This study directly measured whether students use a unit-equivalence strategy and whether instruction increases the transfer of this inquiry strategy. In our sample, we find that SES makes a difference in inquiry strategy process. One possible explanation for this result is that private school students engage in more inquiry. Looking at classroom size, science teachers in a private school have an average of twenty-two students, whereas those in a charter school have around forty. From an instructional perspective, given the attention inquiry instruction

demands of teachers, promoting inquiry may be easier with a smaller group of students, therefore, may happen more often for high-SES students.

We find that school type makes a difference in inquiry, but does instructional condition? The control condition students had a chance to complete *Tuglet* without receiving instructions. Yet, these students displayed a high percentage of inquiry strategy use in the transfer task in comparison to the other conditions. To offer some possible explanation it might be worth separating students by SES given the strong effect of SES on students' inquiry strategy use. For the high-SES students assigned to the control group they might not needed the instruction, and if you look at Table 1 average percentages of taught strategy use, they look similar among high-SES students. In low-SES students is possible that instruction didn't provide enough cues for spontaneous transfer and maybe instead confused them. The *Expanded* condition students had the opportunity to problem solve and then receive an instruction containing both right and wrong strategy use and explanations about why it is good to use the right strategy and cognitive effort of the right strategy to cue students to transfer into new settings. Overall, it seems that students in the *Expanded* condition do better than the students in the control condition. Instruction that cues students when learning an inquiry strategy seems to support inquiry strategy transfer to new contexts. Students in the other two conditions, *SR* and *SR + Exp*, fell in between, perhaps because individual differences are driving the effects in these latter conditions or because these instructional models are not as effective for promoting inquiry strategy transfer to new settings.

The interaction between SES and condition was marginally significant. Results show high-SES students already know a lot about inquiry and are more prepared to learn inquiry. Even the simple form of instruction (*SR*) worked for high-SES students. In the case of low-SES school, students assigned to the *Expanded* condition show the highest transfer of inquiry strategy to new contexts. It is possible that for students with low inquiry exposure, cueing them to recognize when they are using a wrong strategy and acknowledging the cognitive effort, better prepares them to use inquiry strategy in new contexts.

Finding instructional models that promote the use of inquiry strategies should be helpful to students as they move forward in their science learning. This study provides initial evidence that instruction that alerts to common ineffective strategies can promote the transfer of a taught strategy. By hypothesis, pointing out that "just adding things without a plan" is a poor strategy cues students to recognize when they are doing that behavior and reminds them to use the right strategy. Future studies will determine whether showing a wrong (ineffective) strategy vs. wrong strategy with effort cue are key to promote spontaneous transfer. Here, we examined a single strategy – find equivalence to a base unit. There are multiple inquiry strategies, such as the control-of-variables strategy (CVS). If we teach CVS to students using the expanded condition, would students spontaneously use CVS in new contexts? Subsequent studies will look at the effectiveness of the *Expanded* model for teaching other inquiry strategies.

Understanding Success in Library Makerspaces for Assessment Development

Kailea Saplan, University of Wisconsin- Madison, saplan@wisc.edu

Abstract: Makerspaces continue to grow in number and popularity and research on maker education has increased significantly, but most academic literature on maker education investigates the learning outcomes that are possible in these spaces (Mersand, 2021); fewer studies reflect an interest in understanding how we can recognize and assess learning outcomes for patrons (Lin et al., 2020). Current literature asserts that assessment in library makerspaces is a complex and thorny process because of the numerous learning goals and stakeholders that must be considered. This study confirms that success in these learning environments takes many forms. We introduce a Typology of Success that categorizes five types of success library staff value and want to assess. We also suggest an additional layer of complexity in assessment development may be due to the shifting nature of evidence of success that is dependent on the maker activity, the patron's goals, and the patron's disposition when it comes to facilitation.

Major issues addressed

For some, it may seem that the Maker Movement is heading toward the trough of disillusionment within its respective hype cycle (O'Leary, 2008), but educators across many countries are still committed to the promise of student-driven, hands-on learning through making (Eriksson et al., 2018; Milara et al., 2020). Makerspaces continue to grow in number and popularity, and research on maker education has increased significantly, growing from six empirical studies in 2014, to 51 in 2018 (Mersand, 2021).

Most academic literature on maker education investigates the learning outcomes that are possible in these spaces (Mersand, 2021), with particular focus on the learning afforded by makerspace environments and the relationship between learners and making (Peppler et al., 2016b, 2016a). Fewer studies reflect an interest in understanding how we can recognize and assess learning outcomes for patrons (Lin et al., 2020). This gap in literature represents an imbalanced understanding of the educative value of making. Studies that identify what is knowable in maker education only accounts for half of the learning process; we must also explicate how the knowable can be recognized, interpreted, and understood by stakeholders (e.g., educators, administrators, caregivers, learners).

Public libraries, in particular, are embracing maker education (Chang et al., 2019). The second most empirical studies on makerspaces come from the field of Library and Information Science (Mersand, 2021). This is perhaps unsurprising given that a common mission of libraries—to increase patron literacy—demands that they integrate emerging literacies (e.g., maker education, digital literacy) (Mann, 2018). However, only a small amount of the literature on assessment in maker education originates from libraries (Lin et al., 2020). This may be due to the fact that the majority of available assessments are designed for schools with relatively uniform standards and pedagogical expectations, whereas the heterogeneity of library goals, and of making processes and outcomes (Teasdale, 2020, p. 1) fundamentally differ (Rogoff et al., 2016). For instance, library staff may be less interested in assessing individual learners through making and would rather understand how their makerspace supports family learning (Roque, 2016). Endeavoring to assess family learning shifts the unit of analysis in assessment from one learner to multiple learners and would likely demand different assessment tactics. To close the gap in literature, scholars and maker educators across library settings are beginning to place equal importance on studying maker-related learning outcomes and assessment of those outcomes.

Due to unique practical and pedagogical demands, and the axiological commitments of library makerspaces, scholars intending to support assessment in these settings have taken to either developing bespoke assessments (Chang et al., 2020), or sharing assessment-building processes to help maker educators develop their own assessments (e.g., Cun et al., 2019). This study addresses the issue of limited scholarship on assessment in library makerspaces and adds to literature about processes that help facilitators create assessments for their makerspaces. We report findings from a qualitative research project in progress that investigated what library staff broadly consider evidence of success in their makerspaces and seek to assess. We introduce a Typology of Success, which encapsulates five major categories of success that emerged from analysis, and we advance the idea that

 © ISLS

success is, at times, a moving target in library makerspaces that requires flexible assessment tools with the capacity to capture evidence of success as it evolves.

Potential significance of the work

To support facilitators of maker education in their efforts to assess learning in their makerspaces, Cun and colleagues (2019) generated a *library makerspace assessment matrix* to identify the "assessment needs of patrons and librarians" (p. 39). The purpose of the matrix is to clarify which types of assessment tools are appropriate for any given maker activity based on when and how a patron most benefits from assessment and what a librarian wants to learn about the patron using an assessment. The matrix also provides a list of six categories of assessment "that could be implemented given typical librarians' knowledge and resources" (p. 45).

Though a promising tool that contributes to assessment of maker education both practically and conceptually, the matrix centers on a specific kind of learning. By focusing on skill development and mastery of technology, the matrix only documents learning that is "acquisitional" (Sfard, 1998). This theory of learning "implies that there is a clear end point to the process of learning" (Sfard, 1998, p. 6)." A library maker educator assessing for acquisitional learning might administer a pre- and post-survey under the assumption that they can track the knowledge or skill a patron had before and after attending a program. In contrast to learning as acquisition, learning can be participatory. Learning as participation is "a process of becoming a member of a certain community" (Sfard, 1998, p. 6), which is considered an important outcome in literature on maker education (Barajas-López & Bang, 2018; Blikstein & Worsley, 2016; Einarsson, 2021). If one is interested in assessing learning as participation, one might provide exit surveys that ask patrons to describe how welcome they feel in a makerspace or observe moments of collaboration between patrons.

Teasdale's work (2020) incorporates different stakeholder perspectives "to foster in-depth understanding of evaluative criteria for the makerspace in its real-world context, based on multiple sources of evidence drawn from multiple perspectives" (p. 4). She draws from observations of the makerspace, interviews with library staff and leaders to understand the goals of the library, and interviews with library patrons "to investigate their purposes and desired benefits related to makerspace participation" (p. 4). By triangulating these data sources, Teasdale defines outcomes and visions of success that stakeholders want from maker education experiences for the purpose of developing evaluative criteria for assessments. Teasdale presents seven evaluative criteria that reflect conceptions of success held by library staff and makers:

- Access to technology
- Learning to use technology
- Fostering entrepreneurship
- Nurturing creativity
- Strengthening communities and families
- Realizing intrinsic benefits
- Saving money

The seven criteria provide a broad picture of the kind of success that is possible and desired by library staff and makers, extending learning outcomes beyond those captured in the library makerspace assessment matrix. However, as Teasdale notes, each criterion will not be relevant to all participants; a strong assessment would "identify the criteria that were relevant to each participant and apply those specific criteria to data collected from that individual" (p. 8). Gathering data from various stakeholders and soliciting information about their desires and intentions in a makerspace appears to be a promising approach to developing relevant criteria that can be used to assess maker activities. And yet, the criteria Teasdale offers do not clarify for maker educators the types of assessments that might be useful for capturing evidence the way Cun et al. do (2019).

The findings from this study build off the contributions from Cun et al. and Teasdale by introducing a Typology of Success for maker education in libraries. The Typology identifies five categories of success that emerged from interviews with library staff at two libraries. Like Teasdale's work (2020), this study shares conceptions of success that can be used to inform which types of assessments employed or designed for a given maker activity or program. Like the work of Cun et al. (2019), the Typology is meant to direct library maker educators toward a narrowed set of assessment possibilities to aid their decision making.

While the Typology is still being refined, we introduce it as context for the broader finding we present regarding the evolving nature of success. Both the Typology and our general finding contribute to burgeoning literature on assessment in makerspaces in library settings. The main significance of this work is to advance the idea that what appears to be noise in data about assessment in library makerspaces (e.g., responses from library

staff that contradict each other, or constant appeals to "it depends" when a staff member describes how they know a program is working) is in fact a feature of making and learning in library makerspaces that must be addressed more fully to authentically assess these unique environments without losing their richness.

Theoretical and methodological approaches pursued

Theory

The study is grounded in the constructivist paradigm of epistemology, which asserts that "knowing" is a socially and culturally situated process that builds on previous meaning making and the activity of learners both individually and collectively (Efland, 2002). There is nuance and debate within constructivism that is worth exploring (Packer & Goicoechea, 2000), but it is beyond the scope of this paper. Most importantly, this work does not adhere to a positivist paradigm of epistemology, in which knowing, or truth is considered universal, complete, and discoverable. In concert with constructivism, our study was designed to understand how library staff experience assessment, how they practice it, and how they perceive both assessment and success in maker education.

More specifically, the research presented here draws on *evidence-centered assessment design (ECD)* (Mislevy & Riconscente, 2005), a method for designing assessment using data associated with authentic practices in the learning setting in which assessment will take place. ECD is multi-step process of designing assessment that first asks what "complex of knowledge, skills, or other attributes should be assessed" in a learning environment (Messick, 1994, p. 16, as cited in Mislevy & Riconscente, 2005). The five steps include: *domain analysis*, which includes substantial analysis of the content and concepts that will be assessed and identifying what evidence will indicate that the content or concept has been understood by a learner; *domain modeling*, a process of adapting the information gathered from the domain analysis phase into a narrative argument that will become the foundation of the assessment; *conceptual assessment framework,* is the process of adapting the narrative argument into a blueprint of tasks or items necessary to conduct the assessment; *assessment implementation,* which encompasses the development of assessment tools (e.g., tasks, rubrics, and samples); *assessment delivery,* the process of enacting the assessment and reporting its findings to the appropriate audience (Mislevy & Riconscente, 2005). This paper presents findings on the domain analysis portion of ECD, the only phase that has been completed thus far. Although the project was interrupted by COVID 19, we intend to follow the four subsequent steps and develop a suite of assessment tools for maker-based learning based on our domain analysis.

Methodology

This study follows the methodological framework of a basic qualitative study (Merriam & Tisdell, 2016). "A central characteristic of all qualitative research is that individuals construct reality in interaction with their social worlds," and the purpose of qualitative research is to understand "the meaning a phenomenon has for those involved...to understand how people make sense of their lives and their experiences" (Merriam & Tisdell, 2016, p. 24). Our research questions ask:

- What learning goals do library staff and maker educators have for their maker-based learning programs?
- How do they define success in those programs?
- How do they recognize and describe evidence of success and the learning goals they identified?

These research questions allowed us to make sense of what staff want to assess in their maker education programs without placing explicit emphasis on assessment. Focusing on assessment might have been more difficult for staff to articulate, especially if they did not already have robust assessment practices or assessment literacy. To elicit responses to those questions, library staff and maker educators were asked to explain how they know when their program is going well and what evidence they look for.

Study sites

Makerspaces in two libraries serving medium-sized cities in the Midwest were included in this study. Learn to Make Lab (1) serves nine library branches in a single system, though it is physically housed in the centrally located downtown branch. Learn to Make Lab hosts artists-in-residence and drop-in sessions at their physical space, and shares maker-kits which include various materials to the other branches, summer school sites, and outreach programs. Most of the materials at Learn to Make Lab are considered low-tech (e.g., craft materials, art supplies, recycled goods), but they also boast a media lab. The makerspace known as Making an Impact (1) is also located in the main, downtown branch of its library system. In contrast to Learn to Make Lab, it is one of 37 branches that

have sites throughout suburban, somewhat rural, and inner-city regions alike. Due to limited residential housing surrounding this branch, it mostly serves people who commute to the library. Making an Impact has two full studio spaces in addition to other technology common in makerspaces, like 3D printers, laser cutters, robots, and interactive technologies, as well as more analog tools like a button maker.

Sample

Interviews for the full domain analysis were conducted with library staff and maker educators, and library patrons (e.g., learners and their caregivers). In this paper, however, we present findings based on analysis of the responses from library staff and maker educators only. Rather than target a large sample size and make claims about the average response to the research questions, staff were purposely selected to amass a maximum variation sampling of responses for each library site that would illustrate variety and range (Merriam & Tisdell, 2016). Library staff were selected to participate in interviews based on how directly tied their work and responsibilities were to their respective library makerspaces. Each staff member that participated was connected in some way to the maker programs offered by their library, but the staff varied in terms of their exact roles within the library. The majority of staff who participated in the study were maker educators or librarians who also implemented maker education programs; staff supervisors and a manager of operations were also interviewed.

Data collection

Seventeen library staff were interviewed through a semi-structured interviewing process (Rubin & Rubin, 2005). Interviews ranged from 25 to 50 minutes and were conducted in person by two members of the research team (one at each library site). The research team guided the interviews so that conversation focused on learning and engagement in library maker programs, but participants were encouraged to draw from experiences with other programs as well, especially when discussing how learner engagement can look different depending on the programmatic focus. Specifically, they were asked, *what is happening when things are going really well in the Launchpad/Bubbler? How do/would you know? How could you know?* If participants needed more scaffolding to answer the questions, the research team would probe further by asking *What does it look/sound/feel/smell like when things are going well? Even if hasn't happened yet, what would it look like?* They also encouraged participants to share about a specific time or program that was really successful and to describe what happened.

Data analysis

After audio recordings of interviews were transcribed, the researcher who did not conduct the interviews underwent several cycles of inductive, emic coding analysis. Data was analyzed using (a) descriptive coding that highlights the topic of a response, (b) concept coding, which describes the content that is discussed in the response, and (c) subcoding, which assigns a secondary code to enrich the primary or parent code (Saldaña, 2016). The first iteration of coding was conducted using an analytic matrix that included verbatim quotes about success from the transcripts, analytic memos describing the topic and content of each quote from the researcher, and potential codes that encapsulated the main themes in the quote (Maxwell, 2013). The matrix was used to organize the data and trace the researcher's interpretation. The initial phase of coding produced a long list of codes, which were then transferred to a code map (Saldaña, 2016), a list of codes and subcodes organized by theme. The researcher condensed and expanded the codes in the list while reviewing the analytic matrix. Following that, the researcher created a new analytic matrix, free of any analysis or notes, and coded the verbatim quotes again using the list of codes. This process afforded her an opportunity to test whether the same themes emerged. Once the second phase of coding was completed, the researcher updated the code list and began a process of coding the list for thematic patterns and organizing (and reorganizing) them into categories. Those codes were then shared and discussed with the library partner from each site, so they could challenge or confirm their accuracy and potential utility for developing assessment moving forward, a process called member checking (Merriam & Tisdell, 2016). With their input, redundant subcodes were eliminated, and parent codes were reorganized, revised, and condensed into central concepts that related to how library staff know when a program is working. Throughout data analysis, all three research members met bi-monthly to discuss the data and engage in constant comparison of themes or "incidents" in the data as they emerged (Corbin & Strauss, 2008).

Major findings

Typology of success

Five themes emerged when library staff described how they know when a program works and what counts as success in library marker education. Success is encapsulated in the *metrics* they collect, the *lasting impact* a program has on patrons, the moments when patrons experience *learning as participation*, the opportunities to

check off *learning as acquisition*, and the proficiency with which learning is facilitated by maker educators (*facilitation of learning)*. *Metrics* refer to a concept of success as the accumulation and collection of quantitative data on magnitude of outreach and audience demographics, usually over time. When success is understood as *lasting impact*, it means a program influenced patrons in a way that was holistic (e.g., programs connected to school curriculum) or long-term (e.g., patrons are inspired to engage in similar programming outside of the library site). A program is considered successful if it demonstrates *learning as participation*, that is, learning as a "constant flux of doing" inseparable from the learning context and "a process of becoming a member of a certain community" (Sfard, 1998, p. 6). A program may also be considered successful if a maker educator observes *learning as acquisition,* in which a patron picks up a skill or learns something new (Sfard, 1998). Finally, success may be denoted by the *facilitation of learning*, including how "well" learning is facilitated during an activity or by the maker educator's experience of meeting their own teaching and learning goals. These five types illustrate the varied ways in which success in library programming manifests according to library staff.

Again, this Typology is still being refined, but we include it here to provide context for an important idea that has emerged from the data regarding the complexity of assessment in library makerspaces. As it is now, the different success types suggest assessment is meaningful at vastly different timescales, not only formatively (ongoing throughout the course of instruction) and summatively (occurring at the end of an activity, program, or series of programs) (Shute, 2009), but also in relation to whether success is assessed within the learning event (e.g., *learning as participation* or *acquisition*), or over the course of multiple distinct learning events (e.g., *metrics* or *lasting impact*). The types also indicate different units of analysis for assessment, from individual patrons to patrons as a collective or community to maker educators. Importantly, the Typology reflects learning as both participation and acquisition, a feature that is often missing from assessment tools and protocols. The inclusion of both types of learning might be considered epistemologically incompatible, but Sfard insists they are productively contradictory:

> Each has something to offer that the other cannot provide… metaphorical pluralism embraces a promise of a better research and a more satisfactory practice. The basic tension between seemingly conflicting metaphors is our protection against theoretical excesses, and is a source of power. (1998, p. 10)

Ultimately, the Typology demonstrates that the learning outcomes and success library staff value and want to assess differs greatly, by timescales, units of analysis, and even theories of learning. By categorizing types of success that staff care about, this tool may help maker educators select or design assessments for their makerspaces. For instance, when engaging in domain analysis of their own sites, they might start with the Typology to identify the outcomes and models of success they value. Library staff might also conduct their own analysis and compare their findings with the Typology as a way to articulate the timescales, units of analysis, and models of learning they want to focus on. A precise framework for the Typology and a comprehensive guide is outside the scope of the paper but is forthcoming.

Evidence of success is a moving target

In addition to the sheer variety of definitions of success in library makerspaces, our findings indicate that evidence of success, too, is difficult to identify because it can shift. For instance, one library staff asserted that the way they determine a patron's progress "depends on what activity they're doing." In fact, six of the 17 library staff interviewed, about 35%, were coded as responding with "it depends" when asked how they know when a program is working or successful. The staff member went on to say that in the case of a patron who wants to use the recording studio, they are more likely to pose questions if they do not understand what to do, because their session time is limited. In contrast, when people visit the makerspace to explore materials and activities, they may not ask for assistance right away. It is then up to the maker educator to observe their behavior and recognize when a patron is using a tool without fully understanding it. Essentially, the library staff in this example implies that maker activities do not occur in a vacuum; they are socially and culturally embedded, and inherent in each activity are cultural practices around seeking support that facilitators need to be aware of while assessing, because those practices can inform how evidence of success looks.

Another staff member noted that certain maker behavior, like "coming in and just downloading one thing offline that they didn't use or didn't make," may be evidence that the makerspace is not successfully inviting patrons to "progress deeper." However, they admit that such behavior might also communicate success if the patron's goal is to use the library for its available resources. Teasdale (2020) discusses this phenomenon of assessment as a moving target in her work as well, when she writes, "applying (assessment) criteria uniformly

could, therefore, lead to a mismatch for some participants." She calls for "individualized criteria" in assessment instead "to identify the criteria that [are] relevant to each participant" (p. 8).

Moreover, our analysis indicates that evidence of success not only varies by activity or the patron's personal goals, but it can sometimes shift depending on the patron's perceived dispositions. One library staff stated that they could tell "things are well" or that a patron is enjoying themselves or engaged "if they're asking more questions…and they're wanting to find out more about what's going on." When pressed by the interviewer what specifically about the questions or number of questions indicates success, the staff member stated,

> Well, I think it really depends on the type of question. Some people might be the type of person that might not ask any questions, and if I see that they've been sitting quiet and all of a sudden, they start asking a couple of questions about something, that indicates to me that they're interested. They're interest is more piqued. Whereas somebody else might be just asking all kinds of questions about everything, "What is this? What is that? What is that?" If they start ramping up their questions or start focusing their questions on a certain area, I can tell that they're more engaged in that area or they're getting more engaged.

The quote suggests that even when a maker educator is looking for certain behavior or criteria to assess a patron's experience or success, the meaning of that behavior shifts depending on how that person normally behaves. Certainly, whether a make educator can really know in a short period how a patron "normally" behaves is question worth exploring in its own dedicated study. The key point, however, is that evidence of success is sometimes a moving target, adding to the layer of complexity for assessment in public library makerspaces. While more research is necessary to fully investigate the notion that evidence of success can be dynamic rather than static, we share implications for assessing a moving target in the following section.

Conclusions and implications

Across the literature on assessment in library makerspaces, scholars specifically note how difficult it is to design assessments for these settings, because of the numerous learning goals worth addressing and diverse public library stakeholders. Teasdale (2020) comments on how the heterogeneity of patrons and maker educators, and their diverse goals for learning through making, make the challenge of developing or selecting assessment "particularly pronounced for public library makerspaces" (p. 1). Cun et al. (2019) recognize that assessment for library makerspaces is connected to the assessment needs of the library at large, and that part of developing authentic assessments for makerspaces requires compatibility between the two, or there is a risk of assessment being "viewed as having little or no value to a stakeholder of the library makerspace (e.g., a patron, librarian, administrator, library board member, or municipal agency)" (p. 41). Wardrip et al. (2019) note that the vast array of stakeholders associated with libraries pose a challenge when it comes to assessment; the question of "what should be assessed and for whom" is not as straightforward as it may seem (p. 34).

