participants learned the rules and played the game. Empathy and trust are important sensibilities to cultivate in learning environments, and are commonly absent from traditional learning contexts (Cooper, 2010), but are deemed essential and normative in theatre and arts classes (Cummings, 2016). A sense of empathy can be developed through warm-up activities, including "pass the clap." When the claps were not completely synchronized (1 beat), but were syncopated (2 beats), the theatre artist introduced a concept she called "oops - ta da!" which celebrated "mistakes" (like a syncopated or "dropped" clap) and turned them into cause for celebration. If a clap was "dropped" the rest of the class would theatrically say, "oops". The two people clapping would say "Ta Da!" and everyone would clap to celebrate the moment. This practice provided new forms of relationality for students to engage with, and allowed mistakes to be viewed as positive opportunities for growth, empathy, and resilience. In this analysis, empathy is important in that the theatre artist guided the participants to express empathy for themselves as well as for their peers. By taking a group of undergraduates in an educational theory class from seated desks to standing up, clapping, laughing, and making eye contact, the theatre artist used warm-up games to develop new relations and build empathy between participants through a warm-up activity.

These viewpoints-inspired (Bogart & Landau, 2005) theatre workshops supported the development of intercorporeality (Meyer et al., 2017), or a sense of *withness*. Hahn and Jordan (2020) argue that evidence of intercorporeality is a change in participants' identities from "I" to "we". Embodied anticipations begin to stabilize as reciprocal responsibility develops, which also supports empathy and intercorporeal trust. We see this in the

analysis of "pass the clap" as over time, participants shifted their participation strategies - they leaned forward to "catch" the clap, and collectively worked to build a community. Analysis of the students' movements through the space and physical participation in the warm-up showed a developed sense of *withness*, and a substantial repertoire of language and body practices for engaging with this undergraduate course. This broadens conceptualizations of what embodied learning can look like and result in with young adult learners.

This attention to embodied learning and the role of warm-up practices on learning communities signifies "an epistemological and pedagogical shift and draw[s] attention to bodies as agents of knowledge production (Wilcox 2009, 105)," (Wagner & Shahajhan, 2015). Expanding possibilities in higher education through studying physical warm-ups from an interactionist and embodied perspective highlights how individuals' movements can be understood in relation to the whole group activities. Designing embodied practices that are physically and socially accessible to participants is one important way to work towards pedagogy that addresses questions of power, oppression, and privilege (Wagner & Shahjahan, 2015).

Pedagogical challenges raised from science teachers about inviting adolescents in mixed classes to experience full body exercises

Roni Zohar

I developed and investigated an *Embodied Pedagogy for Teaching and Learning Physics* in doctoral research carried out under the guidance of Abrahamson and Eylon (Zohar, 2018). (https://www.youtube.com/watch?v=oLCTJQ-GCLQ). This pedagogy coheres with the embodiment paradigm which impacted educational research (Nathan, 2021). The central principle of this approach is to enable the learners to *physically experience* before using definitions or verbal explanations. "Experience first, signify later." (Abrahamson & Lindgren, 2014). Our assumption is that actual physical experience can be used as a unique resource for learning complex concepts in physics by associating them with daily body activities. The pedagogy involves physical-dynamical engagement such as directed bodily experiences (informed movements); improvisation in movement mediating between imagination and reasoning, body actions and feelings; techniques combining walking and talking; selected aspects of the Feldenkrais method and relaxation (Zohar et al., 2017). In this pedagogy, students work either in pairs or collectively on a choreographic task that gives rise to difficulties of coordinating movements. We argue that solving the coordination problems and expressing explicitly these solutions create significant learning opportunities.

The research was done in a 10^{th}-grade high school for female students (two dance classes and one physics class). We conducted the lessons in the school dance studio using *embodied pedagogy*. Through two case studies, We explored the potential of this pedagogy for learning two complex physics concepts: balance and angular velocity. We found that the students exhibited creativity and a profound understanding of the abstract concepts taught. They linked the ideas to concrete representations, to their personal world and to their private interests. The depth and insight of physics understanding that the students manifested in their summative projects were much beyond what can be achieved in regular instruction (Zohar et al., 2017).

After the doctorate research, I conducted a professional development workshop for science teachers and supported them to implement the *Embodied Pedagogy* in middle and high school classrooms. The following paragraphs depict different ways science teachers responded to the *Embodied Pedagogy* in the context of certain exercises and topics unrelated to the concepts of balance or angular velocity.

Teachers raised issues regarding the implementation of certain full-body exercises among students. For example, in one of the movement exercises for release and concentration, we raised our arms and, in the summer, where there are odors from the armpit area, students asked the teacher not to do the particular exercise. In addition, some female teachers decided not to do other movement exercises involving tapping on the armpit.

Another example is the embarrassment that some students had in pairs or group exercises that require physical closeness or touch. We should be aware that the students will naturally stand next to their friends or next to whom they are attracted to. Science teachers raised this issue in the context of teaching the concepts of attraction and rejection in chemistry and electric current in physics in which students resemble particles.

Adolescents are in a challenging time in many ways and body image and appearance are very important to them, especially when they learn in mixed classes of males and females. There is considerable debate in the literature concerning the issue of teaching adolescents in single-sex classes (Frances, 2011). As illustrated in the examples above this may be a central issue in learning that is carried out in embodied learning environments (especially with full-body). From my experience as a researcher, educator and dance & improvisation instructor, it is important for instructional designers to be sensitive to students' age and cultural settings and conduct such learning in a single-sex classes. My recommendation for the mixed classes is to ask a group of students to demonstrate and if possible, to choose a group with the same gender.

Regarding the personal movement exercises, the teacher should consider recommending to those who do not do the exercises in class to watch the demonstrating students and to try to do it at home after class. This recommendation coheres with research on brain patterns that indicates the potential of learning from watching others (Flanagan & Johansson, 2003). From teachers' reports and from my personal experience some students who decline from participating in class will try to do the movement exercises at home when they are alone.

In conclusion, although according to the *Embodied Pedagogy* approach it is better to experience with our own body and although embodied learning environments can promote understanding of scientific concepts (Zohar et al., 2018), we as researchers, educators, and teacher trainers need to be aware of dignity affirming experiences in integrating embodiment-based experiences in our practice.

Designing Mixed Reality with Indigenous embodied knowledges

Meixi, Sean Dorr, Daniel Keefe, Vicente Diaz

For many Indigenous peoples, coming to know oneself and relations has been an endeavor actualized through whole-bodied intelligences (Simpson, 2017). Learning and knowing through collective embodied experiences with lands and waters is fundamental to cultivating generations of loving, interdependent young people who learn to uphold and advance Indigenous laws and ethics. The growing scholarship on embodiment in the learning or "learning on the move" (Marin et al., 2020), is concerned with how people's mobility between and through places is both the content and the processes of learning (Gutierrez, 2008; Ma, 2017; Marin, 2020; Taylor & Hall, 2013). Interfacing this with Indigenous understandings of mobility and knowing, Indigenous knowledges exist and are advanced through the living and material engagements across human bodies and place (Marin, 2020). In fact, Diaz's scholarship on seafaring (2019) illustrates "how native roots and routes are not mutually exclusive but mutually and powerfully constitutive and generative" (p. 33). In this paper, we focus on the conceptual intersections of embodied participation, Indigenous knowledge systems, and the design of Mixed Reality experiences that begin from Indigenous embodied knowledges (Back to Indigenous Futures, 2019). Additionally, we provide examples of how grounding the design of Mixed Reality technologies can expand intergenerational participation in computer science and Mixed Reality technologies and support the revitalization of seafaring practices in two Indigenous communities in Minnesota.

This paper is based in the Back to Indigenous Futures project partnership with Dakota and Micronesian communities in Minnesota, a community-engaged project purposed towards cultural revitalization and shared learning of their traditional ecological knowledge systems. We view dignity-affirming contexts within the design of Mixed Reality developments in computer science as beginning from the intellectual grounds of Indigenous knowledge systems, specifically, *Paafu*. We target Mixed Reality as the medium specifically because this technology lends itself to embodied experiences.

Designing effective Mixed Reality, embodied experiences is challenging, in part, because the technology can take many forms; these are often described as existing along the Reality-Virtuality Continuum (Milgram et al. 1994). Immersion and presence vary across the continuum and affect the degree of embodiment that is experienced within each. Embodiment in the technological sense refers to what degree one feels the body they are inhabiting is their own, the location of the body is consistent with the mental representation of location, and there is a sense of agency in one's movements (Borrego et. al, 2019). When this definition is juxtaposed with the working definition of embodiment we've used thus far, the question then is not simply how well the technology affords advancing embodied Indigenous knowledge, but also how whole-bodied Indigenous intelligences might advance our conceptions of place, design, and mobility.

Paafu: Indigenous embodied knowledge to support mixed reality development

Paafu, from navigators of the Central Carolines, is a way of organizing the rising and setting of stars for teaching directionality - or simply put, to determine where one is in relation to other markers in seafaring (Diaz, 2019). In the following sections, we highlight the ways in which *Paafu* is conceptually and mathematically advancing the community-based Mixed Reality experiences. Specifically, we highlight using two concepts: (1) wave swells and (2) moving islands, and discuss the ways we are engaging these ideas to create a platform that Micronesian and Dakota families can engage with to tell, listen, and embody their stories of lands, canoes, and journeying across place.

Indigenous design 1: Wave swells In *Paafu*, the outrigger of the canoe faces in the direction of *Tan Mailap* (Altair rising), from whence also flows a major swell from due east of the island of Polowat, for in traditional Carolinian seafaring knowledge, stars and sets of swells serve as proxies for each other in their respective domains (Diaz, 2021), rendering both especially effective instruments for reckoning direction, as well as timing. Moreover, being attuned to the particular and idiosyncratic rhythm and tempo of a particular

swell/rising or setting star, as experienced bodily in the pitch and roll and sonics of a canoe, can also indicate location, direction, and time. Recognizing these embodied skills and knowledges as a set of inherently mathematically dense activity, our design of Mixed Reality experience also acknowledges and builds upon the rigor~~ous~~ of Indigenous design that is embodied in this knowledge set.

Indigenous design 2: Moving islands Likewise, we build upon the traditional Carolinian seafaring concept of etak, or "moving islands," an ancient technique for calculating distance traveled, or position at sea, by triangulating the speed of the islands of departure and destination with that of a third reference island, as these are further "plotted" at sea and in the sky (through the aforementioned reflexivity and indexicality between sea and sky as illustrated in the correlative status between certain swells and certain rising and setting stars. (Diaz, 2011; 2021). Recognizing the sky and the sea as mutual markers and time keepers for directional and navigational purposes is also another way to recognize how Indigenous personhood is reckoned through mirroring relationships with the natural elements through their instrumentalized usage for the purposes of travel in both geographic and ontological terms: relating to the relationships that exist between swells and stars, sea and sky, in nature, is also an example of how Indigenous people "plot" selfhood relationally, in time/space. for the purposes of efficacious travel and for defining one's sense of self historically and culturally. How might this concept, or better yet, technology of moving islands challenge the temporal, spatial, ontological, and bodily-assumptions and norms that inform and underwrite computer graphic design and production? In what ways might Mixed Reality technology help explain as well as benefit from these radically different instruments of time/space imaging?

This paper traces the generative tensions and possibilities of refusing colonial assimilation (Diaz, 2019; Back to Indigenous Futures, 2019) into dominant ideas of the development of Mixed Reality and experiences, by centering the particular knowledge systems of a community and using that as the grounds for digital technology development. Instead of discourses of technological access that presume deficit-orientations common in STEM, we are interested in how first, Indigenous knowledges can advance our understandings of technology, design, and embodiment, and secondly, how these Mixed Reality tools can also further Indigenous knowledge and futures for Indigenous young people, families, and communities.

Building meaningful participation using embodied Mixed Reality technologies

Nitasha Mathayas, Xintian Tu, Joshua Danish, Lauren Vogelstein, and Lana Cosic

We represent a larger team of researchers who developed an embodied Mixed Reality (MR) learning environment that blends elementary grade students' movement through play with a virtual interface depicting various scientific phenomena (Danish et al., 2020). Designed for classrooms, we use motion tracking technology to track the movement of up to 10 students at a time while remaining students make observations and mediate their peers' activity. Our environment focuses on coordinated, collective activity amongst participants, and thus *meaningful embodied participation* occurs when students work collectively, using their bodies and adapting their actions in response to their peers, to explore scientific phenomena.

Although our previous studies show that creating embodied learning opportunities for young children supported complex scientific modeling (Danish et al., 2020), our design has implicitly assumed that all children wanted to participate in this physical way. Their "willingness" to participate in embodied activity over time was never questioned. Espinoza et al. (2020) explain that meaningful participation is deeply intertwined with students' educational dignity influencing how they act in educational environments. This led us to question how meaningful embodied participation through our environment affirmed or did not affirm the dignity of students. In this paper, we revisited a past study to interrogate moments where the lack of focus on dignity affirming designs may have inadvertently led to problematic experiences for our participants. We examined multiple interactions before settling on two episodes for further analysis in which first and second grade students were exploring states of matter. We then utilized methods of Interaction Analysis, IA, (Jordan & Henderson, 1995) to explore how some students' meaningful embodied participation did not appear to elicit a potentially desired response from peers, and yet which upon further reflection in our IA sessions may have thus been disappointing or frustrating for the participants. We discussed how student participation was meaningful, what student interactions were missed by the facilitators (us), or peers during each moment, and questioned how we could have better supported students in dignity-affirming ways. The following case descriptions include the main observations from each case followed by some general implications for embodied technology design.

In the first episode, the class was divided into three groups and each group took turns modeling states of matter using our MR platform. One student, Mary, did not join her modeling group when it was their turn to embody a state of matter. She quietly observed from the back of the class while her group constructed a model of gas particles with their bodies, and other groups shared observations from the sidelines. After the round ended, the classroom teacher asked Mary if she wanted to participate in the embodied activity which she declined. The

teacher then offered Mary an alternative role as an observer and annotator which she accepted. In this way, Mary was provided an alternative way to engage in the modeling without having to physically work with her peers in the moment raising the questions: (1) What methods could we have used to learn why Mary did not want to participate in the embodied activity? (2) As the embodied activity unfolded and Mary's personal goal changed, how could we have made space for Mary to express her changed goals? (3) Might we have benefited from asking Mary and the other students how they'd like to participate in the first place?

In the second episode, the instructors had half the students modeling states of matter by moving while the other half of students gestured to give students-as-particles energy from the outside. As this activity unfolded, the screen depicted particles changing states of matter which caused modeling students to move faster but the gesturing students to stop and watch the screen. We also found that modeling students then dominated the following discussion, even though gesturing students raised their hands to share their ideas. This made us question whether our platform, which is designed to track the modeling students' movement in the center of the room, may have inadvertently privileged their embodied activity over the gesturing students' activity. Since the MR environment is limited by the number of students it can reliably track in a classroom space, how might we adapt the environment to involve the observing students' embodied activity? How might we better support observers in taking as active a role in discussing their peers' embodied activity as they'd like?

Ultimately, these cases suggest the need for pedagogical measures and tools that regularly check for student willingness to participate. Also, designers of embodied classroom technologies need to carefully examine how the different forms of participation might privilege certain students' conceptual contributions over others.

Every Body Belongs: Principles for Inclusive Instruction in Embodied Learning Activities

Morgan Vickery

Often student participation in embodied activities relies on a set of normative ideals that students' bodies look, function, and respond in a particular way. These ideals are grounded in the valuation of mesomorphic, masculine, motor-competent, and 'able' bodies as worthy of attention and praise whereas expressions of difference (in activity participation, in setting, or in degree of physicality) often fails to activate the same level of social capital within peer groups (Fitzgerald, 2005) and is treated as noncompliance by instructors (Goodwin, 2020). I draw upon scholarship related to trauma, disability, physical education, yoga, and dance in learning to consider how principles for inclusive instruction in these domains might provide insights for designing embodied activities where all bodies are welcomed, respected, and valued. Here, I propose a 3-faceted framework for designing embodied learning environments as trauma-sensitive, body-positive, and disability-inclusive.

There is a breadth of work which has been conducted to research and implement trauma-informed practices in schools at the interaction, classroom, school, and system levels. The 'trauma-sensitive' facet of this framework expands on Goodwin's (2020) 'graduated instructional prompts' framework which offers principles for trauma-sensitivity during embodied activities: (a) the avoidance of language which might be interpreted as a demonstration of dominance or function as microaggression (for example "everyone can see you," "stop being disruptive," or the use of condescending/infantilizing tones), (b) respecting bodily autonomy, sanctity, and ownership and thus avoiding physical contact/coercion, (c) recognition that student non-cooperation or resistance to participation may indicate that triggers may be present, and (d) respecting students' refusal to participate.

The second facet refers to dance, yoga, and body-image scholarship to inform principles for constructing body-positive and dysphoria/morphia-sensitive embodied learning environments. Considering how such environments frequently require the collection of video movement tracking data, I raise concerns regarding the use of tools which make depictions of one's body visible to students (i.e. mirrors, projected camera views, etc). The ongoing use of mirrors and self-views in performance arts spaces has been shown to lead to students' use of self-objectifying language, comparison of bodies to their peers, and increased distress resulting from self-focused attention (particularly for students experiencing body dysphoria/morphia) (Radell et al., 2020). Picket and Cunningham (2017) also convey the importance of diverse representation of bodies in embodied learning spaces, acknowledgement of body nonconformity and authenticity by instructors (for example, sharing when a pose is difficult or impossible), the removal of hierarchical and evaluative language to refer to movements (i.e. not referring to certain poses as "beginner" poses), and normalizing asking questions, admitting limitations, approaching discussion of bodies from a holistic perspective (as opposed addressing appearance / size).

The third component for this framework draws on disability and physical education literatures' emphasis on attending to the social dynamics that exist between students; the use of competitive games where students may be excluded or activities in which students may feel the need to "blend in" are cited as problematic in disability-inclusive physical education spaces (Bertills et al., 2019). Furthermore, the explicit teaching and reinforcement

of cooperative learning practices (i.e. shared negotiation of goals, shared decision-making, constructive feedback, approaching individual accountability, etc) in peer groups has been shown to promote inclusion of students with both physical and cognitive disabilities (Grenier, 2006). Grenier (2006) also notes how 'inclusion' is not synonymous with "the same experience for all students in the same setting" but that instructions should work to identify, remove, and/or provide accommodations for barriers that students may encounter in activity.

Together these fields suggest that student experiences in embodied learning environments are multifaceted and cannot always be recognized or explained solely through observable actions and talk. Thus, I argue that we must embrace an expanded version of the 'universal trauma' principle (Goodwin, 2020) to teaching; we must presume that all students have experiences which lead to vulnerability in non-trauma sensitive, non-body-positive, and non-disability-inclusive environments. By making this assumption and over-compensating for these assumptions in our work, we ensure that students do not fall through the cracks regardless of how their trauma, mental health, and disability manifest externally. To conclude, I refer to Fitzgerald's (2005) recognition that the normative ideals that (re)enforce these barriers for students are deep-seated in the habitus of modern-day schooling and thus cannot be resolved exclusively with such instructional "superficial remedies." I acknowledge that the above categorizations should not be treated as comprehensive but rather a vehicle to facilitate discussions about expanding our notions of inclusion in embodied learning activities.

Abstract: This symposium brings together research that examines equity as it relates to facilitation across a diverse set of tinkering and making activities and settings. Drawing on an equity framework for out-of-school learning, we focus on the potential for facilitation to create transformative learning opportunities for learners who have been historically marginalized in making and tinkering activities, including communities of color; note the complexity of equitable facilitation across settings and contexts; and highlight the importance of facilitator reflection to acknowledge and challenge hegemonic approaches in STEAM. Taken collectively, these papers highlight not only how facilitation is essential for making productive connections between making and tinkering and the sociopolitical issues at play in our world, but how those pedagogical practices themselves are sociopolitical, connected with histories and disciplines in ways that can either reify existing inequities in STEAM or create new, more equitable futures for learners and facilitators.

Symposium Focus and Framing

Tinkering and making activities draw upon constructionist traditions of learning which promote knowledge as something that is constructed through experience and gained while building something that is personally meaningful (Papert, 1980). These activities can offer new opportunities for youth to playfully engage in science, technology, engineering, arts, and mathematics (STEAM) – especially for those learners who have been historically marginalized in formal education settings (Calabrese Barton et al., 2017; Halverson & Peppler, 2018). Thus, tinkering and making spaces and activities are viewed as providing more equitable approaches to informal STEAM education than those in traditional classrooms.

Previous research has examined the ways in which equity can be located in learner agency and engagement in their chosen projects (Calabrese Barton et al., 2017), connections to knowledge not typically prioritised in such spaces, such as e-textiles and crafting (Beuchley et al., 2008), and in the power structures inherent in tools and programs offered by such spaces (Melo & Nichols, 2020). However, only a few studies (e.g., Ryoo et al., 2016; Vossoughi et al., 2021) have focused on equity and *facilitation* in making and tinkering activities - that is, how equity is enacted in the moment-to-moment decisions and actions of adults and youth who support learners in those spaces. Vossoughi et al. (2016) have argued that attending to these pedagogical practices is critical for advancing equity in making and tinkering. Focusing on equity and facilitation can push the discussion beyond considerations of access (which, by itself, is not enough to transform educational inequities; Vossoughi,

 © ISLS

2017) to deeply consider what equity *looks* and *feels like* for both facilitators and learners in these informal education settings.

To that end, this symposium brings together research that examines equity as it relates to facilitation across a diverse set of tinkering and making activities and settings. The goal is to examine how equity may be defined or imagined by facilitators in these spaces, what tensions may exist between those definitions and the moment-to-moment interactions between people in each setting, and what implications attending to equity in this way will have for both research and practice. In order to facilitate the beginnings of a shared understanding of equity across each paper, we draw from an equity framework for out-of-school learning first articulated by Vossoughi (2017). She argues for research that is "animated by an equity framework [which] treats all learning as a cultural and sociopolitical process and foregrounds questions of epistemology, power, and justice" (Vossoughi, 2017, p. 2). Specifically, she highlights the questions of "Access to what?" "For whom" "Based on whose values?" and "Towards what ends?" as critical tools for reflection and action in the equity framework. These questions assist researchers in illuminating "the dynamic histories of practice, ways of knowing, forms of joint activity, and value systems present," (p. 4) aspects of the cultural contexts that we believe are critical to understanding equitable facilitation in tinkering and making environments. We have expanded the framework to specify the "how?" and "why?" We believe that this expanded framework can deepen facilitator and researcher reflection on equitable facilitation in making and tinkering activities.

Major Issues Addressed in the Symposium

Firstly, our collective work showcases the ways in which facilitation is a key part of creating space for transformative learning experiences with making and tinkering, especially for communities of color and other communities who have been historically marginalized in STEAM education, by connecting activities with both current and historical sociopolitical contexts, and creating space for new possible futures. Our second point notes that equitable facilitation is a complex practice: it involves values (personal, institutional, disciplinary, etc.) which then come into contact with different learners, facilitators, materials, and informal education settings. These complex human-material and human-human relations can lead to tensions between how facilitators and learners *think* about equity versus how it is enacted (or felt) in the space. For this reason, reflecting on equitable practice in making and tinkering activities is key in surfacing histories, tacit values, and moments of discomfort, all of which can then be used to create space for intergenerational learning and pedagogies of care.

Scope and Significance of Contributions

The papers included in this session consider the facilitation of making and tinkering activities across a wide variety of settings, including online after-school programs, public computing environments, summer programs, science classrooms, library makerspaces, and museum spaces. Additionally, these papers acknowledge that there are many different roles in which one can act as a facilitator for making and tinkering, each with their own tensions and complexities as they negotiate their own positionalities, values, institutional requirements, and disciplinary norms as they intersect with notions of equity. Taken collectively, these papers highlight not only how facilitation is essential for making productive connections between making and tinkering and the sociopolitical issues at play in our world, but how those pedagogical practices and the facilitators themselves are sociopolitical, connected with histories and disciplines in ways that can either reify existing inequities in STEAM or create new, more equitable futures for learners and facilitators.

Equity as a Moving Target: Engaging Informal Learning Educators' Differing Visions of Equity

Ricarose Roque, Ronni Hayden, Celeste Moreno, & Stephanie Hladik

Science museums, libraries, and other informal STEM learning organizations are increasingly incorporating concepts from computer science alongside other STEM activities and spaces. As these efforts are still relatively new, there's an opportunity to interrupt dominant scripts of what "counts" as computing, who participates, and how someone engages with computing to more meaningfully support groups who have been marginalized from traditional computing spaces. Informal learning educators or facilitators in these spaces make key decisions at the micro (moment to moment interactions) to meso (how space is designed, how they recruit people, how they curate activities) (e.g. Vossoughi et al., 2021). Without careful and consistent effort towards equity, these decisions can influence who and how people can participate risking the reproduction of existing inequalities. As facilitators incorporate computing into their spaces, we wanted to examine how educators are engaging youth and families in equitable learning experiences. Our initial research question was: What challenges and barriers do informal

learning educators, or facilitators, face to engage their learners in design-based activities with computing? As we discussed computing activities with educators, we noticed the ways that educators were talking about and applying equity in implicit and explicit ways into their practice.

We interviewed 15 facilitators from three informal learning organizations that included a science museum, a network of makerspaces in a library system, and network of community-based technology centers for youth. All facilitators were based in the United States and represented 5 states. During 90-minute virtual interviews, we asked participants to share a computing-based activity that they had implemented in their space. We also asked questions about their background, goals, and how they considered equity in their practice. In the first round of thematic analysis, we noticed the ways that equity was emerging implicitly and explicitly in how they designed activities. To focus our analysis, we used a framework of questions inspired by an article by Shirin Voussoughi (2017), where she argues that out-of-school spaces committed to addressing issues of equity must ask: "Access to what? For whom? Towards what ends? And based on whose values?" We added the question of "How?" After conducting preliminary analysis, our research team conducted 60-90 minute, virtual "share-backs" where we shared and discussed what we learned with interviewees and their colleagues. In addition, we focused sharebacks on how facilitators were considering equity in their work and added "Why?" as a question for them to consider.

Each of the spaces had different stances on their equity work. The network of library makerspaces focused on providing free and open access to their resources. The science museum focused on examining how their equity work manifested in their pedagogy. Facilitators at the community based tech centers focused on being culturally responsive to the communities they serve. In share-backs with educators, we highlighted different tensions within their stances. For example, when considering "for whom," most library educators focused on "for all" which risks continuing to only serve dominant groups who take up these activities and misses opportunities to really focus on engaging some who would benefit the most from meaningful engagement with their resources. While we initially imagined these "share-backs" as member checks on our data, we saw potential for collective reflection and questioning in our discussions with educators around their equity work. By reflecting on "Why?" as it related to their decisions regarding materials, pedagogies, and goals, facilitators began to question and trouble current assumptions around facilitating computing experiences. Future work will continue these conversations with facilitators and incorporate their shifting visions of equity in the co-design of new computing education activities.

Speculative Fabulation: Narrating Fabulous Possible Futures through Remote Making and Tinkering

José R. Lizárraga

This paper presents findings from a study that examined the learning of student teachers in a teacher education course and youth from non-dominant communities who were linked via a remote Making and Tinkering club called the Speculative Fabulation Lab. As part of this remote after-school club, youth and teachers received take-home maker kits (with simple circuits and other craft supplies) and had remote access to a 3D printer. In this work, we consider how *speculative fabulation* is a type of digital fabrication that is "about worlding 'naturaltechnical' worlds [...], worlds needy for care and response" (Haraway, 2014, p. 242). The work presented in here builds on previous projects that have sought to examine how *everyda*y cultural practices (Gutiérrez & Rogoff, 2003) can mediate meaningful and consequential learning that is, at its core, socio-political and transformative for communities of color (Gutiérrez, Becker, et al., 2019). The following argues that designing making & tinkering learning environments for the *everyday cyborg* (Lizárraga & Cortez, 2020), in this case novice teachers and middle schoolers in a Latinx-serving after school program, fosters an engagement with everyday dilemmas in ways that serve as catalysts for further learning (Engeström, 2006) and the new world-making or *speculative fabulation* (Haraway, 2014).

Participants of this Social Design-based study (Gutiérrez, 2018) included 14 undergraduate novice teachers from diverse cultural, linguistic, and socioeconomic backgrounds, as well as majors including cognitive science, engineering, business, and computer science. Participants also included 10 elementary and middle school students from schools that served a Latinx community. The study draws from 75 hours of after-school program video data (recorded from zoom sessions), 15 hours of interviews, and 112 digital artifacts produced by 24 participants. Data also included data analytics from a custom-designed digitized learning management system. Video and audio were logged on a variety of metadata, interviews transcribed, and digital artifacts analyzed using multimodal analysis (Hull & Nelson, 2005). Codes were developed inductively (Bogdan & Biklen, 1997). Through these analyses, micro-moments were examined to gain an understanding of how meaning-making mediated in virtual making and tinkering interactions. Through remote making and tinkering (with the use of take-

home kits and remote 3D printing), expertise emerged as a distributed phenomenon which novice teachers and young people collectively examined and developed models for engaging with everyday socio-political issues and designing for new possible futures. I specifically highlight what I have coined as *cyborg sociopolitical technical reconfigurations* (CSTR), where learners assembled ideational and material tools to craft objects of learning activity that went beyond those established by teachers and schooling.

From Players to Hackers: Intergenerational Tinkering with the Socio-political in Video Game Play

Arturo Cortez, Kate Baca, & Ashieda McKoy

In this paper, we examine young peoples' and educators' learning and development in the context of a video gaming ecology. Online video-game play has gained traction as a site of digital activism, where young people collaborate with others across the world as they respond to anti-Blackness, capitalism, and other systems of oppression (Cortez, McKoy & Lizárraga, under review). In particular, we examine how young people's valued everyday practices can serve as resources for academic learning, with a specific focus on sociopolitical action, as a making and tinkering activity. Given this previous work, our project designs a learning ecology that centers distributed expertise, where young people, undergraduates, researchers, and in-service teachers learn to build together within the context of video-game play. In this regard, this study offers new theoretical insights for examining the development of relational agency (Edwards, 2017; Gutiérrez, et al., 2019), methodological affordances for studying how young people and adults build together, and pedagogical openings (Cortez & Gutiérrez, 2019) for designing learning environments that center young people's everyday cultural and making and tinkering practices. The focus of our study explores the emergence of distributed expertise as young people and educators tinker with and re-imagine racism, gender-based violence, and other forms of oppression in video games and video gaming practices. In this work, we examine the affordances and constraints of leveraging digital technology and new media to open up emerging forms of agency, activism, socio-political critique, and resistance practices for educators and young people (Lizárraga & Cortez, 2019). Broadly, our project seeks to understand how to design for expansive forms of learning in an intergenerational and interdisciplinary learning context, with specific emphasis on how and if young people and adults can identify and collaborate together, using and sharing valued tools and practices, on shared dilemmas that they experience across their everyday lives.

In this social design-based experiment (Gutiérrez, 2018) we centered the iterative process of designing and studying the naturalistic processes that emerge in gameplay. Our study draws from 115 hours of audio and video recordings and participant-generated field notes by 14 (11 undergraduates and 4 high school students). Video and audio data were transcribed. All data were reduced and coded across themes and using inductive processes (Bogdan and Bilken, 1997). Video analysis processes (Erickson, 2006) were used in order to examine the specific micro interactional moments of collaborative inquiry and distribution of expertise. Findings from our study reveal that young people and educators often contribute differently as they examine video game play. However, by examining the moment-to-moment interactions, our study illuminates how educators and young people leverage each other's expertise to jointly tinker with and re-imagine possibilities in game play and video gaming practices. We seek to identify a learner-centered approach, such that adults and young people are positioned as co-learners. The design of such learning environments are rare in formal K-12 classrooms, and, of importance, we have found that these collaborations open up new possibilities for sustained collective inquiry. In particular, our project examines how adults and young people develop critical civic literacies (Mirra and Garcia, 2020); that is, the disciplinary content that is developed over the course of the identification and resolution of a shared project, as well as the relational expertise that emerges when people learn how to collaborate together. Our study has implications for how to design for the development of critical civics and how it is attuned to social and political interrogations and re-imaginings of injustice in our institutional and everyday relational practices.

Facilitating "Reading" Code in the Context of Symbolic Violence

Simren Trehin, Apoorve Chokshi, & Pratim Sengupta

Our study offers an investigation of facilitation in the context of visitors' experiences of symbolic violence (Bourdieu, 1991; Burawoy, 2019) during their interactions with computational models and maps of racial segregation and ethnocentrism (Axelrod & Hammond, 2003; Sengupta et al., 2021). Our work arises from concerns along two dimensions: a) the paucity of scholarship on facilitation of computational models in informal spaces, with only a few exceptions (Hladik et al., 2021; Ozacar et al., 2020); and b) the entrenchment of computational models of racial segregation in White Innocence (Gutiérrez, 2005; Gotanda, 2004), which reframes

racial segregation in US and Canada as inevitable and emergent while ignoring the role of intentional, institutional and systemic racism (Sengupta et al., in press). Specifically, we ask the following research question: What roles does facilitation play in engaging ethically with visitors/learners of color as they are engaging in experiences that may result in symbolic violence?

The context of this study is a public computing environment (Sengupta & Shanahan, 2017) located in a busy walkway at a large university in Canada. The three large touch screens hold a place of prominence, displaying a multi-agent simulation based on Hammond and Axelrod's (2006) ethnocentrism model and a Racial Dot Map of Toronto, based on the Canadian census data. Visitors can interact with the simulation through manipulating sliders that (among other variables) can adjust world size, immigration rates, birth/death rates, with effects visually presented through changes in populations of different colours of agent over time. The Racial Dot Map illustrates the neighborhood-wise racial segregation in Toronto (Clark, 2011), while the simulation positions racial segregation as an inevitable and emergent phenomenon that arises through prisoner's dilemma-like interactions of co-operation and non-cooperation between individuals belonging to different racial groups, even when there is no initial bias toward segregation in the system (Hammond & Axelrod, 2006). The participant in our study, Sapna, is an advanced graduate student in the social sciences whose parents immigrated to Canada from the Global South. Sapna's interaction with the simulation was facilitated by a member of our research team (Apoorve), while another member (Pratim) video-recorded the interaction, which was also transcribed for analysis. Using a constant comparative approach (Glaser & Strauss, 2017), we identify key vignettes in the interaction between Sapna and Apoorve. Based on Espinoza et al. (2020)'s framework of educational dignity, our analysis of these vignettes focuses on the use of first, second and third person accounts of both the facilitator and the visitor, and we identify salient themes in the nature of experiences of symbolic violence when apparently neutral computational representations are "read" through the use of interpretive explanations and queries, only to reveal dissonances, ambiguities and erasures of experiences of immigrants of color, and the facilitator's responses in these moments.

A key finding is that both learning and facilitation involves simultaneous layering of various forms of work, including both emotional and ethical work in contexts of symbolic violence. These labours are interwoven with both the syntactic and semantic ambiguities inherent in explaining and interpreting code. For example, interpreting the different strategies of cooperation in Hammond & Axelrod's (2006) model involved Sapna recognizing the violence of the term "traitorous" as a strategy that immigrants must use in order to assimilate based on first person accounts, while Apoorve offering a similar first-person account in solidarity. We will present the heterogeneity within such ethical and emotional encounters with code that are essential for recognizing the complexity of both learning and facilitation of computational models of race in informal spaces.

The What, How, To What Ends of (Re)Making of Selves, STEM, and Futures, Understood through the Lens of Equitable Facilitation

Jrène Rahm, Ferdous Touioui, & Delphine Tremblay-Gagnon

In this paper, we focus on emergent relations among facilitators and youth in two very different maker activities. Case 1 implies maker activities inside a four-week summer youth entrepreneurship program offered for free to urban youth by a community organization (CO). Case 2 entails a maker project inside a science classroom in a public high school that adheres to the International Baccalaureate (IB) intermediary program, offering enrichment activities in all subject areas. The same CO mediated that extra learning activity in the classroom, working closely together with the science teacher. We bring to the analysis a critical lens to center voices historically ignored. In doing so, we pay attention to first, how structural and political dimensions sneak up on emergent human-material relations, posing a threat to equity and creativity in ways often promised by maker space projects (Marsh, Arnseth, & Kumpulainen, 2018), but also wished for by teachers and facilitators who care deeply for youth of color given their own histories of marginalization. In doing so, we also pay attention to problems of intersectional marginalization (Crenshaw, 2021). Second, we attend to the manner a vision of STEM education as indispensable, objective, and settled truth sneaked up on the emergent relations, despite intentions to center youth voices and multiple STEM perspectives (Vakil & Ayers, 2019). Third, playing with a materialist and posthuman approach to analysis, we will focus in on "material-discursive entanglements constituted through human, non-human, and more-than-human relationships" (Sheridan et al., 2020, p. 1278), and as captured by Barad's materialist notion of *inter-action* (Barad, 2007). Together, these three different lenses will point to tensions that at least in part undermine the equity driven STEM practices the CO aims to support.

The two cases come from a larger video ethnography, conducted in collaboration with the CO over time and part of a five-year partnership and co-design project (2015 to 2020). For each case study, we rely on data that emerged from interaction analysis among the research team, supplemented by thematic analysis of interview data and fieldnotes. Case 1 relates the story of Burak, one of the youth involved in the young entrepreneur program

and participant in the activities by that CO over four years shared with us how he "participated for real" in the program only the year we documented it. He felt respected by his peers who consulted him every time they needed help, as for instance when they made soap together and struggled with chemicals. Participation in the program "helped me to get to know myself better… and know what I like to do with my future…", after a challenging beginning in the school system in Quebec, where he had to repeat his fourth year in the elementary school, upon arrival with his family from Haïti. Case 2 speaks to interesting parallels in relations that stood out from our analysis of the maker project - parallels between the science teacher and some students, who were both entangled in complex ways with subject positions marked by histories of immigration, deep interest in and expertise in science and technology yet unrecognized locally and othered, despite a deep commitment to becoming somebody in science and entanglement with the maker project. The two cases make evident in what ways taking "a more expansive lens to human learning and political possibilities" (Philip & Sengupta, 2021, p. 331), helps center tensions but also new possibilities of being/becoming in STEM, especially if emergent from equitable facilitation.

Supporting Educators Exploration of Making through Intergenerational Professional Development

Stephanie T. Jones, Sarah P. Lee, Sydney Simmons, I. Mallwitz, Marc Jiang, Megan Butler, & Marcelo Worsley

Since 2017, the MAJIC (Making A Just Inclusive Community) team has collaborated with K-8 teachers in the suburbs of a large midwestern city. These teachers were interested in bringing hands-on making into their classrooms and afterschool programs, but found limited opportunities within their district. In summer 2019, we invited five teachers to participate in a professional development (PD) program to design, test, and discuss hands-on making activities alongside their family members. We intentionally curated this intergenerational environment to surface and emphasize making practices situated within culturally sustaining pedagogies and pedagogies of care (Alim & Paris, 2017; Ladson-Billings, 2014).

We continued this PD virtually in the summer of 2020 to assist three teachers in curating intergenerational experiences for students who were now learning from "home," and in environments surrounded by siblings, cousins, elders, and parents. Given the pandemic, we recognized an urgency to continue centering pedagogies of care and educational dignity for both students and teachers (Worsley et al., 2021; hooks, 1994; Espinoza and Vossoughi, 2014). Thus in this paper we explore: what are opportunities to shift the way we imagine what is possible for facilitating making activities virtually and at home?

In this paper, we draw from video recordings of the 2019 and 2020 summers, synthesizing across 9 and 7 synchronous hours respectively and 45-60 minute long interviews with each of the teachers. As a team we open coded each interview for themes, which we then used to review the video data and iterate on the PD program. Themes included challenges of online pedagogy, pandemic constraints, and family engagement.

During PD, teachers engaged in readings and discussion that drew on and expanded their prior experiences making across lab and home settings with family members (Perez et al., 2020; Worsley et al., 2021). Teachers highlighted challenges such as zoom fatigue, material constraints, and availability of help, while recognizing practices from their existing expertise that they could develop. They identified new concepts from literature which led to incorporating pedagogies of care within intergenerational contexts. This deepened their sensemaking around hands-on making.

Teachers then wanted to create an environment to allow young people to explore literacy and making alongside family members as an additional community. We see this as a way teachers challenged ideas around participation and knowledge and opened opportunities for intergenerational making at-home. This culminated in a virtual Family Maker Night where teachers designed and mailed several book themed hands-on activity kits that students could choose to work on with siblings or adult guardians. The selected book was read in both English and Spanish. Families could incorporate other materials that they had at home and the activities could be worked on in several stages or beyond the synchronous time together. Since then, students that participate in the literacy and making program are selected on a rotating roster with optional family involvement. The ways teachers distributed materials, reduced language barriers, and created an ongoing literacy community highlight how teachers can support equitable intergenerational making.

Future considerations respond to tensions that teachers faced to fulfill district STEM requirements alongside invitations to hold and value other forms of knowledge and experience. As such, we see our role as a team to work with teachers to continue to develop ways that we can make outside of the constraints of schooling and model alternative facilitation for classroom settings. Finally, from holding space for teachers' multiple identities as family members, to the shifting vulnerabilities unique to video calls, we continue to wrestle with how this work looks in different home contexts and what that means for access to materials and support within making.

Abstract: Educators and designers of learning experiences must make critical decisions not only about the *what*, *why*, *to what ends* and *for whom* of learning (Philip et al., 2018), but also *when*, *where* and *at what pace*. This symposium is organized around the conjecture that by more explicitly and systematically considering the time-space dimensions of learning and design processes, we can more reliably surface differences in how we understand learning as well as inequities that result from how it is conceptualized and designed for, helping make progress towards more just educational futures. Collectively, this symposium shows the progress that one group of learning scientists assembled in the ISLS 2021 Early Career Workshop has made in bringing careful attention, useful theory, and systematic approaches to understanding equity issues related to space and time, while also working out ways to attend to these issues in our temporally and spatially distributed design processes.

Introduction

Educators, learners, and designers of learning experiences must make critical decisions not only about the *what*, *why*, *to what ends* and *for whom* of learning (Philip et al., 2018), but also *when*, *where* and *at what pace*. Space and time demand consideration not only as objective dimensions of learning and design unfolding in the real world, but also as subjective perceptions and culturally constructed understandings of our experience that pattern activity. Indeed, different assumptions about and perceptions of learning rate, space and time influence our very understanding of what counts as good, effective, diverse, equitable, inclusive and just learning and design. Many vexing and familiar tensions and failures in designing for equity, for instance, can be traced to differences in the speed with which equity is pursued, or to lack of attention to when and where learners are put into interaction for more equitable outcomes. As a field, the learning sciences must continue to develop new ways of seeing, analyzing and responding to the implications of space and time in learning both *in* and *through* design.

This symposium is organized around the general conjecture that by more explicitly and systematically considering the time-space dimensions of learning and design processes, we can more reliably surface differences in the way we understand learning as well as urgent inequities that result from how it is conceptualized and designed for, thereby helping us make progress towards more just educational futures.

Overview of Structure and Content

Collectively, this symposium shows progress that one group of learning scientists, assembled in the International Society of the Learning Sciences (ISLS) 2021 Early Career Workshop, has made in bringing careful attention, useful theory and systematic approaches to understanding equity issues related to space and time, while also working out ways to attend to these issues in our temporally and spatially distributed design processes. In the first two papers, design processes themselves are examined in terms of the "narratives" that pattern innovation and the "trajectories" of experience and identity development that play out over the course of design. These pieces deal with how the dynamic and distributed arrangements of educational design unfold in ways that prioritize some "protagonists" over others, for instance, and act immediately and explicitly on some goals and measures of equity while tacitly deferring others. The third and fourth papers focus on spatial-temporal dynamics within specific designed learning environments. These papers deal with how individual learners move across and link virtual and real spaces in different configurations at different moments. The studies bring attention to how learners assemble and disassemble in spatial-temporal contexts and emphasize the importance of attending to these dynamics in designing for inclusive and equitable experiences.

The symposium organizers will engage ISLS participants in a discussion of paradigmatic, methodological and practical perspectives that help us grapple with critical questions like the following: (1) Where

 © ISLS

and when is equity being foregrounded and prioritized through learning and design? (2) How does design for equity at one rate, scale or place reinforce, disrupt, or stand in tension with its pursuit at others? (3) How do we make abstract notions of space and time more technical and tractable for the design of contemporary learning in, for instance, virtual and online spaces? (4) And, how do we work across different, culturally- and contextually-specific understandings and experiences of space-time for more equitable and just outcomes?

Time, Space and Equity in EdTech Crisis-Innovation Narratives

Adam Papendieck, University of Texas at Austin

While technology in education is often taken up in the work of designing for more equitable and just futures, scholarship on educational innovation has shown how public narratives and broadly shared assumptions about school and schooling tend to pattern technological integration in ultimate service of status quo goals, beneficiaries and ways of doing things (Cuban, 2013; Sims, 2017; Tyack & Tobin, 1994). Designing for substantive technology innovation in education, in other words, requires *values innovation*. In this study, the case of the EdTech Network, an urban innovation hub, is examined to show how the very spatial and temporal configurations of the stories that these innovators tell about educational change reflect and pattern how they organize and design for more equitable futures.

This study draws upon the concept of *chronotope*—Bakhtin's (1981) way of theorizing how space-time works in novels—to examine narratives of crisis and innovation told by ed-tech innovators. Space and time are treated not (just) as separate, objective dimensions of an independent real world, but more importantly, as interdependent sociocultural constructions that pattern human experience (Ritella et al., 2016), narrative sensemaking (Boje, 2011; Bruner, 1986; Weick, 1995) and the organization of work and learning (Orr, 1996). For the purposes of this study, *technology* is treated as a social-material process of development suspended among different possibilities (Feenberg, 2004). Technology *innovation* is an abductive (Cross, 1999) process of organizing for specific possible futures, and *critical innovation* is a contradiction-driven material-discursive process (Foot, 2002; Miettinen, 1999) that both critiques and works to repattern a persistent, unjust, inequitable orthodoxy.

Method

This analysis was undertaken as part of a larger multimodal narrative case study of the pseudonymous EdTech Network, an open, urban innovation network that meets online and in a downtown coworking space called TechAssembly. Overall, the approach involved collecting and comparing different stories of innovation work from teachers, entrepreneurs, educators, administrators, tech professionals in the EdTech Network. A snowball sample and high-level structural representation of the EdTech Network and its various subnetworks was developed using a name-generator instrument, systematic interviewing and standard community detection algorithms for network analysis. Employing a minimal definition of narrative as a passage from one state of equilibrium to another (Czarniawska, 1998), *crisis-innovation narratives* were identified in the sample of interviews, abstracted and compared. A crisis-innovation narrative was defined as a genre of innovation story that combines (1) some disruptive event or transition that results in a state of educational crisis (i.e., narrative disequilibrium) with (2) some kind of innovative or abductive move or plan to resolve the crisis (i.e., achieve an equilibrium). These narratives were then examined with particular attention to how their chronotopes patterned and reflected the *logic*, *pace, practice, protagonists* and *ends* of equity- and justice-oriented changemaking.

Findings

Two general chronotopes organized many of the crisis-innovation narratives reviewed in this study. First, crisis-innovation narratives patterned by an *institutional chronotope* played out relatively gradually, within and across separate but linked and interdependent organizational spaces. Innovation is both supported and constrained by a complex network of persistent, hierarchical, bureaucratic actors and stakeholders. One inter-institutional group of computer science education champions, for instance, relayed stories of how their work addressed a crisis of "coding skills" (interview transcript) by gradually collaborating across schools, educational institutions, and state and federal funding agencies to develop new curricula, teacher preparation programs, and support networks. The innovational *end*—that is, the resolution of the crisis and establishment of a new, more equitable equilibrium where coding skills are taught and learned system-wide—was seen and acted upon as a decades-long story of concerted, coordinating planning and action in relatively compartmentalized domains by often isolated actors, including individual teachers in classrooms and educational researchers in universities. The abductive *logic* of these narratives promised impact through collective, collaborative, and coordinated action of a relatively complex set of stakeholders.

Other crisis-innovation narratives were patterned by a very different understanding of and distribution across space and time, a *market chronotope*. Within this second chronotope, innovation stories play out more quickly as innovators from different environments "rub shoulders" (interview transcript) in a densely populated, frenetic market, working opportunistically around the TechAssembly innovation hub, their social-material "center of gravity" (artifact text). One entrepreneur, for instance, "pitched" (interview transcript) a story to other innovators at TechAssembly about how virtual reality tools could be deployed to immediately address crises of equitable access to quality curriculum, rapidly scaling virtual project-based learning experiences to a broad network (and market) of schools. The urgency and speed of innovation that characterized stories in this chronotope seems to be related at least in part to the way that innovators experience and value space and time itself in the urban market. Unlike the institutional chronotope, the market chronotope is a shifting, hectic, precarious, and commodified space-time, within which innovators must organize quickly and efficiently to demonstrate both valuable progress on equity goals as well as market value. The abductive logic of an effective crisis-innovation narrative in the market can often be crystallized in the form of a curt "value-proposition" or a promising "return on investment." The *ends* of these crisis narratives are often described in terms of "multiple bottom lines," one of which is new market value and another is a more equitable equilibrium (fieldnotes). At the same time, the urban and social infrastructure that constitutes the center of gravity around which these stories are developed (i.e., TechAssembly) is not particularly accessible to innovators who cannot pay to play by traveling regularly to the urban center or afford to spend time and materials on projects that may not last or immediately pay off. The general chronotopic conditions of openness and precarity favor those who are well-positioned and resourced to act as first movers.

Significance

Without inappropriately confusing what innovators say they do with what they actually do, it seems reasonable that these chronotropic configurations likely also help us understand how and why innovation plays out in practice. For instance, we can see how space-time influences the abductive rationale behind design and innovation by establishing different meaningful *ends* of innovation as well as what amounts to compelling evidence of *pace* and progress towards those ends. Entrepreneurs developing innovations in a frenetic, urban chronotope characterized by precarity and the urgent need to make equity technical (e.g., as an issue of scaled access to curriculum) and demonstrate immediate progress (e.g., through sales or user metrics) may not align with equity innovation patterned per a longer term, cyclical, institutional chronotope, where change is a complex, halting, non-linear, collective journey that may not have an immediate end in sight. Furthermore, we see how chronotope as a material-discursive construction can feed into the maintenance of exclusive innovation *practices and infrastructures*, for instance, by making innovation something that happens in urban centers by those who can afford to pay for heavily commodified space and time. Going forward, careful chronotopic analysis of innovation stories and practices could generate new useful typologies of innovators, innovative practices, and abductive goals of innovation, and contribute to a more sophisticated and inclusive understanding of what counts as innovative and who counts as innovative.

Accounting for Spatial-Temporal Identity Trajectories in Student Co-Design

Gavin Tierney, California State University, Fullerton, gtierney@fullerton.edu

Teacher preparation traditionally follows a model in which teacher candidates complete prerequisites prior to entering into a credential program, then, once in the credential program, participate in a series of siloed courses taught by different instructors, while simultaneously completing field work with a master teacher. This siloed model of learning is similar to other contexts in formal and informal education. Despite efforts to create coherence within teacher education programs and a recognition of teacher education as a moment of identity transition for beginning teachers, the connections between prerequisite coursework, coursework within the credential programs, fieldwork, and future teaching are often unclear (Nolen et al., 2011). One significant detriment of this model is that it does not purposefully or equitably support teacher candidates' developmental trajectories as they navigate multiple courses and new experiences, while also making sense of their developing and new identities as teachers. Courses and experiences tend to lack connections or systematic supports for candidates' developmental trajectories. Within this model of teacher education, success is often defined as completion of course assignments, external measures of teaching, and teaching observations, without a systematic view of development as a professional. For this work, I instead look at teacher candidates' development as professionals who learn and, ideally, enact equitable teaching practices. Nasir and Hand (2008) introduced the concept of practice-linked identities, in which, with the support of different identity resources, learners will be more engaged and develop identities that are linked to specific disciplinary practices. By supporting teacher candidates' identities in and

 © ISLS

across learning contexts, I seek to support their spatial-temporal linkages to specific teaching practices, specifically practices connected to just, equitable, and inclusive education. Researchers have argued that without explicitly and purposefully supporting learners' identity development, learning environments run the risk of perpetuating inequities, focusing too narrowly on measures and content over learners' experiences and development (Banks et al., 2007; Nasir et al., 2006). Focusing on teacher education specifically, without naming and supporting all novice teachers' development perpetuates inequities around whose identities are supported and how identities are supported. As such, a premise of this work is that the onus of identity development falls not just on individual learners, in this case teacher candidates, but that designers of learning environments need to equitably support learners' identities and developmental trajectories over time and space.

Method

This study draws upon perspectives in the Learning Sciences that focus on designing to equitably support learners' identity (Nasir, 2012; Tierney, 2020), student co-design of learning environments (Pitt et al., 2019; Tierney et al., 2021), and the design of digital badge systems to represent learning and development in and across contexts and timescales (Bakhtin, 1981; Davis & Singh, 2015; Horstman et al., 2020; Pinkard et al., 2008) by identifying and supporting teacher candidates' developmental trajectories into and through the Single-Subject Credential Program. Candidates' developmental trajectories were mapped through students co-design of digital badge systems to identify learning and supports for identity development within and across courses and experiences in the program. As opposed to content-centric perspectives of courses, such as curriculum maps or backwards planning, the digital badge systems focus on candidates' experiences and development in specific courses into and through the Credential Program. Built upon the ideas of badges from Boy Scouts and Girl Scouts, digital badge systems are used as the underlying design framework to map out valued learning accomplishments and identity pathways for learners, creating a trajectory for professional development in the program. In essence, the badges serve as a map for what it means to demonstrate professional identity development into and throughout the teacher education program. However, through co-design, the badge systems represent candidates' perspectives and experiences, highlighting how candidates interacted with course content and developed over time.

Findings

Results from the study show what identity trajectories for individual students look like in a classroom co-design context, and how they can be mapped out to inform more equitable co-design processes and outcomes. Specifically, when looking at designing for equity across different learning contexts, it is valuable to orient to not only where learning and development occurred, but also when. By centering on learners' experiences through co-design, the designers negotiated what should be included in the badge systems by also situating the content and learning within their developmental trajectories. This was particularly salient when looking at the discourse of co-designers who were at different points in the credential program.

Significance

Designing for equity across space and time requires an element of narrative. In doing so, it is important to consider who or what becomes the protagonist in that narrative (Iversen et al., 2017). Put another way, what is the organizational framework for thinking about space and time? This study presents one model, in which learners' experience is centered to map out, and then design for, learning and development in and across learning contexts over time.

Charting Learner Experiences of Immersion Across Digital Space and Time

Rebecca M. Quintana, University of Michigan, rebeccaq@umich.edu

Extended reality (XR) technologies hold great promise for engaging and immersive learning experiences. Yet, issues of equity and access related to the use of such advanced technologies for learning are of significant concern. In XR environments, students can experience challenging interactions with content, peers, and instructors. For instance, students may encounter Internet connectivity problems or even have adverse physical reactions such as nausea, hampering their ability to fully participate. Additionally, because XR technologies allow for the creation of highly realistic and immersive scenarios and contexts, there is the potential for students to experience difficult emotional reactions such as fear and anxiety, which could also be a detriment to their learning. Designers of learning environments that include XR technologies have an opportunity to positively shape learners' experiences by carefully attending to a range of design elements that promote equitable access. As XR technologies become increasingly prevalent in educational contexts, it will be especially important to understand how arrangements of

space (e.g., levels of immersion in a learning context) and time (e.g., course structure and sequence) can play a role in advancing equity-focused design goals.

Method

To make progress on these design goals, we investigated the extent to which an online, graduate level XR for Learning course fostered an equitable and immersive experience for students. The course aimed to interrogate claims that are made about the educational value of XR technologies in support of learning. To explore these themes experientially, students borrowed virtual reality (VR) headsets from the university library. Over the course of each class session, students experienced both low-immersion spaces (e.g., a web-based, interactive classroom) and high-immersion spaces (e.g., the university campus recreated in VR). Each class session was carefully structured, creating intentional opportunities for students to "dwell in and step out" (Ackerman, 2004) of these spaces, according to the learning goals for the class and students' comfort with technology and course topics. Instructors offered alternatives for high immersion activities (e.g., watching a video screencast or using a VR application). Instructors' design choices were motivated by efforts to ensure that all students would be supported pragmatically in their use of XR technologies and upheld emotionally in their explorations of sometimes difficult topics and subject matter.

We created visual timelines (Quintana & Slotta, 2017) to portray all pedagogical design elements from each class session. These timelines emphasized two important dimensions of engagement: space (i.e., level of immersion, ranging from viewing non-immersive digital artifacts to interaction in a 3D world through a VR headset) and time (i.e., lesson structure and sequence). We used the Simulation Experience Design Framework (Raybourn, 2007)—a framework to facilitate the design of connected, immersive, and equitable learning experiences— to analyze and reflect on the visual timelines.

Findings

Our analysis and findings are structured according to the four dimensions of the Simulation experience Design Framework: interaction, narrative, place, and emerging culture.

- Interaction: The course design allowed for *co-present action* and *co-present reflection* (Raybourn, 2007). Various XR technologies allowed students to be co-present, engaging in collaborative problem-solving using shared artifacts. In one class session, students met together in the university's central meeting place in virtual reality. For some students, this was their first time "on campus" due to pandemic restrictions. In this setting, students joined a live networking event as part of an XR Summit, meeting with conference attendees including researchers, academics, and industry professionals. Each class session also included opportunities for *co-present reflection*, with structured and facilitated discussion opportunities in small groups, occurring in both low- or high-immersion spaces.
- Narrative: The course design achieved *co-created immersion with and through interactivity* in an immersive and information-rich problem space (Raybourn, 2007). In a low-immersion space (GatherTown), students engaged with various knowledge artifacts connected to the session's topic, such as short lecture videos, digital posters, and interactive whiteboards, together with their peers. Students participated in "fireside chats" around a digital fireplace, which underscored the communal nature of the experience. In high-immersion spaces, students participated in a variety of educational narratives, such as sitting alongside peers in a futuristic lecture hall and co-viewing a movie clip in an "art house" environment. While these experiences all connected to learning goals for the course, they were experienced in a narrative context, with students "taking on the role" of a student or critic.
- Place: The course design allowed for *active immersion through contextual cues* (Raybourn, 2007). In a high-immersion space (e.g., virtual chemotherapy scenario), students interacted with textual overlays, audio cues, and wayfinding symbols. Students were also provided low-immersion alternatives to experience this medical setting through narrated walkthrough videos of the treatment scenario. This allowed students to select the level of immersion that made them most comfortable, while still exploring the contextual cues provided through representations visible in the digital pace.
- Emerging culture: One criticism of XR environments is that they promote single points of view (Raybourn, 2019). An opportunity exists to support multiple points of view and perceptions across multiple spaces. Using this approach allows for a *socially-constructed culture of learning* to emerge (Raybourn, 2007). The visual timelines revealed that the course structure allowed for both homogenous experiences (e.g., students could come together in the same virtual space) and multiple divergent opportunities, such as choice of spatial modality (low or high immersion) and even choice of XR application. To explore the topic of empathy, students chose from applications that highlighted the lived

experience of individuals from a range of social identities. Students had multiple opportunities to share their reflections and reactions through digital workbook entries and small group discussions, contributing to a shared, emerging culture of learning.

Significance

The analysis revealed how arrangements of space (i.e., levels of immersion) and time (i.e., course structure and sequence) contributed to an equitable and immersive experience. Intentional pairing of high-immersion experiences with low-immersion alternatives created options for students who experienced barriers to engagement. Interleaving low- and high-immersion experiences in one class session helped mitigate the "intensity" of XR experiences, while creating a connected experience for students. This study shines a light on arrangements of space and time that contribute to equitable and immersive XR experiences. While findings are promising, we are just beginning to understand how instructors can advance equity-focus design goals in XR.

Integrating Academic and Professional Space-Time with Technology

Nikki James, Northeastern University, ni.james@northeastern.edu

Experiential learning is "the process whereby knowledge is created through the transformation of experience" (Kolb, 1984, pp. 38). In higher education, experiential learning pedagogy is used to assist learners with the process of transferring knowledge from the classroom into a real-world professional setting (James et al., 2020). In a capstone project, students are physically immersed in the classroom with the instructor integrating a real-world context through the introduction of an industry project. In an internship or co-op, students are physically immersed in a professional setting with the internship coordinator integrating a learning context through reflective writing and discussion. Despite which physical context is centered, these pedagogical practices introduce an industry professional into the learning environment, increasing the complexity of delivery and can impact the willingness of instructors to make this pedagogical choice (Jona & James, 2021).

Distance and online learning is often attributed with the role of democratizing and opening up access to education through its ability to mediate the transfer of learning remotely and asynchronously. Despite its benefits, it is not without its shadow sides when it comes to engagement and learning retention. If distance and online learning make access to education equitable and accessible, and experiential learning help learners transfer their learning to real-world contexts, then in order to to broaden participation in experiential learning distance and online options are required. However, combining experiential learning with online learning also combines the complexities they bring. In this new space-time configuration, the learner, instructor, and industry professional are in their own physical space and time making facilitation of the learning experience infinitely more complex.

Framing & Context

Bakhtin's notion of chronotopes (1981) is used in learning science as an analytical tool to examine the changes in space-time relations, particularly as learning adapts as a result of technology innovation and educational reform (Ritella et al., 2016). This study leveraged chronotopes to reflexively examine virtual internships, a technology-mediated learning intervention (hereafter referred to as virtual internship) developed specifically to broaden participation in experiential learning for students who are unable to access place-based and time-bound opportunities like internships that align with more traditional learning environments.

The virtual internship emerged over a three-year design-based research project. Over several design iterations the intervention designers focused on reducing the complexity of online experiential learning so that participation in a virtual internship was feasible for the learner, the instructor, and the industry professional.

Findings

In discussion with colleagues while preparing this symposium it became apparent that our research team was using instructional technology to reconfigure the space-time relationships between the learner, instructor, and industry professional. Moreover, the reconfiguration as opposed to the technology itself enabled a more accessible and scalable model of experiential learning that held its pedagogical integrity for individual students. The virtual internship intervention used technology to pass the work the learner was producing and the feedback the industry professional was providing back and forth between the learner and the industry professional while giving the instructor a birds eye view of the interactions and the ability to intervene in the exchange if required. Using the technology in this way folded the space-time distance between the classroom and professional space.

Significance

A reflexive examination of the 'new' space-time relations between the learner, teacher, and industry partner that the model illuminates two roles the technology was playing:

1. To uphold the operating rhythm and momentum of the virtual internship
2. To clarify and reinforce the agreed roles and responsibilities of the learner, teacher and industry partner.

The technology playing these two roles allowed the learner, teacher, and industry partner to 'sync' with the virtual internship itself. In a time-bound, place based experience the human actors would 'sync' with each other in a team meeting to clarify tasks, align expectations and check project status. Intentionally designing the role of the student, teacher and industry partner upfront and structuring the technology to capture and pass information back and forth enabled them to stay in sync and aligned despite the physical space-time difference.

During the initial phases of the research project the research team identified multiple different configurations of roles and responsibilities used at different research sites. Moreover, multiple different perceptions of the roles and responsibilities between the learner, teacher and industry partner in one virtual internship. Despite these perceptions of the roles and responsibilities having a significant impact on the expected actions of the learner, teacher and industry partner these expectations were implicit, leaving it up to chance whether the student, teacher and industry partner were engaging in the virtual internship with expectations aligned. By using the technology to layout and uphold the roles and responsibilities of the learner, teacher and industry partner the roles and responsibilities within the virtual internship were made explicit upfront and constantly realigned throughout the learning experience. Making the roles and responsibilities explicit up front and leveraging the technology to enforce them enabled the learner, teacher, and industry partner to align and consistently re-align their expectations of each other and stay in sync despite the physical space-time difference.

The key outcome of this reflective examination of the virtual internship through the lens of space-time highlights the need for intentionally considering the role of the technology when designing remote and distance models of experiential learning that are accessible to all learners.

Abstract: Artificial Intelligence (AI) is proliferating in both visible and invisible ways across our society. It is imperative for our new generation to gain a fundamental understanding of how intelligence is created, applied, and also its potential to perpetuate biases and unfairness. Because of the nature of AI, it is important that we take an interdisciplinary approach in order to ground the systems and models in real and meaningful contexts for learner exploration. This symposium explores these approaches with a multi-disciplinary group of researchers presenting empirical studies on designing and studying AI learning environments. These studies provide unique insights towards design recommendations, challenges, and opportunities in the rapidly emerging area of study in K-12 education.

Symposium Overview

Artificial Intelligence (AI) has become essential in daily technology usage, decision-making, and the STEM workforce (Long & Magerko, 2020). More traditional methods in scientific research and STEM occupations are being replaced with AI-based modeling and problem solving. The need to prepare the future workforce for advances in AI, and its potential to perpetuate bias and unfairness, has spurred the integration of AI into K-12 learning settings (Carney et al., 2020; Druga et al., 2017; Forsyth et al., 2021; Touretzky et al., 2019).

An emerging theme and emphasis on K-12 AI education is promoting its interdisciplinarity. The public tends to believe that AI-related work is all about programming. Thus, teachers may avoid introducing AI concepts in non-CS (computer science) classes, and students might view AI narrowly as an advanced CS topic (Long & Magerko, 2020). An emphasis on AI's interdisciplinary applications can help broaden access to AI (Akram et al., 2021). The interdisciplinary view would help students draw connections between application areas of interest and CS, broadening the range of students to whom such AI learning environments can appeal. Despite the many calls to promote AI's interdisciplinarity (e.g., Kusters et al., 2020), there remains a knowledge gap of how to develop meaningful experiences for students and teachers in K-12 settings.

Our contributors are from different disciplines and backgrounds (e.g., learning sciences, literacy education, science education, computer science, and human-computer interaction) and explore interdisciplinary K-12 AI education from different perspectives. Specifically, Zhang et al. investigated teacher learning in integrating AI concepts across disciplines; Walsh et al. explored using AI ethics as an interdisciplinary topic for classroom teaching; Akram and Yoder draw on the perspective of computational thinking to show students' learning in AI modeling of science phenomena; Jiang et al. examined students' data modeling practices that require an interdisciplinary understanding of AI; Payne et al. illustrated unique affordances of embodied learning

 © ISLS

through dancing in helping students to reason about capabilities and ethics of AI systems. Together, these contributions shed light on strategies in promoting AI's interdisciplinarity, teacher learning in integrating AI in different disciplines, and how students explore AI models and technologies (e.g., what students engage with, what their interactions are, and how do these interactions relate to learning of AI and other disciplines). This symposium will be a landmark in the development of our understanding of learning in the rapidly emerging area of study in K-12 AI education.

We will structure a panel discussion following these steps: co-chairs introducing the contributors, contributors briefly presenting their research in a sequence, contributors engaging in a panel discussion facilitated by the co-chairs (discussion topics will be prepared by co-chairs and also selected from attendees), co-chairs summarizing the discussed topics and presenting future directions.

Individual Contributions

1. Integrating AI Education Activities into Middle and High School Classrooms

Helen Zhang, Irene Lee, Katherine Moore, Yihong Cheng, & Beatriz Perret

The rapid expansion of AI is having unprecedented industrial and social impact and necessitates educating a generation of AI literate citizens who are familiar with AI technologies and can work with AI tools in various job tasks in the future. Yet, AI education is in its infancy and early findings on AI Literacy are just beginning to shed light on which topics are appropriate to teach at various grade bands and how learners gain an understanding of AI concepts and processes (e.g., Lee et al., 2021). Further despite the fact that AI itself is an interdisciplinary field, many students believe that only computer scientists or programmers work with AI. Such stereotyped views prevent them from recognizing the interdisciplinary nature of AI or their own capability of interacting with AI tools outside of computer science contexts. More research is needed to explore how AI education activities can raise students' awareness and foster their understanding of the interdisciplinarity of AI.

This exploratory study aims to address this issue by investigating whether/how AI activities can be infused into classrooms across domains and how the integrated AI learning experiences can impact students, particularly those who have been historically underrepresented in STEM and CS education. This study employs a multiple case study approach (Stake, 2013) and reports four cases of teachers who embedded AI into their teaching of the core subject area. The cases were selected from educators who participated in a year-long PD program that prepared them for implementation of an AI education curriculum called Developing AI Literacy (DAILy). The PD program consisted of (1) an online Book Club where educators read an AI book, learned the DAILy activities as a learner, and discussed their experiences and thoughts of AI and the DAILy activities; (2) a practicum where educators co-taught the DAILy curriculum in summer camps to middle school students; and (3) monthly webinars to share classroom implementation plans and experience during the school year. We utilized purposive sampling (Tongco, 2007) to select the four cases to represent the extremes on a continuum (Rubin & Rubin, 2011) and to allow for maximal variation sampling within the PD program. The selection criteria included subject area taught by the teachers (e.g., science, library, technology, math, and communication), teaching structure (co-teaching or teaching individually), and the age group of students (middle or high school students). All the teachers taught in schools with a high percentage of underrepresented students (i.e., at least 80% of the students were from low-income families and/or racial and ethnic minority groups). Multiple sources of data were collected such as interviews with teachers, observations of classroom instruction, and student work.

Preliminary findings demonstrate that teachers in various disciplines are able to find places to integrate AI lessons within the school day. A closer examination revealed differences in teachers' integration: in one case the AI activities were interwoven with the science content whereas in the other cases AI was taught as a stand-alone curricular component that meets the overarching goals of the course (e.g., developing students' information or technology literacy). For instance, in a science class, Ms. P developed an activity that asks students to use Google's Teachable Machine to train supervised models to distinguish between eukaryotic and prokaryotic cells. Students curated a dataset of pictures of both types of cells, labelled the pictures to train the models, and troubleshot and tested the AI model. Their understanding of the science and AI concepts was found to be reinforced through this activity. In the communication/debate class, Mr. D focused on utilizing the AI-generated Deepfakes and misinformation that appear in social media as a motivational hook to engage students. His students learned to use generative AI tools to create stories and art and debated/discussed who should own the copyright of the generated art. Such activities raised students' awareness of AI in media and sharpened their 21st century skills of debating, communicating, and critical thinking. Another finding is that co-teaching is a potentially powerful approach to demonstrate the connections between AI and other fields. In one case, three teachers (who

teach math, technology, and library respectively) chose to co-teach the DAILy activities so that each teacher could contribute examples of how AI is connected to the different fields.

These findings contribute to the AI education field by providing concrete examples of teaching AI across disciplines to help students realize the interdisciplinarity of AI. They also inform the design of PD programs by revealing guidelines on how to support teachers in reorganizing and revamping the learning experiences to make AI a valued and integral part of the schooling for all learners.

2. Adapting and Reinventing Interdisciplinary AI Ethics Curriculum: Co-design with Computer Science, Cybersecurity and English Language Arts Teachers

Benjamin Walsh, Aaron Guggenheim, Bridget Dalton, Stacey Forsyth, & Tom Yeh

The Imagine AI Project team is in its 3rd year of designing, implementing and analyzing Artificial Intelligence Ethics curriculum for middle and high school students. With AI's potential to solve significant social problems (Abebe et al., 2020), while simultaneously playing a role in the widespread violation of human rights (United Nations Human Rights Council, 2021), AI and AI ethics are urgent topics that belong in schools (Touretzky et al., 2019). Our team of Computer Science, STEM and Literacy educators and researchers is dedicated to helping youth become ethical consumers and creators of AI.

We view AI Ethics as an inherently interdisciplinary topic, which can be effectively taught by integrating CS, Ethics and Literacy instruction. We have designed and studied project-based instructional modules that combine original short stories with youth protagonists at the center of AI ethical dilemmas with non-fiction media, and immersive CS tool and simulation experiences (Alverman & Wilson, 2011). Together these modules help students develop a technical and intuitive understanding of how AI systems work, how these systems are affecting individuals and communities in positive and negative ways, and ask them to consider what it might take to design more ethical and empathetic AI. Our modules address topics such as algorithmic bias, the ethics of self-driving cars, recommendation algorithms and social media, and AI art and music. Each module culminates in a digital design task (such as creating a digital comic, an empathetic chatbot, or a creative computing artifact) that asks students to express their own stance on an AI ethics dilemma. We tested these modules in online summer camps and in two 9th grade ELA classes and found that students developed better understandings of how AI systems work, and more nuanced views on AI ethics issues (Forsyth et al., 2021).

We are currently partnering with CS, Cybersecurity, and ELA teachers to bring AI Ethics projects to their classrooms. We believe the best project-based units are customized to fit the needs of a specific group of students, and that teachers are vital co-design partners in making this possible (Penuel et al., 2007). An essential component of project-based learning is striving to provide students with authentic learning experiences (Polman, 2012). Our work has focused closely on ensuring that projects are authentic to the academic disciplines, and that students experience projects as authentic to their own interest, experiences and communities.

Using the Imagine AI modules that we tested in year 2 as a starting point, we have worked with teachers to adapt, extend and reinvent our curriculum to fit their classroom contexts. For example, based on recommendations by a 9th grade Cybersecurity teacher partner, we made a number of small shifts to highlight security concerns related to self-driving cars, facial recognition systems and recommendation algorithms, and added digital design tasks to challenge students with more extensive coding experience, including a new ethical app design challenge as a culminating product. Similarly, a 9th grade ELA teacher took the lead in integrating our materials into a project which examines how AI can reproduce and amplify social inequality. This project incorporates a graphic novel version of the classic text "Frankenstein," and asks students to create evidence-rich multimodal texts (Dalton, 2012) to answer questions such as, "Can AI be monstrous?" This ELA teacher's reinvention of the modules has maintained an interdisciplinary scope appropriate for AI Ethics, while also firmly situating the project within the teacher's primary discipline and academic standards.

Teachers have also played a vital role in helping to ensure that students will experience the AI ethics projects as authentic to themselves and their communities. For example, each partner teacher has shared very specific reasons why they believe particular examples of algorithmic bias are likely to resonate with their students more than others. Furthermore, teachers' co-design and enactment has been essential in helping us live up to Universal Design for Learning principles (Meyers et al., 2014), which help ensure that projects are accessible and challenging for all students. This includes scaffolded design challenges that are appropriate for students with extensive programming experience, and also those who will be writing code for the first time, and providing audio versions of AI ethics stories to support students' learning and language needs.

The various curriculum adaptations and reinventions that are emerging from these partnerships are informing our larger development and dissemination efforts. As we prepare to publish more of our AI Ethics stories and modules (https://www.colorado.edu/project/imagine-ai/resources), we are including alternate texts,

activities and design tools as well as strategies for customizing our curriculum so that teachers across a range of subject areas classes and contexts can implement projects that will better serve the interests and needs of their own unique groups of students and their academic disciplines. Preliminary data suggests that this approach can help the topic of AI ethics resonate with students in and across multiple subject areas classes.

3. Enhancing Computational Thinking Skills in Middle-school Students' Computational Modeling

Bita Akram & Spencer Yoder

Computational Thinking (CT) skills are becoming the new form of literacy. As a result, efforts for integrating CT in the K-12 curriculum have become the subject of increasing focus (Sengupta et al., 2015). One particularly effective approach is integrating CT skills within the mainstream K-12 science curriculum through computational modeling. Many researchers have argued that learning scientific concepts in the context of computational modeling facilitates and strengthens learning across both domains (Weintrop et al., 2016; Sengupta et al., 2015). In this work, we discuss activities for integrating one of the domineering aspects of CT, Artificial Intelligence, with a middle-school science curriculum (Akram et al., 2021) in the form of a computational modeling perspective and propose future directions for improving these activities.

Our activity design focused on two CT frameworks proposed by Sengupta et al. (2015) and Weintrop et al. (2016). Sengupta et al. (2015) argue that CT consists of practices that are essential to computing, computer science, and modeling scientific and mathematical concepts. These practices include problem representation, abstraction, decomposition, simulation, verification, and prediction. Following this framework, Clark and Sengupta (2015) proposed a computational modeling framework that incorporates three scientific modeling practices: model building, ramification, and deployment. This modeling framework shares similarities with Weintrop et al. 's (2016) CT framework that introduces four primary practices for CT: data practices, modeling and simulation practices, computational problem-solving practices, and systems thinking practices.

Specifically, we are developing a block-based simulation environment that models the spread of epidemic diseases through a contact-tracing app. Epidemic diseases and their effects on the ecosystem are among the core disciplinary ideas mentioned in the NGSS (Lead States, 2013). In these activities, middle school students engaged with the model building and model ramification of Clark and Sengupta's framework while practicing problem representation, abstraction, decomposition, simulation, and verification. We will extend our activities to incorporate model deployment and, thus, validation and prediction by providing students with empirical data about the spread of epidemic diseases. Through our proposed activities, students will be engaged in an iterative computational modeling approach where they build a model based on evidence and observations, observe interactions among different variables in their model, and evaluate its effectiveness by comparing the results generated from their models against empirical data. From this comparison, they identify the source of mismatch and revise their model to accommodate for that. This work will spur much-needed research on designing effective block-based programming environments that help students to build a comprehensive view of computational modeling, specifically AI modeling, for science-centered applications.

4. High School Students' Data Modeling Practices: From Modeling Unstructured Data to Evaluating Automated Decisions

Shiyan Jiang, William Finzer, Jie Chao, & Carolyn P. Rosé

Efforts to incorporate data literacy and analytics throughout K-16 education are on the rise (Lee & Wilkerson, 2018). In this paper, we argue that a neglected area of data literacy is dealing with unstructured data as well as the restructuring of structured data to prepare for effective modeling. The unstructured data this paper focuses on is text and building machine learning (i.e., a subfield of AI) models with texts from real-world datasets. This study aims to fill the gap of current research on understanding student modeling unstructured data and evaluating automated decisions from these models.

Through interaction analysis (Jordan & Henderson, 1995) of 28-hours screen recordings of high school students' AI modeling activities, we identified ten data modeling practices: drawing on experiences to create features, making hypotheses about patterns, analyzing confusion matrix, identifying patterns in training data, noticing gap between hypotheses and patterns, pursuing feature surprises, generating "thoughtful" testing data, reasoning about model decision making, describing models in social contexts, and engineering features.

Specifically, *drawing on experiences to create features* refers to the practice of creating features based on students' understanding of the way humans describe positive and negative experiences. For example, students created a feature, "delicious", as from their experiences, humans would use the word "delicious" to describe

positive experiences. In this practice, students leveraged their own experiences and knowledge to create different kinds of features, such as generating a feature "service" while describing how important services were for one's family to select restaurants. *Making hypotheses about patterns* represents the practice of explaining obvious patterns before exploring AI models, such as "if a review has feature 'love', most likely it's a positive review." In the practice of *analyzing confusion matrix*, students examined correctly and incorrectly classified reviews systematically. Through systematically analyzing reviews, students engaged in the practice of *identifying patterns in training data*. After identifying patterns, they noticed that some patterns were different from their hypotheses in the practice of *noticing gap between hypotheses and patterns*. For example, they considered "like" as a good feature for positive reviews (i.e., if a review has feature "like", most likely it's a positive review), but the model showed that almost half the reviews having feature"like" were negative reviews. When reading the negative reviews, they found that "like" could be used in negative reviews such as "don't like" and "taste like soap." To further explore models, students picked features that showed unexpected patterns in the practice of *pursuing surprising features*, such as exploring why feature "die" had a big weight for positive reviews. When testing the model with self-generated reviews, students wrote reviews that the model could classify correctly after realizing that the model only used single words and could not understand contexts when classifying reviews. We described this practice as *generating "thoughtful" testing data*. In the practices of *reasoning about model decision making*, *describing models in social contexts*, and *engineering features*, students explained multiple features driving decision making, discussed humans and social contexts behind data and data modeling (e.g., who would benefit from the model and who would be excluded), and iteratively revised the feature space for better model accuracy respectively.

Our analysis demonstrated that students engaged in a variety of data modeling practices when modeling texts and analyzing model decision making. These practices require an interdisciplinary understanding of AI (e.g., mathematical understanding for analyzing confusion matrix, literacy learning for making hypotheses about patterns, and computational thinning for engineering features). Future studies could explore how students leveraged personal experience and knowledge from different disciplines to build models with unstructured data through investigating patterns of data modeling practices.

5. Lived Experiences with Machine Learning and Dance

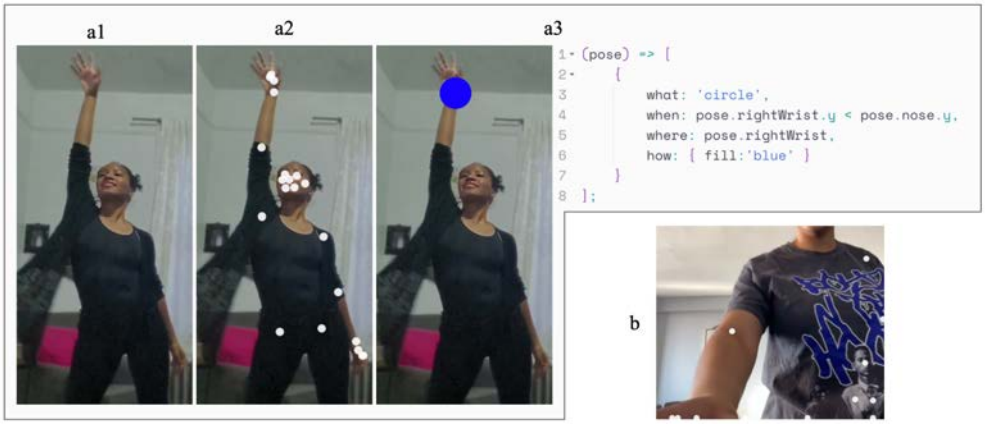
William Payne, Francisco Castro-Norwood, Kathleen McDermott, Yoav Bergner, & Kayla DesPortes

In this symposium, we will demonstrate how open-ended creative activities connecting computational models and dance led to meaningful and personally relevant discussions around the capabilities and ethics of AI systems. Researchers have shown that artistic computing (e.g., through dance) can create engaging and authentic learning experiences that embody learners' identities, experiences, and communities (Lindberg et al., 2020). Furthermore, the incorporation of physical activity may be an enjoyable and powerful method for introducing learners to machine learning (ML) (Payne et al., 2021). We briefly describe the danceON technology that enabled the intersection between modeling and dance then share two vignettes from a recent study in which a diverse group of 6 high school girls (2 Black, 2 Hispanic, 2 Asian) used danceON for 15 weeks, through a paid learning opportunity advertised as an internship.

danceON is an embodied creative coding environment that embeds ML models for pose detection enabling learners to create movement-responsive animations that are drawn and updated in real time on top of a pre-recorded video or webcam feed of solo dance. Learners write code to affix virtual animations to detected body keypoints and 2D coordinates using the keywords *what, where, when,* and *how* (Figure 1). Within this medium, simple animations can take on multi-layered meaning—e.g., learners used circles, superimposed onto dance videos, to represent a sun and moon and color change of dark to bright to signify hope.

 © ISLS

Figure 1
Video uploaded to danceON (a1) featuring pose data overlaid as white dots (a2) and a blue circle coded to appear *when* the right wrist is above the nose (a3). Participant example with shirt image mistaken for body (b).



Vignette 1, My body or my shirt?: Direct engagement with ML is central to danceON's technology and curriculum, and because participants choreographed a new dance nearly every week, they experienced ML system behavior across conditions, e.g., changes in clothing, lighting, camera position, etc. The first creative assignment, "Emoji Challenge," tasked participants in creating two positions, inspired by Merce Cunningham's solo "50 Looks" (1979), and coding a *when*-condition to draw a matching emoji over their face. Many videos yielded inaccurate and missing pose data. We discussed potential causes, and participants identified moments where their positions hid parts of their bodies, e.g., "*if my hand was here one second and then another second it was like behind my head, it would probably think it was still out there and not behind my head*," (Camille, pseudonym). One participant, Elise, demonstrated through her clothing how machine perceptions of bodies differ from human perceptions (Figure 1b): "*it like saw I had a person on my shirt and accidentally went on to that shoulder instead of the shoulder of my body.*" Participants not only discussed limitations of pose detection, but learned to work within its boundaries altering their code and choreography, and, as presented in Vignette 2, leveraged their knowledge when introduced to other ML applications.

Vignette 2, Classifying me and "everyone else": In a wide-ranging discussion in Week 8, participants connected their understanding of AI to personal experiences and publicized instances of bias. danceON integrates body-position classifiers made in Teachable Machine, a free web-application for rapidly training ML models (Carney et al., 2020). They trained models to identify two poses and read articles about misuse of facial recognition and bias towards white voices in AI home assistants (Hill, 2020). They discussed the causes of AI bias from the lack of developer diversity, "*products are right now mostly made by white people and geared towards white people*" (Janna), to the human role in training systems, "*although it is computer learning we're the ones who put it in place*" (Gwen). Caitlyn reflected on her family's Google home assistant, stating "[her parents'] *English isn't like, it's not perfect, so not like mine, or like standard American, so the Google had like a harder time to understand.*" Directly connecting pose detection and facial recognition systems, Gwen argued, "*we widen the range of what can be classified as a human face so it's like you have to take into consideration all features and all face colors and for your poses, like all heights.*" Following the discussion of bias, participants imagined a danceON performance that responds to AI bias. They noted that pose detection performs more accurately for slow movements, which Camille connected to classical dance styles that are "*expensive and only available to like a certain demographic,*" in contrast with fast movements in hip-hop dance. Camille proposed a performance with "two dancers, side by side" with "*code that like glitches for the fast dancer*" to represent the AI bias against that dancer's movements.

While the internship was exploratory and wide-ranging, moments captured in vignettes lead us to believe that future activities may capitalize on authentic encounters with AI with danceON. For example, we could use *when* conditions to illustrate key differences between rule-based AI and ML in which learners complete the Emoji Challenge with hand-written rules and Teachable Machine classifiers and compare/contrast the results. Additionally, learners could also work with each other's' code and classifiers and identify instances in which their systems work less well for others and then implement improvements. We also plan to design culturally sustaining curricula that supports embodied AI ethics education through discussions of AI in society.

 © ISLS

Discussion and Implications

As artificial intelligence (AI) and machine learning (ML) integrate across our society, we bring together a collective set of researchers to understand how we teach about these models and their implementations. Individuals must be equipped to understand the ways in which AI and ML are being operationalized, recognize issues within its implementations, and understand the consequences (benefits and drawbacks) of their use across contexts. The instantiation of these models is inherently interdisciplinary and thus we have constructed a set of empirical contributions exploring how AI education can integrate across various disciplines in K-12 education. Drawing on perspectives of our researchers conducting work across the learning sciences, computing education, literacy education, science education, and human-computer interaction, we pose a set of essential questions and discussion topics for the symposium authors and participants in the learning sciences community.

Promoting Disciplinary Knowledge and Practices

Interdisciplinary educational experiences are important for their ability to relate more honestly to the real world and to promote new practices for learning that develop as we connect across previously siloed content. Through the contributions we will stimulate a discussion around: How we might best support leveraging disciplinary knowledge to develop new knowledge and skills around AI? How can learners develop knowledge about AI that helps learners develop other disciplinary knowledge? How can we create learning experiences that promote reflections, experiences, and work with AI that are representative and embedded in real-world contexts and scenarios? How can the practices across different disciplinary domains with AI create new practices with AI?

Integrating Learners' Perspectives and Experiences

Learners bring a set of knowledge and experiences with AI to the learning environment through direct interaction with agents and models as well as secondary engagement through news and media. We will explore the questions: How can we use interdisciplinary contexts to promote learners' integration and reflection of their current perspectives, experiences, and knowledge surrounding AI? How can learners' lived experiences connect to their work theorizing, developing, and critiquing agents and models?

Critical Explorations of Ethics and Biases

The ways in which AI models are created and implemented have social and ethical implications. Learners must develop critical practices with developing and interrogating AI. Through the various contributions we will examine: How do different disciplinary practices provide entry to critical reflection and iteration of AI agents, models, and their implementations? How do disciplinary practices foster different ways to experience and reflect on biases within AI agents, models, and their implementations? How can we construct new practices within our learners that forefront ethics as part of how they engage in development and implementation of AI?

Abstract: The explosion of Artificial Intelligence (AI) applications along with findings of algorithmic bias toward marginalized populations requires that we redouble our efforts to make AI education equitable to all youth so they can become informed consumers and responsible creators of AI, and can thoughtfully engage with others around equity issues in AI. This symposium focuses on the discussion of five AI literacy programs/projects from across the United States, each attempting to incorporate equity in diverse ways. Together, the five projects explore AI education using multiple pedagogical approaches and learning contexts with unique affordances and constraints.

Symposium focus: Designing for equity in AI education

The concept of equity is laden with multiple interpretations, particularly in the education ecosystem. Within this realm, curriculum providers play a key role in the design of learning experiences and are thus pivotal in ensuring that equity concerns, issues, and topics are embedded into the development and implementation of any curricula. This is of even greater importance in AI curricula considering the increasingly ubiquitous AI applications that affect our daily lives and ethical implications surrounding the AI technologies.

AI education cannot happen without consideration of ethics and equity. However, what this looks like will vary from curriculum to curriculum, and context to context. This brings about the question of how AI learning scientists approach curriculum design. This symposium will bring five curriculum development groups from different organizations and institutions across the United States who are currently developing and researching AI curriculum for K12 education. All five groups identify addressing equity and social justice through the curriculum as one of the goals of their project as well as a design value. As documented and observed similarly in CS education (Santo et al., 2019), equity can mean different things to different people; therefore, how equity is being manifested in these programs and curriculum evidently varies context to context. While there are increasing numbers of projects and initiatives to bring more AI education into K12 settings, the learning sciences' understanding of how we can design AI curriculum for equity and social justice is still nascent. By discussing how each group goes about addressing equity and social justice in their current project in relation to AI

 © ISLS

technologies and supporting young people to develop ethical AI literacy, the symposium aims to highlight different design choices and implementations, allowing the community to learn from each group's current efforts and discuss opportunities and constraints of each approach.

Each group will describe how they think about equity in their own work, and how their current effort, both in terms of processes and products, embodies equity within their AI education activities. More specifically, the presenters will address 1) the framing of equity within their program/project; 2) equity as part of curriculum development--what measures were taken to ensure inclusiveness and relevance to the intended learners? 3) equity during implementation--what type of settings, tools, and populations did they aim to serve? 4) equity as part of the assessment process--how did they design assessments to be more equitable? 5) equity as part of teacher professional development--how did they design and implement student facing workshops and teacher professional development with teachers, with communities, and with AI experts? and 6) equity as a content area in the curriculum--how are issues surrounding ethical dilemmas and harms caused by AI technologies embedded within the curriculum?

How do presentations contribute to the aims?

The contribution from Walsh et al. addresses equity and social justice by embedding ethical dilemmas as a core part of their curriculum. They do so with clever use of multimedia short stories woven into nonfiction texts and media to situate learners; their project-based learning approach engages learners in diverse learning contexts from science discovery summer camps to high school English classes. Zhang and Lee offer further insights into the integration of ethics in an AI curriculum by employing design-based research and using conjecture mapping in their theoretical framework to guide the hands-on experimentation and participatory simulation experienced by the students. The project-based learning approach is bolstered with contributions from Lin et al., who introduce a "sandwich" model of a curriculum that starts with grounding the AI topic in an authentic community-based project. They also illustrate the use of remote codesign methods with middle school students to ensure that student voice is heard from the onset of curriculum design. Aliabadi et al. expand our views on implementation with their focus on community organizations, illustrating a means of designing an educational ecosystem that can make the efforts of AI education more impactful and scalable. Finally, Long and Magerko bring AI education to informal learning contexts (e.g., homes and museums) with elements that can be adjusted to fit learner needs. Together, these papers illustrate diverse framing of equity in diverse contexts and will provide the opportunity for rich discussion at the symposium.

Following, we provide a brief description of each of the five AI projects.

A multifaceted approach to designing for equity in the Imagine AI project

Benjamin Walsh, Bridget Dalton, Stacey Forsyth, Ellie Haberl, Jackie Smilack, and Tom Yeh

Purpose

Our team of Literacy, Computer Science and STEM educators and researchers is developing and studying curriculum modules to support middle and high school youth in exploring critical ethical issues related to artificial intelligence. These project-based learning modules are centered around original short stories that feature youth protagonists at the center of AI ethical dilemmas. Students read stories and non-fiction texts and media and build and manipulate simple AI systems. These experiences support rich discussion that combines social concerns with technical understanding. Each module culminates with students expressing their stances on AI ethics issues using digital media, such as comics, videos, and chatbots. We understand AI Ethics as an urgent topic relevant to youths' current and future lives, regardless of whether they envision a career as an AI developer.

A multifaceted approach to equity

Because of the notable tendency of some AI technologies to play a role in reproducing historical injustices (Buolamwini & Gebru, 2018), we argue that providing access to AI ethics education is itself an equity issue. In addition, we will discuss approaches to fostering equity related to curriculum and pedagogy and study. We pay particular attention to the importance of recognizing minoritized voices and youth perspectives on AI and other CS topics (Lee & Soep, 2016).

Equity in curriculum and pedagogy

We utilize a project-based learning approach to curriculum design, emphasizing Universal Design for Learning principles, in order to broaden access and engagement (Walsh & Dalton, in press). We take a Multiliteracies

 © ISLS

perspective on literacy learning, attending closely to the role of multiple modes and languages in meaning making, actively welcoming a broad set of strengths, perspectives, and experiences into AI ethics discussions (Smith et. al., 2021). Module content and stories feature diverse individuals and explicitly address issues of bias and transparency.

Equity in research contexts

We believe that teaching AI Ethics requires educators to explore structural inequalities associated with race, gender and social class that are now being extended and amplified by AI technologies (Gebru, 2020). Teachers addressing these topics must be responsive to the experiences and beliefs students bring to class, as well as the constraints and pressures placed upon them by school administrators and local communities. In order to better understand how to support teachers in performing this balancing act we have forged partnerships with schools in rural, urban and suburban communities with students representing multiple ethnicities and language groups. Our research contexts include remote AI Ethics summer camps, high school English and Cybersecurity classes, and middle school Computer Science classes. In addition to surveys, interviews, and class observations, we collect students' multimodal products where they express themselves through image, sound, and text, and use heritage and English languages. This data we gather across these contexts is helping us understand how effective we are in helping students develop nuanced, contextualized understandings of AI ethics dilemmas.

Addressing equity in AI and AI education in the Developing AI Literacy project

Helen Zhang and Irene Lee

Purpose

The rapid expansion of AI is transforming our lives and futures. To ensure that youth can productively participate in this future, they must have knowledge of and capability to work with AI. Furthermore, the ubiquity of automated prediction and decision making is altering society by dictating who has access to information, freedoms, and economic opportunity. Those from historically marginalized communities are at greatest risk of the negative impacts of bias in AI. Thus, access to AI education will dictate who has the power to develop AI technology, and also who will be able to audit AI systems and seek justice for themselves and others. Many of the current methods of AI education, however, focus on mathematical underpinnings of AI, making it discouraging to youth who have been historically marginalized in STEM/CS education. This paper reports how the "Developing AI Literacy" (DAILy) curriculum addresses equity in AI education by incorporating a social justice and ethics lens that supports middle school students to become AI literate.

Perspective(s) or theoretical framework

The theoretical framework encompasses two elements: first, integrating ethics into AI curricula motivates learners and enables them to see the relevance of AI (Saltz et al., 2019). Second, pedagogical strategies such as hands-on experimentation and participatory simulation can make AI concepts accessible and engaging for a wide range of students (Squire & Klopfer, 2007).

Methods

Using the Design-Based Research approach (Design-Based Research Collective, 2003) and conjecture mapping (Sandoval, 2014) as the overarching methodology, the research engages in iterative cycles of design and development of DAILy while conducting research to determine the impact of the program (see Figure 1 for the conjecture map of DAILy). This paper reports the analysis and findings from the first design cycle.

Data sources

The quantitative data included student responses to a test, administered before and after a DAILy camp to all participating youth that examined their understanding of AI concepts, attitudes toward AI, and career awareness. The qualitative data included observations, interviews after the camp, and student work.

Results and conclusions

We found high engagement of students with all activities addressing ethics issues. Female students of color were especially active in the investigation and discussion of fairness and the ethical implications and bias of AI. Furthermore, participatory simulations and hands-on investigations were found to be highly engaging. The pre/posttest showed that students developed an objective view of AI and were able to articulate the positive and

 © ISLS

negative potentials of AI tools. The interviews showed that students were able to connect AI ethics to everyday use of technology, technology designs, and their ideation of future selves.

Scholarly significance

Our work contributes to the AI education field by demonstrating that interactive pedagogy approaches and interweaving ethics within AI curricula can engage all students. The emphasis on AI's ethical and societal implications resonates with previous research that students from historically marginalized groups are more drawn to STEM/CS programs that teach the content through social justice lenses (Mark et al., 2013; Vakil, 2018).

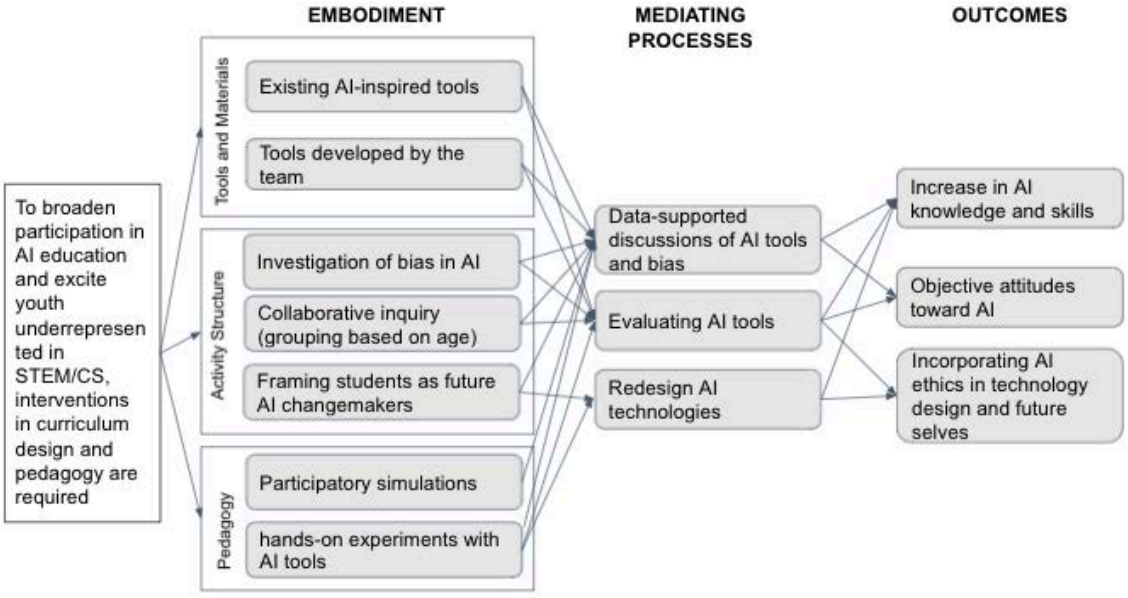
Conjecture map of DAILy curriculum



Responsible AI for computational action: Fostering AI literacy in middle school students

Grace C. Lin, Yoon Jeon Kim, Glenda S. Stump, Andy Stoiber, Amal Altuwaiyan, Hal Abelson, Eric Klopfer, and Cynthia Breazeal

Purpose

The Responsible AI for Computational Action (RAICA) curriculum for middle school students integrates Artificial Intelligence, Computational Thinking, Information and Communications Technology, and Design Thinking. RAICA aims to transform students from AI consumers to conscientious AI contributors who can create AI applications with positive social impact. A key mission of RAICA is inclusion with a focus on equity; the curriculum seeks to serve students from diverse backgrounds whose needs may otherwise be ignored or excluded, especially those who are traditionally marginalized in STEM and CS fields.

The modular RAICA curriculum model takes on the metaphor of a "sandwich." It takes a project-based learning (PBL) approach with each sandwich centered around a driving question and project theme. Ethical thinking is interwoven throughout instead of singling out ethics and biases as stand-alone units. The curriculum provides an opportunity to envision a new model of embedded assessment that supports iterative design thinking processes while providing evidence for AI literacy development. RAICA assessment embodies constructivist and situated cognitive learning principles (e.g. playful, socially mediated); it positions learners as reflective and critical leaders of their own learning, scaffolding them toward sensemaking with multiple forms of evidence that reflect diverse epistemological orientations and local norms and cultures.

Approach to address equity concerns

In the design of the curriculum, we turned to questions from equity scholars who urge the STEM education field to ask, "How do dominant narratives in STEM education position students of color as the taken-for-granted beneficiaries of educational policy, new curricula, or equity scholarship in STEM?" (Vakil & Ayers, 2019, p. 452). Our response to this is to actively co-construct the curriculum with traditionally marginalized students rather than treating them as passive (or "taken-for-granted") recipients or beneficiaries. This conviction is the driving force behind our painstaking approach to codesign with middle school students.

Furthermore, equity scholars voice concerns with representational politics, where STEM education and careers are positioned as the avenue that racially minoritized students *should* pursue, which is also problematic because it does not take into account students' own thoughts and relations to STEM learning (Sengupta-Irving & Vossoughi, 2019; Vakil and Ayers, 2019). Our codesign and project-based learning approach address this concern. Instead of determining top-down what students should do, we explicitly involve students to solicit their ideas of what they think is important to them and what they *want* to do.

Methods

To ensure that the questions posed within modules are relevant to students' lives, their communities, and the broader world, we employ codesign as a research method to engage middle school students and teachers. This method not only allows youth and teachers' voices to be expressed in the framing of our curriculum, but also provides insights into potential content, language use, and structural modifications. To date, we have held a two-week codesign camp with nine students recruited from a Title 1 public school with a large (>90%) Hispanic/Latinx population. We have gathered students' design journals, projects, other artifacts, and video recordings of the sessions.

Results and conclusions

Analysis of codesign camp data identified potential topics to include in future sandwiches, exemplar project ideas, and concrete suggestions for the framing of Driving Questions. Additionally, analysis of the video data promises to provide insights into productive facilitation techniques for this age group, as the power dynamic inherent with adult presence may make it challenging for students to open up and be candid. We plan to apply these insights to the next round of codesign sessions.

Scholarly significance

We employ the deepest level of participatory design with students, wherein they go beyond providing mere feedback as informants; instead they are actively co-creating with developers (Martens et al., 2019). Although previous research has highlighted the use of codesign or participatory design in student empowerment and incorporating student voice (Bovill, 2020) or codesign with teachers (Van Brummelen & Lin, 2021), ours is the first that we know of that codesigns with middle school students in the area of AI education. We anticipate our findings and approach can lead to a more equitable, authentic, and inclusive AI curriculum.

Community-powered problem solving with AI: A case study of Boys and Girls Clubs

Roozbeh Aliabadi, James Carter, and Joel Wilson

Purpose

Can local communities and the after-school spaces promote inclusive AI education? There is no doubt that communities have some of the essential qualities and expertise, and the development of AI skills is nurtured through community organizations and outdoor spaces (Touretzky et al., 2019). We explore how to equip our communities with tools, training, and spaces that promote the full breadth of the AI learning/teaching ecosystem in local communities. We believe schools could also learn from being more open and flexible learning centers with access to quality materials and care in the transition from STEM to STEAM by promoting community-powered problem solving with AI (Wang & Chiang, 2020).

Perspective(s) or theoretical framework

This study takes a project-based learning approach and focuses on the assessment of three areas of competency in AI: application of AI, computational thinking, and innovation and impact (Wangenheim et al., 2018).

Methods

To explore the question, we have designed an ecosystem of recruiting, training, and deploying local community members to teach in local Boys and Girls Clubs in the eastern United States. Furthermore, we have developed a 16-week module of AI classes focusing on the five big ideas in AI. To date, we have pilot-tested the program at four local Boys and girls Clubs in the eastern US where a diverse student population participated in an 8-16 week camp. We have gathered student's projects and artifacts along with teachers' feedback and observations.

Results and conclusions

Initial results of pilot data suggest several areas of improvement in the current project-based learning cycle of professional development, lesson plans, and structuring project-based learning teams based on age and gender. Factors attributed to engagement tend to increase as students perceive project-based learning's link to problems and issues faced in the local communities.

The role of equity in designing co-creative, embodied AI literacy activities for informal learning spaces

Duri Long and Brian Magerko

Purpose

We will discuss the role of equity in our research on designing co-creative, embodied AI literacy experiences for informal learning spaces. We center our discussion on a set of three different AI education activities we have designed for family group learning in home environments and museums. We draw on findings from a codesign study conducted with family groups in a museum (Long et al., 2021a) and user studies conducted to evaluate the efficacy of the activities with families in their homes (Long et al., 2021b; Long et al., 2022). Issues of equity play an important role in the framing of our work, our curriculum design and implementation, and the content of the activities we develop. Specifically, we focus on three key ideas—equitably defining AI literacy, reaching a broad audience via informal learning contexts, and using co-creativity and embodiment as equity design considerations — that frame how we address equity in our work.

Equitably defining AI literacy

One important aspect of equity in AI education is ensuring that learning experiences are both useful and accessible. We have conducted codesign activities with family groups to learn about their priorities and interests, and we will discuss how our findings have informed our definition of AI literacy as a set of skills that can be useful to learners in their everyday lives. We have also designed our curriculum and content to be accessible to learners with no prior knowledge of computing or AI. We will present three different activities that we have developed and describe how the content and curriculum is intended to reduce intimidation, build on learners' existing knowledge, and address equity-related issues.

Reaching a broad audience via informal learning contexts

We focus on designing learning experiences for informal learning contexts such as at-home learning, after-school groups, and public spaces like museums, art events, or parks. Introducing AI education in these contexts has the potential to expand equity by reaching learners who may not otherwise seek out opportunities to learn about AI (Falk et al., 2007; Rosin et al., 2021). Our aim is to develop an AI learning ecosystem that can engage learners across a variety of informal learning contexts. We have developed activities with scalable components that can be adjusted according to learners' needs (e.g. "unplugged" activities that require no access to technology that can be scaled up to museum installations). We will present the activities and discuss how we designed the content/materials to adapt to different implementation contexts.

Co-creativity & embodiment as equity design considerations

We utilize embodied interaction, collaboration, and creativity as three key design considerations in our AI literacy activities. We focus on incorporating co-creativity and embodiment because they have previously been shown to be effective at engaging and fostering learning gains and interest development in groups without prior knowledge of AI/CS (Sulmont et al., 2019) and groups that have been historically marginalized in STEM--specifically girls (Magerko et al., 2016; Werner et al., 2004; Guzdial, 2013; Buechley et al., 2008) and African-American students (Magerko et al., 2016; Eglash et al., 2006). We discuss how we have implemented each of these design considerations in our curriculum and content and reflect on their impact on learning, interest development, and equity in practice, drawing on findings from user studies we have conducted.

 © ISLS

Significance of the contributions

The five projects illustrate how learning scientists in AI education are designing to address equity in this burgeoning domain. Although the varied approaches bring about different challenges and opportunities, it is clear that there is much more work to do, both to define and achieve equitable education in this realm. Including voices historically underrepresented in technical fields like AI will be imperative to reach these goals. AI education is destined to influence future generations as knowledgeable consumers and ethical creators of AI applications; thus, it is of utmost importance that we collaborate and grow as a community to learn how we can design AI curricula that are equitable and promote social justice.

Audience participation plan

This session will be conducted as a panel discussion, with five presenters, a chair, and a discussant. After an introduction to the session by the chair, each presenter will give a brief, 5-minute overview of their project/program. The discussant will then synthesize current challenges and provoke discussion highlighting affordances and constraints of each program. The remaining time in the session will be allocated to audience comments or questions.

Abstract: With the rising demand for data skills across industries and disciplines, and the prevalence of data in all aspects and levels of our lives, it is critical to find new, more effective ways to develop students' data literacies. Stories can be an accessible way for students to personally connect to, and think critically about, data and its implications. But how can data storytelling be effectively implemented into classroom settings, in which instruction is often constrained to focus narrowly on quantitative skills? This interactive poster session showcases eight innovations in data storytelling in the classroom. Together, the contributions consider the various facets and functions of stories for supporting data literacies in contexts that span K-12 to university. By seeking to define the value and roles of storytelling in data literacy learning, this session will inform ways to create more effective and engaging data literacy instruction.

Background and goals

The demand for data skills is rising rapidly across industries and disciplines (Bargagliotti et al., 2020). Recent reports call for early instruction in statistical thinking, probability and variability, and the process of inquiry (Franklin & Bargagliotti, 2020), and for attention to asking statistical questions, working with multiple data types, and building skills to communicate with and about data.

However, the pervasiveness of data in our social lives means that data literacies are not just useful preparation for the workforce, but also critical for making sense of complex cross-cutting issues, such as the

 © ISLS

COVID-19 pandemic and climate change (Engel, 2017; Lee & Campbell, 2020). At the same time, classroom contexts pose numerous challenges to designers and educators who seek to promote students' data literacies. Constraints unique to the classroom, such as the need to adhere to subject standards, the limited time within a school day, and the compartmentalization of instruction to specific subjects, can focus data instruction narrowly on quantitative skills and tools. Ignoring the cross-disciplinary nature of data and the relevance of the social contexts of data limits opportunities for learners to use data for personally meaningful purposes, to address societal issues with data, and to critically examine how data is produced and used.

Stories are one way to engage students with the personal and societal impacts of data. Stories can serve as analytical tools, and for communicating both individual experiences and collective perspectives. By connecting personal, cultural and sociopolitical dimensions of data, stories offer opportunities to humanize data (Lee et al., 2021). This symposium explores innovations in data storytelling in classroom contexts. By showcasing curriculum designs and research insights from projects that span K-12 to university contexts, this symposium will examine opportunities to promote students' data literacy through storytelling and will critique the value added of stories over more conventional approaches to data literacy instruction.

What is the value of storytelling for promoting data literacies?

Stories have long been recognized as tools for sensemaking, identity building and empathy (Bruner, 1985, Cleto & Warman, 2019; Lind & Thomsen, 2018). Storytelling has moreover been mentioned in various ways in relation to data, including in fields such as science, data visualization (Park et al., 2021), and journalism (Matei & Hunter, 2021). It is also a more frequent topic in data literacy education. An informal search for the terms "storytelling," "data literacy," and "education," for example, returns 1320 results on Google Scholar, most, if not all, published after the year 2000.

However, definitions of *data story,* let alone of *story* more generally, vary. Some scholars define stories as a series of causally linked events, while others view it as goal-directed behavior toward resolving a problem, and still others define them in terms of specific components such as characters, settings, and plot (Stein, 1982). Meanwhile, in the context of science communication and data journalism, the term "data storytelling" has been defined as a narrative that offers a causal inference that counters audiences' assumptions (Matei & Hunter, 2021). Others write that good visual data storytelling draws an audience in, and helps to make data more persuasive, easier to understand, and to remember (Ma et al., 2011). Such claims about the value of data storytelling, however, remain largely under-explored (Liem et al, 2021).

In response to the increasing interest in data storytelling in education, this symposium seeks to approach a more robust understanding of the value of storytelling and of the roles that it can have in promoting data literacies in classroom settings.

Overview of contributions

Together, the 8 posters in this symposium demonstrate the various roles of storytelling in data literacy education. They show that stories can be used to contextualize and communicate about data in everyday life (Gebre); integrate different perspectives to represent and make sense of environmental events (Wagh et al.); critically engage with social inequities and stereotypes (Louie et al.); drive scientific exploration (St. Clair & Stephens); make sense of aberrant or unexpected data (Davidesco et al.), reflect on personal implications of data (Tes et al.); reframe sociopolitical crises (Rubel et al.); and identify personal connections to broader data patterns (Wei et al.).

A key theme across posters is that stories serve to humanize data, illuminating social contexts and individual perspectives. Stories are variously used as entry points into bigger ideas, invitations to inquiry, and analytic tools to make sense of data and relate to complex patterns and implications. Importantly, stories invite learners to draw upon various disciplinary practices and ways of thinking that move beyond STEM, including imagination, performance, visual expression, and writing. Together, these activities engage transdisciplinary data literacy practices such as prediction, interpretation, and communication.

Finally these posters identify and address challenges faced in implementing storytelling innovations in classroom settings, including the need to link topics to curriculum standards, and to ensure the authenticity of the different disciplinary practices involved in working with data within the structure of school.

Symposium format

Following introductory remarks by the session chairs, we will provide the audience with guiding questions, and will facilitate two rounds (4 posters each) of interaction among presenters and attendees. By allowing co-presenters to also visit and interact with co-presenters, we seek to encourage rich discussions that cut across issues raised by their own and the audience's projects and experiences.

 © ISLS

Following these rounds of interaction, two discussants will stimulate a broader conversation across presenters and attendees by offering reflections and insights from their unique perspectives: Amy Stornaiuolo, who studies youths' digital literacies and technology integration in schools; and Laurie Rubel, who studies the sociocultural contexts of mathematics education, with foci on data science and spatial justice.

This symposium will spark conversations about such questions as: What makes a data story a story? How is a data story different from an argument or an explanation? How can stories be used to promote data practices in meaningful and accessible ways to a broad range of learners? What challenges, opportunities, and strategies are relevant when incorporating data storytelling in classroom contexts? What kinds of support—technology-based or otherwise—benefit students and teachers in navigating their use of stories for data literacy? How can educators and learning designers leverage the affordances of stories to promote specific data literacies and practices? How can we support students' in moving from exploring data to producing a data story? Likewise, how can we support them in moving from an understanding of data situated in a story's context, to an understanding of the broader implications of data?

In answering these and other questions, educators and researchers will better know how to most effectively incorporate data storytelling into classroom settings to promote data literacies.

Descriptions of posters

1. Learning Design and Everyday Life as a Learning Context for Data Literacy

Engida Gebre

The increasing role of data in various aspects of our life prompted consistent calls for data literacy education. However, educational interventions are focused on developing technical competence and algorithmic aspects of data literacy thereby resulting in a narrow understanding of the concept (Gebre, 2018; Gould, 2017). In his critique of data literacy education practices, Mertala (2020) argued that the way we teach about data in schools is serving as a hidden curriculum for promoting data (il)literacy among students. This is because data is often framed as a "cognitive authority" and instructional practices focus on developing skill sets to deal with spreadsheets of data with limited connection to the role of data in everyday life. Addressing the disconnect between data literacy education and data practices of students in non-academic settings requires a situated data literacy education that considers students' everyday life as a learning context. That is, educators could design learning environments that involve storytelling with data where students learn with and about data as it relates to their everyday life and their communities.

In this proposal, we draw from our previous as well as newly started data literacy projects with secondary school students to a) develop learning design options that consider ways of using students' everyday life as a learning context for developing data literacy, and b) share students' work on storytelling and news reporting with data. More specifically, we build on the notion of learning as "active contextualization" (Gebre & Polman, 2020) and articulate learning design options where students consider the conceptual, competency and contextual aspects of data literacy. Using such an approach raises students' awareness about and understanding of data in everyday life thereby reducing what Brunton and Nissenbaum (2011) referred to as "epistemic asymmetry" related to data (il)literacy.

2 Investigating California Wildfires as a Site for Middle School Students to Engage in Data Practices & Modeling

Aditi Wagh, Engin Bumbacher, Adelmo Eloy, Jacob Wolf, Tamar Fuhrmann, Paulo Blikstein & Michelle Wilkerson

A central goal of science education is to support students in scientific sensemaking of real world phenomena. This often involves developing and evaluating models or representations of the phenomenon in conjunction with data about real world phenomena. The practices involved in coordinating between data and models in this process can offer productive opportunities for science learning (Blikstein, 2014; Fuhrmann et al., 2018; Georgens & Manz, 2021; Gouvea & Wagh, 2018). More research is needed to understand how to integrate these practices to foster science learning.

In this paper, we propose a conceptual framework that characterizes how students draw on different qualitative data and scientific modeling practices to answer a driving question. We draw on video data from a design-based research study on 8th grade students in California working on an inquiry-based unit on wildfires.

They build computational models and analyze actual satellite videos to investigate mechanisms underlying smoke spread from wildfires in their state.

As a lived and shared experience, the California wildfires 2020 present a rich conceptual space for student sensemaking and storytelling (Bruner, 1991). We show that the process of coordinating data and models reflects elements of storytelling identified in our previous work (Wagh & Dickes, 2020) in three ways: (1) Students consider and reconcile competing perspectives as they try to integrate between different understandings of how wildfire smoke spreads from multiple sources (Ochs & Capps, 1996) such as their own lived experiences, their own and peers' scientific models (of the phenomenon) and their analysis of the data; (2) Students construct a theory of events along a temporal dimension as they interpret how successive events impact each other (Ochs & Capps, 1996), and position the models and data at different points along that dimension; and (3) As a class, students construct collaborative meaning through co-authorship, interpretation and multiple retellings of narrative events.

3 How Do Students Use Comics to Engage with Data?

Marian Tes, Kayla DesPortes, Megan Silander, Ralph Vacca, Camillia Matuk, Anna Amato & Peter J. Woods

Creative media provide opportunities to expand on the ways learners explore and find personal connections to data (Bhargava et al., 2015, D'Ignazio & Bhargava, 2016). As a form of creative media, comics offer a unique set of affordances for making sense of data (Bach et al., 2017). However, there is little if any research on how comics can activate young students' engagement with data, which would inform new ways of promoting data literacies in classrooms. This study asks: *How do students use comics to engage with data?*

We co-designed a unit with an art and a math teacher, who implemented it in their classrooms. In the math classroom, students (*N=33*) examined two datasets: (1) a national dataset from the Pew Research Center about teens' views of and experiences with friendships, social media, technology; and (2) students' own responses to a survey we designed asking about their friendships. Based on these data, we prepared boxplots, dotplots, and bar graphs. In their art class, students used the digital comic-making tool, Pixton, to communicate stories about friendship using inferences made from the graphs. We coded students' comics to identify: (a) data reasoning apparent in their comics (e.g., reflecting on one's relationship to the data, questioning the validity of data), and (b) whether data were intrinsically or extrinsically embedded in the narratives.

We found that comics that intrinsically embed data into narratives demonstrated nuanced engagement with data. Whereas some comics served simply as an alternative to reporting statistics (e.g., "You know only 47.8% of people think it's kinda easy to make friends?"), others integrated data in ways that advanced a plot. In one comic, for example, the main character reflects on being a part of the 21.7% of people who find it hard to make new friends, while simultaneously accepting an invitation to hang out with a prospective friend. This study demonstrates how comics can be an accessible way for students to engage with data, and can help teachers identify students' emerging data literacy practices.

4 Promoting Data Literacy Skills through Authentic Research Experiences in the High School Classroom

Ido Davidesco, Noah Glaser & Jimmy Naipaul

Data literacy is critical for students to make sense of complex societal issues, such as the COVID-19 pandemic and climate change. Yet, current K-12 curricula provide limited opportunities for students to engage in rich data practices by gathering, manipulating, analyzing, and visualizing data. BrainWaves was developed to support high school teachers in facilitating student-led neuroscience-inspired investigations. In this curriculum, students first learn about neurons, brain anatomy, and brain plasticity, and then, with support from science mentors, develop a research question of personal interest to them (e.g., how does listening to music affect learning), collect and analyze data, and share their findings at a culminating program symposium (Azeka et al., 2020).

This study explored the nature of student experiences analyzing and interpreting data in BrainWaves. We used a phenomenological methodology consisting of semi-structured interviews with program participants (37 students and 25 teachers). The analysis identified several key themes. First, students and teachers reported tension between having too much and not having enough data. Some students felt overwhelmed by the amount of data and had difficulties seeing the big picture, while others felt that they did not have a sufficient amount of data to address their research question due to difficulties in the data collection process. Second, interpreting data, especially when it contradicted students' hypotheses, was a challenge, which often resulted in students focusing

on aspects of the data that supported their hypotheses. Third, support and scaffolding from teachers and science mentors emerged as a key element in shaping students' experiences of working with data. These findings suggest that student-led research investigations can provide a rich context for students to develop their data literacy, yet sufficient scaffolding and structure are needed.

5 Grappling with data stories of social groups and social justice: A strategy for building interest in data literacy among historically marginalized youth

Josephine Louie, Beth Chance, Soma Roy, Emily Fagan & Jennifer Stiles

The world today is awash in data. Although data science is one of the fastest growing occupations in the U.S., historically marginalized groups such as Blacks and Latinos/as are greatly underrepresented (Priceonomics, 2017). To broaden participation in data science and to help all people thrive in a data-driven world, schools need new strategies to draw more diverse students to data literacy learning.

The *Strengthening Data Literacy across the Curriculum* project has been working on such a strategy. In line with Gutstein (2003) and Ladson-Billings (1995, 2014), the project developed prototype curriculum modules with a social justice focus to promote stronger statistical thinking and interest in data literacy among students from historically marginalized groups. In these modules, students use person-level data from the U.S. Census Bureau to articulate data stories (Pfannkuch et al., 2010) about whether and why group outcomes diverge. Using the online data visualization tool CODAP, students address questions such as: What have the incomes of higher- and lower-income earners looked like over time? What might explain the wage gap between males and females? How might we respond to a claim that immigrants are less likely than the U.S.-born to work?

Pre- and post-survey data from over 200 students in non-AP statistics classes from seven high schools with high proportions of Blacks and Latinos/as indicate that students who used the modules showed statistically significant growth in their interests in statistics and data analysis. Student focus groups and written reflections suggest that students found it engaging and meaningful to use multivariable data to wrestle with stories about real or purported inequalities among groups relevant to themselves and their families. Building students' abilities to tell data-based stories about social group outcomes requires interdisciplinary knowledge and skills, however, with implications for teacher training and professional development to support this learning approach.

6 Using data stories to motivate student exploration of science phenomena

Natalya St. Clair & Lynn Stephens

We want students to have the experience of learning science by doing science (Bell et al., 2005). Data stories can be used to frame guided inquiry so that students can use data they produce (Hardy et al., 2020) to communicate their thinking. In *InquirySpace 2: Broadening Access to Integrated Science Practices,* we frame curricular units with a phenomenon in which students produce data with sensors and then explore those data in an integrated data analysis environment. By developing a set of compatible technologies and approachable activities, students from many backgrounds may learn science by doing science—and communicate their findings with data.

In this exploratory case study, we visited a high school where half of the students are economically disadvantaged and a high proportion are minority students. A 9th grade biology teacher used the question, *Might having a fever affect your ability to digest dairy?* to motivate exploration of how temperature affects the reaction of milk and lactase. Using data she had collected with a glucose meter, one student interpreted the possible effect of several variables. When presenting to the class, the story she told of her data continued beyond the driving question, as she discussed where a lactase enzyme might be produced in the body and why. We consider which curricular and teacher supports may have helped motivate this student to expand on the story that was used to frame the inquiry.

7 Storytelling with Data in Response to Crisis: Shifting Away from 'Maths of the Morgue'

Laurie Rubel, Beth Herbel-Eisenmann Shiyan Jiang, Jennifer Kahn, Vivian Lim & Lee Melvin Peralta

Note on Authorship: This work represents the equal contributions of this writing group. Lead authorship is rotated on publication pieces; subsequent authors are listed alphabetically.

Storytelling in times of crisis–often told from the points of view of governments, corporations, and other institutional actors–typically showcases data using what we call "maths of the morgue" (Lim et al., under review). "Maths of the morgue" presents detached, disembodied, and unemotional views of crises, through visualizations that present an accounting of loss, using dehumanized quantities (e.g., fatalities, case numbers, unemployment rates). This form of storytelling benefits those in power by enabling governments, corporations, and institutional actors to exert and maintain influence over others with the effect that "maths of the morgue" becomes a technology of domination and control (Cisney & Morar, 2015). A "maths of the morgue" approach has become the default in K-16 education (Wilkerson & Polman, 2019), which increasingly emphasizes data and data visualization without adequately attending to the pivotal roles that emotion, action, and the imagination play in data (Kahn et al., under review). This approach to data storytelling in education neglects other possible liberatory functions for data storytelling like cultivating imagination and hope.

We present a reimagining of storytelling with data using a "maths of the living" approach, which draws on a synthesis of critical frameworks that attend to dimensions of power, race, gender and place (Data for Black Lives, n.d.; D'Ignazio & Klein, 2020; Loukissas, 2019). Our conception of "maths of the living" highlights the underappreciated capacity of data and data visualizations to embrace an animated view of life and personal experience; to embrace culture, history, power dynamics, ambiguity, and rule breaking; and to inspire action and shift our ethical orientations rather than representing the world from afar (Lim et al., under review). We formulate suggestions for learning designs that shift away from "maths of the morgue" towards our alternative of "maths of the living" and illustrate this shift using examples of storytelling with data.

8 Storytelling with Data in the Third Space: leveraging students' data literacies for scientific investigation and social change

Xinyu Wei, Cherise McBride & Michelle Wilkerson

The Storytelling with Data for Social Change workshop was designed to develop students' scientific data literacy through investigating, reorganizing, and reasoning the publicly available datasets on the Common Online Data Analysis Platform (CODAP). The workshop aimed to make data science education more accessible for middle school students from socioeconomically minoritized communities.

In partnership with the Lawrence Hall of Science, we recruited seventeen participants ranging from 12 to 14 years old. Participants were mostly from the Greater Bay Area, CA, USA, and from both dominant and non-dominant backgrounds. During five workshop sessions, students journeyed through a scaffolded introduction to the topic of environmental racism. They first read case studies and interviewed family members, then analyzed local datasets using CODAP to situate data patterns in terms of personal and historical contexts. Leveraging their repertoires of practice (Gutierrez & Rogoff, 2003), students used the Story Builder plug-in within CODAP (Wilkerson et al., 2021) or Google Slides to compose multimodal data stories and presented them on the course's last day.

We designed this workshop to be a third space (Gutierrez, 2008), whose curriculum is built on students' underlife (Goffman,1968; Gutierrez et al., 1995) to foster a co-constructed dialogic learning opportunity. We examined how people in different neighborhoods can be impacted by health hazards disproportionally, which inspired some students to investigate why some jobs are dominated by particular racial groups. For example, one 7th grade Latina student noticed the correlation between the dusty air and the frequent usage of eye drops by her father, a long-time construction worker. It prompted her to filter the asthma dataset and compare the mean number in her zip code to other nearby cities.

These stories position students' everyday practices and interests as grounds for expansive learning. They also demonstrate students' data literacies as sociological and historical practice, a frame that enriches data literacy in K-12 classrooms as culturally-sustaining, sociocritical, and ultimately supporting the construction of just social futures.

Abstract: The purpose of this symposium is to consider the embodied nature of failure in different learning environments, contexts, mathematical situations, and age groups. Our exploratory work was guided by the following questions: (a) How is failure represented through our bodily actions? (b) How is failure co-constructed through our bodies? (c) How are our reactions to failure embodied? (d) How might embodied failure be framed or conceptualized across mathematical situations? We explore these questions through a close examination of the intersection of embodied cognition, failure, and mathematical activity as presented and challenged by a diverse spectrum of scholars. While grounded in mathematical activity, this symposium will contribute to the ongoing state of learning science research regarding how the mind, body, and environment work together to highlight student's reasoning and thinking, particularly within moments of failure.

Introduction

This paper begins with two examples from research collected from seven groups of students in grades 3-5. Our goal with these two examples is to illustrate what we as co-organizers were noticing in terms of the embodied nature of failure within a low-notation environment (Williams-Pierce et al., 2021). The task was two-fold. First, students laid a path for Dash, a programmable robot, to traverse by placing sections of tape from one side of the room to the other. Second, students used the Blockly app to program Dash to travel on the path laid by another group. The first example is from a group of Grade 5 students negotiating about a specific angle between two adjacent strips of tape.

> As Ben[1] laid a section of tape to the end of the path, Olivia stated, "Make it jagged. That's way too long." To explain what she meant and perceived, she performed an action of pulling up the tape section from the floor, ripping it into two parts and laid one piece of the ripped tape back down. She then stated, "keep doing that pattern," and pointed toward a specific angle on the path (see Figure 1). Later, Olivia changed her suggestion from 'jagged' to 'zig-zag', saying "We can do zig-zags." Olivia pointed toward the same angle as earlier to illustrate what she meant. Responding to Olivia's suggestion, Red proposed to the group, "We have to make really tight angles." Chris added, "Make it a tight angle." Next Ben added, "Make it zig-zag."

Figure 1
Use of pointing gesture to indicate angle to repeat

 © ISLS

In this example, Olivia perceived Ben's section of tape to be a failure in that it was too long. Olivia corrected Ben's action and provided feedback to him and the group through using her bodily actions to remove and manipulate the section of tape to what she perceived as an appropriate length to construct a zig-zag pattern. In addition, this example highlights how the use of pointing gestures supported Olivia to clearly communicate what she meant by 'jagged' and 'zig-zag' as the group came to a shared understanding of the informal word 'zig-zag' in relation to other words such as 'tight-angle.' The second example is from a group of Grade 4 students testing Dash's movement along the path, particularly if the next line of code – left thirty degrees – was appropriate based on their perception of the angle measure formed between two sections of tape. The enactment, or the testing, of the program by Dash made Patrick conclude that turning left thirty degrees was not enough for Dash to be positioned directly on the next section of tape.

> Patrick stated, "It [Dash] was off a little bit." Before they began discussing and negotiating the angle measure, Almond created a border of the path with his hands (see Figure 2a). Next, he repositioned his body/head to over Dash (see Figure 2b), then stated, "So maybe like thirty-five, thirty-five."

Figure 2
Almond using his body to make-sense of Dash's position

Figure 2a

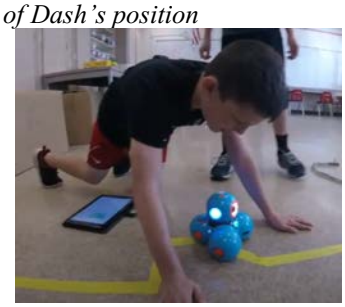

Figure 2b

To make sense of the failure in the code as enacted by Dash, Almond used his body to imagine himself traveling along the next section of tape (Figure 2a) before considering the perspective of Dash as positioned on the path (Figure 2b). In other words, Almond seemed to embody Dash through his bodily actions to conclude that the angle measure should be 35-degrees as opposed to 30-degrees.

Building on our observations, the purpose of this symposium is to consider the embodied nature of failure in different learning environments, contexts, mathematical situations, and age groups. Our exploratory work was guided by the following questions: (a) How is failure represented through our bodily actions? (b) How is failure co-constructed through our bodies? (c) How are our reactions to failure embodied? (d) How might embodied failure be framed or conceptualized across mathematical situations? This collective work is situated within mathematical activity as we are focused on the actions and behaviors of participation in different mathematical practices (e.g., relating, problem solving) across a variety of environments, contexts, and situations (Plaxco & Wawro, 2015). As described by Rasmussen et al. (2015), as students engage in mathematical activity, they enact their understandings while also building and/or expanding their ways of knowing and reasoning. As such, we contend that the implications of this symposium lies in the potential to develop a range of descriptions that highlight the multiplicity of established and potential relationships between embodiment and failure (i.e., embodied failure) and inform the theoretical and/or empirical groundings of ongoing and future scholarship.

Shared theoretical groundings

Each contributor thinks critically about embodiment and failure within mathematical activities– but in a wide variety of ways. We share theoretical groundings in the sense that each contributor considers these elements to be crucial – but how we perceive, operationalize, and analyze each are different. That difference is the subject of this symposium, so we only briefly describe foundational work for embodied cognition and failure below.

Embodied Cognition

Recently, learning scientists argued that human cognition is embodied, human abilities to solve problems are deeply intertwined between body and brain (e.g., Hollan et al., 2018). Our gestures and bodily action can be considered cognitive components because they shape our thinking (Krish, 2013). Gestures play an integral role in interpersonal communication where core problem domain concepts may be difficult to explicate in language

(Nathan et al., 2013; Reynolds & Reeve, 2001), and gestures can contain unique communicative content separate from spoken language (Williams-Pierce et al., 2017). In addition, full-body movements are vital resources for sense-making and understanding and using mathematical concepts (e.g., Hall & Nemirovsky, 2012; Vogelstein, 2020). Central to embodied perspective in learning science is understanding learning in terms of learner's "participation in practices of inquiry and discourse that include interactions with others and with the material, symbolic and technological resources in their environment" (Kozma, 2013, p 206). In this way, an embodied perspective on the nature of tools and representations includes attending to how tools and representations are perceived and used alongside language, bodily actions, and gesture, as well as their roles within rich social and physical interactions (White & Pea, 2011).

Failure

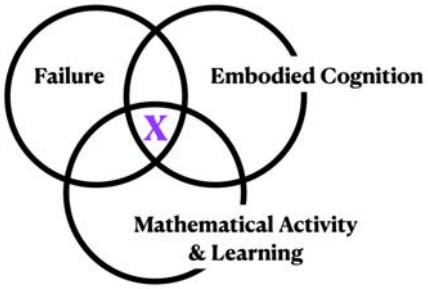
Prior research has highlighted the complex nature associated with failures as it can be viewed as "whatever [felt] like a failure to the person experiencing it" (Bishop, 2017, p. 962), or synonymously referred to as mistakes, errors, desirable difficulties, and unhappy eventualities to name a few (e.g., Simpson et al., 2020). Some consider failure as productive, an opportunity to develop conceptual understanding and engage in the iteration design process (Kapur, 2015; Searle et al., 2018). Conversely, others, for example educators, feel uncomfortable allowing youth to experience failure due to the negative associations and feelings regarding failures within learning environments (e.g., Lottero-Perdue & Parry, 2017). Further, perceptions and feelings about failure experiences do not necessarily transcend learning environments as failure in an academic context may be viewed as a negative, debilitating experience while failure in a DIY-making context as a positive, enhancing experience (Simpson et al., 2018). In the field of mathematics, students too often withdraw from completing a task or a set of problems that is perceived to result in an incorrect response, or in failure, which in turn leads to learned helplessness and a negative attitude toward mathematics (e.g., Chinn, 2012). As this scholarship implies, failure cannot be explicitly or clearly defined as what it means to experience a "failure" is dependent on many factors such as the individual perspective, the environment, the activity, and the interactions with self, others, tools, and materials.

Session overview

As the organizers of this proposal, we have been examining failure and/or embodiment in a variety of mathematical learning contexts (Shokeen et al., 2020; Simpson et al., 2018; Williams-Pierce, 2019). In particular, we invited scholars who approach research in embodied mathematical failure from a variety of different directions that lie in the intersection as illustrated in Figure 3. We contend that the significance of the collective work lies within this intersection, particularly the nature of failure within the teaching-learning process. For example, Soto (Paper 1) primarily focused on embodied mathematical cognition, with failure backgrounded (but still crucial) in their work, while Kapur (Paper 5) focused on productive failure in mathematics classrooms and used embodied cognition to better understand his students' reasoning and communication. Plaxco (Paper 3) and Katirci and Williams-Pierce (Paper 4) both examined the embodied failure of learners when interacting with designed objects that give feedback directly with each interaction, such as a Rubik's cube or touch-screen videogame, respectively. Further, we varied the age of participants, as well as the context of learning - Ellis (Paper 2) examined middle-school students in a teaching experiment, while Baker and DeLiema (Paper 6) focused on informal childhood playground activities. The symposium will be structured as follows: (1) engage the audience in an experience to evoke and reflect upon the embodied nature of failure; (2) individual presentations; (3) the discussants will make connections across individual presentation and discuss implications of the collective work; and (4) questions and comments from the audience.

Figure 3

The intersection of Failure, Embodied Cognition, and Mathematical Activity & Learning is the focus of this symposium.



In the following sections, we introduce the proposed symposium presentations to provide an overview of the breadth of the discussion.

Learning: When our bodies contradict known facts

Hortensia Soto

It has been said that geometric reasoning is to gesture (or other utterances) and diagrams as algebraic reasoning is to speech and symbolism (Soto-Johnson & Troup, 2014). A goal for our students is for these two types of reasoning to work in tandem. Unfortunately, this is not always the case, and in general, students tend to question their geometric reasoning even if their embodied experiences support their geometric reasoning. There are also instances where students believe in the embodied experience, even though it conflicts with mathematical facts that can be proved algebraically. This phenomenon has been observed repeatedly when learners are asked to traverse the sides and internal angles of a triangle. Instead of traversing the internal angles, learners traverse the exterior angles and thus, convey that "maybe the sum of the interior angles of a triangle is 360 degrees." Thus, embodied failure can manifest as a disconnection between the two types of reasoning. This may emerge when learners fail to believe their embodied actions or fail to recognize the inaccuracy in their embodied actions.

Generalizing beyond body-supported dimensions

Amy Ellis

Our talk will consider the effects on students' generalizing of transitioning from contexts in which students can use embodiment to imagine, visualize, act, and determine failure to contexts in which they cannot. Specifically, we report on a teaching experiment with two secondary students who explored the volume of a growing cube and determined expressions for additional volume as the cube grew. In the three-dimensional context, students engaged in embodied actions with physical cubes to validate or invalidate their hypothesized expressions. When shifting to higher-dimensional hypercubes, students no longer had embodied contexts to support their reasoning, and consequently moved from a physical representational register (Duval, 2006) to a combinatorics representational register. We identified and explored these shifts in registers as a supporting mechanism for students' generalizing activity.

Twisty puzzles and intentional temporary failure

David Plaxco

In my recent work, I am developing instructional materials that leverage the Rubik's cube and other twisty puzzles to support mathematical content and practices during transition to upper-level mathematics courses. When solving a twisty puzzle, part of what makes the process so difficult is that the object itself requires the solver to temporarily un-solve the parts that they have already solved, requiring a deal of faith in the algorithms the solver uses to manipulate the pieces of the puzzle. I have come to view this moment in which the solver has (necessarily and intentionally) "messed up" their prior work as a temporary fail state. Naturally, when first learning to solve the cube, this process is not always successful and the solver is set backward in their journey (making the fail state slightly more permanent). Overall, the solving process can be viewed as a fluctuation between fail states and equilibrium states at which the solver has resolved more pieces of the cube. At the moment, this is only a theoretical framing; in my future work, I will apply this lens to actual scenarios that involve participants in order to refine the perspective.

Gesture-failure-feedback (GFF) loop in games

Nihal Katirci & Caro Williams-Pierce

Tablets and mobile phones games have touchscreen technology that promotes the interaction between touchscreen devices and humans through touchscreen gestures. These touchscreen gestures are, for example, tapping (touching the screen with a fingertip), dragging (moving fingertip over the surface without losing contact), and pinching (touching the surface with two fingers and bringing them closer together) (Villamor et al., 2010). These touchscreen gestures, notwithstanding success or failure, is paired with feedback (Williams-Pierce, 2019). The feedback is dependent on how game designers created the system feedback of the game. In many mathematical education games, there is just one correct answer, and the game gives only summative feedback. When the player submits the answer, the game system compares the player's answer and the correct answer. If the player's answer is not the same as the correct answer, the game penalizes the players. However, in well-designed educational

games, games provide feedback in three different ways: formative (Heron, 2010), summative (Deci et al., 2001), and informative (Kim et al., 2018) feedback. Formative feedback is given during the solving of the puzzle and it helps players avoid or learn from failure. Summative feedback is given after the player solves the puzzle. Informative feedback is given when players need extra information or clues to solving the puzzle, such as clicking the Hint icons on the screen. Well-designed games also give space to the players to do comparison themselves. Hence, when players are playing, they are also learning.

Gestures in productive failure

Manu Kapur

In productive failure, students first engage in problem-solving activities that are deliberately designed in a way that students are unable to generate the optimal or correct solutions. Yet, it is precisely this process of generation sub-optimal or incorrect solutions that is the locus of deep learning as it prepares them to learn from subsequent instruction. In the absence of canonical tools and language, students invariably resort to a diverse set of motor actions and gestures to communicate their ideas, representations and solutions. These spontaneously occurring gestures function as grounding actions, anchor and communicate intuitive understandings, aid the development of a shared language during collaboration, and form a bridge for understanding the canonical solutions subsequently.

Mathematizing embodied play and failure

Justin Baker & David DeLiema

In a classic text on mathematical cognition, Lave et al. (1988) argue that “snags” during grocery shopping cause shoppers to question and revise their arithmetic problem-solving. More recent studies on informal parent-child engineering tasks have revealed the role of interactions with physical objects in stimulating externalized mathematical thinking (Simpson et al., 2021), and the impact of caregiver scaffolding and questioning in fostering understanding of mathematical concepts involved in an engineering design task (Simpson & Zhong, 2021). We extend these arguments about the situated nature of mathematical thinking to naturalistic, outdoor play between parents and their young children (age 2-8). We examine how embodied failures during informal play activities serve as generative moments for the intergenerational discussion of mathematical features of problems. Using interaction analyses of video data (Jordan & Henderson, 1995) of naturalistic, outdoor play captured by families themselves, we highlight three play episodes in which children's self-directed pursuits (reaching for a rope, running down a ramp, passing objects through a pool noodle) and subsequent impasses (failing to reach the rope, falling down the ramp, getting a stick stuck in the pool noodle) create an occasion for talk about mathematical features (distance, speed, and size respectively). The talk about mathematical features serves the specific purpose of clarifying the causes of the impasse and/or solutions to the impasse. Children's intrinsic desire to pursue challenging play tasks, and the inevitable embodied failures that occur, combine to create a scenario ripe with potential for this kind of mathematical learning.

Conclusion

Collectively, the presentations will contribute to exploring the intersection of embodied cognition, failure, and mathematical activity, as well as consider the embodied nature of failure in different learning environments, contexts, mathematical situations, and age groups. As such, we contend this symposium addresses the conference topic, elucidating theories and processes of learning and teaching, as we consider the inclusion of failure to contribute to the ongoing theory development of embodied mathematical activity and learning (Hall & Nemirovsky, 2012). As described by Tall (2004), “There is a period of exploration and incubation that precedes the eventual formulation. In this case of the theory…, it is moving towards a stable form, it is still in the process of being filled out and refined” (p. 29). By bringing together a wide variety of scholars who explore embodied mathematical failure in various ways, this symposium will move us towards a more stable and refined understanding of our guiding questions: (a) How is failure represented through our bodily actions? (b) How is failure co-constructed through our bodies? (c) How are our reactions to failure embodied? And (d) How might embodied failure be framed or conceptualized across mathematical situations?

Abstract: Increasingly our field is recognizing the necessity of close, collaborative relationships with educators, policy makers, students and other potential stakeholders if our design and research work is to have a lasting and more equitable impact on education. However, this work is not easy or quick, and we lack both detailed examples of how it is done and training for new (and current) scholars in how to do it. This symposium brings together a group of scholars who actively engage in RPPs and DBIR in order to highlight the lessons that have been learned and extend our discourse into the realities of this work, how to prepare students and current scholars to design their work with partners at the center, and how to accurately plan for work that engages stakeholders.

Introduction

Design-based implementation research (DBIR) seeks to address the reality that even high quality, rigorous research in education often fails to transfer across real educational contexts and therefore cannot have a sustained impact on students' learning. In order to address this issue, DBIR places partnerships at the center of the research and design processes, with the goal of creating interventions that are sustainable and adaptable across settings (Penuel et al., 2011). Research practitioner partnerships (RPP) are often formed as part of DBIR work, and position research as a response to needs of practice, rather than to gaps in the literature (Henrick et al., 2016). RPPs are collaborative partnerships between research teams and practitioners, where defining the problem space and designing solutions is a collaborative endeavor.

This type of work is essential as we begin to recognize the limited impact research in our field has had on education (Wise & Schwarz, 2017), and the significant limitations of traditional learning theories and methods in education for creating equitable learning opportunities that are free from oppression and bias (Nasir et al., 2021). Without research and design that is embedded in partnerships with the intended users and stakeholders, we run the risk of being at best ineffective, and at worst, continuing the cycle of oppression and discrimination seen in educational contexts today.

However, as noted by Fishman and Penuel (2018) the long cycles of collaboration and iterative design and implementation studies are at odds with a lot of the typical structures within educational research (e.g. funding cycles, productivity expectations for early career scholars) and there is little formal training for doing this type of work. In addition, while there are some examples of case studies and descriptions of RPPs (e.g. Farrell et al., 2021) and studies that attempt to analyze the design and collaboration processes (e.g. Lawrence & Mercier, 2019; Lawrence, 2020), we still lack frameworks to understand how this work is conducted across cases (Cheng, Clark & Van Horne, 2020) and critical analyses of the implications of our interactions and design processes.

This symposium brings together researchers who are actively working with partners, in DBIR studies and/or RPPs. The papers represent a range of projects and approaches to DBIR and RPPs, and each presents an opportunity to consider elements of this work. Across these papers, we seek to understand how to establish and maintain RPPs (Benichou et al., Mercier), models and frameworks for conducting DBIR work (Ahn et al., Arce-Trigatti), the infrastructure necessary to develop capacity for DBIR work (Mckenny & Poortman), a microanalysis of the design process (Lawrence) and a reflection on bringing children into DBIR practices (Borge). We will seek commonalities across the work, and also to use the different perspectives to identify future directions for frameworks and capacity building activities.

Paper 1: Boundary Crossing Processes in the Forming Stages of Multi-Sector Research-Practice Partnerships: Three Cases of School-Based Citizen Science

Maya Benichou, Yael Kali & Yotam Hod

Citizen science is a genre of research in which stakeholders from different fields of expertise – scientists and non-scientists – work together to advance scientific knowledge with the assumption that science is not the property of experts but should be made accessible to the general public (Shirk et al., 2012). Citizen science projects have been active around the world for many years, however technological advances have recently led to a dramatic acceleration in projects of this kind in diverse fields (Lewenstein, 2016; Sagy et al., 2019). Leveraging the exciting opportunities of citizen science to bring together citizens and scientists, recently we (and other colleagues) expanded on this vision by creating the nationally funded, *Taking Citizen Science to Schools* (TCSS) research center. At the core of the center is a network of research practice partnerships (RPPs) (Hod et al., 2018) that bring together school practitioners (teachers and administrators), policymakers, educational researchers, and active scientists on a number of citizen science projects. To date, over 90 schools and hundreds of teachers have participated, contributing to this network by sharing challenges and best practices, developing curricular materials and activities, and supporting one another as schools enter new relationships that break the traditional boundaries that separated them in the past.

This paper – which is based on a forthcoming chapter in an edited book about teachers and teacher learning in the learning sciences (Benichou, Kali, & Hod, forthcoming) – zooms into the formation stage of three RPPs that participated in this network, where the first RPP took place prior to the second and third, offering opportunities to redesign the partnerships in the successive round of implementations. The formation stage plays a vital role in creating sustainable partnerships around educational innovations. We focus on the teachers in the formation stage within these partnerships, with an eye on elucidating how the teachers began transcending their existing professional development boundaries. Little is known about the new opportunities for learning and professional development of teachers as part of the multi-sector partnerships between students, teachers and scientists that school-based citizen science affords.

Drawing on extensive field notes, digital communications between the different stakeholders, written reflections, and interviews, we applied a boundary crossing framework (Akkerman & Bakker, 2011) to analyze how identification, coordination and reflection processes took place across our cases. Our research highlights the mistakes made during the first implementation, particularly as part of the coordination processes, that did not fully support the mutualistic relationships that were the goal of these multi-sector RPPs. We show how the nuanced changes made during the subsequent implementations led to far different outcomes, whereby the teachers felt a growing sense of meaning as they expansively framed their work and took productive agency to initiate new citizen science projects in their schools. These insights are important to understand as design-based implementation researchers seeking to foster sustainable partnerships have to negotiate complex, multi-sector relationships in the field (Fishman, Penuel, Allen, Cheng, & Sabelli, 2013).

Paper 2: Developing DB(I)R researcher capacity

Susan McKenney & Cindy Poortman

If design research is to realize its potential contribution to education in general and the learning sciences in particular, then explicit attention must be given to holistically developing Design-Based (Implementation) Researcher (DBIR) capacity. Collaboration between researchers and practitioners is shaped by shared goals and resources, but also by the values, expectations and expertise of the parties involved. For example, early stages of problem articulation and exploration benefit highly from open-mindedness and realism, while one's sense of moral purpose, belief that change is possible, and self-efficacy may prove particularly valuable during the implementation of interventions (McKenney, 2016).

Understanding and accepting the variety of personalities, processes, and convictions present in a particular project is crucial to being able to structure a fruitful process. DB(I)R researchers must be able to do so while they fulfil multiple roles, notably the those of: *Consultant*, *designer*, and *researcher* (McKenney, 2016). While most DB(I)R researchers are afforded formal opportunities to develop their research skills (e.g., through seminars and courses on research design, interview techniques, data analysis, etc.), the consultant and designer skills receive far less explicit attention and tend to be learned informally, at best (McKenney & Brand-Gruwel, 2018). In light of these three roles and four core DB(I)R processes (analysis and exploration; design and construction; evaluation and reflection; and implementation and spread), McKenney and Brand-Gruwel (2018)

 © ISLS

describe four foundational competencies that are required to enact each role. *Empathy* is needed, for example, to explore (un)shared goals or becoming exposed to the incentives, motives, and reward structures in different settings. *Orchestration* helps simultaneously attend to research framing, data collection, solution design, implementation, infrastructure woes and stakeholder ownership. Creative and analytical *flexibility* supports optimization of the human and material resources available in ways that remain aligned with instructional goals. Finally, *social competence* includes having a robust repertoire of interaction strategies to be selected as needed.

This paper focuses on the infrastructure that serves DB(I)R researcher capacity building. Here, infrastructure refers to the human, material, and structural features of context which contribute to the development of the four competencies described above and the ability to fulfill the roles of researcher, designer, and consultant, in ways that respond to the shifts in DB(I)R processes through the lifecycle of a given initiative. This prospective analysis is situated in the context of university campus collaborations between DB(I)R researchers and (communities of) teachers in engineering disciplines who share the goals of (1) redesigning courses and degree programs to be anchored in authentic challenges, and (2) investigating how to do so in ways that are effective and enjoyable (Kirschner & Gerjets, 2006) as well as sustainable. Specifically, the paper presents a framework for inventorying assets and needs with regard to the infrastructure for developing design researcher capacity when working in this kind of setting. A key discussion question during the proposed symposium pertains to the applicability of this framework for researcher growth in other DB(I)R contexts.

Paper 3: Centering Race in DBIR: Methodological Choices and Internal Work

June Ahn, Kimberly Gomez, Ung-Sang Lee & Christopher Wegemer

In this paper, we share our current experiences and insights from a DBIR project that is focused on centering racial consciousness and anti-racist goals. DBIR as a methodology focuses on developing mutually beneficial research agendas with partners, co-designing these research activities, developing solutions, and iteratively testing and improving upon these joint endeavors (Penuel et al., 2011). In our work, we are developing up to 6 partnerships with local schools in Southern California, using a DBIR approach, but exploring how processes unfold and might be facilitated in ways that bring race and anti-racism to the forefront. Our work addresses recent calls by Doucet (2019) and Kirkland (2019) for community engaged researchers to attend to critical issues of who is at the table when developing partnerships, what questions are posed and which are pursued, and to re-imagine the solutions that we design to address key obstacles to racial justice.

Drawing upon a dataset of field notes, reflective memos and team documents, as well as artifacts from the DBIR projects, we will shed light on how the project teams were: (1) initially structured with careful attention to understanding the racial histories of different partners, including ourselves as researchers, and how these histories shape DBIR work at the outset; (2) how jointly negotiated foci of work were developed as a partnership, with an eye towards how different design goals are reshaped when thinking through the lens of anti-racist goals and outcomes; and (3) how the focus of design efforts shift from tools or organizational strategies, to re-designing relational ways of partnering and mobilizing for root issues that more directly impact racial justice. We argue that a racially conscious DBIR methodology requires attention to new facets of practice, that extends and enriches racially neutral processes. A key need in the field is to better articulate how **partnership infrastructures** (Penuel, 2019) and **the relational moves we make** (Hennessy, Howe, Mercer, & Vrikki, 2020) within partnerships, combine to develop DBIR projects for racially equitable aims.

Finally, we will work from the notion of anti-racist, DBIR partnerships, to illuminate how partnerships can observe impacts. Specifically, we hone in on how DBIR partnerships can aim their designs and change efforts on (1) the perceptions that partners express about racism and equity, (2) how partners talk to each other as they do their joint work, and the language they invoke which can reveal their underlying frameworks about race, and (3) how DBIR teams can be positioned within organizations – such as K-12 schools – to best facilitate specific actions (policy, programmatic, or behavioral) that partners ultimately enact, which can also reveal the changing and underlying frameworks at play. The contribution of this conceptual framework is to inform more precise conjectures about how design, implementation, and research can be utilized towards racially just change in local partnerships.

Paper 4: Children as transformational agents in the co-design process

Marcela Borge

In previous work designing technologies to enhance science and collaborative learning, my colleagues and I have often worked with learners of all ages as co-designers or as part of participatory design to help inform design processes in ways that better meet their needs (Borge & White, 2012; Borge & Shimoda, 2019).

Collaborative design of this kind is quite common in HCI and learning sciences related fields, but the purpose of the design is on the end-product, i.e., what the designer is creating (Abbas, et al., 2018; Rosson & Carroll, 2002). With some notable exceptions, such as the work of Yip and colleagues (Woodward et al., 2018; Yip et al., 2013; 2016) fewer researchers focus on other import and aspects of the co-design process like the process of co-design itself or how/what participants learn from the process.

The focus on the process of co-design is of particular interest to me and my research group, because my area of expertise is on collective regulation processes and how individuals and groups reflect on processes for the purpose of improving upon them. However, much of my work has been informed by the work of scholars who lie on the more cognitive end of the learning theory spectrum (Pandero, 2017; Wecker & Fischer, 2011; Winne & Nesbit 2009; White & Frederiksen, 1998). As such, I have historically approached such work from a top-down model, where the goal, even during co-design, was to show participants optimal processes as defined by my group and partner with them to enhance how well my interventions pushed them to use and imitate these processes.

Recently, I have come to realize that this approach to co-design serves me and my group more than it serves the children we work with. Over the last six years my research group has been working in partnership with children ages eight to twelve as part of a design-based afterschool maker space. During this time, our emphasis on the project has shifted from co-design for the purpose of creating more equitable and engaging after-school spaces that help children "optimize" collaborative processes to co-design for the purpose of critical reflection as defined by Paulo Friere (1996).

Critical reflection shares many commonalities with the classic regulation literature; they both view awareness and self-reflection for the purpose of action as an essential aspect of learning. However, critical reflection does not use reflection as a way for learners to compare their actions to models that researchers define as "optimal" for the purpose of getting users to better align with those models. The purpose of critical reflection is for learners to become aware of the artificial designs around them (Simon, 1968) and how they interact with them for the purpose of transforming those designs to better meet their humanistic needs. Thus, reflection becomes a means for learners to engage in sense-making about their world and the ways they behave within it for the purpose of self-empowerment.

As part of this symposia, I will provide examples from our club to show how and why we have gradually made this change based on our growing awareness of our young learners' needs. I end by discussing how we can push Frierre's work towards promoting digital literacy for the purpose of empowering the next generation of technology designers and users. My aim is to help young learners become more aware of how technology is shaping their world and help them and us better understand how they can transform these interactions for the better.

Paper 5: Examining design-based implementation research through linkographic analysis

LuEttaMae Lawrence

There has been much work describing the foundation of DBIR research, including the importance of building relationships, building capacity, attending to sustainability, co-constructing designs iteratively, among other high-level factors (Penuel et al., 2011; Sabelli & Dede, 2013). While this is a widely used methodology in the CSCL community, open questions remain regarding how nuanced practices and decisions in DBIR are made to produce interventions. Innovative learning takes place during the design process, and researchers rarely document or assess this to the same extent as other forms of learning (Kali, 2016). Examining the interactions in the design process can inform how to improve our processes, share insights about scaffolding collaborative conversations, and provide rich examples to scholars learning to collaborate with communities. Responding to the call for more in-depth analysis of collaborative design processes (Kolodner et al., 2016), I examine how an interdisciplinary team of researchers and users designed a collaborative orchestration tool.

In this study, I examine interactions, design ideas, and collaboration within a design brainstorm meeting of eight team members from four disciplines, two of whom were part of the design community and six from the research team. Members of the team had been collaborating within a DBIR project for several years leading up to the meeting, with the broader goal of improving collaborative problem solving in engineering higher education courses at a midwestern university in the United States. The present study describes the collaborative process to create an orchestration tool to support novice, engineering instructors as they facilitate collaborative learning. To explore the co-construction of designs, I used a traditional design method called Linkography to assess the design process at a fine-grained level by visualizing relationships of "design moves" during collaborative design

discussions (Goldschmidt, 1992). This analysis examines, patterns of interaction within discussions to understand how ideas were generated and taken up, and by whom.

In total, 1,984 turns of talk were analyzed in the design process from a three-hour design meeting. Fifty-nine critical moves emerged, defined as turns that were linked to by more than 10 other turns of talk, and the quality of interconnectedness and collaboration fluctuated throughout the meeting, but was overall high (see Lawrence, 2020). Through this analysis, I identified a pattern of interaction, wherein one turn of talk generated a high density of linking, showing that this discussion was highly connected. Through thematic analysis of these patterns of interaction, three themes emerged during the meeting, including segmented, intersected, and integrated areas. Segmented areas were patterns of interaction that were isolated design discussions that did not build on multiple areas; these areas had fewer critical moves and lower levels of collaboration. Intersected areas were patterns of interaction that were linked by one bridging turn of talk. These areas of talk had a wide range regarding quality of collaboration and design ideas that emerged. Integrated areas were interaction areas that were highly convergent conversations. Integrated areas had two to thirteen areas overlapping and had more critical moves and higher collaboration compared to segmented and intersected areas. This analytic approach allowed me to explore how the design process occurred and analyze how the team adapted ideas over time at a fine-grained level. My findings highlight the context around productive and unproductive design discussions and share importance insights for facilitating design meetings with diverse perspectives including scaffolding discussions with common goals, reflecting on tensions in the moment, and documenting ideas to scaffold integrated conversations.

Paper 6: The ebbs and flows of a multi-year DB(I)R project

Emma Mercier and the CSTEPS team

In an ideal situation, a design-based implementation research project emerges from a joint vision between groups of researchers and practitioners, who remain involved in the project throughout, and where the practitioners remain involved in the education context after the project has finished. However, this is not always the case. In this reflective analysis of a multi-year project, we will explore the fluid nature of DBIR in a university context, noting the standard of DBIR sometimes slipped more into a simple DBR project. The goal is to identify processes that fostered true collaboration across the groups, issues that stalled the collaboration and principles to embed in future projects.

This paper reflects on a seven-year collaboration with an instructional team in engineering, focused on redesigning core, required undergraduate courses. The collaboration began as two separate endeavors: 1) a DBR project focused on creating CSCL tools to support the creation of joint representations during collaborative problem solving and 2) a college-level strategic initiative to embed innovative pedagogies in required introductory courses. The DBR project was funded in the second year of the pedagogic initiative, and through a series of serendipitous events, a funding stream dedicated to moving projects from exploratory to development phases and commitment across both groups, the endeavors merged, at times, and in pieces, in such a way as to allow for true collaboration around various aspects of the reform and research processes.

The instructional team consisted of a rotating set of faculty members, with varying degrees of experience and enthusiasm for teaching introductory courses and engaging in pedagogic reform, and due to the reform process, additional support from teaching faculty on content development. In addition, discussion sections were taught by graduate and undergraduate student teaching assistants, who were employed for one or more semesters, often until graduating. The research team consisted of faculty in education and engineering, graduate students, mostly from education, and undergraduate students, primarily from engineering. There was some intentional overlap between the two groups, with a small number of Teaching Assistants hired as Research Assistants during key semesters of the project, and members of the instructional team joining the research team formally during the second half of the project. In addition, one Teaching Assistant moved to education to complete his doctorate, while another continued to work on course content with the research team after graduation. Collaboration occurred at various levels, in large groups, but also in smaller working groups.

Recognizing the importance of not just describing collaborations, but creating frameworks to draw comparisons and critiques across projects (e.g., John-Steiner et al., 1998; Wasser & Bresler, 1996) this paper reports an analysis, based on calendar entries, meeting notes and project plans and report documents. We will first describe the timeline of the project, then identify patterns that emerged over the timeline of the project and finally identify themes from these patterns. These themes are: 1) The importance of time, openness, autonomy and belonging to DBIR projects; 2) The importance of examining difference circles of collaboration, particularly in relation to understanding how different elements of the work were completed; 3) The central nature of ongoing reflection on interpretation of reform experiences from multiple perspectives; 4) Relationship development and

 © ISLS

career transitions in higher education and 5) The co-existence of pedagogic reform and innovative educational technology research.

Paper 7: Lessons Learned from the National Network of Education Research-Practice Partnerships

Paula Arce-Trigatti

The National Network of Education Research-Practice Partnerships (NNERPP) is a professional learning community of education research-practice partnerships (RPPs) based at Rice University. Launched in 2016, NNERPP was created in response to a need for a permanent infrastructure that would allow for ongoing RPP-led learning and support. With NNERPP serving as a key mobilizer of RPP-based knowledge, the network helps catalyze the ongoing development of individual partnerships and the advancement of the field as a whole through four main activities: curation, teaching, leadership, and brokering. An annual forum brings members of our community together to share, workshop, and teach about lessons, challenges, and experiences from their RPP work. Recognizing the need to build and share a strong and robust knowledge base, NNERPP maintains an online repository and a quarterly magazine which serve as channels of communication between various actors in the RPP space sharing new insights, responses to pressing topics, and identifying community-wide challenges.

RPPs can take on many forms and pursue diverse goals, involving a wide array of representatives from research, practice, community, and everywhere in between. This feature is both a strength, in that strong partnerships typically follow the mantra of "form should follow function", and also a challenge, in that it makes learning across partnerships more complex. We have found, for example, that trust building and relationship development, co-production in the research process, and logistical aspects of the work related to project management are all processes that interact with characteristics of partnerships including the number and types of stakeholders represented, the history of the relationships among stakeholders, forms of power/authority across the partnership, etc. It has, notably, proven beneficial to have RPPs of various and diverse forms in conversation with each other, in order to spark new ways of thinking about the work.

Another challenge for the learning community is to collectively understand what it means to be "successful". These definitions emerge from characteristics of the partnership including the longevity of the partnership, what goals were named and whether they were achieved), whether and to what extent their work resulted more narrowly in research use, whether and to what extent student outcomes were impacted, whether district processes were changed, etc. Subsequently, partnerships vary in *how* they measure impact and/or value of their work. Some RPPs have used the framework proposed by Henrick et al (2017) as a starting point, others have developed their own surveys, and some use self-report, asking their partners what's working. The variation in partnership structures, approaches, and ways of documenting their value make the identification and aggregation of best practices challenging.

This poster will present examples of various models of RPPs, focusing on the collaborative processes that have been useful in various contexts of partnerships and how partnerships have judged their success. We will explore how and why particular characteristics and goals of partnerships were critical in shaping the ways illustrative partnerships have conducted their work.

Abstract: There are calls for researchers and practitioners to build joint communities to narrow down research-practice gaps. Regulation of teaching, a process during which teachers direct attention, set goals, plan, monitor and evaluate their teaching for improvement, is very likely to benefit from communication and collaboration between researchers and teachers given its complexity in terms of multiple phases and various levels. This symposium aims to facilitate researchers' and practitioners' direct conversations on self-, co-, or socially shared teaching regulation. A theoretical framework that details different phases of teaching regulation at the self-, co-, or socially shared teaching levels guides teachers' reflections on their teaching regulation, which then serve as a basis for a panel discussion between three (groups of) teachers and three invited researchers. The panel discussion will be focused on identifying practical challenges and research gaps regarding teaching regulation and discussing how teacher and researcher communities can collaboratively respond to these issues.

The overall focus of the symposium

There is an abundance of research on teaching and learning in the field of Learning Sciences. However, the research does not extensively impact teaching practice, which is referred to as research-practice gap (Chi, 2021). The gap between research and practice may be attributed to the following reasons: teachers perceive the questions addressed by researchers irrelevant to their practice; researchers' work is not very accessible to teachers because of writing style and subscription issues; teachers lack time to read research findings; and research-based knowledge may be too general and abstract but not specific enough (Chi, 2021); what works in research may not be effective in local practice (Joyce & Cartwright, 2020). To address these issues, researchers and practitioners should build joint communities that include research and practical focus (Korthagen, 2007), and negotiate problems of practice (Coburn & Penuel, 2016). Despite this call, at our conferences, researchers still mostly communicate with other researchers, while teachers are rarely involved in the discussions.

Among many topics, regulation of teaching might benefit from conversations between teachers and researchers. In practice, teachers often need to revise their teaching practice in order to improve the effectiveness of lesson plans or to respond to the evolving learning theories and changing societal values and structures (Butler et al., 2004). This necessitates teachers to engage in regulative teaching practice, a process during which they apply a variety of activities and strategies to direct attention, set goals, plan, monitor and evaluate their teaching to improve it (Lindblom-Ylänne et al., 2011; Ukrop et al., 2019). However, there lacks specific advice or rules on the process of regulation that teachers can follow. Furthermore, teachers can regulate their teaching practice as self-, co-, or socially shared endeavors. Both make teaching regulation complex and challenging. On the other hand, there is a rich body of research literature on teaching and regulation that can be made better use of to support teachers.

For these reasons, this symposium aims to create an opportunity for researchers and practitioners to have direct conversations on self-, co-, or socially shared teaching regulation. To scaffold the discussion, we provide (a) a theoretical framework that details different phases of self-, co-, or socially shared teaching regulation to guide teachers' reflections on their regulation experiences; (b) reports from three (groups of) teachers on their teaching regulation, which can serve as a basis for discussions. At the conference, the three (groups of) teachers will discuss their practical challenges regarding teaching regulation, and the panel will identify research gaps in

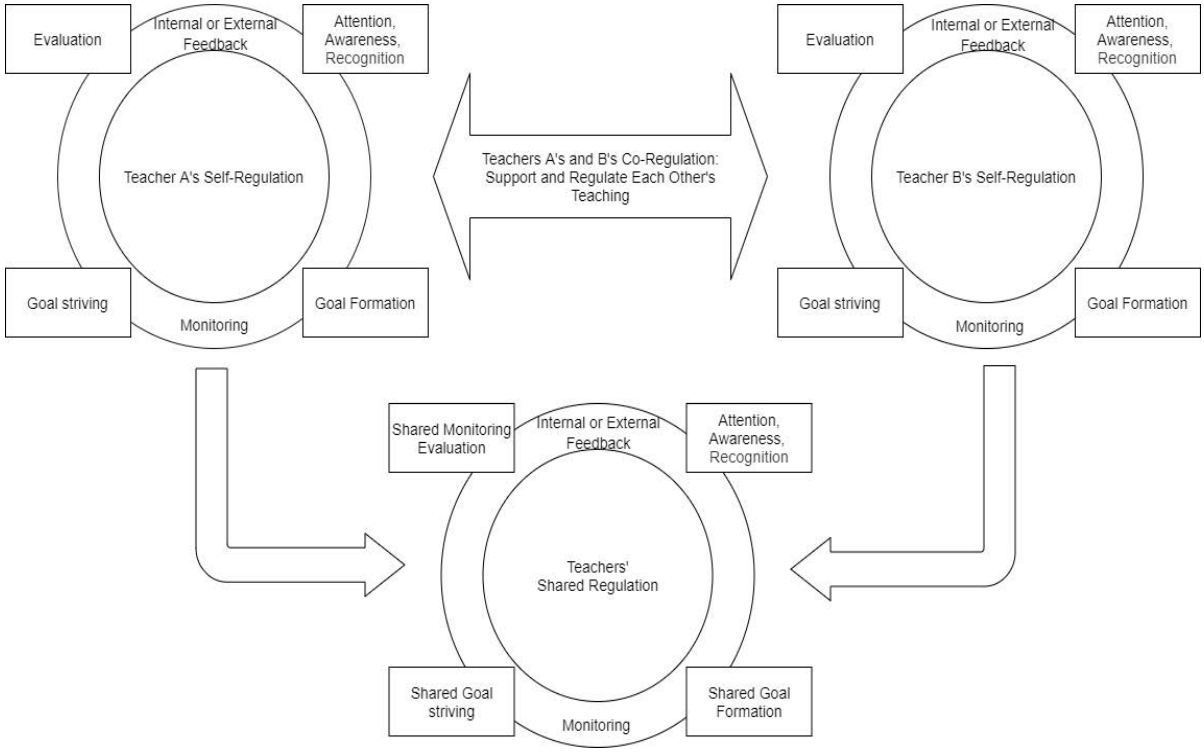
 © ISLS

the field. Then the teachers and researchers will discuss how to bridge and address the practical challenges and research gaps in a feasible and collaborative manner.