This study confirms that success takes many forms. The Typology of Success introduces five different types of success that emerged from interviews with library staff. Additionally, the Typology begins to address the need to understand "success that accounts for makers' and libraries' varying priorities" (Teasdale, 2020, p. 1) and aid in the design or selection of new assessment tools to support assessment of these unique learning environments. For instance, the Typology might be used with maker educators to clarify the success type they most care about, thereby helping them identify the unit of analysis that they might target. Another implication of the Typology is that maker educators and their ability to facilitate learning in makerspaces may be a useful focus for assessment. Educators must make numerous inferences about patrons, particularly when it comes to assessing a patron's progress and providing appropriate feedback to support their learning (Michalchik & Gallagher, 2010); it is worth exploring how well they make those inferences when it comes to assessment and what practices, tools, and professional development can help attune them to making stronger inferences.

In their review, Lin and colleagues (2020) refer to assessment in any makerspace as a "moving target," "with varying students, educators, activities, disciplines, arrangements, and learning outcomes" (p. 3). This study confirms that another layer of complexity in assessment of library makerspaces may be due to the shifting nature of evidence of success, which depends on the maker activity, the patron's goals, and the patron's disposition when it comes to facilitation of a program and their own participation. We imagine, too, that evidence of success may change as a maker educator continuously develops expertise for eliciting evidence from patrons, developing inferences of patrons' learning, and making interpretations of those inferences. One implication for this finding is that library staff need support in identifying success and evidence of success with more consistency, so they might improve their informal assessment techniques (Gahagan & Calvert, 2020) and systematize the claims about their programs.

Another possible implication is that staff members' penchant for saying, "it depends" when asked how they know their program is going well, may not an indication of uncertainty, but rather recognition that what counts as evidence of success can shift in a moment's notice, especially as they take in more information about the patron. This implication evokes several questions. If evidence of success shifts depending on multiple factors, what specifically are those factors? This study begins to answer that by pointing to the activity, the patron's goals, and the patron's disposition when learning, but more research is needed to address that provocation fully. Additionally, if evidence of success is not always static, are formative assessments sufficient to capture its dynamism? Or are other, more flexible assessment tools necessary to capture the evidence of success as it shifts? What do/would those tools need to look like? How would they operate differently from current available assessment tools and practices? Moreover, if evidence of success can be in flux, what does that mean for assessing learners across learning settings? In describing the learning as participation metaphor, Sfard (1998) says,

> Being "in action" means being in a constant flux. The awareness of the change that never stops means refraining from a permanent labeling. Actions can be clever or unsuccessful, but these adjectives do not apply to the actors. For the learner, all options are always open, even if he or she carries a history of failure…Today you act one way; tomorrow you may act differently. (p. 8)

Perhaps our penchant for labeling students as a reflection of their assessment results (e.g, gifted and talented, or below average) will be troubled by the finding that evidence of success is a moving target. If success evolves as the learner does, perhaps we will come to learn that current assessments cannot fully measure students' ability to learn or grow and should not be used in this capacity. Maybe there will come a time when we abandon assessment practices that seek to define students by what they can do, and instead find ways to understand how students' potential for learning expands with each new day.

Abstract: We designed a lesson about Urban Heat Islands (UHI) that features Snap*!* programming challenges. The lesson is designed to enable students to leverage their computational and scientific understanding synergistically to further their learning in each area. The lesson also features fictitious automated college student mentors to enhance students' sense of belonging as they engage in the programming challenges. We report on students' level of success with three increasingly complex programming challenges as well as their level of understanding of how UHI occur after completing the challenges. We also provide brief case studies to illustrate how students used their scientific knowledge to debug their code and solve the challenges. Despite varied success with the challenges, most students were able to demonstrate an understanding of UHI. Many reported feeling interested and nervous when starting the programming challenges and shared they did not feel alone after engaging with the college student mentors.

Objective

Computational thinking (CT) is vital for designing and analyzing models of environmental systems and is a skill increasingly valued by middle school teachers. Participation in the public discourse about environmental stewardship involves questioning and interpreting computational models. Enabling students in middle school science classrooms to engage with models of complex environmental dilemmas such as Urban Heat Islands prepares them to explore phenomena that impact their lives. By leveraging science knowledge, students can detect bugs in their code and make sense of model output. By developing programming knowledge to test their conjectures about remedies for urban heat islands, students can investigate questions that interest them, such as the impact of planting more trees. Further, middle school is a critical time to bolster student identity as a computational thinker and to foster a sense of belonging while engaging in computational activities.

To assess the potential of Snap*!* programming for engaging students in computational thinking in science, we designed, and pilot tested a lesson about Urban Heat Islands (UHI). The lesson features three progressively more difficult programming challenges that support students to explore the heat island phenomenon and generate a solution for a fictitious neighborhood (see Figure 1).

Figure 1

Third programming challenge in the UHI lesson. Students complete if-statements by filling out both condition and broadcast blocks. Scaffolding questions support students to debug their code and make sense of the trials they run with the model to determine the relationship between each surface and temperature.

 © ISLS

Using a computational model, learners can analyze the impact of multiple solutions such as adding reflective roofs or planting trees. Students can evaluate the trade-offs necessary to achieve personal goals such as "space for skating" or "hidden hangout places" by designing a Snap*!* model to reduce urban heat islands in their city. We explored students' feelings while programming using Snap*!* for the first time and investigated ways to support their sense of belonging.

We ask the following questions: How do students apply science knowledge to solve programming challenges? How do students feel when attempting computer programming and how do they feel after engaging with automated college student mentors? What is the teacher's perspective on the value of integrating CT with science?

Rationale

Integrating CT with science understanding

The UHI lesson in this study aims to support students to leverage their science understanding to support the development of their computational thinking skills, while also using computational thinking to deepen students' understanding of the scientific phenomena. This approach of viewing CT and science learning as mutually reinforcing builds on prior work showing that when students learn graphing in the context of science they gain proficiency in interpreting graphs and also increased ability to understand the related science concepts (Wiese, Rafferty, & Linn, 2017; Boda et al, 2020). This prior work suggests the potential of curricula and assessments designed using the Knowledge Integration instructional framework (KI; Linn & Eylon, 2011) to support students to integrate and mutually develop knowledge in computational and scientific domains. As such, the UHI lesson featured in this study was designed according to the KI framework. A KI approach to curriculum design recognizes that learners hold varied ideas that reflect their lived experiences. It advocates for supporting students to develop coherent understanding by *eliciting* students' prior ideas, providing opportunities to *discover* new ideas, using evidence to *distinguish* among existing ideas and new ideas, and guiding students to *make connections* among their ideas to form an explanation or argument (Linn & Eylon, 2011).

To create learning experiences that support students to deepen and integrate their CT and science understandings, we apply the KI framework and prior research in computer science and science education to design activities that: *elicit* students' relevant ideas from prior science instruction and relevant everyday experiences as starting points (Hammer & VanZee, 2006); *guide* discovery of new science concepts and programming patterns by analyzing and modifying computational models (Basu et al, 2017; Sengupta et al, 2013; Wilensky et al, 2014); promote *distinguishing* among ideas by annotating peer responses and comparing solutions (Buffum et al, 2016; Lewis et al, 2012; McElhaney et al., 2015; Vitale et al, 2019); and *facilitate links* among CT and science ideas by guiding use of CT to inform science and science to inform CT, such as for debugging (Hutchins, Biswas et al, 2020). In the UHI lesson, students first use and then create Snap*!* programs where they explore scientific models to connect their ideas about CT and climate. Students deepen their science understanding by first testing the impact of a single variable and then identifying interactions between variables. Students use their science understanding to debug their code and check if their output matches their expectations based on their knowledge of the UHI phenomena. Students distinguish ways to reduce the UHI effect by analyzing tradeoffs between alternative solutions. Ultimately they *connect* their ideas in a proposed solution.

Developing a sense of belonging

Students often report feeling unwelcome in classes involving computer programming (Garcia, 2020; Gorson & O'Rourke, 2020) and benefit most from learning environments that support them to develop a sense of belonging (Jagers et al., 2019; Trujillo & Tanner, 2014). We endeavored to build a sense of belonging where students identify as part of their classroom community and eventually, the computational community by creating automated mentors. Students often feel like imposters or think they are the only ones who are confused, when really many students feel that way. In one study, across three university introductory programming courses, students tended to negatively self-assess in programming situations, like having a syntax error or struggling to debug a program, that are common in professional programming practice. These moments of negative self-assessment were correlated with low self-efficacy and inability to imagine success as a programmer (Gorson & O'Rourke, 2020). Thus, students might not have a clear understanding of the experiences to expect while programming and might benefit from assurance that their feelings are held by others. These patterns of negative self-assessment and frustration impede student pursuit of computer science beyond middle school and can be remedied by collaborative, engaging computational experiences that are personally meaningful (Kafai & Burke, 2013). We designed the automated mentors by asking Computer Science undergraduates who serve as Teaching

Assistants in the non-majors introductory programming course at a large research university to respond to frequently expressed beliefs of middle school students. The automated mentors elicit and affirm the beliefs of the novice programmers and help them connect their experiences to the mentors' similar experiences.

Methods

Context and Participants

The UHI activities were implemented at a public K-12 school located in the United States. This study occurred in one teacher's three 7th-grade science classes (N=72). Students had two 70-minute class periods to complete the lesson. The teacher expressed a strong commitment to environmental science and engaging students in exploring local environmental issues but had no prior programming experience. Students had limited prior programming experience as well; only 11 students mentioned other prior coding experience at home or at school. During the study, students worked in groups of two or three; each group had one laptop. Placing students in pairs allowed them to ask each other questions, problem-solve, and take turns typing responses to questions. When students got stuck and raised their hands for help, the teacher encouraged them to approach their challenge like a scientist; ask good questions, be curious, and experiment. After offering this advice, the teacher walked away and observed that, in most cases, students would turn to each other to discuss ideas and methods for solving the problem.

Curriculum

The lesson is designed in two parts, informed by the KI Framework. The first focuses on developing student understanding of UHI through programming challenges. The second part tasks students with applying their learning to do a city planning activity. The first part starts by introducing students to the phenomenon of Urban Heat Islands by eliciting their prior knowledge about climate change and the effects that result from a changing climate. Students then build on their lived experiences by considering how different surfaces in a park feel and where they would sit if they were having a picnic in the park on a hot day. Next, students discover more ideas through a series of progressively more difficult block-based programming challenges that are designed to scaffold student understanding of and ability to apply programming control structures. In the first activity, students use Snap*!* blocks to set the variables in a model that tests the effect of varied amounts of grass coverage in the neighborhood and the impact on temperature over a month. Before engaging with the next, more difficult programming challenge, students annotate a sample program using pre-authored labels to identify the function of each of the different blocks in the program. Next, students are tasked with filling in a few missing blocks in the conditional if-statements that control the model and then use their code to test varied amounts of tree coverage in the neighborhood. In the third programming challenge, students fill in the gaps to create the majority of the program by writing conditional if-statements to test varied amounts of reflective roofing (See Figure 1). After using code to program the model, students observed the changes in the temperature of a city using a temperature graph, which updated in real-time as the model ran.

In the second part of the lesson, students apply the coding and modeling skills they learned to design a city that could reduce the ambient temperature. Students consider their favorite parts about their own neighborhood and how they would like to improve it. They then map out the city design, considering tradeoffs as they select surfaces that maintain functionality and prevent the city from becoming a UHI. In the final activity, students are asked about how they felt when they began writing computer programs with Snap*!* in the lesson. Students were then introduced to fictitious automated college student mentors (Figure 2) who shared how they felt when they started programming. The mentors' responses are based on ideas shared by the undergraduate teaching assistants described above.

Data sources and analysis

CT and science

Data sources to assess student CT and science learning include Snap*!* code for the three programming challenges and their written explanations of the UHI mechanism in response to the prompt: "Explain why an urban heat island is hotter than the areas around it".

We examined student approaches to solving the programming challenge and identified four progressively more sophisticated approaches: a) did not attempt moving the code blocks, b) attempted the activity and found a partial solution enabling them to test only one condition, c) hacked the code by getting the model to run using an unanticipated solution, and d) programmed the intended solution. See hacked and intended solutions in Figure 3.

Student responses to the UHI mechanism item were characterized by the degree to which they integrated ideas to explain how urban heat islands arise: a) alternative explanations such as "it gets the most sun", b) identifying surface features that contribute to UHIs, and c) connecting surface features to the proportion of solar radiation absorbed and transformed into heat. Our analyses include student groups who completed all programming challenges (N=28).

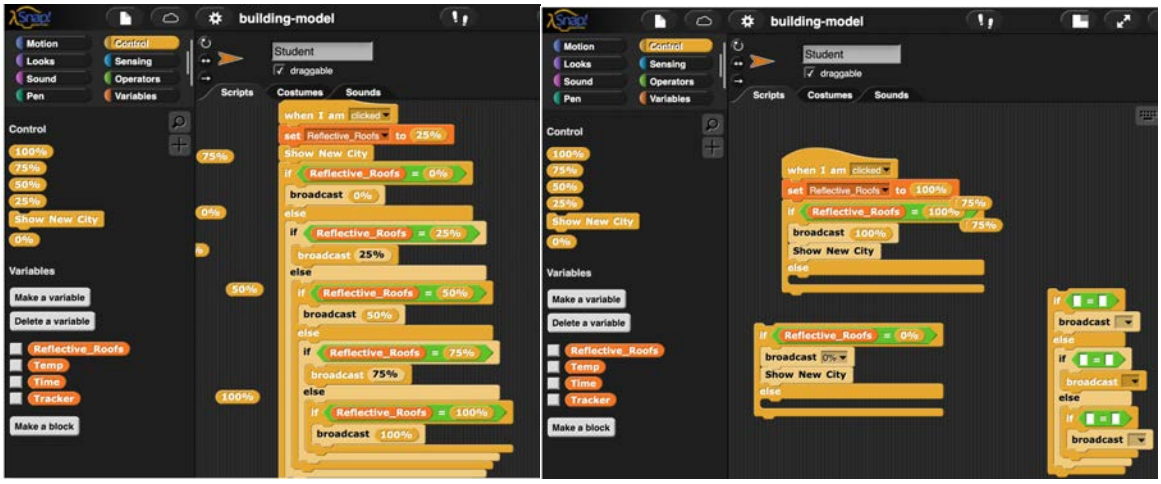
Figure 2

Automated mentors' ideas are modeled on real college students who have experience supporting other computer science students. Each mentor shares how they felt during their first experience writing a computer program.

We also draw on data from classroom observations and Zoom video recordings of three student groups, with one group in each class period. The teacher selected the observed groups from among the students who returned consent forms based on students' expressed willingness to think aloud while working. The students were generally representative of the entire class in terms of prior programming experience. Observation notes were collected in the form of a running transcript, recording dialogue and behaviors, to capture the group's thinking and interactions as they worked with Snap*!*. We reviewed the transcripts to identify moments where students used their scientific understanding to make sense of their computational activities or used their computational skills to deepen their science understanding. We present one such moment from each of the observed groups to provide narrative examples of how students engaged in the programming challenges.

Figure 3

Example of intended programming solution (a) for the third programming challenge and a "hacked" solution (b). In the hacked solution, a student group removed most of the scaffolding blocks that indicate the if-statements in the program. They instead used only one, making the code more similar to the first programming challenge, but requiring them to rewrite the program's conditional each time they ran a new trial.



Sense of belonging

Data sources to gauge student sense of belonging include one multiple choice item asking students, "How did you feel about writing a computer program in Snap*!* during this lesson?" Students could select multiple responses among excited, interested, confident, and afraid. We also analyze student responses to the open responses question, "What do you think and feel after reading these ideas from the college student mentors?" We calculate the percentage of students who chose each multiple-choice option. Inductive coding (Thomas, 2006) was used to identify themes in the student responses. We report the frequency of each theme and representative student responses reflecting the theme.

Teacher perspective

We conducted an interview to understand the teacher's perspective on the success of the lesson and the value of integrating CT into environmental science. Questions included: "How did the lesson go from your perspective; what surprised you?", "What did you notice about students' science learning in this unit? How did it compare to other curriculum they have used?", "Did you see evidence of students engaging in computational thinking or linking ideas about science with ideas about computer models?", and "If you were to teach this again, what support or resources would you want in order to prepare?". The teacher also wrote a reflective memo of her experience teaching, drawing on her field notes.

Results and discussion

Science-CT learning

During the first programming challenge, 60% of student groups were fully successful, using the Snap*!* coding blocks to test varied amounts of grass coverage versus asphalt in the model. All of these students generated the intended solution. Observations revealed how the challenge elicited students' science thinking about energy transfer and transformation. As one student remarked, "Less grass has more heat energy and when there was more grass it was just solar radiation." Students observed that when they programmed the model to have more grass than asphalt, more of the solar radiation was absorbed and transformed into heat energy.

In the second, more difficult programming challenge, 21% of students were able to program the intended solution and another 11% were able to manipulate or hack the code in ways that allowed them to run the model and test the appropriate conditions. The flexibility of Snap*!* enabled the students to experience programming success even when they had not fully developed an understanding of how to write if-statements or how to efficiently combine a series of if-else-statements. A partial solution was achieved by 18% who experimented with moving the Snap*!* blocks and tested one condition. The remaining 50% of students did not manipulate the blocks.

By the third activity, 39% of the students designed the conditional and output statements to test reflective roofing, with 21% completing the activity as intended and 18% successfully hacking the code to create an unanticipated solution. Several student groups who had a partial coding solution during the second activity were able to hack the code and run trials with the model during the third activity. Their experience experimenting with the blocks in the second activity supported them to keep experimenting until they found a solution in the third activity.

Following their programming investigations of the model, 71% of students were able to accurately describe the types of surfaces that contribute to an area becoming a UHI. Of those students, 40% were able to connect their ideas about the surfaces to the energy transformation mechanism. Thus, despite struggling to complete the programming challenges, students gained understanding of the science concepts underlying UHIs.

Case studies

Drawing on observation notes, video data, and student written work of the three observed pairs, we describe instances that illustrate how these students leveraged their science understanding to support their computational practices or used their CT understanding to support their sense-making around science concepts.

Using observations of the model to troubleshoot programming challenges

When starting the first programming challenge, one pair of students we observed worked together to figure out how to move Snap*!* blocks into their program to control the model. They noticed that even when they dragged over the 25% block to set the "grass coverage" variable, they still couldn't see any grass on the model. They were able to use their program to run the model, but their observations indicated that the model did not behave as they expected. With some prompting from the researcher-observer, they noticed they needed to click on the code to broadcast the value they had set for the variable to the model. With a little bit of prompting, they looked more

 © ISLS

closely at the Snap*!* blocks and realized the block where they set the variable was connected to another block (line of code) that said "When I am clicked." Students then clicked the block and saw that the amount of grass visible in the model changed. Once the appearance of the model reflected their expectations, they continued to use their science understanding to make sense of the graphical output from running the code: "When I set it at 25%, I saw more heat. When there was more grass there was less heat energy". The students recognized that as they increased the amount of grass, less solar radiation was converted to heat energy. This helped them to interpret the graph generated by the model and make sense of why the temperature on the graph was lower when they set the amount of grass higher than 25%.

Connecting coding and science by making predictions

After writing the code for the third programming challenge, one group of students closely examined the graph to determine whether their model output matched their predictions. After setting the variable to a high percentage of "reflective roofs", they ran their model. One student in the group remarked, "Oh wait it [the temperature] just went down a bunch!" The other student commented back, "Yeah I was thinking it'd be 105 or something" as the first student observed "It's staying below 100 and above 80." Students were able to use their observations of the connections between the model and the graph to deepen their understanding of the impact that more reflective roofs would have on a city's temperature. Students did not initially predict that reflective roofs would lower a city's temperature and were surprised by what they observed. They were confident in their interpretation of the graphical output from the model controlled by their code. This supported them to revise their initial prediction and deepen their understanding of the role that reflective roofs could play in a solution for UHI.

Applying science understanding and annotated code for debugging

After successfully completing the second programming challenge, one group of students quickly got to work on the third challenge where they were to test the impact of reflective roofs. They began dragging blocks into the missing components of the if-statements without attending closely to what was missing in the statements. They followed their approach from the previous challenge, making sure that everything in each if-statement matched. For example, they wrote lines of code that read, "If 0%=0%, broadcast 0%, else if 25%=25%, broadcast 25%". They began running trials at various amounts of reflective roofs. However, they noticed the graphical output for each trial looked the same and the amount of reflective roofs depicted wasn't changing. Because of their science understanding, the students believed that varying the amount of reflective roofs should result in different temperature graphs. This led them to revisit their code and look for issues. After some time grappling with the code, the researcher asked them whether they had any resources they could go back to help them think about what each part of the code does. The students clicked back to the part of the lesson where they had annotated sample code. Almost immediately one of the students exclaimed, "Aha! I found out!" and clicked back to the coding challenge. They replaced blocks in their if-statements so that it read, "If reflective_roofs=0%, broadcast 0%, else if reflective_roofs=25%, broadcast 25%". They realized the if-statements were the part of the code that changed what was broadcast, depending on what value they set for the variable "reflective_roofs". They tried running the model again and while looking at the model output exclaimed: "There we go!" and "Yay! It works!" Students' science knowledge cued them that something was not working correctly in their code and the annotated code helped them to fix their code and figure out the purpose of the if-statements they were writing.

Looking across all three cases, we see that students drew on both their science and computational understanding to work through the programming challenges. When they struggled with programming tasks or interpreting their computational artifacts (i.e., graphs) students could draw on their developing knowledge of UHI. Similarly, as students succeeded with programming challenges and graph interpretation, they were able to advance their understanding of how different surfaces contribute to UHI. Working together with a peer and having the occasional prompt from a researcher supported students to think through their resources and leverage their understandings in helpful ways.

Promoting belonging

All of the students were using Snap*!* for the first time. They reported feeling interested (64%), confident (40%), excited (16%), nervous (12%), and afraid (24%) when they began the first programming challenge. While two-thirds of the students expressed interest in writing code, many were also experiencing complicating emotions, like feeling nervous or afraid. After engaging with the role models, several themes emerged in student responses. 44% of participants expressed that they felt like they were not alone in their experience or that they identified with the college student mentors. For example, one student shared, "I felt that I wasn't alone and there are people who are thinking just like me." Another participant wrote that the mentors are "like us who were interested but also get confused on how". Several students expressed which of the mentors they most felt alike to: "I think I'm kinda

like Amina." Students also reiterated how they were feeling about their own programming (32%). Some students wrote statements like I feel "interested", "I think the program was pretty fun" or that they felt "good and inspired to help people." 20% shared that it was helpful to learn what older computer science students think. For example, one student wrote: "I feel way more informed and now I know that everyone has a different perspective about there first day on computer science" and another wrote, "I think that it is interesting because I learn what older students are taught and I think I will have fun learning this." The automated mentors helped students to continue to articulate their own feelings and to envision what it might look like to continue learning to program. Importantly, the mentors also provided reassurance to the students that their feelings were valid and not unusual when learning programing.

Teacher Perspectives

Overall, the teacher valued the activity as an opportunity for her students to develop new programming skills while leveraging their science knowledge. The teacher observed, "At least for my students, I think they understood how these different variables [in the Snap*!* model] can have an impact on the city because we've talked about [climate change]." She believed that their science understanding helped them to overcome frustration or discouragement when coding challenges proved to be difficult. The teacher also reported high student engagement in persisting through the challenges. She remarked, "It was neat to see them being challenged in that way. Some of them found it really cool and interesting and spent a lot of time playing with the different tools." She also identified strategies she would use to support students through those difficulties the next time she taught the lesson. She noticed common student questions that indicated the instruction supported students to seek connections between the activities in the lesson and their own lived experiences. She reported students asked questions such as: What could we do to improve our neighborhood?; How fast is the world's climate changing?; How is this information useful for [our state]?; How can we implement green solutions as a community?; What would happen if the world did not have trees or grass? Thus, the lesson prompted students to consider how they could use their science and CT skills to make changes in their own communities. The teacher built on these questions by asking students to consider where there might be UHIs within their own community. Because their school is in an area with high vegetation, the teacher helped students to distinguish between their school setting and other parts of their community. She shared that students really deepened their connections when she got them thinking about the area surrounding their local airport. When reflecting on what was most challenging for her students, the teacher reported that, in general, students struggled the most with the initial programming challenges. However, she also noted that when asked at the end of instruction about what aspect of the lesson they enjoyed the most, an overwhelming majority of students selected the coding and modeling section. Although challenging, once they understood how to properly use the model, it became their favorite part of the lesson. They liked the idea of designing a city that is, "literally cooler", as one student stated.

Conclusion and Significance

Overall, we found preliminary evidence that the design of the UHI lesson activities prompted students to use science and CT ideas synergistically to integrate environmental science and computer programming. Taking a Knowledge Integration approach to the lesson design supported students to connect their science and CT ideas in ways that strengthened their understanding of both. We observed that students' science knowledge and practices supported them to stay engaged and to sustain their efforts while trying to solve the programming challenges. Even when struggling to find full solutions to the programming challenges, students were able to deepen their understanding of UHI phenomenon.

Our findings also suggest the promise of using Snap*!* as a programming language to introduce CT into middle school science. With some guidance from their teacher, many students were able to engage in Snap*!* programming with only two days of classroom instruction. Further, the flexibility of the Snap*!* programming language and interface enabled multiple operational solutions to the programming challenges. This supported students' creativity and allowed students to experience success even if they did not come up with the intended code solution. This experience communicates to students that they have valuable computational ideas and reveals to students the creative nature of computer programming that is not always visible during early programming experiences.

Two thirds of students expressed interest in programming when they began the coding challenges, although many also held complex feelings like nervousness or fear. After engaging with the automated college student mentors, students felt validated in holding multiple, sometimes conflicting feelings. The mentors helped them feel as though they were not alone in their experience by offering reassurance about their feelings. This mentoring practice could be valuable for more complex modeling as well. Taken together, our findings suggest

the value of using the KI-design approach to introduce students to CT through relevant middle school science topics and using mentoring modeled on undergraduate teaching assistants to support a sense of belonging and community.

Abstract: The increasing impact of machine learning (ML) on real-world scientific investigations demands a shift to teaching ML-empowered scientific inquiry to familiarize younger students with authentic science practices. Evidence from previous studies has suggested that glyph-based data visualization is promising for making multidimensional data analysis accessible for novice learners. Little research, however, has examined the contextualized challenges of applying glyphs in K-12 ML-empowered scientific inquiry. Since teachers play a critical role at the frontier of technology integration for learning, as an initial attempt to address this research gap, we investigated the pattern recognition and interpretation behaviors of 18 K-12 STEM teachers when engaged in ML-empowered scientific inquiry during a professional development workshop. Findings confirm that teachers identified and interpreted ML-revealed patterns for scientific hypothesis formulation while it is challenging for novices to analyze and synthesize different patterns conceptually and extensively for more sophisticated inference. Underlying design opportunities and implications are discussed.

Introduction

In real-world science, an increasing number of scientists are applying machine learning (ML) to discover patterns from multidimensional data (Kitano, 2016). The majority of the current K-12 STEM teaching practices, however, focus on bivariable experiments and data analysis, which may limit students' learning opportunities of data analysis to investigate complex scientific phenomena (Kuhn, 2016). Recognizing and interpreting relevant patterns such as category, relationship, trend, and anomaly discovered by ML methods on multidimensional datasets may offer unique learning opportunities for evidence-based science practices aligned with the NGSS science and engineering practices (States, 2013). It is challenging, however, for K-12 students and teachers to recognize and interpret ML discovered patterns in science contexts due to their lack of ML and data literacy. Glyph-based data visualization (Ward et al., 2015), which maps multidimensional attributes of an individual data point to vivid visual features of everyday objects such as faces, stars, and trees, offers promising opportunities to make ML-discovered patterns accessible to novice learners. Glyph-based visualization supports visual reasoning (e.g., search, pattern recognition) over multidimensional datasets with high accuracy (Chung et al., 2015; Keck et al., 2017). There is a neglect of existing studies of glyph-based data visualization on supporting K-12 students and teachers for efficient data interpretation, an important skill for gaining insights into what the visuals show (Rau, 2017).

Teachers play a critical role in integrating technology for learning (Koehler & Mishra, 2009), which is especially important for integrating ML in STEM education. Therefore, as a first attempt to tackle the above research gaps, we (1) propose cluster analysis as an accessible ML technique for K-12 scientific inquiry and (2) examine how K-12 STEM teachers identify and interpret patterns from datasets using a glyph-based visualization tool named SmileyDiscovery (Zhou et al., 2021) in a professional development workshop. SmileyDiscovery utilizes face-based glyphs for data analysis with *k*-means clustering while requiring few efforts in learning ML. We collected log data of what patterns of scientific phenomenon (e.g., ecosystem, heart disease) are identified by 18 in-service K-12 STEM teachers using SmileyDiscovery, and analyzed how teachers interpreted these patterns to form scientific hypotheses. Teachers also provided feedback on potential learning experiences from the student perspective. Our research questions include **RQ1**: To what extent can teachers identify and interpret patterns during cluster analysis for scientific inquiry with face-based glyphs? **RQ2**: What challenges prevent teachers from effective scientific inquiry? The main contributions are:

- A framework on how cluster analysis can be an accessible discovery tool for K-12 teachers and students to conduct exploratory analysis on multidimensional data for scientific inquiry.
- Challenges in ML-empowered scientific inquiry by using face-based glyph visualization.
- Design implications to empower novice learners to analyze ML-generated multidimensional results.

Background

Multidimensional data analysis and visual representation in K-12 Education

Researchers have discovered positive results in developing middle school students' multivariable reasoning skills (Kuhn et al., 2015), training primary and high school students to make informal statistical inferences by modeling with multidimensional datasets (Braham & Ben-Zvi, 2017; Kazak et al., 2021), and facilitating high school students to identify multidimensional patterns from ML-generated results (Wan et al., 2020). These works show young learners' potential to apply ML as an advanced multidimensional data analysis tool for scientific inquiry and highlight the need to enrich more authentic scientific inquiry skills for K-12 STEM learning (Nayak et al., 2016) .

Visual representation facilitates multidimensional data analysis but can confuse students if they do not fully understand the visualized mechanisms and concepts (Rau, 2017). Previous studies have shown that full competence in visual representation comprehension is not achieved even by college and university graduates (Nayak et al., 2016; Roth et al., 1999). To develop students' representational competencies, Rau (2017) argued that two types of knowledge and skills were necessary for students to acquire: (a) visual understanding and fluency, referring to knowledge of general principles about how the visual representation depicts concepts and abilities to efficiently identify the corresponding conceptual meanings reflected by visual features; (b) connectional understanding and fluency, indicating an understanding of conventions for using multiple visual representations together and abilities to communicate conceptual implications of connections (i.e., similarities and differences) between different visual features.

Glyph-based visualization

Glyphs are well-suited for depicting high-dimensional data due to their capabilities of simultaneously displaying information through multiple visual channels, including shape, size, and color (Chung et al., 2015). Several studies have created and shown the effectiveness of glyph-based visualization in promoting multidimensional data analysis. Cao et al. (2011) presented an interactive system, DICON, which combined treemap-liked icons with Voronoi icons to illustrate multivariate data clusters. A case study demonstrated it supported cluster exploration and interpretation of a large dataset in the healthcare domain. Chung et al. (2015) designed a novel glyph and validated it with the analysis of Rugby matches. Findings confirmed its effectiveness in supporting multidimensional visual search and comparative analyses of multiple attributes between different matches. Keck et al. (2017) developed a flower glyph to facilitate big data analyses via clustering algorithms. An experimental study showed that it was more efficient than the traditional tabular displays for task completion and the accuracy for both conditions was almost the same. However, these positive effects are all about pattern recognition through data visualization, while little research has investigated whether or not the glyph approach enhances data analysis in relation to the mapped concepts. Therefore, this study attempts to gain a comprehensive understanding of how glyph design facilitates multidimensional pattern recognition and interpretation. It analyzed data from a study engaging k-12 teachers in pattern exploration enhanced by Chernoff faces (Chernoff, 1973) via *k*-means clustering. Chernoff faces aim to make multidimensional data accessible for human beings since people can easily recognize faces and notice changes in facial features (e.g., nose length, eye radius, and eyebrow slant, *etc*). Previous studies examined the visual effectiveness of Chernoff faces on displaying patterns (e.g., Lee et al., 2003; Morris et al., 2000), but did not address its interpretability in the K-12 STEM contexts.

A theoretical framework of applying cluster analysis for scientific inquiry in K-12 STEM education

Cognitive benefits of applying ML for scientific inquiry

Pattern recognition could support inductive reasoning for scientific inquiry, which is a bottom-up probabilistic reasoning process that derives general principles of target phenomena from a large amount of observation (Rodrigues, 2011). Traditionally, induction plays a key role in hypothesis testing through accumulating evidence (Folger & Stein, 2017) for scientific inquiry. With ML revealing patterns from big data, learners' capability of inductive reasoning can be significantly enhanced not only during the investigation but also at the early stage of generating inquiry or formulating scientific hypotheses (Muller et al., 2016). In addition, ML analysis is usually accompanied by reasoning with contrastive explanation (Folger & Stein, 2017; Miller, 2019), which refers to the generation of explanation when encountering contrastive cases sharing similarities as well as differences in properties (Chin-Parker & Bradner, 2017). Contrastive explanation generates key insights from the puzzling event that occurred during the scientific inquiry (Folger & Stein, 2017; Miller, 2019).

Cluster analysis for inquiry-based learning in K-12 STEM education

As one of the most common ML techniques for data mining, cluster analysis has broad affordances to serve as an initial investigation for diverse directions to further analyze multidimensional data. By grouping similar data objects, it presents big data in a more accessible way, reveals inter-/intra-cluster patterns for further investigation, and discovers early insights for characterization, classification, outlier analysis, *etc* (Han et al., 2011). Thus, cluster analysis has been widely applied by researchers to explore datasets, bringing unique benefits in creating a scientific question, and/or formulating a scientific hypothesis (Romesburg, 2004), which connects with the conceptualization phase in inquiry-based learning for STEM education (Pedaste et al., 2015). For example, after thousands of multidimensional data points about ecological factors collected from field sites are grouped into different clusters, researchers can form hypotheses by contrasting the most dissimilar centroids or make inferences inductively on data clusters, and then investigate with another dataset. Besides the cognitive benefits of inductive reasoning and contrastive explanation, the main mathematical concepts behind clustering (i.e., centroid and distance-based clustering) are relatively intuitive for young learners to readily grasp (Greenwald et al., 2021). Furthermore, the skill to interpret trends and patterns from data could be aligned with NGSS (Next Generation Science Standards). Therefore, we attempted to propose clustering as an accessible and versatile inquiry-based learning tool for K-12 STEM education.

Figure 1

Cluster analysis for conceptualization in inquiry-based learning (Anderberg, 2014; Romesburg, 2004)

1. Pattern revealed by clustering	2. Glyph representation of the pattern in SmileyDiscovery	3. How does the pattern can support conceptualization in inquiry-based learning? Creating a scientific question	Formulating a scientific hypothesis
Similarities and dissimilarities between two data objects		E.g., cluster multivariate dental formulas of different animals. The result shows that the mole and the pig have identical formulas. What research hypothesis could explain this?	E.g., cluster multivariate dental formulas of different animals. The result shows that the walrus' formula is very different from the other carnivores. Does Walruses feeding habit accordingly modified their dental structure?
Intra-cluster pattern: Similarities and variations		E.g., cluster different species of primates based on 34 skin attributes. Intra-cluster pattern shows that the grouping is related to the features of the dermis, epidermis, and sweat glands, which is intriguing for further study.	E.g., within a relatively homogeneous group of ecological field sites created by clustering, sites with lower temperature have fewer small mammals. For this type of ecosystems, is higher temperature less livable for small mammals?
Inter-cluster pattern		E.g., cluster multivariate dental formulas and the sizes of different animals. The inter-cluster differentiating features show no apparent relation between an animal's dental formula and its size. Why?	E.g., cluster different wines based on their chemical factors and quality scores. The inter-cluster patterns show that wines with better quality have lower volatile acidity and more alcohol, which could be a hypothesis for further testing.
Clustering results with different sets of features		E.g., cluster different animals based on (1) the diets of animals, (2) shapes of the teeth, (3) dental formulas. The clusters from the first clustering are more similar to the clusters from the second round than the clusters from the third. Why?	E.g., cluster different people by their income levels with two sets of other factors separately. The first round of clustering generates a better inter-cluster seperation in income levels. Does this set of factors (education, working hours) have a stronger influence on income?

Inspired by previous studies on cluster analysis (Anderberg, 2014; Han et al., 2011; Romesburg, 2004), we summarized a list of main patterns revealed by clustering which can be utilized for conceptualization in inquiry-based learning (see Fig. 1 column 1 & 3). Cluster analysis can help to formulate hypotheses for questions whose truth entails (dis)similarities among data objects. For example, cluster labels assigned to data objects could support the hypothesis of what data attributes lead to such grouping. Intra- and inter-cluster patterns could generate insights to hypothesize on correlations among data attributes for factor analysis or analysis of variance. Clustering with different sets of data attributes can suggest a set of data attributes distinguishing across the groups to a sufficient degree to aid discriminant analysis and classification. Besides assisting to form hypotheses, these patterns revealed by clustering could trigger further scientific questions. Considering the pedagogical and cognitive benefit of cluster analysis in inquiry-based learning, we utilized face-based glyphs to make cluster analysis an engaging and accessible tool for K-12 STEM teachers and students (Fig. 1 column 2). And this work is a preliminary evaluation of the initial design.

 © ISLS

Methods and analysis

Research participants and procedure

We recruited 18 in-service K-12 STEM teachers who were taking a course named Integrating Technology with STEM Teaching, at a research-based university. They have very limited CS/ML backgrounds, different subjects, and various teaching grades (Table 1). The study session was conducted via an online meeting platform Zoom.

Table 1
Subjects and grade levels teachers teach

	Elementary school	Middle school	High school
Science	N = 2	N = 3	N = 6
Math	N = 2	N = 2	N = 3

In this study session, teachers participated in one cycle of scientific inquiry through cluster analysis on a dataset of field sites described by a set of ecological factors (Zhou et al., 2021), involving five steps: (1) generate the concept mapping for the face-based glyph (i.e., mapping each ecological factor to a facial feature) and get familiar with the value mapping (i.e., how the value of an ecological factor changes the corresponding facial feature); (2) compute the similarities between two representative ecological field sites; (3) explore the dataset by manually clustering a few data points around two representatives and interpret intra- and inter-cluster patterns; (4) apply the well-studied *k*-means clustering and interpret intra- and inter-cluster patterns; (5) formulate a hypothesis on how ecological factors dynamically influence each other based on the cluster analysis results. More detailed demonstration of this ML-empowered scientific discovery learning activity can be found in our previous work introducing the SmileyDiscovery system (Zhou et al., 2021).

During the study session, each teacher worked individually on their own device by following the instructional text in SmileyDiscovery, without any external guidance from researchers. Four teachers didn't complete the activity due to technical issues and their data were excluded. In the end, we collected teachers' feedback on potential learning experiences from students' perspectives.

Data analysis

RQ1*: To what extent can teachers conduct cluster analysis for scientific inquiry with face-based glyphs?* We employed system log data (i.e., clicking behavior and text input) and teachers' feedback to answer this question. First, we replicated teachers' clicking behaviors to revivify the concept mapping (i.e., how data attributes are mapped with facial features) and their learning experience. Second, we open coded (Strauss & Corbin, 1990) the text input and feedback on pattern recognition to measure *patterns recognized or neglected by teachers.* Third, we coded teachers' text inputs of scientific hypotheses drawn from clustering-revealed patterns to measure the *quality (i.e., accuracy and sufficiency) of interpretations of these patterns for forming scientific hypotheses.*

RQ2*: What challenges prevent teachers from conducting effective scientific inquiry?* Teachers described difficulties that they encountered when engaging scientific inquiry with face-based glyphs in both text inputs and feedback. We conducted a thematic analysis of the data and generated challenges that prevent effective pattern recognition and interpretation, respectively.

Three researchers coded data independently, met regularly to address disagreements, and refined codes.

Results

RQ1: To what extent can teachers conduct cluster analysis for scientific inquiry with face-based glyphs?

Novice learners' pattern recognition via face-based glyphs

By looking into the system log data recording teachers' clicking behaviors and text input of the patterns they identified for each step in the learning activity, we analyzed how novice learners identified patterns from face-based glyph visualization. During the step where teachers explored the dataset by manually clustering a few data points based on two representatives, some teachers engaged with more fail-and-trial experience by exploring the dataset, selecting more data points to test out the similarities, and removing the dissimilar ones. Other teachers carefully scanned through the dataset and only selected a few faces that were highly similar to the target face. While analyzing the patterns identified and reported by different teachers, we noticed inconsistent tolerance for variations, both across teachers and across facial features. For example, some teachers have a relatively high

tolerance for variations and thus report more data attributes as shared patterns within clusters; teachers with a low tolerance for variations tended to identify most attributes as differentiating features. In addition, we found wrong/missing translations from facial features to data attributes, indicating the high cost of code-switching between science context and glyph visualization.

Five advantages of applying face-based glyphs to identify ML-revealed patterns are mentioned by teachers. First, teachers pointed out the pedagogical benefit of using emojis to visualize multidimensional data, which can be both familiar and playful for young learners: "This could be a fun way to allow students to explore data sets and draw connections in a way that allows for visualization". Second, teachers found that being able to customize the data visualization helps them to have a deeper understanding of different data attributes and how they form a glyph: "I tried to mentally pick ones that matched, like when I see a beetle my eyes get big like I don't want to see one, so to me was eye radius. Or latitude, I used the eyebrow height." Third, teachers appreciated the computation efficiency of using one piece of the glyph to represent a multidimensional data point and overlaying two pieces to compute the (dis)similarities between them. Fourth, teachers found center emojis (i.e., centroids) helpful to represent information in a concise way for more effective pattern recognition. Last, teachers confirmed the potential of applying cluster analysis as a discovery tool as it supports students to identify different types of patterns (e.g., intra & inter-cluster pattern, centroid) for further interpretation.

Patterns interpreted for scientific hypothesis formulation

While formulating a scientific hypothesis in the end, we found that teachers interpreted different patterns recognized from cluster analysis in different ways. First, teachers utilized patterns of inter-cluster differentiating features in three different approaches: (1) two teachers' attention was caught by the cluster with the minimum or maximum value of some data attribute; for example, P1 identified the cluster of field sites that has the highest precipitation, the highest temperature, and the highest beetle richness as evidence for their hypothesis; (2) nine teachers interpreted differentiating features between different pairs of clusters; for example, P12 recognized that, compared to the first field site cluster, the second cluster of field sites are drier, have more beetles and higher canopy, and the third cluster has more beetles, and the fourth has lower latitude, more beetles, higher temperature and higher precipitation; (3) five out of these nine teachers successfully formed hypotheses on relationships among ecological factors by further interpreting the identified inter-cluster differentiating features; for example, P9 hypothesized that "latitude and temperature have a large impact on the beetle richness and canopy height", while P12 was not able to produce a more meaningful hypothesis with eight pairs of inter-cluster differentiating features identified.

Second, three teachers paid attention to inter-cluster shared features. P11 identified canopy height, precipitation, and latitude as the similarities shared among the field sites of interest. Third, while 11 teachers considered intra-cluster similarities, only P2 paid attention to intra-cluster variations: "small mammal richness varies widely even in a cluster". In addition, another very unique pattern utilized is that P13 compared the similarities between each pair of clusters and identified the cluster that is the most dissimilar to the rest clusters, as the most distinct cluster and identified the cluster it is most distinct from.

RQ2: What challenges prevent teachers from conducting effective scientific inquiry?

Cognitive challenges for novice learners to identify multidimensional patterns from face-based glyphs

By analyzing feedback and log data around pattern recognition with face-based glyphs, we identified cognitive challenges related to (1) concept mapping and (2) value mapping in face-based glyph visualization.

Related to the concept mapping where data attributes are mapped to facial features, we identified different causes introducing extra cognitive load into pattern recognition. First, the legend showing corresponding data attributes when the cursor is hovering over a certain area is still temporarily visible, which leads to the lack of connection to scientific context. Second, teachers had attention bias that they perceived certain facial features as more conspicuous than others. Third, from the patterns teachers identified from glyphs, we recognized inaccurate pattern recognition caused by ambiguous or less accurate verbalization of certain visual features due to people's habits in language using while describing faces. For example, six teachers described mouth features with inaccurate language, such as using mouth shape to refer to mouth curvature which caused confusion in the interpretation of mouth size and mouth curvature as both affect mouth shape.

With the value mapping of face-based glyphs where different data attributes' values are translated into different visual channels, we recognized the difficulty in deciding if certain values are (dis)similar enough because of the low separability of the multiple values mapped to one face part (e.g., brow length, brow vertical location, brow slant are all mapped to eyebrows). Teachers also commented that it's hard for them to decide if a certain pattern should be identified as a large/medium/small value or if certain degrees of variations should be tolerant

 © ISLS

because there is no visual indicator for the dispersion of each facial feature. Furthermore, by analyzing the patterns identified during cluster analysis, we identified that teachers have different tolerance for variations in different facial features. On the one hand, teachers discerned deviations in mouth vertical, mouth curve, and eye radius, with 17.5%, 15.63%, and 13.89% instances of high tolerance for variations in hypothesis development, respectively. On the other hand, teachers tended to be more sensitive to changes in eyebrow length (16.67%), eyebrow slant (11.36%), and nose length (11.11%).