Here, we first elaborate on self-, co-, or socially shared regulation. Self-regulation is an individual activity in which individuals plan, enact, monitor and adjust their learning using cognitive and behavioral strategies (Zimmerman & Moylan, 2009). Co-regulation processes are directed to influence the behavior, cognition, and motivation of one specific group member (Grau & Whitebread, 2012). Teachers' co-regulation involves other people such as teacher trainers, advisors, or fellow teachers supporting certain processes of the regulation (Hadwin et al., 2018) and can happen in daily school practice, during school meetings or at professional development activities. Socially shared regulation (SSR) emerges when teachers negotiate their goals, plans, and strategies concerning shared tasks and maintain positive interactions by listening and considering each other's ideas (Hadwin et al., 2018; Malmberg et al., 2015). In SSR, teachers identify shared teaching problems, set shared goals, integrate different knowledge and ideas, and evaluate the process as a group or community (Hadwin et al., 2018). Relating the concepts, self-regulation is the basis of co- and shared- regulation. Compared to co-regulation, SSR emphasizes that a group, as a unit, shares convergent regulation of the team activities, cognition, motivation, emotion, and behavior (Hadwin et al., 2011).

Figure 1

Phases of regulation of teaching at the self-, co- and shared levels



We integrated Järvelä and Hadwin's (2013) socially shared regulated learning model, Borge et al.'s (2018) model of regulatory processes during collaboration, and Nesbit's (2012) self-directed leadership-development framework, constructed a teaching regulation model (see Figure 1), and applied it to the teachers' regulation context. This model specifies four cyclical phases and relevant executed processes in each phase. During Phase 1, a teacher or a group of teachers directs their attention to a specific topic that they are interested in or a specific teaching process that they want to improve because of their beliefs, motivation, or internal or external feedback. In Phase 2, teachers usually form their teaching goals. During Phase 3, goal striving, teachers make efforts and commitment to implement task strategies to achieve goals. This phase is followed by evaluation (i.e., Phase 4) in which teachers reflect on the affective and cognitive consequences of their performance. This phase is usually facilitated by internal feedback arising from one's self-observation (Kolb, 1984) or external feedback from other stakeholders (Ryan et al., 2000). This phase usually circles back to forethought phases. Each phase is accompanied by monitoring to ensure that the aim and function of each phase is sufficiently fulfilled, according to teachers' standards (Winne & Hadwin, 1998).

The four phases of self-, co- and shared regulation are influenced by internal cognitive conditions and external task conditions (Winne & Hadwin, 1998). Internal conditions such as (a) specific knowledge or skills, (b) beliefs, and (c) motivation influence the regulation process. Teachers' knowledge about the context (e.g., students involved; the history of the teaching situation) and skills in integrating different pieces of knowledge plays a crucial role in the regulation process. Moreover, teachers hold beliefs about how knowledge is acquired (Chinn, 2014) and have specific teaching philosophies, which guide them to develop goals and options for action. Goals and action plans are affected by intrinsic and extrinsic motivational incentives. For example, some teachers may be intrinsically motivated to continually improve their teaching while some may be mainly motivated by extrinsic reasons such as demonstrating good teaching performance to principals and colleagues. Furthermore, teachers' regulation processes depend on the availability of external knowledge resources such as literature, social media, and direct personal interactions with fellow teachers. In addition, time constraints limit how extensively teachers may regulate.

Overarching/integrative points that will be addressed by teachers and researchers

The theoretical model described above can help pinpoint, differentiate, and organize teachers' teaching regulation experiences. However, due to lack of research on teaching regulation (Lindblom-Ylänne et al., 2011), it is yet unclear whether and how teachers self-, co-, or socially shared regulate their teaching practice and how to foster their regulation. To better bridge the gaps between practice and research, we create opportunities for practitioners and researchers to identify and reflect on practical and research challenges concerning teaching regulation, and negotiate and co-design feasible solutions to address the issues. Practitioners and researchers will work together at the symposium as follows:

First, three (groups of) teacher experts have shared their regulation practices (e.g., regulation experience, desired goals, gaps and challenges, and support needed) at the self-, co-, and shared-regulation levels, separately. The above-described regulation model informed and structured teachers' reports of their experiences.

Second, these reports will be shared with three researchers from complementary fields ahead of time. Researchers will look at teachers' successful and challenging regulation experiences with scrutiny from their perspectives of expertise. We will request the research panelists to connect research gaps and the practical challenges that teachers face, and invite researchers to draft potential solutions to fill these gaps.

Third, at the conference, teachers and researchers will discuss the feasibility and potential impact of the solutions, and co-design to detail the solutions.

The significance of the contributions

Direct conversations between teachers and researchers benefit both sides. For teachers, the symposium may improve their awareness of the importance of teaching regulation and understanding of regulation procedures and types, and encourage them to take actions in the future. From the perspective of researchers, the symposium tends to help them better understand the practical challenges that teachers face and how they may co-design research with teachers. Taken together, this symposium will serve as a step to better identify practical and theoretical challenges in teaching regulation, and better connect teachers and researchers to respond to the challenges (which is mentioned in the Regulation Experiences of Teacher Experts 3).

Structure of the session

This symposium will include three teacher presentations on their self-, co-, and shared-regulation experiences concerning teaching, respectively, followed by a panel discussion between teachers and researchers on how to better support teaching regulation. We will adopt the following session organization:

1. Welcome and theoretical introduction by session chairs (6 min)
2. Teachers' presentation on self-regulation of teaching (8 min)
3. Teachers' presentation on co-regulation of teaching (8 min)
4. Teachers' presentation on shared-regulation of teaching (8 min)
5. Researchers analyze teachers' experiences, identify research gaps, and propose future research directions to promote positive changes in teaching regulation (24 min)
6. Open discussions between teachers, researchers, and audiences on how to respond to the practical and theoretical challenges on teaching regulation, and the feasibility of researchers' proposals (26 min)

Regulation experiences of teacher expert 1: Self-regulation

Regina Hegele, Parkschule Stadtbergen

Planning, implementation and reflection of lessons

In everyday school life, the choice of content covered in class depends largely on agreements within the colleagues of a grade level, the learning situation (homeschooling or face-to-face teaching), and the textbooks used.

After the contents of the upcoming lesson sequences have been determined in the team, I develop sequence plans that include the contents of the individual teaching units, the competencies to be achieved, learning opportunities and their realization. Here, it is also important to consider where the children might encounter obstacles that are not manageable for them. Furthermore, as far as possible, I attempt to address questions that are currently arising in the class and, if necessary, to include them in the lesson planning. However, this can also happen during the sequence because some questions only arise from the joint work.

Whether a designed unit can be successfully implemented in the classroom depends on many different aspects, not all of which can be planned in advance. However, for a favorable outcome, it is imperative that I keep the learning structure of the class in mind. In my opinion, this includes the performance spectrum of the class (strong and weaker students), the usual forms of work in the class (such as think, pair, share, group work), a positive classroom atmosphere, adherence to the agreed-upon rules of conversation, and the motivation of the learning group. Factors that cannot be planned are already existing knowledge about the chosen content (which, however, can also be integrated spontaneously) or possible short-term events within the class (disputes or other differences).

Reflection on lessons usually happens very briefly and unbureaucratically in everyday life. As a rule, I do not analyze further any units that go as planned when I have gained the impression, while reflecting with the children on the content which we worked on, that the children were able to use the learning opportunities. If this is not the case, I consider at which points the children had difficulties and how these could have been eliminated. After identifying the “stumbling blocks”, I note them briefly, which will be useful when re-using the content. Unfortunately, teachers rarely receive external feedback, as there are currently no models for peer coaching in my state, and as the assessment by the school management, which takes place every four years, is not useful for this purpose.

In order to further develop my own teaching in the interests of the children, I am in close exchange with my colleagues: I hear how they prepare content didactically and what methods they have been successful with and compare this information with my work. We also plan various lesson sequences together and benefit from the experiences and ideas of the team. On the other hand, I regularly attend further training courses, have contact with the university and thus always try to be up to date.

Conditions for optimal lesson planning, implementation and reflection

- Lesson planning: Teachers must be motivated to teach new content to their students. They should have the necessary expertise and have their students in mind.
- Lesson implementation: Small learning groups (maximum 22 students), a warm learning climate, students have skills necessary for successful learning (listening with understanding, ability to work in teams, positive attitude towards learning and achievement)
- Lesson reflection: sufficient time, models that enable joint reflection (e.g., peer coaching)

Challenges in lesson planning, teaching, and reflection

In my eyes, one of the greatest challenges in planning, implementing, and reflecting on lessons is the fact that we have to teach classes that are far too large (sometimes up to 29 students in elementary school), with a very heterogeneous structure in terms of performance (children with disabilities, children with increased special educational needs, children with varying degrees of language deficits). It seems almost impossible to do justice to all the children. In addition, there are more and more "administrative activities" that we teachers have to take on during our working hours. Unfortunately, the resulting time deficits cannot always be compensated for by extra work and additional commitment.

Support for optimal lesson planning, teaching, and reflection

Basically, this point follows from my previous remarks. In my opinion, the following factors would be beneficial: a reduction in class sizes, additional pedagogical staff to support teaching, and a reduction in the number of hours per week for primary school teachers because the workload is very high in full-time teaching and it cannot be ruled out that the quality of teaching will suffer in the long term.

Regulation experiences of teacher expert 2: Co-regulation

Heidrun Printz, Dr.-Max-Josef-Metzger-Schule

How do you give teacher trainees optimum support in designing and reflecting on their teaching?

Effective and lasting support for young teachers will be more necessary than ever in the coming years in order to meet and withstand the changing demands on schools. Ideally, this support should be designed as follows:

The basis for a good start in the teaching profession is mutual trust, willingness and curiosity in learning as well as enjoyment in working with people. Up until their first lesson, teacher trainers attend my lessons to observe, evaluate, discuss and assess certain methods and didactic focuses. For this purpose, these criteria are visualized on a lesson plan. Reflection on lesson observation in this initial training phase is crucial. At this stage of their careers, the complexity of teaching should only be demonstrated very gradually so that the trainee teachers do not feel insecure and also to make them aware that they are allowed to make mistakes.

When planning their own lessons, I allow the trainee teachers to choose their own area of interest in order to promote self-activity and increase intrinsic motivation. A lesson matrix also enables the trainees to reflect on the correct location and design of certain learning phases. The learning goal-oriented action is stimulated by the external or own definition of a minimum learning gain. Even when they are already in the planning phase, I always remind them of pedagogical-psychological and social characteristics and of the pupils' level. If they take the characteristics of the addressees into account, then the learning objectives can be achieved.

In the teacher training college, I encourage discussion about interests, learning content and learning goals as well as learning methods. This supports the development of skill in their particular subject and their teamwork abilities. It also contributes to the development of the teacher's personality by being self-reflective and reflecting upon others.

While the trainees are teaching, I support as much as necessary and as little as possible. I only intervene in the trainees' lessons when there is potential danger, for example in Physical Education. Ideally, I expect the trainees to reflect on their lessons. For example, by introducing a topic in different classes or grades, the trainees realize that there is never just one correct solution pattern.

In the post-lesson discussion with the trainee alone or in the trainee group, I believe it is very important to address and explain the skills necessary for educational and subject-specific action objectively and constructively. I limit my feedback to three main aspects for further development. The feedback on their lesson and what they should be aiming for is communicated in an appreciative and honest manner. It is tailored to each individual trainee's level of teaching and contains practical solutions and suggestions for improvement. In choosing the timing of the trainee's feedback I take their timetable, mental and physical state into account to ensure a productive reflection of their lesson. In addition to the post-lesson feedback sessions, I also comment on the trainees' lesson plans and hand them back at a suitable time. A video recording of the lesson and subsequent discussion of it often provides valuable insight for the trainee and can be an excellent way of observing the interaction between teacher and pupil.

Which conditions do you require to provide optimal supervision for teacher trainees?

A core condition for the optimal supervision of trainees by teacher trainers is up-to-date, well-founded and professional competence combined with curiosity. In addition, it is advantageous if the teacher trainer has a sound knowledge of human nature and a broad range of experience in school, based on the enjoyment of educational and creative activities. The college workload can be reduced by having good organizational conditions, e.g., a teaching timetable which leaves enough room in the college timetable for effective teacher training and study. The technical equipment (e.g., media, subject-specific materials) also has a noticeable effect on the quality of the training. Co-operations with other educational institutions complement and reinforce the objectives of the training at the school and also give the trainees the opportunity to network. They demonstrate that schools are constantly evolving.

What challenges get in the way of your supervision?

I find school days very challenging when plans are changed at short notice, making it necessary to cancel appointments. However, it is also challenging when there are too many appointments: this disturbs intensive, close exchange in the college setting. Progress is negatively affected when trainees can't work well in a team, if they are not honest with each other and also if they demonstrate excessively competitive behavior.

 © ISLS

What support do you require to optimize scaffolding teacher trainees?

Important building blocks for optimal teacher training are, on the one hand, solid support and complete trust from the training supervisor and the specific subject mentor. On the other hand, cooperation, exchange and constructive criticism by the college staff are beneficial. Participation in further training, access to an up-to-date specialist library, and excellent supervision and psychological backup in critical situations as support for self-reflection have a positive effect on the teacher training.

Regulation experiences of teacher experts 3: Socially shared-regulation

Jenny Melo León, Gimnasio La Montaña
Laura Calzado, Dolors Monserdà-Santapau school
Raadiyah Nazeem, Dr. Eric Jackman Institute of Child Study

How do you collaboratively identify your shared interests and goals?

There is always somebody who suggests a topic and then we discuss the topic and see how we can put it into practice. In this current project, our colleague Raadiyah from Toronto said that discussing what a community is could be interesting, and we immediately agreed. It has been fantastic because we have the same shared ideas or shared interest in developing something basic in our class, which is understanding what a community means and what their roles are in the community. In the current project, Jenny, who likes to meet teachers with the same interests, was invited to join the community project. She liked it and worked to fit it into her curriculum. Through a previous project, Jenny and Laura worked together for two years. They were first introduced by Mercè and then joined by the big idea of developing awareness towards Sustainable Development Goals, which are important for their students in Colombia and Spain. Regarding choosing specific global goals to work on, they chose gender equality, specifically, responsibilities at home that can differ from their responsibilities at school. Students also compared their parents' and their grandparents' household responsibilities in order to see if there were gender differences between mothers/grandmothers and fathers/grandfathers. Mercè helped Laura and Jenny through the project.

How do you design to respond to your shared interests or specific goals?

The first thing we did was to create a shared document where we can provide ideas, record our next steps, and have the meeting dates and time. Shared documents help us develop the project step by step, record concrete ideas, and build or design collaboration. Second, we have in mind that we should not stop learning or improving our teaching; rather, we need to make changes whenever it is needed. Third, we have to take some time to meet and discuss how things are going on, not only in the working hours, but also during our own time.

How do you know whether your designs are well implemented in classrooms?

We have a Google Doc where the goals and activities are described. Sometimes we have video conferences to share what students produced, and then we know exactly how the design has been implemented in the classrooms. For instance, in the gender equality and responsibilities at home project mentioned above, Jenny and her students created a mathematics table with Steven balls, while Laura's students created a mathematical table but with numbers and colors. There were two different ways of doing the same visual representations. Laura learned from Jenny's way and presented it to her students. During the implementation, they have to be very flexible because things may need to be changed due to time constraints or according to students' products.

How do you negotiate with your design partners to move forward or improve your teaching?

When we have clear goals, it is easy to negotiate what you're going to do. Having or establishing desired goals at the beginning is very important for the project. Our goals are about promoting students' authentic experiences to communicate with people around the world and let them explore differences and similarities in our cultures. Even though we cannot be in presence, we can take advantage of these technological tools to get in touch with people. No matter what we do with our students and what their products are, it is important that we contribute to the goals. Furthermore, we have to be very flexible and understand that another partner may need more time or does it in a different way. Because we must discuss with the other partners, our teaching can be improved through these international projects.

 © ISLS

Which are the conditions that make your collaborative design, teaching, and reflection possible?

Even if we do not have the physical or time conditions, etc., as we are motivated to work together, see the project clearly and we like teaching, that's the reason why we are here. Furthermore, today the world is global, so we cannot teach just in our class. We have to teach with others and to see what they think about. The international project in a second language makes what the students do more realistic and meaningful. Finally, having support from the school authorization and principals and knowing their interests in promoting these projects make things possible and easier.

Which are some challenges, if any, that hinder your collaborative design, teaching, and reflection?

In the past projects, lacking time was a permanent issue. We had many things that we wanted to do. We planned it in a way and then we had to modify it either because we needed more time to develop this specific part of the project, or students responded in a way that we thought was not very adequate, or what we planned was not really what our students needed. Still in the pandemic, we have more demands at school with the curriculum, so it is becoming harder.

What support do you need to optimize your design, teaching, and reflection?

We need collaboration. It is very important to have somebody supporting us from outside, support in general from the university. The collaboration between schools and universities should be more frequent. Researchers at universities want to improve teaching, we as teachers want to improve our teaching as well. Researchers have new theories and we have teaching experiences, so we should collaborate much more closely. In particular, we need more support on methodologies for projects, how to develop projects and how to better handle each project. Interactions between universities and schools, between experts and people working at schools are fantastic.

In the three reports on self-, co-, and shared-regulation of teaching, some common themes such as collaboration with colleagues and researchers at universities, limited time issue, or teachers' motivation emerged. Further interpretations and discussions will be made at the conference by the panelist, including teachers and researchers.

Invited panelists: Areas of expertise and reasons for participation

Dr. Marcela Borge, Associate Professor of Education (Learning, Design, and Technology), Pennsylvania State University. Dr. Borge's research expertise includes but is not limited to technology supported self-regulated learning, socio-metacognition, design-based research methods, and computer-supported collaborative learning (CSCL). The model of regulatory processes during collaboration constructed by Dr. Borge in her article Learning to monitor and regulate collective thinking processes informed the integration of the regulation of teaching model shown in Figure 1.

Dr. Chew Lee Teo, Senior Research Scientist, National Institute of Education (NIE), Nanyang Technological University. Dr. Teo founded the Knowledge Building Community-Singapore and has led the local and international Knowledge Building Community Network Learning (KBC-NL) series. The KBC-NL brings together teachers and researchers to explore germane issues on 21st century competencies and pedagogies. The KBC-NL sessions have reached out to more than 1000 teachers and researchers. Recently, Dr. Teo and her team have gathered about 200 students and teachers to work on the theme of "Saving Lives, Saving Planet" in Knowledge Building Design Studios.

Dr. Mercè Bernaus, Emeritus Professor, Autonomous University of Barcelona. Dr. Bernaus has rich experiences working as a teacher, researcher, and Ministry of Education officer. She specifically focuses on second language learning and language awareness. For instance, in the Linguistically Sensitive Teaching in All Classrooms Project, Dr. Bernaus and other researchers develop, test and evaluate a reflection tool to help future and in-service teachers become more linguistically sensitive in their teaching, thoughts and attitudes. Dr. Bernaus has long-term collaboration with the invited teachers who will talk about socially shared regulation of teaching.

Abstract: Over the last few years, learning scientists have become increasingly interested in research around student's motivational and emotional processes, guided by a commitment to affirm learners' individual identities and support justice-oriented design and pedagogies. With ample evidence to show that the Covid-19 pandemic has exaggerated learner's struggles with their thoughts, feelings, and identity, the importance of such research has never been higher. This symposium brings together an international group of scholars with varying research contexts (online, in-person, hybrid, blended), working with students of different age groups (K-12, Undergraduates, pre-service teachers) to present their work around affective learning and teaching. The symposium's focus on affective learning designs that acknowledge learner emotions, affirm their identity, foster designer empathy and build a pedagogy of care will springboard deeper discussions in the ISLS community to further explore "global perspectives on equity and justice that promote the empowerment of educational innovation for all" (ISLS, 2022).

Introduction

This symposium responds to repeated calls by UNESCO (2020) and education scholars (Darling-Hammond et al., 2020; Ladson-Billings, 2021) to "redesign, reorient, and realign" and "build back better" beyond the crisis phase of the COVID-19 pandemic by exploring how learning and teaching can be situated in affective contexts that care about the students' being. Such care is deeply rooted in and intrinsically related to emotions, cognitions, and identities (Frijda, Manstead, & Bem, 2000). Understanding this relationship between emotion, cognition and identity would help researchers to reveal complex key issues in the learning sciences research that concern justice-oriented pedagogies. Yet, although research on emotions and learning goes back many years, there has been scant connection with emotions, identities, and care. Further, research and discourse on the nature of nurturing affective empathy in students is lacking. This symposium aims to reflect on the relationship between empathy, emotions, and identities by looking at these co-constructed, overlapping concepts to advance our understanding of learning and teaching in varied contexts. Identities influence the kinds of emotions and beliefs of care and empathy that individuals attribute to themselves and to others. Emotions, in turn, can influence identities and how we construct them. The learning sciences work could leverage such dimensions in novel assessments, learning analytics, and equitable justice-oriented pedagogies.

Overall Focus of the Symposium

Organized as a blended event, the symposium will focus on increased awareness and discourse around humanistic learning designs and pedagogies. In order to "redesign, reorient, and realign", we plan to have all registered attendees of the Conference participate in an optional online identity-awareness activity that will engage them in empathetic scenarios in a simulated environment. These scenarios will be informed by our research and collective understandings of affect. The symposium will be enacted in two parts at the Conference. First, each presenter will introduce their research and present findings and implications of the same, engaging the audience affectively. Second, a panel of discussants including scholars from psychology (Prof. Earl Woodruff), knowledge building (Prof. Marlene Scardamalia) and Engineering (Prof. Greg Evans) alongside a member of the ISLS board will provide insights from their experiences and share paths forward as informed by the presentations from our symposium.

 © ISLS

Major Issues Addressed

As highlighted in the "Identity Feedback in Humanistic Emotional Configurations" paper, humanistic activities as essential to helping learners hold more tentative views of knowledge, be more open to considering and working with different viewpoints, see the connections between the ideas participants advance with their identities, and be willing to give and take feedback both about their ideas as well as their identities. Such identities are deeply connected to emotion. Thus, it is important to investigate what types of emotions students experience and how their emotions evolve in the Knowledge Building process as elaborated in the "Evolution of the Academic Emotions of Academically Low-achieving Students in Knowledge Building" paper. Such affective classroom environments require the teacher to model, dialog, practice and confirm care. The "Caring for the Online Learner" paper describes ways in which the teacher can be supported by learning analytics in fostering caring pedagogies. Another way to foster a caring environment is through empathetic design. Empathy is both a cognitive and an affective process that involves a person's perceptions, thoughts, and feelings and how those concepts become manifested into a deeper understanding of others. The paper on "Developing empathy through a learning progression" shares experiences from senior under-graduate students on their growth as empathetic designers. In our final paper of the session, "Punks, Troublemakers and Inventors" we explore theoretical frameworks and conceptualizations to unpack the phenomenon of troublemaking and deviance in school, thereby bringing the conversation back to affirming identity and building communities and practices of care.

Contributions

This symposium brings together a variety of voices (from the US, Canada, Hong Kong, China, Singapore and Israel) and settings (two in K-8, one in high school, one in undergraduate Engineering and one in teacher education). Our research is focused on students (three papers) and teachers (two papers). We bring experiences from Science, Engineering, Education and Art. Further, we share insights on working with both under-achieving and academically successful students. We explore ways in which troublemakers can be knowledge-builders through humanistic practices and identity affirmation. Finally, we hope to deepen conversations in the learning sciences around what is at the heart of learning: affect, identity, and care.

Identity Feedback in Humanistic Emotional Configurations: An Analysis of a Humanistic Knowledge Building Community

In the learning sciences, human development is often viewed as a process of peoples' transforming participation in the sociocultural activities of their communities (Rogoff, 2003). From this perspective, learning is a matter of identity, whereby people pick up the valued discourses, practices, and values of the cultures where they participate as they gradually become more central members (Lave & Wenger, 1991). This enculturation process is laden with emotions, too, as participants negotiate the unique emotional configurations as they learn how to emote in culturally-valued ways (Mesquita & Leu, 2007; Vea, 2020). Identity and emotions are thus inextricably linked.

With an eye on elucidating some of the ways that emotions and identities are interrelated in the context of schools and classrooms, our research has focused on designing and researching humanistic knowledge building communities (HKBCs: Hod & Ben-Zvi, 2018). This model of classroom communities not only addresses advancing collective knowledge (Scardamalia & Bereiter, 2014), but also aims to support the transformation and growth of its members' identities. We view these humanistic activities as essential to helping learners hold more tentative views of knowledge, be more open to considering and working with different viewpoints, see the connections between the ideas participants advance with their identities, and be willing to give and take feedback both about their ideas as well as their identities.

The current study as part of this symposium focuses on identity feedback, which we define as the stories that participants in a community tell about a particular member about their ways of knowing, doing, or being (Herrenkhol & Mertl, 2010; Sfard & Prusak, 2005). Identity feedback can relate to what a person tells about themselves outside of the community, but the most potent type of this feedback also connects to the way any one person experiences another in the here-and-now of the group (Yalom & Leszcz, 2020). This type of feedback is often overlooked and at times culturally taboo, out of fear of embarrassing a peer. But, under the emotional configurations – combinations of feeling, sense-making, and practice (Vea, 2020) – that are unique to humanistic discourse, participants can be more direct and open with one another, ultimately giving them invaluable feedback that can help them make intentional changes to their identities. The humanistic emotional configurations include active and empathic listening, unconditional positive regard, and being congruent or real (Rogers, 1969).

 © ISLS

For this study, we collected data focused on the identity feedback that several students within a semester-long HKBC received. We used a grounded approach (Charmaz, 2008) to examine every instance of identity feedback that we could find that related to these students. We categorized the hundreds of instances that we found into nine types of identity feedback, each of which could be expressed at three different levels (non-elaborated nor specific, elaborated or specific, elaborated and specific). In this presentation, we will illustrate some of these ways that identity feedback was given in the context of the unique humanistic emotional configurations with the aim of showing how this feedback was consequential to the identity transformations of these students.

Evolution of the Academic Emotions of Academically Low-achieving Students in Knowledge Building

Knowledge Building is a pedagogical approach in which students take collective cognitive, metacognitive, and emotional responsibility to continuously advance the frontiers of their community knowledge (Scardamalia & Bereiter, 2014). Improving community knowledge, which involves continuous cognitive disequilibrium and equilibrium experience, is exciting but challenging, especially for low-achieving students. Low-achieving students usually enter schools with relatively weak collaborative, cognitive, and metacognitive competencies, and limited interest in learning (Becker & Luthar, 2002). Supporting low-achieving students' successful Knowledge Building can greatly benefit them (Yang et al., 2020). The Knowledge Building process can trigger various emotions (e.g., curiosity, confusion) that may promote or hinder idea improvement.

Emotions can critically influence students' regulative actions, motivation, and learning processes and outcomes (Di Leo et al., 2019; Muis et al., 2018; Zhu et al., 2019). Generally, positive emotions (e.g., curiosity, joy) can facilitate learning, while negative emotions (e.g., frustration, anxiety) can hinder learning (Di Leo et al., 2019; Muis et al., 2018). Low-achieving students may be more likely to experience negative emotions because of their relatively weak learning interest and preparation. These negative emotions may lead to unproductive collaboration, and inquiry during Knowledge Building. This study aimed to investigate what types of emotions low-achieving students experience and how their emotions evolve in the Knowledge Building process.

The participants were 120 students from two Grade 9 classes and two Grade 11 classes in Hong Kong. In total, 1,565 Knowledge Forum notes on Visual Arts were collected. Concerning data analysis, first, we classified the notes of each class into inquiry threads. An inquiry thread is a sequence of notes addressing the same problem or topic (Zhang et al., 2007). Second, we conducted content analysis to understand the academic emotions reflected in each thread (each note within a thread as a unit) using an academic emotion coding framework. The framework includes seven emotions: joy, surprise, curiosity, confusion, anxiety, frustration, and boredom; and none to indicate no obvious cues of emotions. The development of the framework drew on the model of impasse-driven emotions (D'Mello & Graesser, 2012) the framework for measuring epistemic-related emotions (Pekrun et al., 2017) and the definitions of emotions proposed by Craig et al. (2008). Finally, we employed sequential pattern analysis to analyze the evolution patterns of emotions in inquiry threads.

Significant sequential transitions of low-achieving students' emotions (Class A as an example)

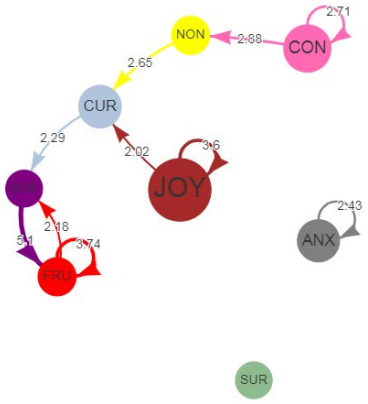

Figure 2
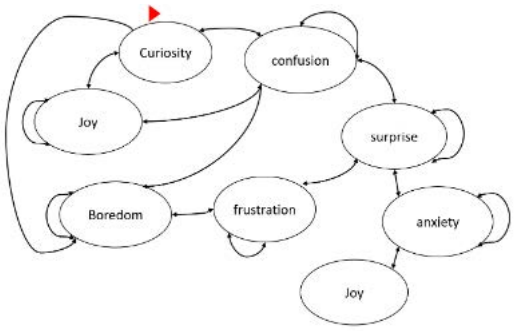
The evolution model of low-achieving students' emotions in Knowledge Building



Caring for the Online Learner: A Role for Affective Learning Analytics

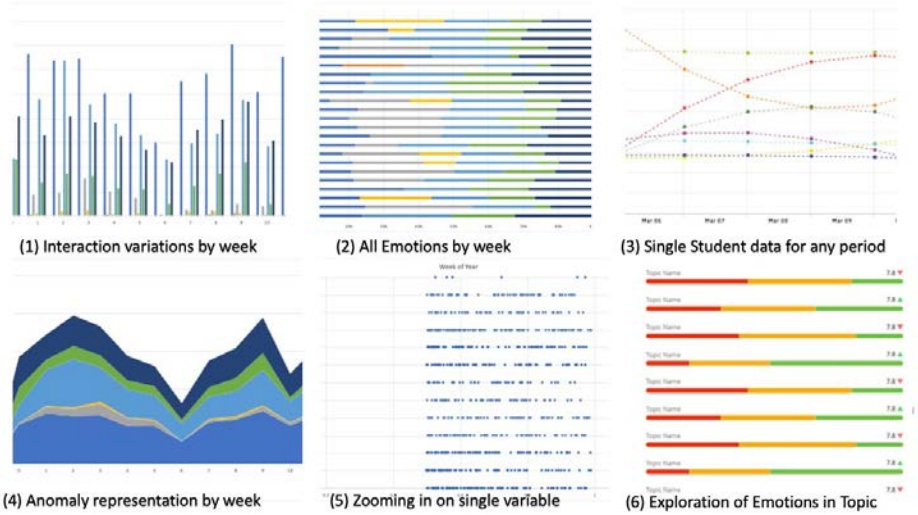
The COVID-19 pandemic has accelerated the shift of higher-education institutions towards online learning (cite), with many institutions continuing to offer online asynchronous courses to provide more flexible access to content and instruction at any time, from any place at a lower cost (Castro & Tumibay, 2021). While research in the online learning field has spanned decades (Means et al., 2009), there is still much work to be done in building and supporting a pedagogy of care in online learning environments.

Caring classroom environments help students "support and be supported by others" (Appleby et al., 2020), "operate from a collective struggle orientation" (Maloney & Matthews, 2020), "support students' perseverance and self-efficacy" (Lewis et al., 2012) and lead to better academic outcomes (Lindmark, 1996). Care, in face-to-face classrooms, is conveyed through active embodied interactions, dialogue and modeling, enabling instructors to experience their student's voice, body language, facial expressions, and shared physical context. Asynchronous online spaces are different and the question of whether, and how these spaces support an environment of care is unanswered. Any studies on care in the classroom would be most effectively situated within Noddings (2010) Framework of Moral Education, which provides a systematic lens through which affective inquiry and constructive classroom orchestrations could be studied. This framework comprises four components: Modelling, Dialogue, Practice and Confirmation, each of which is briefly shown in Figure 3.

Figure 3
Nodding's Pedagogy of care informed by analytics

In this design-based research study (Barab & Squire, 2004), we examine the features and representations of affective learning analytic instructor dashboards (see Figure 4) that provide an integrative view of student interactions, artifacts and tones, and anomalies in individual student data that help make caring intents more visible and provide ways for the instructor to express and enhance care in the online learning community (see Figure 2). Each of these representations will be demonstrated at the symposium and their influence through and on the four components of caring elaborated upon.

Figure 4
A few representations of instructor dashboards designed for the course



Developing empathy through a learning progression: Perspectives of senior-year engineering undergraduate students

Fostering empathy within engineering education may have many benefits, such as promoting the individual engineer's ability to self-regulate interpersonal difficulties, to understand the aspirations of society (Rasoal et al., 2012), to become intrinsically motivated to act selflessly (Batson et al., 2009), or to augment ethical decision-making skills (Oxley, 2011). Nonetheless, within engineering education literature, explicit attention on empathy has been minimal, as shown in a literature review research study by Strobel (2013). Engineering design courses provide space in the curriculum where students are required to empathize with the design context and potential users of their designs. Within design courses, empathy may involve an awareness of the broader context and how elements or multiple stakeholders within that context fit together. Often empathy is instigated by the instructor's encouragement and left to students' willingness and intentions to truly understand their stakeholders. However, in many instances, design requirements include both technical and human-centered constraints. Specifically, due to the vast range of potential target users of products that engineers design for, it is imperative to incorporate the needs, emotions, challenges, restrictions of such clients into the design process (Gray et al., 2015).

Empathy is both a cognitive and an affective process. It involves a person's perceptions, thoughts, and feelings and how those concepts become manifested into a deeper understanding of others. Broadly defined, empathy refers to 'the reactions of one individual to the observed experiences of another' (Davis, 1983). As these distinctions show, even in fields where empathy is frequently used, it is a complex and nuanced construct. Kolko (2014) suggests that empathy, which he believes can be both taught and developed, is imperative for the creation of human-centered products, and that successful design requires the integration of human factors and an empathy with the users. In a developmental sense, there are several stages and schematic models where one moves from less to more advanced cognitive, social, or moral stages/schema through milestones. For example, we used conceptual models that integrate all aspects of development into a single unifying staged theory, be it their cognitive/ethical development (Lochrie, 1989) or their reflective judgment (Zeidler et al., 2009).

In the context of this study, design courses are required for all students across their four-year education and offered through a learning progression called the design spine. We conducted a workshop and designed a reflective assignment for students to reflect on their various design experiences and how empathy played a role in each of the years. Through a thematic analysis, we found that students emphasized that the nature of the first-year design course involved more on framing design problems and allowed them to explore their identities as a designer. Building empathy in the design process starts with making space for self-empathy (Krol & Bartz, 2021)). In the following course, students had to design for a local community. Students pointed out that perspective-taking was essential to understand the problem space that they were designing for at this stage (Hess

et al., 2015). As students advanced into their specialization years, they reflected on the specific tools that they used to gain empathy and how that connected to the norms of the professional world. Lastly, students articulated complex understandings of empathy in their profession such as through team interactions, course objectives, and industry expectations. The implications of empathy in engineering entails a deep understanding of the engineering problem, including the values and perspectives of different stakeholders (e.g. the end users, design partners who may represent different sub-disciplines or geographic or cultural aspects of the project) which will be discussed in the symposium presentation.

"Punks", "Troublemakers" and "Inventors" – A Tension between Aspired and Embodied Values in STEM Education

Particularly in science, technology, engineering, and mathematics (STEM) education, we value innovation, creativity, "thinking outside the box", "pushing boundaries", "challenging paradigms" and "coming up with new solutions" - (Hart Research Associates, 2015). But instead of allowing an unrestricted application of knowledge in order to come up with new solutions, many school systems and learning environments value compliant originality and conforming behavior over independent thinking (Beghetto, 2016). Thus, non-compliant personalities and non-conforming behaviors in young learners are often interpreted in a negative way, teachers try to shut it down (Ripley, 2016) and call the students misbehaving or "troublemakers". As a consequence, classroom management styles like the imposition of sanctions are a first step toward penalizing unwanted behavior. Even suspension is often used due to what the teacher interprets as misbehavior (c.f., Lewis et al., 2008).

There seems to be a clash between aspired STEM attributes and values and what is considered a good student and how this notion is embodied in schooling systems. Defiance, disturbance, and misbehavior in general are serious issues in every-day schooling: It stresses students and teachers (Aldrup, Klusmann, Lüdtke, Göllner, & Trautwein, 2018; Kulinna, 2007) and distressed teachers are more likely to interpret behavior as misbehavior (Herman, Hickmon-Rosa, & Reinke, 2018). Most disciplinary classroom management styles lead to negative emotions, impaired wellbeing, impeded learning or negative student-teacher relationships and do not lead to behavior change (Goodboy, Bolkan, & Baker, 2018).

Unfortunately, a large number of students, who are defiant and do not have the tools to adapt, do disengage, lose interest and may even drop out of school. Furthermore, negative disciplinary actions in an US-context are immoderately applied to non-white and male children, especially African Americans and Hispanics (Blomberg, 2004; Losen et al., 2015; Townsend, 2000) and though male students and students of color and underrepresented minorities (URMs) are disproportionately more likely to be suspended and labeled "troublemakers" by their teachers, and thus suffer negative outcomes.

This contribution to the symposium brings together results on an emergent research agenda on troublemaking sharing (1) theoretical frameworks and conceptualizations to unpack the phenomenon of troublemaking and deviance in school, (2) and preliminary results on teachers' conceptualizations of troublemakers (Strobel & Koch, 2019). The long-term goals of this line of research are to differentiate between individual actions and their intentions of so-called troublemakers; reframing what it means to be a troublemaker and how to respond and support behaviors of troublemaking.

The Neural Basis of Learning through Productive Failure

Cléa Formaz, ETH Zürich, clea.formaz@gess.ethz.ch, Venera Gashaj, ETH Zürich, venera.gashaj@gess.ethz.ch, Dragan Trninić, ETH Zürich, dragan.trninic@gess.ethz.ch, Sven Hoffmann, Distance-Learning University Hagen, sven.hoffmann@fernuni-hagen.de, Manu Kapur, ETH Zürich, manukapur@ethz.ch

Abstract: Productive Failure (PF) is a learning design wherein learners generate solutions for novel problems prior to formal instruction. Research has demonstrated the effectiveness of PF, indicating cognitive mechanisms for why students learn better after encountering difficulties. However, neurophysiological mechanisms underpinning "learning from failure" have yet to be explored, despite robust evidence connecting neural activity, heartbeats, and cognitive processes. The present study explores neural and physiological mechanisms underlying PF, employing neural signature and heartrate variability measurements.

Background of the project

Problem-solving followed by instruction (PS-I), as entailed in learning through Productive Failure (Kapur, 2014), is a powerful design shown to advance students' conceptual understanding and transfer compared to instruction followed by problem-solving (I-PS; Sinha & Kapur, 2021). Within research on PS-I, various cognitive mechanisms have been explored; however, the physiological and neural basis of this design have not yet been studied. The present study-in-progress investigates underlying neural and physiological mechanisms of PS-I compared to I-PS, using electroencephalography (EEG) to measure brain activity and electrocardiography (ECG) to measure heartbeat activity during learning in a naturalistic environment.

EEG research in the past years shows that various neural oscillations or waves are related to cognitive processes. For example, while problem-solving and having an insight, gamma oscillations are enhanced in right prefrontal regions (Rosen & Reiner, 2017), in right anterior superior temporal gyrus (Jung-Beeman et al., 2004), and fronto-central regions (Sheth et al., 2008). Moreover, alpha oscillations are associated with semantic information processing, in particular with searching, accessing, and retrieving information from long-term memory (Klimesch et al. 1997). Since most cognitive tasks draw on these processes, alpha event-related activity can be observed in a wide range of task demands (Klimesch et al. 1997). Theta activity has been related to episodic and working memory as theta event-related synchronization increases parametrically with working memory load and is sustained during the retention period (Jensen and Tesche 2002; Kahana et al. 2001). Since these are all cognitive processes relevant to a learning situation, we measure delta, theta, alpha, beta, and gamma in the present study.

Recent findings have begun to disentangle how different heartbeat measurements are associated with both top-down and bottom-up cognitive processing of emotional stimuli and lower-order cognitive skills (Park & Thayer, 2014; Mather & Thayer, 2018), including for example recalling or memorizing basic knowledge. Specificall, higher resting heartrate variability is associated with more adaptive and functional top-down and bottom-up cognitive modulation of emotional stimuli (Park & Thayer, 2014). We use ECG to investigate different heartbeat measurements, including heart rate variability (HRV), along with differences in EEG activity related to the type of learning situation (i.e., PS-I versus I-PS).

Research goals

With this project I set out to study the physiological and neural mechanisms involved in the Productive Failure learning design. I will investigate the HRV and change of oscillatory brain activity during a learning situation including several simultaneous cognitive processes like attention, working memory, memory retrieval, creativity/search of novel ideas. To do so, I conducted a neuro-physiological study to investigate whether there are differences in brain oscillations between the phases of the conditions (problem solving vs. instruction), between the conditions in the same phases, and how heart rate variability (HRV) is influencing post-test performance. The results will help us understand why the productive failure design is so powerful and what the difference is in terms of cognitive activity in the condition PS-I versus I-PS.

Methodology

We followed previously confirmed methodologies and increased sample size. A total of 60 healthy right-handed participants (age: 18 – 25 years old), randomly assigned to one of the conditions I-PS or PS-I (30 participants in each condition) were tested using EEG and ECG for all participants. We set up a naturalistic EEG/ECG study in

a learning setting. A computerized (Python w/ EEG trigger) version of a validated PF design (Kapur, 2014) was used. EEG data were collected with the Ant Neuro EEGO MyLab 128-channel EEG system at the ETHZ Decision Sciences Lab. At the same time, ECG data was collected with an electrode attached to the limb extremities and chest. The computerized version of the PF tasks had integrated markers sent to the EEG systems accordingly in order to form blocks of baselines, and different parts of the experiment. Additionally, participants' answers to multiple choice formed questions in the posttest were recorded and scored by the computerized task. The EEG data is being processed and analyzed using MATLAB custom scripts and the following toolboxes: EEGLAB for data preprocessing, including Independent Component Analysis (ICA) and artefact correction. Independent Component Analysis (ICA) is being used to identify and remove the eye-blink artifacts. Subsequently, the data will be visually inspected for other large artifact removal. Current source density (CSD) transformation (surface Laplacian) will be subsequently applied to the data in order to attenuate the low-spatial frequency features from the data, especially the cardiac-field artifact (CFA). The power spectral density (PSD) will be calculated using Welch's method. The power values at each electrode for each condition will be averaged over standard EEG frequency bands: delta (1–4 Hz), theta (4–8 Hz), alpha (8–12 Hz), beta (13–30 Hz), gamma (30–70 Hz) and subsequently log-transformed to normalize their distributions.

Statistical analysis: Repeated measures ANOVA and false discovery rate will be used to calculate differences between the conditions.

Expected Findings

Because of the underlying interdependent mechanisms proposed by Kapur (2016) and based on previous electroencephalography research, we expect enhanced gamma oscillations in the PS-I condition (compared to the I-PS condition) in the right prefrontal regions (Rosen & Reiner, 2017), in right anterior superior temporal gyrus (Jung-Beeman et al., 2004), and/or fronto-central regions (Sheth et al., 2008) during the problem-solving phase. Furthermore, we expect enhanced alpha oscillations during the problem-solving phase in the PS-I condition compared to the I-PS condition (Klimesch et al. 1997). As higher HRV is related to a better inhibition, we therefore expect that a higher HRV shows advantages in the PS-I condition (Park & Thayer, 2014).

Supporting Multilingualism in Preschool: A Play Responsive Teaching Approach Mediated by digital technologies

Shengjergji Sofije, University of Gothenburg, Sofije.shengjergji@gu.se
Pramling Niklas, University of Gothenburg, Niklas.pramling@pe.gu.se
Myrendal Jenny, University of Gothenburg, Jenny.myrendal@gu.se

Abstract: This design-based research focuses on timely challenges such as multilingualism and the use of digital technologies that teaching in preschool is facing. Play-responsive teaching is the theory that informs the design and implementation of the study. Data will be generated from recordings where children and teachers engage in playful activities with tablets where multiple languages may be used. Analysis will investigate how teaching in preschool can be responsive to multilingualism by utilizing digital technologies (tablets).

Introduction

In our globalized world, multiculturalism is the societal norm for many contemporary societies and according to Turner and Cross (2016, p.289) today's education reflects an "increasing normalisation of multilingualism". However, even though multilingualism is now regarded as a valuable asset, there is still a need to identify pedagogical approaches, strategies and practical concepts for teaching in such circumstances.

Purpose

The purpose of this study is to produce new pedagogical knowledge oriented towards teaching in the field of Early Childhood Education (ECE) regarding multilingualism and digital technologies. More precisely, by applying a design-based research methodology it will be empirically explored how teaching in preschool can be responsive to a multilingual context, when playful activities with tablets (book creator app) are developed and teachers build pedagogy (teaching) on some principles of play-responsive teaching theory (PRECEC; Pramling et al., 2019).
The research questions are:

- How do activities with digital technologies (tablets) develop in linguistically diverse groups with preschool teachers building pedagogy (teaching) on PRECEC?

- What are the challenges and opportunities preschool teachers identify when reflecting on working according to some principles of PRECEC, in linguistically diverse groups of children and using digital technologies?

Method

Figure 1
A design-based research approach (from Reeves, 2006)

 © ISLS

Design-based Research (Brown, 1992; Collins, 1992) is chosen because it corresponds to the dual focus of this study to develop theory (PRECEC) and to improve practice (teaching in preschool). Design-based Research (DBR) is characterized as theoretically oriented, interventionist, iterative, and collaborative (McKenney & Reeves, 2018). Those characteristics will be included in this study and are viewed as standards/commitments for the quality of DBR (see Figure1).
Two preschool classrooms from two different international preschools in Sweden will participate in this study. The study will consists of observations of preschool environments, field notes, interviews with the principals and preschool teachers, and video recordings of playful activities. Since the study involves video recordings where children participate, it has been ethically approved by the Swedish Ethical Review Authority.

Expected Findings

Findings will clarify:

- How teachers work with some principles of PRECEC to engage multilingual children in playful activities with digital technologies.
- What kind of interactions develop between teacher-children or between peers during these activities.
- An understanding of how the mediation of digital technologies in the playful activities might change or expand the nature of PRECEC.
- Challenges and opportunities that preschool teachers identify after participating in this study.

Conclusion

This study, addressing the issues of multilingualism and the use of digital technologies in preschool, is timely and will make important contributions, both to the existing body of knowledge about and in ECE and to a wider societal discussion on these matters. Generalizability is established by placing the findings of this study in a broad theoretical context (PRECEC) to demonstrate whether and how the study is an example of the phenomenon under investigation.

Abstract: This study investigated conceptualizations of teaching and learning using complex systems theory and network analysis. In 226 impact statements for promotion and tenure in one university we found two conceptualizations. In the Content-Processing conceptualization, teaching is the delivery of content and learning is acquisition of knowledge. In the Framing-Facilitation conceptualization, teaching is preparation of students for future careers and imparting truth, and learning is skill development. We also identified leverage points within each conceptualization.

Background

In complex systems interdependent elements interact in ways that lead to emergent phenomena which cannot be explained through linear cause-and-effect analysis (Bar-Yam, 2016). The interdependent elements in complex conceptual systems are related ideas which together form conceptualizations, leading to emergent phenomena in the form of practices. Because practices are emergent from conceptualizations, changing practices requires that conceptualizations must change. In prior studies we found two dominant conceptualizations of learning (Donaldson & Allen-Handy, 2020). In the Transfer-Acquisition conceptualization, learning is the acquisition and manipulation of knowledge objects. We found this conceptualization to be dominant among the general public (Donaldson, 2018), as well as among STEM educators (Donaldson & Allen-Handy, 2020). In the learning sciences we found widespread use of the Construction-Becoming conceptualization (Donaldson, 2019) which sees learning simultaneously as becoming and as construction of meaning. This study seeks to identify which conceptualizations professors across all disciplines in a Research 1 university use to relate the impact of teaching and learning.

Methods

We collected 226 anonymized impact statements from faculty being considered for tenure and promotion to associate professor across 16 colleges in a Research 1 university in the United States from 2015 to 2019. In MAXQDA Analytics Pro we coded the data using emergent coding processes within the following categories: non-metaphorical characterizations of teaching and learning; metaphors of teaching and learning; practices in teaching and learning; and value statements. The coding stage resulted in a final codebook which contained 291 codes covering 9,383 coded segments. We then calculated code co-occurrence correlations using Pearson's r for all pairs of codes within each category. Symmetrical correlation matrices were created at the $p < 0.05$, $p < 0.01$, and $p < 0.001$ confidence levels. UCINet network analysis software was then used to analyze the matrices as 1-mode networks. We used Girvan-Newman cluster analysis to identify network clusters (Girvan & Newman, 2002), which were visualized using the NetDraw network visualization software with different colors of nodes indicating membership in a cluster. To identify leverage points within each conceptualization, we developed an innovative methodology: semantic network maps in which node sizes were adjusted such that nodes with higher betweenness centrality measures were larger, and nodes with high betweenness values are key leverage points.

Findings

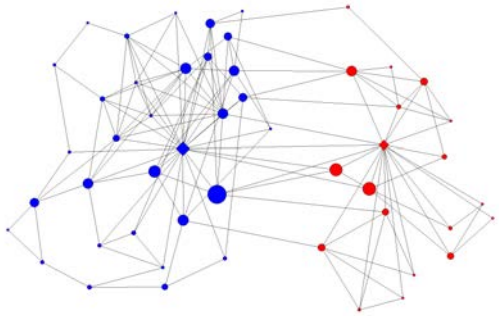
Girvan-Newman analysis identified two conceptualizations of teaching and learning (see figure 1) at Q=319. Although they were significantly distinct non-overlapping clusters, these two conceptualizations of teaching and learning had so much semantic overlap that we suspected they are actually two variations of one conceptualization, which was further supported by the finding that both conceptualizations were aligned with the Transfer-Acquisition conceptualization found in prior studies. In the current study, the Content-Processing conceptualization of teaching and learning (blue cluster - 88.9% of the professors) saw teaching as involving creating courses and structures for delivering and explaining knowledge. Professors who used this conceptual story often seek to improve their courses and teaching practices, often with a focus on trying to motivate students. These professors believed that learning involves acquiring and using knowledge, and often value adjusting their teaching according to their students' learning styles. It often framed teaching and learning in terms of content—

 © ISLS

content which is conveyed to students, which forms a foundation or body of knowledge. This content comes in the form of pieces of information which students obtain. A major focus was covering material which students receive and process. This conceptualization was aligned with the Transfer-Acquisition conceptualization found in prior research. We also found a Framing-Facilitation conceptualization of teaching and learning (83.6% of professors - red cluster) focused on facilitating student development of skills to prepare them for future careers. It used a perspective on learning which sees learning as a process which takes place on the level of the individual student, and the role of the professor is to impart truth and correct facts to students. This conceptualization used visual metaphors such as exposure, illumination, and lenses. This conceptualization was also mostly aligned with the Transfer-Acquisition conceptualization found in prior research, but to a lesser degree than the Content-Processing conceptualization.

Figure 1

Two conceptualizations of teaching and learning at $P < 0.001$ with leverage points



Within the Content-Processing conceptualization of teaching and learning there were leverage points which could be used to help faculty question their assumptions about teaching and learning, including metaphors of knowledge such as "basic" knowledge (large blue node to the lower left of the diamond in the center of the blue cluster) and a knowledge "foundation" (largest blue node in the right of the blue cluster). Other leverage points are thinking of teaching as something which should be grounded in theory (largest node in the upper-left part of the blue cluster) and involving continual efforts to improve teaching methods (large blue node to the upper-right of the diamond). Within the Framing-Facilitation conceptualization of teaching and learning leverage points include framing knowledge as something which is created (rather than acquired or discovered - largest node in the upper part of the red cluster in figure 1) and thinking of learning as focused primarily on understanding (largest red node in the center-left part of the red cluster), which is connected also to preparing students for future careers (the large red node in the center of the red cluster).

Discussion and Implications

This study used an innovative methodology which leverages network analysis tools to investigate these questions, and we were able to further develop the methodology such that it provides insights about key leverage points in complex conceptual systems. We found two conceptualizations of teaching and learning used by professors in impact statements for tenure and promotion. By virtue of identifying these conceptualizations we gain insights into both 1) the motivations for faculty teaching and learning approaches and 2) how faculty members perceive their colleagues value teaching and learning during the promotion and tenure process.

The Gateway for Optimizing Design of Micro-credentials: Higher Education Faculty

Anne Reed, Samuel Abramovich
annereed@buffalo.edu, samuelab@buffalo.edu
State University of New York at Buffalo

Abstract: Despite the growing prevalence of micro-credentials in higher education, there is still no consensus on best design practices. To address this, we identified existing design knowledge held by faculty that designed micro-credentials in a pilot program at a large public research university. We found that faculty may know how to design micro-credentials to address credentialing affordances, but may need support in recognizing and designing for assessment affordances.

Introduction

A micro-credential is a small learning experience in terms of length of time to complete and the amount of knowledge and skills that are assessed (Abramovich, 2016). Relatedly, a digital badge often accompanies a micro-credential as a "visual representation of learning and skills" (Besser & Newby, 2020, p. 484). Because micro-credentials are significantly different from traditional credentials (Ghasia et al., 2019), the same processes and principles that educators apply when designing the corresponding learning experience may not be optimal. Simply put, designing a micro-credential for a learning opportunity is different than designing the learning experience that accompanies a diploma, certificate, or course grade. This is problematic because, although micro-credentials are increasingly used (Besser & Newby, 2020), there is little research about what are the optimal design processes for different types of micro-credentials. This problem is compounded since we know that a design process influences factors such as student persistence, sense of progress, and perceived learning (Gray & Diloreto 2016; Groening & Binnewies, 2019). A misapplied design process may be the reason for unsuccessful micro-credentials (e.g., low interest, misrepresentation of the credentialed knowledge) and may even hamper learning outcomes.

To identify optimal design process for micro-credentials in higher education, we investigated how faculty leveraged the affordances of micro-credentials in their design process. Guiding our investigation were the following exploratory questions: *What are faculty perceptions of micro-credentials? How do faculty address these perceptions when they design a micro-credential?* We intentionally chose broad, guiding questions to uncover "subjective insights, intuitions, hunches, and ideals" that could serve as a "crucial basis" (Nonaka & Takeuchi, 1995, pp. 8-10) for building design knowledge for micro-credentials.

Theoretical approach

This study was informed by literature that theorizes design as a form of knowledge that is enacted (Nonaka & Takeuchi, 1995), and by research of design processes where the designer is a mediator of knowledge (McKenney & Schunn, 2018). Therefore, we aimed to reveal design decisions (i.e., knowledge) held by faculty (i.e., mediators of knowledge) that designed micro-credentials.

Methods

We interviewed five faculty members on their experiences (e.g., practices, processes, decisions) designing a micro-credential as part of a pilot program at a large, public research university. Interviews were transcribed, to which we applied a hybrid process of inductive and deductive thematic analysis. We first conducted open coding, and the concept of 'affordances' emerged as a core theme. Next, we reviewed our initial codes and identified two main subcategories of affordances: assessment and credentialing.

To determine how the identified affordances were considered in the faculty's design processes, we examined literature to identify design attributes of quality assessments and quality credentials. In our final round of coding, we used the design attributes that were repeatedly referenced (i.e., in at least three peer reviewed articles) as an a priori template (Crabtree & Miller, 1999) to analyze how faculty designed micro-credentials to address assessment and credentialing affordances.

Findings and conclusion

 © ISLS

We found that all of faculty perceived micro-credentials in terms of their assessment and credentialing affordances. When describing their experiences designing a micro-credential, faculty recognized the following qualities of assessment design, as applicable to the design of a micro-credential: Formative and summative components; Alignment with delivery method; Sustainable assessment; Clarity of outcomes and criteria; Optimized for the unique aspects of the learning opportunity; Equity-oriented. Faculty recognized the following qualities of credential design, as applicable to the design of a micro-credential: Meets needs of employers; Prepares learners to succeed in the workforce; Understood by stakeholders.

However, in designing a micro-credential, faculty addressed the assessment and credential affordances to varying degrees. While the design attributes of quality credentials were ubiquitously applied by the faculty, few attributes of quality assessments were consistently applied. This suggests that for micro-credentials to be optimized, faculty may need additional support to be as consistent with the affordances of assessment in the design process as they are with credentials. This support could come in the form of professional development, where faculty can explore how credentials and assessment are symbiotic.

Our findings also indicate that some critical attributes of assessment design were largely not discussed, or not applied (e.g., aligning with the delivery method, ensuring clarity of outcomes and criteria, establishing equity-oriented assessment). Therefore, we suggest that faculty may need support in recognizing and integrating assessment qualities when designing micro-credentials. To address this need, support may include planning sessions that highlight strategies for integrating qualities of good assessment design, facilitating meetings with experienced micro-credential designers for knowledge-sharing, and structuring design tasks through templates and models.
We also conclude that further research is needed to refine and build upon the design considerations revealed in this study, and to determine their applicability to micro-credential design practice across other institutions of higher education. More specifically, educational design practice is situated and highly shaped by institutional environment and socio-cultural system (Butler & Schnellert, 2012). We recommend research that extends to other types of higher education institutions, including two-year institutions. Additional research may also identify potential discipline-specific factors relating to micro-credential design. Faculty design decisions are closely related to "discipline-embedded assumptions and beliefs" (Stark, 1988 p. 221). A micro-credential for one type of knowledge may have different assessment and credential affordances than a micro-credential for another field.

Taking up opportunities to practice in a social studies-themed digital simulation game: A quantitative ethnography

Taylor M. Kessner
taylor.kessner@uta.edu
The University of Texas at Arlington

Abstract: We use quantitative ethnography and Epistemic Network Analysis to examine how the social studies-themed digital simulation game *Offworld Trading Company* generates opportunities for players to practice using disciplinary knowledge, skills, and concepts (DKSCs) as tools for taking goal-mediated action. Our study design places particular emphasis on establishing inferences regarding specific game mechanics as generative of such opportunities to practice, as well as the DKSCs they invite and require of players.

Introduction

This poster proposal describes work currently in progress. Preliminary results will be ready for reporting at the time of the conference. Previous research indicates that *Offworld Trading Company* (*OTC*), a digital simulation game thematically aligned to social studies--particularly economics and geography--invites players to practice using disciplinary knowledge, skills, and concepts (DKSCs) associated with social studies to plan, take, and reflect on goal-mediated actions (Kessner, 2021). The goal of the present research is to explore in greater depth the structural design elements that afford these opportunities to practice (OTPs). We define OTPs as embodied interactions in which players are positioned within identities and with access to tools to solve problems; and in which the relevant identities, tools, and problems are disciplinarily integrated.

Good games are excellent learning environments. They privilege experience before text, performance before competence, identity play, and systems thinking; and they present players with interesting, well-structured, and well-sequenced problems players solve by mastering and applying game-valued skills (Gee, 2003). Good games often align better than formal education environments to long-standing claims of situativity theorists that what we learn cannot be disentangled from how and why we learn it (Gresalfi et al., 2009).

For these and other reasons, games have maintained a level of popularity among both educators and researchers. In the context of social studies education, however, a mismatch exists between this interest and the available evidence of effectiveness, as well as conceptual guidance around what (kinds of) games are useful and why. Use of games in social studies education contexts may indeed represent a unique challenge.

Done well, social studies education should prepare students to don the mantle of citizenship, with particular emphasis on active, critical participation in making choices that (re)design the world to align as tightly as possible to shared visions of a just and equitable pluralist democracy (Banks, 2006; Barton & Levstik, 2004; Kessner et al., 2020). This form of civic preparation requires opportunities to practice using disciplinary knowledge, skills, and concepts as tools for taking action. Good games are particularly good at providing such opportunities generally, though what design elements (e.g., game mechanics) generate these opportunities specifically remains unclear in the context of social studies education; far more attention has been paid to these design issues in the contexts of math and science (Sengupta & Clark, 2016).

We use quantitative ethnography (QE) (Shaffer, 2017) to examine small-group play of *OTC* to explore the following research questions:

1. To what extent do learners take up OTPs to practice using DKSCs to take goal-mediated action in *OTC*?
2. What DKSCs do learners leverage while planning, taking, and evaluating goal-mediated actions in *OTC*?
3. What game mechanics generate these OTPs in *OTC*, and which DKSCs do they invite students to use?

Theoretical framework

Humans learn best through embodied interactions with the world. These interactions are further mediated by tools. In the context of games, we frame these embodied interactions as *conversations with the world*, cycles of thinking and action in which people identify goals, plan actions, and gather feedback on those actions from the world (Gee & Gee, 2017). These actions are probes into the world, a kind of question put to it, and the world "talks back" (p. 2). In videogames, players are embodied in the game world as avatars, which come with toolkits (Gee, 2015). It is with these tools and through these avatars that players (are able to) take actions in games. In *OTC*, players' avatars, their associated toolkits, and the problem spaces presented to players, align conceptually to those of economists and geographers (Kessner, 2021); we contend OTPs emerge at their intersection.

 © ISLS

Methods

QE leverages quantitative designs and analyses to make sense of complex qualitative discourse data (Shaffer, 2017). Recent games scholarship leveraging QE has explored how an online game community forum facilitated participants' identity exploration processes (Barany & Foster, 2019), when and why students quit learning-focused games (Karumbaiah et al., 2019), the correlation between students' facial expressions and their understanding of biological and complex systems concepts (Martin et al., 2019), and the connection between multimodal observable behavior and collaborative problem-solving skills (Andrade et al., 2019).

As with the above applications of the method to games research, QE represents articular affordances for the present study. Games are immensely complex systems, making purely qualitative accountings of the connections between many diverse variables difficult if not altogether untenable. Additionally, at least two games take place concurrently during gameplay: the game on the screen, and the game in players' heads. Our research questions are additionally concerned with a third space: the game that takes place behind the screen, which includes game mechanics.

Participants for this study are a class of high school students enrolled in an Academic Decathlon elective course in a public school in the American South. Students came from diverse backgrounds, and their varied levels of academic achievement, from "low" to "high," as measured by school-calculated grade point averages, indicates a wide and potentially representative sample of academic interest and engagement with school. We are collecting discourse data by recording students' conversations as they plan and deliberate which actions to take as they play the game in small groups. We will then transcribe this data for *a priori* coding based on prior analysis of DKSCs implicated in the *C3 Framework*. The results of this coding will guide our segmentation of the gameplay data (screencaptured) and accompanying video data in OTPs. Using Epistemic Network Analysis, we will then identify game mechanics that generated OTPs, as well as which (kinds of) mechanics generated stronger or weaker OTPs and stronger or weaker DKSC use.

Undergraduate and Graduate Student Perspective on Teaching for Critical Pedagogy

Paloma Ortiz Reyes and Carolina Govea
paloma983@tamu.edu, cgovea23@tamu.edu
Texas A&M University

Abstract: In critical pedagogy there is an intrinsically interrelated relationship between education and society. The fundamental purpose for education is to improve society and fight for justice for all. These core ideas translate into a set of principles for the design of transformational learning. These principles involve rejecting positivism and embracing constructivism, developing critical consciousness, questioning assumptions, learner autonomy and authority, and transforming realities. To explore these principles, the first and second author presents an autoethnographic analysis of these principles in their own educational experience.

Background

There is not a set of practices for critical pedagogy, but it provides a set of principles that guide the design of courses, learning activities, and learning environments. The first involves rejecting positivism and embracing constructivist and situative perspectives (Kincheloe & Steinberg, 1998) because positivism reproduces and enforces systems of power that cause marginalization and oppression resulting in social injustice. The second principle is developing critical consciousness—a frame of mind that creates and rebuilds the world by self-transformation of one's context which cannot occur from the traditional "from the top down but from the inside out" (Freire, 1974), and is developed by building knowledge through human and world relations and interactions (hooks, 1994). The third principle is transforming realities towards alleviating the suffering of those around you who are marginalized and/or oppressed. This is only possible when working with learners to gradually understand and embrace their own authority (Donaldson 2019). In critical pedagogy, we have students and teachers in positions of autonomy and authority—the fourth principle (Freire, 1974; Kincheloe, Steinberg, & Tippins, 1999). Developing learner authority and autonomy is necessary to enact all principles of critical pedagogy. The fifth principle is questioning assumptions (Kincheloe, 2008) and recognizing that not everything has one answer, and that answers are constructed by people who have intersecting identities and power.

Methods

We used theory-focused autoethnographic study (Jones 2016) to analyze our own educational experience through the lens of critical pedagogy. We approached our analysis by first delineating three aspects of auto-ethno-graphy. The "auto" (self) aspect includes the experiences of the two authors of this paper. The "ethno" (socio-cultural context) aspect includes three communities: 1) the family and community of the first author, 2) the family and community of the second author, and 3) the community of higher education in a large land-grant university in the United States. The "graphy" (formal research investigation) aspect included analysis of researcher-generated field notes. The first author is a graduate student, first in her family to graduate university. She grew up in a marginalized community in San Antonio, TX, where the community lacked access to healthcare, higher education, and other resources. The second author is an undergraduate student, and will be the fourth in her family to graduate from college. She grew up in a predominantly Hispanic community where many families live below the poverty line. Both authors grew up in low-income communities and attended Title I schools.

Findings

Principle 1 findings: Reflecting on our grade school education, specifically high school, we both remember students at our schools being generalized as troublemakers because of the school's Title I status. Both schools consistently reported low test scores, high pregnancy, and dropout rates, and violations. On the surface, from a positivist perspective based on the statistics and facts, it was assumed that these students didn't care about school—that school was something students had to do, or they would go to truancy court. By rejecting positivism and looking deeper past just numbers, we can understand why the statistics are what they are. Analysis of our own experiences helped us realize that factors like race, citizenship status, mental illness, sex, and class are socially constructed concepts that have real-life consequences, especially in terms of producing and reproducing societal hierarchy. These hierarchies invade institutions like education, creating differences in its quality depending on socioeconomic status. As we continued with our education, we realized that these hierarchies that have been put in place—are not a natural nor inevitable feature of reality. The realization that

 © ISLS

social constructs are not "real" in terms of natural sciences but do have real-life consequences transformed our worldview.

Principle 2 findings: During my undergraduate career, I (the first author) was faced with obstacles that only presented themselves to students who are different from the traditional college student. Being a woman of color from a low socioeconomic background who is also the first in her family to go to college, I quickly realized that the environment of higher education I was experiencing was not created for people like me. And yet, I also realize that even though the system was not created for me, I belong in higher education. I have the right to be here, and a right to succeed.

Principle 3 findings: Do I belong or not? Looking at sociohistorical assumptions in society, I (the first author) was able to recognize that the structures and institutions of higher education were designed by and for white upper middle class men. It became important to me that I challenge these barriers that impact disenfranchised communities. Education is not a privilege but a human right, which contradicts the initial assumption that education is reserved for the higher class. Growing up, college was seen as unattainable in my community and family due to lack of resources and awareness of how to access and navigate higher education. Within higher education, the lack of representation of minority students deepened the notion that students from marginalized communities are unwelcomed. There is a constant battle between knowing I belong, yet being aware of the preexisting systemic issues within the institution of higher education.

Principle 4 findings: During the spring semester of my sophomore year, I (the second author) was enrolled in a course where most class periods consisted of open discussions surrounding the ways in which education has failed marginalized communities, as well as discussion of present and future solutions. This course was one of the first I had that focused on discussion-based learning where students had the autonomy to express their opinions and lead discussions. The professor also allowed students to decide what to research and how they want to demonstrate their understanding. Through the professor's use of open discussion and choice in assignments, they were able to engage students in developing identity. It proved that I have the authority and autonomy to explore what I find interesting, know that I'm intellectually valued, and use my experiences to demonstrate knowledge.

Principle 5 findings: We are currently working in a learning sciences research laboratory that assists faculty from all disciplines conduct research about learning in their own courses. We are able to create a positive impact in higher education. We take different principles from critical pedagogy in order to help faculty revise their courses. In our lab we approach our roles and responsibilities through exercising agency and autonomy. We have the authority to craft our own research projects, collaborate with members in the lab, and work with faculty as co-equals. We support the lab in other ways such as data cleaning and writing overview papers for faculty to better understand learning theories. We are working in collaboration with top professors in their fields to develop more powerful and empowering learning experiences in their courses. This allows us to have an impact on transforming student's learning, as well as their worldviews and critical consciousness.

Discussion

As both learners and scholars, we are driven by a need to work toward creating an equitable education system that benefits everyone. Through learning and collaborating with others we create knowledge that has the potential to change the society we live in. By transforming how we approach teaching and learning by using critical pedagogy we have the ability to create an institution that changes lives for the better. Our autoethnographic analysis found that theoretical constructs from the critical pedagogy literature reflect the truth of our own lived experiences.

Looking Beyond Disciplinary Silos: Students' Interdisciplinary Science Understanding of Carbon Cycling

Hyesun You, University of Iowa, hyesun-you@uiowa.edu
Minju Hong, University of Georgia, mh19985@uga.edu

Abstract: Natural phenomena and scientific issues are intrinsically interdisciplinary. A variety of academic disciplines of natural science are essential for students to explain a phenomenon or related issues along with their reasonings for the phenomenon. The primary goal of the current study is to examine how students' interdisciplinary understanding of carbon cycling manifests itself using the latent Dirichlet allocation model. This study provides important insight into the potential impact on diverse curricular and instructional approaches in science.

Introduction

Natural phenomena and scientific issues are intrinsically interdisciplinary (ID). ID understanding in a variety of disciplines of natural science is essential for students to explain a phenomenon or related social scientific issues. The current science education system focuses mainly on a discipline-based curriculum, but recent national documents and standards for science education in many countries have demonstrated the value and essentiality of ID approaches to learning. Despite a growing emphasis on ID learning and teaching in K–16 education, few researchers have identified the ID connections within student science knowledge. This study involves students' answers to constructed-response (CR) questions in the Interdisciplinary Science Assessment for Carbon Cycling (ISACC, You et al., 2021) to interpret what core science concepts and corresponding disciplines are evident in their answers using topic modeling. We examined the relationship between the proportions of science disciplines and students' scores. The guiding research questions for this project were as follows:

a) How is students' ID knowledge about carbon cycling represented in their written answers?
b) How is the relationship between the proportion of the ID represented in the students' answers and scores?

Theoretical Framework

Interdisciplinary understanding

ID understanding has been defined as "the capacity to integrate knowledge in two or more disciplines to produce a cognitive advancement in ways that would have been impossible or unlikely through single disciplinary means" (Boix Mansilla & Duraisingh, 2007, p. 219). You et al. (2021) argued that the combination of knowledge from different individual disciplines could be a prerequisite for demonstrating ID understanding.

Topic modeling

Interest in the use of topic modeling techniques to discover abstract "topics" in the collection of documents has increased (Nagwani, 2015). The students' answers to the CR items provide an example of the texts educational scholars are interested in. The most popular model of the topic modeling technique is latent Dirichlet allocation (LDA; Blei et al., 2003). It is commonly used to discover the scope of topics and the underlying patterns contained in text documents.

Methods

Participants and ISACC

The ISACC consists of 454 students' responses to 19 items, including 11 multiple-choice (MC) items and eight CR items, collected at a public high school and a research university in Texas (You et al., 2018, 2021). From eight CR items, we excluded three items based on a single discipline's knowledge and the lack of information to extract topic structures. Thus, we analyzed students' written answers for five CR items (i.e., Item 8, Item 12, Item 14, Item 15, Item 19) in the ISACC.

Data analysis

The first step of the topic modeling is data cleaning, which eliminates the meaningless texts, "don't know" texts, and empty texts. In the second step, we preprocessed the data through a) tokenization (i.e., breaking the sentence into multiple words), (b) lemmatization (i.e., converting the words into their

 © ISLS

word stems), and c) stop-word removal. We extracted topic structures using the LDA model and then fitted a regression model to reveal the relationship between topics and students' scores.

Results

After the data cleaning, the average lengths of the written answers were from 19.66 words (Item 12) to 50.78 words (Item 19). Table 1 shows the most representative words for the topics of each CR item. Through the key words, we found interdisciplinary connections between the students' answers and the five CR items. We extracted three topics from Item 8: Topic 1 (integration of biology, chemistry, and earth science); Topic 2 (integration of chemistry and earth science); and Topic 3 (integration of biology and chemistry). The other four CR items had a two-topic structure. Interpretations of the topics of five CR items will appear in the presentation.

Table 1

Representative Words for Topics of Five CR Items

Item 8	Topic 1	ocean, pH, atmosphere, create, acid, organism	Item 14	Topic 1	food chain, carbon dioxide, acid, atmosphere, marine
	Topic 2	CO_2, air, release, temperature, turn		Topic 2	phytoplankton, population, eat, source, organism
	Topic 3	reef, coral, fuel, fossil, warm	Item 15	Topic 1	reduce, intake, animal, create
Item 12	Topic 1	fossil, fuel, burn, atmosphere		Topic 2	tree, atmosphere, balance
	Topic 2	vapor, radiation, cycle, heat, trap, loop	Item 19	Topic 1	solar, season, energy, plant
				Topic 2	sunlight, earth, radiation

We used the proportions of the extracted topics as predictors for estimates of students' scores in a linear regression model. Table 2 shows a linear regression equation of Item 14 that displays the association between topic proportions (independent variables) and student scores (dependent variables) of ID understanding for Item 14. The two topics have made significant contributions in predicting ID understanding scores. The other items' results appear in the presentation.

Table 2

Regression Analysis Summary for the Topic Proportions and Students' ID Scores for Item 14

Multiple R-squared: 0.722	Estimate	S.E.	t	p-value
Topic 1: Chemistry + Earth	1.175	0.236	4.971	<.001
Topic 2: Biology	5.220	0.242	21.559	<.001
$Item14_ID\ Score = (1.175) * (Chemistry + Earth) + (5.220) * Biology$				

Discussion

ID understanding is a key desired outcome in science education. The analysis of the CR items to measure ID understanding revealed how the students integrated their disciplinary knowledge and to what extent disciplinary knowledge was used to build ID knowledge. The significance of this study lies in its potential ability to guide how science could be taught to foster ID knowledge that would explain a natural phenomenon. A metaperspective on multiple scientific disciplines and sufficient knowledge could eventually lead to successful ID teaching, even though the science courses would remain as separate disciplines. The results of the study have encouraged additional development of ID-focused curricula.

Instructional dialogues in an inquiry-based classroom: Towards a typology of teacher self-positioning

Hau Wing So, Ka Lok Cheng
u3546877@connect.hku.hk, chengkla@hku.hk
Faculty of Education, The University of Hong Kong

Abstract: Effective classroom dialogues are vital for knowledge building in inquiry-based classrooms, and the positioning of teachers and students play an essential role. This qualitative study explored the patterns of and decision-making process underpinning the dialogues through analyzing lesson recordings and conducting stimulated recall interviews. Three types of teacher self-positioning were identified, which were associated with considering the cognitive-developmental needs of the respective students and the contextual constraints.

Introduction

The concept of dialogic teaching emerged as more comparative studies on classroom discourses were conducted. Dialogic teaching empowers students to use talk power to collectively construct knowledge alongside teachers' supportive layout and active engagement (Alexander, 2004). A body of literature has studied the dialogue patterns (van de Pol et al., 2017), effects on specific learning skills (VanDerHeide et al., 2016) and talk functions (Boyd & Markarian, 2015). However, the implicit decision-making process behind the instructional dialogues is scarcely explored (Reznitskaya & Gregory, 2013). Teachers constantly decide on and re-negotiate their discursive positions, which could be understood through the lens of positioning theory (Davies & Harré, 1990) by considering how students' rights and duties are being assigned and negotiated. Their self-(re)positioning could uncover the dilemma faced by the teachers regarding their adoption of the dialogic approach. The current study qualitatively analyzed a classroom in-depth to explore dialogue patterns and accentuate the thinking process of participants. This study aims to develop a typology of teacher self-positioning in classroom inquiry processes and provide interpretative accounts of the respective pedagogical intentions. It is hoped that the current effort could sustain the scholarly discussion on positioning theory as an analytical tool of classroom discourse analysis, particularly of the inquiry-based classroom discussion of science-related social issues (e.g., Bossér & Lindahl, 2017).

Methods

Our participants included a teacher and a Secondary 5 (Year 11) class of 32 students at a secondary school in Hong Kong. By far, 12 lessons have been recorded for identifying dialogic elements at the turn- and lesson-levels. The lessons observed were under the subject of Liberal Studies, which required teachers and students to co-construct interdisciplinary understandings of social issues under various curriculum-specified themes. The recordings of the in-class videos were analyzed by the analytical framework derived from the dialogic indicators developed by Alexander (2004) and the dialogic features distilled by Mercer and Littleton (2007). To disentangle the decision-making process behind dialogues, stimulated recall interviews were conducted with the teacher and students to unearth the respective motives of their behaviours in various talk moves, together with the perceived effects of their actions on learning and teaching. The interview data were inductively processed to permit typological frameworks of teacher self-positioning to emerge, with particular attention paid to role assignment and negotiation processes.

Findings

Three types of teachers' self-positioning have emerged from the preliminary analysis, and they were found to influence the substantiation of instructional dialogues: "self-background" (Type 1), "co-construction" (Type 2), and "self-foregrounding" (Type 3). "Type 1" episodes put students in the foreground to their arguments in extended dialogues, whereas "Type 2" episodes involve conversational participation opened to the whole class alongside a foregrounded teacher-student pair. "Type 3" episodes resemble monologic teaching where dialogues are less negotiable. Students' responses are expected to be concise and direct, and the teacher always provides quick evaluative remarks. The characteristics and underlying rationales of the three types of teacher self-positioning are summarized below in Table 1. Other types of self-positioning and additional features of the currently identified types of self-positioning are expected in the subsequent rounds of data collection and analysis.

 © ISLS

Table 1
Types of teacher self-positioning

Types	Self-backgrounding (Type 1)	Co-construction (Type 2)	Self-foregrounding (Type 3)
Foregrounded characters	A particular student	1 Student & 1 Teacher	Teacher
Interlocutors	A student, a teacher	Several students, a teacher	A student, a teacher
Duty of the students	Initiating & sustaining dialogues	Participating in teacher-initiated dialogues	Listening & giving brief responses
Speaking turns per episode	Fewer	More	Fewer
Student thinking time	Shorter	Longer	Very short
Teacher scaffolding	Fewer	More	Very limited
Rationales of use	As challenges for more able students	Students expected to require more help	When time pressure to complete exists

The following excerpt demonstrates a typical "Type 2" episode:

(1) Teacher: Any other thoughts? [answers raised by the audience] Is it Michael?
(2) Michael: Umm…firstly, immoral.
[*Speaking turns (3) – (6) omitted, during which teacher jotted down keywords on board and asked for a further argument.*]
(7) Teacher: And? [other students give cues]
(8) Michael: I did not say I would answer this question.
[*Crowd laughing and teacher stepping backwards feeling surprised.*]
(9) Teacher: Wow, that's such a disclaimer! (Teacher laughing) Why didn't you reject my invitation earlier on?
(10) Michael: Ah, it's okay, let me still try. [*Silence for 20 seconds*]
(11) Michael: Right, I thought of high price levels…
(12) Teacher: Then, what would happen? [*Teacher moving his hand to cue Michael to keep elaborating.*]
(13) Michael: (inaudible)…because of the high price level, people cannot afford it, and that leads to more severe conditions for their sickness.

This excerpt shows how an episode in which co-construction stemmed from a possible misunderstanding. Initially, the teacher declared Michael the preferred interlocutor after seemingly hearing his voice. Subsequently, at the speaking turn (8), Michael challenged the teacher's duty-assignment decision. The teacher softly reiterated that speaking turn (1) was an invitation that Michael had not declined, which resulted in Michael's duty to remain in the dialogue. After the negotiation, Michael resumed his duty again. Despite the teacher's power to assign rules, he gave much wait time for Michael to elaborate his answer and body gestures were used to cue for elaboration. The teacher also allowed space for the students to showcase their independent thinking and viewpoints. This episode contrasts with "Type 3" episodes, in which the teacher usually gives less wait time and emphasizes the evaluation more than individual viewpoints. It is also distinct from "Type 1" episodes, in which the teacher intentionally backgrounded one's self for the students to state their arguments independently.

Effects of narratives on undergraduate student understanding of fundamental concepts in biology

Samuel Tobler, Tanmay Sinha, Katja Köhler, Ernst Hafen, Manu Kapur
samuel.tobler@gess.ethz.ch, tanmay.sinha@gess.ethz.ch, koehler@imsb.biol.ethz.ch,
hafen@imsb.biol.ethz.ch, manukapur@ethz.ch
ETH Zürich, Switzerland

Abstract: Undergraduate students frequently struggle to understand biological concepts. Embedding conceptual information in a historical narrative holds the potential to support their learning. We developed learning materials comparing narrative or expository texts and assessed students' conceptual understanding via post-tests. Results showed that students, who read the narrative text, understood the concept of randomness better. No difference was found for the enzyme energetics concept. Furthermore, students in the narrative group reported higher situational interest after the intervention.

Keywords: Narrative, Biology, Conceptual Change, Understanding, Higher Education

Introduction

Recent studies have shown that university students often fail to fully understand biological concepts, including enzymatic energetics or stochastic processes (i.e., randomness) on a molecular level, and retain incorrect conceptions despite instruction (Champagne Queloz et al., 2016).

Along with university lectures, textbooks, written as expository texts, are a major source of information for natural science undergraduate students. Despite their ubiquitous use in natural science education, there are also caveats regarding presenting concepts abstracted from real-world contexts. For example, theoretical and empirical evidence argues for more context-dependent, enculturating and social forms of learning and teaching (Brown et al., 1989). In contrast, narratives naturally provide a social and cultural learning environment that may reduce the abstractness of concepts (Avraamidou & Osborne, 2009). This could allow learners to better relate new ideas to prior experiences and social contexts (Dahlstrom, 2014). Further, narratives may facilitate the activation of prior knowledge (including knowledge about related concepts from different disciplines) and in addition to that the integration of new concepts into the pre-existing knowledge framework instead of learning isolated knowledge fragments (Dahlstrom, 2014). Eventually, using narrative elements in educational texts could prompt dissatisfaction with incorrect student explanations more efficiently, ultimately supporting conceptual change from prior explanations to scientifically accepted theories. However, recent research findings report contradicting evidence regarding the effectiveness of using narrative-embedded theory elements to improve the understanding of biological concepts in higher education: learning with narratives resulted in higher (Dai et al., 2021), but also lower (Wolfe and Woodwky, 2010) post-intervention performance in contrast to learning with expository texts. Therefore, the present study aims to investigate:

1. What are the effects on understanding when using narratives compared to expository text materials?
2. How do the different text materials affect the situational interest towards the topic affected?

We hypothesize that narrative text materials lead to greater conceptual understanding than expository ones, and that students in the narrative intervention group show increased situational interest in the topic.

Methods

Sixty-one first-year undergraduate natural science students (20.1 ± 1.6 years old; 61.6% female, 38.4% male, 0% non-binary) from a highly ranked Swiss university participated in the study. The university's ethics committee approved the study before implementation. Participation was voluntary, and no compensation was paid.

Text materials covered the concepts "enzyme energetics" and "randomness". These topics were selected as they were shown to constitute frequent difficulties in understanding for natural science students (Champagne Queloz et al., 2016). The conceptual information was embedded in a historical context for the narrative text materials. The expository text focused solely on conceptual information. The validity of the text materials was analyzed with experts in biology and literature. The narrative text was slightly longer than the expository one (narrative: 112 sentences, expository: 79 sentences), but displayed similar text characteristics, including type-token ratio (TTR) (narrative TTR: $M = 0.39$, $SD = 0.12$; expository TTR: $M = 0.39$, $SD = 0.16$) and Flesh readability indices (narrative: 37.02, predicate difficult; expository: 41.56, predicate difficult).

 © ISLS

The conceptual understanding was tested in the post-test using four multiple-choice questions per concept ($\alpha = 0.52$). Correct answers were awarded one point. A single-item question on a five-point Likert scale was used to measure situational interest.

Participants were randomly assigned to read either the narrative text (n = 31) or the expository text (n = 30) before the students took the post-test and were then asked to answer the questions covering putative learning mechanisms. An ANOVA was conducted to determine post-test performance differences. Differences regarding learning mechanisms were assessed by performing a Kruskal-Wallis test.

Results

The ANOVA revealed that students in the narrative group performed significantly better in the randomness test questions ($F(1, 59) = 4.337$, $p = .0492$, $d = 0.51$, 95% CI = [-0.01, 1.04]). In contrast, no statistically significant performance difference was found for the enzyme energetics concept ($F(1,59) = 0.365$, $p = 0.548$, $d = 0.15$, 95% CI = [-0.36, 0.67]). Thus, we found partial evidence supporting the hypothesis stating that learning with narrative texts could lead to greater conceptual understanding. Concerning situational interest, students in the narrative group reported a significantly higher interest in the topic than students from the expository group ($H(1) = 4.52$, $p = .033$, $BF_{10} = 9.80$). Hence, we found evidence in favor of the hypothesis regarding higher situational interest in the narrative intervention group compared to the expository intervention group.

Discussion and conclusion

Prior research has demonstrated the need for novel teaching approaches in biology at the university level. Embedding conceptual information in narratives could constitute an effective way to convey biological concepts than expository texts. In the present study, the use of narrative learning materials resulted in a significantly better performance on a post-test related to questions on the concept of randomness compared to the expository materials. Moreover, situational interest after the intervention was significantly higher in the narrative group. Demonstrating a greater interest could thereby go hand-in-hand with greater cognitive activation and more active engagement with the materials. No differences were found for the enzyme energetics concept, potentially because a relatively low number of questions was used to infer students' understanding of this concept, and a ceiling effect was observed. Hence, extending the number of conceptual questions, as well as adding questionnaires investigating potential learning mechanisms, could help better understand whether and how the different text sorts affect understanding.

In conclusion, our results provide support for the effective use of narratives to enhance understanding of natural sciences in higher education. Given that a well-grounded scientific understanding is crucial to discuss, evaluate, and eventually solve current real-world problems, it will be essential to find ways of improving the learning of core biological concepts. Our study might thus inspire other developments in this area.

Museum Educators' Knowledge Brokering with Boundary Objects

Christopher Ostrowdun, Mount Royal University, costrowdun@mtroyal.ca
Beaumie Kim, University of Calgary, beaumie.kim@ucalgary.ca

Abstract: Museum educators often use objects as part of education programs for visiting school groups. We examined how museum educators leveraged boundary objects and forms of talk to as part of knowledge brokering between the bounded communities of palaeontology and school groups. Findings show how educators broker with talk and objects, and how brokering can fail.

Introduction and background

Commonly, natural history museums are institutions built around collections of objects such as authentic artifacts, replicas, and exhibits (Paris, 2002). Museums and their objects can also facilitate boundary crossing between social worlds, such as between scientific disciplines and the general public. At such boundaries, objects can act as boundary objects, which are useful to the inhabitants of multiple social worlds, but in different ways (Star, 2010). To facilitate boundary crossing museum educators often act as knowledge brokers that translate and communicate specialized knowledge between bounded communities of disciplinary experts and the public (Meyer, 2010). Our interest lies in how museum educators leverage boundary objects and different forms of talk in knowledge brokering processes within education programs for school groups visiting a palaeontology museum.

Studies have examined how museum visitors such as families (Zimmerman et al., 2015) or school groups (Achiam et al., 2016) interact with museum objects, but rarely from the perspective of museum educators who often facilitate such interactions. Boundary objects are "plastic enough to adapt to local needs and the constraints of the several parties employing them, yet robust enough to maintain a common identity across sites" (Star & Griesemer, 1989, p. 393). For instance, a fossil can serve paleontologists as an object of study, the public as a general interest, or school groups visiting a museum to learn about the Earth's history. Museum educators often reside at these boundaries and use boundary objects to broker across worlds. Knowledge brokering always involves making decisions about what to include and what to leave out and what to expand or contract, mediating the experiences of participants' contact with bordering worlds (Crowley & Jacobs, 2002). We explored the following question: How do museum educators facilitate knowledge brokering using different forms of talk in conjunction with boundary objects?

Context and methods of data collection and analysis

We observed and video-recorded three museum educators lead four educational programs for three groups of middle school students visiting a paleontology museum. Each 60-minute program took place within dedicated learning spaces (separate from the public galleries) or outdoors. Each program had a different format including a readers-theatre, a trivia-style game, fossil casting, and an outdoor walking tour. All the educators had a university-level science background and were trained by the museum to facilitate the programs.

Using literature and our data we developed three categories of objects and three forms of talk. The object categories include Authentic, Disciplinary, and Educational objects (Hampp & Schwan, 2015). Authentic objects were original objects such as fossils, rock samples, and geological features (e.g., rivers), but excluded replicas (e.g., fossil casts) or images. Disciplinary objects were those used in disciplinary work and they could be specialized (e.g., dental plaster) or common (e.g., toothbrush for fossil excavation). Educational objects were typically human made for the purpose of explaining or showing information, such as images, diagrams, and replicas or simplified/abstracted versions of other objects. We categorized objects based on how they were used in the observed contexts, even if they were relevant to multiple categories.

The educator talk categories include perceptual, conceptual, and connecting talk (Allen, 2002). Perceptual talk relied on sensory perceptions to interact with, observe, or describe objects, such as when an educator showed and described a fossil's features. Conceptual talk involved the educator using information or observations of an object to encourage students to make inferences and develop causal explanations about objects and concepts. This was often posed as questions in forms such as, "Knowing X about a dinosaur, what do you think will happen when in Y scenario?". Connecting talk invoked prior knowledge and experiences beyond a specific interaction, such as what students might know from school, media, or other parts of the museum.

Findings

The recordings were transcribed and using the categories of talk and objects, we coded a total of 201 utterances and 83 unique objects across all four programs (Ostrowdun & Kim, 2022). We observed the educators use multiple

 © ISLS

combinations of object types and forms of talk with varied success in brokering. For instance, in the walking tour, the educator successfully used all three forms of talk in relation to a petrified tree stump (authentic object). They invited students to observe the tree stump (perceptual talk); described correlations between the object and scientific knowledge of climate, vegetation, and geological history (conceptual talk); and asked students to recall the meaning of rings on the stump (connecting talk).

In another episode, an educator used posters (educational objects) of a Tyrannosaurus Rex skeleton to explain how social worlds are dynamic and evolve, but not always in congruent ways. One poster showed the skeleton in a vertical stance, while the other showed a horizontal stance. The educator explained how advances in disciplinary understanding found that the horizontal stance was no longer considered accurate, but portrayals of Tyrannosaurus Rex in popular media were inconsistent and often still used the horizonal stance. This instance showed how new discoveries and evolving knowledge requires educators to broker and re-broker knowledge and understanding of objects.

The usefulness of an object in brokering has limits and brokering can "fail" when the limits are exceeded. For instance, the educators often referenced a geological timescale (educational object) to relate chronological time periods (e.g., Cretaceous, Devonian) with rock layers and fossils. In one program, plastic rings were stacked chronologically with each ring showing dinosaur glyphs, and students answered related trivia questions (connecting talk). The stacked rings coarsely showed when dinosaurs came into existence relative to each other and time but provided no other details (e.g., climate, environment). So, when the educator referenced the timescale and asked students whether mammoths and Tyrannosaurus Rex coexisted, the object failed as a brokering device because its scope of usefulness was exceeded. Students could not answer the question because they could not glean the necessary information from the object and did not have sufficient background knowledge (e.g., mammoths lived during the ice age, which was too cold for Tyrannosaurus Rex).

Conclusion

Using boundary objects and forms of talk in concert can be a powerful way for museum educators to broker across worlds. However, we observed brokering was most successful, and could bridge students more deeply to disciplinary knowledge, when educators used all three forms of talk in conjunction with boundary objects. Heavy reliance on any one form of talk limits brokering opportunities. For example, connecting talk can promote factual recall and perceptual talk can address observed object features, but on their own each have limited conceptual depth. As well, successful brokering relied on the educators working within an object's scope of usefulness and dynamically adjusting their talk. Brokering is especially challenging in museum programs where educators often know little about students' prior knowledge and have limited contact time (Tran, 2008).

Abstract: With increasing funding for synergistic research and educational solutions informed by multiple disciplines (e.g., learning sciences, computer science), there is a need to build the field's interdisciplinary capacity and nurture the next generation of researchers. In this poster, we share our approach to creating a community of emerging scholars inspired by the concept of *landscapes of practice* and based on a design thinking process. We discuss our approach's key design features, affordances, and challenges.

Introduction

The conference theme, "International Collaboration toward Educational Innovation for All," calls our attention to the importance of international and interdisciplinary collaboration. Indeed, a growing international consensus argues that complex scientific and societal challenges of the 21st century necessitate interdisciplinary ventures, which, in turn, require students and early career researchers to develop new skills and competencies for interdisciplinary approaches (e.g., International Society of the Learning Sciences, 2019; Science Europe, 2018). To have a robust next generation of our society, we need to pay more attention to the learning needs of emerging scholars.

Although challenges of interdisciplinary research work and careers have been well documented even before the COVID-19 era (e.g., Science Europe), the global pandemic created significant additional burdens and barriers especially for the next generation of researchers. In a recent report, Levine and colleagues (2021) identified multiple critical impacts of the COVID-19 pandemic on the early career educational scholars and doctoral students, including the diminished sense of connections and community-belonging with other scholars and absence of networking and professional development opportunities. The authors also reported the emerging scholars' concerns about limited support offered by their home institutions. Hence, there is a need for holistic and purposeful support systems that extend beyond single institutions and address the unique professional needs of interdisciplinary emerging scholars in educational research.

In this poster, we describe our process for creating a community of emerging scholars in the interdisciplinary field of learning and computer sciences. We envisioned this community drawing on the concept of *landscapes of practice* (Wenger-Trayner & Wenger-Trayner, 2015) and used the design thinking process (Stanford d.school, 2010) to distill the following features to guide our community-building work:

- Foreground diversity, equity, and inclusion (DEI)
- Center activities identified as needed by the members of the community
- Identify and implement activity feedback loops to ensure continuous improvement.

Design

Knowledge and identities of interdisciplinary scholars in today's global, interconnected society are shaped by their participation in various communities of practice comprising complex and dynamic landscapes of practice (Wenger-Trayner & Wenger-Trayner, 2015). Each community of practice has its own histories, traditions, and values and influences landscapes of practice and scholars' journeys through them differently. Hence, it is important to understand both how best to support interdisciplinary scholars and how that support might need to change over time. To this aim, the design thinking process with its five stages (i.e., empathize, define, ideate, prototype, and test; Stanford d.school, 2010) was particularly well suited for our task of community creation. It enabled us to understand and empathize with the needs of the emerging scholars, bring clarity to our vision for the community and define its features, generate ideas for possible solutions and prototype, test, and, importantly, iterate the ways of engagement with and support of the community members.

Creating the community with DEI at its core

We launched our emerging scholars' community in January 2021 through calls for participation via the organization's newsletter, website, direct outreach letters to the minority-serving institutions (MSI), and by asking previously funded PIs in the field to encourage their students and postdocs to join. We also emphasized and invited

 © ISLS

inclusion of scholars with disabilities (e.g., deaf scholars) and ensured appropriate support (e.g., American Sign Language interpretation) was available to them when needed. Although we initially conceptualized the community as primarily supporting researchers in the United States, we found that our community was fulfilling the needs of international emerging scholars. Currently, ten months after launch, our community has 123 members from four continents and ten countries.

Implementing need-based activities with feedback loops

After launching the community, we investigated emerging scholars' needs through conversations in our meetings, informal conversations, and a survey. At the time of the survey, our community had 80 members, and 32 responded to the survey. The majority of the respondents were graduate students, postdoctoral researchers, and faculty members. We found that our members needed more opportunities for networking and mentoring with established scholars as well as professional development opportunities (e.g., a session on grant proposal development). In response to the identified needs, we created the following three types of activities: a quarterly small group mentoring series with established scholars, professional development sessions, and affinity groups based on the common research interests of the participants.

To enable timely and meaningful iteration of the existing activities and the creation of new ones, we designed them to include feedback loops (e.g., a participants' survey after each mentoring session). Feedback loops integrate the three key features necessary for continuous improvement in education—Frequency, depth, and system contextualization (Park et al., 2013). These features help us respond to the feedback quickly and at the appropriate level. For example, a participant's feedback after one of the first mentoring sessions led to a change for future sessions and the implementation of a shared document for mentors and session participants to discuss potential topics and exchange contact information before the session. In our poster, we will provide additional details about the praxis of our group and its transformational effects.

Affordances, challenges, and next steps

As indicated by participants' feedback and continued attendance, our small-group mentoring sessions have been effective in providing valuable networking and learning experiences for the emerging scholars. For example, a recent participant reflected on his learning: "I especially loved the discussion on adaptive learning, how different people interpret adaptivity differently and what meaningful adaptivity should include." Although all of our organization-led activities were well-attended and received positive feedback (e.g., mentoring series), getting emerging scholars to assume responsibility for organizing and leading activities (e.g., affinity groups) has been challenging and represents an important next milestone for our community. Additionally, reaching and inviting in new scholars, those at MSIs, and those who do not have advisors and peers engaged in interdisciplinary work remains of paramount significance for our community, organization, and the field.

Examining the Complex Webs of Supports that Sustain Classroom Practices

Laura Zeller, University of Illinois Chicago, lzelle2@uic.edu

Abstract: Reform of educational systems is difficult, with changes often fading or diverting in unproductive ways. To disrupt this pattern and understand why unwanted practices persist and new ones distort, we need to consider how new and old practices are sustained at multiple levels. I discuss the framing and methodological findings from a larger study that investigated practices and supports within an undergraduate course for elementary education majors and discuss how these can inform educational change.

Introduction

Reform efforts in education are often ineffective, either not creating lasting change (Payne, 2008) or losing sight of the key constructs behind them (Dancy et al., 2016). A focus on "best practices" or "Evidence-Based Instructional Practices" reduces the problem of reform to a simple practice change without addressing the supports needed to sustain that change within the complex, contextualized, sociocultural structure that maintains classroom practices (Payne, 2008). In order to make lasting changes, we need to consider how the complex, multileveled system sustains patterns of classroom practices. For example, looking at teacher development framed with process-product logic cannot explain why change efforts fail (Opfer & Pedder, 2011). Reform efforts must consider what supports sustain classroom practices.

The research question I address in this poster paper is: how can systematic examination of patterns and the supports that sustain them inform educational change efforts? Within a larger study (see Zeller, 2022; Zeller, Under Review), I utilized the MoRe Institutional Framework (Anderson & Colyvas, 2021) to look within the classroom for patterns of practice and across multiple system levels for supports that institutionalize these practices. The MoRe Framework offers flexibility for researchers to investigate supports that sustain patterns at a specific level without excluding the influence of the other levels.

MoRe Institutional Framework

Institutional theory offers a framework for considering how patterns of practice are supported and sustained within classrooms. The MoRe Institutional Framework starts with Jepperson's (1991) definition of institutions as "social patterns" that are sustained through "self-activating social processes" that continually reproduce institutionalized patterns (pp. 144-145). The self-activating social processes manifest in various modes and at multiple levels of social systems (Anderson & Colyvas, 2021). Focusing on these modes of reproduction (MoRs) offers a view into why some patterns of classroom practices are sustained while others fade within the complex system of schools.

It is important to not only look at what reproduces desired patterns, but to also consider patterns that have been institutionalized and may stand in the way of desired reforms (Anderson & Colyvas, 2021). Focusing beyond idealized practices illuminates how the MoRs for multiple patterns of practice coexist and interact. Looking across continua of patterns that exist within classroom practice allows researchers to capture complex interplay between old and new practices and break down walls that stand in the way of effective reforms.

MoRs take many forms. Anderson and Colyvas (2021) identify categories of MoRs endemic to education systems including policy, stakeholder interests, identities, and roles. MoRs are distinct from the patterns they reproduce and can act at many levels within a complex system (Anderson, 2017). When looking at an undergraduate course, MoRs may act at levels ranging from individual to global. The sustaining force of a MoR can act at a completely different level than the pattern of practice manifesting at the focal level of a study.

The MoRe Institutional Framework provides a roadmap that helps navigate the intricacies of practices and the supports that sustain them. The investigation of both new and old practices creates a unique snapshot that captures change processes within a single timespan. The discovery of the MoRs that sustain patterns of practice creates the opportunity to leverage change efforts where they are most effective at creating lasting change.

Methods

This work examines the methodological implications of a larger study that leveraged case study and action research to deeply investigate practices within a science content course for undergraduate elementary education majors. In this paper, I explore how methods based on the MoRe Institutional Framework serve such an analysis.

The study investigated a physics and earth sciences course for undergraduate students over the Fall 2020 semester. It is part of the requirements for the university's elementary education major, which focuses on teaching

 © ISLS

in urban environments. The university is a large, R1 institution in the Midwestern United States and a minority-serving institution. The course team consisted of two co-instructors and two teaching assistants (TAs). The author was the physics instructor, while the other instructor was an earth science professor with many years of experience with the course. The course had 72 students and was held synchronously online, with three lab sections led by the TAs. Data collected includes course materials, field notes, and course team member reflections and interviews.

The data collected was initially sorted into either *practices* or *supports* for initial analysis. Data analysis utilized iterative coding rounds that created an in-depth account of how patterns manifested across the semester and supports (see Zeller, 2022). I coded the supports data using Anderson and Colyvas' (2021) categories of MoR. Once the initial practices and supports coding was complete, micro-cycles of iteration occurred as supports suggested practices and practices suggested possible supports. The iterative process resulted in final descriptions of patterns of practice and self-activating supports.

Findings and Implications

In the larger study, I investigated the practices and supports of the continua of science representation (Zeller, 2022) and student vs teacher centering practices. In this poster, I discuss the utility of my framing and methods to inform change efforts that came out of this wider work.

Examining patterns of classroom-system practice and the supports that sustain them inform educational change by illuminating the breadth and depth of how practices manifest within the classroom as well as how these practices are supported via multiple levels beyond the classroom. Within the examination of science-representation practices, a variety of patterns were observed. An overall science representation pattern carried across the course as a whole, but variations were found within the different structures of the course, the different disciplines covered, and the assessments as the semester progressed. Supports for these patterns included taken-for-granted, global-level disciplinary norms about what introductory courses cover and the content available to teach. Supports also included the individual-level roles of the instructional team and university-level shared stakeholder interests in the students as future teachers. The detail that resulted from the systematic investigation of science representation practices and corresponding supports created descriptions with both depth and breadth of what sustains practices and led to implications that informed changes made to the course. This shows that the application of these methods for other practices holds similar potential for informing and guiding change efforts.

The systematic examination of patterns and supports also led to the emergence of theory-rich patterns that created deeper understanding and showed opportunity for future work. Within the examination of teacher- and student-centered instructional practices, a pattern of students building more positive relationships with science emerged that was being supported by the student-centering practices observed. This informed how the patterns the study focused on were in turn supporting patterns in shifts of students' science identities. This illuminated an additional level of findings and implications about student-centered practices. A separate pattern related to the learning of the teaching assistants also emerged from the larger study. This emergent pattern pointed towards a potential new line of study of teaching assistant learning that focuses on learning through participation in course design. These emergent patterns further show the utility of systematic examination of patterns of practice and supports using the MoRe Institutional Framework.

Imagining Inquisitive Futures for Learners With Developmental Disabilities

Marrok Sedgwick, University of Illinois at Chicago, msedgw2@uic.edu

Abstract: Two activists with developmental disabilities designed a learning activity for learners with developmental disabilities. Their talk during design meetings was analyzed using discourse analysis (Gee & Green, 1998) to learn what imagined futures (Gutiérrez & Jurow, 2016) they assumed for the learners. These futures tended towards the inquisitive, and suggest that including activists in the development of learning activities for youth from the communities those activists represent could lead to fruitful new designs.

Introduction

Disabled learners, especially learners with developmental disabilities (DD), are an understudied community of learners within the learning sciences. This community is nonetheless an important part of human diversity, and one whose members deserve justice and equity in the study and design of learning environments, pedagogies, and beyond. One of the central rallying mottos of disability activist movements is "nothing about us, without us" (Charlton, 2000). This motto demands that in order to work justly and equitably, research about disabled people must be led by disabled people (Autistic Self Advocacy Network, n.d.). This study turned to adults with DD who self-identify as activists and have experience working with youth with DD in mentorship and/or teaching roles. Activists with DD are an ideal community of practice with whom to design learning environments because they frequently envision and work towards more just futures for people with DD.

How one imagines potential futures is informed by what has occurred in the past, resulting in imagined futures (Gutiérrez & Jurow, 2016). Therefore, it is important to trace the imagined futures that co-designers of learning activities, curricula, and environments assume learners could take up. Activists with DDs' imagined futures may differ from non-disabled researchers' and educators.'

This poster describes initial findings from a research study that asks: What imagined futures do activists with DD assume while designing a learning activity intended for non-speaking youth with DD? In order to answer this question, an adult activist with a DD engaged in a co-design process with the researcher, themself an activist with DD. This poster describes findings from the meetings between the researcher-activist and participant-activist, while they co-designed an adaptation of an inductive logic game. The researcher-activist and participant-activist are both Augmentative and Alternative Communication (AAC) users. AAC are systems of communication for people who cannot speak, such as text-to-speech devices.

Methods & Findings

In order to trace the imagined futures that activists with DD assume for learners with DD, this research took up discourse analysis, an analytic approach that claims knowledge is constructed via discourse between members of a social practice, rather than existing solely in the minds of individuals (Gee & Green, 1998). Discourse analysis was used to unearth the imagined futures contained in talk during the co-design process. This talk took place across three 90-minute design meetings, which took place on Zoom. The meetings were recorded and transcribed. By engaging in discourse analysis of design meeting transcripts, the researcher-activist learned what imagined futures appear in the co-constructed space between the two designers. Analysis of designers' talk provided a setting within the situated practice of designing for learners (as opposed to methods that occur outside of that process), which afforded unique insight into the activists' assumptions.

The pair designed an activity in which learners can use inductive logic to explore their interests. Design decisions sought to center the learners' ways of being in the world, and position assessment as an opportunity to validate what the learner learned, regardless of how that learning might compare to an external standard.

Data was coded using a grounded theory (Charmaz, 2006) approach. Initial coding delineated the kinds of talk that were present, and which were analytically relevant to the research question. Codes were applied to turns and sometimes to a set of sequential turns, based on emergent themes. While developing these codes, their definitions were recorded in a dictionary of codes.

Next, during focused coding (Charmaz, 2006), the researcher-activist sorted the coded turns into pasts and futures. Turns that did not hold any indication to past or present were left out of this coding step (and this poster). The researcher-activist wrote a memo describing the nature of the past or future contained within each turn and used these to develop a second set of codes describing the types of pasts and futures apparent in the talk.

 © ISLS

This representation revealed stated or implied chronological relationships between codes about the past and the future. This led to the development of several categories of imagined futures assumed in the design meeting talk.

Finally, a member check (Hammel, et al, 2008) was done on this report prior to submission to ensure that the participant-activist was not misrepresented.

Four explicit imagined futures (Validating Futures, Accessible Futures, Inquisitive Futures, and Ableism-literate Futures) and three implied imagined futures (Invalidating Futures, Compliance-centered Futures, Learning-restricted Futures) emerged.

Explicit imagined futures were directly apparent in the talk. For example, in Meeting 3, Turn 32, the participant-activist says, "The one thing I would add to what you wrote is that preferences can change over again, especially depending on how long you call the game to be." Here, they are positioning an imagined learner in an Inquisitive Future, in which the learner might change their gameplay over time to follow multiple lines of inquiry according to their interests and preferences.

Implied imagined futures were not directly described, but were hinted at through descriptions of pasts. For example, in Meeting 3, Turn 7, the researcher-activist says, "Yes. It made me think of algebra class from middle and high school and how much easier it would have been if they explained that stuff [inductive logic] first." This turn was initially coded as "Statements about ourselves that are also about imagined learners," and secondarily coded as "Learning-restricted Pasts." The turn refers to drill-based learning environments the researcher-activist struggled in. A specific future is not named, but the nature of imagined futures as informed by past experiences suggests a Learning-restricted Future.

Discussion

On a whole, the activists in this study imagined validating, inquisitive futures for learners who were given the opportunity to direct their own learning. These futures were explicit in their talk while designing. A number of less-preferred futures were implied, but talk about those futures ultimately fizzled out before it began. Interestingly, the futures that were explicitly talked about had more directly positive overtones, whereas those only implied, through discussion of pasts, tended towards the negative. This is surprising due to the tendency for activists to engage in critical work, pointing out the flaws in the various systems, including educational, that they find or found themselves within. Here, instead, they focused on the imagined futures they preferred, rather than critiques. These explicit imagined futures were embedded in the process of design.

The inquisitive, learner-centered imagined futures explicit in activists' design talk may differ from those non-disabled educators and researchers take up. Working with activists from the non-dominant communities learners are members of may lead to valuable new insights that push educational design towards more hopeful imagined futures.

Strategies to manage scientific uncertainties for productive sensemaking: Case studies from Korean and American classrooms

Heesoo Ha, Center for Educational Research, Seoul National University, snudunoy717@snu.ac.kr
Jongchan Park, Ying-Chih Chen, Mary Lou Fulton Teachers College, Arizona State University
jpark366@asu.edu, ychen495@asu.edu

Abstract: This study aims to explore instructional strategies to manage students' scientific uncertainties in sensemaking activities in the science classroom. Sensemaking activities in four science teachers' classrooms were analyzed for this study, two from Korea and two from the USA. The analyzed data include video-recordings of classroom discourses. Six themes about features of teachers' instructional strategies that supported students' productive management of the uncertainties were identified through analysis.

Introduction and Background of the Study: Sensemaking and Uncertainty

This study aimed to explore features of instructional strategies to support students' management of scientific uncertainties they encounter in sensemaking activities in the science classroom. With a critique on teacher-centered type of classroom, science education studies have widely agreed on enacting practice-focused curriculum in the science classroom (e.g., National Research Council, 2012). The fundamental goal of epistemic practices of scientific communities can be described as sensemaking, which refers to "a dynamic process of building or revising an explanation in order to "figure something out" –to ascertain the mechanism underlying a phenomenon in order to resolve a gap or inconsistency in one's understanding" (Odden & Russ, 2018, pp. 191–192). Researchers have designed curricula and pedagogical strategies to help students make sense of scientific concepts (Schwarz et al., 2021); however, it is not clear whose sense do students make: Is it the scientists', the teachers', or the students'? We notice that students encounter epistemic and content uncertainties entangled together in sensemaking processes. If our goal is to help students develop their own knowledge that makes sense to them so they are capable of explaining a phenomenon, students' scientific uncertainty should be considered as a significant resource in the sensemaking process.

With the view of scientific uncertainty as an umbrella term which includes *content* and *epistemic* uncertainties (Kampourakis & McCain, 2020), this study aimed to examine teachers' supports to manage these uncertainties. Content uncertainty refers to uncertainty regarding *what* knowledge to interpret a phenomenon. Epistemic uncertainty refers to uncertainty regarding *how* to use and generate knowledge to interpret a phenomenon on and *why* the interpretation is valid and reliable (Chen & Qiao, 2020). Building on the definition of scientific uncertainties, we explored the following research question: How can teachers support students to productively manage these uncertainties, which refers to managing uncertainties through meaningful practices in the science classroom? The current study intends to contribute to dealing with this issue by examining scientific uncertainties that emerge in students' sensemaking processes and teachers' instructional strategies to effectively use students' scientific uncertainty as a resource to foster them to make sense of phenomenon, data, and argument.

Research design and methods

This study reflectively analyzed four science classrooms, two in Korea and two in U.S., that adopted sensemaking activities. While two Korean science teachers taught at middle school level, two U.S science teachers were at upper level elementary school. The main data sources of this study were 23 video recordings of the classes and transcripts of discourse in the classes: elven lessons collected from Korean classrooms, twelve lessons collected from U.S. classrooms. In the data analysis, to grasp features of each class, we first iteratively watched the video recordings and read the transcripts. Then, we divided the data into events with the cues of changes in a classroom sessions and discussion topics. The next step dedicated to initial coding of events. Starting from the sign of uncertainty in each event, core concepts, function of uncertainties and teachers' responses were coded. Then, we interpreted processes of managing uncertainties and teachers' responsive supports on these processes. Previous literature and codes were adapted in the coding process (e.g., Chen, 2022; Jordan & McDaniel Jr, 2014). Categories and definitions of the management of uncertainty as a pedagogical resource are shown in Table 1. Last step of the data analysis was to compare the coded events and identify across our database patterns concerning teachers' supports for students' management of scientific uncertainties. We described these patterns as potential themes concerning how science teachers mange scientific uncertainties in sensemaking in the classroom.

Table 1

 © ISLS

Coding scheme for uncertainty management in modeling

Uncertainty Management	Definition
Raising	Raising uncertainty involved any action and utterance applied to elicit students' awareness of an uncertainty to (1) open the problem space, (2) seek multiple alternative opinions, (3) express doubts, (4) state different opinions, (5) disagree with other opinions, or (6) acknowledge non-understanding during discussion
Maintaining	Maintaining uncertainty involved any action and utterance to (1) support, (2) elaborate, (3) rephrase, or (4) increase doubts
Reducing	Reducing uncertainty involved any action and utterance to (1) request more information/an explanation, (2) make a connection between the discussed uncertainty and past experience/prior knowledge, (3) seek a consensus, (4) ask for clarification, (5) clarify doubts, (6) refer to expert resources/authority figures, or (7) suggest a solution
Ignoring	Ignoring uncertainty involved any action or utterance to (1) avoid, (2) disregard, or (3) reject the opportunity to discuss the uncertainty.

Findings

Six themes of teachers' instructional strategies to productively managing scientific uncertainties for sensemaking were identified through our analysis. (a) problematize problems regarding not only what students know (content uncertainty) but also how to explain (epistemic uncertainty), (b) use scientific uncertainty to encourage students to re-collect evidence, (c) use scientific uncertainty to clarify what students learned and construct more sophisticated explanation, (d) encourage students to utilize scientific practices to resolve scientific uncertainties, (e) use scientific uncertainties to reflect on students' reasoning, and (f) use scientific uncertainties to plan further sensemaking processes. Due to limited space, we will present specific explanations of the cases at the conference.

Discussion

This study explored features of instructional strategies to support students managing scientific uncertainties in their sensemaking processes. In the practice-focused curriculum, students are expected to position as agents in sensemaking of the natural world (NRC, 2012). As scientists do, it is evident for students to encounter numerous uncertainties in their sensemaking processes. Instructional strategies are needed to support students to identify, manage and resolve uncertainties. By presenting features of these instructional strategies, this study contributes to developing teaching for students' engagement in sensemaking in the science classroom. Further, this study focused on management of scientific uncertainties, which encompass content uncertainties as well as epistemic uncertainties. This allowed to identify more diverse uncertainties that students struggle to resolve in the science classroom, and add more cases and expand the existing discussions of developing instructional strategies to support uncertainty management in the science classroom.

Designing to Enhance Academic Buoyancy: A Snapshot of First Steps in a Second Level School Setting

Edel Connolly, Paul Flynn and Sara Gartland
e.connolly27@nuigalway.ie, paul.flynn@nuigalway.ie, sara.gartland@nuigalway.ie
National University of Ireland Galway, Ireland

Abstract: Academic buoyancy generally refers to students' ability to respond to everyday challenges in academic settings. This paper presents insights in to a design-based research pilot intervention that is informed by a multi-ontological framework that included conceptual pillars of: engagement, collaboration and reflection. Preliminary findings are presented, the emergence of co-creation as a core element of the success of the pilot is explored, and next steps discussed.

Introduction and Conceptual Background

Clearly identified by UNESCO as Sustainable Development Goal 4 (UNESCO, 2021) the provision of quality education opportunities is critical to the development of our global citizenship. However, in order to support a sustained engagement with education, student adaptability, particularly in the form of academic buoyancy, has a significant role in how individuals respond to the challenges they will experience (Martin & Marsh, 2009) both within and outside formal educational settings. Consequently, there is a clearly established need to develop innovative pedagogically informed initiatives, programmes and interventions that aim to enhance the academic buoyancy of second level students (Edwards et. al, 2007) as they move ever closer to post compulsory education and the world of work where the link between achievement and buoyancy (Martin et al. 2016) is even closer.

The conceptual framework that underpins this work has three pillars. Firstly, collaborative activity is seen to provide students with opportunities to challenge themselves and to develop the ability to be discerning about ideas and content (Hase, 2015). Second, through such collaborative exchanges students are more likely to demonstrate enhanced engagement with both content and social interaction with their peers (Shneidermann, 1998) creating opportunities for positive learning outcomes (Trowler and Trowler, 2010). The third pillar, reflection, seeks to foster student' capabilities for critical thinking and self-evaluation resulting in a more buoyant learner.

When students actively participate in directing their own learning, agentic engagement can occur (Lawson and Lawson, 2013). As an empowering process this can can have a positive impact on participant engagement with a pedagogical intervention. A core aim of the intervention in this study is to produce lifelong learners capable of working collaboratively, assessing their own learning and monitoring their performance. In conjunction with collaboration, reflective practice provides students with opportunities to develop the capability for critical thinking and ongoing self-evaluation thus improving the likelihood of enhancing their academic buoyancy (Martin, 2013). In order to promote awareness among the students, reflection emanated as a keystone of the intervention. Reflection seeks to foster students' capabilities for critical thinking and self-evaluation resulting in a buoyant learner.

This paper reports on the outcome of a Design-Based Research (DBR) (DBRC, 2002; Barab & Squire 2004) pilot project and an emergent need to develop a pedagogical framework to support a curricular co-creation process particular to the development of academic buoyancy with second level students.

Methods

Employing a DBR methodology, this multi-cycle study seeks to iteratively design and refine an innovative pedagogy that supports the enhancement of second level students' academic buoyancy set in the real-work messiness of a second level school setting (Barab and Squire 2004). Such pedagogy will be a guide rather than a proscriptive learning process. Additionally, it will promote higher order thinking skills and the development of self-regulated learners (Shvarts and Bakker 2019). Given that this was a pilot study and the lead researcher is an in-service teacher, convenience sampling was employed for the recruitment of participants into this study. A data collection plan was designed that included the administration of a pre- and post-questionnaire, students' artefacts, practitioner observations and student reflective journals. A process of data triangulation informed and contributed to a thematic analysis.

The lead researcher implemented the pilot intervention with a cohort of second level female students (N=51) with an average age of 15.5 years enrolled in yearlong an elective programme in an Irish secondary school called the Transition Year Programme. The module was delivered through six, single weekly classes of 40 minutes duration and included an introductory session involving co-creation of the main areas of concern for the group

 © ISLS

and in doing so, establishing learning outcomes for the module that related to key characters of academic buoyancy: metacognition, reflection, goal setting and decision making (Martin & Marsh, 2009).

Preliminary Findings

The conceptual pillars of engagement, collaboration and reflection are used here to frame the results of this pilot intervention. Firstly, we found, particularly through our thematic analysis of the student reflections, that students' perceived usefulness of the module and individual classes influenced their level of engagement. It was evident that this was linked to the role that students played in the co-creation of the module which ensured that the outcomes were reflective of the needs of the students. This was corroborated through the observations of the lead researcher who is an experienced teacher and noted a positive change in the classroom atmosphere, teacher-student relationship and inter-student relationships.

Secondly, throughout the six-week pilot intervention students worked in groups of 3-5, depending on the physical layout and the number of students in the class group. Participating students developed a range of social soft-skills as an outcome of their engagement with collaborative aspects of the module despite social distancing restrictions imposed as a consequence of COVID-19.

Thirdly, triangulated data highlighted a relationship between student agency in the co-creation of the module, student engagement and collaboration facilitating a mechanism for students to meaningfully address and design for their own needs as part of an ongoing process of selective practice.

Discussion

The preliminary findings of this pilot study indicate that the approach taken has the potential to enhance the academic buoyancy of second level students. The initial conceptual framework afforded an opportunity to develop an informed, real-world, experiment and at the same time an opportunity to determine the proximal workings of the design. It has become clear to the research team that students played a pivotal role in the design and development process of this module through their participation in a consultative, student-centred learning experience. This process of co-creation, initially not considered a component of the conceptual framework must notw be considered an essential pillar of its initial success. Therefore, next steps include an explicit enabling of the collaborative social learning environment afforded by the co-creative approach embodied in this pilot study.

Student motivation in science learning with embodied Computational Thinking

Niels Bonderup Dohn, Aarhus University, dohn@edu.au.dk
Nina Bonderup Dohn, University of Southern Denmark, nina@sdu.dk

Abstract: In an on-going multiple-case study, we investigate the use of unplugged, embodied Computational Thinking activities to learn topics within biology and chemistry. We utilize Educational Design Research in collaboration with 4 teachers at 2 upper secondary schools, focusing on students' experience and how the activities affect their motivation for learning the topics in question. Tentative results indicate that students find such activities fun, allowing them to address curricular content in new ways, but also confusing.

Introduction: Why use embodied Computational Thinking to learn science?

Computational thinking (CT) is argued to be of prime significance for all citizens in the 21st century (e.g. Vuorikari et al., 2016; Wing, 2006). Wing's definition of CT is often cited: "[T]he thought processes involved in formulating problems and their solutions so that the solutions are represented in a form that can be effectively carried out by an information-processing agent" (Wing, 2011). This definition determines CT as algorithmic problem solving without reference to specific domains, implying that CT is a set of abstract skills that can be generally applied – in Wing's words "a "universally applicable attitude and skill set" (Wing, 2006) that can be used to learn and investigate any subject or discipline. Some dispute remains as regards which skills the set comprises, but decomposition, logical data analysis, modeling, algorithm design (including sequencing in step-by-step procedures), automatization, and generalization are usually listed (e.g. Chongtay, 2018; Shute et al., 2017). A large strand within the literature emphasizes that CT can be performed 'unplugged', that is, without the step of coding the designed algorithm into a computer program (Caeli & Yadav, 2020; CS Unplugged). The claimed pedagogical advantage is that students become familiar with the steps of the problem-solving method without the additional complexity of having to learn a code language. This is particularly relevant when CT is utilized to learn other disciplines than computer science. Here, premature introduction of coding may confuse learners and affect their motivation for learning both CT and the discipline in question (Chongtay, 2018).

The mainstream understanding of CT as a set of abstract skills is challenged by research within the fields of learning and practicing arithmetic, logical, and algorithmic thinking. Research in situated learning (Lave, 1988) and embodied cognition (Abrahamson & Bakker, 2016; Johnson, 1987) show that such thinking processes are learned situatedly and crucially involve embodied cognitive processes. As these thinking processes are adjacent to or part of CT (Wing, 2011), the implication is that CT skills are also situated and will concretize differently within different disciplines. It is further to be expected that their development and use within other disciplines can advantageously be supported – both cognitively and motivationally – by involving embodied activities.

In the present on-going multiple-case study (Yin & Yin, 2018), we investigate the use of unplugged, embodied CT-activities to learn topics within biology and chemistry, acknowledged by researchers (e.g. Düsing et al., 2019) and teachers in practice to be particularly difficult for students to learn. The activities engage the CT skills of decomposition, modeling, sequencing, and generalization. We focus on how students experience these embodied CT-activities, and, in particular, how they affect their motivation for learning the topics in question.

Methodology

The advantage of the multiple-case approach is that it provides opportunity to achieve a high degree of both ecological and external validity. Our sample involves four teachers from two urban upper secondary schools in Denmark and in all six classes of biology and chemistry. The average class size is 26 students. The multiple-case study utilizes Educational Design Research (McKenney & Reeves, 2014) and activities are therefore developed in collaboration with the teachers in a series of iterations. Activities are designed for the individual classes' curricular content and the teachers share their materials for inspiration. Content themes are carbon cycle, nitrogen cycle, phosphorus cycle, chemical analysis, protein synthesis, and balancing chemical equations. All tasks address 'algorithmic processes' through unplugged, embodied activities. In the carbon cycle task, for example, students take on the role of a carbon atom and move around different stations to simulate the dynamics of the cycle. This involves decomposition of the carbon cycle, embodied modeling of the dynamics, and sequencing. For instance, from the Atmosphere station, students may be absorbed into a plant leaf and move to the Plant station. During each move, students note stage and form of carbon. Based on the movements outlined in their notes, they produce a diagram of the carbon cycle and the route of the carbon atom through the cycle. Comparing the routes allows

 © ISLS

them to generalize their model. Another task utilizes LEGO bricks to model the balancing of chemical equations. Students decompose the reaction by letting bricks in different colors represent atoms. They then build reactants and products and reconcile reaction equations by counting bricks in each color on both sides. Finally, they list the sequential steps needed to determine the reactions and try to generalize the list for further balancing tasks.

To evaluate students' experiences, we used self-report with open questions supplemented by classroom observations and informal interviews. In the self-report, students were asked about their positive and negative experiences and whether the activity made the content easier to understand. Observations focused on situations in which students were engaged and on situations where they seemed confused or demotivated. In short (1-4 minutes) interviews, students were asked how they experienced a given situation, why it was or was not motivating.

In the analysis, we searched for signs of how embodied involvement impact students' self-reported understanding of the science content and of motivation. In our search for signs of motivation, we did not limit ourselves to one theory but were open to statements being interpreted inductively in different directions, especially interest (Hidi & Renninger, 2006), self-efficacy (Bandura, 2001), and utility value (Eccles & Wigfield, 2020).

Tentative results

The very tentative results suggest that students find embodied CT-activities fun and interesting, allowing them to address curricular content in new ways. At the same time, many students also report that the CT activities are confusing. Students are challenged as regards experiencing the full picture of the processes, as they tend to focus on specific elements. Besides, they are challenged in making connections to textbook content and in generalizing their enacted algorithmic processes. They need support to understand physical models of processes.

Informing Advanced Digital Technologies' Design for Refugee Language Education in Greece

Anastasia Olga Tzirides, University of Illinois, Urbana-Champaign, aot2@illinois.edu

Abstract: This paper focuses on needs finding for computer-assisted language learning for vulnerable population living in difficult circumstances. It presents semi-structured interviews with teachers and volunteers working with refugee students in Greece. It explores their needs regarding digital technologies in teaching and learning of Modern Greek as a second language. The findings outline the context of technology and Greek refugee language education, the capacity that teachers have, as well as the challenges within this context.

Context

This paper aims to explore the ways that advanced digital technologies, such as mobile devices and applications, and artificial intelligence tools, can enhance second language learning and instruction within the context of refugees in Greece. Refugee language education in Greece is mostly supported by non-governmental organizations, community-based organizations of volunteers and some training language programs that were designed by Ministries, Municipalities and Universities (Kantzou et. al, 2017). The use of digital technologies in such a context appears to have promising results, according to McCaffrey & Taha (2019) who studied the use of smartphones by recent refugees in the US with the purpose to adapt and make sense of the world moving across places and named languages.

Objectives

The research questions associated with this small-scale study include the following:

- What are the needs of refugee language teachers within the Greek context?
- What technology design features would better support refugee language education in Greece?
- What are the potential challenges for teachers working with advanced digital technologies?

Methods and data

This paper follows a qualitative case study methodology. Four semi-structured interviews of approximately 1 hour each were conducted with teachers and volunteers of elementary or middle school educational background, working in informal settings with refugee students in Greece and having an average of 4.25 years of experience in the field. Teachers were identified through snowball sampling during the Fall of 2019. The interview included questions about: Language course structure and material, Use and access of digital technology tools in educational practice, Use and access to digital technologies crafted for language education. The interviews were analyzed following thematic coding analysis. Member checking was realized for validity purposes.

Table 1 shows the main categories and overarching themes that emerged, supported by sample excerpts.

Table 1

Data analysis categories & overarching themes with sample interview excerpts

Overarching Themes	Categories	Sample Interview Excerpts
Technology use in the Greek refugee language education	Limited access to tablets	*"We have used tablets (...) Not enough tablets for all students."* (Teacher 1)
	Access to websites	*"I was bringing my laptop to the camp to show them images and for sounds on YouTube"* (Teacher 3)
	Use of mobile phones	*"Adult students using their mobile phones"* (Teacher 3)
	Achievement of communicative goals	*"(Technology) provides different ways to communicate with people without a common language (...) Really important to achieve communication"* (Teacher 2)
Teachers' needs and capacity	Minimal or no pedagogical training provided	*"We didn't receive formal training about how to teach Modern Greek in these students. Experience taught us most of the things and we are still learning"* (Teacher 4)

 © ISLS

regarding digital technologies	Availability of digital applications	*"There aren't many applications for teaching Greek as a second language. Comparing to English, for example."* (Teacher 1) *"There are many applications for refugee language education, e.g. AR scan to translate and something like Google translate"* (Teacher 3)
Design features of advanced digital tools	Potential of using AI	*"Yes, these tools seem to be very helpful (…) It would be amazing if we could use them in the class. Students would be very happy."* (Teacher 3)
	AI tools to target communication goals	*"(…) important to focus on dialogues, communicative situations, e.g. dialogues/phrases/words on the super market, when buying coffee, etc."* (Teacher 1)
	Digital tools in native language of the students	*"Some students do not know how to read, so they would appreciate an interface that is visually friendly and that would guide them on what to interact with the tool and complete their tasks in other ways and not with text."* (Teacher 4)
Challenges using advanced digital technologies in this context	Digitally illiterate students	"Although the young kids are familiar with digital tools, there are a lot of adults who don't own laptops, they don't know how to use it (…) I can't imagine them using advanced technologies right now" (Teacher 3)
	Lack of a common language for communication	*"I was using English, but they didn't know/ I was speaking only through the translator (…) but the communication was difficult."* (Teacher 3)
	Instability and population movement in the refugee camps	*"(…) very unstable situation. It is difficult to form relations with students, because they are moving, and they are coming and going."* (Teacher 1)
	High cost of AI-enhanced tools	*"There is not enough funding to buy not only AI enhanced equipment, but not enough funding for computers or tablets. for the large number of students".* (Teacher 4)
	Challenging conditions at the camps	*"At the camps, in the beginning, there were no buildings. We were doing our work in tents. People were living (…) with no electricity, water or any of the comfort of a house (…) These conditions did not make our work easy"* (Teacher 2)

Results

Findings illustrate the current context of technology use in the Greek refugee language education, the needs and the capacity that teachers have, the applicability of advanced digital technologies, and its potential challenges. The findings show that websites, mobile applications, or platforms are used and are considered helpful to achieve better communication. Participants highlighted that digital tools' design should aim in improving everyday meaning making and being accessible in the native language of the users. Teachers reported minimal or no training in incorporating digital tools in their instruction and subsequently, they lack proper information about the availability of digital instructional tools for this specific context. About the potential challenges, they mentioned: digitally illiterate students, lack of a common language for communication, high instability and refugee population movement, high cost of the AI-enhanced tools, challenging weather and infrastructure conditions.

Discussion & scholarly significance

Advanced digital technologies seem promising, beneficial and are viewed positively. However, there are more fundamental needs to be addressed alongside the potential of using innovative digital tools, such as the environmental challenges and the inadequate teacher training. Overall, this paper addresses some design considerations for devices, platforms, and applications of second language learning in complex settings.

Teacher Discourse in Scaffolding a Knowledge Building Group：A Case Study

Chunlin LEI, Shanghai University of International Business and Economics, leichunlin@suibe.edu.cn
Junjie ZHANG, the University of Hong Kong, zjjedu@connect.hku.hk

Abstract: In a group of one teacher and 30 students engaged in collaborative knowledge building, the teacher's 165 posts in Knowledge Forum were parsed out for analysis. A coding scheme was developed to categorize the posts into three patterns, namely, *managerial, low order, and high order*. While managerial and low order discourse seemed inevitable, high order discourse was more pervasive. The posts also suggested a shifting role of the teacher in scaffolding knowledge building over time.

Introduction

One important goal of a Computer-supported Collaborative Learning (CSCL) environment is to foster productive discourse among the learners. A wealth of studies has examined the effectiveness of a designed environment through the analysis of student discourse; however, very few studies have examined the role of teacher discourse in fostering productive discourse in CSCL environments.

Knowledge building posits that a learning community shall look ideas as improvable and get them enriched, revised and refined through productive discourse in Knowledge Forum® (KF), a technology-supported discussion platform. However, people often find it difficult to implement the knowledge building approach because there are no scripts to follow. In knowledge building, learner agency is often stressed and the role of a teacher is described as a facilitator or student helper. While a teacher is suggested to shadow its existence and let the students fully play their potentials in progressive inquiry, it is important to investigate how a teacher can achieve such a role. This poses a dilemma particularly in the Asian educational context in which a teacher is often regarded as the authority and expected to assume much responsibility in leading the class.

To obtain productive interaction and quality discourse, teachers should try to ask more high-cognitive-level questions. Wang and colleagues (2016) identified a few examples of teachers' classroom questions that have promoted knowledge building principles. It is also found that higher-order-thinking questions could foster student's deeper thinking and develop their understanding; and when questions are responsive to students' earlier contributions and builds on from them, they can encourage elaborated interaction and promote productive talk activity (Chin, 2006). Traditionally, teachers' questioning practices are exercised verbally with students on face-to-face classroom occasions; however, many CSCL environments are usually mediated by discussion tools where written messages are exchanged and recorded asynchronously. Therefore, it is important to investigate how a teacher may interact with his students in a discussion forum, aiming to prompt the whole community towards collective knowledge advances through productive and deep discourse.

Two research questions are addressed: (1) What characterizes the teacher discourse in Knowledge Forum when knowledge building approach is implemented in a group of Year-1 university students? (2) Are there differences on teacher discourse over time (Semester-1 versus Semester-2)?

Method

This study is based on an earlier knowledge building study in Shanghai, China (Lei & Chan, 2018), which showed students in the knowledge building environment were engaged in productive knowledge building discourse and made collective knowledge advancement. For this study, the teacher's KF posts are retrieved separately for analysis.

Over two semesters and with a group of 30 students engaged in knowledge building, the teacher contributed a total of 165 KF posts, either in the form of a KF note or a KF annotation. A KF note is typical in the forum, i.e. when a post is composed and submitted, it will appear as a tiny square ( ) in the working space where every one of the community could see. While an annotation will not appear in the open space, it is an attached message to an existent note ( ); only when a note is clicked open, the annotation can be seen. All the findings are based on the analysis of the teacher's posts in KF; students' KF notes, especially those prior to or build on the teacher's posts, are frequently revisited in order to understand the interactional contexts.

Findings

 © ISLS

It was found that the teacher wrote 38 notes and 127 annotations over two semesters. Overall, he did not make his presence very conspicuous (posting notes) in KF; he wrote more annotations which were embedded within the students' notes. In other words, student to student interactions were more salient in the dataset.

A qualitative analysis was conducted and teacher's discourse was ultimately categorized into three patterns in terms of its nature and purpose:(1) *managerial*, to encourage and maintain students' KF writing; (2) *low order*, to invoke students' low-cognitive, quick responses; (3) *high order*, to promote knowledge building principles, i.e. involving students' collective responsibility in pursuing new knowledge. Table 1 shows some examples.

Table 1

Examples of managerial, low order and high order teacher discourse

Categories	Examples (excerpts)
Managerial	[Oct 30] Some of the questions concerning technological environment and its impact on business: such as how technology affects employment; how technology helps an industry shift? … [Sep 10] Clive, when you contribute a note, we all see your name under the small icon. So you don't need to indicate your name at the end of the note…; [Oct 05] Yes, I like your explanation and example. Continue your effort on KF. We learn together!
Low order	[Oct 23] How to spell the word "基础设施"(infrastructure) ? [Nov 28] Try to get more solid data to support your ideas and follow the report format [Sep 22] What do you mean "not powerful enough"? …
High order	[Sep 29] You raised a good question – why there is an economic miracle? Could you and the other students find answers from some sources…? [Nov 28] I suggest you read the SWOT note written by Wang Qiaoyan. Also, you can try to summarize the findings … [Mar 29] when you and your group members put the notes together, could you tell us why these clusters of notes are good? Or you can tell us what your group understood previously, and now do you have any new understanding?

Teachers' posts are partitioned into semester-1 and semester-2 discourse according to the date. Table 2 shows the frequencies of managerial, low-order, and high-order teacher discourse in two periods of time.

Table 2

The frequency and percentage of managerial, low-order, and high-order discourse over two semesters

Time \ category	Managerial	Low order	High order	Total (100%)
Semester-1	30 (26.8%)	26 (23.2%)	56 (50%)	112 (100%)
Semester-2	12 (22.6%)	10 (18.9%)	31 (58.5%)	53 (100%)
Whole Year	42 (25.5%)	36 (21.8%)	87 (52.7%)	165 (100%)

Implications

Similar to teachers' classroom questioning, teachers' forum discourse also needs to orchestrate students' inquiry rather than prescribing what they should do (Wang et al., 2016). Traditionally, a majority of teacher questioning is managerial or low-order; however, high order discourse needs to be prevalent in order to stimulate knowledge building principles and productive student discourse. The teacher's posts were significantly decreased in semester-2, which suggested less teacher presence and more student-to-student interactions in the progressive inquiry process. There is a shifting role of teacher and a turning of high level agency to the students over time.

Grounded Creativity

Jonan Phillip Donaldson and Jay Woodward
jonandonaldson@tamu.edu, drjaytamu@hotmail.com
Texas A&M University

Abstract: We used complex conceptual systems theory to analyze conceptualizations of creativity in the context of a course in which students engaged in group projects to develop creativity tests and creativity games. Using semantic network analysis, we were able to identify conceptualizations of creativity and emergent practices. Groups which developed games tended to conceptualize creativity as organic, while groups which created tests conceptualized creativity as an object or state. Different practices were emergent from each conceptualization.

Background

In constructivist perspectives, learning is a generative and creative process. This paper uses complex conceptual systems theory to argue that practices in creativity emerge from conceptualizations of creativity. The Creativity Landscape conceptual framework (Donaldson, 2016, 2018) describes the rich landscape of creativity research by identifying key tenets of the construct of creativity and then categorizing them into four domains: **creative environments** (generativity, playfulness, reduced regulation, and lowered inhibition); **creative mindsets** (perseverance, openness to experiences, tolerance of ambiguity, autonomy, creative self-efficacy, and mindfulness); **creative processes** (identification of problem, framing, preparation, idea generation, incubation, unconscious cognition, insight, and refining); and **creative cognition** (divergent or convergent thinking, including metaphor creation, perspective taking, analogical thinking, frame creation, conceptual combination, abductive reasoning, synthetic thinking, pattern recognition, and elaboration). Each domain is characterized by practices that through their interplay and dynamic interaction help demonstrate how one's *conceptualization* of creativity impacts the subsequent materialization and manifestation of creativity. Optimal facilitation of creativity involves a balance among all four categories, as well as a mix of practices from within each category. The Creativity Landscape framework was applied to analyze a project-based learning task that had groups design unique and original board games or creativity tests. Complex conceptual systems theory (Donaldson & Allen-Handy, 2020) views conceptualizations of creativity as complex systems, and practices in creativity as emergent from different conceptualizations. We investigated the relationship between conceptualizations of creativity and emergent practices, fully exploring how the operationalization of creativity influenced the approaches and actions that were enacted in the genesis of these artifacts.

Methods

Third-year university students in a course for the Creative Studies minor were put in 14 small groups to work on semester-long creativity projects. Half of the groups chose to develop creativity games, and half developed creativity tests. Each group created a document describing in detail the game or test they created, including the creativity concepts and literature which informed their designs. We collected these documents and coded them in MAXQDA for creativity practices as organized through the Creativity Landscape framework, as well as conceptualizations of creativity using categories necessary for complex conceptual systems analysis—namely, metaphorical and non-metaphorical characterizations of creativity. Coding resulted in 257 codes covering 2,331 coded segments. We then calculated correlations between pairs of codes within each category to determine the likelihood that any pair of codes would appear within proximity in the data. We used these correlations to construct symmetrical correlation matrices which we then entered into the UCINET and NetDraw software where we constructed semantic network maps and used Girvan-Newman cluster analysis (Girvan & Newman, 2002) to identify clusters. Clusters of metaphors were interpreted as conceptual metaphors, and clusters of non-metaphorical characterizations were interpreted as conceptual stories. The codes belonging to each cluster were then collapsed in MAXQDA, and correlation matrices were constructed to determine the relationships between conceptual metaphors, conceptual stories, and practices emergent from conceptualizations of creativity.

Findings

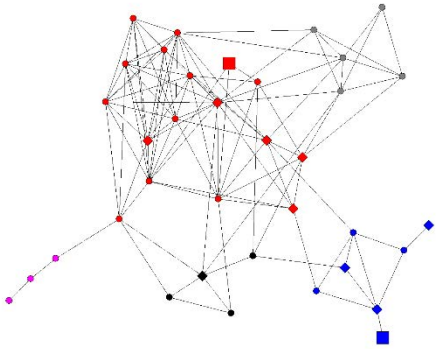
Our analysis resulted in a semantic network map of conceptual elements and practices correlated at the $p<0.05$ level, including 5 clusters at $Q=0.324$ (see figure 1). The red cluster frames creativity through a set of four conceptual metaphors (*Creativity is a Living Organism*, *Creativity is Physical Action*, *Mind is a Computer*, *Mind is Physical Action or Enactive*) and one conceptual story (*Evidence-Outcome*). This conceptualization of creativity was most relevant for the creativity games groups. The use of this frame led to the emergence of particular

 © ISLS

practices. Creative cognitive processes of conceptual combination and frame creation were emphasized. This perspective includes developing a creative environment which promotes generativity, lowered inhibition, and playfulness. The only creative mindset involved here is autonomy. Practices in terms of creative processes were emergent in this conceptualization, including identification of a problem, preparation, incubation, unconscious cognition, and insight.

Figure 1

Network Map of Conceptual Elements and Emergent Practices



The blue cluster was most relevant to the creativity tests groups, and included the *Creativity is Physical or Environmental State* and the *Creativity is an Object* conceptual metaphors, along with the *Contextual-Vague* conceptual story. Elaboration was the only form of creative cognition emergent in this conceptualization. No creative environment or creative mindset practices were emergent, but creative processes of framing and refining were emergent. The black cluster was relevant to both the creativity test and creativity game groups. This conceptualization uses the *Process-Personality* conceptual story, but includes no conceptual metaphors. Emergent creative cognition practices were limited to pattern recognition in this framing of creativity, as well as creative mindset practices around creative self-efficacy along with creative processes of idea generation. The gray cluster was relevant only to the creative games group. This cluster included no framing of creativity through conceptual metaphors or conceptual stories, but consisted of four creative cognition practices (synthetic thinking, analogical thinking, and perspective taking), collaborative creative environment practices, and the creative mindset practice of tolerance of ambiguity. The pink cluster was also only relevant to the creative games group, and included no creativity framing. This cluster included two practices related to creative mindset (openness to experiences and perseverance) and practices to facilitate creative environments which are unregulated or have lowered regulation.

Implications and Discussion

We identified salient themes and significant findings in several domains across both projects. For the creativity games, metaphorical perspectives related to the life-like and organic nature of creativity significantly impacted practices related to creative cognition, processes, and environment. This perspective led to the designing of game-play elements with lower regulation that featured tasks related to generating conceptual combinations along with the eliciting of insight. Analysis revealed different patterns for groups developing creativity tests, with metaphorical perspectives related to the physical properties and environmental elements of creativity impacting practices related to creative process and cognition. The test questions that were designed emphasized framing, refining, and elaboration of responses in a much more structured way. Perspectives related to the creative mindset were apparent in both projects, with practices related to cultivating creative self-efficacy (confidence in one's competence) inherent in responses processes for both. A takeaway from this analysis is that the labels "test" vs. "game" significantly influenced the perspectives of the groups as they designed their projects and influenced the practices that they put into place in the attempt to measure or generate creativity amongst their participants.

"You Are Not Valued As They Said": Re-constructing A U.S. Higher Education Environment Negotiated By an International Student

Pei-Jung Li, Indiana University Bloomington, peijli@iu.edu

Abstract: This paper responds to the call for examining and promoting a more diverse and equitable education environment by shedding light on an international student's experience in U.S. higher education. Using narrative analysis, the author unfolds the participant's proactive actions and resistant voices. The results also show the hidden "de facto" in the environment that the participant experienced with, further contributing to the education practices by unveiling the limitations of the current U.S. educational system.

Introduction

In the past decade, the number of international students at universities in the United States has grown from 690,923 to 1,075,496, increasing from 3.4% to 5.5% of the total student body population (Institute of International Education [IIE], 2020). Many universities now have a more diverse student body and increasingly emphasize the importance of equitable and inclusive educational practices. Despite this, international students' needs continue to be overlooked, with a growing body of literature suggesting that they persistently experience discrimination, microaggressions, and/or a lack of support from the educational system (Marginson et al., 2010). In addition, scholars argued that much of the research focused on international students has taken up a deficit perspective. Page and Chahboun (2019) noted that much of the current research on international students has been based on the assumption that international students simply serve to "internationalize the curriculum" (p. 873), resulting in little attention being given to the everyday experiences and perspectives of the international students themselves. Xu (2018) also argued that ample research used the acculturation model when studying international students' overseas experiences. Such a model assumes that the goal is for international students to adapt to the host country's culture. Such deficit models serve to overgeneralize international students' motivation for studying in another country, simplify their overseas trajectories, ignore their agency, and minimize the challenges they face.

Despite international education experience is a self-forming process, Tran and Vu (2018) revealed that there is a lack of study in understanding how international students negotiate their agency. They clarified that the achievement of agency is not merely students' effort. It is an inter-relationship among the individual (micro-level), the resources and spaces given by the institutions (meso-level), and the larger structure (macro-level). This study will contribute to scholars' call for unfolding how international students negotiate and express themselves within the U.S. educational system, and also to reveal the hidden norms of the U.S. higher education. The results can also create dialogs for policy-makers, educational practitioners, or scholars who work on higher education study or with international students.

Methods and Data

The data were from my larger project exploring international doctoral students' academic trajectories in the U.S. The study was conducted in a predominantly white university in the mid-west U.S. with 6 participants in total. In this specific study, I focus on Tabitha, a Chinese female international doctoral student's data because (1) the research activities were done in narrative forms; and (2) the research meetings have lasted for a year since August 2020 until now, therefore creating a rather complete trajectory of her academic experience; (3) a similar challenge of funding-searching was identified as a critical event (Mertova & Webster, 2012) that had been consistently emphasized and later changed her personal beliefs and attitudes toward the education environment she locates within. The meetings were conducted in an online format because of pandemic. There were 16 meetings up-to-date resulting in a total of 44 hour's video recording. Tabitha also created monthly diaries with her reflections on her life. Negotiation of funding re-occurred and became critical in the past year in Tabitha's life. I started the analysis with the segments directly related to these events. Data were the video recordings and the written journals on September 21st, 2020, March 1st, 22nd, and April 18th, 2021. Both the videos and her diaries were analyzed using qualitative data analysis software ATLAS.ti 9. Data were analyzed in its original language, Mandarin (the mother language of both the participant and myself), and later translated into English for reporting. As I watched the recording or reading through the journal, I marked the components in the narratives (e.g., characters, events, actions…etc.) and also analyzed the meaning behind the narrator's interpretations, decisions, and reflections.

For each segment, I summarized and generated the following: (1) critical moments: what are the events that are presented as influential in her narratives in that specific period; (2) key persons: what are the critical characters in these moments, what roles do they play; (3) emotion: how does the narrator feel about these

 © ISLS

experiences/interactions; (4) narrator's voice and explanation: how does the narrator perceive these moments and reproduce these moments through her narratives; (5) decision or action: what action does the narrator decide to perform in response to the experience; (6) de jure vs. de facto: what the narrator considers things/the system should be vs. what actually happened; and (7) macro-meso-micro structure: through her narratives and the analysis of the above themes, re-construct the system that the narrator negotiates herself within, the system that allows these experiences happen. Finally, I compared these themes across the four segments/across these time spans, therefore generated a clearer picture of how an international student posits and voices herself in the funding-searching experience under the U.S. higher education system.

Summary of Results

With the seven analytical structures that I proposed in the method section, I was able to re-construct an U.S. higher education environment where Tabitha interacted with by the following findings: (1) individualism seems to be an underlying culture. In the environment Tabitha locates within, many staff and faculty members do not actively pay attention to students' external needs (e.g., resources, academic works) or internal needs (e.g., mental status or personal development). Even when Tabitha requested help, some replied with the most basic, "official" answers while some rejected to give a hand by shirking responsibility. Tabitha described the phenomena using "playboy" as a metaphor, that: "they did not deny my questioning yet they also gave no response; and they took no responsibility" (041821). (2) When university people hiring graduate assistants, there seems to be a hidden pre-assumption and pre-requisition to international students' language ability before getting to know their other strengths. Such as when R (Tabitha's advisor) queried around the funding opportunity at the institutional level, he received a response directly stating Tabitha, as an international female student, is unlikely to get a position. The staff answered without asking for further evidence to support her ability. When Tabitha tried to apply to other positions, she sensed that native-speaker-level English proficiency seemed to be a baseline for many jobs, even the employers do not explicitly stated it on the job post. (3) Mentor/advisor plays a critical role in international doctoral student's trajectory. This strongly influences how an international student perceives the host country's educational culture. Across Tabitha's trajectory, her advisor R's role switched from a powerful protector, a father figure that seems to be omnipotent, gradually to a faculty member that acknowledged and also carried out a certain degree of the norms established by the institution. Tabitha reflected that "In my first year, I thought our program was supportive. Now I started to sense the gap [the problems of it]" (041821). Her perceptions toward the institution changed as time passed and as R started to be bounded by the implicit rules of the rules set by the institution.

On the other hand, Tabitha positioned herself as an active character who fights against challenges. For example, knowing R became the scapegoat that the office blamed on, Tabitha insisted that she will not accept such a result and instead respond with "quitting". Here, "quitting" is a weapon and a voice that Tabitha took to speak out for the unfairness she saw and encountered, which is different from what some literature posits as a passive result and the ending of a student's trajectory. Many reports also tend to position international students as consumers and customers of overseas education (Marginson, et al., 2010). Some universities and scholars assumed that quality education attracts international students. After admission, it is the international student's responsibility to accept and adapt to the host country's educational system. Tabitha's reflection provides another perspective, showing international students are not merely passive receivers: "From the decisions made by the department and the program [on how they decide to support us], we also, at the same time, evaluate if this is the place that worth staying. It is a fair position for both side" (030121).

Uplift modeling for educational data

Ting Zhang, East China Normal University,51204108032@stu.ecnu.edu.cn

Abstract: Traditional learner model focuses on modeling students' mastery level of a knowledge component based on their historical learning trajectories. Uplift modeling tries to predict the difference between the treatment group and the control group so that the model can predict the actual causal effect of the intervention. We found that the hint effectively increases the learning gain and learners' prior probability is an important factor affecting the learning gain.

1 Introduction

Adaptive learning systems provide personalized learning supports for students. There are many factors affecting learning, and the mechanism of learning is not clear. It is difficult to carry out research through traditional experimental research, so it is still difficult to track the learning gain of students. However, many student modeling studies only focus on modeling the change of students' knowledge ability level over time, such as Bayesian knowledge tracing and deep knowledge tracing. In contrast, uplift modeling allows for the addition of control groups, designed to clarify the difference in outcome probabilities between the modeling control group and the treatment group, and is therefore more suitable for educational data analysis. The Uplift Model is an incremental Model designed to predict the causal effects of an intervention on an individual's state or behavior. Uplift modeling is receiving increasing attention from the business analytics research as an improved example of predictive analytics for data-driven operational decisions.In this paper, the effectiveness of hints in adaptive learning systems on learning gain will be explored by using uplift modeling. Measuring and predicting "incremental improvements" resulting from interventions (such as hints) in the adaptive learning system reflects the effect of "intelligent tutoring".

2 Uplift Modeling

The uplift modeling is an incremental model designed to predict the causal effects of an intervention on an individual's state or behaviour. The calculation formula of user I's causal effect is as follows:

$$\tau_i = Y_i(1) - Y_i(0) \quad (1)$$

The goal of the uplift model is to maximize τ_i, which is an increment, the gain of the intervention strategy versus the no-intervention strategy, which is simply the difference between the outcome before and after the intervention. In practice, the estimated value of the expected causal Effect of all users will be used to measure the Effect of the whole user group, which is called Conditional Average Treatment Effect (CATE). Mathematically, it can be expressed as the difference between two Conditional probabilities:

$$CATE: \tau(X_i) = p(Y_i(1)|X_i) - p(Y_i(0)|X_i) \quad (2)$$

X_i is the characteristic of user I. τ_i represents the user's intervention measures, which is a binary variable (1 represents intervention, 0 represents no intervention). Y_i represents the user's results (e.g., whether the student got the answer right or not); $\tau(X_i)$ represents the causal effect of the treatment group relative to the control group. Conditional means based on user characteristics.

Formula (2) is the ideal uplift calculation. In fact, it is not possible to observe the output of user I with treatment and control at the same time, i.e. it is not possible to obtain $Y_i(1)$ and $Y_i(0)$at the same time. Therefore, formula (2) can be modified to obtain:

$$Y_i^{obs} = T_i Y_i(1) - (1 - T_i) Y_i(0) \quad (3)$$

Where $Y_i^{obs}$is the output observed by user I. $T_i$is a binary variable,$T_i = 1$ if user intervention is used, $T_i = 0$ otherwise.

Thus, the expected estimate of the conditional mean causal effect is:

$$\tau(X_i) = p\left(Y_i^{obs} \middle| X_i, T_i = 1\right) - p\left(Y_i^{obs} \middle| X_i, T_i = 0\right) \quad (4)$$

However, it should be emphasized here that Uplift modeling has high requirements for samples and must be subject to the Conditional Independence Assumption (CIA) that X and T are mutually independent, that is, user characteristics and intervention strategies are mutually independent:

$$\{Y_i(1), Y_i(0)\} \perp T_i | X_i \quad (5)$$

3 Experiments

In this experiment, Python package Pylift was used for the experiment, and Class Transformation Method was used for uplift modeling. The KDD CUP2010 data set we analyzed came from the research data of adaptive

 © ISLS

learning system. The study was divided into two groups: the no-hints group (as the control group for this study) and the hint group (as the treatment group).Figure 1 shows the QINI curve. As you can see, overall, the treatment group got 0.8% more correct answers than the control group. The Adjusted Qini curve is shown in Figure 2. FIG. 3 shows the cumulative gain curve. The area between qini curve and random line AUUC= 0.29; The area between aqini curve and ideal curve AUUC=0.08; The Cumulative gain curve and the area between the best practice curve AUUC= 0.11. From the experimental results, it can be seen that the hints in the adaptive learning system can improve the learning gain of students.

Figure 1

The Evaluation metrics for the KDD cup 2010 data

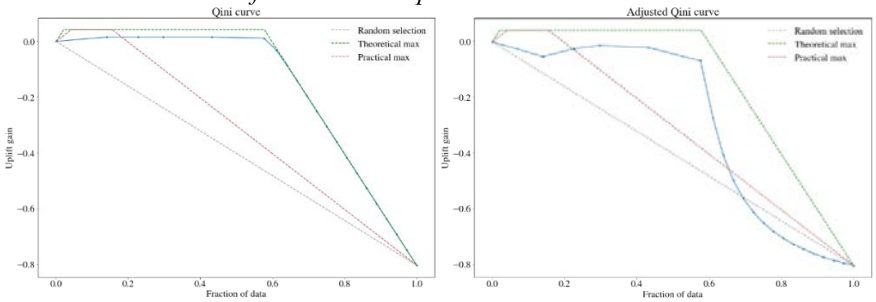

Figure 1-a The Qini curve *Figure 1-b The Adjusted Qini curve*

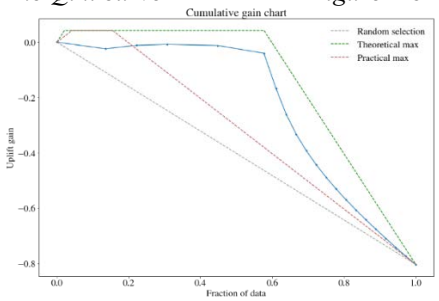

Figure 1-c The Cumulative gain curve

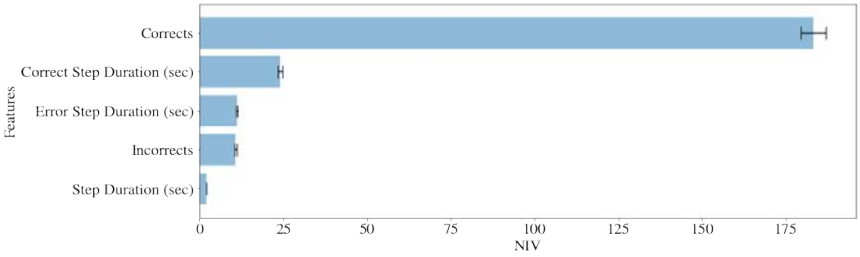
Information value (IV) provides a good framework for exploratory analysis and variable screening of binary classifiers. IV Consider the independent contribution of each variable to the result. The net Information Value (NIV) measures the strength of a given variable. The NET Information Value (NIV) figure obtained after uplift modeling (FIG. 2) shows that "Corrects" has the largest weight. Therefore, it can be seen that learners' initial ability (i.e., prior probability) when entering the system is an important factor affecting learning gain.

Figure 2

The net information value of partially variable



4 Conclusions and future research

This paper uses the uplift model to model the educational data in the adaptive learning system, and explores the influence of the personalized intervention in the adaptive learning system, hint, on the learning gain. The experiment shows that hint is effective, and the learning gain of the treatment group is higher than that of the control group. In addition, we also found that the prior probability of learners entering the system is an important factor affecting learning gain. Future studies will add datasets to explore the applicability of the uplift model in the field of education.

The influence of an intervention on students' historical arguing skills

Hulders Iris, Voet Michiel, De Wever Bram
Iris.Hulders@UGent.be, Michiel.Voet@UGent.be, Bram.DeWever@UGent.be
Tecolab, Department of Educational Studies, Ghent University

Abstract: Despite the importance of reasoning skills in today's knowledge-based society, students do not appear to possess sufficient arguing skills. This study aimed to examine the improvement of those arguing skills after implementing an intervention in grade 8. In total, 699 students participated, and data was collected using a document-based essay. Results show that students receiving limited and full arguing lessons showed significantly better progression from pre- to post-test compared to students not receiving the intervention.

Keywords: historical reasoning skills, arguing, intervention

Theoretical background

Historical arguing means to formulate and weigh arguments in support of different conclusions to answer a historical question. As part of formulating an answer, students must present arguments in support, counter arguments, and rebuttals. Finally, students must be able to base their arguments on several references found in the sources (De La Paz & Felton, 2010; van Drie & van Boxtel, 2008; Voet & De Wever, 2017). A recent study of Hulders et al (*n.d.*) shows that students in grade 8 (age 14) achieve poor results for arguing. It shows that students do not manage to give a substantiated answer. When answering a historical research question, most students only give their own conclusion and one single argument in support, but have no attention for counterarguments, rebuttals, or references to sources. However, students' arguing skills, as one of the key competences of historical reasoning skills (De La Paz & Felton, 2010), are important to make sense of the information in the 21st century (Wineburg & Reisman, 2015). Because, like to the information today, historical sources are often contradictory (Van Drie & Van Boxtel, 2008). One promising approach to enhance students' historical reasoning and arguing skills is 'inquiry-based learning' (IBL; Voet & De Wever, 2017). So, the aim of this study is to investigate the impact of a new developed lesson series, following the principles of IBL, on students' arguing skills.

Method

Participants

699 students from 42 classes in 18 Flemish (Belgium) schools participated in this study. This sample consisted of 367 boys (i.e., 52.50%) and 332 girls (i.e., 47.50%). Their average age was 14 (SD = 0.42).

Design of the study

An intervention study with pre-post-test design was set up from January until June 2020 (i.e., pandemic). In the experimental condition, teachers implemented a lesson series to enhance students' arguing skills during regular class hours. This intervention lasted for 8 weeks (2 sessions a week, 16 sessions in total). The lessons focused on teaching students how to argue with historical sources (i.e., essential elements of a substantiated answer and many practice opportunities). Teachers in the control condition followed their own curriculum (i.e., business as usual).

Instruments

Data were collected through a document-based essay during the history-lesson (50 minutes), under the supervision of the teacher. This test contained three authentic historical sources about the death of Emperor Claudius. In each source, information about the author and the context was given. After reading the sources, students were asked to give a substantiated answer to the question "Was Claudius murdered by order of his wife? Explain why you think he was or wasn't." The same test was administered as pre and post-test. All teachers had to present the pre-test to their students before the start of the Romans (pen-and-paper-test) and the post-test just after the end of that topic (online test). None of the groups received extra information about the death of Claudius during the intervention.

 © ISLS

Data-analysis

The students' answers were scored using a rubric on the presence of (1) a conclusion, (2) arguments in support, (3) counterarguments, (4) a rebuttal, (5) references to the sources and their value. To answer the research question, a univariate regression with arguing as dependent variable and condition as fixed factor was carried out.

Results and discussion

The condition variable consists of three subgroups. 304 students were part of group 1 who followed the business as usual. Group 2 were students who saw the lessons about arguing in a limited way (e.g., shorter, less exercises, …) and consist of 110 students. 285 students were part of group 3 who engaged in all the arguing lessons in class. Originally only two groups were planned (i.e., control and intervention group), but due to the pandemic not all teachers were able to implement all lessons. However, it might be interesting to include the group of students who saw the arguing lessons in a more limited way, as it could possibly point out fundamental aspects of the lesson series. Students' arguing scores on the post-test and students' progression can be found in Table 1.

Table 1

Students' arguing scores

Condition	Mean score on pre-test /10	Mean score on post-tests / 10	Mean progression
Group 1: business as usual	1.82	1.90	0.08
Group 2: limited lessons	1.72	2.45	0.73
Group 3: all lessons	1.85	3.51	1.66

The univariate analysis shows that condition has a significant impact on students' progression between pre- and post-test in arguing skills ($F_{(2, 698)} = 31.82$, $p<.001$). It shows that students in group 3 have a significantly better progression on arguing compared to students in group 2 ($t_{394} = 5.47$, $p<.001$) and group 1 ($t_{598} = 12.73$, $p<.001$). On the other hand, students in group 1 have a significantly worse progression on arguing compared to students in group 2 ($t_{403} = -3.92$, $p<.001$). Looking more closely at the subskills of arguing of group 3, frequencies show that average response to a historical question consist of (1) an own point of view (96.14%), (2) one or two arguments in support (respectively 58.95% and 31.58%), (3) one counterargument (25%), (4) a rebuttal (20.70%) and (5) several references to the sources (28.95%). This means that students' answers on a historical reasoning question are more elaborated after they received the arguing lessons.

Theoretical and educational significance

In the context of 21st century skills, arguing skills are important (Wineburg & Reisman, 2015). However, research shows that these skills are limited among students (Hulders et al., n.d.). Therefore, this study aimed to improve students' arguing skills. For this purpose, a lesson series was developed. Despite the implementation of the intervention in the pandemic, a significant progression of arguing skills between pre- and post-test was found among the students who had seen the arguing lessons. This is an important finding as it means that teaching materials can be used to improve students' arguing skills. Although group 3 had significantly better progression than group 2, their main score remained quite low. This means that historical reasoning is a complex skill.

Data-driven badge design for gamified learning app

Julian Langenhagen, Goethe University Frankfurt, langenhagen@econ.uni-frankfurt.de

Abstract: Although badges belong to the most used game elements in gamified learning tools, little is known about their optimal design. This poster will therefore discuss a data-driven approach to determine an optimal set of badges based on usage data from the corresponding learning tools. This approach will be tested with actual usage data from a learning app that was used for four semesters in a university lecture.

Introduction

Badges are among the most used elements in game-based learning (Antonaci et al., 2019). However, little is known about their optimal design in the educational domain. Optimal design in this context means that a badge can only be earned by following a learning strategy that leads to better learning outcomes. The inspiration for the design of badges in game-based learning often comes from entertainment games. However, the goals of such games are usually different from those of learning tools used in school or higher education (Loh et al., 2015). This difference also applies to commercial learning apps such as Duolingo. In Duolingo, for example, it is possible to earn a badge called "Weekend Warrior" if you use the app on a Saturday or Sunday and a badge called "Photogenic" if you upload a profile picture (1). These two badges are presumably intended to maximize usage time or identification with the app and are not necessarily aimed at an optimal learning strategy. Since designers of game-based learning tools may use such apps as a blueprint, they run the risk of copying badges that motivate non-optimal learning strategies. To date, no study has empirically investigated optimal badge design in a learning context. Easley and Ghosh (2016) only analyzed optimal badge design with a game-theoretic approach from a general and not an educational point of view. In their literature review, Antonaci et al. (2019) link the effects of game elements on learning outcomes in order to investigate the question of which game elements cause which effects. They find that some game elements can have either a positive or a negative effect depending on the context. The individual effect of a game element seems to depend on the specific setting, the other game elements used and the personality of the students. This result is also confirmed by recently conducted meta-studies (Bai et al., 2020; Huang et al., 2020; Sailer & Homner, 2020). They all report an overall positive significant small to medium effect size of game-based learning on learning outcomes. However, it is still unclear which factors contribute most to the success or failure of game-based learning. In addition, the meta-studies above shed light only on the overall effects of combinations of different game elements. A more in-depth analysis of different designs of badges (or other single game elements) does not exist yet. Facey-Shaw et al. (2017) provide an overview of different badges designs and their functions in various educational applications. Still, they do not link the different designs to the achieved effects on the learning outcomes. The present study will contribute to this research gap.

Data Sources & Research Strategy

The data set used in this study consists of usage data of a gamified learning app that has been in use for four semesters in an accounting course at a large German university. The app's core element is a quiz with over 550 questions covering all nine chapters of the course. In addition to the question types single and multiple-choice, there are also sorting and cloze text tasks. The students can collect learning points in the app to unlock more chapters and earn badges for different achievements. The use of the app is voluntary and no extra credits or advantages for the final exam can be earned by collecting points in the app. The required achievements to earn the badges include specific amounts of consecutive usage days or answered questions. The corresponding goals were developed based on learning theories and practical experiences from past lectures but without any empirical validation. In the four semesters that the app has been used so far, there have been no scheduled changes to the lecture design. The teaching staff, as well as the learning materials have remained identical. However, due to the outbreak of COVID-19, after two semesters the instructors were forced to switch from classroom lectures to online videos. The goal of this study is to use temporal and sequential analysis to classify the app users into clusters and match these clusters with the goals of the available badges. This will help answer the question of whether students who aligned their learning strategy to the given badge goals performed better on the exam. Based on the results, the basic direction (e.g., surface vs. deep learning) but also the levels of the badges will be discussed. For example, the badge for the number of answered questions in the current data set has three levels. The highest level is earned when a student answered 1,000 questions. Unless a large proportion of the top students answered that many questions in the app, you could conclude that the level might be too high. If the level is too high, earning that

 © ISLS

badge could even be a predictor for a bad performance in the exam, i.e., students who answer too many questions might overestimate the app as a learning tool and neglect other learning materials. Past studies have already shown that learning performance does not necessarily increase with learning time (Plant et al., 2005). In addition, the analysis might reveal optimal learning strategies that have not yet been incentivized by any of the existing badges.

Conclusion

The goal of this research project is to find an optimal set of badges for a gamified learning app. Given an optimal set of badges was found, the follow-up question is whether this set is valid for all four semesters. Especially the different teaching conditions due to COVID-19 could lead to changed optimal learning strategies. Prior studies have already shown that the explanatory power of a general model that predicts learning outcomes can differ significantly between different courses (Conijn et al., 2016; Gašević et al., 2016). To further contribute to the topic of portability, the results of the present study could be applied and compared to the settings of other researchers. In the current setting, no data about the personality type of the students was collected. As past studies have already shown that personality traits can play a decisive role in adopting a learning strategy (Matcha et al., 2020), this could also be a promising avenue for future work.