Challenges in more sufficient pattern interpretation during hypothesis generation

By measuring the quality of teachers' pattern interpretation for evidence-based hypothesis generation in the end, we identified teachers who (1) failed to illustrate the patterns, (2) needed further inference, (3) needed to analyze the direction of the correlation, (4) needed to have a contrast group to make the inference. We found two main causes of deficient hypothesis generation:(1) the insufficient interpretation and synthesis of different patterns, (2) lacking in-depth analysis for more sophisticated multidimensional data inference.

First, five out of six teachers who hypothesized relationships among ecological factors didn't further elaborate on whether the relationships are positive or negative by interpreting the value mappings in the patterns identified. For example, P14 interpreted that clusters with different latitudes have different amounts of precipitation, instead of elaborating that the field sites with higher latitudes share lower amounts of precipitation than the cluster with lower latitudes. Besides such insufficient interpretation of data attributes' values, we observed that five teachers lacked synthesizing multiple pattern interpretations to formulate a more meaningful scientific hypothesis. Such insufficient synthesis could indicate the need for some basic domain knowledge about ecosystems to guide learners' attention to what patterns could be more interesting to focus on or how the information behind different patterns can be effectively synthesized and form a scientific hypothesis leading to a more in-depth understanding of the domain. By looking into the interaction data of two teachers who failed to illustrate the patterns from cluster analysis, we found that one of them only compared two centroids, and the other only examined one cluster centroid. Both of them didn't explicitly identify the value mapping during pattern recognition. This further indicates that the insufficient interpretation and synthesis of different patterns may lead to unsuccessful evidence-based hypothesis generation and corresponding scaffoldings are needed.

Second, some teachers lacked more careful analysis of different patterns and missed more sophisticated inferences on different ecological attributes. For example, P4 hypothesized that canopy height influences beetle richness. Without digging into the other shared or differentiating features among clusters, P4 didn't interpret that only for field sites with medium amounts of precipitation, canopy height and beetle richness are positively related. Therefore, P4 missed introducing precipitation as a moderator to form a more elaborated data-driven scientific hypothesis. We also observed the case where teachers didn't include multiple contributing features as independent variables for the dependent variables in their hypotheses, and the case where a teacher didn't more carefully support their hypothesis with comparison from patterns identified.

Discussion

For each challenge identified from novice learners' data recognition and interpretation in clustering-supported scientific hypothesis generation, we summarized a set of fundamental learner needs underneath all the challenges we identified from novice learners' pattern recognition and interpretation for generating clustering-supported hypotheses with face-based glyphs (Table 2). **First**, learners need more in-time access to the scientific context and more effective scientific communication with smoother code-switching between glyph visual features and data attributes (N1.1, N1.2). Therefore, more design opportunities lie in the embedded legend design for glyph visualization with continuous visibility or an intelligent mapping mechanism creating concept mapping with better learnability (Chung et al., 2015). **Second**, during identifying multidimensional patterns from glyphs, learners are viewing all data attributes at once and thus need scientifically guided attention to select features of interest and interpret the visual channel in a more informed and accurate way (N1.3, N2.1). This suggests a potential design of an intelligent value mapping mechanism utilizing people's varying attention across facial features and visually related glyph features (Chung et al., 2015). **Third**, when digging into the interpretation of a specific data attribute, learners need more measurable displays of that attribute's spread and deviation (N2.2, N2.3). Thus, more in-time indicators of a comprehensive list of parameters describing the distribution of each data attribute (e.g., center, spread, shape) are needed for glyph visualization. **Fourth**, various multidimensional patterns can be identified and interpreted for cluster analysis, which is challenging for novices to analyze, interpret and evaluate as different forms of evidence in relation to potential scientific hypotheses (Kuhn & Lerman, 2021) (N3.1, N3.2). This could be scaffolded via probabilistic reasoning and contrastive explanation in the context of ML-enhanced scientific inquiry (Miller, 2019). For example, when commonalities between two clusters are observed, then learners can be reminded of what patterns are missing as comparisons in order to indicate correlations between data attributes.

Table 2
Design opportunities of face-based glyph visualization for multidimensional data interpretation

Challenges	Underlying fundamental needs as design opportunities
C1.1 Extra cognitive load from the temporarily visible concept mapping	***N1.1*** Easy access to the scientific context behind the data
C1.2 Less precise verbalization	***N1.2*** Effective scientific communication of multivariate data and patterns
C1.3 Attention bias across facial features	***N1.3*** Guided attention for more informed and effective selection of features of interest
C2.1. Low separability of some visual features ***C2.2*** Absence of the scale	***N2.1*** Independent interpretation of each visual channel ***N2.2*** Spread of each data attribute
C2.3 Uncertainty in variation interpretation	***N2.3*** Deviation of each data attribute
C3.1 Insufficient interpretation and synthesis of different patterns	***N3.1*** Guided analysis and synthesis of all the potential patterns and their relations
C3.2 Lacking in-depth analysis for sophisticated multivariate inference	***N3.2*** Evaluation of different patterns in relation to intended inferences

As the initial stage in an iterative design of data visualization and interaction for ML-enhanced K-12 STEM learning, we only set up a preliminary framework connecting cluster analysis with the conceptualization in inquiry-based learning and haven't fully implemented and evaluated it with both K-12 teachers and students. Additionally, we noticed that the step-by-step scaffolding for cluster analysis in the current learning activity design could guide more learner attention to intra-cluster shared features and inter-cluster differentiating features. Therefore, as a next step, we are planning to create new scaffoldings for a more open-ended learning environment to empower students to explore the data and create scientific questions or hypotheses. Besides collecting feedback from teachers with student perspectives, we will evaluate new designs with young students.

Conclusion

This work proposes a framework showing the pedagogical and cognitive potential of using face-based glyphs to introduce cluster analysis as an accessible and versatile tool for K-12 inquiry-based learning. Eighteen K-12 STEM teachers conducted scientific inquiry through cluster analysis. We evaluate their performance under pattern recognition and interpretation for hypothesis generation. Challenges are identified in recognizing patterns with face-based glyphs, conceptually and extensively synthesizing different types of patterns, and scrutinizing for more sophisticated multidimensional relationships. We reflect on the fundamental learner needs behind these challenges and discuss corresponding design opportunities and implications.

Embodied responsive teaching for supporting computational thinking in early childhood

Virginia J. Flood, X. Christine Wang, Michael Sheridan
vflood@buffalo.edu, wangxc@buffalo.edu, ms264@buffalo.edu
University at Buffalo, The State University of New York

Abstract: Tangible programming toys support body syntonicity, where children use knowledge of their own bodies to solve problems computationally. However, we currently know little about how teachers can support these embodied computational learning processes. In this study, we examine how teachers are *responsive to* and *support* preschoolers' embodied engagement in three computational thinking practices: problem decomposition, debugging, and abstraction. Through interaction analysis, we show how teachers re-"voice" embodied proposals by purposefully taking up and transforming preschoolers' body syntonic problem solving efforts to focus, recontextualize, and decontextualize them. Implications for the embodied teaching and learning of computational thinking with tangible programming toys are discussed.

Introduction

There is broad consensus that tangible programming toys are powerful tools for young children learning to program, problem solve, and engage in a range of *computational thinking practices* (Bers, 2008; Hamilton et al., 2020; Wang et al., 2021a). One promising mechanism through which tangible programming toys support computational thinking is through what Seymour Papert called *body syntonicity*: Children are able to leverage knowledge of how their own bodies move and react, and use this embodied knowledge to engage in a wide variety of computational practices (Papert, 1980). Although there is increasing attention to the role of body syntonicity in learning to program and think computationally (e.g., Berland et al., 2011, Cho et al., 2017, Farris, 2021; Sung et al., 2017), little is known about the role teachers and other adults can play in supporting children's embodied forms of computational thinking with tangible programming toys.

In this paper, we demonstrate how teachers attend and respond to the seeds of computational thinking (K–12 Computer Science Framework, 2016) in preschoolers' (ages 3-4) embodied activity as children work with a tangible programming toy. To reveal the fine details of these instructional processes, we adopt an approach to interactional analysis inspired by ethnomethodology, conversation analysis, and Goodwin's co-operative action framework (2018). In particular, we illustrate how teachers purposefully take up, re-use, and transform learners' embodied ideas to focus, recontextualize, and decontextualize body syntonic knowledge to support students' engagement in the computational practices of problem decomposition, debugging, and abstraction. Overall, our investigation contributes to a better understanding of interactional mechanisms that support computational thinking in early childhood and the nuanced ways in which responsive teaching (Pierson, 2008; Robertson et al., 2016) is a multimodal, embodied phenomenon (Flood et al., 2020).

Background & Theoretical Framework

When children of all ages make sense of STEM ideas, they often use their bodies as meaning making resources to physically adopt the point of view of the phenomena under consideration and draw parallels through body syntonicity (e.g., Crowder, 1996; Keifert, 2019). Through this process, children act out and work through possibilities as if they were the phenomena, leading to important insights into how and why things behave the way they do. Notably, practicing scientists and mathematicians at the frontiers of discovery also use body syntonicity for thought experiments, taking on the viewpoint of and physically embodying abstract theoretical entities and phenomena (e.g., a super-heated crystalline lattice) they are trying to imagine (e.g., Ochs, 1996). Since Papert's seminal research, a number of studies have examined how students use body syntonicity to successfully program, problem solve, and develop computational thinking skills (e.g., Berland et al., 2011; Farris, 2021; Kopcha, 2021; Sung et al., 2017). Children engage in computational thinking practices with their bodies to break down complex problems into manageable parts (decomposition), identify common features to create generalizations (developing and using abstractions), and to recognize, find, and fix errors (debugging), among other practices (Papert, 1980; Berland et al., 2011; Fadjo et al., 2009; Kopcha et al., 2021; Wang et al., 2021b).

In the last decade, there has been an influx of tangible programming learning environments and tools specifically designed to capitalize on and support children's embodied engagement with computational problems (Yu & Roque, 2019). One increasingly popular type of tangible programming learning design includes toy animals and robots that can be programmed to navigate through and interact with the world. Examples include: BeeBot (a

 © ISLS

bee), Cubetto (a cube-shaped robot with a smiley face), Topobo (a dragon), and Code-a-pillar (a caterpillar), among others. These engaging toys have imaginary needs and desires, bodies, facial features, and ways of moving that children can physically relate to, and offer rich opportunities for computational thinking through body syntonicity. In addition to providing powerful playgrounds for computational thinking, tangible programming toys also foster mathematical thinking and learning, art and design skills, storytelling, and the development of fine motor skills (Bers, 2008; Bers et al., 2014).

However, despite the generally well-accepted role the body plays in sense-making while learning to program, there is still much unknown about how teachers can support children's use of body syntonicity to foster computational thinking. Our study joins recent investigations of how educators support students' embodied learning in STEM contexts such as makerspaces (e.g., Vossoughi et al., 2020; Vossoughi et al., 2021) and mathematics (e.g., Flood, 2018; Flood et al., 2020). In particular, we know little about how teachers are responsive to children's use of *body syntonicity* and how they take up and work with embodied knowledge in the classroom. In STEM education, *responsive teaching* involves eliciting, recognizing, and responding to children's ideas with potential disciplinary value or substance, and adapting instructional guidance to make use of these student contributions (Pierson, 2008; Robertson et al., 2016). When teachers take up and are responsive to the "seeds" of disciplinary STEM ideas and practices, it increases students' participation and promotes learning (e.g., Pierson, 2008). In this paper, we investigate what *embodied* responsive teaching (Flood et al., 2020) looks like in the case of preschoolers learning to program a tangible programming toy.

One powerful form of responsiveness is the use of *revoicing* where teachers take up, repeat, and reformulate the ideas children express (O'Connor & Michaels, 1993). Adults' revoicing (also known as recasting) plays important roles in how young children develop language and abstract concepts (Baker & Nelson, 1984; O'Connor & Michaels, 1993). In preschool classrooms specifically, revoicing is ubiquitous and accomplishes a number of functions including building linguistic skills, positively evaluating students' ideas, seeking clarification, and comparing and contrasting different ideas (Yifat et al., 2008). In particular, one of the most important functions of revoicing for all ages is the *reformulation* of learners' ideas, and the reflection of these reformulations back to students (Cazden, 2001; O'Connor & Michaels, 1993). Studies of classroom discourse have identified a number of ways that teachers reformulate the information students contribute. These include: (1*) focusing* students' contributions, where teachers will selectively revoice only parts of what students said, and omit parts that are incorrect or superfluous from a disciplinary perspective; (2) *recontextualizing* students' contributions, where the reformulation shifts or extends the scope of the original contribution, often making new connections with additional information or details that may have been omitted by the student and are relevant to the topic at hand; and (3) *decontextualization* where students' contributions are reformulated to be more general, all-encompassing, or less situated in the immediate, specific details of the situation or context compared to the original contribution (Cazden, 2001; O'Connor & Michaels, 1993).

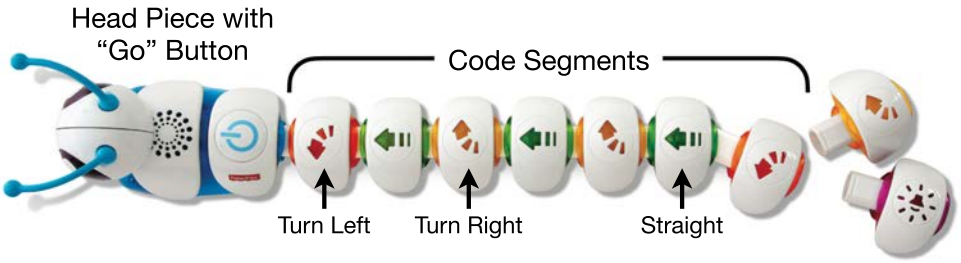
To date, however, studies of revoicing and recasting have tended to investigate revoicing in speech and have paid less attention to how teachers attend and respond to children's embodied ideas. Drawing on Vygotsky, Goodwin (2018) argues that a fundamental feature of how people learn is through dialogic interactions where more capable others (parents, teachers, mentors, etc.) carefully attune to the bodily experiences of newcomers and are responsive to, take up, and reformulate *all* of the multimodal, embodied communicative resources (e.g., gesture, gaze, bodily demonstration) that newcomers make available when they share ideas or make proposals. Consistent with this perspective, recent work in STEM at the secondary level has demonstrated that teachers are responsive to how learners use their bodies to express and work through ideas multimodally; and they often selectively repeat, reformulate nonverbal resources like gesture or full-body demonstrations, in addition to what learners say (Alibali et al., 2019; Flood, 2018; Flood et al., 2020; Shein, 2012). Inspired by this recent work in secondary STEM education, our present study seeks to better identify and characterize how preschool teachers use embodied responsive teaching, and specifically, how they re-"voice" and reformulate learners' body syntonic engagement with computational problem solving as they work with a tangible programming toy.

Study Context & Methods

This study emerged from a broader investigation of how to support young children's computational thinking with a commercially available tangible programming toy: Fisher-Price's Think and Learn Code-a-pillar (https://www.youtube.com/watch?v=3d4zXauy6EM). As part of this study, a series of programming sessions with the Code-a-pillar were video recorded over 12 weeks at a university-affiliated preschool. Children worked in small groups to complete 15-minute programming challenges with the toy once or twice a week, guided by experienced classroom teachers. Twenty-two children and two teachers participated. The programming challenges involved "helping" the Code-a-pillar navigate to desired locations. The Code-a-pillar (named "Rapunzel" by the children) has color-coded interchangeable body segments that each provide a command: turn right, turn left, go straight,

and play music (Figure 1). As part of each challenge, children engage in a range of computational thinking practices including defining computational problems (e.g., decomposing), developing abstractions (e.g., identifying patterns), and testing and refining programs (e.g., debugging). In each challenge, children spontaneously used their bodies to problem solve with the teachers' guidance.

Figure 1. *Code-a-pillar, a tangible programming toy with body segments that provide commands*



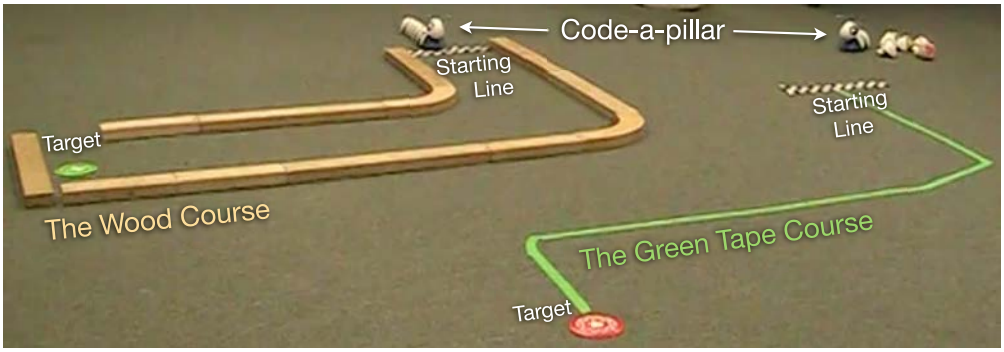
We reviewed the 12-week corpus in its entirety and located each instance where the teacher repeated or reformulated students' ideas that were expressed through gesture, demonstrative action with the Code-a-pillar, and/or full bodily activity (e.g., crawling through an obstacle course). Drawing on ethnomethodology, conversation analysis (EMCA, Mondada, 2012), and Goodwin's co-operative action framework (2018), we microanalyzed these interactional sequences to understand what multimodal, embodied resources students used to make proposals, and what aspects of these multimodal and embodied resources were repeated, omitted, or modified in teacher's subsequent revoicing turns. The goal of EMCA is to uncover and document the precise methods and resources participants use to negotiate and make meaning together (Mondada, 2012). Goodwin's co-operative action framework (2018) enriches EMCA by focusing on the embodied ways in which participants take up and transform each other's embodied, multimodal contributions (e.g., gesture, facial expression, prosody, talk, and so on). Each multimodal utterance a participant contributes is considered to be a substrate that can be broken down, reused, and reshaped in the process of co-constructing emergent new ideas and meanings together. Our findings emerged from the careful comparison of student and teacher turns.

For this paper, we selected one focal lesson involving three different groups of children to illustrate three representative cases of how teachers can be responsive to children's body syntonicity through (1) focusing, (2) recontextualizing, and (3) decontextualizing embodied proposals to support the computational thinking practices of (1) problem decomposition, (2) debugging, and (3) abstraction, respectively. We created detailed transcriptions of participants' body movements, gesture, speech, gaze, facial expressions, and vocalizations using conventions adapted from conversation analysis and Goodwin (2018): degree signs for quiet speech (°°); capitals for louder speech; question marks for rising intonation (?); periods (.) for falling intonation; timed pauses appear in parentheses (2.5); colons denote elongated syllables (::); and square brackets show overlapping actions ([ ). Embodied actions are illustrated and co-timed speech is outlined with boxes.

Findings

Throughout the 12 weeks, children spontaneously used their bodies to take the perspective of the Code-a-pillar to complete each programming challenge. The teacher was responsive to students' use of body syntonicity and in almost every case, re-"voiced" students' contributions. Our analysis breaks down students' embodied contributions and the teachers' multimodal revoicing turns to demonstrate how the teacher engages in (1) focusing, (2) recontextualizing, and (3) decontextualizing their embodied proposals. We present a representative example below for each of these forms of embodied responsive teaching. In the focal lesson, children have been tasked with a programming challenge to "help" the Code-a-pillar navigate a path surrounded by wood blocks (The Wood Course) and a path made of green tape (The Green Tape Course) to reach targets at the end of each path (Figure 2). During this challenge, a number of opportunities for computational thinking arise. As children work together to complete the task, they must break down the complex spatial trajectory of The Wood Course and The Green Tape course into a series of discrete steps (decomposition) and select appropriate segments for Code-a-pillar. If Code-a-pillar deviates from the course, they must recognize there is a problem, locate the segments that are responsible, and develop an alternative solution (debug). Finally, students are also asked to notice and investigate patterns that arise for their potential to simplify or aid with the planning process (abstraction).

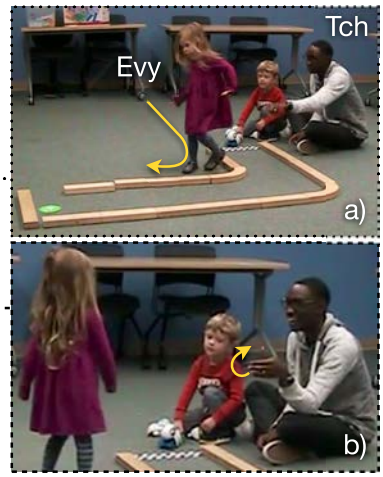
Figure 2. *The challenge: program Code-a-pillar to reach the targets at the end of each course*



Focusing embodied proposals to support body syntonic decomposition

In Excerpt 1, Evy, Cal, and the teacher are working on helping Rapunzel the Code-a-pillar navigate The Wood Course to reach the green target at the end. To "help" Code-a-pillar navigate the curved path to her target, children must decompose a continuous spatial route into discrete programmable steps. Then, they must attach body segments with commands such as go straight, turn left, and turn right in the appropriate sequence. Decomposition involves breaking down complex problems into smaller or more manageable parts (Shute et al., 2017). In this case, Evy, Cal, and the teacher have already attached a straight segment to Rapunzel and are now examining the course and deciding what to do next. Evy uses her whole body to make a proposal by walking the path: Taking the Code-a-pillar's perspective, she begins from the starting line, strides forward, and then rotates her whole body to the right where the track curves, as if she is Rapunzel the Code-a-pillar (E1.a). As she turns, she raises her arms up and points her hands forward. During the full-body turn, she shouts "left" (E1.05). Her suggestion, from start to finish, is performed in one continuous, fluid motion.

Excerpt 1. *Which Way?*



```
01 Tch: And then which way does Rapunzel need to turn,
02      [after she goes straight.
03 Evy: [((walks straight))
04      ((turns right))
05      LEFT!
06      (0.9)
07 Tch: Or [right
08         [((curves and waves hand to the right))
09      [(0.3)
10 Evy: [°Ri::ght°
11 Tch: Right. But you got the right idea,
12      yeah right, so put on the next piece.
```

Evy's suggestion uses body syntonicity to make a proposal for how to navigate the beginning of The Wood Course and thus contains productive beginnings of decomposition. However, although Evy enacts a right turn, her proposal for what to do next is ambiguous because her bodily activity does not clearly separate the first step (a straight) from the second step (a right turn). When working with Code-a-pillar, children sometimes don't recognize that certain distances will likely correspond with more than one command. Although unclear from her actions, it is possible Evy believes a single turn segment would be sufficient to navigate Code-a-pillar to where she walked to. In addition, Evy's suggestion contains a mismatch in speech and bodily activity (Alibali et al., 1993), since she describes the right turn she enacts as a "left" (E1.05).

The teacher is responsive to Evy's body syntonic proposal for the Code-a-pillar: He takes up and reformulates the proposal to highlight the aspects of decomposition that it embodies. By carefully attending to her embodied proposal, the teacher is able to see that Evy has productive embodied knowledge about the situation, despite the mismatch between her speech and bodily activity, and the potential inclusion of an extra step (the straight). He selectively repeats just one part of Evy's embodied proposal by curving and waving his hand to the

 © ISLS

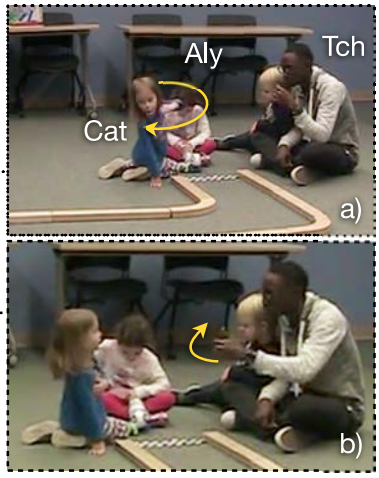
right. This simplification focuses attention on the right turn and not the straight motion. As he re-creates the right-turn motion, he also describes it as a "right" turn (E1.07). Omitting superfluous and ambiguous aspects of the multimodal contribution reinforces a productive direction for the decomposition of the problem: The next step after the straight already added is a right turn. Thus, although Evy's original embodied proposal visually contained two steps (straight and right), the teacher provides a narrower focus to help the children decide on the next step. Evy takes up the teachers' reformulation and repeats "right" (E1.10), and working with Cal, they attach a right turn segment.

Recontextualizing embodied proposals to support body syntonic debugging

In Excerpt 2, Cat, Aly, Ted and the teacher are working to help the Code-a-pillar reach the target in The Wood Course. Currently, the Code-a-pillar has a straight segment, two right turn segments, and another straight segment attached. The group has sent Code-a-pillar for a test run, and during the run, the Code-a-pillar runs into the wooden boundary. As the children simultaneously grab the Code-a-pillar to start pulling off body segments, the teacher asks them to consider what the second-to-last segment (referred to as "it" in E2.01) made the Code-a-pillar do to help them debug their current set of commands. Debugging describes the processes of recognizing, finding, and fixing errors in computer programs. In order to detect, locate, and resolve the bugs that arise with Code-a-pillar's programmed routes, preschoolers must first recognize discrepancies between the program's behavior and the desired outcome (e.g., Code-a-pillar deviates from the desired path), then isolate the problematic command segment(s), and successfully replace them with segments that will cause the desired result.

Excerpt 2. *The Crash*

01 **Tch:** What did it make her do?
02 **Aly:** Str[ai::ght?
03 **Cat:** [Cwra:::sh.
04 [*((twists torso clockwise,*
05 *reaches left hand around right shoulder))*
06 **Tch:** It makes her [crash
07 [*((thrusts hand quickly to the right))*
08 into that block. Yeah. Okay.
09 **Aly:** *((removes second segment))*



To answer, Aly says "straight" (E2.02), and Cat makes a different embodied proposal (E2.a). Her upper body moves as if she is the Code-a-pillar, in the same direction that Code-a-pillar makes the problematic turn into the barrier. She twists her whole torso towards the location where the Code-a-pillar struck the wooden track, and she also stretches her right arm across her body, twisting her right hand past her left shoulder to point at the crash site. As she turns, she gazes towards the exact location where the collision occurred. To make this turning motion and twist her arm around, she contorts her body in a way that appears uncomfortable, which may be an attempt to illustrate the discomfort, awkwardness, or the undesirability of the situation. As she moves, she says "cwrash" (E2.03). Cat's bodily activity provides important information that is not captured in her speech about the location of the crash and the undesirable nature of the situation. In particular, exactly where along the track the collision occurred is valuable information that has the potential to help them locate and confirm the source of the bug, and decide which of the segments (the end piece or an earlier piece) was responsible for the undesirable outcome.

The teacher takes up Cat's embodied proposal and is responsive to the productive beginnings of debugging that it contains. He *recontextualizes* this proposal by extending and reconnecting the undesirable outcome Cat embodies with its *cause.* With his hand, he transforms Cat's embodied twist into a quick jerking motion to the right, depicting the direction of the crash. The quick speed of his hand motion preserves Cat's depiction of its undesirable nature (E2.b). While his gesture depicts the right turn that results in the crash, the teacher's speech *extends the context* of Cat's contribution and links the undesirable outcome (the crash into a particular part of the wooden track) back to the specific code segment they are discussing. He performs this extension by adding "it" (which *ties* the idea back to the second segment; Goodwin, 2018) "makes her" (which adds the *causal link*) (E2.06). This addition also clarifies the agency involved in the crash: It is the programmer's choice of commands that is responsible for the error, not the Code-a-pillar herself, and the faulty command can

 © ISLS

be isolated and changed by the children. Overall, this additional information recontextualizes Cat's proposal in the specific details of the situation – the reason for the crash – and implies a potential fix, which are all important aspects of the debugging processes. Although Cat does not immediately respond, Aly, who is holding the Code-a-pillar, demonstrates her understanding of the recontextualized proposal and removes the problematic segment.

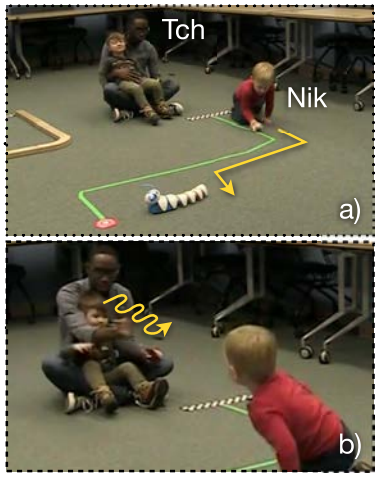
Decontextualizing embodied proposals to support body syntonic abstraction

In Excerpt 3, Nik, Pat, and the teacher are working to help the Code-a-pillar navigate to the target at the end of The Green Tape Course. After some trial and error, they eventually program a route where the Code-a-pillar mostly stays on the green tape and ends up very close to the target. The teacher asks the children to reflect on this route, and asks what they have done to get Code-a-pillar near the target. Nik answers, grabbing a spare Code-a-pillar segment and tracing it along the Green Tape Course where the Code-a-pillar traveled (E3.a). As he traces, he also crawls the path and narrates the processes, starting with "She went this way" (E3.01). As he makes each turn, he narrates with the same sound effect "zoom" (E3.02, E3.04). When he gets to the end of the route, he changes the sound effect to "vroom," (E3.06) pretending to connect the segment he is holding to the Code-a-pillar.

Nik's embodied proposal is body syntonic and adopts the point of view of the Code-a-pillar as he crawls through the course, demonstrating the specific ways the Code-a-pillar moved to get to where she is. His embodied idea contains productive beginnings of *abstraction*: He uses the word "zoom" to punctuate *both* the left turn and the right turn, marking them as similar, and potentially, as members of the same category (or type of thing).

Excerpt 3. *Keep Turning!*

```
01 Nik: She went this way
02      [°zoom°
03      [((turns segment and crawls right))
04        [°zoom°
05        [((turns segment and crawls left))
06      [and vroom.
07      [((pretends to add segment to caterpillar))
08 Tch: So you added on
09      [different pieces that helped her keep turning
10      [((turns hand back and forth))
11      to the food.
12      ((turns hand back and forth again))
13 Nik: Yeah.
14 Tch: Yeah.
```



The teacher is responsive to Nik's embodied proposal and the potential elements of abstraction it presents. He takes up and re-"voices" the proposal, but modifies it in a way that *decontextualizes* it and increases the level of abstraction: While Nik's full-body enactment through the course is environmentally-coupled (Goodwin, 2018) and preserves the precise *location* and *direction* of the left and right turns, the teacher uses a more general gesture, turning his hand back and forth left and right, to represent the *general* case of turns (which can be in either direction). In speech, he provides a more generalized description of what helped the Code-a-pillar get to the target: "keep turning" (E3.09). He also re-emphasizes the causal connection (i.e., adding the code segments) and the children's agency in the process.

Computational problem-solving processes can be simplified by recognizing patterns and similarities within and across situations. Nik's original proposal is situated in the specific context and details of their last run of the Code-a-pillar on The Green Tape Course. Identifying common features in complex scenarios (e.g., the *turns* in a winding course with several left and right turns) is an important aspect of pattern finding and abstraction. To support the children's abstraction and pattern finding, the teacher's reformulation extracts relevant, common information from Nik's proposal and recasts it with less detail. After the reformulation, Nik agrees with the teacher's generalized version of his proposal (E3.13).

Concluding remarks, significance, and implications

By closely examining the ways in which teachers take up and respond to preschoolers' *body syntonic* problem solving with the Fischer Price Code-a-pillar, this study helps to expand our understanding of embodied responsive teaching practices and strategies teachers can use to support children's engagement in computational thinking. In particular, we showed how a teacher attended and responded to the productive beginnings of problem

decomposition, debugging, and abstraction present in children's embodied problem solving. To be responsive, teachers can reformulate children's embodied proposals by (1) focusing them, (2) recontextualizing them, and (3) decontextualizing them, which each can respectively support different computational thinking practices.

In each case, elements of the spatio-dynamic and kinesthetic information children shared with their bodies were preserved by the teacher's use of gesture. This provided a visual, embodied bridge for the children to see connections between their original idea and the teacher's reformulation. This process is congruent with the mechanism Vygotsky (1986) proposed for how interactions between adults and children drive learning and development: It provides an arena for spontaneous, intuitive interpretations of the world (e.g., those that arise from body syntonic experiences) to grow together with cultural and academic concepts. By reformulating children's embodied proposals, teachers may help children reconcile body syntonic intuitions and interpretations with specific cultural and disciplinary ways of organizing the world and approaching problems (e.g., in computer science, processes of decomposition or abstraction). In addition, reflecting these embodied ideas back to children may provide them with important opportunities for increased examination of their own ideas (Flood et al., 2020).

In particular, we argue that understanding how teachers support young children's learning with tangible programming toys requires careful attention to bodily activity and multimodal resources. By attending and responding to body syntonicity, teachers are able to shape the computational thinking that emerges through this physical activity. Our study demonstrates how a focus on speech alone would provide an incomplete picture of the nature of the instructional support in these settings. In addition, understanding children's embodied learning in this setting is irreducible to each child's isolated, individual ideas. Instead, it is necessary to expand the unit of analysis for learning with tangible programming toys to the broader interactional context. Our investigation joins other recent approaches in the learning sciences (e.g., Farris, 2021; Vossoughi et al., 2020; Vossoughi et al., 2021; Wang et al., 2021b) to show how the intricacies of computational thinking practices can be distributed across participants' bodies and co-constructed between preschoolers and teachers. We demonstrated how Goodwin's co-operative action framework (2018) provides a powerful analytic approach for illuminating the embodied nature of responsive teaching that may otherwise go overlooked: The multimodal microanalysis of interaction provides a powerful tool to understand the nuanced ways in which teachers take up, re-use, and transform students' embodied utterances during programming sessions.

Notably, teachers' abilities to be responsive to young children's embodied computational thinking also suggests that children need not have sophisticated vocabulary and language skills as a prerequisite for meaningful engagement in practices like abstraction, decomposition, and debugging. As computer science, programming, and computational thinking are increasingly being introduced in early childhood, teachers sometimes feel unprepared to teach these areas to young children. Our study illustrates how teachers can adapt techniques from their existing repertoire of teaching practices (e.g., revoicing) in embodied ways to support children's computational thinking. In addition, creating professional development to support teachers to recognize and embrace early learners' embodied forms of computational thinking may be especially important since, historically, embodied competencies and ways of knowing have been delegitimized in STEM spaces (Takeuchi et al., 2019).

One limitation of our study is that we cannot know from our current investigation how these embodied responsive teaching practices impact longitudinal learning outcomes surrounding computational thinking. As Cazden (2001) notes, any one instance of revoicing where focusing, recontextualization, or decontextualization occurs is not likely to result in mastery of academic topics or practices. However, Cazden argues that continuous engagement with adults, in which children's ideas are frequently taken up, reformulated, and reflected back to them, provides a powerful sociocultural mechanism for learning through socialization. Given the well-established importance of body syntonicity in children's development of computational thinking, more research is needed to understand how embodied responsive teaching supports children's computational thinking and what impact this has over time.

Developing Productive Classroom Dialogue Using Analytics-Supported Video-Based Approach for Teacher Learning

Yuyao Tong, Carol K. K. Chan, Gaowei Chen, Pengjin Wang
yyttong@hku.hk, ckkchan@hku.hk, gwchen@hku.hk, wangpj@connect.hku.hk
The University of Hong Kong

Abstract: This study investigates the role of a video-based teacher professional development approach supported by a visual learning analytics tool, Classroom Discourse Analyzer (CDA), for helping teachers to understand and to enrich their classroom dialogue in the teacher education context. Data were drawn from three teacher educators and their pre-service student teachers (n = 52) spanning over six months on enriching classroom dialogue. Teacher educators met regularly in six teacher meetings to discuss and reflect on classroom dialogue using video clips enriched by CDA visualizations. Coding of classroom talk using accountable productive talk moves indicates changes in teachers' increased use of productive classroom dialogue moves. Qualitative analysis of teacher reflection and discussion illustrated how CDA supported teachers in noticing their own and student discourse, using dialogue moves as the framework for reflection, and developing deeper meanings of dialogue using CDA as objects of inquiry. Implications of the designed analytics-supported video-based teacher professional development approach are discussed.

Introduction

Developing productive classroom dialogue is a major research theme and gaining significance in light of changing global and educational contexts for dialogical education (Mercer et al., 2019). While research on classroom dialogue is well established (Howe & Abedin, 2013), teachers often meet challenges in orchestrating productive classroom discourse in teaching and learning (Chen et al., 2020). Compared with the traditional initiation-response-follow-up (IRF) pattern (Sinclair & Coulthard, 1975), productive classroom dialogue requires teachers to encourage students to engage in dialogic interaction-practice by sharing, build-on, arguing, elaborating and reflecting in the classroom discussions. To help teachers conduct productive classroom dialogue, research into teacher professional development (TPD) has given substantial attention to using classroom videos to support teacher learning and teacher collaboration has played a vital role in these video-based TPD programmes (Beisiegel et al, 2018; Shrien & van Es, 2009). With the advances in technology, the use of video-based TPD supported by teacher collaboration has been recognized as a major approach for teacher learning in the learning sciences. This paper presents an analytics-supported video-based approach that aims to help teachers and students foster productive classroom dialogue.

The social-cultural theory emphasizes social interaction as a key mediator to support learning (Pifarré & Staarman, 2011). Increased attention has been paid in recent years to the notion of productive classroom dialogue for mediating joint understanding. For example, Mercer (2008) identified exploratory talk as productive dialogue through which students engage in collective knowledge construction in the form of critical and constructive building on each other's ideas. Michaels et al. (2008) discussed accountable talk, which is a productive form of discourse emphasizing accountability to the learning community, accurate knowledge, and rigorous thinking. Productive classroom dialogue, as a form of talk, is well examined to be effective for students' learning (Howe et al., 2019; Murphy et al., 2009). Given the important role of productive classroom dialogue, an overarching question is proposed for educators that how to help teachers learn and foster productive dialogue in classrooms. There has been considerable research interest in strategies training for teachers in the TPD programs, in turn, to orchestrate productive dialogue with students in the classrooms (e.g., Chen & Chan, 2022; Chen et al. 2020; Pehmer et al., 2015).

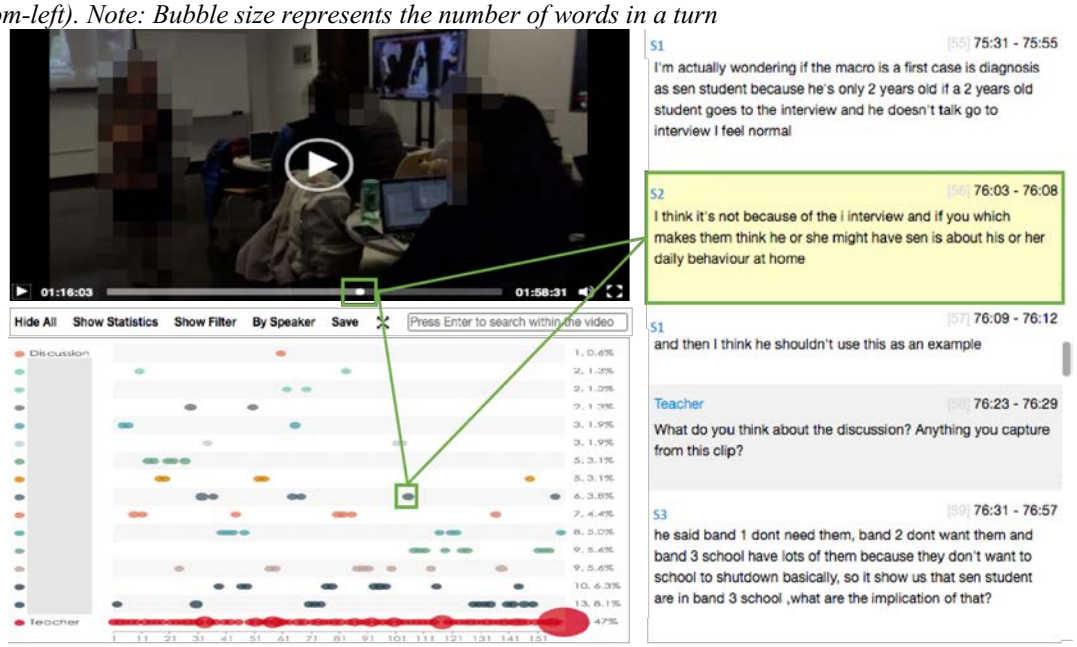
Although video-recording of classroom dialogue is a central tool in TPD to help teachers to reflect on classroom teaching, challenges still exist due to the large amounts of classroom dialogue data that teachers must process, especially to identify useful video clips and episodes. Different approaches have been taken to address the problem such as teachers selecting their video clips and collaborative discussion among teachers (Sherin & van Es, 2009). In recent years, researchers have developed visualization and analytics tools to help teachers notice and identify salient classroom events. Specifically, the Classroom Discourse Analyzer (CDA), a visual learning analytics tool (Chen, 2020), was developed to visualize classroom dialogue using analytics data. Using CDA, teachers can navigate and synchronize selected classroom events (video clips) with classroom talk (transcripts) and productive dialogic moves (dashboard analytics) (Figure 1). CDA has different affordances, including

 © ISLS

multiple representations, interactive visualization, and contextualized evidence. The CDA platform provides strategies for solving the difficulties teachers meet in reflecting on and analyzing classroom dialogue, including those related to large datasets, coding, visualization, and tracking and comparison (Chen, 2020).

Figure 1

Classroom Discourse Analyzer interface, with classroom video events (top-left), classroom discourse utterances/transcripts (right), dashboard-analytics information on teacher dialogic moves and student talk turns (bottom-left). Note: Bubble size represents the number of words in a turn



Current research on classroom dialogue spans different educational levels and subjects and has mostly examined in-service teacher learning from K-12 levels. It is also important to examine the development of a dialogical approach among teacher educators, as they are modeled for pre-service teachers whose experience would aid future school transformation. In particular, the focus in teacher education is often placed on subject matter knowledge and pedagogical and teaching skills, rather than collaborative and dialogical learning. Jurow et al. (2012) discussed the need for incorporating a learning sciences lens in teacher education, noting that a dialogical approach would be fruitful. This study was conducted in a teacher education setting to examine teacher change towards developing productive classroom dialogue. Specifically, its goal was to integrate the development of a visual learning analytic tool to help teachers orchestrate academically productive talk moves in classroom teaching. Specifically, two research questions were addressed: (1) Did the teacher educators increase their use of academically productive talk moves, and what characterized these productive dialogic moves? And (2) How did teacher educators employ visualization and analytics information from CDA to promote their understanding of academically productive talk in the classroom?

Methods

Research context and participants

Data were drawn from three teacher educators and their preservice student teachers (n = 52) who participated in a six-month programme for developing productive classroom dialogue for teacher development. The group consisted of eight university teachers who met once a month to share their practices in teaching a pre-service teacher education course on Educational Inquiry. Other teachers also joined the discussion at different times, but these three teachers opted to make a more focused inquiry into their own practice, including video analysis supported by CDA. Altogether, six teacher meetings were held, including discussing the classroom dialogue scheme adapted from the accountable talk (Table 1) (Michaels et al., 2008), teachers sharing video clips of their classroom teaching, and using CDA to examine and interpret classroom dialogue.

Data sources and analysis

Teacher educators' classroom dialogue moves were examined using two classroom videos obtained from each of the three teachers during the early and late phases of intervention (TPD discussion on classroom dialogue). There were six classroom videos, with each class lasting 120 minutes. The classroom transcripts were analyzed and coded using the adapted "academically productive talk" (APT) scheme (Chen et al., 2020; Michaels et al., 2008; Resnick et al., 2010). Table 1 shows the five main talk types: sharing their own ideas (elaborating), deepening their reasoning (reasoning), listening carefully to one another (listening), and engaging with others' ideas (thinking with others). In addition, based on a theory- and data-driven approach, we added a new type – reflecting with others (reflecting). A second rater coded 20% of the data and the inter-rater reliability was .87 (Cohen's kappa; Cohen, 1968). Teacher discussions in TPD meetings were transcribed and qualitative analyses were conducted to examine salient events and themes on how CDA supported teacher learning.

Table 1
The framework of teachers' academically productive talk moves – adapted from Chen et al. (2020), Michaels et al. (2008) and Resnick et al. (2010)

APT Strategy	APT Moves	Description and Examples
Type 1: Elaborating	Say more	Ask students to expand on their ideas by saying more ("Can you give an example?")
	Revoice	Revoice students' reasoning and provide opportunities for them to verify it ("Are you saying…?")
Type 2: Reasoning	Press for reasoning	Ask students to explain their reasoning ("Why do you think that?")
	Challenge	Challenge students or give a counter-example ("Does it always work that way?")
Type 3: Listening	Restate	Ask students to repeat or rephrase the idea of others ("Can you rephrase or repeat what (s)he just said?")
Type 4: Thinking with others	Agree/disagree	Ask students to apply their reasoning to another's reasoning ("Do you agree/disagree?")
	Add on	Prompt students to extend the idea of others ("Who can add to that idea?")
	Explain other	Ask students to explain what someone else means ("Why do you think he said that?")
Type 5: Reflecting	Refer back	Prompt students to summarize or link previous ideas ("Can you summarize/compare what they said?")

Results

RQ1. Did the teacher educators increase the use of academically productive talk and what characterized these productive dialogic moves?

We first provided basic quantitative data on the amount of teacher and student talk in the three classrooms. Using the CDA, we assessed the mean of the "percentage of words" used by teacher educators and student teachers. Table 2 shows that for all teachers, there is a decrease in the amount of talk whereas their students increased the amount of talk from early to late phases (pre-post intervention).