How a teacher's personal reflections shape her decision making for classroom management

Georgia Pelekanou, Loucas T. Louca
gp172545@students.euc.ac.cy, L.Louca@euc.ac.cy
European University Cyprus

Abstract: We investigate how a teacher's personal reflection shapes her decision-making process in classroom management. Following open coding, we analyze the teachers' reflections seeking to identify her rationale in the decision-making process during the language arts lessons. Our findings indicated that her thinking was based on the student's behavior, the student's personality, the educational context, her own emotional perspective and condition, her pedagogical knowledge, and her reflective experience. We discuss the theoretical and methodological implications.

Theoretical Framework

Teachers' personal reflection is a powerful professional development tool, which contributes to the improvement of educational practice, leading to positive educational change (e.g., Colwell et al., 2015). It can be adapted in several educational fields, such as classroom management, which is a process by which teachers establish a productive learning environment able to promote cognitive and socio-emotional development of all students (Evertson & Weinstein, 2006). It is described as a complex process, which requires continuous, immediate, and effective decision-making during educational practice (Aho et al., 2010). Adapting reflection in classroom management is associated with strengthening teachers' ability to reflect on their daily teaching work, making informed decisions for classroom management, addressing students' behavior, and it can result in a positive educational change for the school unit (Bilac& Milijkovic, 2017).

Although reflective practice has been recognized as an important element of the effective decision-making process (e.g., Allan, 2018), there is a lack of evidence about how teachers' personal reflection can guide a successful decision-making process (Lloyd, 2019) in classroom management (Aho et al., 2010). Therefore, there is a need to investigate our understanding of teachers' decision-making for classroom management and the elements that consist the teachers' rationale during the process of decision-making. Thus, the purpose of this study was to investigate how a teacher's (the first author's) personal reflection captures and shapes her decision-making process for classroom management during the language arts lessons during a school year, seeking to describe how her rationale in decision making is been constructed.

Methodology

This is a self-case study (Yin, 2017) utilizing action research strategies (Somekh, 2006). The participants were 11 first grade students of an urban primary school. We collected data during the Language Arts lessons for 7,5 months during 2019-2020 school year. The main source of data was 66 teacher's personal reflections before, during, and after teaching, around classroom management issues that occurred during her teachings. The first author identified 112 classroom critical incidents lasting 1-5 minutes during teaching that at the time they seemed interesting and memorable. We broke down the 112 critical incidents into 312 smaller units (sub-incidents) based on a teacher's response to a student's action. Then, we analyzed each line based on the Louca et. al (2012) 3-dimensional scheme structure. We coded the data related in respect to the way in which the first author thought, interpreted, and evaluated each student's action, including data from the first author's personal reflections, multiple readings of critical incidents, her research notes during the actual event, and memos during data analysis.

Findings

The analysis of the teacher's reflections revealed that the rationale of the teacher's decisions for her students' actions was based on six elements: (1) 18.59% of the cases were based on the student behavior (acceptable or non-acceptable); (2) 34.94% of cases were based on the student personal information such as family, language skills, social and cultural background; (3) 6.09% of cases were based on the educational context at the moment of the incident; (4) 6.41% of cases were based on the emotional perspective and the emotional condition of the teacher at the moment of the incident; (5) 23.4% of the cases were based on the teacher's pedagogical knowledge; (6) 10.58% of the cases were based on the teacher's reflective experience which was developed through the reflective process during the data collection period.

 © ISLS

The teacher's reflective rationale focusing on both acceptable or non-acceptable student's behavior included cases in which she thought responding to the issue on a personal or public level, to acknowledge the incident publicly or to publicly provide feedback to the student(s) involved, focusing on reinforcing the particular behavior for the whole classroom. In other cases, it was based on the information available to the teacher at the time of the incident that was related to the personality of the students involved in the incident. The teacher's response to critical incidents was also based on the educational context at the moment of the incident, and on her emotional perspective directly related to her personal characteristics, which guided her way of thinking. In some instances, the teacher's rational was based on her pedagogical knowledge, which included the teacher's knowledge from the relevant literature about classroom management, her previous experiences in managing student behavior, her pedagogical knowledge of classroom management and teaching methodology, as well as her understanding of her personal and professional limitations. Finally, the teacher's reflective rationale was based on her reflective experience which was built through the systematic reflection of her practice during the data collection period and included her knowledge from previous reflections on action (e.g., effective strategies in similar classroom management incidents), as well as her knowledge acquired from the management of a previous event through reflection in action.

Our analysis also revealed that in 13.74% of the total cases, the teacher's reflective rationale about the critical incidents emerged and resolved through a reflective conflict, in which the teacher reflectively examined her conflicting rationale about the way to respond to the incident. These instances included among others, cases in which the teacher misresponded to student's action in a previous incident which had a negative impact on the current incident, a student behavior was identified by the teacher as both acceptable and non-acceptable and cases that the teacher was thinking to respond to either non-acceptable behavior or depending on the teacher's knowledge of student's personality.

Discussion

Although our findings have some similarities with Aho et al.'s (2010) work, our research differs in a methodological and theoretical manner. In a methodological level, the action research strategies we used allowed us to describe aspects of the investigated area that could have not be visible by using other research strategies, leading to the development of better understanding about the process of classroom management (Somekh, 2006). Furthermore, the analytic structure that we used for the data analysis (Louca et. al, 2012) allowed the data to receive a second level of reflection and, thus, a deeper level of analysis, which let more pluralistic and detailed themes to emerge. In a theoretical level, we aimed to direct the attention to the connection among classroom management, the decision-making process involved, and the reflective practice, which lacks evidence. Hence, we contend that the classroom management through the reflective practice lens could lead to more informed, conscious, and student-centered decision-making, and better understanding of the theories and tacit knowledge that guide the teacher's thinking and actions in managing students' behavior.

Meeting People Where They Are Can Alter Where They Are

Sybille Bruun, Caroline Geithner, & Deanna Kuhn
ksb2180@tc.columbia.edu, ccg2155@tc.columbia.edu, kuhn@tc.columbia.edu
Teachers College, Columbia University

Abstract: Asking people to "think again" can have unexpected consequences.

A polarized society has become an ever-greater concern. As people continue to confine their interaction to the like-minded, all outside their chosen circle are seen as increasingly more distant, less understood, and less worthy of consideration. Exposure to views of the differently minded would seem the remedy, but it is at its best only modestly successful and risks further polarization, excessive certainty and confidence, and reduced complexity of an individual's thinking about the issue (Fernbach & Van Boven, 2021; Kuhn, 2020; Kugler & Coleman, 2020), in particular the tendency to account for complex phenomena in terms of a single factor (Johnson, Merchant, & Keil, 2020; Kuhn & Modrek, 2018, 2021; Lombrozo, 2007), "explaining away" others if they are considered at all (Lagnado, 2021; Tešić et al., 2020). A more recent approach suggests "meeting people where they are," by engaging them in discussion of their own view on an issue, by reflecting on, exploring, and clarifying this view. Or, as Adam Grant puts it in a New York Times Op-ed, to *Think Again,* the title of his book advocating the approach. It emphasizes careful listening and questioning, getting a person to talk about the specifics and the implications of their position. The objective is to lead them to a more nuanced, potentially less hardened view.

We wanted to try Grant's recommendations for ourselves, hoping to make those we talked to less certain in their commitment to their position and more open to further examining it and considering alternatives, potentially leading to enriched, more multi-faceted thinking about the issue. We sought an issue that did not submit readily to easy, single-factor solutions and chose this: *"What should be done about the problem of young people brought to the US illegally as children; should they be allowed to stay or sent back*? Law-and-order hard-liners can easily justify their *Send-back* position based on the single factor of upholding law. Are progressives more open to thinking further? The very term 'progressive' suggests so. Progressives favoring the *Stay* position must work harder to justify this position, and therefore we chose to talk to this group (who dominated their politically progressive urban locale). *Stay* proponents must bring together two competing sets of considerations –those of the society and its laws and those of an individual who did not knowingly violate them. Single-factor thinking that ignores one of these has not fully addressed the issue. Addressing it requires the richer, more nuanced thinking about a difficult sociopolitical issue that we hoped discussion would encourage. We were therefore surprised by our findings.

Participants were 61 community adults approached in various public places in a large US city. Genders were equally represented and 64% reported having graduated from college. We asked individuals to explain their *Stay* position, encouraging them to elaborate, and included these follow-up questions:

What about their parents who brought them to the US? Should they be allowed to stay?
What about grandparents who want to keep the family united?
What about aunts and uncles and other relatives who would like to stay too?
What about others not related but close to the family?

For half the sample (condition E2), these questions were asked first, before seeking explanations. All were also asked how strongly they felt about the issue and how certain they were regarding this position, each on a scale 1-10.

Contrary to our expectations, these individuals did not tackle the complexity these questions invoke, to arrive at a more nuanced, richer position. Instead, they simplified their *Stay* position. Over 90% favored extending residency to grandparents, over 80% to aunts and uncles, and roughly half to unrelated persons close to the family (Table 1) .

A majority (73%) offered only a single factor or consideration (e.g., "they've worked hard") to support their position. Rather than becoming elaborated and enriched, their thinking became simplified and single-dimensional. Strength and certainty ratings were uniformly high in both Conditions E1 and E2, with median ratings of 10 and negligible change following interviewing.

Two additional groups of 50 participants served as control groups, one from the same community population as the main sample and the other solicited from Mechanical Turk. Both were similar demographically to the main sample, with genders equally represented and 64% and 56% respectively reporting having graduated from college. Control conditions differed from the experimental conditions in two ways. First, participants were asked to indicate

 © ISLS

their position but were at no point asked to justify or explain it in any way, on either the main question or the follow-up questions. Second, they had no interpersonal interaction with an interviewer. In control condition 1, a sheet was handed to passersby in the same locations as those in the experimental condition, asking them to indicate their answers on the sheet and then deposit it in a box that sat nearby. Those in the second (Mechanical-Turk) control condition responded online and were asked only the middle (aunts-and-uncles) question.

Table 1. Proportions of Participants Responding Yes to Follow-Up Questions by Condition

	Condition E1	Condition E2	Control Condition 1	Control Condition 2
Parents stay?	100%	100%	94%	
Grandparents stay?	90%	94%	88%	
Aunts & uncles stay?	83%	81%.	62%.	56%
Close others stay?	43%	55%.	28%	

Why did further contemplation lead the experimental groups to become more positive and generous in their responses to the follow-up questions than they presumably would have been prior to the interaction (as indicated by the control group responses)*?* Why did a majority assert that anyone from the aunts and uncles of undocumented youth to anyone else who knew them be granted residence, a view at striking odds with US immigration policy as well as public opinion? "Did our participants really believe what they were saying?" we wondered.

Coordinating the perspectives of stakeholders who have competing positions on an issue is a cognitively demanding task. In the case of this issue, law-and-order conservatives understandably might be less inclined, but who better than those who champion progress would be more up to taking it on? Yet our politically progressive sample most often took the cognitively easier path of simply extending their *Stay* position to broader and broader groups, rather than invest the mental effort that constructing and justifying distinctions requires. One explanation is cognitive laziness (Stanovich, 2011). Another is self-presentation. Having taken a position and elaborated on why it was the right one, one ought not appear uncommitted or inconsistent, especially to someone unknown.

Our intention had been to enrich more than change people's views. Should our findings be taken as discrediting the strategy of meeting people where they are? We maintain not. Where better to meet them? But we may need to develop more nuanced approaches to the discussions we engage them in. Our findings also have implications for public opinion assessment methods, which may need to become more cautious than is typical.

How do learners use in-game learning support in digital game-based math learning?

Chih-Pu Dai, Fengfeng Ke, Yanjun Pan
cdai@fsu.edu, fke@fsu.edu, yp10d@my.fsu.edu
Florida State University

Abstract: Learners often encounter difficulties in constructing knowledge in digital game-based learning. In-game learning supports offer in-situ guidance for knowledge-constructive gameplay. Yet, how learners use learning supports are still inconclusive. With a mixed methods study, we investigated learners' varied usage of different learning support features in digital game-based math learning. Preliminary findings with 22,615 speech utterances of thirty-four students revealed seven clusters of learning support use.

Introduction and theoretical background

Digital game-based learning environments are open-ended problem solving spaces that can be used as a sandbox for disciplinary practice, experiment, and exploration. In such learning environments, learners are given a high degree of agency for knowledge discovery and construction (Ke, 2016), whereas oftentimes learners encounter problems that lead to unsatisfying learning outcomes (De Jong & Van Joolingen, 1998). In-game learning support and scaffolding that offer in-situ guidance are critical to sustain learners' efforts to regulate planned and systematic discovery, reflections, and sense-making (Chang et al., 2008; De Jong & Van Joolingen, 1998). The types of learning support and its effects have been explored in the literature (Chang et al., 2008; Puntambekar & Hubscher, 2005). However, how learners use learning supports are still inconclusive (cf. Roll et al., 2014), especially in digital game-based math learning.

Without an understanding of how do learners use learning support when experimenting and discovering in digital game-based learning environments, the design of learning support may not meet the learning needs. Thus, this exploratory study aims to address the following research question*: how do learners use learning support features in digital game-based math learning?*

In-game learning support research has been dominantly focused on cognition and meta-cognition by depicting the "*whats*" (i.e., the content knowledge). Using learning supports for knowledge development of *why* and *how* to learn math during gameplay is also crucial to make learning personally meaningful (cf. Jankvist, 2009), yet has been largely underexplored. In this study, we investigate two types of learning supports featuring different knowledge in game-based math learning. *Task planner* is designed to assist learners' systematic and planned efforts for math problem solving, or *hows*. *Math story*, featuring historical stories and real-life applications of math concepts, is a support feature aimed to scaffold the understanding of *whys* of learning math (Jankvist, 2009).

Method

A convergent mixed methods study was conducted to address the research question by validating findings with both quantitative and qualitative techniques (Creswell & Plano Clark, 2018). We collected data from 34 college students who used two types of learning support (i.e., *task planner* and *math story*) in a math learning game called *E-Rebuild*. Each participant completed a two-hour gameplay, think aloud (in-situ gameplay speech), and semi-structured interviewing (gameplay speech and learner experiences) session. The data were in the form of video- and audio-recording; they were then transcribed verbatim by a professional speech-to-text service and reviewed by human coders. These transcriptions were served as text-based speech data for natural language processing and subsequent analysis. The preprocessing raw data consisted of 22,615 speech utterances (208,649 words).

We used unsupervised machine learning techniques with k-means cluster analysis for data-driven exploration of how did the learners use learning support in this study. Toolkits in *Python* (i.e., *pandas* and *sklearn*) were used. For example, speech data were vectorized into computer-recognizable features for extraction and used for nested (clustered) analysis based on the keywords. Qualitative data were analyzed through open coding. The data collection and analysis are ongoing; we present preliminary and tentative findings in this proposal.

Findings

The text-based cluster analysis validated by qualitative analysis revealed seven preliminary and potential clusters that the learners have used and interacted with the learning support features. For *task planner*, learners were found to use it for procedural problem solving, meta-cognitive awareness, and reflection. For *math story*, learners used it for reflection, reasoning, motivational support, and conceptual learning.

 © ISLS

Table 1
The preliminary results of the cluster analysis supported by qualitative analysis for learning support features

Text-based clusters	Text-based cluster instances by key words (*italicized*)
Task Planner-Procedural Problem Solving (20%)	Like sort of *guide* you through those *steps* of how to do it.
Task Planner-Meta-Cognitive Awareness (13%)	I just needed, like *a reminder*, like I haven't ran into similar problems like this before. I just need to see like how to solve it.
Task Planner-Reflection (11%)	I *think* it gives you like the exact math of what you're doing so you can see how the volume of one *relates* to the volume of other, and then how you combine that information.
Math Story-Reflection (19%)	The families one, that's probably where I saw the most *connection,* and the ratios, like the two to one family ratio one and then, how I forgot what it was one of the civilizations that are talking about it was Egypt, how they use the fraction…computations…just like to see the overlap.
Math Story-Reasoning (16%)	It (Math Story) *explains* the different symbols and what numbers they stand for in hieroglyphs…it shows another way of like doing simple math. Like these symbols and everything…students have to go back (to the game) and see what each symbol stands for and multiply that by whatever it's asking.
Math Story-Motivational Support (15%)	It's just *fun* to…like it was just *interesting* to watch it; the math story is definitely *interesting*...it adds to *the beauty of math*.
Math Story-Conceptual Learning (6%)	(Math Story: "completing the square" method) Like the shape revealing algebra…I *don't really know* that *before*.

Discussion and conclusion

In this study, we empirically investigated learners' usage of learning supports featuring different types of knowledge development in digital game-based math learning. Preliminarily, in alignment with prior research findings, learning support of *task planner* was found to support learners' exploration of cognitive and meta-cognitive problem-solving strategies (De Jong & Van Joolingen, 1998). *Math story* appeared to support learners to explain and make connections between the game tasks and math concepts. It also supported learners' motivation to learn and supplement pedagogical values to the existing digital game-based math learning.

The Power of Gestures: Video Club to Support Teacher Awareness of Gestures as a Form of Multimodal Science Instruction

Blue, Laura, Pierson, Ashlyn
bluele75@gmail.com, ashlyn.e.pierson@gmail.com
The Ohio State University

Abstract: Teacher candidates attend to many responsibilities and interactions during lesson enactment. Video club (Barnhart & van Es, 2020; Jilk 2016) can narrow reflection to focus on specific aspects of teaching. This study explores the power of video club to develop awareness of multimodal resources, such as gestures. We analyze data from a science methods course, finding that video club makes visible teachers candidates' subconscious gestures and can position gestures as resources for inclusive science teaching.

Objectives and significance

Gestures offer powerful representations of science that promote understanding (Herrera & Riggs, 2013; Johnson & Cotterman, 2015; Williams, 2020). Yet, the complexity of teaching can prevent teacher candidates (TC) from noticing the subconscious gestures that they use to support learning and the gestures that students use to express understanding (Johnson & Cotterman, 2015). To this end, we ask: How can video analysis help science TCs see their gestures and students' gestures as powerful learning tools that support student sensemaking? This paper illustrates the power of video as a reflective tool for TCs to notice and leverage gestures, focusing on how video club (Barnhart & van Es, 2020; Jilk, 2016) can be used to draw attention to gestures as ways to support science learning by: (1) creating safe spaces for students, (2) directing attention, and (3) representing science concepts.

Method

Data for this study comes from a middle childhood science methods course at a large university in the midwestern US (20 students total). As part of the course, TCs participated in video clubs in which they selected short video clips of their teaching (3-4 minutes) from their field placement to watch and discuss in small groups (five TCs and a facilitator from the research team). We use pseudonyms that were chosen by TCs to represent themselves. In this paper, we focus on one video club in which a TC, Luke, shares a video clip. The facilitator (Blue) noticed the significance of gestures in the clip and focused the discussion on the role of gesture. The video was watched one time through without interruption. During the second playback, the video was repeatedly paused for discussion (Johnson & Cotterman, 2015). At the conclusion of video club a brief survey and semi-structured interview captured TCs' key "take-aways" from the experience. Interaction analysis and inductive coding were used to explore how video club supported teachers in noticing how gestures can be used to support science learning (Charmaz, 2006; Jordan & Henderson, 1995).

Findings and discussions

Our analytic focus on gesture emerged from a video club segment where Luke used her hands to talk about tectonic plate movement. She described these gestures as subconscious: "I also talk with my hands, that's just happening, it's subconscious." We show how video club helped Luke and her peers focus on these subconscious gestures as resources for learning that they could leverage intentionally in their future teaching. We propose that video club allowed TCs time and space to slow down and see gestures that they might not have noticed in the moment as they were teaching. Here, we focus on how viewing and discussing the video helped TCs attend to gestures to support learning by: (1) creating a safe space for students, (2) directing attention and (3) conveying scientific information.

First, TCs attended to gesture as a means to create a safe and inviting space for students. Abbey commented "Your body language was really positive. Of just like 'come on up.' I feel like that's kind of underestimated in teachers today, like creating that safe space for kids." Blue built on this comment by asking how body language might affect class dynamics. Elton replied, "I notice what Luke's doing. She's spending more time facing outward, towards them, her arms out giving a very open, welcoming body language." Additionally, Elton interpreted the body language of students as providing valuable feedback to Luke regarding student engagement: "While the students, instead of having their back to her and looking behind their shoulder, they're actually turned towards her. So that shows that

 © ISLS

they're engaging because their bodies are towards her." Second, Xavier noticed that gesture could help students connect to content. He paused the video to note that Luke's body language helped direct students to a pictorial representation of plate boundaries, saying: "I think that sort of positioning (Luke turned towards the screen) gives students a cue to kind of also put their attention on that graphic." Third, Blue explicitly connected gesture to science concepts. She pointed out that Luke brought her hands together to illustrate a convergent plate boundary, then moved them apart to demonstrate a divergent plate boundary, while at the same time verbally emphasizing the prefixes of each word to bridge hand motion to new science vocabulary (Williams, 2020). In this way, Blue offered TCs a lens for seeing gestures as visual representations of science content to support student understanding.

Prior to video club Luke identified her use of hand gestures as being "subconscious." Video club allowed Luke and the other teachers in their group to attend to gestures as resources for learning and to consider intentional uses of gestures in their future teaching. The impact of gestures was evident through its emergence as an analytic focus during the last two video clubs. It also surfaced during interviews where three of the five TCs referenced gestures as memorable. Lindy stated, "Body language was something I recognized a lot in others' videos and my own." Xavier described how he embodied Luke's movement in his field placement, "I am more of, like, a lower energy kind of presence in the classroom. So, like that next week, like I tried to step it up a little bit. You know, I had a little extra coffee and moved around a lot more." Xavier's effort to enact movement in his own classroom is evidence of the impact of video club on his teaching.

Conclusions and implications

Our data demonstrate how video club can help TCs see the power in gestures, elevating them from subconscious motions to resources that can be intentionally used to support learning about science concepts. Video club allows TCs time to pause and reflect on this singular aspect of teaching, even though they may have been attending to other elements as they were teaching. Our findings suggest that video clubs could be used to support noticing and reflection about gestures in this and other contexts (science education courses, professional development), which could support effective and inclusive science teaching.

Using Electronic Textiles to Visualize the Loss of Tribal Lands Over Time

Kristin A. Searle and Liam Fischback
Utah State University
Kristin.searle@usu.edu, lfischback@gmail.com

Abstract: This poster shares the design and development of a data visualization project that brings together social studies, Indian Education For All, and computing to center understanding of the loss of tribal lands by the Blackfeet Nation in Montana. Students utilize Circuit Playground Express microcontrollers to program LEDs representing the percentage of original (pre-contact) tribal lands still owned by the Blackfeet Nation at various points in United States history.

Introduction

There is growing interest in incorporating data science into K-12 education. When students engage in understanding, analyzing, and making inferences from data and data visualizations, they are developing data literacy skills. While data literacy involves math, science, and computing, it is frequently situated within social studies. In the United States, the National Council for the Social Studies (2015) College, Career, and Civic Life (C3) Framework has a focus on geography, including the construction and use of maps, graphs, and other data visualizations. By the end of fifth grade, students should be able to know how to use and construct maps and other representations of data. In this data visualization project, we are focused on fourth and fifth grade social studies standards in the state of Montana and Montana's Indian Education For All curriculum.

Background & Project Design

Data visualization in social studies can be used to support the factual histories teachers want to engage their students in (Naimipour et al., 2020). Particularly when these narratives are not the dominant narratives in U.S. history data visualization can be a powerful tool to counteract more dominant narratives, such as those of Westward expansion and Manifest Destiny. For students, making sense of second-hand data can still be a meaningful experience connected to one's own sense of race and place (e.g. Wilkerson & Laina, 2018). Further, Lee and colleagues (2021) present a three-part framework for thinking about how students engage data across the curriculum. They suggest that such engagements can be meaningful personally, culturally, and socio-politically.

The goal of the Shrinking Lands Project is to get fourth and fifth graders in Montana to think about how tribal lands were impacted by treaties with the U.S. government and to visually represent the percentage of indigenous lands occupied by each tribe in the state of Montana today. This project is part of a larger undertaking that intends to bring together Montana's Indian Education For All curriculum with the state's new computer science standards through curricular integration across content areas. The Shrinking Lands project is part of a curricular unit focused on the assimilation, termination, and relocation of Montana tribes. Students are tasked with selecting 3-4 significant treaties for one of the 12 tribes in Montana and then using LED lights programmed with a Circuit Playground Express microcontroller to visualize what percentage of indigenous lands remains after the signing of each treaty. For instance, Figure 1 depicts data for the Blackfeet Nation. The small, gray area represents the present-day lands of the Blackfeet Nation and it is such a small percentage of indigenous lands that it does not even merit an LED light. This design method can easily be adapted for other Indigenous nations in the United States and elsewhere in the world.

The quantity of land held by Montana tribes is readily available through the United States Geological Survey and the websites of individual tribal nations. Because some treaties are over 150 years old, most sources only provided maps of lands held by tribal nations before and after treaties. As this project displays the history of lands held by Native American tribes, we used sources available on tribal websites to obtain land treaty maps from 1850 to the present. Maps of each treaty were used to create proportional maps made of felt, and to calculate the area of each land treaty map. Using the land treaty maps for each tribe in Montana, we then superimposed the maps on google earth and used the measure function to calculate the land area in square miles. After calculating the land area associated with each treaty for each nation, we divided the data by nation to prepare the data to be transformed into ratios that can be displayed using LED lights and the Circuit Playground Express.

 © ISLS

Figure 1: Shrinking Lands of the Blackfeet Nation in Montana.

The Circuit Playground Express board features eight programmable ports than can be linked to external lights, which students will use to display changes in land area over time. Using the square miles of indigenous lands as a base, we standardized the ratio for each tribe to be 10/10 and then calculated the ratio of land that remained after each treaty. Because each light represents a ratio of 1/10 of the land area of indigenous lands for that tribe, we rounded each ratio to a whole number. With this standardized ratio, we then took the difference between the area of the indigenous land area ratio and subtracted the land area ratio of the first treaty. The difference between the two land areas equates to the ratio of tribal lands that were lost due to the first treaty. We then performed this same calculation with each subsequent treaty (e.g, treaty 1 land area ratio – treaty 2 land area ratio = ratio of land area taken by second treaty. When this final ratio was calculated, we assigned the corresponding ratio of lights to each treaty land map to display the ratio of land that the treaty reduced tribal lands by.

Educational Implications

Indigenous peoples are an important and overlooked aspect of United States history and that of other settler colonial nations. Developing tools that support youth in thinking through non-dominant narratives is imperative for promoting understanding and empathy across difference. Further, for Montana's Indigenous students, this project provides a way to connect with their own tribal and familial histories.

Using Delivery Simulation Experiences in Hiring in the Technology Field

Stephanie Weber, University of Nevada - Las Vegas, webs@websonthewebs.com

Abstract: Technical assessments and interviews are a unique facet of the technology field. Unfortunately, they have gaps that lead to frustration for candidates and result in companies missing top talent. I propose using delivery simulation experiences to better assess and meet the needs of a modern workforce.

Introduction

The recruiting and hiring process is rife with challenges. Some of the issues are found in all fields; for example, over and underemployment (Kulkarni et al, 2013), inclusion (Nota et al, 2013), and implicit bias (Fisher, 2018) are not unique to the technology field. However, there are some problems that are more unique to the technology field. One such problem is technical interviews. Using the connectivist lens, this paper will examine the traditional technical interview process and a theoretical alternative - the delivery simulation experience.

Why use connectivism

Developing software and the problems being solved within the tech industry are complex problems. As Siemens (2006) points out, with increased complexity, in order to solve problems, the knowledge to do so resides in the collective. Connectivism addresses the pace at which knowledge is constructed and changes in a modern society (Siemens, 2006).

Delivery simulation experiences

Delivery simulation experiences are mock environments where candidates work alongside their prospective team for some fixed amount of time and the work being done reflects the actual work that would be done and problems that would be solved in the job for which the candidate is applying. Table 1 presents a comparison of the traditional technical interview compared to delivery simulation experiences through the lens of connectivist principles.

Table 1

Comparison of traditional technical task/interview and DSEs using connectivity principles

Connectivist Principles (Siemens, 2006)	Traditional	DSE
Decision making is learning. Learning is a network of specialized nodes that requires a diversity of opinions to choose the best approach and knowledge may reside in non-human appliances, and learning is enabled/facilitated by technology.	In take home technical challenges, the candidate may use existing technological resources like previous projects. In in-person technical interviews, the candidate is expected to have all the knowledge to solve the problem or answer the question (Behroozi et al, 2019; Chrupcala, 2021; Morahg, 2021).	Candidates may use any of the technological resources typically used during the team's day-to-day activities as well as tools with which the candidate is familiar. They may also take advantage of the team and specializations (e.g. product specialists and designers) to inform decisions.
Learning and knowing are constant, on going processes (not end states or products). Currency (accurate, up-to-date knowledge) and capacity to know more are the priority and the intent of all connectivist learning activities.	Capacity is focused on and limited to what the candidate currently knows (Behroozi et al, 2019; Chrupcala, 2021; Indeed Editorial Team, 2021; Morahg, 2021).	The intent of a DSE is to assess how a candidate uses and seeks knowledge to fill knowledge gaps. The team and candidate are engaged in the process of learning as they work through the problem together in search of a solution.

 © ISLS

Connectivist Principles (Siemens, 2006)	Traditional	DSE
Ability to see connections and recognize patterns, choose what to learn, adjust to incoming information, and make sense between fields, ideas, and concepts is the core skill for individuals today. The right answer now may be wrong tomorrow.	Technical assessments are presented largely in isolation. The purpose is to test the candidate's individual knowledge. Presented with a problem that gives the candidate an opportunity to showcase these skills, this can be done in a traditional technical interview (Chrupcala, 2021; Indeed Editorial Team, 2021).	The work being done in a DSE reflects authentic work because DSEs are collaborations. There are opportunities for the candidate to demonstrate connections and adjust to new information not only with fields and ideas, but with the hiring team.

Conclusion

Delivery simulation environments can't replace the entire hiring process. They can provide an opportunity for both candidate and team to assess one another on more realistic and holistic terms. DSEs have the potential to be a better fit from a connectivist perspective than the traditional technical task or technical interview. More research is needed in order to explore and collect evidence to better understand what DSEs have to offer.

Professional Learning to Promote Three-Dimensional Teaching Using Computational Modeling in Remote Classroom Contexts

The Concord Consortium

Abstract: This study explores how to support teachers in developing and implementing effective pedagogical strategies to promote students in making sense of phenomena through computational modeling in remote contexts. Qualitative analyses of eight teachers' interviews were conducted to characterize their pedagogical strategies to achieve three-dimensional learning. Findings indicate that typical teacher strategies include the teacher and students co-constructing a model and using whole class or group discussions to support students' modeling practices.

Introduction and theoretical framework

The central notion of three-dimensional (3D) learning is that learners should understand science as a specific way of knowing and should develop capabilities to both understand and apply appropriate strategies to solve problems (National Research Council, 2012). We developed a Professional Learning (PL) program by integrating the crosscutting concept of *systems and system models* with the science and engineering practice of *developing and using models* and disciplinary core ideas selected by teachers to support teachers in the complexities of teaching remotely with open-ended modeling tools to support 3D learning. Based on project-based learning theory (Krajcik & Shin, 2022), we posit that teachers are themselves active learners and that they too should employ the same 3D learning goals as their students, especially as they learn new technologies and learning activities to bring to their classrooms. This study investigates two research questions: 1) What PL design principles could be applied to develop a PL program for supporting teachers to incorporate open-ended modeling tools in remote learning contexts? and 2) What pedagogical strategies do teachers adopt and adapt from the PL and use to promote student 3D learning in remote open-ended modeling learning contexts? Seven design principles and associated strategies from the PL program are reported in major findings and discussion.

Methods

The participants were 13 teachers from 1 elementary, 1 middle, and 11 high schools in 3 states from the eastern U.S. The content focus of the PL was on 3D learning using a web-based systems modeling tool called SageModeler (https://sagemodeler.concord.org). Thirteen PL sessions throughout the 2020-21 school year were held over Zoom. We conducted interviews with eight teachers who implemented an integrated computational modeling curriculum in their remote classroom contexts. A thematic qualitative analysis (Braun & Clarke, 2006) was employed to characterize teachers' pedagogical strategies used to promote 3D learning, as well as any adaptations of the PL design principles (DP) behind them. Two researchers discussed all codes to meet 100% agreement.

Major findings and discussion

Strategies associated with DP1, *Use collaborative activities among researchers and participants,* include a) foster collaboration between participants as colleagues with similar or shared goals; b) build community between researchers and participants and among participants; c) engage in collaborative activities among researchers and participants working in small groups (2-3 teachers by subject or grade and 1-2 researchers); d) introduce teaching and learning strategies from researchers ("top down") and encourage participants to share pedagogical tips ("bottom up"). All teachers responded that they highly valued the collaborative activities they experienced, including building system models together, discussing their plans with researchers and peers, and sharing resources with each other. Teachers went on to design collaborative lessons for their students around building models together and giving feedback to peers' models.

DP2, *Demonstrate pedagogical strategies*, and DL3, *Include active construction of tangible products,* are grouped together because the pedagogical strategies focus primarily on teaching about and with models. In

 © ISLS

the PL, researchers were explicit about pedagogical strategies—e.g., describing the "teacher moves" they were making and the reasons for those moves—as they involved the teachers in actively constructing models. All eight teachers used pedagogical strategies they experienced in the PL program, indicating that the explicit modeling of strategies was successful in embodying ways teachers could work with their students. For example, teachers demonstrated the computational modeling process with SageModeler as an example for the whole class by first working together to construct an initial model in a whole class discussion, then having students build their own models (individually or in groups) and holding whole class or group discussions to support students in revising their models. Teachers asked questions to link their students' prior experiences (e.g., lab activities, videos) as they learned key concepts in order to support them in revising their models.

DP4, *Provide individualized support*, DP5, *Scaffold with learning technologies*, and DP6, *Sustain professional learning over time* fall under the common theme of supporting participants' learning. All teachers received individualized support through the PL program by a) working one-to-one with a researcher to meet individual needs as well as working with other participants who have similar questions or modeling challenges; b) receiving just-in-time support; and c) having ongoing support related to their needs for integrating a computational modeling tool into their teaching practices. As they had experienced in the PL, all teachers tracked their students' modeling progress, diagnosed issues or difficulties, and discussed them with the whole class, a group, or individually, depending on the situation. In order to support a wide range of students in classroom contexts, the main pedagogical strategies used across teachers were to avoid framing specific answers as "the correct answer" (e.g., indicating a specific model was "the right one") and to be flexible regarding the kind of model they accepted as "good" (e.g., scientifically appropriate for the phenomenon being studied).

DP7*, Engage 3D learning goals,* and DP8, *Use relevant phenomena,* strategies include inviting teachers to model phenomena relevant to their lives or to their teaching contexts and providing them with driving questions (DQs) to guide their exploration with SageModeler. They also used collaborative documents such as Google Documents and Jamboards to explore DQs during the PL. These activities focus on 3D learning goals to provide opportunities for participants to integrate target DCIs and CCCs with SEPs to explain phenomena. In implementing 3D teaching and learning materials using SageModeler, all teachers used phenomena relevant to students in various ways: daily experiences, lab experimental activities, or field trips to link students' prior knowledge and pique their interest in the learning goals. Teachers reported that starting with a DQ supported a continued focus on 3D learning goals and helped define the system boundaries for the models.

Conclusions and implications

Across teachers we interviewed, they commonly used three pedagogical strategies: 1) questioning students about their models, 2) holding class and group discussions, and 3) grouping students to build and revise models. A common pedagogical strategy to support 3D learning was to facilitate teacher-led or student-centered discussions using student models as referents. However, some teachers disclosed that they need both additional guidance in providing differentiated materials to their students with varied learning needs and examples of high-quality curricula integrating 3D in classrooms. Additional pedagogical strategies (e.g., by grade level and lesson topic) are needed for teachers to be able to support students' revisions through testing and debugging their models.

Emotion objects: An embodiment of learning socioscientific issues with heart

Jessica Shuk Ching Leung, The University of Hong Kong, leungscj@hku.hk
Maurice Man Wai Cheng, The University of Waikato, maurice.cheng@waikato.ac.nz

Abstract: This multiple-case study examined students' patterns of emotion objects and their learning of obesity as a socioscientific issue. We tracked the emotion objects of four university students over a 12-week general education course on obesity. We found that students with different depth of learning had distinguishable sets of referents of emotions. This paper points out the need to attend to and specify emotion objects as a key variable in future research regarding emotions.

Introduction

Emotions play a role in our learning of an issue and our interpretation of what to do about the issue (Moors, 2014). Emotions are *about* something (Keltner & Lerner, 2010). For example, when we are angry, we are angry *about* a specific referent, such as an event, or something that someone has said or done. Following this logic, there are at least two key elements of emotions in operation. One is the emotion *per se* (i.e., what is the emotion?). The other key element of emotions is their referents (i.e., what is the emotion *about*?). Being specific about referents would help us better understand students' emotions. Although the referents—the *aboutness*—of emotions are known as emotion objects, they do not only refer to physical objects. They can be a variety of phenomena, problems, information, concepts, stakeholders, or experiences.

Foregrounding emotion objects is particularly important in learning socioscientific issues (SSI), which are inherently complex, demand on-going inquiry about ideas and phenomena related to the issues over an extended period of time, and involve perspective-taking. These features mandate that even examining a single SSI involves different phenomena, problems, information, and concepts (Zeidler et al., 2019). When making decisions about strategies to address obesity, students need to consider what is good/bad, just/unjust, and right/wrong from the vantage points of various stakeholders, and reflect on their notions of caring and concern for others. In this sense, having emotions about these emotion objects could be a target of learning (Vea, 2020).

Besides examining students' reasoning (i.e., learning SSI with heads), it is also important to identify the ways that their decisions relate to their emotions (i.e., learning SSI with hearts). The concept of emotion objects allows us to identify a variety of emotions with specific referents, which goes beyond discrete emotions of generic referents. Based on our findings of students' conceptual changes about obesity as an SSI, as manifested in adhering less to a reductionist view about obesity and more to a systems view that consider political, marketing, socioeconomic, technological, and cultural dimensions (Leung & Cheng, 2020), our research question was: "For students with different extents of conceptual change, in what ways did their emotion objects differ?

Method

From a cohort of 114 students who took the university general education course on 'obesity', we purposefully selected two students who demonstrated significant conceptual change and two demonstrated little change. This multiple case study (after Yin, 2018) relied on multiple sources of data to answer the research question.

Weekly reflective journals (time span: 12 weeks)

Throughout the course, the students kept a weekly journal to record their reflections on learning about obesity. Open and iterative coding was performed for emotion objects and the associated emotions. The coding and analysis process involved several rounds of collaborative discussion and refinement. Discrepancies were discussed until consensus was reached.

Follow-up interviews (time: six months after the course)

We conducted individual semi-structured interviews with all those who indicated that they were available. These interviews probed a deeper understanding of the emotions experienced in their learning about obesity. Four cases were selected from these interviewees for the contrasting observations we made of their post-course survey, in which they were asked the extent to which they would assign responsibility for obesity to each of the following categories: government, the food industry, science and technology, society, and individuals. Sylvia and Syrus (all pseudonyms) only assigned 10% of the responsibility to individuals. With the support of other data also, they were regarded as holding a systems-level view of obesity. Reynold and Rebecca assigned 50% of the responsibility to individuals, suggestive of a more reductionist view about obesity. After developing an emotion

 © ISLS

profile for each case, we conducted a cross-case matrix analysis (Miles & Huberman, 1994) to reveal similarities and differences among the four participants.

Major findings

Social phenomena

Sylvia expressed helplessness and worry about phenomena. These negative emotions were often accompanied by her action tendency in response to the concerned issues. A similar pattern was also observed in Syrus.

> I have never imagined the influence of the business sector on policy making or public education and feel helpless about that. As a citizen, I recognize the responsibility to be critical about different information … (Week 3, Sylvia)

In contrast, despite expressing her helplessness about phenomena, Rebecca did not demonstrate any action tendency.

> Such a potential problem does cost a lot to society, undoubtedly some measures are needed to ease this obesity trend ... However, most of the measures are not very effective… (Week 12, Rebecca)

Stakeholders

Another key expression by Sylvia was empathy for the obese, which was also noted in Syrus's reflections, but neither Reynold nor Rebecca expressed such emotions.

> Obese people *suffer* a lot from mental burden owing to our *prejudice and misunderstanding*... Sometimes they have no choice about being obese … but they are *born to be forced to accept teasing* by others ... Respect should also be given to obese people for they are also born to be protected by universal human rights. (Week 10, Syrus)

A key stakeholder within obesity is the obese. While both Sylvia and Syrus expressed empathy for the obese, Reynold and Rebecca expressed little emotion about the obese in their reflections.

Discussion and conclusion

This study found that students who underwent significant conceptual change demonstrated a specific set of emotion objects. These emotion objects included obesity as social phenomena and the obese people as key stakeholders. We found that those who demonstrated little conceptual change did not tend to have emotions about these social phenomena and stakeholders.

In this sense, identifying emotion objects is important not only to enhance our understanding of student emotions but also to make better sense of their learning. That is, emotion objects are a key variable associated with their success of learning SSI. As our data shows, these emotion objects are indicative of what matters to students. The findings of this study offer valuable insights that can guide future teaching on learning SSI with hearts by directing students to specific emotion objects at stake to the SSI.

Fostering TPACK via Idea Improvement in Teacher Education

Chih Hui Seet, National Chengchi University, 105152014@mail2.nccu.tw
Yu-Hui Chang, National Sun Yat-sen University, yhc@mail.nsysu.edu.tw
Guo-Tsai Hung, National Taichung University of Science and Technology, barryhuck@gmail.com
Huang-Yao Hong, National Chengchi University, hyhong@nccu.edu.tw

Abstract: This study examined 38 pre-service teachers' ideas regarding TPACK development in their lesson design during online discussion. Data include all discourse posts and the findings showed three main kinds of idea development processes existing in teacher's discussion. Such results indicate that to help advance teachers' TPACK, teachers' idea development must go through an integration process instead of stagnating at a diversification or elaboration stage.

1. Introduction

In many Asia countries with an examination-oriented culture and a rigid administration atmosphere, teachers tend to be teacher-centered and traditionally, covering more concise and pragmatic-use knowledge for school tests or nationwide exams. Lately, there has been an education reform in the curriculum guideline in Taiwan: putting the learner at the center of teaching and encouraging teachers to co-design lessons interdisciplinarily. Teachers now are asked to move away from being merely a lecturer to becoming a designer in organizing and integrating their teaching into a technology-enhanced learning environment in the post-pandemic era. Recent research also suggested supporting pre-service teachers' understanding of the connection between TPACK and their practical development is critical (Tondeur et al., 2020). Therefore, teachers must immerse themselves in sustained idea improvement processes (Hong & Sullivan, 2009) while co-designing lessons. These processes include idea diversification to enrich idea quantity, idea elaboration to enhance idea quality, and idea integration to innovate or rise-above ideas to advance knowledge. However, it is not easy for teachers to suddenly shift their teaching mode in response to the reform due to long-term habits. Under this background, our research aims to reveal how pre-service teachers develop ideas to build on TPACK knowledge. The research questions concern: In pre-service teachers' discourse, what is the idea development process, and what frequency of TPACK related ideas are found? How do they develop their ideas regarding TPACK to design their lesson?

2. Context and Method

Participants were 38 pre-service teachers in Taiwan. They enrolled in a course that required them to work in a group (with 3-4 people) and design a web-based, e-learning lesson to help them develop TPACK more explicitly. As a case study, an online platform called Knowledge Forum was employed for participants to explore, discuss, and design their web-based lessons. This learning environment was guided by three idea-related design principles (Scardamalia, 2002), including (1) idea diversity (**ID**), (2) idea elaboration (**IE**), and (3) idea integration (**IT**) while developing their TPACK (see Figure 1). The research team collected online discourse and conducted discourse analysis through two analytical phases. Firstly, ideas were identified as the units of analysis (see Figure 2 presenting 15 ideas contributed by a group of participants). Secondly, researchers analyzed and quantified each idea to examine its TPACK dimension (see Table 1) and idea improvement activities (see Table 2).

Figure 1.
The design of this study (left) ***and*** *the discussion space on Knowledge Forum (KF) (right).*

 © ISLS

Table 1.
The coding example for TPACK knowledge

Dimension	Example
TPK	They also set up an extra website [T]. This may lead them *(children level's learners) to* have a clear learning procedure [P] and a more pleasing experience while learning. (S3)
TCK	I feel that more links to related websites, information or videos [T], and picture books about ocean knowledge [C] or courses-related can be put in the course. (S9)
TPACK	You *[the teacher designer)* can consider trying to wrap the learning activities and course contents in a more integrated way with the use of google map so that the learner would know why they need to learn this way [TPACK]. (S26)

3. Result

Primary findings showed that all three idea improvement activities (including ID, IE, IT) were not focusing on TPACK (F=1.079, p >.05; F=1.751, p >.05) (Table 2.), indicating that there is still room for students to deal with more advanced TPACK knowledge and to engage in higher-level idea improvement activities. On the other hand, the discourse analysis showed that ID, IE, and IT were all essential for TPACK development. As shown in Figure 2., students initially proposed many diverse ideas talking websites and videos, followed by elaborating specific ideas and digital materials for presenting target content. Finally, they discussed how to integrate ideas to best create an instructional design in a technology-enhanced learning environment.

Table 2. *The comparison between T-related knowledge and ideas development*.

	M (SD)			F	p-value
	TPK	TCK	TPACK		
ID	1.132 (1.234)	2.711 (3.161)	1.816 (2.649)	3.856	<.05
IE	2.184 (2.078)	1.684 (1.454)	1.289 (1.575)	2.572	>.05
IT	1.132 (1.319)	1.658 (1.632)	1.263 (1.245)	1.437	>.05

4. Conclusion and Discussion

Research on teacher learning is challenging to examine knowledge, practice, and work contexts (Fishman et al., 2014). Pre-service teachers need to develop TPACK knowledge and integrate it with their ideas to strengthen instructional designs toward student-centered learning environments. In this study, we argue the importance of idea development should be considered. We further examined how pre-service teachers interact with group ideas dynamically through ID and IE and build on TPK and TCK. Our results indicate that the IT process is essential to driving pre-service teachers to develop TPACK knowledge. We conclude that to deepen the idea development among pre-service teachers, teacher educators should identify the early stage of idea diversification and elaboration and, most importantly, encourage opportunities for idea integration.

Learning and developing positive psychology via knowledge building

Jing-Hua Chen, Army Academy R.O.C., jinghua@aaroc.edu.tw
Mei-Ju Chen, National Tsing Hua University, meiju@mail.nd.nthu.edu.tw
Huang-Yao Hong, National Chengchi University, hyhong@nccu.edu.tw

Abstract: This study explores how 56 college students engaging in knowledge-building to advance their knowledge about positive psychology. Data include online behaviors, course evaluation results, and a survey. The findings showed: 1) students were able to work collaboratively to discuss online about two psychological theories; 2) knowledge-building, esp. knowledge-sharing, was significantly related to final course assessment; 3) surveys showed improved well-being scores among students.

1. Introduction

Well-being, as a predictor of psychopathology (Keyes et al., 2010; Wood & Joseph, 2010), has been deemed as important for mental health (Keyes, 2007). In order to enhance well-being, scholars have used positive psychology interventions (PPIs) (Allen et al., 2021; Fordyce, 1977; Seligman et al., 2005) --defined as psychological interventions (e.g., teaching, training, therapy) aimed at raising people's positive cognitions, feelings, and behaviors with the help of positive psychology (Sin & Lyubomirsky, 2009). Layous et al. (2013) suggested that during participants' practice of PPIs, use of a strategy called "peer testimonials" by which students share their life experiences may enhance their understanding of the nature of PPIs and their mental health. Knowledge-building (KB) is a pedagogical approach that regards ideas as basic units of knowledge construction, and values sustained idea generation and improvement to co-construct knowledge (Scardamalia & Bereiter, 2006). Knowledge Forum (KF) is an e-platform to support knowledge building (Scardamalia & Bereiter, 2006) via students' working collaboratively with ideas for in-depth discussion (e.g., about one's testimonials during PPIs) to advance community knowledge. This study aims to explore the influence of developing PPIs while sharing peer testimonials in KF in a positive psychology course. By encouraging students to discuss how to apply positive psychology theories in life, we expect students to be able to design relevant PPIs while sharing their testimonials in KF to improve learning and promote well-being. Accordingly, the research questions are: (1) Can students interact intensively in KB activities, and if so, how? (2) Is there a relationship between KB and students' course assessments/grades? (3) Can KB, with focus on PPIs and testimonials, enhance students' well-being?

2. Method

Participants were 56 Taiwanese college students taking a positive psychology course. The course asked students to discuss 3 topics: (1) PERMA—i.e., using Positive emotions, Engagement, Relationships, Meaning, and Achievements to build "good memories" in life (Seligman, 2018); (2) VIA-IS—i.e., Virtues-in-Action Inventory Strengths (such as using courage, temperance, etc. to share character strengths); and PPIs—i.e., to design PPIs by applying PERMA and VIA-IS in daily life. In terms of study procedure, building on Fredrickson's (2001, 2009) broaden-and-build conceptualization, students engaged in knowledge building in KF to design their PPIs (Figure 1). During the course, students discussed PERMA and VIA-IS and contributed, read, share, and built-on ideas in the form of notes in KF, to develop their testimonials in their PPIs. Regarding the 3 data sources, the first pre-post survey items were taken from: Taiwan Subjective Bell-Being Scale—Short Form (TSWBS-SF) and Taiwan Depression Scale (TDS), with 5 items coming from the TSWBS-SF (i.e., items about psychological well-being, such as "Some people think that life has no purpose, but I don't", and 6 items coming from the TDS in terms of emotional aspect (such as "I am stressed"). Second, online activity logs were concerned with notes created, modified, read, and replied to by students in KF. Third, the final course assessment was a well-established evaluation method required by the university, which was calculated by combining the results of midterm written reports, final audiovisual presentations, and class participation.

3. Result

First, Table 1 shows how students worked interactively online in KF. Students were found to consistently work with ideas by creating, revising, and reading notes over three topics/stages in a semester. The three activities were also correlated (all r's>.69**), indicating the more notes generated, the more also being read/modified/replied. Overall, students were able to collaborate as a class community. Second, regarding relationship, regression analysis showed that the number of notes read had a significant relationship with academic achievement, $\beta = .36$, $p < .001$. But there was no significant relationship between academic achievement (i.e., course assessment) and

 © ISLS

notes created (β = .82, p = .59) or notes modified (β = -.76, p = .62). As the final assessment grades were mainly based on students' knowledge, this indicates that online reading (i.e., idea sharing) plays a crucial role in fostering students' in-depth understanding of the psychological theories learned in this course. Third, the survey results also showed significant differences in the mental-scale (Table 2), indicating KB is related to improved mental health.

Fig. 1 Integrating Fredrickson's broaden-and-build theory into knowledge building activities in KF

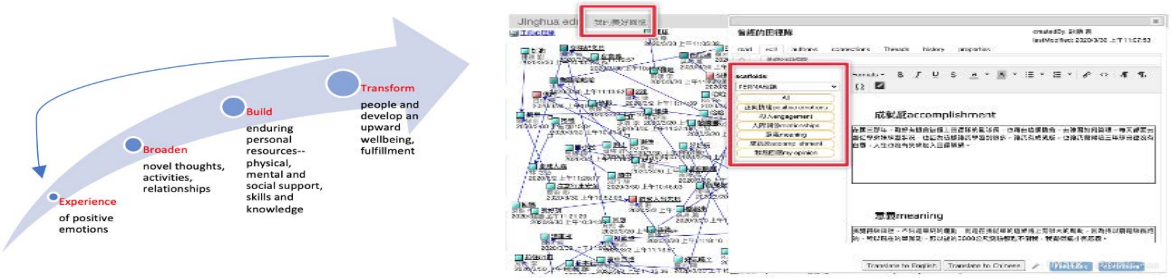

Table 1. Descriptive Analysis of Students' Activities in KF (N = 56).

KF activities	Topic/Stage 1		Stage 2		Stage 3	
Activity frequency	Total	Percentage	Total	Percentage	Total	Percentage
Creation	163	10%	126	16%	307	13%
Modification	423	24%	251	32%	697	28%
Reading	1157	66%	413	52%	1453	59%

Table 2. The Difference Between the Pre-Test and Post-Test of the Mental Scales t-test (N = 56).

Items	M(SD)		df	t-value	p	Effect sizes(d)
	Semester beginning	Semester end				
Psychological well-being	17.13（3.12）	18.07（2.81）	55	-2.12	.038	.32
Depression-emotional	5.82（3.93）	4.86（3.46）	55	-2.37	.022	.26

4. Discussion, summary and conclusion

In contrast to the traditional instructional method that tends to highlight the process of acquiring, understanding, or internalizing theoretical concepts via knowledge-telling in a positive psychology course in Taiwan, this study used knowledge-building theories with the support of KF platform to design a community-based positive psychology course. Students discuss how to apply the PERMA and VIA-IS theories online to developing their testimonials within PPIs, and it was found 1) students were able to work collaboratively to discuss online about two psychological theories; 2) knowledge-building in general, esp. knowledge-sharing (i.e., reading) in particular, was significantly related to final course assessment; 3) surveys showed improved well-being scores among students. In conclusion, the online process of idea-centered discussions to achieve a collective goal of knowledge construction in the field of positive psychology by sharing testimonials via the progressively idea improvement leading to the development of PPIs seems to have served as a way for deeper learning about one's own cognitive understanding and mental well-being. Further data analysis on the actual note content will be performed to triangulate the present findings in this work-in-progress paper.

Multiplicity Matters: The Development of Interest Profiles During Dynamic Institutional Transitions

Jael Draijer, Larike Bronkhorst, Barbara Flunger, Sanne Akkerman
j.m.draijer@uu.nl, l.h.bronkhorst@uu.nl, b.flunger@uu.nl, s.f.akkerman@uu.nl
Utrecht University

Abstract: Students pursue multiple interests within their daily lives. The current study aims to describe the development of interest profiles (the total composition of all interests one pursues) in terms of the amount of interests, their domain divergence and developmental stages. Using Latent Growth Models on interest data of 309 students over the course of three years (10 timepoints), we will specifically explore interest profile development, also in the context of institutional transitions and COVID-19 measures.

Introduction

Students pursue multiple interests within their daily lives (Akkerman & Bakker, 2019; Hofer, 2010). Given limited time and resources in daily life, interests develop relative to one another and students may experience competition between interests. For example, a student may have an interest in both playing *tennis* and *hockey*, but may only be able to pursue one of these sports due to the costs involved and the required time investment. This may prompt unconscious or deliberate weighing of tennis versus hockey, forcing a choice to continue pursuing only one or the other. The weighing of interests against each other may also be more subtle, not forced by external factors but by internal prioritization (Draijer et al., 2022). For example, if a student is interested in both painting and drawing because engaging in these interests allows them to express their emotions creatively, they may over time choose to pursue only one of these, allowing them to still express their creativity but simultaneously pursue a new interest serving a different purpose, for example *going out with friends* in order to satisfy their social needs.

Studying the development of interest profiles (i.e., the total composition of all interests one pursues at a certain point in time) is key in understanding the continuation of a single interest. Whether an interest is continued over time may depend on the amount of parallel interests one pursues, the *developmental stage* of these interests (i.e., how novel or developed the interests are), and their *domain divergence*, i.e. the degree to which the interest object is of similar or different domain from parallel interests. The amount of interests one actively pursues may decrease as one grows older due to specialization, possibly enhanced by changing life-wide circumstances. Previous interest studies theorize that, as an interest develops over time, the object of interest becomes more valued and the individual desires to become more skilled or knowledgeable (Hidi & Renninger, 2006), prompting them to spend more time engaging with it. This also relates to identity formation: as a student grows older they increasingly realize who they are and what is important to them, including which interests they want to continue pursuing (Hofer, 2010; Krapp, 2002). This process of specialization may result in a decreasing amount of parallel interests as the growing interest takes up time and resources previously spent on other interests. Domain divergence may also decrease when the objects of interest that remain are similar in content (e.g., someone studying in IT and engaging in various computer games in their spare time). On the other hand, individuals may also drop interests that concern similar domains, so as to retain variety (as in the above example about painting and drawing). Changing life-wide circumstances, such as transferring to tertiary education, likely contribute to interest profile development as the new environment offers new opportunities or takes others away (Hofer, 2010).

The research question we aim to answer is: *How do interest profiles develop over time in terms of amount, domain variety and predominant developmental stages?* More knowledge about intrapersonal interest dynamics can enrich theory on interest development: studying an interest in relation to the student's whole life yields a broader understanding of the value and development of the interest than studying it in isolation. For example, parallel competing interests can aid richer understanding of declining STEM interest (Potvin & Hasni, 2014).

Methods

Participants

Participants of this study concerned 309 students aged 14-30 (M = 19), with 70% female. These students were enrolled in diverse educational tracks in the Netherlands, including (pre-)vocational education, general (professional) and (pre-) university education (in Dutch: *mavo, havo, vwo, mbo, hbo, wo*). All students were sampled in the penultimate year of their current study program.

 © ISLS

Materials

In this study, an ESM (Experience Sampling Method) smartphone application called *inTin* was used to capture (changes in) daily-life interests of the participating students. Students used this application to log their existing and novel (incidental) interests that they experienced within a week. When adding an object of interest to the application, participants filled out six scales about the characteristics of this interest (e.g., how novel the interest is to them). Participants were free to give any name to their objects of interest instead of choosing from pre-existing categories, doing justice to the idiosyncratic nature of interest (Akkerman & Bakker, 2019).

Procedure

Students used inTin for ten waves (consisting of one week) total, spread out equally across three years. For most participants, the transition to another program, gap year or job took place between wave 5 and 6. Before wave 8 the COVID-19 crisis started, which meant that both wave 8 and wave 10 (second COVID-19 wave) were spent in lockdown, e.g., with schools being closed and restrictions on inside sports. All participants signed an informed consent form and for participants who were younger than 16, a parent or caregiver signed an additional permission form. Ethical approval for this study was given by the departmental Ethics Committee.

Analysis

In order to map the development of students' interest profiles, each object of interest is to be coded into one of 21 domains (sports, social, music, et cetera). We will run several Growth mixture modeling (GMM) models for parallel processes in MPlus (Muthén & Muthén, 1998-2017). This allows us to test growth trajectories in terms of amount of interests, developmental stages and domain divergence, also allowing for different types of growth trajectories for different (groups of) students. Linear and quadratic effects are compared for this purpose. To describe domain divergence, we use the amount of domains in someone's interest profile as outcome variable, and for developmental stages we use the ratio of less-developed interests versus well-developed interests (indicating that, for example, someone has relatively many novel interests in wave 1, and fewer novel interests at wave 10). If applicable, follow-up analyses are conducted, for example to get more information on which domains are increasing or decreasing.

Anticipated results and discussion

We anticipate that overall the amount of interests will decrease over time, and that the domain divergence either remains similar or decreases as well. When both the amount of interests in a profile and the domain divergence decrease, this will confirm that processes of specialization take place in interest development over time. Alternatively, when the amount of interests decreases and the domain divergence remains on a similar level throughout time, this will indicate that individuals strive to retain a degree of variation in their daily interest-related pursuits. Results may indicate individual variety in these growth patterns. In addition, results may show that a longstanding interest can indeed fall away during times of transition, but is likely to be replaced with an object of similar domain and purpose. Results are likely influenced by COVID-19 measures, we will discuss the suspected impact of these on interest profile development.

International Society of the Learning Sciences

The Role of Visual Representations in Impasses During Collaborative Problem Solving in Undergraduate Chemistry

Joel P. Beier, Martina A. Rau
jpbeier@wisc.edu, marau@wisc.edu
University of Wisconsin – Madison, 1025 W Johnson St, Madison, WI 53706

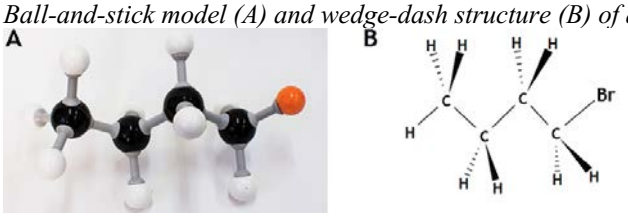
Introduction & Theoretical Background

Visual representations play a key role in disciplinary discourse. They are tools for communicating and problem solving (Wertsch, 1997). Because these representations are part of the community's culture, becoming part of a disciplinary community involves learning representational discourse (Kozma & Russell, 2005). For example, chemists frequently use representations like the ones in Figure 1 to communicate about molecules. STEM communities often use representations in collaborative activities. Representations can enhance the quality of collaboration, and collaboration can help students make sense of how the representations show information (Rau et al., 2017). However, collaboration with representations involves impasses (Strickland et al., 2010).

Impasses are points in a learning trajectory where a student does not know how to proceed because they lack knowledge (VanLehn, 1988). From a cognitive perspective, impasses are learning opportunities if the student receives information on how to proceed (VanLehn, 1988). From a socio-cultural perspective, impasses are opportunities for students to receive guidance on how to align their use of representations with those of more central members of the community (Hutchins, 1993).

Little research has characterized students' use of visual representations to navigate impasses. Hutchins (1993) showed that impasses and the ensuing feedback helps students to gradually align their representation practices with the community's norms. Strickland and colleagues (2010) found that representations can make impasses visible my revealing divergent views on how to solve a given problem. However, it remains unknown how students' use of representations during impasses differs from their use of representations during regular problem solving. To address this gap, we investigate: What is the unique role of visual representations during impasses students encounter during collaborative problem solving?

Figure 1
Ball-and-stick model (A) and wedge-dash structure (B) of a chemical molecule



Methods

We conducted our study in the context of an introductory undergraduate chemistry course. Our study occurred in week 5 of the course, which covered chemical isomerism and used the representations in Figure 1. We randomly selected seven student pairs (n = 14 students) from five lab sessions. All interactions were video-taped.

Students completed ten problems that asked them to construct a ball-and-stick model (Figure 1A) of a given chemical molecule. Then, students modified the ball-and-stick model to show its isomers (i.e., groups of molecules that have the same molecular formula but with different atom arrangements). For each, students had to draw a wedge-dash drawing (Figure 1B). Students collaborated with a partner for about 2.75h.

Videos were transcribed and segmented by turn-of-talk, yielding 8,054 turns of talk. In addition, manipulations of representations and gestures relating to the representations were transcribed. To investigate the role of representations during impasses, we first combined qualitative and quantitative approaches do develop a coding scheme that described students' use of representations and impasses; interrater reliability was Kappa = .90 on 18.6% of the transcripts. Second, we used sequential pattern mining to identify frequent sequences of codes in the transcripts. We defined frequent sequences as those sequences that occurred in at least 65% of the transcripts (i.e., met a support threshold of .65). We ran the sequential pattern mining algorithm separately on the portions of the transcripts that involved impasses (n = 2,731 lines of the transcript) and on the portions without impasses (5,322 lines). This yielded a set of frequently occurring sequences of interactions with representations that characterized interactions with representations during regular problem solving and during impasses. Third, we

 © ISLS

examined the frequent sequences that were unique to impasses using a qualitative approach. This yielded an understanding of students' unique ways of interacting with representations when they encounter impasses.

Results

The grounded theory approach revealed four ways in which students used visual representations during collaborative problem solving. First, students used representations for EXPLORATION when they manipulated a representation while directing their attention to the representation without verbally describing the representation. Second, students used a representation for JUXTAPOSITION when they held the ball-and-stick model adjacent to a wedge-dash drawing for comparison and directed gaze between the representations. Third, students used a representation as a tool for MEDIATION among the collaborating students or between the students and the TA when they manipulated representations while describing related concepts. In these cases, manipulations of the representations were not duplicated verbally. Fourth, students used representations as a REFERENCE to support their arguments when they pointed at a representation. In these cases, students verbalized aspects of the representation. Students most frequently used representations for MEDIATION, followed by REFERENCE and EXPLORATION. Students used representations for JUXTAPOSITION relatively infrequently.

The sequential pattern analysis identified frequent sequences of codes that described students' use of representations. All sequences were unique to either regular problem solving or to impasses. For regular problem solving, we found two sequences: EXPLORATION followed by MEDIATION, and MEDIATION followed by EXPLORATION. During impasses, we found eleven frequent sequences. Six sequences started with REFERENCE (alone or combined with MEDIATION), followed by one to three interactions coded as MEDIATION. Two sequences started with MEDIATION followed by REFERENCE (alone or combined with MEDIATION). The three remaining sequences included two to four interactions coded as MEDIATION and involved no other codes.

Our qualitative inspection of the frequent sequences found for impasses revealed that impasses were usually characterized by one or two students having difficulties interpreting how a wedge-dash structure showed a specific chemical isomer. To resolve the impasse, students used a ball-and-stick model to illustrate the isomer and make sense of isomers by establishing connections between the two representations. In this joint sense-making process, they used both representations as REFERENCE and MEDIATION tools to connect the representations to the underlying concepts until both were satisfied.

Discussion

Taken together, our findings shed light into how representations help students navigate impasses during collaborative problem solving. We found that students use representations as mediators that illustrate aspects that are difficult to describe verbally and as references that disambiguate their verbal descriptions. Using representations in these ways allows students to identify the source of an impasse and to jointly resolve it. Our findings illustrate that impasses engage students actively in joint meaning making with the representations. Future research pending, our findings suggest that joint representation tools may help students learn during impasses.

Brazilian Educators' Perceptions of STEAM Education

Roseli Lopes, University of São Paulo, roseli.lopes@usp.br
Irene Ficheman, University of São Paulo, irene.ficheman@lsitec.org.br
Elmara Souza, Bahia Department of Education, elmara.souza@enova.educacao.ba.gov.br
Dennys Maia, Federal University of Rio Grande do Norte, dennys@imd.ufrn.br

Abstract: This paper investigates the perceptions of Brazilian educators of STEAM education. The analysis was based on an online survey of participants of the STEAM TechCamp Brasil program. We analyzed two open questions using the Discursive Textual Analysis method. Results indicate that participants perceive STEAM as a pedagogical approach, but have a restricted view of the sciences. This discussion contributes to the current understanding of STEAM in Brazil and to the evolution towards a self-contained conception.

Introduction

In Brazil, STEAM education practices are still embryonic. In a survey of STEAM approach experiences, developed and published in the country, the few records found by Maia, Carvalho & Appelt (2021) indicate that they are concentrated in four Brazilian states that are more economically developed. Research shows that, considering Brazil's social, cultural, and educational specificities, it should follow the example of other nations that implemented the STEAM approach in their curriculum and have achieved promising educational results. Therefore, innovative pedagogical practices need to be developed throughout the country, which has continental dimensions, cultural diversity and deep social inequalities. Brazil demands the design of specific STEAM environments and not just the reproduction of models from other countries.

In search of a self-contained STEAM approach, that is, connected to the reality and educational needs of Brazilian youth, some initiatives are being developed by educators and institutions. One of them is the STEAM TechCamp Brasil, which aims to create a network of teachers and education professionals to articulate and improve actions aimed at active learning of STEAM in public K-12 networks in Brazil. The STEAM TechCamp has a strong potential for disseminating STEAM experiences in the country.

This article aims to investigate the perceptions of participants about STEAM practices that are being developed in the country and how they contribute to the construction and dissemination of a unique STEAM concept connected to Brazilian reality.

The STEAM Education as an Approach

Some STEAM experiences do not innovate in education, nor do they change learning experiences. In these experiences students are asked to learn and memorize information presented by their teachers or to develop projects defined by their schools or teachers. They are asked to reproduce experiments, instead of observing, identifying problems and creating solutions. Nevertheless, the STEAM approach may reinforce agency, creativity and critical thinking. It is about pedagogical practices that stimulate students to identify problems, develop projects, test hypotheses and present solutions to the problems they identified. These problems are commonly related to the students' context. As Sawyer (2014, p.2) highlights, to work in today's knowledge economy, more than memorizing facts and procedures, people "need a deep conceptual understanding of complex concepts and the ability to work with them creatively to generate new ideas, new theories, new products, and new knowledge".

Methods

This preliminary study is based on an online questionnaire sent to the 80 participants, responsible for 41 projects that received small grants to implement projects related to the STEAM approach. All Brazilian states were represented and awarded the resources. We received 29 responses from 15 states, ensuring representation from all 5 regions of the country, and participants from each of the 4 cohorts of the STEAM Tech Camp (2018-2021).

We emphasized the questions in which respondents showed their conceptions of the STEAM approach. Two open questions were selected and their answers analyzed with elements of Discursive Textual Analysis (DTA), which is a technique that intends to verify different perspectives presented in the respondents' discourse, based on meaning units (Moraes & Galiazzi, 2011). The answers about: "How do you define STEAM?" and "How do you understand the 'S' in STEAM?" were categorized into meaning units and analyzed.

Thus, as indicated by the DTA procedures, we selected extracts of the participants' responses as context units, which are fragments of the respondent's discourse considered central and representative of the response. Then, we identified and categorized these units, with the intention of grouping them into categories that allow

 © ISLS

counting their frequency. At the end, we defined the thematic axis of these responses. These DTA methodological procedures favor the categorization and analysis of the discourse in the responses so that we can make inferences about the data in order to make it more understandable and capable of formulating evidence, based on the objectives of the study and the theoretical framework adopted.

Results

Regarding the first question, which aimed to understand the STEAM TechCampers' conception of the definition of STEAM, we organized the 29 responses, condensed into 4 thematic axes (*educational approach; educational innovation movement; teaching and learning methodology; meaning of the acronym*) from 10 units of meaning (*approach; movement; methodology; science, technology, engineering, arts and mathematics; strategy system didactic-pedagogical actions; new way of interaction; innovative and inspiring; way of thinking education*).

A high frequency of respondents defined STEAM as an educational approach (n_i = 12) or even a movement (n_i = 4) that seeks educational innovation through pedagogical practices based on interdisciplinarity, investigative spirit and creative learning. This suggests that most of the STEAM TechCampers are not disseminating STEAM as a mere educational technology fad. The thematic axis – Education Approach and Educational Innovation Movement – together, corresponds to 69% of respondents.

With regard to the second question, there was a predominance of the indication of "sciences," due to the meaning in the acronym, followed by two occurrences related to the "scientific method." We managed to group the 29 responses into 4 axes, namely: Natural Sciences, Subject, Scientific Method and Broad Sense. There is a balance between two conceptions of the "S" in STEAM: i) the one that understands the concept of "S" as restricted to natural sciences (34.5%), that is, a very limited view of doing science which excludes other areas and paradigms of science; and ii) one which highlights the scientific method (34.5%), or the methodological procedures inherent in investigative practice. This data shows us that the second perspective, although expanding the compression of "Science", it was not possible to perceive whether the participants understand the methodological procedures of other areas of Science like Human Science or Social Science. This view of science in a broad sense was evident in the speech of 21% of respondents.

Conclusions

The results show that most participants understand STEAM as an interdisciplinary pedagogical approach or even an educational innovation movement that intends to develop learning practices focused on the learner, based on scientific, investigative, creative and real-world thinking. This concept is in line with what is expected and desired for the Brazilian reality due to its educational, economic and social development demands.

As for the conception of science, it is necessary that educators, including STEAM TechCamp Brasil participants, expand the scope of the areas that make and produce scientific knowledge. The restricted or more specific view of natural or exact sciences, represented mainly by subjects related to science and mathematics in schools, is probably due to the technicist perspective present and for a long time perpetuated by STEM. Because of this, the examples usually brought as application of STEAM experiments focus on projects with procedures and fundamentals from physics, chemistry, biology and mathematics to the detriment of social science and humanistic subjects. The inclusion of the arts, in addition to the concern with design and development of pertinent soft skills, should include application in the real world, with attention to living beings and the environment, objects of study in the human, social and health sciences.

A Growing Problem: Student-Worker Retention at an Urban Farm

Marc T. Sager, Lily Binford, Dr. Anthony J. Petrosino,
msager@smu.edu, lilyb@smu.edu, apetrosino@smu.edu
Southern Methodist University

Abstract: We investigate student-workers' motivation at an urban farm situated on a Historically Black College's campus. This is one phase of research embedded within the beginning stages of a larger research practitioner partnership (RPP). This paper aims to address: How do student-workers stay motivated to continue their work placements at an HBCU's urban farm in the Southwest US? The basis of our analyses are interviews, observation field notes, and artifacts collected over the course of this research. We examined the data to identify recurring themes which led to student-worker turnover and discuss opportunities for improvement of student-workers' learning motivation. As a whole, we seek to support key partners, as the ICLS 2022 calls for, by investigating innovative learning environments.

Introduction

Consistent with the "investigating innovative pedagogies, technologies, and learning environments" theme for ICLS 2022, researching innovative learning environments plays an important role to diversify educational experiences. To achieve these new educational experiences, we must look at new systems for marginalized communities and individuals to access systems of power. We report on a budding research practitioner partnership (RPP) between the researchers and an HBCU's urban farm, to examine and address student workers' motivation to learn at an urban farm. The purpose of this place-based research alliance was formed to investigate and understand the overall driving question for this RPP: How can we strengthen the connections between learning and student engagement in perceived community spaces? The research questions were co-designed with stakeholders using Penuel and Gallagher's (2017) RPP framework of finding questions of mutual concern. The overall study aims to answer the following research questions: How do student-workers stay motivated to learn in their work placements at an HBCU's urban farm? What are organizational strategies that are used by the university and urban farm to allow for continued collaborations between student-workers and community partners? What does the process of learning look like for student-workers at an urban farm, and how do the expert-novice roles come into play? This paper will focus on question one.

Theoretical Framework and Methodology

We found using an RPP framework beneficial to look at the initial stages of this project, with goals to become a long-term and sustainable RPP. There is a wealth of literature on informal and interest-based spaces (Rogoff et al., 2016) from amateur and hobbyist astronomers (Azevedo, 2013), middle school field trips to science museums (Whitesell, 2016), and adult social events at children's museums (Harris et al., 2016). However, there is a dearth of research within the learning sciences surrounding food-based spaces. This research is also informed by studies related to students and adults' motivation to learn (Coker, 2003;)

This budding partnership is comprised of the researchers, the college's urban farm, the community, and a local National Football League (NFL) franchise. The researchers include a professor and two doctoral students in STEM education. The college is a HBCU work-study college in an urban setting. In 2010, said HBCU converted one of its sport fields into a four-acre urban farm which began to and continues to grow seasonal vegetables. The community members involved with the partnership are local benefactors of the farm – representatives of local food banks and community centers. The final partner, a local NFL franchise, works with the farm to purchase locally grown produce to supply their restaurant, both at their training facility and their stadium. The research problem and question were jointly identified by the key stakeholders, who took a participatory design approach by listening, specifying problems of practice, mapping systems, and identifying shared values (Penuel & Gallagher, 2017).

The urban farm is situated within an informal learning and interest-based participation setting (Azevedo, 2013; Rogoff et al., 2016). This participatory research study was conducted at a historically Black work-study college's urban farm in the Southwest U.S. The participants of this portion of the study include three staff members of the college, three current student-workers, and two former student-workers. The researchers worked at the urban farm site to build trust and establish a rapport with the partners. All research activity and materials were supported by the stakeholders. Data collection included participating on the urban farm, observations, microethnographic field notes, interviews, and artifacts. Rigorous data was collected until saturation was met. The

 © ISLS

researchers were complete participants to establish rapport and assist with necessary farm duties (Creswell & Poth, 2018). All names listed in this paper are pseudonyms.

Findings

In analyzing the qualitative data related to student-workers' motivation and retention, it was apparent that there were both student-level and organization-level challenges and successes. Student-worker interviews identified reasons for leaving their positions and staying in their positions. First, student-workers discussed complications that prompted their peers to leave. The time and amount of work involved at the urban farm was much more strenuous and demanding compared to other on-campus positions for the same financial incentives, which prompted students to take advantage of the less stressful job sites. Additionally, there was always a shortage of student-workers to help on the farm, leaving the remaining students and staff responsible for the ongoing demands of a working urban farm.

Second, students proposed reasons for staying on the urban farm, despite the implications offered in the above section. There were two primary ideas that were raised in the first round of coding: interest-based motivations and gaining new skills. Student-workers mentioned their desire to expand their experiences by learning new transferable skills related to farming and gardening. Also, student-workers disclosed how they gained necessary 21st century skills that will prepare them for the workforce. One student-worker, Jane, said, "[the farm] taught me patience and trusting the process," by:

> Working on the farm and gardening, we take the process of planting a seed, you have to trust the process of watering it daily, giving it what it needs to be fed, the nutrients, so it can become a sprout and flower or fruit or vegetable or whatever it is you're trying to grow. It's not going to happen right then and there on the same day. It's going to take time.

These skills were deemed important to this student worker to stay in their placement at the farm so they could continue to grow as learners. This unique learning environment, which is situated within a formal context provides a complex layer of the site.

Scholarly Significance

The initial findings from this study parallel the learning motivation in similar studies. For example, Coker (2003) examines Black females adult learners' motivation. She finds that black female adult learners continue their educational journey for self-development, family development, and community development. Similar to Coker's (2003) study, the current student workers continue their work placements to further enhance their self-development by becoming more marketable in the workforce and inspiring confidence. Additionally, the student-workers have found a sense of purpose working on the farm by positively impacting their community, which is echoed in Coker's (2003) research. This study will start the process of studying agriculture and food systems using research and theoretical tools from a learning sciences perspective. The initial findings from this study can continue to advance and contribute to the RPP literature about student-worker's motivation to learn within an urban farm context.

Growing Student-Workers as Informal Learners

Marc T. Sager, Lily Binford, Dr. Anthony J. Petrosino,
msager@smu.edu, lilyb@smu.edu, apetrosino@smu.edu
Southern Methodist University

Abstract: We investigate an urban farm as an informal learning setting and the interactions between experts and novices using situated cognition as our framework. The poster is situated within a large research practitioner partnership (RPP). Initial findings are reported as they relate to learning in a novel environment, and that it relates to the 2022 ICLS theme of "elucidating theories and processes of learning and teaching."

Introduction

Consistent with the "elucidating theories and processes of learning and teaching" theme for ICLS 2022, researching innovative processes of learning plays an important role to diversify educational experiences. This research is part of a broader project to understand how an urban farm can strengthen the connection between student learning and engagement in perceived community spaces through a research practitioner partnership (RPP). In this poster, we present the first phase of our analysis, which: (a) identifies informal learning that occurs at an urban farm embedded on a university campus; and, (b) initiates the discussion for interactions between the expert(s) and novices on the urban farm. The research questions guiding this poster is: What are the characteristics of learning embedded within the urban farm project?

Theoretical Framework and Methodology

There is a wealth of literature on informal learning, interest-based spaces, and expert-novices (Azevedo, 2018; Harris et al., 2016; Hmelo-Silver et al., 2007; Rogoff et al., 2016). However, there is a dearth of research within the learning sciences surrounding agriculture and food-based spaces. Additionally, this research is guided by literature focusing on the Black lived experiences and how that influences their learning (Vue et al., 2017). This research is grounded using situated cognition as a theoretical framework. This framework states that learning is situated in a particular context, social in nature, and distributed across the individual, other people, and tools (Brown et al., 1989). The urban farm is situated within an informal learning and interest-based site, the learning involves multiple participants (farm staff, student-workers, and the researchers), and the knowledge is distributed across the individual, other farm workers, and the tools being used at the farm.

This participatory research study was conducted at a historically Black work-study college's urban farm in the Southwest U.S. Participants included two staff members of the farm and seven student-workers. The researchers' data collection included observations, microethnographic field notes, semi-structured interviews, and artifacts. The first round of data analysis included inductive coding using situated cognition (Brown et al., 1989) and expert-novice frameworks (Hmelo-Silver, 2007). Future iterations of analysis and this research will aim to pull from literature of lived experiences of the Black students, and how that influences their learning.

Initial Findings

Learners – staff and student-workers – fully participate on the farm, from planting crops, tending to the raised beds, harvesting crops, marketing, and delivering the produce to clients. Additionally, the more novice student-workers collaborate with the more expert farm staff to ask clarifying questions related to different aspects of the farming cycle. Student-workers can apply their existing knowledge of gardening/farming, biochemistry, or business with their experiences at the farm. One student-worker worker was able to utilize their experience with growing peppers to experiment with different types of soil and growing methods, to identify what works best for their operation.

In Figure 1, a farm staff member presents the proper techniques to plant collard green seeds. The situated and distributed nature of the learning is presented by first showing the student the steps and providing a verbal explanation of the steps and justification. The student then demonstrates his understanding by verbally restating the steps while practicing the planting.

Discussion

Learning in a garden-based setting was examined by Dewey (1916), and he argued that in occupational and vocational education, there is a focus more on the trade or skill which, inhibits and perpetuates the existing industrialized complex (Dewey, 1916; Kliebard, 1987). Focusing solely on the trade or skill, limits the more

 © ISLS

expansive and holistic type of learning that can occur. For example, during the planting process, there is a missed opportunity for the expert to discuss the importance of the larger science concepts and processes that are and will be at play, such as, biology, chemistry, and physics. However, during an interview there was an example of vocational education stepping beyond the intended industrialized idea of social control and occupational training. A student was able to use the agricultural science knowledge from the farm and apply her skills obtained from her classroom instruction to develop and implement a marketing plan for a community farmers market. This parallels the expert-novice literature, such as Hmelo-Silver and colleagues (2007), which asserts and points to more productive learning gains in not only the procedures of farming but also the STEM topics embedded in such activities (soil composition, growing cycle, chemical components of fertilizers, biomass growth). The situated nature of the learning between the experts and novices at the urban farm provide an interesting insight to the learning and knowledge building for those involved. To reiterate, this is only at the beginning stages of analysis and will continue to build the situated nature between the experts and novices, as well as using Dewey's work to move forward and beyond vocational and occupational learning of a skill.

Biology Isn't Black and White: Deconstructing Biology Instructors' Knowledge Networks of Biological Processes to Explore Nuance

Sharleen Flowers and Stephanie M. Gardner
sflower@purdue.edu, sgardne@purdue.edu
Purdue University

Abstract: To fully appreciate the intricacies of biology, undergraduate students must understand how the components and processes of complex biological systems relate to each other over space and time. However, building normative knowledge networks and transferring across biological contexts is a challenge. In this study, we sought to identify the features of a model describing the relationships between three fundamental processes in biology: cell-cell communication, gene regulation, and phenotypic expression. Through interviews with six biology instructors, we found a diversity of knowledge networks relating the processes. Further investigation revealed that their knowledge networks are influenced by their definitions of phenotype, their biological disciplines, and accumulated professional experiences. Our data reinforce the idea of situated cognition and suggest that a single, acontextual knowledge network is difficult to transfer across biological contexts. We suggest educators invite students to critique models and to engage in explicit instruction about how and when to use them.

Understanding complex systems in biology

A core concept in undergraduate biology education is for students to understand 'Systems,' which describes how organisms "integrate internal and external information, incorporate feedback control, and allow them to respond to changes in the environment" (Brownell *et al.,* 2014, p. 208). Cell-cell communication (CCC), gene regulation (GR), and phenotypic expression (P) are three relevant biological processes cells and organisms use to interact with and respond to their environment. To explain how biological phenomena occur, it is important for biology students to understand the relationships between these three processes and how to apply them to understand a complex system. The theory of knowledge integration serves as a useful framework to investigate how individuals relate the three processes. During knowledge integration, learners process new information, organize these ideas or facts, and then integrate their thoughts into a network of knowledge (Clark & Linn, 2003). Ideally, a knowledge network built in one biology classroom can be transferred and utilized in another biology classroom. To facilitate the construction of knowledge networks and their transfer across contexts, educators can use simple frameworks as a tool to scaffold student learning (*e.g.,* Hmelo-Silver & Pfeffer, 2004). Therefore, to aid students in their learning of biological systems, we sought to derive a normative model regarding the relationships between CCC, GR, and P. We leveraged the theory of knowledge integration to reveal and describe instructors' knowledge networks and answer an overarching research question: What are the features of biology instructors' knowledge networks in regards to three foundational processes in biology (*i.e.,* CCC, GR, and P)?

Methodology

Population. We recruited 6 biology instructors from a large public Midwestern university with very high research activity who had previously taught introductory courses to biology major students. (IRB #1806020745)

Procedure. These data come from a larger study aimed at revealing knowledge of and the connections between the three biological processes: GR, CCC, and P. We used semi-structured, think-aloud interviews guided by the theory of knowledge integration to elicit and characterize knowledge networks such as definitions of the processes and what ideas they use to describe connections between the processes. In this paper, we present results from the question, "How are these three processes related?" in which instructors diagramed and explained their knowledge networks. The interviewer also asked follow-up questions to fully explore participant ideas.

Analysis. We used knowledge integration as an analytical framework and built models (*i.e.,* knowledge networks) to represent how the participants connected the three processes based on the participant-drawn diagrams and conversations. The diagrams drawn by each participant were used as the foundation of the relational models, and features of the models were described using field notes and thematic coding (Creswell, 2013). Through an iterative process involving independent coding, consensus discussions, and revision, a final codebook was developed to describe the knowledge networks. Finally, coding of the full dataset by the first author and an outside reader was conducted. All coding was discussed to complete agreement.

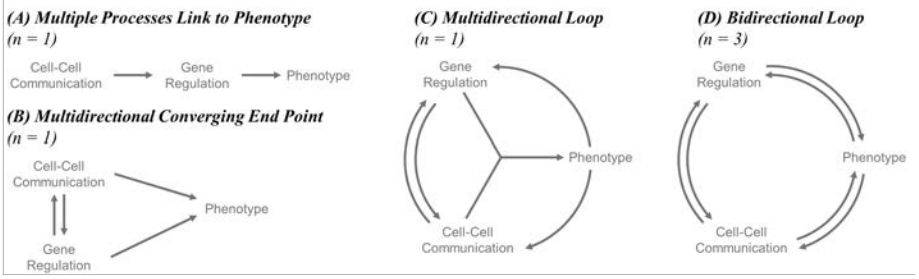
 © ISLS

Results and discussion

We categorized the 6 instructors' models relating the three processes into four groups (Figure 1).

Figure 1

Knowledge networks of instructors



Variations in definitions and the importance of context

Most of the instructors (4/6) described phenotype as an *effect or the outcome* of the genotype or as an end product of gene regulation. In contrast, some instructors (2/6) *loosely defined* phenotype and viewed it as any physical or measurable characteristic of the cell, not strictly coming from gene regulation. We found that instructors with the *loose* definition described P as interconnected and intimately involved with CCC and GR (Figure 1D) whereas instructors with the *outcome* definition did not (Figure 1A, B, and C). With further probing of the 4 instructors who viewed phenotype as an *outcome*, 2 instructors declared that they could not conceptualize P as having any feedback to GR or CCC, but the other 2 instructors conjectured that there are certain contexts where P could affect GR or CCC. Indeed, most instructors (5/6) acknowledged that the relationships between the three processes can be drawn differently in other biological contexts, for different purposes, and depending on the individual (*e.g.,* personal definitions, expertise). To this point, we found two instructors who chose to describe their knowledge networks in the context of their disciplinary backgrounds.

Conclusions and implications: appreciating the nuance

In our study, we did not identify a single, normative relational model of the three biological processes. Although educators desire to give students common frameworks that they can transfer and apply to multiple subjects, it is clear that the relational model in our study is strongly context-dependent and its transferability is limited. The issue is that transferability neglects the nature and circumstances in which the specific knowledge content was built (Brown *et al.,* 1989). While practicing application of the acontextualized model across biological contexts could still be beneficial, a more useful approach would be inviting students to reflect and critique the model and engaging in explicit instruction about how and when to use the framework (*e.g.,* layering on detail, exceptions, uncertainty, nuance). Biology is a complex subject with few rules and boundless flexibility. This same flexibility needs to be applied when teaching and reasoning with foundational processes.

UTeach/NYC: A Research Practice Partnership to Expand and Improve Computer Science Education For All

Dr. Anthony J. Petrosino, Southern Methodist University, apetrosino@smu.edu
Kimberly Hughes, The University of Texas at Austin Hughes@uteach.utexas.edu
Marc T. Sager, Southern Methodist University msager@smu.edu
Max K. Sherard, The University of Texas at Austin mksherard@utexas.edu

Abstract: This 3-year Design-Based Implementation Research (DBIR) study focuses on a Research Practice Partnership (RPP) that encourages broad student participation in computer science (CS), looking at underrepresented urban youth in New York City. In particular, the research examines what organizational conditions, processes, and supports are associated with improved participation by Black and Latino/a students in CS, as measured by the diversity of students enrolling in CS courses. Results indicate an increase in trust has been reliant on the strides made from the partners involved, as well as building upon the RPP framework. Improved communication has resulted from continuity of meetings, regular exchanges of email, and having detailed agendas and expectations for the partners involved.

Introduction

Key to this work is imagining new ways of conducting inquiry; cultivating partnerships, working with communities as authentic partners and engaging in larger-scale research practices, such as multi-sited ethnographies, accessing population level data, utilizing new forms of data and data analytics, integrating data sources that intersect with education and developmental stages to inform the design of classrooms, schools, and systems in the service of equity. We report on a Research Practice Partnership (RPP) between The University of Texas Austin (UT Austin) and New York City (NYC) public schools to examine the degree to which co-design of curriculum, instructional practices, and teacher supports can build organizational capacity to support equitable computer science (CS) teaching and learning as called for by the CSforAll national movement. This study focuses on remaining questions about the organizational conditions and instructional practices that encourage broad student participation in CS, looking at underrepresented urban youth. This paper will focus on the first of the research questions from the grant: What organizational conditions, processes, and supports are associated with improved participation by Black and Latino/a students in CS, as measured by the diversity of students enrolling in CS courses?

Perspectives/Theoretical Framework

Education researchers have long attempted to bridge the divide between research and ongoing challenges of practice faced by educators through pedagogy, technology, and methodology innovations (Anderson 2012; Koehler et al., 2007). Impediments to the successful development and implementation of innovations have hampered and stifled innovations from being adopted to support students (Potvin et al., 2018). Most obviously, educators and administrators in K-12 schools and districts may lack the expertise to properly implement technological innovations to the rationale that stems from research for improving teaching and learning (Louie & Buffington, 2018).

Methods

Methodologically, a Design-Based Implementation Research (DBIR) approach was employed to address the three overarching research questions. In addition, using Penuel and Gallagher's (2017) design template to effectively design curriculum adaptively across levels and settings, partners developed curriculum using an iterative and collaborative design process from joint feedback between UTeach CS teachers, NYC DOE, UTeach curriculum designers, and researchers.

The project implementation and impact section aimed to capture significant accomplishments over the last academic year, including a success story and major activities completed within the year. The next question addressed whether or not the professional development and/or the curriculum was changed for the past academic school year, including changes made to address diversity and inclusion. The third question in this section asked to describe the relationships among RPP members, specifically, a sense of trust, open communication, and working together to build the capacity of educators and researchers. The fourth question in this section aimed to answer whether any other outcomes have resulted from the project to date. The fifth question in this section addressed primary barriers and challenges in the project, and how they were addressed - both outside of COVID-

 © ISLS

19 and related to COVID-19. And lastly, the evaluators aim to understand the plans and goals for the next year of the project.

The Starting Strong unit is used to introduce the course to students, embed non-cognitive strategies, activities, and supports in the curriculum, provide for more student choice in course activities and projects (more differentiation) and add career content to course materials. Starting Strong teacher materials prepare them for the course, classroom set up, strengthen how culturally-relevant pedagogy is addressed, provide more examples, how-to videos, and student work examples spanning range of performance, improve pedagogical support content for teachers, especially Project- Based Learning (PBL). Embedding CS background content in teacher materials strengthen opportunities for students to address personally relevant problems, and improves access to course content for English Language Learners (ELL) students (specifically in Big Data and Internet units). Additionally, teachers participate in an intensive, in-person, summer PD, and are provided in-person support sessions throughout school year, designed to foster community- building, create opportunities to collaborate, and provide on-demand supports. Researchers are collecting data on student interest, engagement, and mindset and data are immediately returned to teachers so that they can adapt instruction accordingly. Researchers also facilitate unit debrief sessions with teachers to review and discuss student data and outcomes.

Results

Three years of Advanced Placement (AP) CS exam results, provided by the College Board, show that students in UTeach CS Principles courses nationwide include more females and other underrepresented students and these students performed slightly better than national averages. In total, 75% of UTeach students passed the exam compared with 72% nationally, and female students passed at a rate of 75% compared with 69%. Pass rates for African American and Hispanic students in UTeach were 43% and 57%, compared with national pass rates of 41% and 55%. Finally, 62% of underrepresented students overall in UTeach courses passed compared with 55% nationally. Both females and underrepresented students comprised a higher proportion of the total number of exam takers in the UTeach CS principles (CSP) group compared with national participation rates.

The progress made over the course of the RPP is reflected in the interview/survey responses from the third-year evaluation. Respondents noted that there is an increase in trust from all key stakeholders, overall positive responses, improved communication, and "more of a solid team." An increase in trust has been reliant on the strides made from the partners involved, as well as building upon the RPP framework (Penuel & Gallagher, 2017). The improved communication of has resulted from continuity of meetings, regular exchanges of email, and having detailed agendas and expectations for the partners involved. An increase in flexibility throughout the 2020-2021 academic year was outlined by the respondents in their role of supporting teachers during this unique year. Additionally, respondents provided recommendations for the upcoming academic year: to elevate the role of the practitioner, continue to receive and enact PD feedback, and for the practitioners and researchers to continue to work closely together.

Significance of the Study

This project will contribute to knowledge about effective organizational conditions, as well as instructional interventions to promote participation, engagement, and learning across diverse groups of students in AP CS Principles, the professional learning and support necessary to prepare teachers with diverse content backgrounds to teach CS, and the strategies employed to address problems of practice through collaborative, iterative design.

Embodied Cognition in Virtual Reality to Support Learning of Scale

Tyler Gampp, Cesar Delgado, Matthew Peterson, and Karen B. Chen
twgampp@ncsu.edu, cdelgad@ncsu.edu, mopeters@ncsu.edu, kbchen2@ncsu.edu
North Carolina State University

Abstract: This work-in-progress poster reports on the development process of a virtual environment to support embodied cognition about the scale of scientific entities from subatomic particles to galaxies. Research shows that learners struggle to comprehend the sizes of entities beyond human scale. In order to determine specific entities to use in the virtual environment, a document analysis of US K-undergraduate science education standards was undertaken. Entities, categories of entities, and ranges of sizes were identified.

Introduction

The US Next Generation Science Standards propose "scale, proportion, and quantity" as a crosscutting concept that pervades science and can aid students in making connections across topics, disciplines, and grades in order to construct a more robust understanding of science (National Research Council, 2012). While cutting-edge STEM is being conducted at extremes of scale, research shows that learners of all ages hold inaccurate ideas about the size of scientifically relevant entities (Delgado et al., 2015; Magaña et al., 2012; Tretter et al., 2006a, 2006b). Science standards require that students consider scales that exist beyond their direct everyday experience. To address this issue, our research project is developing a virtual reality (VR) in which students shrink or grow to the size of atoms or galaxies, and experience scientific entities directly and in an embodied manner through VR. This paper reports on our process of selecting entities for the Cave Automatic Virtual Environment.

Theoretical Background

The theory of embodied cognition holds that understanding the mind requires acknowledgment of its inextricable relationship to a "physical body that interacts with the world" (Wilson, 2002). Virtual reality has the power of creating vivid three-dimensional representations of entities that cannot otherwise be experienced directly. The multimodal immersive experiences of VR may enhance a learner's experiential lexicon of scientific *entities* through embodied interaction and cognition — "[a]n entity is an iconic thing, a meaningful whole on its own," which instantiates a concept (Peterson et al., 2021, p. 321). This embodied cognition may support the learning of well-developed, accurate conceptions of scale. We posit that this understanding of scale can help fulfill the promise of crosscutting concepts in supporting the development of connected understanding of science. The entities selected to populate the virtual environment will play an important role in student learning, ideally becoming scale landmarks (Tretter et al., 2006b) that serve to anchor a mental number line for scale. Entities mentioned in the standards likely appear in the curriculum, and may become landmarks in student cognition.

Methods

We conducted a document analysis of the K-12 (NGSS Lead States, 2013) and college science standards (College Board, 2009) to determine what entities are referenced. The first author, a doctoral student in science education, analyzed the standards, using a constant comparative method (Corbin & Strauss, 2008) with an *a priori* code of named entities (e.g., sea otter, amoeba). Upon analysis of the initial list, the team determined that the standards frequently referenced *categories* of entities (e.g., microorganisms, autotrophs) rather than specific instances, or phenomena that span a *range* of sizes. A category is a group of entities with a small variability in size; a range involves groups of entities or phenomena that spanned several powers of 10. We incorporated categories and ranges as emergent themes into the analysis. We again reviewed the standards, coding for categories and ranges. Some entities were not included because they were pieces of a whole (e.g., human foot, head of a pin). Some groups of entities were not included because ranges could not clearly be defined (e.g., mentions of "all objects"). We then determined the absolute size of each entity using the largest measurement in any given direction. We foresee productive discussions with colleagues from other countries with different educational standards, who may have different insights as to what entities, categories, and ranges are important in science.

Findings

The analysis of the standards yielded 251 entities, 194 categories, and 14 ranges. Examples of each are presented in Table 1, for a subset of sizes (10^{-10} to 10^{2} m). The largest named entity was the Milky Way Galaxy (10^{21} m) and

 © ISLS

the smallest was the electron (10^{-18} m). The categories spanned large portions of the scale with the smallest being subatomic particles and the largest being galaxies. Ranges were limited in quantity but also spanned the entire range; they included gamma rays on the lower bound and solar system bodies on the upper bound. The named entities are concentrated within ranges of the scale with approximately 53% of entities falling between 10^{-2} m to 10^{1} m, approximately 23% between 10^{-10} m to 10^{-9} m, and approximately 7% appearing above 10^{2} m.

Table 1
Sample Entities, Categories, and Ranges for 10^{-10} to 10^{2} m

Size, m	Named Entities	Categories	Ranges	
10^{-10} to 10^{-9}	Water Molecule		X Rays	Electron and Scanning Probe Microscopes
10^{-9} to 10^{-8}	Chromosome	Cell components		
10^{-8} to 10^{-7}	Plasmodesmata		Ultraviolet/Visible Light	Optical Microscope
10^{-7} to 10^{-6}	HIV virus	Viruses		
10^{-6} to 10^{-5}	Mitochondrion, Bacteria	Cells		
10^{-5} to 10^{-4}	Animal Cell		Infrared Radiation	Visible
10^{-4} to 10^{-3}	Amoeba	Insects		
10^{-3} to 10^{-2}	Drosophila (Fruit Fly)			
10^{-2} to 10^{-1}	Bumble Bee		Microwaves	
10^{-1} to 10^{0}	Chipmunk	Mammals		
10^{0} to 10^{1}	Sea Otter			
10^{1} to 10^{2}	Box Elder	Vehicles	Radio Waves	

Discussion and Implications

Document analysis of US science education standards suggested a set of entities, categories, and ranges that can be used purposefully in a virtual environment to support embodied cognition and learning about scale. The emergent finding that categories of entities and ranges of entities or phenomena are prevalent in the standards widens the variety of entities to be conceptualized in terms of scale. Exemplars from categories can be selected based on our experience with science curriculum and their feasibility in the virtual environment. Ranges might correspond to multimodal cues; for example, entities in ranges below the reach of optical microscopy might be rendered in grayscale. Preliminary research with a prototype virtual environment shows that undergraduates and teachers find it helpful in developing their conceptions of scale.

Science Teachers' Ideological Shifts about Multilingual Learners

Bethany Daniel, Vanderbilt University, bethany.r.daniel@vanderbilt.edu
Ashlyn Pierson, Ohio State University, pierson.199@osu.edu
Danielle Keifert, University of North Texas, danielle.keifert@unt.edu
Sarah Lee, Vanderbilt University, sarah.lee@vanderbilt.edu
Rachel Askew, Freed-Hardeman University, raskew@fhu.edu

Abstract: Drawing on theories of ideologies in interaction, this poster considers the extent to which professional development supported elementary teachers' rearticulations of monolingual ideologies toward expansive views of young multilingual learners' capabilities in science.

Motivation and conceptual framework

In STEM classrooms, leveraging multilingual and multimodal resources can contribute to more equitable learning environments for multilingual learners (Pierson et al., 2021). However, learning is shaped by dominant ideologies that privilege "standard" language varieties such as (academic) English, positioning minoritized language varieties as deficient (Flores & Rosa, 2015) and limiting opportunities for meaningful sensemaking. This study considered the extent to which a professional development (PD) project supported teachers in rearticulating monolingual ideologies that constrained learning for multilingual learners in science.

We conceptualize ideologies as powerful and politically non-neutral lenses used to interpret and make sense of students, classrooms, and society (Louie, 2020; Philip, 2011). Ideologies can be constraining, reproducing the status quo, and they can be expansive, challenging and disrupting dominant beliefs about the way things should be. Furthermore, ideologies are complex, fluid, and contradictory, rather than static across contexts (Louie, 2020; Philip, 2011). They can also be rearticulated through interaction (Philip, 2011; Philip et al., 2018).

Method

This work builds on a larger research study supporting elementary teachers in implementing model-based science learning sequences. Yet equitable teaching may have been constrained by pervasive monolingual ideologies (Daniel, 2021). To trace teachers' ideological sensemaking, we drew on Philip's (2011) concept of stance—verbalized sensemaking dependent on the positionality of the speaker. Using interaction analysis (Jordan & Henderson, 1995), we analyzed moments of stance-taking in ideological discourse. We focus on an illustrative case of Marie M., who shifted toward expansive ideologies in the context of our design.

Findings

We compare two moments from our PD. In both moments, Marie (all names are pseudonyms) shared with colleagues a narrative about her 4th grade student Mila's participation in a science lesson on rainbows and light. Mila was a multilingual learner who spoke Swahili and had limited experience with English. We argue that significant shifts in Marie's retelling of the narrative illustrate rearticulations of language ideologies in our larger PD community (see Figure 1).

In our design, our research team initially failed to develop shared language around multilingual learners. As a result, our teachers most often used the term "English Learner" or "EL," the label assigned to students by the school district. However, the use of the label was often expanded beyond students who received district language services. Marie used "EL" in her first narrative (February 2020) to refer to any student who spoke a language other than English. To address this limitation of our design, we spent time in June 2021 discussing systemic labels and how they cast multilingual learners and their language resources as deficit. These conversations were reflected in Marie's second telling of her narrative (June 2021). She noted that some of her students were labeled ELs by the district, and some had exited out of the program, but all students were bilingual. Her clarification demonstrated a shift in her understanding of the EL label by discussing multilingual learners with greater nuance and a greater awareness of bilingualism as a resource (Menken & Sánchez, 2019).

A second shift highlighted how through their interactions as a community, teachers took up more expansive ways of thinking about science sensemaking for multilingual learners. In February 2020, Mila's participation was positioned by Marie as looking, emulating, and copying, assuming that Mila did not understand what she was doing. This was taken up by the group as "step one". The teachers recognized Mila's participation but did not necessarily acknowledge that participation as science sensemaking. By contrast, Mila's participation was framed in June 2021 as one of understanding and engagement. Mila's actions of looking and copying were transformed into seeing and observing, actions that allowed Mila to "catch onto things", leveraging her own

 © ISLS

abilities to draw and her peers' thinking to engage in her own sensemaking. Rather than merely emulating, Mila's participation was reframed as an active effort to draw on multimodal resources to communicate her understanding. The teachers' (re)construction of Mila's participation in the science activity suggests a shift from more constraining to more asset-based ideologies around science learning for multilingual learners.

Figure 1

Science Teachers' Ideological Shifts

Shift 1: Redefining the "EL" label		**Shift 2: Reframing science participation**	
February 2020	**June 2021**	**February 2020**	**June 2021**
Marie: [T]hat's something I've learned this year, because this is my first year working with ELs…my whole class is ELs except for one student, so I have 22 out of 23 students	**Marie:** [Looking at student work] Well, I was trying to, I was trying to determine if they were EL students, but I don't believe that any of these students were. They're all bilingual. But…I think they had tested, they'd exited.	**Marie:** And even…my one little student, my little Mila who has no language, and she does not speak Spanish, she speaks Swahili, she was able to draw a picture just from seeing what the other kids were doing. So, she was able to participate… [S]he can look. And she can kind of emulate what the kids are doing. And sometimes, you know, she can copy…She doesn't know what they mean…But she's learned how to just like copy. **Toni:** Step one. **Sarah:** Step one. **Marie:** Step one, yeah.	**Marie:** [Mila] could see **Sarah:** Right **Marie:** and she could draw. **Kourtney:** [Overlapping] She still had ways to communicate. **Marie:** and she still had ways of also observing her peers….[S]he just observed and was able to just kinda catch onto things.

Discussion and implications

The examples presented here illustrate the rearticulation of ideologies about multilingual learners. We acknowledge that beyond our PD, other factors contribute to these shifts. For example, Marie was seeking EL certification in summer 2021, influencing the ideologies that frame teachers' participation in our PD. We also acknowledge that deficit ideologies such as hierarchical views of language varieties and a privileging of academic vocabulary persisted in our PD discourse, despite activities designed to surface and challenge these ideologies. Further research is needed to understand how PD can support ideological shifts toward equitable science teaching with elementary multilingual learners.

Visualizing Family Engagement in Museum Settings

Ariel Han, UC Irvine, hanjy3@uci.edu,
Anna Keune, Technical University of Munich, anna.keune@tum.de,
Joey Huang, UC Irvine, chujenh@uci.edu,
Kylie Peppler, UC Irvine, kpeppler@uci.edu

Abstract: The purpose of the study is to explore the affordances and limitations of information visualization for analyzing video data of small family groups in museum settings. In this paper, we analyze visitor engagement by visualizing space, time, and group interactions. Using observational video data from a museum exhibit, we designed three visualization techniques: *transcript variations, floor plan diagrams,* and *infographic charts*. Using variations of these techniques, we examine each approach's affordances and limitations.

Visualizing visitors' interaction in museum settings

Information visualization involves telling graphical stories, using data for effectively presenting and conveying their meaning, and capturing their patterns in a comprehensive way. Although most visualizations have been utilized heavily in quantitative research, there is still a lack of research on how the method can analyze qualitative data including videos and interviews (Shapiro et al., 2017). High-quality information visualization helps researchers, museum curators, and learning designers understand and analyze visitors' engagement and interaction of the learning process. In this paper, we develop visualization techniques to support analytical processes. We focus on family groups in museum settings due to their complexity but explore applications more broadly for educational research. For the purposes of this research, we created three unique visualizations using video data from a designed museum exhibit that included space, time, and social group interactions. We then evaluate the effectiveness of the visualization techniques by analyzing how those visualizations afford an understanding of visitors' interactions.

Methods

Our research was built on secondary data analysis of *The Walk* exhibit that has been installed in a science museum in the Midwestern United States. The exhibit was developed to support data visualization literacy by allowing visitors to generate and navigate visualization with embodied (i.e., walking and running) interactions at the exhibit (Börner et al., 2016; Peppler et al., 2021). *The Walk* exhibit provides three distinct stations for the experience: a) a *data input station* where visitors can enter their personal data (i.e., height, age, zip codes, favorite activity) on the touch screen, b) a *walk station* where visitors walk towards the finish line for generating embodied data in seconds, and c) a *MAV data output station* that displays data output from previous stations as an interactive data visualization in various styles (i.e., scatter plots, tables, geo-map).

We observed a total of 74 visitor groups and selected three groups, including youth ages 7 to 13. The three groups engaged at the exhibit for more than 8 minutes (i.e., over the average time of 8 minutes) to visualize their interactions. We used three different types of video data across the exhibit: a) videos captured by the *data input station*, b) the *broader view* camera, and c) videos from the *data output screen*. We used the video recordings to track visitors' movement in the exhibit as well as to measure the time spent at each station. We focused on the MAV data output station video to examine visitors' conversations, alongside semi-structured interviews that one of our researchers collected while visitors navigated the MAV data visualization screen. We also used the broader view videos to map visitors' experience at the exhibit by tracing each member's movement and track time spent (i.e., dwell time: how long they stay at the exhibit) at each station along with the layout of the exhibit (Peppler et al., 2021).

Creating visualization techniques

We iteratively developed visualizations to show different aspects of the visitors' engagement. There are three parameters to consider when analyzing the visitor's engagement: 1) visitors' *time*, as a measure of their attention span (Shapiro et al., 2017), 2) visitors' *interaction* (i.e., conversation across the space), and 3) visitors' *movement*. These three parameters apply time and space to represent engagement through the behavior of people. Our visualization techniques include using symbolized icons and graphical illustrations to represent quantitative (i.e., time) and qualitative data (i.e., text, image).

We designed the three categories of visualizations to explore different ways of representing visitor engagement: First, we used transcript variations, typical qualitative research tools used in the learning sciences that show various forms of engagement (Shapiro et al., 2017). We illustrated transcript variations in a table format, which described the observations in each cell as sequences, to evaluate visitors' behavior across the exhibit (see Figure 2a). Second, we generated floor plan diagrams, which presented a layout of the spatial settings across a range of angles in the exhibit. We

 © ISLS

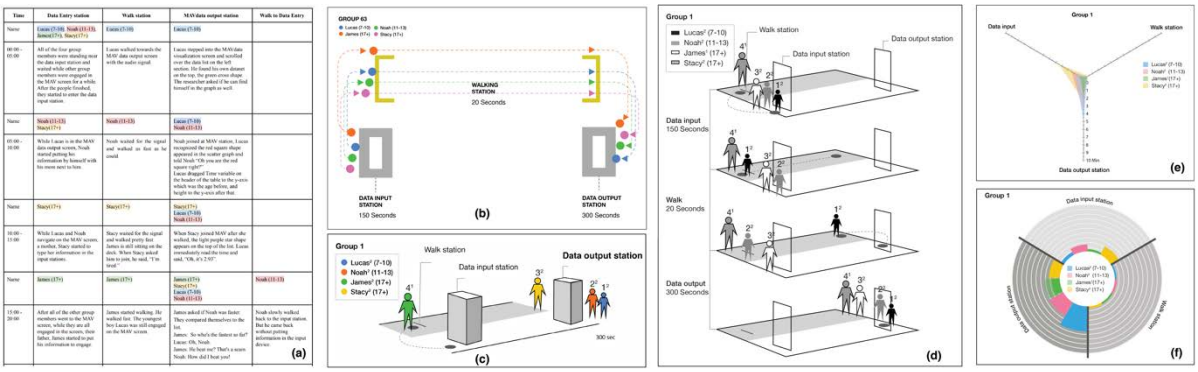
created the floor plan diagrams to illustrate visitors' movement and trace their migration patterns (see Figures 1b, c, d). Lastly, we created infographic charts, which are used to efficiently communicate by creating simplified graphics with design elements using complex data (see Figures 1e, f). The infographics visualization techniques focused on the numeric values such as the *time* spent and the *number of trials* (i.e., some of the visitors tried the exhibit several times).

Findings and Evaluation

We argue that each of the visualization techniques—transcript variation (1a), floor plan diagrams (1b, c, d), and infographics (1e, f)—possesses strengths in one of the three data variables 1) visitors' group interaction, 2) spatial settings, and 3) dwell time. Our findings showed that the *transcript variations*' advantage is to highlight visitor groups' verbal and gestural *interaction*, because it provides textual descriptions on how visitors' make sense of the exhibit. *The floor plan diagrams* focus on visitors' movement across the museum floor, and the layout of the exhibit shows movement patterns. For example, from the top-down bird's eye view floor plan, we can see where each person is located and how they navigated through the exhibit by following the lines. The arrows help make sense of the directions and flows of peoples' movements. The advantages of *infographic charts* (see Figure 1e, f) are in highlighting quantitative values (i.e., dwell time) with the graphical elements (i.e., shapes, colors) with the simplified, symbolized data variables such as individuals, time, and locations. The visualizations are like graphics such as bar charts and scatter plots.

Figure 1

Representative visualization variations under the visualization techniques



Discussion and Implications

This project was conducted through the lens of learning scientists involved with designing information visualization of group interaction in a learning environment. The combination of these three types of visualization techniques will be helpful for showing different perspectives on the visitor's experience in the exhibition. Further, the study shows the potential of using these visualization methods in diverse settings such as schools and homes to review, reflect, and evaluate people's experiences (Shapiro et al., 2017). Approaches of ongoing works around visualizing group interaction can enhance collaboration across data visualization, education, and museum studies. Researchers and museum practitioners will benefit from new opportunities with the visualization techniques in examining and understanding people's engagement in space.

Co-Design of AI-enhanced Learning Analytics: Considerations for Ensuring Diversity, Equity, Justice

Ismail Celik, Hanni Muukkonen, ismail.celik@oulu.fi; hanni.muukkonen@oulu.fi
University of Oulu, Finland

Abstract: The majority of the participatory/co-design research has somehow ignored the considerations tackling the diversity, equity, and justice challenges in the design process of learning analytics. We suggest four considerations: (1) while determining the needs and expectations of targeted learners, consider all subgroups of populations (2) determine the transparent and inclusive algorithm for meeting the needs (3) consider diversity and equity for model training data (4) consider heterogeneous participants while testing prototypes of learning analytics.

Introduction

Although learning analytics has huge potential in serving personalized learning opportunities, there are also prevalent concerns on crucial ethical issues such as discrimination and fairness. Specifically, these concerns are related to the degree to which learning analytics can provide different learners from numerous socio-cultural and economic backgrounds with fair intervention (Hansen & Reich, 2015). Due to the integration of artificial intelligence (AI) into learning analytics, algorithms and automated computational methods have been widely utilized. In this regard, algorithmic decision-making of learning analytics has raised some questions on inclusiveness and discrimination levels of these algorithms (De Cremer & De Schutter, 2021).

In order to effectively overcome diversity and equity challenges, the possible solutions require an interdisciplinary collaborative approach involving all stakeholders who benefit from AI-enhanced learning analytics systems (Dollinger & Lodge, 2018). This approach is closely related to the participatory/co-design process. Although important research and initiatives are focusing to (co)- design effective and efficient learning analytics systems with particular learners, the majority of this participatory/co-design research has somehow ignored the considerations /demands of tackling the diversity, equity, and justice challenges in early design and testing process of learning analytics systems (Holstein & Doroudi, 2019). The purpose of the current paper is to determine considerations for ensuring diversity, equity, and justice in the co-design process of AI-enhanced learning analytics. Researchers and developers have utilized the co-design approach to give a voice to learners. Nowadays, co-design has become a well-established approach to facilitate the inclusion of the different stakeholders` needs in the design process. In the current study, the main components of co-design are shown in four iterative steps. The relevant components with descriptions are as follows: *Empathize & Problem Definition (1):* identification of target learners, description of contextual factors *Ideate (2)*: decision on learning approach, identification of learning variables and data modality, determination of AI methods, role of AI methods in the learning analytics tools. *Development of Prototypes (3)*: selection of low fidelity and high-fidelity prototypes. *Test (4)*: implementation of usability test, deployment of LA tools in a real classroom setting.

Methodology

The considerations for co-design of AI-enhanced learning analytics were determined by reviewing literature from various disciplines namely learning analytics, responsible AI use in education, and co-design process for educational technologies. Through the review of related literature, the consideration was selected based on the diversity, equity, and justice from the well-known publications in each research area. The considerations for co-design of AI-enhanced learning analytics were determined by reviewing literature from various disciplines namely learning analytics, responsible AI use in education, and co-design process for educational technologies. Through the review of related literature, the consideration was selected based on the diversity, equity, justice from the well-known publications in each research area (e.g., Hernández-Leo et al., 2019).

Results

The preliminary results as considerations are presented in this section. Initially, we determined four important considerations (C1, C2, C3, and C4).

C1: While determining the needs and expectations of targeted learners, consider all subgroups of populations

As researchers and developers interview or meet with learners to grasp their needs, the participants should represent all learners for equity. In this step, the gender, race, socio-economic characteristics of groups should be formed as equal as possible. C1 can be tackled in the empathize & problem definition (1) step of the co-design process.

 © ISLS

C2: Determine a transparent and inclusive algorithm for meeting the needs and expectations

The prediction results of algorithms should be checked not only for accuracy but also inclusiveness. Transparency of algorithms is also important for justice. Transparency is one of the common ethical use principles and considerations of many AI-based systems (Kitto & Knigt, 2019). Transparency makes AI algorithms of learning analytics more accountable and, thus, the outcome of learning analytics such as adaptive feedback might be more visible and measurable (Ananny & Crawford, 2018). C2 can be performed in the ideate (2) step of the co-design process.

C3: Consider diversity and equity for model training data

In order for AI algorithms of learning analytics to make fair decisions, training data should properly represent targeted learners. Before training AI algorithms based on the data, developers must know how the learners are distributed in the training data set (De Cremer & De Schutter, 2021). The discrepancy could stem from an unbalanced training set within some subgroups due to historical bias. Also, it is more likely that researchers might be biased when they focus conclusions derived from skewed data privileging behavior patterns of more prepared, lower need students (Meaney & Fikes, 2018). C3 can be applied in the ideate (2) and development of prototypes (3) steps of the co-design process.

C4: Consider the heterogeneous participants while testing prototypes of learning analytics

In the testing step of the co-design process, the first versions (prototypes) of developed learning analytics are utilized by learners. Deep understanding is needed to improve prototypes; therefore, the participants testing prototypes should be as diversified as possible. If any learners from different sub-groups have no chance to provide comments, the last version might be lacking their views, intentions and expectations. C4 can be employed in the development of prototypes (3) and test (4) steps of the co-design process.

Conclusions

Personalized and adaptive approaches of learning analytics highlight the advantage of enhancing the equity of learners at different stages. For maximizing this advantage, researchers and developers should perform some co-design considerations. In the current study, we defined four preliminary considerations for ensuring diversity, equity, and justice in the learning analytics systems. Learning analytics developers might integrate these considerations when they carry out the co-design process.

Towards a Theory of Dialogic Play for Learning

Matthew Gaydos, National Institute of Education, matthew.gaydos@nie.edu.sg
Aline Nardo, University of Edinburgh, aline.nardo@ed.ac.uk

Abstract: In this paper, we argue that differentiating dialectic from dialogic play can illuminate important differences between current approaches to game-based learning and can suggest new directions for the field of game-based learning. Expanding on Vygotsky's work on imaginary play, we work towards a theory of dialogic play with particular focus on the role of vulnerability in learning and propose it as an alternative to prior approaches that emphasize content learning or tool-mastery. Because it encourages curriculum that supports new ways of relating to difference and otherness, we believe that dialogic play is important to consider in play-based learning, as it more closely aligns with sociocultural approaches that address issues of power and may be useful in the design of related curriculum.

Introduction

Play is regarded as an important part of learning and child development (e.g., Golinkoff & Hirsh-Pasek, 2006) and has a long history of integration in education (e.g., D'Angour, 2013). In the learning sciences, studies have begun more recently to explicitly explore its role in learning. For example, Saleh et al. (2019), define collaborative inquiry play as: 1) rule-based imaginary situations that provide challenging problems and 2) experiences that present agentic multiplayer interactions and DeLiema, Enyedy and Danish (2019) studied the way play-based practices can drive an inquiry activity, examining how best to support these practices. From these studies, we are better defining and understanding the particular types of play that are good for formal and informal learning, the different contexts in which it occurs, and gaining a better understanding of how that play can be supported. In this paper, we begin to articulate a theory that differentiates two ways to view play - dialectic and dialogic - and argue that this difference can illuminate important differences between current approaches to game-based learning and can inform the design of educational games that are focused less on mastery learning (especially regarding in-game systems and symbols etc.,) and more on players' socially situated and developing identities as well as their relationships with other agents involved in the game (e.g. designer, player). Games and play viewed from this perspective, we argue, can better incorporate a concept of learning as relational and ecological, making them suitable for learning domains that are particularly difficult to teach in higher education, such as ethics (Nardo & Gaydos, 2021). Prior research has noted the importance of post-game discussions for learning (Bado, 2019), and has developed theoretically sophisticated models of the role and relationship between dialog and play (e.g., Chee, 2011). Our theoretical work is different in its focus on the nature of play itself and is rooted in (but departs from) Vygotsky's conception of play-based learning as predominantly dialectic.

Revisiting Vygotsky's Theory of Play

To Vygotsky, play is an important driver of learning and development as it enables children to separate their field of vision from a field of meaning. He points out that it is often mischaracterized as 1) predominantly symbolic action or 2) as simple pleasure-seeking behavior; he rejects both. First, Vygotsky argues that considering play as symbolic action or taking a predominantly cognitivist perspective (e.g., players as algebraists) misses the emotional and motivational components that undeniably drive (especially childhood) play. Second, he maintains that while play includes players taking motivated action to seek pleasure, there are many other activities that children engage in that are more consistently pleasurable (e.g., sucking a pacifier) and that don't include the sometimes-strong negative feelings that accompany play (e.g., losing a game). Play thus seems to involve something distinct from symbolic action and simple pleasure-seeking behavior.

In Vygotsky's conception of play, the child creates *imaginary situations* – play is "the illusory realization of unrealizable desires." On the one hand, this act of imagination can be liberating. Action is untethered from the constraints of reality: "In play a day can take half an hour, and a hundred miles can be covered in five steps." Thinking becomes acting; what the child wishes to happen, happens. On the other hand, playful imagination is purposefully restrictive: Play relies on the creation and expansion of constraints, rules, and boundaries. Through the creation of imaginary situations that enable freedom of action bound by rules, children in play can explore new fields of meaning that adopt increasing sophistication - a stick and later a postcard can transform into a horse, depending on the rules of the game and the developmental state of the child. Because of the rules derived from these imaginary situations, the freedom of meaning exploration is constrained, such as in the way that the child must resist the immediate impulse to treat an object as they see it

 © ISLS

or must abide by what she imagines constitutes a "sister" while role-playing as one. In play, the immediate impulse must be renounced and subordinated under the rules of the game. This constraint creates further opportunity for playful experimentation, for example the subversion of established social rules, or the pleasurable exploration of 'forbidden' emotions (e.g., 'schadenfreude', gloating, feelings of superiority): "For example, the child weeps in play as a patient, but revels as a player", Vygotsky writes.

It is with reference to this rule-following that Vygotsky's description of play can be dissected and alternative views presented. In this poster presentation, we explain our approach in which we frame play as dialogic, drawing on Wegerif's (2007, 2011) notion that learning involves an individual seeing things from two perspectives at once. Reiterating Bakhtin (1987), he argues that "relationships between things are very different from relationships between voices" (Wegerif, 2007, p. 43) and that learning is dependent on establishing and maintaining a dialogic relationship between the learner and the 'other.' This relationship between voices involves creating a 'space' between the self and other within which both "mutually construct and reconstruct each other" as they seek understanding (ibid). A dialogic approach is thus close to but distinct from a dialectic approach, particularly in its purported aims. In a dialectic approach (a la Vygotsky), effective cultural sign and tool use is the primary goal. The dialog is the pedagogical method. The aim of the dialog (under a dialectic model) is for the student to acquire, and for the teacher to transmit, a shared understanding of the socially constructed meaning of tools (Daniels, 2014, p. 20). In formal education, what is to be learned should be congruent with already-established culture norms (e.g., mathematics).

On the other hand, in a dialogic approach to learning, the role of the tool and sign is to provide support and expand dialogues between people with different viewpoints and understandings (Wegerif, 2011). Unlike dialectic learning, tool use and representations may take on multiple provisional meanings as one attempts to understand what the other is saying, these representations may or may not align with cultural norms. Dialog, in this case, creates the opportunity for development (i.e., the ZPD) that does not arise from the difference between the individual's understanding of the tool and the culturally evolved meaning of said tool, but rather from the different interpretations held and voiced by interacting individuals. The result of this kind of dialog is not the dialogic reduction of difference towards a particular aim, but the construction of new meaning that is not already present between the dialog participants (Daniels, 2014). This process of dialog interpretation may involve listening, trying to proceed in conversation, and addressing our own prejudices as we comprehend what the other says and contribute our own voice to the conversation (Vilhauer, 2010). Implications for this alternative approach are further detailed in the poster.

To Wait or Not to Wait: Adding to the Debate on Immediate Versus Delayed Feedback

Hannah Smith, Vy Ngo, Adam Sales, Avery H. Closser, Jenny Yun-Chen Chan, Erin Ottmar
hsmith2@wpi.edu, vngo@wpi.edu, asales@wpi.edu, ahclosser@wpi.edu, jchan2@wpi.edu, erottmar@wpi.edu
Worcester Polytechnic Institute

Abstract. Prior work investigates the impact of feedback timing on math performance; however, *when* feedback is most effective remains unclear. We define immediate and delayed feedback and examine how timing affects student algebra performance. 1,629 students were randomly assigned to an immediate or delayed feedback condition, completed a two-hour intervention solving math problems in an online tutoring system, and received immediate or delayed feedback. We found overall learning gains, but no differences between the conditions.

Objectives and theoretical framework

Feedback is commonly used across educational contexts. However, there have been contradictory findings as to *when* it is most effective to provide students with feedback (Fyfe et al., 2021). Feedback timing has been examined in labs (e.g., Brackbill et al., 1963), classrooms (e.g., Sturges, 1978), and online settings (e.g., Kehrer et al., 2013), making it difficult to compare the effects of timing across different environments. Further, prior research has defined immediate and delayed feedback differently, creating a challenge to distill findings. *Immediate feedback* has been used in reference to feedback given post-attempt (Brackbill et al., 1963) as well as immediately after completing a problem set or test (Kulhavy & Anderson, 1972). *Delayed feedback* has been used in reference to feedback delivered at some point after immediate feedback, such as a few seconds post-item (Lintz & Brackbill, 1966), immediately post-assignment (Sturges, 1978), or minutes (Mason & Redmon, 1993) to months post-assignment (Sassenrath et al.1968). Further, research on the effects of feedback timing has shown mixed results: studies have found differing results when comparing the effects of immediate and delayed feedback (Kehrer et al., 2013). For example, Many Classes (Fyfe et al., 2021) compared the effects of immediate feedback, defined as immediately post-assignment, and delayed feedback, defined as one to five days post-assignment. Across 38 college classes and 2,081 participants, the authors did not find a significant effect of timing posttest assessments. We add to the ongoing debate by testing the effect of feedback timing in an online algebra intervention for middle-schoolers. In the current study, we employed two timings of feedback: immediate and delayed. We define *immediate* feedback as hints and correctness feedback provided immediately after a response to a problem and *delayed* feedback as correctness feedback provided immediately after completing an assignment. We pose the following questions:

1. Do students improve their mathematical understanding after completing four assignments?
2. Does immediate or delayed feedback on practice assignments impact students' learning gains?
3. Does students' prior knowledge moderate the effect of feedback timing?

Methods, data sources, and materials

The sample is from a randomized controlled trial run in a district in the Southeastern US during the 2020-2021 school year (Woodrow et al., in prep). We investigate the effects of immediate vs. delayed feedback within ASSISTments (Heffernan & Heffernan, 2014), an online tutoring system. Our sample includes 855 seventh graders (51% immediate; 49% delayed) who started pre- and end-of-semester assessments. Genders were 50% male and 50% female. In terms of race/ethnicity, 52% were White, 27% Asian, 13% Hispanic/Latino, 8% other.

Procedure

All study sessions were administered online in math classrooms during instruction periods. Students worked individually at their own pace on their own device. The analyses focused on the assessment data at 2 time points: start of the semester, and end-of-semester after four 30-minute intervention sessions. Students in both conditions solved the same math problems in ASSISTments. The problems were adapted from three open-source curricula. During the intervention sessions, students had 25 minutes to complete the problems, and five minutes to review their performance on each question. In the *immediate feedback* condition, the hints and correctness feedback were

 © ISLS

available *during* and *after* problem-solving. As students answered the questions, they received immediate correctness feedback after each answer attempt. If students answered the question correctly on the first attempt without using any hints, they received a green check as correctness feedback. If students entered an incorrect answer or used a hint, they received an X. Students received this correctness feedback after each answer attempt and had to enter the correct answer to advance to the next problem. In the *delayed feedback* condition, the hints and correctness feedback were available *only* in the session report *after* assignment completion. Students could not request hints and did not receive correctness feedback during the intervention sessions; they simply answered the problem then advanced to the next question. When students submitted their answer to a question, a blue dot appeared on the screen indicating that the system recorded their answer.

The *algebra knowledge pre-assessment* consisted of 10 items from a previously validated measure that tapped into conceptual understanding, procedural knowledge, and flexibility with a mirrored end-of-semester assessment (Star et al., 2015). Each item was scored as correct (1) or incorrect (0). The total score on the end-of-semester assessment was included as the outcome and the score on the pre-assessment was included as a covariate in analyses.

Results

RQ1. Across both conditions, students' end-of-semester assessment scores were, on average, 0.63 points (95% CI: [0.48,0.77]) higher than their pre-assessment scores, $t_{854}=8.5$, $p<.001$.

RQ2. When condition was the sole predictor, a regression model suggests a small benefit of immediate feedback on students' end-of-semester scores (0.248±0.260), $p<.10$. When including students' pre-assessment scores, fifth-grade state standardized achievement scores, English to Speakers of Other Languages status, Early Intervention Program status, and Individualized Education Program status, gender, and overall academic achievement (above or below grade level) as covariates, the effect of being assigned to immediate feedback was somewhat smaller (0.195±0.248; $t_{723}=1.5$, $p=.12$). Although we cannot confidently determine the sign of the average effect of feedback timing on students' end-of-semester assessment scores, the magnitude of the effect was small ($d<.17$).

RQ3. The interaction between condition and pretest scores was tested with the covariates, and the model shows that the Condition × Pretest interaction (0.062±0.088) was not statistically significant, $p=.169$.

Conclusions and significance

Aligning with the mixed findings in the literature, our results showed that effects of feedback timing on performance—if any—was small in magnitude. However, we did find that students improved from pre-assessment to end-of-semester assessment across conditions, suggesting that both feedback interventions might be beneficial.

Using Organizational Change Theories to Examine Women-in-Computing Groups

Jue Wu, David H. Uttal
juewu2015@u.northwestern.edu, duttal@northwestern.edu
Northwestern University

Abstract: The gender imbalance in computer science is getting worse, with computer science being the only Science, Technology, Engineering, and Mathematics (STEM) field in which women's representation has steadily declined throughout the past few decades. This study focuses on one attempt to redress the lack of women in computer science—Women-in-Computing (WiC) college clubs. Drawing on organizational change theories, we ask: How do students engage in WiC? Do WiC clubs engender changes? If so, how? We argue that WiC is an identity, a community, a safe space, and the beginning of a career-long practice of mentoring future women in computer science. Moreover, changes driven by such clubs have brought impacts to both the individual level students and the organizational level computer science departments. This study offers a new perspective on applying organizational change theories and contributes to the broader research community on diversity, equity, and inclusion in higher education.

Introduction

There are many more men than women in the field of computer science (CS) (e.g., Cohoon & Aspray, 2006; Margolis & Fisher, 2002). And the gender imbalance is getting even worse; computer science is the only STEM field in which women's representation has steadily declined throughout the past few decades (Cohoon & Aspray, 2006; Corbett & Hill, 2015). How can the problems that limit women's participation in computer science be redressed? There have been many efforts, but many may be difficult to replicate on a larger scale, as they relied on a great deal of investment of time and money from high-level administrators.

The current study focuses on one attempt to redress the lack of women in computer science that may provide some of the same benefits as these prior efforts but is relatively expensive and hence more likely to scale, namely, Women-in-Computing (WiC) groups. WiC groups, as one type of on-campus college student groups or clubs, have evolved and developed in the past few years across the U.S. Still, up to now little has been known about the values embedded in these groups and the practices they enact. Because college student groups could potentially benefit student development, leadership development, and organization development (Derby, 2006; Foubert & Grainger, 2006), which may in turn lead to more women participating in computer science, a deep dive into such groups' practice might provide crucial knowledge to understand both the current status of Women-in-CS groups and their future development.

Framework

In *How Colleges Change: Understanding, Leading, and Enacting Change*, Adrianna Kezar (2014) invited readers to think differently about organizational change and provided a multi-faceted framework for understanding change. Through research on how to successfully create change, Kezar (2014) reviewed elements of this change framework that were critical in understanding the change process, including but not limited to *agency of change*, *resistance and obstacles during change*, and *types and levels of change*. By connecting these various features back to the theories of change, Kezar (2014) provided a rationale for why they are important for facilitating change and moving toward action. Therefore, in the context of studying WiC's practices and its impacts, this framework can be extremely useful in articulating the process of change driven by WiC, by decomposing change process into these elements and features. This analytical framework allowed us to examine changes at both the individual level and the organizational level, as well as the group level—which is the club itself—in between.

Method

The participants in this study were members of the Women in Computing (WiC) club at a private university in the Midwest in the United States. Besides general WiC members, particular attention was paid to WiC junior board members and WiC executive board leaders, who hold leadership positions and are in charge of planning and executing WiC events. We chose this focus because WiC execs are not only active members of WiC but also leaders who make organizational level decisions to achieve WiC's goals and reflect WiC's values. The main source of data included participant observations with field notes and video recordings, as well as individual

 © ISLS

interview recordings. We began our qualitative analysis by identifying salient themes, and then focused coding was used to closely examine relationships between themes and identify patterns of relationships. Evidence that we considered in coding included both the actions and movements enacted by the students during the events and the conversations that WiC members had during the events and from the interviews.

Preliminary findings

Our preliminary findings suggest that WiC is an identity-based rather than a membership-based community. Evidence to support this claim comes, in part, from the gender identity and college major of those who attended meetings: Sometimes men attended the events, and there were attendees who self-identified as non-CS majors in almost all of the WiC events. Because WiC stands for Women in Computing, ostensibly these people seem not to fit the definition or purpose of WiC this definition. Then, why did they come to WiC events?

The former president of WiC provided an answer: *"You're in WiC if you are a WiC, like if you're computing, if you want to support. We keep saying it's an identity. There is no membership. You don't have to come to every event… It's an identity. It's a community…"*

The organizational change perspective allowed us to uncover various ways in which WiC is carried on by people in the club. WiC has been sustained through interactions between faculty and students, between upperclassmen and underclassmen, and between the senior executive board and the junior executive board.

Moreover, we gained insight into changes engendered by WiC and the mechanisms for those impacts. At the individual level, WiC organizes events to address imposter syndrome for individuals, and to increase women's sense of belonging in the computer science arena more broadly. At the organizational level, WiC also brings positive impacts to the computer science department, by having its members actively engaged in open dialogues about departmental issues and advocating for recruiting more female faculty members. These efforts ensure cultural and institutional change, which may then help sustaining changes in the long run.

Understanding change is more than assessing impacts; it is also about interpreting and articulating how changes occurred. Guided by our analytical framework, we identified both top-down and bottom-up leadership strategies employed by the WiC exec board, as well as how the exec board functions as a collective leadership.

Implications

Although organizational change theories have been used extensively to examine reform in higher education (e.g., Awbrey, 2005; Gumport, 2000; Kezar, 2011; Kezar, 2014), this perspective has rarely been used to examine changes initiated by college clubs. Therefore, this study is a new attempt to apply organizational change theories in the context of one particular college club and unpack change process by closely examining levels of change, agency of change, and resistance and obstacles. This cross-level approach is useful for describing change phenomenon and change impacts, and also for articulating change process and change mechanisms.

As diversity and inclusion initiatives become increasingly important in higher education, finding new approaches for understanding and facilitating change merits more attention. Because college clubs that are run by students act as a natural bridge between students in the clubs and higher-level institutional leaders who oversee the clubs, the cross-level perspective can be extremely valuable in providing actionable insights for group level changes that serve both individual level and organizational level.

Despite the new approach this study provides, questions remain regarding how representative this particular WiC is, whether findings from this WiC can be expanded or generalized to other Women-in-CS groups or even other types of college clubs for diversity and inclusion missions. Further research is required to fully understand how best to harness the power of college student clubs that allow for broader long-term impacts related to issues of underrepresentation of women in STEM and more general diversity and inclusion issues.

Validating a Code-Free Computational Thinking Assessment for Elementary School Students: Preliminary Results

Arif Rachmatullah, Carol Tate, Andrea Beesley, and Elise Levin-Guracar
arif.rachmatullah, carol.tate, andrea.beesley, elise.levin-guracar@sri.com
SRI International

Abstract: Computational thinking (CT) assessments are increasingly available, but it is still challenging to measure the impact of CT interventions. Assessments employing the same coding context as the intervention confer an advantage to treatment students, and possibly also to comparison group students with prior coding experience. Here we report initial findings of our effort to validate a CT assessment without a coding context and to account for prior coding experience in the validation process.

Introduction

The increasing number of computing-related careers has expanded the essential skills students need to develop throughout their school years. Such skills include computational thinking (CT), which Shute et al. (2017) defined as "the conceptual foundation required to solve problems effectively and efficiently (i.e., algorithmically, with or without the assistance of computers) with solutions that are reusable in different contexts" (p. 151). Due to its roots in computer science (CS), CT has been nurtured through engaging students in computer programming or coding-infused activities, such as scientific computational modeling where students build simulations of scientific phenomena in a coding environment. Therefore, many available CT assessments use coding languages as the context of questions (e.g., Román-González et al., 2017; Wiebe et al., 2019). This practice does not align completely with Shute et al.'s CT definition, which includes contexts beyond programming. In addition, using coding contexts in a CT assessment gives students with prior coding experience an advantage because they are more familiar with such representations compared to students with no experience. Hence, such an assessment might lead to biased interpretations and difficulty measuring the impact of CT activities. Relatedly, code-centric CT assessments might not be usable when conducting a study comparing computational modeling activity to a 'business as usual' condition in which students have not been exposed to coding, as the assessment would be overly aligned with the intervention. We encountered such a situation in the project from which this validation study stems. In response, we assembled a coding-free CT assessment for elementary school students to minimize pre-existing differences in students' prior coding experiences. The questions in this CT assessment measure five out of six CT facets proposed by Shute et al. (2017): decomposition, abstraction, algorithms, debugging, and generalization. This paper attempted to answer one research question: is this CT assessment valid and reliable?

Methods

Context and Participants

This study is part of a larger project focused on exploring the impact of learning mathematics through computer programming on fifth graders' CT skills. The study is still ongoing; the data we used in this paper were from the pilot study. A total of 127 fifth-grade students (age $M = 10.52$, $SD = 0.66$) participated in this pilot study and took the CT assessment. These students were from rural areas in a central US state and predominantly White (72%), 2% Black/African American, 1% Latinx, 6% mixed-race, and the remaining 19% did not provide their racial group information. Regarding gender, 46% of students identified as female, 48% male, and 6% opted not to answer the question. The number of students who reported never having any experience with coding (31%) was almost equal to the number of students who had some coding experience (at least a one-time experience learning how to code; 64%), and 5% of students did not report their prior coding experience.

The Code-Free CT Assessment

The pilot assessment was comprised of 16 questions. The questions were drawn mainly from three CT instruments for elementary school students: Bebras CT Challenges, the National Assessment of Educational Progress's (NAEP) mathematical problem-solving questions, and Math and Computational Thinking Through 3D Making (MPACT) assessment. Among the 16 questions, nine were from Bebras Challenges, five were from NAEP, and two were from MPACT. These questions were selected based on their concordance with Shute et al.'s (2017) CT facets. Each question measures multiple CT facets. Hence, we conceptualized that this assessment is unidimensional – measuring one construct, which is CT.

 © ISLS

Analysis and Validation Procedure

Rasch modeling was performed to gather evidence of the assessment's construct validity. Infit and outfit mean-square (MNSQ) values generated through Rasch modeling were used to evaluate whether each question could differentiate students with low CT scores from ones with higher CT scores. The MNSQ cutoff of 0.7 – 1.3 proposed by Wright and Linacre (1994) was used in this study. In addition, differential item functioning (DIF) analysis was run to identify any questions exhibiting bias based on students' prior coding experience. We used the cutoff of $p < .01$ for X^2_{13} to identify significant DIF as suggested by Choi et al. (2011). The questions either flagged as biased in the DIF analysis and/or having infit and outfit MNSQ values outside the acceptable range were removed. Reliabilities were computed using Rasch item and person reliabilities and Cronbach's alpha.

Initial Findings and Future Directions

We found that almost all questions had MNSQ values within the acceptable range and were not flagged as DIF prior experience, except Questions 13 and 16. Question 13 particularly had both MNSQ values outside the acceptable range and were flagged as DIF item, and Question 16 was flagged as a DIF item. We then removed these two questions and re-ran the analysis. The fourteen-question assessment (Table 1) had acceptable person and separation reliabilities as well as Cronbach's alpha values which were .64, .61, and .66, respectively. Furthermore, even though the findings do not yet have high interpretative power due to the limited sample size, we believe that the results are promising, especially toward establishing a more generalizable CT assessment. Hence, we plan to collect more data to strengthen the current findings and to have a more valid and reliable CT assessment for elementary school students.

Table 1

Psychometric properties of the final fourteen-questions CT assessment based on preliminary analyses

Learning Natural Selection through Computational Models in a High School A.P. Biology Classroom

Bradley Davey, Amanda Peel, Michael Horn, Uri Wilensky
bdavey@u.northwestern.edu, amanda.peel@northwestern.edu,
michael-horn@northwestern.edu, uri@northwestern.edu
Northwestern University

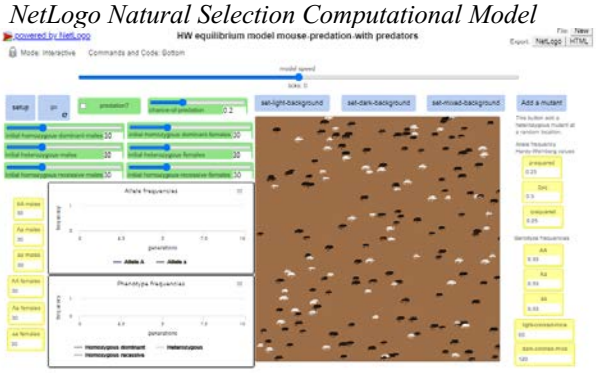
Abstract: Science education communities understand the importance of computational thinking but lack empirically tested learning materials. We report the implementation of a computationally driven natural selection unit in an A.P. high school biology classroom. Epistemic network analyses of student responses indicate that computational tools can facilitate learning of natural selection, and to varying degrees. We interpret these results to show that attention should be given to the fit between computational tools and natural selection concepts.

Introduction and Methods

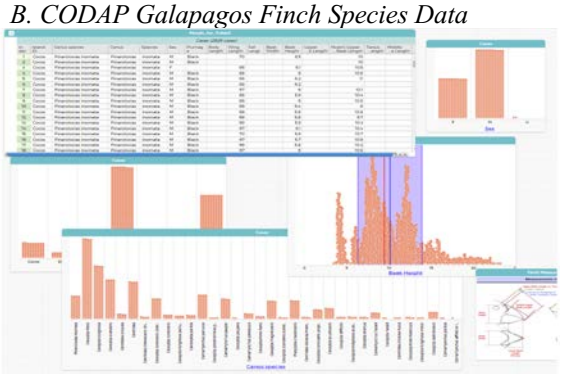
Computational tools and methods have restructured the nature of science. In response to this paradigm shift, and others, computational thinking (CT) has surfaced as a national and scholarly research interest. Due to CT's relative novelty, much of the research on CT has focused on the design of standards and curricular frameworks. Less attention has focused on empirically testing learning materials and exploring CT's ability to promote K-12 science learning (Grover & Pea, 2013). In this paper we report the implementation of a computationally driven unit to address these gaps. Moreover, we extend from previous work involving students' computational modeling of evolutionary processes (Dabholkar et al., 2020) to address the well-established and considerable difficulties students have in learning natural selection (Rosengren et al., 2012). Students in this study (N=35) interacted with four computational tools across an 8 week, 7-lesson unit on natural selection in an A.P. high school biology classroom within a large public school in the U.S. Midwest. We report two tools below in Figure 1: A computational model of natural selection (Dabholkar et al., 2020) developed in NetLogo (Wilensky, 1999) and an interactive data environment about Galapagos finches developed in the Common Online Data Analysis Platform (CODAP, 2014). The following research question guided our work: "How do computational tools facilitate learning of natural selection concepts?" Three researchers used a coding guide (Peel et al., 2019) to code unit questions and student responses. Interrater reliability was high across all codes (K_{avg} = 0.91). We analyzed student responses to two questions embedded in the unit that correspond to distinct computational tools and therefore distinct opportunities to investigate the influence of computational tools on student reasoning. We conducted epistemic network analyses (Shaffer, 2017) to understand (1) student use of natural selection in reasoning about speciation and (2) the effect of computational tools on student use of natural selection concepts.

Figure 1

A. NetLogo Natural Selection Computational Model



B. CODAP Galapagos Finch Species Data



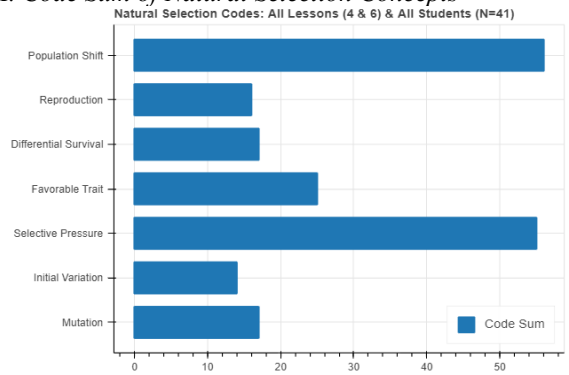
Results

In Figure 2A we report the sum of natural selection concept codes for all students and both questions. In Figure 2B we disaggregate the natural selection concept codes by question and associated computational tool. Figures 2C and 2D show comparative epistemic network graphs of student demonstration of natural selection concepts with the NetLogo computational model (Figure 1A) and after the lesson with CODAP (Figure 1B).

Figure 2

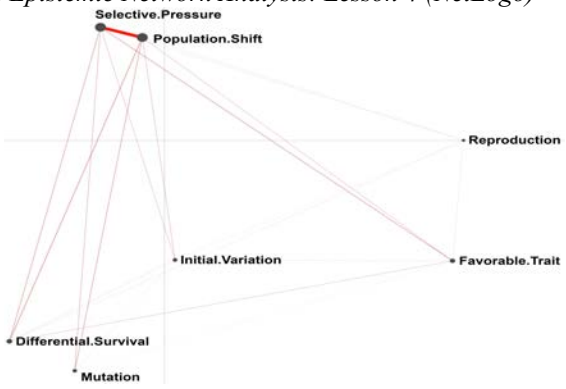
 © ISLS

A. Code Sum of Natural Selection Concepts

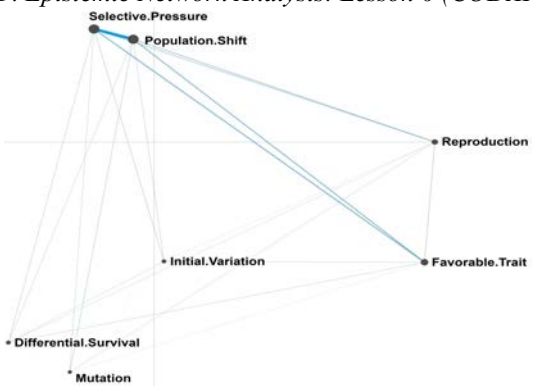


B. Natural Selection Concepts by Lesson (Tool)

C. Epistemic Network Analysis: Lesson 4 (NetLogo)



D. Epistemic Network Analysis: Lesson 6 (CODAP)



Discussion

Analyses indicate that computational tools can facilitate learning of natural selection, and to varying degrees. For example, in lesson 4 students used selective pressure and population shift concepts to explain natural selection in rock pocket mice, but fewer of the five remaining concepts (Figure 2B). Students then applied knowledge of natural selection to explain speciation of finches in the Galapagos and exhibited greater knowledge of favorable traits and reproduction (Figure 2B). We suspect this difference reflects the foregrounding of favorable traits and reproduction in the CODAP environment, which indicates that the explicitness of natural selection concepts in computational tools may lead to deeper learning. Comparative epistemic network analyses (Figure 2C and 2D) further support this interpretation and show that the NetLogo model elicited cooccurrences with differential survival, a key design principle of the model. On the other hand, student reasoning relied more on reproduction in the CODAP environment. Both tools surfaced initial variation and mutation concepts to lesser degrees, corroborating prior challenges found in teaching and learning evolution (Peel et al., 2019; Rosengren et al., 2012). Taken together, these results indicate that future work should investigate the fit between computational tools and natural selection concepts so that designs may better facilitate student learning.

Exploring Identity Resources in Co-designing Chatbots

Ha Nguyen, University of California-Irvine, thicn@uci.edu

Abstract: Co-design with students honors their lived experiences and invites participants to create novel solutions. We present insights from designing with youth ages 14-16 to create a collaborative chatbot in science. We explore the identity resources (material, relational, and ideational) embedded in the design activities, with implications for how designers and educators can provide access to resources and expand how youths participate in design practices.

Introduction

Co-design invite stakeholders such as students to reimagine learning environments, bring in lived experiences from other contexts, and creatively develop novel approaches (Bang & Vossoughi, 2016). Co-design centers young people's voices and challenges the power structures that underlie learning and participation. Central to recognizing youth's voices is an understanding of the different identity resources—material, relational, and ideational—that they draw from to relate to shared design practices (Nasir & Cooks, 2009; Roque, 2020). Material resources describe the physical artifacts and settings for the practice. Relational resources capture the social relationships that enable youth to strengthen their connections to the practice. Finally, ideational resources describe how youths position themselves and their values within the practice. Individuals use these identity resources to develop their positions within "figured worlds" of socially constructed norms and expectations (Holland et al., 1998). Figured worlds may overlap. For instance, the figured world of a design session might intersect with the figured world of interactions between co-designers and facilitators, and the larger figured world of designing. We explore (1) the features of identity resources that may foster participation in design practices, and (2) how these resources support the figured worlds of design and youths' lived experiences to overlap. Overlapping figured worlds allows individuals to adapt their positions and participation in design practices.

Methodology

The project took place in an environmental science curriculum for students in grades 8-11 in the southwestern U.S. Students learned about a local park's efforts to restrict overfishing, created models of the marine ecosystems, collected and analyzed data on the park's biodiversity, and made recommendations about conservation efforts to park scientists. The chatbot was part of a small-group modeling activity to provide conceptual and participation prompts to students. The research team conducted co-design meetings to align the chatbot's designs and talks with students' values. Participants included one male and four female students (hereon addressed as co-designers). The co-designers, who self-reported interests in science and design, were recruited from classes implementing the curriculum. The design team participated in four 60-minute online sessions over 2 months, where they engaged in activities facilitated by the researchers (a graduate and undergraduate student in Education).

Data sources included design artifacts (e.g., participants' chats, co-designed digital artifacts), field notes written by the facilitators during and immediately after each design session, and participants' verbal reflections before and after the design process. Examples of the reflection questions were "What are you hoping to gain from this experience" and "What are your takeaways from the design process?" The author and a research assistant analyzed data through the lens of identity resources (Nasir & Cooks, 2009), with a focus on how participants interacted with the physical materials, relationships, and self-positioning within design practices.

Findings

Below, we present the material, relational, and ideational resources that may bridge designs and participants' lived experiences, with elaboration on how individuals took up those resources. We further link the resources to the figured worlds that participants mentioned in the design process: A figured world of co-design in which participants and facilitators learned from one another, the figured worlds of home lives, schools, and local environments, and the larger worlds of design. All names are pseudonyms.

Connect material resources to participants' lived experiences

Material resources involve the physical space in which design meetings occurred and the activities and artifacts within that space. The activities intentionally involved artifacts familiar to the participants. The first activity asked participants to find an object in their home and describe how their desired chatbot may take up the object's features (texture, shape, characteristics, etc.). Alice (11th-grader, Asian American female) immediately grabbed a blue stuffed animal on her desk, and stated that the bot should be "round, soft, and cute". Meanwhile, Alex (11th-grader,

 © ISLS

Asian American male) showed the group his home assistant and mentioned "smart and responsive" as desirable chatbot characteristics. Involving familiar objects might have allowed participants to connect the figured world of design and agents and relationships in their home experiences. For example, in designing how the chatbot could provide hints to students in the modeling activities, Manila (10th-grader, Latinx female) stated: "You know, like my Google Home or Alexa, when you ask it questions it replies with information. Our bot can do the same: Oh you're stuck. You can start by thinking about fish, sand, planktons, whales, ..."

Furthermore, the activities spanned beyond the physical space of virtual meetings. Co-designers completed weekly cultural probes (e.g., "take a photo that connects your daily activities such as commuting to schools and the marine ecosystems"). Annie (10th-grader, Latinx female) reflected on how her conversations with friends had revolved around a recent oil spill close to school. This observation led to a discussion in the co-design group around how prompts focused on memorable events might enrich students' responses to the bot.

Promote dialogues

Relational resources involve opportunities for connection with other co-designers and facilitators. The facilitators were intentional about promoting dialogues among participants. Opportunities for connections with others, such as through design role-playing, might enable participants to empathize with the users they were designing for. Consider the overlap of figured worlds of designing, schools, and personal lives in the following vignette.

In a design session, co-designers joined an empathy mapping activity to imagine the profiles of future users with the chatbot, the challenges these fictional profiles may face, and the design opportunities that arose. Co-designers engaged in role-playing to create and act out learner-chatbot dialogues, based on the learner profiles they identified. *Distracted George* was a profile that co-designers came up with, as someone with average science knowledge and can be easily distracted. Co-designers came up with solutions to remind the fictional George that he was *going off-task* or to *alert* the teachers. When asked about the rationale for these solutions, Alex stated that "it's a classroom norm that kids react to". This comment illustrates how youth grounded designs in experiences as learners, often with teachers' monitoring. Later in the design session, following role-playing between the imagined bot and "George", co-designers identified a new strategy for the bots to *share experiences*. Manila suggested: "The bots can say: I will tell you my experience maybe it will help you remember what´s yours, and then tell a little story. This will make it more human and personal." Manila's comments illustrate a shift in her design lens to weave experiences and multiturn, relational conversations with users into the chatbot's dialogues. She positioned the chatbot as a guide for narrative construction, acting as a "human and personal" facilitator.

Foster participants' agency as ideational resources

Ideational resources refer to what is valued within a practice and how youths evaluate their success as designers. Prior to the design sessions, some participants like Manila and Annie had reservations that they were "not computer scientists" because they "haven't built technologies". They often turned to the facilitators to evaluate the design solutions with questions such as "does that sound right?" We saw this as an opportunity to remind students of practices that designers leveraged, such as user testing. Between the third and fourth design sessions, the co-design team administered a written survey to an external audience—38 eighth-graders who were also taking the marine science curriculum. The survey asked the eighth graders to choose between the co-designed dialogues (e.g., off-task nudge versus storytelling). Co-designers then went over the survey results together. This process allowed youth to position themselves as designers evaluating their work with a broader audience. Manila reflected, "I'm excited because there are only a few of us here, so it's nice to hear how others like what we design".

In this work, we outline the identity resources that allow young people to build from experiences at home, in school, and as designers. We highlight the utility of materials and artifacts that bridge across physical spaces, the role of dialogues among participants, and the focus on youth's agency to develop ideational resources.

Machine Learning for Evaluating Critical Data Literacy in Open Online Learning Environments

Doreen Mushi, North Carolina State University, drmushi@ncsu.edu

Abstract: The study highlights the application of machine learning in assessing critical data literacy in an open online learning network. The study uses Support Vector Machine algorithm to build a predictive model based on a labeled dataset with students' comments on data visualizations. Features that indicate reflection and curiosity can be used with machine learning algorithms to assess the level of critical data literacy in activities that are adaptive to data representation.

Introduction

The use of data visualizations in education is vastly growing and its application in online learning communities is becoming more and more prevalent. In response to this trend, the ability for students to critically reflect, reason and make sense of data is significant in today's learning and teaching processes (Ben-Zvi & Arcavi, 2001; Kjelvik & Schultheis, 2019). This implies that the development of critical data literacy is imperative in order to nurture competent problem solvers and well-informed digital citizens. Critical data literacy goes beyond the ability to use data, it entails the ability to reason and demonstrate higher order thinking and evaluate data in rich contexts (Hautea et al., 2017). As much as there has been a surge of open learning environments that use data visualizations for teaching and learning, there is still a gap in effective assessment of how students engage and demonstrate critical data literacy in these contexts. We therefore take advantage of machine learning to assess critical data literacy since it presents potential in conducting evaluations of complex environments (Zhai et al., 2020). In this study we base our investigation on an open learning network, New York Times Learning Network (Peralta et al., 2021), by extracting students' comments from the following four data visualization activities: Climate Threats (Network, T. L., 2020a), World Cities' Air Pollution (Network, T. L., 2021), U.S Wellbeing (Network, T. L., 2020b), and First Vaccinated (Network, T. L., 2020c). The main objective of this study is to highlight how machine learning can be used to assess the demonstration of critical data literacy in open learning environments. The main research question guiding this study is: How can machine learning be used to assess learners' critical data literacy in open online learning environments?

Method

The source dataset consisting of 1024 student responses from New York Times Learning Network data visualization activities was used for building a machine learning model. Since the analysis took the form of supervised learning, the dataset consisted of a human-labelled column called *More Information*. Kappa was found to be above 0.8 for this label, indicating good reliability. The label relates to the extent to which the student demonstrates curiosity about other data that the featured visualization did not show. This could be a future trend or when the student sought more contexts to interpret data trends. The column had binary labels of "1" and "0". Label "1" for the comments that indicated demonstration of data literacy and "0" for those that did not indicate a connection to critical data literacy. The study deployed a cross-validation train-test approach to split the dataset into two parts at 67% and 33% respectively.

The modelling process was done on LightSIDE, which is an open-source machine learning application for text classification (Mayfield & Rosé, 2013). The initial process involved feature extraction from the training dataset that included 687 observations. The feature configurations were primarily set to unigrams and included punctuations to account for the nature of the prediction exercise which is intended to classify text based on the demonstrated level of curiosity. In this phase a set of 3092 features from the training dataset were extracted as a feature table. The baseline model was built by the Support Vector Machines (SVM) algorithm it was tested on a dataset containing 337 observations. The competing model had the accuracy of 73.77 % and Kappa statistic of 0.27. In order to improve the model, the second feature extraction was performed and at this time, basic feature configuration was set to include "bigrams". The new constructed model had a marginal improvement with accuracy of 76.33% and Kappa of 0.31 ($p=.077$, $t=1.773$).

Findings

 © ISLS

The exploration of the confusion matrix (Mayfield & Rosé, 2013) was performed to identify features that can be used to predict critical data literacy in online learning platforms. The analysis and identification of features was done by considering two elements in LightSIDE, feature weight and frequency. The ideal predictive feature should have high frequency and weight. An analysis of instances containing the features was also performed in order to evaluate the contextual application and to validate the classification. The main identified features were "I_wonder" with feature weight of 0.30 and frequency of 168. This makes the feature a prominent predictor since this combination of words can be associated with curiosity in evaluating data visualizations. The second predictive feature is "graph" which has feature weight of 0.25 and frequency of 152. The feature is a feasible predictor since in analyzed instances, students referred to visualization in their descriptive responses which can be an indication of deep reasoning with data (Lee et al.,2021). The other identified feature is "countries" which had frequency of 24 and weight of 0.148. While tracking this feature in the instances, it was noted that students did comparative analysis between the U.S and other countries which demonstrates application of critical data literacy. Based on these results, we can conclude that, students can demonstrate deep reasoning by expressing curiosity in their descriptive responses and by making contextual references to examined data visualizations in the learning environment. However, despite these results, we have to acknowledge that there are still some gaps, both in the modeling task and in the quality of student responses in the platforms. In the testing set, there are 52 instances that did not indicate critical data literacy. There is an urgent need of developing innovative open learning resources that can support building capacities in critical data literacy.

Conclusion

The increased use of data visualizations in education drives the need for developing innovative solutions for assessing students' demonstration of critical data literacy. The results of this study indicate that machine learning provides promising approaches for evaluating critical data literacy in open learning environments. Features that indicate reflection and curiosity can be used with machine learning algorithms to assess the level of critical data literacy in activities that are adaptive to data representation. The study also calls for the need to develop open educational resources that can support building critical data literacy for students.

Game Design Experience for Teachers' Design Thinking in Participatory Design Culture

Yanjun Pan, Fengfeng Ke, Chih-Pu Dai
yp10d@my.fsu.edu, fke@fsu.edu, cd18m@my.fsu.edu
Florida State University

Abstract: This case study explored how the experience of game design in the culture of participatory design contributed to teachers' design thinking. Three in-service middle school teachers were invited to be game design partners in an 8-hour workshop, aiming to enhance the reliability and validity of an architecture-based game. Data were collected from in-field observation, screen recording videos, and semi-structured interview debriefing. Three salient themes were extracted to explore teachers' game design experience in relation to their development of design thinking.

Introduction

Design thinking which refers to an analytic and creative process to solve problems is considered as a crucial skill that all students should possess (Razzouk & Shute, 2016). As a result, teachers, as the most important practitioners in K-12 classrooms, play vital roles in teaching design thinking to students in K-12 settings (Bressler & Annetta, 2021). Prior research suggested that the experience of game design is conducive to the development of teachers' design thinking (Bressler & Annetta, 2021). In these studies, teachers were given predefined game design scenario and placed in the position of independent game designers to design their own games.

However, the process of the design and development of a game is complex and difficult in the real world (Hauge et al., 2020). The success of the game design needs efforts and contributions made by various stakeholders (Khaled & Vasalou, 2014), which is called participatory design (PD). As a participatory designer, teachers will act as design partners in the game design process. However, few studies explore whether the experience of game design during the participatory process could contribute to teachers' design thinking. Therefore, it is warranted to investigate what benefits could bring to teachers when involving as game design partners in a situation of PD. Specifically, in the current study, we seek to have teachers contribute their creations to the educational game design process and at the same time learn knowledge and skills with respect to game design to advance their design thinking. The research question guides the entire study is: *How could the experience of game design during the participatory process contribute to teachers' design thinking?*

Methodology

We adopted a descriptive, holistic single case study approach (Yin, 2009) to examine the process and nature of learning by design within the context of participatory design in the case of computer game making. Three in-service math teachers at a suburban middle school in the southeast of United States were invited to be design partners for refining and designing a game called *E-Rebuild*, which is an architecture-based game for teaching conceptual understanding of mathematical concepts and problem solving for middle school students (Ke, 2019). Teachers participated in an 8-hour workshop, including program orientation, play-testing the prototype, as well as integrated brainstorming and interview. We collected data from in-field observation, screen recording videos, and semi-structured interview debriefing. All the collected qualitative data were analyzed by systematic coding followed by thematic analysis.

Findings

Three major themes found in the study pertain to participants' design thinking, including (a) cultivated problem solving skills through iterative troubleshooting, (b) better understanding of the principles of game design, and (c) improved divergent design thinking.

Cultivated problem solving skills through iterative troubleshooting

As observed, PD activities provided participants with iterative troubleshooting and hence cultivated their problem-solving skills. When involving as game design partners in the real-life context, teachers were given opportunities to identify "problems" of game design with respect to their knowledge, skills and expertise. For example, during the interview session, all the participants left comments stating that

 © ISLS

they "*have not done with the Q, E (keys)*". After analyzing this issue in terms of students' abilities, teachers confirmed that their students "*need more assistance in technical operation*". Subsequently, they had fruitful discussions of how to resolve it in the session of brainstorming. For example, Participant 1 suggested "*Hav(ing) a picture with Q, E functions*" as a supplement for "WSAD" keys. Participant 3 suggested associating keys to specific meaningful words, such as "*S equals back, like backwards; and W means forwards*." Even though participants did not have chance to evaluate the feasibility of the proposed solutions in a workshop, they were given opportunities to cultivate problem solving skills which included defining and representing the problem, formulating an expected result, and exploring a possible way of solving the problem.

Better understanding of the principles of game design

Qualitative interviewing indicated that PD activities could support participants' better understanding of the principles of game design. Such learning generally happened during the discussion between participants and members of game design team (e.g., researchers, game designers, and game developers). For instance, one of the design discussions was about "teaching versus experiencing". Participants tended to identify "*What is the idea of learning (unfamiliar game operation) through initiated playing (which caused) students' frustration for the first four or five hours*" instead of "*direct teaching*". Through discussion, participants were informed with the design intention from game designers' perspective that students would better master technical operations (i.e., input mappings) through their experience of interactions in the game.

Improved divergent design thinking

Involving teachers in PD provided opportunities to improve teachers' divergent design thinking, which was a vital stage for constructing individual design proposals. It was occurred when teachers tried to locate similar information in existing data (*E-Rebuild*) and connect it with their previous skills, knowledge, and experience. For instance, in the brainstorming, Participant 3 proposed a solution corresponding to the way to monitor game players' progress. She stated, "*Some thoughts like what a lot of mechanism all you know. Like kind of game success sound effects. I hear like 'Ching-Ching'. Just let you know (what has happened).*"

Discussion and Conclusion

The findings indicated that when participants were actively engaged in the PD process, they had many opportunities to foster their design thinking. Specifically, the experience of game design during the PD process cultivated teachers' problem-solving skills through iterative troubleshooting. Also, the findings show that PD could reinforce participants' design thinking by understanding the basic principles of game design through the discussions with team members. It is in line with the prior research that the PD provides teachers with opportunities of improving their understanding of game design (Bressler & Annetta, 2021). Furthermore, our findings are aligned with prior research that involving teachers in PD helps improve their abilities of divergent design thinking (Hu et al., 2018).

The Practices of Documenting in Research-Practice Partnership

Ethan Benjamin Rubin, UC Irvine, ebrubin@uci.edu
Carlos Sandoval, WestEd, csandov2@wested.org
Dana Marie Conlin, UC Irvine, dconlin@uci.edu

Abstract:
Documenting is critical for shaping and codifying processes in research-practice partnerships (RPPs). Prior work highlights a need for further theorizing of how documenting can support or undermine equitable partnership work. Drawing on practice theory, we examine how RPP documenting practices relate to participation and outcomes. Findings indicate a continuum spanning two affordance-constraint dyads: durable/static versus dynamic/ephemeral. This continuum illustrates how documenting surfaces and addresses tensions, which can inform decisions in RPPs regarding practices of documenting.

Introduction

As research-practice partnerships (RPPs) have emerged as an approach to educational improvement, so too have calls for close analysis of techniques, strategies, and enactment to examine how these partnerships operate. (Coburn & Penuel, 2016). To date, scholars such as Bang and Vossoughi (2016), Philip and colleagues (2018), and Vakil and colleagues (2017) have examined how partnerships come to be enacted through power dynamics. These papers also call on RPP researchers to examine how issues of power and equity come to be lived in partnership work. This poster draws inspiration from these scholars by attending closely to the enactment of partnerships and, more specifically, to the facilitation practices that come to constitute them. By attending to facilitation practices, we argue that insight can be generated into how partnership work comes to be carried out while creating opportunities to interrogate the practices of partnership work to improve them.

In our poster, we seek to surface, interrogate, and complexify *documenting* as a central facilitation practice for RPPs; here, documenting refers to the practice of inscribing actions, words, and relations into artifacts that represent and shape partnership work. While seemingly mundane and commonplace, the practice of documenting is fraught with contradictions that shape how people participate in partnerships. We illustrate how documenting simultaneously excludes and includes, produces durability and enables dynamism, and centralizes and peripheralizes perspectives and people. In this submission, we offer a brief theoretical framing, drawing on practice theory and actor-network theory to focus on practices generally and on documenting specifically. We then illustrate the practice of documenting using cases from two RPPs: one focused on curriculum development and another on participatory design. We argue that attending to the complexity of documenting is essential for talking about, studying, and enacting partnership work, particularly as it pertains to issues of power and equity.

Theoretical framework

Our focus on practices and the practice of documenting in particular is framed by practice theory and actor-network theory. Practice theory is centrally concerned with understanding how social life and organizations come to be produced through situated and recognizable actions (Feldman & Orlikowski, 2011). A core theoretical move in practice theory is to transcend dualisms; rather than viewing two phenomena as opposites (i.e., structure vs. agency), practice theorists view them as relational and mutually constitutive, where structure constrains and enables agency and agency (re)produces, modifies, and combats structure. We use this conceptualization of practice to highlight documenting as a situated and patterned action that is simultaneously inclusive, exclusive, durable, and dynamic (Latour, 1990; 2005).

Methods

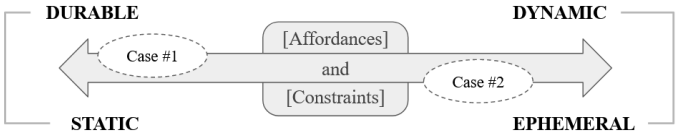
We use qualitative case study methodology to examine the effects of internal documenting practices in two RPPs. The first case focused on implementing culturally relevant science curriculum included four university researchers and six high school chemistry/physics teachers. In the second case, educators and researchers co-designed an interactive web-based tool for pre-service teacher education. Partners included three university researchers, two secondary mathematics teachers, and one community educator. For both cases, videos, transcripts, meeting agendas, field notes, and researcher memos were analyzed using thematic coding and descriptive narrative strategies to represent how practices of documenting took place within each RPP and how they influenced facilitation, processes, and outcomes (Charmaz, 2006; Langley, 1999).

 © ISLS

Findings

The first case illuminated practices of documenting that promoted durability of overall RPP processes. University researchers created meeting agendas, feedback surveys, and PDs enabling the creation of routines, known expectations, and decreased workload on partners. However, the lack of documenting partners' needs ultimately led to withdrawal. Partners experienced the static aspect of documenting practices in this RPP as alienating and noted that the concepts and decisions made durable in the process were misaligned with their working contexts. In the second case, participants experienced the commitment to dynamic, open-ended activity as an obstacle to design work due to the ephemeral character of documenting progress. In response, facilitators provided support through a design template intended to increase the durability of participant contributions while still affording opportunities to revise, rearrange, and recontextualize their ideas. The practices of documenting in these cases indicate a continuum that spans between two affordance-constraint dyads (See Figure 1).

Figure 1
Continuum of affordances and constraints in practices of documenting



On one side, the affordance of durable documentation comes with the constraint of being static; by inscribing ideas and choices in permanent forms, RPPs simultaneously enable future activity to refer to past work *and* limit participants' agency to revisit or change the premises of that activity. On the opposite side, the affordance of dynamic documenting entails the constraint of being ephemeral. By keeping the practices of documenting open to change and revision, RPPs both prioritize participants' voice and power in the working process *and* limit the ability of future activity to build on a stable foundation.

Implications

Our findings indicate that the opposing affordances of durability and dynamism are not only both valuable, but coexist to varying extents across different approaches to documenting. As a documenting practice approaches one affordance, however, the attendant constraint exerts a stronger effect, e.g. emphasizing durability entails increasingly static products and participation, while over-valuing dynamism can lead to problematic ephemerality (Latour, 1990). The impact of these constraints manifest as issues of participant agency, inclusion or exclusion, and the centering or marginalizing of participant voices (Vakil et al, 2016; Bang & Vossoughi, 2016). This indicates that while effective and equitable documenting might prioritize one of these affordances, partnership work benefits from cultivating deliberate balances between the two, treating them as a continuum as opposed to mutually exclusive properties. We suggest that facilitators consider which affordance (if either) better supports the context or aims of the activity at hand to inform their decisions about documenting work.

Embodied Learning in Classrooms: Machine-learning-enhanced Computer Vision for Geometry Math Game

Hunhui Na, Florida State University, hn20b@fsu.edu

Abstract: Embodied learning has been considered as an effective way of teaching and learning, having pedagogical potentials. Motion-tracking devices have been frequently used in research; however, it was difficult to apply them in classrooms. To bring embodied learning interventions into K-12 classroom settings, this research used machine learning enhanced computer vision techniques. Three hand gestures that are expected to be mathematically relevant were designed and implemented in a geometry math game through the techniques.

Introduction

As an alternative to Cartesian dualism, embodied learning is based on the belief that the mind is not the only source of knowledge, but rather that learning is taking place within an integrated form of mind and body through sensorimotor activity (Abrahamson & Bakker, 2016). Based on this perspective, embodied learning has been considered an alternative way of teaching and learning in education, garnering the attention of learning scientists and educational researchers working in STEM education (Lindgren et al., 2016; Núñez et al., 1999).

With the development of motion-tracking devices, studies in STEM education have been conducted incorporating embodied learning with digital technologies in various contexts. Lindgren et al. (2016) used a laser-based motion tracking system in a mixed-reality environment to prompt understanding of physics concepts, and Fischer et al. (2016) used digital dance mats arranged in a 3x3 layout to promote mental number-line representation. Focused on learning geometry, Smith et al. (2014) used Kinect for body-based angle tasks to enhance developing ideas about angles. With motion-tracking devices, these research projects have provided significant implications for technology-enhanced embodied interventions; however, it was difficult to bring these technologies into classroom settings.

To bring embodied interventions into K-12 classroom settings, this research used machine-learning-enhanced computer vision techniques in a geometry math game. With the help of machine learning techniques, body movements of students can be precisely tracked by webcam of a laptop or mobile device, without any external devices. Considering an important premise that mathematical understanding should be constructed by connections between mathematical concepts (Hiebert & Carpenter, 1992), I chose geometric concepts to be learned together, based on the mathematics standards in Common Core State Standards. To connect geometric concepts and embodied learning experiences, three hand gestures were designed and implemented in the geometry math game. This poster will lead to productive discussions regarding embodied interventions in STEM education and will provide meaningful ideas on how technologies could impact the way of teaching and learning.

A machine-learning-enhanced computer vision geometry math game

This research used machine-learning-enhanced computer vision techniques with a webcam, instead of using external devices. To detect body movements and hand gestures in real-time, MediaPipe was used. A game engine, Unity3D, was used to display webcam video, game contents, and detected body segments on the device screen. Game contents were gamified with giving rewards systems to increase students' motivation.

A math game focused on learning geometric concepts on two-dimensional shapes. With six two-dimensional shapes ranging from triangles to octagons, students are requested to identify vertices, sides, and angles on the two-dimensional shapes using hand gestures. Various game tasks guide students to embodied learning experiences, and students are requested to engage in certain types of body movements to achieve the goal of the game task. This game design was based on an assumption that students can enhance their understanding when they are engaged in mathematically relevant body movements. Three different hand gestures involve *outlining*, *clapping*, and *making angles*. These hand gestures were implemented in a game using the machine learning enhanced computer vision technique (Table 1).

Outlining is a hand gesture students need to do when they learn about sides of two-dimensional shapes. It refers to moving an index finger from the start to the end of a side on shapes. This hand gesture requires students to infer what sides look like and how many sides are on the shapes. For instance, in a game task for learning about triangles, students need to identify what sides are and move their index finger along the sides of a triangle. *Clapping* is a hand gesture used when students learn about vertices on two-dimensional shapes. As its name represents, clapping refers to two hands clapping. This gesture was implemented to provide experiences of identifying the location of vertices and counting their number. *Making angles* is two hand gestures that students

 © ISLS

need to use for game tasks about angles on two-dimensional shapes. It refers to making a certain angle with two hands, holding the wrists or middle fingers connected, to make an A or V-like shape. These hand gestures request students to think about the concept of angles and can promote the mathematical meaning-making regarding angles. For instance, in a game task for learning angles on a triangle, students need to identify the center of angle, a vertex, and then represent the size of an angle using two hands.

Table 1

Types of gestures and their implementation in the math game

Type of gestures (Target geometry concept)	Gesture	Implementation in a math game
Outlining (sides)		
Clapping (vertices)		Making angles (angles)		

Discussion and future work

With the continuous improvement of machine learning techniques and their pedagogical potentials, educational researchers now have more opportunities to facilitate embodied learning in classrooms. In this poster, a machine-learning-enhanced computer vision game was introduced as an effective way of enhancing embodied learning for geometry in classrooms. For future work, this project will investigate the impact of embodied learning on students' geometry understanding, self-efficacy, and engagement, in classroom settings.

Abstract: Learners in an informal, STEM-focused summer camp (n = 19) spent one week exploring hypothetical versions of Earth and known exoplanets in a customized version of the digital sandbox game, Minecraft. On the third day of camp, learners were asked to draw their own exoplanets and incorporate various scientific measurements used in the game (i.e. oxygen levels, temperature, etc..). A semiotics analysis was applied to the drawings to understand how learners use representations to explain scientific phenomena and convey specific contextual themes related to the content of the camp. Outcomes showed about 70% of learner drawings included multiple celestial objects, depicting planetary system relationships.

Introduction

Informal spaces offer opportunities for learners of diverse backgrounds to engage with and explore scientific phenomena. One way to capture how leaners consolidate and make sense of what they experience in a simulation is to ask them to create phenomenological drawings of the representations they interacted with throughout. The research presented in this paper explores how learners in a STEM-focused summer camp represent knowledge and understanding of basic astronomy principles and general scientific relationships through creative drawings of possible exoplanets. A majority of the time in the camp was spent exploring simulated hypothetical versions of Earth (i.e. Earth without a moon) and known exoplanets in the digital sandbox game, Minecraft, and activities such as drawing exoplanets were used to augment the digital experience. Our research explores how learners take concepts from simulated worlds in a digital game and represent them in a generative drawing activity.

Background Literature

Drawing serves as a means to consolidate learning of presented material through choices of how to represent concepts, which allows learners to reason and represent like a scientist trying to communicate ideas to a broad audience (Ainsworth et al., 2011). Drawing is seen as a generative exercise, which can result in deep learning for students (Fiorella & Mayer, 2016).

Visual representations are common in Astronomy textbooks, and learners often adopt features and sample existing conventions they see in textbooks in their own scientific drawings of phenomena (Galano et al., 2018). A semiotic framework created by Tang, Won, and Treagust (2019) took drawings from learners in high school Physics and Chemistry classes and deconstructed all relationships down into presentational, organizational, and orientational representations. To conduct our analysis, we adopted this framework to analyze how middle school learners take what they observe in a digital game setting, Minecraft, and translate those concepts into self-generated visual representations.

Methods

Our summer camp took place at non-profit community center in the Midwestern United States for underrepresented middle and early secondary learners (n = 19, 47% female, all participants identified as Black or African American, age range = 11 – 15 years, all participants eligible for free and reduced lunch). Remote consent was obtained from at least one guardian of each participant.

Participants attended a total of five camp sessions, with each session lasting 3 hours. Most of each camp session was spent exploring hypothetical versions of Earth and known exoplanets in the digital sandbox game, Minecraft. On the third day of each respective camp, participants were given a lesson on known exoplanets: how they are discovered, what we can infer about conditions on specific exoplanets, and whether experts think they might be hospitable to biological life. Simulations of three known exoplanets were then explored in Minecraft. Following exploration, participants were given blank worksheets and asked to draw their own exoplanet. Using the analytic framework from Tang et al., (2019) an undergraduate and graduate student looked at how the drawings were used to convey scientific information and represent relationships between objects. All aspects were discussed and mutually agreed upon.

Results

 © ISLS

Our analysis found most participants (68.4%) depicted multiple objects in their drawings (see *Table 1*). For those that did include multiple objects, we then looked at other categories within the broad frames of presentation, organization, and orientation. Included in Table 1 are the categories and relationships represented by many of the drawings. Considering categories of Distribution, Relative Scale, and Formality, we perceive that most participants drew a representation in earnest that closely resembled what they thought an existing exoplanet could look like and how objects around the planet might be oriented. One relationship we added under the category of Simplicity was "Layered", which we define as using a mix of colors to represent diverse composition of planetary features or atmosphere. This feature was present in 15 (78.9%) of the drawings, and even when participants only drew a single object they often differentiated regions of the planet to represent changes in temperature, oxygen, weather, oceans, or landforms.

Table 1

Semiotic analysis of student-generated drawings

Category	Relationship	Proportion (n = 19)	Definition
Association	Multiple	13 (68.4%)	2 or more objects in relation to each other
Distribution	Pattern	11 (57.9%)	Objects arranged in deliberate distribution
Relative Scale	Realistic	11 (57.9%)	Relative spatial and size accuracy
Abstraction	Macroscopic	19 (100%)	A view seen with the naked eye
Formality	Iconic	13 (68.4%)	Resemblance to real objects
	Layered	15 (78.9%)	Uses color to represent diverse composition
Text Context	Label	11 (57.9%)	Text for individual objects
	Caption	5 (26.3%)	Text for entire diagram

Discussion and Future Directions

Most drawings attempting to depict what could be a realistic situation, absent elements of fantasy or desire, was an encouraging result from an open-ended exercise that did not have any explicit assessment of learner knowledge. This form of self-related information processing has shown promising evidence for triggering interest in science and offering opportunities for learners to develop their interest in STEM (Renninger & Hidi, 2021). Even students who did generate planets that represented personal interests did include some labels or features consistent with themes explored in the informal camp experience.

Future analyses will consider fidelity to concepts conveyed throughout the camp and a more formal assessment of how drawings do convey knowledge and understanding of content presented through discussion and in Minecraft. Scoring drawings could then be correlated with other indicators of student interest in STEM.

Pre-service Teachers' Growth in Epistemic Cognition through Learning Pedagogical Knowledge

Miho Kawasaki, Jun Oshima, Ritsuko Oshima
kawasaki.miho@shizuoka.ac.jp, joshima@inf.shizuoka.ac.jp, roshima@inf.shizuoka.ac.jp
RECLS, Shizuoka University

Abstract: This study examined pre-service teachers' growth in epistemic cognition by learning pedagogical knowledge. We evaluated whether pre-service teachers could describe a classroom practice's aim, processes, and ideals coherently by referring to the pedagogical knowledge they had learned in a course on learning theories. The results suggested that they did not necessarily recognize that aims, processes, and ideals should be coherent as components of the lesson.

Background and Research Purpose

Many studies in recent years have focused on how teachers promote adaptive epistemic cognition. Epistemic cognition is important for teachers to reflect on existing teaching practices and improve them (Lunn Brownlee et al., 2017). Barnes and Fives (2020) investigated in-service teachers' epistemic cognition as the teachers evaluated students' classroom assessments and revealed that the components of epistemic cognition, including *epistemic **A**ims and value, epistemic **I**deals, and **R**eliable processes* (Chinn et al., 2014), emerged in these teachers' assessment processes. However, the teachers rarely justified the reliable processes by citing a source to support their use. Accordingly, preparing teachers to ground their decisions in scientific theories as well as in their own experiences and observations would be a critical focus in pre-service teacher education (Hartmann et al., 2021).

In line with these studies, this study examines whether understanding scientific theories about teaching and learning could promote pre-service teachers' epistemic cognition. We particularly focused on pre-service teachers' cognitive engagement in epistemic performance, identified as an aspect of apt epistemic performance (Barzilai & Chinn, 2018). The purpose of our research was to reveal pre-service teachers' growth in epistemic performance through learning pedagogical knowledge when they have epistemic aims to interpret one recorded lesson presented by video. As a reliable process for this task, we evaluated whether pre-service teachers can describe the lesson's aim, processes, and ideals coherently by referring to the pedagogical knowledge they learned.

Method

Course Description, Participants and Video-based Evaluation

The course that was used in this study comprised a three-day summer intensive course on the design of classroom lessons for 21st century skills. Eighteen university students took the course as part of their program requirements. The course comprised three modules, in which students learned knowledge-centered approach, collaborative learning, and self-regulated learning. Their activities in each module were designed as collaborative multiple text integration using Jigsaw method.

The same video was used to measure pre-service teachers' situation-specific epistemic cognition at the beginning and end of the course, which helped us evaluate their growth after taking the course. The video was a summary of a science lesson on weather and pressure. It was about eleven minutes long. In the video, an experienced female teacher taught eighth-grade students. The students watched the video twice and were asked to describe on their worksheets (1) what they noticed as aims of the lesson, (2) what they noticed as reliable processes, and (3) what they noticed as ideals. The evaluation procedure took about forty minutes in total.

Data Analysis

We developed a coding scheme to capture descriptions of the lesson's aims, processes, and ideals based on pedagogical knowledge that students could have learned through the three modules of our course. In terms of the lesson's aim, we assessed whether the overall goal of the lesson was described. For the processes and ideals, the descriptions were evaluated from the viewpoint of each of the three modules: knowledge-centered approach, collaboration, and self-regulation (1 point for each valid description, 0.5 point for partially valid description).

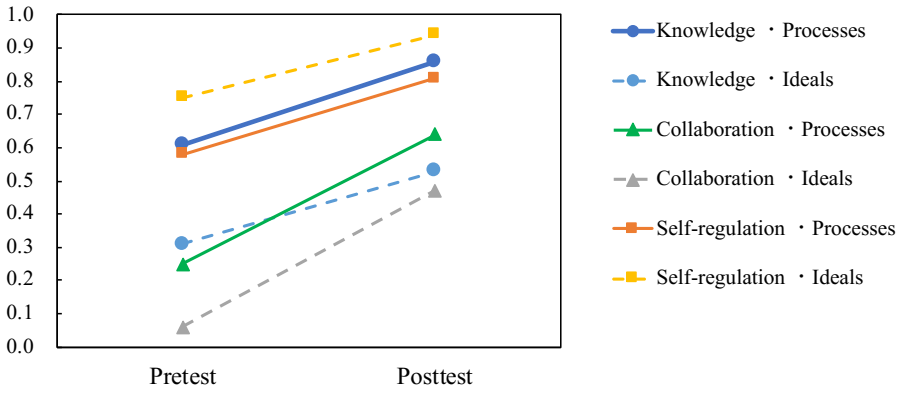
Results

Almost all students could describe the lesson's aim at the pretest (valid: eight students, partially valid: nine students), and at the posttest (valid: thirteen students, partially valid: four students). We analyzed whether the

 © ISLS

students could describe the lesson's processes and ideals coherently. Figure 1 shows the average scores for the processes and ideals. We conducted a three-factor within-subjects ANOVA for each scale on time (pretest/posttest), modules (knowledge-centered/collaboration/self-regulation), and components (processes/ideals). Significant main effects were identified for the time factor ($F(1,17)=38.08$, $p<.001$), and module factors ($F(2,34)=13.67$, $p<.001$). The total average score increased from pretest to posttest, and multiple comparisons showed significant differences in the module factor (self-regulation > knowledge > collaboration, $p=.05$). Furthermore, a simple interaction effect between modules and components was found ($F(2,34)=5.09$, $p<.05$), and multiple comparisons showed significant differences in the knowledge module (processes > ideals, $p<=05$), in the process component (knowledge, self-regulation > collaboration, $p=.05$), and in the ideal component (self-regulation > knowledge, collaboration, $p<.05$). In the knowledge module, the results showed that the pre-service teachers did not necessarily examine the presented lesson from the viewpoints of both processes and ideals.

Figure 1
Results of the pretest and posttest



Discussion

The findings indicate that pre-service teachers learned to explain the lesson using supportive learning theories during our course. Regarding the knowledge module, they did not necessarily grasp that aims, processes, and ideals should be cohesive as lesson components and tended to focus on processes rather than on ideals. Thus, it was found that our course should be redesigned to support pre-service teachers' epistemic growth in the awareness of coherence among this component. Additionally, the background of those outcomes should be examined by further analysis of the process data, such as the recordings of group discussions or worksheets during our course. Finally, epistemic aims that our students may have had when performing the evaluation task should also be considered. Redesigning the course to promote metacognitive aspects of apt epistemic performance would be beneficial for educating pre-service teachers to explain and question classroom practices in order to improve as teachers and learners.

A Study of the Development of Evaluation Methods for Dialogical Reports in PBL Classes

Minori Makino, Go Shoji, Shigeto Ozawa
minorimakino_trp@akane.waseda.jp, go.shoji@akane.wasda.jp, ozawa@waseda.jp
Waseda University

Abstract: This study developed methods of evaluating students' outcomes in remotely conducted project-based learning. "Dialogical reports" which used a hypothetical interview were introduced to encourage reflection on learning outcomes from others' perspectives. As a result of qualitatively analyzing the questions of dialogical reports, it was found that dialogical reports have the potential to encourage reflection on courses from the perspectives of others.

Background and Research Purpose

Higher education is adopting project-based learning (PBL), including inquiry-based learning. While the process of project-based learning gives rich experience to students, evaluating the process of what students have learned and the way they learned is difficult (Shirouzu, 2013).

In project-based learning, it is important that students inquire a lot of questions. Also, when engaging in problem-solving projects, it is important to see things from the perspectives of others. Ordinary report assignments, however, pose only one question, and are therefore not suitable for evaluating the process of project-based learning. It is necessary to promote the creation of interactive deliverables.

We propose "A dialogical report using a hypothetical interview" adopted as the final assignment for the classes in this study. The aim of this study was to verify whether such reports encourage learners to effectively review their learning from the perspective of others. To this end, we focus here upon the questions used in hypothetical interviews, analyzing the types of questions in the dialogical report.

Method and Analysis

The summer quarter classes of 2021 at Y Faculty of X University were conducted over 7 weeks. They were PBL classes related to learning and design, consisting of lectures, practical activities, and group work (Kolodner, 2002). The classes were inquiry-based, and involved paper prototyping, project activities, and review. About 90 students participated in the classes via Zoom. Six teaching assistants joined, facilitating students' discussions.

A dialogical report with hypothetical characters was used for the evaluation. Writing an account of one's own learning outcomes, via dialogue with the characters in a hypothetical interview, is called a dialogical report in this study. Such reports are backed by the multi-vocality concept proposed by Mikhail Bakhtin (1981), in which a variety of opinions from differing positions are presented.

Three important conditions underpin dialogical reports: 1) they are written in a question-and-answer format; 2) the target audience that is expected to read the article is clearly determined; 3) they contain hypothetical characters like interviewer, student, professors, and teaching assistants. The reports were required to be around 2,000 characters in Japanese. In this study, 82 reports were analyzed based on other assignment submissions.

Based on the questions and answers in the hypothetical interview, we analyzed whether they were from the perspective of others (Shirouzu, 2013). The questions in the report were classified as "Facts" or "Recognition". "Facts" refers to questions addressing the facts of course content, and "Recognition" refers to questions addressing the recognition of the author of the report.

Results

The average number of characters in the interview section of the analyzed reports was 2224.4 (SD = 335.2). In hypothetical interviews, the dialogue of one character is defined as a "unit," and one conversation is taken as one unit. This definition of a unit is based on the concept of multi-vocality of Shirouzu (2013).

The average number of units per report was 22.5 (SD = 8.7). In this study, these units were first categorized as "questions" or "answers." Also, units that did not fit into the "questions" or "answers" categories, such as filler words and sounds given during a conversation to show comprehension, were categorized as "other."

From a total of 82 reports, 1,848 units were extracted. The breakdown of the units is as follows: 677 questions, 697 answers, and 474 other units. Among the 677 units categorized as questions, tendencies in 522 questions posed by the interviewer were investigated. Among the 522 questions, 321 (61.5%) were posed by the interviewer to students, 117 (22.4%) were posed to professors, 56 (10.7%) were posed to TAs, and 28 (5.4%)

 © ISLS

were posed to other people outside of these conditions. Because approximately 40% of questions were posed by the interviewer to professors, TAs, and people outside of these conditions, the dialogical reports promote viewing from the other people other than oneself.

The questions were categorized along with the content of the answers. As a result, two categories were created, questions inquiring into "Facts" of classes and questions inquiring into the "Recognition" of the author. Table 1 shows the results of an analysis of the types of questions the interviewer posed to the characters.

Table 1 Proportions of questions posed by the interviewer to characters

Category	Subcategory	Students	Professors	TAs	The others	Total
Facts	Course overall	22(6.9%)	37(31.6%)	9(16.1%)	3(10.7%)	71(13.6%)
	Prototyping	7(2.2%)	9(7.7%)	2(3.6%)	2(7.1%)	20(3.8%)
	Projects	142(44.2%)	11(9.4%)	12(21.4%)	15(53.6%)	180(34.5%)
	Methods	6(1.9%)	21(17.9%)	4(7.1%)	0(0.0%)	31(6.9%)
Recognition	Knowledge acquisition	16(5.0%)	0(0.0%)	3(5.4%)	0(0.0%)	19(3.6%)
	PJ reflection	37(11.5%)	3(2.6%)	9(16.1%)	5(17.9%)	54(10.3%)
	Overall reflection	65(20.2%)	3(2.6%)	4(7.1%)	3(10.7%)	75(14.4%)
	Relativization	25(7.8%)	10(8.5%)	3(5.4%)	0(0.0%)	38(7.3%)
	Intentions	1(0.3%)	23(19.7%)	10(17.9%)	0(0.0%)	34(6.5%)
Total		321(100%)	117(100%)	56(100%)	28(100%)	522(100%)

Regarding the subcategory "Project" of the category "Facts," we will focus on questions from the interviewer to students. As a result, it is apparent that 142 questions (44.2% of questions posed to students), a high proportion, concerned the specific content of projects.

Also, regarding the subcategory "Intentions" of the category "Recognition," we will focus on questions from the interviewer to professors and TAs. As a result, it is apparent that a high proportion addressed the intentions of the course design. In the subcategory "Intentions" of the category "Recognition," there were 23 questions to professors (19.7% of questions to professors) and 10 questions to TAs (17.9% of questions to TAs). Thus, it seems that by creating a dialogical report, learners were able to consider the intentions of the course design by inferring the viewpoints of TAs and professors.

The following is a sample citation from a question regarding "Intentions". An interviewer asks a hypothetical TA if they kept anything in mind when giving support to students in projects. In response, the TA says that they did not give answers directly. It means that the learner created the dialogue based on her experiences.

> Interviewer: This is a question for the TA. Was there anything you kept in mind when giving advice to students?
> TA: Not giving the answer directly (…) Rather than simply telling students they were mistaken or providing the answer, I consciously asked questions designed to make students aware of their mistakes.

Discussion

We have focused on the possibility of the dialogical reports encouraging reflection on their learning. Creating the hypothetical interview can help reflection on their role and viewpoints in the project-based learning. The dialogical reports acted as a tool that allowed learners to review learning outcomes, while themselves assuming a monitoring role (Miyake 1986) and switching viewpoints with others.

However, this study leaves some issues unresolved. We will analyze data such as the discussion process to reveal a relationship between the reports and the learners' learning processes in the PBL.

Scaffolding math learning and motivation by integrating casual play in computer-based practice for fifth graders

Lavi Shay, Elon Langbeheim, lavi2shay@gmail.com, elonlang@bgu.ac.il
Ben-Gurion University of the Negev, Israel

Abstract: The difficulties experienced by many students in mathematics are characterized by anxiety and lack of motivation to learn. Intrinsic and even extrinsic integration of play, can influence students' attitudes and increase their motivation to learn. The purpose of this study was to examine the effect of external integration of play as a break between exercises in a computer-based tutorial on the topic of fractions. We hypothesized that compared to non-game-based learning, students' perseverance in solving math exercises would increase, which is reflected in performing more questions while investing sufficient time in solving the problems. Our pilot study compares the number practice questions solved between two groups of 5th graders: 30 students in the play condition, and 33 in the control condition. The results show that there is no significant difference in the number of questions answered in each condition, but that integrating play moderates the differences between motivated and less motivated students.

Background

The main challenge in designing digital games for promoting mathematics learning is to balance enjoyment of play and pedagogical support for understanding. A design with *intrinsic integration* of the mathematical content blends the mathematical challenge and the game challenge, whereas *extrinsic integration* combines a sequence of mathematical challenges or tasks with separate, game-based components (Habgood & Ainsworth, 2011). Intrinsic integration has been shown to enhance student learning when compared to an equivalent game with extrinsic integration (Habgood & Ainsworth, 2011), but later studies show that intrinsically integrated digital games do not have significant advantages for learning when compared with paper and pencil exercises, except for enjoyment of the learning process (Castellar, De Marez, & Van Looy, 2015). In addition, educational games that include intrinsic integration with standard mathematics content are much more difficult to develop, than interspersing mathematical tasks with games in extrinsic integration. Specifically, extrinsic integration of mathematics exercises with action games, using score points as incentives is a growing effort (e.g., Rahimi et al., 2021), but there is still little information of its effects on students' motivation to perform mathematical learning activities (Barzilai & Blau, 2014). This poster presents a study of the effects of an extrinsically integrated casual game wrapped together with a mathematics training platform, on student motivation and mathematics learning.

Design

We developed an integrated platform that combines a casual game between the stages of a mathematical training task. The mathematical training task (Figure 1, left) entails fraction comparison questions, that players solve to accumulate points. The casual game (Figure 1, right) is based on a common game - "Flappy Bird" in which the bull-shaped player must collect packages of hay to gain points and avoid obstacles. When the players lose their health points, they are redirected back to the training tasks, and after completing more than six training tasks successfully, the player is redirected to the casual game. The score in the casual game is added to the score of the training task thereby weaving the two activities together.

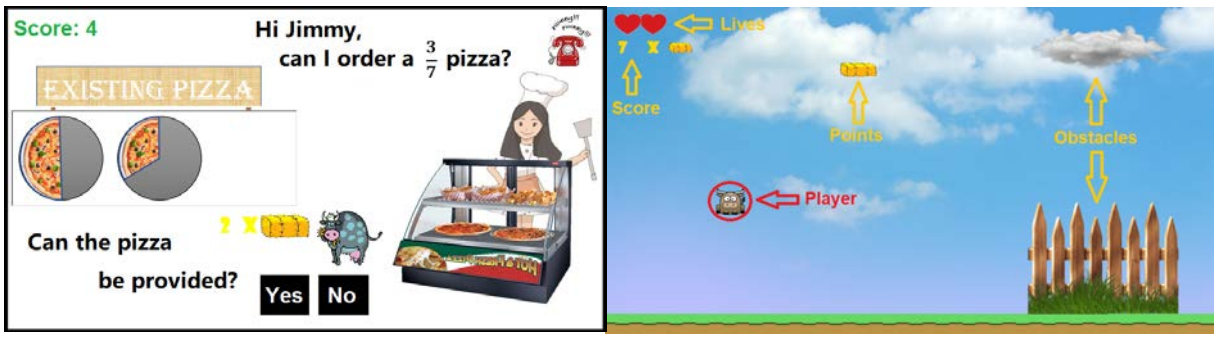

Figure 1 -The two parts of the extrinsically integrated learning platform, with the exercise task (left) and the "jumping bull" casual game (right). Note the "hay stack points", that players can accumulate in both parts of the game

 © ISLS

Method

The study was conducted with 63 students from two fifth grade classrooms from a state religious school with only boys. There were 35 students in classroom A and 28 students in classroom B. We randomly assigned 30 students to the play condition and 33 students to the control condition. The activity spanned 45 minutes and entailed 30 fraction comparison questions as shown in figure 1. We used persistence in completing exercises and the score of correct responses to fractions questions as dependent measures of the effect of the game on motivation and perseverance (Lucas et al., 2015). The time spent on solving questions was also examined and the data was based on log files. Our main hypothesis was that interspersing play during the fraction questions will raise students' motivation that will promote perseverance. However, we also hypothesize that the lure of gameplay will decrease the time students spend on solving, and may be detrimental to solution accuracy. Our research questions were:

1. Is there a difference in the total number of questions answered by the play group and the control group?
2. Is there a significant difference in the average time students devoted to solving questions and in their solution accuracy in each condition?
3. How much of the variance in students' math solution scores, is explained by their game score and time on task?

Results

Both the control group and the play group students answered an average of 27/30 of the questions, but classroom A students (from both groups) answered significantly less questions (26/30) than their counterparts in classroom B (29/30) ($p=0.05$). Also, students from classroom A scored lower on the mathematical exercises (37.5 points) than their peers in classroom B (42.7 points) although the difference was not significant ($p=0.11$). The difference in scores associated with the classroom, was much larger in the control condition (35.8 in A and 44.1 in B) than in the play condition (40.8 in A and 41.8 in B).

To study the 3rd research question, our analysis, revealed that question solution scores in the play condition were strongly correlated with their score on the casual game ($r=0.45$, $p=0.01$). The correlation of the math solution scores with the average time for answering each question was much smaller and non-significant ($r=0.25$, $p=0.19$). In the control condition, the correlation between average time per question and overall performance score on the math problems was significant ($r=0.395$, $p=0.02$).

Discussion and conclusions

Our study examined the effect integrating a casual game into a mathematical tutor on learners' mathematical problems solving. We found that motivation and consequent perseverance in problem solving of the students in classroom A was lower than those in classroom B as indicated in the average number of questions they solved in the tutor, and their average overall scores. However, we also show that the play condition mitigated some of the differences between the classrooms in terms of perseverance in answering the questions, and the overall scores - both were closer in the play condition than in the control condition. Moreover, the correlation between the game score and the tutorial score, indicates a possible motivational connection between the two. In the absence of play, less motivated students in the control condition spent less time on the questions, and their variance in performance was probably a result of their predispositions and grit (Lucas et al., 2015). Our use of the game between the stages of the educational task reflects extrinsic integration since it is detached from the educational content. Previous studies (Habgood & Ainsworth, 2011) have shown that such a combination is less effective than a combination of intrinsically integrated learning software. However, our study indicates that also extrinsic integration which is easier to develop, is beneficial for reducing motivational differences between students in mathematics.

Online Pre-Service Teacher Learning Communities as a Tool for Teacher Education

Thea Skoulia, Loucas Louca
T.Skoulia@euc.ac.cy, L.Louca@euc.ac.cy
European University Cyprus

Abstract: The purpose of this descriptive case study was to better understand the characteristics of Teacher Professional Learning Communities(TPLCs) of pre-service teachers(PsTs). Data were derived from 2 TPLCs in which 15 PsTs volunteered to participate, within the context of a pre-school Science Education course they were enrolled in. We analyzed transcripts of videotaped TPLC meetings following the thematic analysis approach. Our findings provide insights about how this group of PsTs utilized opportunities for professional growth.

Theoretical framework

Teacher Professional Learning Communities (TPLCs) as a form of teacher professional development is widely recognized to serve school development associated with better student achievement (e.g., Vescio & Adams, 2015). TPLCs have led to a paradigm shift in teacher professional development (Vescio, Ross, & Adams, 2008), giving teachers a framework to act as students and schools as learning communities, for the teachers themselves (Clarke & Hollingsworth, 2002) in a collaborative, reflective, mutual and collective responsibility (McLaughlin & Talbert, 2006). Participating in TPLCs as early as during their university studies, may provide pre-service teachers (PsTs) the opportunity to be involved in the processes of monitoring and responding to students' learning, and cooperation and mutual support with other teachers. Despite the lack of professional experience, limited or no teaching experience (Kagle, 2014), the involvement of PsTs in TPLCs may provide opportunities for experiencing collaborative learning, reflective practice and the ability to link between teaching practice and learning outcomes. A number of studies have investigated the participation of PsTs in TPLCs. Bond (2013) suggested that through TPLC meetings PsTs started to think critically, to approach pedagogical problems from different perspectives, and to support each other. Kagle (2014) found that PsTs working in TPLCs built basic pedagogical skills, reflected on their practice and professionally addressed the educational challenges. Hoaglund, et al. (2014) reported that PsTs working in TPLCs showed an improvement in their perceptions of the various indicators studied.

The purpose of this study was to develop a better understanding of the characteristics of TPLC of PsTs in the context of their undergraduate studies.

Methods, data sources & analyses

This descriptive case study (Yin, 2017) took part during the Fall 2020 semester, in the context of an undergraduate course in Science Pre-school Education in Cyprus. PsTs in the course volunteered to participate in TPLCs organized as online synchronous sessions. Two TPLCs were created in which a total of 15 PsTs participated for a total of 7 1-hour meetings. All the participants were in the 3rd third year of their studies. They also had no previous experience of participating in TPLCs. All TPLC meetings were video-recorded and transcribed for analysis. Following the thematic analysis approach (Braun & Clarke, 2006; 2012), the two authors read the transcripts independently to identify characteristics of TPLCs of PsTs. During this process, we started with a list of relevant codes from the literature (e.g., Cox, 2004), which was revised and enriched during the process. All data were analyzed by both authors independently and differences were resolved through discussion.

Findings

Our findings suggest several TPLC characteristics related to the nature of running the TPLCs online with PsTs.

1. Student vs Professional Culture: PsTs recognized the need to work within a different culture when it comes to providing feedback to each other. They suggested that when received peer feedback, they mostly got positive comments, without any justifications of comments or any suggestions for improvement. They also acknowledged that solely positive feedback does not lead to any improvement. They suggested the need to work more "professionally", expressing their honest, “still-under-development” professional opinion, and providing more specific comments to each other, so that the feedback can be used to improve their work.

2. TPLC time was used for reflection on the course experiences. PsTs were comfortable sharing and criticizing issues related to the topics discussed in the course, the way their course meetings were structured, and the tasks they had to complete as part of their course obligations. They also talked about their concerns about the

 © ISLS

online form of lectures. This reflection also seemed to help participants use pedagogical ideas that they had discussed during course lecture time, to talk about and evaluate their learning experience in the course.

3. Engagement in small groups. TPLCs participants reported satisfied working in group activities during TPLC meetings regardless of the members of their subgroups. They talked positively about this collaboration and its result.

4. Recognition of the work accomplished in the TPLC meetings. The participants highlighted the importance of the way they worked in the TPLC and the outcomes of their participation. They recognized the effect of the TPLC meetings on the tasks that they had to fulfill, but also on the way they dealt with understanding ideas discussed during the course meetings.

5. Sharing individual/community challenges and outcomes with peers. PLCs participants discussed their responsibilities and the tasks they had to complete as part of their course requirements; they also talked about the feedback they received for particular tasks from the instructor and their peers. They were comfortable sharing the instructor's and their peers' comments. They also referred to personal or group issues from the lecture that they did not understand.

6. Sharing individual/community outcomes with peers. During TPLC meetings, participants felt comfortable sharing both individual and community outcomes from their participation in the course. They referred to outcomes that arose either from the way they work or from the activities they completed in a specific lecture.

7. Identifying ways of collectively responding to individual or community challenges. TPLCs participants recognized the need for a collective response to both individual and collective challenges. In several cases they identified different ways to do so. They referred to actions that they need to take in order to improve the outcomes of their various course assignments, and they talked about ways to resolve their concerns about the ways the course was taught.

Discussion

Most PsTs peer group work is related to working on group assignments or studying together for an exam. However, if TPLC is an instrument of professionalization in the teaching profession (e.g., Vescio & Adams, 2015; Warwas & Helm, 2018; McLaughlin & Talbert, 2006), it is important that PsTs become familiar with it as early as during their teacher education. In combination with university courses on practical issues and phases of internship, participation of PsTs in TPLCs offers the opportunity to anticipate the job, and to practice and to reflect on practical experience. The findings we presented provide insights into the process of professionalization of PsTs. Despite their limited professional experience, PsTs can easily participate in TPLC as early as their teacher studies.

Eye Movement Tracking During an Embodied Collective Activity in Science Teacher Training

Roni Zohar, The Weizmann Institute of Science, roni.zohar@weizmann.ac.il

Abstract: Middle-school science teachers who trained in the field of embodied pedagogy for teaching and learning physics, experienced an embodied collective activity for learning the concept of angular velocity. We tracked the teachers' eye movements during the collective activity in order to characterize their gaze behavior. The findings show that the subjects looked ahead during the activity, in contrast to their verbal report but in line with studies showing that eye movements can precede body movements.

Background

Neuro-pedagogy is an interdisciplinary field that integrates perspectives of the learning sciences and neuroscience. One of the main areas of this field is the study of teaching and learning strategies. Observing the brain can enable an understanding of the effects of different teaching environments and pedagogics. This is a central objective of the research presented in this poster. The pedagogical aspect of our research is based on embodied pedagogy for teaching and learning physics (Zohar et al., 2017). The neurobiological aspect of our research is based on eye-gaze tracking to discover interesting patterns from the field of vision (Duchowski, 2002). A unique feature of this study is the use of eye-tracking for investigating collaborative learning of complex concepts in *full-body movement,* which to the best of our knowledge has not been studied before.

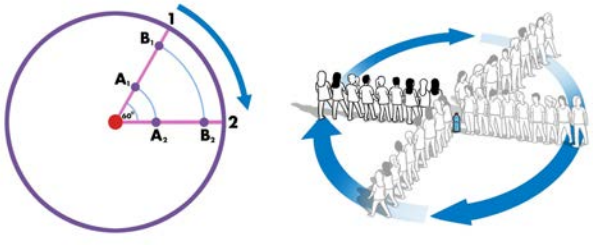
The concept of angular velocity and the embodied collective activity pertaining to it

Embodied pedagogy for teaching and learning physics (Zohar et al.,2017) coheres with the embodiment paradigm that affected educational research (Abrahamson et al., 2020). The assumption underlying this pedagogy is that actual physical experience can be used as a unique resource for learning complex concepts (e.g. angular velocity in physics) by associating them with daily bodily activities.

Angular velocity is defined as the angular displacement of a body over time in a circular path. In Figure 1, we see an example depicting the concept of angular velocity and the embodied collective activity ("collective circular exercise"), which pertains to learning this concept according to our approach. The angular velocity of points A and B moving from their respective point 1 to point 2 is the same because the segments connecting each of the points to the center of the circle advance at the same time at the same angle (see Figure 1a, the angle is 60°). In the collective circular exercise, the learners are asked to walk together around a bottle (see Figure 1b). Using trial and error, they negotiate, verbally and using gestures, a collective method to circle the bottle together. They move to keep the row intact with those farther away from the bottle who walk faster.

Figure 1

Illustration of angular velocity (a), The collective circular exercise: enacting angular velocity by walking around a fixed-point (b).



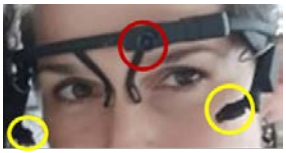
(a) (b)

Methods and Analysis

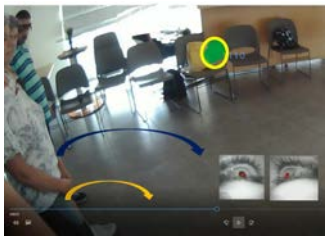
Thirty middle-school science teachers experienced the collective circular exercise described above, moving in 6 groups. The teachers were unfamiliar with the concept of angular velocity. This study examined the 12 teachers who stood at the edges of the moving lines (see Figure 1b). We collected data from video recordings and eye movements. We used Pupil Labs eye trackers, which were connected to a cell phone attached to the subject's clothing. This eye tracker device has two cameras for each eye and a head world camera (see Figure 2a).

 © ISLS

Figure 2
Pupil Labs eye tracker device with one head world camera (circled in red) and two eye cameras (circled in yellow) (a). Snapshot from the Pupil Labs software while performing the collective circular exercise (b). The green dot circled in yellow is the gaze point.



(a)



(b)

The collective circular exercise lasted approx. 30 seconds and data from 6 of the 12 subjects was reliable enough for analysis based on the Pupil Labs software. Video tracking analysis used the Pupil Labs software to track the subjects' gaze points during the walking activity. Figure 2b shows a snapshot of the activity as viewed by the subject standing near the bottle at a certain time. The green dot circled in yellow is this subject's gaze point. The output from this subject's two eye cameras is shown in small square images in the bottom right of the figure. The blue and yellow curved arrows indicate the directions of the teachers' movement. Calculations using the software's output provided a measure of the distance gaze from the teachers' walking line in each snapshot in which the gaze could be seen. The distance gaze from the walking line is represented by an azimuthal angle, which is a horizontal angle where the vertex is the subject's head.

Findings and Discussion

Looking-ahead during the embodied collective activity - The graphs in Figure 3 show the distance gaze of every subject from the walking line relative to time during the collective circular exercise. The four graphs at the top of Figure 3 pertain to the subjects who stood near the bottle, and the two graphs at the bottom of Figure 3 pertain to the subjects who stood at the end of the walking line. Dots on the horizontal axis represent a situation where the subject was looking at the walking line, so the measured azimuthal angle is zero. In calculating the average time the subjects looked at the walking line, we found that this was the case in only about 16% of the duration. This finding contradicts the subjects' verbal report, stating that they were constantly looking at the other teachers in the line. However, this coheres with studies showing that eye movements can precede body movements We used a binomial test to examine whether the subjects indeed looked at the walking line for 50% of the activity time, and for each subject, the statistical test showed rejection at a level of $p < 0.05$.

Figure 3
Findings from the collective circular exercise - one graph per subject.

Leveraging student-written chapter summaries to assess understanding and motivation in an introductory statistics course

Stephanie Yang, Harvard Graduate School of Education, szhang@g.harvard.edu
Gahyun Sung, Harvard Graduate School of Education, gsung@g.harvard.edu
Mary C. Tucker, University of California, Los Angeles, maryctucker@ucla.edu
Bertrand Schneider, Harvard Graduate School of Education, bertrand_schneider@g.harvard.edu

Abstract: Instructors often assign students to write summaries of what they have learned. Beyond being a helpful learning exercise, written summaries can reveal latent models of what students do and don't understand about the instructional content. Drawing on data from an introductory statistics course, the current study assessed the relationship between written summaries and student understanding and motivation in the course. Findings revealed significant associations which can inform support for struggling learners.

Introduction

Summary writing is an effective method for students to synthesize knowledge, identify misconceptions, and build a mental model of the learning content (Radmacher & Latosi-Sawin, 1995). While a range of research has demonstrated the benefits of summary-writing as a learning exercise, less research has assessed what the content of summaries reveals about student understanding, and how this information can be leveraged by instructors. A handful of studies have utilized advanced natural-language processing algorithms to analyze the syntactic and semantic quality of summaries (Strobl et al., 2019). However, these tools are primarily designed to help students improve their writing skills, not directly to assess understanding. Additionally, to our knowledge, prior research has not studied what a student's written summary reveals about their motivation in the course. Frequent and unintrusive indicators of student motivation can be crucial in preventing learner burnout and dropout, particularly in STEM courses where the 'leaky pipeline' is especially prevalent (Burke, Mattis & Elgar, 2007). The current study analyzed data from an introductory statistics course to examine the relationship between written summaries and student learning and motivation. These preliminary findings lay the groundwork for interventions that can identify and support struggling learners.

Methods

Data in the current study was sourced from 166 students who participated in an introductory statistics course taught in the winter of 2021 at a large public university in Los Angeles. The primary instructional tool was an online textbook developed by the course instructors (see Stigler et al., 2020, for more details). The textbook contained twelve chapters, each of which covered a different statistics concept, such as distributions and modeling variation. Prior to beginning each chapter, students self-reported their motivation by answering three questions that probed their expectancy and value for the course. These questions were abbreviated from the expectancy-value-cost scale developed by Kosovich et al., (2015). At the end of each chapter, students wrote a summary of what they learned and took a practice quiz.

For the purposes of this study, the chapter variables we focused on were the self-reported motivation scores, written summaries, and the end of chapter quiz scores. Metrics from this data were calculated for each student and for each chapter. We also incorporate the students' final exam grade in the analyses. However, due to the COVID-19 pandemic, students were not required to take the final exam, so the sample for these analyses was significantly decreased. Two primary metrics were generated from students' written chapter summaries: summary length and semantic content overlap. Semantic overlap was calculated using the cosine similarity between the term-frequency, inverse-document-frequency (tf-idf) of the chapter text and the students' chapter summary. Table 1 presents examples of student-written summaries from the data with high and low tf-idf similarity values.

Results

The results showed that the length of a chapter summary was positively correlated with chapter quiz score ($r(1818) = .17$, $p < .001$), expectancy ($r(1649) = .10$, $p < .001$) and value ($r(1646) = .08$, $p = .001$). The semantic content similarity between the chapter summary and the chapter content was also associated with quiz score ($r(1818) = .16$, $p < .001$), expectancy ($r(1649) = .17$, $p < .001$) and value ($r(1646) = .10$, $p < .001$). Additionally, average semantic similarity between summary response and chapter content throughout the course was

 © ISLS

predictive of performance on the final exam (R^2= .16, $F(1, 41) = 7.51$, $p < .01$). However, this association did not hold when controlling for summary length.

Table 1

Examples of students' written chapter summaries with high and low tf-idf cosine similarity values

	Chapter summaries of Chapter 10: Confidence Intervals and Their Uses	tf-idf similarity
Student 1	*"The reason we invoked sampling distributions is to model variation in our estimate (in this case the mean) across samples. Sampling distributions help us deal with sampling variation—how much samples from the same population (or Data Generating Process) might vary. We used the sampling distribution to estimate the margin of error—how far off the population mean could be from our estimate…*	0.57
Student 2	*"In this chapter we learned about estimating errors. We also learned about confidence intervals. We further learned about how to use the bootstrapping method to conduct CIs."*	0.03

Discussion

Our findings revealed that summary length and the semantic similarity between summary and chapter content was positively and significantly correlated with both chapter quiz score and student motivation. The link between summaries and quiz scores reveals that written summaries can be an indicator of student knowledge and how well they learned the material. However, due to the correlational nature of these findings, it is difficult to ascertain the direction of causality. For example, it could be that writing a comprehensive summary that drew on diverse content allowed students to learn the material better and perform better on the chapter quiz, a finding well established in the literature. On the other hand, a student who already had a good grasp of the content would write a better summary and perform better on the quiz. We also found that average semantic similarity of summaries was predictive of final exam scores. However, the association did not hold when controlling for summary length. This suggests that more sophisticated metrics of semantic analysis for summaries are necessary to better differentiate student understanding. One future direction is to use latent semantic analysis or keyword and entity extraction in order to pinpoint the exact concepts that students may or may not understand. Interestingly, our results also revealed a positive correlation between summary metrics and student motivation at the beginning of the chapter. One potential explanation for this finding is that motivated students write higher quality summaries. On the other hand, the act of writing a comprehensive summary could increase student motivation in the course. Again, the direct interpretation is elusive and future research should explore the chain of causality, but the significant correlation suggests that summary metrics may serve as a frequent and unobtrusive method to probe motivation in a course.

Conclusion

Although course instructors will often ask students to write summaries of what they have learned, these are most often assigned as a useful learning exercise. However, the findings presented demonstrate that instructors can also derive important insights from this data. Notably, it can indicate how much students retained and their current state of motivation in the course. Instructors can apply this information to tailor instruction or to provide support for students who may be struggling with course content or who are feeling unmotivated. Future studies should explore methods that allow instructors to pinpoint exact misunderstandings from summary data and explore techniques to help instructors digest and act upon this data.

Student Profiling on Behavioral Patterns in an Online Mathematics Game: Clustering Using K-Means

Reilly Norum, renorum@wpi.edu
Ji-Eun Lee, jlee13@wpi.edu
Erin Ottmar, erottmar@wpi.edu
Worcester Polytechnic Institute

Abstract: This preliminary study examined whether distinct student profiles ($N = 760$) emerged based on their behavioral patterns in an online algebraic learning game. We applied k-means clustering analysis to clickstream data collected in the game and then examined how students' behavioral patterns varied across the clusters using data visualization. The results identified four groups of students based on their in-game behaviors, showing that there was a large variation in their behavioral patterns for engaging with the game.

Introduction

With the rapid development of game technology, there has been an increasing interest in the use of online educational games in mathematics learning. Previous studies have reported that well-designed online games are effective in improving students' mathematical knowledge, skills, and engagement (Chang et al., 2016). However, due to the greater flexibility and interactivity of online educational games compared to other types of educational technology tools, their effects largely depend on many factors, in particular, student behavioral patterns in games (Martin et al., 2015). Thus, it is important to understand how individual students behave differently in the game and how their different behavioral types relate to learning outcomes in order to provide more personalized learning environments (Vandewaetere et al., 2011).

Our team has developed an online mathematics learning game to help middle-school students' algebraic learning. Our previous work has shown that the game is effective in enhancing students' algebraic understanding, but the efficacy varies depending on students' behavioral patterns in the game (Authors, in review). In this study, we aim to replicate the findings of our previous work with a larger dataset that includes a more diverse sample in terms of instructional level and race/ethnicity. Our study addresses the following research questions: 1. How many different clusters emerge based on students' behavioral patterns in the game? 2. How do the students' behavioral patterns vary across the clusters?

Method

The game was developed based on perceptual learning theories to help students' algebraic learning. The goal of the game is to transform the expression into the mathematically equivalent, but perceptually different, target goal using various gesture actions. The game allows students to dynamically manipulate and transform numbers and mathematical symbols on the screen so that they can identify algebraic structures easily and think flexibly. Our sample consisted of 760 (55% male, 45% female) 7th-grade students from ten middle schools located in the Southern U.S. The students played the game individually for nine 30-minutes intervention sessions. For cluster analysis, we included four variables of in-game behaviors that correlated to learning outcomes identified in our earlier work (Authors, in review). These variables were the total number of problems completed, the average number of resets, the proportion of reattempts (i.e., revisiting the completed problem again), and the average pause time (i.e., the amount of time spent before making the first action).

Results

The elbow method was used to determine the optimal number of clusters, suggesting four clusters. The k-means cluster algorithm, selected for its scalability and guaranteed convergence, divided the entire sample into four clusters of students based on their behavioral patterns: Cluster 1 ($n = 188$, 24.7%), Cluster 2 ($n = 186$, 24.5%), Cluster 3 ($n = 76$, 10%), and Cluster 4 ($n = 310$, 40.8%). Figure 2 shows the box plots of four variables of student behavioral patterns by cluster.

The clusters were labeled based on the most dominant characteristics appearing in each cluster: Slow Progressors (Cluster 1) included students who completed the least number of problems, with the lowest proportion of reattempts and average number of resets. Fast Progressors (Cluster 2) included students who completed the largest number of problems but had a low average number of resets, proportion of reattempts, and average pause time. These students sped through the game, completing as many problems as possible, rather than taking time to think about their first step. Slow-Steady Progressors (Cluster 3) included students who had the highest proportion

 © ISLS

of reattempts and average number of resets. This cluster carefully progresses through the problems, resetting and retrying along the way. Intermediate Progressors (Cluster 4) included students who showed middle values for all variables.

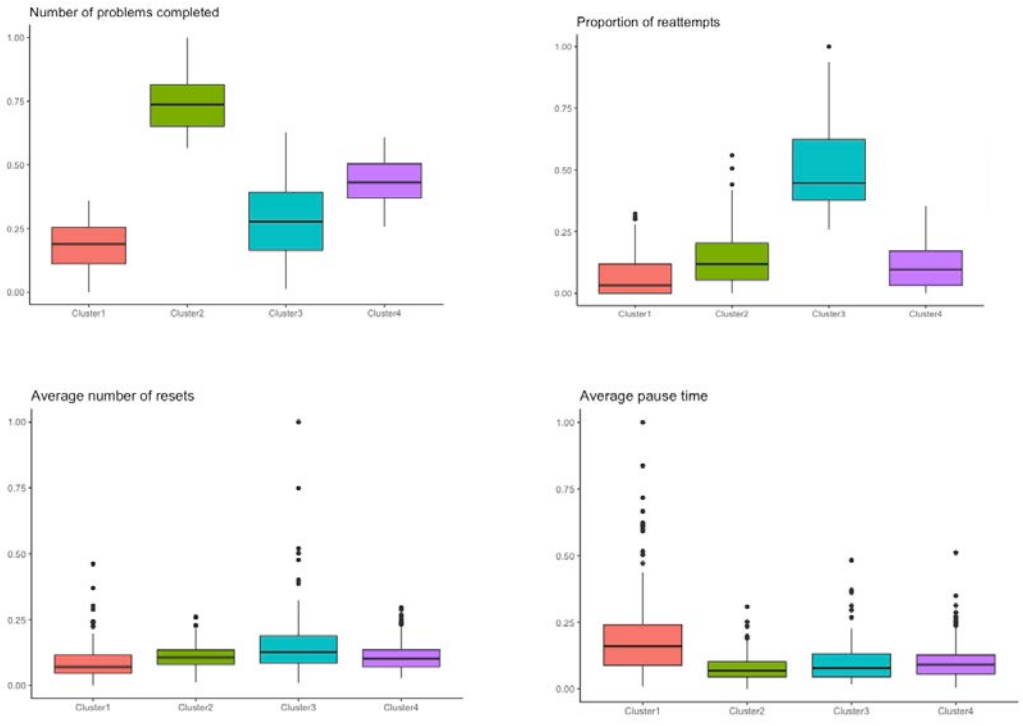

Figure 2

Cluster results depicting the distribution of variables of behavioral patterns for four clusters (Note: Red: Cluster 1- Slow Progressors. Green: Cluster 2- Fast Progressors. Turquoise: Cluster 3- Slow-Steady Progressors. Purple: Cluster 4- Intermediate Progressors)

Discussion

This preliminary study examined whether distinct student profiles emerged based on behavioral patterns in an online algebraic learning game. The results of the k-means cluster analysis identified four distinct groups of students based on in-game behaviors, showing that there was a large variation in their behavioral patterns for engaging with the game. The student profiles identified from the cluster analysis can serve as a basis for building an adaptive learning environment (Vandewaetere et al., 2011). Further research should be done to investigate how these different behavioral patterns correlate to mathematics performance.

What We Ought to Know: How Digital Museums Can Facilitate Reflection and Discourse of The Nigerian Civil War

Jennifer Aduro, University of Nottingham, adurojennifer@gmail.com
Pryce Davis, University of Nottingham, pryce.davis@nottingham.ac.uk

Abstract: The Nigerian Civil War is a key event often unspoken of in public or taught in schools, despite its aftermath still being felt decades later in Nigerian society. In this paper, we make a case for how a digital museum offers room to reflect, discuss and remember this important part of the country's history. We use design-based research to develop a digital museum to improve access to this history through a diversity of voices.

Introduction

The Nigerian Civil War (NCW), also referred to as the Biafran War, took place from 1967-1970 when Nigerians from the Eastern part of the country made a secession attempt. The number of lives lost are estimated to be between 500,000 to 3 million people (Anthony, 2014). As important and definitive as this event is in Nigerian history and current life, this war has received little productive discourse or reflection in schools and public spaces.

Recent technological advancements in culture and history preservation such as digital museums have provided an opportunity to curate cultures and histories, some of which are controversial, in a low-pressure environment while engaging directly with the public and those impacted by it.

Objectives

With this study, we seek to understand how Nigerians currently learn about the civil war, the role technology can play in this learning process and the importance of spaces of memory in the preservation of history, through the design of a digital museum. As virtual museum spaces are often a replica of physical museum structures inspired by architectural designs, we aim to design a space that is informed primarily by the needs of visitors and those affected by the war, and allow those needs drive the interaction with the exhibition. We also seek to generate more conversations and research on providing more accessible learning materials for learners using virtual reality tools.

Background

There are multiple accounts of the NCW across academia, literature, and media (Dalley, 2013; Omaka, 2014). The digital museum is drawing from these multiple accounts, as well as interviews with a diverse group of Nigerians, to paint a bigger picture in one space where they can be analyzed and studied side-by-side to construct a better understanding of the war and facilitate critical exploration of its different parts.

Virtual museums, offer ideal spaces for cognitive actions of critical thinking, and reflection on some of the more devastating effects of war—like destruction and death—can take place safely with the support, guidance, and scaffolding available for the learning. They also provide an environment for a community of learners to develop where meaning can be constructed and mediated.

Methodology

The paper presents the first iteration of a design-based research project. This first step of this iteration involved carrying out a needs analysis to identify the current issues in the learning about the NCW within Nigeria. This was achieved through interviews with nine Nigerians (between the ages of 18 and 65). The interviews followed a semi-structured protocol designed to elicit personal understanding and experience of the war and individual narratives about the war. These interviews were thematically coded, and the emergent codes allowed us to build a framework to guide our design for a virtual museum focused on the NCW. The framework to understand the learning needs was patterned in the following order: 1) Identifying the current understanding and gaps, 2) uncovering hidden stories and alternative narratives, and 3) highlighting the goals of the study with evidenced-based research, all these with the overall outcome of a richer and more nuanced understanding of the war.

Before describing the design, we first present a summary of the interview responses and analysis.

Interview Results and Analysis

The responses showed a wide range of understanding of the war and how it should be addressed. Some responses evidenced a parallel in thoughts and opinions, while others showed a divergence in opinions and may provide a

 © ISLS

clue as to why even today, this topic remains divisive. We discuss a few of the responses below to highlight particularly important themes:

- *Knowledge of the war.* Most of the participants showed a comparable understanding of basic information around the war and revealed parents and books are the recurring primary sources of information.
- *Silencing of war narratives.* Silencing of historical trauma and personal narratives has been identified as being a prominent outcome in areas with a history of conflict (Liem, 2007). Participants discussed why they thought the war wasn't being discussed enough as a country and explained the existence of the culture of silencing people they believe has been adopted with regards to the war.
- *Monuments and memorials.* Participants expressed the importance of informal spaces, monuments, and memorials about the war. Many comments referred to them as symbols of remembrance, to honour victims and a part of national memory.
- *Future of history Education.* Participants also suggested digital materials and informal spaces such as a digital museum as an ideal platform to present a history of the war, as its controversial nature could make it unsuitable for the formal structure of a classroom, a concern identified by Lindquist (2010).

Design of the Digital Museum

The museum design is guided by the themes that emerged from the interview analysis and the framework of understanding the learning needs referred to in the methodology. Below we describe our first iteration of the design, which can be viewed at www.nigeriancivilwarmuseum.com

Poor knowledge of the war and its impact on the availability of learning resources and spaces was frequently alluded to during the study. To bridge this knowledge gap, the museum is curating learning resources and instructional materials for students and for teachers to incorporate into their lesson plans for use within and outside the classroom. As respondents identified, this digital representation places a low demand on the educational resources available.

The discussion forum in the museum facilitates constructive interaction and fulfils the vital and enriching social aspect of learning. Here, visitors can engage in detailed analysis and productive conversations drawing from the various resources located in different parts of the digital museum space. These interactions also promote varied opinions in the dissection of the history and give strength to minority accounts that often get drowned out. The exchanges are characteristic of a community of learners and the kind of activities that improve the scholarship of the community.

Conclusion

The history of a nation to her people is of great importance, and the education of same is vital. This study proposes a non-traditional approach to achieving this and implementing it within and beyond the classroom and school structure. This digital support of history pedagogy seeks to concretize learning, improve understanding, and provide a more inclusive approach to education using the history of the Nigerian Civil War as an example. Future design iterations will review a more robust curriculum, include more minority voices, engage public and private stakeholders, and aim for integration into the traditional school structure. Through these future iterations we hope to truly impact people's understanding of the Nigerian Civil War and unsilence the important stories and lessons its history can teach the world.

Designing for Connected Arts Learning through Culturally Sustaining Practices

Maggie Dahn, Lora Cawelti, Emily Schindler, and Kylie Peppler

University of California, Irvine

Abstract: Community-based arts organizations curate and build experiences rooted in local culture through culturally sustaining practices. Through analysis of interviews with leaders at community-based arts organizations, we found that each took a different route to supporting culturally sustaining arts practices, which enacted relational elements of connected learning environments. We describe three models of culturally sustaining arts approaches (i.e., heritage and history, intergenerational, and youth culture) and suggest that each supports relational elements of connected learning.

Introduction

Connected learning is learning that transpires at the intersection of interests, supportive relationships and academic, civic, and career opportunities (Ito et al., 2020). Community-based arts organizations put connected learning into practice by building learning experiences rooted in local community cultures and culturally sustaining practices (Paris & Alim, 2017). To address key problems of practice facing community-based arts organizations, including communicating the legitimacy of arts education and issues concerning equity (Peppler et al., 2021), we argue that arts organizations can take different routes to supporting culturally sustaining arts practices that enact relational elements of connected learning environments (i.e., shared purpose, shared practices, sponsorship of youth interests, and making connections across settings) to support a framework for 21st century arts learning that includes a broader range of opportunities and outcomes of arts education. To detail the relationship between connected learning and culturally sustaining practices, we compare data from three arts organizations that prioritize culturally-inscribed arts practices for youth. Through analysis of interviews, here we show how three arts organizations take up culturally sustaining practices in different contexts with particular arts practices and organizational priorities, to arrive at cultural sustenance as a learning goal. We consider this work to be a theoretical innovation for describing the different ways in which culturally sustaining arts practices might constitute connected arts learning ecologies with practical implications for the design of arts learning experiences.

Methods

We drew on culturally sustaining pedagogies (Paris & Alim, 2017) and connected learning for our theoretical frame. Taken from a larger dataset, we analyzed interviews with five leaders at three arts organizations, including: 1) The executive director at a multidisciplinary arts organization in Brooklyn, New York; 2) The founding artistic director and executive director at a performing arts organization in Boston, Massachusetts; and 3) The executive and deputy directors at a media arts organization in Salt Lake City, Utah. Organizations were chosen based on practices in alignment with connected learning principles such as making connections to opportunity (for a longer discussion, see Peppler et al., 2021). In our sampling we also aimed for diversity in geographic location and types of arts experiences emphasized (e.g., dance vs. media arts). We took a deductive approach to analysis, using the three domains of connected learning (interests, relationships, opportunities), as well as resonant connected learning themes around shared practices, shared purpose, making connections across settings, and sponsorship of youth interests. As we engaged with the data, we attended to culturally sustaining practices as an emerging theme that enacted elements of connected learning.

Findings: Culturally Sustaining Arts Toward Enactment of Connected Learning

We found that arts organizations took different routes to enacting culturally sustaining arts practices that emphasized relational elements of connected learning environments (i.e., shared purpose, shared practices, sponsorship of youth interests, and making connections across settings). Table 1 presents an overview of models that describe different ways in which organizations supported a culturally sustaining arts approach within their programming. We acknowledge that organizations could take more than one route toward integrating culturally sustaining arts, though we found that one model of culturally sustaining arts prevailed at each organization. In Table 1 we describe each of these models of culturally sustaining arts and use examples to highlight the ways in which arts organizations might leverage relationships with teaching artists to support elements of connected learning environments.

 © ISLS

Table 1
Enacting of culturally sustaining arts across arts organizations and programs

Culturally Sustaining Arts Model	Description of Approach to Culturally Sustaining Arts	Examples of Relational Alignment with Connected Learning Design Principles
Heritage, and History Sustaining Arts	Often found in Black-serving organizations through intentional use of African languages and arts programming grounded in traditional practices, connecting Black neighborhoods where youth live with African heritage *Example: West African drums, conga, capoeira*	Role of the teaching artist is to facilitate interactions that call youth to interrogate history and culture toward a *shared purpose* in better understanding themselves, their communities, and unique histories. "We start from what it means to be a person of African descent, not in relation to whiteness, but in relation to how that impacts how I move through the world" - *Executive Director, Arts Org 1*
Inter-generational Sustaining Arts	Takes a familial, intergenerational approach, understanding how to leverage family relationships to support youth cultures, histories, and art forms *Example: Student and alum arts instructors; parent participation*	Role of the teaching artist is to bring in families as part of the co-organization of arts learning toward *making connections across settings* for learning in youths' lives such as between home and out-of-school contexts. "There's respect, protocol for eldership … this idea of rites of passage ... it's woven into the fabric of what we do and we have found it has been very beneficial for the young people, as well as their parents who learn from their engagement with us." - *Executive Director, Arts Org 2*
Youth Culture Sustaining Arts	Takes a service perspective, working to understand how to best grow and support student voice within the local community context; centers youth culture, often through their interest-driven learning in media arts and technology *Example: Media arts and youth storytelling; Performances to community audiences*	Role of the teaching artist is to *sponsor youth interests* in the arts by celebrating and explicitly connecting them to opportunities, as well as engage in *shared practices* to support interest-driven forms of collaborative artistic production. "They're contributing to the civic discourse in their communities and they're talking about the stuff that's really important to them. The artistic piece is the vehicle for that voice and digital media in particular is really critical" - *Executive Director, Arts Org 3*

Conclusion

Our findings highlighted different models for how arts organizations took up culturally sustaining practices in different contexts (i.e., heritage and history, intergenerational, and youth culture) as well as how through the role of the teaching artist, each culturally sustaining approach supported elements of connected learning. These findings show that arts organizations are actively leveraging culture in its dynamic forms as they work toward curating connected arts learning experiences. Each organization emphasized the role of arts media and traditions to not only engage students through interest-driven learning and boost connected learning environments, but also to connect them to history, family, and their developing voice. Importantly, this work reminds the field to consider the community and cultural roots of youth interests. Practical implications include how arts-based learning and programmatic design might be tailored around connected learning design principles to support culturally sustaining outcomes such as connections to history or youth culture. The theoretical implications of this work include extending how connected learning conceives of culturally sustaining practices through the arts.

Abstract: The pandemic has forced higher education to shift from onsite to online environments. This novel situation may increase students' exam stress and induce new stressors. In the present study, we identified stressors in online exams by conducting an exploratory factor analysis of a novel questionnaire. The analysis revealed five factors that categorize students' experience of stress. Preliminary descriptive results suggest that possible system failures and social pressures cause the highest stress for students.

Introduction and related work

Writing an online exam from home was uncommon until a few years ago but has become common practice for many students due to the Corona pandemic. However, to date, only little is known about the students' subjective experience in such new settings and about the stressors they might face in online exams (Harley et al., 2021). For instance, writing an online exam from home involves that students are asked to provide their own technical infrastructure (e.g., hardware, software, internet access). Thus, technical issues presumably arise due to a slower internet connection, poorer hardware quality or outdated or incompatible software. Besides technical problems, also social and emotional aspects of online exam settings might be challenging and stressful for students. Since a higher stress level negatively impacts one's performance (Hafeez et al., 2018) the identification of potential stressors in those novel exam settings is highly relevant. Thus, our goal for this study was to identify and investigate stressors in online exams via exploratory factor analysis. Our results may provide insights for the development of futures online exams.

Method

As part of a larger project at our university, we investigated the subjective experiences of students during online exams. The sample of this study consisted of 93 psychology bachelor students (73 females, 19 males, 1 diverse; M_{age} = 26.81, SD_{age} = 5.14). After finishing their individual exams at the end of the spring semester in 2021, participants were invited (via email) to participate in an online survey (conducted via EFS Survey (2021)) including a total of six scales concerning their subjective experiences in online exams (stressors, emotions, appropriateness of exam formats etc.). Participation in the study took an average time of 16 minutes. The stressors questionnaire consisted of 26 items (e.g., Stress_14; "*The exam software no longer works*") which were created following the scales used in a study by Caltabiano et al. (2021). The participants reported their level of stress (i.e., "*For each of the following statements, please indicate how stressful the situation is for you during an online exam.")* on a scale from 1 – "not stressful at all" to 5 – "extremely stressful". To examine the questionnaire, we conducted an exploratory factor analysis.

Findings

Since a multivariate normality test indicated a non-normal distribution, we conducted the factor analysis with axis factoring instead of maximum likelihood. Moreover, we decided to use an oblimin rotation, which is better suited for an exploratory factor analysis, as we had no indicators for possible correlations between the factors (Osborne, 2015). The exploratory factor analysis yielded five factors, with 18 items indicating sufficient loadings to a factor (> .3) and low complexity (factor loadings are presented in Table 1). The following five factors were derived and named based on the items' common subjects (see Table 1): (1) The factor '*system failures'* consists of items that apply to possible external failures of the exam software or the technical infrastructure. (2) The factor '*social pressure'* includes items regarding stressors that stem from either monitoring through a proctor or social comparison. (3) The factor '*self-inflicted noises'* includes items relating to self-produced noises. (4) The factor '*time indication'* consists of items that convey to stressors inflicted by time indication. Finally, (5) the factor '*external disturbances'* consists of items that assesses stressors inflicted by external factors. We refrained from attributing a total of eight items to the factors, since either the factor loadings were too low, the item was too complex, or the item did not semantically match to the other applied items (even though the factor loadings would

 © ISLS

have been high enough). In a next step, we descriptively investigated the level of stress induced by the respective factors as perceived by the participants. The results suggested that the factor *system failures* caused the highest level of stress (M = 4.67, SD = 0.59), followed by *social pressure* (M = 3.67, SD = 0.75), *external disturbances* (M = 3.35, SD = 0.91), *time indications* (M = 2.47, SD = 1.00), and lastly *self-inflicted noises* (M = 1.63, SD = 0.82). In conclusion, students seem to be afraid that the technical infrastructure, (i.e., soft- or hardware) may cause problems, which presumably might affect their performance in an exam. Moreover, *social pressure* including monitoring during online exams was perceived as second largest stressor by students. Monitoring may also include the presence of a proctor (e.g., through webcam) which – apart from ethical considerations – might also result in additional perceived stress. As a next step we plan to increase our sample and expand it to more universities to subsequently validate the questionnaire with a confirmatory factors analysis. Nevertheless, this study helped us in further developing the questionnaire for future survey of subjective experiences in online exams and may also provide insights for related research.

International Society of the Learning Sciences

Co-developing Immersive Learning Experiences in Interdisciplinary Projects in Upper Secondary Education

Professor Hans Christian Arnseth, University of Oslo, h.c.arnseth@iped.uio.no
Professor Kenneth Silseth, University of Oslo, kenneth.silseth@iped.uio.no
Professor Rolf Steier, Oslo Metropolitan University, rolf.steier@oslomet.no

Research topic and aim

Through dialogic design practices, we explore how we can create innovative learning designs with immersive technologies. Existing research has demonstrated the benefits of such technologies in education (see Markowitz et al, 2018), but there is a need to generate more knowledge about how immersive technologies can be integrated with collaborative learning activities (Enyedy & Yoon, 2021). Our aim is to create digitally mediated learning experiences targeting the special interdisciplinary curricular topic of "health and wellbeing". Researchers are working together with teachers from language arts, social science, and sports science to employ Augmented Reality (AR) and Virtual Reality (VR) technologies to create embodied learning experiences that both align with and disrupt existing classroom practices. We do not develop technical immersive solutions, but rely on pre-existing tools. Our focus is on understanding the potentials and pitfalls of introducing immersive experiences, pursuing a dialogic and participatory "bricolage" approach to design practices where participants make creative re-use of available technologies (Richter & Allert, 2017).

The project is ongoing (2020-2023) and in this poster, we account for the project framing, collaborative design work, and concept development. It is important to reflect on the lessons learned during these initial and middle phases of design-based projects, as these processes are often obscured and given less attention in the learning sciences community (Svihla & Reeve, 2016; McKenney & Reeves, 2018). Our study is guided by the research question: *How does teacher-driven innovation develop in the context of the design of immersive pedagogies*?

Across the narrative description of the design work presented below, we identify three ideas as particularly innovative and relevant for the learning sciences community: (1) the unique organization of a design-based project that is initiated and deeply driven by teachers themselves; (2) the "health and wellbeing" concept as a driver of design work; and (3) our approach to immersive technologies as dialogic and collaboratively oriented.

Theory and methodology

In designing and researching immersive technologies in learning, we draw on sociocultural and dialogic approaches emphasizing a more comprehensive understanding of the learner as well as a focus on how learning is inextricably bound up with motivation, identity and features of learning ecologies that learners dwell in (Silseth & Arnseth, 2011). Classrooms are complex learning ecologies and the effects of innovations can be unpredictable. Through developing and testing prototypes, we study how teachers and learners adjust innovative ideas to the classroom context. Prototypes represent solutions to concrete problems and they enable us to test innovative ideas in practice. They also enable and support collaboration through externalizing knowledge into objects that we together can act on. In order to research how design ideas emerge and become materialized into more elaborate designs, we document the process by video-filming activities. We draw on design-based research where the strategy is to engage in mutual development of ideas and practices together with teachers and students (Sandoval & Bell, 2004). Our collaborative relationship with the school came about because the teachers wanted to explore how AR and VR could make learning more engaging and abstract concepts more tangible and meaningful to students.

In the past decade, an increased emphasis has been put on the contributions and status of stakeholders in design-based methodologies, such as social design experiments (Guittérez & Jurow, 2016), research-practice partnerships (Coburn & Penuel, 2016), and recent interpretations of DBR (Bang, et al. 2016). However, we often find that university researchers lead the innovation process. It is therefore important to underline that the problems and issues emerged in and through teachers practical experiences.

Narrative description of the trajectory of design work

Rather than engaging in design and re-design iterations, where these processes are clearly distinguishable, we pursued a dialogic design practice mediated by conceptual artefacts such as sketches, prototypes, or technological resources. In our first meeting, we introduced examples of VR and AR applications to teachers and challenged them to specify and articulate their understandings of the new interdisciplinary topic of "health and wellbeing". Through dialogue issues related to students understanding of the body and how it works came up, as did issues related to

 © ISLS

digital images of the self and how people use filters to play with their appearances and identities. Issues related to how we can design for embodied experiences of gender and identity also came up as ideas to explore.

Before the next workshop, we summarized these ideas into a conceptual artefact and introduced a more systematic suggestion for an interdisciplinary topic. Based on teachers' initial ideas, we suggested focusing on the topic of "The body across physical and digital spaces". We did not suggest any clear learning goals or learning activities at this point, because we wanted these specifications to come from the teachers themselves. The teachers found this topic interesting and we decided to continue specifying and operationalizing the topic into more concrete pedagogies.

In the third meeting, the researchers visited the school. Here, the purpose was to test different types of immersive technologies. The teachers tested VR headsets and tried out different types of games and software. At this stage, it was important that the teachers involved actually got first-hand experience with AR and VR resources. This was also done to engage the teachers and enable them to search for and explore applications that could be relevant for them in their daily work and what they wanted to accomplish in their classroom and work on the interdisciplinary topic "health and wellbeing". The teachers were interested and fascinated, particularly with VR games and design programs such as 'tiltbrush', as well as voicing concerns with implementing VR/AR as part of a more comprehensive learning activity and making experiences available to all members of a classroom community. Through dialogic design practices, the concerns and opportunities of immersive technologies dynamically emerged instead of being inferred or presupposed.

In the fourth workshop, which took place at the University, we tried to more explicitly develop and articulate prototypes for learning designs. We split into two groups and teachers, researchers and designers together tried to come up with ideas for learning activities. We did not want to put limits on the teachers' creativity, so they were urged to come up with as many ideas for learning activities as possible. Our aim was to enable teachers to reflect upon learning goals and pedagogical methods and strategies. This became an interesting session where the teachers contributed with insights about both opportunities and challenges when designing for immersive learning environments. Through dialogic design, the contextual framing for understanding the opportunities and constraints of immersive technologies for learning were gradually introduced and made more complex for participants.

In the fifth meeting, we continued to work on the development of the prototype. Between the last two meetings, teachers had also had the chance to discuss and test VR and AR solutions amongst themselves. As a result of our dialogic design practices, it became clear that it would be premature to develop and test a comprehensive learning design with students. Among other things, this was because the learning situation would be too complex and there would be a high risk for not being able to go through a common activity for all students at the same time. Therefore, we agreed to include a set of VR/AR experiences for students as learning stations in the classroom, split students into groups, and have them test the technologies, as well as reflect on what they experienced and how these immersive technologies can be used meaningfully in future classroom activities.

Through our co-design pedagogical concepts are emerging, namely one task focusing on identity and ethnicity through immersive video and construction of avatars, one task focusing on body representations and a more open task focusing playing with the possibilities for social interaction using RecRoom. The next step in our joint design work will be to further involve students in the dialogic development of innovative immersive learning designs through in-class pilot testing.

Conclusion

We found that it was important that teachers themselves initiated and have ownership of the project. Even though it has been challenging to organize the project and for the teachers to find time to innovate during a pandemic year with many constraints, they still have a stake and interest in the project. This is crucial for further innovation. In our design work, we have been careful to not simply develop a design independently and bring it to the school. We have been concerned with organizing the design work dialogically, and our suggestions have been sensitive to teachers' voices in the emerging design work. At the same time, during the development, we have analyzed and reflected on what kind of support teachers need to create pedagogical innovation. The teachers' everyday experiences of immersive technologies and of "health and wellbeing" concepts were transformed into new pedagogies through dialogic design processes with us. We have experienced that it is challenging to align immersive technologies with collaborative activities, because the number of devices needed would not be feasible and because aligning attention across multiple devices is difficult. Still, it is important to emphasize that immersive experiences makes up only a fraction of the overall activities. Small group discussion and design work and whole-class reflection are planned to occur before, during, and after the immersive experiences.

Development and Formative Evaluation of a Learning Game for Overcoming Typical Difficulties in Historical Thinking

Ryohei Ikejiri, The University of Tokyo, ikejiri@i-timemachine.net

Abstract: Research has been conducted on teaching materials for historical thinking using historical sources. However, historical thinking encounters challenges in the use of historical sources, and short-term interventions have limited effectiveness. This study developed a learning game by combining the ideas of a studying-errors guideline and game-based learning to overcome typical difficulties in historical thinking using historical sources. The formative evaluation showed that the learning game affected challenging historical thinking using historical sources.

Introduction

Historical thinking is an important part of education in many countries. Although there are multiple definitions of historical thinking (Wineburg, 1991; Van Boxtel & Van Drie, 2018), historical thinking using historical sources (UHS) is emphasized in all. History is unique in how it manipulates and interprets historical sources for reasoning about the past. Here, historical thinking UHS refers to understanding or interpreting the past with historical sources.

Several methods for fostering historical thinking UHS have been developed, but short-term interventions have limited effects (Fox & Maggioni, 2018). There are two reasons for this. First, Wineburg's (1991) novice-expert research shows that beginner students have difficulty with sourcing (the act of looking first to the source of the document before reading the body of the text), corroboration (comparing documents with one another), and contextualization (situating a document in a concrete temporal and spatial context) when interpreting the past using historical sources. Generous and step-by-step support is needed to overcome these typical difficulties. Second, controlling the complex historical discussions necessary for developing historical thinking is difficult. It is essential to have an ideal historical discussion that promotes historical thinking UHS and includes individual feedback.

This study develops a learning game that provides an ideal and individualized learning experience to overcome typical difficulties in historical thinking UHS and supports formative evaluation.

Development

This study focused on two teaching methods to address the challenges in fostering historical thinking UHS. The first is the studying-errors guideline, a method that involves a mixture of correct and incorrect examples—both of which students learn from. This approach is more effective than learning from correct examples alone (Renkl, 2018). The second approach is game-based learning, which can provide step-by-step, individualized learning experiences and individualized feedback that is adapted to individual players.

A learning game called *Rekiseeker* (Figure 1) was developed by combining these methods to foster historical thinking UHS. This game's objective is to present a valid historical account using historical sources. The concrete goal of the game is to locate errors in the historical account of the opposing characters who interpret the past without sourcing, corroboration, or contextualization and to demonstrate valid historical accounts. When a player makes an incorrect choice, scaffolding and feedback are provided by an allied character. These features then enable an ideal historical discussion to overcome typical difficulties in learning historical thinking UHS among all players. One play of the learning game takes about 15 minutes. The game's theme centers on labor issues during the Industrial Revolution, which is covered early in the Japanese history curriculum in high school. The historical thinking UHS learned in this game is intended to support learning in later units (e.g., the Lincoln unit).

Formative Evaluation

A formative assessment was developed to measure whether the historical thinking UHS acquired in the learning game, especially sourcing, contextualization, and corroboration, would transfer to other history unit tasks. Data were collected in an 80-minute session with six Japanese high school students (three pairs) after classes on October 26, 2021. Each student read historical sources related to the transfer task, and each pair discussed during the transfer task. Then, each student played the learning game, and each pair discussed during the same transfer task, and each student responded to the post-questionnaire. In the transfer task, the question "What kind

 © ISLS

of person was Lincoln?" was approached using three historical sources that provided contradictory versions of Lincoln's image. Historical thinking UHS is needed to resolve this. The post-questionnaire determined whether the learning game impacted students' post-discussions in the transfer task and, if so, what kind of awareness it promoted in free-text format.

After collecting data, we investigated whether student statements related to sourcing, corroboration, and contextualization increased in the post-discussions in the transfer task relative to the pre-discussions and whether sourcing, corroboration, and contextualization were mentioned in the post-questionnaire. The effects were discussed along with the results.

Results and Discussion

While sourcing was not performed by all pairs in the pre-discussion task, references to it were found in two of three pairs' post-discussions. Although no student explicitly mentioned it as an effect of the learning game, analysis of the conversations in the transfer tasks suggested that the learning game affected the students. With regard to corroboration, all pairs compared the historical sources with one another in the pre-discussion task, and there were no changes in the post-discussion task. However, considering that one student in Pair 1 and one in Pair 2 mentioned the impact of contextualization in the post-questionnaire, both pairs seem to have compared historical sources with one another in the post-discussion task. Therefore, this learning game supplemented the historical thinking UHS that had been lacking in each pair. All pairs situated the historical sources in a concrete temporal and spatial context during the pre-discussion task, and two of three pairs were aware of and referred to new historical contexts in the post-discussion task. In the post-questionnaire, four people (one each in Pairs 1 and 2 and two in Pair 3) wrote about the impact of contextualization. This indicates that this learning game helped develop greater awareness of the historical context in the students.

These results show that the learning game successfully combines the ideas of a studying-errors guideline and game-based learning to overcome typical difficulties in historical thinking UHS. Future issues include conducting more elaborate experiments and verifying whether such a learning game format is also effective in developing thinking skills in other subjects.

Self-Regulated Learning with Task-Centered Microlearning

Amit Palti, Rinat B. Rosenberg-Kima
Amit.palti@campus.technion.ac.il, rinatros@technion.ac.il
Technion – Israel Institute of Technology

Abstract: The need for self-regulated learning (SRL) skills was intensified during COVID-19, with schools shifting to online-learning. Using microlearning (short videos with self-evaluation) may promote SRL while an organizing-task may help assemble learning-units into a wider concept. We propose a task-centered microlearning framework for promoting SRL and other 21st century skills. Our pilot with middle school students revealed practicing aspects of SRL such as controlling the learning-environment, self-reflecting, and overcoming obstacles by using peers' support.

Introduction

As educators, we need our instructional methods to consider skills and competencies that are required for our students' career mobility as grownups. These skills, often referred to as 21st-century skills, include Self-Regulated Learning (SRL), critical thinking, collaboration, and more (Ananiadou & Claro, 2009). The need for SRL was intensified during COVID-19 worldwide spread, which drove school systems to online-learning and required students to learn by themselves.

Microlearning is a set of small chunks (5-10 min of length) of digital media learning units (microunits) that target small learning objectives and are usually delivered online. Microunits include short videos accommodated by short tasks for self-evaluation (Hug, 2007). Using the video operating keys and the embedded tasks, the student controls his learning environment and monitors his progress, both are pillars of self-regulated learning (Zimmerman, 2002). Furthermore, microlearning may reduce some of the cognitive load involved as the units are structured in learner-paced segments (Mayer, 2002).

Microlearning by itself may not be sufficient when there is a need to acquire complex concepts since a single microunit covers only a fragment of a curriculum concept and the student needs to relate between sets of microunits and put them into the appropriate larger context. An organizing-task may help the student cognitively assemble different learning units and engage him in the learning activity by providing meaning and motivation (Ahlfeldt et al., 2005; Krajcik & Blumenfeld, 2006). In addition, timely teacher interventions and facilitation (Goodyear & Dudley, 2015) are crucial to monitor the student's progress. We developed and piloted a task-centered microlearning framework with 18 microunits centered around a team's task of creating a digital escape room. We intend to further assess how this framework promotes self-regulated learning & 21st-century skills in general.

Research Goal and Questions

Our research intends to evaluate the promotion of SRL skills and additional 21st-century skills with the proposed task-centered microlearning framework. The research questions are: (1) Which SRL skills are promoted through Task-Centered Microlearning? And how? (2) Which other 21st-century skills are promoted through Task-Centered Microlearning?

Method

Participants

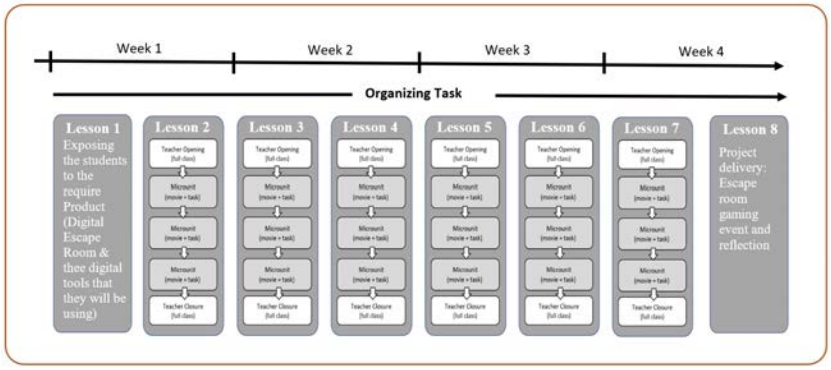
Our research includes four science teachers and 23 8th grade students from one middle school. The participants signed a consent form approved by the institutional ethics committee.

Materials

The program lasted four weeks. During the first week, the teacher explained the program's collective task (building a digital escape room), introduced three digital tools for the digital game creation, and exposed the microlearning platform. During the following three weeks, the students individually learned environmental concepts by watching 18 microunits and completing the unit's microtasks. In parallel, the students, working in teams, developed a digital escape room. The final week is devoted to the projects' presentation and a reflection process. See figure 1 below.

 © ISLS

Figure 1*The task-centered microlearning progra*m



Research Tools

We used mixed methods, including quantitative and qualitative data research tools. We used the adjusted MSLQ questionnaire (Pintrich & Others, 1991) to measure students applying aspects of SRL related to controlling their learning environment and managing time/goals. We used open-ended questionnaire to collect aspects of SRL that the students were applying while facing obstacles during the program., In addition, we collected qualitative data regarding applying aspects of SRL and other 21st-century skills by interviewing the teachers.

Preliminary Findings and Discussion

As part of this pilot study, twenty-three 8th grade students used the framework for learning about the human impact on earth resources. We found, following the preliminary analysis of the data, that the students were practicing one or more aspects of SRL, such as controlling and replaying the videos to ensure self-learning ("I replayed the video over and over again until I understood all of it"), self-balancing between learning and off-learning, and overcoming obstacles by using their colleagues', teacher's, or parent's help.

The teachers reported that the students were actively engaged through self-controlling their microlearning environment, demonstrated ownership of the learning outcomes, and applied critical thinking.

Next, we plan to use a Learning Management System (LMS) based environment, to automatically-collect data related to the students' control of the microlearning environment, including usage of the video control buttons, partial watching, rate of completion unit's tasks, etc.

We also plan to explore the promotion of additional SRL aspects with this task-centered microlearning framework, such as evaluating personal progress and motivation to learn. Since the proposed framework fits remote and face-to-face learning, this research may contribute to a worldwide need for effective tools and methodologies for online and blended learning. It may also extend the knowledge about Microlearning applicability in K-12 education.

Intertwining Research and Practice in Higher Education: Presenting LPI's Learning Sciences Master Program

Esra Çakı, Valentin Corneloup, Franck Zenasni
esra.caki@cri-paris.org, valentin.corneloup@cri-paris.org, franck.zenasni@cri-paris.org
Université de Paris, LPI

Abstract: The LPI and Université de Paris have developed the AIRE Master program to train future change-makers and researchers in response to the transformation happening in our world. This innovative program offers high-level training through a learning-by-doing-based curriculum and social implications. It aims to embark on a rich discussion between various stakeholders on how research and hands-on practices can be combined in such a way to transform our higher education system.

Introduction

Today's world is changing rapidly, becoming more interconnected, technologically complex, and economically competitive (Sawyer, 2014). Meanwhile, we are facing global and social challenges that require us to take immediate action. Yet, the traditional pedagogies have failed to train our society to overcome such challenges. To succeed in confronting these challenges, we need to co-construct and share new ways of teaching, learning, doing research, and mobilizing collective intelligence. In other words, we need a "learning transition" that enables us to learn how to learn and support the learning of individuals everywhere and anytime. In response to this challenge, LPI (Learning Planet Institute) and Université de Paris have developed a master's program to train future change-makers and researchers concerned with the way we teach, learn, and conduct research as well as work, create, and collaborate. The program, namely AIRE (Interdisciplinary Approaches in Research and Education), offers high-level training in learning sciences and intertwines research and practice, the collaboration of multiple stakeholders, and an interdisciplinary approach to transforming our way of teaching and learning.

General Overview of The Program

The program aims at enabling students to comprehend the concept of teaching and learning harmonized with needs and changes, design and implement effective learning environments, and bridge research and practice to address problems through an evidence-based approach. One of the significant objectives of the program is to develop the ability of students to face and deal with a diverse range of analyses. As (Doise, 1986) proposed, human actions, such as learning, can be explained through the conceptual framework of the four-level of analysis: intra-individual processes (level 1), inter-individual but intra-situational dynamics (level 2), effects of social position in a situational interaction (level 3), and intervention of general beliefs (level 4). In this perspective, the program enables students to understand and experience themselves at these different levels through being exposed to various disciplines and being involved in diverse types of (a) community, (b) ecosystem, and (c) internships. In line with (Renn & Arnold, 2003) and based on Bronfenbrenner's Ecological Systems Theory (1986), the program strives to let students comprehend that any learner is in the "center of concentric rings of environments", ranging from immediate (microsystem) to most distal (macrosystem) contexts.

Curriculum

The curriculum aims at providing students with a global understanding of the transformation happening in education, and it encourages them to design relevant and challenging entrepreneurial projects. Based on the figure of social-scientist-entrepreneur, the interdisciplinary teaching units aim to transmit the fundamental knowledge of sub-disciplines related to learning sciences and develop associated skills. The courses are offered in a block mode to increase engagement and accelerate learning (Zepeda & Stewart, 2006). It starts with an intense four-week bootcamp where students discover the basics of learning sciences and develop initial reflections about learning. Following this, a variety of courses (e.g., instructional design, learning theories, game design, critical thinking, data science, etc.) and activities are offered to enrich students' learning paths through theory and know-how, practical knowledge, seminars and masterclasses, research methodologies and statistics, and project management foci. Moreover, as part of the curriculum, students do three internships in research labs, NGOs (Non-governmental Organizations), or companies to gain hands-on experience working on learning-related issues.

Pedagogy

The pedagogical modalities of the program are developed to enable students to acquire knowledge and crucial

 © ISLS

skills and apply them to everyday life. It is based on the concept of "learning-by-doing" to enable students to gain knowledge and skills through working in real-life contexts. For instance, internships and various courses (e.g., learning by doing curriculum and learning by doing research) provide students with opportunities to acquire practical knowledge and transversal skills through experiencing firsthand. Moreover, it offers project-based learning by bringing bachelor's, master's, and doctorate students in the LPI ecosystem together to address challenging interdisciplinary problems. For example, the 'creative week' is organized every year for master's and doctorate students from diverse backgrounds to work collectively on an interdisciplinary project and present it to the LPI community. Also, the program values peer-to-peer learning as it develops a spirit of collaboration amongst learners and lets them enhance their in-depth knowledge by learning from each other. Lastly, it attaches great importance to mentorship as it provides continuous improvement throughout the process.

Social Implication

The program not only aims at enriching students' knowledge and skills but also equipping them intellectually to be able to reflect upon their own actions and how these actions affect their immediate social and physical environment. In an attempt to compose a learning environment and curriculum that support students in functioning in social reconstruction, the program put emphasis on three significant elements: (a) diversity, (b) national/international networks, and (c) sustainable development goals (SDGs). Regarding diversity, it welcomes each year a cohort of passionate students from diverse backgrounds and nationalities. For example, 14 students from 12 different countries (e.g., China, France, Russia, India, USA, UK, etc.) across the globe were admitted to the program for the 2021-2022 academic year, and their majors range from business to psychology, art and design, education, social sciences, and engineering. Students' desired career paths in the program vary as they strive to hone relevant skills and knowledge in the area of their greatest interest. Graduates the program may choose, for example, a career in educational research within or outside academia, work in a company (e.g., e-learning manager, instructional designer, etc.), in NGOs, as creators of educational materials or educational consultants, and so on. Almost 35% of our alumni in an academic year apply for a Ph.D. in the field of learning sciences. Furthermore, the program attaches great importance to sharing best practices, experiences, and knowledge with large and enthusiastic international and national networks, learning from each other to achieve goals that cannot be achieved alone. For instance, students get immersed into the LPI ecosystem where they work collectively with other stakeholders such as scientists, researchers, students, and individuals who are willing to bring about a change. Lastly, the program cultivates a sense of belonging to humanity and responsibility to take action to address changing societal needs, thus fostering mutual understanding and orchestrating SDG-oriented activities towards sustainability.

Conclusion

We need a "learning transition" that transforms the way we teach, learn, and do research to keep pace with the fast-changing world. In light of this, the AIRE Learning Sciences Master program aims to intertwine research and practice, the collaboration of multiple stakeholders, and an interdisciplinary approach through innovative curriculum, adaptive pedagogy, and social implication to train future change-makers and researchers.

Abstract: Simulated learning environments, such as serious games, have the potential to significantly advance engagement and conceptual understanding for all students. The need to bolster engagement and conceptual understanding is pronounced for students with learning disabilities and difficulties. Dream2B includes a web-based video game designed with the Universal Design for Learning framework to maximize access, advancement, and power for fourth through sixth grade students in supplemental mathematics instructional settings. A demonstration of the game-based curriculum's design and development are shared.

Keywords: Rational Numbers, Special Education, Technology, Equity

Traditional K-12 STEM education does not fully address the unique issues of access to and advancement of STEM knowledge for students with LD (DeWitt, 2020). Game-based mathematics interventions may be a powerful way to improve students' engagement and learning outcomes, especially in difficult to teach content areas such as fractions. Summaries of gaming research have identified the potential of games to enhance STEM content accessibility, increase problem-solving, promote self-regulation, and allow students to explore mathematics in ways that were previously inconceivable for students with disabilities (Ke & Abras, 2013). Developed using the Universal Design for Learning (UDL) framework, Dream2B maximizes accessibility and engagement by providing fraction conceptual understanding challenges rooted in authentic STEM careers. Tutorials, action adaptive prompting, and authentic formative and summative assessments are included within the user interface. Game-based problem-solving and after-game play discussion activities promote connections and strategically link to National Council of Teachers of Mathematics (NCTM) standards. Below, we unpack Dream2B's core components. In session, we will demonstrate each component and explain how to use the program within Tier 2 intervention settings.

Demonstrating Dream 2B Core Components

Dream 2B is a narrative-based mathematics game where students play the role of "Bunny" who helps various STEM/ICT career specialists complete tasks by demonstrating their conceptual understanding of fractions. In a dream, Bunny is introduced to different career specialists who are each encountering an issue at work and are seeking Bunny's help to fix it. Therefore, Bunny's role in the dream (or game) is to solve these challenges. Each challenge requires Bunny to engage in problem tasks that involve creating and quantifying fractions. There are six worlds in the game, with the first five worlds corresponding to the different STEM/ICT careers: wind technician, solar engineer, fire inspector, photogrammetrist, and programmer. Each of the first five worlds corresponds to a specific career; world six is a combination of tasks from all careers. We take an innovative approach to tiered instructional design by integrating the following core components into Dream2B based on Hunt et al's (2020) curriculum: (a) Game Tasks along a Fraction Learning Trajectory, (b) Universal Design for Learning, (c) Action Adaptive Self-Regulation Prompts, and (d) After Game Concept/Skill Connections.

Fraction learning trajectory. Dream2B's challenges and tools are based on a documented learning trajectory of fractions for students with LD (Author). Learning trajectories are not the same as a task analysis, the amassing of skills, or longitudinal cognitive patterns, such as processing or working memory. Instead, learning trajectories consist of a learning goal, developmental stages of thinking, and activities (i.e., problem tasks, representations) designed to explicitly promote each stage of thinking (Author, year). The stages of thinking are grounded in students' conceptual development toward the goal, with each stage growing more sophisticated than its predecessor. Author's program documented six developmental stages of fractional reasoning within and among an inclusive group of students in authentic school settings that aligned with research in math education. Students' engagement in the progression of trajectory stages yields a concept of fractions as coordinated units of measure.

 © ISLS

Students build the concept by engaging in the actions of partitioning, iterating, and splitting as they solve fraction problems. In session, we will demonstrate each core component.

Universal design for learning. Universal Design for Learning (UDL) is a proactive design framework for meeting the needs of neurodiverse individuals (CAST, 2018). The framework is organized around nine guidelines and 31 checkpoints, organized vertically to provide: (1) multiple means of engagement, (2) multiple means of representation, and (3) multiple means of action and expression. Version 2.0 of the framework (see Figure 1) added horizontal alignment to identify how students could access, build, and internalize learning materials as they strive toward the goal of becoming expert learners who are purposeful, motivated, resourceful, knowledgeable, strategic, and goal directed (CAST, 2018). King-Sears (2020) pointed out UDL-based interventions must include a flexible, purposeful design in order to engage a maximum number of learners.

Action adaptive prompting. A growing line of research on student-centered math interventions reveals further design elements promoting robust STEM abilities. The most prominent - promoting noticing and reflection upon students' thinking while solving problems - are underutilized in instruction for students with LD. However, without the appropriate support, students often face difficulties self-regulating their learning. Thus, students' reliance on ineffective regulatory processes and communication of reasoning often continues because self-regulation is left unsupported in the midst of learning. The first step in addressing these issues is ensuring students have the opportunity to utilize and regulate their own problem-solving strategies while developing rich concepts for fractions. Dream2B provides students this opportunity through the use of problem-solving challenges and Action Adaptive prompting. Action Adaptive prompts are narrated, real-time responses from a game agent to students as they engage in gameplay actions. The agent provides feedback to help the player (a) set problem solving goals, (b) notice or monitor their game-based actions, and (c) reflect upon the results of their actions, which often feeds back into their goal setting within and across challenges. The prompts were designed as a part of Author's (year) learning trajectory, which maps common strategies students with disabilities used to solve fraction tasks for each conceptual stage.

After game concept/skill connections. In Dream2B, we re-conceptualized Author's (2020) curriculum to integrate students' gameplay with opportunities for students to engage in mathematical explanation and justification through game replays, worked examples, number strings, and language routines. *Game replays* involve students re-creating a strategy for a problem they solved in the game and explaining and justifying their solutions. *Worked examples* engage students in explaining and justifying a problem that has already been solved (McGinn et al., 2015). In Dream2B, the worked examples relate to a concept students are working toward within gameplay or a related skill that connects to a concept built up in gameplay. *Number Strings* engage students in mentally solving a "string" of related equations. The repetitiveness encourages students to notice a particular mathematical concept or make use of a particular strategy. When paired with conversation about how students solved a problem, specifically discussions that highlight efficient strategies and how the strategies work, number strings can support abstraction of mathematical concepts (McGinn et al., 2015). In Dream2B, the number strings relate to a skill that connects to a concept built up in gameplay. Tiered number choices allow for differentiation.

Each worked example or number string is paired with a mathematical *language routine* (Zwiers et al., 2017), which is a structured format for amplifying, assessing, and developing students' language related to a given concept. They provide productive opportunities for students to revise and refine not only the way they organize and communicate their own ideas, but also to ask questions to clarify their understanding of others' ideas. Together, worked examples, number strings, and math language routines can promote students' understanding of concepts, skills, and reasoning through explanation and justification. In session, we will demo a sample curriculum lesson, complete with gameplay.

Machine Learning and Student Reasoning Patterns in NGSS Assessments

Lei Liu, Dante Cisterna, Yi Qi, Devon Kinsey, Xianyang Chen, Brian Riordan

Educational Testing Service

Abstract: SPIN-NGSS (Student Reasoning Patterns in NGSS Assessments), an NSF funded project, responds to the national need to document various student reasoning patterns in three-dimensional (3D) science assessments and tied machine learning techniques to automated diagnosis and feedback to support science learning. This presentation describes a framework of student reasoning patterns illustrated by example student responses, the development and evaluation of machine learning methods, and an exploratory study on how students reacts to the automated system.

Introduction

The SPIN-NGSS project addresses critical challenges faced in research and practice in the implementation of NGSS or NGSS-like standards in many states. Capitalizing on existing assessment data and machine learning techniques, the SPIN-NGSS conducted a proof-of-concept study to develop an automated diagnosis and feedback tool to support student science learning. SPIN-NGSS responds to the national need to document various student reasoning patterns in response to 3D science assessments and support students' 3D learning through real-time, automated diagnostics. This presentation describes the assessment material and data resources, a framework of student reasoning patterns illustrated by example student responses, the development and evaluation of machine learning methods, and a discussion on potential uses of these AI models in science classrooms.

Sense-making as Building off Student Reasoning

Learning as sense-making of the world has been emphasized in the Next Generation Science Standards (NGSS Lead States, 2013) and various National Research Council reports (NRC, 2008; 2012). Sense-making should build on student reasoning about science. There has been abundant research on analyzing how scientists reason (e.g., Kind & Osborne, 2017). There is less research, however, on categorizing student reasoning patterns, partly because the previous assessments do not necessarily elicit how students reason about science during their problem solving or sense-making. With ongoing NGSS-aligned assessment development efforts, it is possible to conduct a systematic analysis of student reasoning patterns. These NGSS-aligned assessments should provide evidence about how students reason and inform characteristics in their reasoning.

Assessment and data resources

SPIN-NGSS investigates student data in constructed response items collected from a scenario-based ecosystems assessment task developed in an IES funded project (Liu et al., 2021). The ecosystems task requires students to use their understanding of the crosscutting concept of systems and system models, and knowledge of relationships among organisms in ecosystems to come up with an argument through engaging in the practice of model-based argumentation. The constructed response item followed a simulated activity of the corn rootworms invasion on the corn field and how adding a predator (harvestmen) into the farm ecosystem impacted other system components including rootworms and corn yield. The constructed response item asked students to use data generated from the simulation and construct an explanation for why adding harvestmen into the system did not resolve the rootworm invasion issue. A total of 864 student responses were used to develop and validate a student reasoning pattern framework.

Student reasoning patterns

Student reasoning patterns are typical ways of student thinking when making sense of a natural phenomenon. They are essential stepping stones to use and interpret student data to inform evidence-based instruction. Leveraging existing NGSS assessment data, SPIN-NGSS developed a framework that described four typical patterns, three of which were associated with 3D science learning. The first pattern represents unidimensional reasoning, focusing on Science and Engineering Practices (SEP) only. In other words, student responses only include data patterns or data points, but no mention of scientific principles. The second pattern also represents unidimensional reasoning, but only focuses on Crosscutting Concepts and Disciplinary Core Ideas. For example, student responses only mention system mechanisms like "rootworms eat corns" or "harvestmen get rid of

 © ISLS

rootworms" without reference to data or data patterns. Note that we combined crosscutting concepts and the third pattern represents integrated reasoning with a mix of practice and system mechanisms, a so called multi-dimensional response. Text relevant to the practice dimension will be highlighted in blue, and text relevant to system mechanisms in orange. The fourth category (unidentifiable pattern) is for student responses that are too vague or irrelevant to identify their reasoning pattern. Among the 864 student responses, the distribution of the above four categories were the following: 36.34% for unidimensional SEP, 16.32% for unidimensional DCI/CCC, 26.62% for multidimensional, and 20.72% for unidentifiable pattern. Note that we combined DCI and CCC due to much overlaps between the specific CCC of systems and system models with the specific DCI of interactions in the ecosystems, which would make it extremely difficult to disentangle them.

AI Model Development and Evaluation

Automated scoring tools are in high demand by K-12 educators to provide timely feedback to students. The complex 3D learning makes it challenging for teachers to provide timely feedback. With high quality assessment data, it is possible to train the machine to learn about how students reason about science and identify what is still missing in their reasoning regarding the three dimensions of science. The machine generated diagnosis can be used to define differentiated feedback to support individual student needs. However, to develop reliable machine learning based AI innovations, it is important that we have appropriate assessment data and reliable human codes to train the machine.

To achieve reliable human codes, iterative training and revisions took place to reach high human interrater reliability (ranging from 0.67 to 0.83 of Cohen Alpha value). Then we deployed two phases of AI model building. Phase 1 model building focused on predicting the reasoning pattern label and phase 2 model building aimed to predict spans of text corresponding to NGSS dimensions. In phase 1 AI modeling, we compared two models. The first model was a Support Vector Classifier (SVC) with features extracted from the words in student responses. The second model was a fine-tuned BERT transformer model, which took the Google model trained on massive amounts of English texts and adapted it to the language in our student data. We used 10-fold cross validation to evaluate the prediction in terms of accuracy and macro f-score. The transformer model outperformed the SVC model, achieving over 78% accuracy in label prediction (compared to 73% for the SVC). Phase 2 AI modeling aimed to automatically highlight relevant textual evidence corresponding to NGSS dimensions in student responses. We treated this as a sequence labeling task and used a fine-tuned BERT with Conditional Random Fields to annotate three types of evidence: SEP related evidence, DCI/CCC related evidence, and PROMPT evidence when students copied texts in the assessment prompt into their responses. The highlighted texts could be useful information for teachers to interpret student assessment data associated with the three dimensions in science learning. Phase 2 modeling achieved over 80% accuracy at the word level compared with human annotations.

Discussion and Future Work

There are critical challenges in the implementation of NGSS or NGSS-like standards in many states. Providing a score only is insufficient to support learning and teaching and, teachers need support to understand student reasoning. The SPIN-NGSS AI innovations have the potentials to help teachers hone the knowledge of attending to student thinking by identifying student reasoning patterns. We just completed the data collection of 45 students to explore how students used the automated diagnosis information to revise their explanations and will report the results in the presentation. Our future work includes collaborating with teachers to optimize the AI tool use by incorporating their knowledge about individual students' needs, learning contexts, and other background information essential to their learning pathways.

What do teachers learn about assessment via Co-Design of Game Dashboard

Yoon Jeon Kim, University of Wisconsin-Madison, yj.kim@wisc.edu
Jennifer Scianna, University of Wisconsin-Madison, jscianna@wisc.edu

Abstract: Increased use of educational technologies, such as games and simulations, requires classroom teachers develop new assessment literacies and practices related to understanding data affordances of playful learning environments. In this paper, we discuss how a co-design process that involves teachers to develop dashboards for an educational game can serve as a constructionist model of teacher professional development and report two ways the co-design process shifted teachers' understanding of assessment.

Introduction

Increased use of rich, interactive technologies such as games requires teachers to make sense of student performance from the volumes of data generated. These technologies are often equipped with teacher dashboards that display a variety of data, from low-level descriptive statistics (e.g. how many students in this class have finished Quiz 1) to machine learning driven predictions (e.g. who is likely to fail this class?). The increase of use of games in classrooms thus requires new practices around use of data and assessment. However, little is known about what teachers' assessment practices look like in game-based learning. For example, Nousiainen and colleagues (2018) report that teachers who are using games in classrooms should be able to envision evidence for learning using the collection of process-related data to plan how the game-based activity produces this evidence.

A question arises as to how professional development can support teacher adoption of innovative assessment practices. Co-design has been widely adopted in educational research as a form of design-based research (Penuel et al., 2007) where researchers, students, and teachers are all equal stakeholders who are co-constructing how educational innovations work in a particular place (Datnow et al., 1998). While still nascent, co-design also has been recognized as a form of professional development, especially to introduce innovative practices (Voogt et al., 2015). Teachers' learning from participating in a co-design process can be understood via the lens of constructionism (Papert & Harel, 1991). That is, teachers are actively constructing artifacts in collaboration with the design team, where the design team provides prompts, probes, interactive tools, and prototypes. Through this process, we expect teachers to adopt new insights and practices towards game-based assessment.

Method & Analysis

The research team implemented a 12-month co-design process with 8 practicing teachers (called *design fellows*) to develop analytics models and data visualizations for an online game, *Shadowspect.* The research team facilitated (1) 10 co-design workshops where the design fellows and research team participated in generative to identify and define learning analytics that the teachers value and need to act on, (2) individual think-aloud sessions with various iterations of the prototypes, (3) whole group and individual reflection of the co-design process.

Two researchers conducted thematic analysis (Braun & Clarke, 2014) by reviewing the pre- and post-interviews. The guiding question was, "*How were teachers thinking about the connection between assessment and student learning, and how did the co-design process play a role in shaping their understanding?"* Working independently, descriptive codes were generated; they were then reviewed together to either combine codes, generate new themes, or to reassess whether a new code might need to be applied to the original data.

Preliminary Findings

In general, teachers came into the co-design process with similar assumptions about assessment. The teachers reported utilizing assessment tools that showed what students could do in-the-moment through brief questions that reviewed material at the start or end of class. The digital tools teachers reportedly used did not encourage diving into the data. After participating in the co-design process, teachers demonstrated their thinking about assessment shifted in two key ways: (1) from skill/knowledge demonstration to process oriented and (2) from algorithms as "truth" in a black box to algorithms as products of human work that can be critiqued.

 © ISLS

Themes	Pre-process perception and examples	Post-process perception and examples
Demonstration to Process	Teachers were primarily concerned with whether students demonstrated evidence for what they know by answering questions correctly, completely, and efficiently during assessment.	Teachers were encouraged to seek alternative representations of student thinking and process. Teacher 3 remarked a shift towards looking to see "if the process is sound and there's just a minor mistake that's affecting them from getting an end result." Teacher 2 further explained that "showing mathematical thinking is not just showing step by step processing, that's like procedural thinking."
Algorithms: Black Box to Human Product	Teachers did not consider algorithms as something that can be critiqued. Teacher 1 saw the algorithms associated with learning platforms as being able to calculate a "truth": "I trust a calculator, so I trust this program too."	Teacher 1 pivoted in their exit interview to describe algorithms as a product of "choosing what it is that fits into the measurement." Teacher 4 elaborated how describing algorithms as choices breaks them out of obscurity, "unboxing of what's kind of happening." They go on to describe that, "there usually isn't a great support system around it unless it's other teachers," demonstrating how important it is that designers are able to explain the inner workings of the algorithm. Teacher 5 summarizes this ultimate connection between algorithm and designer as ultimately being important for use: "I'm very willing to take a lot of these algorithms on faith as long as I have a kind of higher-level faith in the people who have made the product."

Discussions and Implications

This study provides an opportunity to investigate how a co-design process can help teachers to learn emerging practices for assessment and critically reflect on conventional assumptions for assessment and common tools. Creating opportunities for teachers to play with their own understanding of students alongside dashboard prototypes supported the change in perspectives.

While this analysis focuses on the bookends of the co-design experience, further investigation into this data will allow the research team to construct an understanding of which activities led to the greatest shift in teacher thinking as well as further theorizing how to design a co-design process to support teachers' learning. Furthermore, this work of co-design as a constructionist activity can be expanded into other domains to identify its value beyond that of student assessment and data collection.

Beyond the Design of Assessment Tasks: Expanding the Assessment Toolkit to Support Teachers' Formative Assessment Practices in Elementary Science Classrooms

Sania Zahra Zaidi, University of Illinois at Chicago, sania@uic.edu
Samuel Arnold, University of Illinois at Chicago, sarnol4@uic.edu
Elizabeth M. Lehman, University of Chicago, emlehman@uchicago.edu
Carla Strickland, University of Chicago, castrickland@uchicago.edu

Abstract: Teachers experience challenges in effectively using formative assessment practices in their classrooms. In the US, only 28% of elementary teachers report using formative assessment. This study highlights the need to design resources to meet teacher needs and support teachers in making sense of assessment information to inform three-dimensional learning and teaching. By surveying and interviewing five elementary school teachers, we identified specific barriers in using assessment information and 10 key needs from resources designed to support their formative assessment practice in science.

Introduction

Formative assessment practices are important in advancing student learning but difficult to implement (Hattie & Timperley, 2007; Heritage, Kim, Vendlinski & Herman, 2009). Formative assessment applies to the function assessments serve in providing evidence that can be used to support and inform instructional adaptations (Black et al., 2003). To engage in the practice of formative assessment, teachers must use evidence from student responses to determine where students "are in their learning, where they need to go and how best to get there" (Assessment Reform Group, 2002; pp. 1-2). Historically, science education has been inadequate in elementary classrooms (Trygstad, Smith, Banilower, & Nelson, 2013). Elementary schools tend to restrict science instructional time in favor of English language arts (ELA) and math. Given lack of emphasis on science instruction, elementary grade teachers' experience with implementing instruction and formative assessment that is in line with the Next Generation Science Standards (NGSS) (NGSS Lead States, 2013) is limited. Only 28% of elementary school teachers reported using formative assessments to monitor student learning in science (Smith, 2020). To better understand how to support teachers' formative assessment practices, this study explores the following research question: *What do elementary teachers need from resources designed to assist them in making sense of student responses on 3D science assessments?*

Theoretical framing

The formative assessment framework proposed by Wiliam and Thompson (2007) conceptualizes five key strategies for successful formative assessment: (1) clarifying and sharing learning intentions and criteria for success; (2) engineering effective classroom discussions and other learning tasks that elicit evidence of student understanding; (3) providing feedback that moves learners forward; (4) activating students as instructional resources for one another; and (5) activating students as the owners of their own learning. We use this framework to categorize what teachers need from resources designed to aid their formative assessment practice.

Methods

This study is part of a larger project that aims to design and use 3D assessment tasks to help build elementary teachers' capacity to instruct and formatively assess in science. These tasks are developed to measure the 3D performance expectations (PEs) of the NGSS. The five teachers who participated in this study are collaborators in the larger project and were invited to provide feedback on rubric design. These teachers have at least 5 years of experience teaching at upper elementary grades (3–5) and used an NGSS-aligned curriculum.

Data and analysis

Our data consisted of (1) a survey about making sense of assessment information by using resources such as rubrics, (2) a focus group on what teachers find important and useful, and the barriers they face in using resources designed to make sense of assessment information, and (3) individual interviews with teachers to gather feedback on an initial rubric design. We examined the data for emerging themes that would help in identifying key resources

 © ISLS

for teachers. We first enacted an open coding approach followed by focus coding to develop themes from our data (Maxwell, 2013), then created conceptual categories in which claims were grounded in data (Emerson, Fretz, & Shaw, 2011).

Findings and discussion

In math and ELA, teachers report frequently using rubrics for two key purposes: (a) to grade student work and (b) monitor student progress over time and on multi-day projects. In science, teachers do not tend to use resources such as rubrics, citing the lower prioritization of science, which led to lower instructional time and fewer assessment opportunities in science. Teachers reported that students have not had adequate opportunities to learn and are wary of using rubrics which will rate a majority of the students on the low end of the scale. In addition, given the lack of in-depth experience with 3D learning targets, it is often not clear to teachers how to make sense of information about students' 3D learning that is contained in resources such as rubrics.

We identified 10 key needs of teachers that should be addressed by resources that accompany assessment tasks. We have categorized them under the key strategies for successful formative assessment practice and highlighted how we will address these needs through resources designed within our larger project.

Of the resources suggested, we gathered feedback from teachers on the initial design of an analytical rubric through individual interviews. The multi-component feature in the rubric provides a fine-grained picture of what students know and can do and allows teachers to focus on a targeted aspect of 3D learning. One major feature in our rubric design is that we have separated evaluating the student response based on criteria from determining proficiency level. By delineating these two, teachers can focus more on whether a student response has met a given criterion and not focus on what it means with respect to proficiency. After evaluating a response on all the criteria, the level of proficiency can be determined by tying the criteria back to the proficiency being measured. Teachers noted that applying the criteria to student responses was straightforward and quick. Teachers reported that they were able to concentrate on whether a criterion was met without making a simultaneous determination about students' proficiency level. This facilitated consistent use of the criteria to make claims about student proficiency. Most teachers said this allowed them to be more objective and consistent in applying the criteria and determining student proficiency. While grading was not the focus of the rubric, all teachers mentioned that it would be straightforward to use this design for grading, if need be.

Significance of the work

This work provides insight into the needs of teachers in resources accompanying an assessment and the use of information from the assessment to make 3D claims about what students know and can do. High-quality assessment resources that address teacher needs can positively impact teachers' use of these resources to make sense of student learning. As a result, teachers will have better insight into what students know and can do, and can make instructional decisions to support 3D learning for all students. Absent accompanying resources that address their needs, teachers are unlikely to use the assessment effectively to guide practice.

What do diagrams reveal? A comparative analysis of impact of different external representations on conceptual understanding

Anveshna Srivastava, Indian Institute of Technology, Bombay, anveshna@iitb.ac.in

Abstract: Learning is both guided by and constrained by the features of the external representation (ER) used for developing conceptual understanding. This work uses a case-study design to study three groups of 5 pre-college biology students (n=15) who used three different ERs- *concept-map*, *symbolic model* and *molecular model*, to perform tasks related to the structure of the DNA (Deoxyribonucleic acid) molecule. A descriptive synthesis analysis of students' diagrams revealed ER-specific changes in their conceptual knowledge.

Introduction

As science education researchers and practitioners, we use different external representations (ERs) to influence the processes and outcomes of learning. These representations carry some aspect of the represented concept and there are some aspects which are specific to the representation itself (Palmer, 1978). This is one of the reasons why different ERs provide different extent of support to the process of learning (Scaife & Rogers, 1996). And, hence, we have literature reporting different ERs, like concept maps (Novak & Gowin, 1984), diagrams (Kindfield, 1994), models (Malacinski & Zell, 1996; Srivastava, 2016), animations (Falvo, 2008) and others, to have wide-ranging impact on students' learning. The present study makes a move in this direction and tries to elicit the influence of specific features of three different ERs-*concept-map*, *symbolic model* & *molecular model*, on learners' ability to both visually and verbally manifest their conceptual understanding about one specific biological concept. Since concepts in Genetics are known to be difficult, especially the ones concerning structural and dynamic aspects of biomolecules (Lewis & Kattmann, 2004; Tang & Teng, 2005), this study focuses on the structure of one of the most complex biomolecules that holds our genetic information- the Deoxyribonucleic acid (DNA).

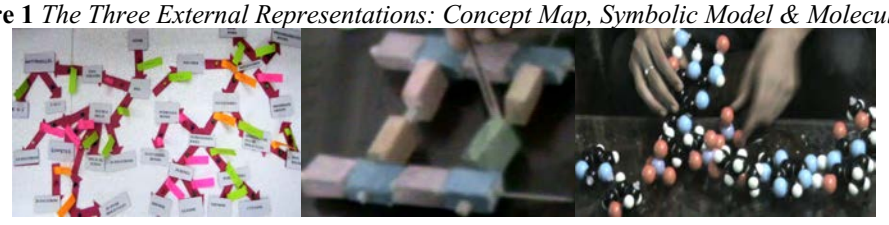
Theoretical Framework

This study relies on the power of student-drawn diagrams as windows into students' extant conceptual understanding and to capture conceptual shifts that an intervention generates. This reliance is theoretically grounded in multiple strands of literature that use student-generated diagrams to measure thought processes & way of reasoning (Schönborn & Anderson, 2009; Schwonke, Berthold and Renkl, 2009). The overall workflow of the study follows the principles of 'descriptive syntheses' proposed by Schönborn & Anderson (2009), where student-generated data (here, pre- and post-intervention diagrams) is studied to reveal and describe students' understanding and the differences that emerge from the groups.

Methods

Fifteen pre-college and college biology students participated in the study and all of them provided their written consent for the same. The study followed a case-study design, where interactive sessions were closely followed through video recordings and notes. Three groups of five students each (3*5) were asked to work with one of the three ERs (see Fig. 1), sandwiched between two diagram-making sessions, where individual students were asked to draw a diagram of the 3-D structure of the DNA molecule.

Figure 1 *The Three External Representations: Concept Map, Symbolic Model & Molecular Model*



The concept map group was asked to construct a concept map (see sample in Fig. 1, left picture) using given type-written concept cards (n=36) related to the DNA structure and to specify linking phrases using pin-up labels. The symbolic model group was asked to dissect the given symbolic model (see Fig. 1, center) made from knitting needles and colored styrofoam blocks, to identify 5 DNA structural elements: nucleotide, nucleoside,

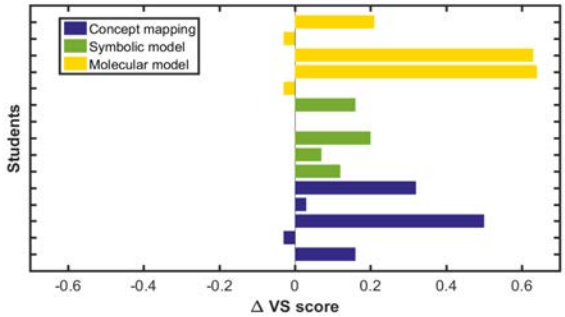
 © ISLS

nitrogenous base, phosphate group and deoxyribose sugar molecule. The molecular model group was asked to dissect the given molecular 3-D model (see Fig. 1, right), made from colored balls, to identify similar DNA structural elements as in the symbolic model dissection task.

Analysis & Findings

The pre- and the post-task diagrams of each student was analyzed to compute a quantitative measure of diagrammatic competence- the verbal-spatial (VS) scores. VS-scores were calculated per diagram by dividing the number of concepts represented verbally (through labels) and spatially (marked using arrows) divided by the total number of concepts represented in the diagram. We illustrate the change in students' VS scores (plotted on X-axis in Fig. 2) in their diagrams for the three groups (Fig. 2). Overall, we found that the interventions led to enhanced verbal-spatial performance in 73% of students in the post-test diagrams. However, the effect of molecular models was more pronounced than concept-maps and symbolic models. We also found several representation-specific errors and corrections which were correspondingly absent or present in the post-task diagram. For instance, all participants of the concept-map group either incorrectly mapped or did not use the 'planar molecule' concept card, likely because they did not realize that DNA base pairs are 'planar' or flat structures. In another instance, all the symbolic modelers got the four nitrogenous bases correct, while all the molecular modelers got it wrong. This can be attributed to the difference in the visual affordances of the models.

Figure 2 *Improvement in Verbal(V)-Spatial(S) Scores for all the three groups*



Low VS scores signify the missing link between students' understanding about specific concepts and their spatial locations, and along with the ER-specific errors, can act as cues to help instructors identify difficult concepts and improve the pedagogical process.

Robots in Science: How middle school science teachers design integrated robotics units for their science classes

Debra Bernstein, TERC, debra_bernstein@terc.edu
Michael Cassidy, TERC, michael_cassidy@terc.edu
Karen Mutch-Jones, TERC, karen_mutch-jones@terc.edu
Jennifer L. Cross, Tufts University, jennifer.cross@tufts.edu

Abstract: Robotics activities can provide students with opportunities to engage in computational thinking (CT) as well as support disciplinary learning goals. The goal of the Robots in Science project is to create, implement, and refine a PD program for middle school science teachers to design and implement robotics and CT-integrated science lessons. Two case studies illustrate how teachers used robotics activities to provide opportunities for science learning.

Introduction and framework

Robots are becoming increasingly familiar in K-12 schools, and with good reason. Robotics activities provide students with opportunities to engage in critical thinking, computational thinking (CT) practices, problem solving, and collaboration (Sullivan & Heffernan, 2016). Integrating robotics design activities into disciplinary courses is an exciting way to increase students' exposure to technology and engineering while supporting disciplinary learning goals and students' use of CT practices within the STEM disciplines. In physical science, integrating robotics activities has been shown to support students' learning of force and motion, energy, and electricity (Souza & Duarte, 2015; Williams et al., 2007).

However, teachers may shy away from using robotics in their disciplinary classes if they do not feel confident in using the technology or prepared to make it 'relevant' to their discipline (Khanlari, 2016). There is little research on how best to design integrated interventions and to facilitate this process with teachers. In response, the Robots in Science (RiS) project provides professional development (PD) for middle school teachers to gain confidence with robotic technology while exploring physical science disciplinary connections and creating new instructional materials. By supporting middle school teachers to design integrated robotics lessons, our project facilitates the creation of integrated instruction that enables students to build, program, and use robotic models to explore, describe, and investigate scientific phenomena. Also, working with these models provide opportunities for students to engage in CT practices (Dong et al., 2019). Our work addresses the following research question: *How do teachers design integrated robotics units to enhance students' science learning?*

Methods

Data presented in this poster is drawn from the second cohort of educators in a multi-year project. The goal of the RiS project is to create, implement, and refine a PD program for middle school science teachers to design and implement robotics and CT-integrated science lessons. Thus far, the project has served 16 teachers and approximately 370 students in two states. We present preliminary analysis in the form of two case studies (Yin, 2018) from this larger data set. These two cases are intended to be comparative – in one case, the teacher replaced a previous lesson focusing on the same content but saw an opportunity for lesson enhancement based upon the affordances of the robotics kit; in the second case, two teachers worked together to develop a new lesson based on a newer state standard. Each case highlights the potential of a robotics integration approach.

Due to the COVID-19 pandemic, Year 2 PD was presented virtually. The goals of the 3-day PD were: (1) Help teachers get comfortable with the Hummingbird robotics kit and programming in MakeCode, (2) Learn about CT, and how engaging in CT practices could enhance students' understanding/experience with science concepts and the robotics kit, and (3) Discuss how robots could support students' engagement in modeling and experimentation during science class. Following the 3-day PD session, teachers also participated in approximately 3-4 hours of school-year PD focusing on sensor use and approaches for designing integrated units.

Data sources include teachers' implementation logs and follow-up interviews, artifacts (teacher unit plans, student work from integrated lessons), and classroom video. For this poster we analyzed two teacher-created lessons, focusing on the design and intended enactment of each lesson. The first two authors wrote memos about each lesson (Saldana, 2011) and discussed them with the research team. Memos were guided by questions drawn from Roehrig et al.'s (2021) analysis of integrated curriculum materials: what is the performance expectation/central goal?; what are the main concepts to learn in each lesson?; was the science content relevant and necessary for making robotics design decisions?; did the robotics contextualize science learning or vice versa?

 © ISLS

Findings and discussion

Case 1: Using robots to study energy transfer

A technology integration specialist, collaborating with two 6th grade science teachers, designed an integrated robotics and CT activity to help students understand the relationship between potential and kinetic energy. This integrated unit replaced a previous lesson where students built a rollercoaster out of foam tubing and observed marbles moving through the rollercoaster but were not able to collect speed data. In contrast, the integrated robotics unit enabled students to build and program cars outfitted with distance sensors, and use the cars to engage in pull/release experiments which allowed them to calculate and graph speed and displacement, and examine their data to contemplate the question, "how does the distance you pulled the car back affect the kinetic energy?"

Case 2: Using robots to study waves

Two 6th grade science teachers developed a unit to help students investigate how light waves travel through materials. The teachers first presented relevant vocabulary (transmission, reflection, refraction, absorption) and CT definitions. Then students collected data about whether LED light could be detected through different materials (e.g., sponges, felt, water, clear blocks), by programming a rotation motor to spin when light was detected via the light sensor. A 'trial sheet' was created by the teachers for students to use while collecting data (see Figure 1). The unit supported some student engagement with CT as well as investigation of absorption and transmission of light waves.

Figure 1

Student data collection sheet from the waves unit

TRIAL SHEET

Now that you've tested the light to see if the sensor could pick it up, you need to determine what the material did to the light wave. In the following chart, use the code you made to see if the light on the hummingbird **refracts**, **transmits**, **reflects** or **absorbs** through the various materials. In the third column explain **WHY** you chose what you did.

Material options: Mirror, Water (in glass jar), colored felt (write the color you used), plastic blocks, foil, sponge, 2 materials from sensor check

Material	Did the light sensor sense the light? Yes or no	Transmission? Reflection? Refraction? Absorption?	WHY

In case, 1 the robotics activities provided opportunities for students to investigate the transfer of energy. In case 2, robotics activities provided an opportunity for students to investigate and describe a property of light waves. Future research will explore how PD supports can help teachers further integrate CT into their lessons, specifically to support students' exploration of science concepts. For example, teachers in Case 2 could be supported to develop an experimental approach that allows students to systematically vary where they place the light, sensor, and materials while collecting data, detect patterns in their data, and identify properties of materials that transmit, absorb, reflect, and refract light.

Examining the development of perspective-taking through social annotations in collaborative text study

Shai Goldfarb Cohen, Ben-Gurion University, goldfars@post.bgu.ac.il

Abstract: Reading literature has been found to be positively related to perspective-taking. We studied perspective-taking through the use of social annotations of texts and asked how perspective-taking develops during collaborative text study, and which elements of social annotation support perspective-taking development? Specifically, we studied an undergraduate education philosophy course in order to gain insights about perspective-taking in online spaces, using a social annotation tool.

Literacy and perspective-taking

Studies have shown that reading literature is positively related to perspective-taking (PT) (Ivey & Johnston, 2013) and that reading literary fiction, more specifically, led to higher levels of perspective-taking as opposed to other types of genres (Kidd & Castano, 2013). A literary text also provides resources for reading a text through new voices. By doing so, the person who reads engages in perspective-taking as she reads and uses their social imagination of the other as part of a conversation with one's "self" (Lysaker et al., 2011). Thus, reading literature leads to increased perspective-taking among students who constructed meaning in their lives (Ivey & Johnston, 2013). A strong engagement with the text can be viewed as going beyond just "putting yourself in another person's shoes" but rather "be" that other person.

One of the ways to teach students how to read through the perspective of the character is through *dialogic pedagogy*. In such settings, the teacher demonstrates authentic responses to text such as empathetic response and perspective-taking. This is then an invitation for the students to make similar connections in their reading process. Through this kind of modeling, the teacher is actively presenting his relationship to the text as seen in facial expression or intonation and thus demonstrating how one reads. This process includes creating a connection between the text and personal life experiences, expressing different feelings toward the characters, and taking their perspectives while reading (Lysaker et al., 2011).

The benefits of reading may extend to other abilities such as understanding and sympathizing with others' emotions or motivations. Kozak & Recchia (2019) refer to this set of abilities as *social understanding* and propose different classroom activities to promote them. For example, asking students to retell the story, or parts of a story, from the perspective of a different character, writing a letter to one of the characters, writing reading responses, or turning a novel into a play requiring the students to interpret the perspectives of the characters in this process.

In this study, we chose to use social annotations as a prompt to do close-reading of the text as students ask questions, make comments, or create a connection between the text and additional sources. Our goal was to use social digital annotation to facilitate interaction with the text both individually and collaboratively.

Social digital annotations

Annotations are usually informal and unstructured comments written in the margins of a text as one reads the text. They may include a question regarding the text, a correction, explanation, interpretation, and more (Johnsrud et al., 2017; Nielsen, 1984). A *comment* is one kind of text that is reactive, short, and asynchronous (Kalir & Garcia, 2021). Annotations can also be used to present an agreement or disagreement with the author, mark important information, or answer a question (Marshall, 1998). In addition, annotations can include drawings or links to additional texts (Marshall, 1997). In this regard, annotations can be viewed as the reader's way of talking to or with the text. A *text* according to Kalir & Garcia (2021), has an author and is defined by its content as it communicates a message through different modes or styles.

Kalir & Garcia (2021) demonstrate how previous interdisciplinary research has shown that annotation, whether written by hand or in a digital format, assists learners in thinking, reading, and writing, and can also motivate their learning, both in the K-12 and higher education classrooms. Therefore, such online annotation platforms increase student learning. However, annotation can help the learning process when it is supported by other activities. Today, annotations can be digital as part of online annotation systems which also enable users to share their annotations, making this process collaborative.

By working collaboratively in online networked environments, students are required to generate and share their own understandings. Such participation creates a dynamic knowledge-building process through social interaction, an important characteristic of computer-supported collaborative learning (Järvelä et al., 2004). Textual

 © ISLS

computer-mediated communication can also establish productive argumentation as learners reread and revise their comments, both before and after they post them, allowing them to reflect on their work (Asterhan & Schwarz, 2016). Such reflectiveness can also promote critical thinking and perspective-taking (Tay et al., 2018).

As a computer-mediated communication tool, the option of social annotations allows learners to collectively read and annotate different material online. Social digital annotations in educational assignments have been referred to by scholars as a type of learning arrangement called *anchored discussion*. This occurs when students "talk" with one another about a shared text through digital annotation. Other studies have shown that annotations enable a rich conversation requiring students to actively read the text and use the social annotations to elaborate their thoughts as well as learn from other perspectives through additional interpretations of the text (Kalir & Garcia, 2021). *Higher-level discussions* are characterized by mutual negotiations including theory-based postings and postings of new points or questions. Therefore, as students engage in high-level discussions, they are likely to show high levels of PT and this study aims to provide an online space that supports such learning outcomes (Järvelä & Häkkinen, 2002).

Methods

We used *Perusall*, a platform designed to allow students to share annotations and sometimes respond to each other's comments while creating shared understanding. This social annotation tool allowed students to reflect upon their own reading process as well as their peers', making this a collaborative knowledge-creation experience. By analyzing changes in PT levels that occurred as a result of collaborative discussions in the form of social annotations, we used qualitative methods to study PT on an individual and collective level. Although this study is still underway, it contributes to the literature on PT in humanities classes and teaches us how social annotations can be used to foster PT.

Florida State University

Abstract: This article describes the development of a chatbot designed to simulate students in a 3D virtual environment for the purpose of pre-service teacher training. Using a generative pre-trained transformer-based deep neural network model, researchers created an artificially intelligent chatbot using language resource data from authentic classroom dialogues. Results indicate that the chatbot needs to be fine-tuned with additional programming. This program is intended to be used in future research on teacher-training in virtual simulations.

Introduction

Virtual 3D environments provide a convenient and immersive space for pre-service teacher training to take place. In these virtual spaces pre-service teachers can practice classroom discourse and classroom management without the pragmatic difficulties of undergoing such training in actual classroom environments with real students (Dieker et al., 2014). Presently, most 3D virtual teacher-training environments rely heavily on puppeteered student avatars to avoid the complexity of natural language processing associated with machine generated discourse (e.g., Cohen et al., 2020). Puppeteered avatars detract from the authenticity of the dialogue and can also be resource intensive because an individual must be employed to play the role of the students. Therefore, this study saw the development of a chatbot which can be used to program student virtual agents to simulate authentic science, technology, engineering, and mathematics (STEM) classroom environments for training purposes.

The contributions of the study are twofold. Firstly, the development of a custom designed chatbot by fine-tuning a pre-trained deep neural network model on classroom conversation data. And secondly, the generation of real-life dialogic responses for domain specific queries using a the chatbot.

Method

The foundation of the chatbot is a generative pre-trained (GPT-2) transformer-based deep neural network model which was developed by OpenAI (Radford et al., 2019). Pre-training of GPT-2 model was done on a large volume of web data from Reddit making it capable of generative quality text (Fig. 1). For the purpose of the study, the "medium" 355M parameter model (1.5 GB on disk) of GPT-2 was selected, to ensure a good balance between scalability for fine-tuning with large amounts of data and creativity during text generation. The model takes a sequence of tokens as an input and choses a sequence of output tokens, based on probabilities determined by the inner neural network.

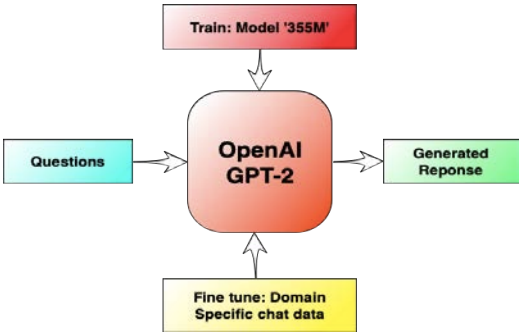
In order for the chatbot to produce dialogue that simulates the diversity and richness of teacher-student interactions in STEM classrooms, data were collected from video recordings of real lessons and manually transcribed. The videos were obtained from online open-access sources such as (https://rme.org.uk/) and (https://ambitiousscienceteaching.org/). Thus far, about 13.5 hours of classroom dialogue have been transcribed, and 9.5 hours have been provided to the chatbot for training. The remaining 4 hours of data were withheld for testing the chatbot.

After the transcription of the dialogue data, it was annotated with tags by two researchers, which guides the chatbot for a more logical and consistent output during response generation. The tags were formatted in a specific order "<Person>_<Domain>" to maintain singularity as well as preserve scalability for future integration with newer datasets. Once the data format was ready, the chatbot parameters were set for fine-tuning the model. For our study the model was fine-tuned for 500 steps, saving the checkpoints every 100 steps. We also set the temperature parameter to 0.6 to keep a balance between the coherence and randomness of the generated responses. The chatbot is deployed in virtual machine in Google Cloud with 128 GB memory and Nvidia Tesla V100 GPU.

Preliminary testing of the chatbot was done by providing it with authentic queries from the transcribed data withheld for testing purposes. Chatbot responses were assessed subjectively using a linguistics-based metric.

Figure 1
Workflow of the designed chatbot

 © ISLS



Results

The chatbot was inconsistent in its ability to produce appropriate responses. The following example demonstrates the chatbot could return relevant, and appropriately concise answers with the testing data.

> *Query: Well that's a very good question. Obviously, how many points do I really need to make a line?*
> *Chatbot answer: Two.*

However, the same question met with an inconsistent answer when it was paraphrased. Asking "*What number of points is needed to create a line?*", the chatbot answered *"Three."*

Another noted difficulty in the preliminary analysis is that a lack contextual information forced chatbot responses to be interpreted in isolation. For instance, in the following example the data were taken from a classroom activity in which the teacher was demonstrating the properties of pressure by blowing up a balloon.

> *Query: Ok, so what happened? What are your observations?*
> *Actual student response: You applied pressure and it got bigger.*
> *Chatbot answer: Um, that it's hard.*

Although pragmatically and grammatically, the chatbot answer was not necessarily infelicitous, and indeed might be observed from a student in an actual classroom, the lack of contextual information regarding the balloon makes the chatbot a difficult partner in an ongoing dialogue.

Discussion and conclusion

Programming a chatbot to accurately portray the verbal behavior of student avatars is an iterative process central to the creation of a classroom simulation which does not rely on puppeteered avatars. One likely reason for the chatbot's answers being inconsistent despite queries aimed at producing identical answers is that the temperature parameter, here set to 0.6, may be too low for the chatbot to interpret queries that stray too far from the original text in the data. Setting this parameter very low will produce only responses found in the dataset and setting it very high may produce incoherent responses. Furthermore, programming the chatbot to incorporate ongoing dialogue into its resources might allow it to show more consistency in its responses by following dialogic threads.

The authors intend to employ the chatbot with virtual agents using *Open Simulator*, which will be used in studies addressing the efficacy of using virtual simulations for pre-service teacher training.

What *Songo* board game can teach us about culture and literacies

Rebecca Y. Bayeck, Ph.D, Utah State University, rebeccabayeck@usu.edu

Abstract: Contending that gameplay is a constellation of literacy practices could imply that video/digital games are the only spaces where players engage in literacy practices. Literacies in game environments have mainly been evidenced by video/digital game research. Literature on board game literacies is still scarce. This paper investigates literacy practices in the gameplay of the board game *Songo* and demonstrates that culture shapes literacies.

Introduction

The New London Group multiliteracies theory has reframed and advanced our understanding of literacy in various contexts. Multiliteracies theory explains that there are multiple ways of communicating and brings to light cultural and linguistic (Perry, 2012; Sang, 2017). Game research has used multiliteracies as a theory and framework to investigate, explain, and demonstrate the literacy practices players engage in during gameplay (Ellison & Solomon, 2018). Yet, this research leaves out board games, and specifically African board games such as *Songo*. This study engages the literature from a multiliteracies perspective to start uncovering literacy practices in *Songo* (Figure 1) and shows the cultural situatedness of these literacies.

Literature shows board games as learning spaces. Board games enhance deep learning (Azizan et al., 2018) and facilitate learning of various science, technology, engineering, and mathematics (STEM) content (Bayeck, 2020). Computational thinking (Berland & Duncan, 2016); collaboration, scaffolding, and mathematical thinking are other practices board gameplayers engage in (Tsarava, Moeller & Ninaus, 2018). *Songo,* a board game played in Cameroon. It is a competitive strategic game with two rows played by two people, with 70 /seeds^2, equally divided between players and consecutively drop in clockwise direction in the 14holes that make up the game (Bayeck, 2019).

Figure 1. *Songo* board game

Theoretical perspectives and Methods

Multiliteracies serves as a framework to examine literacies in *Songo* board gameplay. Using video recordings of gameplay, this microethnography employs interaction analysis as discussed by Erickson (2006) to investigate the different modes of communication employed by players during gameplay. Therefore, this analysis will include language and other forms of expression (e.g., body movements, or gestures) occurring during gameplay in Yaoundé, Cameroon. Participants were adult players.

Study Context

On the cultural spectrum, Cameroon identifies more with collectivist cultures (Legare &Nielsen, 2015). Cameroon has two official languages, French and English, as a result of the colonial past. However, these official languages interact with local languages. Different languages such as pidgin-English or Camerounism, peculiar to Cameroon have emerged from this interaction (Nkwain, 2014). Camerounism draws on local languages and distance itself from standard French (Biloa, 2012). The communal approach to life and ways of doing facilitates interactions among the multiple ethnic groups that make up the country (Bayeck, 2019). The city of Yaoundé, where the study was conducted, is multiethnic, located in the French speaking part of the country, and has the Ewondo ethnic group as first dwellers. Interestingly, the literacy practices discussed below echo the complex cultural make up of Yaoundé, and Cameroon

Findings

Findings from this study indicate that meaning making is shaped and informed by the cultural context. The following paragraphs highlight the interplay of language use and collaboration with the cultural context.

Language Use. The language used during *Songo* gameplay in Yaoundé, Cameroon was informed by the cultural context. As shown in the excerpt below, in a game opposing Caulet and Abi, language was a combination of local and former colonizers' language, that is, French.

Excerpt 1.

 © ISLS

Caulet : tu auras les pourrissons (plays the second hole on his right)
[You will have pourrissons]
Abi : qui pourrissons ?
[*Who pourrissons?]*
Caulet: tu auras les pourrissons (plays the third hole on his right)
[you will have the pourrissons]

The exchange between both players exemplifies the use of a language that is peculiar to Cameroon. Words like "pourrissons" is the combination of the French verb "pourrir *[to rot*] and the suffix "ssons" which is a form for French verbs conjugated in the first plural person of the present tense. "Pourrissons" is used here as a noun to mean seeds with no strategic importance because they cannot lead to victory. Similarly, "bricole and bricoler *[tinkering*]" is a camerounism that means not doing well or succeeding in the activity one is engaged in.

Culturally-informed collaboration: The cultural practices explain audience participation and collaboration with players during the game. The excerpt below illustrates interaction between players and the audience in a game opposing Nti to Ngibi. Nti, in difficulty, benefits from his collaboration with Pierro an audience member.

Excerpt 3
Pierro: [to Nti] ta case a combien?
[How many seeds do you have in your hole]
Nti: (counts seeds in the third hole on his right)
Pierro: c'est combien?
[How many seeds?]
Ngibi: [to Nti] il faut qu'on te montre
[They need to show you]
Pierro: 23 (gazing the board game)
[23 seeds]
Nti: (plays the fourth hole on his right)
Pierro : [to Nti] eh, pourquoi tu as mis 24 ? Heureusement que lui aussi il est comme ça
[Eh, why did you make it 24? Fortunately, he is not that good]
Nti: [to Pierro] j'ai normalement 16 (showing seeds in his hands)
[I currently have 16 seeds]
Pierro: non va comme ça Nti (points to a hole on the right of Nti)
[No play like this Nti]

Conclusion

Findings in this study show that literacy practices in board gameplay are culturally situated. The field of New Literacies Studies has contributed to our understanding of the cultural situatedness of literacy. However, it only focuses on communities' peculiar use of reading and writing skills (Mills, 2010). This study contributes to research on board games by focusing on literacies. It highlights the influence of culture on literacy practices in games. Game researchers are yet to extensively explored the role of culture in shaping literacies in gameplay. These findings will inform game studies and advance our understanding of meaning making in various cultural contexts.

Design of an Argumentation-based Learning Activity: Connecting Veterinary Students to Real-world Problems

Yingying Zhao, Sean Kao, Jonan Phillip Donaldson, Kristin P. Chaney
fhlzhaoyy@tamu.edu, sean.kao@tamu.edu, jonandonaldson@tamu.edu, kchaney@cvm.tamu.edu
Texas A&M University

Abstract: The study investigated the design of an argumentation-based activity that focused on animal welfare and advocacy in a first-year veterinary class. The objective was to understand students' learning experience and to provide evidence-based insights for future improvement. The reflections of eighty students were analyzed using semantic network analysis. We found that allowing for topic selection, providing background resources, and scaffolded evaluation of biases and evidence may be important design considerations.

Introduction

Argumentation skills are of great significance for students and scientists as it is commonly used in daily thinking in science learning and research. The use of argumentation has been associated with positive learning outcomes such as critical thinking, logical reasoning, and problem-solving skills (e.g., Boğar, 2019). However, it is challenging to engage students in argumentation (Noroozi et al., 2020). Learning occurs through interacting with artifacts. More specifically, the construction of knowledge occurs when learners construct mental models by generating, experimenting, and modifying artifacts - particularly when such artifacts have real-world impact (Papert & Harel, 1991). Thus in the course design investigated in this study, students were introduced to authentic situations and construction of authentic artifacts for the purpose of observation and constructing valid argumentation. The objective of this study was to understand students' learning experience in a learning activity combining argumentation and real-world work to provide evidence-based insights for future improvement.

Method

This study used semantic network analysis methods. Data for this study were students' reflections about their learning experience in an argumentation-based learning activity. Students from a first-year veterinary class were asked to compose a letter to their legislator advocating for or against the issue of equine slaughter. A 30-minute online teaching module was provided for students to provide background information that could support formulation of an advocacy position. After writing the letter to the legislator, students were then asked to reflect on the benefits, struggles, activity design, and suggestions. For the eighty students completing the reflection activity, MAXQDA Analytics Pro software was used to code the data. A codebook was developed, with 42 codes and 548 code segments. We then calculated the Pearson's r among all codes and imported the correlation matrices into the UCINET software to create semantic network maps using Girvan-Newman cluster analysis (Girvan & Newman, 2002).

Findings

A semantic network analysis map is presented in figure 1. We identified 3 clusters from codes at the $p < .05$ level at the robust confidence of Q = 0.43. Some students struggled with *information selection* to build a sturdy logical foundation of their argument (black cluster in figure 1). The data shows that there were students struggling with *understanding laws* and a *lack of background knowledge* in regard to the topic chosen by the instructor. The primary suggestions center around the *topic* and *options for participation* which correlated with the strengths of the *overall evaluation* and *research/reiterate* aspects of the assignment. Several students expressed that they benefited from the practice of researching, organizing, and writing the arguments based on facts and data using real-world problems they may or may not be familiar with. The data suggested that instructors can consider providing multiple topics for students to choose the one they are most interested in. Also, some students were struggling with the *word/paragraph limit* when writing the letter to their legislator. *Expanding the page limit* can be an option for those students who feel comfortable communicating with more words.

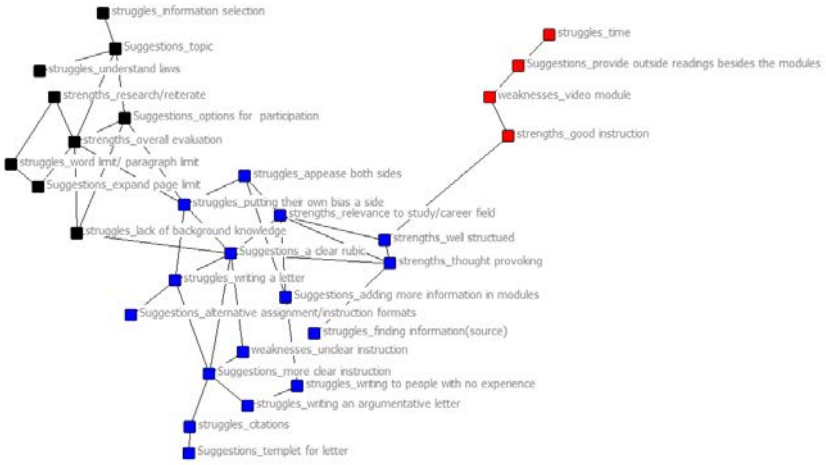
A strength of *good instruction* of the assignment was identified (red cluster in figure 1), which interconnected with design strength of *well structured*. However, a design weakness in the video module has surfaced due to a lack of supplement instructional resources. Some students found rewinding instructional videos back and forth to be troublesome. It is suggested that instructors *provide outside reading beside the module* to help students gain more contextual knowledge. However, some students found the given materials already hard to cope with due to *time* issues.

 © ISLS

Some students found it difficult to *put their own bias aside* (blue cluster in figure 1), which was correlated with another struggle about the desire to *appease both sides*. They also struggled with *writing to people with no experience*. One design suggestion to help with these struggles is to provide more information in the video module so they could make a more informed decision and explain it well. The suggestion of making the instruction more clear was linked to the weakness of *unclear instruction* and multiple struggles including *writing a letter*, *citations*, and *writing an argumentative letter*. Considering that students may not be familiar with the letter format, we need to further clarify expectations and requirements in the instruction. For instance, a reference guideline and format explanations need to be added in the instruction in the future class.

Figure 1

Semantic network map of student reflections on the activity



Conclusion

This study provided evidence that connects the literature about argumentation (Boğar, 2019) and the literature of real-world impact learning (Papert & Harel, 1991). Our findings suggest that development of argumentation skills may be facilitated through construction of authentic argumentation artifacts such as letters to legislators in this study. Through analysis of the relationships between student struggles, student suggestions, and design strengths we were able to develop some tentative design principles to enhance student success in this activity. First, limiting the selection of topic may be less powerful than providing multiple options. Second, unless students are familiar with the topic(s) at hand, it may be prudent to provide a robust set of background resources for them to leverage in developing their arguments. Finally, constructionist argumentation activities may require practice and scaffolding, particularly in helping students identify and understand their own biases in relation to the evidence in which they ground their arguments.

Analyzing Teacher Learning in a Research Practice Partnership

Enisa Selimbegovic Akgul, Alison Castro Superfine
eakgul2@uic.edu, amcastro@uic.edu
University of Illinois at Chicago - Learning Sciences Research Institute

Abstract: Teachers are increasingly participating in RPPs with the goal of improving their schools and districts. This context provides teachers with unique learning opportunities as they directly take part in school improvement work, yet we know little about what teachers learn from their involvement in RPPs. This study explores teacher learning over the course of the first year of a multiyear RPP with a team of researchers from a local university.

Introduction

Research Practice Partnerships (RPPs) are long-term collaborations between practitioners and researchers in which the collective engages in school improvement work by investigating persistent problems of practice and solutions (Coburn & Penuel, 2016). RPPs are increasingly utilized for school improvement purposes because they address local problems of practice and enable greater use of research in decision making (Coburn & Penuel, 2016). Despite a growing body of literature and rise in popularity of RPPs, there is a need for more detailed research on the processes and outcomes of these partnerships (Klar et al., 2018). What teachers learn from participating in RPPs is one such outcome that requires more research. Previous studies have focused on the learning of district leaders (e.g., Rigby et al, 2018), but few previous studies have focused on teacher learning within RPPs. Since RPPs offer teachers the opportunity to engage in district-wide instructional improvement work, this raises the question of teacher learning in such a context. In this study, we investigate what teachers learn from these partnerships by examining the following research question: How does teacher's reasoning about improvement work shift over time as they engage in RPP work?

Conceptual Framework

This study is grounded in a situated theory of learning which identifies learning as shifts in participation within a community of practice (Lave & Wenger, 1991). A community of practice is a group that collectively engages in a shared repertoire of routines as they work towards a common goal (Wenger, 1998). In this study, we explore how teachers' participation patterns shift over time as they engage in a routine of school improvement meetings. Through these regular meetings, a community of practice is formed between the participants.

We define the teachers' participation in this community of practice as their contributions to the collective discussions. More specifically, we conceptualize these contributions as episodes of improvement work reasoning (EIWRs), an adaptation of Horn's (2007) episodes of pedagogical reasoning (EPRs). Horn (2007) defined EPRs as detailed instances of teacher reasoning, focused on issues or questions about teaching practice. We define EIWRs as episodes of elaborate reasoning about the purposes, obstacles, and methods of school improvement work. We make this distinction as teachers are participating in discussions about district-wide instructional improvement and not teaching practice.

Methodology

This study draws on a case study approach (Yin, 2014) and employs an embedded multiple-case study design. The data for this study comes from a larger multiyear RPP project in which a team of researchers from a large Midwestern university collaborates with several local K-8 school districts with the aim of investigating issues and solutions surrounding math education within each district. A subgroup of members from each of these teams meets regularly to plan the work of the respective whole RPP team. This study centers on these subgroup meetings because they prompt teachers to engage in rich discussions as they engage in meaning making (Horn, 2007) surrounding instructional improvement work. The four teachers on the Bay School District subgroup are the focus of this study. The district's subgroup also includes a district administrator, one university researcher, and one university-affiliated math coach, all of whom also engage in the subgroup's discussions.

Data Sources and Analysis

This study utilizes four data sources: (a) 26 hours of video recordings of 15 subgroup meetings, (b) transcripts of subgroup meetings, (c) transcripts of initial interviews, (d) transcripts of end-of-year interviews. The unit of analysis for this study is individual EIWRs shared by teachers during subgroup meetings and interviews. First, EIWRs were identified in each data source. Then, EIWRs were coded by topical content so that similar themes

 © ISLS

can be compared over time (Horn, 2007). Several categories of EIWRs emerged, such as problem identification, norms, roles, data use, and solution formulation, amongst others. Due to space limitations, only a small subset of EIWRs concerning problem identification is presented here.

Findings

Preliminary analysis indicates teachers' reasoning about relevant problems of practice shifted over time (see Table 1). In initial meetings, as the subgroup laid the foundation for improvement work, they discussed problems associated with the district's math program. During this phase, each of the teachers pointed to a different issue they thought contributed to unsatisfactory outcomes of the math program. In the first meeting, Lenny brought up the lack of cross-grade level collaboration opportunities for teachers. During the third meeting, Nicole spoke about low test scores, while Frankie highlighted the lack of math interventionists and coaches. During subsequent meetings, as they continued to engage in discussion surrounding problem identification, all three teachers zeroed in on the fact that the district's teachers lacked a uniform understanding of high-quality math tasks. Thus, as the teachers engaged in RPP work, their reasoning about issues associated with the quality of their math program shifted, becoming more unified and clearly defined. In the poster, we will show the trajectory of participation for each teacher during Year 1.

Table 1

Teacher's reasoning about issues associated with the quality of the district's math program

Teacher	Early EIWR	Later EIWR
Lenny	**Subgroup meeting #1:** "… I know that we've talked about before was talking across grade level teams, but then also, fifth grade being able to spend time [with] sixth grade and vice versa, some of those types of things."	**Subgroup meeting #4:** I think that that was the question that was asked in the interview is, what do you think a high-quality task is... Some people [are] like I don't know if I'm right or not... So then, having an opportunity to look at what other people are thinking to refine as a district what we think."
Nicole	**Subgroup meeting #3:** "…we just feel that there is a problem and we need to address that problem… the staff knows that there's some sort of… we are seeing them [MAP scores] flat line."	**Subgroup meeting #6:** "…teachers have to have a reason why they're picking, choosing something [a task]. Not just because they feel like it…. There has to be a reason."
Frankie	**Subgroup meeting #3:** "Like what's going on? Why is this not progressing, not changing?… reading has tons of interventionists and coaches... Well, we've brought up a lot of times, well what about math?"	**Subgroup meeting #7:** "…if we still have team members… that are still questioning high quality. Like what does it that look like, I think we definitely need to back up and like assess what we want to continue with because we want to make sure everyone's on the same page."

Data for one of the four teachers is omitted because she did not participate in initial meetings.

Tensions in Supporting Equity During Sense-Making Activities in Mathematics

Wan-Yue Zhan, Nicole L. Louie
wanyueh.chan@wisc.edu, nlouie@wisc.edu
University of Wisconsin-Madison

Abstract: This paper demonstrates how pedagogical practices that are deemed to be equitable may lead to both inclusion and exclusion effects. We present an illustrative vignette of a mathematics lesson. The teacher demonstrated practices that are consistent with what has been suggested in discourse around epistemic agency as equity. However, the interaction manifested the assumptions of what count as sense-making in mathematics that have historically functioned to differentiate kinds of students.

Problems and objectives

There is widespread agreement that equity issues should be centered in recent educational reform efforts. Despite many discussions around "equitable sensemaking" and "equitable practices," however, scholarships around equity in mathematics education have scrutinized that pedagogical practices that claim to be equitable may instead reinforce systemic exclusion of certain kinds of students. For example, pedagogical practices that are designed to enable student intellectual agency may operate in ways that perpetuate the assumption of ability hierarchies in mathematics. Such exclusion is tied to larger discourse that is historically and systemically shaped—what Louie (2017) has termed "the culture of exclusion in mathematics education." This calls into question what counts as "equitable" in mathematics learning spaces.

In this paper, we examine how pedagogical practices that are deemed to be advancing equity may inadvertently lead to both inclusion and exclusion effects. The following question guides this study: What are the tensions of supporting equity during sense-making activities in the classroom? In particular, we demonstrate how practices that are claimed to be supporting epistemic agency can function in ways that reinscribe historic and systemic assumptions of what counts as mathematical thinking and ideal students.

Theoretical Framework

We adopt the theoretical construct "inscription practice" to elucidate how inclusion and exclusion can paradoxically occur during mathematics learning. *Inscription* refers to the process that a set of taken-for-granted values and orders are constantly enacted and reinforced, and the boundaries that define these values and orders are historically resembled (Popkewitz, 2004). Inscription is built upon a historicizing approach that juxtapose past and present (Foucault, 1977) to examine the set of assumptions that fabricate what is desired and make up particular kinds of people as ideal citizens. Mathematics classrooms are fundamental sites where inscription practices operate due to the assumptions of what counts as legitimate knowledge and sense-making in mathematics (Yolcu & Popkewitz, 2018). While valuing intellectual resources that students bring into classrooms and treating students as agents who are capable of making sense of mathematics is important, what remains at issue is the set of taken-for-granted assumptions that is constantly enacted and paradoxically denied students who act outside of the boundaries of these assumptions.

Methods

The study was conducted at a public elementary school located in a town in the United States Midwest. Slightly more than half of students were identified as economically disadvantaged, 40% as English learners, and 15% as students with disabilities. Fieldnotes were collected in Ms. Zoe's fourth-grade classroom (9- and 10- year-olds). A total of 17 weeks of data was collected

To explore how inscription practices occur, we adopt a historically-comparative approach (Stinson, 2017) to analyze the sense-making activities taking places in mathematics lessons. Classroom vignettes were analyzed with two different lenses. First, we identified the vignettes in which Ms. Zoe demonstrated substantive support of student epistemic agency. Second, we investigated the historically-resembled assumptions about mathematics abilities and learning manifested in these vignettes through building on the existing historicizing studies in mathematics education.

Findings and Discussion

 © ISLS

This section presents an illustrative vignette to instantiate how inscription practices occurred. The vignette records interaction between Ms. Zoe and four students: Elliot and Ricky (African American boys), Janet (an African American girl), and Taevy (a Cambodian girl).

Valuing student epistemic resources and sharing epistemic agency

Ms. Zoe set up a context for the students to make sense of skip-counting. She showed the students a box of 24 crayons. She guided the students starting with counting one row of crayons in the box (8 crayons) and proceeded to counting two rows (8x2 crayons). Then, she asked the group how they counted all of the crayons in the box. The students came up with different strategies of skip-counting. Elliot and Ricky counted it by 8, and Taevy counted it by 3. Ms. Zoe affirmed each of their ideas and ensured that their ideas were made public. She repeated, clarified the ideas, and wrote them down on her white board (e.g., She asked Janet, "So you kind of use the same method like Elliot, right? Did you count 17, 18, 19, … after 16?"). Different skip-counting strategies were affirmed. Then, Ms. Zoe introduced number-lines as a strategy to make sense of skip-counting. She handed Elliot her marker, asked him to draw his strategy of counting by 8. Then, Ms. Zoe drew Janet' strategy, and asked Elliot to draw Taevy's strategy of counting by 3. Before the end of the lesson, Ms. Zoe asked the students to draw their own strategies in their notebooks. Ms. Zoe positioned her students as sense-makers rather than knowledge absorbers; she not only invited students' ideas but also allowed them to keep the ownership of their ideas. The ways in which Ms. Zoe supported her students are consistent with scholarship that suggests fostering students' epistemic agency as essential in supporting equitable sense-making because it disrupts the conventional assumption that students' ideas are inferior.

Inscribing what counts as mathematics abilities

Elliot was the only one given the authority to hold the marker and show his idea. This shift of epistemic authority from Ms. Zoe to Elliot explicitly positioned him as intellectually capable. The history of the class suggests ongoing appreciation of Elliot's mathematical strengths. Elliot always finished his tasks accurately and faster than other students, and Ms. Zoe would push him to work on extra problems that were more challenging.

Elliot fit in with conventional conceptions of a good sense-maker in school mathematics. He not only solved problems quickly and accurately but was also good at asserting his ideas in public. He was always able to follow the problem contexts that Ms. Zoe set up for students to learn mathematical strategies, just like what occurred in this vignette. The other students in this group, however, did not quite fit in with such fabrication of good sense-makers. Both Janet and Taevy worked at a more deliberate pace, and Ricky often stopped working and got frustrated when encountering a difficult problem.

The values and expectations of mathematics sense-making that were manifested in this vignette do not simply function locally. These values resemble historic assumptions around to how students should participate in mathematics learning and what mathematical thinking is desired. Students whose ways of knowing and learning fit in with these assumptions have more opportunities to be positioned as good sense-makers, while students who act outside of these assumptions are frequently described as "at risk," "disabled," "unmotivated," "disadvantage," "not producing" (Kirchgasler, 2017). We call into question the assumptions regarding what counts as valuable thinking in mathematics classrooms along with prevailing discourse of epistemic agency. Our analysis of inscription practice suggests a need of complicating understanding of supporting equity in mathematics education.

Directed Actions Scaffold Gestural Insights in Geometric Reasoning

Fangli Xia, Kelsey E. Schenck, Michael I. Swart, and Mitchell J. Nathan
fxia24@wisc.edu; keschenck@wisc.edu; mswart@wisc.edu; mnathan@wisc.edu
University of Wisconsin - Madison

Abstract: Spontaneous gestures often express thoughts that differ from speech. Priming students to perform *directed actions*, movements designed to foster conceptual understanding, may give a way for students to organize their thoughts by providing a gestural vocabulary. G*estural insights* are nonverbal expressions of movement that reveal students' mathematical reasoning even when they were unable to verbalize their insights. This case study demonstrates how body-based resources like directed actions can foster gestural insights that support conceptual thinking.

Introduction and Theoretical Background

During mathematical reasoning, teachers and students naturally communicate key ideas using descriptive language, verbal inference, and gestures of the arms and hands (Alibali & Nathan, 2012). These co-speech gestures are a crucial form of multimodal discourse that reflect cognitive processes. Researchers have shown that the knowledge conveyed through gestures can differ from and complement speech (Goldin-Meadow et al., 1993; Pier et al., 2019). These *gestural insights* are phenomena in which students' gestures exhibit mathematical insights that are otherwise absent in their speech. Specifically, this case study explores how embodied thinking in the form of gestural insights contributed to a student's mathematical conceptualizations while generating geometric proofs.

Spontaneous co-speech and co-thought gestures often express one's cognitive processing (McNeill, 1992). Nathan et al. (2014) found that performing cognitively relevant arm movements contributed to superior insights into mathematical proofs. Thus, scholars hypothesize that directing learners to perform movements may provide effective embodied interventions that improve reasoning and learning (Nathan & Walkington, 2017). *Action-cognition transduction* proposes that instructing learners to perform *directed actions* will influence one's reasoning in ways cognitively congruent with the actions performed through nonverbal means (Nathan, 2017). Therefore, we ask: How do directed actions contribute to gestural insights and mathematical understanding?

Methods

This case comes from a larger study investigating the impact of directed actions and predictions on mathematical reasoning and focuses on one conjecture — *The diagonals of a rectangle always have the same length* (Figure 1; Xia et al., 2022). The participant was prompted to first perform directed actions and then read the geometric conjecture, consider its veracity, and provide a verbal justification. Recordings of participants' verbal responses and actions were transcribed and coded for correct mathematical reasoning, gestural insights, representational gestures, and dynamic depictive gestures (Xia et al., 2022).

Figure 1
Directed Actions for the "The diagonals of a rectangle always have the same length." conjecture

Note. These directed actions are intended to convey a key insight related to this conjecture – that the diagonals must be congruent because they each are the hypotenuses of left and right triangles with equal arm lengths.

Results

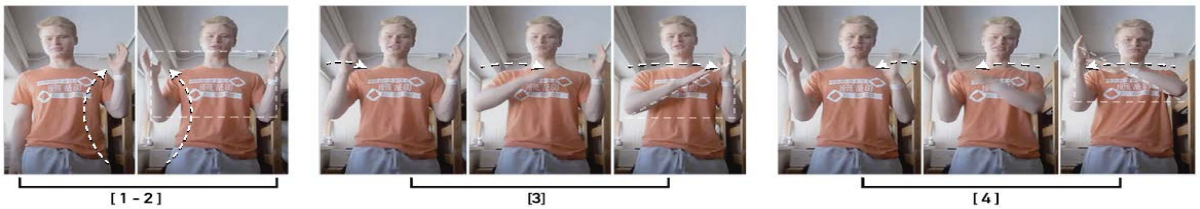
Student 1's (S1; Figure 2) intuition reflects their assertion that the diagonals of a rectangle must be the same length (Line 1). Mimicking the second pose from the directed action sequence (Figure 1, Frame 2), S1 arms

 © ISLS

represent their mental construction of the rectangle (Line 2). Next, they rotate their right arm to create a diagonal while saying "I rotate one to create a diagonal" (Line 3). S1's gestures reveal their understanding that diagonals intersect the bottom corners of the rectangle and must therefore have the same base angles intersect the top corners of the rectangle (Line 4). S1 does not provide a generalized rationale for why this conjecture must always be true as it makes no mention of the mathematical properties of rectangles. Non-verbally, S1's gestures demonstrated that a rectangle has a set of congruent and parallel opposite sides (Line 2), expressing a generalized understanding that both diagonals are equal (Lines 3-4).