Table 2
Percentage of teacher and student talk words at pre- and post intervention of program

	Teacher Talk		Student Talk	
	Pre	Post	Pre	Post
Teacher A	88%	79%	12%	21%
Teacher B	79%	66%	21%	34%
Teacher C	69%	66%	31%	34%

We then examined the teacher educators' use of productive dialogic moves in two lessons at the early and late phases of the intervention program. Table 3 shows the frequency of use of the five types of productive classroom talk moves for the three teacher educators.

Table 3
Frequency of the five productive classroom talk moves at pre- and post-intervention of program

	Elaborating		Reasoning		Listening		Thinking with others		Reflecting	
	Pre	Post	Pre	Post	Pre	Post	Pre	Post	Pre	Post
Teacher A	14	19	5	3	0	2	2	17	0	2
Teacher B	5	13	1	2	0	3	4	13	0	2
Teacher C	7	18	5	12	0	0	2	10	4	2

A paired sample t-test was conducted to examine whether teacher educators increased their use of academically productive talk moves. Analysis showed that teacher educators significantly improved their overall use of the five types of academically productive talk strategies between early phase (M = 16.33; SD = 5.69) and late phase (M = 40.00; SD = 4.36), $t(2) = 26.835$, $p < .01$. Specifically, there were significant changes in the use of *Elaborating*, $t(2) = 4.619$, $p < .05$ (Pre: 8.67(4.73); Post: 16.67(3.21)), and *Thinking with others*, $t(2) = 4.880$, $p < .05$ (Pre: 2.67(1.15); Post: 13.33(3.51)). Generally, these results suggest that the teacher educators increased the orchestration of productive classroom discourse after the TPD intervention.

We also included classroom dialogic examples to show how these productive dialogic moves were employed.

> 1. Teacher (T): Take a look at this cartoon shown on screen (topic: Catering for individual difference), what do you think when you see this cartoon?
> 2. Mary: One size fits all. [term used in lesson PowerPoint]
> 3. T: One size fits all? Can you tell us more? [Teacher invites a student to *elaborate*]
> 4. Mary: Um... Cartoon shows teaching fitting stuff into the box. It seems here that the teacher thinks one set of materials is good. And if students do not perform well, then it is their problem... Just fitting students to the box.
> 5. T: What do others think about what Mary said? (Some silence, wait time) [Teacher invites students to *add on*]
> 6. T: Anything you want to add? You can agree or disagree with Mary? [Teacher invites *thinking with others*]
> 7. Tom: Um I do not like the image shown in the cartoon.
> 8. T: Tell us more. What do you not like? [Teacher invites *elaboration*]
> 9. Tom: It is like what Mary said.
> 10. T: What did she say earlier? Can someone rephrase that? [Teacher *listening*]
> 11. David: She (Mary) said one size fits all may not work well. As in this picture, the teacher just tried to shape or modify the student to fit into the box. It may be like one size fit all strategy the teacher used.
> 12. Dennis: Yes, because not all teaching strategies fit the students. But often students just try to pretend they understand.
> 13. T: That is interesting... pretending to understand? [Teacher follows up on Dennis' ideas. *Listening*]
> 14. Dennis: I mean with this one size fit approach. I may feel confused about what the teacher taught. But I see other students seem to understand, so I am afraid to ask more questions. [Student elaborating his ideas]

In this example taken from Teacher B from the lesson taken later in the program, the teacher was working at incorporating the different productive dialogue moves in her classroom teaching. She started by showing a cartoon to the student teachers to generate open responses and have the students set the direction of classroom talk. Rather than just asking closed-end content-related questions, she employed different moves including inviting the students to elaborate [Lines 3 and 8, *Can you tell us more*?], to add on and think with others (Line 6, *you can agree or disagree with Mary?*), to listen to others and to paraphrase what is said earlier (Line 10, *what did she say earlier? Can someone rephrase that?*). And following up on what the student teachers had suggested (Line 13, *that is interesting…pretend to understand?*). Teacher B has been using the student-centered approach in her university teaching, and this dialogic framework presented in the TPD project helps her to use a set of productive talk moves more systematically. These productive talk moves also help encourage student teachers to express more (longer speaking turns) and to build on peers' different ideas moving towards enriching classroom dialogue.

RQ2. How did teacher educators employ CDA visualization and analytics in supporting their understanding and enactment of productive classroom dialogue?

We included examples and analyses of how CDA supported the teacher educators' reflection and discussion to develop their understanding of productive classroom dialogue. In one teacher meeting, CDA visualizations of Teacher A's classroom teaching in two lessons (early and late phases) were shared and discussed. Both the CDA lessons and the visualizations were selected and prepared by the research team. Figures 2a and 2b focus on the

 © ISLS

amount of talk and speaker turns – the vertical axis includes teacher and student names and their contribution, and the horizontal axis shows all turns over time The size of each bubble indicates the length of the talk, with teacher talk at the bottom of the graph. Figures 3a and 3d focus on Teacher A's use of dialogic talk moves in the two lessons, based on the adapted Accountable Talk scheme (nine types). Teachers also referred to video events and excerpts in relation to the CDA analytics information (Figure 1) in their discussion.

Figure 2

Visualization of teacher educators and student teachers' frequency of talk and speaking turns in two lessons

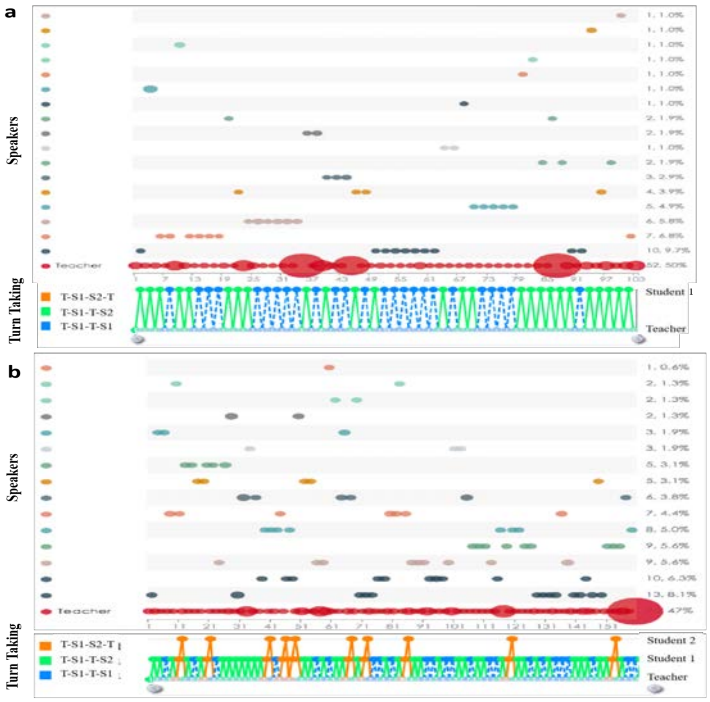


Figure 3

Visualization of Teacher A's frequency of use of different dialogic talk moves in two lessons

 © ISLS

The teacher educators discussed how CDA visualization supported their understanding and enactment of classroom dialogue. Several themes emerged:

Facilitating the noticing of teacher and student engagement in discourse

Teacher educators used the CDA visualization to help them notice their own and students' dialogue patterns that would form a basis for change. For example, Teacher A commented,

> "When I looked at my CDA graph (pointing to the bubble of talk, Figure 2a), I was surprised at the length of my talk...I didn't know I was talking so much…Possibly, the common pattern in our university teaching is long teacher talk and relatively short student responses."

Using the CDA visualization, Teacher A was aided to notice the length and amount of his classroom talk. This revelation may have come as a small surprise to the teachers who had joined the project, as they tended to see themselves as relatively good teacher educators. The realization may have helped Teacher A reflect on his practice for possible change. Teacher B used a different lens when looking at the CDA graphs and visualization, emphasizing student engagement and dialogue,

> "I can see how much more or less different students are participating in classroom talk quite quickly now. Also, there is an ongoing temporal dimension… I can also see the sequence of student talk… So, AG is starting and then I see what TM is talking about, and then WK also says something though it is shorter. We can move around video parts/excerpts quickly. So, we can find out more about what student teachers are saying and thinking… Nice to know which different aspects of the topics they found interesting."

Supported by CDA, teachers broadened their views from noticing their own classroom talk engagement to noticing student participation and talk patterns. Noticing student engagement is important for advancing dialogic interactions for productive classroom talk. The CDA-analytics-enriched discussion of students' dialogue patterns enriched teachers' noticing. As Teacher A remarked,

> "I am looking at my other lesson now and it is good to look at both my own and students' talks. It is nice to see I am speaking relatively less... I still have a big bubble and possibly was making a long conclusion. I am also looking at what the student teachers were doing…It is good to see from the graph that a few more were participating (Figure 2b) and speaking more and they also talking longer than before. A little different from my other classes, with shorter student responses."

Increasing teacher awareness and supporting reflection using the dialogic move framework

CDA visualization supports teacher educators to understand more about the use of dialogic classroom moves to enhance their awareness of dialogue. As Teacher B noted,

> "These classroom dialogic moves are quite complicated and may mean different things to teachers, but we can now see what they may look like using these video clips and visualizations. We can also see the utility of different dialogical moves...In this case (referring to Figure 3), the talk move please 'say more' was more commonly used; it may be an easier dialogic move to use and good to try."

Teacher A also expanded on his understanding of these dialogic moves:

> "I think the talk moves shown on the CDA graph can be used to assess our teaching but can also be used to help us do something different. The dialogic moves may be some kinds of external support…providing a certain kind of framework. We may have our way of doing our questions and dialogue all the time, but here they help to enhance our awareness of what is really happening in our classroom dialogue."

Primarily, using dialogic moves is challenging for teachers and the CDA visualizations, examples, and codes could help teacher educators develop more understanding and consider using different moves.

Providing diverse representations of teacher talk as objects for shared inquiry into the deeper meaning of dialogue

CDA representation of teacher-student talk patterns also inspired the teacher educators to ponder the meaning of dialogue for further inquiry and design. CDA differentiated teacher-student turns into 1) T-S1-T-S1, 2) T-S1-T-S2, and 3) T-S1-S2-T (blue, green, and yellow) (referring to Figure 2) depicting centralized versus distributed classroom dialogue. The discussion of these patterns brought new questions from the teacher educators. For example, Teacher C said,

> "CDA provides us with the number and patterns...I am also interested in the changes in these turns, not just the number but also the contents and teacher intentions…From there, I hope to know more about the intentions of the teachers and students... what lies behind these different speaker turns."

Teacher C's question points to an important issue – how teachers understand classroom dialogue involving teachers' meaning-making. The combination of video clips to illuminate different speaker turns and dialogue moves may provide more opportunities for teachers to understand the content and intentions of talk moves. Teacher C continued,

> "I also want to build onto the earlier point of Teacher B about the time sequence of student dialogue moves and turns. I hope we can have more analyses of the time sequence based on these different turns. It would be good if CDA in the future could include some kinds of network representation, say, how the talk moved from S1 to S2 to S3. It is almost like social networking for understanding the dialogue among student teachers better."

These CDA objects also function as boundary objects, mediating the discussion and opening new areas of inquiry among teacher educators and, possibly, deepening their understanding and enactment of productive use of classroom dialogue.

Conclusion and implications

The study has examined how a group of teacher educators improved their use of academically productive talk moves after participating in an analytics-supported, video-based, teacher professional development project. Video-based teacher professional development is now a major approach to teacher learning in the learning sciences (Chen et al., 2020; Sherin & van Es, 2009). Concurrently there is also considerable research development in using analytics information to support teaching and learning in classrooms (Wise et al., 2021; Wise & Schwartz, 2017). This study integrated the use of video-supported TPD with visualization and analytics information to address the issue of overwhelming data and selection problems in using classroom videos. Specifically, the use of video-based analytics approach is developed in the area of helping teachers employ productive classroom dialogue and the use of visualization and analytics would be particularly helpful. Results of the study using coding of classroom dialogue indicate that teachers increased their use of academically productive talk moves after the intervention, especially for *elaborating* and *thinking with others* talk types. At a more general level, teacher educators and student teachers changed the amount of total talk in the classroom with student teachers increasing their engagement in classroom talk. Analysis of teacher reflections and discussions at teacher meetings identified several key themes, including how CDA can support the noticing of current and changing teacher and student practices, facilitate their understanding and enactment of dialogical moves via providing a systematic framework, and identify how different CDA representations provide shared objects of inquiry for developing deeper collective inquiry into the nature and meaning of productive dialogue.

This study contributes to the literature on video-based supported teacher learning highlighting the role of visualization and analytics-supported reflection, with learner-generated information (classroom talk) provided to participants for them to reflect on their ongoing inquiry for making changes to their current practice. The integration of technology and pedagogy and analytics in CDA helps provide different possibilities. Many studies show the important role of classroom dialogue and this study also shows how the approach may support the development of dialogic practice. This study is of particular significance, in investigating how teachers could be helped to overcome video data selection problems by harnessing analytics information on their classroom dialogue and providing objects of shared inquiry for understanding and enacting dialogic practice.

Harmonized Mutual Development through Exploring and Creating Sound

Angela N. Booker, Victor Minces
a1booker@ucsd.edu, vminces@ucsd.edu
University of California, San Diego

Abstract: The science of sound presents a holistic learning opportunity to engage embodied intelligence and lived experience in mutually shared soundscapes where material objects become sites for the pursuit of curiosity and aesthetic beauty. When young people are presented with this view of the realm of science learning and practice, the possibility for alignment and harmony between personal knowing, social relations, and a living environment can emerge. And even more compelling, the possibility for what we describe as harmonized mutual development in a community of learners moves within reach. This paper explores the potential of a curricular and pedagogical design to produce a kind of collective ethic in learning that is often elusive in formal learning environments.

Introduction

The pervasiveness of sound, its ease of measurement, and its cultural relevance reveal the sonic world as a "natural laboratory" through which young people may become intuitively familiar with waves and their properties. From speech, to music, to street noise, sound is an integral part of our everyday lives. People are intuitively familiar with many aspects of sound waves and their perceptual signatures such as pitch, timbre, loudness, direction, and echo. People are also familiar with many objects that generate sound (vocal cords, flutes, drums, strings). Listening to Waves (LTW) is an educational program that guides students to learn the hidden and ubiquitous world of waves through the exploration of sound and vibrations. In LTW, students make and analyze sound, create waves and vibrations in physical objects, build musical instruments, use digital technology to analyze waveforms and acoustic properties and to create sound and music, and explore how sound is propagated through the environment and represented in the brain. The program was designed by Dr. Minces, a neuroscientist specializing in the science of music, and Dr. Alexander Khalil, an ethnomusicologist. The design draws from their experiences as scientists and their experimentation with sound.

Being together in a soundscape provides the basis for the design of a set of science workshops. We make a series of moves to grow roots in a disposition toward scientific thinking and practice that prioritizes everyday access to beauty and wonder. First, the design aims to re-prioritize the soundscape as an active context for learning. Second, the design honors social environments that cohere learning environments as fundamental to what makes science practice meaningful. Third, the design re-privileges embodied ways of knowing, situating learning trajectories within young people's sensed and shared experiences (Marin, 2020). Fourth, the design aims to forge a meaningful connection between personal learning and collective, mutual learning that animates shared life. This includes aesthetic, material, contextual, and social relations.

Our program design is informed by a theoretical understanding of learning and development as situated. Young people who participate arrive with their own ideas and experiences with sound and science. This program supports them to expand and integrate those experiences with new ways of exploring, representing, and understanding sound. We consider students' socio-historical sense of both sound and science, their processes of identity development, and their practices for taking on new roles (Bell et al., 2012). LTW uses a project-based design that supports students to connect their everyday knowledge and practices with disciplinary science practices (Barron & Bell, 2016) while inviting them to become increasingly full participants in a community of scientific practice (Lave & Wenger, 1991). The program design integrates middle school students, their teachers, and scientists into joint activity to support development and sustained participation. In this way, the design establishes conditions for making visible and analyzing when and how these project-based activities can support the development of particular identities and sustained engagement (Vygotsky, 1978; Chaiklin, 2003). The designers' relational challenge is of particular importance here.

Becoming and development: A relational design tension

How do designers navigate existing classroom practices that constrain learning environments toward performances of individual intellectual competence and classroom behavioral management while working to establish parallel—and at times, disruptive—forms of meaningful collective learning? Designs for collective learning in classrooms as formal learning environments encounter some practical impediments born of a set of

 © ISLS

developmentally-framed obligations: (a) for students to demonstrate competence independently, (b) to maintain dominant patterns of knowledge production, (c) to accept separation as necessary—as a severing of the social conditions of human learning, and (d) for educators to effectively assess individuals, allowing for students' independent and hierarchically organized advancement or delay. Even the most collectively designed academic task must eventually be filtered into individual grades, advancement, and future placements. When and how can designers effectively honor the social, cultural, historical, political, and ethical conditions of learning?

Our research design endeavored to work in concert with these challenges. We asked, what does a collective learning design allow for in terms of relationality and future practice? In what ways can individual sensory awareness yield mutual and shared learning conditions, and in turn, a learning environment where social engagements directly yield creative inquiry that makes scientific practice and science identities accessible to and sustainable for the full collective of participants? When can individual styles, approaches, interests, and knowledge be activated in service of mutual advancement in practice that moves the whole beyond what could be accomplished individually? In essence, we wondered, what would be the symphonic version of this design, and in turn, the learning opportunities that move beyond the efficiency of collective delivery (and yield more than a system aiming to avoid holding back the individual)? For learning designers, we see this as a threefold challenge intertwined with frames of development, assessment, and organizational differentiation that sort students into groups of more and less capable. Assessment practices and organizational differentiation are pre-existing conditions of classrooms and schools. Developmental frameworks may be the most pliable of the three, and therefore, the most accessible to different approaches in design.

Given our interest in identity, practice, and transformed participation, we have increasingly focused on questions in the realm of human development and processes of becoming. In our observations and in survey results reported elsewhere (Minces et al., 2021), we recognized processes of becoming in young people's engagement with the program. Likewise, we noticed our tendency to look for signals of development-in-progress in our qualitative data, yet were drawn up short by the ways in which developmental frames are frequently used to render students—like those who participated in our study—as behind a developmental norm due to contending with under-resourced circumstances and underrepresentation in science-based fields more broadly. Increasingly, the developmental frame seemed to be in tension with aspects of our situated approach to design and the processes of becoming that most intrigued us during field observation and analysis. Our design emphasized processes for engaging as a learning community in a learning environment that prioritized relationships with self, social environment, and soundscape that could reposition young people's relationship with science and prioritize equity (DiGiacomo & Gutiérrez, 2014).

Matusov's studies of democratized learning environments align with the ethos of the learning environment designed through LTW: "The participation inquiry involves issues of what facilitates and hinders such transformations, what are their directions (and how they are desired by community members), what are means for the transformations …" (Matusov, 1997, p. 340). By designing the learning environment first as a space of relation, we aimed to theorize means by which design can contribute to a prioritized collective ethic in learning while contending with the persistent perceived conflict between individual assessment and practice as communal.

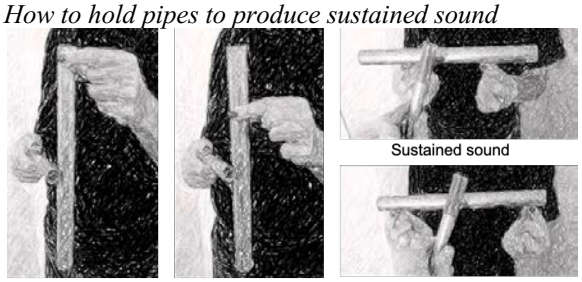
As learning scientists have continued to advance theoretical approaches to understanding development in relation with learning, the notion of becoming has been conceptualized to address equity and ethical relations in learning environments. This approach to relational aspects of becoming gives us analytical purchase on the processes of transformed relationship with science that are at the heart of the pedagogical design: "Pedagogies aimed at social transformation therefore involve examining and rearticulating the meanings that degrade our perceptions of, and relationships with, others as well as ourselves (Philip, 2011). Political-ethical becoming, as we theorize it, is thus not simply reorganizing our thoughts, but reshaping our relations" (Vossoughi et al., 2021, p. 204). Students participating in LTW workshops arrive having already been "embedded in relational ecologies" (Vossoughi et al., 2021 p. 217) that have organized their existing relationships with science at school, soundscapes, sound and music-producing materials, and formal learning environments. The design seeks to ally with students in reconfiguring relationships with the environment that emerge from re-prioritized social and peer relations of the classroom cohort. Prioritizing shared moments of surprise and access to beauty through sound and waves traveling through material requires shifting power relations in learning in that personal and peer sensory experiences are privileged in processes of producing knowledge. Given the theoretical problems we have described, the following questions arise: What mediates engagement in an environment that can be repurposed as a means for young people to forge their own pathways toward science and its potential and presence in their lives? And in what conditions can the design of the learning environment support transformed relationships between the intellectual progression of individual students and a collective intellectual practice where students contribute to the community of practice in ways that matter to the collective, in turn, expanding social practices in the classroom beyond behavioral means and toward political-ethical becoming?

Program Design

LTW program contains several modules that are integrated into eighth-grade science classes, and have been implemented primarily with underrepresented and low-income students. Participating in the program has been shown to improve the students' attitudes towards science, including the perception of themselves as capable of doing science and their intention to pursue a science career (Minces et al., 2021). This paper focuses on one of LTW's modules, the *sound vibrations lab*. A fuller description of the program can be seen in (Minces et al., 2021). The *sound vibrations lab* was facilitated by Dr. Minces. In it, students explore how pipes vibrate, which allows them to understand how musical instruments are built. For the reader to understand this module, they need to know that, for an object to vibrate freely, it needs to be held at points called vibrational nodes, referenced colloquially as sweet spots. When a pipe is held at a sweet spot, it produces a long musical tone; when it is held at other points, it produces a short "thunk!" sound (see Figure 1). A video of the pipes making these different sounds can be seen at www.listeningtowaves.com/ISLS. Building on this surprising phenomenon, this module alternates between children exploring how pipes vibrate and discussing their observations collectively.

Figure 1

How to hold pipes to produce sustained sound



Methods

We paid close attention to students' self-conception as science learners and doers as well as their sense of their potential to become members of (or their existing sense of membership in) a scientific community. The results of survey data addressing this question are outside the scope of this analysis (see Minces et al., 2021). Here we focus on students' thinking practices during project-based work (e.g., how students notice, investigate, and describe sound) and students' recognition of and/or attention to connections across school and daily life contexts. We gathered artifacts of student work, field notes from observations, and multi-camera video recordings of workshops. Our video analysis attended to student strategies, question types, negotiations among group members, responses to challenges, use of tools, proposed solutions, and descriptive practices. Our unit of analysis was the learning environment established through the project-based learning design. Our analytical goal was to understand whether and how the environment supported individual and ensemble engagements with science practice and identities and the degree to which personal interest in sound could become a bridge to personal interest in science.