Figure 2

Transcript #1



[1] The statement is always true [2] because when I hold a, make a rectangle of my arms, [3] I rotate one to create a diagonal, [4] it's gonna hit my arm in the same spot, regardless of which side it's on.

Discussion & Conclusions

This case shows that students who were unable to provide verbal mathematical reasoning demonstrated their emerging understandings through gestures. With these findings in mind, we revisit the research question.

This case shows how mathematical understanding is conveyed through movement. S1's geometric construction depicts two equivalent diagonals originating from consecutive corners of the rectangle. This insight highlights how dynamic gestures expand students' ability to convey their mathematical understandings. S2 integrated the directed action sequence in their gestures in their mathematical reasoning. This integration suggests S2 may have recognized the cognitive relevance of the directed actions to the conjecture. Moreover, S2 expressed generalized features in their gestures that were not found in their speech. In this case, we see how directed actions scaffolded the student's geometric reasoning and revealed potential for embodied interventions to help elicit gestural insights that foster conceptual reasoning.

Gestural insights may demonstrate ways students are extending their zones of proximal development (Goldin-Meadow & Church, 1993). Studies on geometry proof processes—and mathematics more generally—focus on verbal descriptions of mathematical insights (e.g., Xia et al., 2022). Students' gestures reveal nonverbal ways of knowing that could be used to guide learner-centered instruction by expanding formative assessment practices to include embodied expressions of knowing.

Intertwining art and STEM: An analysis of STEAM activities

Abstract: The integration of Art with Science, Technology, Engineering, and Mathematics (STEAM) has been growing in popularity, however, there are a variety of conceptualizations of what it looks like. This study explores images of STEAM by examining activities created by informal educators. We found that STEAM activities were conceptualized as using one discipline in the service of another, intertwined, or parallel. This provides concrete images of what STEAM can look like in educational settings.

Introduction

STEAM, or the integration of Art with Science, Technology, Engineering, and/or Mathematics, has become increasingly popular, for various reasons. STEAM is important for the economy, leading to increased creativity and innovation (Allina, 2018; LaMore et al., 2013) and job preparation (National Academics of Sciences, Engineering, and Medicine, 2018). Others argue that integrating art with STEM broadens participation of those traditionally underrepresented in STEM (Buechley & Perner-Wilson, 2012; Mejias et al., 2021; Peppler, 2013). Many argue for the importance of STEAM as it leads to new perspectives and ways of understanding that would not occur through disciplinary thinking (Bevan et al., 2020; Quigley & Herro, 2016; Siler, 2011). With burgeoning interest in STEAM, there is a need for more concrete images of what STEAM looks like in educational settings. We aim to add to the developing body of STEAM work by exploring the STEAM activities that informal educators created as part of their participation in a STEAM professional development program. We investigate the question: What are the qualities of participants' STEAM activities?

Theoretical framework and methods

We drew from a variety of conceptions of STEAM from the literature for our analysis. For example, in an interdisciplinary conception, two or more disciplines can work together without changing each other (Siler, 2011). Peppler and Wohlwend (2018) argue that STEAM should be transdisciplinary, where "…new understandings and artifacts emerge that transcend either discipline" (p. 88). This offers a view of STEAM integration where the disciplines not only support each other, but also work together in ways that move beyond the learning that could happen through disciplinary approaches. Mejias and his colleagues (2021) theorize STEAM along pedagogical and instrumental axes in four major quadrants (Mejias et al., 2021, p. 218). Their conceptualization of STEAM, including one-sided and mutually instrumental rhetoric, supported our analysis of how integrated the STEAM fields were in practitioners' activities.

The study's context was a STEAM professional development program developed for informal educators, (e.g., librarians, afterschool art and science teachers). It consisted of a two-day, in-person workshop followed by a mini-online course. The culminating project was to design a STEAM activity. The program was enacted with five different groups from geographic locations across the U.S. We analyzed 48 STEAM activities from all 47 participants who submitted written activity plans (one participant submitted two activities). We analyzed the data using emergent coding (Strauss & Corbin, 1998), looking for what images of STEAM the educators portrayed through their activity plans. From our analysis, three categories emerged: 1) In service of another discipline, which included STEM in the service of art and art in the service of STEM; 2) Intertwined; and 3) Parallel. These will be described in the findings.

Findings

We found three images of STEAM in the activities the educators developed. The first category was *in service of another discipline,* where one discipline was used to inform another discipline, but not vice versa (e.g., art in the service of STEM, where art was used to help learn STEM (thematically, materially, and/or conceptually). An example of *art in the service of STEM* was an activity where youth created a diorama of a rainbow to communicate their understanding of what causes rainbows. In this case, the focus was on learning about the science of how rainbows form and then art was used to help the students communicate their understanding of rainbows.

 © ISLS

The second category was *intertwined*, where the activity showed feedback between art and STEM, where the learning of Art and STEM depended on each other, continually informing each other throughout the activity. An example of *intertwined* was an activity where youth were given a problem to solve, in this case they were commissioned to design a wheelchair accessible ramp at a county fair. The ramp needed to be large enough to fit the needs of the people in the wheelchairs and also contain design elements relevant to the ideas and values of the members in the community. The activity positioned youth as architects so they could, according to the activity designer, "see how art and design both have a place in the STEAM content area" and identified various aspects of the activity as science (how the materials worked together), technology and engineering (how to assemble the materials), art, math and technology (how to design the solution), and math (determining the cost of the project and how to make it cost effective.

The third category was *parallel*, where the art and STEM explorations could be done separately and did not rely on, or inform, each other. An example of this was an activity where the youth learned STEM concepts in order to create a kite. The activity designer identified the following STEM concepts the youth would learn as they created their kites: forces (science), measurements (math), and how the shape and materials affect the kite's ability to fly (engineering). Once they created a kite, the youth could decorate it using crayons, pencils, or chalk with designs that were personally meaningful. In this activity, the art (decorating the kite) did not depend on understanding of STEM concepts, nor did it interact with these concepts in the functional design of the kite.

Conclusions and implications

We believe that there are places and times for a variety of types of STEAM activities, depending on the learning goals and needs of the youth. The purpose of this analysis was to explore a spectrum of images of STEAM, as there is much need for more concrete examples of STEAM in educational settings. As educators are increasingly being asked to consider designing and implementing STEAM, whether as a means to broaden participation in STEM, deepen engagement and understanding in STEM, or encourage creativity and critical thinking, we need to have a better understanding of the possibilities, as well as the constraints and affordances of varying approaches.

Effects of Level Trajectory on Mathematical Gameplay

Luke West, Fengfeng Ke, Chih-Pu Dai, Byung Joo Kim, Ram Chaulagain,

Florida State University

Abstract: We investigate the effect of free-choice versus adaptively recommended level trajectories on gameplay for middle-school learners playing a 3D architectural game involving ratio and geometric reasoning. We compare data between groups examining students' game performance and level selection patterns to examine the potential impact of level trajectories on a learner's gameplay performance and process. Using data from an online-facilitated study (n=23) we find that students playing with an adaptively recommended level trajectory spend more of their time on the target math-related levels. We confirm this with data from an onsite-facilitated study (n=51) and propose that adaptive level recommendation guides learners toward game levels relevant to target learning objectives while allowing some freedom of choice.

Background

Designing a learning game with discrete game levels can be useful for isolating certain skills and compartmentalizing learning objectives, but with multiple game levels come sequence and presentation design choices. Story progression across levels can be linear, where players complete fixed sequences, or structured such that progression through the story emerges from and is impacted by gameplay, as designers prefer (Fullerton, 2019:101). Non-linear level trajectories can also be a function of difficulty, adapting to performance level. Level trajectory mechanisms like Dynamic Difficulty Adjustment can support overall game experience and reduce self-consciousness but may also lower a player's sense of control (Ang et al., 2017). Turning to learning games specifically, Shute et al. (2021) found that students' learning was not significantly affected by different game-level delivery, including four methods: adaptive, linear, free choice, and a control group. In their study involving a 2D physics sandbox game, game performance measures (e.g., levels completed) was not affected by the type of level trajectory, but rather the type of support—physics animations were found to have the most positive effect (Shute et al., 2021). We revisit the question of level trajectory effects in a 3D math game, exploring differences between (1) students freely choosing levels and (2) students recommended levels based on their competency.

Method

Study Procedure

In a 3-week experimental group-comparison study, 21 students each completed 7-9 thirty-minute gameplay sessions during a summer school program, monitored by teachers on site and facilitated by research team members by Zoom. To confirm our initial findings, we analyzed data from a later fall study, with onsite facilitators, a larger group of middle-school students (open-path: n=26, recommended-path: n=25), and more gameplay (fifteen 45-minute sessions). All students in the summer and fall studies began gameplay with 5 movement training levels (not involving the target math objectives) to familiarize themselves with basic movement and manipulation of objects in the 3D game world. We randomly assigned students to path "open-level," where students complete training levels and then choose which game level to play next, or "recommended-level," where a Bayesian network recommends levels via student performance on learning objectives in previous levels' game actions.

Results

Students in the open-level and recommended-level paths showed similar group averages for total level attempts, successful level attempts, and % of successful level attempts. Inferential statistics were used to assess the remaining three metrics, which appeared to differ between groups (time spent on movement training, total gameplay time, and % of time spent on movement training). An independent samples t-tests comparing open- and recommended-level paths for all 6 gameplay-related metrics revealed no difference between groups except for percent of time spent on movement training. As Table 1 shows, percent of time spent on movement training was over 20% higher for the open-level path with marginal significance ($t = 2.26$, $df = 22$, $p = 0.03$) and a large effect size (Cohen's $d = 0.93$, Hedges $g = 0.86$). Levene's test for homogeneity assumption showed that group variances did not differ significantly for any of the measures we investigated.

Table 1
Game Performance Statistics for Students in Two Level Trajectory Paths (Online Facilitation)

	Open n = 11	Recommended n = 10	t	df	Sig. 2-tail	Mean Difference	SE Difference
Total level attempts	10.85	11.1	-0.66	22	0.52	-1.97	2.99
Successful level attempts	6.31	7.90	-1.25	22	0.23	-2.60	2.08
% of successful levels	60.77%	64.40%	-0.37	22	0.572	-4%	0.09
Movement training time	29.93	35.31	-0.62	22	0.54	-5.29	8.50
Total gameplay time	44.58	61.73	-1.23	22	0.23	-21.49	17.41
% of time spent on movement training	84.43%	63.80%	2.26	22	0.03*	24%	0.10

Note. *Significance threshold of $p<0.05$; time is reported in minutes.

As seen above, groups did not differ significantly in the other measures. We ran t-tests to assess whether the significant difference in % of time on movement training between groups held for both females and males. For males, the difference was marginally significant ($t = 1.956$, $df = 10$, $p = 0.079$), while for females, there was no significant difference ($t = 1.201$, $df = 10$, $p = 0.257$). To confirm this finding, we ran another independent samples t-test on data from middle school learners playing the same game in the onsite-facilitated study, this time with more students, more gameplay, and more careful facilitation (i.e., on-site). As seen in Table 2, students in the recommended path spent around 7% less of their gameplay time on non-math training levels.

Table 2
Game Performance Statistics for Students in Open-level and Recommended-level Paths (On-site Facilitation)

	Open-level mean n = 26	Recommended-level path mean n = 25	t	df	Sig. 2-tail	Mean Difference	SE Difference
% of time on movement training	24.63%	13.48%	2.70	49	0.01*	11.16%	4.13
% of level attempts movement training	31.92%	19.92%	2.67	49	0.01*	12.00%	4.49

Note. *Significance threshold of $p<0.05$; time is reported in minutes.

Discussion

One reason recommended-path students spent 7% more of their time on content-related levels may be that whereas students in the recommended-level path only saw new level choices appear as they completed levels, students in the free path had to navigate multiple menu steps to find new levels. If a student is drawn to readily visible levels, level recommendations would encourage new levels by displaying them and not requiring extra menu navigation. Second, unlike game levels, training levels lacked math problem solving. If students meet challenging game levels beyond their competency they may opt for the training levels which they can confidently complete. Students recommended levels adapted to their math competencies are likely more comfortable attempting new levels. We recommend designers consider an adaptive difficulty-driven level trajectory with recommendations to maximize learners' engagement with challenging content-related game levels, while giving learners freedom of level choice.

Dynamic Modelling of Collaborative Sensemaking: A Case Study

Ada Abes, Haggai Ben Ami, Shulamit Kapon
ada.abes@campus.technion.ac.il, haggai.b@campus.technion.ac.il, skapon@technion.ac.il

Abstract: How do explanations emerge and evolve in collaborative sensemaking? We present a preliminary attempt to model the evolution of collaborative sensemaking over a short timespan with high temporal resolution. We operationalized Sherin et al.'s (2012) node-mode framework of individual knowledge systems to a distributed knowledge system and examined its dynamics in high temporal resolution.

Introduction

In an attempt to examine why, and under what conditions, students generate coherent explanations in clinical interviews, Sherin, Krakowski, and Lee (2012) examined a large corpus of interviews with students about seasons and climate. Their analysis was situated within the Knowledge in Pieces (KiP) epistemological perspective (diSessa, 1993). Sherin et al. (2012) suggested that students' reasoning draws on a set of interconnected knowledge elements. They used the term *nodes* to describe elementary pieces of knowledge; and *modes*, to describe interconnected collections of nodes that are stable and are activated as a whole. They described sensemaking and reasoning as a process in which individuals create *dynamic mental constructs* - unstable and temporary knowledge structures comprised of *nodes* and *modes* that are activated and ad-hoc connected for the purpose of constructing an explanation.

The current study focuses on collaborative sensemaking, in which collaborators create and use a joint problem space (JPS) that provides a platform for meaningful communication in support of the sensemaking process. To construct their JPS, collaborators need ways to introduce and display knowledge in the JPS as well as methods to monitor differences in meaning and to resolve obstacles to the collaboration (Roschelle, 1992; Roschelle & Teasley, 1995). Inspired by studies of distributed cognition (Hutchins, 1995), we aim to model collaborative construction of explanations as drawing on a distributed knowledge system, and we suggest an operationalization of Sherin et al.'s mode-node framework for a distributed cognition, for example, a pair of students working in collaboration. We examine the dynamics of the collaborative knowledge construction with high temporal resolution. We use the term *shared nodes* to describe nodes introduced and accepted into the JPS, and the term *shared modes* to describe shared knowledge structures that are re-used in the JPS. The term *shared dynamic constructs (SDCs)* is used to describe the unstable and temporary knowledge structures that are connected for the ad-hoc purpose of constructing an explanation created in collaboration.

Methods

The data is drawn from a group interview with a pair of eleven-grade students who study advanced-level physics. The students knew each other and collaborated on previous occasions. The students were asked to discuss and explain why is it warmer in the summer than in the winter. This question was selected because it can be tackled using naïve knowledge, but it requires making sense of several natural phenomena and the connections between them, and thus answering it is far from trivial. Another reason for this particular choice was its use by several research groups in the past (Lelliott & Rollnick, 2010; B. Sherin et al., 2012) which allowed comparisons.

The interview was video recorded. The recordings were transcribed and specific episodes which were rich in *shared* knowledge construction were selected for analysis. The analysis involved the identification of *nodes* (Sherin et al., 2012), *shared nodes*, *SDCs* and *shared modes*. Relational expressions (such as "because", like, etc.) were identified and used to code attempts at knowledge construction and successful connections between *shared nodes,* both resulting in *SDCs*, as well as the creation of *shared modes*. A temporal representation of the collaborative knowledge system was created for each episode (here we present one).

Results

The temporal representation of the collaborative knowledge system in one episode (3:50 minutes) is presented in Fig. 1. The Y-axis of the graph shows the *nodes* that are used in this episode. The X-axis reflects the conversational turns, and colored dots identify the speakers using the respective *node* in their utterance.

The episode starts with the collaborators setting the stage for the process by introducing *nodes* into the JPS. Both partners contributed *nodes* and engaged in attempts at assembly, using *nodes* that they introduced into the JPS as well as *nodes* introduced by their partner. This symmetry in participation is an important feature of a

 © ISLS

collaborative interaction (Dillenbourg, 1999)and validates the construct of *shared nodes*. Following are attempts to combine the *shared nodes* into *SDC*s. Successful attempts are characterized by well-defined connections between the *shared nodes* in the utterance, via expressions like "because", "and then" or "is". They are marked in green in the graph. Conversational turns which included *shared nodes* without a meaningful connection between them were coded as "attempted connection", depicted in the graph as yellow connections between nodes. Those included for instance sentences in which there was an "if *node* A" phrase, but the "then" part was missing, or "let's say that *node* A and let's say that *node* B". Attempted connections were sometimes scientifically wrong. Interestingly, both attempted connections and successful ones resulted in the generation of *shared modes* identified as the re-use of previously developed structures in subsequent conversational turns. Some SDCs were created in collaboration and thus span more than one conversational turn (see turns 18-19 as well as 22-23-24), in line with our assumption that *shared dynamic constructs* are generated by a distributed cognition, similarly to the way an individual creates *dynamic mental constructs* (Sherin et al., 2012). This type of collaboratively-created SDCs was coded when the participants continued each other's ideas.

In this episode, a repetition of the question asked at the beginning of the interview (turn 27), intended to check if the shared knowledge structure provides an acceptable explanation, led to its collapse, but *shared nodes* that were created in the process were used in further turns in this episode and along the rest of the interview.

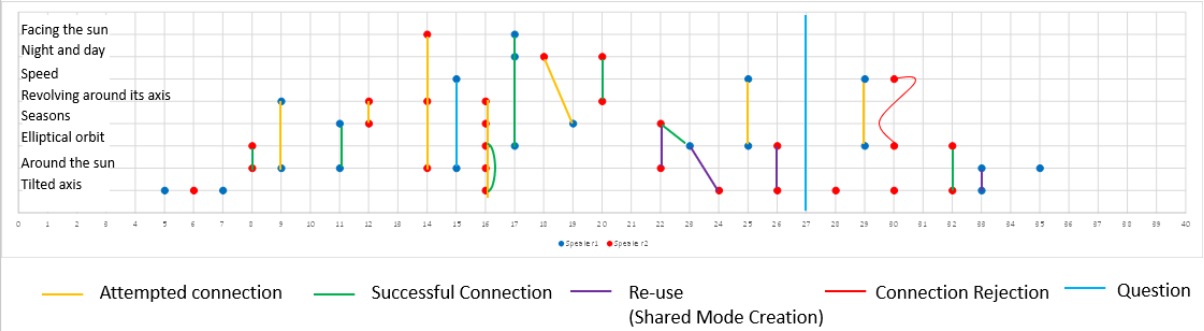

Figure 1
Knowledge Construction in Collaboration

Discussion

We operationalized Sherin et al.'s (2012) node-mode framework of individual knowledge systems to a distributed knowledge system and examined its dynamics in high temporal resolution. The analysis captures how the distributed knowledge system evolves in collaborative sensemaking and guides this process. While this is a preliminary attempt, we believe that it provides insights into the emergence of explanations in collaborative inquiry. Further investigation will aim to refine the model by specific attention to available materials and tools, and specific attention to the nature of the interaction.

Preparation for future learning and disposition development in a social studies-themed digital simulation game: A quantitative ethnography

Taylor M. Kessner
taylor.kessner@uta.edu
The University of Texas at Arlington

Abstract: We use quantitative ethnography and Epistemic Network Analysis to examine how the game mechanics of a social studies-themed digital simulation game may facilitate disposition development and preparation for future learning.

Introduction

Previous research indicates that *Offworld Trading Company* (*OTC*), a digital simulation game thematically aligned to social studies invites players to practice using disciplinary knowledge, skills, and concepts (DKSCs) associated with social studies to plan, take, and reflect on goal-mediated actions (Kessner, 2021). We are interested in how *OTC* might be leveraged towards two ends: (a) preparation for future learning; and (b) the ability and sensitivity elements of disposition development. We are particularly interested in identifying how game mechanics generate problem spaces in which these two goals might be facilitated.

Good games are excellent learning environments. They privilege experience before text, performance before competence, identity play, and systems thinking; and they present players with interesting, well-structured, and well-sequenced problems players solve by mastering and applying game-valued skills (Gee, 2003). Good games often align better than formal education environments to long-standing contentions of situativity theorists that what we learn cannot be disentangled from how and why we learn it (Gresalfi et al., 2009). For these and other reasons, games have maintained a level of popularity among both educators and researchers. In the context of social studies education, however, a mismatch exists between this interest and the available evidence of effectiveness, as well as conceptual guidance around what (kinds of) games are useful and why. Use of games in social studies education contexts may indeed represent a unique challenge.

Good social studies education prepares students for active participation within a pluralist representative democracy (Banks, 2006; Barton & Levstik, 2004). Civic preparation, Kessner and colleagues (2020) argued, should include citizens coming to see the world as designed and redesignable, and themselves as possessing agency over those designs in the form of designerly agency. Economics, the heart of which comprises problem framing and decision making, offers a particularly potent disciplinary toolkit for identifying, considering, and planning, taking, and reflecting on such design problems. Nevertheless, research on economics education remains decidedly scant relative to its fellows under the social studies umbrella; and while scholars have attended to the economics of the videogame industry as well actual in-game economies, we are unaware of serious scholarly attention to videogames as sites in which economics education may present.

We use quantitative ethnography (QE) (Shaffer, 2017) to examine small-group play of *OTC* to explore the following research questions:

1. To what extent might playing *OTC* influence learners' ability, as measured by the appropriate use of disciplinary discourse, to use economics concepts to attend to real-world problems, and what game mechanics might be associated with such development?
2. To what extent does playing *OTC* develop learners' sensitivity to economics in the real world, and what game mechanics might be associated with evidence of changes in this sensitivity?
3. To what extent does playing *OTC* prepare students for future learning in the domain of economics, and what game mechanics might be associated with positive evidence of preparation for future learning?

Theoretical framework

By *dispositions* we mean the bridging of the ability to do something and actually doing it. Dispositions comprise three elements: ability, sensitivity, and inclination (Perkins et al. 2000). Dispositions are also part of the fast-thinking system of the brain, which relies heavily on prior experiences for decision making (Kahneman 2011; Seligman et al. 2016), experiences which occur as embodied interactions with the world mediated by tools. Gee (2015) described this interaction as *conversations with the world*, cycles of thinking and action in which people identify goals, plan actions, and gather feedback on those actions from the world. Learners probe the world with actions, and the world "talks back". In videogames, players are embodied in the game world as avatars, which

 © ISLS

come with toolkits (Gee, 2015). It is with these tools and through these avatars that players (are able to) take actions in games. Thus, games provide a solid theoretical foundation for disposition development. The ways in which *OTC* presents core deep-structure problems relevant to social studies in myriad surface-feature configurations also, we contend, supports transfer of knowledge to novel real-world scenarios, which is essential to disposition development (Bransford & Schwartz 1999). Furthermore, we suggest that engaging with these problem spaces prepares students for future learning in the domain (Schwartz & Arena 2013).

Methods

QE leverages quantitative designs and analyses to make sense of complex qualitative discourse data (Shaffer, 2017). Recent games scholarship leveraging QE has explored themes from how an online game community forum facilitated participants' identity exploration processes (Barany & Foster, 2019) to the correlation between facial expressions and understanding of biological and complex systems concepts (Martin et al., 2019). QE represents particular affordances for the present study, as well. Games are immensely complex systems, making purely qualitative accountings of the connections between many diverse variables difficult if not untenable.

Participants for this study are a class of high school students enrolled in an Academic Decathlon (AD) elective course in a public school in the American South. This year, AD has an economics theme. Specifically, we are working with underclassmen enrolled in the course but who did not make the competition team. Students come from diverse backgrounds, and their varied levels of academic achievement, from "low" to "high," as measured by school-calculated grade point averages, indicates a wide and potentially representative sample of academic interest and engagement with school. While prior learning would be a concern in a traditional economics classroom, the English Language Arts teachers sponsoring this implementation of AD are trained neither as economists nor as economics educators, and they historically rely on senior students who already possess the requisite knowledge. The students who did not make the competition team, then, by definition are unlikely to possess significant prior knowledge.

The intervention consists of students playing *OTC* in diads during class time for one week. Instruction on relevant economics concepts will be taught by the researchers in a just-in-time fashion (Squire, 2011). Gameplay will be screencaptured, and student discourse data will be audio recorded. At the end of each lesson, students will be tasked with skimming news headlines for relevant social studies concepts, which they will bring to class the next day to discuss. Transcribed discourse data, gameplay data, and student work will be analyzed through Epistemic Network Analysis to identify connections between gameplay and student talk that either directly leverages disciplinary discourse or otherwise implicates discipline-relevant thinking.

Learning Geometry Through Collaborative, Embodied Explorations with Augmented Reality Holograms

Candace Walkington, Southern Methodist University, cwalkington@smu.edu
Mitchell J. Nathan, University of Wisconsin-Madison, mnathan@wisc.edu
Jonathan Hunnicutt, Southern Methodist University, jdhunnicutt@smu.edu
Julianna Washington, Southern Methodist University, jcwashington@smu.edu
Kasi Holcomb-Webb, Southern Methodist University, kholcombwebb@smu.edu

Abstract: Novel forms of technology, like shared Augmented Reality (AR) holograms, can spur the discovery of new hypotheses about cognition and how it is embodied and distributed. These holograms have affordances for exploration, collaboration, and learning that have never been seen before. In the present study, we examine the multimodal ways that high school students interact with shared AR holograms while exploring geometric conjectures. Through multimodal analysis, we fine both possibilities and important design considerations.

Introduction

Advances in Augmented Reality (AR) allow 3D holograms to be projected into students' real-world environments, controlled through intuitive hand gestures. Even more significantly, students can engage with these holograms collaboratively, with each student able to manipulate the holograms and see the effects of others' manipulations. These are literally new collaborative objects. We investigate students using AR goggles to explore geometry conjectures and describe the possibilities for collaborative embodiment and access to mathematical ideas.

Theoretical Framework: Collaborative Embodiment

Collaborative embodiment is defined as the ways students co-create actions and embodied ideas that become extended (Clark, 2012) over multiple learners. *Gestures*, spontaneous or purposeful hand and arm movements that often accompany speech, are a powerful way in which mentally-simulated actions can give rise to physical movements (Hostetter & Alibali, 2008). *Collaborative gestures* (Walkington et al., 2019) are gestures that are dependent on the gestures of interactional partners, like echoing or repeating gestures. AR and VR environments also happen at a scale where students engage in whole body movements – students might move around virtual 3D objects to take different perspectives (Walkington et al., 2021). Finally, students engage in collaborative forms of speech, using talk moves like Negotiating, Representing, and Planning (Andrews-Todd et al., 2019). It is through this multi-modal account of communication with speech, gestures, and collaborative embodiment that students generate shared mathematical meaning. We explore these research questions: (1) How do learners use resources like gestures, actions on virtual objects, body movements, and speech to explore conjectures in an AR environment? and (2) What barriers do students encounter to reasoning through collaborative embodiment?

Methods of Inquiry

Participants included 28 high school students enrolled in an enrichment program at a local university intended to support high school students likely to become first-generation college students. Twenty-three of the participants were female and 5 were male; 12 identified as African-American, 14 as Hispanic, 1 as White, and 1 as Other. Participant dyads were asked to reason about 8 geometry conjectures, without AR goggles on. Then they would put on the Microsoft HoloLens 2 goggles and justify 3 to 4 of the conjectures a second time. They used an app developed by GeoGebra for direct mathematical object manipulation (Hohenwater & Fuchs, 2004).

Results

The dynamic, 3D nature of the holograms offered powerful affordances for mathematical reasoning and embodied collaboration. In Figure 1, we see a dyad's second attempt to prove the sphere conjecture in Table 1, this time with the aid of the holograms. Having access to the 3D shape seems to give the students novel insights, and we see them using body movements to change the perspective they have on the sphere and to look at each other. We also seem them using gestures to reference the sphere and collaborative actions to dynamically modify the sphere, all while engaging in collaborative talk. The students exhibited substantial progress of their embodied understanding of 3D figures and how they interact with each other (Lines 1-16). However, students were not always able to use the holograms and their associated embodied resources and motions to reason more effectively. Multimodal analysis revealed that the students encountered issues with mathematical language in many episodes and struggled to decipher the culturally-bound, closed-ended, written medium of mathematical conjectures.

 © ISLS

Figure 1
Two participants reasoning about a conjecture about a plane intersecting a sphere at 0, 1, or infinite points. Red arrows were added to the image to show motion or change.

1. S101: I feel like we looked at that all wrong.
2. S102: Yeah, uh uh.
3. S101: Ooh, when I was thinking about –
4. S102: That would be true.
5. S101: When I was thinking about this in my head, I was like, "a plane is just gonna go around and around and around."
6. S102: So, it's true.
7. S101: It's true!
8. Researcher: Why do you think it's true or false?
9. S101: Because, if you really look at the plane – I'm making it bigger.

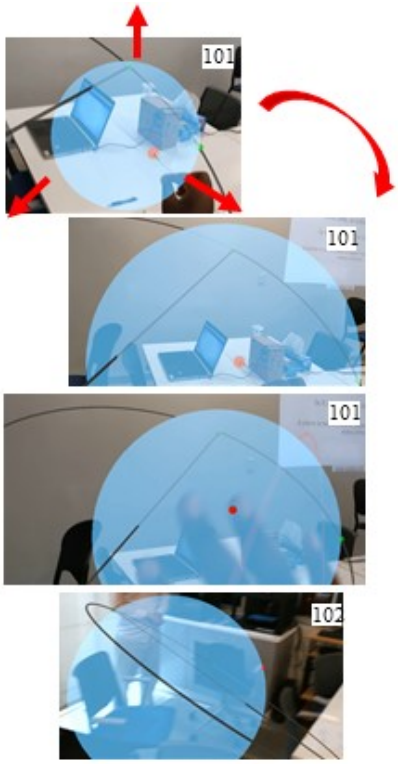
(adjust the sphere so that it is larger)

10. S102: There's many more ways you can intersect it at.
11. S101: It's more ways that it can go in and out!
12. S102: Yeah.
13. S101: Oh wow!
14. S102: There's like, many more ways.
15. S101: Okay, yeah, I was looking at this all wrong in my head. Now that I see it, I can say that it's true.

(gestures to the plane and where it is intersecting the sphere)

16. S102: Okay, yep, many more points that you can –

(steps back to view the plane intersecting the sphere)



Discussion

A variety of rich multi-modal forms of interaction come together in this shared AR environment to support students in creating meaning and constituting students' knowledge. AR holograms may be more powerful and appropriate for concepts that are inherently 3D, as these objects leverage AR's profound affordance for 3 dimensions, like our sphere simulation did. Finally, AR allows students to interact with and explore objects in novel and unconventional ways. However, if you bring traditional "school" tasks into an AR environment, students' reasoning and attempts at meaning-making can be restricted. Tasks in shared AR environments become particularly meaningful if they come from students and their embodied, collaborative experiences.

Abstract: It is not common for big construction companies to call upon educational researchers to collaborate with them in efforts at reducing worksite accident rates. In this paper, we describe one such collaboration, including the background and rationale for it, and the progress that the small team of educational researchers and construction company managers have made in the first 7 months of the project. We outline some of the processes through which strategies for addressing the problem have evolved, and consider how it may be possible for a project like this to manifest characteristics of the four dimensions of quality that Furlong and Oancea (2005) proposed for applied, practice-based educational research (epistemic, economic, technological, and capacity building and value for people). Our overall aim is to reflect on the extent to which educational researchers may be able to contribute to a more diverse range of applied research.

Introduction

Many educational researchers engage in applied research, but such activity is almost always firmly focused on the development of new knowledge for teaching and learning (Dodd & Epstein, 2012). However, there are cases where the research remit is broader and goes beyond addressing teaching and learning challenges. In this paper, we describe such a research project: one in which educational researchers collaborate with management of a big construction company in an effort to reduce accident rates in that company.

Background to and rationale for the project

The collaboration originated from a discussion between the fifth author, who is the Manager of the Safety Management Department of Toda Corporation, and the second author, who is a doctoral candidate and owner of a private tutoring school, who have known each other for many years. They discussed a pressing challenge being faced by Toda Corporation: how to reduce its accident rates. The company was established 140 years ago and is one of the major construction companies in Japan at the present time.

Although, compared to the average of all construction companies in Japan, Toda Corporation's rate of occupational accidents is lower, it is nevertheless at a level that is considered too high by those in the construction industry. Its frequency rate of accidents (which is measured as the rate of occurrence of an accident per million hours of work) was 0.51 in 2020, but its target rate is 0.30. Reducing accident rates is extremely important for a number of reasons, including the company's ethical responsibility for ensuring safety for workers and the general public, and its liability on many fronts – civil, criminal, and social – whenever accidents occur. In the past six years, the company has implemented a number of strategies, including the development of a new system of classifying the causes of human errors (based on Takagi, 2006), the appointment of a director to manage general safety and health, implementation of a database for accident information sharing, and use of web cameras for remote monitoring of work places. However, the company had not directly engaged with academic researchers.

The main purpose of the research collaboration described in this paper is to identify and address relevant human factors that may hinder or promote safety. In the original discussion between the second and fifth authors, they realized that although the company may have been addressing various work tools/resources and procedures to improve safety, they had not adequately considered human factors (e.g., worker perceptions, beliefs, and motivations). In subsequent discussions with the first author (who is the second author's doctoral supervisor), the idea of addressing such factors to promote greater safety was therefore developed.

Progress to date

At the time of writing this report (7 months from the start of a 2-year project funded by Toda), the "research team" involved in this collaboration comprises the first author (university professor in educational psychology), the second author, another two of the first author's doctoral students (who are able to participate only in very limited capacities because of their other work and study commitments), three part-time research assistants (two working with the first author – one of whom is the third author; and one working with the second author) and, on the Toda

 © ISLS

Corporation side, the fourth author (Deputy Section Manager of the Safety Management Department) and the fifth author. Two other senior staff members of the company participate in main meetings that are held.

Strategies in development

The educational researchers have proposed several strategies to the Toda staff which they are now working on together for implementation and evaluation. One of those is to make some modifications to the requirements for contract bidding and decision making. Many smaller construction companies bid for contracts to undertake work for Toda Corporation, but the safety performance records of such companies have not been taken directly into consideration in the award of contract work. This strategy is therefore to determine ways to realistically but effectively incorporate safety as a key consideration in bidding and awarding of contracts so as to better align the company's message of valuing safety and its management practices in awarding contracts.

Another strategy in development is aimed at improving the training provided to prevent worksite accidents, the most common of which involve injuries from the use of machinery, structural collapse, and falls when working in high places. Toda staff already know essentially why those accidents occur (e.g., taking careless or risky actions especially when in a hurry, ignoring safety protocols) and training of various forms is already in place. However, such training focuses primarily on information provision, and so workers may well learn about the dangers and what they are expected to do, but they may not sufficiently understand the direct relevance to their own selves and the seriousness of the consequences of such accidents. Hence, the objective of this strategy is to improve training methods to more actively engage workers in the learning process.

At the time of writing this report, surveys/questionnaires are also being developed to find out specific details about various aspects of workers' beliefs and perceptions, interactions, and work environments. Identifying variations in these, particularly in relation to accident rates, can then be used for the development of interventions to further reduce accidents. For instance, factors such as team leadership, sense of belongingness and cohesion, levels of trust, and coordination and sharing of knowledge may be related to workers' sense of responsibility not only for themselves but also those they work with (e.g., Fruhen & Keith, 2014). Finding out such information can help in the development of team building strategies and in the cultivation of safety-oriented worksite leadership.

Evaluating the success of the collaboration

Furlong and Oancea (2005) proposed four dimensions to consider when evaluating the quality of applied and practice-based research in education: (1) epistemic, (2) economic, (3) technological, and (4) capacity building and value for people. As this research is still in its early stages, it is not yet possible to properly evaluate its quality according to these four dimensions. However, we can consider how this research might be able to meet these quality dimensions, and examine some indicators that might indicate whether the project is progressing in the right direction. Where the epistemic dimension is concerned, the team is constantly considering the cause-effect chains associated with planned interventions and how it may be possible to reliably document and measure those. Concerning the economic dimension, the research project is focused on reducing the accidents rates of the company which, if achieved, would certainly bring multifaceted benefits to the company. Satisfying this dimension will depend on the effectiveness of strategies that are developed and implemented, and the extent to which favorable changes (i.e., reductions) in accident rates can be attributed to those strategies. We also believe that there is potential in research projects like the present one to provide knowledge, new ideas, and other useful contributions to the practice of education, and hence to satisfy the third, technological dimension of research quality. Finally, in preparation for writing this submission, we (the authors) undertook individual reflections on our perceptions about the progress of the project to date, including our own roles and progress in relation to work that needs to be done, and our feelings about what has gone well and what can be improved. These reflections, which were written down, provide clear indications that this research is contributing toward the fourth dimension of capacity building and value for people (our team). Thus, we have reason to believe that a collaboration like this with a broader research remit can meet the quality dimensions proposed by Furlong and Oancea (2005), but we will need to continue monitoring our progress until the project's conclusion to more accurately determine that.

Using Interest and Identity to Design for Mentor Persistence

Kay Ramey, Wade Berger, Naomi Thompson, Nichole Pinkard

Northwestern University

Abstract: Mentorship is identified as a successful approach to supporting youth in out-of-school learning. However, less attention has been paid to how to develop and support a mentor workforce. This study examines how to design supportive infrastructure that encourages mentors to persist in mentoring by providing opportunities for interest and collaborative identity development. Drawing on two case studies constructed from interview and interaction data, we demonstrate how these processes unfolded in a summer mentoring practicum.

Introduction

Mentors and mentorship are identified as successful approaches to supporting youth in out-of-school learning (e.g., Barron, Gomez, Pinkard, & Martin, 2014). Less attention has been paid to how to develop and support a mentor workforce, especially a diverse, STEAM mentor workforce. This study examines how to design supportive infrastructure that encourages mentors to persist, despite day-to-day difficulties. We explore this question in the context of STEAMbassadors, a summer mentoring practicum co-designed by community partners in two neighboring midwestern cities, with the goal of developing community college students into a diverse, out-of-school, STEAM mentor workforce, serving historically oppressed neighborhoods. Mentors participated in shared core training but were then placed, based on their interests, at different sites and given additional training to lead specific camps. They were assigned to sites in pairs or groups and participated in peer reflection sessions.

We argue that these layers of supportive infrastructure were consequential for mentor persistence, because, based on prior research, we conceptualize interest and collaborative identity development as supportive of persistence (e.g., Azevedo, 2011; Eccles, 2009; Hidi, 2006). Conceptualizations of persistence as a personal characteristic (i.e., "grit", Duckworth, Peterson, Matthews, & Kelly, 2007) have gained significant traction. However, we align ourselves with critics of this approach (e.g., Zembylas, 2021) who argue that focusing attention on individual grit misdirects attention toward "fixing" individuals rather than fixing inequitable ecosystems. We chose, instead, to focus on the designed ecosystem of STEAMbassadors, the interactions made possible by that ecosystem, and how these layers of context supported interest, identity, and persistence processes. We propose that mentors supporting youth in exploring topics of shared interest would support mentor persistence. Based on research on relational work among learners (e.g., Uttamchandani, 2021), we also propose a supportive role for peer-to-peer interactions among a cohort of mentors collaboratively developing their mentor identities.

Method

In Summer 2021, 30 mentors participated in our research. These mentors were part of the second STEAMbassadors cohort, who conducted their work one year into the Covid-19 pandemic. This meant that many pandemic restrictions were still in place, leading to hybrid or outdoor-only camps and low youth participation. We collected video of Zoom semi-structured pre- and post-camp interviews, and observations and video of group Zoom reflection sessions. We coded the video for themes related to interest, identity, difficulty, and persistence. For the reflection session data, we also conducted interaction analysis on moments identified as relevant to these themes, to examine how mentors were supporting one another by responding to each other. Finally, to illustrate themes in our dataset, we identified two focal mentors and conducted case analyses. These mentors were selected because their individual stories are rich and representative of other mentors and also because they came together in a significant interaction in a reflection session that represents how mentors supported one another.

Findings

Dante was a Latino male attending college to become an engineer. Prior to joining STEAMbassadors, he had worked as a summer camp counselor. He was also interested in becoming a DJ. Consequently, Dante was excited that, at his practicum site, there was a DJing station, run by a professional DJ. In his end-of-camp interview, when we asked him about time when he had helped a young person develop an interest, he said, "I would say it was with the DJ, where we had this one girl who was really into it, and she liked learning more about it from our DJ." This positive reflection contrasted with Dante's critical reflections on day-to-day frustrations at his practicum site. He said that the drop-in camp model made making meaningful connections with youth difficult, that outdoor

 © ISLS

recreation activities like skating competed with the STEAM learning stations for youth attention, and that the overall number of campers was low. However, he also described having close relationships with fellow mentors.

Kiara was a Latina female college student. She had many interests (art, science, math, acting), but was considering majoring in either business or computer science, with a focus in cybersecurity. Thus, she was excited to be assigned to a cybersecurity camp, a nature camp, and a hip hop history camp. She framed the cybersecurity camp as a positive experience learning alongside youth, since she hadn't yet taken a cybersecurity class. However, she mentioned challenges, such as low attendance and participation. She also mentioned frustrating interactions with peers, after she was asked to manage fellow mentors at her site, who were older and more experienced than she was. She said, "I don't really know how to explain it, but they wouldn't really give--do the tasks that I would give them or they'd agreed to." In contrast, Kiara also served as a peer reflection session facilitator and described this experience positively. She noted that in one particularly productive session, "[mentors] were able to communicate with us the struggles and where that frustration was coming from, so I think that was great." Kiara said she was glad to be able to support and validate other mentors' struggles and learn that it was okay to struggle.

In the reflection session that Kiara cited as productive, there was a consequential interaction between Kiara and Dante. It demonstrates how shared interests and experiences and opportunities for collaborative identity development with fellow mentors encouraged them to persist. In this session, Dante explained a struggle, saying, "[W]e came up with a great idea, we're going to do a leaderboard and everything, and they would get gift cards, and that just fell apart immediately." Kiara responded, "So what went wrong exactly, because I know gift cards, we have gift cards too, and that definitely get something going, at least the participation wise. So what do you think...made it fall apart?" Dante responded that the idea had not progressed over the weeks of his camp, and expressed frustration about that. At this point, other mentors asked questions and made suggestions. Dante and another mentor from his camp provided more details. Moments from this discussion were fraught, as Dante voiced several tensions. The tone of the conversation changed, however, when Kiara encouraged Dante to think about what a positive session might look like. This led Dante to focus on positives, including connecting with the girl who was interested in DJing and time spent with coworkers. Kiara's empathy for Dante and her challenge to him proved critical for him to focus on these positives and their role in shaping his mentoring identity and experience.

Discussion

We have documented here the supportive role that interest and collaborative identity development played in encouraging mentor persistence in STEAMbassadors. Although both Dante and Kiara experienced frustrations, both ultimately viewed the practicum positively. For Kiara, the opportunity to learn about cybersecurity alongside youth and help her fellow mentors articulate their struggles and successes outweighed her frustrations. For Dante, the opportunity to help youth explore DJing and form close bonds with fellow mentors also made the experience worthwhile. In both cases, reflecting as a group allowed mentors to bond over shared experiences and to collaboratively develop their mentor identities, rather than being isolated, as is sometimes the case for mentors who are the only educators at their organizations. These interest and collaborative identity development opportunities designed into the infrastructure of the program allowed mentors to work through difficulties and persist. Educators and researchers can draw on these findings to design intentional supports for mentors, including having mentors work with youth on topics of interest, giving them opportunities to be positioned as leaders, and making sure that they have the support of a peer cohort with whom to share and develop collaboratively.

Elementary Students' Epistemic Ideas Within Design-based Learning Projects

Qingna Jin, University of Alberta, qingna.jin@ualberta.ca
Li Ke, University of Nevada, Reno, keli8796@gmail.com

Abstract: Students' epistemic ideas influence how they engage in science practices. This study employed the Epistemologies in Practice (EIP) framework to explore elementary students' epistemic ideas within design-based projects in a science classroom. Data were collected from multiple sources and analyzed qualitatively. Findings indicated that students meaningfully used their epistemic considerations while engaging in their design projects. It was also found that contextual factors such as task settings influenced how students prioritized their epistemic ideas.

Background

Scientists use their epistemic knowledge to evaluate the validity and accuracy of scientific products such as models and arguments to generate and advance scientific knowledge. In science classrooms, it has been suggested that students' epistemic ideas influence how they engage in science practices, such as scientific inquiry and problem solving, and understand the nature of science (Pluta et al., 2011). Therefore, science educators have been supporting the development of students' epistemic understandings by promoting their meaningful engagement in science (e.g., Ke & Schwarz, 2021; Kelly & Cunningham, 2019; Ko & Krist, 2019). To contribute to this issue, this study aimed to explore elementary students' epistemic ideas within design-based learning projects and investigate how contextual factors influenced students' epistemic considerations in action.

In this study, we employed the Epistemologies in Practice (EIP) framework (Berland et al., 2016) to understand elementary students' epistemic ideas within their design-based learning projects in science. The EIP framework emphasizes that "one's epistemology is made up of a flexible network of [epistemic] understandings that can be drawn from based on understandings of what is most appropriate and relevant to one's goals in the current setting" (Berland et al., 2016, p. 1085). From this perspective, we view students' epistemic ideas as contextualized and tied to specific content and context.

The EIP framework focuses on four considerations that are not only meaningful to scientific communities, but also to the knowledge building science classrooms (Berland et al., 2016). They are:

- What kind of answer should our knowledge product provide? (Nature): Students' considerations to this question range from *detailed description of what happened* to *causal mechanisms to explain the How and Why.*
- How does our knowledge product relate to other scientific phenomena and ideas? (Generality): This is related to students' understandings of specific experiences or phenomena with one another and with general abstractions. Students' considerations range from *specific scientific phenomena do not relate to one another or to the generalized science ideas* to *knowledge products are created from and should explain a range of phenomena.*
- How do we justify the ideas in our knowledge products? (Justification): Students' considerations range from *no need to justify* to *necessity of constructing, evaluating, and justifying the knowledge product with interpretation of the available information.*
- Who will use our knowledge products and how? (Audience): Students' considerations range from *our knowledge product is for the teacher to evaluate our understanding* to *we collaboratively construct and use our knowledge products with our audience.*

Curriculum Context and Research Methods

This four-month-long research was designed as a qualitative case study (Merriam, 2016). This study took place in a Grade 5/6 science classroom in a public school in Canada. Nineteen students and their science teacher participated in this study. During the research period, the students engaged in a design-based learning project on the topic of astronomy. In elementary classrooms, astronomy topics could foster curiosity and imagination and is an effective method of inspiring student motivation in science (Plummer et al., 2010). Despite attracting children's interests and affecting their everyday lives, research indicates that some astronomical phenomena are difficult for students to understand and challenging for teachers to teach (Plummer et al., 2010). To support their engagement in exploring other planets and their moons in the solar system, this unit was organized around a project: Design to further space exploration. In this project, students worked individually to design a new technology to further

 © ISLS

the current space exploration. Students knew from the beginning of this project that they would make a presentation and that their technologies would be evaluated by their classmates. Their designs were to be based on their experiences, knowledge learned in this unit, and information from online research on their topics.

Multiple methods were employed for data collection. For this paper, we mainly analyzed the data collected with classroom observation and student interviews. These data were analyzed qualitatively for thematization to understand students' epistemic considerations within their design projects. Our data analysis was informed by the EIP framework focusing on the four considerations discussed in the previous section. We first analyzed the data separately. Then, through critically comparing and examining each other's interpretations, we achieved collective data interpretations.

Findings and Discussions

In this section, we present preliminary findings on elementary students' epistemic considerations during their design projects. It was found that students in this study meaningfully used their ideas related to the four epistemic considerations in the EIP framework.

"What kind of answer should our knowledge product provide?" In this study, we found many of the student participants thought they should explain the *why* and *how* in their knowledge products (i.e., presentations). For example, one student shared during the interview "… this is going to happen, but how? We need to explain the how part, then people will understand what my technology is." Some students also related their epistemic considerations to the task requirements by comparing this design project with their previous ones: "we've never done this before. In this project, you really need to persuade … it is not like the trees [project] which you can only list what you found online … this one you really need to explain the *why* to persuade."

"How does our knowledge product relate to other scientific phenomena and ideas?" In this study, we rarely found students addressing *generality* in their presentations. Most of the students' design did not include connections to others' ideas. It is conjectured that it is due to the specific task setting in which students designed their own innovative technology. This finding confirmed that epistemic ideas are situated, contextualized and tied to specific content and context.

"How do we justify the ideas in our knowledge products?" All the students in this study realized that they needed to justify with evidence, yet their understandings about evidence were varied. For example, one student shared during the interview "we need to persuade with information, much information … the more information you have the better." Another student insisted "I want to keep mine concise … you do not need to talk a lot, a few pieces, but really good, is more powerful." They both realized the necessity of justification with evidence but had different ideas regarding importance of the quantity or quality of evidence.

"Who will use our knowledge products and how?" In the study, classmates were introduced as the audience who would evaluate students' design by examining whether the design would contribute to current space exploration. Instead of collaboratively constructing knowledge with the audience, students viewed their audience as ones who are consumers of their designs. This finding also supports that context impacts students' epistemologies that are in practice. Based on understandings of the context and goals in the current setting, students prioritize epistemic ideas they think most appropriate (Berland et al., 2016).

Using immersive augmented reality to guide families' observations and visualizations of pollinator habitats in outdoor spaces

Penn State University

Abstract: Immersive AR technologies can support students' learning processes and deep engagement with outdoor science pursuits, yet few studies explore these technologies with out-of-school learners. We analyze how immersive AR features built into an outdoor-based mobile app shaped nine families' learning experiences as they explored pollinator habitats. Preliminary findings revealed that immersive AR scanning tools built into the *Pollinator Explorers* app guided families' observational practices of real-world objects through virtual overlays representing pollinator habitats.

Introduction and conceptual framework

Prior work on the use of immersive augmented reality (AR) technologies in outdoor spaces (i.e., hiking trails, schoolyards), posits that when designed using situated learning pedagogies, apps can support students' engagement, learning processes, and problem-solving skills (e.g., Georgiou & Kyza, 2017). Whereas this prior work has mainly focused on student populations, we aim to better understand how family learning processes (Ellenbogen, Luke, & Dierking, 2004) are shaped by outdoor-based immersive mobile AR (MAR) technologies, particularly because family groups comprise the majority of visitors to informal learning sites (Bell et al., 2009).

Eberbach and Crowley (2017) define disciplined noticing as "a critical dimension of observational practice and involves learning to detect the signal from the noise" (p. 24). In alignment with this prior work, we aim to provide families with a mobile learning experience that guides them to pick out and scientifically observe the different components of a pollinator habitat while being physically situated within the dynamic and complex space of an outdoor learning setting. With the addition of immersive MAR technologies into our mobile app designs, we strive to elevate these observations so that families are supported to "see the unseen" through digital elements overlayed onto real-world phenomenon (Zimmerman et al., 2021). As such, we ask the following research question: *How did a learning-on-the-move app's immersive AR features shape families' learning experiences and observations of pollinators and their habitats?*

Methods: Context, participants, and data

Using a design-based research methodology (Sandoval & Bell, 2014), we explore this first iteration of a learning-on-the-move MAR app designed to foster observations of healthy pollinator habitats at a rural nature center in the northeast United States. The *Pollinator Explorers* app is focused on a specific type of pollinator—solitary bees—and what they need to thrive in a forest and meadow habitat (where this app tour was situated). Families in our study used the app to tour six different stops around the outside perimeter of the nature center and collected evidence (through photos) of what these native bees need to live and thrive in this habitat. Two of the six tour stops included digital augmentation of science phenomena (i.e., bee nests inside of logs, microscopic pollen grain) layered over real-world objects to further families' observations and immerse them in more deeply understanding bee needs and habitats. We focus here on the immersive AR design features at the log nesting tour stop.

Nine families agreed to participate in the research (29 individuals; 14 adults, 15 youths). Families' self-reported racial affiliations were White (93%) and Black or African American (10%). Children (female: 47%, male: 27%, did not report: 27%) were primarily between the ages of 5-12 (73%). Family groups individually participated in the *Pollinator Explorers* tour for an average of 43 minutes. Families were provided with an iPad pre-loaded with the app, and screen-recordings were enabled throughout the duration of each family's tour experience. Additionally, one individual per family donned a GoPro video camera attached to a baseball cap to collect audio-visual data from the perspective of the learner. We implemented video-based qualitative analysis of the GoPro data using an interaction analysis framework (Jordan & Henderson, 1995) to understand the families' talk and gestures as they related to their experience with the first design iteration of the app. The research team created detailed narrative accounts of each family's tour with the app with a focus on moments when the app facilitated families' real-world observations of pollinator habitat components around them. The first author vetted the narrative accounts and selected to analyze families' interactions at Stop 3 (Log Nesting Locations for Solitary Bees) due to the immersive nature of the AR technology embedded within the app design at this tour stop.

Findings

From an analysis of the full video dataset, 100% of families completed the immersive AR activity to visualize potential bee nests inside of real logs at Stop 3. This design feature aided families' observational practices in two ways. First, families were guided to find an example of a potential bee nest site by locating two side-by-side logs nearby on the ground. After locating this real-world object, families next used the AR scanning tool in the app to "see" what a bee nest inside the logs would look like. In several families, we noted that affective responses (e.g., apprehension about a potential bee nest site) signaled immersive moments where the digital augmentation blurred with the real-world phenomena. In Table 1, two examples from our dataset portray the ways in which two family groups interacted with the immersive AR activity (**bold font** represents family talk related to real-world observations and app use; *italicized font* denotes our analytical interpretation of the data).

Table 1

Two Families' Interactions with AR Technology to Support Real-World Observations of Bee Nests

Dad Simon and sons, Peyton (12) and James (8)	Mom Sharon, Dad Ryan, Nicholas (8) and Eli (2)
Peyton: Wait. And we will scan them to learn more. **Oh, we're here.** *[app supports location of bee nest site]* **I don't want to go there if there's a nest**. *[affective response signals an immersive learning experience: the potential for a bee's nest in the logs became real through the AR scanning tool]* Dad: Stand up here and see what it does. Scanning. Oh, that's cool. Peyton: Oh my gosh. Dad: Oh, **so that's where the nest is?** Oh, wow. *[digital AR supports connection of science content with real-world observation of bee nest site]*	Mom: Oh, that's cool. Look at that, **it's showing us what's inside**. **Here, let's go closer so we can look at the real thing.** *[digital AR supports connection of science content with real-world observation of bee nest site]* Nicholas: Is it really active right now? Mom: I don't know. Nicholas: I'm scared it's active. *[affective response signals an immersive learning experience: the potential for a bee's nest in the logs became real through the AR scanning tool]*

Discussion and implications

Our preliminary work with the *Pollinator Explorers* app suggests the potential for guiding families to be more disciplined observers within these rich authentic learning environments (Eberbach & Crowley, 2017). We posit that the immersive blending of real-world phenomena with virtual augmentations—an activity previously argued to facilitate high school students' learning (Georgious & Kyza, 2018)—deepened families' scientific observations and awareness of surrounding bee habitats and behaviors. Future iterations of our work will expand upon these immersive AR experiences in different outdoor learning spaces to broaden our understanding of outdoor family science learning with MAR technologies.

Technological Repurposing: Extending Pedagogical Design Capacity to Include Technological Adaptations

Nicholas Witt, Western Michigan University, nicholas.e.witt@wmich.edu

Abstract: This report builds upon Brown's (2009) Pedagogical Design Capacity Framework, to describe instances of "technological repurposing" of technologically-enhanced curriculum developed with prospective mathematics teachers (PMTs). The presentation will highlight the progression of one PMT's understanding of compactness and how this contributed to making an innovative technological adaptation in a set of lesson resources developed to help middle school students make sense of Gerrymandering.

Introduction

Given the omnipresence of technology in today's mathematics classes, it is important to better understand what enables teachers to adapt their curriculum resources to meet their instructional goals. A number of influential policy documents in the U.S. have advocated for Mathematical Action Technology (MAT) (Dick & Hollebrands, 2011) to play a major role in mathematics classrooms due the its ability to present content in novel, more accessible ways (e.g., NCTM, 2018). The purpose of the study was to examine the effect of the instructional unit on the PMTs' abilities to revise technology-based curriculum materials to incorporate their own knowledge. My research question is, "In what ways do PMTs adapt technologically-enhanced curricular resources that they have engaged with as learners when they are tasked with thinking about how their future students might engage with the same or similar content?"

Theoretical framework

In Brown's (2009) *pedagogical design capacity* (PDC) framework, the constructs of *offloading, adaptation, and improvisation* are discussed. Brown describes *offloading* as the practice of utilizing curriculum as it is written and *improvising* as the work teachers engage in when utilize their knowledge to build new curricular resources. In this paper, I described certain acts of *adaptation* as acts of *technological repurposing* due to the way that much of the original technological components remained intact. I define technological repurposing as an acknowledgement of or adjustment made to an existing piece of technology that is meant to develop an understanding of a particular content goal which may differ from the original intent of the technology.

Methods

My analysis utilizing the PDC framework and my conceptualization of technological repurposing, included classroom video data, discussion transcriptions, and the PMTs' documentational work (e.g., their submitted lesson revision assignment). For the analysis at hand, I focus only on identifying technological repurposing in my students' lesson revision assignment. When the technological capabilities along with the questions prompts and informative content appeared to be copied, but then modified to support a new goal, I referred to this as *repurposing*.

Results

Of the eight participants, *repurposing* in five student submissions and was observed in the following ways(see Table 1): the slide was copied, then the text was changed to provide more information or ask new questions (*textual*) or the slide was copied and the MAT component was reset or reprogrammed to encourage the development of a new goal (*technological*). The technological repurposing was observed in three of the participants' work.

Table 1
Repurposing Summary

PMT	Description of Repurposing	Type
Brooke	- question prompts for new goal -preset dynamic technological feature	-textual -technological
Megan	-animated technology -changed questions prompts for new goal	-technological -textual
Ruth	-added background information	-textual

 © ISLS

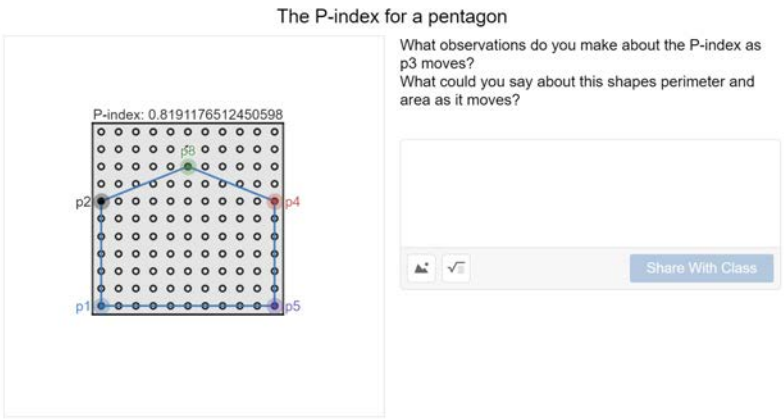
	-changed question prompts for new goals -preset technological feature	-textual -technological

Megan's technological repurposing

In Megan's submitted revised activity, she provides the following rationale for the repurposed slide below (figure 1),

"…I added the pentagon with the slider because I wanted students to narrow down their thinking and observations. I didn't feel like I made the connections between the area and perimeter and compactness and pp index very well. I thought by adding this and asking students to look at the difference in the pp index while considering how their area and perimeter changes, they might grasp that better…"

Figure 1.
Megan's repurposed slide



This adaptation differs from her experience as a learner with this material (figure 2) in which the goal was to simply, "describe some characteristics of the shape." In this slide, the (green) point p3 varies to highlight her goal.

Conclusions and discussion

The role of *technological repurposing* could be an important area of future research due to the necessity of technology integration in mathematics classrooms, but also because it is often necessary to adapt curricular resources to meet teachers' varying instructional goals. Though this study included, but did not focus on the role of sociopolitical context in the intervention lesson, this is an ongoing project to better understand how teachers utilize a wide variety of knowledge sources in their practice of planning.

Processing Team Feedback: Exploring Emotional and Cognitive Responses to Team-Level Feedback

Catherine Gabelica, IESEG School of Management, c.gabelica@ieseg.fr
Vitaliy Popov, University of Michigan Medical School, vipopov@umich.edu

Abstract: Research on feedback in teams acknowledges the importance of feedback mechanisms to team success. However, although processing performance feedback in teams is seen as an important prerequisite to its effectiveness, the processes emerging after feedback reception have been overlooked in past research. This paper provides insights into the emotional and cognitive reflective responses of graduate students (N=111) to team-level feedback. The results of our explorative study reveal that (a) students from high-performing teams generally report positive activating emotions and generally reflect on feedback when prompted to do so, (b) many students from low performing teams were able to show adaptive emotional responses to team-level feedback, and (c) there is a complex interplay between feedback valence and affective and cognitive reactions to team feedback as evidenced and visualized by Epistemic Network Analysis model.

Introduction

The purpose of the present paper is to explore emotional and cognitive responses following team-level feedback of different valences. Specifically, we explore the extent to which members of high vs. low performing teams express (a) (de)activating positive or negative emotions and (b) feedback processing and feedback handling intentions (i.e., reflective statements and formulation of a general vs. specific focus and/or a general vs. specific strategy) when prompted to react to team-level feedback. We are primarily interested in examining how students made judgments about their emotions and states relative to their team performance (self-evaluation), and what they perceived that they needed to do to improve future team performance (adaptive inferences) using microanalytic protocols (Cleary et al., 2012). This paper contributes to understanding in three related areas: nature of emotions following team-level feedback delivery; relationships between feedback valence, types of emotions and feedback cognitive processing; and team-level considerations of feedback processing.

Methods

Subject and setting

The participants (N = 111) were last-year business students attending a Performance Management course at a French university. This simulation-based course aimed to provide students with opportunities for practice of and reflection on instruments and techniques to track, monitor and communicate about the employee performance. Students were assigned to teams of five to complete team tasks. Over 3 days, they functioned as units of a fictitious company that produced folded paper flowers colored with felt-tip pens.

Intervention

We used microanalytic protocols, a type of structured interview, to access students' emotional and cognitive responses to feedback. They target students' beliefs and processes after engaging in well-defined tasks. We used two questions: (a) a self-evaluating question (i.e., You have just received customers' feedback on the product that your team has been crafting for the last two days. What was your immediate reaction to this feedback?) and a strategic planning question (i.e., Moving forward, how will you use this feedback to improve your team performance? Please be as specific as possible). We received 111 responses for Q1 and 82 responses for Q2.

Measures

To understand how students perceived their feedback, meaningful units of analysis (i.e., phrases, sentences or series of sentences), were hand-coded using two coding schemes to affective and cognitive dimensions of feedback perception: team reflexivity coding scheme, and the taxonomy of academic emotions. Authors collectively coded all responses using a joint codebook and reconciled disagreements via social moderation.

The team reflection coding scheme was adapted from Gabelica et al. (2014) to capture the degree to which team members engaged in three cognitive (reflective) behaviors. Each student response to Q1 was coded as 0 (absence of reflective behavior), 1 (evaluating or reviewing team performance and strategies), 2 (looking for alternatives), 3 (Making decisions). Please see Table 1 for behavior descriptions and examples from the data.

 © ISLS

To code emotions, we adapted the taxonomy of retrospective outcome emotions from Pekrun's (2006) using a combination of categorical (e.g., discrete categories such as anger, happiness), and dimensional (valence: positive or negative; activation: activating or deactivating) approaches to emotion measurement. When emotions of opposing valence (e.g., excitement and anxiety) were expressed by the same subject, they were coded as 'mixed emotions.' Each student response was hence coded as: (1) positive activating, (2) negative activating, (3) positive deactivating, (4) negative deactivating, or (5) mixed emotions. Another important aspect of this study was the examination of prospective self-regulatory processes or 'feed-forward' to adjust based on received feedback. Students' forethought response to feedback were coded using Cleary et al. (2012) microanalytic self-regulation coding schemes: (a) a general focus, (b) a specific focus, (c) a general strategy, (d) a specific strategy.

Results

The results of our team-level qualitative analyses show that members of high-performing teams predominantly express activating positive emotions when asked for their immediate reactions to feedback. Additionally, they provide little evidence of initial team reflection compared to members of low-performing teams that express more team reflexivity in the first place (Q1). However, it seems that when members of high-performing teams are asked to think about how to use their team feedback for enhancement purposes, they start processing it cognitively. When prompted to strategic planning, they predominantly state (general) strategies to act on feedback. This trend aligns with and extend results from individual-level research on feedback and emotions (e.g., Winstone & Carless, 2019). Though positive feedback can elicit positive emotions, it could concurrently reduce their motivation to invest future effort, more specifically when not prompted to cognitively process feedback.

Low-performing teams seem to show more complex patterns of feedback processing. Half of those teams express positive, activating emotions. There are no teams that express team reflexivity statements and negative emotions. Further, team reflexivity rather occurs in teams that have most members expressing positive emotions. Half of those teams already engage in cognitive thinking/processing of feedback at the first stage (Q1). However, after the second question that prompts team strategic planning, even teams expressing deactivating negative emotions state a focus and a strategy. Half of those teams even express a specific focus for their next team task. It appears that members of those teams resolved their negative emotions and moved on to cognitively assessing and integrating data from their feedback. Further, in contrast to high- and medium-performing teams, the individual network for low-performing teams show that (de-)activated negative emotions are linked to strategic planning comments. This indicates that generally, low-performing teams can harness the emotional impact of their negative team feedback and plan productive actions accordingly. We find more diverse trajectories for those teams. Some teams seem to show ability to separate emotional and rational responses to feedback and show striving for improvement; others jumped immediately to rational responses, while a few remained stuck at the emotional level of feedback reception. We could speculate that team members of low-performing teams that did not process feedback cognitively had difficulty determining what actions they should take based on feedback given by external customers (Winstone & Careless, 2019).

Conclusion

Our results align with and extends the broader literature on emotion and learning (Winstone & Carless, 2019) which has shown that the premises that negative emotions lead to detrimental outcomes while positive emotions fuel positive outcomes, are too simplistic to explain the effects of emotions on cognitive reactions in team feedback situations. We have rather shown that interplay between affective and cognitive reactions to different types of feedback can lead to differential behavioral responses to team feedback.

Student-Created Math Walks in Informal Learning Spaces

Candace Walkington, Saki Milton, Anthony Petrosino, Marc Sager
cwalkington@smu.edu, slmilton@smu.edu, apetrosino@mail.smu.edu, msager@mail.smu.edu
Southern Methodist University
Koshi Dhingra, talkSTEM Inc., koshi@talkstem.org

Abstract: Math walks are a form of inquiry learning where students can observe and create mathematical meaning from their everyday surroundings. Here we report on a study of 5th and 6th graders in an informal learning setting where they create and present their own math walks covering concepts of ratio, scale, and proportion. The students may have developed more positive attitudes towards math and were able to meaningfully engage with powerful math ideas.

Conceptual Framework

Much of the research in informal math learning has examined how people use math in their everyday life (e.g., Civil, 2007; Nunes, Schliemann, & Carraher, 1993; Walkington et al, 2014). There is a lack of research on math in designed informal learning environments (Pattison, Rubin, & Wright, 2017), although this is a growing area of interest (Mokros, 2006). Math walks, or "math trails" as they are sometimes called in the literature, are walks that learners go on to experience and bring out the mathematical properties of their surroundings – including art, architecture, and nature (e.g., English et al., 2010; Richardson, 2004). Math walks may trigger and maintain students' interest in learning mathematics (Hidi & Renninger, 2006), increase math ability beliefs (Perez-Felkner et al., 2017) and lower math anxiety (Bai, Wang, Pan, & Frey, 2009). They also may allow students to engage meaningfully with math concepts, including using problem-posing as students are engaged as the creators of their own math walks (Wang, Walkington, & Dhingra, 2021). Creating walk stops can be an "on ramp" to learning math concepts that begins with students' lived experiences. In the present study, we investigate the following research questions: How does experiencing and creating math walks stops allow learners to engage meaningfully with mathematical ideas? How does it impact their math interest, math ability beliefs, and math anxiety?

Method

The study took place at a Community Center with ten 5th and 6th grade students participating after school over 4 1-hour periods. Nine students identified as African-American and 1 as bi-racial, with 2 males and 8 females. The math walk lessons focused on issues of ratio, proportion, and scale, and was facilitated by two teachers who taught math at the school associated with the community center. Students first went on a math walk at the Community Center that had been co-constructed by students at the Center and researchers and video-recorded by a professional videographer, starring the students. Then they worked in groups of 3 to create their own math walk stop, using a process where they first would notice and make observations, then brainstorm different questions they could pose given their observations, and then choose one question to pursue. They would create the walk stop by taking and annotating pictures and giving a formal presentation of their stop to club members and other stakeholders. Students took previously-validated pre- and post-surveys measuring math interest, anxiety, and ability beliefs.

Results and Conclusion

Although none of the pre-/post differences reached statistical significance, effect sizes were examined given the small sample size and likely lack of appropriate power. Results suggest an increase in students' math interest (from 3.9 to 4.5 on a 5-point scale, $d = 0.75$), an increase in math ability beliefs (from 3.6 to 4.2 on a 5-point scale, $d = 0.60$), and a decrease in math anxiety (from 2.4 to 2.0 on a 5-point scale, $d = 0.46$). An examination of students' final presentations and their artifacts (Figure 1) revealed the novel and creative ways in which they were experiencing math in their surroundings. They engaged with issues of ratio in the dance room of the Center, posing questions about the size of the mirror versus the size of the floor. Another group examined how glue sticks could be used to create an informal measurement unit to better understand the size of a classroom at the Center. During their post-reflections, students highlighted how much they appreciated the collaboration and the freedom to select sites and mathematical ideas to focus on and explore. They also readily pointed out strengths of their peer's work. Math walks seemed to have immediate, positive impacts on kids' views of mathematics and the worlds, but an important question is how and whether this effect could be sustained. In current work, we are also examining video footage of student discussions. We are interested in the kinds of support it takes to move students to create more novel walk stops that differ substantially from the examples they saw in the professionally-made videos, and that more strongly express their personal mathematical curiosities as they interact with the world around them.

Managing Deference, Leadership, Vision, and Voice: Dilemmas from Antiracist School-University Partnerships

Nicole Louie, University of Wisconsin–Madison, nlouie@wisc.edu
Leema Berland, University of Wisconsin–Madison, leema.berland@wisc.edu

Over the past two years, our university-based team and leaders at two elementary schools have partnered to collaboratively design and instantiate antiracist school communities.[1] Our partnership with the first school, Eastwood, emerged from and evolved according to their needs, rather than following any explicit vision.[2] Over time, it became clear that our implicit visions for an antiracist school were not aligned. We approached the principal at the second school, Lawrence, with a firmer sense of what we were interested in working on together. She responded enthusiastically, and with a seemingly shared vision, we dove into partnership. But again, as time passed, we had difficulty holding to our vision. With this poster, we aim to engage conference participants in discussions about how to negotiate a shared vision in school-university partnerships, in the context of antiracist work in which competing visions and understandings are especially likely to present not only conceptual difficulties but also ethical, interpersonal, and deeply personal challenges. We give particular attention to negotiating the role of parents of color,[3] who are increasingly seen as essential players in antiracist school transformation but whom schools are rarely equipped to authentically engage as partners (Ishimaru, 2020).

A participatory approach to building antiracist school communities

Our approach to building antiracist school communities is rooted in two bodies of thought. First is scholarship emphasizing the cultural wealth, knowledge, and capital in communities of color (e.g., Yosso, 2005). Students and parents of color have intimate understandings of how "the school system is marginalizing, criminalizing, and otherwise failing our Black and Brown kids" (Oluo, 2019, p. 124). These understandings uniquely position them to resist oppressive systems with determination, joy, and hope, and to radically reimagine just and humanizing schooling. Their voices and perspectives are thus indispensable for efforts to advance antiracism in education.

We complement this asset-based, anti-deficit perspective on students and parents of color with scholarship outlining participatory methods for studying and enacting educational change toward justice (e.g., Bang & Vossoughi, 2016). This scholarship emphasizes the importance of dismantling typical hierarchies among students, parents, teachers, school administrators, and university researchers. Participants must learn to coordinate their varied knowledge, practices, perspectives, and goals to forge new ways of thinking, doing, and being. These new ways must support participants to learn with and from one another, across differences, rejecting the dehumanizing "racialized institutional scripts" that denigrate the knowledge, authority, and power of students and parents of color (Ishimaru, 2020, p. 121).

Taking a participatory approach to partnership implies that no party, including university researchers, should enter collaborative work seeking to impose their vision on others. We have instead attempted to build a shared vision with our partners. While we have found easy agreement around the goal of building antiracist school communities, what such communities are has proven to be slippery and abstract, and our efforts to collaboratively establish a more concrete vision—particularly with school principals, who have mediated our access to students, parents, and teachers—have been unsuccessful, as we describe below.

Eastwood: general agreement but misalignment on specifics

The majority of Eastwood's students are students of color. The staff, meanwhile, is 90% white. In the spring of 2019, Eastwood teachers and administrators asked for our support in their efforts to become an antiracist school community. That summer, members of our team led a six-day retreat, during which they pushed Eastwood principal Amy and other school staff (who attended on a voluntary basis) to acknowledge their own racist assumptions and to change rules for behavior in the school's hallways, which made the school feel prison-like. The following school year, Amy invited us to lead portions of the monthly meetings of the school-based leadership team (SBLT). We agreed, expecting to use that time to develop a shared vision of an antiracist school and pursue concrete plans for enacting that vision, with parents as full partners. But, as we worked together, it became clear that Amy did not share our expectations. For example, meeting time was often filled with Amy's priorities, which were shaped by district requests and mandates (e.g., the looming deadline for the mandatory school improvement plan). Furthermore, as the partnership continued, we realized that although we had come together around the general goal of building an antiracist learning community at Eastwood, we had specific misalignments which reflected different underlying conceptions of what an antiracist learning community was and how to build it. For example, the kind of collaboration with parents that we came to articulate as central to our work did not align with

 © ISLS

Amy's understanding of antiracist change, although she had been able to honestly agree with our initial vague statements about parents as partners. In particular, she seemed to prioritize what she called the "inner work" of "looking in the mirror and saying, I'm racist." Her understanding of this work did not seem to require interaction with families as much as internal reflection. Our point here is not to evaluate the merits of focusing on "inner work," but to observe that this focus got in the way of working with parents of color as partners in a meaningful way to change school policies, relationships, or instruction.

Lawrence: waiting to be "ready"

Lawrence was demographically similar to Eastwood, except for being significantly smaller. We began our partnership at Lawrence with some of the lessons we had learned at Eastwood in mind—namely, a need to begin with an explicit discussion of vision and the role of parents. This discussion was optimistic; as a small neighborhood school with most families living just a short walk away, Lawrence was well-positioned to bring parents in as partners. Further, principal Nadine made routine home visits, showing that she valued relationships with parents and families; she also identified developing stronger relationships between teachers and parents as an important area for growth, noting that many teachers were afraid of contacting parents and that these fears were likely racialized (given that most Lawrence teachers were white while most parents were not). But in subsequent months, each time we raised the idea of inviting parents to our meetings with faculty and staff, Nadine argued that faculty and staff weren't "ready." This may have been in part because of concerns we had discussed about the possible harm of bringing parents in only to have their experiences and concerns belittled (although some team members had also argued that parents of color were used to having that happen, and that we should manage this possibility in the moment rather than allow it to prevent us from engaging with parents and caregivers). Another concern Nadine repeatedly raised was that faculty and staff needed to work on their relationships with one another first, because if they did not feel comfortable having critical conversations amongst themselves, they could not be expected to have such conversations with parents. As the pandemic deepened and with it, teachers' isolation, this concern became increasingly salient for Nadine. Again, our purpose is not to evaluate its validity, but to note that it stopped us from bringing parents and caregivers into our partnership for more than a year.

Discussion and implications

At both Eastwood and Lawrence, the university team struggled to balance deference and leadership. On the one hand, we recognized that Amy, Nadine, and their colleagues were in their schools every day and had intimate knowledge of their students and staff. Consistent with our principles for collaboration, we wished to honor this knowledge. On the other hand, these same principles required us to press our partners to bring parents to the table, honoring *their* voices and building on *their* knowledge. This was not necessarily a problem; we saw pushing our school partners beyond their comfort zones as part of our role, and our partners valued that. However, we have spent more than a year at each school and still have yet to succeed in engaging parents in anything more than preliminary conversations about antiracist change at their children's schools.

Building knowledge about how to navigate the challenges we have described is absolutely essential if efforts to study and effect educational change are ever to center the voices and perspectives of parents of color, as participatory approaches to research and design suggest. More generally, better understanding how to democratically negotiate a shared vision is essential to many kinds of partnership in education. We look forward to discussing these issues with conference participants.

Endnotes

(1) Our team includes Carl Grant, Mariana Pacheco, Kathleen Nichols, and Laura Roeker, as well as the two of us.
(2) All names are pseudonyms.
(3) We use "parent" expansively, including any adult who takes caregiving responsibility for a child or children. We use "of color" to refer to people who identify as members of racially minoritized groups, including Black, Indigenous, Hispanic/Latina/o/x, and Asian Pacific Islander Desi Americans.

Teachers Noticing Student Interest: A Micro-interactional Foundation for Interest-driven learning

Dr. Emily Schindler, Dr. Kylie Peppler, UC-Irvine
eschind1@uci.edu, kpeppler@uci.edu

Abstract: This study shares a descriptive framework for noticing student interest, building on extensive scholarship in teacher education on Teacher Noticing. Scholarship presented here documents differences in educator narratives of student interest, which has implications for how they then go on to sponsor it in their immediate learning environment. The overall contribution of this work is a nascent framework for operationalizing educator noticing skills to support student interest.

Introduction

The concept of teacher noticing, or the awareness educators bring to features of student understanding, has been taken up heavily across the field of teacher education (as a resource for preservice and in-service teacher development, e.g. van Es & Sherin, 2008) and the learning sciences (see Walkoe & Luna, 2020, for a review and critique). However, as Russ (2018) points out, these efforts have concentrated on domain-specific constructs, like skill and conceptual development, and not as much on domain-general constructs, like interest. The guiding logic of teacher noticing holds that educators cannot appropriately respond and adapt to student understanding unless they first notice it.

Background

Van Es & Sherin (2002) theorize teacher noticing in three parts: identifying what's important, making connections between what's happening in the classroom and existing pedagogical knowledge, and reasoning within the given context. Following Russ's observation that teacher noticing literature often ignores domain-general constructs, like interest, we attempt to remedy this by building a descriptive framework showcasing what teacher noticing might look like. We argue that noticing student interest is the first step toward sponsorship of youth interests (Ito, et. al, 2020), and therefore warrants further examination.

Methods

We draw upon interview data with out-of-school educators collected as part of a program evaluation performed during the summer of 2021 in partnership with Design, Make, Learn, an arts nonprofit in Long Beach, CA. We adapted van Es & Sherin's (2002) framework to include noticing student interest, in line with a constructivist grounded approach (Charmaz, 2000). Following two rounds of grounded open coding, we matched educator stories of student interest with the emerging descriptive framework.

Data: Descriptive Framework for Noticing Learner Interest

Summary Table

Framework: Level of Expertise and Rationale	Educator Narrative of Noticing Student Interest	Analysis and Next Steps
Expert: Teacher stories are fully analytical, supporting their noticing with evidence, interpretation, and empathy.	**Frida:** So I was thinking that doing leaf prints would be fun. I just had them bring out paper and pencil and collect leaves. And we sat down here, you know, on the steps, and basically did leaf rubbings and talked about artists that came up with that kind of kind of art, you know, so like Max Ernst and all the Dada surrealists, so I talked a little bit about the historical context about that. Some students had never done [leaf rubbings] before so I thought it was interesting and then we went into "let's figure out what else makes a print?", so the kids tried dandelions--you know, the yellow? The dandelion or the grass [became options]... They tried dirt and soil and bark, random other leaves and flowers. [cut for length]	Frida's noticing story demonstrates d/Discourse of both interest and educator noticing. She begins by empathizing and projecting about student interest ("I was thinking that doing leaf prints would be fun"), which she uses as the foundation for her educational design. Then, she describes the embodied implementation/practice of the educational design. And, in the course of that implementation, she noticed youth interest in the materials, and how their use could be extended to meet the original design objectives (leaf-rubbings). This noticing results in collective exploration of new, ambient materials (dandelions, grass, dirt, soil, bark, leaves, and flowers) as (literally) organic extensions of the original learning objective.

 © ISLS

Proficient: Teacher stories call out student interest and support with corresponding evidence and interpretation, but may also judge these moments as "good or bad"	**Cesar:** ...we were using paint markers and lettering alphabets and tracing paper. We had a student...and he's like, this is something that my brother does, and then he got super into it. So I showed him all these different tools. And so [we were doing] old English lettering, which is like a big part of LA culture. But it really grew out of protest art and it was based on, you know, medieval lettering. So you know, that's all part of the discussion. But the thing is, it's so ingrained in the culture here that kids don't even know where it comes from. So he's just like, Oh, my brother does that. Let me learn what my brother does... it's one of those things where it's like, all I'm doing is serving your culture back to you.	Like Frida's story, Cesar's story shows a clear design intention for learning, evidenced by the choice of tool and activity as relevant to the historical/social context of implementation. Additionally, Cesar notices the youth's connection to their family as signaling interest, which he feeds for the student by situating the interest in history and immediate cultural uses ("...old English lettering is a big part of LA culture"). In this way, Cesar follows student interest to historically and socially contextualize the students existing knowledge and family practices as instrumental to domain-specific learning in art.
Intermediate: Teacher stories call out student interest, but lack "corresponding evidence or interpretations".	**Nathan:** We were doing an improv workshop for an organization that dealt with at-risk youth. ...there was one young man who started and he was literally kind of slumped back in the corner with his arms crossed the hoodie on.... And then the very last exercise we did was called, it's called freeze tag...So this young man came up and tagged one of the teachers and then stepped in and he started rapping. He just created this whole improv rap, that was a story... Just watching the progress of him, very quiet, individual to just being the center of attention.	Nathan identifies the activity itself as the source student interest, and is surprised (positively) when the student uses the activity to play to an area of individual strength (interest). Nathan is able to interpret student body language as dis-interest, and participation as interest. However, the introduction of interest-based student learning is happenstance, and largely due to the risk-taking of the student, which Nathan notices and appreciates, but does not elicit.
Novice: Teacher stories are predominantly descriptive, describe students becoming interested only, without rationale. There is little pedagogical response.	**Carter**: We had a concert, I played drums and [another teaching artist] was playing guitar and flute. And we had a bit of a performance at the end of the day, and this particular student. However, after that specific concert workshop, I remember he came up to me as like, 'oh, wow, that was really interesting. I'm kind of interested in like, learning how to play an instrument, or drums or something.'	Carter is able to identify student interest when they explicitly articulate it, but does not relate any plans to feed, broaden, or extend that interest. Additionally, Carter interprets student interest as activity-based (e.g, related to drumming), when it may actually be broader or more specific than that.

Discussion & Implications

Our analysis shows that van Es & Sherin's framework for teacher noticing can be usefully adapted to include noticing domain-general constructs, like interest. This work has several potential implications for educator learning. First, it is notable that this data on educator noticing comes from an out-of-school learning environment (a summer STEAM program), because an important extension of scholarship on teacher noticing would be to include pedagogies at work in informal environments. Second, this framework adaptation to a domain-general construct represents an important step forward for considering teacher noticing. Third, and most importantly, this framework opens a pathway into understanding how youth interest does or does not get noticed by educators, which we theorize as an essential first step to the sponsorship of youth interests.

AI Voice Tutor Usability Study: Understanding Impact on Math Self-Efficacy and Metacognition Among Middle Schoolers

Eunhye Grace Ko, Gen Marconette, Roza Atarod, Kaci Nguyen, Min Kyung Lee
eko@utexas.edu, gmarconette@utexas.edu, atarod@utexas.edu, kacinguyen@utexas.edu, minkyung.lee@austin.utexas.edu
The University of Texas at Austin

Abstract: We present CAI, a voice-based intelligent tutor that helps middle schoolers learn pre-algebra concepts. Users interact with CAI by solving math problems presented by the AI-tutor, each with a varied mode of narration and type of feedback. We describe the design, methods, and findings from our testing with middle schoolers. We provide insight into how voice-based intelligent tutors can impact motivation and metacognition, yet also require personalization and complementary video-based instruction to improve their performance.

1. Background

Previous research demonstrated discrepancies between human and AI-based tutoring systems in their granular feedback and their ability to target relevant and frequent student responses (Kolchinski et al., 2018). Our research aims to understand how designing a voice-based AI tutoring system might close the equity gap in accessing human tutors. Current online learning platforms offer video-based lessons, yet these are limited in interactivity. Thus, AI tutors can enhance learning by providing personalized feedback, adapting to student responses, and enhancing AI tutors' presence and motivational support among middle schoolers. We prototyped an AI-tutor named CAI to have two primary tone-based narrative styles and five types of instructional feedback. As a pilot study, we explored the research questions through user testing with five middle schoolers employing CAI: (1) What impact does an AI tutor's narrative styles (standard vs. motivational) have on middle schoolers' math self-efficacy and metacognition? Which style do they find more compelling? (2) What impact does an AI tutor's types of feedback have on middle schoolers' math self-efficacy and metacognition? Which type do they find more effective? (3) What are the techniques for designing features of an AI tutor?

2. Prototype design

We used Voiceflow, a conversational app prototyping tool, to prototype AI-tutor named CAI. Because the ability to learn through multiple channels concurrently increases the chance of remembering knowledge compared, we applied the cognitive theory of multimedia learning (Mayer et al. 1998). Accordingly, we integrated voice, text, and visuals to explain math concepts. For tasks, we created three scenarios employing a combination of two components: speech style and feedback type (Melis & Andres, 2005) (See Appendix A).

3. Methods

We conducted the usability testing with five middle schoolers based on convenience sampling—demographics in Appendix B. A demographic survey included questions on math self-efficacy. Following the survey, four pre-algebra math tasks were given; in each, CAI explained a pre-algebra mathematical topic followed by a question. All math concepts and questions were provided at a similar difficulty level. Based on the students' responses, CAI provided five types of instructional feedback: knowledge of result (KR), knowledge of correct result (KCR), answer until correct (AUC), instruction-based elaboration (IBE), and extra-instructional elaboration (EIE). Task 1 to 3 served as treatment conditions with differing AI-tutor's narrative styles and types of feedback; Task 4 served as a control condition where the students underwent a video-based instruction (Khan Academy) followed by a math question provided on Google Quiz form. After completing all tasks, the students took a post-experiment survey to provide feedback on the AI tutor's design features. An overview of the research is described in Table 1.

We conducted the Friedman test on motivation and metacognition. To add qualitative understanding, we analyzed each task's observation notes by color-coding and creating affinity diagrams. Furthermore, to analyze desirable design components for an AI-tutor system, we ran descriptive statistics for the post-experiment survey. For the post-experiment interview, open coding was followed by affinity diagrams of thematic elements.

Table 1.

An overview of the research design

Stage	Topics	Activity	Measurement

 © ISLS

Pre-experiment	N/A	An ice-breaker question on the preference of AI-tutor character	Pre-experiment survey on demographics, previous math learning experiences, and self-efficacy (7 questions)
Task 1.	Calculate the mean	AI tutor experience 1 (motivational narrative, feedback type 1: KR, AUC, EIE)	A post-task survey on usability (4 questions), motivation (5 questions), and metacognition (4 questions)
Task 2.	Find the median	AI tutor experience 2 (standard narrative, feedback type 2: Reflection time, KCR, IBE)	
Task 3.	Calculate percentage	AI tutor experience 3 (motivational narrative, feedback type 2: Reflection time, KCR, IBE)	
Task 4.	Calculate probability	Control task experience (google form with a quiz, combined with a video from Khan Academy)	
Post-experiment	N/A	Post-experiment interview	Post-experiment survey (4 questions)

4. Results

The testing highlights can be viewed here: videos 1 and video 2. For motivation, the Friedman test showed no significant result. In the qualitative analysis, we found four main themes: (a) metacognition, (b) motivational moments, including persistence and resistance to learning, (c) learning process, (d) CAI's positive and negative performance. Motivational moments were observed in all four tasks, and persistence in learning was most salient in Task 1. As Task 1 included AUC feedback, students were given a choice to take multiple attempts, and all took multiple attempts. For metacognition, the Friedman test was not statistically significant. However, in descriptive statistics, we found that AI-tutor conditions had a more significant impact on metacognition than the control. The observation data revealed that metacognition was more frequently observed in AI-tutor conditions (T1=28.1%, T2=34.6%, T3=29.2%) than the video-based (20%). In Task 2, students showed metacognition most frequently and two students attempted to fill in the knowledge gap by scrolling up to the explanation.

A few design implications were found. For narration, three participants preferred the motivational narrative. For feedback type, four identified instruction-based elaboration as the most effective. It provided information on "what to do to get the correct answer" and guided them with a formula that "makes it easier to solve problems." In the post-experiment survey, they thought the AI-tutor was helpful in terms of pacing learning (M = 4.4, SD=0.55), explaining solutions (M = 4.4, SD=0.55), and providing feedback when they got questions wrong (M = 3.8, SD=1.79). Regarding the positionality of AI-tutor in comparison to video-based instruction and human tutors, they rated 2.8 (SD = 1.30) for CAI's similarity with human tutors and 3.4 (SD = 1.14) for whether they learned better compared to video-based instruction. In the interviews, the pros of AI-tutors included the opportunity to ask questions, interact, and receive feedback based on progress. In contrast, what was found to be a deficit in AI-tutors (the limitations of speech recognition) was found to be a pro in video-based instruction.

5. Discussion

The findings revealed that the video-based instruction and CAI provided complementary benefits rather than counteracted. As a pilot study, we discuss two main issues for prototype redesign. (1) Personalization of AI-tutor: This study showed high variance between the participants in motivation and metacognition, reflecting individual students' confidence, math ability, and preference. User control over personalized AI configuration is suggested: allowing users to control the speech rate, tone, pause time, as well as AI's involvement level and intervention frequency. (2) Strengthening AI-tutor's impact on metacognition: With reflection time and instruction-based elaboration feedback, students showed improved metacognition. They also indicated that an AI-tutor's respect for learning pace and explanations of solutions to be effective. Additionally, we found potential in AI tutors' "non-judgmental" support in learning math. Thus, AI-tutor redesign should define and validate design features that affect metacognition. The study's limitations were the sample size, short experiment time, and students' attention span. As we confirmed methodologies, we aim to address the limitations with a larger sample in future.

Learning in Your Own Direction: Examining Relationships Between Non-Sequential User Choice and Learning

Ethan P. Valentine, Minot State University, ethan.valentine@minotstateu.edu

Abstract: This study sought to address an aspect of learner control known as non-sequential user choice. Leveraging open driver education resources, this research explored how learners' chosen learning sequences and the time they spend with each learning resource relate to performance on an assessment of learning. The study examined learning outcomes for subjects with free choice over learning sequence based on time spent and chosen sequence. Analyses yielded a significant regression model and raise the possibility that time spent and chosen order may be able to predict performance.

Introduction

The open learning movement has grown significantly in recent years as a result of work in both the public and private sectors. Inherent in the open learning movement is the notion of choice-based learning: that is, that learners can and should be given substantial control over their learning processes. Unfortunately, significant gaps remain in the research literature examining the effects of giving learners extensive control, particularly with regard to learners' control over the sequence of the learning process (Koseoglu & Bozkurt, 2018).

Background

Non-sequential user choice is defined as the ability for individual learners to use a set of learning materials in a non-linear fashion (Chou, 2003). Existing research has found mixed effects of this type of choice. For instance, Taub et al. (2020) found that a moderate amount of choice led to larger learning gains than high- and low-choice conditions, while Nebel et al. (2016) found motivational benefits but not improved learning gains. The present research seeks to further explore this issue, with a focus on the effect of users' specific choices and pacing.

Methods

Materials and data sources

The open learning materials used for this study were developed to target specific gaps in drivers' knowledge of advanced car safety systems as identified by McDonald et al. (2016), and leverage the mental model-oriented design framework from Beggiato & Krems (2013). They are divided into three main sections focused on Adaptive Cruise Control (ACC): Understand, Challenge, and Play.

Participants & Study Procedures

42 college undergraduates were recruited via mass email and tasked with learning about ACC. Only individuals who were familiar with conventional cruise control but *unfamiliar* with ACC were included in the present study. Participants were required to use all three learning resources, but were able to choose the order in which they interacted with them, as well as their pacing. The order in which the resources were listed on the choice screen was counterbalanced. After choosing a resource, participants could interact with it for as long as they wished. Following engagement with all three resources, participants' knowledge of ACC was assessed using a post-test assessment developed by Valentine et al. (2018) for this set of learning materials.

Analysis

Post-test scores were calculated for each subject, and those scores were used as the outcome variable in a multiple linear regression analysis (alpha = .05). The regression analysis involved four predictor variables: chosen order, time on the Understand resource, time using the Challenge resource, and time spent with the Play resource.

Results

Descriptive statistics

The large majority (36/42) of the participants chose to use the Understand (U) resource first. Of the remaining six subjects, four chose to use the Play (P) simulation first (P,U,C), and two chose to solve the Challenge (C) problems first (C,U,P). Subjects who chose Order 1 (U,C,P) scored slightly lower on the post-test (M = 11.35)

 © ISLS

than did those who chose Orders 2 (U,P,C), 4 (C,U,P), or 5 (P,U,C; M = 13.00, 13.75, and 13.375, respectively), but these mean differences were not tested for significance due to the small number of subjects in each order. Orders 3 (C,P,U) and 6 (P,C,U) were not chosen by any participants. Participants spent far more time using the Play (M = 635.02s) and Challenge (M = 467.02s) resources than the Understand resource (M = 106.74s).

Regression analysis

The multiple linear regression analysis found a significant regression equation ($F(4,37) = 3.930$, $p < .05$) with an R^2 of 0.298, indicating that order and timing variables predict a significant proportion of the variation in post-test score in this sample. Participants' predicted post-test score is equal to 8.745 + .002a -.002b + .023c +.446d, where Challenge time is coded as *a*, Play time as *b*, Understand time as *c*, and chosen order as *d*. Although the overall model was significant, Understand time was the only individually significant predictor of post-test score.

Discussion

Non-significance of chosen order

The present research sought to examine the relationships among chosen learning sequence, time spent on learning, and performance on an assessment of learning. The results indicate that timing and chosen sequence can be used to predict post-test score, but time spent on the Understand resource was the only individually significant predictor. Surprisingly, chosen learning sequence was not an individually significant predictor of post-test scores.

One possible explanation is the homogeneity of learning sequences chosen by study subjects. As a result of this homogeneity, it becomes much more difficult to detect any significant predictive value of chosen order. The descriptive statistics point to the possibility that choice homogeneity obscured an effect, with learners who chose Order 1 (U,C,P) scoring lower overall on the post-test assessment. This suggests that Order 1 could represent a poor choice of sequence and that participants may be performing worse on the post-test as a result.

Potential significance & future research

These findings present an intriguing extension upon previous research by Bamberger and Tal (2005) and Taub et al. (2020). Namely, that previous work suggests that the *provision* of choice matters in learners' performance, while the present research indicates that the specific choices learners *make* in those situations may not be crucial.

Although chosen order was not found to be an individually significant predictor of post-test performance, descriptive statistics suggest that its influence may have been obscured by the homogeneity of participants' sequential choices. Studies with a larger sample size or forced sequencing may be better equipped to investigate the effects of specific learning sequences, as well other types of choice, varied levels of choice guidance, and different learning contexts/materials.

Makerland: Mathematics in Makerspace resources to enhance Maker-based Learning

Charles Soares Pimentel, FabLearn Fellow, Universidade Federal do Rio de Janeiro, pimentelufrj@gmail.com

Abstract: This work investigates the Math concepts that are applied when using the resources of a Makerspace. The research highlights Math concepts that are usually employed throughout the modeling, prototyping and production processes. An exploratory study was conducted on a Brazilian high school, and the results indicate that students can identify the Math concepts and that the systematization of these subjects can be used as a learning object.

Introduction

Recent studies show that different factors lead students to have poor performance in Mathematics. Ziegler & Loos (2017) indicate that the difficulty that students have in their learning is related to the lack of connection of the subjects covered at school with the real world. Niss and colleagues (2017) point out that the need for Mathematics to be taught within a functional context has been the basis of educational reforms in some countries.

To collaborate with this discussion, this paper seeks to relate Mathematics in the Makerspace resources with the Mathland metaphor presented by Seymou Papert (2020), that compares the Math language learning process with the way a person learns French when growing up in France. Thus, inspired by the term coined by Papert, this work presents the Makerland metaphor, when considering that the Makerspace and its resources are elements to enhance the learning of Math concepts while students develop their projects.

Based on this reflection, two complementary points in the prototyping of learning objects stand out. The first is the development of projects that aim at the explicit application of Math concepts. These projects are related to the production of resources that aim the learning of the subject during the planning, execution and presentation stages. The second point is the learning of Math concepts in the use of Makerspace resources during the prototyping and production process. In the Laser Cutter, for example, the relationship between the speed of the equipment while cutting a resource and the laser power, as relationships between variables and Cartesian coordinates, are usually applied. This paper discusses this second point.

Theoretical foundation

Considering the great advance of new information and communication technologies, Seymour Papert's theory of learning, Constructionism, stands out. The theory is based on Piaget's Constructivism and highlights that learning happens more effectively when students are co-authors of their own knowledge and share it with their peers (Blikstein, 2008). The constructionist learning theory was forged on the exploration and teaching of Math concepts through technological resources and contributed to point out a new path for Math Education.

Thus, the Logo Language was created by Papert's research group for a teaching process where students and educators are learners, and everyone learns from their mistakes (Papert, 2020). Similarly, the Makerspace's prototyping resources also provide for the creation of Microworlds (Papert, 2020) for learning Mathematics. In this sense, Maker-based Learning helps learners deal with unexpected problems for which there are no pre-established explanations, acquiring the necessary skills to participate in the construction of new skills (Gavassa, 2020).

So, when it comes to Math Education in Brazil, the country has undergone significant reforms. In 2018, the Brazilian Ministry of Education approved the Common National Curricula Base (CNCB – BNCC in Portuguese), a document that defines the essential knowledge that all K-12 students have the right to learn. In the field *Mathematics and its technologies*, the BNCC conceptualizes the subject as:

> "Human science, the result of the needs and concerns of different cultures [...] and a living science, which contributes to solving scientific and technological problems and to underpin discoveries and constructions, including impacts on the world of work". (BRASIL, 2018, p. 267)

In the Brazilian reality, the Mathematics subject is organized into 5 Thematic Units (TU). They are: (i) Numbers: developing skills related to numerical thinking; (ii) Algebraic Thinking: identifying the dependency relationship between two quantities; (iii) Geometric Thinking: interpreting and moving a figure on the Cartesian plane; (iv) Quantities and Measures: building and expanding the notion of measure by studying different quantities; (v) Probability and Statistics: building sample space for equiprobable events.

In addition, the CNCB also includes Computational Thinking (CT) in the scope of Mathematics. The CT is an approach used to carry out thinking processes and can be applied in areas of knowledge that go beyond Computer Science.

 © ISLS

Methods

An exploratory study was conducted with 21 students, users of Makerspace, from a high school in a state capital in Brazil. A questionnaire was designed for this study by observing the routine of students when prototyping their projects in the Makerspace. The first questions in the questionnaire investigated how much students perceived the use of Math concepts in the Makerspace, and at which stage of project development their use was noticed. The remaining questions related to a preliminary study, which identified the main Mathematics issues that are explored during the use of resources in the Makerspace. These subjects were organized in Thematic Units.

Collected Data and Discussion

The responses from the questionnaire revealed important insights into the interaction of students in the Makerspace using Math concepts. 57.1% of students indicated the most important equipment for their projects is the Laser Cutter, followed by Low Tech Resources, 3D Printer and finally Robotics & Automation. Regarding the perception of the use of Mathematics in the process of carrying out projects, 57.1% stated that its use is very frequent and 19% reported that it was only frequent.

Regarding in which stage (Modeling and/or Production) students noted the greatest use of Math concepts, 61.9% of respondents said that for them in both stages Mathematics is used, and 38.1% said that during Modeling stage only. Finally, Table 1 shows which Math concepts students perceived being explored while using Makerspace resources, according to the organization of the scope of the subject in Brazil.

Table 1

Math concepts that students perceives being explored in each resource

	Laser Cutter	3D Printer	Robotics & Automation	Low Tech Resources
Numbers	6.8%	5.7%	6.7%	3.7%
Algebraic Thinking	23.8%	19.7%	15.6%	6.2%
Geometric Thinking	16.0%	13.9%	15.6%	19.8%
Quantities and Measures	31.6%	37.7%	28.9%	40.7%
Computational Thinking	21.8%	23.0%	33.3%	26.9%

The table indicates students understand that Quantities and Measures is the most used TU in Modeling, Prototyping and Execution processes. This result points to the perception of the importance of this TU when dealing with material resources, which require calculations related to measurement units.

Conclusions

This study sought to analyze the relationship between the application of Math concepts and the resources available in the Makerspace, from equipment to software. The application and analysis of the questionnaire pointed to the relationship between the Mathland metaphor and the proposal of a Makerland where resources used in the Makerspace are Microworlds and topics related to Mathematics are naturally explored.

The students identified the use of Math concepts during the Modeling, Prototyping and Production processes and their perceptions aligned with what was identified in the preliminary study. Next steps of this study include systematically organizing these issues so that they can be explored in an objective way when students carry out projects in the Makerspace, so that assessment and evaluation can take into account what is applied and learned during the prototyping process.

Viviendo Aquí: Designing for Transformative Agency through Museum Exhibit Curation with Latinx Youth

Kristina M. Stamatis, University of Nebraska Omaha, kstamatis@unomaha.edu
Joseph L. Polman, University of Colorado Boulder, joseph.polman@colorado.edu
Jose Rogelio Manriquez-Hernandez, University of Colorado Boulder, jose.manriquezhernandez@colorado.edu
Emily Zinn, Museum of Boulder, emily@museumofboulder.com

Abstract: This paper showcases preliminary research on the process of curating a museum exhibit with Latinx youth. During the 2020-2021 school year, a group of Latinx teenagers developed an exhibit with a local museum. They reported feeling excited to see themselves and their stories represented in their mostly white community. This paper explores preliminary analysis of their engagement with the museum project and the potential community curation holds for disrupting whiteness perpetuated in public spaces.

Introduction

Community curation has emerged as a common practice for museums working to engage community members in the interpretation and storying of artifacts. However, the boundaries of museum curation and the communities that curation is meant to reflect raises questions about the relationships between communities, artifacts, and curators, particularly when the stories being curated center issues of justice (Black, 2010). This paper showcases preliminary research on the collaborative curation of a museum exhibit to showcase the lives and stories of Latinx youth. Viviendo Aquí which took place over the 2020-2021 school year, included a series of 14 workshops where youth designed and curated a museum exhibit featured at a U.S. mountain-west museum. Youth participants engaged in conceptualizing, planning, and designing the Viviendo Aquí museum exhibit. Our research included: How do activities engaging youth in exhibit curation afford opportunities for transformative agency? How do youth use material, relational and ideational resources? What hybrid practices were developed and what opportunities did those provide for reconfiguring power relations within the museum and the community?

Background

For this study, we drew on notions from sociocultural, cultural-historical, and practice theory to begin interpreting boundary work of community curators. We understand youth participants as experts in distinct communities of practice with boundaries that contrast those of historically white institutions. Youth became agentic actors who drove expansive learning (Engeström, 2001). To make sense of the trajectories of identification and participation (Polman, 2012) of those involved in curation boundary work, we adapted Nasir and Cooks' (2009) framework of material, relational, and ideational resources. We examined how resources act as mediational means, influencing identifications and participation of youth and educators in this context (Polman, 2006; Wertsch, 1998).

Methods

Drawing from participatory, community-based research, the Viviend Aquí exhibit took place in three phases over the 2020-2021 school year during the COVID-19 pandemic. Viviendo Aquí was designed as a series of 12 two-hour workshops that were held in a hyflex environment that took place both person and online depending on the constraints presented by the pandemic. A core design group of three teenage co-designers collaborated with one undergraduate research assistant, two university researchers and one museum educator to design the exhibit. 41 middle and high school students participated in the final phases of the project. All youth participants and the undergraduate researcher were bilingual and identified as Latinx, Chicano, Mexican, and Mexican American. The final exhibit was displayed from April to June of 2021 and drew more than 1,500 visitors. Researchers collected audio recordings, artifacts, and interviews and used ethnographic approaches to establish themes across the data.

Findings

Initially, the researchers, museum educator, and teen designers met to understand the museum context and co-design workshops that would engage additional youth participants. Throughout workshop sessions the designers developed ideas to support participants in telling their stories. The design team questioned the histories of museum practices and defined the questions the exhibit would address. Participants and their families were invited to the exhibit on its opening night (see Figure 1). Below, we describe one boundary practice youth added to the exhibit design to leverage their own material, relational, and ideational resources within the museum context.

 © ISLS

Figure 1
Museum Exhibit and Shadow Box

In the first weeks of their engagement with the exhibit, the design team decided to focus on supporting youth participants to tell the "stories of their lives and cultures" in the mountain west. As they engaged in storytelling, the youth voted to focus on "stories of the senses—stories that focused on taste, touch, smell, sights, and sounds"—that they felt defined and represented their experiences across the localities where they had lived, learned, and engaged with family and friends. While these sensory stories led them to design potential exhibits around food, clothing, music, and family gatherings, the design team eventually recognized that they wanted to engage more deeply with the materiality of museum exhibits. Due to the pandemic, the museum's archives and makerspaces were closed to visitors, which meant that participants had fewer opportunities to engage in traditional museum design practices. However, these barriers meant that designers were offered more opportunities to bring in their own ideas for engaging in building their exhibit.

The design team engaged in conversations about the colonizing practices of museums. To disrupt these practices, Teyo, a teen designer, suggested using shadow boxes to allow participants to "tell their stories." The shadow boxes, which had not before been used in exhibits at the museum, featured materials that participants collected or made and offered youth opportunities to represent their ideational resources—their cultural identities, stories, and relationships—and take on roles as designers. For example, Figure 1 illustrates the ways that Leigha, a high school participant, chose to share the story of her family's immigration. She explained, "I was born in Durango, Mexico; my parents, my sister and I came to the U.S when I was 4 years old. The scorpion represents where I come from…Durango is known as the 'land of the scorpions.'" The shadow box acted as her own miniature museum in which she leveraged material resources to depict cultural and familial identities. She went on to explain that she chose the paper cutouts to represent her family members because it was a way to "show how we're so close." Connecting these figures acted as a means of representing her family's bond, one that was forged both through the hardships they faced when immigrating to the U.S. and through their love of their culture and the mountains that characterized home in both Mexico and in the U.S.

Significance

Expansive learning is characterized by transformation (e.g., Engeström, 2001). By learning about museum curatorial practices and then disrupting those practices to build new boundary practices defined by their own material, relational and ideational means, the youth who participated in Viviendo Aquí were able to reconfigure what it meant to be a museum curator. As Ana, one of the youth designers explained, "I felt like a designer … we can show other people that we, the Latinx community, doesn't struggle all the time. We also have our culture that's very important to us." As Nasir and Cooks (2009) suggest, when youth have opportunities to engage the multitude of resources embedded in their cultural identities, they can leverage their identities toward more expansive and agentic forms of learning and representation.

Training a text classification algorithm to predict the presence of dispositions and learning shifts in students' self-reflection

Tessa Forshaw, Harvard University, tforshaw@fas.harvard.edu
Maureen Carroll, Stanford University, carrollm@stanford.edu
Carissa Carter, Stanford University, carissa@dschool.stanford.edu

Abstract: The body of literature on how to best leverage learning analytics to measure students' acquisition of 21st-century dispositional skills is in emergent stages. This project, based on over 800 student self-reflections, leverages natural language processing and qualitative data analysis to attempt to train a text classification algorithm to predict the presence of dispositions and learning shifts in students' self- reflection.

Rationale For The Algorithm

Society is facing an increasingly uncertain, turbulent, and changing world. The needs of the 21st century are different, and institutions, schools, and academics are building models of a 21st-century future that focuses on the soft skills and dispositions needed to thrive (Dede, 2010). This impacts educational researchers, who challenge us to rethink what we are teaching and what we are measuring so that we can support students as they confront the challenges and opportunities before them.

Stanford University's Hasso Plattner Institute of Design (the d.school) focuses on a similar direction. In 2016 the d.school conceived of eight design abilities essential to enabling students to thrive, persevere, enact change and take risks in the uncertain and changing world (Carter, 2016). These eight design abilities are both a theoretical frame and central to the pedagogical practices enacted in d.school classes.

Yet, measuring student learning of 21st-century skills and dispositional abilities can be very challenging, especially at scale (Dede, 2010), and metacognitive practices such as self-reflection or thinking routines are a commonly cited methods (Richhart, Church, & Morrison, 2011). Fortunately, emerging learning analytic techniques such as applied natural language processing and machine learning text classification can automate the analysis of a large corpus of student data in natural human language (Martin & Sherin, 2013)

This poster describes a formative study of qualitatively coded student self-reflections from d.school classes between 2018 and 2021. These reflections were used to train an Auto ML Text Classification algorithm to identify self-reflections that demonstrate the d.school design abilities and other shifts in learning.

Creating The Algorithm

In 2018 the Teaching and Learning team at the d.school instituted an effort to make their students' thinking visible. They leveraged a Making Thinking Visible thinking routine from the Project Zero Lab at Harvard Graduate School of Education (Richhart, Church, & Morrison 2011). The thinking routine, I Used To Think… Now I think… is a routine for reflecting on how and why students' thinking has changed. Students are prompted to reflect on their d.school class and write a response using each sentence prompts: "I used to think…" and "Now, I think…" Approximately 40% of the classes participated. Within those classes, compliance varied between 50-and 70%. Seven hundred fifty-two total statements were collected between 2018 and 2021.

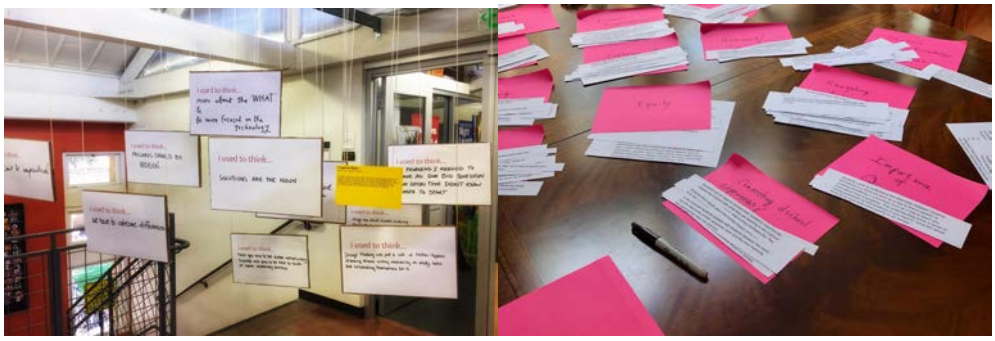

Figure 1: Photos of I Used to Think, but Now I Think statements. *Left: Worksheets on display at a community event. Right: Statement classification according to grounded theory code.*

The research team coded the statements using inductive and deductive approaches and used an inductive and grounded theory approach. First, each reflection was read to capture a sense of the response. Next, the data

 © ISLS

was synthesized into initial categories: agency, creativity, purpose, failure, ambiguity, and collaboration. The themes shifted as statements were added to the data set each year. Finally, five grounded theory-informed codes emerged: Changes in Mindsets and Worldview, Changes in Knowledge and Tools, Changes in the World, Changes in Perspective, and Personal Change. Additionally, 752 statements were coded using a deductive approach aligned to the eight d.school design abilities.

The 752 statements were used to train a Google Cloud AutoML Custom Text Classification algorithm. Auto ML uses a machine-learning algorithm built via neural architecture search to analyze the meaning, structure, and sentiment of natural language data. It allowed for creating a supervised learning, multi-label text classification model. After importing the dataset, Google Cloud validated it and conducted a series of quality checks. The tool randomly withheld 20% of the data to utilize 10% for validation and 10% for testing. Once the dataset was validated and imported, the data was initiated to start training the model, and then its strength was evaluated, and it was manually trained to hone precision. An additional 82 student self-reflection statements were used to test the model against d.school educator predictions.

The AutoML Custom Text Classification algorithm was selected after experimenting with other Natural Language Processing tools. AutoML leverages Neural Architecture Search to build the custom model by automating the design of neural networks. This allows for greater precision than the research team's ML skills might otherwise have enabled.

Learning From The Algorithm

Initially, the research goal was to understand two things: (1) can qualitative coding of student self-reflections be used to train supervised classification algorithms to predict the presence of the design abilities and learning shifts in students' self-reflections? and (2) does training the classification algorithm result in alignment between what the supervised classification algorithms predict in student self-reflection and what educators predict?

Preliminary results for this research indicate that the answer is “yes” to both of these research questions. Qualitative coding can be used to teach text classification algorithms to identify the eight design abilities and other learning shifts in student self-reflection. The average precision of the model is 0.876, although there is variance in the precision for each of the individual classifiers. This high average precision (*1 is the highest*) suggests that the model largely predicts what d.school educators predicted in the training data.

Additionally, the algorithm highlighted at a 95% confidence threshold that many of the 13 classifiers had very high prediction accuracy but also a reasonable rate of false negatives. Meaning that when the algorithm says a classifier is present, it likely is, but it may well be when it says it isn’t present. This finding suggests that our mental model of what a classifier indicates may be too varied and inconsistent.

This is a work in progress and an ongoing body of work. Nevertheless, this small study indicates that text classification has a role in research and shows promise in assessing 21st-century abilities and dispositions. The next steps in the study include (1) assessing the inter-rater reliability between the algorithm predictions and the parallel teacher evaluations by measuring Cohen’s kappa. (2) determining if the algorithm can continue to reasonably predict the presence of classifiers in unstructured student self-reflection, and (3) exploring how researchers can refine their mental model of a qualitative code through analysis of algorithmic decisions.

Inquiry of (Re)configurings: Toward a Review of Posthumanist Methods for the Study of Learning

Anna Keune, Technical University of Munich, anna.keune@tum.de
Paulina Ruiz-Cabello, University of Bristol, paulina.ruizcabello@bristol.ac.uk

Abstract: Educational researchers are increasingly adopting posthumanist approaches, questioning methodological assumptions toward the study of learning. Yet, it remains under documented how researchers align methodological doing to this aim. The present poster presents two studies that employed posthumanist perspectives and how they led to think methodologically with theory. The paper points to the need for a systematic review of posthumanist methodological approaches and decisions for the study of learning.

Introduction and background

Scholars across fields of educational research are increasingly adopting posthumanist perspectives (e.g., Kuby & Rowsell, 2017), claiming more recently for the need to articulate how these perspectives contribute to studying learning (Peppler et al., 2020). Posthumanism proposes a notion of social life and, therefore, of learning that decenters the human to attune to the inextricable connection between people and the physical world. To decenter people, research methods become "(re)configurings of the world" (Barad, 2003, p.816; sic): performative entities of the research process that make and remake the world. The tools and approaches for viewing aspects of the world actively contribute to what the world becomes both socio-historically and ontologically (Barad, 2003).

However, the reconfigurations that researchers and methods undergo in the process of aligning methodological doing toward the study of learning with posthumanist perspectives remains under documented. Following Sørensen's (2009) call to inquire about methodological shifts that posthumanist perspectives require, we asked: *How do methods align with posthumanist perspectives? What do they allow to capture?*

We drew on two of our own studies and analyzed how participant observation and video data analysis were reconfigured when applying a posthumanist lens. First, we examine participant observations and field notes around the informal presence and use of 15-16 years-olds' mobile phones in two high schools in Chile as a complex relational production space. Then, we turn to an inquiry that aligned video-based research to move toward flattening power relations between humans and non-humans in the context of computational crafting. Both studies provide insights into methodological reconfiguring based on posthumanist perspectives, such as considering human and non-human practices, and changing the *point of* view by filming from above. Our analysis points to the need for a systematic review of posthumanist methodological approaches for studying learning.

Methods

We selected two studies for analysis that were part of our own research because we have deep understanding of their methods evolution. The first study was the *mobile phones in schools* project, an ethnographic study in two stated-funded schools in Chile examining the negotiation process of 10th-grade students' phone use in school. Posthumanist perspectives informed tracing of how people, phones, discourses, and identities played a role in phone use and negotiations. The second study was the *computational crafting* project, which investigated fiber crafts as a context for computational learning in a middle school context. Posthumanist perspectives informed the data collection and analysis to highlight relational reconfigurations of people and craft materials that produced opportunities for computational learning. We analyzed how the studies looked for relationality, integrated researchers' points of views, and flattened movements to gain an understanding of how important aspects of posthumanist theoretical orientations informed methodological understanding of studying learning.

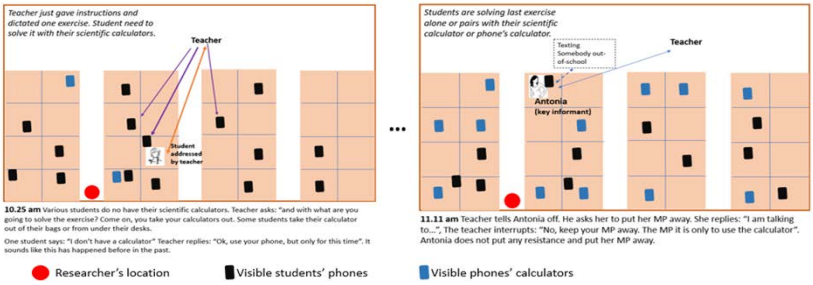
Findings

Mobile phone in school used a relational and socio-material approach (Burnett et al., 2012), in which phones were part of entanglements of positional identities, practices, objects, and discourses. The theoretical commitments led to field notes on what occurred *within* and *throughout* the phones' physical presence in the classroom, with teachers, peers, and objects (i.e., textbooks and calculators) in classes, and peers and parents outside of them. The theory guided focusing on relationships and connections of phone use within and across the classroom. students were invited to bring their phones into subsequent interviews to talk about and recreate observed practices. Preliminary analysis of observations during fieldwork (Figure 1) pointed to the complexity of relationships and identification of events, which then were further co-analyzed with students and teachers. That analysis showed that phones had a key role in how classes were being organized and how students were (dis)engaging in classes.

 © ISLS

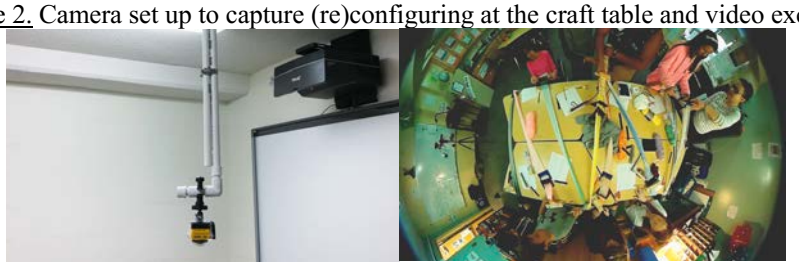
For instance, the phones acted as an entertainment source to ease self-declared moments of frustration, or as a substitute for non-existent educational tools in the study classrooms. The visual analysis (Figure 1) also pointed to negotiation and emerging practices that were *initiated* by the phones *themselves.* The relational and posthumanist perspective traced the emergent *discursive-materiality* (Barad, 2003) of the phone as a personal object, a communication device, and a contested educational tool.

Figure 1. Visual analysis of observational data with field notes (excerpts) in school 1, Chemistry class.



Computational crafting aligned with the Baradian (2003) notion of (re)configurings of relationships of people and things. Video data recorded the craft table from a birds-eye-view angle, showing what people and materials did to each other as they came together to shape opportunities for domain learning (Figure 2). The data analysis looked at patterned coming together of people and materials that produced computational moments. For instance, in weaving loom-youth movements produced conditional statements one dimension at a time: youth drew the threads of the loom vertically in space (either up or down) and paired this movement with a horizontal movement as they moved their yarn across the loom from left to right or from right to left. The study analyzed (re)configurings of the patterns and what happened when repetitions broke down. While youth called them mistakes, a human-centered reading that assumes a deficit notion, the analysis showed that (re)configurings physically expanded computational possibilities (e.g., including a range of additional pairings of loom-youth movements).

Figure 2. Camera set up to capture (re)configuring at the craft table and video excerpt.



Discussion

The posthumanist methods that we analyzed looked for relationality (e.g., human and non-human practices within the classroom), integrated researchers' points of views (e.g., changing the research process on the fly), and flattened movements (e.g., filming from above). A posthumanist lens made it possible to reframe deficit orientations into generative opportunities for learning. This study suggests the need for a more in-depth review of researchers' experiences and decisions across the wide range of posthumanist educational research.

Abstract: Computational thinking (CT) is ubiquitous in modern science, yet rarely integrated at the elementary school level. Moreover, access to computer science education at the PK-12 level is inequitably distributed. We believe that access to CT must be available earlier and implemented with the support of an equitable pedagogical framework. Our poster will describe our Accessible Computational Thinking (ACT) research project exploring professional development with elementary teachers on integrating computational thinking with Culturally Responsive Teaching practices.

Computational thinking (CT) is ubiquitous in modern science, as scientists work with ever larger and more complicated data sets and turn to algorithms and computer programming to sort and analyze data more effectively (Restuccia et al., 2017). Despite its importance, the explicit teaching of CT and computer science concepts in PK-12 schools is typically only accessible through foundational computer programming classes that are not offered until high school and are offered in schools that primarily serve affluent students (Code.org et al., 2021). Meanwhile, research suggests that computing should be integrated into curricula earlier and more widely: elementary schools serve all students and so can be important spaces to increase student interest, identity, and capacity in computer science (Code.org et al., 2021). Given this and how integral CT is to modern science, we argue that CT should be integrated into elementary science education.

We believe that integrating CT into elementary science education requires attending to equity. White men are significantly overrepresented in most STEM fields, especially in computer science, engineering, and the natural sciences (Fry et al., 2021). This lack of diversity has consequences for scientific and societal progress; for example, the underrepresentation of women and Black, Latino/a/x, and Native American (BLNA) people in computing leads to the development of biased algorithms that reproduce societal inequities (Noble, 2018). Moreover, access to computer science education at the PK-12 level is inequitably distributed, with BLNA students and students who are eligible for the National School Lunch program having the lowest access to computer science courses (Simoni, et al., 2016).

Therefore, we believe that access to CT in science education must be available earlier, more broadly, and implemented with the support of a pedagogical framework specifically targeted towards equity. Various frameworks—such as Culturally Relevant Pedagogy (Ladson-Billings, 1995), Culturally Responsive Teaching (Gay, 2002), Culturally Sustaining Pedagogy (Alim et al., 2020), and Culturally Responsive Computing (Madkins et al., 2020)—can inform equity efforts in computer science education (Madkins et al., 2020). For our work, we are adopting the framework of Culturally Responsive Teaching (CRT) as articulated by Gay (2002). In brief, this approach involves teachers being involved in their student's communities and cultures, designing lessons that reflect diverse cultures, and valuing their different ways of knowing and being (Gay 2002).

For our NSF-funded Accessible Computational Thinking (ACT) project, we are designing and implementing a professional development (PD) program to support elementary educators in integrating CT into science lessons using CRT practices. We will be working with elementary teachers from schools in both the southwest and northeast of the United States which have significant populations of BLNA students. These teachers will participate in summer PD workshops on CT and CRT, during which they will adapt existing science lessons to integrate CT with CRT practices. Over the subsequent school year, we will support teachers in implementing CT-integrated science lessons with CRT practices. We will provide ongoing PD meetings and collect data through classroom observations, teacher interviews, and assessments.

The below two figures represent visuals presented on our poster. Figure 1 provides a conceptual depiction and Figure 2 provides a timeline of our project's first two years.

Local-global Maker-places: Toward an Instrument for International Maker Education

Anna Keune, Technical University of Munich, anna.keune@tum.de
Ryan Cain, Weber State University, ryancain@weber.edu
Maggie Dahn, University of California, Irvine, dahnm@uci.edu
Tolga Kargin, Usak University, tolga.kargin@usak.edu.tr
Naomi Thompson, Northwestern University, naomi.thompson@northwestern.edu

Abstract: After the establishment of a makerspace in any context, sustainability is becoming increasingly important. As an international group of early career scholars with experience in maker education, we engaged in a series of reflective conversations that called us to consider visions for makerspaces as sustainable maker-*places*. We offer a representation that cuts across visions for sustainable maker-places with the intention to begin to develop an instrument for international maker-education.

Place-based approach toward international-maker education

As ecological challenges continue to affect human life, questions related to preparing people to identify local solutions to global problems gain importance. During the past decade, maker educational approaches have found international resonance with maker environments rapidly spreading across settings (e.g., Blum-Ross et al., 2020). Such environments foster local communities and are situated in national and international socio-historical discourses and materialities. They are local instantiations of international scale. Although maker education is well represented in the learning sciences, international perspectives are underrepresented.

Guided by place-making as a theory of learning that highlights how people co-construct spaces as personally and socially meaningful (Taylor & Phillips, 2017; Marsh, 2020), the authors came together in search of language for developing a framework for supporting a sustainable global future for making that is rooted in local communities and centers the artifact across ecologies (e.g., Peppler et al., 2021). Distinct from spaces, we note that "places bring together people who engage in a common activity, may share a particular history, or identify with a locality in a particular way" (Taylor & Phillips, 2017, p. 594). We argue that makerspaces are made into maker-*places* by the individuals and communities that co-construct them. At this project proposal stage, to begin work toward a framework for thinking about the place-ness of makerspaces (i.e., the makerspace as a maker-place), as an international group of early career scholars, we engaged in a series of reflective conversations that considered visions for sustainable making and makerspaces within our local contexts, revolving around the question: *Considering your history with maker education, what vision do you have for a sustainable future for making?* The goal of this early ideational work is to suggest the development of instruments for the design of makerspaces as maker-places that account for the local historical, cultural, and social dimensions of maker-places as sites for learning as well as the possibility for making to support innovative responses to global challenges.

Conversations toward a shared vision of international maker-places

The author team is an international group of early career scholars spanning North America, Western Europe, and Western Asia. We chose to come together as our work deals with making in disparate and related ways in contexts with an array of similarities and differences. As we came together, we took cues from autoethnographic trends that frame critical reflection as a form of methodology (e.g., Morley, 2011). We asked ourselves a series of discussion questions and ultimately crafted a single question for individual reactions. After responding to this prompt individually, we came back together to discuss, react to, and revise visual representations that team members had generated (see Figure 1 for the result of this discussion). Then, we revised our individual responses to capture reactions to the visual representations. The visualization served to support our conversation toward creating a design tool for maker-places that are sensitive to local and global forces.

Toward sustainable futures for maker-places

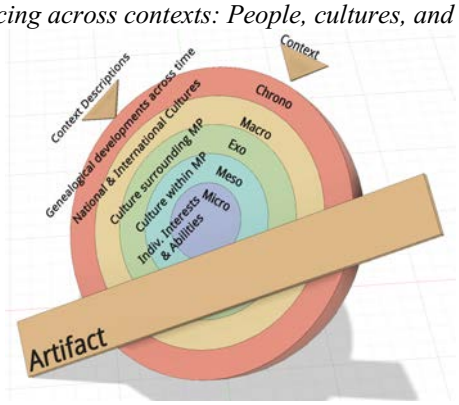
For making to remain sustainable, maker educators will need to consider multigenerational approaches that support learners in building and sustaining community. Teachers and mentors, family members, and community stakeholders must work together to continue to provide opportunities that are relevant for learners and their families, encourage individual and collective development, and make visible potential future pathways. Next, physical materials play a fundamental role in maker-places, contributing to the co-development of places and people, STEM domain learning, and gender equitable pathways within STEM. Integrating understanding of

 © ISLS

ecological, economic, and socio-historical dimensions of maker materials can inform localized material ecologies that break global inequitable material lifecycles toward local sustainability. Additionally, a sustainable future for making requires attending to the interactional dimensions of making spaces into maker-places, including social, historical, and material relations. This future requires attending to the parallel settings and places in which people interact and connect (i.e., online, home, out-of-school settings) so as to forge greater connections across these settings for meaningful learning experiences. Furthermore, maker-places should attract local people and keep them coming back. While designing such maker-places, we should consider three levels of context: micro, meso, and macro (Marsh, 2020). The skills and interests of the target group in the micro context; the culture, beliefs, and interests of the local community in the meso context; and the national and international developments in maker education in the macro context. When considering the various contexts maker-places should engage with, we combine ideas from Marsh (2020) and Peppler et al. (2021) in Figure 1.

Figure 1

Artifact slicing across contexts: People, cultures, and temporalities



Discussion

By coming together from different parts of the world and bringing perspectives on creating sustainable maker-places, the author team provided a representation to support design. The representation highlights the importance of considering both the maker (micro context), their immediate community (meso context), and the space for making (exo context), as well as the global histories (macro context) and current challenges (chrono context) in designing maker-places. The representation, as approximated in Figure 1, serves as a nascent tool to prompt us as authors and conference attendees to ideate ways to encourage makers to deliberately engage with and across the layers of place-making. The visualization is an intermediary step toward the design of a *Maker-Place Design Tool* (MPDT). We intend for the visualization to inform the analysis our collective observations and experiences in maker educational settings toward generating exemplary vignettes that represent each layer of sustainable future maker places. The vignettes are intended to inform the creation of the MPDT. The MPDT will include prompts, statements, and case studies to support maker-place researchers, designers, and educators to engage in discourse across contexts as they produce artifacts toward sustainability. Although early in development, the MPDT promises to provide both practical and theoretical support for maker-place makers to thoughtfully engage with and across layers and to consider their *place* in *making* solutions and designing futures.

Exploring Elementary School Students' Clusters in Blended Mathematics Learning

Suwon Lee, Hagik Elementary School, cellina93@snu.ac.kr
Young Hoan Cho, Seoul National University, yhcho95@snu.ac.kr
Yejin Han, Seoul National University, yejinv2@snu.ac.kr
Seungmin Lee, Baesan Elementary School, leeradi07@gmail.com

Abstract: Blended learning is effective in enhancing meaningful learning in online and face-to-face learning environments. For adaptive learning supports, teachers should understand the diversity of students and identify student clusters with different educational needs in blended learning. This study explored the clusters of Korean students in a mathematics class, collecting blended learning data for one month. This study found three clusters: (1) students with the need for integrated support, (2) students with positive affective characteristics and high-level, self-regulated learning skills, and (3) students with high-level academic achievements and online learning participation. Thus, this study determined unique characteristics of Korean students that were typically overlooked by teachers.

Introduction

Blended learning can be effective to overcome the limitations of a traditional school system that does not sufficiently consider the diversity of students. Students have more autonomy in online learning activities because they can decide when, where, and how to learn, whereas teachers can provide adaptive support in face-to-face learning environments. To enhance the effectiveness of blended learning, teachers should understand the educational needs of students, which are the basis of differentiated instruction or personalized learning (Boelens et al., 2018). Learning analytics helps teachers effectively and timely identify the needs of students, using data collected from online learning platforms and digital devices. Teachers can explore student groups who share similar characteristics and behavior patterns to provide different learning tasks and adaptive support for each group (Han et al., 2021).

Although learning analytics is helpful for adaptive learning support in blended learning, previous studies have seldom explored clusters of elementary school students. Thus, it is necessary to investigate the diversity of elementary school students by analyzing multiple data sources such as academic achievements, online learning participation, affective characteristics, and self-regulated learning skills. In addition, there is a lack of research on East Asian students who may have different characteristics and educational needs from those in Western countries. To design personalized learning or differentiated instruction for Korean students, this study intended to explore clusters of elementary school students, using data collected from blended mathematics learning.

Methods

Participants

This study was conducted during the COVID-19 pandemic at a blended learning research school in Busan, South Korea. A total of 70 fourth-grade elementary school students participated in the study as part of their mathematics class, using the online learning platform MS Teams. All participants used a laptop provided by the government for online learning at school or home.

Data collection

This study collected data on mathematics learning (i.e., addition and subtraction of fractions) for four weeks. The data included academic achievements, subject interest (Sang et al., 2020), achievement emotion (Lichtenfeld et al., 2012), self-efficacy (Pintrich et al., 1991), self-regulated learning skills (Pintrich et al., 1991), and online learning participation. The surveys of affective characteristics and self-regulated learning skills had high reliabilities (Cronbach's alpha = .81 ~ .95). Data of online learning participation included the frequencies of submitted tasks, viewed tasks, and submitted quizzes.

Data analysis

The principal component analysis (PCA) was carried out to identify key components from data collected in blended learning. The PCA revealed four components: academic achievements, affective characteristics, self-regulated learning skills, and online learning participation. Using the four components, we conducted the two-

 © ISLS

stage cluster analysis including a hierarchical cluster analysis and a K-means cluster analysis. After finding three clusters, One-way ANOVAs and Kruskal-Wallis tests were carried out to investigate how the clusters were different from each other.

Findings

This study found three clusters of elementary school students regarding academic achievements, affective characteristics, self-regulated learning skills, and online learning participation. Cluster 1 (n = 35) had low grades (M = -.38, SD = .78), negative affective characteristics (M = -.63, SD = .7), low self-regulated learning skills (M = -.47, SD = .74), and low online learning participation (M = -.54, SD = .61). This cluster requires integrated support from an instructor because the students showed lower achievements in diverse aspects of blended learning than others. Cluster 2 (n = 20) had the highest academic achievements (M = .76, SD = .25) and actively participated in online learning activities (M = 1.14, SD = .63), but did not show high or positive results in affective characteristics (M = .15, SD = .78) and self-regulated learning skills (M = -.25, SD = .56). Cluster 3 (n = 15) had positive affective characteristics (M =1.26, SD = .43) and high self-regulated learning skills (M = 1.44, SD = .54), but their academic achievements (M = .37, SD = .64) and online learning participation (M = -.27, SD = .91) were not high. ANOVAs and Kruskal-Wallis tests showed that Cluster 1 had significantly lower academic achievements (H = 35.34, $p <$. 001) and more negative affective characteristics (F = 41.23, $p < .001$) than other clusters. Cluster 2 more actively participated in online learning than other clusters (H = 31.84, $p < .001$). Cluster 3 showed significantly higher self-regulated learning skills (F = 46.39, $p < .001$) and more positive affective characteristics (F = 41.23, $p < .001$) than other clusters.

Conclusion

This study determined three clusters of elementary school students in blended mathematics learning. The results indicated that students have different educational needs, requiring adaptive learning support and differentiated instruction. For Cluster 1, systematic support is necessary because students showed low achievements in diverse aspects of mathematics learning. Teachers and school counselors should collaborate to help students overcome the low achievements, which may be caused by instructional methods, mathematics curriculum, and family issues, as well as the COVID-19 pandemic. In addition, teachers should pay more attention to non-cognitive achievements of Cluster 2. The findings related to this cluster are consistent with the conclusion that Korean students show high achievements in mathematics but low confidence and interest (OECD, 2013). For Cluster 2, teachers should support their motivation by providing authentic tasks and enhancing their autonomy in blended mathematics learning. Teachers also need to explain and demonstrate self-regulated learning skills, such as how to plan, monitor, and control the learning process and environments. Lastly, teachers should encourage students in Cluster 3 to participate in online learning activities more actively. Teachers can provide feedback to prevent students from overestimating their participation and achievements, using the dashboard of an online learning platform. Future research is necessary to explore clusters of students in diverse contexts, to identify their educational needs and provide adaptive learning support.

Tinkering in Parallel: Pathways for Professional Learning in Education

Ciara Thomas Murphy, University of California, Davis, cthomasmurphy@ucdavis.edu
Lee Martin, University of California, Davis, leemartin@ucdavis.edu

Abstract: This study explores professional learning that occurred during a summer program in which educators engaged with a series of tinkering activities facilitated online. Analysis revealed two primary themes: (1) generative starting points with multiple pathways for exploration, and (2) resolution of sticking points through social connections. An analytic frame of parallel process, adapted from counseling psychology, highlights the way these themes simultaneously speak to learning through tinkering and to professional development.

This study explores the learning experiences of a group of STEM educators who completed an informal online professional development program in summer 2020 that featured a series of tinkering activities.

Background

Educators must develop a skillset that is well grounded in learning theory and empirically supported pedagogical techniques, yet also flexible enough to respond to students' needs (Athanases et al., 2020). Learning to facilitate tinkering activities is a prime example of this challenge, since these activities are open-ended and invite creative exploration rather than fixed lesson plans (Vossoughi & Bevan, 2014). The ways educators have adapted to pandemic challenges underscore the need to conceptualize learning in terms of repertoires of practice that are flexible, responsive, and grounded in supportive pedagogical relationships (Gutiérrez & Rogoff, 2003).

Research design

Data come from 23 interviews with 12 educators who engaged with a series of tinkering activities facilitated online by the Exploratorium: Exploring Spinning, Chain Reaction, Cranky Contraptions, and Video Sensing. Activity prompts were introduced by email, and participants were encouraged to document their process and connect with others on social media. Interviews were semi-structured and were designed to elicit narrative accounts of participants' tinkering experiences. Analysis began with open coding to identify high-level topics that were salient across narratives; subsequent analysis elaborated upon each code in turn. Here we focus on two crosscutting themes that emerged in the second phase of analysis: (1) generative starting points with multiple pathways for exploration, and (2) resolution of sticking points through social connections.

Findings

Generative starting points with multiple pathways for exploration

In all 23 interviews, educators described the need to find a personally meaningful starting point to begin engaging with each activity. Generative starting points were associated with a sense of emotional resonance and playfulness; emotions that frequently came up in participants' narratives included excitement, inspiration, and curiosity. Because starting points were linked with personal sense making, many participants favored prompts that were open-ended enough to leave space for creative exploration while also providing a clear sense of direction. We believe these tinkering activities engendered fruitful learning in part because they were amenable to a variety of starting points and multiple pathways for exploration. We identified five types of starting point that generated engagement; Table 1 provides a description of each type, including observed frequency.

Resolution of sticking points through social connections

In 17 of the 23 interviews, educators described encountering sticking points in their exploration. These moments were characterized by intense frustration and interruption in the flow of engagement with an activity. Sticking points typically arose when participants encountered limitations, either in the material resources available to them at home, or in their individual knowledge about a particular tool or resource. In these moments, there was a disjunction between their original idea or vision and the implementation of that idea, which led to emotional overwhelm and impasse. For many participants, resolution was facilitated by social interactions, either with family members in person or with colleagues online. In these connections, participants found emotional support to persist through difficult moments. While sticking points typically arose for technical reasons, their resolution tended to be characterized not by technical troubleshooting, but by a shift in perspective and emotional regulation brought about by supportive, encouraging interactions and relational care. Perhaps surprisingly, many participants reported

 © ISLS

that the frustration of sticking points turned out to be a valuable part of their learning, and that they subsequently felt a greater sense of satisfaction and excitement about their tinkering experiences after they had worked through these difficult moments with emotional support from others.

Table 1

Five Types of Starting Point

Type	Freq	Description
Physical Materials	21	With focus on the properties of physical materials, participants thought creatively about how to use materials that were readily available at home and explored emergent interactions between materials.
Previous Experience	19	With focus on previous experience, participants activated existing knowledge and used past exploration as a template for new efforts or as motivation to try something different.
Practical Goals	10	With focus on a practical goal, participants designed an object to accomplish a personally meaningful task and structured their tinkering according to that goal.
Narrative Elements	8	With focus on a vivid image or character, participants created aesthetically appealing stories to guide exploration and link their creations with personally meaningful themes.
Scientific Concepts	8	With focus on a scientific concept, participants investigated physical phenomena and tested various factors or parameters related to a particular phenomenon.

Discussion

Since our participants were educators who engaged with these activities for the purpose of professional development, we note that each theme discussed above may serve a dual analytic function, simultaneously speaking to the nature of learning through tinkering and to the nature of professional development. Tinkering is recognized as a valuable mode for students' STEM learning (Resnick & Rosenbaum, 2013); here we note that it may be just as valuable for professional learning. The benefit of activities that include diverse learning pathways and ample opportunities for social collaboration may be equally applicable to facilitation of tinkering in STEM education and to provision of professional development. When considering educators as learners, it is useful to attend to both sides of their dual role in professional learning. Learning through tinkering allows educators to explore affordances of activities with their own practices in mind, developing a flexible pedagogical repertoire. Emphasis on adaptive practice is useful to address parallel challenges that arise in student learning and professional learning, such as shared challenges of adapting to pandemic constraints. In the context of counseling psychology, parallel process refers to dynamics in clinical practice that are mirrored in professional supervision (Sarnat, 2019). This concept is a useful analytic frame to conceptualize the value of tinkering for professional learning, where an educator likewise holds a dual role with respect to teaching and learning.

Exploring the Interaction between L2 Learners and AI Translator in English Writing

Hyeeun Kim, Opo Elementary School, kim5039@snu.ac.kr
Young Hoan Cho, Seoul National University, yhcho95@snu.ac.kr
Seehee Park, University of Southern California, seehee@usc.edu

Abstract: This study investigated how L2 learners interact with an artificial intelligence (AI) translator for English writing and explored the effects of the English writing skills on interaction patterns. L2 learners (n=21) wrote an essay in English using an AI translator. As a result, three clusters were found: English writing, Korean writing, and Interactive writing. The interaction pattern was different according to the expression scores. The results provide implications in designing interactions between learners and AI.

Introduction

In the era of digital transformation, learners should develop literacy in terms of how to interact with new technologies like artificial intelligence (AI) tools. Learners who effectively interact with AI tools may exhibit higher performance and learning gains than those who overly depend on or ignore AI tools. AI literacy education is necessary to help learners to develop competencies to well collaborate with AI tools for an authentic task. Despite the importance of interacting with such tools, there is a lack of in-depth research of exploring the interaction between learners and AI tools, which can provide implications not only for the development of AI tools but also AI literacy education.

Based on activity theory, this study explores how L2 learners interact with an AI translator while writing an English essay. Although the AI translator is easy to use, learners may interact with it in different ways according to their English writing skills. Learners with low English writing skills are likely to have higher needs of using the AI translator. This study explores the activity system of interaction between an L2 learner and an AI translator, consisting of multiple actions and operations (Kuutti, 1996). The following research questions are addressed: (1) How do L2 learners interact with the AI translator in writing an English essay? (2) How are the interaction patterns related to L2 learners' English writing skills?

Research methods

Participants

A total of 21 undergraduate and graduate students (13 female, 8 male) participated in this study. All participants were studying different majors and also had different competency in English writing. Participants exhibited differences in content (M=2.81, SD=.981) and expression (M=3.05, SD=.865) scores of English writing competency.

Procedure

First, we explained how to use the AI translator, Papago (https://papago.naver.com), and allowed participants to sufficiently explore the tool. Second, for the assessment of English writing skills, participants individually wrote an English essay without the AI translator. Finally, they wrote another English essay, whose topic is different from the previous one, with the AI translator. We recorded the second writing activities on video to analyze how learners interacted with the AI translator.

Data collection and analysis

The video was analyzed by applying Jordan and Henderson's (1995) human-computer interaction analysis framework for analyzing the interaction patterns of learners. We developed a coding scheme consisting of actions and operations to analyze video data. The coding scheme includes planning, composing, and revising actions including sub-actions. The video data were independently analyzed by two researchers and then discussed to resolve differences in coding results (Cohen's Kappa = 0.792). To identify interaction patterns of L2 learners and the AI translator, we analyzed the percentage of time spent on each action and then carried out K-means cluster analysis. We found three interaction patterns and then conducted the Kruskal-Wallis test to examine the differences in the actions according to the interaction patterns. In addition, two researchers evaluated English writing with a rubric consisting of content (Cohen's Kappa = 0.712) and expression (Cohen's Kappa = 0.734). The possible score of English writing ranged from 1 to 5 for each of the content and expression.

 © ISLS

Results

Interaction patterns between L2 learners and AI translator

The cluster analysis results revealed three different interaction patterns between L2 learners and the AI translator: (1) Korean writing with limited use of the AI translator, (2) English writing with limited use of the AI translator, and (3) interactive writing with the AI translator. The Korean writing cluster (n=8, 40%) wrote the entire text in Korean and then entered it into a AI translator. The English writing cluster (n=7, 35%) wrote most of the text in English by themselves, but if necessary, Korean at the level of words and phrases was entered into the AI translator. Lastly, the Interactive writing cluster (n=5, 25%) displayed the high proportion of time spent revising translation results. Kruskal-Wallis tests indicated that the Korean writing cluster had significantly more "writing in Korean" action (H=17.449, p<.000), and the English writing cluster had significantly more "writing in English" action (H=17.166, p<.000) than other clusters. The Interactive writing cluster exhibited the highest proportion of actions for "revise and use" (H=9.316, p<.009) than other clusters. Other actions were found not to be statistically significant.

Differences in interaction patterns according to learners' English writing skills

The results of the Kruskal-Wallis test to analyze English writing competency by interaction patterns revealed the difference in the content score was not statistically significant (H=1.803, p=.406). However, the expression score (H=6.113, p=.047) was statistically significant between the clusters. In particular, the English writing cluster displayed the highest expression score, while the Korean writing cluster showed the lowest. Both the learners with high and those with low English writing scores had a limited percentage of interaction with the AI translator. It was found that learners with both high and low scores had low interaction with the translator; however, there was a difference in the number of inputting words in their writing task.

Table 1

English writing skills by clusters

English writing skills	Interaction patterns						Total	
	Korean writing		English writing		Interactive writing			
	M	SD	M	SD	M	SD	M	SD
Content	2.38	.09	3.14	.17	3.00	.20	2.80	.98
Expression	2.50	.12	3.57	.11	3.00	.00	3.00	.84
Total	4.88	1.13	6.71	1.80	6.00	1.00	5.80	1.54

Discussion

This study found that L2 learners interacted with the AI translator in three different ways. While some learners interacted with the AI translator well, others spent a lot of time on writing an English essay without the AI translator. Learners with low English writing skills tended to overly depend on the AI translator, so they seldom revised its outputs. In contrast, learners with high English writing skills were not easily satisfied with the translation outputs, so they might consider how much they would use the AI translator for English writing. Some learners actively interacted with the AI translator, whereas others seldom used it due to the lack of usefulness. This result is consistent with Chartterjee and Bhattacharjee (2020), who argue that attitude toward AI tool has a significant impact on behavioral intention of the individuals to adopt AI in education. Future research is necessary to investigate how the interaction patterns influence the development of L2 learners' English writing skills. This study implies that AI literacy education should focus on the interaction between learners and AI-based tools.

Meaningful Movement towards Campus-Based Outdoor Learning: Characterizing Pre-Scenery with Stakeholder Perspective

Annette C. Schmidt and Steven Zuiker
acschmi3@asu.edu, Steven.Zuiker@asu.edu
Arizona State University

Abstract: This study seeks to characterize what matters to stakeholders as a school moves towards campus-based outdoor learning. Results from a survey (n=87) demonstrate stakeholder alignment in relation to a long-standing outdoor education movement and emerging movements responding to COVID-19. Discussion considers the polylogic of local communities that work to inspire, enable, and sustain commitments to campus-based outdoor learning.

Traditionally, public and private schools alike have separated outdoor education from formal education (Adkins & Simmons, 2002). Against this backdrop, utilizing an urban school campus to organize and sustain outdoor learning opportunities embodies an uncommon and noteworthy institutional commitment. We seek to characterize this commitment as an ontology in motion (Akkerman et al., 2021) by exploring both what outdoor learning currently is and what it is becoming within the institution as well as the community in which it is embedded. Therefore, as part of an ongoing partnership with a US K-8 charter school committed to campus-based outdoor learning, we explore the aspirational goal of organizing a majority of instructional time outdoors. This study specifically explores institutional and community stakeholders' perceptions of outdoor learning and well-being in order to (re)consider what matters to each group and in wider relation to shifting educational norms associated with COVID-19 mitigation strategies. We employ a descriptive strategy to characterize what at hand or about to happen as these outdoor learning commitments emerge and, in turn, to answer the following questions: (1) what are stakeholders' general perceptions of outdoor learning? (1a) How do these perceptions compare? (1b) how do stakeholders perceive outdoor learning as a response to COVID-19; and (2) how do stakeholders perceive their own current well-being in the midst of COVID-19?

Methods

This study reports efforts to attune to what is happening and what matters in the present (Akkerman et al., 2021). Campus greening represents a meaningful movement in motion that involves both physical environments and social constructs like well-being. To understand stakeholder perceptions of taking learning outside, a survey of internal and external stakeholders examined their perceptions of outdoor learning and community well-being.

We developed and distributed an online survey via emails to all internal school stakeholders (e.g. parents, teachers, admin) and a sample of external stakeholders who live in the three zip codes nearest the school. The survey generated data about demography, outdoor learning, nature relatedness, and well-being. We developed outdoor learning items based on the relevant literature. We utilized validated scales for nature relatedness (Nisbet & Zelenski, 2013) and well-being (Stiefel et al., 2020), the latter of which was created in response to COVID-19. Fifty-one adult internal stakeholders (6% response rate) and 36 adult external stakeholders (4% response rate) responded. Meanwhile, 201 students also responded (55.8% student response rate). For analysis, we generated descriptive statistics for all RQs and ran independent samples t-tests to compare perceptions (RQ1a).

Results

In general, a majority of all stakeholders perceived benefits to outdoor learning (RQ1) (see figure 1). We note that participants unanimously responded that outdoor learning is moderately to extremely effective at promoting social and emotional well-being. Similarly, respondents agreed a little (25.3%) or agreed strongly (67.5%) that students who participated in outdoor learning would build positive social and emotional well-being. We also sought to describe the influence of COVID-19 on participants' perceptions of outdoor learning (RQ1b), and found that 82% of participants somewhat agreed (14%) or strongly agreed (68%) that they would support campus-based outdoor learning. An independent samples t-test found no significant differences between internal and external stakeholders on this question, demonstrating a strong, shared perception of immediate and direct relevance.

We also compared the positions of different stakeholder groups on outdoor learning in terms of its effectiveness and influence on student outcomes (RQ1b) (see Figure 1). With respect to effectiveness, responses suggest general stakeholder

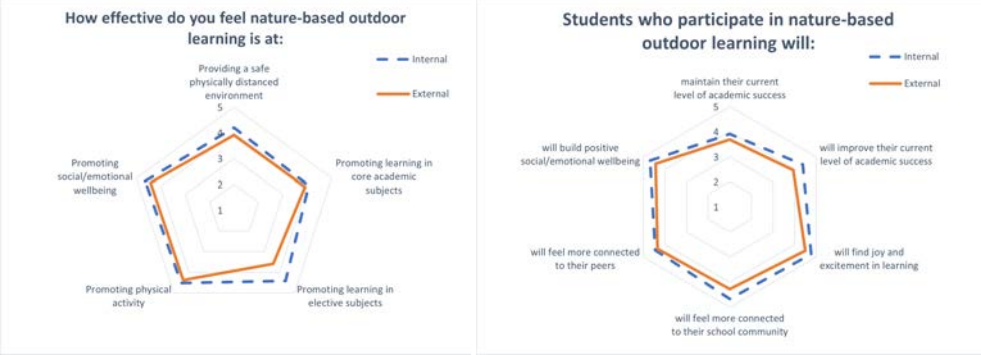
 © ISLS

alignment. An independent samples t-test found significant differences for one aspect only--the effectiveness of outdoor learning to promote learning in elective subjects ($p<.001$)--which often reflects differences in relation to barriers (e.g lack of technology). With respect to student outcomes, responses again suggest general stakeholder alignment around three positive student outcomes. However an independent samples t-test found statistically significant differences ($p<.05$) among stakeholders with regard to increasing students' current level of academic success and students feeling more connected to their school community.

As a final consideration, we examined individual well-being (RQ2) and found that adults generally labeled their wellbeing good (internal 64% thriving, 0% suffering: external 56% thriving, 0% suffering). Meanwhile, student results (35% thriving, 6% suffering) suggest stronger adverse effects associated with the pandemic. The immediate and direct relevance of outdoor learning cannot be understood apart from a sense of well-being anchored to ongoing health threats and pandemic mitigation.

Figure 1

Internal and external stakeholder perceptions of campus-based outdoor learning effectiveness and student outcomes



Discussion

This study represents an initial, methodic approach to listening and learning from stakeholders as their local school makes meaningful movements towards outdoor learning and the results establish a pre-scene that accompanies the school's commitment to "take it outside" by greening campus-wide outdoor infrastructure. Results demonstrate strong, positive alignment on campus-based outdoor learning both as a part of formal education and as an influence on physical activity and well-being for students, particularly in relation to COVID-19. These preliminary findings are promising but also remain limited. First, a small sample size, particularly for external stakeholders, precludes generalization about community perceptions but results justify recruiting more participants in subsequent implementations. Second, while the survey results are consistent with a meaningful movement in motion, items written by researchers, risk objectifying this movement and can be qualified locally through a complementary ethnographic approach to understanding the community context, which we consider in closing.

In conclusion, Akkerman et al. (2021) underscore that an ontology in motion must attend to participants' positions, purposes and possible futures at specific points in time (actuality principle). We conjecture that stakeholder perceptions about what matters in relation to (post-)pandemic schooling does not unfold exclusively in a normative space of outdoor learning, but rather in the polylogic space of local communities that are continually in motion, amplified by COVID-19-related challenges (cf. Leander, 2002). As an effort to attune to what is happening and what matters presently for these stakeholders, this study considers multiple logics that work to inspire, enable, and sustain commitments to campus-based outdoor learning.

An Adaptive, Agile Learner-Centered Computer Science Curriculum Design Approach Based on Deep Knowledge Tracing

Ruiwei Xiao, Washington University in St. Louis, ruiwei@wustl.edu
Chris Chi, Harvard University, cchi@gse.harvard.edu

Abstract: While the focus of the curriculum is on the students, their voices are rarely heard in the creation or adaptation of the curriculum. It is often impractical and difficult to try to address the needs of each student in a single curriculum. With the use of Deep Knowledge Tracing (DKT), we propose a learner-centric curriculum design that is adaptive and agile, performing interventions on an individualized basis.

Introduction

A curriculum should enable learners, teachers, and managers to know and fulfill their obligations in relation to the programme or course (Grant, 2019). Yet, as the central focus of the curriculum, student voices appear to have little impact on its design or adaptation (Jagersma, 2010). Though students may submit suggestions through course evaluation questionnaires, it is unlikely that such adjustments will be made in time and on a personalized basis. This paper proposes an adaptive and agile approach to learner-centered curriculum design. Following the assessment of specific learning objectives, the curriculum is then adapted according to the student's learning model, which is determined by pre-instructional and post-instructional tests. We implemented our technique using Deep Knowledge Tracing (DKT) on an online course study platform for several undergraduate courses in Computer Science (CS). Our design approach will incorporate students into the curriculum design process, develop a study plan tailored to the needs of the individual student, and provide educators and administrators with an increased understanding of the design and instructional methods of the courses.

Theoretical background

Student Voice

The importance of student voice has been demonstrated both by the role of students in learning processes as well as the positive correlation between student voice and better academic performance (Jagersma, 2010). The Curriculum-ideas-Analytics (CiA) program, for example, uses Knowledge Forum and text mining tools to navigate and incorporate student voice into curriculum design (Teo et al., 2021). However, despite the success of existing approaches in identifying issues from students' voices, few of them suggested practical approaches to improve current curricula. Additionally, students' suggestions are sometimes difficult to articulate precisely.

Adaptive Learning and ACT Theory

Adaptive learning, or intelligent tutoring, uses computer algorithms and artificial intelligence to orchestrate the interaction with the learner and deliver customized resources and learning activities to address the unique needs of each learner (Kaplan, 2021). The theoretical basis of adaptive learning is ACT theory, which holds that cognitive skill acquisition involves the formulation of thousands of rules-relating task goals and task states to actions and consequences (Anderson, et al., 1995). ACT-based intelligent tutoring applications such as Cognitive Tutors for Mathematics have been prevalent in thousands of US schools (Ritter, et al., 2018).

Deep Knowledge Tracing (DKT)

Knowledge Tracing (KT) is a strategic approach in which machines are employed to model the knowledge of a student as they interact with their coursework. As one of the most prominent KT approaches, Deep Knowledge Tracing (DKT) makes use of Deep Neural Networks to simulate a student's learning behavior and achieves significant improvements in prediction performance over traditional KT models, such as Bayesian Knowledge Tracing (BKT) (Piech et al., 2015). DKT offers greater modeling capability for complex cognitive processes, and it identifies one instance for all skills, whereas BKT identifies an instance for each (Montero et al., 2018).

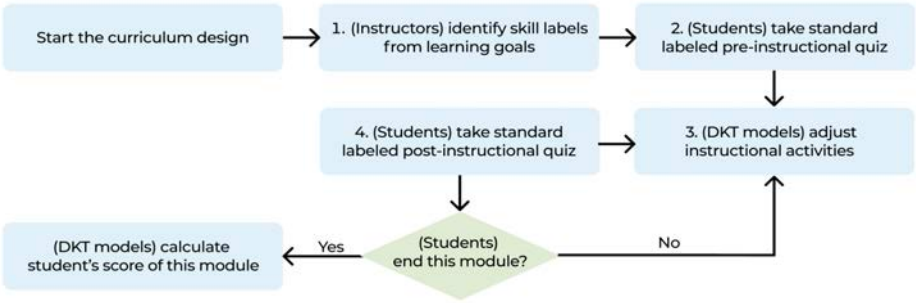
Methodology

To illustrate the iteration of our methodology, we include three activities: pre-instructional quiz, instructional activity and post-instructional quiz in each module of the curriculum for a CS course *Introduction to C Programming*. During each iteration of curriculum design for a module, we follow four steps (Figure 1):

 © ISLS

1. ***Identify learning goals and break them down into skill labels***. Labels are the meta inputs of DKT models. As the different learning goals are composed of one or more skills, we disaggregate each learning goal into skill labels, which act as a common unit of measurement and analysis.
2. Assess students via a standard labeled pre-instructional quiz. Questions in the pre-instructional quiz encompass all the skills that students will learn in this module, and DKT calculates a baseline model by using the student's mastery of each skill to recommend personalized instruction for the student.
3. Adjust the instructional activity using the data of pre-instruction activities. The instructional activity is categorized by skill and includes lectures, practice questions, and readings. A student who is weak in a particular skill will be assigned more instructional activities according to the DKT model.
4. Assess students via a standard labeled post-instructional quiz. There are different questions in the post-instructional quiz, but the difficulty and skill levels are the same as those in the pre-instructional quiz. Following submission of the quiz, DKT will update the student's learning model. Students are now presented with the option of completing this model's study and receiving their module score or engaging in the instructional activities suggested by the updated learning model and retaking the quiz. A participant is not restricted to taking this quiz a specific number of times, however, when they begin a new attempt, questions will be refreshed.

Figure 1
The Four-Step Iteration for Each Module



Ongoing and future works

Currently, we are creating skill labels and labeling existing activities and questions. In spring 2022, 200 undergraduate students who register for the class will use the system without DKT modeling and recommendation. Data collected from the study will serve as training data for the DKT algorithm in addition to the control group. We hope to undertake a curriculum design experiment with DKT in the fall semester of 2022.

Real Work with Real Consequences in an evolving classroom context: Consequential and Connected STEM Learning

Rebekah Jongewaard and Michelle E. Jordan
rjongewa@asu.edu; michelle.e.jordan@asu.edu
Arizona State University

Abstract: In this DBR study, we explore how one middle school STEM teacher designed for real work with real consequences by supporting students' agentive and productive participation in community-based engineering activities across virtual, hybrid, and face-to-face settings across multiple project cycles.

Introduction

This study focuses on innovative pedagogical practice informed by theories of consequential learning and rightful presence in STEM and enacted by one middle school teacher in an evolving classroom context across three project cycles. Specifically, we explore how the teacher sought to support students' agentive and productive participation in community-based engineering activity as Covid responses evolved in her district. The research question guiding our analysis is, *what can we learn about how to support real work with real consequences in classroom settings by examining one teacher's instructional practices as she aimed at engaging her students in real, consequential energy engineering across virtual, hybrid, and in-person STEAM classes?*

Drawing on Jordan et al. (2021), we believe that supporting real work with real consequences means designing for PDE with consequential and connected learning. Productive disciplinary engagement (PDE) (Engle & Conant, 2002) involves students in making intellectual progress on the real problems of a given discipline. To foster PDE, teachers should give students opportunities for problematizing disciplinary concepts and authoring solutions to problems they or others raise, hold students accountable to each other and disciplinary norms while providing resources and scaffolding. While PDE is a necessary component of real work with real consequences, it is not sufficient. Jordan et al. (2021) argued that the concept of PDE alone lacks the elements of consequentiality and connectedness needed in "risky design work" (p. 251). *Consequentiality* means that students are not invited guests into someone else's world, but are rather rightful participants and problem solvers in a shared world of real problems that they, the students, can have a hand in shaping and solving (Calabrese Barton & Tan, 2020). *Connected learning means* that learning and work is connected with community beneficiaries, community purposes and a "social infrastructure of care" (Greenberg et al., 2020).

Method

The context for this design-based research was a 7th grade STEAM class in a public Title I school located in a metropolitan area of the southwestern U.S. in a Latin@-dominant community. In the summer prior, the teacher, Ms. Catrell, participated in a research experience program focused on agrivoltaics (coupling solar power with food crops) and creating equity-oriented curricula that positioned youth with agency in community-based engineering projects. School closures left Ms. Catrell with both the disappointment of frustrated plans and the opportunity to plan responsively with the evolving contingencies of pandemic schooling. In fall 2020, the class met virtually. In spring 2021, learning was in a hybrid setting; the teacher met FTF students in the classroom and used Webex to bring virtual students in simultaneously. In fall 2021, a new cohort returned to fully in-person instruction. Data interpretation relied on analysis of recorded classroom interaction focused on the teachers' instructional practices within and across the virtual, hybrid, and FTF instruction (~19 hours), as well as interpretive analysis of artifacts. We first classified learning activities that met our criteria for "real work", those that coupled PDE with opportunities to plan and enact disciplinary projects that benefit the community beyond the classroom. We then analyzed the teacher's pedagogical actions, coming to see her expansive framing of the activities as central to her support of real work across the 3 settings (Engle et al., 2012).

Findings

We identified three instructional units in which episodes of real work were evidenced in coupling disciplinary activity and consequential and connected engagement across the virtual, hybrid, and FTF settings: Unit 1- Growing plants, Unit 2- Designing with PV panels, and Unit 3 - Imagining a solar future (See Table 1).

Table 1
Community-Based Engineering Activity Across Three Settings for Learning

Context	Disciplinary Activity	Real Work
At Home Fall 2020	● U1: Grew plants at home, conducted plant research and community ethnography on ● U2: Designed & built PV racking system from construction paper & found materials ● U3: Solar home hack design challenge; solar panel kits to prototype a device they chose	● In preparation for the garden they were planning for their community ● Prototypes for a system they planned at scale when returned to school ● Redesigned devices in their homes for energy equity and sustainability
Hybrid Spring 2021	● U2: Constructed models of 3D solar art installations inspired by architecture guests ● U3: Wrote solar futures stories set in a local park; support from guest speakers	● Created installations they imagined for neighborhood contexts ● Imagined futures in which community is inspired by their work
Face-to-Face Fall 2021	● U1: Designed, built and planted garden bed; analyzed and interpreted garden data ● U2: Built full-scale PV racking systems for garden; re-designed prototypes with build kits ● U3: Wrote localized solar futures comics	● Neighborhood high school collaborators helped graph data ● High schoolers acted as critical peers for STEAM students' video pitches and solar future comics

The three learning settings posed myriad challenges to Ms. Catrell's and the students' efforts. The three settings sometimes forced, sometimes afforded, ways for the teacher to position students as consequential learners. Ms. Catrell supported students' PDE through expansively framing activities as significant, not as discrete moments of learning but over the long term, in a variety of places, for a variety of people. As an illustrative example from the virtual setting, the challenges to doing real work at home occasionally forced Ms. Catrell to shift focus from the consequentiality of work in the here and now to the benefit of their current work to the community over time. In one conversation, she drew the students forth in time through the end of online learning, through the end of the school year to the anticipated end of Covid restrictions, encouraging them, "Next year…what you build and leave for people...[we're setting a firm] foundation so that what we do next year will be better than what we could have done this year. Can you imagine leaving that legacy?!" This move to help students envision a bright future they helped create seemed especially appropriate to facing the challenges of online learning, but could also be a strategic practice in any setting, strengthening the connections between present and future.

Discussion

Ms. Catrell's instructional moves suggest that expansively framing across time, places, and people supports real work with real consequences. However, studies of expansive framing to date have largely been concerned with creating encompassing contexts for transfer of intellectual knowledge and skills. Ms. Catrell's expansive framing went further. Through moves appropriate to each of the three settings, Ms. Catrell framed place not only as locations in which students would apply knowledge but also as contexts that could be transformed by knowledge. She framed people not only as audiences for student learning but also as partners and beneficiaries of student action. If we want teachers to cultivate rightful presence and consequential learning in their classes through real work, we should consider how we can support them in framing students as changemakers purposefully acting to benefit the socio-cultural and geographic communities where they live.

Sociomateriality of apprenticeship learning in ecological fieldwork

University of Hong Kong

Abstract: Learning in and through fieldwork usually occurs as apprenticeship in a situated, real-life context. This Interactional Ethnography of an ecology fieldwork initiative in Hong Kong adopts a microethnographic discourse analysis (ME/DA) using video recordings from point-of-view (POV) glasses. Analysis of university ecologist and secondary biology student micro-interactions illustrates how the ecologist shuttled between two sociomaterial 'presences' weaving scientific reasoning with the physical manipulation of natural objects in the field.

Introduction

Learning in and through fieldwork usually occurs as apprenticeship in a situated, real-life context. Students in the field encounter authentic problems across a range of tasks supporting development of expertise across knowledge, skills, and dispositions in a community of practice (CoP). Sørensen (2009) argued, however, that this traditional framework does not fully account for how learning transpires as "knowledge emerges at different places" due to "the relation between circulating humans and immobile references" (p. 180). Studies in the materiality of learning are examining interactional and spatial "heterogenous assemblages" (Fenwick, 2015). This Interactional Ethnography (IE) addresses the 2022 ICLS call for "elucidating theories and processes of learning and teaching" with a microethnographic discourse analysis (ME/DA) of one ecology fieldwork session in Hong Kong involving secondary school students and university ecologists (Green et al., 2020). Ecologists view the skill of species identification as the basic prerequisite for understanding biodiversity and environmental issues; however, students can normally exhibit such skill only at higher taxonomic levels, not at species levels (Randler, 2008). Mentally relaying species names and morphology is a key goal for apprentice ecologists (Kontkanen et al., 2016). This study of the sociomateriality of fieldwork asks, *how do university ecology experts circulate between materiality and scientific reasoning to facilitate students' species identification in fieldwork and their thinking like ecologists?*

Methodology

IE is founded on sociocultural conceptualizations of learning *in situ*. This ME/DA study adopted Sørensen's (2009) concept of materiality as a lens to examine the spatiality of learning and "sensitively account" for the multiplicity of "forms of knowledge and presence" in a natural environment (p. 189). Analysis centers on an excerpt from the second of two field-trip components (mid-2021) in a place-based secondary biology initiative in Hong Kong. Field trips involved a rocky shore transect survey (~1 hour) at an intertidal section of a beach in close proximity to the school. Senior secondary students (n=21-22; 15-16 yrs) were grouped with 2-3 pre-assigned peers. Six university scientists specializing in rocky shore ecology (4 ecologists, 2 research assistants) led the fieldwork with two schoolteachers. Group materials included sampling quadrats (1 gridded, 1 blank), clipboards, record sheets, a species ID sheet, a graphical food web, magnifier, forceps, and small box. Participants consented to recording with four tripod-mounted static cameras at the backshore capturing transect group macro-interactions while personal, first-person point-of-view (POV) glasses and audio pens worn by selected group members and the university ecologists captured micro-interactions (~26 hrs total). Transcriptions (Cantonese to English) were reviewed by an interdisciplinary team of educationalists and ecologists. An event map (Figure 1) with spatial mapping of macro-level geographical distributions traced the historical roots and trajectory of a telling case study of one university ecologist and a senior secondary student co-constructing knowledge for identification (Table 1).