LTW was implemented at a large urban middle school near the United States-Mexico border (87% Latinx, 8% African American, 47.5% English Learners, 91.5% low SES), involving 350 8th grade students. The program's duration was one month and was incorporated into the 8th-grade science curriculum, in which students learn about waves. We worked with each cohort of students for three two-hour sessions. We used grounded theory to categorize and code qualitative data (Glaser & Strauss, 1967; Charmaz, 1983). Our analysis identified four contexts across which embodied collective inquiry emerged: shared sensory environments, repurposed everyday materials, personal curiosity and awareness, and distributed social relations for learning. We then categorized three types of practices where students generated and sustained these relational contexts: a) manipulating the soundscape to notice new conceptual opportunities, b) expressing interest in sound, everyday objects, and peers' strategies, and c) embodied expressions of knowing to guide interpretation and meaning. Data revealed a distributed interest in contributing to one another's learning and accomplishing together.

Analysis

Data for this analysis comes from a series of Object Vibration Lab workshops given with six middle school science classes taught by three teachers. Each session was held in the school's library where the students were spatially positioned around six long tables arranged in a u-shape configuration, in such a way that they could easily alternate between attending to the facilitator and working together in small groups. In the vignettes described here, 26 students were seated as follows: 10 on the left, 10 on the right, and 6 at the base of the u-shaped configuration.

Video data highlighted two girls at the bottom of the frame in Camera 1 and four boys at the top of the same frame as well as four boys at the top of the frame in Camera 3, which was across the room from Camera 1 at a diagonal. All students in between were engaged in various similar modes of social engagement, making each other laugh, exploring, and listening. In the vignettes that follow, the activities described are exemplars of participants' observed experiences during the Object Vibrations Lab. These vignettes occurred roughly fifteen minutes into the workshop and were simultaneous, as is represented in Table 1. In general, the Object Vibrations Lab alternated between small group and personal exploration punctuated by moments of facilitated demonstration and brief instruction (e.g., defining terms, explaining observed phenomena, and guiding practice).

Public demonstrations: Exploring the movement of vibrations through objects

The opening experience of this workshop led students in this class to pause in surprise and good humor. The facilitator quietly picked up a pipe and a mallet (another pipe with duct tape wrapped around the end), and he began playing it. The tone rang out a few times and all of the students quickly turned their attention toward him, beginning to listen. A few students shushed each other. After playing a few times, he walked over to a group of boys visible in Camera 1 and handed the pair of pipes to Hugo (1), one of the boys who shushed his friends. Hugo tried and produced the unexpected "thunk" to quiet smiles (see Figure 1). He tried again and got a small ring out of the pipe, not quite as resonant as the facilitator's turn. The facilitator said, "pretty good," as he took the pipes and turned to offer them to another student, which led to the following exchange about five minutes into the session:

Student 1:	Me, me! [waving hands as facilitator silently held up a pair of pipes, offering another turn. Then, upon receiving them, he produced several muted "thunk" sounds causing giggles and looks of surprise around the room.]
Facilitator:	[He handed the pipes to a second student. Again, this student's effort resulted in several "thunks." A third student repeated this process to murmurs of, "Ooohhh."]
Student 4:	My turn, my turn, my turn…[reaching out for the pipes]
Facilitator:	Let me show you again. [He played the pipe several times with a wringing tone.]
Multiple:	Oh, Oh, Oh, Oh! [as if something just became clear to him]; You gotta…(inaudible); I got you. I got you! Four students then stretched out their arms, waving for the pipes; the facilitator gave them to Bianca, also visible in Camera 1.]
Bianca:	[She grasped the pipe lightly between her thumb and pinky a quarter of the way down, struck it lightly with the mallet a few times, and produced a sustained ring.]
Facilitator:	Oh, nice! [smiling and nodding]

Students around the u-shaped table were then watching intently as she made the resonant sound. The facilitator then continued to offer turns as students waved for a turn. More "thunks" were produced as surrounding students then began to offer them suggestions, as they sensed they had discovered the secret. It is important to note that the production of the soundscape as a learning environment emerged through a series of unmet expectations. Initially, the facilitator's first ringing tones garnered attention as if someone had rung a bell. However, when he handed the pipes to Students 1 and 2, and the tones were thunks, the successive inability to produce the same tone drew everyone's attention to a place of shared wonder. When the facilitator provided a second demonstration, the students began attending to three aspects at once: his body position as some noticed how he held the pipe this time (embodied practice), the quality of the tone that confirmed a sustained tone could be produced at will (the soundscape), and the pipes themselves as reliably resonant objects (repurposed material). A distributed desire to test their new ideas ran through the room, evident in the change in how they offered suggestions to peers.

Negotiating the soundscape as a learning environment

The next step in the workshop was to give every student a pair of pipes, with one fashioned as a mallet with duct tape wrapped around one end. Having experienced a collective mystery, the facilitator explained to the group that they would be exploring how things vibrate in advance of a future workshop where they would begin making musical instruments. He let them know he would eventually explain how to get the pipes vibrating in the most effective way, but first, students were encouraged to explore and discover different sounds they could make.

Students spent the next several minutes trying different ways to make sound with the pipes. Their attention was sustained, and they had to be interrupted for the next period of instruction. The sound in the room was a blend of the tinkling of metal, a series of thunks, and some sustained sounds. In many ways, it was like the sounds of windchimes on a windy day. The students worked together in small groups and independently when

taken with an idea. They effectively turned their shared environment, through the soundscape, into a space of relationship which came with mystery, aesthetic value, and the opportunity to test ideas and to theorize about the materials and how vibration moved through them. In so doing, the subtle possibility of becoming began to emerge. In Table 1, below, roughly one minute of simultaneous activity is presented in the table. The first row presents the facilitator's discussion. The second row highlights Diego, who was sitting to Hugo's left, was visible in Camera 1, and was called up to the front of the room to volunteer to demonstrate how to find the "sweet spots" that would allow sustained vibration. The third row represents Bianca, who played the first successfully sustained tone in the early demonstration, and her classmate, Maya. Simultaneously, students were engaged in personal exploration while negotiating their activity with peers as the facilitator offered instruction.

First, we note the negotiation that took place between Bianca and Maya. As the facilitator brought attention back to the front of the room to reveal the "nodes" that allow the most vibration to pass, also called sweet spots, Bianca continued to quietly play her pipes. While it was nearly inaudible on the recording, Maya clearly sought quiet to listen. To be clear, Bianca also signaled her interest in listening, keeping her eyes on the facilitator and trying out things the facilitator suggested. Likewise, the room was far from quiet during this bit of instruction. Sounds of quieted attempts to play the pipes continued. Maya, quietly and repeatedly muted Bianca's pipe with her hands. Eventually, as Bianca ignored Maya's efforts, Maya took all four pipes, and they laughed before returning attention to the front of the room.

Meanwhile, Diego and Hugo were engaged in a similar negotiation. They settled it by sharing the pipes and playing on each other's before turning their attention back to the facilitator. In each case, personal exploration was negotiated in tandem with peers, all the while, making sure not to miss the instruction about how to find the "sweet spots". As the facilitator sought a volunteer (Diego) to come demonstrate at the front of the room, negotiations were winding down. At the same time, the facilitator began comparing their pipes with instruments like the marimba and the xylophone, noting that the *keys* on those instruments are held at the nodes. The students signaled their readiness for more, quieting as a whole and observing the demonstration.

During the Object Vibration Lab, the learning environment, which can be influenced and changed, is the soundscape. It acts as a pull on students' practice and attention. The *shared* experience of delight or discovery worked to amplify the effects of experience. As the soundscape and the material (pipes) were reprioritized for more than pattern maintenance or extracting information, sound became available as a shared context for the pursuit of understanding, and in turn, began to extend meaning to acts of exploration that were distributed through the collective rather than grasped by individuals alone. In asynchronous or independent circumstances, persevering in the exploration of vibration through material and sound would take more effort to sustain. In socially supported circumstances, negotiating practices and processes of exploration granted momentum to the group. In other words, as practices emerged to respond to the change in the role of the soundscape, so, too, did the possibility of becoming part of a new way of knowing through practice. Their practices mattered personally and also socially. They were acting as curious explorers in search of patterns, surprises, and beauty, in addition to agreed-upon understanding. In that sense, the possibility of being part of science practice opened the subtle possibility of becoming a member of a science-oriented community, in an embodied and sensory-based way.

Table 1

Finding "Sweet Spots" together – material + soundscape

Time →	*15:07*	*15:13*	*15:17*	*15:23*
Facilitator	"So, the pipes have two sweet spots. Now, when you see a marimba or a xylophone, you'll see that the keys are held at these two specific sweet spots."		Facilitator looked to Diego, gesturing toward him and asked, "What's your name?" He responded, "Me?" "Yeah." "Diego."	"So…so…[pause to await Diego's arrival at the front and give the group time to quiet down]…So, Diego will be holding the keys at the sweet spots. Okay?" Facilitator gestured with both hands as if a pipe was resting on the thumb and index fingers of each hand.
Cam 1 Boys including Hugo &	Diego played two pipes, holding one upright in left hand a little above the "sweet spot" while tapping	As Hugo quietly tapped his other pipe, holding it near the node and smiling, Diego	"Can you come help me out, Diego?" Facilitator invited Diego to the front of the room.	Diego stood by, facing his classmates from the front of the room and smiling.

Diego (volunteer)	with the other. Hugo, who only held one pipe, also upright in the left hand, reached for one of Diego's. At first, Diego pulled it back and laughed, then gave it over.	reached over with his own pipe and tapped Hugo's once. He then turned to the front of the room. A moment later, the facilitator looked over.	Diego rose from his chair saying, "Yes, en inglés."	
Cam 1 Girls including Bianca & Maya	Bianca held one pipe vertically near the node with her left hand while tapping it lightly with the mallet, keeping her eyes on the facilitator.	Maya watched the facilitator. Without looking at Bianca, she took hold of Bianca's pipe and laid it on the table.	Bianca immediately picked it up again. Maya repeated the action, taking the pipe and setting on the table, this time sparing a brief glance directly toward her friend.	Bianca picked up the pipe again, and, again, Maya took the pipe saying, "stop." She then took all four pipes, and they chuckled. Both then turned their attention to the front of the room.

Aligning "felt" aesthetic experience with emergent science-rooted & personal identities

At this point, the facilitator began explaining what nodes are and how they function in a vibrating material, such as the pipes in students' hands. The explanation was both modeled and embodied. Having received the first signals of possibility when students struggled to produce sustained tones, and having explored on their own and in small groups, the students could hear and experience for themselves that finding the "sweet spots" signaled a subtle relationship between vibration and material. With Diego volunteering, the students were about to learn that each pipe had two nodes. They explored this idea, mimicking holding their own pipes at the nodes while watching Diego and the facilitator model the practice at the front of the room. At the same time, they began to negotiate the aesthetic value of the various sounds they produced. They began a pursuit of beauty, first encouraged by the facilitator in describing the workshop and attempting to make connections with their own aesthetic judgements.

Facilitator: First, um, can you put your fingers like this? [holding palms upright 6 inches apart, pinching thumb and forefinger together.] [Diego's hands were in his pockets and eyes were on his feet. Then he matched the facilitator's gesture while his friends smiled and chuckled.]

Facilitator: Perfect. Okay. Hold steady, okay? [He then placed the pipe on Diego's fingers as Diego laughed and glanced toward this friends.] First I will put the pipe on [pause]…Diego is holding it at points that are not sweet spots. [Diego slightly bent his knees and then stood upright in acknowledgment of not being on the nodes.]

Facilitator Now check this out. [He repeatedly tapped the center of the pipe causing "thunks."]

Diego: Muy feo. [Diego stated this playfully as he shook his head. The facilitator nodded in appreciation.]

Facilitator: Yeah, you couldn't really hear it, right?

Student 5: "I like that!" [stated definitively in swift counter-response to Diego's assessment.]

Facilitator: So now, I'll move you to the sweet spots. [As he repositioning Diego's hands until he held the pipe at the nodes, another student leaned forward for a better view.]

Student 6: Oh, yeah!

Facilitator: "Let's see what happens." [The room quieted briefly. The facilitator struck the pipe one time, and it rang in a sustained way.]

Diego: Hermoso. [He nodded and smiled at the facilitator with a knowing look who thanked Diego and let him return to his seat.]

Then everyone began, again, to explore in earnest. It is notable that their connection with the learning environment and available materials continued with gathering momentum. Rather than experiencing a loss of interest once the initial mystery was explained, the students continued to study patterns of sound and vibration personally, among peers, and through observations of other's approaches. When Diego returned to his seat, the boys in his group smiled at him in acknowledgement. Having explained that the nodes, or sweet spots, could be found one quarter length from either end of the pipe—which they had begun referring to as *keys*—the facilitator

encouraged everyone to play for a few minutes and suggested playing in pairs using both nodes. Hugo held his pipe at the node, and began to play rhythmically as a kind of performance for himself and the room. He danced along as he played, and the boys nearby began to pretend to play along (acting as if they were drumming their pipes together but not quite striking them…like playing air guitar). While others had been striking their pipes in the cacophony, this stood out as intentionally musical. This sound carried, and others across the room joined in, un-choreographed and seemingly unintentionally. For instance, a group of boys on the other side of the room, visible on Camera 3, were finding the nodes when one of them suddenly pretended to play the pipe in rhythm like a drum. This occurred as rhythmic sounds echoed from Hugo's pipes across the room.

These subtle processes of generating alignments between embodied sensory experiences, personal aesthetic preferences, and the discovery of new conceptions of relationships between sound, material, and environment positioned students in an emergent relationship with their own ways of knowing and validation of their practices in ways that related to the ways professional scientists experience, discover and explore the world. The satisfaction of new discoveries for the students was evident in their consistent drive to share findings, and their continued openness to receiving instruction that enhanced what they were already inclined to do in their explorations of material. For many of the students who participated in LTW workshops, recognized science identities seemed inaccessible, as described in pre- survey data. LTW opened student-driven opportunities for just-in-time feedback from their own practice, peers, and a pedagogical design that aligned their practices, strategies, and interests with what scientists do and what science aims to achieve. It was subtle yet meaningful.

Discussion

The design of Listening to Waves consistently brought students to awareness of a shared soundscape that was part of each of their daily lives, and therefore accessible and familiar. As with the start of typical classes, students quieted and oriented toward the facilitator, an act of respect that grants a limited use of the soundscape for the collective. The designed practice—to model the use of two small metal pipes to produce a sustained resonant tone and then to invite student after student to do the same—produced a shared response of wonder and curiosity. When everyone witnesses the same action and result and then, each in turn, fails to produce the same effect, the everyday nature of sound and material produces access to a new conceptual context, and in turn, a site of inquiry (see Table 2). In Table 2, we note the ways that observed practices began to overlap across four relational contexts students generated over time. It was collective experience that amplified curiosity that could power active engagement.

Table 2

Becoming an embodied collective in inquiry

Shared sensory environment	*Everyday materials repurposed*	*Personal curiosity validated*	*Social relations validated for learning*
Noticing a new conceptual opportunity			
	Everyday objects organize & coordinate attention		
		"Felt" ways of knowing guide interpretation & meaning	

As a connection was established between familiar experience and conceptual opportunity, students were subtly made aware that everyday objects presented renewed sites for learning about interactions between sound and materials as vibrations and then as waves. The subsequent modeled repurposing of everyday objects both as unexpected conduits for novel sounds and as an introduction to the world of waves that had previously been invisible, organized students' attention in two ways. First, it returned attention to their embodied experience of learning. They were free to touch, tap, blow, roll, slide, pluck, and generally manipulate everyday materials for aesthetic interest, guided by their own curiosity. Second, it validated their social engagements as part of their inquiry practices. They readily observed and adopted each other's strategies in their inquiry process. They invited both peers and teachers to join in their discoveries. They sought mutual recognition of the beauty and wonder they were discovering as well as validation of their practices for investigating the possibility and producing sound. As they shifted their conceptual awareness of the shared soundscape, and in turn, experienced repurposing everyday materials to explore vibrations and waves through varied materials, their personal curiosity, or lack thereof, and their social worlds became increasingly valid resources for pursuing their learning. Exploring together in person, in shared space, with this pedagogical design strategy functioned like an accelerant to making science-related experiences of the shared environment and, in turn, science-related identities accessible. We, in turn, conceptualized the notion of *harmonized mutual development* defined as a process in which individual explorations of a shared environment yield an increasingly integrated intellectual practice allowing individuals to

develop and mutually align their inquiries toward a collective practice of becoming, much like what is experienced by individual musicians who form musical ensembles.

Harmonized mutual development was a possibility we sensed as we observed during LTW. As we analyzed the data with a developmental frame, important aspects of students' participation were obscured. Rather than individual processes of internalization, we recognized mutual instances of becoming. When we can understand and clearly signal what harmonized becoming can look like, the competitiveness and stage-based performance demands can be lessened, and the whole group can move at an accelerated pace toward both content knowledge and access to alignment as a full participant in science worlds—not only to pursue careers, though that path is more available through removal of self or system imposed exclusion. Students can begin to move beyond identities like, "I'm just not a science person." Instead, young people can move into mutual engagements that amplify and accelerate sites of becoming. Here, we are concerned with the ways young people come into contact with science learning as a process of engaging their experiences in the world with sustained wonder, curiosity and an awareness of the presence of potential beauty. We argue that embodied collective inquiry generates conditions for harmonized mutual development.

Disciplinary Design and Design Thinking in Scientific Inquiry

Leslie Atkins, ShaKayla Moran
leslieatkins@boisestate.edu, shakaylamoran@u.boisestate.edu
Boise State University

Abstract: Design thinking (DT), strategies from engineering and business for designing, is gaining traction in education. However, little attention has been paid to how design heuristics and techniques may be domain dependent, particularly in cases where the designed artifacts address epistemic goals in disciplinary communities. In addition, authentically engaging in DT strategies may be challenging in classrooms where outcomes are focused not on students' novel solutions but acquisition of canonical content. This paper describes why we might anticipate DT to be generative outside of engineering and business contexts, and why we might anticipate that disciplines will have unique strategies for design as well. We present one case of a design generated by undergraduate students in scientific inquiry, with a focus on how design problems emerge and challenges and successes students meet in designing solutions.

Overview

Design thinking (DT) (Brown, 2008) is receiving increased attention in education in general (Razzouk & Shute, 2012), and in STEM education in particular (e.g., Li, et al, 2019; Goldman & Kabayadondo, 2016; Chin, et al, 2019). While models of design thinking exhibit heterogeneity, they all share an emphasis on methods for creating solutions to complex, real-world design problems for which there is no one "right" answer. The approach is promising for a range of reasons: the strategies of design thinking, as Chin, et al., (2019) point out, may help novice designers avoid "tendencies that can inadvertently interfere with effective design." In addition, design thinking in education positions students not as reproducing known solutions to acontextual problems, but as active participants in the construction of novel solutions to genuine problems sensitive to context. And while design thinking is an approach developed in engineering and then business (Razzouk & Shute, 2012) with the goal of improving designs of products for consumers, all disciplines engage in some form of design (e.g., Li, et al, 2019). Scientists, for example, could be considered uniquely adept designers of scientific models, experiments, and representations, to name but a few artifacts produced in the process of scientific inquiry.

At the same time, it's reasonable to expect that design thinking may require adaptations, as strategies for generating and evaluating designs may look quite different in different disciplines. For example, the emphasis placed on a "user-centered, empathy-driven approach" (Goldman & Kabayondo, 2019) is not as relevant to the experimental designs a scientist creates in a lab where the user is the scientist. Prototyping may look quite different for experimental designs where a rough design is often good enough. And constraints, often construed as material, financial or temporal, may instead be driven by disciplinary aesthetics, conventions and conservation laws. So while DT points out the importance of explicit attention to how disciplinary artifacts are designed, it is also the case that disciplines have unique techniques and attending to those is critical for developing design thinking in settings outside of engineering and business. The broad research agenda behind this paper is articulation of what disciplinary design thinking in science (particularly physics) looks like.

In science education research, a range of constructs make contact with DT. "Developing models," "constructing explanations," and "obtaining and communicating information," from NGSS represent designed artifacts. And these practices position students as designers: developing, constructing and obtaining. And so the strategies for meeting those standards may point towards design thinking processes that are productive in science.

But in most instantiations, these artifacts are not students' designed solutions to complex problems of science (e.g., Stroupe, 2014). Instead, curricula often expect that the students will recapitulate the "disciplinary core ideas" of NGSS. This seems almost inescapable. As Li, et al (2019), note, "design activity … can be easily perceived as creating new terms and procedures, activities often viewed as belonging to professional mathematicians and scientists, not students." This stands in contrast to an engineering course, in which it is not just *anticipated* but *expected* that design thinking will generate truly novel designed artifacts; science courses expect students to converge upon sanctioned solutions, as highlighted by Miller, et al (2018).

Novel design in scientific inquiry: Background and methods

The study takes place in a semester-long junior/senior undergraduate course on science research for future secondary STEM teachers (Atkins & Salter, 2015, Atkins Elliott, Jaxon & Salter, 2016). The broad goal of the course is engagement in scientific inquiry, which we define as the pursuit of coherent, mechanistic models of

 © ISLS

natural phenomena (Hammer & van Zee, 2004). We generally start with a puzzling phenomenon (e.g., a spring-driven clock) or question (e.g., is every color in the rainbow?), and, through mediated class conversations, small group work and individual work, make progress towards modeling the phenomena.

Over several iterations of the course, materials and designs made with those materials emerged as a critical, and undertheorized, aspect of students' activity. For the purposes of this research, we consider **design in science** as designed solutions to open-ended problems that arise in the pursuit of mechanistic models of natural phenomena. And we define **design thinking for science** as novel practices and strategies that support powerful and epistemically appropriate designs in response to those problems. Finally, the types of design challenges we are interested in are those that are **emergent from and in service of students' epistemic goals**. While designs need not be physical artifacts, for this paper we will limit our discussion to those.

We ask the following questions of these artifacts: **(1) When do opportunities for design in science emerge in students' scientific inquiry? (2) What challenges do students face in developing solutions to those problems?** and **(3) What "design thinking" strategies lead to productive design solutions in light of those problems?** In this paper we focus on the first two questions, and make conjectures for the third.

Research methods & definitions

Data: All class sessions are taped, artifacts and student work and lab notebooks are photographed, and field notes collected. To characterize extended periods of design thinking, we begin by identifying novel and complex designed artifacts, as described below, and then constructing design narratives around those objects.

Identifying designed artifacts: identifying a novel designed artifact is a gray area; even copied designs often contain some differences. For this study, we were interested in characterizing **designs that are prolonged, intentional, novel designs by students in pursuit of scientific problems.** We began by purposeful sampling, based on field notes and images, ultimately identifying 14 designed artifacts for closer analysis.

Design narratives: For these artifacts, the researchers developed, through field notes, images, and video, narratives of the designs. The narratives considered: initial design problems students sought to solve or goals for the artifact, its relationship to our ongoing modeling of phenomena, designed solutions, iterations and outcomes.

Designs in Scientific Inquiry

Below we highlight one example of design from the course: a design that is a novel, student-developed solution to an open-ended, emergent problem that also highlights tensions and challenges for productive design. Due to space limitations, we do not offer detailed moment-by-moment interactions that produced the designs, instead offering an overview of the driving questions, challenges and revisions that took place.