Analysis and results

The identified rich point (Table 1) illustrates a complex intertwining of talk and materiality. ME/DA unpacks synchronous, micro-level discourse and proxemics. It begins at 26:11 when the Cantonese L1 ecologist (pseudonym Jenny) picks up an *Echinolittorina radiata* (Obj 1) within the quadrat and, holding it in her palm, asks a group member (pseudonym Kelvin, Cantonese L1) to identify. He offers an incorrect response, "塔結節濱螺" (*Echinolittorina malaccana*). In the absence of a species ID sheet as a cognitive prompt (26:16), Jenny enters a deductive process to enunciate the differences between the two species of the same genus, initially by focusing on species-level features (surface colors of spires; aperture features; 26:18). She picks up a second organism (Obj

 © ISLS

2) located outside the quadrat as a contrasting example. Holding it in her fingertips in front of Kelvin, she points out specific species features. When Kelvin incorrectly identifies the organism again, Jenny moves it closer to his face (26:48) asking him to carefully 'read' the key characteristic of *Monodonta labio*. Assessing that he was yet to attain the identification skill at species level, Jenny finally redirects him to find his species ID sheet.

Adopting Sørensen's (2009) framing of three forms of presence (authority-subject, collective, agent), the 'authority-subject presence' as delineated by normative teacher-student power relations and reliance on a validated teaching instrument (species ID sheet) is transformed into 'agent' presence through the rhythmic intertwining of progressively closer proxemics aligned with schema-structured discourse. By engaging the student in the situated, discursive process of connecting features of discovered field organisms (Objs 1 & 2) to the expert's internal dichotomous schema for identification (Table 1; Figure 2), the ecologist facilitates the apprentice's (re-)performance of knowledge in collaboration with the expert (ibid). When this fails, she re-employs the standardized picture-based identification key to support 'imitation' (26:51), which is less cognitively challenging. By repurposing the classroom object in the field, they return to an authority-subject presence.

In the apprenticeship of ecology, fieldwork provides the expert a familiar space for creating different presences to facilitate learning and to assess an apprentice's proximal development. This ME/DA telling case study illustrates an ecologist 'shuttling' between two sociomaterial 'presences' by weaving scientific reasoning discourse with the physical manipulation of natural objects and learning artefacts in the field. It contributes to theorizing micro-processes of apprenticeship in ecology and supports the inclusion of university scientists in school-based fieldwork.

Table 1

Excerpt of discourse and associated video frame grabs of key event and rich point (J: Jenny; K: Kelvin)

Time		Discourse (translated from Cantonese)	Material assemblages
26:11	J	It is not the "塔" (*malaccana)* one/ do you have that paper ((species ID sheet))?/	
26:16	K	((I)) haven't brought it	
26:18	J	((laughs)) OK/ haha ((pause))/ the *Echinolittorina malaccana/* we just said is really triangle/ oh/ there is one here **((picks up organism))**/ this type **((holding between fingertips))**/ first/ it is much deeper in color/ also/ it has granules at the bottom/ and the whole of it is pointy/ but most of those here are this one ((showing an *Echinolittorina radiata*))/ it is round/ so/ if you turn this one open/ can see it is a bit pointy/	**On palm, rock level (Obj 1)**
26:44	K	*Monodonta labio*	**Between fingers, chest level (Obj 2)**
26:45	J	It is round here/ and then gets pointy/ what did you say?/	
26:47	K	*Monodonta labio*	
26:48	J	Does it have teeth ((*donta*))?/ Have a clearer look/ **((moves organism closer to K's face))**	**Fingertips, eye level (Obj 2)**
26:50	K	No/	
26:51	J	Yes/ so/ it is neither *Monodonta labio*/ it **is also** *Echinolittorina*/ but it is not *Echinolittorina malaccana*/ it is *Echinolittorina radiata*/ Yeah/ so/ therefore/ we need to fetch your paper ((species ID sheet))/

-Embracing Diversity and Connectivity for Entrepreneurship Education Innovation: An Observation Study of Co-Creation Pedagogy for Design Thinking Capacity Building Program of Higher Education

Lan Cheng, The Hong Kong University of Science and Technology, lchengan@connect.ust.hk
Yi Peng, Zhejiang University of Finance & Economics
Alex Chan, The Chinese University of Hong Kong
Wen Chao Zhang, China Central Academy of Fine Arts
Yang Wang, The Hong Kong University of Science and Technology

Abstract: With the growing popularity of design thinking capacity building initiatives for entrepreneurship education, educators are striving to explore technology-supported learning environments and pedagogy to achieve the inter-disciplinary, easily accessible, and student-oriented entrepreneurship education innovation. The lingering effects of unfinished learning amid the COVID-19 and mixed-mode learning have become part of a new normal, we designed and implemented a novel learning framework to put co-design pedagogical structures in place that allow educators, students, and stakeholders to form new learning experiences and create innovation together. Through the case study we designed and implemented in three universities across different regions, we propose and investigate an approach that enables micro-level analysis of knowledge creation model for student's design thinking capacity building as well as macro-level understanding of learning dynamics for entrepreneurship education. This study presents a pedagogy-based template, and the findings have implications for the design of technology-empowered educational interventions and pedagogical innovation.

Keywords: Collaborative Learning, Entrepreneurship Education Innovation

Introduction

Under the global COVID-19 pandemic, policy makers, educators, and students are challenged by the high cost of this prolonged period of remote learning, from rising rates of student learning loss. The global pandemic has set back normal learning routine for all students. However, it is well noted that the pandemic dramatically fuels global growth of entrepreneurship program. This wide phenomenon is practically evident in higher education institutions.

Entrepreneurship education has become a strategically important part of the university learning experience as it engages students with pressing real-world problems, develops design thinking, and broadens their life skills both for academic and non-academic advancement (Hansen &Wyman, 2021). More specifically, how to equip learners with the design thinking capacities for knowledge creation and innovation has become a great challenge facing education. The OECD has undertaken national reviews of the impact of higher education institutions in supporting entrepreneurship. Recommendations include the encouragement of an entrepreneurial mindset, problem-based learning, enhancing interdisciplinarity, and linking students with the local, regional, and international community (OECD, 2019).

Gaps: "Can entrepreneurship be taught?"

Over the past two decades, universities provided students with business entrepreneurship course and experiential programmes alongside extra-curricular activities. However, business schools struggle to teach entrepreneurship because there are not unified standards in entrepreneurship courses, such as course content, anticipated learning outcome, program delivery. Researcher, educators, and students think there are ambiguity in standardizing the curricula as it is important to tailor entrepreneurship education to specific learning environment, business contexts, and community needs.

Entrepreneurship education has been embedded in a design thinking lens, as evidenced by the increasing number of that have roots in design element (Garbuio et al. 2018; Glen, Suciu, and Baughn 2014). Yet there is limited understanding and empirical research of the conceptual underpinnings and the implementation of such practices. Additionally, whether fully online, hybrid, or in-person with social distancing constrains, these learning formats represent a substantial departure from normal study year.

 © ISLS

Objectives and Research questions

To address the above learning, research, and practical gaps, this study seeks to explore these issues by examining the following research questions (RQs):

- RQ1: How student groups differ in design thinking capacity building learning mechanism during knowledge mapping, knowledge transfer and knowledge creation process in the three case studies?
- RQ2：How Co-Design pedagogy plays a critical factor in providing the collaborative learning environment from multi-stakeholders for student learning outcome achievement?

Scholarly Value

By explicitly linking co-design learning process to knowledge creation for entrepreneurship capacity building, this paper introduces a novel educational framework that provides a valuable pedagogical structure for entrepreneurship education. We provide theoretical links to build up a conceptual framework on one observation study featuring cross-sector Co-Design as participatory pedagogy and propose recommendations with a multi-stakeholder learning model which empowers learning pathway in future learning ecosystem and suggest a wider applicability so that the framework will be valuable also for other teaching and learning program for higher education as well as inform ongoing relevant program re-design and improvements. Our observation study focused on how students worked together with their program advisors, peers, and user groups to co-design a prototype from defining the real-world problem to deliver the value with the community members.

Argumentative characteristics of equal and active participation in project-based learning

Sixiong Peng, University of Tokyo, speng@s.h.k.u-tokyo.ac.jp
Haruka Matsuya, University of Tokyo, matsuya-haruka789@g.ecc.u-tokyo.ac.jp
Hiroshi Nemoto, Miyazaki Omiya Senior High School, hiro41nemo10@gmail.com

Abstract: Equal and active participation is a desirable team state in the process of collaborative learning. In this study, we analyzed an argumentative aspect of equal and active participation in project-based learning: an 8-day online innovation workshop. Epistemic network analysis revealed that learners engage in elaborative discourse when they participate equally and actively. Furthermore, such time can be clustered into two types which have a distinct mechanism for facilitating participation.

Introduction

In project-based learning, learners collaborate in teams to work on projects in real-world contexts. Although the quality of collaboration severely influences the learning outcomes, learners are not always able to collaborate effectively, which raises needs to support their collaboration. One of the important aspects to analyze quality of collaboration is participation (Weinberger and Fischer, 2006). Over a course of project, the level of learners' participation fluctuates depending on their motivational, emotional, and cognitive states. At the team level, equal and active participation is desirable. Although existing research investigates and the process leading to equal or active participation and how it is sustained in other learning situations (Sinha et al, 2015), deeper understanding is needed particularly in project-based learning, where learners explore questions, generate ideas, and critique and improve their ideas through discussion. To this end, we investigate argumentative patterns in periods when teams participate equally and actively in an authentic case of project-based learning.

Methods

This study used video record of an 8-day workshop on innovative solutions to the challenges of a super-aging society, held at an off-campus educational program in Japan. There were 34 participants, including students and working adults, in six teams of five to six people. The entire workshop was conducted online using Zoom, Slack, and Apisnote. Apisnote is a digital sticky note system for information structuring (https://www.apisnote.com/).

We selected the second day and the seventh day for our analysis and processed 27 hours of video record to computationally identify the start times and end times of each speaking turn, and manually transcribed them. Next, the entire period was divided into 3-minute segments, and the amount of speaking time and the number of turn-taking of each team member in each segment were calculated. We define an equally-participating segment (ES) as a segment where coefficient of variation of both the amount of speaking time and the number of turn-taking among team members are below median of those among all segments. Similarly, actively-participating segment (AS) are defined as a segment where sum of both the amount of speaking time and number of turn-taking among team members are above median of those among all segments. There were 46 segments that are both ES and AS (equally-and-actively-participating segments, EAS), which accounts for 8.3% of the whole segments.

Then, we chose 30% of all segments which include all of the EAS and coded the utterances in these segments for the epistemic network analysis (Shaffer et al., 2016). We employed coding scheme of Kuhn et al (2020) with modification to adjust to our data, which includes Agree, Counter, Claim, Clarify, Elaborate, Elicit, Socio-emotional interaction and Residuals. We compared EAS and other segments to clarify differences in argumentative characteristics between them. Besides, we clustered and compared EAS based on coding results using k-means algorithm with silhouette approach for identifying the ideal number of clusters.

Result and Discussion

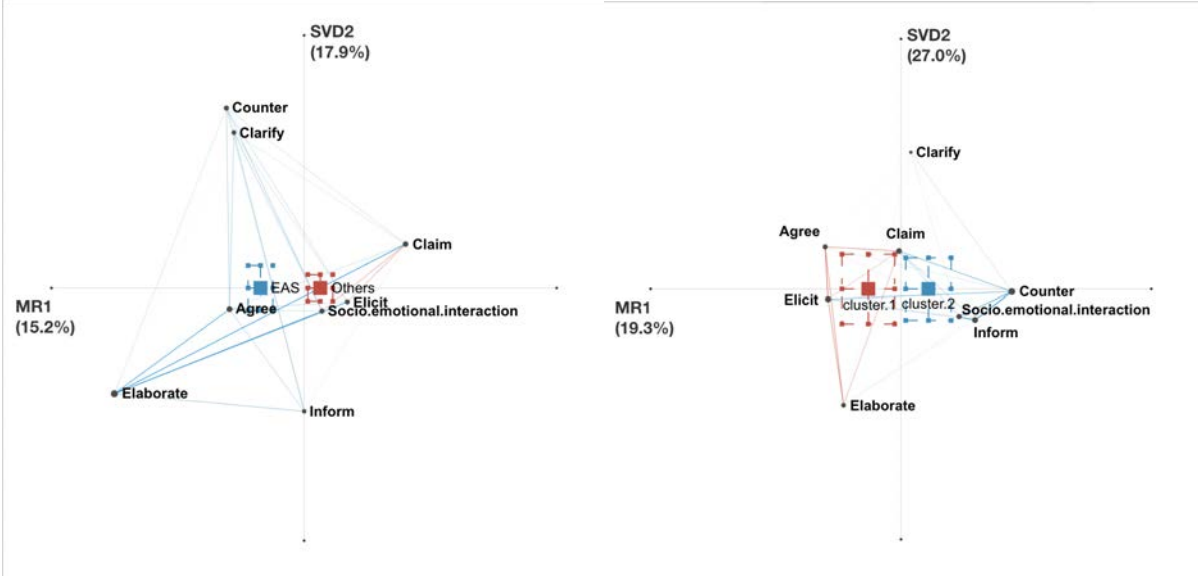
As shown in Figure 1 left, there was a difference between the EAS and other segments on the X-axis, which is statistically significant ($U = 4267$, $p = 0.00$, $r = -0.5$). Links between Elaboration and other codes were particularly strong in EAS. This means that members listen to each other and make new claims based on the other's claim in EAS. This type of utterances might help to maintain the attention of more members towards ongoing discussion topics by rewarding and integrating their contribution, which facilitates equal and active participation of team members as a result.

 © ISLS

Furthermore, k-means clustering of EAS resulted in two clusters (average silhouette coefficients = 0.19). The difference between two clusters is shown in Fig.1 right, which is statistically significant on the X-axis (U = 409, p = 0.00, r = -0.56). In cluster 1, links between Agree, Elaboration, and Elicitation were strong, while in cluster 2, links between Counter, Inform, and Socio-emotional interaction dominate. In cluster 1, some members tried to build a common understanding of ongoing topics by confirming their perceptions or tried to make consensus through questions eliciting others to share their opinion (Elicit and Agree). These were followed by new claims (Elaboration) based on the common understandings or the consensus that they had just made, advancing discussion rapidly as a result. On the other hand, in cluster 2, teams typically make critical arguments (Counter) while utilizing supporting facts (Inform) or laughing (Socio-emotional interaction) to form friendly moods. In this way, team members could express their critical views which provoke others' explanations while avoiding interpersonal conflict. Stories of both clusters seem to be related to the equal and active participation of teams. Attentional and coordinative factors seem to be at play in both clusters; an advance in a topic which induces new consideration and development of common understandings or consensus which ensure common grounds in cluster 1, and a critical view which requires explanation and supporting evidence and a friendly mood which maintain an interpersonal relationship in cluster 2.

Figure 1

The comparison plot between EAS and other segments (left) and between clusters of EAS (right)



Our initial result suggests a mechanism that equal and active participation occurs and sustains in project-based learning. As well as increasing cases for validating our findings, future works will compare teams that experience more or less of certain types of equal and active participation and reveal underlying factors explaining their differences, which leads to a concrete way for supporting collaboration in project-based learning. Also, the effects of experiencing different types of equal and active participation for learning outcomes are of interest. In our case, teams that experienced the cluster 2 type of EAS more received higher evaluations for their final products from participants in the workshop, which suggests different effects among types of equal and active participation.

Developing Computational Thinking via Knowledge Building

Hsien-Sung Huang, National Chengchi University, Taiwan, 108152009@nccu.edu.tw
Yu-Hui Chang, National Sun Yat-sen University, Taiwan, yhc@mail.nsysu.edu.tw
Huang-Yao Hong, National Chengchi University, Taiwan, hyhong@nccu.edu.tw

Abstract: This study explored the impact of knowledge building pedagogy within a collaborative learning community on students' understanding of computational thinking (CT). The participants were 101 middle school students who attended a 6-week course to work on Scratch programming guided by knowledge building principles. An international challenge test on computational thinking called "Bebras Challenge" was employed to evaluate students' CT. Primary findings indicate that students significantly improved their CT skills in the end of the course.

Introduction

Computational thinking (CT) involves adopting a set of problem-solving skills and techniques which software engineers use to design programming code, including the core competence to break down complex tasks into simpler components, algorithm design, pattern recognition, generalization and abstraction (Wing, 2006). While integrating CT has already in K-12 school in many countries, it is still at its early stage in Taiwan due to lack of innovative teaching and pedagogy. Under this context, a community-based learning site, MIT's Scratch, has become one of the popular learning environments to develop learners' CT in K-12 courses in Taiwan recently. Accordingly, a recent call for education reform in Taiwan has begun to transform curriculum guidelines by asking teachers to provide more learning opportunities for students to learn together collaboratively. Learners thus are expected to contribute collaborative ideas and work creatively in their community. While using Scratch as a programming learning context can help learners develop CT (Zhang & Nouri, 2019), educators in Taiwan are still on their ways to explore diverse pedagogical approach and to engage students in developing CT competency in a collaborative learning environment.

In this study, we adopted knowledge building pedagogy and engaged students as a knowledge community (Hong & Scardamalia, 2014) to work on Scratch programming via collaborative grouping and re-grouping strategies. Through interactive discussion and mutual assistance among group members, students were guided to collaboratively complete the programming problems/tasks assigned, learn problem-solving skills and develop the core competence of computational thinking. By facilitating the whole class as a knowledge community, we investigated if such learning environment can foster the development in CT.

Method

Context

Participants were middle school students (n=101) from two classes (7th grade and 8th grade) in an urban city in Taiwan. They enrolled in a 6-week course called "Scratch Programming" with 45-min per week. One researcher was the primary facilitator to lead the course. Under the guidance of knowledge building principles of "real idea, authentic problem" and "idea diversity" (Scardamalia, 2002), students were asked to work in small group and to work on guiding examples via Google Form. They then solved the assigned programming tasks while guiding by the principle of "real idea, authentic problem: Then they exercised the CT by translating group-generated and -shared ideas (as guide by the principle of "idea diversity") into practice to test out their programming ideas on the Scratch platform. Afterwards, they documented group results in Google sheet. Specifically, students were in homogenized grouping of 3 to 4 people in a group based on the pre-test results of Bebras Challenge.

Data

Bebras Challenge was the instrument to evaluate CT performance. We conducted it at the beginning and the end of the course to collect pre- and post- test for quantitative analysis. Paired-sample t-test was performed to examine whether there was any significant difference between the pre-test and post-test. There were 10 single-choice questions to evaluate students' the core competences of computational thinking and problem-solving skill, such as the ability to break down complex task into simpler components, algorithm design, pattern recognition, pattern generalization and abstraction. The scoring rubrics including 3 points for correct answers, with 1 point being deducted for wrong answers, zero points for unanswered questions, and the maximum score was 30 points.

 © ISLS

Result

Table 1 shows the overall results. It was found that after engaging in group-based collaborative knowledge building for 6 weeks, regardless of the grades, all the participants' understanding of computational thinking significantly improved from pre-test to post-test (t=-5.018, p<.01). Table 2 further shows that there is a significant difference between 7th and 8th grade students, with 8th graders significantly outperforming the 7th graders in the pre-test scores (t=-3.830, p<.001). This is due to the fact that 8th graders were more knowledgeable with one more year of schooling ahead. But there is no significant difference in the post-test (t=-1.157, p<.243), indicating that the 7th graders were able to benefit more from knowledge building guidance than the 8th graders. In brief, after this course, all participants demonstrated a more informed understanding of computational thinking.

Table1

Understanding of Computational Thinking (Paired-Sample T test)

Grade	N	Pre-test		Post-test		t-value	Sig. (2-tailed)
		Mean	Std. Deviation	Mean	Std. Deviation		
7th and 8th	101	10.25	6.128	14.74	9.056	-5.018	.000***

*p<.05 **p<.01 ***p<.001

Table2

Understanding of Computational Thinking (Independent-Sample T test)

Grade	N	Pre-test		t-value	Sig. (2-tailed)	Post-test		t-value	Sig. (2-tailed)
		Mean	Std. Deviation			Mean	Std. Deviation		
7th	46	7.87	5.463	-3.830	.000***	13.59	9.872	-- 1.157	.243
8th	55	12.24	5.984			15.71	8.281		

*p<.05 **p<.01***p<.001

Conclusion

In summary, the findings indicate that students improve their understanding the concepts of computational thinking after the study. Prior to the course began, 7th grade students have not learned the method of computational thinking to solve problems while 8th grade students have already had a year of learning. Therefore, there was a significant difference between 7th and 8th grade students in the beginning. However, after the six weeks course, students have improved their core competences of computational thinking. Finally, there is no significant difference in the post-test. In conclusion, after engaging in knowledge building pedagogy for six weeks, students demonstrated a significant improvement in the core competences of computational thinking. In future research, we will focus on "how" students changed and further analyze their collaborative learning process during this course.

Reading Minds: Exploring Relationships between Sensor-Data and Self-Reported Cognitive-Affective States of Learners

Sharanya Lal, Tessa H.S. Eysink, Hannie A. Gijlers, Willem B. Verwey, Bernard P. Veldkamp
s.lal@utwente.nl, t.h.s.eysink@utwente.nl, w.b.verwey@utwente.nl, b.p.veldkamp@utwente.nl
University of Twente

Abstract: Cognitive-affective states (CASs) strongly affect learning outcomes. Therefore, learning systems need to be CAS-aware to truly cater to learners' needs. In this study, we explore the possibility of multimodal sensor data as reliable indicators of learner CASs. Data collected will include skin conductance, heart rate, skin temperature and global gaze properties, which will be compared with self-reported CASs of learners. Linear mixed models will be applied and results will be presented at the conference.

Introduction

In this paper, we submit a multimodal approach to detect cognitive-affective states (CASs) in learning environments. This is crucial because learning outcomes are greatly influenced by the cognitive affective state (CAS) of the learner (Pekrun, 2006). Specifically, positive emotions such as enjoyment and pride are associated with high levels of engagement and high learning outcomes, whereas persistent negative emotions such as anxiety and boredom are strongly related to low learning outcomes (Pekrun, 2017). Therefore it is pertinent that today's intelligent learning systems take into account a learner's CAS while providing support or feedback. For this to be possible, there must be a way for a system to actually perceive a learner's CAS. This is the need our study aims to address.

One obvious way of ascertaining CASs is to always ask the learner. Naturally this is obtrusive to the learning experience. Ideally an intelligent learning system would, by employing discreet means to collect information from various modalities, build a reliable impression of a learner's CAS. In other words, the key to a highly perceptive learning system is unobtrusive multimodal data collection. Our research project explores precisely this with a focus on sensor technology that can be deployed in real-world classrooms. Therefore we work with data that can be collected via pervasive computing technology – portable computers, unobtrusive sensors and wearables. In this study, we focus on skin conductance, heart rate, skin temperature and global gaze features. This is because past studies have found strong relationships between stress during difficult tasks (Brouwer et al., 2018), emotional arousal (Jindrová et al., 2020) and skin conductance. Research also finds that changes in heart rate and skin temperature may indicate cognitive-load (Larmuseau et al., 2020). Moreover, gaze features such as fixations, saccades have previously been used to determine attentional or mind-wandering states (Hutt et al., 2017). In this study, we investigate whether (a combination of) these measures can give us a reliable (and fuller) picture of a learner's state. The possibility of discriminating between sustained positive and negative learner CASs is of particular interest to us. For example, low skin conductance accompanied by a large number of fixations could indicate an attentive low arousal state whereas the same accompanied by a low number of fixations could indicate an inattentive low arousal state such as boredom which in turn negatively affects learning outcomes (Pekrun, 2006). In essence, this is an exploratory study of the relationship between (combinations of) sensor data and CASs as described by self-reports.

Methods

Participants will comprise of 30 BSc Psychology students from the University of Twente. Participation will be voluntary and active consent will be obtained from all participants before the start of the experiment. Data will be collected via self-reports (described below), the Empatica E4 biosensing wristband (https://www.empatica.com/research/e4), Tobii Pro Fusion (https://www.tobiipro.com/fusion/), a screen based eye-tracker and a generic webcam. All participants will spend an equal amount of time doing three tasks. The first task will be to play Tetris (www.tetris.com). Tetris has been selected because it is an extremely popular and widely studied (Mayer, 2014) game that can bring players into a positive CAS of effortless attention (Harmat et al., 2015). The second task will be to repeatedly match pairs of two-dimensional shapes. The third task will be to "solve" a coordinate geometry puzzle. This will be a wild goose chase because the researcher will never accept an answer as correct. Based on pilot testing it is expected that participants will experience CASs that are positive high-

 © ISLS

arousal (Tetris), negative low-arousal (shape-matching) and negative high-arousal (coordinate geometry puzzle). It is also expected that the baseline (a relaxing music video) will induce a positive low-arousal CAS. The study will use a counterbalanced design for the three tasks to mitigate order-effects. A multiple baseline approach will be employed with 1 minute cooling off periods between tasks. At regular intervals during the study, participants will complete 4 self-report items:

1. The Affect Grid (Russel et al., 1989), a 1-item scale of CASs along two dimensions, arousal and valence,
2. a five-scale item, "This task is: 1) Too easy 2) Easy 3) Just right 4) Difficult 5) Too difficult",
3. a 7-scale item, "I am actively engaged in what I am doing. 1 (not at all) to 7 (very much)" (Kirtley et al., 2019), and
4. An open-ended fill-in-the-blank statement: "I am feeling __".

Results

Within-subject relationship between self-reports and physiological signals will be explored using linear mixed models while controlling for demographic data. Pairwise comparisons will be computed after having applied Bonferroni correction. Results will be presented at the conference.

Practical and ethical considerations

Detection of CASs is highly relevant because it allows us to consequently design intelligent learning systems that are tailored to the needs of each individual learner. A sensor based approach to CAS detection means that this 'tailoring' is informed by a user model that is updated dynamically during a lesson as opposed to the traditional approach of user profiling based on information known before a lesson (for example, sex, age, prior knowledge, race etc). We believe that this increases fairness in the artificial intelligence by mitigating human bias.

Student Reflections on Data Investigations of Local and Extreme Weather: A Cultural Historical Activity Theory Perspective

[1]Asli Sezen-Barrie (asli.sezenbarrie@maine.edu), [2]Josephine Louie (jlouie@edc.org), [2]Brianna Roche (BRoche@edc.org), [2]Emily Fagan (EFagan@edc.org), [2]Pam Buffington (PBuffington@edc.org), [3]Brian, Fitzgerald (bfitzgerald@mountwashington.org), [2]Kevin Waterman (kwaterman@edc.org), [4]William, Finzer (wfinzer@concord.org), [5]Deb L. Morrison (eddeb@uw.edu)

Abstract: This study analyzes middle-school students' reflections on working with large-scale scientific data to investigate local extreme weather using the digital tool CODAP. Drawing from student focus group interviews and Cultural Historical Activity Theory, we examine factors that appeared to impede or facilitate data science learning in a sample of rural middle schools.

Introduction

There is increasing demand for data science skills in modern science (e.g., developing climate data models). Data science requires the use of digital tools to manage, visualize, analyze, and communicate findings from extensive amounts of data (Hey, Tansley, & Tolle, 2009). Many argue that learning data science can lead to enhanced scientific literacy among the public (Ceccucci, Tamarkin, & Jones, 2015). Middle school students currently have limited exposure, however, to working with authentic large-scale data (Wilkerson & Polman, 2020). Our project has been collaborating with rural science teachers in northern New England to design and implement two curriculum units in which students investigate local extreme weather phenomena using large-scale weather data and the data analysis tool CODAP. Drawing on student focus group interview data, this study examines challenges and opportunities for integrating data science into rural middle-school science classrooms.

Theoretical Framework

We use Engstrom's (1987) Cultural-Historical Activity Theory (CHAT) to analyze students' science classroom contexts and factors that may impede or facilitate data science learning. CHAT suggests identifying the following activity components: *Subjects,* or the histories and characteristics of major participants; the *object,* or the activity's goals; *tools* or *mediated artifacts*, or the socially shared cognitive or physical resources; *rules and norms*, which govern social interactions; the *community,* or the group context; the *division of labor,* how responsibilities are shared; and the *outcome,* or the product of the activity. CHAT attends to the contradictions (i.e., conflicting ideas or experiences at the time of change or reform) and affordances of activity components to understand why activities may succeed or fail. Previous studies have used CHAT to understand how subjects' backgrounds and interests may shape scientific norms, rules, and practices and affect classroom activities (e.g., Saka, Southerland, & Brooks, 2009). Others have looked at contradictions in science teaching activities to gain insight into the culture and outcomes of specific programs (Roth and Tobin, 2002). Using CHAT, this study addresses the following question: What contradictions and affordances for learning data science are present in rural middle-school science classrooms when investigating local extreme weather?

Methods

Study participants were middle-school students (ages 12-14) from four U.S. rural schools in northern New England. Study data are from five student focus group interviews conducted in winter/spring 2021, each lasting 45-60 minutes with 2-4 students per group. All interviews were conducted through Zoom, recorded, and transcribed. Initial coding categories were based on CHAT components. Coded excerpts were analyzed using micro-level discourse analysis (Gee, 2010). For instance, microanalysis led to the following subcategories for Subjects: a) student academic background in data and b) student experiences with local weather phenomena. Themes were organized around contradictions and affordances.

Findings

Preliminary findings suggest that contradictions and affordances fall under four major themes: 1) building a local classroom data source, 2) digital tools for conceptual and epistemic learning, 3) prior student experiences/interests, and 4) shifting scientific and pedagogical norms. Below we provide an example of two of these themes—the first a contradiction, and the second an affordance.

 © ISLS

Building a local classroom data source

Students suggested that a challenge they faced in one activity was assembling a classroom data table with 14 days of weather measurements from each student. In each participating classroom there were students who did not complete their measurements (and therefore did not do their part in the class division of labor). A student lamented that incomplete data from his friends prevented them from achieving their goal of making data comparisons:

Researcher: What did you like about this activity, and what did you not like?

Student 1: One thing that most of us didn't really like is that when we were doing a class discussion about the day-before weather, some kids didn't actually write down the data, so we didn't have as much to compare.

Digital tools for conceptual and epistemic learning

Students suggested that CODAP is a tool that supports conceptual sensemaking and the norms of scientists and statisticians. The excerpt below illustrates how students used authentic scientific data and CODAP to make sense of data patterns, and how they draw on scientific and statistical norms to make a claim if weather is extreme.

Researcher: How would you say you decide if a weather event is extreme or not?

Student 1: Yeah, if you compare it to like the average temperature, and it's like what is low and what is above the temperature. So like yeah, it'd be extreme.

Student 2: Yeah. Just comparing like the average temperature with the wind speed to the typical weather. That would tell if it's extreme or not.

Researcher: Was that helpful when looking at the thirty-year averages versus the storm?

Student 1: Yeah, I think the CODAP really helped with the thirty-year graph.

Discussions and Conclusions

Integrating authentic data practices in science classrooms goes beyond "cognitive skills and statistical algorithms" (Radinsky, Tabak, & Adach, 2021, p. 1072). It requires attention to social-cultural dynamics within classroom cultures and the histories students bring to their learning activity. Because daily-life decisions and future careers are becoming more data dependent, learning scientists are exploring effective ways to integrate data in school curricula. Building innovative, digital tools and meaningfully designed educational activities are crucial steps. However, researchers need to understand how students engage with these tools and view the importance of data for their lives and communities. We contribute to these efforts by offering a CHAT perspective for analyzing students' reflections, which can help reveal unseen social, cultural, and historical factors when learning data science skills in a weather science context.

Opportunities and Challenges for Enacting Equity and Justice-centered CS Learning In "Drag vs. AI" Workshops

Janet Ruppert, Ricarose Roque, R. Benjamin Shapiro
janet.ruppert@colorado.edu, ricarose@colorado.edu, dude@colorado.edu
University of Colorado Boulder

Abstract: We present initial reflections from a study investigating how learning materials and moment-to-moment interactions can enact equity and justice-centered learning in youth STEAM programming. We explore these questions in the context of *Drag vs. AI*, a library workshop in which a professional drag queen leads teens in an exploration of facial recognition technologies (FRTs) and drag makeup as a tool to subvert, fool, and refuse recognition. We are examining ethnographic data from workshops at two sites and plan to conduct follow-up interviews. We will share insights and reflections from our in-progress data analysis around the affordances and limitations of materials and interactions for justice-centered computing education.

Introduction and theoretical background

STEM and STEAM education that attends to power is an urgent and widely felt priority in the learning sciences. Scholars are designing and theorizing at this intersection with a variety of analytic approaches and learning contexts. Considering the growing role of big data in educational, housing, and employment opportunities, several studies have focused on critical data literacies, which allow people to understand, use, and produce data with critical orientations. This scholarship has established bias, exclusion, and discrimination in data representations as a generative topic for advancing critical data literacies among youth. However, there is a lack of queer, trans, and intersectional approaches to research around carceral technologies and algorithmic bias (Paré, 2021, pp. 12-16).

We build on justice-centered computing education research by exploring learning in a drag queen-led STEAM workshop that engages teens hands-on with makeup as a medium to fool FRTs, framed in critical discussions of FRT systems. In *Drag vs. AI* (Algorithmic Justice League, n.d.-a) participants learn about FRTs and use drag makeup techniques to camouflage themselves and refuse classification. The website where participants can test how AI guesses their age, emotion, and gender is a platform for embodied experimentation with AI, where teens can build on and refine existing, intuitive youth practices for reverse-engineering algorithmic literacies (Algorithmic Justice League, n.d.-b). We modified the workshop to include local connections (e.g. a new statewide digital ID app) relevant to participants.

Research questions

With curiosity about how *Drag vs. AI* workshops might support critical, justice-centered CS learning at the intersection of technology and power, we explore the following questions: (1) How were equity and justice-centered theories and pedagogical approaches to CS learning enacted through materials and moment-to-moment interactions in *Drag vs. AI* workshops? (2) How can queer values, epistemologies, and pedagogies emerge and support justice-centered CS learning? (3) How can the design and facilitation of *Drag vs. AI* support transformative sociotechnical knowledge production and identity development?

 © ISLS

Figure 1

Workshop host Cardi Acarrest presenting on facial analysis.

Data collection and analysis

Ours is the first empirical study of *Drag vs. AI* over two workshop enactments, one at a public library and one at a queer youth resource center in the Western US (see Figure 1). We recorded audio, video, and fieldnotes during workshops. After each workshop, we recorded memos and audio of debrief sessions with facilitators, including community partners. In our data analysis, we are applying inductive ethnographic approaches and qualitative coding to better understand how justice-centered CS education was supported in workshops.

In-progress analysis has yielded insights into how participants developed critical algorithmic and data literacies while manifesting queer values and epistemologies through their interactions with the AI platform and moment-to-moment interactions. In our next steps, we plan to investigate how drag pedagogy (Keenan & Hot Mess, 2020) can support theoretical elaborations and practical learning design considerations of justice-centered CS learning.

CT for All?
Computational Thinking in Danish Language Arts

Roland Hachmann, Post-doctoral Researcher, University of Southern Denmark
Stig Børsen Hansen, Associate Professor, University of Southern Denmark

Abstract: This poster presentation discusses ongoing, design-based research that investigates how middle school pupils use computational thinking strategies as part of their collaborative effort to write interactive stories, using the online tool Twine within the school subject of Danish (L1). A tool, specifically designed to support pupils' processual text production is introduced, and its affordances and constraints as a structuring resource, supporting the pupil's computational participation and literacy skills, are discussed.

Introduction: the basic challenge

This poster serves to 1) foster a conversation in the learning sciences community around materiality as a design constraint regarding pupils' computational thinking strategies, 2) document a design for learning computational thinking beyond a STEM context in primary school. 3) initiate a discussion of the reach and applicability, beyond computer science, of computational thinking. A key motivation for utilizing tangible things in designs for learning CT is the need to negotiate two ideas: That CT is an abstract mode of reasoning that can be applied in a wide array of settings beyond computer science (Denning & Tedre, 2019) and the idea that learning is situated (Lave, 1988; Dohn et al, 2020). The use of tangibles supports the latter point; the integration of tangibles with use of software supports CT as a more abstract form of knowledge. The use of CT beyond computer science can be framed as a matter of a new form of literacy that is fostered and exercised in different avenues (Kafai & Proctor, 2021), or as a matter of designing for transfer or transformation of knowledge and skills (Dohn et al, 2020).

Theoretical foundations: Computation, transfer and situativity

"Computation" can be understood as a mechanical process being performed on symbols for concepts as well as symbols for numbers. The manipulation of symbols for concepts has its roots in Ramon Llull's *Ars*, the numerical in Leibniz's thinking, and they were synthesized in Boolean algebra (Hansson, 2018). The conceptions share the notion that computation is a certain "mindless", "mechanical" or "procedural" feature of thinking (Hansson 2018). Being mechanical, the task of thinking is transferred from a human to an external, physical piece of equipment or agent. Two aspects of computation are emphasised in this design experiment: The manipulation of concept-words rather than numerals, and the externalisation of thinking to something physical. This, in turn, is intended to facilitate pupils' computational literacy.

Both traditional approaches to transfer (Gentner et al., 2003) as well as traditional conceptions of information emphasise the abstract character of transfer and information, respectively. In contrast, recent developments, both in learning (Levi, 2009) and understandings of information (Dourish, 2017) have emphasised the importance of the material aspects of learning and information. As Dourish suggests, materials produce interesting constraints in computer science, and we follow Levi and others in proposing that they are equally of relevance to learning. The close integration of physical manipulation of concept-representations with use of software is motivated by these more recent developments.

The empirical study

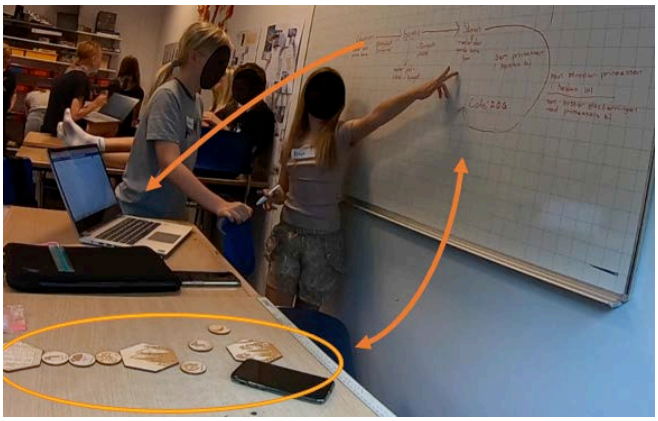
The Design-Based Research (Amiel & Reeves, 2008) reported on here takes place in two Danish middle schools with pupils aged 10-12 (grade 4 and 5). A pedagogical design and a specifically designed tool were tested. At this point in time the 1st iteration is completed, and 12 groups (2-3 pupils) were followed and studied. 6 groups were videorecorded and materials that were produced have been collected and preliminary analysis of recordings have been conducted.

First, the pupils were introduced to the beginning of a fictional text, *The Horrible Hand*. The story was read aloud in class as a starting point for the pupils to continue developing their own stories. To aid the pupils in this task, a tool (fig. 1) was developed consisting of 19 wooden pieces (5 large and 14 small), with different motives engraved into them. On the backside of the 5 large pieces, the pupils could access small excerpts of the original story (via a QR code to a homepage) picked by the designers. The pupils could use these as inspiration

 © ISLS

but were not forced to do so. Lastly, the pupils were asked to produce an interactive story in the open-source application called Twine (twinery.org).

Figure 1: Figure 1: The wooden pieces are organized on the table, where they mediate the pupils' structuring and negotiation. They use the whiteboard as further support before writing in Twine.



Preliminary findings and discussion points

Finding 1: The tangible materiality of the wooden pieces (fig. 1) constrain the pupil's construction of the story to step-by-step sequences, both allowing them to decompose their ideas into smaller parts as well as arrange and re-arrange elements of their story in a meaningful way. Finding 2: Further, the wooden pieces foster opportunities for pupils to develop new strategies for structuring the narrative in their stories. It points to a positive impact on the way pupils can survey and organize their text and adds both concrete and embodied experience and new forms of reifications (Wenger, 1998) to their negotiations of the different elements of their stories. Finding 3: The tools (B) place requirements on the pupils' abstraction and literacy skill. Preliminary findings suggest that although the tools are material representations and constrain the writing process into smaller parts, some pupils need support. The question remains whether design solutions can be made, that to a greater extent guide pupils and scaffold their learning process.

Early indications for the next iteration of the design suggest that less firm scaffolding, carried out by the teacher, in the initial stages of the writing and ideation process increases the pupils' creative use of the wooden tools, resulting in more diverse and well written products.

Draw-a-Computer-Scientist-Teacher? Designing for expansive identities in undergraduate Computer Science

Joanna Weidler-Lewis, Colby College, jweidler@colby.edu
Stacy Doore, Colby College, sadoore@colby.edu

Abstract: This poster investigates integrating teacher identities with disciplinary identities in the domain of computer science. Initial findings from a study analyzing undergraduate perceptions of both computer scientists and teachers are presented. Drawing on socio-cultural theories of learning and identity, we argue, and our findings suggest, that surfacing perceptions of both computer scientists and teachers is a productive exercise to reveal areas of commonality and contradictions to overcome in our designs for learning in both domains.

Introduction

Multiple rationales support increasing access and expanding competencies in computational thinking and literacy across the K-12 curriculum (Blikstein & Moghadam, 2019). Much of the work on teacher learning related to this domain has focused on designing professional development for teachers to better integrate these computer science (CS) skills into their classrooms (e.g., Grover & Pea, 2018; Yadav et al., 2016) with the skills themselves seen as having significant value independent from the CS disciplinary domain in which they originated. While encouraging teachers to include CS skills in their teaching practice is desirable, we also think more CS disciplinary experts ought to recognize how teaching supports an extension of their disciplinary practices (Weidler-Lewis, DuBow, & Kaminsky, 2017.) Our research is broadly interested in how to best support the integration of disciplinary identities with teacher identities and blends Learning Science topics of disciplinary learning, identity, and the fields' nascent focus in teacher learning. We are primarily interested in creating novel entry points into teaching from disciplinary domains both for disciplinary experts and for undergraduate students. We are currently in the process of designing complementary undergraduate learning opportunities to support students' pathways into disciplinary practices, such as CS, and into teaching in K-12 settings.

An impetus for the current work-in-progress study we are reporting here, came from the findings of data collected in introductory undergraduate CS courses from the "draw-a-computer-scientist" activity (Manzo, Doore, & Harmon, 2019). Building on the popular draw-a-scientist task (Chambers, 1983), the computer scientist version helps educators better understand student stereotypes of who they think becomes a computer scientist, and then shape curriculum and instruction to combat problematic stereotypes and increase representations of who is and can be a computer scientist. Our data included student responses to the task to list three words that come to mind when thinking of a computer scientist. Given our interest in developing supports for undergraduates to identify with and pursue both teaching certification and CS degrees, an open question emerged that we are now seeking to answer: *What are the similarities and differences between how undergraduate CS students describe computer scientists and how they describe teachers?* We argue answering this question will help us see opportunities to strengthen CS majors' pathways into teaching as well as the potential contradictions that may need to be overcome in students' perceptions of these disparate identities.

Theoretical Perspectives

We take a broadly sociocultural approach to learning, acknowledging identities play a significant role in our ability to learn and act in the world and in disciplinary ways (e.g., Gee, 2000). We see our role as undergraduate educators to create possibilities for students to see themselves as future teachers and CS professionals by providing them with "trajectories of identification" (Polman, 2010) into these domains. While we recognize the relationship between a teachers' disciplinary identity and how they engage pedagogically as a teacher (Luehmann, 2016), we prioritize expansiveness insofar as we do not prescribe any one way of being a disciplinary or teaching expert, but rather embrace a multiplicity of identities in and across domains. We believe such a perspective is necessary if we are to increase representation and access into disciplines that have historic patterns of identity association (e.g., computer science is often characterized as white and male.)

Methods

This study is a work-in-progress that builds on our prior work (Manzo, Doore, & Harmon, 2019). In our current iteration, we are administering the modified draw-a-computer scientist test used in our previous study that now adds the questions: *what adjectives best describe a teacher* and *what adjectives best describes a computer scientist teacher* in addition to the questions on the original draw-a-computer scientist test (Martin, 2004). We will have

 © ISLS

data from four introductory computer science classes at a college in the American northeast with an expected participant count of 100. For our purposes here, we have analyzed data from two classes (participant $n = 39$). We will conduct a more thorough analysis of the complete data, including word associations and pairs across the participants. Here we are presenting frequency percentages of terms to look for similarities, patterns, and contradictions across the terms.

Findings

Initial examination of our current data provides compelling evidence that this is a generative activity to think about the ways in which our students perceive both teaching and computer science as well as their intersection. Table 1 shows the top three terms for how students perceived computer scientists, teachers, and computer scientist teachers with the percentages of students using the term.

Table 1 *Top terms for computer scientists, teachers, and computer scientist teachers with percentages reporting*

Computer Scientist Terms	Percentage of Students	Teacher Terms	Percentage of Students	Computer Scientist Teacher Terms	Percentage of Students
Smart	25.6 %	Caring	30.8 %	Knowledgeable	23.1 %
Intelligent	20.5 %	Knowledgeable	28.2 %	Intelligent	17.9 %
Knowledgeable	17.9 %	Intelligent/compassionate	12.8 %	Patient	12.8 %

These finding are similar to our prior work in which CS students' highest reported term at 18.8% was "smart". Note that being "knowledgeable" is reported at a greater percentage for a teacher than "smart" is for a computer scientist, and being "smart" drops off the top three list for how students perceive computer scientist teachers with "patient" moving into the top three terms. For non-CS-teachers, "patient" was report 10.2% and "smart" at 5.1%.

Discussion and Conclusion

The shared terms across the different domains provide compelling evidence for what characteristics we ought to foster while designing expansively for learning across these domains. A significant finding for us is the lack of any explicit contradiction in students' perceptions across domains (i.e., being "smart" is not inherently contradictory with being "caring"). This will help us in our designs for learning, however, equally important are the terms not in the top three. For example, "white" and "male" were reported for computer scientists, while "white" and "female" were reported for teachers, suggesting we still have to work at combatting gendered and racial perceptions of these fields. As our findings demonstrate, and the Learning Sciences advocates, surfacing perceptions about identities in the domains we are designing for is an important step toward designing for greater access and equity.

'Bridging the Distance': Developing Entrepreneurial Thinking in an International and Interdisciplinary Learning Environment

Einat Gil, Kibbutzim College of Education, Einat.gil@smkb.ac.il
Anat Even-Zahav, Kibbutzim College of Education, anatez@gmail.com
Justyna Siemionow, University of Gdansk, justyna.siemionow@ug.edu.pl

Abstract: The Covid19 pandemic presented challenges and opportunities for students' learning worldwide. An international interdisciplinary learning environment was designed to bridge the distance, address students' socio-emotional needs and to develop entrepreneurial thinking, a skill needed in times of uncertainty. Twenty-four education students from two countries took part in six online sessions. Initial results support the contribution of the project to developing the participants' entrepreneurial thinking and to the role socio-emotional aspects play in it.

Introduction

The continuation of the Covid19 pandemic confronts higher education with challenges and opportunities such as finding ways to address the quality of distance learning instruction and addressing social and emotional needs of those who partake in teaching and learning. The importance of understanding both challenges and opportunities are significant for orchestrating future learning, dealing with crisis situations and for improving aspects of teaching and learning in the higher education systems (Engeström & Käyhkö, 2021). Elias (2003) suggested that to conduct life successfully, students need to learn how to understand and manage their emotions as well as how to resolve unexpected problems. Teaching pre-service teacher by looking at self-answering such questions may provide them with socio-emotional competences that lead to personal well-being and employment success (Price et al. 2020).

Developing Entrepreneurship thinking is considered an individual's ability to turn ideas into action and involve creativity, innovation and risk-taking (EU Skills Panorama, 2014). Thus, Entrepreneurial thinking might be an asset for students at this very time of accelerated ambiguity.

In this study we seek to promote entrepreneurial thinking and skills through the design of an online, international, interdisciplinary learning environment that is attentive to studying during the Covid19 era. The program was named "Bridging the Distance" project to signify overcoming forced distancing caused by the pandemic in the local communities; Yet it sought to enable, closeness within the international community, by exploring commonalities and characterizing modes of progression – similar and different in each county.

Our study objectives aim to examine: 1. How does participation in an international and interdisciplinary learning environment contribute to the development of entrepreneurial thinking? 2. What are the characteristics of learning design in an academic course that support developing entrepreneurial thinking among the participants? Our initial findings point to the potential development of entrepreneurial thinking for the students. It also points to the place that socio-emotional aspects play among students during the Covid19 period. Furthermore, it emphasises the importance of the projects' tasks design, which relate directly to the need for socio-emotional support.

Method

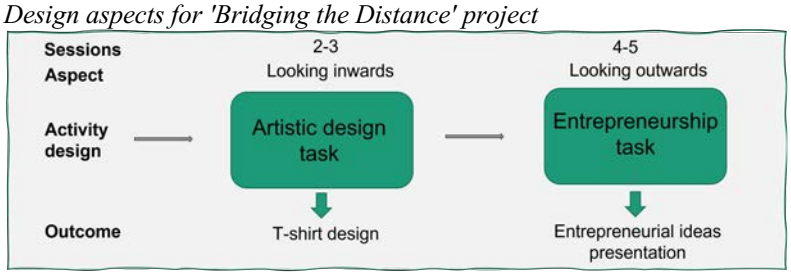
To address these research questions, we designed a learning environment that spans across six synchronous sessions, between Education students in Israel and Poland. The Israeli students enrolled in the *Pedagogical Entrepreneurship* course conducted as part of the *Regev* Excellence program for pre-service teachers at Kibbutzim College of Education and students who study pedagogy at the University of Gdansk University in Poland. The design was led by the Center for Innovation at the Kibbutzim College in collaboration with academic and professional contributors.

Apart from the introduction and summary (meetings 1&6), the learning design included two main teaching units. The first, invites 'inward looking' on challenges of studying during the pandemic using a design task to collaboratively design a t-shirt using a composition of images and text; The second, 'outwards looking' at the challenges and opportunities of this time, creating a proposal for a social, business and/or pedagogical project presented to potential investors (Figure 1). These activities were held during online meetings in mixed international groups and under the guidance of instructors from both institutions.

We use design-based research (Barab & Squire, 2004) aiming for both theoretical and practical contribution in the context of designing an innovative learning environment. Research tools included two questionnaires for the students (n=24); Video documentation of the six synchronously learning sessions; Student

 © ISLS

Figure 1
Design aspects for 'Bridging the Distance' project



written reflections; Interviews with six students; Students' outcome analysis and team design notes. We report on early finding from thematic analysis conducted on the interviews and outcome analysis (iteration 1, 2021).

Results

Our findings point to the contribution of the unique learning environment to motivating participants to collaborate through discussion, design, and entrepreneurial ideas to meaningful learning outcomes. It also points to the incorporation of social interactions that were developed during the study sessions in small groups (3-4 participants) as well as identifying cross-cultural shared challenges among participants to do with studying during the Covid19 pandemic.

The six groups' t-shirt design reflected socio-emotional aspects such as loneliness, the need to look forward in a positive way, and the desire to be together. The entrepreneurial initiatives related to topics such as facilitating anonymous expression of mental health issues, creatively resolving international library book lending and assistive traveling - during quarantine and/or amidst covid19.

The incorporation of social-emotional aspects into the learning design and into the design of tasks of the international project turned to be crucial. From the interviews, several social-emotional aspects were identified as contributors/supporters to the development of students entrepreneurial thinking among them: (1) Instructors' respectful teamwork, acting as role model for collaboration and management. (2) International Students' personal connection and meaningful interaction in small groups. These aspects together with the task design, seemed to assist in facilitating students' Entrepreneurial skills: personal, technical & management (OECD, 2014).

For example, S2 reflected on the connection between people: "I think the first course took place in a zoom where the atmosphere was really really really good socially and also among the lecturers. [..] it was important for everyone to talk and get to know." S3 related the T-shirt task design to bridging the distance: "I believe that it was a very adequate task because it made me think about the pandemic, about what I have lost, so primarily the aspect of interpersonal relations, or rather lack of them." Another student (S5), related to life improvement and innovation: "The second task was also great because it showed me that the knowledge about pedagogy/ education/ psychology, which is what we are studying can be used to improve life, to improve the quality of life… Such knowledge can be translated into actual actions and innovations."

Results from this study contribute to the design of international collaborative learning environments that promote interdisciplinary entrepreneurial thinking enabled by socio-emotional support. Such environment that are built upon students needs in the Covid19 era might help them discuss their challenges together, as well as enable them to suggest innovative ideas to social/educational problems. Further analysis of the data is needed for more precise findings to contribute theoretical and practical insights for an emergent design patterns for international collaboration around theses study aims.

University of North Carolina at Greensboro

Abstract: The pandemic has brought an abrupt shift from in-person community-based programming at an informal weekly STEM-rich making club with minoritized youth, to one of socially-distanced, solo-work only, virtually-facilitated experience. We explore what such an abrupt pivot from in-person to virtual programming meant, including the challenges and tensions, for the design of pedagogical materials and virtual facilitation practices, when facilitators aim to maintain an asset-based, relational engagement where youth can make in agentic ways, pandemic notwithstanding.

Purpose

The Covid-19 pandemic has surfaced many inequities in STEM education, especially for youth of color. Learning environments as youth have come to know them remain unstable, exacerbated by the sudden and necessary pivot to virtual platforms that youth and STEM educators have had to learn to navigate very quickly. While pandemic-related discussions around learning environments in formal classrooms have been robust (McKinney de Royston & Vossoughi, 2021), how, for whom, and to what ends informal STEM settings might pivot during the pandemic have been largely left out of the conversation. This proposal investigates the *virtual* pedagogical practices of informal educators in a community-based makerspace (Make Club) at a local Boys and Girls Club (BGC) that, prior to the pandemic, had operated as a sustained, weekly in-person program for youth. Our overarching research question is: What are the design features built into the virtual pedagogical practices aimed at supporting and maintaining youth maker agency and everyday concerns amidst the pandemic? As STEM education researchers and informal STEM facilitators, we are interested in how youth and informal STEM educators, suddenly limited to virtual programming engage, pivot to continue engaging in rigorous STEM-rich making as a result of the Pandemic, including the challenges, insights, tensions and unanticipated possibilities.

Theoretical Framework

We draw on Cultural-Historical Activity Theory (CHAT) (Engeström, 2001; Gutiérrez & Arzubiaga, 2012) and youth identity (Holland et al., 2001) in learning as guiding frameworks. Youth bring in other identities into the community youth makerspace and there is a plurality and fluidity between their identities-in-practice as youth engage in any particular figured world, either in-person or virtual. CHAT as a framework helps us probe youth engagement on two levels: 1) It allows us to unpack how youth are utilizing what particular pedagogical tools made available in the virtual programming to result in what kinds of STEM-rich making engagement; 2) it makes visible how particular dynamics within an activity system (e.g., different combinations of tool-rule-community) impact youth engagement. Overlaying CHAT with youth identity is helpful in gaining insights into what germane identities-in-practice youth are bringing to bear when negotiating the virtually facilitated Make club activity system.

Methods, Data Sources & Data Analysis

Context: At this BGC Make Club, youth have fostered a community where they have a strong bond and sense of ownership (Calabrese Barton & Tan, 2018). Group collaboration and iterative design are core features of Make Club, for example, youth surveyed club-mates for community concerns that resulted in a semester of building toys such as race cars and coding games on scratch, that Make club youth shared with all BCG children for feedback and further refinement. However, since the pandemic, Make Club has been drastically reconfigured. As a result, by the time virtual Make Club begins at 3:45pm on a Tuesday, Make Club youth participants would have already spent an entire school-day worth of time physically at the BGC, 6 ft socially distanced, with a chrome book. This was due to youth attending school virtually while physically at the BGC. Pandemic rules also dictated only solo work and virtual facilitation by Make Club facilitators. A BGC club staff distributes Make Club materials, individually bagged, from a sanitized table.

 © ISLS

We engaged in participatory design (Bang & Vossoughi, 2016) in our dual roles as long-time Make Club facilitators and researchers. Data includes fieldnotes, zoom videos of Make Club sessions, 18 check in/exit surveys with youth, and educator (Worsley) made artifacts (powerpoints) that surface the pedagogical patterns related to the learning experiences of each youth, analyzed in the grounded theory (Glaser, 1992) for 7 months of 45-minute weekly programming (13.5 total programming hours). The making activity was to create a pop-up book with light-up elements that document significant stories of youths' experiences during the pandemic. While the pop-up cards were the primary project, youth also worked with snap circuits.

For data analysis, we are mapping the trajectory of pedagogical design decisions as informed by, a) pre-pandemic Make Club norms to, b) specific features of pedagogical materials meant for virtual programming, to, c) how youth took up, changed or resisted the making activities planned for. An example of a core analytical thread centers on considering the nature of in-person to virtual pivot of one of the core features of pre-pandemic Make Club --intentionally twinning social design features with technical ones rather than "front-loading" technical know-how as most school STEM activities are wont to do.

Initial Conjectures & Next Steps

Through mapping CHAT triangles for various virtual sessions layered with identity analysis a recurring theme emerged –the imbricated nature of relational representation with pedagogical content modeling and with community building during an isolating pandemic. Even though youth were physically together in a room at the BGC, they were isolated from one another. We mapped the ways in which relational representation were made manifest in the weekly powerpoint slides. First, video representation of an established, embodied presence was helpful in creating short videos (boomerangs) featuring Worsley, the primary Make Club facilitator who shares identifiers with the youth. These videos were used as a direct result of the shift to virtual facilitation. It was important and meaningful for the youth to "see Ms. T show us". Short videos featuring Ms. T's hands "making" included doing particular pop-up folds, showing the trickiness of working with flimsy copper tape, explaining her social reasons for designing a particular pop card. This way, we were "there" with the youth demonstrating and modeling the technical steps as we engage in dialogue with them in real-time, through zoom. In our years of experience as STEM facilitators, youth have also consistently remarked of the lack of representation of Black people in making videos or STEM videos one could locate online. To exemplify relational representation we intentionally populated the slides with Black people, characters, and cultural references as well as pictures of BGC staff and ourselves. We are analyzing how these representations impacted how various tools (including physical materials like copper tape, scaffolding activity sheets showing different types of circuitry from simple to parallel, other art-based materials) were taken up by youth as they navigate the activity system, in connection with which salient identities. For example, many youth were experiencing personal loss in their families to Covid-19, which brought somber designs to the cards. We are further investigating how youth-centered design for virtual programming could facilitate needed caring during stressful times as such.

Supporting Elementary School Teachers in Their Learning of Programming and Robotics: A Case Study

Tugba Boz, Dublin City University, tugba.boz@dcu.ie
Martha Allexsaht-Snider, University of Georgia, marthaas@uga.edu

Abstract: We examined elementary school teachers' learning of block-based programming and robotics under the guidance of an instructor in a professional learning (PL) course. Data consisted of teacher artifacts and videos recorded in the PL course. Data analysis revealed that the type of guidance and support the instructor provided helped teachers develop their programming skills and shaped their attitudes toward programming integration in elementary schools. The instructor's guidance also posed a few barriers to teachers' learning.

Introduction and background

Many scholars recognize the importance of teaching programming in elementary schools to develop students' computational thinking skills and increase their interests toward computer science and programming starting from early ages (e.g., Lye & Koh, 2018). The literature has some preliminary answers that propose ways to prepare current elementary school teachers to teach programming. These answers generally come from end of program or training teacher evaluations (Cooper et al., 2011), teacher artifacts such as lesson plans (Savard & Highfield, 2015) or programs/scripts of programs (Gabriele et al., 2019). However, more studies are necessary to reflect the complex processes of teacher learning. As Cochran-Smith et al. (2014) claimed, teacher education research should "resist simplification, and account more fully for teacher education's contexts and processes" (p. 105). Therefore, we undertook a case study of how to support teachers in their learning of block-based programming and robotics. We pursued this research to reflect the complexities involved in teachers' learning of programming and robotics and to present ways to support teachers closely in professional learning (PL) contexts. In this qualitative case study, our research question is: How do instructors facilitate K-5 teachers' learning of programming and robotics or pose learning barriers to their learning in a professional learning course?

Context and methods

As a part of a nationally funded research project, a rural school district and a university in the southeastern United States collaborated and organized a professional learning (PL) course, *Robotics for Teachers*, for third through fifth grade elementary school teachers. Nineteen teachers participated in the PL course in the spring semester of 2019. The course composed of four face-to-face class meetings (approximately fourteen hours of training in total) and weekly assignments. Two robotics kits and their programming platforms were used in the course: Ozobot/OzoBlockly and RoboRobo/Rogic. When the teachers worked on in-class tasks in these four face-face-face class sessions, the instructors supported these teachers' learning during their engagement with in-class group or individual tasks. In this paper, we focused on the case of one instructor, Dr Z (not one of the authors of this paper) as he worked with the same group of four teachers from the beginning of the course to the end. We could track these teachers' progress under Dr Z's guidance throughout the course. The teachers he worked with were Isabel, Malia, Neal, and Hope *(all names are pseudonyms)*. Data consisted of the videos recorded in the PL course during which Dr Z worked with this group of four teachers and teacher artifacts (teachers' Rogic and OzoBlockly programs/weekly assignments). We used the systematic whole-to-part inductive approach and part-to-whole narrative evolving in sampling and analyzing video data (Erickson, 1982). The patterns in the phases of interests, facilitators and barriers in Dr Z's guidance, were revealed and reported.

Findings

We observed that Dr Z supported teachers' learning of programming and shaped their attitudes toward programming integration in elementary schools. He also posed a few barriers to teachers' learning.

Dr Z helped the four teachers develop their programming skills and debug their programs through providing support and direct instruction on the essential blocks to have RoboRobo robots move and turn. For example, when Malia encountered a problem with her program, in which her robot completed half the task and stopped, Dr Z guided her and explained the logic behind setting the delay (*duration*) blocks in her program. Although the PL course instructor earlier instructed teachers in using the delay blocks to move their RoboRobo robots, teachers still needed further guidance when they were actively working with their robots to complete class activities.

 © ISLS

Furthermore, Dr Z shaped teachers' attitudes about programming instruction through giving examples from real life elementary classrooms. In the first face-to-face meeting after the course instructor directed teachers to use level 4 out of 5 levels on OzoBlockly, Isabel and Olivia told Dr Z that their students would not be able to use level 4 (manipulating the wheel speeds to have robots turn: one wheel goes faster/slower than the other to make the turn) rather than level 2. Isabel then asked Dr Z why they had been asked to use level 4 instead of level 2 (using degrees in turns: turn 45 degrees). Dr Z replied, "With one of the teachers I was working with last semester, she was using the routing with the wheel speed function (in level 4). This was fourth grade, ESOL (English for Speakers of Other Languages) class. And they were able to do it." The teachers looked surprised to hear it; however, Isabel still remained skeptical of using wheel speeds with elementary school students. She said: "Maybe it was a different task." She also asked whether that teacher was from their school district. Dr Z confirmed she was from their school district and added that the teacher initially set the wheel speeds and then let her students reset them to figure out the rotations. At the end of the discussion, Isabel and Olivia were more receptive of the idea of using wheel speeds on level 4. Olivia added that she would use whatever level her students wanted to use with Ozobots.

Dr Z also posed a few learning barriers with his guidance. The barriers occurred when Dr Z directly told the teachers which blocks to use without providing much context. For example, during the second face-to-face meeting, Dr Z assisted Olivia with debugging her program. She was working on the third task. She needed to use *if then* block with this task, but she was not aware. Dr Z directly told her to use *if then* block and Olivia just followed whatever block he asked her to use. They did not discuss what those blocks meant. Although Olivia's programs worked on her robot, it was observed that she generalized the use of the *if then* block to every program she developed possibly thinking that *if then* block was essential in every program.

Discussion and Conclusion

Our study showed that Dr Z's systematic guidance and direct instruction helped the teachers with their learning of programming. However, when he directly told which blocks to use without providing much context for the use of those blocks, teachers developed misconceptions around the use of those blocks. Teachers' attitudes toward using a particular task and level with their students changed when Dr Z shared that students in another teacher's classroom was able to work on the same task and the level. We concluded that it is important to support and closely guide teachers in many aspects of learning programming and robotics such as in debugging, developing understandings of key programming concepts and ideas. Teacher educators need to provide real life classroom examples on programming integration in elementary classrooms. Additional research can be performed to advance our understanding of how to effectively support teachers' or students' needs in learning about programming.

Online Instructional Coaching During the COVID-19 Pandemic

Jeanna R. Wieselmann & Marc. T. Sager
jwieselmann@smu.edu, msager@smu.edu
Southern Methodist University

Abstract: With COVID-19 necessitating a shift to online teaching and professional development, a unique opportunity to study online instructional coaching emerged. With prior evidence that the provision of a STEM curriculum unit and online coaching supported a first-year science teacher in improving his instructional practices, this study utilized interaction analysis to explore the coaching moves that were implemented by three STEM instructional coaches and identify the online coaching moves that prompted teacher reflection. Findings highlight the distinct coaching styles of the individual coaches and the range of moves that preceded teacher reflection. Implications for online instructional coaching are considered.

Introduction and rationale

The COVID-19 pandemic caused many aspects of teaching, including professional development (PD) to shift to online modalities. Researchers have called for more studies of online PD programs (e.g., Dede et al., 2009) and have raised concerns about the quality and effectiveness of online PD (Lynch et al., 2019). The present study is grounded in distributed cognition theory, which emphasizes the social and collective nature of knowledge construction (Hutchins, 1995; Zhang & Patel, 2006), and recognizes the central role of reflection in instructional coaching (Knight & Cornett, 2009). In our previous study of teaching practices, we found that the provision of a STEM curriculum unit and online coaching supported a first-year science teacher in utilizing research-based best practices for teaching within the COVID context (Wieselmann et al., in review). The present study sought to better understand the nature of virtual coaching that supported this teacher and addressed the research questions:

1. What coaching moves do STEM instructional coaches implement in an online coaching environment?
2. What coaching moves prompt a first-year teacher to reflect on his instructional practices?

Research methods

We utilized a multiple embedded case study design (Yin, 2014) to explore the phenomenon of online instructional coaching. Each of three instructional coaches represents a case, and turns of speech served as the units of analysis. The coaches, two of whom are the authors of this paper, worked with a first-year science teacher to support his implementation of an integrated STEM unit focused on physics concepts of force and motion in his seventh-grade classroom. All three coaches had prior science teaching experience in a range of contexts.

The unit was taught over the course of five class periods, each of which was 90 minutes long. Prior to each class period, the coaches and teacher met on Zoom to discuss the day's lesson plan. The coaches observed the teacher's implementation of the lesson and again met with the teacher on Zoom following the lesson, utilizing these debrief meetings to promote reflection and consider any modifications that needed to be made to the subsequent lessons. All of the planning and debrief meetings were recorded and transcribed for analysis. Utilizing interaction analysis methods described by Jordan and Henderson (1995) and collaborative viewing of the meeting videos, we developed a codebook and coded the data using inductive process coding (Saldaña, 2016) to capture the coaching moves evident in each speech turn. This inductive and collaborative approach to coding helped reduce bias (Jordan & Henderson, 1995). As disagreements among coders emerged, we refined our codes and their definitions and ensured that we were calibrated in their use (Wasser & Bresler, 1996). The final codebook included 24 codes. Once coding was complete, we conducted code frequency counts for each coach. We also examined the temporal relationship to determine which coaching moves preceded the teacher's reflective practice.

Findings

Our interaction analysis revealed that Coach 1 performed a total of 165 coaching moves, drawing upon her prior knowledge and expertise to provide an affirmation-rich approach to coaching that focused attention on student learning, revising lesson plans, and prompting reflection. Coach 2 performed a total of 138 coaching moves and used her expertise surrounding the subject content and the state standards to focus on pedagogical knowledge, how students learn, and sharing her personal teaching experiences. Coach 3 performed a total of 69 coaching moves and employed his expertise surrounding integrated STEM curriculum design and the learning sciences to promote a focus on integrating technology and pedagogical knowledge.

 © ISLS

The teacher reflected on his practice and student thinking on 28 distinct occasions. Because of the unit of analysis focusing on speech turns, it was possible for more than one coaching move to be used in the turn preceding teacher reflection. As expected, reflection was often preceded by a coach prompting this reflection (13 occasions). However, even in the absence of explicit prompting, the teacher reflected on 15 occasions. In analyzing the coaching moves that preceded these occasions of reflection that were not explicitly prompted, several moves were most frequent. In descending order of frequency, these coaching moves included affirming (9 occasions), focusing on pedagogical knowledge (6 occasions), focusing on science content (5 occasions), focusing attention on how students learn (4 occasions), and developing or revising lesson plans (4 occasions). Providing the teacher with feedback on his instructional practices only prompted reflection on one occasion.

Discussion and implications

While there was overlap in the coaching moves used by the three coaches, each coach also adopted a distinct coaching style in the online environment. Coach 1, who was the most senior, adopted a coaching approach that emphasized the positive aspects of the teacher's practices through affirmations. This may have served to make the teacher more comfortable with being observed and open to discussing his teaching practices. Coach 2 drew heavily upon her knowledge of general pedagogical strategies, offering suggestions for everything from classroom management to ensuring equitable participation by using a random name generator. Coach 3 had extensive experience with technology integration and was able to share specific advice related to the hybrid format of instruction with both online and in-person learners. Each coach leveraged their position and distinct set of experiences in unique ways in developing the coaching relationships.

With reflection being one of the key elements of instructional coaching (Knight & Cornett, 2009), it is critical to consider how teacher reflection was prompted and supported in the online coaching setting. While explicit prompts for reflection were effective in eliciting reflection, the teacher also reflected in the absence of such prompts. Interestingly, the coaching move of affirming the teacher was the most frequent prompt that led to reflection. It is possible that the teacher felt more comfortable critiquing his own instructional practices when he had already been affirmed by the coaches.

This study of instructional coaching was grounded in the notion that knowledge was distributed across the three coaches as well as the teacher. While limited in scope, it provides a practical codebook for use in future studies. It also reveals promising opportunities for online instructional coaching. Given the evidence of improved teaching practices (Wieselmann et al., in review) and the range of coaching moves that prompted teacher reflection, findings from this study can be used to inform instructional coaching decisions.

Reframing Design for Transformative Change: Supporting Pre-Service Teachers in Adopting Designerly Stances Towards Inquiry

Douglas B. Clark, David Scott, and Sandra Becker
Werklund School of Education at University of Calgary

Abstract: We need transformative change in K-12 education to address the myriad challenges and inequities facing the world today. Traditional approaches to design in education as taught to pre-service teachers, however, support incremental improvements to efficacy and efficiency rather than transformative change. Guided by contemporary theory and research from design fields, we propose a framework for conceptualizing K-12 educators' stances towards design organized along a continuum from technical rational to designerly. We use this framework as a lens to analyze data drawn from a case study examining 28 pre-service teachers' conceptualization and engagement in design within the context of a design course taken by over 400 pre-service teachers. Our analysis of a range of data sources demonstrated that most participants adopted either a technical rational or exploratory stance towards design by the end of the course. We conclude by explicating why certain shifts took place and proposing ways pre-service teachers could be supported in adopting more human-centered approaches to design.

Theoretical framework

Insights from design fields suggest that a designerly stance towards design for K-12 educators focused on problem finding and framing – in contrast to the more traditional focus on solution finding – would emphasize four key themes as follows: (a) view of the problem space (e.g., Buchanan, 1992; Norman, 2013; Schön, 1984), (b) approach to stakeholders and inquiry (e.g., Bang & Vossoughi, 2016; Christensen et al., 2016; Krippendorff, 2004), (c) framing and frame creation (e.g., Buchanan, 1992; Dorst, 2011), and (d) conceptualization of the design process (e.g., Norman, 2013; Owen, 2006). These elements overlap and interrelate with one another and share, in many instances, common themes. We created a detailed rubric based on these four areas that we used to guide this study and data analysis. Space precludes including the full rubric here, but we will share the full version at the conference.

Research Questions

1. When viewed through the theoretical framing outlined above, how do pre-service teachers' understandings of design evolve in a course that includes an emphasis on design-based thinking from the perspective of the design fields as well as perspectives on design from the field of education?
2. Which aspects of design as defined in the theoretical framing come most naturally to pre-service teachers and which aspects require more support, revisions, or emphasis?

Building on these two core questions, our discussion also considers how articulating a design framework based in the broader literature from the design fields might provide insight into avenues for improvement in pre-service teacher education to improve these outcomes.

Methods, Data Sources, and Coding Schema

We employed case study research (Stake, 2005; Yin, 2014) to consider how, and the extent to which, pre-service teachers engaged in designerly stance towards design within the context of a mandatory five-week course taken by 400 students at a university in western Canada focused on a range of design processes in the field of education including perspectives from design fields (Design Council, 2007; Norman, 2013) as well as design perspectives in education including design thinking (IDEO, 2012). The bracketing of the boundaries for this case involved limiting the focus of the research to data gained from this course. In total, the team analyzed the work of 28 pre-service teachers across the 18 sections of the course who consented to allow their work to be used as data in this study. Data in this regard were drawn from three course pre and post reflections and design projects.

Findings

In the sections that follow, we analyze the data set in relation to our conceptualization of the four proposed themes for a designerly stance to design. Each theme is presented as a continuum from technical rational through exploratory to a designerly stance (Table 1).

View of the problem space. Findings from this study indicated that conceptualizing the problem space

 © ISLS

was the most challenging area for participants. As shown in Table 1, pre-service teachers demonstrated almost no progress from Pre to Post in terms of Problem Space. Our analysis of the data suggested that most of the pre-service teachers in this study entered and left the course with a largely technical rational view of the problem space, particularly in relation to complexity. The majority of participants continued to view problems as uncomplicated and stable with the goals to be achieved largely fixed and predetermined (Schön, 1984). Participants additionally demonstrated difficulties making well-developed connections concerning how the problems they chose to focus on were implicated in larger macro structures and societal challenges.

Table 1. Summary of Findings by Design Theme

Design	**Problem Space**			**Inquiry**			**Framing**			**Process**		
Sophistication	Pre	Post	DCP	Pre	Post	DCP	Pre	Post	DCP	Pre	Post	DCP
Designerly	0%	0%	0%	5%	4%	11%	0%	4%	11%	0%	4%	0%
Exploratory	32%	30%	63%	50%	78%	74%	73%	74%	68%	55%	78%	63%
Tech Rational	68%	70%	37%	45%	17%	16%	27%	22%	21%	45%	17%	37%

Approach to inquiry. One notable area where the participants demonstrated growth from Pre to Post occurred in the area of inquiry as shown in the table and figure. In particular, we noticed an uptick in attempts to gain empathy for stakeholders, particularly students. Although we noted that more participants began to see the importance of an ongoing empathic consideration of students as stakeholders, the overall trend did not suggest a fully designerly approach to inquiry from the perspective of our theoretical framing.

Framing and frame creation. Our analysis of the data set suggested the pre-service teachers started at a more exploratory stance towards framing and frame creation but made little progress beyond that during the course. They overwhelmingly associated design with the creation of more active and engaging learning environments involving a shift away from traditional approaches to education rooted in teacher-centric pedagogies, passive learning, and content coverage.

Conceptualization of the design process. An area where participants demonstrated substantial growth occurred in relation to process. Pre-service teachers initially displayed a range of technical rational and early exploratory perspectives that shifted towards primarily exploratory stances by the end of the course. In particular, pre-service teachers became much more attuned to the iterative nature of design. Given these shifts, there was little evidence of a fully designerly stance in how participants conceptualized and engaged in the design process.

Scholarly significance

The significance of this study is threefold. Our study offers one of the few fully articulated frameworks for conceptualizing K-12 educators' stances towards design. This framework provides both a lens for pre-service teachers to reflect on how they engage in design, as well as a tool for research, critique, and re-envisioning of pre-service and in-service programs. Insights gained from this study additionally offer ways educators might be more intentionally and purposefully supported in moving towards more designerly stances that could position them as agents of change in service of preferable educational futures. Ultimately, helping educators move toward more designerly stances will support them in becoming more comfortable with the ill-defined nature of problems and their societal and cultural roots as well as the critical role of moving beyond traditional teacher-centered frames in educational discourse that have limited educational possibilities for transformative change.

Sociopolitical Discourses within Student Farms and Gardens

Marc T. Sager, Southern Methodist University, msager@mail.smu.edu
Max K. Sherard, The University of Texas at Austin, mksherard@utexas.edu

Abstract: We identified 46 university-based student farms or gardens' (SFG) mission statements from around the U. S. and used sociosemantic analysis to describe and compare the individuals involved, the actions conducted, and the objects involved. Two discourses emerged from our analysis: (a) a depoliticized framing of SFGs as sites for producing food for higher education communities; and, (b) a politicized framing of SFGs as sites for engaging with issues of social and environmental justice within the broader community.

Introduction

This research is part of a broader project to understand the learning that occurs amongst participants at a university-based student farm/garden (SFG). At many junctures in this project, we noticed tensions between the purposes of student farm workers (e.g., growing food to donate to community members) and the purposes of the university personnel (e.g., selling produce at local markets or using produce in promotional events). We see these tensions as arising from conflicting *discourses* regarding the purposes of university SFGs. Discourses are "particular way(s) of representing some part of the (physical, social, psychological) world" (Fairclough, 2003, p. 17). For example, SFGs can draw on various discourses to inform their daily work (ex. community service, food security, university pride). We see these various discourses and the conflicts between them as important to understand to make sense of day-to-day participation in SFGs. To that end, we have 'zoomed out' from our local context to gather a broader understanding of the various discourses which inform SFGs. In this paper, we collect mission statements from 46 SFGs at land grant universities around the U. S. and ask the following three research questions:

1. Who is involved? (ex. students, professors, 'the community', or others?)
2. What do they do? What actions do participants of these SFGs engage in? Towards what or who?
3. What objects or ideas are involved? (ex. Science learning, skills, tools, produce, etc.?)

Data Analysis

To analyze the 46 SFG's mission statements, we drew on a CDA technique called *sociosemantic analysis* (van Leeuwen, 1993) which involved three steps. First, we read each mission statement and annotated three features: *participants* (people or institutions involved in the SFG), *processes* (actions of the people or institutions in the SFG), and *objects* (materials, ideas, or social relations related to the SFG). Second, we developed a codebook to capture the different themes amongst participants, processes, and objects. Third, we create a frequency count for each theme and reflect on the variation amongst the set of SFG mission statements. In the next sections we summarize the themes among participants, processes, and objects included in SFG mission statements. We close with a discussion about the two discourses we see surrounding the purposes of SFGs.

Who are the Participants?

Participants fell into three primary groups among the 46 SFG mission statements: (a) the garden/farm itself; (b) participants from the university or college; and, (c) participants from beyond the university or college. The most frequently mentioned participant was the student farms or gardens themselves. All 46 of the mission statements referenced the farm or garden as a social actor. 25 of the 46 mission statements *only* include the SFG as a participant, and make no mention of other participants in their mission statement. The second most frequently mentioned participants were social actors from the university or college in which the SFG is situated. Students were included as participants in 14 of the 46 (30.4%) mission statements. Faculty and Staff were included as participants in 2 of the 46 (4.3%) mission statements. Far less frequent, were mentions of social actors outside the boundary of the university or college. Families were included as a participant in 1 of the 46 (2.2%) mission statements. Food banks or non-profits were included as participants in 2 of the 46 (4.3%) mission statements. 'Community' was included as a participant in 10 of the 46 (21.7%) mission statements. And 'Society' was included as a participant in 1 of the 46 (2.2%) mission statements. In these instances, SFGs are positioned as organizations whose purposes extends beyond to social actors who are not directly involved with university or college.

 © ISLS

What are the Processes?

We focus on processes as a way to see how SFGs delegate actions to different participants involved in the SFG. In this poster, we describe the *directionality* of processes. By directionality, we mean which social actor conducts the action of a process. Three directionalities emerged from the data: (a) processes conducted by the SFG towards other participants; (b) processes conducted by other participants; and, (c) processes conducted by the SFG and other participants together. Most process directions were those conducted by the SFG towards other social actors. All 46 SFG mission statements included some processes conducted by the SFG. Far less frequent were instances where social actors other than the SFG conducted processes. Nine SFG mission statements included processes conducted by participants outside the SFG (19.6%). Three SFG mission statements included processes conducted by the SFG together with other participants (6.5%).

What are the objects?

Student farms or gardens provide produce (material), knowledge about sustainable practices (mental and material), and friendship (social). We focus on objects as a way to see what services are rendered available by SFGs. The objects identified from the mission statements can be classified in four categories: (a) nature and food; (b) social objects; (c) education; (d) and justice. The primary objects involved in SFG mission statements were related to nature and food. Nature and food objects are any object that is provided from the natural (as opposed to cultural) realm. 39 of the 46 (84.8%) mission statements include some mention of nature and food. For example, Dilmun Hill at Cornell University "seeks to empower students through active engagement in ecological agriculture". Social objects were also frequently mentioned in SFG mission statements. Social objects were any object related to community, partnerships, collaboration, and students. 30 of the 46 (65.2%) mission statements include some mention of a social object. For example, the Community Gardens at Auburn University "provides access to local produce through community partnership". Educational objects were also frequently mentioned in SFG mission statements. Educational related objects are those related to learning, knowledge, and interest. 31 of the 46 (67.4%) mission statements mention education as an object to be provided by the SFG. For example, The Gardens at Texas A&M University "engage the community in a living teaching environment." Justice related objects were the least frequently mentioned category of objects. Justice objects related to sustainability, environment, sovereignty, and hunger. 22 of the 46 (47.8%) mission statements include justice related objects. It stands to note that the majority of these SFG mission statements (19 of the 22) addressed sustainability and the environment (environmental justice); whereas, only 3 SFG mission statements mentioned made any mention of objects related food sovereignty and hunger (*social* justice). Perhaps most stark, was the complete absence of any discussion of race or racism amongst the 46 SFG mission statements.

Two Emerging Discourses

We have begun to notice the contours of two differing discourses about the purposes of SFGs. One discourse portrays SFGs as politically neutral and bound to the space of the institution. This discourse is characterized by mission statements which: (a) draw a distinct boundary between the SFG and the broader community; (b) ascribe most social actions or processes to the garden itself (and therefore fewer social actions ascribed to other participants); and, (c) focus on delivering objects (whether natural, social, educational, or justice-oriented) to participants in the garden or to community which the garden serves. A second, far less frequent discourse portrays SFGs as politically engaged and embedded within larger communities, regions, and cultures. This discourse is characterized by mission statements which: (a) embed the SFG in broader communities; (b) ascribe social actions to a range of participants; and, (c) discuss objects as being exchanged amongst participants who are both a part of the SFG and a part of the community. Furthermore, this discourse focused more explicitly on justice as a product of SFG (ex. food security, food sovereignty) rather than solely generating produce, social experiences, or educational experiences. Now that we better understand the landscape of discourses which inform SFGs around the U.S., we aim to document the discourses which are employed in our local research context (whether in advertising materials, or in interaction). We do this to examine tensions that arise between participants on the student farm to trace how competing discourses mediate learning and interaction.

Exploring Different Facilitator Roles in Maker-based Learning

Eda Zhang, UW-Madison, eda.zhang@wisc.edu
Annie White, Fred Rogers Institute, anniemacwhite@gmail.com
Katie Todd, Children's Museum of Pittsburgh, ktodd@pittsburghkids.org
Peter Wardrip, UW-Madison, wardrip@wisc.edu

Abstract: The purpose of this study is to investigate how different facilitator roles (educator, adult caregiver, peer and self-facilitation) influence children's learning engagement--specifically, the learning practices of seeking and sharing resources (SSR)--in a museum's makerspace. We address two research questions: 1). In what ways do learners' engagement vary when facilitated by different facilitator roles? 2). In what ways do different types of facilitators influence SSR practices across age ranges? The results show that facilitation from caregivers and self-directed facilitation is associated with significantly more SSR practices. Additionally, we found that the influence of different types of facilitators on learning engagement varies across ages. Self-directed learning is associated with an increase of SSR as children grow, while facilitation from caregivers is associated with a decline of SSR as children age. Based on these findings, we discuss implications for facilitation in museum makerspace.

Introduction and background

Facilitated museum makerspaces can function as a nexus for creative learning experiences. However, learning does not come inherently with a museum makerspace. Facilitation is a key element of supporting children's learning and development that can boost satisfaction and create a gateway for equitable access through personalization of a learning experience to learners' needs and interests (Gutwill et al., 2015; White et al, 2021). In successful facilitated making, the educator helps a child progress in the complexity of learning, connects the child to activities at a reasonable challenge level, and encourages interest and engagement (Gutwill et al., 2015).

The focus of prior research on facilitation in museums, more generally, often centers on educators; more research is needed to investigate the influence of different types of facilitators in a museum makerspace (Krange et al., 2019). In this paper, we explore how the facilitator role influences children's learning engagement -- specifically the learning practice of seeking and sharing resources (SSR). In this study, we address two research questions: 1) In what ways do learners' SSR vary when facilitated by educators, adult caregivers, peers, or working independently? 2) In what ways do different types of facilitators influence the SSR practices across age ranges? Through this study, we gain insight about which facilitator role tends to support learners to seek and share resources and how this varies by age. The more we understand how to differentially support learners across developmental stages, the more we can train educators and offer suggestions to caregivers to be meaningful partners in learning. Second, this work builds upon previous research to understand how to conceptualize and study learning through making (e.g. Wardrip & Brahms 2015). In particular, this work can more explicitly articulate learners' engagement in seeking and sharing resources through the lens of the Learning Practices of Making framework and how facilitators are partners in the learning process.

Theoretical and methodological approaches

The perspective of overt learning behaviors guides this work. *Overt* behaviors that learners display in a learning environment can help researchers to understand and analyze learning engagement (Chi, 2009). The Learning Practices of Making framework articulates forms of overt learning behaviors in a museum makerspace. One such behavior is seeking and sharing resources (Wardrip & Brahms, 2015). The practice of seeking applies to tools, information, or other supports. Sharing refers to an individual offering to others material objects, help or support, suggestions, or ideas.

We used the SSR Tool (White et al, 2022) to measure learners' seeking and sharing practices in the makerspace. This study included 51, 3-minute video clips including one focal learner (ages 0-18) engaging in a maker activity. The video included seeking and sharing resources prompted by 4 facilitator roles including educators, caregivers, peers, and children themselves. Two researchers coded the video clips with the SSR tool and yielded a high interrater reliability for SSR practices (alpha=0.94).

Initial findings and implications

 © ISLS

To explore whether different types of facilitators played a role in SSR practices in a museum makerspace (RQ1), we conducted a one-way ANOVA. The result indicated that facilitation from caregivers and self-directed facilitation is associated with significantly higher SSR practices than facilitation from peers or educators. Compared to educators, when facilitation is prompted by caregivers ($p<0.01$), and when learners self prompted ($p<0.05$), they yield a higher amount of SSR practices. This highlights the important role that caregivers and self-directed facilitation can play in a makerspace.

Table 1

*One-way ANOVA & Regression Models (Standard errors in parentheses, ** p<0.01, * p<0.05)*

	Model (1) ANOVA	Model (2) REGRESSION
	SSR Practices	*SSR Practices*
Age		-4.065 (2.514)
Peer	-1.023 (3.061)	-24.92 (27.29)

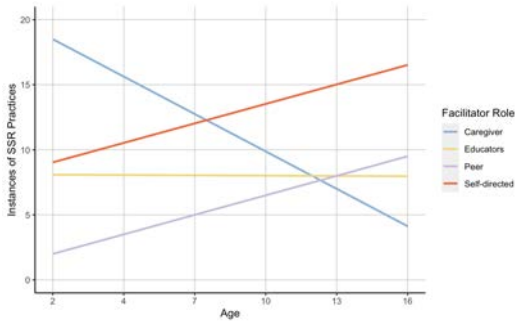
Observations	51	51
R-squared	0.240	0.312

Figure 1

Predicted linear regression of each type of facilitators across age



The multivariate regression results (Table 1) suggested an interaction effect between age and facilitation among groups of caregivers and self-directed learning. As children age, we expect to see fewer instances of SSR when facilitated by caregivers and more instances of SSR when engaged in self-directed facilitation. A graph of predicted linear regressions for each type of facilitator illustrates the interaction effect of the caregiver group and self-directed group (Figure 1). In the self-directed facilitation group, SSR practices increase as children grow older. On the contrary, children's SSR practices decline when the facilitation is led by their caregivers as they age. Additionally, we see a slight downward trend in the educators' facilitation as children's age increases. Facilitation from peers also showed a positive correlation with SSR as age increases. Multivariate regression analysis indicated that the influence of different types of facilitators on learning engagement varies across ages.(RQ2) In our analysis, we see an incline in self-directed facilitation in the makerspace as learners get older, with older learners tending to seek and share resources independently. We also observed that peers play an increasingly important role in makerspaces for children in the early adolescent stage.

These findings opened up additional potential approaches to further support and promote engagement in informal learning environments. First, it would also be beneficial to provide support and guidance for caregivers so that they can better facilitate childrens' learning other than just supporting educators. Our study suggested that museums also encourage self-directed learning of young learners. Future design decisions, including the exhibit and facilitation design, should also consider how to further enhance the self-directed learning of young learners.

Novice versus Advanced Undergraduate Computing Students' Engagement in Collaboration in an Online Flipped Classroom

Morgan Vickery, Indiana University - Bloomington, moravick@iu.edu
Shamima Mithun, Indiana University - IUPUI, smithun@iupui.edu

Abstract: This paper explores students' engagement in collaborative learning activities within two data science courses (one introductory and one advanced) taught synchronously online during the 2020-2021 academic year. Here, we draw on a multidimensional perspective of student engagement to understand novice and advanced computing students' collaborative learning practices and propose instructional design elements informed by students' unique needs and the limitations of the virtual format.

Introduction & Rationale

Considering the mass shift to online learning due to the Covid-19 pandemic, instructors of undergraduate students have been tasked with adapting their course material and instructional practice to be appropriate for remote instruction. For disciplines in which peer and instructor interaction are paramount in the development of industry-authentic interpersonal 'soft' skills, the constraints of online learning formats have proven to be a barrier to student engagement. Computing is one such discipline that experiences these tensions.

There is furthermore an increasingly widespread view that flipped classroom approaches engage students in developing these interpersonal skills and practices through active student participation and interaction (e.g., Bishop & Verleger). The flipped classroom model allows students to use class time to engage in iterative problem-solving, collective sense-making, and critical thinking through collaboration with classmates and instructor support. In our prior work, we identified a set of instructional design factors which the literature showed to be effective for flipped classroom implementations (Mithun & Luo, 2020; Mithun et al., 2021).

In this research, we consider how computing students engage in online small group collaborative learning activities in an introductory data science fundamentals course and an advanced database design and management course. We use a multidimensional (Fredericks et al., 2004; Sinatra et al., 2015) and sociocultural (Danish & Gresalfi, 2018) framework of student engagement to understand the behavioral, cognitive, and emotional aspects of students' engagement intersected with their social engagement in collaborative learning settings. We then use these insights in conjunction with instructor observations to identify how the current instructional design for each course can be revised to better suit the unique needs of each group of students. We pose the following questions:

1. How do novice and advanced undergraduate students behaviorally, cognitively, and emotionally engage during peer collaborative activities in an online data science course?
2. How does understanding students' engagement enable instructional design modification?

Methods

A variety of data sources were used to analyze undergraduate students' experiences in the introductory database fundamentals course (n = 21) and the advanced database design and management course (n=12). Students completed an end-of-semester (EoS) survey designed by the authors and a collaborator with expertise in student engagement as multidimensional (see Humburg, 2020). Students also completed university-mandated course/instructor evaluations and participated in an informal focus group facilitated by a third-party evaluator. Novice students additionally responded to weekly exit-ticket check-ins; each week's survey featured a new question about students' experiences within the context of the course, school more broadly, and/or their personal lives.

Quantitative data from the EoS engagement survey was segmented based on the target dimension of engagement, individual versus collaborative setting, and course enrollment. Basic statistical descriptives and comparisons were calculated across all segments in addition to student course/instructor evaluation data. We then ran significance tests across courses for each dimension of engagement and the individual/collective ownership items. We additionally coded all qualitative data (i.e., focus group reports, exit-ticket survey responses, instructor observations, and responses to open-ended text-based survey questions) using two coding schemes.

Findings & Discussion

Our analysis revealed that novice students were confronted with several barriers to engagement in small group collaborative settings which we seek to address in the next implementation of this course. First, we recognize that

 © ISLS

students' lack of behavioral engagement could be attributed to a lack of instructional mechanisms for maintaining individual accountability in group settings. Gaps in cognitive engagement were frequently linked to students not understanding the value of collaborations for their learning and thus, a lack of motivation to participate. Furthermore, novice students struggled to develop meaningful relationships with their peers throughout the semester – a phenomenon students attributed to the inconsistent and random group assignment and lead to a lack of group regulatory interactions.

Thus, we propose the following tweaks to novice students' instruction: (1) negotiating longer-term group assignments during class rather than relying on random weekly assignment, (2) introducing low-stakes 'peer/group evaluations' to more effectively identify and respond to moments of labor imbalance in groups, (3) requiring that in-class work is submitted to the instructor to allow for monitoring of individual students contributions, and (4) increasing transparency around the 'point' and value of collaborative learning activities for each content area.

For seniors, small group collaborative settings enabled the sharing of diverse ideas and perspectives; they recognized that collaborative activities aided in developing interpersonal skills authentic to those they will need after graduation. However, students cited frustrations around the lack of connection between concepts addressed in individual versus group settings. Thus, we take a similar approach as described above and plan to explicitly mention target concepts and practices for each given activity to draw connections between the multiple learning objectives. We also plan to review the current curriculum to better align the core concepts and learning objectives between individual and group activities.

We additionally suggest that student groups could benefit from the integration of mechanisms during large group discussions to make participation be perceived as less 'high stakes.' To do this, we hope to design discussion spaces where contribution is both more accessible and less intimidating for students. We anticipate better incorporating multimodal means of participation (the chat, reactions, polls, asynchronous feedback, collaborative whiteboards etc.) into group discussions to enable students to choose the mode of participation that is most comfortable for them as opposed to not engaging entirely. These approaches to increasing multimodal participation would prove particularly valuable for identifying students' misconceptions as they arise, opening interactional opportunities for group regulation and negotiation, leverage synchronous online tools in instruction as an asset rather than a limitation.

To conclude, we affirm that there is no 'one size fits all' instructional design solution for collaborative learning activities in computing and data science education, but that the students' unique barriers, perceived objectives, and learning preferences be considered in conjunction with affordances of the learning environment to inform theoretically grounded yet context and audience-appropriate instruction.

"I Would Rather Argue a Point": How Academic Argument Writing Mediates Civic Cognition and Stifles Democratic Dreaming

Nicole Mirra, Rutgers University, Nicole.mirra@gse.rutgers.edu
Antero Garcia, Stanford University, antero.garcia@stanford.edu

Abstract: This study explores how the forms of writing that young people utilize to discuss civic issues with each other mediate their understandings of the nature and purpose of civic life and open (or close) potential communicative pathways to creative and empathetic forms of civic worldbuilding. Drawing upon a theoretical framework of speculative civic literacies and scholarship in civic cognition, democratic education, and academic argumentation, this study analyzes the discourse practices of 238 high school students from six communities across the United States who participated in a social design-based experiment aimed at fostering democratic dialogue across lines of geographic, social, and cultural difference. Findings from a content analysis of students' digital posts and a qualitative case study of one student's civic literacy repertoires demonstrate that student leveraging of normative academic argument writing structures largely stifles understandings of divergent perspectives and vulnerable civic communication by flattening considerations of identity, affect, and ideology.

Introduction

This study represents one strand of inquiry from the Digital Democratic Dialogue (3D) Project, a social design-based experiment comprised of six high school literacy teachers and their students (n=238) from demographically distinct U.S. communities who leveraged digital media to communicate across time and space in order to excavate their civic histories, analyze their current civic experiences, and dream of collective civic futures. We sought to understand how the forms of writing that young people utilized to discuss (or "argue") civic issues with each other reflected their understandings of the civic and opened (or closed) potential pathways to expansive forms of civic cognition. Specifically, we asked: 1) How do writing structures mediate the nature, tone, and purpose of youth civic communication? Drawing from a theoretical framework of speculative civic literacies, initial findings indicate that the use of normative forms of argument writing largely precluded understandings of divergent perspectives and empathetic civic connections because they invited competitive debate, encouraged the use of civic heuristics, and minimized the role of affect.

Civic Cognition, Democratic Education, and Academic Literacy Instruction

The model of academic argument writing rewarded on standardized literacy exams (and thus taught in an overwhelming plurality of public schools) follows a formula developed by rhetoricians in the 1980s involving the statement of a thesis supported by a collection of claims, evidence, and warrants (Toulmin et al., 1984). When the Common Core policymakers situate this model as effective preparation for deliberation in civic life, they presuppose a utilitarian public sphere in which claims are judged logically on their merits and in which citizens take actions aimed at furthering the collective public good. The underlying assumption is that teaching students how to craft arguments in language approximating objectivity using credible evidence will increase the likelihood that they can successfully advocate for their priorities within U.S. civic institutions (Gutiérrez, 2009). This assumption minimizes what integrative theories tell us about the social and cultural aspects of civic learning that must be attended to in instructional design to disrupt societal inequality (Nasir et al., 2021). Civic cognition is deeply tied to expressions of identity and community membership and decisions often rely upon heuristics and appeal to emotion, which suggests that conventions of academic argumentation do not map well onto the project of successfully advocating for priorities in the world as it actually is (Bougher, 2012).

Speculative Civic Literacies

The speculative civic literacies framework argues that normative practices of literacy and civic engagement are insufficient building blocks for the creation of liberatory social futures; instead, it calls for the cultivation of "expansive, creative forms of meaning-making and communication aimed at radically reorienting the nature and purpose of shared democratic life toward equity, empathy, and justice" (Mirra & Garcia, 2020, pg. 297). The framework takes up Thomas & Stornaiuolo's (2016) approach of "restorying" existing narrative forms by supporting young people to interrogate and innovate the civic narratives that are too often foisted upon them. By supporting the development of new literacy practices that speak to new social potentialities, re-story the existing

 © ISLS

world, and are grounded in the cultural and historical truths that young people possess, this framework evaluates writing practices based on the extent to which they push on the normative and reach toward the speculative.

Methods

We organized the 3D Project as s social design-based experiment that sought to collaboratively reimagine syncretic civic literacy learning experiences for the purposes of social transformation (Bang & Vossoughi, 2016). Six high school teachers representing the states of Alaska, California, Colorado, Michigan, Pennsylvania, and Texas were recruited from the National Writing Project network to participate in the study with one or more of their classes. Our team developed and enacted three design cycles during the 2018-2019 school year that teachers implemented in their ELA classes as part of their core curriculum. For the purposes of the specific inquiry detailed here, we focused on the discursive practices in which students engaged during Design Cycle 2 when they organized themselves into 30 online discussion groups drawing from 14 topics ranging from animal rights and the environment to healthcare and homelessness. We analyzed 372 exchanges across the 30 discussion groups, defining an exchange as a discussion consisting of at least two posts in which students took turns responding to each other about an initial posting (median of 12 exchanges across each of the discussion groups.

Preliminary Findings

When analyzing Design Cycle 2's cross-school civic discussion groups, the 3D Project teacher team found that the great majority of students gravitated initially toward writing that drew upon the academic argumentation paradigm – and that the utilization of this paradigm tended to end exchanges quickly. We found that 83% of the discussion exchanges began with an academic argumentation move. When other students in the discussion group responded with further academic argumentation (which occurred in 74% of cases), the exchange typically ended within three further moves (87% of cases). By contrast, exchanges that began with or transitioned to civic dialogue moves tended to foster lengthier and more complex exchanges. In one example, the writing practices that Cory, a white, male 11th grader living in a small Alaskan town, leveraged during his participation in the 3D Project demonstrated how academic argumentation can serve to both mask the social, cultural, historical, and political nature of civic cognition and forestall vulnerable engagement with different perspectives. During the first design cycle of the project, Cory stated, "I do not enjoy talking about myself [and] would rather argue a point." He attempted to create a dichotomy between himself and the points that he espoused throughout the project by appealing to principles of academic argumentation, yet his claims continually remained subjective and served to reify the very identities he sought to downplay.

Implications and Next Steps

This study's analysis of student civic writing and communication practices raise important questions for the fields of literacy and civic education about the cognitive processes involved in perspective-taking and the effectiveness of current paradigms of academic argumentation to support the development of productive – let alone speculative – civic dialogue. In further analyses of the 3D Project, we seek to explicate the conditions under which the practices of questioning and storytelling led to more generative and imaginative forms of dialogue between students. In future studies, we seek to conceptualize and test alternative writing models that could support new paradigms of stance-taking and civic value-sharing.

Key Elements of a Critical Approach to Financial Literacy

Jose Sandoval-Llanos, The Pennsylvania State University, jfs@psu.edu

Abstract: Financial Literacy is a topic of recent emergence, still subject of debate about its epistemology and disciplinary background. While Latin American governments are implementing National Strategies for Financial Education under the guidance of multilateral institutions, arguments against these initiatives consider that they perpetuate oppressive practices while displacing the focus of the problem from the financial system to individuals. This poster presents a theoretical proposal for a critical approach to financial literacy to address these concerns.

Introduction

Scholars from disciplines like education, sociology, anthropology, and geography have raised concerns about the dominant paradigm of financial literacy promoted by multilateral organizations (e.g., OECD, the World Bank, AFI, among others) (Blue & Grootenboer, 2019; Hutten et al., 2018; Lucey, 2022; Pinto, 2017; Willis, 2017; Zokaitye, 2017). Financial literacy initiatives have been focusing on increasing individuals' involvement with financial system (Prabhakar, 2019), aiming to foster economic growth and reduce economic inequality. However, these expectations remain unmet and, in most countries, the gap between the richest and the poorest is increasing.

In this context, several Latin American governments, supported by multilateral organizations are developing and implementing *Estrategias Nacionales de Educación Financiera – ENEF*. 'National strategies for financial education' provide the guidelines for deploying financial education, defining common goals, identifying relevant challenges and obstacles, and establishing priorities and a coordinated plan at the national level (OCDE/CAF, 2020). These strategies are highly relevant considering that they configure power and politics in financial education, thereby influencing the definition of the why, how, with whom, and for whom of financial literacy initiatives.

The purpose of my poster is to discuss the theoretical foundations of a critical approach to financial literacy useful to assess the impact of these national strategies and to direct the attention of these policies to the interests of the most vulnerable populations.

Challenging the dominant paradigm

Different voices within the learning sciences field have been calling on scholars to embody the political context in their research questions in recent years. For example, The Politics of Learning Writing Collective (2017) advocates incorporating issues like culture, identity, gender, race, and power in the discussion about learning. Philip and Sengupta (2021) urged scholars to adopt a contrapuntal approach in their designs and theories for recognizing and challenging the sociopolitical contexts in which learning happens. Finally, Penuel's (2019) idea of infrastructuring acknowledges the need to redesign infrastructural components of policymaking to support learning sciences innovations that otherwise would not be sustainable or scalable. Research on financial literacy would benefit from the adoption of these approaches in their analyses.

Sociocultural perspectives present useful frameworks to study how people learn to manage their finances while paying attention to context and relationships between individuals. For instance, Esmonde's (2016) six distinctive elements from sociocultural theories to analyze power provide a solid base to describe the power asymmetries between people and the financial system. Gutierrez's (2008) sociocritical literacy framework offers an alternative perspective to inspire individuals to find alternatives to the oppressive practices of the financial system, respond to the poverty caused by capitalism, and design their own futures.

Elements of a critical financial literacy framework

This proposal of a critical financial literacy framework elaborates on ideas previously discussed by authors from different disciplines. For this discussion, I will introduce three elements from these discussions that follow the ideas presented in the previous section.

The first element is the importance of offering immediately relevant, age-appropriate, and inclusive content (Pinto, 2017). The design of financial education interventions requires careful consideration of the audience to assess their characteristics, needs, and expectations. One-size-fits-all designs have proven to be ineffective and are considered perpetrators of systemic inequity (Lucey, 2022). The second element problematizes the excessive focus on individual wealth accumulation as the principal purpose of financial education (Blue & Grootenboer, 2019). If the goal is to reduce inequality, a holistic approach that privileges collective well-being

would be more appropriate (Pinto & Coulson, 2011). Finally, the third element relates to financial literacy as a response to the influence of financialization (i.e., the presence of finance in all aspects of everyday lives) (Lucey, 2022). Instead of playing a normative role following the premises of financialization, it is essential to facilitate the critical engagement of individuals with the growing sphere of finance (Hutten et al., 2018) enabling them to think about the economic and financial implications of their decisions (Willis, 2017).

These elements provide important perspectives to be included in the study and design of new strategies and interventions about financial literacy from a critical approach.

Discussion and further steps

Considering financial education as a mere tool for increasing financial inclusion is simplistic and doesn't respond to individuals' needs or welfare. Financial education's potential to help people make better decisions and think critically should be acknowledged and privileged instead of considering that people will do better only because they hold a financial product. Moreover, implementing ENEFs in Latin American countries could provide new opportunities for their citizens if they adopt a critical financial literacy framework.

Understanding what people need and expect from financial education and the financial system in general, is indispensable to designing better programs. At the meso- and micro-levels, design-based research (e.g., social design experiments, DBIR) could be helpful to implement the ideas presented and assess the effectiveness of alternative designs of financial education. Anticolonial frameworks could provide practical elements to consider in alternative designs. Future research projects should focus on groups highly affected by inequality and poverty like women, youth, and rural populations in Latin America.

Methodological Progress in Co-Regulation and Socially Shared Regulation of Learning Research: A Systematic Review

Belle Dang, University of Oulu, FI, huong.dang@student.oulu.fi
Yvonne Hong, University of Auckland, NZ, e.hong@auckland.ac.nz
Bich-Phuong Thi Nguyen, University of Languages and International Studies, VN, bichphuong@vnu.edu.vn
Andy Nguyen, University of Oulu, FI, andy.nguyen@oulu.fi

Abstract: Self-regulated learning (SRL), co-regulation (CoRL), and socially shared regulation of learning (SSRL) have been essential for successful learning and collaboration. However, it is challenging to objectively capture the "invisible" cognitive and emotional processes at the foundation of learning regulation. To better understand and support SSRL, the study reviewed 118 journals published between 2003 and 2020. Results highlighted the need for methodological development of reliable multilevel analysis methods to analyze multimodal data at different proximal levels.

Introduction

Regulation Learning Theory has moved beyond the scope of cognitive process and outcome, to defining SRL as a social, interactive, dynamic, temporal, and developing process (Malmberg et al., 2017) that require a shift toward new forms of instructional tools, data collection, data analysis that acknowledge social entities and shared tasks. Sequencing data and state-of-the-art data mining algorithms are thus utilized to study and represent this transition. Increasing acknowledgment of the interactive role of motivation and emotion (Järvenoja et al., 2020) likewise leads to the exploration and inclusion of physiological measures such as electrodermal activity data, facial recognition of affective triggers and triangulation of multichannel data as a new approach to capturing critical phases of SRL.

Although recent methodological progress has been made to better examine (S)SRL and extend our understanding of the SRL processes, it is still somewhat unsatisfactory. The methodological progress and related challenges have been subject to considerable discussion, and there is an increasing demand for innovative methods with high reliability to advance the field of study. Accordingly, this systematic review highlights the relevant research gaps in guiding the methodological development in (S)SRL research. This study seeks to address the following questions: (1) how has research methodology in CoRL and SSRL of learning progressed over the period between 2003-2020? and (2) What are the key methodological challenges for CoRL and SSRL?

Research methodology

The content analysis approach was adopted to identify methodological gaps in regulation research and suggest implications for the future research agenda. The search string to retrieve relevant articles from the Scopus database is: TS = (TITLE-ABS-KEY ("co-regulation" OR "co-regulated" OR "shared regulation" OR "socially shared regulated" OR "shared regulated") AND TITLE-ABS-KEY (learning)) AND (LIMIT-TO (PUBSTAGE , "final")) AND (LIMIT-TO (DOCTYPE , "ar")) AND (LIMIT-TO (SUBJAREA , "SOCI") OR LIMIT-TO (SUBJAREA , "PSYC") OR LIMIT-TO (SUBJAREA , "ARTS")) AND (LIMIT-TO (LANGUAGE , "English")) AND (LIMIT-TO (SRCTYPE , "j")) AND (EXCLUDE (PUBYEAR , 2021)).

Result and findings

In total, 118 relevant articles on CoRL and SSRL were screened and selected for the systematic review. Table 1 presents the methodological research gaps, while Figure 1 visualizes the frequency of each data type utilized.

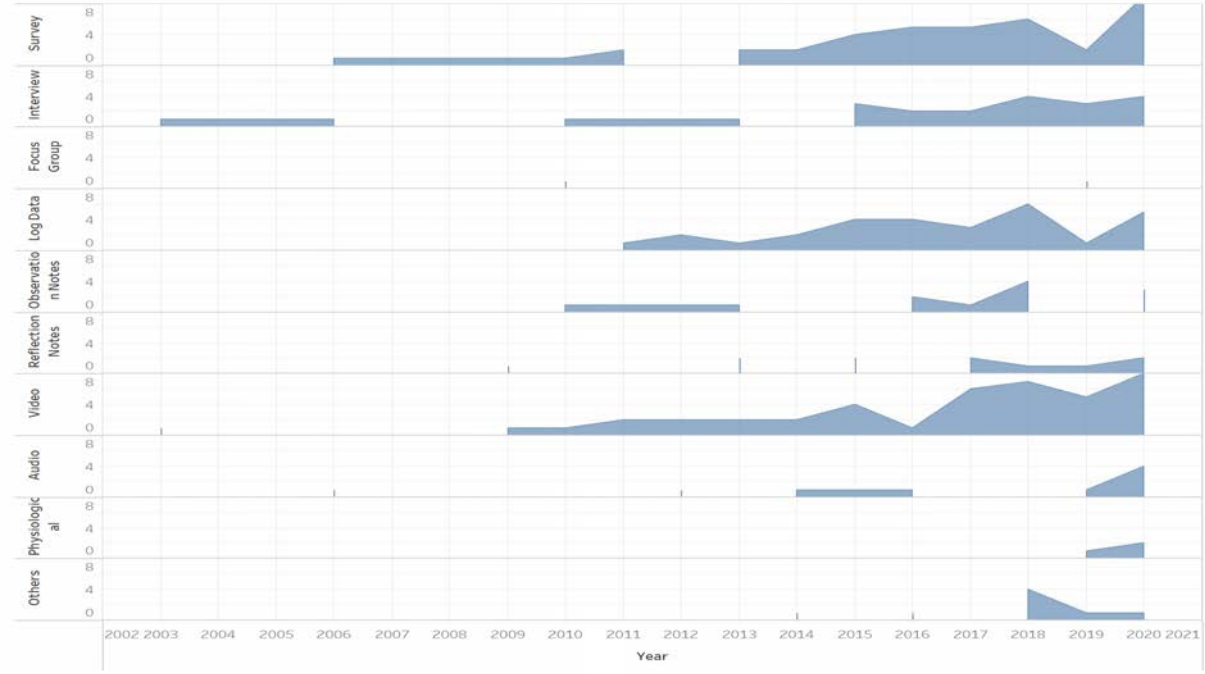
Data Collection	Lack of diverse data collection, need to transition from self-reported data	10
	Sampling bias	5
	Small sample size	29
Data Analysis	Need for integrated multilevel analysis	11

Figure 1: *Types of Data Used for CoRL and SSRL Research*



The Need to Examine (S)SRL at Different Proximal Levels

The majority of SRL studies do not take a longitudinal approach. Since SRL features learners' ability to take ownership of their learning processes, temporal behavioral changes are insufficient to constitute the longitudinal trajectory of change in regulatory efficacy and beliefs. Therefore, we argue there is a need to measure (S)SRL at various proximal levels: capture critical temporal small-scale moments that trigger regulated learning, and longitudinal studies to examine protensive changes of learning behaviors and strategies influenced by these.

The Need for Multimodal Data Collection

Although there are merits concerning the different data collection methods for SRL studies, researchers have noted the limitations of the self-reported data approach, whereby data collected may not be accurately measured as learners overestimated their SRL skills and the lack of domain-based skills measures. The multimodal data approach to CoRL and SSRL research would be a fruitful area for further research.

The Need for Reliable Multi-Level Analysis

By nature, SSRL associated with metacognitive, cognitive, behavioral, and motivational negotiation and adaptation are intertwined with individual, social and environmental conditions that influence and are influenced by regulatory activities. Thus, nested levels of individual data in that group should be explored to determine the reciprocal relationships among different measured variables. Multilevel analysis shows its efficiency in recognizing hierarchical structure and partition of such individual-level and group-level variables.

Towards Automated Tracking of Affect: Testing the Use of Continuous Self-Reports and Multimodal Metrics

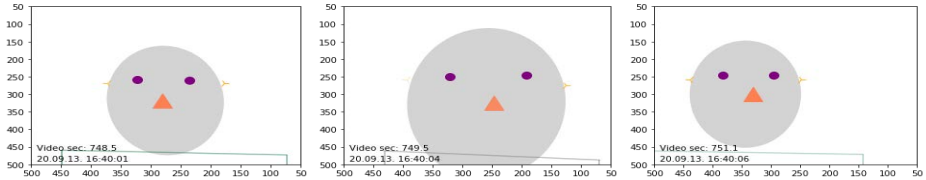
Gahyun Sung, Harvard Graduate School of Education, gsung@g.harvard.edu
Javaria Hassan, Harvard Graduate School of Education, javariahassan@gse.harvard.edu
Bertrand Schneider, Harvard Graduate School of Education, bertrand_schneider@g.harvard.edu

Abstract: The affective states of students while studying outside of class hold rich information about how students are doing in a course and how instruction could be improved. In this paper, we test the co-occurrence of webcam-based nonverbal metrics with self-reported student affective states during an instructional video. Preliminary results suggest that low-level, self-reported affect can be a promising ground truth data for research, and that nonverbal metrics created from webcam streams can be associated with this self-reported affect.

Introduction and setting

The affective states of students while studying outside of class is generally unknown to instructors – However, this information can help instructors better support student needs. With this motivation in mind, we collect two data sources an introductory data science course that could help track student states: continuous self-reports of affective states, and multimodal data via a webcam-based data collection tool, EZ-MMLA. The system does not save video data, and gives students access to their data (see Schneider, Hassan & Sung, 2021, for more details). From the x, y position of the eyes, ears, nose, and upper body joints, four known cues of affect are detected by simple rule-based algorithms: head tilts and nods (e.g., Lee & Marsella, 2006), zoom-ins (e.g., Zhao et al., 2020), and hand over face (e.g., Behera et al., 2020). Figure 1 shows a data sample labeled as "zoom-in".

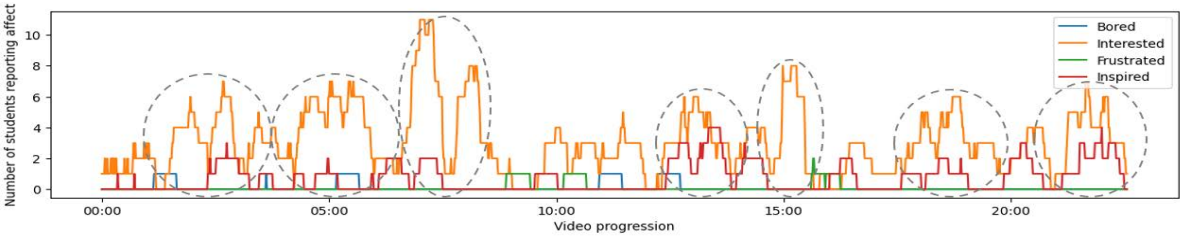
Figure 1
A Student zooming in close to the screen



Results

We first explore affect self-reported with reaction buttons next to the video, to see whether this could serve as ground truth. Then, we perform statistical analysis to check for the existence of links between self-reports and multimodal metrics. Figure 2 illustrates student affect responses throughout the duration of a video. The y-axis shows the number of students reporting an emotion within 30 seconds of a given time. For legibility, we visualize four contrasting emotions (bored/frustrated, interested/inspired), and describe the remaining two (aha, confused).

Figure 2
Self-reported affect for all students: Boredom, interest, frustration and inspiration



Students most frequently reported being 'interested' out of all six possible emotions. Reports tended to congregate around points (circled in dotted lines), indicating moments in the video that students commonly find interesting. While feeling 'inspired' is rarer, the patterns match expectations as they seem to be reported only during times where interest was high. Students rarely reported that they were bored or frustrated. We suspect these emotions may have been underreported, given prior research that documents the prevalence of boredom during learning (Baker et al., 2010). However, we note the few instances of boredom or frustration that exist

 © ISLS

tend to occur in where there are valleys in reported interest. Visual inspection also showed the existence of clusters for "aha" and "confused" reports, and a pattern of confusion preceding "aha" moments.

For the nonverbal metrics, chi-squared tests of independence indicate that all four metrics have significant associations with affective states (nodding: $\chi^2(3, N = 2410) = 37.23$, $p < .001$; tilting: $\chi^2(3, N = 2410) = 13.67$, $p = .003$; hand on face: $\chi^2(3, N = 2410) = 19.56$, $p < .001$; zoom-in: $\chi^2(3, N = 2410) = 69.57$, $p < .001$). Boredom and frustration were excluded due to suspected underrepresentation, and subsequent violation of the size requirement for the chi-squared test. Cramér's V, a measure of effect size that corrects for sample size, indicates that only nodding and zoom-ins are substantially associated with affective states (Cohen, 1988). We summarize the co-occurrence between these four affective states and two metrics of interest in Table 1.

Table 1
Contingency table for the co-occurrence of metrics and affective states

	Nodding	Not nodding	Zooming-in	Not zooming-in
Aha	38 (+9.30)	420 (-9.30)	**20 (-18.39)**	**438 (+18.39)**
Confused	**33 (-18.19)**	**719 (+18.19)**	**105 (+41.97)**	**647 (-41.97)**
Inspired	0 (-15.66)	230 (+15.66)	31 (+11.72)	199 (-11.72)
Interested	**93 (+27.03)**	**876 (-27.03)**	**46 (-35.30)**	**924 (+35.30)**

Each cell shows how long in seconds a behavior was observed during an affective state, and deviance from chance (in parenthesis). For instance, during 'aha' states, zooming in was observed for 20 seconds, which is 18.39 seconds less than expected by chance. As expected, we observe nodding much more than chance when students felt interested, and less so than chance during confusion. Students also zoomed in much more than chance during states of confusion, and less than chance with reported interest and 'aha' moments. We understand this as students moving closer to the screen only while they need to scrutinize the material to resolve their confusion, moving away prior to reporting aha moments or higher levels of interest.

Conclusion

We investigated the use of continuously self-reported affective states and nonverbal multimodal metrics for tracking the affective state of learners outside of the classroom. Coherent patterns within and between emotions indicate students are using the button as intended, and that continuous self-reports could be a promising way to collect ground truth data for research. However, further investigation is needed to ensure that students are reliably reporting states, particularly for negative emotions. Additionally, based on these self-reports, we were able to discern two promising non-verbal metrics for automatic tracking of student affect, nodding and zooming in. These metrics were most consistently tied with two emotions: interest and confusion. These prevalent affective states are noteworthy for their relevance in supporting students, e.g., knowing when students are interested and bored to update the learning material. In future investigations, we plan to expand and refine nonverbal metrics to gain more accurate proxies of student affect. Ultimately, our goal is to track previously invisible student states outside the classroom with the help of automatic, non-intrusive multimodal metrics.

Developing a boundary practice for collaborative task design in a design-centric research–practice partnership

Gabriel S. Ehrlich, Robin Jephthah Rajarathinam & Emma Mercier
gse2@ rjrthnm2@ mercier@illinois.edu
University of Illinois Urbana-Champaign

Abstract: Collaborative learning needs tasks suitable for collaboration. As part of a project to study the design of collaborative environments, we describe how a partnership with an undergraduate mathematics professor led to the development of a boundary practice for collaborative task design. Initially there was a tension between the researchers' preference for ill-structured tasks and the professor's priority of conceptual over computational problems. We discuss how focus on a single task resolved the tension and gave both researchers and the professor useful design tools for meeting their respective goals in subsequent task revisions.

Introduction

The design of a collaborative task is critical to the success of collaborative learning. Here we explore the role of the partnership with a professor in the development of task design conjectures (Sandoval, 2013) and the iterations on task design for collaborative tasks in an undergraduate mathematics class. Design-centric research–practice partnerships (RPPs) are characterized by tacit, conflicting motives (Kali et al., 2018). Developing a shared vision by surfacing contradictions is essential to create new practices for the collaborators (i.e., "Boundary Practices," Akkerman and Bakker, 2011). We describe how the task design iterations allowed for engagement within the boundary space to create an understanding of the learning goals for this course and the collaborative tasks.

Setting, design, and methods

We developed five collaborative tasks to be used for remote learning in an undergraduate applied linear algebra course. The team began work 5 months before the semester began. After 2 months, we began meeting weekly with the professor to discuss task iterations. A significant shift (henceforth "breakthrough") occurred in our thinking 1 month before the start of the semester while discussing revisions to the Week 5 task, leading to revisions of the three existing tasks and a streamlined design process for the remaining two that continued into the semester.

Data were notes from meetings and our task iterations. We constructed descriptions of our design conjectures for collaborative task design before, during, and after the breakthrough. Then we connected them in a narrative of the significant elements of our process that contributed to the occurrence of the breakthrough.

Findings

Initial designs

Our initial work was based on prior work on engineering tasks (Shehab & Mercier, 2017), in which ill-structured problems played a central role. Accordingly, we initially designed activities around an authentic, ill-structured task. We conjectured that many solution pathways would encourage the group to take up members' proposals, while the need to agree on a solution would incentivize moves to find agreement (Fernández et al., 2001). A scenario and visualization were used to create authenticity and offer multiple layers of meaning to be used to come up with solution ideas. Each task had structured subparts that were intended to prepare students to engage with the central task. The task concluded with reflection questions that we conjectured would reframe the shared experience of problem solving as an opportunity for discussion, rather than in terms of getting the right answer.

The Week 5 task was unusual in that there were no scenarios or visualizations. Students had to prove a symbolic mathematical statement about matrices, with general guidance on how to devise solution ideas. The task was authentic in that engineers may need to abstract proofs to characterize the behavior of a modeled system.

RPP negotiation

We first identified the purpose of the tasks: to teach students to solve conceptual problems, as contrasted with computational problems. The researchers initially understood the ill-structured tasks they had designed as achieving this goal: students would have to construct conceptual heuristics to simplify the complex problem enough to communicate about it and make progress. However, the professor maintained that the problems were too computational, other than Week 5, which seemed promising.

This tension resulted in a breakthrough in the RPP. The researchers realized that when using the phrase "conceptual problem" the professor was referring to a specific genre of mathematical problems, a distinction which did not exist in the STEM fields in which the researchers were trained. Week 5, which asked students to prove a mathematical statement, was a good example; other weeks, which involved constructing a design followed by significant calculational work, were not—except for the structured subparts intended to prepare students for the ill-structured problem. Subsequently, the researchers realized that in pilot tests of the tasks, the preparatory subparts themselves afforded collaborative work. We tabled the conjecture that ill-structured problems could afford collaboration and revised the existing tasks to focus on the structured, conceptual-problem subparts.

Without the conjecture about ill-structured tasks, the researchers decided to revise Week 5 to give it more structure: a walkthrough in six parts of how a mathematician might approach thinking about the proof, including explicit quotations of what the mathematician might be thinking at each step. The professor found this structure in line with his pedagogical goals. Whereas previous worksheets that he had written consisted of isolated problems for students to *practice* solving in groups, he would go on to use the "mathematician's walkthrough" in future tasks to turn the problems into opportunities for students to *learn* a mathematician's perspective.

Modified designs

Subsequent revisions to the design conjectures were minor. Without the ill-structured problem, the structured problems took priority and could be refined. We realized that the multiple layers of meaning offered not only a source of ideas for the group, but also a means to communicate those ideas, such as by drawing on or pointing to the visualization. We also had more time to devote to reflection questions, which during pilot tests were effective at prompting conceptual discussion. We placed reflection questions at different points in the worksheet to reflect on smaller key ideas that were critical to understanding and solving the overall task.

The final structure for all tasks except Week 5 consisted of an easy introductory problem to help students begin confidently, two problems divided into subparts, each followed by a reflection, and a final "challenge problem" without any scaffolding to further engage groups who finished the first three parts.

Discussion

We began developing task iterations five months before the start of the course. The early development of tasks gave us a boundary object to use to align our visions and substantively revise our design conjectures. The professor's learning goal priorities led the researchers to focus on a relatively neglected aspect of the task design, which improved the design and our theorizing about affordances for collaboration for this context. In turn, the researchers' new ideas for collaborative task design offered the professor an idea for how to design tasks that would better meet his learning objectives. Viewing the task iterations as boundary objects allowed them to become joint representations of the collaboration, and a malleable tool for fostering understanding and knowledge growth within the team, rather than static objects provided by the researchers to the professor to use.

Designing to Support Teacher Mediated Strategies for Student Learning in a Remote Kindergarten Music Class

Lora Cawelti, University of California, Irvine, lcawelti@uci.edu

Abstract: Using a single-setting, iterative DBR approach to program design, along with the multimodal affordances of music learning, I consider resource design to support teacher mediated student learning in remote contexts. Throughout the KinderMus program, teachers adapted their teaching in remote spaces, finding ways to mediate learning through language, social interaction, and active learning, and considering limitations around access to externally oriented artifacts. Findings have implications for design in both remote and in-person settings.

Introduction

As K-12 education moved almost entirely online in the 2020-2021 school year, many of the strategies regularly employed by teachers to scaffold teaching had to be modified for the unique context of remote learning. This move was especially challenging for early childhood teachers. The change in environment physically separated learners from their peers, reducing opportunity for collaboration, and challenging teachers to rethink active teaching strategies for students seated in front of a computer monitor at home. Many of the strategies like group and partner work, games and movement-based activities regularly employed by teachers required modification. While challenging, this new context offered an exciting opportunity for designing to support teacher development around teaching in remote learning contexts for kindergarten students while simultaneously supporting student learning. Using design principles rooted in design based research (DBR) (Design-Based Research Collective, 2003) along with the multimodal affordances of making music, I consider how teachers adapted and codesigned resources to develop new strategies for mediating learning in remote kindergarten classrooms, with implications for design of both remote and in-person learning environments beyond the present context.

KinderMus Program Design

The objective of the KinderMus program was to both support teacher development around mediating learning in remote contexts and provide opportunity for student learning in music. The design is based on understanding that students learn best when they are actively engaged, when instruction is multimodal, and within a social context along with their peers (e.g., Vygotsky, 1978) and I chose music as a disciplinary focus because it engages students in listening, singing, moving, and playing. As both researcher and music teacher, I grounded the program in general music theory with opportunities for teachers to practice music teaching techniques and engage with students in their music learning, and for students to engage actively with the songs and activities. Lessons were responsive to weekly teacher feedback and reflection. The design of the resource-driven program is based on principles of DBR (Design-Based Research Collective, 2003) and elements of effective teacher PD (Darling-Hammond et al., 2017; Desimone & Garet, 2015).

The program is based on four main design elements. First, KinderMus is content focused on music, incorporating singing, playing, moving, modelling, and peer interaction. Multimodal teaching strategies engage students through active learning and can also be applied in other academic areas. Second, the program is centered on resources and artifacts (Kazemi & Hubbard, 2008). Components include prerecorded, interactive video lessons, written lesson plans, weekly student assessment rubrics, and weekly teacher reflections. Teachers used video lessons during synchronous instruction, directly delivering music content and vocabulary and modelling movements and games. Third, KinderMus is designed in and for real world settings, as interactive resources allow for practice in the classroom context with students (Design-Based Research Collective, 2003; Desimone & Garet, 2015). Students learn both directly from the video resource and from their teacher's interactions with the videos. Fourth, the program employs responsive design strategies (Design-Based Research Collective, 2003). Teachers inform the initial design by providing weekly assessments and reflections. Feedback is directly applied to lessons and resources are constantly updated for student interests, engagement, and learning pace.

Methods

For this exploratory study, I took a single-setting, iterative DBR approach to program design. The study was conducted from fall of 2020 through winter of 2021 at an elementary school site in south Los Angeles County that delivered synchronous lessons remotely during the COVID-19 pandemic. I analyzed weekly teacher survey responses to open-ended questions asking how teachers were using the lessons and their perceptions of student learning as the program progressed, as well as three semi-structured post program interviews conducted with each

 © ISLS

teacher participant. With an iterative approach to data analysis, themes around mediated learning emerged, with descriptive codes emphasizing the verbal, social, and instructional moves individual teachers made to interact with the videos and their students in support of student learning.

Findings

Even in the remote context, teachers were able to adapt many typical classroom teaching strategies to mediate student learning. Responsive design increased teacher and student engagement in music activities. Teachers described mediating learning through language, social interaction, and active learning, and considered limitations around access to externally oriented artifacts (see Table 1).

Table 1

Ways in which teachers adapted to mediate student learning in remote music class

Mediation in music class	Description	Examples from teacher interviews
Language: Verbal scaffolding	Teachers provide verbal guidance, cues, and ideas while students participate in music class; they also make connections to prior knowledge and other student interests	*They liked having their turn so sometimes I would have to give an idea, you know, that was the only one that was hard sometimes. I would have to feed an idea in there.*
Social interaction and imitation	Teachers and peers provide modeling and interaction so students can imitate and participate in group activities	*If I'm dancing to the music. I see them dancing to the music ... I just automatically thought I have to do it. They have to see me model. So I danced and I jumped. I did all that stuff.*
Play: Movement and activity	Learning and meaning-making through active learning activities and play including pantomiming action words in a song, and clapping, stomping, and dancing; lack of opportunity for free play	*The students definitely like to participate. They look forward to me pausing so that they can input their own movement to the songs.* *I really like that everyone can pat and sing and participate so that they don't get bored or lose concentration.*
Artifacts and tools (externally oriented)	Use, adaptation, or lack of books, instruments and other manipulatives to support music learning; home tools are adapted for music making	*...if we were in the classroom, like instruments, you know, like when you are doing the drums ... I have a big box that has cymbals and sticks. So if we all had that ... that would be awesome.*

Conclusion

The Design-Based Research Collective (2003) emphasizes the importance considering how context "can lead to improved theoretical accounts of teaching and learning" (p. 7). Through this DBR project, teachers adapted their teaching in remote spaces, finding ways to mediate learning through language, social interaction, and play-based instructional strategies, and considering limitations around using externally oriented artifacts. While this exploratory study was conducted under somewhat extraordinary circumstances, the idea of designing resources that simultaneously support teacher development and student learning may be adapted for in-person learning and useful in subjects where teachers may have less personal content knowledge and expertise.

Adolescents' Interdisciplinary Learning in Self-Driven Learning

Gaoxia Zhu, Nanyang Technological University, gaoxia.zhu@nie.edu.sg
Anthony Burrow, Cornell University, alb325@cornell.edu

Abstract: Increasingly complex societal and environmental issues demand interdisciplinary solutions. However, there are barriers to implementing interdisciplinary learning, especially in the K-12 context. This study explored whether adolescents (i.e., mainly high-school-age students) chose to pursue interdisciplinary learning topics when they could choose learning topics. Through a content analysis of the application materials of 800 adolescents (M_{age} =16.59) participating *GripTape* – a 10-week self-driven learning program, we found that 44% of learners chose interdisciplinary learning topics. The results suggest that adolescents care about complex societal issues and are willing to tackle them using interdisciplinary knowledge in self-driven learning.

Introduction

Tackling complex real-world issues usually requires interdisciplinary thinking and knowledge. There is a need to foster interdisciplinary learning that is concerned with learners integrating knowledge derived from multiple disciplines to deal with complex problems, situations, and themes (Ivanitskaya et al., 2002). The Next Generation Science Standards suggest that subjects such as science, engineering, and technology are interdependent, mutually supportive, and together affect human society and natural environments (NRC, 2012). However, it is challenging to implement interdisciplinary learning in the school context considering the organization of current curricula, students lacking competencies to navigate across disciplines, and teachers' limited experiences and knowledge in supporting students' interdisciplinary learning. These challenges make us wonder whether self-driven learning, which usually happens outside of school, promotes interdisciplinary learning topics. Self-driven learning emphasizes students' own responsibility, agency, and motivations for pursuing meaningful goals (Ferlazzo, 2015). This study aimed to explore whether youth chose interdisciplinary learning topics in a self-driven learning project, *GripTape*, in which they can determine the learning challenges.

Method

The participants were 800 youth (58.25% female, M_{age}=16.59) accepted by *GripTape* from 2016 to 2020. The project offers youth between 15- and 19-years old opportunities to pursue learning challenges that they are passionate about. Among the participants, 20.75% identified themselves as Hispanic or Latino; 19.63% as Black or African American; 11.88% as White, Non-Hispanic; 7.88% as Asian/Asian American; 2.75% as American Indian or Alaska Native; 0.75% as Native Hawaiian or Other Pacific Islander. The other participants did not report their race information or reported "other". The data source was participants' textual responses to the questions "*What topic or skills are you planning to explore during this Challenge"*. Guided by the common subject classifications and inductively added new categories based on the data, we included the following categories in the final coding book when analyzing participants' determined topics: Arts & Humanities, Business & Economics, Clinical, Pre-Clinical & Health, Computer Science, Engineering & Technology, Life Sciences, Physical Sciences, Social Sciences and Law (Times Higher Education, 2020). Two raters independently coded 258 (31.73%) youth responses and achieved a substantial average agreement in all the categories (Cohen's kappa=0.62, Landis & Koch, 1977). The rest of the data were split and coded by the two raters. The learning topics involving one topic area were labeled as single-subject topics while the ones involving two or more topic areas were labeled as interdisciplinary topics.

Results and Discussion

Figure 1 shows the distribution of youth's learning topics. We can see that Arts & Humanities, Business & Economics, and Social Sciences were the three more prominent topic areas. A similar percentage (around 5%) of youth's learning topics fell into the categories of Clinical, Pre-Clinical & Health, Computer Science, Engineering & Technology, and Life Sciences. Relatively fewer youth chose Physical Sciences and Law relevant topics.

 © ISLS

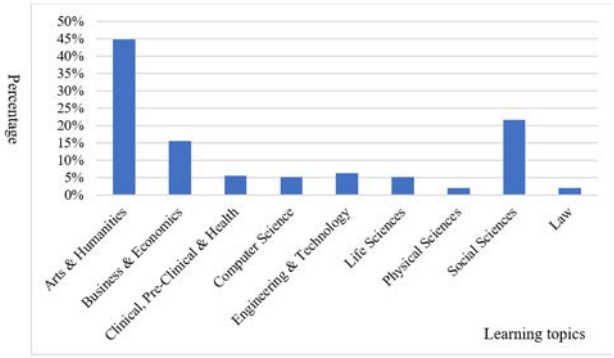

Figure 1. The distribution of learning topics

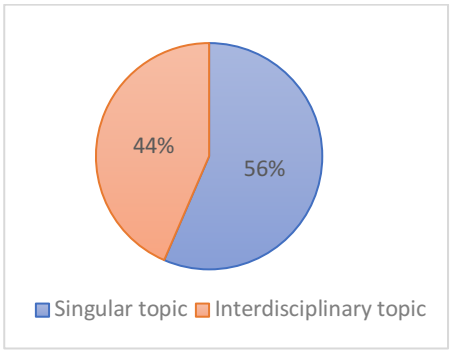

Figure 2. The distribution of singular versus interdisciplinary topics

As Figure 2 shows, 56% of participants chose singular-subject topics in their learning challenges while the other 44% of youth chose interdisciplinary topics. The following is an example of a single-subject topic that was coded as Arts & Humanities because the participant mainly aimed to explore music and singing in the learning challenge.

> *"I plan on exploring music and singing during this challenge. I want to buy music equipment so that I can record the songs that I have written (and hopefully post videos on Youtube). I am passionate about this because music is all that I know. I have been singing and writing songs since I was a little girl, about 6 or 7 years old, I really want to make it into the entertainment field…"*

The following example was coded as both Arts & Humanities and Psychology, and therefore, was identified as an interdisciplinary topic. This participant not only wanted to pursue photography but integrated it with youth self-esteem.

> *"I hope to pursue study in photography and the increase of self-esteem of youth that come from the inner city (using cameras and images), specifically at James Hillhouse school. I'm passionate about this because I was once bullied and didn't have the person in my life besides my mother, (who was alive at the time) to help me build that inner confidence with this project I hope to alleviate some of that pain that students like myself have faced."*

This study found that 44% of youth chose interdisciplinary learning topics when they were not constrained by curriculum structures and were empowered to make decisions. Real community or society issues tend to be authentic and complex and may require the participants to acquire related knowledge, resources, and approaches from several disciplines to make sense of (You, 2017). Interdisciplinary learning benefits learners' deep understanding, positive affect, and creation. It can provide "relevant, challenging, and enjoyable learning experiences" to learners (Scottish Government, 2008, p. 21) and contexts for creativity to arise (Madden et al., 2013). Schools and positive youth development organizations can consider how to enhance youth's self-driven learning by incorporating their agency and voice in learning.

The Effects of Affective Feedback on Learners' Emotions in Asynchronous Video-Based Learning

Seunghye Ha, Hyo-Jeong So
seunghye.ha23@gmail.com, hyojeongso@ewha.ac.kr
Ewha Womans University

Abstract: This study examined the effects of affective feedback on learners' boredom, confusion, and frustration in asynchronous video-based learning. Affective feedback messages and writing activity were used to deliver the utility value of learning topics. Facial expression data from 30 adult learners were collected and analyzed to identify changes in affective states. The findings suggested that the utility value message had a significant on reducing learners' boredom.

Introduction

During the COVID-19 pandemic, asynchronous video-based learning was widely adopted in various learning situations to support emergency remote learning. Despite its flexibility, asynchronous video-based learning has been criticized due to the lack of interaction and delivery-centered content presentation. Learners with fewer self-regulation skills tend to experience various emotional states, including confusions, frustration and boredom that negatively influence learning processes and outcomes. In general, feedback approaches to influence online learners' emotions have been cognitively-oriented, such as the provision of question items. While cognitive feedback is essential to help learners better understand learning content, it is equally important for learners to understand why they learn, such as the utility value of learning tasks, to sustain their attention and interest during online learning. Pekrun (2006) argues that achievement emotions are mainly influenced by two appraisals: control and value. Control refers to the perceived causal influence over the learning process and outcomes such as the belief that learning will be completed through one's efforts. Value refers to the perceived valence of action and outcomes, such as the meaning that learners attribute to performing certain learning tasks.

With this backdrop, this study focuses on the role of values on academic emotions, especially utility values' effects on online learners' affective states. Utility value refers to how a task fits one's future plans (Wigfield & Eccles, 2000). This study used two approaches to increase the utility values perceived by learners who took a video lecture about big data: affective feedback message and writing activity. First, we designed affective feedback messages to deliver the utility value of learning content and tasks. Second, we designed writing about the utility value of the lecture topic (i.e., big data) as a pre-learning activity. Writing or reading about the utility value of a learning topic is effective to help learners establish relevance to learning. Among various emotions, this study particularly focuses on boredom, confusion, and frustration that have been reported to have effects on engagement and disengagement in learning situations (D'Mello & Graesser, 2012). In sum, the goal of this study was to investigate the effect of utility value feedback and writing activity on learners' boredom, confusion, and frustration in the situation of asynchronous video-based learning.

Method

The participants were 30 Korean adult learners (20-35 years old) recruited via convenience sampling. The participants were randomly assigned to one of three groups: control group, feedback only group, feedback, and writing group. The feedback only group received feedback messages during watching the video lecture. Based on previous research, we designed four types of utility value messages: (a) utility for daily life (e.g., Data analysis is closely related to our lives. Let's try a little harder!), (b) utility for jobs (e.g., Data analytics is a competency required by various jobs. Let's study hard until the end!), (c) utility for membership groups (e.g., Data analysis can be useful at school or work. Shall we do our best to study?), and (d) social utility (e.g., Data analysis is a good topic for conversations with people from different disciplines. You are doing very well!). In contrast, the feedback and writing group performed an additional task to write about the utility value of big data analysis within 250 words before watching the video lecture. We conducted the Wizard of Oz (WoZ) experiment in a quiet room where the participants interacted with the online learning system controlled by the researchers. The participants were asked to verbally express their emotions (emote aloud protocol). In a separate room, we listened to their verbalizations and send out online feedback messages when verbalizations included words related to boredom, confusion, and frustration (see Figure 1). Corpus grouping respective to each emotion was done before the WoZ experiment (i.e., boredom: I want to quit). For data collection and analysis, we recorded learners' facial expressions and analyzed facial muscle movements called Action Units (AUs) based on the Facial Action Coding System (FACS) to identify learners' emotional states.

 © ISLS

Figure 1
Feedback Message

Results

We extracted 1,671 AUs from the recordings and then AUs less than three seconds were excluded as transitory states. This left 1,123 AUs for final data analysis. Boredom in the control group was the highest (M = 31.00, SD = 14.40), followed by the feedback only group (M = 16.50, SD = 12.78) and the feedback and writing group (M = 11.50, SD = 6.17) (Table 1). As there was a significant correlation between the frequency of frustration and confusion (r = .38, p < .05), MANOVA was conducted to investigate the differences in the frequencies of emotions. There was a significant difference in the frequency of boredom among the groups. Scheffé's test result suggested that the frequencies of boredom between the experiment groups and the control group were statistically significant (p < .05). No significant differences across the groups were found in confusion and frustration.

Table 1
The Frequency of Boredom, Confusion, and Frustration

Type	Frequency			F	η^2
	Feedback only group (n = 10)	Feedback and writing group (n = 10)	Control group (n = 10)		
	M (SD)	M (SD)	M (SD)		
Boredom	16.50 (12.78) [a]	11.50 (6.17) [a]	31.00 (14.40) [b]	7.53*	.36
Confusion	4.50 (4.22)	12.60 (8.58)	6.30 (8.97)	3.16	.19
Frustration	9.20 (7.58)	9.90 (10.05)	10.80 (11.02)	0.07	.01

[a],[b] refers to the values designated with different superscripts within a row differ at α = .05.
* p < .01.

Conclusion and implications

Among three types of emotions, affective feedback had significant effects on learners' boredom while the writing activity had no effect on all three emotional states. As boredom is known to be closely related to disengagement, the feedback assisted learners to remain more engaged. While the existing research suggests that confusion and frustration turn into boredom (D'Mello & Graesser, 2012), the participants tended to experience boredom from the beginning. Follow-up interviews indicated that the participants needed more control over the learning process such as choosing the relevant topic. This finding implies that coupling utility value and control is essential to prevent learners from easily entering the boredom status from the early stage of online learning. We also discovered that the utility messages motivated the participants to remain focused as they emphasized the usefulness of the video. We plan to conduct a follow-up study to further investigate the coupling of control and values and the effects of utility messages.

Othering: Overcoming a Sociocultural Obstacle to English Proficiency among ESL learners in Malaysia

Joyce Morris Kapong, Universiti Putra Malaysia, joyce@upm.edu.my

Abstract: This study aimed to see how othering affects Malaysian students' English language learning. This article presents insights from data acquired during an interview and examined thematically. It explores three themes that emerged from the interview with Malaysian ESL learners regarding their experiences with othering and how personal growth has helped them overcome the effects of othering.

Introduction

English, being a global language, is a necessary skill for integrating into the real world. Accordingly, English plays a significant role in the Malaysian educational system, where it is viewed as a second language and a language of knowledge that may aid Malaysians in obtaining better work (Kasuma et al., 2021) and hence a higher social position (Zulkefly & Razali, 2019). Learners are encouraged to practice the languages outside of class to improve their skills. However, speaking English outside the classroom is a greater challenge for its users. When learners interact in English, they claim to feel 'othered' by their community members. Othering happens when English language learners are purposely segregated from their ethnic group due to a biased mindset (Lee et al., 2010). This research investigated the impact of othering on Malaysian learners' English language acquisition. The study's findings can provide English learners with an understanding of how to recover from the effects of othering.

Methods

An interview protocol was used to acquire a thorough overview of the participants' experiences with othering when attempting to communicate in English at school or in public areas. The questions were designed to extract information regarding the participants' personal experiences as ESL learners, especially on the problem of othering faced by learners in Malaysia. The interview questions centered on identity, marginalization, motivation, and barriers to learning English. Thematic analysis was conducted by a six-step approach (Braun & Clarke, n.d.; Braun & Clarke, 2006): familiarization, coding, theme generation, theme review, theme definition and naming, and writing up.

Findings

Data from the interview produced three themes: othering belittles one's linguistics ability and cultural identity, being othered compels learners to adjust their viewpoint, and learners experienced personal growth.

Theme 1: Othering belittles one's linguistics ability and cultural identity

Mocking is one of the negative behaviors associated with othering. Many of the incidents include ridiculing the learners' willingness to communicate in English in the presence of non-English users. The mockery made the learners feel embarrassed and upset. In addition, they were mocked for trying to communicate in a foreign language and accused of abandoning their cultural identity.

Student 2: *"Kenapa kamu mau cakap BI sedangkan bahasa kamu tu bahasa Iban sendiri?" Boleh kata sedihlah sebab BI ni universal lah. Semua orang boleh cakap BI. Selalunya saya senyap."* ("Why do you want to speak in English when your language is Iban?" It was sad because English is universal. Everyone can speak English. Usually I just stay silent.)

Student 4: *"I remember the first time my family went to the Iban church. I remember everyone was like, "They talk English. Orang putih." Then they went to ask us, "Orang putih ka?" Then I said, "No, no. I'm Iban."* (I remember the first time my family went to the Iban church. I remember everyone was like, "They talk English. White people." Then they came to ask us, "White person?" Then I said, "No, no. I'm Iban.")

Theme 2: Being 'othered' compels learners to adjust their viewpoint

 © ISLS

Following a firsthand encounter with othering, the participants reflected on the experience. As a result, they came to understand the point of view of people who mocked them. This thoughtfulness is a critical adjustment - seeing through the mockers' eyes may assist learners in moving beyond their pain and continue learning and using English.

Student 7: *"Mereka rasa jijik; mcm pelik. Orang ini dia Iban atau Melayu. Lepas tu dia cakap BI macam dia cakap BM tu. Pelik lah. Lepas tu mereka rasa terancam sebab mereka tak boleh bercakap BI. Jadi mereka rasa pelik atau cemburu, jadi mereka mula ejek."* (They felt disgusted; it was weird. This person is Iban or Malay. Then he speaks English the way he speaks Malay. Odd. Then they feel threatened because they can't speak English. They feel strange or jealous, so they start mocking.)

Theme 3: Learners experienced personal growth

Surprisingly, personal growth develops as a result of the encounter. Despite the unpleasant experience, the learners chose to rise above it by refusing to let incidences of othering impede their language acquisition.

Student 1: *"Kena jadikan itu sebagai galakan untuk cakap BI, lepas tu jangan fikir apa yang orang lain fikir. Just do whatever you want."* (You have to use that as an encouragement to talk in English, and then don't think about what other people think. Just do whatever you want.)

Student 4: *"Beri saya semangat untuk lebih belajar BI ni supaya dapat buktikan bahawa saya ni boleh, dan mereka akan hormat."* (Encourages me to learn more English so that I can prove that I can, and they will respect me.)

Discussion and Conclusion

Attacks on English learners' cultural identities show that they have lost their cultural identity and become outsiders in their ethnic community when they speak English. This is an example of sophisticated othering, as defined by Brons (2015), in which the person committing othering expects the othered to communicate in their native language. This odd method of preventing people from speaking English may be related to the mockers' lack of linguistic abilities and feelings of insignificance when they encounter someone who speaks or attempts to speak English well (Ibrahim et al., 2018). However, language acquisition is crucial to a learner's personal growth (Schmidt, 2014); therefore, the participants chose to improve their English skills instead. Furthermore, they did not appear resentful or conflicted, as they knew that not everyone would support them. Instead, they believed that learning English would benefit them in educational, social, and professional aspects.

Creating Comics about COVID-19 to understand the intersections between Science, Community, and Equity

Sameer Honwad, Shakuntala Devi Gopal, Anthony White, Ryan Rish, Jessica Scates ,
sameerho@buffalo.edu, sdgopal@buffalo.edu, alwhite3@buffalo.edu, ryanrish@buffalo.edu,
jmscates@buffalo.edu, University at Buffalo (SUNY)

Abstract:. The COVID-19 pandemic is a complex socio-scientific problem that needs to be understood and addressed at local and global levels. The problem has illuminated inequities among and within communities around the world. Given the importance and complexities of this concern, we targeted COVID-19 to examine student understanding of the interconnectedness between the science (What is COVID-19?), the local context (How does COVID-19 impact community?) and equity (How does COVID-19 impact different members of the community?).

Introduction:

The COVID-19 pandemic is a complex socio-scientific problem in that the virus (science) impacts communities in several different ways and requires people living in those communities to alter their behavior and lifestyles in order to address the problem. In this presentation we describe and present evidence for how storytelling can be a powerful approach that can be used for teaching and learning complex socio-scientific problems. Teaching and Learning about complex socio-scientific problems such as COVID -19 and climate change requires educators and learners to use many non-traditional pedagogical tools and approaches (Shepardson, et al 2012; Authors 2014; Lenzen, Day & Murray, 2002) where in individuals would: (a) teach and learn how to make decisions/take actions that are local, keeping in mind global impacts (Ostrom, et al. 1999); (b) address inequities caused by the problem (Schlosberg & Collins, 2014); (c) teach and learn in ways that are grounded in local epistemologies (Bang & Medin, 2010); (d) teach and learn how to use data that is available to understand future scenarios (Resnick & Welinsky, 1998); (e) learn about and apply knowledge from both formal and informal learning environments (Bell et a., 2009) (f) teach and learn how to collaborate across local and global communities while addressing the power dynamics between and within those communities (Esmonde & Booker, 2017). Storytelling is an approach that can allow individuals to embed scientific content and data in their stories and also discuss how science problems can impact their communities. For centuries people from many different cultures and societies have taught principles of how to solve moral and ethical problems through storytelling (Wilson, 2008, Iseke 2013). Storytelling is a globally practiced approach to teaching and learning that is shared across all cultures and can be used an avenue that allows learners to leverage funds of knowledge (Moll et al.,1992) from their communities. Stories and storytelling provides a pathway for learners to make deep connections between funds of knowledge and learned knowledge in order to see complex socio-scientific problems more comprehensively. Further, research and practice on storytelling pedagogy advances educational equity generally, as centering and affirming the lived experiences of diverse student populations challenges both dominant educational narratives (Ladson-Billings, 2016; Solorzano and Yosso, 2016) and colorblind educational policies which have been found to maintain white supremacy (Bradbury, 2020; Gillborn, 2013, 2016).

Learning Environment Design

The COVID-19 pandemic is a complex socio-scientific problem. It is also a global challenge that impacts all everyday aspects of human life and has altered the social fabric of nations and local communities. This pandemic has illuminated inequities among and within communities with marginalized communities, in particular, having been impacted most acutely (Katamneni, 2020). The complexity of this problem requires nations to work together with local communities on issues of science, economics, socio-cultural norms and equity (Pirouz et al., 2020). Given the importance and complexities of this concern, we targeted COVID-19 to examine student understanding of the interconnectedness between the science (What is COVID-19?), the local context (How does COVID-19 impact community?) and equity (How does COVID-19 impact different members of the community?). We used the authoring of comic books as an approach to engage the youth from three different nations (United States, India and Mexico) in understanding the three questions mentioned above. The youth (13-18 years old) conceptualized stories about how the virus impacts their local communities. This presentation describes the design of a program to help students understand the intersections between science, community and equity. We also take this opportunity to describe how the students approached their work and presented their stories/comic books, which illustrated their understanding of how a complex science problem (COVID-19) impacted their community and different socio-cultural groups within their community. Given COVID-19 restrictions, we designed a virtual

 © ISLS

program on Zoom that would take place three days a week, two hours each day over the course of three weeks. The program was voluntary and one of the measures of engagement was the extent to which students were punctual and actively engaged through the Zoom platform (video and chat) during the two-hour sessions.

Program Activities

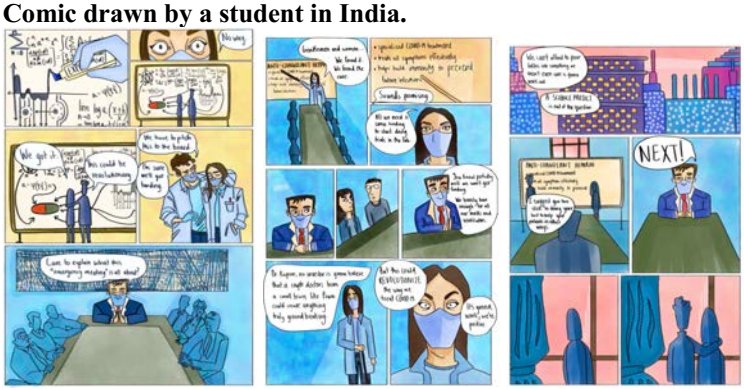
We devised and utilized three main goals, each with an associated question in student friendly terminology, to frame our program design and learning content, such that students were constantly thinking about one or more of the following: Goal 1. Complex systems thinking: How can I make sense of, and address, complex problems? Goal 2. Community based science: How do scientific phenomena impact different communities, and in what actions can/do communities take in order to respond to scientific phenomena? Goal 3. Equity: How does inequity further complicate a complex problem, and what can be done to address inequity in order to better address the complex problem? During week one we focused on getting to know each other in terms of identity, sharing and discussing perceptions of COVID-19, thinking about communities that are being impacted inequitably due to COVID-19, and identifying student-generated topics for graphic novels. During week two we focused on the elements of story-telling and graphic novel design, which included creating storyboards, giving and receiving feedback on storyboards, learning about the various design features comic artists use to tell a story visually, and beginning to design comics using Pixton software or hand-drawing to create graphic novels. During week three we focused on providing students with feedback on storylines and graphics, and learning more about how graphic novels can impact sociopolitical agendas. And on the final day of programming, students presented their completed graphic novels to invited guests, including parents, students' school administrators, and faculty from SUNY at Buffalo. Students were organized into three teams, such that there were students from different countries in each team and discussion in the teams were led by a member of our research team.

Analysis and Findings

Students presented various stories as a part of their graphic novels. The stories included how students thought about the intersections between science (what is COVID-19?), community (how does COVID-19 impact their community?) and equity (How does COVID-19 impact different members of the community?).

Figure 1

Comic drawn by a student in India.



For example, in a story created by student A (Figure 1), the student highlights dilemmas the scientific community is facing in India. In the hand drawn comic below, the student shows as a part of the story how since drug trials cost money and Indian medical scientists have less funding than western medical scientists, it is difficult for Indian scientists to try out new treatments for COVID-19. The student also shows the everyday life challenges faced by medical practitioners in India to treat COVID-19 patients.

Developing comics in a learning environment not only fosters student engagement, but also offers an alternative method for assessing student comprehension of concepts and systems. Creating a comic offers students an avenue for applying systems thinking to a scientific concept in a creative and personally relevant way, as students can use graphic elements and a storyline of their own choosing to articulate learned themes and academic content. Comics additionally enable students to express and connect their identities to what they know, what they have learned, and what is important to them in artistic form.

Constructionist Design for Sustainable Development

Sawaros Thanapornsangsuth, United Nations University, Tokyo Institute of Technology,
sawaros.t.aa@m.titech.ac.jp

Abstract: This poster introduces "Constructionist Design for Sustainable Development" as a design principle to engage students in a constructionist learning experience while addressing environmental and social challenges. To this end, we conducted a two-year qualitative design-based research project that engaged undergraduate and graduate-level students, lecturers, and community members from two universities in Thailand and Japan to design and build innovations that solve environmental and social problems in their communities.

By 2030, the United Nations' Sustainable Development Goals (SDGs) hope to ensure all learners acquire knowledge and skills needed to promote sustainable development. Yet, many countries' roads to education for sustainable development (ESD) remain a challenge. While many universities are cultivating partnerships to promote sustainability on campuses and offer ESD courses, little attention has been put on immersing students in environmental and community-based problems through hands-on learning experiences. This research develops a design principle for creating a constructionist community-based approach to ESD that empowers students to tackle problems and provides the foundation for sustainable development.

The learning processes for ESD should empower students with transformative actions for sustainability (UNESCO Executive Board, 2019). ESD is not just adding sustainability as an extra topic to the curriculum but rather enabling learners to contribute to sustainable societies through critical thinking and active problem solving (Lambrechts & Hindson, 2016). Students should engage in analysis, reflection, and action for local and global citizenship and active participation while acknowledging the rapidly changing and interdependent world (Honan, 2005). Scholars in environmental education believe that knowledge and values on the environment shouldn't operate in isolation; learners should have the opportunities to connect with nature, environmental stewardship, and interest in learning and discovery (Cutter-Mackenzie &Edwards, 2013; Stern et al., 2008). Thus, cultivating active participants requires teaching methods that go beyond lecturing. *ESD for 2030* suggests that learners must first step outside of their safety status quo and become critically aware of the world's existing problems and conditions. Finding opportunities to launch critical inquiries about society and being empathetic with others allows young learners to activate values and a lifestyle corresponding to their sense of identity.

The constructionist design paradigm shares many similarities with literature on the ESD learning process. Constructionists believe that learners learn best when designing and making personally and socially meaningful (Papert, 1993). Learning should be experiential and connected to the real world (Ackermann, 2001). It is also influenced by Dewey's progressive education, which focuses on experiential learning and building connections to the real world (Blikstein, 2013). Through constructionist learning, learners can take an active role in their learning by creatively designing, building, and exploring their projects based on their personal and social interests. It liberates learners from being taught when they are empowered to connect everything they wonder, know, and feel about expanding themselves into learning new things (Blikstein, 2013). To bring constructionism and ESD into higher education, the instruction should allow students to see themselves as a part of the community. They believe that they can succeed and then make connections between their community and global communities. Ladson-Billings' (1994) work on culturally relevant teaching emphasizes the importance of creating relevant cultural connections to students' learning experience. By doing things personally and socially meaningful to their communities, students can reflect on their achievements.

This poster presents a design principle to better support authentic making in higher education by engaging students from various disciplines and the broader community. We situate this research in two universities located in Bangkok and Tokyo. We argue that the principle could be a model for other university-based ESD courses. The Constructionist Design for Sustainable Development (CRSD) should design: (1) For the learners to make connections with their peers and community members by working toward solving social and environmental problems of their interests; (2) to explore and experiment with novel ideas in working on personally and socially meaningful projects; (3) with high expectations of all students while supporting the integration of their prior knowledge and experiences; and (4) for the students to be reflective of their achievement and ability concerning the environment, their community, and beyond.

To provide empirical evidence supporting CRSD, we conducted a qualitative design-based research project with over 60 undergraduate and graduate-level students, lecturers, and community members from Thailand and Japan. The study employs qualitative research methods across three locations (in-person and online). Each implementation is one semester-long. The course's learning goal is to empower the students to be designers and create inventions to solve social and environmental challenges. Students' projects covered but weren't limited to

 © ISLS

sustainable lifestyles, human rights, gender equality, and global citizenship. They followed the design thinking process by empathizing with community problems, constructing problem statements, and brainstorming to achieve the goal. Then they will create a prototype to help them think, learn, and gain feedback from the community and iterate on their designs. Students were encouraged to use digital fabrication equipment such as 3D printers and laser engravers to make their innovations. Towards the end of each course, the students presented their projects and shared knowledge with community members.

The preliminary results show how Constructionist Design for Sustainable Development takes shape as a (1) way of establishing making as a part of connecting students, environment, and community, (2) space for students to work together and collaborate with peers, and (3) form for the students to connect with the problem that they once thought couldn't be solved by themselves. Students showcased their creative and innovative nature in tackling everyday environmental and social problems. For example, a group of pharmaceutical science and economics students made "BraceMed"—a handmade bracelet with a 3D printed pillbox—for a member's grandmother to remember to take medication. The team came up with the idea after learning about the grandmother's high blood pressure due to missing medicine (See Figure 1). Making and designing a bracelet together also serves as a joyous family activity. Another group experimented with different methods to create the most durable shopping bag using zero-waste and 100% degradable materials (See Figure 2). They even went to a local print shop to help recycle their paper waste. Finally, students reflect on their accomplishments and their parts to achieve the Sustainable Development Goals- doing useful solutions with a creative spirit and drive for innovation. We believe that Constructionist Design for Sustainable Development is possible when students develop connections to the problems and people within their community. Additionally, the learning environment must encourage the students to design and experiment with new ideas. Students can be empowered by collaboratively designing solutions that impact their community and themselves.

Figure 1

A student and her mother made "BraceMed" for the grandmother (left) and Students' bio-gradable paper making process(right).

Engaging in a hands-on constructionist class that addresses ESD challenges, students propose and design solutions for the betterment of the community as a tool for engendering change for the environment. The research contributes to the global intellectual community by creating design principles supported by empirical evidence, especially designing environmental education by innovating for their community and environment.

Creating Space for Formative Peer Feedback in a Community-oriented MOOC

Jacob M. Aguinaga, Rebecca M. Quintana
jmagu@umich.edu, rebeccaq@umich.edu
University of Michigan

Abstract: To advance community-oriented instructional approaches within MOOCs, we examine the impact of creating space for formative peer feedback using a digital workbook in a Resilient Teaching MOOC. We use a coding scheme for classifying peer feedback to analyze responses to shared workbook entries. Findings revealed the presence of five attributes in the feedback: content, explanations, advice, questions, and community connections. Our study elaborates approaches for creating productive forms of knowledge exchange among peers.

Introduction

Massive open online courses (MOOCs) generally embody *individualistic* approaches to instruction (i.e., valuing independence), which could hinder opportunities to engage in significant learning with peers. We investigate how MOOCs can become more *collectivist* (i.e., valuing communities), exploring ways that instructors can pragmatically advance forms of social interaction that connect learners, their coursework, and their peers' ideas.

This study investigates peer feedback exchanged in a custom digital workbook and gallery space situated in a MOOC on Resilient Teaching. Our overarching aim is to advance community-oriented approaches in open, online learning environments. The following research questions guide our inquiry:

- What can we observe about the ways in which learners "take up" opportunities to give formative peer feedback in a MOOC on Resilient Teaching?
- What are the characteristics of the feedback offered?
- In what ways might opportunities for formative peer feedback allow instructors to advance collectivist approaches within open, online learning environments?

Relevant literature

Shute (2008) defines formative feedback as "information communicated to the learner to modify their thinking or behavior to improve learning" and asserts that the aim of formative feedback is to "increase student knowledge, skills, and understanding of content areas and general skills" (p. 154).

To understand the quality of peer feedback (formative or summative), scholars have developed various frameworks to assess it. Prins et al. (2006) advanced a framework that included the following categories: content-related remarks, explanations of remarks, suggestions for improvement, questions to foster reflection, and formulation and structure of feedback. The Prins et al. (2006) framework is the basis of the coding scheme we used to understand the characteristics of formative feedback given and received by learners in our study.

Research context

The Resilient Teaching MOOC launched on the Coursera platform in June 2020. A stated goal of this community-oriented MOOC was to foster a sense of connection and community amongst learners in the course. The course culminated in a resilient teaching plan, a final project that learners could apply in their respective instructional contexts. Throughout the course, a digital workbook developed by the authors' home unit incrementally supported learners' development of their resilient teaching plans through a series of reflection prompts indexed to course topics. The digital workbook included 12 total prompts distributed throughout the course. The digital workbook included a gallery space that allowed learners to share portions of their teaching plans and receive formative feedback from peers that could inform their final assignments. Learners could browse shared entries, ask questions, and offer feedback on their peers' submissions. For this unstructured task, learners were encouraged to review gallery submissions and leave open-ended comments on peers' entries.

Method

Data sources

We collected data from the Resilient Teaching MOOC from the time of course launch in June 2020 to October 2021. During this time, 2,247 learners were "active" participants in the course, meaning that they engaged with

 © ISLS

at least one course item (e.g., watching a video). 1503 workbook entries were shared, 72 of which received peer feedback. We restricted our analysis to initial conversation thread responses (n=72).

Coding scheme and coding approach

We simplified Prins et al.'s (2006) coding scheme to develop our codebook for classifying feedback: content, explanations, advice, and questions. Two coders collaborated to code peer feedback responses using a directed content analysis approach (Hsieh & Shannon, 2005). They applied all relevant codes in the codebook to peer feedback responses (i.e., simultaneous coding). Coders did not apply any code to responses that could not be considered "feedback" (i.e., one word or off-topic responses) (n=22). Coders evaluated the remaining viable responses that did not fit the coding scheme and developed a new code to describe these responses—community connections—and updated their codebook to include the new code and re-coded all viable responses (n=50).

Findings and discussion

Analysis revealed the following distribution of codes: content (n=17), community connections (n=12), questions (n=9), advice (n=5), and explanation (n=3). We structure our findings according to our three research questions:

The ways in which learners "take up" opportunities to give formative peer feedback. The majority of shared entries did not engender peer feedback, with only 5% of entries receiving a response. Of these, roughly two-thirds were "viable" feedback, available for coding. We discovered two unanticipated behaviors: *self-responders* (20.8% of total analyzed responses) and *super-posters* (55% of total analyzed responses) (Huang et al. 2014). Self-responders provided context for their original post, shared additional connections to course content, and requested others to review their work (i.e., community connections).

The characteristics of the peer feedback provided. The majority of responses drew connections between course *content* and their peers' ideas. Our analysis also revealed instances where a peer offered specific pedagogical suggestions, indicating that the peer likely shared a similar instructional background and thus felt comfortable offering advice. These types of comments were less frequent, however, as evidenced by the lower occurrences of the *explanation* and *advice* codes. When guiding *questions* were posed, they aimed to direct peers to useful alternative instructional approaches or encouraged peers to refine their initial teaching plan. Responses coded as *community connections* included elements such as the sharing of personal experiences and instructional approaches, expressions of appreciation for peers' efforts, and requests for feedback.

Opportunities to advance collectivist approaches within open, online learning environments. The responses we analyzed demonstrated that many learners embraced the ethos of a community-oriented learning environment. Learners elaborated on their peers' ideas and critiqued peers' applications of course themes as they pertained to their final resilient teaching plans. These behaviors embody the collectivist mindset advocated by Ladson-Billings (1995), necessary to achieve deeper understanding and higher levels of academic success.

Limitations and future work

Despite a sizable pool of shared digital workbook entries (n=1503), only 50 of these received substantive responses worthy of analysis. This low rate of interaction between peers severely limited our investigation of formative peer feedback in a MOOC. Future work will explore how providing more structure and guidance around formative feedback tasks in community-oriented MOOCs could influence the way that learners take up the practice and shape the characteristics of feedback exchanged.

Physical Microcosms: Potentials for Enriching Classroom Investigations in Ecology

Amanda Dickes, Gulf of Maine Research Institute, Email
Panchompoo Wisittanawat, Vanderbilt University, fai.wisittanawat@vanderbilt.edu
Richard Lehrer, Vanderbilt University, rich.lehrer@vanderbilt.edu

Abstract: Ecologists construct physical microcosms that exemplify mechanisms and relations in ecosystems. This poster describes how a 7th-grade classroom complemented field study of an intertidal ecosystem with design of classroom microcosms. Initial designs appeared constrained by literal resemblance. As students' inquiry increasingly focused on interactions among organisms, they configured microcosms to facilitate observation of these interactions. Microcosms became sites for studying processes that could be inferred from field data but rarely observed directly.

Introduction

Physical microcosms are often employed by scientists to investigate more closely how components of a system interact (e.g., Strayer et al., 2006; Tyrrell et al., 2006). When scientists construct microcosms, they do not merely copy a system but instead deliberately select and arrange for conditions in the microcosm that make more salient relations and mechanisms of interest in a natural system. Designing and employing microcosms as investigative tools introduces students to crucial considerations about the status of models as approximations of the world, their utility as investigative tools, and their status as explanations of system structure and function (Lehrer et al., 2008). Because microcosms resemble the target system in some critical ways, they offer students an entrée to modeling, partly because the analogical distance between model and system is visible (Lehrer & Schauble, 2002). However, previous research indicates that for students to perceive the microcosm as a model, and not simply a copy, they must have agency in its construction, especially in decisions about what to amplify and what to suppress, and in articulation of how the microcosm will help answer one or more research questions (Lehrer & Schauble, 2012). Having a hand in some aspects of microcosm construction and use also helps students understand that modeling is performative, and not only a matter of representing objects and relations symbolically.

Research Design & Context

This work provides an account of one seventh grade classroom's use of physical microcosms to exemplify aspects of an intertidal ecosystem for the purpose of investigation. This work takes place within a larger, multi-year design-based research study investigating how students' conceptions of and practices for representing variability inform their construction and revision of models of ecosystems. The context of this work is a statewide middle school citizen science curriculum focused on understanding how the relative abundance and distribution of native and invasive species of crabs are changing due to climate-driven factors. In designing and investigating classroom microcosms, our goal was to consider how physical microcosms might enrich classroom investigations of the target system and to investigate learning opportunities as well as conceptual and material challenges students might encounter as they used microcosms to investigate intertidal ecology. Our design privileged giving students time to observe the microcosm; to "get-to-know" the organisms of the intertidal, and how they relate to each other and the larger system. As thinking progressed, we invited students to "stretch" the components of their microcosms into forms that lend themselves to quantification and investigation of relations among quantities (Lehrer & Schauble, 2006), a process still ongoing in our focal classroom.

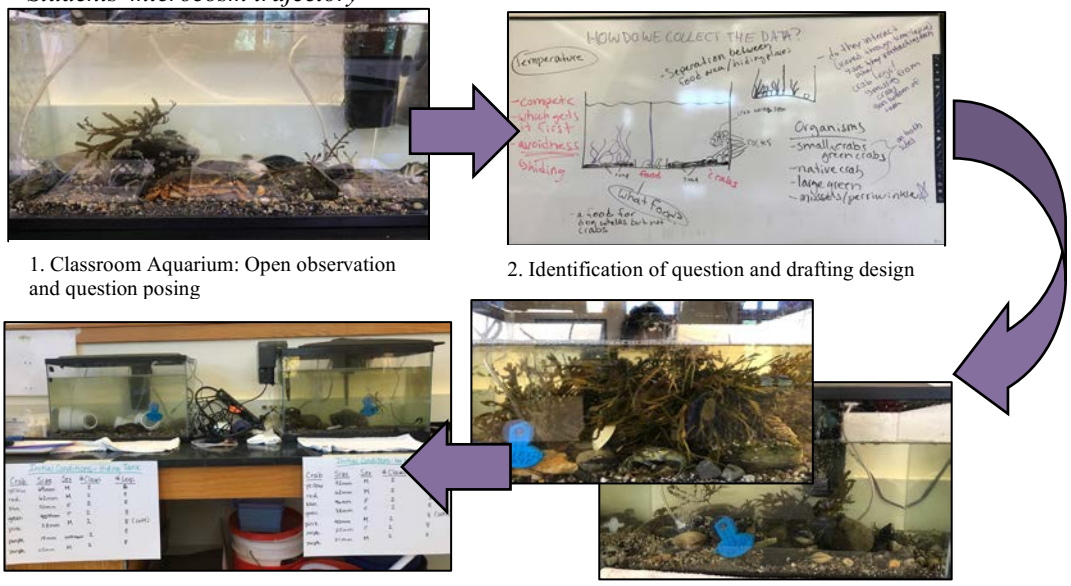
Findings & Implications

Although work on the project is still ongoing, consistent with previous work (e.g., Lehrer et al., 2000) we have found that although students initial microcosm designs privileged overt resemblance with the system, over time those commitments to resemblance created a material impasse which forced students to reconsider the purpose of the microcosm and its relation to the intertidal. Moving forward, they prioritized microcosm arrangements that facilitated observations of processes of interest—such as animals' refuge seeking—and that supported the collection of measures (Figure 1). After a period of open observation where students cultivated close looking, considered the purpose of microcosms in science, and posed questions, students completed two rearrangements of conditions to answer the question: *Do the amount of hiding spaces impact green crabs' behavior?* Students investigated this question by designing microcosms with two different hiding conditions: hiding and no-hiding.

 © ISLS

After a lively debate on whether the animals in the tank should be fed (one contingent of students insisted not feeding the animals would ensure "natural" behavior while another argued the environment was already artificial and therefore required providing food), the students settled on providing food in a central location ("hunger games style") to instigate foraging behavior and promote interactions between organisms. During this round of investigation students noted that their reliance on natural materials to create shelter for the animals prevented their own observations of behavior in the "hiding" tank. A second rearrangement of the microcosms using artificial materials was then undertaken to support seeing more of the processes and behaviors the students were interested in (e.g., "Maybe we should change it so that we can see them better."). With inquiry now stabilized, microcosms were now sites of study for processes, such as foraging and refuge-seeking strategies, that could be inferred but rarely directly observed in the field.

Figure 1:
Students' microcosm trajectory



1. Classroom Aquarium: Open observation and question posing

2. Identification of question and drafting design

3. First rearrangement: Hiding (top) and No-Hiding (bottom) Conditions using natural materials

4. Second rearrangement: Hiding (left) and No-Hiding (right) Conditions using artificial materials

Computational Thinking into K-12 Classrooms: Experiences and Challenges from Professional Learning Experiences

Zhichun Liu, Zarina Gearty, Eleanor Richard,
Chandra Orrill, Shakhnoza Kayumova, Ramprasad Balasubramanian
zliu11@umassd.edu, zmadan@umassd.edu, erichard1@umassd.edu, chandra.orrill@umassd.edu,
skayumova@umassd.edu, r.bala@umassd.edu
Kaput Center for Research and Innovation in STEM Education, University of Massachusetts Dartmouth

Abstract: Teachers often find it challenging to learn computational thinking (CT) and integrate it with classroom learning. In this systematic review, we focus on how professional learning experiences have supported K-12 teachers to integrate CT into their classrooms. The findings suggest some effective strategies for building professional learning experiences but highlight the need for more agreement about the nature of CT.

Introduction

Computational thinking (CT), defined as problem solving processes, skills, and dispositions needed to develop software (e.g., ISTE & CSTA, 2011), has garnered national attention as important skills and processes required for all students. While CT is tied to CS, it can be developed as a problem-solving approach. Despite the importance of CT for 21st-century education, opportunities to engage in CT are often present only in informal learning settings such as after-school clubs and limited to coding skills (Sengupta et al., 2018). Teachers often find it challenging to learn about CT and integrate it with classroom learning (Ketelhut et al., 2020). To this end, we sought to understand what kinds of learning experiences teachers had related to CT. To this end, we conducted a systematic review of the literature synthesizing research on how CT-focused PLEs have supported K-12 teachers to integrate CT into their classrooms. Specifically, we pursued two research questions:

- What are the learning goals and conceptualizations of the existing CT PLEs?
- How did prior studies support teachers to integrate CT into classrooms?

Method

We conducted a systematic literature review based on PRISMA protocol of recent research on CT PLEs across four bibliographic databases: ERIC, Web of Science, IEEE Xplore, and ACM digital library. The search terms combined CT + professional-development-related terms or CT + outcome-related terms. In total, we screened 1,792 articles with pre-established eligibility criteria. After reviewing all articles at the title and abstract level, 179 were determined to have met our initial criteria. Three reviewers examined those articles at the full-text level. Full-text screening resulted in 50 articles that reported CT-related PLEs with K-12 teachers and 27 of which reported PLEs with component(s) on CT integration (see Figure 1 for the literature review process).

For each of the 50 articles, we recorded basic study and participant information. Then, we coded the details of the PLE and the outcomes. All the articles were discussed and coded collaboratively by three reviewers. The consensus was established through iterative discussion, and discrepancies were resolved at group meetings.

The PRISMA Flowchart

 © ISLS

RQ1: Goals and conceptualizations

Overall, the goals of the PLEs focused on teachers' understanding of CT-related concepts, tools, and pedagogies. The goals included advancement of knowledge, change of perception or awareness, and improvement of skills. We saw a wide range of conceptualizations of CT and CT integration. The most prevalent goals included CT principles (c.f., ISTE & CSTA, 2011), which were viewed as problem-solving processes involving skills such as pattern recognition, problem decomposition, algorithmic thinking, abstraction, etc. Other goals focused on specific knowledge and skills in Computer Science (n = 5), computing concepts or practices (n = 4), and robotics (n = 2). The wide spectrum of foci reflects CT education in the K-12 world. On the one hand, CT can be viewed as a development of higher-order thinking skills that support problem solving (e.g., ISTE & CSTA, 2011). On the other hand, CT can be operationalized as specific content knowledge associated with different computing tools.

RQ2: Supporting CT integration

We identified two themes in terms of supporting teachers to integrate CT into teaching practices. First, certain supports were reported to be effective. Studies that involve prolonged engagement with teachers often report positive reactions and substantial change at a behavioral level (e.g., Hestness et al., 2018; Ketelhut et al., 2020). Additionally, personalized mentoring has been reported to support teachers' professional growth. Such support can take various forms (e.g., coach in Hamner et al., 2016). Aside from the technical supports, teachers also need pedagogical supports to actively integrate CT into their classrooms (Dong et al., 2019). CT integration has often resulted from supports from a community of practice (e.g., Hestness et al., 2018). Second, we identified the specific experiences, provided through the supports, that are beneficial to teachers. For example, many studies addressed the role of feedback and reflection in PLE in supporting teachers' CT integration (e.g., Ouyang et al., 2018). Teachers need to develop conceptual understanding and have opportunities for practice to support CT integration. Thus, teachers need to actively plan and teach in CT-integrated classes.

Discussion and Conclusion

Overall, CT integration can be challenging because supporting teachers in changing their attitude, knowledge, beliefs, and practices take time (Ketelhut et al., 2020). Although CT is closely related to coding, we need to incorporate broader theoretical perspectives. Further, more research is needed on computational literacy in K-12 contexts (Kafai & Proctor, 2021). While the field is beginning to understand how to create PLEs that support teachers in teaching certain aspects of CT, more work is needed to understand what should be taught in K-12 CT and how best to support teachers in that endeavor.

Rotating Bodies Bulge Outward: A Novel Intuitive Resource for Rotational Motion

Jared Arnell, Utah State University, jared.arnell@usu.edu
Hillary Swanson, Utah State University, hillary.swanson@usu.edu
Boyd Edwards, Utah State University, boyd.edwards@usu.edu

Abstract: Physics students routinely struggle to understand the Coriolis force and the centrifugal force. While investigating students' prior knowledge resources in these domains, we observed the use of an intuitive element regarding the "bulging" demonstrated by rotating bodies. This element exhibits similar characteristics to a previously described class of intuitive knowledge resources for making sense of physics phenomena: phenomenological primitives (p-prims). We document the attributes of the "bulging" resource and compare them to the expected traits of p-prims.

Introduction

Inertial forces, such as the Coriolis force and the centrifugal force, are notoriously difficult to teach. Numerous errors about both can be found in the thinking of physicists and lay people alike (Grof et al., 2020). Our team has been working on a novel conceptual approach to teaching the Coriolis force which utilizes the wealth of knowledge that students have amassed about the physical world prior to their formal education (Minstrell, 1992). While cataloging the knowledge resources shared by our participants, we observed a pattern of responses which shared attributes with a previously documented class of intuitive knowledge elements. Here, we describe the observed properties of this potential intuitive resource and make a case for its classification.

Theoretical framework

Knowledge in Pieces (KiP) is a constructivist theory of knowledge and learning. It views knowledge as a network of individual elements, which are connected and activated through recognition. Naïve learners acquire elements to describe natural phenomena through their interactions with the physical world. These foundational resources are called phenomenological primitives, or "p-prims" (diSessa, 1993). P-prims provide "common sense" explanations for the causal mechanisms in the natural world. They are activated when relevant features of a problem-solving context are recognized by the learner, or when a closely related neighbor element is activated. At times, learners may unwittingly create erroneous connections by missing relevant information or over-applying concepts. These faults can be the root of difficult-to-dispel "misconceptions" and can interfere with the learner's construction of new understanding (Smith et al., 1993). As they advance from novice to expert, learners reorganize existing connections to better align with physics precepts and construct higher-order knowledge structures to create interdisciplinary cohesion (diSessa, 1993; Minstrell, 1992). This refinement repurposes p-prims into a supportive role for the larger knowledge structures. By understanding the productive and counterproductive connections in their students' knowledge, educators can improve their strategies to better address the incongruities and support the development of robust, reliable knowledge structures (Brown & Clement, 1992).

Methodology

Eleven undergraduate physics students at a large university in the Intermountain West participated in 1-on-1 Zoom interviews, during which they thought out loud about phenomena influenced by the Coriolis force. Five students had not yet taken the upper-division course in which the Coriolis force is formally taught, while six students had completed this upper-division course. The participants were asked background questions before being guided through a set of thought experiments which visualized the earth as rotating and non-rotating, spherical and oblate, and from inertial and rotating reference frames. The students made predictions about the motion of an object moving across the surface of the earth in each scenario. The audio recording of the interviews was transcribed and student responses were analyzed to uncover the knowledge elements underlying their reasoning.

Results

One element of knowledge, which emerged when the students discussed rotating objects, shared many similarities with p-prims. Nine of the eleven participants were aware that the earth's shape deviated slightly from spherical. Most students explained that this is a consequence of the earth's rotation. Throughout the interviews, the students continuously displayed an intuitive expectation that rotating bodies are "supposed to" be pulled outward,

 © ISLS

regardless of the context. The ubiquity of this assertion prompted closer inspection. We named this element "*bulging*" and compared it to the expected attributes and identifying principles of p-prims (diSessa, 1993).

There was a noticeable difference in the way the two groups of students spoke when explaining the phenomenon. The students who had only taken Introductory Physics tended to offer rotation as a de facto mechanism that needed no further dissection, which is an example of the "principle of impenetrability," by which p-prims are self-sufficient for naïve explanations. In comparison, the students who had taken the upper-division course used more advanced terminology like "inertia" and "centrifugal force" to describe the mechanism. This shift matches the predictions made by KiP: advanced physics instruction co-opts intuitive knowledge within larger frameworks to act as a supporting tenet to higher-order schema. The advanced students reorganized their thinking and used broader topics to explain *bulging* in a way the more naïve students had not yet discovered.

The students mentioned *bulging* in multiple contexts which had little in common beyond the topic of rotation, such as pizza dough, pottery wheels, and carnival rides. This shows that the *bulging* primitive was not associated with any particular object or material property, but rather with the rotation itself. This method of connection via an easy-to-observe abstraction demonstrates the "principle of ready availability." It also supports the "principle of functionality," as having an intuitive explanation for *bulging* would be useful to naïve learners. Students also utilized *bulging* to describe the common experience of feeling pushed to the outside edge of a turn while driving in a vehicle. This exemplifies the "principle of body," which predicts that p-prims will likely have strong roots in physiological experience and will be described by novices using their bodily sensations, as well as the "principle of obviousness," which expects p-prims to form around familiar or universal experiences.

Finally, when asked to predict what would happen if the earth were to rotate faster than it currently does, all eleven students (including those who were previously unaware of the oblate shape of the earth or had not understood its connection to the earth's rotation) instantly predicted that it would increase the size of the bulge. This was a consistent, reliable activation of *Ohm's p-prim*, in which a larger input predicts a larger result. This could be evidence that the *bulging* primitive forms a strong syllogism with another well-established knowledge element. Additionally, students sometimes describe orbiting bodies as being trapped in place by the opposing gravitational and centrifugal forces. This explanation could be recontextualized as an interaction between *bulging* and the *supporting* or *clamping* p-prims. These interpretations showcase the "principle of diversity" and the subtlety that exists between primitive knowledge element activations.

Discussion

Overall, it appears that *bulging* is a good candidate for a phenomenological primitive as it displays many of the key characteristics of p-prims and agrees with a wide range of identifying principles. Ultimately, it will require more targeted scrutiny than this study was able to provide to make a definitive conclusion. Future explorations of *bulging* could endeavor to determine the origins of *bulging*, expand the list of contexts in which *bulging* is activated, clarify the interactions between *bulging* and other p-prims, and assess the role that *bulging* could play in physics instruction. Investigating *bulging* could shed light on the difficulties that many educators have experienced when teaching about the centrifugal force and rotational motion. Instead of fighting against this primitive by labeling inertial forces as "imaginary" or "illusory" (which implies that the students are incorrect in their own perception and memory), educators could acknowledge and reinforce the bodily experience of students to situate the *bulging* primitive within a broader context. With careful refinement, the *bulging* primitive could come to serve a unique and powerful role in the knowledge structures of intermediate physics learners.

University of California, Davis and Stanford University

Abstract: We examine how a researcher-practitioner research group collaborated to adapt noticing practices in the face of disruptions brought on by the COVID-19 pandemic. We used a progress monitoring tool and cognitive field notes to support teacher partners' systematic reflection and to gauge teacher learning. Initial findings suggest these tools helped identify tensions around implementing online class discussions. We highlight the process the teacher partners engaged in as they re-conceptualized engagement, participation, and interaction.

Introduction and Theoretical Approach

The COVID-19 pandemic and the move to online teaching and learning disrupted established teaching practices. We analyze how a group of in-service English Language Arts (ELA) teachers who were committed to dialogic teaching (Mercer, 2008) collaboratively adapted their pedagogy in response to two pandemic-related challenges: (1) students' reluctance to offer spoken responses during synchronous online classes, and (2) identifying students' needs without access to typical feedback sources that teachers have during co-present teaching.

We conceptualize teacher learning as an active process (Bakkenes et al., 2010), and we ask: How did a group of ELA teachers collaboratively adapt their noticing practices in the face of disruptions brought on by the COVID-19 pandemic? We define *teacher noticing* as a teacher's capacity to attend to, analyze, and respond to student thinking (Barnhart & van Es, 2015; Hand, 2012). Such noticing is intentional and guided by experiences, pedagogical commitments, and other factors (Patterson et al., 2020). Here, we examine teachers' adaptations in noticing in their remote teaching, as they facilitated through a series of collaborative workshops.

Data Collection and Analysis

In Fall 2020, we conducted seven workshops to support teachers' noticing in this new context, centered on digital tools: a "progress monitoring tool" (PMT) where teachers recorded student behaviors (e.g., unmuted to speak, turned camera on) over time, and a "cognitive field notes" (CFN) tool (Gutierrez & Vossoughi, 2010), where teachers engaged in guided reflective writing on their noticing practices. Each teacher implemented the PMT and/or CFN in their class and reported back to the group. During workshops, teachers discussed teaching challenges, uses of the tools in their classrooms, and data they collected. Additionally, they critically renegotiated meanings of key terms such as engagement, participation, and interaction prompted by our team's focus on classroom discussion. Study data include written teacher reflections, notes on development and implementation of noticing tools, teacher-provided transcripts of classroom discussions, and meeting notes, recordings, and transcripts. Analysis examined how teachers adapted their practice in the digital space. Inductive coding of reflections, notes, and transcripts resulted in identification of several key themes, outlined below.

Findings

Analyses revealed that teacher partners adapted their teaching practices and their conceptualization of what it means for students to engage, participate, and interact in discussions in the digital space. Teachers' interactions with the tools surfaced tensions around what they could observe in a new teaching context. In particular, noticings aligned with teachers' shifting definitions of key constructs: engagement, participation, and interaction. These definitions were sometimes inherited from teachers' in-person interactions with students, and teacher partners worked collectively to make sense of these terms to help them adapt their noticing practices to remote settings. The teacher partners used phrases like, "I'm currently struggling with the right questions to ask," and "what would be best to record/observe" in their CFN reflections.

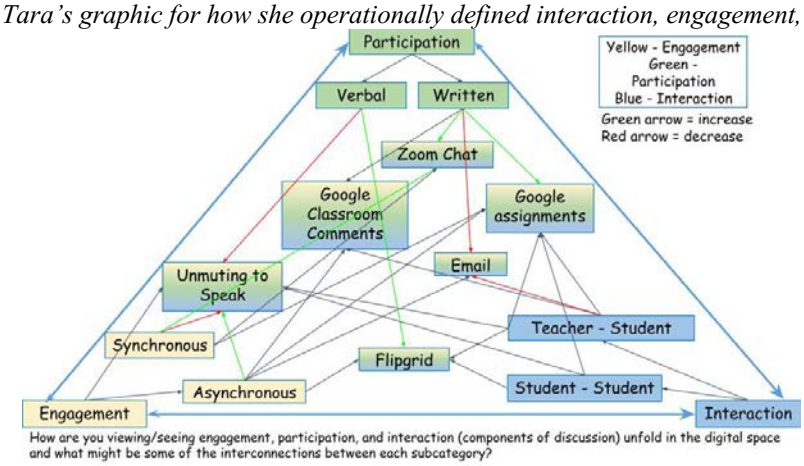
Collaboratively, the teacher partners worked through these disruptions by co-constructing a collective learning space that supported reevaluation of what it means to participate and engage in classroom learning when going dialogic in the digital space. One salient workshop activity (late 2020), involved (1) defining engagement,

 © ISLS

participation, and interaction in writing as well as graphic form; (2) discussing the choices that teachers made in their definitions; and (3) revisiting the definitions at the conclusion of the workshop. Figure 1 (below) is Tara's graphic from this activity, and shows that Tara had begun to complexify her conceptualization of engagement, participation, and interaction, including features from the digital teaching space, after a few months of participating in teacher partner and research team discussions and working with the PMT.

Figure 1

Tara's graphic for how she operationally defined interaction, engagement, and participation.



Tara's view of participation, engagement and interaction broadened over time. Her assessment of student engagement expanded to include asynchronous and synchronous participation, allowed for student-student interactions, and a focus on modes of engagement after participating in collaborative, facilitated efforts to build adaptive expertise in applying the principles of dialogic instruction to online instruction. In a reflection, Tara shared, "It was cool to see discussions unfold that took place half out loud through the speaker and half in the chat … Now that was something I never would have expected" .

Discussion & Next Steps

Our data speak to how teachers adapt their teaching practice by learning to see anew in changed circumstances. These teachers were working within a broad and multifaceted crisis – the COVID-19 pandemic – which disrupted many of their teaching practices. Introduction of new noticing tools (the PMT and CFN) highlighted a particular disruption in their ability to notice student engagement, participation, and interaction, which prompted a collaborative and cascading set of reconsiderations of the definition of engagement and its various instantiations within an online classroom, all facilitated through a variety of reflective activities. Our initial findings point to the power of collaborative sensemaking, particularly around noticing student thinking, facilitated through the introduction of explicit noticing tools and reflective activities.

Examining Learning Opportunities for Integrating AI Education in English Language Art Classrooms

Cansu Tatar, North Carolina State University, ctatar@ncsu.edu
Shiyan Jiang, North Carolina State University, sjiang24@ncsu.edu
Jie Chao, Concord Consortium, jchao@concord.org

Abstract: We conducted a co-design study with high school ELA teachers to investigate their perspectives in the integration of a technology-enhanced AI curriculum. The teachers explored the AI and text mining activities and reflected on them from teaching and learning perspectives. The findings of this study suggest that building models with texts positioned ELA teachers as experts in AI teaching and they were empowered to identify existing learning resources and opportunities in ELA classrooms that could be leveraged in integrating AI learning in their classrooms.

Introduction

Understanding of AI concepts, the ability to use AI knowledge in real-world settings, and analyzing the potential long-term benefits of AI are turning into essential 21st-century skills (Steinbauer et al., 2021). These skills are the basis of future career opportunities. Therefore, providing high-quality AI training to our young generation, especially underrepresented K-12 students, is a critical way to provide equal learning opportunities for these essential skills they need in an AI-empowered society. Following this trend, scholarly attention has turned to examining how to support K-12 AI education with resources, tools, and projects. Many attempts have been made to motivate K-12 students in understanding AI through developing machine learning (ML) models (Yoder et al., 2020). Yet, the field calls for more empirical studies investigating how to support students to learn modeling data in k-12 classrooms (Steinbauer et al.,2021). On the other side, to integrate these technologies into the K-12 curriculum, teachers' perspectives play a critical role in successful implementations (Lindner et al., 2019). Thus, we developed the AI curriculum activities and the StoryQ application, a web-based text-mining and narrative modeling platform, to bring AI education to high school non-computing classes, in this study, ELA classes. This study addresses the following research question: *What are the ELA teachers' perspectives to integrate AI education in their classrooms as they reflected on their interaction with the AI and text mining activities?*

Methods

Two ELA teachers from two public high schools, Martin and Emma (pseudonyms), participated in co-design workshops on the AI unit and technology. Martin has 20 years of teaching experience in ELA while Emma has 10 years of ELA teaching. We focused on ELA teachers in this study as our prior co-design experiences with ELA, mathematics, and computer science teachers indicated a critical need to learn more about the learning opportunities in the ELA classrooms (Tatar, 2021).

Martin attended approximately 10 hours of co-design sessions to test the initial designs of the curriculum from 2020 to 2021. Emma attended the 2021 February workshop for three hours with her colleagues to learn the basics of AI and test the curriculum. After the February workshop, we invited Martin and Emma to attend the 2021 August workshop to test the new design of the curriculum. The August workshop was held on Zoom for two days (seven hours per day). In the workshop, Martin and Emma were guided to complete five lessons related to extracting features from texts, building models, and classifying texts. We collected 27-hour video recordings, including the teachers' interactions in the StoryQ while completing the activities, their responses to the learning tasks, and their discussions. This study draws on the case study approach (Crowe, 2011) regarding thematic analysis methods (Clark et al., 2015). We analyzed the transcript of the recordings using the thematic analysis method. We first closely examined the data to investigate the teachers' experiences, expectancies, and their understandings of how AI works. Then we discussed and finalized the themes and categories in weekly meetings.

Findings and Conclusion

We found that after the teachers analyzed features and built AI models, they started to foresee the opportunities to integrate these lessons into their classrooms. The teachers identified these opportunities as enriching their

students' ELA understanding and raising awareness of the impacts of AI on their future careers. In the workshop, Martin and Emma worked collaboratively to complete the learning tasks. They developed models and then created a confusion matrix (i.e., a visual representation to make comparisons) to investigate where the model made mistakes. With the help of the confusion matrix, they identified specific sentences which the model mislabeled. While reviewing these reviews, they discussed how people use first-person pronouns when they complain about something. Also, they realized that people tend to use third-person pronouns when they like something. Based on their experience with the model, Martin mentioned that "…we tell students to speak from their own experience, speak in the first person, we set these goals and we never explained why". He believed that this activity could be a part of their "norms of communication" unit and illustrate how different statements are used in different contexts. Emma also agreed with him and saw the value of showing different examples to reinforce students' ELA understandings.

Another opportunity that the teachers pointed out was to show students how language arts play out to express feelings. As a part of the learning activity, Emma and Martin trained the model by using the word "love" as a feature. After training the model, they created a visual representation to investigate in which reviews this feature was used and how. They then examined different instances to understand how the selected feature was placed in both positive and negative labels. During this activity, Martin discussed how people expressed their feelings while complaining. Based on the instances, he claimed that when people complain about a restaurant, they use "certain language that's more general appraisals that decrease the weight of the praise". After that, Emma joined the discussion and brought another perspective by thinking of the classroom implementation. She believed that discussing the form and content of the words could help students in the language analysis like "they're trying to access someone's trying to express either a favorable opinion or an unfavorable opinion". Moreover, she further explained that this lesson can be used in the poetry class to analyze emotions. She stated that "…I feel like this lesson would just be set up perfectly for poetry...that's valuable in and of itself, we see words of positive connotations, positive tone…". From these examples, we can clearly see that while engaging with the activities, the teachers developed a basic understanding of how AI models work through exploring features in the text data and examining the visual representations to compare human and AI-predicted labels. After they developed an understanding, they discussed the connections between ELA classrooms and the curriculum lessons. They considered the learning opportunities to enhance their students' ELA understandings by integrating the AI lessons into their classes.

This study contributes to the K-12 AI education on integrating an accessible text mining learning environment into ELA classrooms to engage high school students in developing an understanding of machine learning concepts through building AI models regarding to ELA teachers' perspectives. Taking an ELA perspective to design AI learning activities could potentially broaden access to AI through leveraging students' insights of texts, drawing from their own cultural backgrounds. Future studies could examine different culturally relevant pedagogical strategies to provide widely inclusive AI experiences to engage high school students from underrepresented, diverse backgrounds. In conclusion,

Do Current Visions of Engineering Literacy Capture Family Engineering Practices? A Microgenetic Analysis of Engineering Learning in a Museum Makerspace

Megan Goeke, Tayler Loiselle
goeke018@umn.edu, loise011@umn.edu
University of Minnesota, Twin Cities

Abstract: The recent Engineering Learning framework (ASEE, 2020) calls for research on how students can be supported to reach full engineering literacy in PreK-12 education. The current study analyzes a microgenetic engineering moment with a child, parent, and staff member in a museum makerspace. We found evidence of the Engineering Learning framework, but instances where the framework did not fully represent some nuances during making.

Although many states have adopted the Next Generation Science Standards (NGSS Lead States, 2013), which integrate engineering and science practices, engineering education has overwhelming adopted a single vision of engineering, the Engineering Design Process (Carr, Bennett, & Strobel, 2012; Arik & Topçu, 2020). Recently, a new three-dimension framework, called the Engineering Learning framework, has been proposed for formal PreK-12 curriculum that includes Engineering Habits of Mind (EHM), Engineering Practices (EP) including the Engineering Design Process, and Engineering Knowledge (EK). The ASEE (American Society for Engineering Education, 2020) report calls for research to apply the Engineering Learning framework in order to understand how engineering learning is progressing to reach the "end goal" of full engineering literacy for all students. However, the current framework is unclear on how the vision of full engineering literacy is achieved or even visible when still in development. We take up the call to use the Engineering Literacy framework with a preliminary exploration focused on applying the framework to the documentation of microgenetic engineering learning.

Data and Analysis

As a preliminary exploration on the potential of Engineering Learning (ASEE, 2020) as an analytical framework, we utilized data collected as part of a larger project developing a cardboard-focused makerspace at a large Midwestern science museum. Data was collected from May-June 2021 during museum-hosted private events with community partner groups who invited families that are historically and currently underserved by museums to experience and critique the makerspace. Based on a data review with engineering practitioner partners, we selected a single video clip that was consistently identified as an example of engineering. The Engineering Learning framework (ASEE, 2020, p. 25-26) proposes three primary components to engineering education that should be woven throughout curriculum; for the purposes of this analysis, we used the definitions of these components as supplied in the ASEE report as our coding framework. The authors thematically coded (Braun & Clarke, 2006) the transcript based on each of these three components for each major sub-clip of the video clip.

Results and Discussion

Table 1 presents a step-by-step narrative and analysis of the one selected clip where the youth (9 years old) discusses with their parent and a museum educator how to construct a ladder. The clip starts with the child in front of a table that has various materials scattered on it, including scissors, tape, popsicle sticks, string, etc. There was a previously constructed box by the child on the table. A staff member is standing on the opposite side of the table, and the parent comes in the clip later.

Table 1.
Narrative description of segments of one minute and eight second clip with Engineering Literacy coding, specifically Engineering Habits of Mind (EHM), Engineering Practices (EP), and Engineering Knowledge (EK). One-time codes are highlighted in grey.

Seg.	Narrative	Engineering Literacy		
		EHM	EP	EK

 © ISLS

1	The child picks up the box and is describing their desire to build a ladder using a piece of string that she had already attached to the top of the box, and was hanging down. The child, talking to the staff, describes how in scary movies, everybody has to get out somehow, so she would like to build a ladder for that purpose.	Conscientiousness; Collaboration	Engineering Design – Problem Framing	
2	The staff member asks the child if they still wanted to use the popsicle sticks for the ladder, which the child eventually does pick up one popsicle stick and begins wrapping string around the stick, describing "like you know how wigs- you can hold it and gonna make you stay still."	Collaboration	Material Practices	Other
3	The parent then suggests that the child use two popsicle sticks, to which the child responds "how you do that?" The parent takes the popsicle stick and string out of the child's hand and adds a second popsicle stick, which she places down on the table and adds the string on top.	Collaboration	Material Practices; Engineering Design - Ideation	
4	The child is watching while the staff and parent discuss ways of attaching the string and popsicle sticks together. The parent suggests gluing, to which the child replies that there is no glue, so that is why they were going to keep using tape. The child then grabs tape and brings it near where the parent is working on the ladder now.	Collaboration	Material Practices	
5	The staff member then suggest tying the string instead of tape, but the parent struggles to tie it. The staff member says there is a way to tie it, a certain kind of know, but that "you just have to be a little creative there."	Creativity; Collaboration	Material Practices	

The analysis showed that the video clip involved some components of the Engineering Literacy framework. However, in the one instance where the youth explicitly called on her existing knowledge of how wigs are secured in solving the engineering challenge, the Engineering Literacy framework did not have a category to capture this contribution, perhaps because the existing Engineering Knowledge categories are heavily based in professional domains. Thus, we see promise in using the Engineering Literacy framework to understand microgenetic engineering moving forward, but we caution that the existing categories may over privilege professional engineering knowledge. Future plans are to code the rest of the videos in our data set, as well as using data collected from surveys and interviews to understand families' own perspectives of engineering and how that can inform the Engineering Learning framework.

Fake News Literacy: Intuitive vs. Analytic Processing

Christian Scheibenzuber, Dilara Isik, Nora Krasniqi, Nicolae Nistor
c.scheibenzuber@psy.lmu.de, dilara.isik@campus.lmu.de, nora.krasniqi@campus.lmu.de, nic.nistor@lmu.de

Abstract: Understanding the cognitive processing of fake news is essential when planning to counteract fake news effects, such as through media literacy training. In this study, we aim to provide an insight into how news recipients assess dubious information and how accurate their appraisal of exemplary news is. We conducted interviews with $N = 51$ participants and found evidence for the role of emotions as well as the importance of design and layout when trying to discern true from fake news. Additionally, two particular cases illustrate the different ways of assessing news credibility: through intuition or analytically. In consequence, we suggest a model of online news processing including individual traits such as social influence, attitudes (e.g., political beliefs), and media literacy.

Introduction

Potentially everybody is exposed to huge quantities of information: Fake news, i.e., news content that mimics news articles while neglecting journalistic duties and aiming to mislead recipients (Pennycook & Rand, 2021), play a major role in this regard. Therefore, understanding and fostering fake news literacy has become an important topic of educational research and practice. Developing intentions and forming a cognitive perspective are the results of a decision, for which information needs to be processed (Greifeneder et al., 2021) either intuitively (Schwarz & Jalbert, 2021) or analytically, using methods that discern truth from falsehoods such as fact-checking. However, several factors can bias the processing of information, such as source credibility, social consensus or supporting evidence (Schwarz & Jalbert, 2021). Recent research has further added to the suspicion that failure to identify fake news is often rooted in familiarity and source heuristics (Pennycook & Rand, 2021).

Research Questions

The insight in the cognitive processing of fake news is still insufficiently differentiated. Hence, in this study we aim to explore the cognitive processing routes (mainly intuitive vs. analytic) online news recipients utilize. We examine the following research questions (RQs): *RQ1:* How do online news recipients assess news credibility? *RQ2:* What is the accuracy of their assessment?

Methodology

This exploratory study was built upon a mainly basic, qualitative design with semi-structured interviews for data collection. The interview protocol included 42 questions about demographic data, usage of the internet and online media, specific experiences with dubious news articles, and reactions towards those. In addition, we presented the participants two snippets of news articles, one true and the other fake, and asked them to rate these and describe how they dealt with them. The interviews were conducted in June 2021.The participants were a convenience sample of $N = 51$ German internet users (23 female, 27 male, 1 n/a), from which 40 were 18–30, 4 between 31–49, and 7 between 50–60. The majority of participants (26) were university students, 13 of them had already graduated. When describing their own self-confidence in dealing with online news and its credibility, we found our sample to be very self-confident (43) with only nine accounts of moderate confidence, and one person who described themselves as very insecure on this account. As to whether our participants thought of themselves as intuitive or analytical when dealing with problems, decisions, or information, 25 participants strongly relied on their gut feelings and 27 moderately trusted their intuition. Only 10 participants described themselves as being "head-persons".

For this study we also chose to highlight two special cases. *Participant A* (female, 22 years old) was a communication design student born in Germany and working in an information technology firm. She felt moderately self-confident (4 on a 10-point scale) in handling online news, and reported to seldom question news credibility or check sources. *Participant B* (female, 24) was a media and communication science student, born and grown up in Madrid, and working in Germany. She had already taken part in media literacy training during her studies. She rated herself as highly confident (8 out of 10) when handling online news.

 © ISLS

Findings

RQ1. Many participants (18) explained that they would read an article entirely before passing judgement over its credibility. Some others only read the headline (14) or specific parts of the article (14). However, a deciding factor seemed to be the source of the news content and level of interest in it (32). Throughout the three news examples, the layout and design played the most important role in our participants assessments (11 for participants' own examples, 31 for our real news, 24 for our fake news). In contrast, the source seemed to play a less important role (8, 4, 8). *Participant A* named a majority opinion towards a topic or the comments under the news as the main assessment criterion for news credibility. In absence of such information, she asked other people, friends and family, to share their beliefs and then adopted those of who she thought highly of. *Participant B* mentioned focusing on the content and source of an article when analyzing its credibility, with trusted sources being the established news media formats. She rated our real article as credible because of its content. She rated the fake article as not credible at all, again based on its content.

RQ2. In terms of credibility assessments, we found some disparities between the real and fake news articles. The real article was rated as moderately credible (18), not credible (14), or very credible (12). On the flipside, the fake news article was rated as not credible by a majority (26), moderately credible (14), or very credible (4). Our cases varied substantially in terms of their accurate credibility ratings. *Participant A* gave the real article a 3 out of 10 (not credible). On the other hand, she rated the fake news article as credible (7 out of 10). *Participant B* accurately identified both pieces of news, giving the real article a 10 out of 10 rating, i.e., very credible, and the fake news a 1 out of 10 rating, i.e., not credible at all.

Conclusions

This study was aimed at gaining insight into the cognitive routes utilized by news recipients when dealing with dubious online content. When assessing news credibility, our participants mainly focused on design and visual factors (intuitive route), less on the content itself (analytic route). Furthermore, we found a tendency towards overconfidence in regards to dealing with online news. While the participants in our sample were quite sure of their ability to accurately detect fake news, their results in the two exemplary tasks did not match their self-assessment—this was mainly associated with intuitive online news processing.

The issue of overconfidence when dealing with media effects is not new. It stands to reason that susceptibility to fake news is also rooted in third-person beliefs, i.e., thinking of oneself as not being as vulnerable towards misinformation as the average citizen (Ştefăniţă et al., 2018). Additionally, our two cases can offer some more specific insight into how recipients deal with online news. The great degree of trust *participant A* put into her social circle when assessing truth paints an interesting but worrying picture of recipients who simply do not think for themselves but rely solely on intuitive processing through social cues. Social consensus is a major factor when discerning truth from falsehoods (Schwarz & Jalbert, 2021) and can largely open the door to misinformation. Finally, *participant B* may have shown us the value of prior media literacy education through concise and accurate assessments of our exemplary news articles.

Altogether, this study suggests a classification of online media consumers: critical thinkers, such as *participant B*, with a high degree of media literacy and solid source knowledge who do not bother investigating dubious news but simply ignore them based on their experience, and naïve non-thinkers like *participant A*, who solely follow social cues but not necessarily experts and do not evaluate credibility at all. For future research endeavors, it may be worth investigating the interplay between personal characteristics (e.g., a strong focus on the social environment), prior consolidated attitudes (e.g., political beliefs), and specific media literacy competencies (e.g., high degree of source knowledge) in regards to which factors really help people identify misinformation and how to foster them with targeted educational interventions. These individual traits may be part of a conceptual model of online news processing, which we aim to validate in future research.

Mental Simulations to Advance Adaptive Teaching Expertise in Reflection-based Instructional Coaching

Marguerite E. Walsh, Christian D. Schunn, Lindsay Clare Matsumura, Dena Zook-Howell
m.walsh@pitt.edu, schunn@pitt.edu, lclare@pitt.edu, dkz5@pitt.edu
University of Pittsburgh

Abstract: Reflection on classroom artifacts is a core feature of teacher professional development. Despite its ubiquity, however, reflection as a learning mechanism is often ill-defined and lacking clear connection to a larger theory of teacher learning and change. Here, we present Mental Simulations for Teacher Reflection (MSTR) as one kind of robust teacher learning routine. Our aim is to offer a well-specified routine that embodies core principles for developing adaptive teaching expertise in expert-guided reflection contexts.

Introduction

Education researchers increasingly emphasize adaptive teaching expertise, i.e., the ability to read, interpret, and flexibly respond to students' developing thinking during instruction, as critical for student-centered instruction (van Es & Sherin, 2002). Despite wide consensus that adaptive expertise is an important teacher learning goal, research to understand the nature of its development and cultivating these processes in practice is still relatively thin (Carbonell et al., 2014). Reflection-based instructional coaching is recognized as one promising approach for developing the kind of pedagogical knowledge and skill needed for adaptive teaching expertise. However, significant variation exists in the effectiveness of such programs for transforming teaching practice, both within and across program designs and instantiations. More work is needed to understand what specific mechanisms underlie robust teacher learning in these contexts, and how they can be concretely supported in coaching practices and routines. Here, we present one kind of teacher learning routine—Mental Simulations for Teacher Reflection (MSTR)—that culminated from the work of one interdisciplinary research team focused on this issue. In what follows, we provide a summary of the conceptual backdrop, basic components, and quality dimensions of MSTR, followed by a concept map to illustrate how MSTR connects to larger mechanisms for developing adaptive teaching expertise. We conclude with implications for future work.

Research Background

MSTR primarily draws on adaptive expertise research to define the learning and change processes associated with developing a well-connected base of conceptual and procedural knowledge for student-centered pedagogies. We particularly focus on how to elicit and scaffold teachers' pedagogical reasoning processes in ways that support two key components of adaptive teaching expertise: (1) Recognizing, interpreting, and resolving instructional ambiguities and discrepancies; and (2) Iterative linking between teaching specifics (e.g., teacher moves, lesson contexts) to more generalized representations (e.g., larger pedagogical dilemmas, goals, and principles) to support knowledge building and conceptual change (Walsh, 2021; Kavanagh et al., 2020; Bransford et al., 2005).

Mental simulations for teacher reflection

Mental simulations, as a process for systematically engaging 'what-if' reasoning processes to generate causal inferences in ambiguous and uncertain situations (Markman & Dyczewski, 2013) provides an empirical framework for a coaching routine aligned with these theoretical perspectives. Adapting mental simulations to a teacher learning context, MSTR includes three basic components: (1) **Establishing Ambiguities**: coach and teacher iteratively discuss and refine shared understanding of the problem space, situating the context for the simulation; (2) **Proposing Alternatives**: coach and teacher iteratively propose alternative teaching moves for addressing instructional ambiguities; (3) **Weighing Alternatives**: coach and teacher iteratively hypothesize and weigh the potential of selected alternatives for advancing pedagogical goals and principles.

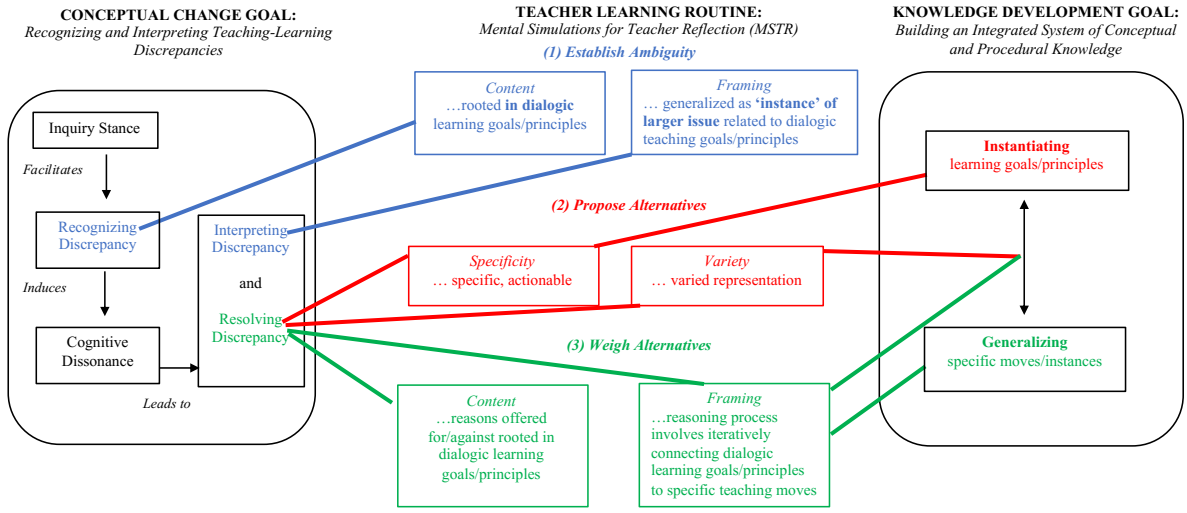
Table 1 (below) presents the quality dimensions of the interactions within each MSTR component that link to goals for adaptive teaching expertise. Lastly, Figure 1 captures the rationale for MSTR as a robust teacher learning routine. Specifically, it (1) describes the quality dimensions associated with each component of MSTR, and (2) illustrates the links between MSTR components, quality dimensions, and processes involved in knowledge development and conceptual change (i.e., provides an explanatory model).

 © ISLS

Table 1. *Quality Dimensions and Examples for each MSTR component*

MSTR Component	Quality Dimensions	Example
Establish Ambiguity	**Content**: Ambiguity 'topic' rooted in dialogic goals/principles **Framing**: Specific moment in a lesson or lesson plan is generalized to a pedagogical issue relevant across contexts	Student misconceptions problematized in terms of holding students accountable to rigorous thinking
Propose Alternatives	**Specificity***:* Alternatives are articulated in specific and actionable terms **Varied representation:** Multiple alternatives (2–3) are presented or an alternative is articulated in varied terms	Multiple specific talk moves or phrasings are proposed to address misconception (e.g., "where's your evidence for that claim?" or "what makes you think that?")
Weigh Alternatives	**Content:** Reasons offered for or against different alternatives are rooted in dialogic goals/principles **Framing:** Process of reasoning through alternatives includes both *instantiating* (connecting dialogic goal/principle to a specific move) and *generalizing* (connecting a specific move to dialogic goal/principle)	Relative merits of proposed alternatives are iteratively discussed relative to conceptual learning goals (e.g., students draw sound conclusions about text meanings) and dialogic principles (e.g., supporting students to assume responsibility for their learning)

Figure 1. *MSTR Components and Quality Dimensions to Facilitate Conceptual Knowledge Building and Change*



Discussion and implications

MSTR represents one artifact that emerged from our ongoing efforts to advance more robust, theory-based empirical frameworks for studying teacher learning mechanisms. By explicitly describing the components and quality dimensions within a coaching routine, MSTR can be leveraged to inform more effective coach training and serve as a foundation for future hypothesis testing.

Coalescing Knowledge Within Networks of Research Practice Partnerships: The Case of a School-Based Citizen Science Network

Keren Aridor, University of Haifa, keren.aridor@edtech.haifa.ac.il

Abstract: Synthesizing valuable insights developed within diverse partnerships that are part of a network is challenging. This study explores implementation stories of school participation in Citizen Science and insights shared by participants as part of two workshops, intended to increase cross-fertilization among participants. Six new abstract design principles were identified as corresponding with learning through Citizen Science. This study illustrates how these principles' identification can support cross-fertilization between partnerships and amalgamation of the dispersed knowledge.

Introduction and theoretical background

The Taking Citizen Science to School (TCSS) center is a network of Design-Centric Research-Practice Partnerships (DC-RPPs, Kali, et al., 2018), that includes members from different organizational, scientific, theoretical, and practical backgrounds. Each partnership within the network, implements a different Citizen Science (CS) project offered by the center in one or more schools, and co-designs or adapts curriculum materials to local contexts. This requires members to cross cultural boundaries of the various expertise. In doing so, members collaboratively advance educational practice, educational-research and the CS-related scientific research. As a result, unique knowledge and insights develop within each partnership, which have the potential to be valuable to other members in the TCSS network (Sagy, et al., 2019). The challenge of TCSS is to amalgamate this dispersed knowledge and make it accessible to all members of the network. This goal is in-line with the educational research challenge to increase and scale the educational innovations' applicability (Law, et al., 2021). The approach we chose is based on identification and abstraction of design principles (DPs, Linn, et al., 2006), within implementation stories of school participation in CS, which were perceived as effective for this challenge (e.g., Kidron & Kali, 2015). DPs connect theories of learning and instruction (know-why) with features of implementation (know-how, portrayed here by the stories) and provide a way to encompass, synthesize and present the knowledge gained in the diverse DC-RPPs, communicating the conceptual design ideas behind the implementations. Members of RPPs can then further adapt these emerging DPs to their RPPs' needs (Kali, et al., 2018). This poster describes how this approach was examined in two workshops, as a first step towards synthesizing the insights developed within the various DC-RPPs.

Method

To provide opportunities to identify, share and discuss cross-project DPs while enriching existing design knowledge and amalgamating the TCSS network's dispersed knowledge, we designed two workshops. In each workshop, participants (N=38, 30) worked in groups (five in the first and four in the second) where they: a) shared implementation stories of CS activities within their schools; b) identified or formulated DPs for school-based CS that may be integrated in these implementations; and c) shared and discussed those DPs in a plenary session. A description of 25 DPs for implementing CS in schools, which stemmed from the Design Principles Database (Kali, 2006) for science education was used as a resource. By integrating practical (know-how) and theoretical (know-why) knowledge, participants developed what Bereiter (2014) calls principled practical knowledge, intended for further use by the TCSS network. Data from both workshops was recorded, transcribed and analyzed deductively and inductively with the aim of identifying references to DPs as well as overarching insights beyond existing principles. The process of developing new DPs based on these insights was validated by the six authors of this research and triangulated with current learning science and educational research literature.

Initial findings

Altogether, 128 statements that related to DPs were identified. These statements were chosen as they included insights that made an abstraction of the practice. 23 of the 25 DPs were referenced in one way or another. Three DPs were not referred to at all (e.g., "Cultivate productive discourse norms"). Overarching insights provided bases

for six DPs that were later on validated and articulated, capitalizing on learning sciences and educational research literature: "Encourage active citizenship", "Freedom of choice", "Multidisciplinary and interdisciplinary learning", "Flexibility and adaptability", "Promote educational leadership" (e.g., Ballard et al., 2017, Iyengar & Lepper 1999, Kidron & Kali, 2015, Bransford et al., 2000, Ado, 2016 and Bandura, 1997, respectively).

To illustrate the process that enabled the articulation of new DPs we focus on the emergent "Encouraging active citizenship" DD. Twelve statements (of 128, three in the first workshop and nine in the second) mentioned the idea of active citizenship, by six groups. One group, for instance, found that what connected between their implementation stories was that CS partnerships can foster empowerment of students, caring, and agency to contribute to their local environment. To add this emergent DP to the pool of DPs available to the network, we used language participants brought to the table and integrated it with learning theory. Within the description of each DP, we included also practical examples and citations of workshop participants, acknowledging their contribution as part of the DP's authorship. For example, the 'Encourage active citizenship' DP's description resulting from this process, which became a resource for use and refinement to networks' members follows:

> Participation in CS involves students in active citizenship and provides them with opportunities to contribute to their communities and wider society. Importantly, encouraging active citizenship tends to provide students with meaning to their activities outside the school's boundaries, connecting them with current issues such as climate change and biodiversity, while fostering students' sense of agency and self-perception as contributing citizens.

Discussion

The initial findings portray the potential of sharing implementation stories and relating them to DPs as a mechanism to support amalgamating of the dispersed DC-RPPs' knowledge. The workshops led to refinements of existing DPs and articulation of six new DPs. It also informed the design of a pilot version of a Web-based platform for supporting networks of DC-RPPs in coalescing principled-practical knowledge.

"It's so frustrating!" Understanding Design Dilemmas in Co-Design through Curricular Values

Katarzyna Pomian Bogdanov, Northwestern University, kpomian@u.northwestern.edu

Abstract: Co-design is an increasingly common process for curriculum development in science education, where teachers and researchers work together to create curricula, drawing on mutual knowledge and expertise. In efforts to understand this process, I looked at design dilemmas that occurred during design meetings and categorized the ideas that emerged in terms of underlying curricular values. I characterize these emerging curricular values and identify ways in which participants work to achieve and balance them.

Introduction

In the last decade, there has been a strong movement to transform science teaching and learning in the United States to be more student-centered, equitable, and meaningful (NRC, 2012). Curricular materials are an important step in achieving these goals—both to provide tools for teachers to use that reflect these reforms, and to help them develop the practices needed to use these tools (NRC, 2015). Curricula developed through cooperative design by teachers and researchers are an important strategy that brings together different kinds of expertise needed to achieve curricula that reflect target reforms and are tailored to the realities of classrooms (Penuel et al., 2022; Reiser et al., 2000). A co-design approach can also provide opportunities for teacher professional development of pedagogical and subject matter knowledge (e.g., Peel et al., 2020), and support teachers' agency (e.g., Severance et al., 2016).

Yet, developing designs for classroom learning involves balancing different priorities that need to be addressed (Penuel et al., 2022). Furthermore, tensions can arise between teachers and researchers working together due to their differing agendas (Couso, 2016). I aim to understand how these design intricacies unfold by examining (a) the curricular values that emerged regularly throughout the design process in one curricular co-design context and (b) how they were balanced in conversation during team meetings.

Project overview and methods

I take an in-depth look at the work of one design team of 3 teachers, 3 researchers, and a district science curriculum specialist who developed a Next Generation Science Standards (NGSS)-designed pilot high school physics wave unit during 25 90-minute weekly Zoom meetings across 7 months. The development work was part of the OpenSciEd project, a collaboration between inquiry Hub at University of Colorado Boulder, Biological Sciences Curriculum Study, Denver Public Schools, and Northwestern University. OpenSciEd is an ongoing partnership which strives in part to lead the development of research-based NGSS-designed classroom materials made available to the public.

All meetings throughout the creation of the unit were recorded and transcribed. I fulfilled the role of a participant-observer in the setting, diving more intimately into the design work to be better familiarized with it. I watched the recordings of meetings and identified *design dilemmas*—times when team members were at a crossroads in the curriculum or were faced with problems that had multiple possible directions. Within these design dilemmas I characterized the *curricular values*—criteria that were used to make design decisions—that were evident in specific utterances. I also identified *tensions*—moments when curricular values were at odds with each other.

Results and discussion

Table 1 presents the range of curricular values I identified, along with indicator questions that operationalize the values being offered. I found that co-designers' utterances fell into seven different categories of curricular values: *coherence, coherence from the students' perspective, student engagement, equity focused science education, alignment with the standards, scientific accuracy,* and *teacher's pedagogical approach* (see Table 1). These curricular values were sometime stated independently from other values; for example, "I'm looking for more fun things to do here" was a concern for the need to reach the value of *student engagement.* More often values were stated as aligned toward achieving a certain goal or at odds with each other. For example, during a deliberation on how to incorporate energy into the lesson, Matt, a teacher participant, stated "There might be a tension between how we are thinking about energy for this application [as a model in which fields carry energy] (*coherence from the students' perspective*) and how we

 © ISLS

are thinking about energy in our whole course (*coherence*) and in the NGSS [as systems carrying energy] (*alignment with the standards*)." Based on preceding utterances, it is evident that the first "we" used here positioned Matt in "student hat"—as if he was a student experiencing the lesson. The value he was naming was *coherence from the students' perspective* which he portrayed as in tension with 2 other values: the coherence of the "whole course" (*coherence*) and "the NGSS" (*alignment with the standards*). For Matt, the "whole course" and "the NGSS" were aligned toward the same goal. Therefore, the underlying values were not in opposition with each other, but both conflicted with the value of *coherence from the students' perspective*. This led to a segment of utterances in which the team deliberated over how to proceed with the lesson using curricular values as criteria for their proposed directions.

Table 1

Curricular values that were found during design team meetings, the indicator questions used to operationalize the values, the definition of each curricular value, and examples of identified corresponding utterances.

Curricular Values	Indicator Question	Definition	Examples of Utterances during meetings
Coherence	How do we—designers—understand this curriculum?	The layout of the lesson and unit makes sense and is logically organized to the design team.	"Alright, so let's see if I understand this correctly. I'm reading it as a little bit of a contradiction within the same paragraph, that we're going to think of it as a photon."
Coherence from the students' perspective	Will this make sense to students?	Designers develop a path that is motivated by anticipated student questions and interests.	"...if I'm a kid, I'd be like 'teacher I want something that compares all those'. And then, bam, here is the spectrum."
Student Engagement	Is this fun and exciting?	Students are excited about and engaged with the lesson or unit.	"I can see that excitement there." "I'm looking for more fun things to do here."
Equity focused education	Is this equitable?	Being mindful of the ways in which science education is culturally and socially responsive and meaningful. Making curricula for all students.	"The history that we know around most of these experiments are white guys from Europe and um that can be really problematic when students are going through the curriculum and every single example looks exactly the same."
Alignment with Standards	What do the standards tell us to do?	The Performance Expectations and Disciplinary Core Ideas outlined in the NGSS are incorporated.	"Do you think that we might get pushback from other people on the fact that it's high school and we're not using terminology from the NGSS?"
Scientific Accuracy	Are we doing good science? What does physics say?	The science present in the lesson and unit needs to be precise and correct.	"Yeah, it's not really accurate to call all particles molecules, but I think you can call all molecules particles. So then let's just use the word 'particle.'"
Teachers' Pedagogical approach	How does this approach to the task reflect our pedagogical commitments?	Ideas expressed by a participant of the design team from teaching experience.	"I am always for never using vocabulary...I just, I hate voca… I don't know, it gives me like PTSD to like pre-teach vocabulary. I just, I don't like it."

This work introduces *curricular values* as useful metrics or evaluation criteria in design work. This study highlights that it is possible to identify these values systematically, and that these values are at the core of design dilemmas. Theoretically, this work deepens the understanding of deliberations within design dilemmas and helps to discern what stakeholders bring into the co-design space. Further understanding underlying curricular values and relationships between them can inform models of how to support co-design as a vehicle for implementing reforms.

Science Learning Through Drawing

Qingna Jin, University of Alberta, qingna.jin@ualberta.ca

Abstract: Engaging students in visualization, especially constructing visual representations has been suggested as fruitful to support science learning. This study explored how elementary students learn astronomy, which is a challenging topic for both teaching and learning, through drawing and communicating with others about their drawings. Data were collected from multiple sources and analyzed qualitatively. Findings indicated that drawing as cognitive and epistemic resource facilitated students' reasoning in both individual and social domains.

Background

Visual representations such as drawing are integral to scientific thinking and reasoning (Prain & Tytler, 2012; Tytler et al., 2020). Scientists use visual representations (e.g., drawings, diagrams, sketches) to make discoveries, test ideas, explain findings, and elaborate knowledge (Gooding, 2006). Researchers in science education broadly agree that students need to learn how to interpret and construct visual representations of science concepts and processes (Prain & Tytler, 2012). In particular, there is an increasing focus on student-generated drawings as research suggests engaging students in the process of visual representation construction supports learning better than simply interpreting experts' visualization (Yoon et al., 2021). Researchers suggest the role of visual representation should be to support learning with representation, instead of learning from representation. This study aimed to explore how elementary students learn astronomy science with and through constructing visual representations and communicating with audience about their visualizations.

Seeing from socio-cultural perspectives, representational work as epistemic practices of science is embedded in and cannot be separated from its social and cultural contexts (Yoon et al., 2021). Drawing to reason is the use of cultural symbolic and semiotic tools to make sense of the phenomena and solve problems (Tytler et al., 2020), thus is mediated by the tools used and constrained by its context and various physical and conventional resources available (Gooding, 2006; Lundin & Jakobson, 2014; Prain & Tytler, 2012).

Constructing and refining representations is a core epistemic activity within science and should therefore be a major emphasis in the science classroom. Rather than "tools for something more fundamental, such as conceptual knowledge," students' representational work such as drawing is "enacting science learning and reasoning" because it is consistent with how knowledge is developed and communicated in the science community (Prain & Tytler, 2012, p. 2757). In constructing and refining drawings, students need to consider the extent to which it is coherent both within component parts of the drawing and across related representations (Tytler et al., 2020). The consideration of coherence is a key feature of model-based reasoning central to the epistemic practices of science (Lehrer et al., 2008). In this way, drawing is constrained by the need to achieve specificity of detail and the requirement of unambiguous communication (Prain & Tytler, 2012).

Curriculum Context

There are many reasons for astronomy to be a part of the education system and culture. Astronomy is deeply rooted in the history of almost every society because of its practical applications and philosophical effects. Astronomy is mainly based on descriptive methodologies, which are different from other science domains, in which scientists conduct experiments to test their hypotheses. Thus, astronomy shows an alternative approach to the "scientific method" in school context (Plummer & Tanis Ozcelik, 2015). Further, engagement with astronomy topics which fosters curiosity and imagination is widely suggested as a method of inspiring students to further study of science. Nevertheless, research indicates that some astronomical phenomena are difficult for students to understand and challenging for teachers to teach (Plummer & Tanis Ozcelik, 2015).

Throughout the four-month research period of this study, a classroom science teacher and her nineteen students from a Grade 5/6 science classroom in a public school in Canada worked on an astronomy science unit. Students were encouraged and supported to learn characteristics of other planets and their moons in the solar system by drawing a design to further current space exploration. Students' drawings were to be based on their experiences, knowledge learned in this unit, and information from online research on their topics. At the end of the unit, each students presented their ideas with drawings to their peers.

Research Methods

This qualitative case study employed multiple methods for data collection, including observing students' drawing processes, interviewing students to learn how they drew from their perspectives, and collecting students' drawings.

 © ISLS

Data from multiple sources were analyzed together for thematization to understand how students learned elementary astronomy by constructing and communicating with others about their visual representations.

Findings

Findings from this study were organized into the following two themes:

(1) In the individual domains, drawing has cognitive and generative functions for interpretation and sense making. Drawing as a cognitive resource can enact students' reasoning within the inquiry process. As a form of representation construction and refining, drawing provided students with opportunities to coordinate, integrate, and synthesize information in a coherent way to interpret the astronomical phenomena under investigation. Students in this study examined the coherence across multiple representations, including their own drawings, texts in books and websites, and online audio and video resources, to form their plausible claims. While achieving the coherence, students negotiated, refined, and advanced their understandings of the astronomy topics. For example, in this study, a student, Nate (pseudonym), explored characteristics of Triton (i.e., Neptune's moon) through drawing his design which is a rover for sample collection. During the interview, he shared how and why he made changes to his rover' wheels in his drawing.

> They were like the wheels of car, then I changed … I know that to have the right wheels, I need to know what the surface [of Triton] looks like, so my rover can move … NASA says it is all ice … wheels have cleats will not fall on the icy surface …

By exploring relevant online resources, Nate collected helpful information based on which he refined his drawing. Through drawing, students coordinated, integrated, and synthesized information to form interpretation.

(2) In the public realm, drawings have social and critical functions for communication. When students' designs and claims were introduced to the classroom community, their drawings were crafted into and functioned as an epistemic resource that could provide pictorial evidence for their claims. The community as audience examined the clarity of the visual representation, as well as the coherence among elements of the representation, to determine whether the visual claim was plausible and acceptable. For the purpose of communication, students always included other representations, such as annotation, images and gestures, together with their drawing to explain their designs. For example, to help his peers to understand how his rover's wheels looked like, Nate also created a 3D physical model with foam balls and toothpicks. In addition, trough social interactions, students' drawings were further refined, as well as their understandings about the astronomical topics.

Conclusions and Discussions

Findings from this study indicated that drawing as cognitive and epistemic resource facilitated student science learning in both individual and social domains. With its cognitive and generative functions, drawing helps students make sense of the phenomena as it enacts student reasoning. In the social context, students' drawings function as epistemic resources for the purpose of communication.

Despite attracting children's interests and affecting their everyday lives, many teachers have found astronomy challenging to teach (Plummer & Tanis Ozcelik, 2015). Finding from this study suggest that it could be fruitful engaging students in visual representation construction such as drawing to learn elementary astronomy.

Centering Ethics in AI Education: Cutting Through the Controversy

Andy Stoiber, Yoon Jeon (YJ) Kim, & Amal Altuwaiyan, University of Wisconsin-Madison
Email: acstoiber@wisc.edu, yj.kim@wisc.edu, altuwaiyan@wisc.edu

Abstract: Current efforts teaching the ethical implications of AI neglect current dilemmas rooted in biases. We propose two design considerations for curriculum designers in this area: embedding ethics across the curriculum and foregrounding authentic problems facing the AI field. Our proposals are compared to a responsible AI curriculum we are helping build to explore the implications of each approach to ethics in AI.

Introduction

As encounters with Artificial Intelligence (AI) subside from the surreal and remarkable to the ordinary and mundane, a new literacy is emerging. How are we to make sense of these modern marvels we interact with everyday, that shape our lives in powerful ways? AI technologies answer questions I pronounce in my kitchen, decide if I qualify for a credit card, and scan my face to access my phone. Yet the technology appears impervious to inspection, shielded in a black box, suggesting no questions need be asked. But the consequences of these ubiquitous technologies are not neutral nor fair, but biased and ethically fraught. To prepare a public to contend with the ramifications of our increasingly AI-driven world, education researchers have called for students to learn not only the technical knowledge and skills related to AI, but the societal implications (Zhang et al., 2021; Lao, 2021). In response, lessons on AI have been designed and implemented for children as young as 4 (Ali, Payne, Williams et al., 2020).

However, current efforts addressing the ethical dimensions of AI in education fall short of realizing their promise. These nascent endeavors focus on identifying stakeholders and their values to explain AI as socio-technical systems (DiPaolo et al., 2020), products of design agendas and biased datasets. But learners are presented with scenarios disconnected from real-world dilemmas— cats, dogs, and peanut butter and jelly sandwiches figure prominently (Ali, Payne, Williams et al., 2020)—and neglect how AI design decisions may cause harm. Our project intends to fill the gaps in this freshly poured foundation. As part of a team building a responsible AI curriculum for middle schoolers, we are envisioning a new set of principles centering ethical thinking in the design, teaching, and learning of AI in school. We propose ethics must be embedded, with authentic problems facing the AI field foregrounded. This poster begins to explore why ethical thinking must be woven into and emphasized throughout AI curricula, and how ethical dilemmas should be approached.

Roots of Bias in AI

Ruha Benjamin (2019) explains how "[w]ith emerging technologies we might assume that racial bias will be more scientifically rooted out. Yet, rather than challenging or overcoming the cycles of inequity, technical fixes too often reinforce and even deepen the status quo." Indeed, it is the rising awareness of systemic bias, of unfair decisions made by humans making up an organization, that results in outsourcing organizational processes and practices to AI. In AI we trust, may the logic read. However, outsourcing decision-making that is historically biased to AI simply embeds the social bias into a technical artifact. This can be seen across time, whereby dehumanization caused by AI today echoes a legacy of oppression championed in the sciences.

For example, an AI technology used in the U.S. criminal justice system to predict recidivism rates *incorrectly* flagged black defendants as likely to commit future crimes at rates nearly double that of white defendants (ProPublica, 2016). Bonilla-Silva & Zuberi (2008) remind us "that the founder of statistical analysis also develop[ing] a theory of White supremacy is not an accident. The founders developed statistical analysis to explain the racial inferiority of colonial and second-class citizens in the new imperial era" (p. 5). That is to say, scientific progress and technological innovation often act in tandem with logics of domination, particularly White Supremacy and anti-Black racism (Gould, 1996).

Design Considerations for AI Education

 © ISLS

Our proposal is to center the reality of bias in AI by grounding content in real-world problems. Teaching how image classification works should occur in a context connected to its use by industries and effects on consumers. Datasets using cats and dogs may be effective at teaching the technical aspects of image classification, but essentially ignores the sociological, and presents a problem of transfer for students expected to discuss ethical issues when their hands-on engagement revolves around cute animals.

Our second design consideration, embedding ethical thinking content throughout the curriculum, intends to better reflect the AI-creation pipeline, where decisions with significant ethical consequences occur every step of the way (Suresh & Guttag, 2021). Learners need to be confronted with scenarios that allow them to leverage their prior knowledge to make meaning about how AI impacts their lives, with the goal of helping them understand how they can affect change in their communities.

Currently, little research exists regarding the teaching and learning of AI and its inherent dilemmas. Based on their literature review, Long and Magerko (2020) identify ethics as one of 17 key competencies substantiating AI literacy. Based on their literature review of 150 documents, only two intersected AI with curriculum design for non-technical learners and ethics. Thus, ethics is an imperative component of a robust AI education, while a body of research that could help direct efforts integrating this competency into AI curricula remains almost nonexistent.

Applications: The case of RAICA curriculum

Responsible Artificial Intelligence for Computational Action (RAICA) is a design-based research project to develop and research a project-based AI curriculum for middle school students in the U.S. and Dubai. Our overarching research question asks *how can we transform students from AI consumers to conscientious AI contributors?* A curriculum module spans 20-25 lessons, 50 minutes a piece. Students learn core AI concepts, such as supervised learning and natural language processing, by creating a technical solution (using simple coding tools such as Scratch) that leverage AI technologies (like image and audio classification).

The curriculum designers struggle with the question of controversy—-i.e., How can we include real ethical dilemmas that might be controversial without damaging the sense of safety for teachers and students? For example, we adapted the activity featuring cats and dogs to explain image classification, but noted how detached from real world dilemmas this technology is implicated in: Black people being labeled gorillas or primates by Google and Facebook (Mac, 2021; BBC, 2015); deep neural networks detecting sexual orientation based on a subject's face (Wang & Konsinski, 2018); and military applications, such as Project Maven, which intended to identify people and objects in drone footage (Wakabayashi & Shane, 2018).

The RAICA curriculum bookends ethical questions, sans scaffolds between understanding bias with datasets featuring cats and dogs and what that can mean when applied to humans. We propose for future iterations to embody these two design considerations to present learners first and foremost with scenarios based on real-world dilemmas. We will then investigate the impact these proposed principles have on students' grasp of AI's ethical implications compared to the initial implementation. Considering transfer, we expect students to have a richer understanding of how AI shapes their world and how ethical considerations apply across different AI technologies.

Empirically-driven Multiple Choice Response Options

Aubrey Condor, University of California, Berkeley, aubrey_condor@berkeley.edu

Abstract: We introduce an empirical method for generating multiple choice (MC) response options for educational assessment. Developing quality response options for MC questions is labor intensive, especially when parallel items are necessary for repeated assessments or multiple test forms. We propose a data-driven, iterative approach for creating an item bank of MC questions by first collecting a sample of open-ended student responses that are subsequently rated by subject-matter experts. Contextual sentence embeddings of the observed student responses as well as the expert ratings are used in conjunction with hierarchical clustering to create MC options that span the desired ground truth rating levels specified by the item creator. We evaluate the quality of the automatically generated response options qualitatively, based on existing research relating to best practices for item writing.

Introduction

Although the grading of multiple choice (MC) items is less time consuming than open-ended (OE) items, constructing quality response options for MC items can be more labor-intensive and difficult (Gierl, 2012). Previous research on item design suggests that response options should include feasible student conceptions about the topic of interest, whether they be correct or incorrect (Haladyna, 2010; Zimmaro 2010). In addition, related research suggests that MC options should be homogeneous in content but different in their level of correctness (Burton, 1990). Finding plausible distractors that reflect common student misconceptions and are contextually related to other options requires considerable effort and can be hindered by expert blindness (Nathan, 2003). We suggest that the application of artificial intelligence (AI) can help mediate such issues and aid in constructing items that exemplify these item writing guidelines.

The motivation for this work is to reduce a common time burden for educators, as well as suggest a more objective, data-driven method for creating quality MC response options for both single item creation, and the creation of a bank of parallel items. We propose an iterative item development method as such: first, desired items are created as OE items and a preliminary data collection is performed to obtain a sample of student responses. Once subject-matter experts rate the observed responses, we create vector embeddings of the responses, and use hierarchical clustering to automatically identify contextually similar response options that reflect real students' conceptions.

Multiple Choice Response Option Generation

The data we used for this project was sourced from a 2019 field test of a critical reasoning in mathematics assessment developed by a team of researchers at the Berkeley Evaluation and Assessment Research (BEAR) center. The data included responses to 30 different mathematics related items. However, for this study, we focus on the 6 items with over 300 responses each. Student responses were each rated from 0 (fully incorrect) to 3 (fully correct) by multiple researchers at the BEAR center.

Our method for automatically generating MC response options is as follows. We first use Sentence-BERT (SBERT; Reimers, 2019) to create sentence embeddings of the collected responses. SBERT is a modified version of BERT that utilizes siamese and triplet network structures to create semantically meaningful sentence embeddings. Next, we reduce the dimension of the often-sparse sentence embeddings from vectors of size 768 to size 50 using truncated singular value decomposition (SVD). With the reduced sentence embeddings, we perform hierarchical clustering with the Ward linkage criteria. Hierarchical clustering consists of a family of algorithms that form clusters by merging or splitting data points in succession, and the Ward linkage method performs merging by minimizing the sum of squares within the clusters. We use the silhouette coefficient to search for the best number of clusters from 3 to 6.

Finally, we filter for clusters that include at least 20 responses to make sure there are enough responses from which to sample. We randomly sample response options from the user specified rating level categories to create an item version. If it is the case that the cluster from which we are sampling does not contain all rating categories needed, we sample from a different cluster. Once the final item responses are created, we recommend that a human intervenes to perform a quick pass of final necessary modifications to the responses such as making sure that all responses either end in a period or do not, removing clear grammar mistakes, etc. Item writing recommendations specify that answers should use similar language, there should not be any grammar issues or misspelled words to prevent obvious incorrect answer elimination (Burton, 1990).

 © ISLS

Results and Discussion

As this project is a work-in-progress, we evaluate the goodness of the generated items qualitatively. Figure 1 shows a 2D visualization of the response clusters for an item that references a graph of an exponential function. For each of the four clusters, example responses are included as well as their respective ratings. The examples shown for clusters 2, 3, and 4 may serve as fixed response options for three different parallel items. The options span the 4 ratings levels, but the user can also specify to sample one fully correct answer (rated as 4) and the rest fully incorrect answers (rated as 0). Cluster 1 seems to contain "I don't know" type answers which should be avoided, and only answers rated as 0 or 2. Our method would not sample from this cluster because responses do not span the desired rating levels. Noticeable issues in some of the sampled response bundles include drastically uneven response lengths and the lowest rated responses being nonsense answers such as "I just guessed". However, as previously suggested, human intervention is necessary for final touches and filtering out unusable bundles of response options.

Further evidence is needed to validate the utility of our method. Anticipated future work includes qualitative evaluation of the response clusters from education professionals, as well as psychometric evaluation to ensure that parallel items are of similar empirical difficulty. However, we believe the proposed method for empirically generating of MC response options illustrates how technology can be a practical aid to educators.

Figure 1

2D visualization of hierarchical clusters of student responses. Example responses (some truncated) for each cluster are included as well as the expert rating levels from 0 to 3.

Predicting Learning Gains in an Educational Game using Feature Engineering and Machine Learning

Seyedahmad Rahimi, University of Florida, srahimi@ufl.edu
Curt Fulwider, Florida State University, gcf16@fsu.edu
Shiyan Jiang, North Carolina State University, sjiang24@ncsu.edu
Valerie J. Shute, Florida State University, vshute@fsu.edu

Abstract: In this study, we use feature engineering and machine learning (ML) to develop a regression model to predict students' learning gain while playing an educational game. Specifically, this study used the log data from 199 students' gameplay to build a logistic regression model. The model we created includes 14 features with an accuracy of .61.

Introduction

Educational games are complex environments that can assess students' learning process and outcome. As students interact with the game, they produce rich data which provides evidence of learning. Using machine learning (ML) techniques, we can make use of game data to derive models that predict students' experience. By doing so, we can create educational games that will respond—providing supports or adaptive challenges—to student's learning needs. In this study, we use feature engineering and machine learning to develop a regression model to predict students' learning gain (pre to posttest) using gameplay data from *Physics Playground* (*PP*; Shute et al., 2019).

Method

We examined a dataset (n = 199) from 9th to11th-grade students (*Male* = 104, *Female* = 91, *Other* = 4) in a large public school in the southeastern United States (see Shute et al., 2020). Students self-reported a diverse range of ethnicities: White (42%), Black or African American (31%), Other (19%), Hispanic (8%). Collectively, these students generated about 6 million data points in 5 days of gameplay (about 1.5 hrs of gameplay per day). *PP* is a 2D computer-based game (including 81 levels) created to help secondary school students learn Newtonian physics. Using simple physics agents (e.g., ramp, lever) or manipulating physics parameters (e.g., mass of the ball), students hit a red balloon using a green ball in *PP*'s levels. To access the learning supports, students click on the help button, which is always available during gameplay. The game's incentive system includes earning money resources and spending money opportunities (e.g., buying background music, background image, new ball, or a solution video). We collected log data of students' interactions with the game. The log file contains nearly 17,500 events representing each level played by all 199 participants. 13,312 events were used for modeling after removing missing values. A set of features was distilled based on our prior work on developing evidence-based assessments (Shute et al., 2020). We originally considered 45 features that show students' actions in each game level, such as the coins students earned (gold or silver) and how long students played a level. Our refinement and selection of the feature space was guided by the theory of game-based learning (Plass et al., 2015) and literature about predicting learning gain with interactions with technologies (Crossley et al., 2020). After several rounds of feature selection based on training data for reducing overfitting, we selected 14 features (Table 1) for modeling learning gains using a logistic regression model. The learning gains were measured through two isomorphic tests with multiple-choice items (pretest = 18 items, α = .77; posttest = 18 items, α = .82). The higher the absolute value of a feature weight in a regression model, the stronger its influence on learning gains. All features were normalized using z-score normalization. We tuned the regression model to achieve high accuracy in predicting learning gains.

Results

Our final model achieves a cross-validated accuracy of 0.61 and a cross-validated kappa of 0.12. The features explain 5.31% of the variance of those who had learning gains. The confusion matrix shows that the model had the majority error cases in predicting events that should be false but were predicted as true. This indicates that in the future, we still need to revise the feature space so that the model could identify patterns for positive learning gains. As shown in Table 1, game levels with challenging physics concepts (concept difficulty), learning support, game mechanics difficulty (GM), and agents drawn are good predictors for learning gain while not solving the game level (solved), money earned, number of help button usage, game supports viewed, and number of physics animations viewed negatively predicted learning gains.

 © ISLS

Table 1
Definitions of Features and their Weights

Feature	Weight	Definition
Performance		
Time	-0.001	The time, in seconds, a player spends in the level.
Solved[1]	0.720	Whether the player solved the level or not (yes/no).
Money earned	-0.030	The amount of money earned playing the level.
Wallet balance	-0.001	The amount of money in the player's wallet at the end of a level.
Support		
Help button usage	-0.090	The total number of times the help button was used within the level.
Learning support viewed	0.080	The total number of learning supports, of all types, viewed in a level.
Game support viewed	-0.060	The total number of game supports, of all types, viewed in a level.
Physics support viewed	-0.060	The total number of physics supports, viewed in a level.
Physics animations (PA) viewed	-0.010	The total number of physics animations viewed within a level.
Engagement		
Agents drawn	0.020	The number of mechanical agents (e.g., ramp) drawn within a level.
Objects drawn	0.007	The total number of objects (excluding agents) drawn in a level.
Level Traits		
Type[2]	0.003	The type of level. Either manipulation or sketching.
Concept difficulty[3]	0.200	The difficulty of physics concepts included in the level.
Game mechanics (GM) difficulty	0.070	The difficulty of game mechanics included in the level.

[1] Compared to unsolved; [2] Focus is sketching type levels; [3] Focus is hard difficulty

Discussion

Looking at the features contributing to positive learning gain, we can see variables that are related to game performance. Specifically, solving the game levels and drawing agents (simple machines). Other than game performance variables, learning support-related variables are also good predictors of learning gain. That is, the total number of learning supports viewed was a positive predictor of learning gains. Variables that predicted learning loss included variables other than gameplay (e.g., clicking the help button, money earned, game support, and physics animations viewed). These variables indicate that students needed help and showed that students spent time doing tasks which took them out of gameplay. Finally, variables related to a game level's difficulty were also important predictors of learning gains. Specifically, the concept difficulty was a strange predictor compared to game mechanics difficulty. This indicates that difficult concepts and difficult levels in terms of game mechanics contribute more to students' learning. The model we came up with can be used for early detection of learning gain.

Mentors' Learning Support Roles and Their Impact On Girls' Identity Imaginations

Naomi Thompson[1], Bo Ju[2], Denise Nacu[2], Sheena Erete[2], Nichole Pinkard[1]
naomi.thompson@northwestern.edu, bju1@depaul.edu, dnacu@cdm.depaul.edu, serete@cdm.depaul.edu, nichole.pinkard@northwestern.edu

Abstract: Mentoring programs have been intentionally designed to support Black and Latina girls in pursuing STEAM. Here, we examine how the support roles mentors play in an OST STEAM program relate to younger girls' imaginings of their own identities. Findings from surveys taken by middle-school girls and mentors indicate that by the end of the program year, girls showed more willingness to imagine themselves in various identities, relating to the support roles mentors most often played.

Introduction and Background

Black and Latina girls are traditionally and still dramatically underrepresented in science, technology, engineering, and mathematics (STEM) fields. Several studies have explored the reasons behind the gap, citing factors such as negative stereotypes, lack of opportunities, and more (e.g., Margolis et al., 2008; Wang, 2013). Out-of-school time (OST) programs have been designed to spark and sustain girls' interest in STEM as early as middle school when their interest starts to decline (e.g., Barron, 2006). Studies have shown that mentoring is a promising means of promoting girls in STEM, and women who have chosen courses, college majors, or careers in STEM emphasize the importance of role models in their decision-making processes (e.g., Stoeger et al., 2016). Our previous work has shown that mentors helped create a counterspace (Ong, Smith, & Ko, 2017) -- a safe place to explore their identities and interests in solidarity with one another and to imagine potential futures for themselves -- during a year of online programming due to the pandemic by adapting quickly to youth needs, highlighting and celebrating the full, authentic selves of the learners, and by remaining mindful of the challenges associated with intentional community building (Thompson et al., 2021). In addition, a number of generative roles have been identified to describe how educators including mentors and caring adults can advance learners' technological knowledge and skills (Nacu et al., 2014; Barron et al., 2009). In this study, we build on those frameworks in an OST STEAM program—adding art and design into STEM—for middle-school girls, asking: How do the support roles that mentors see themselves play relate to the STEAM identities of youth over a year?

Methods

The Digital Youth Divas (DYD) is an OST STEAM program serving primarily Black and Latina girls in middle school. The program is designed to foster community between youth participants and high-school to college-aged mentors who facilitate the STEAM activities. In the 2020-2021 program year, there were 30 girls participating consistently in virtual programming 1-3 times per week. There were 12 mentors working with the youth. Eleven of the twelve identify as women, and all identify as Black, Latina, and/or Asian.

Youth took a survey at the beginning and end of the program year. For this preliminary analysis we looked at the item: "How much would you use the following words to describe yourself?" followed by words such as "reader, student, engineer" etc. Fifteen of the youth answered this question on both the pre- and post-surveys and thus are included in the analysis here. The mentors took part in weekly planning and professional development meetings, including a workshop on support roles for learning. At the end of the program year, mentors took a survey asking questions about their perceptions of how the program went, and what support roles they felt they played. For this paper, we noted changes between youth pre- and post-survey responses. Then, we identified the support roles the mentors said they were most likely to play. Finally, we considered these two sets of data in relation to one another and looked for themes or relationships that emerged.

Findings

Youth responses to question "How much would you use the following words to describe yourself" were generally more positive on the post-survey than on the pre-survey, meaning that youth were more likely to choose "Very Much" or "A little, or sometimes" to each word choice on the post-survey. This demonstrates that the girls showed more willingness to imagine themselves in multiple potential futures in STEAM after participating in the program. Specifically, the descriptors entrepreneur, performer, fashionista, designer, and visual artist showed the most

 © ISLS

positive growth among all the descriptors. The only descriptors that did not show positive gain were computer programmer and athlete. Our poster will display additional details from the data.

On the mentors' post-survey, they most often reported "always" playing the roles of encourager (80%), friend (80%), and monitor (60%). These roles primarily centered around validating youth's ideas (encourager, friend) and supporting the learning processes (monitor). The mentors elaborated in open-response questions on the survey, reflecting on the most meaningful parts of the mentoring experience. They shared that "being able to build relationships with the girls" and "connecting with the girls and learning alongside them" were the most valuable parts of the experience. A mentor shared:

> *I had a strong STEM identity coming in as a Divas Mentor, since I was a declared computer science major by the time I signed up for the position, but being a mentor has allowed me to take that identity and share it proudly with youth girls, at an age where I knew I was also a STEM kid but wasn't sure if I should embrace it.*

This mentor took joy and pride in acting as an encouraging role model for the youth, and knew it was a crucial time to support girls of color in their STEM journeys. The roles played by the mentors are active, highly supportive, and uplift the girls' sense of self, which can in turn impact their openness and imaginations. Although not all the descriptors chosen by the girls are strictly-STEM related, it is likely that the support of the mentors helped the girls feel more confident in embracing all their interests and identities, allowing them to see themselves as complex and unique individuals with many possibilities open to them in the future.

Discussion

We do not seek to imply that the mentors alone caused the changes in the girls' responses. Rather, we expect there are several factors at play, including the program curriculum, parent involvement, other STEAM learning opportunities, or other influential people in the girls' lives. However, we do know that mentors play a crucial role in girls' OST STEAM learning, so it is likely that the mentor roles influence this development in some ways. Correlational analyses in the future could further tease apart this relationship, and also support future work around ongoing training and support for mentors. As a limitation of this study, we acknowledge that we present here tentative findings from a small data set. However, with a relationship between mentor actions and girls' imaginations becoming visible even at this small scale, we are encouraged to more deeply explore how mentors can support and encourage Black and Latina girls in their social dreaming and ideas about the multiple future pathways their lives could take.

Abstract: Climate justice involves recognizing the deeply intertwined relationships between people and their environment, along with the recognition and validation of the fact that climate change has a disproportionate effect on the most vulnerable populations on the planet. This poster session shares the design and findings of a Climate Justice Map-mediated Scientific storytelling project designed to support students' learning and action of climate justice by deepening and personalizing their involvement in locally situated climate issues.

Introduction

Climate justice involves recognizing the deeply intertwined relationships between people and their environment, along with the recognition and validation of the fact that climate change has a disproportionate effect on the most vulnerable populations on the planet--historically marginalized communities and other living things. Thus, issues related to climate change need to be addressed by approaches that allow for important conversations of equity (racism, patriarchy, economics) alongside climate change science. Climate Justice Map-mediated Scientific storytelling (CJMAPS) is one such approach that supports student learning and action of climate justice by deepening and personalizing stakeholder involvement in locally situated climate concerns. This poster discusses the design elements that make the CJMAPS approach a way to address issues related to equity alongside science. The poster will also present findings from data collected during Spring 2022, when the first iteration of the approach is implemented.

The CJMAPS learning environment is designed around the driving questions: How do we organize and build relationships with people and natural world in a time when the climate is rapidly changing everything in our immediate and distant environment? Relationship building between and within communities for a cause is not an easy task (Krishner 2015). The related attitudes and behaviors are complex and dynamic, and are likely influenced by personal experience and knowledge as well as cultural and political knowledge and values systems. For example, research has shown that cultural and political values play an important role in how individuals understand climate science (Leiserowitz et al., 2012). Similarly, building connections to the natural world also requires people to reflect and attend to their own identities and positionalities and to the consequences caused by their actions. Through the CJMAPS program, learners use their lived experiences and construct a story using ArcGIS Storymaps software. The learners will: explore an issue related to climate change; research the personal, socio-cultural and political aspects of the issue; and then create a story using the ArcGIS software that will reflect their understanding of how the issue is connected to self, their community members and land. For the first iteration of the study we have asked students to seek out how birds (local and migratory) have been impacted by climate change.

Birds connect people of different racial, ethnic, and socioeconomic communities by virtue of nesting and migrating through several different places. However, birding exists within the racialized context of a society in the U.S. that normalizes whiteness and white identities in the outdoors, the environmental movement, and science. This context was exemplified in the U.S. news in May 2020 when Christian Cooper, a Black man who was birdwatching in Central Park in New York City, asked a white woman to obey park rules and leash her dog. The woman called the police to say he was threatening her. Cooper took a video of the incident, which went viral and prompted increased attention to the racialized experiences of people of color in birding, the outdoors, and STEM fields (see e.g. #BlackBirdersWeek2021). This context highlights the need for climate justice education to attend to the sense of belonging and identities of educators and participants in the learning environment. Bird ecologist J. Drew Lanham (2013) talks about his experience as a Black bird watcher in the United States, satirizing about belonging and identity. Thus, although researching about local and migratory birds might at face value seem a neutral activity, like every scientific endeavor researching birds is also a segregated and racialized activity. We hope that through building stories about birds and birding students will be able to understand the socio-cultural and political dimensions that surround their research on climate change and birds.

 © ISLS

Theoretical background

CJMAPS seeks to use technology mediated tools to create space for racially and ethnically diverse students to explore authentic climate justice issues while also strengthening their relationships with the land and their communities. Students' exploration of their relationships with land and community are central to learning environmental science (Tuck et al., 2014). However, environmental learning is often framed by Western scientific meanings of place (e.g. land ownership versus reciprocity) and ignores the historical and ongoing eradication of Indigenous peoples who inhabit or formerly inhabited lands and the history of forced landlessness among chattel slaves (Engel-Di Mauro & Carroll, 2014). In contrast, CJMAPS draws upon land-based pedagogies and centers students' and community members' voices and perspectives to provide space for multiple epistemological understandings to be incorporated to students' sensemaking. When learners are supported to understand how scientific content interacts with the socio-cultural contexts of their lives and in particular with their relationships with land and communities, science learning and engagement flourish (Bang et al., 2014). Each ethnic group has their own socio-cultural and political history that impacts their interactions with land and community. For example, historically African Americans were denied land ownership. As Smith (2007) discusses, "Forced for generations to work the earth without just reward, without the right to own land, without even the freedom to travel, what meaning could they find in America's pristine wilderness? Locked in a struggle for social justice, what interest could they have in the claims of nature?" (p. 3). African Americans have a long tradition of caring for land in ways that are distinct from other Americans (Finney, 2014). All students need space and time to understand their relationship with lands they inhabit. Map-mediated storytelling fosters students' exploration of their unique relationships with the land and their community. Mapping these relationships supports their visualization and development of their stories within a climate justice and community-driven context.

Prior research that examines participant learning in locally relevant science identifies the following: students draw upon multidisciplinary understandings of science and local communities to develop relationships with selves (identity development), nature, and their local communities (Bang et al., 2010; Schindel Dimick, 2016); and students leverage community-driven science understandings when learning is situated within place (Birmingham & Calabrese Barton, 2014). Incorporating place-based science and structuring science learning for multiple voices to contribute to meaning making provides significant opportunities for students from diverse and historically marginalized backgrounds to engage in science (Bang & Marin, 2015). This work has implications for understanding how map-mediated stories and what aspects of these stories influence how students make sense of place-based climate justice.

E-textile Fashion: Designing Maker Activity for Chinese Migrant Girls

Xintian Tu[1], Jing Yang[1], Qiu Zhong[1], Chaoran Wang[2], Adam Maltese[1]
[1]Indiana University, [2] Colby College
tuxi@iu.edu, yangjing@iu.edu, zhongqiu@iu.edu, chaowang@colby.edu, amaltese@indiana.edu

Abstract: We present a low-cost STEAM workshop for twenty-five Chinese migrant girls to learn electronics through making hats. Data sources include video recordings of all classroom activities and post-interviews of students. We analyzed post-interviews of all participants and then narrowed our focus to Meimei, a girl who expressed an interest in art design. We hope this study will inspire future designers and educators to design maker activities for local schools.

Introduction

In the last three decades, China experienced the world's largest rural to urban migration. Because migrant families do not possess an urban household registration, children from these families are excluded from full access to free compulsory education (Goodburn, 2015). Therefore, migrant schools, usually funded by charities, become an option for migrant children. Lacking stable funding for resources and qualified teachers, children in these schools likely do not receive an education as good as their peers in public schools (Lu & Zhou, 2013). Compounding the issue of unequal resource distribution, female students in China experience additional documented inequities based on cultural traditions (Goodburn, 2015). With these inequity issues in mind, our project aims at providing more learning opportunities to those underrepresented students. More specifically, we would like to engage young migrant female students in making activities as a form of STEAM learning.

Design

Our workshop was designed for an internal grant with the goal to empower Asia-Pacific women in STEM education. We focused on the migrant girls in Shenzhen, China, because it has the most migrant population in the country. We expect our making-oriented workshop to offer an entry point for migrant students to join local maker events. The design of our workshop referenced Buchholz's work (2014) that e-textile toolkits offer females expanded access to materials and tools and provide with them opportunities to take leading roles in advanced technical activities. Our workshop consists of five sessions (60 -120 minutes per session). Each session has explicit learning goals to reduce teachers' concern that making activities are not directly connected to curriculum standards. In the first four sessions, students worked in group of two to design hats, sew circuits, and prepare posters in the innovation room. The layout of this classroom naturally encourages group work, as opposed to traditional classrooms that desks were lined up and facing the front. On the last day, they presented their projects to their peers, teachers, and Makers from the local community in an open space.

Method

Context and participants

We implemented the workshop in an elementary school in Shenzhen, China. Twenty-five 5th and 6th graders participated in this workshop. The workshop was led by three researchers, who designed the workshop collaboratively. Students worked in groups of two or three to participate in four sessions of making activities. On the last day, students gave poster presentations to students and teachers in the participating elementary school and makers from the local community.

Data analysis

We analyzed the post-interviews with the purpose to understand students' design goal, and their motivation in the workshop, what difficulties they had and how they solved problems they had during the workshop. With the analysis, we found a girl, Meimei, a fifth-grade student, who explicitly demonstrated interest in design and challenged advanced materials. Meimei's story was the epitome of how 25 migrant girls engaged in our workshop. We applied video analysis on Meimei and her partner Lei's work in classroom. Based on Meimei's interview response, we focused on the difficulty Meimei faced in classroom, and re-watched video of focusing on what Meimei's team has learned through making, their attitudes towards making, and how they collectively work on the project and solve problems.

 © ISLS

Results

In the post-interviews, seventy percent of the groups mentioned the most difficult parts were 1) calculating hat dimensions from measured head circumference and 2) sewing the circuit. And fifty percent of the groups recognized the importance of working with their teammates to solve problems collaboratively. Meimei is one of the girls who explicitly said her dream is to "be a fashion designer" in the future, and she was very interested in fashion and design. Meimei was a member of the Art Club, and she was one of the few students who tried to connect a tri-color LED in her in design. In Meimei's interview, she also mentioned that she faced several problems like other students, such as measuring and sewing the circuit. But her intrinsic motivation to advance her design helped her to explore how to sew the circuit.

Meimei's case: sewing a circuit with her partner

To better understand how Meimei was engaged with workshop, we focus on Day 3, the first day when we introduced circuits to students, with the goal to light up an an LED light on their hat. We found Meimei and her teamate Lei worked collaboratively to solve problems and actively participated in the workshop. Through tinkering with the materials, they recognized the concepts of positive and negative ends in an electronic circuit. In the beginning, Meimei's group had difficulty connecting the circuit. Lei, Meimei's teammate, sought help from teachers and peers, while having Meimei concentrate on tinkering with their toolkit. They both participated and allocated their time wisely. After getting brief facilitation and rounds of tinkering, Meimei started to sew the circuit on their hat, while Lei observed and offered verbal instructions. There was a moment that Lei pointed out that the circuit was in the wrong direction. Then she pointed it out to Meimei. But Meimei was confident of the direction because she identified the negative end of the circuit. Here, Meimei used a formal science term, "negative end," to refer to the direction of conductive thread, a concept she had never learned. Meimei mentioned the lights were in different shapes as she thought, but she seemed comfortable with the new materials. Applying formal science language to unfamiliar materials is a sign that Meimei started to understand the concept. Besides, during the workshop, Meimei and Lei were always collaboratively and actively participating in making. When they were sewing a circuit to their hat, Meimei was in charge of sewing at the beginning. Lei soon nudged Meimei and said, "Let me sew, let me sew, let me sew." Meimei secured the knot for Lei and passed her the needle. Even though only one of them was needed to sew the circuit, Meimei offered Lei help and observed her sewing closely. In their collaboration, they found ways to address each other's feedback and suggestion. They also rotated roles so that they both had almost the same amount of time to try working on the materials. There were also examples of Meimei and Lei working closely together on their project in the video data, we hope to present more data in our final presentation.

Significance

In this study, we designed a low-cost e-textile workshop for migrant girls in Shenzhen, China. Within the one-week workshop, students worked in groups, designed a hat, and sewed simple circuits on their hats. In our post-interview analysis, young girls mentioned the workshop was "a meaningful learning experience for learning electronic circuit, sewing, and design" and "would love to introduce the workshop to our friends." Our focused analysis on a girl named Meimei demonstrated how she took the initiative in her hat design project, overcame difficulties, and collaborated with others. Our workshop provided girls with different learning experiences as they claimed. With our follow-up communications with the participating school in 2021, the participating teachers were able to run another round of e-textile in the school. This also showed the potential to design accessible, meaningful hands-on integrated STEAM learning activities for young girls. We call upon maker educators and curriculum designers in China and other countries who are interested in gender equity to consider learning through making and develop activities relevant to students' local communities.

Eliciting Multimodal Strategies: Early CT Assessment by Design

Lise Welch, Deborah Silvis, Jody Clarke-Midura, Jessica Shumway, Utah State University
Victor R. Lee, Stanford University
lisewelch@hotmail.com, deborah.silvis@usu.edu, jody.clarke@usu.edu, jessica.shumway@usu.edu, vrlee@stanford.edu

Abstract: Performance assessments can provide meaningful insights into young children's knowledge; however, documenting assessment responses as incorrect or correct limits our understanding of students' abilities. One method of improving our ability to measure student understanding is by documenting the strategies students use to engage with assessment tasks. In this study, we describe how purposeful assessment design can provide insight into students' thinking by qualitatively examining how students solve performance assessment items using multimodal strategies.

Introduction

Performance assessments allow for documentation of the process used in solving a task and the outcome. For example, the Research-Based Early Math Assessment (REMA; Clements et al., 2019) documents correct and incorrect responses as well as additional student response codes. These additional codes, called strategy codes, provide insight into *why* a student may or may not answer the assessment questions correctly. Accounting for the *strategies* (student performance observables) students use makes it possible to interpret student understanding, not just discrete skills. This paper describes how purposeful assessment design can provide insight into students' thinking by examining how students solve performance assessment tasks using various multimodal strategies. We designed our assessment to measure computational thinking (CT) in early childhood. We begin by describing a design process for building an early childhood CT assessment, then present an analysis of students' strategies in responses to assessment items. Finally, we discuss how students' multimodal strategies allowed us to interpret their CT skill understanding.

Framing perspectives

We used the Evidence Centered Design (ECD) framework to design our assessment, an approach in which designers make explicit the behaviors and evidence associated with specific tasks. ECD is designed around fundamental questions about whom we assess, for what purposes, and under which constraints. The five layers of ECD include: (1) domain analysis, (2) domain modeling, (3) the conceptual assessment framework, (4) assessment implementation, and (5) assessment delivery (Oliveri et al., 2019). In the first two layers, the focus is on the purposes of the assessment, the nature of knowing, and structures for observing and organizing knowledge. In the third layer, the focus is on the student model (the skills being assessed), the evidence model (how do we measure it), and the task model (situations that elicit the behaviors/evidence). In prior work, we have written about the first three layers in our assessment design process (see Clarke-Midura et al., 2021). In the present study, we focus on the conceptual assessment framework (CAF). We designed our assessment to measure early childhood computational thinking (CT), which involves "the conceptual foundation required to solve problems effectively and efficiently…with solutions that are reusable in different contexts" (Shute et al., 2017, p. 151). We view coding as an important context for developing CT and use tangible robot coding toys as a context for promoting CT.

Participants, data, context

Seventy-seven kindergarteners (5–6 yrs.) in two Title 1 schools (n=17, n=60) in the western United States participated in a pilot CT assessment. The interview-based format accounted for kindergarteners' emerging literacy skills and took about 15 minutes to administer. We analyzed video of 77 participants responding to 14 pilot assessment items (approximately 9.5 hours). Students were asked in the assessment to enact, sequence, or debug programs depicted by coding cards in order to move an agent (a small figurine) around a 10"x10" grid. The program codes consisted of four directional arrow commands that instructed the agent to move forward, backward, rotate left, and rotate right. For example, in Algorithmic Thinking item 8 (AT8), children were asked to write a program (FORWARD, FORWARD, ROTATE LEFT, FORWARD, FORWARD) for moving the agent from one point to another as marked on the grid. This current analysis focuses on the *strategies* children used to reach this goal- not the programs or *products* themselves.

Data analysis

 © ISLS

To understand students' strategies, we asked two questions: *What strategies do children demonstrate?*, and *Do students use these strategies to engage in the assessment tasks?* We conducted iterative rounds of qualitative analysis of the assessment events. First, we conducted iterative rounds of open coding to systematically document assessment strategies for sub-sets of items designed to measure specific CT components. Next, we applied focused coding to categorize observable indicators and identified three engagement modalities: *gesture and body movement* (G), *interacting with the assessment materials* (M), and *language/sound use* (L).

We observed G strategy indicators in students' head movements, hand gestures, and body orientations. An example of a G strategy is *gestures along path in various parts,* wherein students trace a path with their finger. When exhibiting M strategies, students moved the agent and/or manipulated coding cards. Students using the M strategy *enacting incremental movement* might move an agent in a hopping motion. L strategies provided insight into students' thinking through students' use of directional language (i.e., forward, turn), number words (i.e., two, one more), sequencing language (i.e., first, then), and nonsense sounds (i.e., onomatopoeia, popping sounds).

Some strategies were multimodal, meaning students demonstrated the strategy using two of the three primary modalities. For example, some students used the *make a sound for each enacted movement* by attaching a nonsense sound to each agent movement, combining M and L modalities. We accounted for multimodal strategies by adding the categories *gesture and movement + material use* (G+M), *material use + language use* (M+L), and *language use + gesture and movement* (L+G) (See Table 1).

Table 1
Number of Strategies Categorized as Each Modality

	G	G+M	M	M+L	L	L+G
Total Strategies (*N=33*)	2	2	18	5	5	1
Observed Strategies (*N=26*)	2	2	13	5	3	1

Results

For AT8, students exhibited 26 of 33 pre-identified strategies. The most common strategies were *visually references the path and program* (G; 47% of students), *enacts/builds program in chunks* (G+M; 37%), *enacts with incremental movements* (M; 35%), *enacts program after writing it* (M; 27%), *puts multiple codes on a program at once* (M; 23%), and *tests the program while building it* (M; 15%). All other strategies were each used by 10% (n=6) or fewer students. We accounted for the different number of strategies per category by averaging the number of students using each strategy with the strategies/category. The average number of students using G were 17, using G+M were 12, using M were 7, using M+L was 4.7, using L were 5.3, and using L+G was 1.

Discussion

Designing early childhood assessments to elicit students' knowledge through multimodal means allows preliterate learners to demonstrate their knowledge, which may otherwise be inaccessible through traditional assessment measures. For example, a student using the *enacting incremental movement* strategy moved an agent in a hopping motion when enacting a program. By using this strategy, the child indicated an understanding that one code equals one discrete movement, a critical skill for programming in early grid-based CT contexts. Applying an understanding of one-to-one relationship is also a key skill in early childhood mathematics. Only examining a student's final answer limits an assessor's inference of student's knowledge to a single point of evidence whereas connecting strategies to a student's performance provides multiple inference points and a more comprehensive perspective of a student's knowledge. Increasing points of inference is important for implementing equitable assessments with preliterate children and for operationalizing computational thinking in early childhood.

Abstract: This poster presents emerging strategies for engaging students in extended investigations with computational modeling. Drawing on the literature on modeling and co-design with teachers over a year, we present 3 strategies and describe how they support student sense making and learning: 1. Curricular coherence and consistency; 2. Integrating multiple forms of data and modeling while foregrounding uncertainty; and, 3. Enabling unpacking blocks as a way to balance between ease of use and expressivity in modeling.

Introduction & Background

There is considerable research exploring how, through design and pedagogy, educators can lower the barrier to computational modeling. Modeling environments that make use of accessible media like domain-specific toolkits (e.g., Kahn, 2007; Wilkerson, Wagh & Wilensky, 2017) ease the technical aspects of programming, whilst pedagogical approaches such as bifocal modeling (Blikstein et al., 2016) support conceptual aspects of computational modeling. Thus far, however, much of this work has involved one-time or short exposures to computational modeling through specific projects or activities. Less is known about how to make computational modeling a *sustained* practice in classrooms.

This poster presents a design-based research study that seeks to design for and study the role of sustained engagement in computational modeling in middle school science classrooms. We build on the broader modeling literature in which extended investigations with modeling and iterative refinement are part of what students do (e.g., Lehrer & Schauble, 2012) to identify three strategies: 1. Coherence and consistency: By "coherence", we mean repeatedly revisiting a small set of disciplinary core ideas from multiple perspectives to pursue extended investigations (Lehrer & Schauble, 2012). Prior work has shown that linking multiple units with a core conceptual idea helps by providing a broad range of contexts to make sense of a conceptual idea (Fortus et al., 2015); 2. Integrating data and modeling: Physical experimentation is a common practice in many middle school science classrooms. We leverage this practice by juxtaposing data and modeling to highlight--rather than dismiss--discrepancies between models and data, bringing noise, uncertainty, and intrinsic differences between them (Blikstein et al., 2016; Gouvea & Wagh, 2018), and, 3. "Unpacking" blocks: We propose the construct of *unpacking* blocks to balance between ease of usability and expressiveness in domain-specific modeling environments.

Design methodology

Our aim in this poster is to present design strategies that have emerged as important through teacher co-design for engaging students in extended investigations through computational modeling in science class. We iteratively refined and modified the A2S modeling environment and unit design through monthly co-design sessions with 4 middle school science teachers over 1 year and an additional 4 teachers over 6 months, a 3-day intensive co-design workshop with 8 teachers, and observations and design reflections from 224 students engaging with the units in science class. Out of 4 target units, we have developed and implemented 2 curricular units.

Findings: Design strategies for sustained computational modeling

Below, we present the design manifestation of each of the three design strategies.

Coherence & consistency

Based on teacher feedback, we use diffusion or the movement of particles from high to low concentration as a disciplinary core idea in the first two units. In one unit, students examine how diffusion impacts ink spread in

 © ISLS

hot and cold water, and in a second unit, they examine how it impacts the spread of wildfire smoke. To underscore that the same disciplinary idea relates to both units, the library of blocks for particle behaviors the two units in the modeling environment considerably overlap. For instance, random movement ("move"), particle collisions ("bounce off") and behaviors representing student ideas such as combine ("attach") or disappear ("erase") are present in both block libraries. In the poster, we will present whether and how students attend to, make sense of and link identical behaviors in these two different phenomena.

Integrating data and modeling

We aim to build uncertainty into student investigations through data to create resistances for students to consider, tackle and possibly resolve (Manz, 2015). The A2S modeling environment enables students to link modeling with real-world data. In the first unit, students build and compare their models with a video of an experiment they conduct in class. In the second unit, they build and compare models with satellite videos of smoke spread from California wildfires. In the poster, we will present how students engage in integrated data and modeling practices to make sense of target phenomena.

Unpacking blocks: Balancing ease of use and computational expressivity

The goal of "unpacking" blocks is to enable students to be able to open up a defined block to view and modify its definition. The idea is for students to be able to view and redefine how a domain-specific behavior such as "interact" or "move" is encoded and enacted. For instance, students can define interaction between two particles as them bouncing off of each other or combining together or one particle changing another particle's color. Conceptually, this is a place for students to test their theories about agent level mechanisms, and how they can impact the model. In the poster, we will present whether and how unpacking blocks provides a way for students to computationally express more sophisticated conceptual ideas in code.

Discussion

This poster contributes to the literature on computational modeling by examining design strategies that can support students and teachers in classrooms to engage in extended investigations with computational modeling. In the poster presentation, we will present each of these strategies and how they enable students to engage in sustained modeling investigations of two different phenomena. We will also reflect on some of the challenges in designing for extended investigations in computational modeling.

Learning health sanitary practices through scaffolded questioning in interactive eBooks for young children

Ju Hui Kang, Gi Woong Choi
kang2ji@mail.uc.edu, giwoong.choi@uc.edu
University of Cincinnati

Abstract: Adult assistance during the usage of digital devices may not always be available for children in certain circumstances. Taking this into account, we seek to study how far young children can learn in a scaffolded environment through interactive eBooks without adult intervention. Using the topic of learning sanitary hand practice concepts, the eBook will use scaffolded questioning methods to guide the child in the self-learning process.

Introduction

Since the pandemic, children's dependency on digital devices has increased with the number of work-at-home parents and quarantine lifestyles (Wong et al., 2021). This adds to the issues where parent/teacher direct supervision in informal learning environments may not always be available, especially for those not as privileged to have that timely and economical benefit. Meanwhile, the significance in health awareness education has also risen, where many digital learning platforms using different instructional methods emerged to help children learn related issues and information during the pandemic (Tiwari, 2020).

The usage of interactive eBooks or mobile apps as a medium between an adult and a child for educational purposes have been examined. Some have looked into the strategies that are used to steer the learning process (e.g. Tiwari, 2021), and some have investigated how scaffolding methods during mobile and science-related learning increased performance and motivation (Callaghan & Reich, 2021; Georgiou & Angeli, 2021). Uscianowski et al. (2018) examined storybook sharing methods, which was effective in easing the cognitive understanding process for young children. Saliminen et al. (2021) studied the usefulness of scaffolded dialogues in toddler classrooms which enhanced learning in academic activities. However, there is a need for further research on scaffolding features that contribute to the success of young learners (Shoukry et al., 2015, as cited in Callaghan & Reich, 2021). Therefore, this study seeks to expand existing theory by identifying how young children can cognitively process and engage in understanding the importance of health practices through eBooks. Our research questions are: 1) What aspects of scaffolded messages through technology are most effective for children during the early learning stages? and 2) How much are they able to foster deeper learning by themselves with the guidance of scaffolded eBooks?

Theoretical background

Scaffolding uses cognitive support methods which are known to be an effective strategy towards young students who especially need help in learning difficult tasks (Georgiou & Angeli, 2021). Diverse scaffolding methods exist, such as feedback using hints to foster motivation and guidance (Callaghan & Reich, 2021). Salminen et al. (2021) mention the importance of dialogue with early child learners as it helps them build “deeper thinking and communication skills through shared meaning making” (p.13). Like feedback and dialogue, questioning approaches help children develop reasoning and reflection of their own thoughts (Uscianowski et al., 2018; Wasik & Jacobi-Vessels, 2016). Since the use of praise with feedback can stimulate learning and connect real life situations (Callaghan & Reich, 2021), we will integrate questions in quiz form with their corresponding feedback into the eBook in lieu of adult questioning methods to probe deeper thinking (Wasik & Jacobi-Vessels, 2016).

Overall layout of the eBook

The design of the eBook will apply a storybook flow using the topic of teaching sanitary health practices in relation to the pandemic era. It aims to use scaffolded questioning and feedback methods in the form of hints and answers to guide preschool and early elementary children towards comprehending new concepts. The story will incorporate structured questions, feedback, and dialogue in the form of hints along the journey for the child. As an example (see Table 1), the first quiz will be presented after the opening narration and will question the actions needed after an outdoor activity. It will be examined if this will help replace the role of an adult questioning the

 © ISLS

child about a certain topic before delving deeper into the contents (Wasik & Jacobi-Vessels, 2016). This narration will guide the reader to reflect on everyday activities until they reach the quiz probing self-thinking towards the topic to be learned throughout the book. Praise and hints will be used to provide encouragement and instruction for the children when they answer the quizzes (Callaghan & Reich, 2021). As an additional function, an audio option will be provided in consideration for children with different needs, such as age-based, or those with dyslexia and the visually impaired (Tiwari, 2021; Chang et al., 2022). This button feature next to the written text will read aloud the sentences for the children, hence, becoming an interactive feature and acting as a role for the need of adult supervision when understanding the writing.

Table 1

Screenshot examples of quizzes and feedback in prototype

Quiz	Answers	Feedback/Hints (incorrect answer)

Future work and implications

With our prototype, we plan to investigate how interactive eBooks can be used as a scaffolding tool to aid young children in understanding health-related concepts. We plan to observe how they navigate through the eBook and how questioning can scaffold their understanding of sanitary practices during pandemics and flu seasons. While previous research examined teacher/parent and child interaction (Chang et al., 2022; Callaghan & Reich, 2021), this study will probe into how far technology can itself play the role of a physical adult, and how far into the learning process should the scaffolding be preserved (Georgiou & Angeli, 2021). In addition, the study hopes to provide information for creating instructional methods directed at young children for diverse needs, including those who cannot always be supervised by an adult during a digital learning process.

Abstract: We draw on notions of space-making as relational and constituted in interaction to explore how teaching artists construct space as power is redistributed in the online theatre classroom. We use case study methods to illustrate how the shift in power has impacted the design of online learning environments. Findings highlight tensions and possibilities for how power is negotiated and the importance of student voice, with implications for the design of more equitable online learning spaces.

Introduction

In the wake of COVID-19, the shift to online instruction has raised new questions, tensions, and possibilities for how power is distributed amongst teachers and students in the classroom. Such a shift in power can be observed through the way space is created within online settings. In the arts, which often involve voluntary activities and tap into learners' inherent interests, it is especially compelling to explore how power has been negotiated within online learning spaces and how that shift has impacted the design of online learning environments. In this poster, we turn to teaching artists who have shown to be adaptive and innovative during the present pandemic times (Dahn et al., 2021) to address the following research question, *How do teaching artists negotiate power relations in the co-construction of online spaces for theatre learning?*

Space-making: New possibilities and tensions for the online theatre classroom

This poster is grounded in notions of space-making as both physical and socio-culturally constituted through interaction (e.g., Massey, 2005). The shift to online learning amidst the COVID-19 pandemic has presented new possibilities and tensions for making space together in classrooms. The theatre/performing arts classroom in particular presents a special case in which power is negotiated, highlighting student voice and positioning students as authors of their own learning. While conventional teacher-student power relations tend to be hierarchical, with the teacher holding authority over the student, some pedagogies disrupt this dynamic by granting students more power in classroom interactions (e.g., Matusov et al., 2019). The shift online presents such an opportunity for reshaping classes as a more equitable and shared space, and positioning students as having voice and agency (Mills & Comber, 2013).

Methods

Chicago Arts Partnerships in Education (CAPE) is a Chicago-based, non-profit arts organization that fosters long-term partnerships between Chicago Public Schools teachers and CAPE teaching artists toward inquiry-driven arts-integrated curriculum in K-12 classrooms and afterschool programs. Our study is part of a larger project, situated in the context of CAPE's initial shift to online arts instruction between March and August 2020 following teaching artists' transition to remote instruction. We focus on a summer theatre class as a case study to understand how teaching artists negotiated power relations in the co-construction of online spaces for theatre learning.

We took an illustrative case study approach (Stake, 1995) to investigate the transformed power relations between teachers and students within the digital space, the resulting tensions, and the impact on the construction of space. Through one CAPE teaching artist's experience, we illuminate key components of the digital space, as impacted by a shift in power. Theatre teaching artist Sonja had been with CAPE for 4 years and for her summer theatre class with elementary school students, she co-constructed with her teacher partner and students a virtual space toward addressing the following inquiry question: *How can theatre help us process our experience of quarantine?* Through an iterative thematic analysis of a semi-structured interview with this CAPE teaching artist and a multimedia reflection post written by the teacher-teaching artist pair, we highlight emergent themes around the construction of online spaces for the theatre classroom during unprecedented circumstances that altered existing power relations.

 © ISLS

Findings

Shifting power relations toward more equitable online learning spaces

The collapse of the physical space to an arguably more restricted, digital one within the theatre classroom prompted teaching artist Sonja to consider the question of what learning is now available when "there is no 'room'," what was once essential for rehearsing and performing in a shared space, and for taking chances. By its very nature, the digital space has the potential to constrict learning opportunities, due to the sizable lack of a shared physical space to support collective inquiry, characteristic of the theatre classroom. As Sonja mused, "without the room uniting us (...) how do we go after things that are individually challenging or difficult?"

Indeed, students in Sonja's summer class were less likely to go outside their comfort zone and engage in the same way they would have in the physical theatre classroom, with some deliberately turning their camera away when approached to participate in a task that made them uncomfortable. As Sonja noted, "You could start talking about democracy. Power, you know, all these other things that have shifted when we all have the same screen, space on the screen and anyone can just click their thing and be gone." The digital space thus embodied a shift in power, with students electing in which activities to participate and becoming authors of their own learning. Though the space for learning may have been restricted by the digital platform, in limiting risk-taking and experimentation, it also allowed students to participate and engage in ways that they see fit, constructing a more equitable learning space.

Foregrounding the relational nature of space-making

Despite the noted challenges and tensions, opportunities emerged in the relational nature of space-making, which necessitated a change in expectations and a prioritization of class structures that honor students' needs. Keeping students engaged and present thus became the highest priority in constructing online spaces for learning, involving the construction of a social space that recognizes the limitations of the present and nurtures an atmosphere that looks to "protect the fragile ecosystem of our collective." What that essentially meant was "meeting kids where they're at," as to "keep them with us." In the case of Sonja's theatre class, the collapse of the physical classroom was mirrored by the collapse of existing power relations, which guided the construction of a space that was predicated on relationships that aimed to build connection as the primary goal in the design of the learning space.

Sonja and her teacher partner supported the relational nature of space-making through embodied activities, foregrounding the social space of the online classroom, by prioritizing routine in the form of regular check-in's with students and theatre games, reminiscent of pre-pandemic times. To preserve the performance aspect of a theatre class, in constructing the digital space, Sonja and her teacher partner centered individual performance through first, having students memorize monologues, and later, having students write and perform their own original monologue around their quarantine experience. In shifting the focus of performance to the level of the individual, individual experiences and student voice were highlighted and honored. Constructing digital spaces for theatre learning in particular, which is highly reliant on establishing a connection, could thus benefit from self-expression in opportune places.

Toward sustaining connection for its own sake

This study explored the shifting power relations within the digital space and the resulting tensions and implications for the construction of online learning spaces. Sonja's case foregrounded that "connection for its own sake" is more than enough, and "may potentially be both the most urgent achievement, and the lowest common denominator," considering that students can opt out at any point. The digital theatre classroom observed a shift in power and a more equitable class structure, which is arguably unique to the theatre classroom, with the arts often elective and voluntary, making it especially pertinent to keep students present. In reshaping expectations and meeting students where they are at, teaching artists could support students in their learning and together turn challenges into opportunities.

Promoting Authentic Research Experiences in the High School Classroom: Opportunities and Challenges

Jimmy Couzens Naipaul, Stony Brook University, jimmy.couzennaipaul@stonybrookmedicine.edu
Ido Davidesco, University of Connecticut, ido.davidesco@uconn.edu
Noah Glaser, University of Missouri, drnoahglaser@gmail.com

Abstract: This study examines the nature of student experiences conducting open-ended scientific investigations as part of a new high school neuroscience curriculum. Semi-structured interviews with program participants (37 students and 25 teachers) revealed both challenges, mainly reading primary research articles and making sense of data, as well as opportunities for increasing students' self-efficacy and college readiness. These findings can inform future efforts to promote authentic research experiences in K-12 classrooms.

Background

Despite efforts to promote inquiry-based learning, many K-12 science classrooms, especially in underserved schools, still heavily rely on direct transmission of pre-packaged knowledge, and practical work that does take place is often overly orchestrated, not allowing students to experience the open-ended investigative nature of science (Burgin, Sadler, & Koroly, 2012). By engaging students in authentic scientific inquiry, they can gain an understanding of the dynamic nature of science as a process that involves developing theories, testing them empirically, and then revising the theories based on data (Schwartz & Crawford, 2006).

To address this need, our team has developed a semester-long neuroscience curriculum for high school students ("*BrainWaves*") that emphasizes student-led investigations. In this program, students first learn about neurons, brain anatomy, and brain plasticity, and then, with support from science mentors (Ph.D. students and postdocs), develop a research question of personal interest to them (e.g., how does listening to music affect learning), read background literature, design an experiment, collect data from their peers, analyze data, and share their findings at a culminating program symposium (Azeka, Carter, & Davidesco, 2020).

In the current study, we asked how students and teachers experienced the process of conducting open-ended science investigations, what kind of scaffolding students needed, and what kind of challenges and opportunities were encountered in this process. This work is grounded in participatory inquiry learning, a sociocultural perspective on learning that emphasizes rich, authentic problems and co-construction of knowledge and ideas with community members (Barab & Hay, 2001).

Methods

To address our research questions, a phenomenographic methodology was deployed (Larsson & Holmström, 2007). Phenomenography is a research approach used to describe the different perspectives of people (in this case, students and teachers) and to understand a phenomenon (here, open-ended scientific investigations in the classroom). To that aim, semi-structured interviews were conducted with all 25 teachers who implemented the neuroscience program between 2018-2021 as well as with 1-2 students from each classroom (37 students total). All teachers and students were from public high schools in a large northeastern city in the United States. The interview questions were designed to help researchers understand students' past experiences in science classes, their experience in the program, and their outlook on science and college preparedness. Interviews lasted approximately one hour and were audio-recorded with the participants' consent.

Transcribed interviews were coded through a thematic analysis process outlined by Braun and Clark (2006), which suggests a six-step framework of, (1) familiarizing oneself with the data, (2) generating initial codes, (3) searching for themes, (4) reviewing themes, (5) defining and naming themes, and (6) producing the report. Two trained researchers conducted the analysis and met frequently to discuss and refine the codes and how they were operationalized. Following preliminary data analysis, the research team grouped codes into broader overarching themes by analyzing the statements associated with each code.

Findings

Four overarching themes emerged from both students' and teachers' perspectives. First, there were reported challenges in conducting background research. Some students struggled with finding relevant literature, while others felt overwhelmed by the amount of literature that emerged from their search. There were also reported challenges in understanding scientific jargon and the basic structure of research articles. For example, one of the students reported: "I have never read that type of scientific literature, it was a new experience… For one it was a

lot harder to read. Some of the ones we read were like stuff you can get from google scholar, but other stuff was like well there is this really obscure thing with words that we do not even know. So we had to search what things meant, like what is the amygdala and the drugs they use to turn it off and other things." This sentiment was shared widely with another student remarking, "It was like I want to say confusing but like brand new it has the abstracts and it is different from other articles that we read in my prior science classes."

Second, interpreting data, especially when it contradicted students' hypotheses, was a challenge. This often resulted in students focusing on aspects of the data that supported their hypotheses. For example, one teacher reported: "I think the idea of being open to whatever your data shows you is important because a lot of times students are looking to prove their hypothesis and so it is difficult for them to first of all understand that they are just supporting their hypothesis and but also the fact that their data might disprove their hypothesis."

Third, findings indicated that support and scaffolding was a key element in shaping students' experiences of conducting research. For example, one of the teachers pointed out that "the science mentors came in and they really helped me when it came to checking the proposals before they started it and checking their research questions and methods, which was all part of their proposal. That was really like the big chunk of like making sure that they were going in the right direction before they actually got started." Similarly, a student commented, "Oh yes the mentor showed us how to identify if a site is credible or not and she helped us to um factor in more variables and factor in things that could help us or affect the experiment that we were doing."

Lastly, despite the challenges, the overall experience of conducting research was highly positive. In particular, it seems that this experience helped increase students' self-efficacy and college readiness. One student told us: "I think it (the program) prepares us for college because if we have that experience and exposure now we won't receive that as a shock in college and say like oh my god what is this it is like no we need to know now so that we are not overwhelmed at college and end up failing the course." Relatedly, one of the teachers reported, "that was fun to see them sort of like kind of be able to become more independent learners and when they were proud of themselves when they came up with something unique."

Significance

These findings suggest that student-led research investigations can provide a rich context for students to develop their science self-efficacy. However, sufficient scaffolding and structure are needed to help students overcome challenges related to reviewing background literature and designing an investigation that can yield interpretable data. This work could help shape questions for further research, such as how to prepare teachers to support students' data practices. This work could also impact how teachers facilitate students' investigations while balancing student autonomy and curriculum requirements. At the conference, we seek to explore how these findings can provide direction for others seeking to bring authentic science research literacy into K-12 classrooms.

Positioning Self and Others Through Sympathizing, Empathizing, Anthropomorphizing, and Zoomorphizing: A Case Study

Adam Papendieck, Flávio S. Azevedo
apapendieck@utexas.edu, flavio@austin.utexas.edu
The University of Texas at Austin

Abstract: We investigate the relationship between learning and identity by analyzing students' positionings and attendant reasoning in the context of a university seminar designed to engage STEM undergraduate and graduate students in examining the broader impacts of their STEM fields and practices. Specifically, we highlight students' discursive use of sympathizing, empathizing, anthropomorphizing, and zoomorphizing as ways of projecting self onto humans and nonhumans, reasoning "as if the other."

Introduction and Theoretical Framework

Sociocultural studies of learning and identity have often highlighted processes of *positioning*—of self, group, and others—as key sites for investigating students' *reasoning*, disciplinary (Bell, van Horne, & Cheng, 2017) and beyond. Here we contribute to these efforts by analyzing how students reason to position themselves and their science in socially and ethically articulate ways. The student discourse and interactions we study played out in a university seminar designed to engage STEM undergraduate and graduate students in examining the broader impacts (societal, cultural, environmental) of their STEM fields and professional practices.

We borrow from sociocultural and critical theories of learning and frame identity as lenses through which one positions oneself (through discursive moves; Gee, 2001) and through which other practice participants position such a person relative to socially and culturally relevant categories, locally or more broadly defined (Azevedo & Mann, 2021). For example, in the context of schooling children develop academic and disciplinary identities—say, as "good," "average" or "bad" students and as "doers" or "non-doers" of mathematics or science—and these processes are seen in the mutual, reflexive positionings of individuals and their interacting parties, both peers and teacher (Bell, Van Horne, & Cheng, 2017; Nasir & Saxe, 2003).

Empirical Context and Methods

Data for this study were drawn from a larger, ongoing project of design-based research (Barab & Squire, 2004) on a three-credit semester-long course taught by the first author on the broader social and ethical impacts and consequentiality of science. While offered via a geosciences program, the course drew students from many STEM disciplines, including geology, environmental sciences, physics, math, computer science, STEM education, and others. A total of 26 students were enrolled in the two semesters it was taught, approximately 42% of whom were female. Our data corpus consisted of 48 whole-class forum discussions, over 66 hours of recorded video of Zoom-based class discussions, three iterative drafts of issue investigations for every student, and the readings and resources that students assembled and cited in framing their issue investigations. The research team systematically examined these as artifacts of student participation in the course, independently logging aspects of their work that revealed the ways they reasoned about their science and identity, and meeting periodically to share and code logged data.

Analysis and Results

We identify four highly visible ways that students positioned self and others in thinking ethically about their discipline.

In mathematics, *homomorphism* refers to a variety of ways that one mathematical structure might be mapped onto another of similar form, and here we have adapted the word as a general term for a number of kinds of *empathetic* and *sympathetic* reasoning where students identify themselves with other humans. In responding to a writing prompt about whether science can be good or bad (as opposed to neutral), Caroline made the rhetorical choice to humanize science, reasoning that science is carried out by scientists, who are, after all, people: "I probably believe in 'good' or 'bad' science to some extent but it's kind of like believing in 'good' or 'bad' people." (written reflection, Jan 20, 2021). This kind of homomorphizing enabled her to *sympathize* with science, and map characteristics, imperfections and accountabilities she knows as a human onto science as a group of humanized others. Students also reasoned empathetically. In response to another student discussing the historical mistreatment of certain groups by scientists, Aiden agreed and posed the rhetorical question: Considering this history of mistreatment, "why would those other groups now start to simply accept scientific discoveries at face

 © ISLS

value?" He did not include himself in "those other groups," but rather *empathized* with them in a way that allowed him to push back on received Western notions of science as objective, neutral and uniformly beneficial.

Anthropomorphizing refers to ways of attributing human characteristics, behavior, and feelings to nonhuman things in the world, be they living or otherwise. One culturally ubiquitous example of anthropomorphizing that clearly permeated the discourse of the students was their reasoning about *mother earth*. Prompted in the first week of class to write about her scientific interests, Rebecca, a geology major, described her research on geothermal energy as the study of "how we can use the heat that comes from Earth's center in a way that doesn't hurt our Earth," revealing anthropomorphic reasoning that positioned her in care of the earth (written response to prompt). Responding to the same prompt, Sylvia, an undergraduate in environmental science, showed signs of anthropomorphic reasoning for similar positioning, writing about "the world" as something she wants to "give back to," in part by figuring out "ways in which humans can join with the world" and better understand the "world's problems" (written response to prompt).

Finally, *zoomorphism* is a type of discursive device where traits of non-human living things are imagined in or ascribed to humans (c.f. anthropomorphizing human traits to non-humans). We use *zoomorphizing* to refer to a type of positioning move through which a person maps or ascribes aspects of non-human *living things* to humans. In the closing passage of Caroline's final paper on anthropocene science, she presented a brief vignette about a neighborhood walk that she frequently took past a patch of cacti, cacti that had been impacted by an extremely deep and long freeze. Previously, Caroline and others had linked this freeze to anthropogenic climate change. In equating the "somewhat messy transition state" of the recovering cacti to her own self, Caroline formed an emotionally articulate relationship to the non-human world, and positioned herself as something of a cactus grappling with anthropocene conditions of climate change: initially "stalwart," then "defeated" by the freeze, now "naive and pliable," still vulnerable, but remembering and growing. Through this reasoning, she drew from the non-human world to pattern a characterization of her own affective state, and in doing so made some sense of her own identity as a scientist living in the Anthropocene.

Discussion and Conclusion

Acts of positioning self and others in the course of practice participation, moment-to-moment and over the long haul, are key events in which a student enacts and/or works out multiple identities relative to school subjects and disciplinary practices. Prior research has helped us understand students' identity work and development, attempting to work out terms for how one positions and is positioned by important *local actors* in the learning process (notably student peers, teacher, and parents) (e.g., Nasir & Saxe, 2003).

Our analysis adds to current understandings by (1) showing how student positioning considers actors more remotely detached from their daily lives and sometimes imagined/idealized (i.e. *distal "others,*" including non-humans), and (2) showing the ways in which students achieved these positionings (i.e., through discursive devices of sympathizing, empathizing, anthropomorphizing and zoomorphizing). Crucially, these various forms of projecting self onto human and nonhuman others (and vice versa) afforded students a means of *pivoting* into a different, imagined "world," much like Vygotsky's (1967) formulation of imaginary play. Here we find students' use of certain discursive devices allowed them to pivot into the imagined perspective of other actors, and to draw insights that would not be possible otherwise.

It is likely that students deploy a wide variety of subtly different strategies for *reasoning "as if the other*." For example, we note that *chremamorphizing* is a common way of writing that is similar to zoomorphizing, except that humans are ascribed aspects of non-living things. All of the discursive strategies of *morphizing* we have examined here appear to be particularly salient to and tractable in student's disciplinary identity work. This is due to both the conceptual *and* affective affordances they provide for knowing and valuing different imagined worlds, worlds that students might ultimately realize as more inclusive, equitable and just.

Enabling Self-Regulated Learning in MOOCs Using Community of Practice

Mingming Jiang, University of California, Berkeley, mingming.jiang@berkeley.edu

Abstract: One of the main reasons for learners to drop out from Massive Open Online Courses (MOOCs) is the lack of self-regulated learning (SRL) skills necessary to learn effectively in online environments with low levels of support and guidance. Although there is an agreement on the importance of SRL for MOOC learners, little research has examined which SRL strategies learners need help the most, or how to help them practice those strategies to further develop their SRL skills. This study identifies key SRL strategies that are crucial for MOOC learners to develop in order to improve their learning outcomes and increase course completion. Based on results from interviews and a questionnaire, recommendations were presented on using a chat feature embedded on MOOC platforms to enable the community of practice and help learners practice SRL strategies effectively.

Introduction

COVID-19 pandemic has enabled a surge in enrollment across Massive Open Online Courses (MOOCs) on platforms including Udemy and Coursera (Impey & Formanek, 2021). But MOOCs suffer from extremely high dropout rates of 90% or more, and the lack of self-regulated learning (SRL) skills can be an important factor that leads to high dropout in MOOCs (Terras & Ramsay, 2015). Nawrot and Doucet (2014) found that the most common reasons for dropping out from MOOCs can be related to time management and metacognitive strategies such as goal setting and strategic planning, both of which are part of SRL.

Although there is an agreement on the importance of SRL to improve learning outcomes for MOOC learners and reduce course dropout rates, little research has examined which SRL strategies learners need to develop the most, and how to help them practice those strategies to further develop their SRL skills. The purpose of this study is to identify key SRL strategies that are crucial for MOOC learners to improve their learning outcomes and increase course completion, and explore new features MOOC platforms can implement to help learners hone SRL skills. The study aims to answer the following questions: What are key challenges for MOOC learners to self-regulate their learning? Which SRL strategies can help MOOC learners improve learning outcomes the most? How can MOOCs be improved to help learners practice crucial SRL strategies?

Methods and data analysis

In order to understand key challenges for MOOC learners to self-regulate their learning, 15-minute interviews with 31 MOOCs learners were conducted. All were recruited from an email sent to a group of graduate students in a research university in the United States. They all had taken multiple MOOCs before and were in their late 20s to late 30s. 16 (51%) were female and 15 (49%) were male. Questions in the interviews focus on the learners' personal learning experiences, attitudes toward MOOCs, and key challenges learning in MOOCs.

To identify SRL strategies that are most helpful for MOOC learners to practice, a questionnaire aiming to evaluate MOOC learners' level of mastery of six different SRL strategies was sent to the same 31 participants. The questionnaire was adapted from the work of Kizilcec et al. (2017) with 18 statements (3 statements per SRL strategy) that participants can select on a 5-point scale (1=not at all true for me; 5=very true for me) how true each statement is describing them while learning on MOOC platforms. The questionnaire was implemented in Google Forms, allowing participants to make their selections easily on a likert scale.

Findings

Four types of challenges from MOOC learners emerged from the interviews: lack of time, boredom, lack of pressure or urgency, and lack of peer interactions. 74% participants mentioned the lack of time as a key challenge, and 77% participants mentioned boredom as an important reason that they dropped out. The third type of challenge for MOOC learners is the lack of pressure or urgency mentioned by 84% participants. One participant said, "I would love to have more strict deadlines and clear objectives for learning on MOOCs." Lack of peer interactions was named by 90% participants as another key challenge. According to one participant, "I want an accountability buddy to check in regularly on my progress and goals and to ask questions."

Most of these challenges the participants are facing as MOOC learners can be interpreted as needing to learn SRL strategies. For example, the lack of time can be interpreted as needing time management and goal setting strategies, and the lack of pressure or urgency can be interpreted as needing strategic planning strategies.

 © ISLS

The lack of peer interactions can be lessened by applying help seeking strategies. The qualitative data helped uncover key areas of SRL strategies that students should practice to overcome those challenges: goal setting, strategic planning, and help seeking strategies.

According to the questionnaire, elaboration and task strategies have the highest means, with 4.76 and 4.57 respectively, whereas goal setting and help seeking have the lowest means, with 4.10 and 4.19 respectively. It shows that participants have a high level of mastery of SRL strategies such as elaboration and task strategies, but need more support with learning about goal setting and help seeking. Elaboration has the lowest standard deviation of 0.42, whereas help seeking has the highest standard deviation of 0.83, showing a high variation of participants' evaluation of their mastery of help seeking.

The results revealed that goal setting and help seeking are SRL strategies that MOOC learners should practice the most, which also matched with interview data that goal setting and help seeking are two of the four challenges MOOC learners are facing. It is important to focus on learners with a low level of mastery in goal setting and help seeking, and design interventions to help learners build SRL skills more effectively.

Recommendations and implications

How can MOOCs be improved to help learners practice these SRL strategies like goal setting and help seeking? In order to foster help seeking, a sociocultural perspective is chosen because each MOOC includes a learning community. Because MOOCs attract learners with different backgrounds and levels of expertise, in the context of legitimate peripheral participation, some learners who are new to the subject are at the periphery of the community, whereas others are considered full participants (Lave & Wenger, 1991).

The recommendation proposed is an embedded chat feature based on the idea of connecting more advanced learners to learners who need help in a community of practice. When learners need help and open the chat, they can see a list of other learners who are available to help, as well as their learning score which has been calculated using the course surveys, their engagement on discussion boards, and their assessment results. The learning score shows the level of expertise a learner has on the subject, and can be seen as the learner's position in the community of practice. Learners are advised to ask for help from people with learning scores higher but not too high compared to their own scores. This simulates the community of practice, where more advanced participants help less advanced ones move closer to the center. After a learner identifies a potential helper, they can connect in real-time and work on the problem together.

One expected effect this solution will have on learners is that it can encourage them to ask for help, since the chat feature is part of the platform and is easy to access. By making it easier for learners to ask for them, this solution can help learners practice the help seeking SRL strategy. Another expected effect is that the learners can feel a greater sense of belonging to the MOOC community. They can realize that they are not simply individual learners, but learning community participants who can get help and offer help to others.

How young children pursue their interests with questions

Vien Nguyen(CO), Reed Stevens(CO)
viennguyen2026@u.northwestern.edu, reed-stevens@northwestern.edu
Northwestern University

Abstract: This case study is an investigation of how children pursue their interests and concerns in interaction with adults. This processual focus led us to study children's spontaneous questions, which have mostly been at the margins of research on children's learning and development. Our analysis found that questions are important interactional tools that allow children to simultaneously pursue their interests and concerns while also working within the familiar asymmetries of adult caregiver and child.

Introduction

One of Piaget's insightful ideas was that "There is no better introduction to child logic than the study of spontaneous questions" (Piaget, 1923, p. 162*).* Piaget himself did not really study children's spontaneous questions. Instead, he favored making inferences about children from their spontaneous *answers* to his questions and the tasks he posed for children. Mostly, developmental psychology followed Piaget in giving limited attention to naturalistic observation, favoring Piagetian style clinical interviews or experimental tasks as preferred methods. As a result, the topic of children's spontaneous questions has been largely at the margins of the study of children. This study seeks to make children's spontaneous questions and their role in children's lives and their learning more central.

More broadly, this study seeks to contribute to a line of research that establishes children's interests and concerns as a core topic for the learning sciences (Stevens, 2020). Our goal is to understand *what* children's interests and concerns are and *how* children pursue these interests and concerns. This processual focus has led us to children's questions. In this paper we build on an original insight of one of the founders of conversation analysis, Harvey Sacks, who identified a type of question children use that a) indicates an understanding of some of the basic machinery of conversation (i.e., adjacency pairs), b) recognizes their unequal rights in interaction with adults, and c) pursues their interests (e.g., getting 'the floor' in conversation with adults) in the context of this recognition. When children want the floor, they will often pose the question (to a parent or other adult caregiver), "Guess what?" That question invites an adjacent 'answer' in the form of another question from the adult, "What?". This responding question from the adult is then a first part of a new adjacency pair and the second part answer from the child is expected *and* gives them an open floor to share what they want to share (Sacks, 1972). We wondered: what are some of the other ways that children use spontaneous questions? What occasions spontaneous questions, what work do they do in interaction, and what do they tell us about children, particularly when embedded in the context of extended interactional sequences that involve joint projects and joint inquiry with adults (Goodwin, 2007; Keifert & Stevens, 2019; Stevens, Keifert, Davis, & Mehus, 2012)? We analyzed four cases from one family, centered around a 4-year-old boy named Ben, demonstrating how Ben uses questions to initiate, secure, and pursue his learning and project interests with his adult caregivers. In our discussion, we explore how these cases may generalize to other children and in differing family arrangements.

Data collection

The case study of Ben and his family is drawn from a large corpus of recordings collected with pre-school aged focal participants in their homes and at their preschools. The goal of this larger study was to directly investigate, rather than speculate about, how different home and school contexts organized learning and participation and how children responded. The methods that we used to analyze four segments selected from the recordings made with Ben's family involve interaction analysis of ethnographically collected video recordings (Hall & Stevens, 2015; Stevens, 2020). To select children's questions out of the much larger data corpus, we used previously coded content logs that identified children's questions. We then created a computer program to extract the portions of the content logs that identified children's questions and then looked at the frequency and density of questions within families and across families. This allowed us to identify extended segments of the recordings to transcribe and from these transcripts we selected the segments considered here.

 © ISLS

Summary of cases

For young children, adult caregivers largely control and structure their time, often around activities that adults regard as necessary. This was the case for Ben. Ben nonetheless used questions to find openings *between* these adult-organized activities to pursue his own learning and project goals. In the first case, Ben used request-centered questions to pursue a paper airplane project immediately after a family dinner, repeatedly seeking his mother's help even though she had arranged some time alone for herself. Ben also used questions to shape the substance of an adult-organized activity in the direction of a preferred interest of his with the recognition that it was not in his power to stipulate the activity. The second case shows how Ben's question moved the family to make his preferred pasta dish for the family's dinner. The third case showed how Ben uses request-centered questions to effectively restart a craft project by shifting collaboration to one parent, after recognizing that the other parent would not make herself available at the moment. Finally, even when Ben's projects got deferred, Ben used questions to work to be involved in new activities of his interest. This showed in the fourth case, in which Ben was collaborating with Dad on a craft project when Dad got diverted by a common household task (replacing batteries in a device). Ben asked a question similar in form to what conversation analysts call a pre-invitation (Goodwin & Heritage, 1990) to seek to be involved in the new activity of interest (replacing the batteries). Across the four cases, Ben used questions that indicated a dual recognition of his asymmetric rights in conversation and of basic machinery of conversation that would allow him to pursue his learning and project interests even with this asymmetry.

Discussion

In academic psychology, children's questions have received little attention despite Piaget's endorsement of what they might reveal. When they have been considered, they are almost always framed in narrowly cognitive terms, as information seeking utterances (Chouinard, Harris, & Maratsos, 2007; Davis, 1932). While we don't dispute this characterization, this analysis and others (Stevens, 2020; Keifert & Stevens, 2019; Stevens, Penney, Keifert, Davis, & Mehus, 2012) enlarge it significantly, suggesting that children are using request-centered questions as "social action" (Goodwin, 1990)—to organize and direct activities in their social and material worlds. Questions were interactional tools that allowed Ben to work around and through the familiar asymmetries of adult caregiver and child to pursue his interests and concerns. Of course, these examples are drawn from only one home and we expect important variations within families (Keifert, 2020), across families with different cultural backgrounds and families with different kin relations. Directed towards understanding *what* young peoples' interests and concerns are and *how* they pursue them in their everyday lives, this study contributes to a line of research that establishes children's' interests and concerns as a core topic for the learning sciences (Stevens, 2020).

Shifts in Positions, Epistemic Authority, and Epistemic Agency in a Secondary Mathematics Classroom

Nessrine Machaka, University of Illinois at Urbana-Champaign, machaka2@illinois.edu
Erika David Parr, Rhodes College, parre@rhodes.edu
Elizabeth B. Dyer, University of Tennessee, Knoxville, edyer@utk.edu
Christina (Stina) Krist, University of Illinois at Urbana-Champaign, ckrist@illinois.edu

Abstract: In this study, we investigate the interactional positions negotiated among students and the teacher during joint mathematical exploration in the classroom. Using qualitative coding of two video episodes in a secondary mathematics classroom, we found participants take up positions of uncertain knower and explorer in addition to positions of knower and actor identified in previous research. These additional positions help illuminate collaborative knowledge building and negotiation of shared epistemic agency and authority in learning.

Student collaboration and productive disciplinary engagement, such as exploration of disciplinary questions, is seen as a strategy to bring about meaningful learning but is still a challenge to support in classrooms (Damşa et al., 2010). Thus, it is crucial to understand teacher and student interactions that position students as active epistemic agents. We examine how joint mathematical exploration is established and maintained as students and the teacher investigate mathematical questions. We aim to identify the interactional positions the teacher and students take up as evidenced by negotiation moves. We investigate the following questions: (1) What positions do students and teachers take on while establishing and maintaining joint exploration? (2) How do shifts in positions reflect how epistemic authority and agency are distributed?

Theoretical Perspectives & Background

We combine a sociocultural perspective toward classroom interactions and positioning theory (Davies & Harré, 1990) as a theoretical lens to investigate the roles that teachers and students move between in instances of joint exploration. We define *joint exploration* as "the collaborative activity of investigating disciplinary questions and ideas among students and/or teachers through interaction" (Dyer et al., 2021, p. 548), and in which students and the teacher take on and shift between various socio-epistemic roles. Traditionally the teacher takes on a role of someone who gives knowledge and requests actions (Amit & Fried, 2005), and the student receives knowledge and performs actions. Within joint exploration, students would need to take on active roles in guiding the exploration process and in deciding when and how ideas are validated. Thus, this type of activity likely requires negotiation of authority over disciplinary knowledge and redistribution of epistemic agency. Previous research, using discourse analysis methods, has found that students take on and shift between positions of *primary and secondary knower*, as those who give and receive information, and *primary and secondary actor*, as those who request and perform actions (González & DeJarnette, 2015; Lo & Ruef, 2020). In joint exploration, rather than only exchanging information, individuals jointly explore and exchange strategies and may actively seek knowledge together, not in another individual, but tested and validated among the group. Therefore, we hypothesize that aspects of joint exploration include different types of negotiations, and thus, positions.

Methods and Data Sources

To characterize the teacher and students' interaction, we analyzed transcript and video of two episodes of joint exploration during small group work identified in a previous study (e.g., Dyer et al., 2021). These episodes occurred during mathematics lessons in a class with grade 10 and 11 students. We illustrate these findings using one episode of joint exploration when James, a student, poses a new problem when the teacher was with his group. The two students and teacher are not certain of the answer to this question in the beginning; however, it ends with students having consensus and the knowledge to answer this problem.

The first two authors coded the video and transcript of the two episodes using Lo and Ruef's (2020) group work positions coding scheme and resolved disagreements through discussion. These disagreements revealed positions not well-captured in the existing coding scheme. Thus, the researchers used open and axial coding to characterize the negotiation moves associated with these new positions as additional codes and applied the revised coding scheme to the episodes. These new codes included: "E1-Primary Explorer", "E2-Secondary Explorer", and "K1-U: Primary knower uncertain." Two researchers coded the episode with this revised coding scheme, checked for inter-coder agreement, and resolved any disagreements through discussion.

 © ISLS

Results

Our analysis found that individuals took on positions in which they were exploring ideas collaboratively and the "known" answer was not yet clear. Rather, the "known" answer was the object of their investigation. These positions are not adequately captured by the knower and actor in previous analytical schemes (Lo & Reuf, 2020). Thus, our analysis identified added the positions of "E1-Primary Explorer", "E2-Secondary Explorer", and "K1-U: Primary knower uncertain" (RQ1). The new positions of uncertain knower and explorer allow us to understand knowledge as not solely possessed by an individual but constructed through joint activity.

The position of *primary knower uncertain* captures negotiation moves that propose knowledge in a way that is tentative. This position happened while establishing joint exploration, such as when a student, James, suggested a possible solution. We were not able to accurately capture James' position by the "knower" positions, since James appeared to suggest a possible idea for others to consider rather than stating a relevant piece of information that he seemed to be confident about.

The position of *primary explorer* captures moves to seek knowledge through investigation when it is not known for certain. This position occurred while maintaining joint exploration when the students and the teacher sought knowledge that they did not yet have. For example, James took on a position of a "primary explorer" by leading the charge to find the solution. Unlike the primary and secondary knower, James did not have the knowledge that was being sought and was not seeking knowledge in another person. James is positioned with some knowledge of how to go about exploring that requires him to have intellectual courage and have a recognized epistemic authority, not simply request or perform an action associated with the "actor" position.

The position of *secondary explorer* captures moves that position people to support the investigation to seek knowledge. This position occurred while maintaining joint exploration. Sergey, the other student, supported the suggested exploration path and refined the offered solution. This position has less authority than primary explorer since the position follows the pathway that was led by the "primary explorer."

Positional shifts often coincided with the redistribution of authority and agency (RQ2). For example, James and Sergey shift from being the primary and secondary explorers to primary knowers and start seeking confirmation in each other once the solution has been tested. Similarly, a student took on a "primary knower uncertain" position while establishing joint exploration and transitioned to explorer positions in maintaining it.

Significance

The three new positions captured the interaction regarding the knowledge building in group work, including how students negotiated shared epistemic agency (Damşa et al., 2010). They offer a way to characterize negotiation moves that are at the heart of authentic collaborative learning, in which knowledge is not solely possessed by an individual but constructed through joint activity. Moreover, the shifts in positions illuminate the redistribution of authority and agency and how joint exploration is established and maintained. This study motivates thinking about the contributions of how teachers, educators, and curriculum designers might design and think about activities in a way that allows students to take on positions of explorers and teachers to redistribute epistemic agency.

Jim Slotta, OISE, University of Toronto, jslotta@gmail.com

Abstract: To help Chinese teachers understand and implement competency-based curriculum design, we established a teacher innovation community in China. During the summers of 2020 and 2021, K-12 teachers and researchers jointly designed STEM courses on climate change during 6-week workshops. Researchers use social platforms to share teaching experience to help teachers better understand and implement innovative courses.

Research background

Countries all over the world are vigorously promoting competency-based curriculum teaching reform. Since 2017, the Ministry of Education of China has begun to revise the syllabus of K12 schools, and put forward relevant concepts such as core literacy of Chinese students. But at present, most teachers still only focus on teaching content in the classroom, and don't really understand the competency-based curriculum design. This work presents a new study of a professional development community for K12 interdisciplinary teachers to design and enact new competency-based inquiry lessons.

Research questions

How can we best help teachers to complete a good design that they will actually use in their own teaching?
How can we help teachers make progress in changing their practice? How can we help them to help each other?

Methods

Design-Based Research is a method used to improve design practice and enhance the scientific understanding of how design affects learning (Barab & Squire, 2004). Design-based research is suitable as the methodology of this research, because it will help generate new understandings, theories, products and strategies, explain and potentially influence knowledge construction and learning in the professional community of teachers. We engaged in two cycles of design, in the summers of 2020 and 2021 respectively, with overlapping groups of teachers. We made revisions in 2021 based on the outcomes of 2020. Below we describe these methods

2020 Workshop:

The pretest revealed that almost 70% teachers have no project-based learning experience. The main objective of the 2020 summer workshop was how to design STEM inquiry units, and teachers met for six weeks to engage in design activities, working in teams. Teachers made use of the WISE (Web-based Inquiry Science Environment) platform to create interdisciplinary climate education projects.

Participants: There were 45 K12 teachers participating in six weeks of online workshops, from a range of disciplines, including science, math, language, social studies, geography and art.

Outcomes: ten teachers from ten schools developed lessons and tried them in classrooms (Figure 1).

Figure 1

Schools are implementing relevant courses on garbage disposal

Discussion: A startling outcome was that teachers did not risk letting students explore independently. Task-

 © ISLS

driven teaching was more comfortable, with teachers paying more attention to integrate subject knowledge into projects. Teachers did not fully understand the goals of project-based learning, and were cautious.

2021 Workshop:
The pretest revealed that most teachers have project-based learning experience. But did not understand the notions of competency-based curriculum designs, which was chosen as the main focus for the 2021 summer workshop. The workshop ran for five weeks, with weekly meetings of one hour.
Participants: There were 59 teachers from 31 schools,19 returning from the 2020 workshop. Teachers met in Zoom and other formats, and represented a wide range of disciplines and grade levels, as in 2020.
Outcomes: ten lessons were designed, with twelve teachers (so far) trying out their designs in classrooms (Figure2)

Figure 2

Guangdong Middle School - implementing the "Future City Cantonese Architecture" unit

Discussion: Teachers were engaged by the topics and worked hard to create STEM inquiry. Those returning from 2020 were able to work in teams with newcomers, some improving on their designs from 2020. Teachers continued to improve their teaching strategies for students' skills in the 21st century. Once again, however, we found resistance from teachers to implement new kinds of inquiry in their classroom. We began working more closely with one group of teachers to add smaller scale “icebreaker” activities to help get teachers started.

Conclusions

It was an engaging experience for these teachers to design an inquiry unit (often in STEM topics), but still another challenge in how to use those designs effectively with students. Teachers have no experience with these forms of teaching, and did not learn in this way when they were students. So, these new inquiry approaches are unfamiliar, and teachers found themselves somewhat paralyzed when they tried to engage these methods. We found that teachers need more guidance, particularly at the outset, and are now developing methods for support.

This research has established a teacher community for innovation in China. The 2020 and 2021 summer workshops enabled K12 teachers and researchers to jointly design climate change-themed STEM curricula. The workshops and subsequent school trials also allow us to discover the problems of teachers, conduct targeted discussions, and help them to design competency-centered courses according to their school conditions. Members of the research team visit these classrooms and capture videos of teachers to share with other teachers, in order to help them understand better.

From a learning sciences perspective, this effort can help us investigate the specific challenges experienced by teachers, account for their difficulties, and develop support. This project is significant because it is part of a wider effort called the Critical Action Learning Exchange (CALE) that includes teachers from many countries, and tries to develop a critical action curriculum that is appropriate to cultural context.

Emotion as a Condition and Target of Learning Design During Emergency Remote Teaching

Jacob Fortman, Rebecca Quintana
jfortman@umich.edu, rebeccaq@umich.edu
University of Michigan

Abstract: In this study we seek to understand the recursive relationships between feeling, sense-making, and rapid online course design at the onset of COVID-19. To elucidate how emotion was implicated in learning design decisions, we offer a qualitative analysis of nine instructor interviews from diverse academic disciplines. Originally developed for an open online course, these interviews exemplify how instructors at a large midwestern university moved their residential courses online at the onset of the pandemic.

Introduction

The purpose of this research is to elucidate the relationships between feelings, sense-making, and the practice of learning design during the period of emergency remote teaching during the early months of COVID-19 (Hodges et al., 2020). To advance these insights, we draw on situative theories of learning (Lave, 1991), emotional configurations (Vea, 2020), and reification (Wenger, 1998) as analytic lenses. Through a qualitative analysis of nine instructor interviews in an open online course, we highlight how instructors' and students' emotions operated recursively as both a *condition* and *target* of learning design. In detailing the recursive dynamics of emotion, we specifically attend to the process of reification and the ways that emotion was both reified and served as a condition for reification. The research question that guides this study is: *How did instructors relate feelings, sense-making, and learning design during the period of emergency remote teaching at the onset of the pandemic?*

Theoretical Perspectives

Situative theories of learning foreground *meaning* as a process of negotiation between people in a specific social context. This process of (re)constructing meaning is "not just doing in and of itself" but the "doing in a historical and social context that gives structure and meaning to what we do (Wenger, 1998, p. 47).

Emotional configurations can be understood in similar terms as situative theories of learning. Rather than conceptualizing emotions such as grief, anger, and anxiety as static, internalized states, emotional configurations attend to the relationships people make between feelings, sense-making, and social practice. In this way, emotion becomes meaningful when it shapes—and is shaped by—social practice and sense-making (Vea, 2020).

Following Wenger (1998), we understand reification as the process by which people project meaning onto the material world. This process of reification gives material "points of focus around which the negotiation of meaning becomes organized" (p. 58). In the context of our study, we are specifically interested in how emotion—as a target of learning design—becomes reified, and as a condition for learning design, how it serves to reify other design considerations.

Data and Method

Our data set consists of nine academically diverse instructor interviews created for use in an open online course on resilient teaching. The interview protocol consisted of five questions, which instructors could answer via video call or through a written response. We used directed content analysis (Hsieh & Shannon, 2005) and a conceptual framework developed by Vea (2020) as a starting point for analyzing the data. In the first round of coding, the researchers open-coded the data set for language that explicitly referenced emotional states (e.g., anxiety, worry). After the initial round of coding, two coders worked within a smaller subset of coded data to identify segments of discourse where emotion was implicated within instructors' course design process. After collecting segments of data that linked emotion to learning design, the researchers began to generate sub-themes that were common across multiple segments of data. During the iterative process of generating sub-themes and merging sub-themes into larger themes, the researchers were guided by theoretical considerations from situative theories of learning and emotional configurations.

Findings

 © ISLS

We detailed two broad themes to characterize the ways instructors related feeling, sense-making, and course design during the period of emergency remote teaching. Collectively, these findings show how emotion functioned recursively as a *condition* and *target* of course design.

Emotion as a condition of practice

Emotions such as isolation, concern, and anxiety were common among instructors during the period of emergency remote teaching. The loss of classroom community and collaboration in particular were often cited as catalysts for these emotions.

As a condition of learning design practice, the emotions of concern and anxiety functioned to reify instructors' desire for community and connection within online classes. For instance, some instructors articulated that the role of the teacher in emergency remote teaching shifted away from didactic lectures towards relationship building within the class community.

In an effort to keep the class connected, some instructors adopted a"flipped classroom" where short video lectures were pre-recorded and posted online, and synchronous discussions were offered as opportunities to discuss the recorded material. In this way, feelings of concern and worry flowed through the practice of course design, and motivated a desire for increased community and connection; these desires subsequently reified community building practices such as the "flipped classroom."

Emotion as a target of practice

While emotions such as concern and worry flowed through the practice of course design, emotion was also reified as an explicit target of design efforts as well. For instance, instructors overwhelmingly acknowledged that student stress and anxiety had increased due to the pandemic. To alleviate those negative emotions, instructors shaped new practices and materials with the intent of positively impacting students' emotions. In one illustrative example, an instructor included light-hearted hippopotamus videos at the beginning of class time explicitly to "lighten the mood."

Reifying student emotion as a target of course design also came with certain tensions, particularly concerning the course goals that had been articulated before the pandemic. While many instructors wanted to provide additional flexibility and accommodations during this difficult time, there was a perception that doing so would be inauthentic to the professional field they were training students for. When a theater instructor explained her decision for extending deadlines, she noted that it ran contradictory to the common practices of the profession: "In theater, deadlines are very firm (opening night is opening night) but in these stressful times, it would have been inhumane to be that strict." These tensions suggest that reifying emotion as a target of learning design implicates other considerations within the milieu of the learning environment.

Discussion

While there is little doubt that emotion figured prominently in learning design during the phase of emergency remote teaching, the question remains how such insights will influence the field of Learning Sciences more broadly. One promising direction for future inquiry may be attending to the tensions that arise when emotion is reified as a target of learning design. While our study showcased how reifying emotion as a target of learning design proved incongruous with pre-defined course goals, future studies may find that reifying emotion comes with different tensions given different contexts.

Digital Literacies in Algorithmic Cultures: Critical Literacy as 'Working the Algorithm'

Christian Ehret and Anita Hagh
christian.ehret@mcgill.ca, anita.hagh@mcgill.ca
McGill University

Abstract: Research on literacy learning and algorithms has been limited to how youth understand their operations as computational systems. Through a case study of one young adult's practice of 'working algorithms' across social media platforms, this poster presents new pathways for researching critical, digital literacy learning in algorithmic cultures. It provides evidence of how youth use their literacies in the critical production of algorithmic cultures, and toward more just and diverse communities.

Rationale and research focus

Humans' everyday experiences with literacy are increasingly entangled with non-human actors, such as computational objects like bots and data, and larger computational systems such as algorithms and platforms. Scholars across disciplines have worked to understand the implications of these entanglements for the production of culture and information at the same time that the implications of these entanglements have impacted everyday life at multiple scales: from the online amplification of post-truth politics across the globe, to the algorithmic personalization of digital ads for individuals. Analyzing these communicative conditions that are produced through the relations of human and non-human agents online, scholars have employed terms such as algorithmic culture (Galloway, 2006) and platform society (Van Dijck et al., 2018). Meanwhile, learning scientists are contending with changing experiences of literacy in these collective, global conditions—forced to think anew about evolving demands on critical literacy (e.g., Leander & Burriss, 2020).

This poster poses novel questions that contribute to this emerging area of inquiry, and it presents worked examples from the third year of a five-year design-based study of adolescents' (14-17 yrs-old) and young adults' (18-22 yrs-old) literacies with emerging technologies and digital cultures. In developing these worked examples, the poster follows Gee's (2010) recommendations for using small pieces of data to illustrate the potential of new theories or ideas, especially around emerging digital literacies. These worked examples bring into sharper relief the complete imbrication of human and non-human relations in the production of *algorithmic cultures* through youths' uses of their literacies, and it develops theories of digital literacy learning to better account for such imbrication. *Algorithmic cultures* refer to the processes by which the constant flow of human activity online creates 'big data' that is parsed and fed into algorithms that help shape new culture phenomena (Galloway, 2006).

Worked examples focus on one young adult's, Mella's (20-year-old, gender-queer Canadian), uses of her literacies across social media platforms, including TikTok, Facebook, and Instagram. Analysis of Mella's practice of what she calls *working the algorithm* across platforms provides novel insight into how contemporary youth practice critical, digital literacies while participating in, and producing, algorithmic cultures. Questions guiding analysis of the poster's worked examples of Mella's literate practice of working the algorithm will open productive discussions for learning scientists researching emerging forms of learning online, and especially those researching critical, digital literacies, which cannot ignore the imbrication of human and algorithmic activity: **(1)** What agency do humans have in the co-production of posthuman, algorithmic cultures? **(2)** How do humans shape algorithmic cultures to create diverse communities and to support diverse identities and personal desires beyond those imagined by the social media corporations that produce and constantly adjust algorithms?

Conceptualizing critical, digital literacies in algorithmic cultures

Adolescent literacy learning, for youth such as Mella, requires developing facility in the discourse practices of specific cultures, and critical literacy learning requires a developing understanding of the ideologies and systems that shape discourse and participation in such cultures. Learning scientists have recently begun developing critical literacy frameworks for contemporary online data flows, and these frameworks position youth as authors and interpreters of online data collected about them (e.g., Stornaiuolo, 2020). However, attention to algorithms has been limited to how youth understand their operations as computational systems. Research on critical literacy must also account for youths' participation in, and co-production of, culture in relation to algorithms. Critical digital literacies should encompass how youth learn to *work* the algorithms with which they interact online for their own purposes. As Mella's case illustrates, those purposes include producing cultures meaningful to them, and critically resisting, and re-authoring, the data-driven, normative, neoliberal, and sometimes racializing (Dixon-Roman, 2016), cultures that most corporate algorithms produce.

 © ISLS

‘Working the algorithm’ as emerging critical, digital literacy for cultural production and participation

Data come from a year-long, ongoing relationship with Mella established through a multiyear design-based research project. These data include semi-focused interviews related to her online life. Mella describes her daily life on social media platforms as less about ‘liking,’ and ‘posting,’ and more about what she calls ‘working the algorithms.’ Table 1 presents three categories of social practices and related literacy practices in which Mella engages to critically co-produce algorithmic cultures. For example, in relation to her social practice of intentionally co-authoring social media algorithms, she discusses specific literacy practices of posting, liking, sharing, and ignoring posts to train algorithms on TikTok to create a safer more inclusive space for herself to share queer content. In relation to her social practice of maintaining her well-being in relation to charged discourses, Mela describes writing DMs (direct messages) in response to users’ politically charged content, but not actually sending them. By not sending these DMs, she is training the algorithm not to include her in these charged discourses, whilst still engaging critical conversations on her own terms. In relation to creating in-person communities from online cultures, Mella uses mobile apps to create queer content when she is in public spaces in order to prompt the apps to connect her (e.g., by suggesting new friends to follow) with like-minded users nearby. She thereby works the algorithms to create community and culture around her, aware of the location-based technologies that collect geographical data for social media algorithms. Short, worked examples of each literacy practice are provided on the poster for discussion.

Table 1 *Mella’s critical literacies for working algorithms*

	Intentional co-authoring of platform algorithms	Maintaining well-being in relation to charged discourses	Creating in-person communities from online cultures
Literacy practice 1	*Reading to monitor and distinguish between platform’s algorithms*	*Reflecting offline rather than engaging online*	*Reads queer identities offline through trends seen online*
Literacy practice 2	*Posting, liking, sharing, and ignoring to train algorithms for her own purposes*	*Writing reflective messages that she doesn’t send*	*Discusses queer issues offline to later re-train algorithms online*
Literacy practice 3	*Using platforms’ mobile apps based on location to train algorithms*	*Discusses online content in personal, safe relationships offline*	*Trains algorithms to connect her to other queer users in close physical proximity*

Conclusion

Mella’s case illustrates that critical digital literacy learning requires understandings of how humans’ actively co-author culture and social life with non-human agents such as algorithms. Mella’s uses of her literacies in working algorithms are critical because they intentionally resist the cultural normativity and racializing tendencies of social media algorithms driven by big data. If, as learning scientists have argued (e.g., Stornaiuolo, 2020), algorithmic cultures tend toward aggregating big data into normalized ‘big culture,’ then learning critical literacies that work algorithms toward more just, diverse purposes is essential.

Designing for an emerging paradigm in computer programming - towards hybrid human-computer creation of artifacts

Marcelo Worsley, Northwestern University, marcelo.worsley@northwestern.edu

Abstract: Computer science education has experienced many noticeable changes since its inception. Today, students encounter considerably more user-friendly and intelligent IDEs, far less confusing error messages, and much simpler program compilation processes. Learners are also likely to encounter programming environments that can combine human created artifacts with programmatically created content. Even so, much of computer science education assumes a paradigm where only the computer directly manipulates the final artifact. This paper describes an emerging human-computer hybrid paradigm as seen through Scratch, Minecraft Education Edition, and the Dash and Dot. By thinking about these three platforms, the paper motivates more intentionality in how we design for learning in this hybrid paradigm.

Introduction

Learning computer programming has generally made significant advances over the past several decades. Long gone are the days of paper punch cards that are fed into room-sized machines. Today's programmers can conceivably execute computer programs from anywhere in the world. The environments for writing code have also changed in dramatic ways. Today's integrated development environments provide countless tool-tips, automatic completion, and easy linking among source files, libraries, and other resources. Moreover, with the emergence of block-based programming, users, kids, and adults alike, can author intricate threaded computer programs without typing a single line of code. Broadly speaking, these advances have shifted who is able to create computer programs, and how the programs are used.

One thing that has seemingly remained stagnant in the world of computer programming, however, is the relationship between the human, the program, and the resultant artifact. By and large, programmers write code for the computer to execute in the creation of a digital artifact. The creation of the computer program is the responsibility of the programmer. The program subsequently creates the artifacts. If the artifact is not satisfactory the programmer adapts the code and reruns the programs. They repeat this process until they are pleased with the outcome. This process has worked well for decades and will likely remain a dominant paradigm. That said, this paper explores an alternative paradigm that involves both the human and computer program directly contributing to the final artifact. The paper describes three examples that demonstrate how this paradigm is enacted and serve to highlight ways that it differs from the traditional approach. These points of distinction inform some suggested considerations that may be unique to this human-computer-hybrid programming paradigm. Furthermore, the novel design possibilities that they afford may give rise to more programming experiences utilizing this paradigm.

Case studies

This paper uses Scratch, Minecraft Education Edition, and the Dash and Dot robot platforms as driving cases for this hybrid paradigm. The reader is encouraged to explore these three platforms at their leisure. Important aspects of these three platforms can be represented in terms of two dimensions. The first dimension considers how much the programming environment compartmentalizes the human created artifact (i.e., to what extent can the computer program permanently damage the human created components). The second dimension is about the resultant artifact's physicality (i.e., is it virtual or physical). Looking across Scratch, Minecraft, and Dash and Dot, we see a shift from compartmentalized environments to decompartmentalized, and from virtual artifacts to physical artifacts. The compartmentalized environment of Scratch meant that the code could minimally modify any student created artifacts. On the other hand, in both Minecraft and with Dash and Dot, the actions of the program can cause extensive, seemingly irreparable changes to the human-created artifacts. We also see a transition from virtual artifacts to physical artifacts. Both Scratch and Minecraft exist within virtual contexts where the artifacts created are digital. With the Dash and Dot SketchKit, the artifacts are physical in nature. These shifts will be important as we think about how to design for learning within this new paradigm.

Discussion

With these three scenarios in mind, we now transition to discussing what it means to design for this paradigm by thinking about some of the challenges and opportunities they present.

 © ISLS

Creations do not (necessarily) rely on code

The first commonality is that in all three scenarios, users can create content or artifacts without coding. This includes sprites and backgrounds in Scratch, intricate buildings in Minecraft, and drawings with Dash and Dot (as derived from pushing a sequence of buttons to guide the robot), for example. This difference necessitates both intentionality and flexibility in the design of the experience. Intentionality is needed to authentically engage users in coding. Absent opportunities for programming to enable obvious advantages, some youth will invariably elect not to code. Hence, it is essential to consider how the benefits of coding are articulated to participants and the types of activity structures that make these benefits apparent.

Errors are costly

Whereas the dominant computer programming paradigm tends to be forgiving to errors, within these hybrid human-computer collaborations, errors can be quite costly, with the exception of Scratch. In Minecraft the propensity for significant and costly errors is quite high. Something as simple as running your code facing the wrong direction can lead to hours of time spent undoing that action. In the case of the Dash and Dot robot, an error can ruin a manually drawn sketch. In both platforms, there are various strategies to overcome this problem. For example, students might save a copy of their world before running their code, or they can use the agent to build and watch as the agent completes the different actions. Similarly for Dash and Dot, students can reduce the cost of coding errors by doing additional tests on unwanted materials and carefully watching the robot execute the instructions received.

Programmatic replication of human-created artifacts

The high cost of errors is one motivation for having students complete their entire designs using coding. If all aspects of the artifacts are created with code, there is increased reproducibility and easier ways to address any errors. For instance, if the program can create the entirety of the Minecraft structure, including the intricate details, users do not have to deal with recreating those parts if something goes awry. That said, one reality of these design environments is the ways that manual manipulation of the materials (i.e., Minecraft blocks, graphics, or sprites) can often spur student ideation. Hence, it is not simply a matter of students creating their desired components using coding. Without the manual design work, students may lose opportunities to realize their intended artifact. Instead, the high cost of errors might motivate additional innovation in computer programming where, presumably using artificial intelligence, a program can be generated to programmatically create what a user may have manually created. This would make it easy to redo existing artifacts.

Taking a step back though, the high cost of errors disincentivizes utilizing coding and alters the debugging process. For example, we might see that students undertake better decomposition of their programs to be more certain that it will work as intended. Some of these changes in behavior may be associated with better learning and programming outcomes, while others may not. These are questions for further exploration. Either way, designers of these environments should consider how some of the characteristics of this type of human-computer hybrid environment influences different ways of engaging the programming process.

Conclusion

The field of computer science continues to see rapid advances in how we educate future computing professionals. From increasingly intuitive programming environments to developing more inclusive and culturally sustaining curriculum, to integrating wearables and e-textiles, many aspects of computer science education have significantly changed throughout the past few decades. As youth experience these learning innovations, they are regularly introduced to a relatively new paradigm in computer science that is typified by the combination of human and computer program generated artifacts. Operating in this paradigm challenges some of our typical assumptions and practices for teaching computer science. Nonetheless, this paradigm also holds significant promise for realizing the potential of human-computer collaboration. To best leverage these potential developers, practitioners, and researchers need to be intentional about designing for this space and create learning experiences and platforms that better reflect the unique constraints and challenges that exist along the spectrum of this paradigm.

Justice-Centered Ambitious Science Teaching in Community Spaces: Foregrounding Creativity, Connectedness and Joy

April Luehmann, Yang Zhang
ALuehmann@warner.rochester.edu, yzh240@u.rochester.edu
University of Rochester
Jeremy Smith, Freedom Scholars Learning Center, freedomscholarslc@gmail.com
Kyle Sullivan, University of Rochester, ksulli31@u.rochester.edu

Abstract. This poster explores the unique and powerful affordances of justice-centered ambitious science teaching (JuST) in two intergenerational community spaces as reflections of an interdisciplinary theory of learning. The results of a cross-case analysis exploring ways JuST practices impacted learning in two related but distinct educational settings spaces revealed boundaries between teaching and learning as blurred, agentic creativity that led to connectedness and joy, and leadership by people of Color as shaping perspectives and priorities.

Major issues and significance

We lack lived examples and nuanced understandings of educational settings that align with current, interdisciplinary theories of learning, accounting for the cultural, social and emotional aspects of learning, while maintaining criticality related to fundamental assumptions of what science is, who does it, and for what purposes (Nasir, et al., 2021). This cross-case analysis comparing learning affordances of a teen showcase with those from a neighborhood forum revealed ways that intentionally and creatively structuring science education in community spaces to be justice-centered and ambitious has the power to lead to deep and equitable learning. Compared to formal learning settings, community spaces can more easily draw together and connect people from different generations, people who have different areas of expertise, and people who span cultural backgrounds, thereby potentially challenging typical roles of leader and follower, teacher and learner. Learning in community spaces is not held hostage by the same political and accessibility pressures felt by schools, inviting agentic creativity. It also invites unique ways of relating, connecting and sharing emotions around shared interests. Agentic creativity, connectedness and joy are transformational elements of a justice-centered ambitious science teaching lens (explained below) that offers a framework for considering how particular aspects of science learning in community spaces can lead to deep and equitable learning in potentially unexpected ways. The two cases share a common focus on science learning used to promote COVID safety, especially for communities of Color. Both cases involve leadership composed primarily of people of Color. This study aligns strongly with the conference aims: to promote equity, investigate innovative learning environments, and elucidate theories of learning.

Analytical and methodological approaches

Learning is rooted in the intersecting facets of human development (biological, social, cognitive, emotional); thus, it is necessary to support the whole-person development by creating learning environments that address these needs (Nasir et al., 2021). Learning takes place in cultural practices across people's lives as experienced and embodied through social interactions, beyond the ways reflected in most current classrooms. Implications of this more expansive and interdisciplinary theory of learning involve fostering deep learning, engaging learners as their full selves and disrupting patterns of oppression and inequity (p. 557). Creativity, connectedness, and joy are transformational foci as they touch on the social, cultural and emotional realms of human development and push the boundary in what counts as science and what science is for.

Ambitious Science Teaching (AST; Windschitl, et al., 2018) outlines sets of teaching practices that center collaborative sensemaking. Though AST intends to offer all learners access to meaningful science learning, these practices fall short of challenging the inequitable and unjust contexts, constraints and consequences that shape learning for marginalized learners. As a response, we articulate a goal of Justice-Centered Ambitious Science Teaching (JuST) that explicitly identifies equity imperatives beyond simply access. Leaning on Phillip and Azevedo's (2017) work, JuST practices challenge the core foundations of what it means to do science, by whom and for what purposes. JuST practices thus align with Nasir et al.'s (2021) learning theory, highlighting the range of community and cultural experiences across life courses and across multiple settings that count as science learning while also underscoring the need to attend to, name and disrupt the systemic injustice at work. From these frameworks, creativity (agency), connectedness (relationship), and joy (emotion) become points of emphasis in designing for transformational environments.

In this study, we employed a cross-case analysis (Stake, 2006) to explore the ways JuST practices nurtured participants' engagment in two diverse events related to the same overarching project, which shared a common focus on becoming COVID literate in order to keep our circles safe, especially for communities of Color. Particularly, we asked

questions about how creativity, connectedness, and joy were realized in community spaces designed for transformational science learning and what design elements led to these outcomes. The first case explores a public showcase where middle school teens who participated in a seven-week afterschool science club shared the practices, findings, and implications of their inquiries with family, school personnel, and others through hands-on demonstrations and video-based public service announcements. The second case explores a neighborhood forum organized by an intergenerational team of urban community members to offer fellow residents opportunities to engage with three physicians employed at a local hospital. This forum was facilitated by Author #3, a young Black man who leads and facilitates ongoing community work with the organizers. Both initiatives focused on critical equity teaching and learning in and through science. Primary data included photographs, transcribed recordings, and written field notes from both events. Codes were generated from the analytic framework and included agentic creativity, connectedness, emotion, ways of knowing, and criticality.

Major findings, discussion and implications

Creativity, connectedness, and joy were realized in both community spaces through expansive aims and experiences prioritized by people of Color who led the learning in each setting. Throughout the teen showcase, in student-led interactive stations as well as student-created films, youth, the majority of whom are students of Color, positioned themselves centrally as scientists, science educators, and other experts. Authoring the questions that were pursued (COVID myth posters), defining scientific methods employed (mask experiment data), creating scientific explanations (solo cup tower-building to stimulate protein synthesis), and drawing implications (COVID prevention messages in public service announcements), youth shaped and owned science, meaningfully expanding the forms and formats traditionally considered to be "science." Participants were engaged physically and in many different forms. As stars of the scientific show who taught adults including family members, school personnel and unknown others, youth engaged groups of attendees with rigorous science *on their own terms* - wearing Einstein wigs, throwing COVID stuffies to interrupt protein building, and pretending to be doctors to diagnose attendees' dramatized imaginary symptoms. Laughter was core to the science doing, thinking and talking; youth designed laughter into their science and did not edit it out for public professional presentations. Youth situated their messages in student-scripted dramas that contextualized *their* understandings of science, COVID and community (e.g. situating a storyline in the context of *Twilight*, a familiar teen novel turned movie).

In the Neighborhood Forum, Author #3 and the community organizers, all people of Color, selected and directed the activities, ways of interacting and foci of the discussions. Though physicians had prepared to explain the science of COVID, community members were the drivers of the conversation. Not only did community members choose the focus of the science that was to be shared by authoring the questions, they situated these questions in their own lived experiences. Scientific ways of knowing, which for many people of Color are situated in mistrust of the medical field, took back seat to historicized and lived ways of knowing. Laura, a mother of teenagers who have not yet been vaccinated, cried as she shared her rationale, "My children are my whole life! I am their own sense of protection." After she explained her tensions in navigating messages about vaccination, physician Amy validated the sense of pressure associated with parenting, responding with a surprising answer, "Don't trust us because we're experts; instead prioritize the voice of an expert who has, over time, earned your trust." Community leaders, along with other neighbors in attendance, served as judges of the usefulness of the event, highlighting what mattered most to them, namely humility and accessibility. Feeling heard and understood mattered more and was valued over being convinced by studies and citations. Evidence of relationships being built was seen throughout in honesty, transparency, tears, laughter and explicit words of appreciation.

Science, in its traditional form, prioritizes some people while invisibilizing others. In order to meaningfully address equity, what counts as science, what science is for, and who benefits from science had to be critiqued and expanded. Centering voices from marginalized groups, nurturing creativity and agency while legitimizing the outcomes, and honoring the necessarily emergent nature of the learning interactions and outcomes contributed to the transformational power of science learning in these community spaces. Attending to the cultural, social, and emotional aspects of learning afforded by community spaces, JuST practices that centered sensemaking in expansive ways for expansive purposes led to a) creativity in forms of what counted as legitimate scientific data, analyses, expressions and interactions; b) connectedness across generations and social groups through roles, personal recognitions and physical positioning in circles; and c) joy and other emotions steeped through most interactions that were both light-hearted and deeply felt. When we view learning through a critical lens, we reimagine the potential and importance of creativity, connectedness, and joy.

An exploratory study of how informal educators engage with formal educators in a community of practice

Ezequiel Aleman, Iowa State University, ealeman@iastate.edu

Abstract: Expanding graduate programs for educators in the Learning Sciences beyond a traditional focus on classroom instruction requires widening learning contexts to engage out-of-school educators. In this preliminary study, a cohort of 24 in-school and out-of-school educators formed a community of practice. Their engagement in discussion forums was analyzed. Preliminary results suggest that reflections through storytelling resulted in higher levels of interaction between formal and informal educators.

Introduction

This poster describes the development of an online graduate Learning Design Master's program in Uruguay which seeks to integrate both in-school and out-of-school educators in a community of learning designers, thus providing opportunities to understand how informal and formal educators make sense of learning spaces and experiences both in and out of schools.

This ongoing study is informed by notions on communities of practice (CoP). CoPs are formed by groups of people who share similar interests which are expressed through specific shared activities (Wenger, 1998). The CoP framework suits this research context as it provides opportunities to explore engagement and knowledge-sharing across different contexts. Engagement is an essential component of a CoP and a fundamental process of how we learn (Wenger, 1998), thus, the first step of this exploration focused on how formal and informal teachers engaged within their community.

Methods

This in-progress design-based research (Barab & Squire, 2004) project incorporates elements of case study to explore the relationships between educators and the development of their community using a communities of practice (CoP) framework. The current iteration of this study is asking the following questions: how do formal and informal educators engage and share knowledge in a community of practice? To answer this question, this study analyzes the levels of engagement among participants, the themes that lead to higher levels of interaction and the practices that support knowledge sharing between formal and informal educators.

A cohort of 24 educators, (12 out-of-school and 12 in-school educators) coming from a wide variety of backgrounds (37.5% STEM, 37.5% Education, and 25% other Human Sciences) participated in the first year of an online master's degree in Learning Design. The first class of this program positioned teachers as co-designers of learning spaces and artifacts for community-based learning spaces such as museums, non-profit organizations, and after-school programs. The course also served as a foundation to start building a community of practice by providing opportunities for discussions, collaborative and inquiry-based activities, as well as design projects.

Educators were requested to participate in five discussion forums during the course. Each discussion topic was based on one of Engeström's (2017) five layers for expanding education: bringing elements of societal practices into other learning spaces, conceiving learning spaces as communities of learning, promoting learning in activity systems outside school, involving alternative funds of knowledge and epistemologies, and taking local, regional, and global movements as contexts of learning. This theoretical perspective, while originally conceived for science education, served as a means to organize students' discussions about community and knowledge across multiple spaces.

To measure engagement with each discussion topic, a matrix adapted from Hafeez et al. (2018) was used to systematize the data collected from the discussion forums. The matrix presents four layers of analysis: intensity, referring to the number of replies, topics discussed, and the number of views; duration of engagement, measured by the total period of discussion in days; stage of engagement, which describes which participants tend to initiate or end discussion topics; and degree of centrality, where the number of times a participant has engaged in a discussion is counted, including the number of words.

The five topics selected for this preliminary analysis were all organized as text-based discussions in the Moodle learning management system. One limitation to this data collection process was that other forms of communication and knowledge sharing were excluded such as video discussions and collaborative annotations.

 © ISLS

Preliminary findings

After analyzing the five discussion forums, it was found that two of them sparked a significant amount of interest: "What makes an educator" was a question that sought to extend a prior discussion about activity systems outside schools. The question engaged 24 students, and 10 of them received at least one reply. There were 208 views of the discussion forum, and the total number of posts was 49. The second most discussed topic was "Where does knowledge come from?" where participants discussed funds of knowledge and indigenous epistemologies. Participants in this discussion were encouraged to engage in storytelling to describe how their local communities had acted as funds of knowledge in their lives. The question engaged 24 students, and 7 of them received at least one reply. there were 195 views of the discussion, and the total number of posts was 37.

Regarding the differences between formal and informal educators, the five discussion topics were initiated by formal educators. However, participation was higher among informal educators (68% of total posts) who also showed more interest in prolonging discussions by replying to previous comments more often (78% of total replies to posts) and participating in the discussions even three to four weeks after the thread had been initiated. The two most discussed topics were also the topics with the highest levels of participation from informal educators. The only question that showed lower engagement from informal educators compared to formal educators was "How does social media affect our lives?", a question which required students to reflect on a specific reading providing factual arguments.

Discussion

One noticeable finding in terms of discussion engagement across participants was that the most discussed topics involved narrating stories based on personal experiences both in-school and out-of-school. Unlike the other three topics where participants had to provide arguments to support specific claims, these two topics specifically encouraged storytelling to connect previous discussions with personal experiences. This approach seems to have served as an inclusive point of access for both types of educators in finding common grounds to make sense of their personal learning experiences.

Further analysis needs to incorporate discourse analysis to visualize what funds of knowledge educators tap into when developing their answers to the discussion questions and to determine whether tacit knowledge is transferred among educators in the discussion process. For this discourse analysis, it will be necessary to incorporate other sources of discussion which were not considered for this study such as video discussions and collaborative annotations.

For the current iteration of this graduate program, a more systematic approach to storying as knowledge sharing is being implemented where stories from different educators are intertwined in a single digital experience.

Title: Measuring Belonging for Neurodiverse Computer Science Students

Rachel Bonnette, Sam Abramovich
rnbonnet@buffalo.edu, samuelab@buffalo.edu
University at Buffalo

Abstract: Neurodivergent students can thrive in undergraduate Computer Science programs with support, but research on effective learning and teaching practices is limited. The neurodiversity movement advocates an approach to research and design that examines social (i.e., external) barriers to student success and seeks to remove or mitigate them. We suggest that this research must begin with productive measures of student success. This poster presents a survey instrument to measure neurodivergent CS students' *sense of belonging*.

Keywords: belonging, computer science, neurodiversity, research, intersectionality

Introduction

Neurodivergent students (e.g., with autism spectrum disorder and other neurological differences) experience the world differently and often possess highly valued skills, such as creativity and systematic thinking (Baron-Cohen et al., 2009). These are especially valued skills in Computer Science (CS), such that major international employers like Microsoft now actively recruit neurodivergent people. But, with neurodivergence often comes disability, largely as a product of outside barriers that limit neurodivergent success (Kapp, 2020). Post-secondary programs, for example, are usually designed for neurotypical students (Fabiano et al., 2018), creating unnecessary challenges for neurodivergent students, who then struggle with mental health, sensory processing disorders, and communication (White et al., 2011). Standard accommodations, even when provided, do not mitigate this problem (Sarrett, 2018). Most neurodivergent students drop out of four-year post-secondary institutions (Wei et al., 2014) despite high levels of interest in CS (Wei et al., 2013).

CS teaching practices and learning environments can be designed for inclusivity, but in order to do this, there is a need for research to identify incongruities between student needs and existing practices. For example, instructors teaching facial recognition software coursework in Artificial Intelligence classes may assume that students can, inherently, correctly interpret facial expressions. Neurodivergent students do not always possess this skill, and accommodations like time on tests or extended deadlines will not be sufficient. But what if instructors in this case taught about facial expression as well, or created collaborative projects where students were expected to examine their biases about facial expression interpretation? This is just one example of an opportunity to research student needs and design for better, more inclusive learning.

We suggest that the first step research step in designing for inclusivity for neurodivergence in CS is to determine reliable metrics of student success. Grades and graduation rates are insufficient because they do not accurately reflect learning for neurodivergent students. Instead, we believe that *a sense of belonging*, a necessary factor for both neurodivergent and neurotypical students (Morrow & Ackermann, 2012; Vaccaro et al., 2015), can be used to formatively and summatively assess how *all* students are succeeding.

Measuring Belonging for Neurodiverse Students

This poster presents the development of a survey instrument for neurodiverse students' sense of belonging in Computer Science, and we invite discussion about the constructs measured and research directions. Examples from existing measures that may be useful to measuring belonging are presented in Table 1, below.

Table 1
Measures of Belonging in Neurodiverse Computer Science Programs

Measure	Example Question	Source
Mastery	I am confident in my mathematics abilities.	Mooney & Becker, 2020
Self-Advocacy	I feel uncomfortable advocating for my rights and responsibilities as a student with an invisible disability.	Lombardi et al., 2011 (modified for neurodiversity)
Relationships	My instructors make me feel valued.	Mooney & Becker, 2020
Neurodiversity	Do you consider yourself to be neurodivergent (e.g., autism spectrum disorder, ADHD, dyslexia, etc.)?	Kapp, 2020

 © ISLS

A *sense of belonging* is vital to all students' success (Morrow & Ackerman, 2012), but especially neurodivergent students in post-secondary programs (Vaccaro et al., 2015). Belonging for students with disabilities depends on—and in turn impacts—students' sense of mastery of their student role, ability to self-advocate, and ability to develop relationships with peers and faculty in their program. Accordingly, measuring belonging requires measurement of these underlying variables. Table 1 provides examples of survey instrument questions for each. Additionally, an intersectional (Collins & Bilge, 2020) perspective suggests the need for questions that acknowledge the complex experiences of discrimination and privilege students face. Women and many ethnic or racial groups remain underrepresented in Computer Science as a field, for example, but are also least likely to receive diagnoses and services for autism and other neurodivergent conditions. Existing instruments account for belonging among underrepresented students in CS based on gender and ethnicity (e.g., Mooney & Becker, 2020), but to date, no survey instrument also accounts for neurodiversity. In addition to measuring mastery, self-advocacy, and relationships in a way that accounts for intersectionality (see Table 1, Relationships Example), measures of neurodivergent student success should also address demographic questions about whether students consider themselves a minority (Mooney & Becker, 2020) or neurodivergent. There are many reasons students may lack formal diagnosis, but still rely on additional supports that could be provided without risk of unfairness (e.g., providing facial expression interpretation guides). Although most universities rely on a medical model of disability to determine fair access to supports, many support services recommend accepting self-diagnosis as evidence of student needs. Taking this approach in research will support identification of the ways that teaching practices and learning environments can change to meet the needs of all students.

Turning Ourselves Inside Out: Reading and Creating Graphic Medicine in Community

Sarah A. Evans, Lacy Molina, Joanna Davis-McElligatt
Sarah.Evans@unt.edu, LacyMolina@my.unt.edu, Joanna.Davis-McElligatt@unt.edu
University of North Texas

Abstract: An interdisciplinary team designed a graphic medicine project to address health inequalities, implementing it in public libraries with underserved populations. Participants read graphic novels about experiences with illness, then create a 4-8 panel comic about a health-related experience of their own. Research questions are 1) what personal insights about health arise when reading and discussing graphic narratives? and 2) what community insights about health arise when creating and sharing stories in the comics format?

Issues addressed and potential significance of the work

The recent pandemic has brought mainstream attention to the health disparities beneath the surface of our wealthy nation. Researchers attending to these issues know that underserved populations such as Black, Latinx, and Indigenous communities and those from lower socioeconomic backgrounds suffer not only from lack of access to health care, but also access to health information. This paucity of information is actually a two-way street – while these populations receive less health information, their health experiences remain underrepresented in medical research. The health perspectives and experiences of underserved groups must be brought forward and made visible to decrease persistent health inequalities.

An effective tool for addressing this inequality in health information comes from the emergent field of graphic medicine. Graphic medicine refers to health narratives and medical information created and shared in the format of comics, which, when collected, create a sequential art story called a graphic novel. Originally conceived as a way to increase the empathy of medical students, it has expanded to include the communication of health information to various populations as well as a tool for participatory personal expression of health experiences. In their *Graphic Medicine Manifesto*, the interdisciplinary field's founders state, "Graphic medicine is also a movement for change that challenges the dominant methods of scholarship in healthcare, offering a more inclusive perspective of medicine, illness, disability, caregiving, and being cared for" (Czerwiec, et al, 2015).

This paper reports the initial findings from a graphic medicine project hosted by public libraries in three communities with underserved populations, including rural and urban locations. The project curriculum was iteratively designed by an interdisciplinary team, which includes researchers from learning sciences, information science, English, journalism, and health services. The project research questions are 1) what personal insights about health arise when reading and discussing graphic narratives? and 2) what community insights about health arise when creating and sharing stories in the comics format?

Theoretical and methodological approaches

Our research is guided by sociocultural-historical theories, bringing the focus of the analysis to people learning in context through mediational means, in this case, language and images (Cole, 1996). Graphic novels lend themselves to Bakhtinian analysis through their heteroglossic structure that "borrows pervasively from other cultural genres and discourses, and in doing so appropriates a range of cultural and intellectual ideas and narrative and discursive forms" (McCallum, 1999, p. 258). Through the lens of "funds of knowledge," we view the participants as "competent, they have knowledge, and their life experiences have given them that knowledge" (González, Moll, & Amanti, 2005, p. x). Each participant brings their funds of knowledge to the library program and actively produces meanings for the texts they read, discuss, create, and share. As researchers, our close attention to these activities in context illuminates the informal learning experience.

This qualitative research project takes the form of a comparative case study (Merriam, 2009) in three public libraries. A maximum of 10 patrons sign up through each library location, for a total of 30 participants. Data includes a) pre- and post-program surveys about experiences with graphic novels/comics and with health and health care, b) video recordings of the eight online program sessions, and c) the four to eight panel comic stories created by participants.

The research team qualitatively codes data from the surveys, sessions, and participant-created comics through the lens of the previously discussed theoretical framework. Team members complete a round of open coding, then compare results to create a series of closed codes. Using these closed codes, team members re-code

 © ISLS

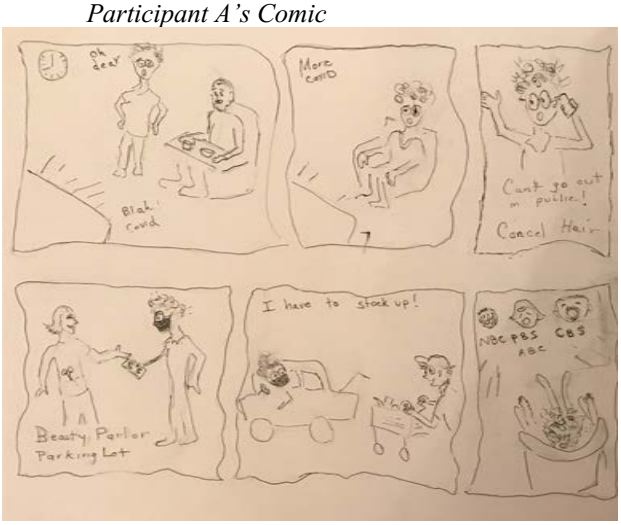
the data corpus until an acceptable level of agreement is reached (Merriam 2009). This process will be completed by June 2022.

Findings and implications

Initial findings come from a rural library, where the solicitated participants were older adults in their 60's and 70's. Led by a member of the research team, the group first discussed the book *Cancer Made Me a Shallower Person: A Memoir in Comics* by Miriam Engelberg, followed by *My Degeneration: A Journey Through Parkinson's* by Peter Dunlap-Schohl. In the earliest conversations, participants often commented on new knowledge gained about the disease discussed, i.e., "I didn't know that…" As discussions continued, participants shared more of their personal health experiences the had some similarities to the experiences of the comic authors. A common theme amongst these senior citizens was concern about losing greater control of their bodies and the burden it will place upon others.

While initially apprehensive about their ability to create a comic, they all reported feeling capable thanks to the step-by-step coaching from another member of the research team. In the next to last session, this member asked everyone to reflect on a moment from their experiences in the pandemic in order to create a storyboard. As they shared their drawings, common themes arose of anxiety and its impact on the body. For example, in Figure 1, Participant A uses motion lines to represent information bombarding her, with the final panel showing her body shaking while watching the news.

Figure 1
Participant A's Comic



As the project continues in new locations with different kinds of participants, the research team look forward to comparing and contrasting the insights about health that the graphic medicine format affords people both personal and as a community.

Brigham Young University

Abstract: The need for students to learn online continues to increase. Many students report feeling unprepared, lacking the skills and confidence to succeed. Efforts are needed to bridge a student's transition from traditional learning environments to online. We developed Thrive Online, an asynchronous short course aimed to increase students' knowledge, skills, attitudes, and self-efficacy to learn online. A pilot study evaluated the impact of Thrive Online with a sample of 28 students, with results reporting promising data this course can support students' successful transition to online learning.

Online learning

The adoption of online courses has temporarily or permanently increased due to the COVID-19 pandemic (Arum & Stevens, 2020), which relied on emergency remote teaching and learning (Hodges et al., 2020). Online classes are different, and when developed in haste, they may lack some of the traditional safeguards of traditional classes that help students. Indeed, some students in fully online classes report feeling more disconnected from their peers and instructors, feeling more responsibility to be self-directed, since they receive less help from their instructor and can also feel intimidated by the technological expectations of the online learning environment (Holley & Oliver, 2010; Otter et al., 2013). Students transitioning from a traditional high school to college may feel disconnected from their peers in an online classroom because they are unfamiliar with how to appropriately connect to other learners.

In education, it is important to focus on assisting students in learning how to learn (Barron & Darling-Hammond, 2008) and build not just content knowledge but also 21st-century skills. These skills will help learners navigate formal learning opportunities, cultivate new mindsets and learning habits (Fischer, 2000)., and meet the demands of changing technologies and job expectations. Formal education should prepare learners with these skills and the desire to be a lifelong learner. In addition, it should enable them to be flexible as new expectations arise so the learner can be successful in whatever learning environment. This is a description of an effort to improve student learning capacity and self-efficacy to successfully learn in an online environment.

Thrive online design

In the last year, we have collaboratively designed and implemented the Thrive Online course to address the various needs of learners at a large private university in the United States. This course was designed to increase students' knowledge, skills, attitudes, and self-efficacy navigating the online learning environment and is guided by Gagné's principles of instruction (Gagné et al., 1992). The Thrive Online course is a 2-week asynchronous course. It was designed with five strategies: (a) creating engaging activities, (b) creating an environment that values the knowledge and experience of the learners, (c) regular communication with instructors and teaching assistants (Tas), (d) manageable workload for the learning conditions, and (e) multiple means of processing the material to diversify and scale the learning materials that are relevant and applicable to the students' learning needs. Using these strategies, the course material include: (a) orientation to the learning management system, (b) online learning technical skills, (c) learner wellness, (d) online learning strategies, (e) developing a growth mindset, (f) accessing campus resources to support online learning, and (g) connecting with instructors, TAs, and other learners.

Methodology

We used design-based research (Barab & Squire, 2004; McKenney & Reeves, 2018) to frame our approach and develop the course, providing an opportunity to iteratively tackle a problem of practice in online learning. We designed learning modules and resources with input from learners and pilot studied the implementation. We used mixed methods (Creswell & Plano Clark, 2018) to capture the experiences, knowledge, beliefs, and attitudes of learners. This work is guided by the following research question: How do students' perceptions, knowledge, and confidence with online courses change after participating in the Thrive Online course?

 © ISLS

Participants

Participants included 28 undergraduate and graduate students who were enrolled in an online course at the university. Participants were randomly selected from over 20,000 students; participation was voluntary.

Data collection and analysis

Data was collected from pre/post-surveys focused on participants' knowledge, attitudes, and self-efficacy. We incorporated a Short Instrument to measure Students' Confidence with 'Key Skills' (SICKS; Bray et al., 2020). Using results from the SICKS, students gained an understanding of their deficiencies and strengths in online learning and set goals accordingly. All data is informing future design changes and improvements. Quantitative data from the surveys was analyzed for differences from pre to post.

Results and implications

The pre/post surveys provide a promising picture of the support that the Thrive Online course gives to students. The survey focused on student perceptions, knowledge, and confidence in connecting with other students online, the value of connecting with others online, value of improving their knowledge and skills in online courses, managing their mental health, setting goals, and applying the skills and strategies they have learned. The percentage of students who were undecided, disagreed, or strongly disagreed about these different areas was higher before taking the Thrive Online course. There was an increase from pre/post in all areas for students who strongly agreed. After taking the Thrive Online course, 63% of the participants indicated that they strongly agreed they now know how to connect with other students in the online environment. And with that, 57% strongly agreed that it is important to connect with other students in the online environment.

It is promising that with a short 2-week bridge course students are noting positive changes. As a pilot study and with iterative design we believe the Thrive Online course will continue to be helpful for all online students at the university. With a very small sample size in this pilot work though, we cannot make sweeping claims, but as Glazier (2021) points out that to make human connection online, there must be intentional actions, whether you are an instructor, TA, or student. Thrive Online provides a means for this to happen.

Thrive online next steps

We continue to explore when the most valuable time is to expose students to these learning principles and techniques to successfully implement new knowledge and skills into their credit carrying online courses. Future iterations will include supports for the unique needs of marginalized student learners. We also want to know more about student confidence and ability to succeed in an online learning environment.

Can Schools Fix the Gender Gap in STEM? A Comparative Study in the Global South about Gender Participation in Maker Education

Renato Russo, Tamar Fuhrmann, Akio Goya, Paulo Blikstein

Abstract: Research established that most learners perceive STEM learning environments as settings that exclude diverse ways of thinking. We investigate factors behind this trend in two sites that recently implemented fully-equipped makerspaces, but have deeply different socioeconomic contexts. We identify factors associated with increased self-efficacy and attitudes toward STEM among male and female students.

Introduction

Research in the past decades has established that STEM learning environments are not only largely male-dominated but are also widely perceived as such (see, for example, Nasir & Vakil, 2017). Building on Turkle and Papert's (1992) foundation of "epistemological pluralism," researchers have discussed principles of a maker, constructionist education that equally acknowledges the repertoires of different groups of learners (e.g., Buechley et al., 2008). This research tradition led to remarkable advances on diversity in STEM education. However, it focuses almost exclusively on contexts in the US and Europe. Driven by the question of applicability to contexts in the Global South, we investigate factors that may influence STEM learning in makerspaces in two contexts: one school in Hong Kong serving affluent families and two schools in an economically depressed area in Brazil. These schools underwent dramatic curriculum redesign, including extensive professional development on maker education. We present analyses of *quantitative survey data* from both sites to identify factors that affect the attitudes of girls and boys towards and self-efficacy in STEM.

Data collection and analysis

Students answered an online survey (Table 1) containing open-ended, multiple-choice, and multiple-answer questions gathered from validated instruments to assess students' self-efficacy in science and engineering and their attitudes toward STEM (Siegel & Ranney, 2003; Wang & Berlin, 2010).

Table 1: *Comparison of data collected in Brazil and Hong Kong*

	Country		Type of variable		
	Brazil	**Hong Kong**			
Number of schools	2	1			
Number of respondents (N)	242	89			
Response variables					
Attitude toward STEM	Y	Y	Quantitative		
Self-efficacy (Engineering)	Y	Y	Quantitative		
Self-efficacy (Science)	N	Y	Quantitative		
Explanatory variables					
Mastery of makerspace techniques	Y	Y	Quantitative		
Grade	Y	Y	Categorical		
Gender	Y	Y	Categorical		
Participation in experiments	Y	Y	Categorical		
Perceived expectations of parents	N	Y	Quantitative		
Grades	10, 11, 12	7 and 9			

Results

Data from each nationality were analyzed using linear regression models (Cohen, 1992) for each gender and response variable separately. Due to space considerations, we report the results in an abbreviated table (Table 2).

 © ISLS

Full tables are available at bit.ly/russoetal-isls-2022. The analysis revealed that groups of students had different significant predictors for their attitude towards STEM and self-efficacy.

Table 2: *Unstandardized regression and part correlation coefficients for linear regressions*

	Class experiments		Parent expectations		Techniques		Grade	
	β	Part corr.	β	Part corr.	β	Part corr.	β	Part corr.
Hong Kong								
Attitude towards STEM								
Female	–	–	1.20*	.26	.34*	.27	-5.51†	-.21
Male	–	–	–	–	–	–	–	–
Self-efficacy (engineering)								
Female	–	–	–	–	.18**	.42	–	–
Male	–	–	–	–	.14†	.35	–	–
Self-efficacy (science)								
Female	–	–	.54†	.26	–	–	-3.30 †	-2.9

Note: †$p \leq 0.1$. *$p < 0.05$. **$p < 0.01$. ***$p < 0.001$

Discussion and conclusion

When analyzed as a whole, these results highlight a bigger issue regarding the role of schools in effective societal change across class and gender. Consider that the school in Hong Kong offers state-of-the-art makerspaces and laboratories, including female maker teachers, arguably the peak of hands-on K-12 technology education. Still, gender differences persist and differentially influence girls' and boys' self-perception (e.g., participating in class experiments is a statistically significant predictor for self-efficacy in science for boys in both countries, but not for girls). If this phenomenon can be observed even at those close-to-optimal school conditions, one may wonder what the limits are in terms of how much effect in systemic change schools can have. It is necessary to acknowledge that schools are parts of a broader system with their own paradigms and prejudices, and that kids may bring those values into schools in significant ways. Gender questions in STEM education should be more broadly contextualized--not assigning to schools the entire responsibility of addressing them, but considering larger societal questions and movements.

Studying the Development of Marginality in Collaboration: Methods for Examining the Interplay of Peer & Teacher Interactions

Karlyn R. Adams-Wiggins, Portland State University, karlyn@pdx.edu
Cameron M. Haluska, Portland State University, cameronhaluska@gmail.com

Abstract: Inquiry-based science learning environments emphasize learners' engagement in scientific practices, yet we need to better understand how to promote equitable interactions to ensure all students benefit. Using Wenger's (1998) concept of marginal non-participation, the present study examined patterns of interaction across teacher- and student-led phases of instruction for a focal group in which marginality was previously observed. Findings indicated reliance on ignoring off-task commentary across both phases of instruction, facilitating marginality for two group members.

Introduction

When power is redistributed from teachers to students in inquiry-based science classrooms, peers shape each other's participation in scientific practices and thus may play a role in mediating their teammates' ability to identify with the discipline. Further, as teachers retain the authoritative role of orchestrator and convey motivational messages, teacher discourse and instructional practices likely inform equity in peer interactions (e.g. Cohen & Lotan, 1995; Forman et al., 2017; Modrek & Sandoval, 2020). Yet, after accounting for the benefits of authentic inquiry, reform-oriented curricula can intersect with the question of equity in a potentially adverse fashion: extant research indicates small group learning can involve inequitable opportunities to learn and develop discipline-linked identities (e.g. Carlone et al., 2011). To address this problem, the current study employed microgenetic methods to examine the development of marginality inside collaborative groups in middle school inquiry-based science, with a focus on the interplay of teacher-student and peer interaction across teacher-led and student-led phases of instruction.

Theoretical Framework

Marginality is an adaptation of Wenger's (1998) concept of marginal non-participation and describes movement away from deepened, fuller participation in a community and its defining activities. From this perspective, learning has four facets: belonging in a community, engaging in that community's practices, making meaning of one's experiences with the community and its practices, and the process of becoming a member in said community of practice. Importantly, Wenger's social theory of learning aligns well with science education reforms' reconceptualization of proficiency in science, as proficiency now involves socialization into the role of a scientific thinker. The new indicators of proficiency include making sense of scientific explanations, producing and evaluating scientific evidence and explanations, understanding how scientific knowledge develops, and engaging in scientific practice and using scientific discourse. Inquiry contexts inform learners' opportunities to be recognized as a member of community of competent thinkers in the science classroom, opportunities to practice norms of the discipline, opportunities to experience meaning-making about scientific concepts, and opportunities to become a scientific thinker or pursue a career in science.

Methods

An intensive qualitative case study was conducted to clarify the role of teachers in tandem with peer interactions for constructing marginality. We used videorecorded observations and end-of-semester student interviews previously collected in a larger study: participants were selected from the classrooms of four seventh-grade science teachers in an ethnically-diverse, suburban middle school in the United States and all classrooms were participating in a series of inquiry science units over the course of a semester. Students used evidence to build, revise, and evaluate scientific models; they also engaged in both oral and written argumentation as part of the process. While features of the curriculum should support a shift of authority to students and offer increased opportunities for learners to engage in discussion and peer interactions, previous findings also suggest students peer interactions can be oriented toward constraining participation by groupmates, thus raising questions about the nature of exclusion in collaborative groups and inquiry science classrooms. The present study expanded analyses of a single group for whom group-level marginality-relevant interactions during student-led group

 © ISLS

activity had already been coded and presence of marginality for at least one group member had already been established. We used a purposeful operational construct sampling strategy (Patton, 2015) to choose a group and class date, with the selected group having previously been identified as having episodes of marginality for more than one group member and the student-led period being of an uninterrupted and extended duration. We selected videorecordings of teacher-led instruction for the previously coded class period's group activity. This included ~18 minutes of student-led activity and ~25 minutes of teacher-led whole-class activity. Semi-structured interviews with students in the selected group were reviewed to support interpretation of teachers' role in constructing marginality. Analyses of all data sources were triangulated.

Results & Discussion

The primary task the teacher assigned the class for the observed period was to discuss and evaluate the first in a series of pieces of evidence intended to support competing models of cell nuclei. The first ten minutes of the class period involved the teacher giving directions to the class and checking in with groups around the classroom, stopping multiple times to ask different students outside the focal group to sit still. Prior to the groupwork phase of the period, the teacher offers positive evaluations and comments emphasizing speed of response to two of the four focal group members (e.g. "You're fast, you're amazing"; "Ooh, you two are *really* fast!"; "Your hand went up really quick, how would you rate Evidence A?"; calls on each of the two students to answer questions; evaluates the two students' responses as correct). The teacher also asked one focal group member to return to his seat in one instance and ignored his raised hand in another instance, only for him to blurt out nominally on-task comments in the whole class discussion. Upon transitioning to the groupwork phase, the dynamic of two group members being on-task and two mostly being only nominally on-task continued. Three patterns were identified across the entire class period. First, the group as a whole and the teacher alike struggled with one student's frequent nominally on-task comments, as these typically diverted the teacher or the whole group away from the primary task. The teacher and groupmates alike responded to this most often by ignoring the comments, but occasionally responding briefly before explicitly redirecting him back to the intended task. Second, the tendency to ignore the nominally off-task comments eventually escalated to the group splitting, with two on-task members avoiding interaction with the two off-task group members. Third, the failure to channel the first nominally off-task group member into productive forms of engagement also created space for constructing the second off-task group member as marginal with respect to the peer group. In sum, within a class period, the teacher's interaction with focal group members mirrored focal group members' peer interactions. These findings raise the question of whether group members were specifically emulating the teacher's approach to interacting with a potentially disruptive groupmate, or drawing on other motivators. Accordingly, additional analyses in progress will be presented. These will include more class periods for the same group and one additional group, with attention to interactions occurring earliest in the semester, norms of interaction developing over the semester, teacher and student talk reflecting motivational messages, and other instances of teacher intervention during groupwork phases.

Becoming a STEM Teacher: Examining teachers' practice-linked identities through practice-based autobiographies

Kristina Stamatis, Michelle Friend, Paula Jakopovic
University of Nebraska Omaha
kstamatis@unomaha.edu, mfriend@unomaha.edu, pjakopovic@unomaha.edu

Abstract: To provide equitable high-quality STEM education, teachers must be prepared to engage with the tools and practices *and* to adopt STEM identities. This project investigates the ways teachers' self-described histories and conceptions of materials and relationships embedded in their STEM experiences fostered or inhibited practice-linked STEM identities. Preliminary findings explore how practicing and pre-service educators conceptualize STEM and how their understanding of STEM both supports and challenges their teaching practice.

Introduction

Engagement in science, technology, engineering, and mathematics (STEM) disciplines continues to be lauded as a means to prepare youth for a multitude of possible futures. However, equitable access to learning environments where these skills are centered continues to be elusive, not least because many of the teachers who are expected to incorporate these skills into classrooms do not see themselves as STEM educators (e.g., Stamatis et al., 2021). In this preliminary analysis, we conceptualize STEM as a "figured world" (Holland et al., 1998). From this perspective, the ways an individual conceives of the world of STEM education has implications for how they perceive their own participation in the STEM education community of practice and how they use the material and interpersonal resources available to form practice-linked identities (Nasir and Cooks, 2009). We ask:

1. How do these teachers understand their own practice-linked identities with regards to STEM & CS?
2. What materials, relationships, and ideas do the teachers name as resources that strengthen or challenge their identities in STEM & CS?

Background

We frame this study through notions of practice-linked identities (Nasir & Cooks, 2009; see also Keiler, 2018) to build understandings of the ways educators who are learning to teach STEM subjects use material, relational, and ideational resources to adopt identities as STEM educators. Nasir and Cooks (2009) define learning and identity in practice as "shifts in the use of artifacts...for problem solving, sensemaking, or performance" and identity to be "one viewing participation in the practice as an integral part of who one is" (p. 42). We use this analytical frame within the larger sociocultural context of "figured worlds" and understand STEM as a "socially and culturally constructed realm of interpretation in which particular characters and actors are recognized, significance is assigned to certain acts, and particular outcomes are valued over others" (Holland et al., 1998, p. 52). From this framing, we see the resources identified by teachers and the ways in which they interact with these resources as informed by individual's understanding of STEM and what it means to be a legitimate participant in the STEM education community (Wenger, 1998).

Methods

This project incorporates multiple sets of data with more than 90 educators who were engaged in teaching STEM in formal educational contexts. In the first dataset, pre-service elementary teachers wrote "mathographies" about their experiences with mathematics at the beginning of a mathematics teaching methods course (Drake, 2006) and then completed a follow-up reflection at the end of the course. In the second dataset, in-service teachers seeking an add-on endorsement wrote autobiographical essays about their experiences with computer science. The final data set is a series of ethnographic interviews with pre-service and practicing teachers where questions were codesigned to elicit understandings of teachers' identities with STEM. Teachers were asked to describe their previous experiences with STEM and the ways that they identified or did not identify as STEM educators. Preliminary analysis used rounds of emic and etic coding to establish understandings of the ways that teachers described materials, relationships, and ideas and how their descriptions mapped onto their identities as STEM educators. Following Nasir and Cooks (2009), we also looked for the ways that participants across data sets described their experiences with and goals for learning STEM tools, practices, and expertise.

Findings

 © ISLS

Across these projects the context of data collection was within programs explicitly designed to train educators to build practice-linked identities in STEM through engagement with tools and materials, specific practices, relationships with other participants, and engagement in communities of practice beyond their own institutions. While several educators used their reflections and discussions to reinforce the ways they were developing these identities, the ways participants identified with STEM varied depending upon their past experiences, the strength of the relationships they built, their access to experts and peers outside of these programs, and their feelings of agency within their schools and careers. Expertise in STEM fields was sometimes a barrier to identifying as a STEM educator because some of these individuals did not identify as "teachers." However, perceived lack of expertise with STEM was also a barrier when teachers felt their participation in the STEM community of practice was not legitimate or would always be peripheral.

For example, our initial analysis pointed to the ways that some participants described alignment with computer science education because of early experiences playing video games. These educators' willingness to see themselves as having previously engaged with STEM materials and environments meant that they saw fewer barriers to accessing and engaging with the tools and practices taught in these programs.

Conversely, participants who described negative childhood experiences with mathematics often experienced anxiety when tasked with completing time-based assessments, such as fact fluency tests, or engaging in conceptual or procedural work around rational numbers, seldom identified as "being a math person," despite speed of computation being an indicator of mathematical understanding.

In contrast, a few individuals who had transitioned into education from previous STEM careers, such as engineering, had established expectations for a STEM community of practice prior to engaging in these programs. While some of these educators leveraged that experience to suggest norms and collaborate to build relationships with peers, others expressed frustration with "teachers that don't have a ton of experience" and even used their expertise to set up barriers for participation such as refusing to engage with peers until they had mastered certain skills or computational literacies. While these teachers had framed themselves as STEM experts, their ideas about the figured world of STEM did not necessarily align with the kinds of ideas required for educators.

In alignment with Nasir and Cooks (2009), our initial analysis suggests that access to materials and relationships supporting engagement with the STEM education community make it easier to have an in-bound trajectory toward a STEM identity. Even an understanding of the discipline that might be considered illegitimate by experts can lead to an in-bound trajectory if the individual feels successful and supported in what they believe are the practices of the community. Participants' adoption of identities as STEM educators was also sometimes complicated by their other identities and by their understanding of what it meant to be a STEM educator.

Significance

Nasir and Cooks (2009) call for examining learning and identity as "intimately related to one another but also…[as] distinct processes" (p. 58). Our emerging findings align with these researchers' notions of practice-linked identities as mediated by "engagement, persistence, and goals" (p. 58). As teacher educators and researchers continue to seek ways to support more equitable access to STEM skills for students, we must also consider the ways that educators have access to the tools, relationships, resources, and ideas that will allow them to develop in-bound trajectories to communities of practice and figured world(s) of STEM (Holland et al., 1998). By continuing to develop understandings about the material, relational and ideational resources that STEM educators require to embrace these identities, we can better support them to build the confidence necessary to offer access to all students.

The hidden meaning of physical interaction with exhibits: the relevance of the Instrumented Activity Situation model

Ilona Iłowiecka-Tańska, Katarzyna Potęga vel Żabik
ilona.tanska@kopernik.org.pl, katarzyna.potega@kopernik.org.pl
Copernicus Science Center

Abstract: Authors discuss the relevance of The Instrumented Activity Situation (IAS) model in analysis of visitor–exhibit interactions. Observing visitors playing with exhibits in science museums raises questions about the relevance of the actions they undertake. We argue that visitors' conceptual understandings of scientific phenomena are seeded via rapid iterative cycles of explorative co-attuning between processes of instrumenting and instrumentalization. In our analysis we have demonstrated how the adapted IAS model helps to analyze visitors' interactions with exhibits.

The major issue addressed

Observing visitors playing with interactive exhibits in science museums raises questions about the relevance of the actions they undertake. Observation of these processes prompts museum facilitators to intervene and provide visitors with instructions. But does such "mistaken" interaction lead visitors to new knowledge? The phenomenal logic of exhibits is deliberately obscured yet discoverable, rather than transparent and explicit. We argue that visitors' conceptual understandings of scientific phenomena are seeded via rapid iterative cycles of explorative co-attuning between processes of instrumenting and instrumentalization. The Instrumented Activity Situation (IAS) model (Verillon & Rabardel, 1985) highlights the intermediary status of instruments. It orchestrates multiple relationships which bind together the three elements constitutive of instrumented activity situations: subject (visitor), object (goal), and instrument (exhibit).

The potential significance of the work: the science center context

Exhibits are designed to provoke a series of anticipated physical manipulations that guide the visitor through potential physical actions with the object. Ideally, as a result, the visitor discovers the *exhibit effect* and further explores the scientific phenomena. Research provides evidence of visitors' signification of their physical experiences. Some researchers interpret visitors' continued repetitions of purposeful attempts to achieve the *exhibit effect* along with their exploratory behaviors as pre-symbolic perceptions and actions (van Schijndel, et al., 2010). Under this paradigm, the process of conceptualization can be envisioned as a negotiation between naïve (embodied) and cultural (verbalized) ways of perceiving phenomena. This negotiation can be seen as a dialogue that celebrates both perspectives while seeking reconciliation between them (Abrahamson, 2017).

The theoretical and methodological approach: towards an understanding of visitors' epistemic practices

The Instrumented Activity Situation model highlights the intermediary status of instruments (here: exhibits). It orchestrates the multiple relationships which bind together the three elements constitutive of instrumented activity situations: 1) subject (visitor), 2) object (goal), and 3) instrument (exhibit). The use of an instrument is indicative of the triad and of the multiple interactions which result from it, forming the common core characteristic of instrumented activity situations as a class. Accordingly, an exhibit becomes an instrument only when a visitor (subject) "has been able to appropriate it for himself – has been able to subordinate it means to his ends – and, in this respect, has integrated it with his activity" (Verillon & Rabardel, 1985, p. 85). Precisely at this moment, when an exhibit is treated as a tool (instrument), the visitor becomes a designer of the action in his or her own right. In the ISA model, the instrument mediates the subject–object interaction. In the case of the visitor–exhibit interaction, the exhibit is the instrument for the effect-object. Thus, the adapted ISA model focuses on the subjects' intentionality – their goals and actions – with rapid iterative cycles of explorative co-attuning design interpretations. The exhibit design plays a mediating role between the instrument and the object.

Design is hence understood as the concept of an artifact (exhibit) posited by a designer, that is interpreted by a user. Thus, the exhibit as an instrument of action is conceptualized equally by its designer and the user (visitor). Visitors' *action* is thus the (re)interpretation of the artifact, (re)discovering an exhibit's design. Possibilities for action are discovered by a visitor in real-time. Often, we can observe tension between the *exhibit*

 © ISLS

effect and the visitors' goal (i.e., what the user wants to do with the exhibit at the moment). Usually, visitors' *goals* are multiple, provisional, and change during the interaction – they emerge or get updated as the visitor goes along, constantly (re)developing sensory-motor schemas. Through exhibits, the science center aims to model a particular kind of scientific practice. This practice enables visitors to experience the type of agency that occurs during a design process. Therefore, in this paper, we investigate 2 cases of the visitor–exhibit interaction as a design situation.

Case Swirling Sands: a case of high confluence between the designers' and visitors' designs

The Swirling Sand exhibit consists of three slowly spinning disks covered in fine-grained sand (Figure 1). As the disks turn, visitors can draw in the sand using their hands or props, such as paintbrushes, scraper tools, and small scoops, available at the exhibit. Visitors can also change the speed of the disk's rotation using a small knob. The motion of the rotating disks and visitors' fingers produces a variety of intricate circular patterns and shapes. The three workstations also add a social dimension to the interaction through which visitors can observe and re-mix each other's work. The data excerpts presented below are from a young female adult visiting the Swirling Sand exhibit for the first time. Using a flexible protocol, the authors engaged participants in using the exhibit. The interactions were videotaped for subsequent analysis. Once the researcher asked the participant to use the exhibit, no additional instruction or cues were provided. The participant decided by herself what to do and how long the interaction should take. After she ended her interaction with the exhibit, the participant ("Pola") was shown a video recording of her interaction and was asked to describe her actions and goals. If the participant omitted certain actions, the researcher asked additional questions, such as "What were you doing at this point?" and "Why?" The goal of the semi-structured stimulated recall protocol was to examine the participant's conceptualization of her goals and actions. Pola used the exhibit for approx. 5.5 min. She was the only person interacting with the exhibit during that time. An analysis of the interaction is presented in the table below. Pola spent almost 80% of interaction time exploring the exhibit and its various features. She began using the exhibit with some sand on the plate and a relatively high rotation speed. After 5 min., Pola decided to start making patterns using the exhibit as a tool to achieve the effects predicted and intended by the designers.

Conclusions

In our analysis of these two examples, we have demonstrated how the adapted ISA model helps to analyze visitors' interactions with exhibits. One direction for further discussion is the evaluative value of the model. Is the degree of intuitiveness of an object equivalent to the extent of the confluence between designers' and visitors' effects? Conversely, does dissimilarity of designers' and visitors' effects entail a design failure, or rather successful discovery? How does the visitors' signification of their physical experience change according to the formal or informal context? Such discussion holds promise for implications for exhibit design and facilitation.

Design Considerations for A Middle School Computer Science Pedagogical Content Knowledge Instrument

Satabdi Basu, Daisy Rutstein, Carol Tate, Arif Rachmatullah, and Hui Yang
satabdi.basu, daisy.rutstein, carol.tate, arif.rachmatullah, hui.yang @sri.com

Abstract: K-12 Computer Science (CS) education is developing rapidly but still lacks a comprehensive measure for CS teachers' pedagogical content knowledge (PCK). We respond to this need by describing the design of a CS-PCK instrument for 'Algorithms and Programming' that measures three broad constructs: (a) teachers' understanding of standards and standards-alignment, (b) teachers' formative assessment practices, and (c) teachers' self-efficacy for teaching and assessing CS.

Introduction and significance of the work

Various theoretical and empirical studies have emphasized the significance of teachers' pedagogical content knowledge (PCK) in determining the quality of instruction and student learning. PCK is defined as teachers' ability to integrate their knowledge of content and pedagogy to guide, "ways of representing and formulating the subject that make it comprehensible to others" (Shulman, 1987 p. 9). In K-12 Computer Science (CS) education, the dramatic increase in recent years in the number of CS course offerings and thus the need for qualified CS teachers highlights the need for research on promoting teachers' CS PCK. Early research in CS education focused primarily on developing curricula and software that lower the barriers to computing and inspire student interest, and less on the pedagogy for K-12 CS education. In order to promote and improve CS PCK, it is critical to have an accurate and comprehensive way to measure it that can inform the design of teacher professional development (PD) aimed at improving CS PCK.

The CS PCK literature is currently limited and has mostly been informed by work conducted in other disciplines such as science and math education because key elements of PCK are similar across disciplines. Research in these fields has suggested that teachers have distinct PCK for different topics, resulting in PCK being measured with topic-specific instruments rather than subject-specific ones (Hill et al., 2008). Also, some studies have measured teacher PCK using labor-intensive qualitative methods such as analyzing teachers' lesson plans, and interviewing and observing teachers (e.g., Park & Chen, 2012). Topic-specific instruments and labor-intensive methods have made it challenging to scale measurement of PCK. In CS, one well-known PCK instrument is that by Yadav and Berges (2019) in which teachers are presented with vignettes describing student programming challenges and are asked to select strategies they would use to identify and/or address the challenges. While less labor-intensive and more amenable to scaling, this instrument does not include various common PCK components such as teacher knowledge of CS standards, ability to analyze CS curricula, and formative assessment practices which are aspects of PCK highlighted in the CS teacher standards (what teachers should know and be able to do) outlined by the Computer Science Teachers Association (CSTA, 2020). Further, this PCK instrument does not include measures of teacher efficacy and attitudes as suggested by the literature (Park & Chen, 2012).

To address the abovementioned issues, we developed a CS PCK instrument aligned with the topic of middle school 'Algorithms and Programming' that assesses teachers' knowledge of CS standards and standards-alignment, formative assessment literacy and practices, and self-efficacy for teaching and assessing CS. While not completely comprehensive, our instrument will allow for the measurement of many different aspects of CS PCK within one CS content area and may serve as a model for others developing additional CS PCK instruments.

CS-PCK Instrument design and development

We aligned our instrument with the 'Algorithms and programming' content area and a set of skills and abilities outlined by the CS teacher standards. We expect the instrument to take teachers 30-40 minutes to complete.

Component 1: Knowledge of standards and standards-alignment of CS activities

An important aspect of PCK is a deep understanding of disciplinary standards and ways in which students can engage with standards. It includes an understanding that each standard is a broad statement that can be further decomposed into a set of fine-grained learning targets. This component of our instrument targets teachers' understanding of CS standards (CSTA, 2017) and ability to identify what standard(s) and what aspects of standards a given CS activity is targeting. We developed 3 multiple-choice PCK tasks that provide an example of a CS curricular activity or a CS assessment task and ask teachers to select aligned standards and/or learning targets.

 © ISLS

Component 2: Formative assessment literacy and practices

This component of our PCK instrument targets teachers' formative assessment practices, in particular teachers' ability to (i) select appropriate formative assessment tasks to elicit evidence for (or against) particular student challenges, (ii) design rubrics to evaluate and interpret student responses to CS activities, (iii) predict outputs of student-generated correct and incorrect code, (iv) interpret student work and identify potential student challenges and causes for student errors, and (v) determine appropriate follow-up strategies based on student performance.

We developed a set of 8 PCK tasks involving a combination of selected and constructed responses. As an example, for one PCK task, we present a CS programming task and ask teachers to evaluate three student responses for both correctness and level of sophistication. In another task, we assess teachers' ability to select appropriate formative assessments by presenting a few tasks and having teachers select which student challenges they would be able to identify using the tasks. A third type of PCK task asks teachers to outline aspects of student responses to include in a rubric for a given CS activity. This will provide information on how well teachers are able to identify critical aspects of student work and recognize the importance of rubrics that go beyond correct/incorrect scoring of student responses. Another category of PCK tasks assess teachers' ability to interpret student work and diagnose student challenges on programming concepts. While it is important for teachers to be able to interpret student work, it is also critical that they know what to do with the information, especially if they have diagnosed student challenges. To address this aspect of teacher PCK, we developed three tasks that assess teachers' knowledge of instructional strategies. Each task starts with a vignette describing an instructional activity and targets a specific programming challenge. Teachers need to diagnose the student challenge and then select from a list of pedagogical approaches to indicate which approach(es) they would use to address the challenge.

Component 3: Self-efficacy for Teaching Algorithms and Programming

To create a measure of CS teacher self-efficacy for teaching algorithms and programming concepts and using formative assessments, we selected and adapted existing items from validated surveys that measure teachers' self-efficacy for teaching CS and using formative assessments. An example item for teaching self-efficacy is "I understand the algorithms and programming concepts well enough to be effective in teaching them to my students." For using formative assessment, an example item is "I understand how to diagnose students' understanding of algorithms and programming concepts in all stages of instruction." A total of eight 5-point Likert-type items with four for each sub-component constitute this component of our PCK instrument.

Next steps and future directions

This PCK instrument is part of a larger project to promote middle school CS teachers' PCK by supporting their understanding of CS standards and ability to use formative assessments related to these standards. Next steps on this project include piloting the PCK instrument for validation purposes, analyzing teacher responses to the tasks, and using the instrument as a pre-post-measure of how the project intervention is affecting CS teachers' PCK.

Emergent Social and Emotional Learning Outcomes through Collaborative Reasoning Discussions

Greg Friedman, Sisilia Kusumaningsih, Jingjing Sun
gregory.friedman@umontana.edu, sisilia.kusumaningsih@umontana.edu, jingjing.sun@umontana.edu
University of Montana

Abstract: Social emotional learning (SEL) has been identified as critical to meet students' needs. This study examined the potential of a small group discussion approach, Collaborative Reasoning (CR), on supporting students' SEL. Transcripts of debriefings after CR discussions and students' post-study interviews were analyzed for indicators of interpersonal competencies. Findings suggested students benefited in social awareness and relationship building skills after taking part in a series of CR discussions.

Introduction

The global experience of the Covid-19 pandemic has drawn increased attention to the social and emotional learning (SEL) needs of students. Yoder et al. (2020) found that more than two-thirds of states in the United States have identified SEL as a top priority and that more than four-fifths of states said that SEL has increased in importance during the pandemic. At the same time, schools are addressing concerns about academic learning gaps that have arisen even in well thought out pandemic responses (Engzell et al., 2021). It is clear that schools need to consider and implement practices that simultaneously address both academic and SEL needs.

The Collaborative for Academic Social and Emotional Learning (CASEL) has worked to identify programs that best promote the SEL competencies. They recognize that programs may take on different forms: explicit instruction in social and emotional skills and attitudes, interactive teaching practices such as class discussions, and integration of SEL with academic learning (CASEL, 2020). Among the fifty elementary school programs identified by CASEL only five utilized academic integration a means of supporting SEL. Further, only two of those five tracked and found significantly improved academic outcomes alongside SEL outcomes (CASEL, n.d.). These findings suggest that there is a lack of evidence-based programs that use academic integration and interactive pedagogy.

Small group collaborative discussions are one promising option for addressing the cognitive and affective learning needs of students through interactive pedagogy. Social constructivist theory (Vygotsky, 1934) suggests that communities of students that learn from and with each other create positive social structures to support academic learning while also promoting prosocial behaviors. Collaborative Reasoning (CR) is one model of structuring small group class discussions aligned with both academic and SEL goals.

CR is "an instructional method designed to engage elementary school children in group discussions about controversial issues raised in their readings" (Reznitzskaya, et al., 2009). In CR, children read a story and engage in peer-led and teacher-supported interactive argumentation on a Big Question arising from the text. The majority of prior research on CR has demonstrated the positive cognitive outcomes for students experiencing CR, such as enhanced argumentation skills. It is less known, however, whether CR can lead to SEL benefits. Li et al. (2007) identified children's emergent leadership during CR, which is potentially linked to some SEL skills such as social awareness. Lin et al. (2021) found that CR students exhibited greater peer acceptance and less aggression towards others. This study aimed to expand on this developing body of research around the benefits of CR discussions on children's SEL competencies. More specifically, we asked: Can CR support students' development of interpersonal SEL competencies that include social awareness and relationship skills?

Methods

76 fourth-grade children and their three teachers from an elementary school from northwestern U.S. participated in this six-month study. Two groups of five to eight students were randomly selected from each class to be videotaped during the eight CR discussions. The stories used in the CR discussions were deliberately selected to present multiple perspectives for students to consider. This included both fictional scenarios (*Should a mouse dentist help a fox in pain?*) and scenarios about children they might relate to (*Should Tyler be allowed to climb Mt. Everest?*). Transcripts of debriefings after each CR discussion as well as a post-study decision making interview (n = 68), were coded using the indicators of interpersonal SEL competencies identified in the CASEL literature (CASEL, 2021). Due to space limitations of this short paper, a subset of the relevant indicators (one from 'Social Awareness' and one from 'Relationship Skills') are presented in Table 1 below to highlight emergent SEL competencies that appeared during or after the CR discussions.

 © ISLS

Table 1
Coding Scheme: CASEL Indicators of Interpersonal Competency: Social Awareness Relationship Skills

CASEL Indicator	Example
Recognizing strengths in others (Social Awareness)	"I like how Lisa spoke up and also, like, how Ryan used kind of her schema //. And kinda, she took what Danielle thought--it was kind of like she challenged, it kind of felt like she was challenging her own thinking." (reflection)
Resolving conflicts constructively (Relationship Skills)	"They should at least talk it out on a group, respectfully, and nicely, instead of fighting like that or fighting over which one-idea is better. It's better to work to-together…" (interview)

Results

The discussion debriefings and student interviews revealed that CR discussions helped students recognize different perspectives, one essential component of social awareness. For example, a more talkative student shared in the first debriefing: *"…and not interrupting other people even if you're excited about your idea. Wait for the other person to end their idea."* This quote illustrates the student's developing social awareness and the recognition of the need to exercise self-management. As shown in the example in Table 1, students gained greater awareness of their peers' ideas and strengths by actively listening to each other.

Meanwhile, students suggested and implemented practices to foster better group interactions, a critical element of relationship skills. In the second example in Table 1, a student transferred their learning about working as a group to a hypothetical group that was "stuck." Other interviews and debriefings included ideas around effective communication, offering help and support when needed, standing up for the rights of others, practicing teamwork and collaborative problem-solving, and resisting negative peer pressure. One student shared: *"I think they should like put it together and see what the ideas are together. Maybe they can work together to make it all work."* Students that experienced CR were able to move from a largely "I" perspective to greater peer recognition.

Discussion

The findings of this study support and expand on prior work examining the benefits of CR on students' SEL competencies. Although still at the preliminary stage, our analyses revealed a promising confirmative answer to our research question, that is, students are likely to further develop social awareness and relationship skills during CR discussions. This finding is aligned with previous research on emergent leadership during CR (Li et al., 2007) where students successfully managed the group discussion, as well as research on the benefits of CR on students' social relationship with peers (Lin et al., 2021). This finding might particularly interest school administrators and state stakeholders who have been searching for an interactive approach to integrate SEL within academics.

Designing a Method for Turmoilization of Understandings through Multi-voiced and Multi-contextual Reflection

Hideyuki Suzuki, Ibaraki University, hideyuki@suzuki-lab.net
Hideo Funaoi, Soka University, funaoi@umegumi.net
Yoshihiko Kubota, Tamagawa University, kubota@kubota-lab.net
Hiroshi Kato, Open University of Japan, hiroshi@kato.com

Abstract: This study first points out the importance of "Turmoilization of understanding," that is, reconstructing a coherent understanding once established through multi-voiced and multi-contextual reexaminations into a form that incorporates indeterminacy. Then, we propose a method to support the turmoilization of understanding. The pilot study suggests some aspects of the effectiveness of this method. In future work, we will establish a method through a detailed effect examination.

Introduction

Understanding is the act of associating facts and associating pieces of knowledge into a coherent whole (Nickerson 1985). To apply or restructure the understanding in various places, the learner needs to incorporate indeterminacy and conflicts into their understanding, rather than simply tracing the partially consistent theory given by the teacher. In other words, it is necessary to develop relatively subjective and incomplete "personal knowledge" (Entwistle & Smith 2002, Fyrenius et al. 2007). Murray (2006) argues that the uncertainty of knowledge (ambiguity and paradox) is the impetus for creation and that eliminating the uncertainty limits knowledge and makes it unusable. In recent years, it has been pointed out from studies of "Negative Capability" (e.g., Senge et al. 2004) that the incorporation of indeterminacy into understanding is effective for its subsequent utilization and expansion.

Although there are previous studies on the significance of incorporating indeterminacy into understanding, no systematic training method for reorganizing understanding in such a form has been proposed. Therefore, in this research, the authors propose a training method for understanding turmoilization.

Turmoilization of understanding

What does it mean to "turmoilize" an understanding once it has been established? For example, if you have understood what ZPD means through textbooks or lectures. The understanding is coherent, and there are no uncertainties. Here, we are convinced that we have understood it. However, this state is nothing more than an illusion of certainty (Bencze & Hodson 1998). To break this illusion, learners should reexamine the understanding from a perspective other than themselves—assimilated into a textbook, and try to reconstruct the understanding in a context different from the context of the lecture. Due to the reconstruction, the understanding once established becomes a conditional understanding, and other possibilities of interpretation or expansion are embedded into the understanding. It is important to try to eliminate such indeterminacy, but it is more important to keep an understanding as a form that includes such instability. Such an understanding can be an embryo for the expansion of learning. This discussion corresponds to the dual function of the text pointed out by Lotman (1988). That is, Lotman argues that the text comprises two distinct functions: a univocal function that perfectly matches the interpretation of the speaker and the listener, and a thinking device-like function that finds a new interpretation from the disagreement between the speaker and the listener. Turmoilization of understanding can be seen as adding the function of a thinking device to the established univocal understanding.

Designing a method to enhance “Turmoilization of understanding”

Here, we propose a training method for the turnover of understanding based on the above considerations. This method comprised four stages. That is, A. expressing initial understanding, B. mutual commenting activity based on given viewpoints, C. reflection, and D. reconstruction of the expression of understanding. In A, the learner represents their understanding as a written article. In B, the learners are supposed to comment on each other's articles from the given person’s perspective. This can be regarded as an application of the mutual teaching method (Palinscar & Brown 1984) in that the processing performed within the individual is externalized as a role between individuals. The viewpoints are tentatively set as follows to provide a scaffolding for reexamining understanding from the viewpoints of others and other contexts: a) a person who seeks an interpretation of their experience; and b) a person who seeks a means of problem-solving based on the related knowledge. By engaging in this activity, learners are expected to be able to internalize multiple perspectives for understanding and utilize them in internal

 © ISLS

dialogue. In C, the learner examines the comments received from other learners and verbalizes how their understanding has been shaken. Metacognition is important during this stage. Therefore, as a scaffolding, we introduce "reflection from the viewpoint of a commentator." Through this support, students can calmly look back and grasp how their understanding is turmoilized from an objective perspective. In D, the student rewrites his understanding based on C.

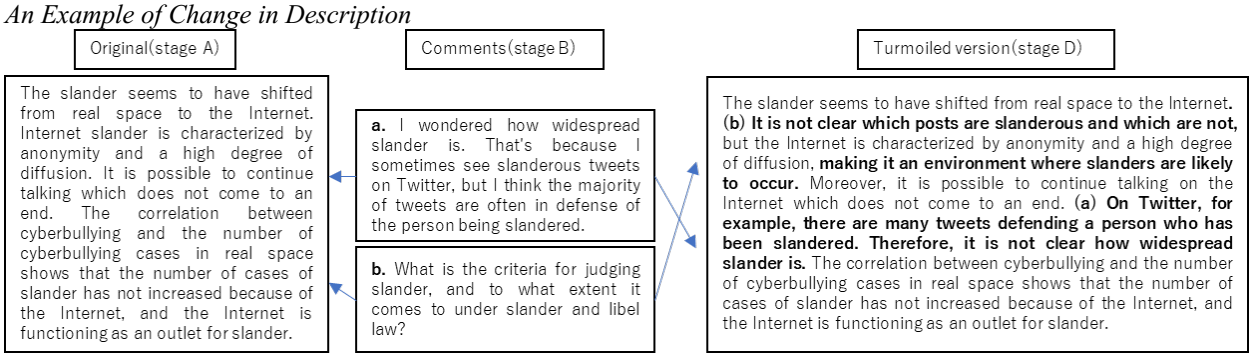
Pilot study

A pilot experiment using this method was conducted with 18 undergraduate students. In this pilot study, the students first read a report on slander on social media, and after a brief discussion, they expressed their understanding of the rules of writing. Afterward, they exchanged documents with other students and conducted mutual comment activities from two viewpoints. The viewpoint set in the experiment was as described above. The subjects then examined comments on their documents. Then, they rewrote their expression of understanding into the form of having a fluctuation of understanding in the expression of their understanding. To simplify this procedure, reflection based on the commentator perspective was omitted to focus on the evaluation of stage B.

This preliminary study suggests that the proposed method may facilitate the turmoilization of learners' understanding. Figure 1 shows how one subject's original description was revised into a turmoilized version based on the comments from two perspectives. The final description of the understanding contained uncertain elements. These are considered effective in expanding understanding and applying knowledge. However, notably, the turmoilized version only incorporates comments as is, and there is limited inter-text interaction between the original description and the comments. To support this, a review from the commentator's point of view in Stage C would be effective.

Figure 1

An Example of Change in Description



Conclusion

In this study, we discuss the importance of incorporating uncertain elements in understanding and propose a method for this. The pilot study demonstrated the partial effectiveness of this approach. In future work, we will establish a method through a detailed examination of the effect of this method.

Does where you start matter? The interaction between prior knowledge and effectiveness of game-based interventions

Abstract: The current study investigated how prior knowledge moderated the effects of three educational technologies (*From Here to There*, *DragonBox 12+,* and problem sets in *ASSISTments*) on seventh-grade students' later algebraic knowledge. Pretest scores only moderated effects of *From Here to There*, with larger effects among students with higher pretest performance. Our findings have implications for understanding how prior knowledge interacts with design features within game-based applications to impact algebraic understanding.

Introduction

Algebra is a critical foundation for advanced mathematics, but many middle school students struggle to understand basic algebraic concepts (Kieran, 2006). Much of the difficulty stems from understanding how to create, transform, and interpret statements expressed in standard algebraic notation. Educational technologies use varying design philosophies to address this difficulty and teach algebraic concepts. Some tools, such as *From Here to There* (FH2T; https://graspablemath.com/projects/fh2t) and *DragonBox 12+* (DB; https://dragonbox.com/products/algebra-12), engage students in game-based learning, allowing students to interact with algebraic notations and solve puzzle-like problems in a playful environment. Other tools, such as online problem sets in *ASSISTments* (Heffernan & Heffernan, 2014), provide timely support and feedback on traditional homework problems. However, how the impacts of these different approaches vary with prior knowledge have yet to be thoroughly examined. Understanding whether students with higher or lower prior knowledge gain more from these technologies is important for providing effective and efficient instruction that supports all students. On one hand, students with high prior knowledge may be more equipped to benefit from these interventions compared to students with low prior knowledge (e.g., Swanson et al., 2008; Wood et al., 2020). On the other hand, students with low prior knowledge may have more room for improvement (e.g., Murphy et al., 2020; Ramani & Siegler, 2011). The current study builds on our prior work comparing the impacts of three distinct educational technologies—two game-based applications, FH2T and DB, and two modes of online problem sets in *ASSISTments*—on algebraic understanding among 1,847 seventh-grade students (Decker-Woodrow et al., in prep.). We present preliminary analyses of whether students' prior knowledge moderated the effects of these technologies on students' algebraic understanding.

Method

Seventh-grade students (N = 1,847) were recruited from 10 middle schools within a large suburban district in the Southeastern United States. Students completed nine 30-minute intervention sessions in one of four educational technology conditions (randomly assigned at the student level within each class): FH2T, DB, problem sets with immediate post-response feedback, or problem sets with post-assignment feedback (control condition). Teachers chose the days that their students would work on the assignment in class, and students had two weeks to complete each assignment. The study occurred between September 2020 and April 2021, during the peak of the COVID-19 pandemic in the United States. Prior to the fall semester, students and their families chose whether to attend school 100% in-person or 100% virtually, with the option to change their selection during the year. Regardless of instructional modality, all study assignments were administered online, and students worked individually at their own pace using individual devices. Before and after the intervention, students received a 40-45 minute 10-item pre- and post-test algebraic knowledge assessment (Star et al., 2015; α = .89).

Results

We conducted two, 3-level hierarchical linear models, with students nested within classrooms (n = 127), nested within teachers (n = 34). The outcome variable was students' post-test scores; classroom format (in-person vs. virtual) was a Level 2 predictor, and all other variables were Level 1 predictors. Covariates included race/ethnicity,

 © ISLS

gender, and participation in advanced mathematics classes, an Early Intervention Program, or an Individual Education Plan. Pre-test scores were grand mean-centered, and all other covariates were dummy-coded. The first model revealed a significant intervention main effect ($\chi2(3) = 23.3$, $p < 0.001$), in which FH2T and DB significantly outperformed the control condition on the post-test. Next, a significant interaction was observed between intervention condition and pre-test scores ($\chi2(3) = 11.0$, $p = 0.01$) but only for FH2T ($\gamma = 0.14$), reflecting larger FH2T effects among students with higher vs. lower pre-test performance.

Discussion

After a 4.5-hour intervention, students in both FH2T and DB significantly outperformed students in the control condition on algebraic knowledge, suggesting that game-based contexts may increase students' interest and engagement with mathematics, and in turn, support their performance. However, only FH2T had larger effects among seventh-grade students with higher pre-test performance. One key difference between the two technologies is that FH2T grounds in-game actions in algebraic notations from the start, whereas DB gradually transitions students from pictures of monsters to abstract notation as the game proceeds. Thus, for this age range, FH2T's immediate introduction of algebraic notation may be more effective for those with higher starting algebraic understanding. Future work will explore potential mechanisms (e.g., if prior knowledge promotes greater engagement when algebraic notation is introduced from the start, or if prior knowledge supports connections between gesture-actions and concepts). The findings provide evidence that game-based learning platforms are effective for improving algebraic understanding, but that students' starting points need to be considered.

Game-Based Punctuation Training to Promote Clause Analysis: A Proposal

Luke West, Jiabei Xu
law19a@my.fsu.edu, jx13@my.fsu.edu
Florida State University

Abstract: High-school-level standardized exams devote 10-15% of its content to grammar and punctuation skills, yet the rules of and best practices for training punctuation are often elusive. We describe an ongoing pilot study where students preparing for the ACT/SAT participate in game-based training sessions for advanced English punctuation. Game levels require active organization of sentences, and students are supported through (1) text from a virtual agent, (2) hints, and (3) a visual cognitive organizer.

Introduction

In this proposed study, we explore the impact of a browser-based ACT/SAT-level grammar training game on students' grammar performance, simultaneously comparing two implementations of a learning support tool. First, for the quantitative component, we use pre-/posttest scores and in-game performance data to assess whether mandatory or optional learning support is more effective and determine what factors contribute most to improving learning and engagement. Second, for the qualitative component, we use gameplay observations and learner interviews to identify patterns in learner confidence and motivation during gameplay, as well as tutors' preferences and questions surrounding the use of games in teaching punctuation strategies to their students. We supplement our investigation with interviews with online tutors working 1-on-1 with the same population of students to better understand tutors' perspectives on student needs and obstacles facing educators concerning the use of such online tools in remote learning settings.

Background

In this study, we investigate the potential of a web browser-based game for training grammar skills at the college entrance exam level (e.g., ACT/SAT). Students often struggle remembering and applying punctuation rules, particularly in complex, multi-part sentences. Practicing using correct punctuation in a computer game with access to sentence organization tools may help students (1) identify patterns in how sentence parts are joined, and (2) accurately complete punctuation-related problems in standardized testing situations.

The general question of providing assessments and learning support in game-based learning has been the subject of reviews concerning best design practices (Ke, F., & Shute, V., 2015). Second, the practical importance of punctuation skills for students preparing for the ACT/SAT is evident in that one fourth of each exam is devoted to English grammar and editing strategies. Game-based learning can reduce anxiety for students (Yang et al., 2018). Wouters et al. (2015) also note that instruction can be helpful in game-based learning, especially when it involves identifying relevant new information for learners. This provides motivation for the qualitative component of this study, wherein we investigate the role instructors (in this case, tutors) can play in game-based learning for their students—if overt instruction by a human is helpful for students during gameplay, then it is important to better understand the perspectives and attitudes of tutors toward engaging with their students in digital game-based learning. Because the ACT and SAT exams are specifically for high school students preparing for collegiate study in the US, this criterion helps limit the subject pool to high school students for whom advanced English punctuation skills are relevant. Recruitment focuses on students either preparing for the ACT/SAT or independently studying English as a second language because these are the two groups for whom the intervention and research questions are most pertinent.

Methods

The learning intervention is a browser-based punctuation training game, wherein subjects create a virtual character and help "decode encrypted messages" by assigning correct punctuation to multi-clause sentences. Each level comprises a single sentence divided into four parts (Figure 1), in-game support such as pop-up text hints (Figure 2), and an organizer tool displayed as a screen overlay where subjects can label sentences and see common punctuation patterns as a reference while solving each level (Figure 3). As a web application, students can access this through most browsers on most computers, tablets, and smartphones, but subjects are recommended to use computers or Chromebooks or tablets while completing the 21 game levels for this study, to ensure consistent performance by the software. Learners are individuals preparing for the ACT or SAT exam,

 © ISLS

or are studying English as a 2nd language. Learners are excluded if they cannot complete the intervention either in a session with their tutor or independently outside of tutoring sessions (they must not complete only half of the intervention outside of session, for example). Learners are also excluded if they are below grade 9.

There are two types of data collection. First, learners take a pre-test (10 questions) in ACT/SAT English format, and after learners complete 21 game levels, they are given a post-test. Pre-test and post-test scores are saved automatically, as well as game performance data for each round they complete, including how much time they spend on certain game-tasks, how many times they answered correctly or incorrectly, and how long they viewed feedback text or the organizer tool. The second type of data collection is an open-ended survey for learners and informal interviews with professional online tutors who have a chance to use the intervention with their student(s). These are brief interviews with open-ended questions where tutors can share their general thoughts and experience with the intervention and related learning games. Pre-/post-test data and in-game performance data are all collected automatically through the RPG Maker MV game engine.

Recruitment of learners began in July, 2021 and continues on while learners participate in the intervention. This depends on learner availability. Learner surveys will be administered after learners finish the main portion of gameplay (21 levels + post-test). Informal interviews with tutors will take place sometime convenient for them after their students have completed the intervention (1-3 weeks after).

Analysis

Quantitative data is coded anonymously, downloaded, and analyzed using IBM's SPSS software. Survey and interview data is coded using a qualitative framework. For the qualitative component of this mixed methods study, main themes that arise through analysis of interviews will be summarized and presented to subjects who participated in the interviews by email within 1-6 months of the completion of research procedures. Subjects will have the chance to voice agreement or disagreement (text responses by email) with how their stories will be represented and the researchers will update qualitative summaries accordingly. Like all other data in the study, this will be stored using the coded name of the participant and under the same password protection.

Finally, we will continue to explore results to identify game performance and affective patterns as students engage with the game. By comparing data from the two groups, we address whether the delivery of learning support made an impact on how students engage with the game. We will also address to what extent student interaction with in-game support features interacted with learning outcomes or affective states during gameplay, such as engagement and confidence level.

Table 1

Post-test score improvement and number of correct submissions and toggles of the organizer.

Participant	5	2	7	8	1	4	6	9	10	3
Posttest - pretest score	-3	-2	-2	-1	0	2	2	2	2	3
Correctly completed organizer	3	17	12	15	13	21	15	21	20	20
Organizer accuracy	63%	51%	54%	83%	26%	74%	40%	50%	78%	78%
Times organizer toggled:	48	150	130	121	89	101	81	118	103	155

Note. Post-test and pretest scores are the number of correct questions out of 10.

As seen in table 1 above, preliminary results from our first 10 participants point to a general trend where students showing score improvement on the post-test (4, 6, 9, 10 and 3) completed the organizer for more game levels and tend to have higher organizer accuracy overall. However, these students are not always the ones who toggle the organizer most often (row 4). How accurately students complete a sentence-part organizer support tool with higher accuracy is a better predictor of SAT/ACT-level grammar accuracy improvement than how often learners access the support. When designing similar learning interventions, designers may consider incentivizing accuracy and full completion of syntax-focused learning support to enhance learners' score gains.

Intergenerational Conversations Through Redesigning Tabletop Games: Playing, Designing, and Learning with Canadian Families

Beaumie Kim, Reyhaneh Bastani, Justin Acton, Jerremie Clyde
beaumie.kim@ucalgary.ca, reyhaneh.bastani@ucalgary.ca, justin.acton@ucalgary.ca, jvclyde@ucalgary.ca
University of Calgary, Canada

Abstract: In this poster, we present our study of the activities for families in Canada to redesign tabletop games, reflective of their interest and culture on their own time during the global pandemic. We collected data through online communications (e.g., video recordings, games). We describe how they expressed what matters to them individually and collectively.

Research has shown that game play and design position learners as individuals who engage creatively and critically with disciplinary ideas. Many tabletop games are played across generations (e.g., *Mancala* in Africa), and are reflective of cultures and ways of knowing, learning, and being. Using movements and gestures with physical objects also makes tabletop games suitable for supporting communication among players of different ages and linguistic backgrounds (Kim et al., 2021). Our research explores how tabletop game redesign activities can help participants invent ways to draw on and connect with intergenerational differences and cultural practices, by seeing individual differences as resources for social learning (Ladson-Billings, 1995).

Cultural Practices and Tabletop Game Redesign

Our work is supported by the cultural-historical significance of tabletop games. Crist et al. (2016) described how board games were used to facilitate interactions "across kinship, ethnic and socio-economic boundaries" (p.181) and were adopted into varying societies by being decorated and reimagined appropriately to their cultures. While designing games engages learners in inventing alternative ways of knowing (Civil, 2002), *re*designing activities could enrich linguistic and cultural diversity. In a study of students' redesigning a game for mathematics learning (Kim et al., 2021), students demonstrated their reimagined play by adopting rules from the games from their cultures and showed that culturally-relevant games have the potential to bring historical and cultural contexts to disciplinary thinking (e.g., mathematics; Bayeck, 2018). Historical and school game redesign work resembles how culturally sustaining pedagogy seeks cultural and linguistic pluralism in schools (Paris, 2012, p. 95), and may help educators capitalize on learners' diverse resources. Learning should be seen as critically enriching strengths, moving away from replacing deficits and aligning with linguistic and cultural hegemony (Lee & Walsh, 2017). Here, we see cultures as meanings and practices of the families and other social groups they may belong to, inherited or (being) formed individually and collectively.

Research Design

A pilot study was conducted through distant video communications with Canadian families during the global pandemic. The research team created a general guideline for their game redesign process. We explored the families' approach to the project, the game they selected, their ideas for designing their own game, and their experience of game redesign as a family. They provided written descriptions and visual data from their in-progress designs and final artifacts. In our analysis, we reviewed our notes and recordings of the online meetings and identified how they interacted as families and how redesign ideas formed. We examined their artifacts (i.e., games, play-recordings, photos, blog) to understand the connections made with their different interests and practices.

Tabletop Game Redesign by Families

Many adult participants intuitively identified the shortcomings of existing games, compared cultural gaming practices from their youth, and reflected on intergenerational relationships and games they play in different occasions. On the other hand, the game design process and the redesigned games did not exhibit overt cultural markers. Instead, we observed that games and game design practice could allow cultures to exist and influence action and decision-making in the process. Through this process, the families may engage in understanding their own cultures and what matters to their family members more deeply.

Understanding and expanding a child's cultural practices

Some families focused on understanding and expanding a child's practices through the process. For example, one family (Caucasian) redesigned the card game *Love Letter,* led by Ellie (the 5th grade daughter), "to correspond to

[her] current favourite book series, *Warriors* by Erin Hunter" (blog post). In our conversation, they discussed how there are parallels between the life represented in the renaissance courting theme of *Love Letter* and the hierarchal nature of the *Warriors* series' characters: "((In)) *Warriors* there's different ranks. There's a leader, a deputy and medicine cat or you're, um, kind of an apprentice" (Ellie). They crafted cards to play-test the game as family to see how the game works and to adjust rules. Supporting the redesign of the card game and playing the redesigned game provided an opportunity to learn about the literature that Ellie was invested for this family. Ellie was also motivated for the possibility of contributing to the *Warriors* online community. After the redesign was complete, the family created a blog page to share with the *Warriors* community to download the cards and the rules.

Exploring the different interest of all family members and engaging in intergenerational conversations

Exploring the different interest of family members was another pattern. A family with Chinese background redesigned *The Game of Life* to make it more relevant to their current and future experiences. This game was of interest to the two daughters in grade 5 and 7, Alia and Eira. While brainstorming, they pointed out how the choices and life paths in this game do not resonate with their perspectives. For example, they considered the careers in *The Game of Life* "outdated" and discussed a collection of careers to add to the game. The process of choosing the careers sparked conversations through which the parents got to know the careers the kids knew about and introduced other careers that they did not know. They also decided to create a board that reflect each family member's interest and put all four boards together to create the game. "Originally, all of us had different ideas and now we could pare it down into more of a team effort.... I think it was interesting because each of us had a role to guide one another... how we want to start this ((the game)) and how to end this" (Hailey, mother). Across the boards, they explored how action and chance cards could be similar but also different. Through redesigning the game, they had the opportunity to learn and appreciate each other's interest and find ways to make them as a coherent whole. They underscored how each tried to attend to others' viewpoints and what they valued.

Discussion and Conclusions

We explored how families invent ways to draw on and connect with intergenerational differences and cultural practices while redesigning tabletop games. We observed that the families focused mainly on expressing their interest through the design while noticing invisible boundaries between them. Without explicitly exploring their cultural practices, families expressed what mattered to their members individually and collectively. They had opportunities to value and support the members' interest, while the cultures outside of their family boundaries (e.g., fan-based practices, other cultures) contributing to their practices. They did not see their current game design as the end but as having the potential to evolve and expand. They demonstrated the value of redesigning an existing game by questioning what is depicted as dominant, taken-for-granted practices in the original game, which shows the glimpse of family's developing critical consciousness. In our pursuit of redesign activities, we see the significance in: (1) identifying traditional and evolving ways of acting in diverse social and cultural systems; (2) creating activities to develop critical consciousness; and (3) positioning diversity as resources for interdependence (Joyce, 2017; Ladson-Billings, 1995; Paris, 2012). This pilot study showed the tabletop game redesign as an initial step to deepening intergenerational conversations and develop critical consciousness as families.

Categorization and Framing Teaching Discussions in an Online Physics Classroom

Gregory D. Dunford, Bahar Modir, Robynne M. Lock and William G. Newton
"gdunford@leomail.tamuc.edu, bahar.modir@tamuc.edu, Robynne.Lock@tamuc.edu,
William.Newton@tamuc.edu"
Texas A&M University-Commerce

Abstract: We analyze written discussions of in-service high school physics teachers as part of the coursework of an online Master in Physics with Teaching Emphasis program. We categorize the form and scope of teaching talks made in response to course structure using the theories of community of practice and framing: *Strategies for Teaching Math in Physics; Integration of MPTE Course Content into High School Courses; Pedagogical Strategies for Teaching Physics.* We discuss the instructional implications.

Introduction

Physics Education research (PER) has led to the development of research-based curricula such as tutorials that can be directly implemented in physics classrooms by instructors. However, many of these efforts historically do not include pedagogical insights of instructors in the development process. (Elby & Yerdelen-Damar, 2020). When teachers dialogue around teaching practices, their classroom experience could provide a valuable perspective in considering how curriculum is developed and implemented. This provides a venue for teachers to form a community and discuss the shared goal of teaching practices in high school physics curriculum aligned with the definition of the community of practice (Wenger, 1999).

An online Master in Physics with Teaching Emphasis (MPTE) program has been developed to strengthen high school physics teachers' content and pedagogical knowledge. The course work includes 6 core courses. A central part of each course design is participation in weekly online discussion boards which gives rise to teaching discussions. We categorize teaching talks and contribute examples of teachers' discussions by exploring how teachers share about their approach to teaching physics concepts in their own high school classrooms, the mathematical concepts that is used in teaching physics, pedagogy, and how to connect advanced math and physics topics that they learn as part of the MPTE program into high school classrooms.

Structural factors can promote classroom community formation and participation in practices (Irving & Sayre, 2014). In our community, we observed that the course structure (content of lectures and prompts from the course instructor embedded in the video lectures) tends to inspire different forms of teacher talk. For instance, physics lectures focused on the 'advanced math content' tend to fuel more discussion related to *Teaching Math in Physics*, while prompts presented in the video that asked 'How do you teach this physics topic in your class?' prompted more discussions related to *Pedagogical Strategies for Teaching Physics*. The theme related to *Integration* was represented in most of the weekly discussions, as the MPTE course content design is intended to be relevant to the teachers' teaching topics (See Table 1).

Methods and Context

In this study, we focus only on teaching discussions that form as part of the online problem solving discussion forums of a 12-week Electricity & Magnetism for Educators course in the MPTE program. Each student is required to make at least two posts weekly. Students in this program are mostly in-service high school teachers. Of the 38 teachers from Spring 2018, 22 participated in the study. Two independent researchers first read the posts followed by discussions. Analysis of the first 5 weeks with existing teaching talks revealed commonalities among posts, which led to development of an initial coding scheme. Another round of analysis of further weeks revealed that some of the posts that overlap in the discussion theme are different in scope.

Framing provides a window to better see the scope of the practices in a situation based on the expectation of 'What is going on here?' (Tannen, 1993). Prior study has applied framing to problem solving situations, where a student in a narrow frame tends to focus on a task at hand, whereas a student in an expansive frame is more open to take a general approach (Irving et al., 2013). Taking the guide from the study by Irving et al. (2013), we characterized expansive vs. narrow discussions in the teaching context. Narrow teaching discussions describe activities that are more focused and implemented to the 'in the moment' of the classroom, such as when teaching a math skill in a specific way to make it understandable for the students. On the other hand, expansive teaching discussions describe teaching practices that can be applied across multiple classroom contexts (e.g. other physics classes), such as teaching students to use mathematical equations in physics.

 © ISLS

Table 1
Teaching discussion themes and frames discussed by teachers

Theme	Narrow Scope	Expansive Scope
Strategies for Teaching Math in Physics	Discussing teaching a specific math concept/skill needed in physics	Discussing teaching a math concept/skill applicable to various physics concepts
Integration of MPTE Course Content into High School Courses	Discussing boundaries for curricular expectations for a specific course/level	Discussing whether a broad physics topic is represented in the curriculum teachers teach
Pedagogical Strategies for Teaching Physics	Discussing a specific technique to address student confusion of a particular physics concept	Discussing techniques for supporting student learning of physics that can be applied throughout the broad curriculum

Findings and examples

For the theme of *Strategies for Teaching Math in Physics*, in narrow discussions, teachers tend to identify specific mathematical skills and concepts that students must utilize while studying physics. Teacher 1 addresses student difficulty with a particular mathematical concept (dot product) used in physics. The teacher suggests that teaching students to use the relevant trigonometric function rather than defining the 'dot product' has avoided their student confusion. We classified this comment as a narrow scope as it is focused on teaching a specific math skill. The teacher is not discussing a broad teaching strategy of how to address a mathematical approach but instead focusing on a small topic of how to teach 'dot product' to students. The teacher has chosen to 'neglect' addressing the comparison of 'dot product' to 'cross product', which reinforces the limited scope of the teaching practice, as making this connection for students would have been an expansive approach.

> *Teacher 1: I have so far neglected mentioning 'dot product' versus 'cross product'… and I've never really had a whole lot of confusion from the students based on that idea.*

In an expansive discussion, teachers request for or discuss with each other general strategies for teaching math in physics. Teacher 2 discusses a general approach for teaching math skills in physics problem solving with variables (e.g. alphabet soup) vs. numbers. The teacher suggests a flexible teaching method of providing some numerical examples initially and then transitioning to more symbolic examples. We classified this comment as an expansive scope as it can be applied to different physics problem-solving situations.

> *Teacher 2: I too prefer the alphabet soup, but my students are not always with me. I generally start with problems with numbers and angles, so that my students can get comfortable with the process and then do some with just the alphabet.*

Conclusions and implications

The categorization scheme presented in this study can be useful in analyzing discussions among teachers in a learning community. Additionally, the examples suggest that teachers make intentional decisions about utilizing a particular scope of their instruction in the classroom to support their students' learning process. The reasons behind these choices can inform and aid in the development of physics curriculum for high school students that which portions of it might benefit from a narrow or an expansive perspective.

Developing Dynamic Dashboards for Classroom Orchestration

William Goss, University of Wisconsin-Madison, wgoss2@wisc.edu
Indrani Dey, University of Wisconsin-Madison, idey2@wisc.edu
Rachel Dickler, University of Colorado Boulder, rachel.dickler@colorado.edu

Abstract: Classroom orchestration is a multifaceted pedagogical challenge, requiring teachers to simultaneously manage activities across multiple social levels and under various constraints. Teacher dashboards are commonly developed tools to aid orchestration; however, many fall short in real-time classrooms. To address this impediment, we used participatory design sessions with teachers to better understand their needs, based on which, we plan to build a dynamic dashboard with real-time actionable metrics.

Introduction

Classroom orchestration is the process of managing the flow of activities, student configurations across multiple social levels (individual, group, and class), materials, and class progression within a learning environment during its enactment. The need to monitor these various facets of the classroom in real-time and providing both conceptual and logistical support is challenging and places a heavy load on teachers (Dillenbourg et al., 2009). Dashboards have seen growing interest as a tool that can potentially reduce orchestration load as it provides a lens into classroom activity and progress, which is helpful because teachers cannot simultaneously attend to all groups in their classrooms (Matuk et al., 2015).

Teacher dashboards typically present data at three levels: progress of individual students, progress and participation patterns from groups, or trends across the whole class (Tissenbaum & Slotta, 2019). Different performance metrics can be useful for each level, e.g., participation metrics can provide insights on which group members are contributing to discussions (Martinez-Maldonado, 2019), whole-class metrics can alert the teacher which students need help, and individual progress metrics can provide insights if a particular student is off task or has a question (Dickler et al., 2021). Providing a lot of information while the class is in progress can overwhelm teachers and not all the information is always relevant (Tissenbaum & Slotta, 2019). We propose a dynamic dashboard that is customizable and addresses the changing needs in a classroom.

We conducted participatory design sessions with teachers to better understand their orchestration needs and inform our resulting dashboard designs. Participatory design necessitates teachers' involvement in the development of the technologies they will be implementing in their classrooms to ensure its usefulness and usability (Holstein et al., 2019; Matuk et al., 2015). In the first study, we asked teachers about what types of information might be most useful to them. We created mockups of a dashboard interface based on their input, and in the second study, showed the teachers the mockups and asked for their feedback on specific features.

Participatory design studies with teachers

Study 1

Our objective in the first study was to understand what dashboard features and progress metrics teachers would be most interested in, given different classroom situations. Eight middle school science teachers from the Midwestern U.S., with teaching experience between 9 and 34 years, participated in the initial study. It was conducted via Zoom over three sessions, each lasting two hours, with no more than three participants.

Teachers were presented with three scenarios focusing on: *individual students* (e.g., progress, focus, etc.), *groups* (e.g., participation patterns or off-task discussions), or the *whole class* (e.g., covering challenging material) and what information would allow them to best refine their classroom strategies. After the scenarios were verbally explained to the teachers, they placed the functionality they found most useful for each scenario on a blank tablet template. Researchers were available for further explanations on functionalities or scenarios.

Results

The teachers chose a maximum of nine functionalities across the 20 dashboards they created across different scenarios, including both *features* (e.g., messaging students) and *metrics* (e.g., question analysis). Different teachers chose different metrics depending on the presented scenario. For example, 100% of the teachers

 © ISLS

thought a *close-ended question analysis* metric would be useful in the whole class, compared to 33% in the group, and 57% in the individual scenarios respectively. All the teachers chose the *student participation in groups* metric for the group scenario but none chose it for the individual and class scenarios. A 0% or 100% consensus was found in only nine out of the 45 possible functionality-scenario combinations (20%), together with a constant shift between selected functionalities, highlights the need for a dynamic dashboard.

We identified six key metrics based on the teachers' responses, i.e., at least one teacher requested a particular metric across all three scenarios, or more than 50% of the teachers requested that metric in at least one scenario. They are: (a) *Class Status* (a high-level insight on what is happening in the class as a whole), (b) *Group Progress* (which group is at which point in the activity), (c) *Group Participation* (amount of individual participation in group discussions), (d) *Close-ended Questions* (an overview of students' responses to close-ended questions (e.g., multiple choice)), (e) *Open-ended Questions* (insights on how students are utilizing science ideas and concepts in their essay writing, using different NLP techniques), (f) *On-task/Off-task Behavior* (granular insights on which students are off-task). As we need more time to determine how to capture off-task behavior (f), we used the first five metrics (a-e) to create low-fidelity dashboard designs.

Study 2

The aim of our second study was to get teachers' feedback on the initial dashboard designs based on the results of Study 1. Study 2 was conducted in-person with six teachers, four of whom had participated in Study 1. All were middle school science teachers in the Midwestern U.S. who had taught science for 7 to 34 years. We presented teachers with five dashboard designs visualizing information on class status, group progress, and individual progress. We found that teachers had differing ideas about the relative importance of specific information, in terms of when the information will be most useful and how they will use it in the classroom. Based on the teachers' feedback, we have been working on a generalizable framework that includes *what* information should be displayed, *when* the information should be displayed, *how* to visualize the information (charts, sounds), and *who* should have access to the information (teacher, assistant, etc.). This will enable us to design dashboards that are dynamic and customizable by teachers.

Conclusion and Future Directions

Our studies emphasize the importance of participatory design to co-create technologies that teachers would actually use in their classrooms and the need for a dynamic dashboard that teachers can customize to their specific needs. Future studies will focus on building a dynamic dashboard with the identified five key metrics (Class Status, Group Progress, Group Participation, Close-ended Questions, and Open-ended Questions).

Exploring Epistemic Network Analysis Diagrams as a Tool for Developing Teacher Noticing of Classroom Dialogic Features

S Sushil, Sherice N Clarke
sushils@ucsd.edu, snclarke@ucsd.edu
University of California San Diego

Abstract: Our designs for teacher learning focus on generating representations that help teachers attend to how they structure opportunities to learn for students of color. This paper explores the affordances of Epistemic Network Analysis (ENA) for generating representations of epistemic networks in science class discussions for teacher reflection on their facilitation. We examine representations of data of two secondary science teachers and discuss the possibilities of ENA for mapping the intellective nature of science discussions.

Our work takes the view that equity can take shape in micro-level interactions in classroom dialogue, and teachers play a critical role in providing robust opportunities to learn science, particularly in classrooms that serve students of color. There is a growing body of research that highlights the impact of dialogic pedagogy on student learning (e.g., Clarke et al, 2015). However, large-scale surveys of classroom dialogue highlight the scarcity of these forms of pedagogy in low-performing schools that serve minoritized children (Kelly, 2008). In this paper we ask, *how do we build teachers' noticing of how their classroom discussion facilitation shapes opportunities to learn for their students?* This paper proposes an amalgamation of the techniques of Epistemic Network Analysis (ENA) by Shaffer et al. (2016) and Hennessey et al.'s (2015) analytical frame for decomposing classroom dialogue, to generate representations of classroom discussions that afford possibilities for teachers to notice (e.g., van Es & Sherin, 2006) how dialogue is deployed in their classrooms.

Theoretical Frameworks

ENA helps identify and quantify connections among elements in coded data and represents them visually and statistically through network models (Shaffer et al., 2016). This is useful for data where patterns of associations between different elements of the data may be meaningful in illuminating the extent to which the dialogue is academically productive. The ENA representations, therefore, offer a powerful way to help teachers develop their professional vision (Goodwin, 1994) for productive dialogue. To codify the classroom discussion data for ENA, Hennessey et al. (2015) offer a Scheme for Educational Dialogue Analysis (SEDA) which speaks directly to our interest in academically productive dialogue. Their scheme helps classify parts of discussion data or "communicative acts" according to their dialogic function.

Methods

ClassInSight is a study of teacher professional learning around classroom dialogue. It is a research-practice partnership with two school districts in north and south county San Diego, which serve a diverse (ethnic and linguistic) population of students. Science classroom discussions of two high school science teachers were audio-recorded, transcribed, and verified. These lesson transcripts were then segmented into turns and coded by a team of three researchers using a coding scheme adapted from SEDA (Hennessey et al. 2015). Each pair of coders achieved a Cohen's Kappa of .7. Data were segmented into sequences using Wells and Arauz's (2009) notion of a sequence as an intermediate unit of analysis between an episode and an exchange. The coded files were then appropriately formatted according to the recommendations of Shaffer et al., (2016) and uploaded to the webkit. 'Whole conversation' was used instead of a 'moving stanza' because all associations within a given sequence were meaningful.

Findings

ENA in conjunction with an adaptation of SEDA was found to be useful in developing coarse representations of associations between dialogic moves in classroom discussion and to also contrast representations within and between teachers. This is illustrated through a comparison of two teachers' lessons below.

Illustration: Teacher H and T's lessons

Teacher H's lesson represented in Figure 2(a) was a guided activity to make different structural isomers of a molecule using manipulatives. Teacher T's lesson represented in Figure 2(b) was also a guided activity to identify

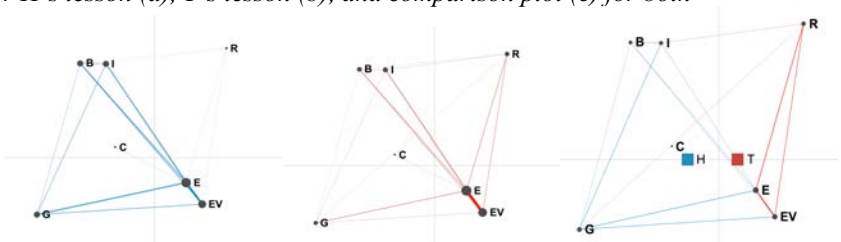
 © ISLS

types of rocks. So the students were prompted a lot to share their ideas (classifications of rocks) which were evaluated by T. Figure 2(c) is the comparison plot which is Figure 2(b) subtracted from 2(a)

The representations show that both classes had complex interactions with frequent co-occurrences of E(expressing or inviting ideas)-I(invitation for elaboration or reasoning), E-B(building on ideas), and E-G(guiding the discussion) pairs along with E-EV. However, we can also see from the comparison plot that H engaged in more G moves as they helped students construct various structural isomers. While T engaged in more frequent R (reasoning) moves as they helped students explain their reasoning for their classification of different rocks and evaluated the reasoning. Therefore, these diagrams are effective in characterizing how dialogic moves were deployed by them to help students engage in specific kinds of learning experiences.

Figure 2

ENA diagrams for H's lesson (a), T's lesson (b), and comparison plot (c) for both



(a) (b) (c)

Discussion

Such ENA diagrams can highlight for teachers how codes co-occur in their discussions and, therefore, help them reflect on the extent to which they align with their objectives and/or on how they *think* discussions operate in their classroom. Hypothetically if teacher H intended to use this classroom discussion as a way to gauge students' comfort with the concept of isomers, then the extent to which they were guiding the students instead of observing them would be a cause for reconsideration of their approach to this discussion. Thus, there is ample possibility for the ENA diagrams developed by facilitators of teacher professional development to help teachers notice dialogic features of their classroom which structure the learning in it and instigate dissonance (Clarke et al., 2020) for the teachers, which could be triggers for reflection, learning, and refinements in dialogic practices.

Conclusion

This paper sought to offer a possibility of using the techniques of ENA and a coding scheme for classroom dialogue to help scaffold teachers' noticing of how dialogue operates in their classroom discussions to structure learning experiences. Further inquiry in this regard is necessary but the approach appears to provide promising opportunities for teachers to reflect on how they use classroom dialogue to structure students' opportunities to learn.

Trajectories of Practice: Characterizing Students' Decision Making Agency in Science Investigations

Robert Hayes, Tufts University, robert.hayes@tufts.edu
Julia Gouvea, Tufts University, julia.gouvea@tufts.edu
Aditi Wagh, Massachusetts Institute of Technology, awagh@education.mit.edu

Abstract: An aim of science education is for students to be able to participate in science by making adaptive local decisions that interconnect and integrate scientific practices. We build towards this goal by articulating a *trajectory of practice* -- a series of moves students make to pursue the scientific aims of their investigations, and showing how this description can be used to investigate the role of curriculum in supporting students exercising decision making agency.

Motivation for Trajectories of Practice

Describing science as a "practice" is an alternative to depictions of science as an ordered list or cycle of activities—e.g., "the scientific method" (Ford, 2015). While scientific practice is composed of component practices, expertise entails more than just an ability to successfully perform these components in isolation. Practice foregrounds the decision making processes required to "adopt" and "adapt" component practices to the needs of specific contexts (Manz, 2015), a kind of knowledge that Ford described as a "grasp of practice" (Ford, 2008).

In this view of scientific practice, agency is central. In part this is because of the inherent uncertainty in the activity of science, which is often captured in spatial metaphors that describe practice as unfolding in a "field" or "space" of possibilities (Pickering, 1995; Gooding, 1990). Navigating through this space requires scientists to engage in reasoning about where they are, where it makes sense to go next, and how such choices will be viewed by the scientific community. In this way, the path through this space can be considered a unique trajectory that emerges as scientists encounter and respond to the particular difficulties and opportunities that they encounter as they attempt to satisfy their goals.

Pickering (year) described these choices as "free moves", expressions of human agency made by scientists to pursue the aims of their investigation. These moves, or accommodations, are shaped in response to resistances to achieving scientific aims. We propose the idea of a trajectory as a way to characterize students' scientific decision making as enacted in context, over time.

A trajectory of practice is guided by an orienting aim that describes students' intentions for how to carry out their scientific investigations. Descriptively, orienting aims are useful for cohering accounts of students' decision making in science investigations. They also situate resistances as *resistances to aims*, which is aligned with Pickering's (1995) description of the Mangle, and is implicit in the account Manz (2015) gives of student activity with the wild backyard. For example, when Manz described "the changing nature of plants" as a resistance it is as a resistance to "students attempt(ing) to draw conclusions about them." (Manz, 2015, p. 104)

The trajectory further describes a series of accommodations to resistances, comprising local aims, generative moves, and evaluations (see Figure 1). Each of these components foregrounds student decision making. Local aims describe students' bids to overcome a resistance, generative moves represent the construction of ideas or practices adapted to meet the local aim, and evaluation represents students' assessment of how well the move served to accomplish the local aim and accommodate to the resistance.

This work provides a way to identify and characterize student agency in scientific investigations, a necessary precursor to understanding the instructional and curricular features that support it.

Figure 1
Trajectory of practice constructs

 © ISLS

Study Context

This research takes place within an introductory-level undergraduate biology laboratory course. The central design emphasis is on students conducting their own investigations, in groups of three to four, by designing experiments with organisms, and conducting simulation trials within an agent-based computer model (Gouvea et al., in press).

Using Trajectories of Practice to Unpack Student Activity: Two Case Studies

In this poster we illustrate two episodes of student groups' scientific activity using trajectories of practice. In the first episode, Group A works to design an experiment. We describe how their moves, such as turning to the simulation to validate their ideas when stuck, sustains their design work in the face of theoretical and practical challenges to their initial experimental proposal. In the second episode, Group B works to make sense of unexpected experimental data by replicating their experiment on a computer simulation. We describe how their moves, such as carefully calibrating the simulation *inputs* to match their wet-lab design, leads to them expanding their conceptualization of the study system, through reasoning across and within these two data production modalities (experimental design and computational model).

We then show how this description of decision making activity can be used to identify features of the curricular implementation which contributed to sustaining Group A's engagement in conducting the design of their experiment, and to expanding Group B's conceptualization of the system.

Discussion

This work is an initial attempt to expand the research on students' decision making agency in science investigations. Our focus is on identifying evidence of students making local, adaptive decisions that contribute to a sustained engagement in making progress towards their own research aims.

We see this characterization of student-driven trajectories as an important refinement of resistance and accommodation as a dynamic articulation of emergent, locally adapted scientific practice for two reasons. By making orienting aims an explicit construct we can consider how resistances *to aims* intersect with student framing of lab spaces. For instance, if a student frames the lab as about demonstrating a fact about how plants grow, and sets their orienting aim around doing so, then resistances caused by unexpected patterns in plant growth might prompt an accommodation of searching for experimental error, rather than developing more productive sensemaking practices (Hayes, 2021). Furthermore, expanding accommodations to include student decision making around local aims, generative moves, and evaluation provides researchers with a concrete way to identify evidence that students are engaging in a dialectic of construction and critique that comprises adaptive scientific practice (Ford, 2008; Manz, 2015). With these markers identified, researchers can investigate the role of curricular enactment in supporting such student activity.

Using Participatory Software Design to Reconfigure Traditional Power Asymmetries Between Dominant School Systems and Nondominant Families

Jarek Sierschynski, Elizabeth Kelly, Scott Spaulding, Mischa Shiomi McManus
jareks@uw.edu, scott2@uw.edu, empowers@uw.edu, mischm@uw.edu
University of Washington

Abstract: We describe an iterative participatory development of a software application based on Ishimaru's (2019) model of equitable collaboration between nondominant families and dominant school systems. We share (1) findings from our qualitative analysis and collaborative software design with two family focus groups, (2) the design process that led us to the development of a family notebook to balance traditional power asymmetries, and (3) the current version of the software design.

Introduction

In this paper we present the current results of an iterative participatory-design research project (Bang & Vossoughi, 2016) and social design experiment (Gutiérrez & Jurow, 2016). Our collaborative design centered nondominant families as experts (Barajas-López & Ishimaru, 2020) in the design of a software application aimed at facilitating communication between families and early childhood settings during their children's behavior support process. Given the historical inequities between nondominant families and dominant school systems, our design was grounded in Ishimaru's (2019ab) work on equitable collaborations in an attempt to address the power asymmetries between nondominant families and dominant school systems.

Participants

We collaborated on the software design with 10 families. The family participants spoke English and Spanish. They identified as white, Black, Latino, and Hispanic. Nearly all of their children had an individualized behavior support plan and several had already been suspended or expelled from preschool or other early learning settings. The final design of the software application was grounded in the expertise of Black and Latino families.

Methods

As part of our participatory design research process, we conducted and recorded data from two different focus groups (FG1 and FG2 hereafter); those involved qualitative, survey, and informal methodologies as part of our initial data collection. We recorded, transcribed, and coded conversations between family members as well as collected design artifacts. As part of our design process, we asked families to respond in a semi-structured interview and discussion format to questions about their partnerships in early childhood programs. The families made it clear to us early on that given their inequitable experiences with school systems, the software had to facilitate communication and position families as equal participators in their children's support process. Talking about their past and present experiences families expressed feelings of shame, fear, and guilt when hearing negative and judgmental communication about their child. Thus, they emphasized the importance of positive, reciprocal, and human centered communication, i.e., communication that is compassionate, respectful, and strengths-based. Families also expressed a clear desire to learn about their child's behavior and the behavior support process from professionals in their child's early learning program, while also being able to provide their own expert feedback to program staff. Lastly, families wanted to contribute to and be acknowledged as part of their child's support process. When asked questions about technology, families requested a practical communication system allowing for transparency and quick access to their child's process.

After analyzing the initial data from FG1, we set out to translate our findings into several graphic versions. We arrived at a family-school notebook as a design which addressed reciprocity, family contribution as well as access and transparency. To confirm whether we correctly interpreted the family voices, we brought the first family notebook design a few months later back to the families from FG1 for member check as well as to some new families. We asked our FG2 to further help clarify and improve on the design. For our design activity with families in FG2, we printed out the first family notebook design and then asked families to write, mark, and place stickers indicating questions, approval, or disapproval.

 © ISLS

Results

Nondominant families in the focus groups were much more likely to share negative experiences about their relationships with their children's early learning programs. Their experiences had a profound impact on our design thinking. Two questions that arose in response were, (1) how can software design help ameliorate the trauma and stress of nondominant families in dominant school systems? And (2) how and what aspects of the traditional power asymmetries could we shift (or balance) through collaborative software design and architecture?

In response to our first question, the main aspect of the family notebook that attempted to ameliorate stress was an intentional slowing down of the communication process. Unlike common formats of communication made available through messaging apps (i.e., immediate, instant, and dialogic), the design of the notebook asks families and teachers to leave notes for each other asynchronously (family members can also communicate with each other). Once logged in, for a family member to see teacher notes and vice versa, family members must leave their side of the notebook by toggling a switch to the teacher's side of the notebook.

To address the notion of power in our design, we analyzed our qualitative data through the lens of Ishimaru's (2019a) framework of equitable collaboration. A major feature that addresses the main *dimensions of equitable collaboration strategies* allows family members to invite other family or community members e.g., advocates, translators, or community elders to be part of the family notebook with access to all documentation as well as the ability to communicate with the teachers and each other. The ability of families to add as many members of their family, friends, advocates, or community members to the notebook as needed is directly linked to existent power asymmetries. This design move inherently shifts (1) the intervention level from individual/parent/student to a collective expertise, family, and community level. (2) Moreover, the shared space created by the notebook shifts the unilateral power held traditionally by school systems towards shared and relational power by making transparent the documentation of the child's support process to the families and those members of the notebook that families choose to add. In the same context, (3) the notebook design shifts the directionality of possible partnerships between schools and families from a historically unidirectional to a reciprocal mode of interaction.

Conclusions

The family notebook design is currently in its next phase of user testing. There were two main design components that we translated from the input by our family experts into a core feature of the notebook which addresses equitable collaborations. The one feature we wanted to focus on in this short paper was the ability of families to add as many collaborators to their notebook as they wanted. It is a subtle feature, not explicit, yet one that directly engages with the equally subtle violent ideologies present in learning settings. Equally subtle, the concept of place as understood by cultural and human geographers (e.g., Cresswell, 2014; Tuan, 1977), i.e., "produced by practice that adheres to (ideological) beliefs about what is the appropriate thing to do" (Cresswell, 1996). The notion of place was an everpresent heuristic in the transformation of power asymmetries in an intermediate space between families and learning settings, i.e., the notebook, connected to a dominant system of education, yet with its own specific set of rules. In the case of our social design experiment, those rules were (re)defined by a software architecture designed by those who occupy nondominant positions on the power spectrum.

How do middle school students think about climate change?

Sarah Bichler, University of California, Berkeley, sbichler@berkeley.edu,
Allison Bradford, University of California, Berkeley, allison_bradford@berkeley.edu,
Brian Riordan, ETS, briordan@ets.org,
Marcia C. Linn, University of California, Berkeley, mclinn@berkeley.edu

We use natural language processing (NLP) to train an automated scoring model to assess students' reasoning on how to slow climate change. We use the insights from scoring over 1000 explanations to design a knowledge integration intervention and test it in three classrooms. The intervention supported students to distinguish relevant evidence, improving connections between ideas in a revised explanation. We discuss next steps for using the NLP model to support teachers and students in classrooms.

Objective

This research connects two studies to characterize students' understanding of factors impacting climate change and improve student ability to evaluate actions that slow climate change.

Embedded assessment "Group Effort"

We designed the Group Effort item to engage students in reasoning about ways to slow climate change. Students use an online data tool with rates of electricity usage for several devices from a local gas and electric company to evaluate plans for reducing electricity usage proposed by three fictitious students. Key to the analysis is that each device uses electricity at a different rate. Students record the pounds of CO_2 saved for each plan to compare, evaluate, and explain what the three friends could do to increase their impact.

Knowledge integration guidance

The knowledge integration (KI) framework outlines four key processes to help students develop coherent understanding of science phenomena: *elicit* student ideas so they can be compared and refined, *discover* new ideas by exploring models, *distinguish* between initial and new ideas, and *reflect to connect* their ideas (Linn & Eylon, 2011). Curriculum designs using the KI principles engage students in multiple cycles through all four KI processes, providing students with opportunities to continuously integrate their new ideas with their prior understanding (Gerard et al., 2020). Student performance on embedded assessments might reveal that they still need support to fully integrate their ideas. We argue that, at this point, students benefit from guidance to distinguish between alternative perspectives or conflicting evidence.

Study 1: Students' ideas and NLP model

Participants, data source, and scoring approach

Seventeen middle and high school teachers from 8 diverse schools administered an online science assessment at the end of the school year, including the Group Effort question. We analyzed 1146 student responses.

We developed a scoring rubric (1-3) to assess students' understanding of the mechanism (connecting energy use to CO_2 emissions and human impact on climate change) and data practice (using evidence to evaluate plans). A knowledge integration score (1-5) indicates whether students connected ideas within and/or across dimensions. Two researchers independently coded 70 responses, iteratively refining the rubrics until reaching Cohen's Kappa of > .85 on each coded dimension. Then each researcher coded 50% of the entire data set.

NLP model building & results

We used a state-of-the-art neural network scoring model architecture that leverages a pre-trained transformer language model "fine-tuned" for the KI scoring task. These models have been pre-trained to identify words that have been masked from the input and to predict whether one sentence follows another. The word representations the model learns to do these tasks and the self-attention based transformer architecture, yields word representations that are useful across many NLP tasks. We used a model based on the Bidirectional Encoder Representations from Transformers (BERT) model (Devlin et al., 2019). This model architecture, adapted for the KI scoring task, has achieved state-of-the-art performance on the ASAP Short Answer Grading dataset (Steimel & Riordan, 2020). The models were trained to predict an ordinal score from each response's text. Since KI is concerned with the content of the response, the models did not consider grammatical or usage errors in scoring.

 © ISLS

Human-machine agreement was good with weighted Kappa of .79 for the mechanism, .88 for data practice and .89 for KI. By analyzing students' responses, we learned that students often used time on a device as evidence to judge the effectiveness of the solutions rather than kWh of energy use, indicating students need support to distinguish between time a device is used and how much energy per hour each device uses.

Study 2: KI guidance intervention

To help students distinguish between relevant evidence, we developed a KI guidance intervention. Students use a data tool to analyze a TV, video console, and desktop computer. They reduce the use of each device from 2 to 1 hour, enter the evidence in a table and compare how much CO_2 is saved. Students then rank each device according to how many kWh and pounds of CO_2 are saved. Students then revise their Group Effort explanation.

Participants, data source, analytical approach, and statistical analysis

Three middle school science teachers from two schools and their 397 6th grade students participated in the study. The Group Effort item is embedded in an online unit on global climate change featuring interactive models and activities (https://wise.berkeley.edu/). A total of 345 students completed the activity during remote instruction.

We used the NLP model to score the initial and revised responses to the Group Effort item which are logged in the learning environment. We used repeated measures ANOVA to test whether students' understanding improved from before to after the KI intervention. We used the open-source statistical software jamovi, set an alpha level of 5% and applied Bonferroni correction ($\alpha/n = .05/3 = .02$) to control for multiple testing.

Effectiveness of the KI intervention

We used the initial KI score as measurement point 1 and the revised KI score as measurement point 2 and included the teacher as a between subjects factor to test if there was a teacher effect. Students' KI scores increased from initial ($M = 2.79$, $SE = 0.05$) to revised explanation ($M = 3.23$, $SE = 0.06$), $F(1, 342) = 90.42$, $p < .001$, $\eta^2 = 0.04$. A non-significant interaction effect between time and teacher indicates that students' KI scores did not increase at different rates across teachers ($F(2, 342) = 1.36$, $p = .257$, $\eta^2 = 0.001$).

To unpack whether the change in KI is due to students connecting more ideas to explain the mechanism or use data as evidence, we used repeated measures ANOVA. Students connected more ideas about the mechanism in the revised DCI ($M = 1.42$, $SE = 0.04$) than in the initial ($M = 1.24$, $SE = 0.03$) explanation $F(1, 342) = 43.11$, $p < .001$, $\eta^2 = 0.02$. They also connected more data as evidence: initial $M = 1.50$, $SE = 0.04$ and revised $M = 1.77$, $SE = 0.04$ explanation, $F(1, 342) = 62.44$, $p < .001$, $\eta^2 = 0.03$.

Discussion and conclusion

The NLP scoring model can be used in future classrooms to provide teachers with information about their students' reasoning or to adaptively guide students (Gerard et al., 2020). The KI intervention targeted towards sorting ideas not only helped students to engage in the sophisticated practice of distinguishing between time versus kWh as evidence, but also helped students integrate this data practice with a mechanistic understanding as they connected their ideas about electricity usage, CO2 emissions, and human impact on climate.

Nayah-Irú: the design of a participatory game to foster critical data literacy through storytelling and

Ezequiel Aleman, Iowa State University, ealeman@iastate.edu

Abstract: Countering oppressive practices in digital spaces is essential to prevent control and exploitation. Youth need to be empowered to reflect on their use of such spaces. In this poster, I present a design for an alternate reality game that engages learners in participatory research and storytelling in a virtual world to develop data tactics to repurpose data practices.

Introduction

In understanding how technology can become oppressive for youth, I focus on the inequalities present in digital spaces. With the growing use of personal digital devices and mass platforms, there is an unprecedented rate of data generation, often collected without the individual's knowledge. Without the knowledge to counter oppressive practices in digital spaces, youth are often traced, tracked, and policed through the use of their personal data leading to a state of automated inequality (Eubanks, 2018). Using Pangrazio and Selwyn's (2019) framework of personal data literacies, I seek to explore how storytelling and games in virtual worlds can support the development of data tactics to counter or repurpose current data practices within a youth participatory action research (YPAR) framework where the boundaries between fiction and research are purposefully blurred.

The use of stories to engage youth in making sense of digital spaces can be drawn from indigenous practices regarding place-making. Abenaki author Lisa Brooks used *awikhigawôgan,* an ongoing and collective writing activity, to reconstruct the community (2008). According to Basso (1996), building "place-worlds" is a deeply human activity that does not require any storytelling skills but a sense of curiosity. Through the use of letters, scrolls, maps, portraits, and photographs, Brooks (2008) was able to engage in making sense of the different spatial experiences of the community. In this design, I imagine *awikhigawôgan* as virtual worlds created by learners to make sense of their experiences with data in digital spaces.

Based on Freire's (1992) notion of the "consciousness of the possible," I seek to understand how learners can engage in a collective experience of designing possible futures through virtual worlds that could reverberate to inspire change in their communities. To engage in storytelling, I designed an alternate reality game (ARG); a game that takes place in the real world by intertwining fictional elements. This game was inspired by Ask Anansi, an ARG developed by Antero Garcia (2017) where youth connected with a fictional character who engaged them in a research process through questions and conversations. While Ask Anansi was mostly an in-person experience for students, the research context for my design required the development of a virtual world. This poster describes the design principles that support the game.

Design principles

In order to engage learners in recontextualizing their relationships with digital spaces, the game introduces, Nayah-Irú, a 16-year-old girl from the future who claims to be from what was once known as Uruguay. After a series of puzzles and cryptic messages, Nayah-Irú reveals that she lives in a future where all forms of digital space have been banned. Nayah-Irú, who is fascinated by the digital spaces in the 21st century, ignores the ban and finds a way to communicate with students through multiple platforms to find out why they were prohibited.

Context and purpose: an ARG environment to support a spatial analysis of data practices

In July 2021, Nayah-Irú contacted a group of 18 students aged 15-20 from rural Uruguay who attend a secondary education center for learners who have fallen out of formal education. The program provides instruction in core knowledge areas, physical education, vocational workshops, and information technology. The game was played with learners during two weekly periods over twelve weeks during the information technology class.

The main character interacted with learners in three ways. Through automated bots that asked questions to students during the week or sent text messages when student solved a puzzle; through e-mails and social media posts which often introduced the weekly challenge; and finally, as a character in the Gather platform, an avatar-based videoconference system which served as the virtual world for the game. I played two roles in this design: I facilitated the meetings with students using my personal identity, and I also engaged in conversations with learners as a fictional character.

 © ISLS

The main purpose of this design is to provide learners with a platform to reflect upon data use in digital platforms in order to imagine possible ways to resist or repurpose oppressive data practices (Pangrazio and Selwyn, 2019). The game design was structured in three stages which provide learners with opportunities to understand the digital spaces they inhabit, engage in performative work through storytelling, and eventually transform their communities by extending their performance towards shared knowledge (Garcia, 2020).

Making sense of data in space

During the first stage of the game, players are required to explore different worlds created by Nayah-Irú in Gather. The activities are designed as scavenger hunts which lead to videos, story fragments, or illustrations that promote reflections and discussions. As they solve each challenge, they uncover more fragments of the story. One feature of the game in this stage is that players are not allowed to share any personal information since Nayah-Irú believes their communications may be intercepted. Thus, students engaged in discussions using their avatars and usernames without revealing their identities. After six weeks, Nahay-Irú shifts from the game puppeteer and leads players into asking their own questions. In turn, students turn from participants in the story to storytellers.

Nayah-Irú requests information about the nature of datafication in their lives which she will use to stand against her regime. To answer these questions, students had to develop their own research questions to understand why digital spaces are banned in the future. Some of the questions in this first iteration of the game focused on how data can be tracked, the addictive characteristics of social media, and the impact of digital spaces on mental health.

Mapping new spaces for the community

Students were trained to use a wide variety of research methods discussing their ethical implications, the quality of the data they were collecting and how the data would serve the purpose of telling their story. Once students collected data to answer their questions through interviews, observations, and surveys, they were encouraged to design a virtual space to communicate their message. At this stage, participants designed their own scavenger hunt where they hid their message to Nayah-Irú. Students had to discuss whether they wanted to give Nayah-Irú a grim perspective of digital spaces which could justify the digital ban or incorporate a rich myriad of perspectives to support her decision to resist. The storytelling is discussed by students to determine whether this is a story of hope.

Since students are not capable of sending the virtual space to Nayah-Irú into the future, she suggests they place a physical poster around their city with a link to the virtual space. This activity allowed learners to create their own cryptic puzzle to impact their community. By interacting with the poster, community members could visit the virtual space, solve the mystery, and listen to the videos and messages designed by students.

Current progress and future work

At the time of this poster, a working prototype of Nayah-Irú has been piloted with a group of students and received feedback from both the students and other educators. The second iteration of the game will involve a new cohort of students and incorporate new characters designed by the current participants.

Some of the areas to be explored within this design are the affordances of virtual worlds for youth to engage in participatory research through storytelling and how educators can facilitate game-based participatory research experiences with youth.

Writing to rewrite dominant discourse(s): Some design dilemmas from global south

Gautam Bisht, Northwestern University, gautambisht2025@u.northwestern.edu

Abstract: This poster considers some design elements that can potentially work through the double bind of English education for culturally marginalized students in post-colonial contexts. English writing in such contexts often plays out as an overwriting on native consciousness. Using the framework of counter stories, I look at the Facebook compositions of Sangita, a young indigenous girl from India. Her composition illustrates the potential to rewrite dominant notions around indigenous food systems and offer some possibilities for design.

Introduction: Double bind of english language learning

In postcolonial settings, learning of the English Language presents one of the most complicated double binds. The historical origins of English language education in India emerged primarily as a tool for governance. Almost two centuries later, language scholars argue that the colonial tendency of the English language is far from over, as it continues to play a strong imperialistic role in the global south (Phillipson, 2009). On the other hand, in a caste ridden society like India, English is pitched as the only language of emancipation for the marginalized (Ilame, 2020). In a society where educational opportunities were reserved for some; English became a tool to bypass the upper caste hegemony. In such a situation, English is both empowering and disempowering for learners from culturally and linguistically marginal backgrounds. This calls for a culturally responsive English language learning framework that works through this double bind.

Writing counter stories

What do great writers who come from marginalized communities do and should do? For pragmatic reasons they emulate the structures of successful writing and earn economic and social recognition. But often they engage in counter storytelling, which means presenting the world from a position of marginality. They write into the discourse, that which resists being written. They write in ways that it challenges the contours of what writing is supposed to look like. At a level of abstraction all great artists produce that which is not a part of the dominant conversation or that which may subvert common sense. Thus, I argue, that counter stories are a good format on which writing may be modeled. The concept of counter stories has been evoked under similar names like 'critical storytelling' and 'counter- narratives', and it emerged in various disciplines like law, social work and critical pedagogy (Miller et al., 2020). The concept was eventually more formally grounded in the domain of education (Solórzano & Yosso, 2002). Over the years, some studies have tried to integrate counter storytelling as powerful way to engage with literacy and language development (Kelly, 2017).

Research context and analyses

In this poster I provide an illustration of writing by an 18-year-old Santhal girl Sangita. Santhal community is an indigenous community in India. She is one amongst the many Santhal youth who are part of on online language learning project. When Sangita started posting on Facebook, she made all kind of posts. For my analyses I focus on the posts that centers indigenous/local food systems. We do so, because local food systems are a central node to understand various layers of identity, culture, and knowledge. In addition to this, there is an urgency to the health and nutrition crisis in the region. At a social level, Santhal food items are threatened because of the dominant discourse around 'civil food'. Dominant stories around what is 'good food' dissuades young indigenous people away from a whole range of local food practices, which are categorized as 'backward' (Bose, 2016).

In one of her posts (Image a) she explains the context of rat hunting in terms of the agriculture cycle. Hunting of field rats is play, pleasure, group activity, learning and a form of nutrition that kids (boys) generate for themselves. She centers her world and normalizes it by asking her non-Santhal Facebook friends if they have ever done rat hunting. The children are placed strategically, holding the bunch of rats in the middle through a stick along their shoulders. In the background one can get a good glimpse of a path and some younger children, who over time would also learn this traditional practice. The children are not hunting in the picture, but rather a thumbnail of the practice is stylistically choreographed. Thus, these posts do not just re-produce, but rather re-style and reinvent the cultural connections for their audience and for the Santhal youth themselves. I want to highlight two key counter story elements to this post. First, it unsettles the hierarchy of food in the region, where rat eating is usually something that Santhal community considers a guilty pleasure. Second, this

 © ISLS

image runs in contrast to images that national newspapers carry about the community and nutrition crisis. Generally, rural children are portrayed as recipient of free meals, looking up in desperation of relief. In another post (Image b) she asserts the significance of local food systems in the times of Covid. There has been a huge movement to get rural ingenious communities integrated with markets, and then the lockdown enforced the closure of all markets for many weeks. Within such a context, she makes a case for the sustainability of locally available 'wild' food. Apart from the content, her Facebook composition is noticeable for translangauging and multimodality.

Figure 1

Some students used Santhali, Hindi and English in their own ways to compose their posts. Here it reads- "Two children have hunted down field rats. After the rice harvest, Santhali people engage in this hunting activity. At this time you get a lot of rats in the field. Do you also for rat hunting?"

a.

Slowly they started making use of more English in their composition. More importantly student in the post highlight the importance of relying on locally available food at a time when lockdown was prevalent.

b.

Implications for design

What can we learn from such online compositions of indigenous youth? What implications it has for designing writing spaces for culturally marginalized students in postcolonial contexts? One element that needs to be incorporated and engaged with is the practice of translanguaging. This comes fraught with the tensions and hierarchy that exist within multiple languages and the explicit desire to move to a 'pure' English space. Another major component that needs to be part of the design is a critical engagement with community knowledge. One way to do that is using mentor texts that illustrate counter narratives. Another way to do that is to build on the aspect of multimodality. By encouraging students to use images and visual expression, we may allow for community knowledge and practices to enter classroom discourse. I think another important aspect of writing on community practices, involves integrating community experts in the process of writing. This may be done as part of student's research into an issue, that has the power of remediating relationships in the community. A major challenge would be to design novel criterion for assessing such writing artifacts. Standard ways of assessment and standard writing methods (5 paragraph essay) may undermine some of the innovative aspects of composing counter narratives in this way. Finally, to really engage with the double of english language, it would be crucial that writing designs are informed by and generative of theories from the global south, rather than confirming to frames set by the global North.

Abstract: Transdisciplinary computing arts experiences provide potential to merge practices and cultures from across disciplines to create an inclusive learning environment. However, this can be hard to do, especially when instructors within these spaces feel their expertise lies mainly within either computing or the arts. In our work, we analyzed facilitator reflections on the co-design and implementation of a 14-week online computing-arts experience designed to integrate computing, poetry, and visual arts. We found that focusing on the static and changing roles assumed by the co-designers provided a lens to understand how to build knowledge across one another's disciplines in the pursuit of creating new practices within transdisciplinary education.

Introduction

Co-design has been defined as a "team-based process in which teachers, researchers, and developers work together in defined roles to design an educational innovation, realize the design in one or more prototypes, and evaluate each prototype's significance for addressing a concrete educational need," (Roschelle et al., 2006). The practice emphasizes collaborative meaning-making, connecting design to a real context for learning, and integrating reflective practices for developing an understanding of the design. In transdisciplinary education, once siloed disciplines have the opportunity to become something new as the practices, norms, and cultures merge (Nicolescu, 1999). Much of the work in artistic computing education emphasizes how learners can explore CS concepts in a discipline that they care about as they leverage their prior knowledge to develop computing-artwork that becomes meaningful through the expressivity of learners' identities and cultures and ability to be shared beyond the environment. Few works examine how arts educational practices can change processes within the learning environment outside of the artifacts. Our work explores how a co-design team composed of three professional teaching artists and three CS education researchers from New York University and Georgia Tech reflected on roles within the design and implementation of an online physical computing, visual, and literary arts experience. We analyze teaching activities, individual interviews, an instructor focus group, and learners' final presentations examining the research question: *How do roles emerge and change within a co-designed computing-arts experience among its facilitators?*

Methods

This research took place within Community-Word Project, a non-profit arts organization that provides K-12 arts education within New York City public schools. During the 2020-21 school year, the facilitation team co-designed a remote curriculum in which students incorporated elements of their identities and cultures in conjunction with art activities and physical computing "tech" kits to create artifacts belonging to socio-futurist communities. The tech kits contained introductory programmable digital components, such as a BBC micro:bit, servos and sensors.

We collected semi-structured interviews and a one hour focus group with all facilitators to capture the facilitators' thoughts, feelings, and personal gains from the co-design experience. We also obtained a recording of the curriculum's 2-hour finale in which students presented their final projects to each other, parents, and community members. The data was analyzed using thematic analysis (Braun & Clarke, 2012). We identified how facilitators reflected on various elements of the program and their role in supporting learners and mediating between disciplines. Through multiple rounds of coding transcriptions of the collected data, we generated a codebook composed of themes of exercising roles within the planning and execution of the program.

Findings and discussion

Assumed, avoided, and adopted roles

Each facilitator approached the collaboration with a strong sense of identity and confidence in their own skills and contributions, therefore assuming a specific role within the co-design process. Among the co-designers, the

 © ISLS

roles of *tech-person*, *art-person*, and *researcher* were used to describe themselves and each other. While the facilitators were interested in crossing the disciplinary content, they still connected primarily to these roles.

Facilitators also distanced themselves from specific activities and disciplines. For example, two teaching artists felt disconnected from the research efforts of the program and deferred research-oriented roles to the CS ed researchers. Avoided roles became apparent when discussing facilitators' varying levels of comfort with computing technologies, as one of the teaching artists candidly said referred to herself as "not a tech person" despite a history in making digital art. In contrast, one CS ed researcher distanced herself from literary arts, saying she does not consider herself someone who practices poetry. We observed that facilitators openly expressed uncertainty and concerns around how the different roles would contribute to the curricular goals and shared vision for the program. Some facilitators found it challenging to envision how the tangible art making and physical computing practices would be integrated throughout the curriculum, both in students' artifacts and in the literary activities preceding them. One teaching artist was most concerned with being unable to support the students in the computing tech components, while a CS ed researcher was concerned with overshadowing the artistic learning goals with computing in the curriculum.

Facilitators discussed acquiring knowledge and skills that had the potential to contribute to their own identities, empowering them to adopt new roles during the program and after. One teaching artist who at first struggled with the writing and poetry activities and self-identified as a "visual person" was really motivated to start her own journal (an activity students practiced in the program) and write more. The teaching artists each had their own tech kit so that we could test out the instructional resources and enable them to play with, build, and program a circuit. One of the teaching artists shared how she found the electronics challenging at first, but that it led to valuable learning that she was happy to receive.

The CS ed researchers did not experiment with the arts activities since there was less uncertainty of failure of those activities. However, they did reflect on learning from teaching artists' disciplinary practices. For example, one researcher reflected on a writing exercise led by a teaching artist after the verdict of the George Floyd police violence case was announced. They were impressed with the "ways [the teaching artists] handle different situations," and how it led to insightful discussion with the students. Another CS ed researcher echoed this sentiment and saw new purpose in writing and talking about one's personal community.

Pushing beyond static roles

We found that the facilitators' instructional and disciplinary practices aligned with the roles they assumed in the co-design process. Further, as they distanced themselves from certain roles, they also distanced themselves from certain disciplinary practices—i.e., not practicing poetry. Despite building new knowledge through an understanding of each other's roles, a majority of the co-design led to recognition rather than implementation, such as the CS ed facilitators recognizing the power of the poetry activities but never leading any. Our work suggests that embodying roles within an interdisciplinary environment provides opportunities for identity work that can help instructors bridge disciplinary boundaries in order to push beyond them. While the teaching artists identified the ways they learned about computing as a discipline, the CS ed researchers did not identify learning art practices. We hypothesize that this may have been because the CS ed researchers did not engage in enacting roles of the teaching artists in the arts activities while the teaching artists did so with the computing activities.

Disciplinary and instructional roles also carried implications for facilitating greater engagement of the co-design team with the role of *researcher.* The role of researcher was dominated by the CS ed researchers, which created an imbalance in the focus and practices enacted within the research. Prior to assisting with data analysis, the teaching artists felt *disconnected* from that aspect of the co-design. This is important because researchers in these spaces are more often coming from computing disciplines than the arts. Drawing on participatory action research approaches could present useful tools to engage teaching artists in research framing and investigation design in order to center the role of researcher in the co-design process and address power imbalances.

Examining Gender Differences in Identity Development Within an Online, Global, Collaborative, Informal STEM-learning Community

Danielle P. Espino, Pepperdine University, danielle.espino@pepperdine.edu
Megan Hokama, University of Arizona, megan.hokama@pepperdine.edu
Taylor Lowe, California State University - Northridge, 1taylorlowe@gmail.com
Eric R. Hamilton, Pepperdine University, eric.hamilton@pepperdine.edu

Abstract: This study examines how a learning environment that incorporates aspects of intergroup contact might impact identity development and expression. Adolescent students collaborate on creating STEM-related media projects in this global, virtual environment during weekly video conference calls, which were coded for social and self-identity constructs and analyzed using epistemic network analysis (ENA) to compare differences by gender. Literature anticipated that female students would reflect social identity constructs and male students reflect self-identity constructs, but the opposite was found indicating intergroup contact might defy expected outcomes and complement student identity development among adolescents.

Introduction

Adolescents shape perceptions of self and others based on lived experiences and socio-cultural norms. The development of self-concepts is essential in how an adolescent views themselves in their educational contexts. By engaging students with intergroup contact, bias between groups can be reduced and potentially form positive group and self-identity concepts that can overcome their societal identity. Allport (1954) recognized that intergroup contact can reduce prejudice and discrimination with four factors to reduce prejudice: (1) equal status amongst group members, (2) common goals, (3) intergroup cooperation, and (4) the support of authorities. Social identity theory posits that an individual's self-concept is informed by their role in a social group or groups and the emotional attachment one gives to that role (Taijfel, 1981). Previous research indicates that social identity correlates more so with females, whereas self-identity is attributed more so to males (Hwang, 2010). Social identity consists of three constructs (group self-esteem, self-categorization, and commitment to the group) and two for individual self-identity (personal self-esteem and personal identification).

This study involves an afterschool community of adolescent students across four continents who collaborate together on developing media artifacts such as videos and presentations related to science, technology, engineering, and math (STEM) topics of their choice. Students from two or more countries participate in video conference calls to share ideas and projects (online global meet-ups) supported by a facilitator. Four components of intergroup contact theory are present: a virtual setting produces a space for students to join as equals, interact in a collaborative manner that creates intergroup cooperation, work towards a common goal of promoting peer-led STEM learning, all while receiving support from the facilitators throughout the process. This study explores the effect of intergroup contact on identity development through an initial comparison by gender.

Methods

The data used in this analysis consisted of discourse from transcripts of five online global meet-ups: February 2020 (3 females, 7 males), April 2020 (3 females, 3 males), August 2020 (6 females, 7 males) and two in March 2021(one with 5 females, 1 male, the other 1 female, 3 males) with participants from Brazil, Cameroon, Kenya, Mexico, Namibia and the U.S. The transcriptions were coded (see Table 1 for codebook) for three social identity and one self-identity construct adapted from Ellemers et al. (1999) and three identity-oriented constructs unique to the data. Coding was done independently by two raters, followed by social moderation.

Table 1

Codebook of Identity Constructs Included in the Analysis

Category	Code	Description	Example
Social Identity	Group Self-esteem	Expressing positive feelings about the group or referencing another individual	*"I really liked the presentation and I think that every topic…it's been much needed…."*
Social Identity	Self-categorization	Identify with other members of the group	*"I think the same as [student]…"*
Social Identity	Commitment to the group	A want to continue working with the group; Dedication to group goals	*"…we will do this though it requires a bit of much research. But I know we will collaborate"*
Self-identity	Personal self-esteem	Belief in one's own abilities; State confidence that they can accomplish tasks as well as others	*"…I like to explain to people, about math and physics. So, I think that I could do it."*
Identity-oriented	Knowledge Acquisition	Reflective of learning or acquiring new knowledge	*"I never knew they could use… materials to filter water…I learned something."*

 © ISLS

Identity-oriented	Curiosity	Seeking clarification, elaboration for better understanding of content-related issues	*"...question for you....are you addicted to smartphones?"*
Identity-oriented	Self-Awareness	Indicative of the state of recognition, realization, or emotion about oneself,	*"I'm really bothered before exams..."*

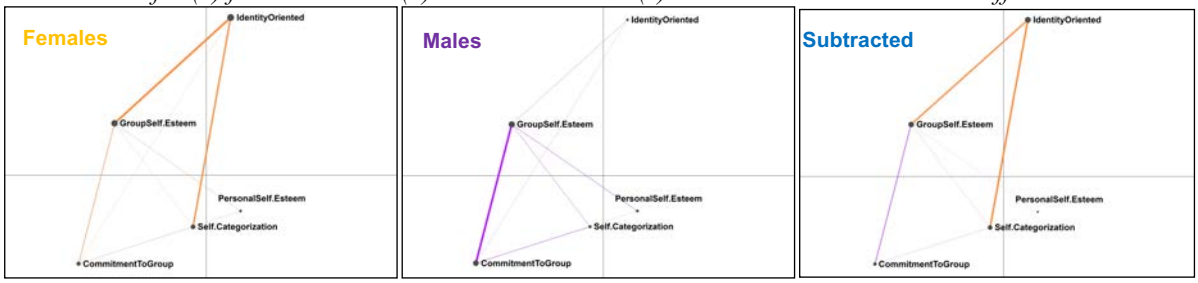
After the coding process was completed, data was examined using epistemic network analysis (ENA), an approach in quantitative ethnography to visualize data through statistical methods, to identify patterns among the relevant constructs. ENA generates network models of the connections among relevant constructs by quantifying the frequency of their co-occurrences within conversations in the data (Shaffer, 2017). For this study, each utterance (separated by turn of talk) was used as the unit of analysis, and each meet-up by date constituted a conversation to which the connections were limited. Only patterns of student discourse were examined.

Results

The ENA models of identity constructs for female and male students can be seen in Figure 1. The nodes represent each coded identity construct and the lines between the nodes (edges) which represent the strength of the connection between each construct within the stanza window size. A thick line indicates a stronger connection between the constructs while a thin line represents a less strong connection. Edges were scaled to 3.5.

Figure 1

ENA models for (a) female students (b) male students and (c) subtracted network to show differences.



(a) (b) (c)

In examining both the female student and male student network models, they share complementary patterns. Females draw more connections to Identity and Group Self-Esteem and Self-Categorization, while males exhibit stronger connection between Group Self-Esteem and Commitment to the Group. While there is no statistically significant difference between the compared groups, the network models help visualize the similarities among the construct patterns. The subtracted network model provides further insights on the female students' stronger connections to self-identity oriented constructs and male students' stronger connections to social identity.

Discussion

Based on previous social identity research, it was anticipated that males would demonstrate a stronger association to self-identity constructs, whereas females would show stronger affiliations to social identity (Hwang, 2010). However, the results found that males showed stronger connections to social identity constructs: group self-categorization and group self-esteem while female participants exhibited stronger connections to identity-oriented constructs. The unique context of this learning environment may have impacted the hypothesized relations between gender, and social- and self-identity. Using ENA, these insights help show how a learning environment that incorporates aspects of intergroup contact can shift what is expected in identity development.

Chin Youths' Epistemic Agency in an Afterschool STEM Learning Environment

Margaret Jeong and Minjung Ryu
mobrie33@uic.edu, mjryu@uic.edu
University of Illinois Chicago

Abstract: We implemented an afterschool STEM program for Chin youth to engage them in critical science literacy while using their full linguistic repertoires. For the present study, we conducted a grounded theory analysis of 24 interviews from this project to reveal how translanguaging supported epistemic agency in this space. Our findings from four youths' narratives suggest that the youth integrated translanguaging as an extension of their everyday discursive practices to foster shared epistemic agency among their peers. In addition, we identified structures from their school science classrooms that inhibited translanguaging and stunted their epistemic agency.

Introduction

Our research has explored the way in which multilingual refugee youth engage in critical science literacy through *translanguaging* in informal learning programs (Ryu & Daniel, 2020). Translanguaging is the fluid and flexible use of full linguistic repertoires that integrate multiple named languages to achieve specific communicative purposes (Blackledge & Creese, 2014). In the present work, we contrast Chin youths' experiences in our community-based after school setting and school science classes to explore whether and how translanguaging fosters shared epistemic agency in STEM learning.

We draw upon Miller et al. (2018) to operationalize epistemic agency as "students being positioned with, perceiving, and acting on, opportunities to shape the knowledge building work in their classroom community" (p. 1058). Furthermore, we draw on the idea that shared epistemic agency arises "during collaborative activities aimed at the creation of shared knowledge objects" (Damşa et al., 2010, p. 146). Specifically, learners exercise shared epistemic agency through collaboratively identifying gaps in knowledge, naming problems, and generating ideas. With these constructs in mind, we asked, *How does translanguaging support Chin refugee youths' epistemic agency in STEM learning environments?*

Context and methods

We conducted our afterschool program for high school-aged youth in collaboration with a non-profit Burmese Organization in a historically White neighborhood on the outskirts of a major city where Chin people established an ethnic enclave (see Ryu & Daniel, 2020). We conducted and analyzed 24 total interviews with 14 youth who regularly attended the STEM program to understand their relationship with science learning in our program, in school, and in their daily lives. For this paper, we draw on four youths' narratives: Nyunt, Kevin, Joshua, and Da Zin. Although we identified epistemic agency throughout the data set, the excerpts here were particularly powerful and salient.

We used constructivist grounded theory methods (Charmaz, 2014) to center the youths' voices in the analytical claims. After transcribing the interviews verbatim, the first author engaged in an iterative qualitative analytic journey. After multiple rounds of initial and focused coding, initial codes such as "translanguaging to help others," and "naming who has authority over English" coalesced to relate to themes of agency, positioning, and power. To better articulate these themes, we visited the literature in science education, sociocultural theories, and refugee studies. The second author drew on field notes and earlier analysis of the data set to provide ethnographic insights into the construction of our findings.

Findings

Our analysis revealed that translanguaging is an essential practice of the Chin youths' sensemaking and daily life. Thus, the youth in our program exercised shared epistemic agency through translanguaging. However, school science classrooms marginalized their linguistic assets which restricted opportunities to exercise epistemic agency.

The youth in our STEM program translanguaged every day. Across the 14 regular attendees, they spoke a total of 13 named languages and dialects. In the interviews, they shared that it was "fun", "special", "comfortable", and "normal" to mix languages with their classmates, friends, and family. For instance, Nyunt learned the Mizo language growing up, Burmese in school, English throughout resettling, and Matu after she arrived in the U.S. because her parents wanted to preserve their ethnic heritage language. Nyunt shared that she

 © ISLS

and her friend Rosie frequently translanguaged in the STEM program: "When she talk in Matu, I just reply to her in Burmese. We do that all the time." The youth readily translanguaged because it was historically, socially, and politically embedded in their lives.

In our STEM program, the youth exercised their shared epistemic agency by organically generating ideas to make sense of terminology through translanguaging. The Chin youth faced a unique linguistic conundrum in science: There were no direct translations for many Western scientific jargon among the languages they spoke. In Joshua's group, the group mates took turns sharing their conceptions of terms after they did some researching. He said, "We did by group, we split like 2 or 3… The vocabulary, the word, we tried to find what does that mean and after that we explained to other people, like presentation." Kevin, one of Joshua's group mates, was persistent in getting their small group to translanguage, even though none of them were entirely confident speaking each others' primary language. Kevin elaborated, "Since he [another peer] don't speak English, I just talking to him, 'Tell me in Falam,' and then [if] the things that he say is kind of easy, then I make him to say it [in English]. Then if I think it is kind of hard to say it, I kind of translate it [from Falam to English]." Through translanguaging, the youth positioned one another as collaborators in scientific sensemaking, expanding the shared epistemic agency among them.

Contrary to the possibilities realized in our STEM program, the dominant assumptions and practices in school science classrooms constrained the youths' opportunities to translanguage. Subsequently, they were positioned with less epistemic agency relative to themselves in our STEM program and to their American peers in school. Kevin, who worked hard to build linguistic bridges between his peers in the STEM program, brought to light exclusionary behaviors by his school peers: "There's people who just don't interest in making friend with whoever is not American… If the teacher told them to work with non-English people, they will never talk to them, even if they sit together. They will not even stare each other." Another youth, Da Zin, who also felt excluded by American students, said she felt "embarrassed" and "angry" because they would not let her help. The American students' behavior and expectations dominated the classroom norms such that everyone else was positioned as "not English" to the detriment of their participation in school science.

Discussion

These Chin youths' epistemic agency is contingent on positioning and opportunities with respect to translanguaging. Whenever the Chin youth congregated together, translanguaging was the norm, and it fostered their epistemic agency in science learning. In their school classes, the monolingual English-speaking Americans determined the norms which rendered their translanguaging resources ineffective. Although it could not be represented here, the shared epistemic agency reflected in these youths' narratives will be further corroborated by video data in future analyses. We urge researchers and practitioners to embrace heterogeneity to equitably expand epistemic agency in science learning.

Fostering Community for Current and Future Latinx Science Teachers Through *Testimonios* and Co-Design

Samuel Severance sseveran@ucsc.edu
Noemi Avenido navenido@ucsc.edu
Karina Rosales kirosale@ucsc.edu
University of California, Santa Cruz

Abstract: This study explores how a network of current and future Latinx secondary science teachers engaged in co-design activities to explore and attend to the issue of Latinx underrepresentation among US science teachers. Using *testimonios* as data to inform the design of an infographic report, the co-design process yielded insights into the Latinx science teacher shortage and provided a valued community space for participants to find support.

Introduction

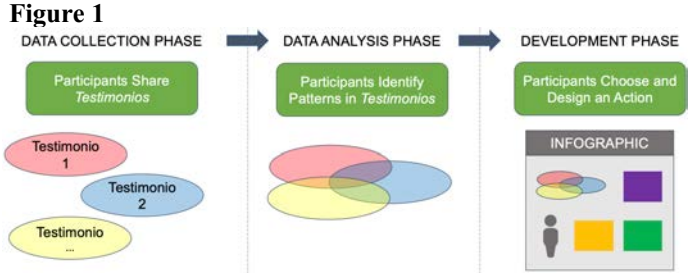
Despite evidence of the benefits of having a more diverse teacher workforce (e.g., Dee, 2005), minoritized demographic groups in the US remain underrepresented in the teacher workforce. In science education at the secondary level, only 8% percent of science teachers in the US identify as "Hispanic" (Taie & Goldring, 2020), although nearly 1 of 4 US students identify similarly (Fry & Lopez, 2012). While several studies have broadly examined the "pipeline" issue for Latinx teachers (Ocasio, 2014), the challenges faced by Latinx students as they seek to become science teachers remains underemphasized (Basile & Murrey, 2015). For this study, we recruited a network of current and future Latinx science teachers to engage in collaborative design (co-design; Voogt et al., 2011) focused on exploring and developing an action to address the Latinx science teacher shortage. Our research questions were: (Q1) How well can co-design activities surface insights into the Latinx science teacher shortage?; and (Q2) How might current and future Latinx science teachers' benefit from engaging in co-design activities?

Methodology

Design Methodology

Situated learning, particularly the notion of "communities of practice," informed our organization of the co-design process. We purposefully recruited participants with differing levels of participation in becoming science educators. Participants included two female undergraduates with no science teaching experience, three graduate masters students (two female, one male) working to receive their science teaching credential, and one early career male science teacher. Participants in this study all identified as Latinx. Undergraduate and graduate students attended the same western US university. The science teacher received his masters and teaching credential from there as well. Co-design occurred in three phases (see Figure 1) over eight 3 hour sessions spread over 6 months.

Figure 1



All activity took place online via Zoom during the 2020-21 school year. Researchers played an important role in facilitating each session. Of note, participants' personal *testimonios* served as the main source of data within the co-design process. Testimonio is a knowledge sharing genre common to Latin America where presenters seek to contextualize their experiences by seeking "to bring to light a wrong, a point of view, or an urgent call for action" (Reyes & Curry Rodríguez, 2012, p.525). Participants shared their story (so far) of becoming a science teacher and gave special emphasis to the academic, familial, and societal challenges they personally faced. Participants then analyzed each other's testimonios to identify and discuss patterns of challenges – as well as promising supports – they deemed significant. With researcher assistance, participants chose to develop an infographic highlighting the patterns they identified. This infographic has begun to be shared via social media with members of the university and local community and has already been viewed several thousand times.

Research Methodology

 © ISLS

While participants' own analyses of their testimonios provided a compelling emic perspective for Q1, researchers performed a separate complimentary analysis in order to discern insights into Q2. All Zoom meetings underwent verbatim transcription and a joint coding process consisting of rounds of inductive and deductive coding (Emerson et al., 2011). This process reduced the data to excerpts which served as patterns of evidence for making claims.

Findings

Claim 1: Co-design surfaced compelling challenges for Latinx science teachers

Participants identified three main challenges across their testimonios (see Table 1).

Table 1

Challenge	Description from Participants	Example of Evidence from Testimonios
Family Expectations	All of our families scaled obstacles (e.g., immigration) to provide us with opportunity. While studying science was accepted, science teaching was less accepted.	*"When I was telling [grandma] that I was going to pursue teaching instead of health care...She called me a glorified babysitter.*" -Undergraduate Student 1
Systemic Roadblocks	Nearly all of us struggled early on in college with many of us feeling unprepared, particularly in our first required STEM classes (i.e., "weed out" courses)	*"In high school your teachers generally don't want you to fail. But in college, it's like, no, you can fail."* -Graduate Student 1
Maintaining Community	Many of us noted the importance of community as a support and motivator. We need more opportunities to belong and contribute to community.	"*Where is this place where we gather and support each other? And talk to each other?*" -Graduate Student 2

Claim 2: Co-design provided a valuable community space for participants

All but one participant explicitly noted how engaging with other Latinx science teachers (current or future) in the co-design space provided them with a supportive community. For example, the current science teacher noted how his participation provided community he had previously lacked, "Like I've said before, I didn't realize how much I needed to talk to other Latinx teachers before this… I would really like this to continue and see where I can help." Similarly, Graduate Student 2 shared how she felt she found community within the co-design work: "[w]hen you're looking for community, like you're definitely gonna stay if you end up finding it. I know, like, I look forward to these meetings."

Discussion and Conclusion

This study provides a promising example of how researchers can utilize co-design to work closely in partnership with minoritized teacher populations to surface not only new insights into longstanding issues of equity in education, such as the underrepresentation of Latinx science teachers in the US, but how to foster much needed support and community for participants. Notably, the use of testimonio in this study provided an innovative and wholly effective anchor for co-design activity, providing highly contextualized data as seen in previous testimonio work (Reyes & Curry Rodríguez, 2012), which sparked rich discussions among participants that mediated the development of community as well as ownership of products like the infographic. Additionally, this study demonstrates the promise of organizing co-design spaces to include participants at differing levels of participation in becoming teachers, and points to possible future directions for participatory design research methodologies.

Acknowledgements

Special thanks to the current and future science teachers who took part in this co-design work.

Examining Learning-by-Teaching Effect in a Secondary Math Course

Chien-Chang Pan and Ben Chang
pan.ccamy@g.ncu.edu.tw bchang.tw@gmail.com
Graduate Institute of Learning and Instruction, National Central University, Taiwan

Abstract: The present study aims to identify which phases during learning by teaching play the critical roles and to investigate how student ability and pairing types mutually influence students' performance in each phase and the overall achievement. To this end, learning-by-teaching was applied with the form of reciprocal peer tutoring in a seventh-grade math course. Students' achievement scores, preparing-to-teach worksheets and verbal records during tutoring were collected for future conversational and quantitative analysis.

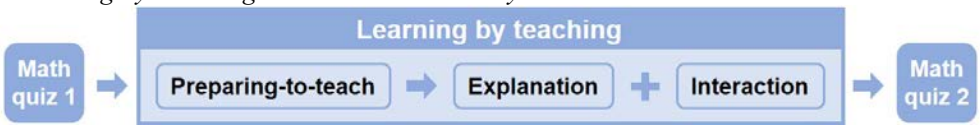
1 Introduction

It is well-studied and well-supported that *teaching* can be an effective strategy to facilitate learning (Fiorella & Mayer, 2016). *Teaching* encompasses more complex mental processes than only learning for oneself (Duran, 2017). According to Chi's Interactive-Constructive-Active-Passive (ICAP) framework (Chi & Wylie, 2014), learning increases when students behave higher-level cognitive engagement. Particularly, the act of explaining can strengthen deeper and longer learning effect than solely preparing to teach (Fiorella & Mayer, 2013). Furthermore, interacting, such as questioning and answering, helps tutors avoid the proclivity for *knowledge-telling* and stimulates them to generate *reflective knowledge-building* (Roscoe, 2014).

Learning-by-teaching has also been implemented in classroom practices with various forms, such as cooperative learning, peer tutoring, reciprocal peer tutoring (RPT) and so forth. Ample studies had revealed the benefits of those tutoring activities on students' academic achievement (Alegre, Moliner, Maroto, & Lorenzo-Valentin, 2019). However, in addition to overall advantages, there is still a lack of classroom study that further investigate the respective effect of each phase within tutoring process (Fiorella & Mayer, 2016). Hence, the present study not only implemented RPT in a seventh-grade math course but also applied Kobayashi's (2021) three-phase teaching framework to explore students' learning patterns and outcomes in each phase (Figure 1). That is, throughout RPT sessions, all students were required to prepare for their own teaching and thereafter to tutor each other through explaining and interacting. Two questions are examined in the study:

- Q1: To what extent did preparation, explanation and interaction influence overall learning achievement?
- Q2: How did student ability and pairing types influence tutoring performance and overall achievement?

Figure 1
Learning-by-Teaching Framework in the Study



* The framework was adapted from Kobayashi's (2021) face-to-face teaching framework.

2 Methodology design

The study was conducted in a seventh-grade math classroom at a public middle school in Taiwan, involving 23 students (11 females and 12 males). Written informed consents were obtained from all the students and their parents. A total of six RPT sessions were implemented: three training sessions and three formal sessions with a three-week break in between. Each RPT session was carried out after the math teacher's one- to two-week instruction for the topic. The math topics covered in the six sessions were (1) *Intro to Exponents and Scientific Notation*, (2) *Factor and Multiple*, (3) *Greatest Common Factor and Least Common Multiple*, (4) *Laws of Exponents*, (5) *Simplifying Algebraic Expressions*, and (6) *Algebraic Equation*.

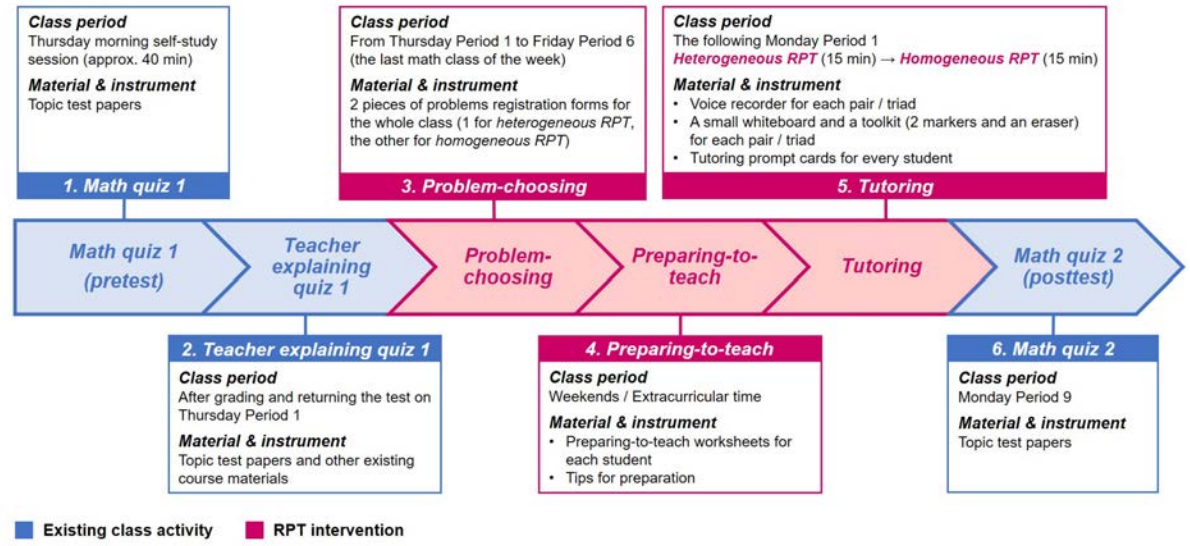
Prior to the beginning of the study, the students had been assigned to fixed pairs or triads by the teacher. Because each *tutoring phase* also encompassed two sub-phases — *heterogeneous RPT* and then *homogeneous RPT*, every student had two different pairs or triads (i.e., one for *heterogeneous RPT* and the other for *homogeneous RPT*). Accordingly, ten pairs and one triad were included in *heterogeneous RPT*, and six low-achieving pairs, four high-achieving pairs and one high-achieving triad were contained in *homogeneous RPT*.

 © ISLS

Procedure for each of the six RPT sessions was identical. Figure 2 outlines the involving phases, class periods for implementation, and required materials and instruments. For each session, all students took the *pretest* after the teacher completed instructing in the topic. The pretests contained a combination of multiple choice, calculation and word problems. During *problem-choosing phase*, students picked out their problems from the pretest paper and filled in the *registration forms* so their partners could see and prepare to teach those problems. Then, during *preparing-to-teach phase*, students were required to write their teaching preparations (i.e., problem-solving processes and math concepts or formulas used in the problems, etc.) on the *preparing-to-teach worksheets*. In each RPT session, students were expected to prepare four problems totally (two for each of *heterogeneous RPT* and *homogeneous RPT*). Afterwards, in *tutoring phase*, students worked in pairs/triads and took turns being *tutors* or *tutees*. The first 15 min were *heterogeneous RPT*, then students re-grouped and turned to *homogeneous RPT* for the next 15 min. At last, all students completed the *posttest*. Question types and difficulty level of the posttests were the same as those of the pretests. All tests were graded from 0 to 100.

Figure 2

Procedure of Every RPT Session



Pretest scores, posttest scores, and students' *preparing-to-teach worksheets* from six RPT sessions were collected. Verbal interaction from all pairs and triads during *heterogeneous* and *homogeneous RPTs* in three formal sessions were recorded and transcribed. Data analysis is in progress: marking rubrics for *preparation quality* and *qualities of verbal explanation and interaction* are in design; quantitative descriptive analysis, correlation, multiple regression, and ANOVA are expecting to carry out for answering the two research questions. Although taking with small sample and might filled with unmanageable confounding variables, the present study made attempts to evaluate *learning-by-teaching effect* of every RPT phase in a real classroom setting.

Routledge
Taylor & Francis Group

Selected Publications at the ISLS Annual Meeting 2022

Routledge Advances in Learning Sciences Book Series

The Routledge Advances in Learning Sciences book series is a high quality and trans-disciplinary international series publishing cutting edge research. The term 'learning sciences' covers research and development in the understanding of how people learn and the design of novel environments for learning.

Series Editors:

- Mike Sharples, The Open University, UK
- Chee-Kit Looi, National Institute of Education, NTU Singapore
- Keith Sawyer, The University of North Carolina at Chapel Hill