Corrugated surfaces: a series of designs to select between models

Context: This semester, the course focused on energy, beginning with the observation of a Gauss Gun: a simple arrangement of metal ball bearings and strong disk magnets. When an incoming ball is released, it accelerates towards the magnet, strikes it, and an outgoing ball is ejected at great speed. The sudden appearance of kinetic energy is surprising and begs explanation, and offers a rich context for modeling energy for a range of disciplines (Atkins Elliott, Sippola, & Watkins, 2018; Atkins Elliott, et al., 2019).

One student group argued that the magnet itself must supply the energy to the outgoing ball, and thus predicted that the ejected ball would leave at a higher speed than the incoming ball. Other groups disagreed. With a skeptical audience for their claim, the first group sought to determine the two speeds. Here, the design question of how to measure the speed of an object that gains and loses speed very rapidly became the core activity of their group over multiple weeks.

Designs: This group began by using a slow motion setting on their phone camera. However, the data was too blurry to make any claims; better cameras did not solve the problem. They then decided to slow down the "reaction" in a viscous fluid (syrup) and record this. While the reaction was slower, it was qualitatively quite different. They attempted to have the incoming ball fall just before striking the magnet and determine the speed from its trajectory, but the attraction was too great and the ball would not fall, but stick to the magnet. Motion detectors brought in from the undergraduate physics lab were not sensitive enough. The group then thought to roll the balls over a ridged surface and listen for a sound - anticipating that the audible "prtrtrtrtrtrt" sound would indicate speed and answer the question. After trying to use readily-available evenly-ridged surfaces (computer cds), which were not loud enough to analyze, they strung fishing line across a track at regular intervals, but the ridges were too far apart to capture changes in speed. This inspired them to 3-d print ridged surfaces.

The sound was not audibly different, and so the students went to a recording lab on campus. One student processed the waveform of the audio file, expecting that the peaks of the waveform would represent the

ball striking a ridge, allowing the group to calculate the time between strikes and therefore the speed of the ball. The waveform, however, was more complicated than expected, and peaks did not always represent the striking of a ridge. By this point, the other two groups in the course had convincing arguments against this group's model (relying on an argument from conservation of energy), and the group abandoned their efforts.

Findings & future directions

Opportunities for design in scientific inquiry

In the brief case presented above, and in most of the cases selected for our study, we notice the following relationships between scientific inquiry and design opportunities that address the above, *When do opportunities for design in science emerge in students' scientific inquiry?*

1. **Dissent can present a rich opportunity to engage in design**. When students developed different models of phenomena, they readily recognized that empirical evidence could serve as an arbiter, and turned conceptual problems ("which model best describes this phenomenon?") into design problems ("how do those models differ in observable ways, and how do I create that observation?"). We expect that it is not only the curiosity and/or confusion generated by competing models that drives students' engagement and persistence in the design (e.g., Watkins, et al, 2018), but social interactions as well: there is a genuine and skeptical audience for the claims they develop. In this way, the grasp of practice that Ford (2008) identifies, wherein scientists are constructors and *critiquers* of claims, is not imposed but emergent from the activity. Students are genuinely skeptical, even critical, of their peers' ideas and experimental designs -- driven by, and speaking to, that skepticism and critique -- offer a relatively objective arbiter.

2. **Designs themselves can generate novel design "sub"problems**. Nascent designs often contain components, some of which require their own (relatively self-contained) designs. In the example above, we see students who have the design goal of measuring speed with a slow-motion camera, engaged in creating a version of the experiment submerged in syrup. Later, the design problem was how to print a ridged surface.

3. **"Failed" designs generate novel design challenges.** Designs, of course, frequently do not fully work as anticipated. As Pickering (2010), notes, the world can offer "resistance," refusing to participate in anticipated ways, and requiring accommodations by the scientists in what he describes as the "mangle of practice." In this "mangle," we see students needing to change course, with novel designs or problems. The need to arbitrate between models became a need to measure speed, which was revised to be a way to measure sound. And designs frequently do not fully work as anticipated, with components requiring re-design.

Challenges encountered in addressing design problems

When we consider the second question, *What challenges do students face in developing solutions to those problems?* we note the following:

1. **Invisible content knowledge demands:** In the case presented here, students' designs would be strengthened or facilitated (or even obviated) by additional content knowledge. And while we value developing content knowledge in authentic contexts, where students' goals require developing the ideas, we note that students themselves did recognize their lack of knowledge (e.g., that white paper does not function as "nothing" but is reflecting the light back through the filter).

2. **Lack of familiarity with common tools or designs**: Seeing students struggle with long-solved problems (e.g., a ballistic pendulum for speed measurements), and contrasting this with their use of familiar tools (e.g., a 3-d printer), highlights the value of introducing tools, particularly ones that can be flexibly used in a range of scenarios.

3. **Lack of necessity for experimental designs:** Again, in the case presented here (and in several others) we note that there are strong scientific arguments to be made that would obviate the need for an experimental design. Frequently we see students readily turning what could be basic conceptual problems into complex empirical ones.

Disciplinary design thinking in science

We now offer some brief speculation on design thinking for science-- particularly in experimental design. First, we anticipate a tension, as noted above, between supporting students' own designs and building familiarity with standard practices that facilitate more complex designs. We also anticipate that attending to the role experimental design plays in selecting between models will require attention to statistical reasoning from data, which has not been a part of our course. Finally, we note that students often quickly engaged in constructing designed solutions when theoretical solutions (e.g., conservation of energy), which do not require additional empirical data, may be more efficient. Having more extended experience in design throughout their science

education may have prevented some of the theoretically and experimentally "clumsy" mistakes that students made in these and other design scenarios. It also positions students as designers of scientific ideas, who create authentic and unique solutions to scientific problems.

At the same time, we note that "failed," unnecessary, or inefficient designs are not synonymous with unproductive activity or a lack of progress; they can point students toward important theoretical ideas, reify those ideas in important ways, or strengthen connections between theory and evidence. Moreover, as noted in Pickering (2010), failed designs are common in science and part of the rich mangle of practice. Constructs in the math and science education literature, such as productive struggle (Warshauer, 2015), productive failure (Kapur, 2010), and invented science (Russ & Berland, 2019) highlight this distinction, and suggest further research to better articulate the value of engaging in design in scientific inquiry and identifying potential benefits and drawbacks of students' failed designs.

Epistemic Commitments: A Lens for Heterogeneity in Science

Ashlyn E. Pierson, The Ohio State University, pierson.199@osu.edu
Corey E. Brady, Vanderbilt University, corey.brady@vanderbilt.edu
Douglas B. Clark, University of Calgary, douglas.clark@ucalgary.ca
Pratim Sengupta, University of Calgary, pratim.sengupta@ucalgary.ca

Abstract: Research about modeling emphasizes the importance of heterogeneity in science, yet also seeks curricular convergence. In response, we propose two constructs. *Heterogeneity-seeking curricula* emphasize multiple representations of phenomena, offering an image of science as messy and nonlinear. *Commitments* parallel epistemic cognition by focusing on values that shape students' modeling; however, rather than looking for disciplinary practices in students' modeling, we take students' values as a starting point to articulate commitments. Using commitments, we analyze six implementations of a heterogeneity-seeking 6th grade modeling curriculum, comparing commitments to epistemic criteria and considerations.

Objectives and significance

Research about modeling in science classrooms highlights the importance of heterogeneity in science learning (Rosebery et al., 2010), emphasizing the complexity involved in developing scientific expertise (Pierson et al., 2021; Jaber & Hammer, 2016; Manz & Suárez, 2018). At the same time, a growing body of scholarship seeks curricular pathways for convergence of epistemic and representational practices (Barzilai & Chinn, 2017; Berland et al., 2016; Reiser et al., 2021). In this paper, we amplify the productive tension between heterogeneity and convergence with two constructs. *Heterogeneity-seeking curricula* emphasize multiple perspectives of phenomena across representational forms. Though we acknowledge shared understandings are essential for classroom praxis, in a heterogeneity-seeking classroom, knowledge products constitute an emerging, shared vocabulary that gives voice to students' ideas and questions rather than being end-points of inquiry. *Commitments* offer a lens for exploring the values that motivate and inform students' interactions with models and with one another. Our notion of commitments, paralleling epistemic cognition, focuses on students' values. However, whereas epistemic criteria (Pluta et al., 2011) and considerations (Berland et al., 2016) look for disciplinary practices in students' modeling, commitments take students' values as a starting point, mapping them to disciplinary resources that are sometimes overlooked in classrooms. These constructs offer lenses for noticing and capturing the discursive life of models in a classroom community by emphasizing students' values and ideas, problematizing how phenomena have been positioned as objective and external to students' modeling work (Reiser et al., 2021), instead showing them to be a production of the classroom's discourse.

Conceptual framework

Though "commitment" has been used in varying ways (e.g., Chinn et al., 2011), we conceptualize commitments as fine-grained resources (Hammer et al., 2005) that shape how students use, value, and learn from models. From a resource perspective, commitments are activated and expressed by individuals in response to conceptual and social contexts (Elby et al. 2016). Yet, commitments do not reside solely in individuals; at a group level, emergent epistemologies are jointly constructed and reconstructed from resources within communities of practice (Goodwin, 2018). As a result, individuals can enact and display sometimes-conflicting commitments (Clark, 2006; diSessa et al., 2004), including those that represent their membership in multiple communities (Bang & Medin, 2010). We propose that commitments can function in some similar ways to the "ideals" of the apt-AIR epistemic cognition framework (Barzilai & Chinn, 2017), though their role for researchers and for students extends beyond epistemic cognition. As an analytic lens, epistemic cognition frameworks take disciplinary values as a starting point, searching for forms of these values in students' work (e.g., Berland et al., 2016). In contrast, commitments take students' values as a starting point (identifying students' values and mapping these commitments to disciplinary constructs). This perspectival shift opens analysis to a wider range of students' resources that may not align with science education's normative conception of disciplinary values. We distinguish between these lenses in three ways. First, because commitments emerge from students' modeling activities, they include material and phenomenological aspects that are backgrounded in research about epistemic ideals. Second, while some commitments in our data aligned closely with primary epistemic ideals, others would be considered "secondary," "vague," "nonepistemic," or "less sophisticated" using existing frameworks for epistemic criteria (Pluta et al., 2011) and practical epistemologies (Berland et al., 2016). Third, commitments played different roles for students' modeling than epistemic ideals; rather than only being used to evaluate models, commitments were also used (a)

 © ISLS

to explain why or how one model should inform another, (b) to position models as complementary, and (c) to relate models to broader contexts. In the context of this heterogeneity-seeking curriculum, we use a resource-focused lens to ask two research questions: What commitments emerged that influenced students' modeling? and, How can a lens of commitments help science education researchers identify and analyze students' values and their role in modeling?

Method

We analyze data collected during a design study (Cobb et al., 2003) that iteratively refined a modeling curriculum about ecosystems. This study was conducted in a public middle school in a small suburban school district in the southeastern US in collaboration with a STEM teacher, Ms. S. Six of Ms. S's 9-week 6th grade classes participated (August 2018 to March 2020, 105 students total). From each class, 5-6 students were selected by the 6th grade teaching team as representative of their peers, and these students were interviewed about their experiences in the unit. All iterations of the curriculum foregrounded modeling. Throughout the unit, students were instructed to create diagrammatic, physical, computational, and embodied models. The unit was framed by two design challenges: students designed a biosphere, a closed-system physical model that included plants, snails, and guppies (a typical pet fish in the US); and they programmed a computational model that represented a larger ecosystem of plants, snails, guppies, and guppies' competitors and predators. Throughout the unit, the students gathered information and iteratively re-represented the guppies' environment with increasing complexity. We analyze focal student interviews and whole class discussions to identify students' commitments and how they shaped students' modeling using inductive coding (Charmaz, 2006). To identify commitments, we transcribed interviews and whole class discussions with turns of talk as the unit of analysis. We created initial coding categories in part based on students' language (e.g., "real world"). We compared these categories to studies of professional science and to research about epistemic ideals in science classrooms. In this paper, we have grouped commitments into categories (see Findings). This structure is not hierarchical (no commitment is considered more "sophisticated" than the others), and these commitments could be named and organized in a variety of ways; thus, rather than focusing on the relationship between these four commitments, we focus on the nature of these commitments and their role in a heterogeneity-seeking modeling curriculum.

Finding: Commitments

In interviews, most focal students (26 out of 33) valued connecting their models to the **"real world."** This commitment maps to several epistemic criteria. From Pluta et al. (2011), it maps to the primary criterion of "accuracy" ("how faithfully the model depicts the target") and the secondary criterion of "realism" ("use the word real"). In prioritizing representing the real world, some students' responses also map to the primary criterion of "explains-2" (Pluta et al., 2011), because they value models that "show how and why" (Carlos: "how a giant biosphere works"). From Berland et al. (2016), valuing models that "show how and why" addresses the question, "What kind of answer should our knowledge product provide? (Nature [of account])" (p. 9). Explaining "how and why" suggests a mechanistic account, which Berland et al. have characterized as "more powerful" for constructing and evaluating knowledge" (p. 13) compared to a descriptive account (Carlos: "tell how it looks like"). In contrast, in our data, students did not always prioritize mechanistic accounts; for example, Caleb wanted to explore a descriptive question: how much oxygen a guppy needs.

A majority of focal students (24 out of 33) also valued models that could **"show"** phenomena to themselves or others. The commitment to seeing and showing phenomena maps to several epistemic criteria. Like the commitment to real-world, seeing and showing in some cases connects to "explains-2" (Pluta et al., 2011) and "Nature of Account" (Berland et al., 2016), because students valued models that showed mechanistic explanations (e.g., Nora: when algae are spread out, guppies die faster) although they sometimes also appreciated descriptive accounts (e.g., Nora: "more environmental" food web representation). This commitment also connects to "clarity" ("model is easy to understand;" Pluta et al., 2011, p. 496) and "audience" ("Who will use our knowledge products and how?"; Berland et al. 2016, p. 9).

Several focal students also valued models that enabled them to **"control"** variables by holding them constant or to "change" variables by manipulating them (15 out of 33). This commitment overlaps with several epistemic ideals about evidence; however, whereas these epistemic ideals are primarily evaluative, students in our classroom typically foregrounded controlling and changing variables when they were designing models. In a convergence-seeking curriculum, students might evaluate a model by considering the quantity and quality of evidence that was included ("quality of support" and "accuracy" in Pluta et al., 2011; "Nature of account" and "Justification" in Berland et al., 2016). In retrospective reflections, students' commitments functioned in a similar, evaluative way (e.g., Carlos: "it was kind of like testing soil differently"). Yet, as they were designing or using models, students more often emphasized affordances for investigations (e.g., David: "the computational model

won't go wrong unless you tell it too"). This forward-looking stance toward models positions models not only as "knowledge products" that can be evaluated but also as generative tools for exploring ideas.

Over half of the focal students (18 out of 33) voiced a sense of responsibility to **care** for the plants and animals in their biospheres or for the species or environments represented by their models. Caring for model components and their referents influenced how students thought about designing, using, and learning from models. There is no analogous epistemic ideal in Pluta et al. (2011) or in Berland et al.'s (2016) epistemic criteria or considerations. While Barzilai and Chinn's epistemic cognition framework includes affective and ethical dimensions (e.g., "caring about… epistemic performance" and "aspiring to epistemic justice;" 2017, p. 13) based on research that demonstrates that science learning is inextricably intertwined with students' *epistemic* affect and *epistemic* motivation (Jaber & Hammer, 2015), these aspects are narrowly focused on the production of (disciplinary) knowledge rather than broader axiological dimensions of learning.

Discussion: Nature and role of commitments

In these classrooms, commitments functioned as resources (Elby et al., 2016; Sandoval, 2005). Students' commitments were pressing but unstable (interpreted and enacted differently by different students and by given students at different times). Commitments were also linked to models in a perspectival, rather than an inherent, way (took on different meanings for different students in relation to models). As a result, commitments were not a "property" of models or of students – they instead influenced how students valued and interacted with their models. In our data, commitments functioned in *some* ways like epistemic ideals by acting as evaluative resources during modeling. Yet, because each of these commitments connects to different, yet overlapping, aims, commitments were not hierarchically ranked. As a result, we would not expect to see students' progress toward "sophisticated" (Krist, 2020) or "primary" (Pluta et al., 2011) commitments, as they might with epistemic ideals. And because commitments were not stable across models, we also would not expect to see students develop a shared set of criteria that could be used to evaluate models generally, an activity common in convergence-seeking curricula (Pluta et al., 2011; Ke & Schwarz, 2021). Instead, a lens of commitments emphasizes making connections across multiple representations and ways of knowing (Warren et al., 2020).

First, students used commitments to justify one model informing another. For example, Karla suggested using the plant investigation to inform the computational model. She explained that students "did not really use [the plant investigation] as much as they needed to" to make the computational model "accurate with real life." In other words, she wanted to use the plant investigation to strengthen connections between the computational model and the ***real world***. In other cases, students saw the computational model as informing the design of "real" models. For example, Nataly used her computational model to imagine the guppy in her biosphere jar; her commitment to ***caring for*** the guppy helped her empathize with the guppies. Because she was concerned that the computational guppy looked lonely, she suggested her group include two guppies in their jar.

Second, students used commitments to position models as complementary–by connecting their own models (of different types, e.g., computational, food web), and also by connecting their models to their classmates'. For example, Lacie characterized all her models as "helpful because, like, you can find out different things." She described how she could ***change variables*** in the computational model ("make guppies do what you want them to do) and explained how she could ***show phenomena*** in the food web ("helps you show, like, what they're gonna eat"). Students also positioned models of the same type as complementary. For example, when Nora and Sean presented their food webs, rather than positioning one model as correct, they described how each group's model ***showed*** different perspectives of ecosystems (Nora's "energy pyramid" and Sean's "more environmental" model). Just as commitments were not ranked hierarchically, models were not seen as competing with or replacing other models. Instead, each model offered new perspectives that contributed to an assemblage of representations that became more valuable as models and perspectives were incorporated.

Third, students used commitments to relate their models to other experiences. For example, Wade wanted to give the plants "a chance at life," and Dolores and Hunter suggested that the biospheres could teach guppies how to "survive on their own in the wild." In these cases, a commitment to ***caring*** guided how students interacted with their models. Commitments also helped students think about why models might be used to investigate phenomena. For example, Micah explained that a scientist would need to "test the stuff on the computational model and do it in real life [in a biosphere] to see how the effects would turn out… so you don't mess up the river," explaining how the models could be used to protect ***(care for)*** populations in a river. As in these examples, students' commitments helped them consider the roles of models in the outside world.

In summary, while commitments aligned in some cases with epistemic ideals, their roles in these classrooms extended beyond those of epistemic ideals. Epistemic ideals are used to evaluate models. They support convergence-seeking aims by providing students with agreed-upon standards for developing and assessing knowledge. To this end, they guide students in creating mechanistic and "gapless" explanations (Ambitious

Science Teaching [AST], 2014, p. 3), producing abstract and generalizable knowledge (Berland et al., 2016), and justifying claims with evidence (Krist, 2020; Pluta et al., 2011). These are important goals for epistemic education (Barzilai & Chinn, 2017) that can help students appropriate powerful disciplinary practices. However, exclusively foregrounding these goals for epistemic education could limit the values that students use to navigate their STEM learning. Our data indicate that students can draw on a broad range of values to guide modeling, which sometimes resemble professional practices that are backgrounded in science education.

Multimodal Data Fusion to Track Representational Flexibility of Adolescents with Autism Spectrum Disorder during Virtual Reality-Based Training

Jewoong Moon, The University of Alabama, jmoon19@ua.edu
Fengfeng Ke, Florida State University, fke@fsu.edu
Zlatko Sokolikj, Florida State University, zs09f@my.fsu.edu
Shayok Chakraborty, Florida State University, shayok@cs.fsu.edu

Abstract: We implemented multimodal data fusion to develop a prediction model tracking representational flexibility (RF) of adolescents with autism spectrum disorder (ASD) in virtual reality (VR)-based training. RF is a key competency related to individuals' capability to select, coordinate, and create alternative representations inherent to STEM subjects. To promote ASD adolescents' RF development, research has used VR-based 3D simulation design tasks. However, it remains a challenge to track ASD adolescents' RF development during VR-based training. Using supervised machine learning, we implemented decision-level data fusion with RF evidence from multiple data sources. To train the model, we used a total of 178 audio- and screen-recorded VR training sessions of eight ASD adolescents. We compared model performance metrics of several candidate classifiers. Methodological details, findings, and implications of multimodal data fusion will be discussed.

Keywords: Multimodal data fusion, virtual reality-based training, autism spectrum disorder, representational flexibility

INTRODUCTION

Adolescents with autism spectrum disorder (ASD) are underrepresented individuals in STEM education. ASD features developmental delays that include cognitive and social skill challenges that cause difficulty in STEM education. ASD learners typically lack representational flexibility (RF), which is a competency related to individuals' ability to choose and execute various representations inherent to STEM subjects. Researchers stated that RF leads to deeper understandings of multifaceted and complex tasks in STEM education. However, they have difficulty in developing RF. Recent research has introduced virtual reality (VR)-based training to foster ASD adolescents' RF development. VR enables students to experience various 3D design tasks and these design tasks can foster students' representation practices. However, it remains an open question regarding how to track ASD adolescent's RF development during VR-based training. Given that ASD adolescents' cognitive-affective states are dynamic, it is essential to track their needs to provide ASD adolescents with timely and adaptive learning supports during VR-based training. There is a lack of empirical research tracking ASD adolescents' multimodal interactions during VR-based training. This study aims at developing a prediction model that tracks ASD adolescents' RF development using a multimodal data fusion approach. The primary research question is: how does multimodal data fusion predict ASD adolescents' RF development during VR-based training?

Literature Review

Representational flexibility in integrated STEM education

RF is an individual's cognitive capability to switch attention and choose different modes of representations for knowledge comprehension (Herbert & Hayne, 2000). RF enables an individual to understand, reproduce, and apply knowledge to adjust problem-solving behaviors and solutions to surrounding circumstances. STEM practices typically require students to perform knowledge synthesis and application through multiple rounds of problem-solving. Enhanced RF enables students to better select and compare various representations aligned with design tasks. Researchers state that ASD adolescents' low RF explains their difficulty in academic achievement in STEM education (Moon, Ke, & Sokolikj, 2020). It relates to their difficulty in identifying, executing, and evaluating design task features during problem solving. It may subsequently lead to disengagement, as evidenced by ASD individuals' dynamic cognitive-affective states.

Virtual reality-based training for learners with autism

 © ISLS

Virtual reality (VR) has been used to promote cognitive and social skills development of ASD individuals, by fostering ASD learners' engagement and immersion (Parsons & Cobb, 2011). VR can act as a promising platform for promoting ASD learners' RF development. VR enables ASD learners to choose and compare various representations as 3D stimuli at a high degree of learner control. Recently, Moon et al. (2020) implemented VR-based cognitive skills training that engaged ASD learners in a variety of virtual engineering design quests (i.e., designing elevation bridges to fulfill different environmental and social contexts). In another study, Ke and Lee (2016) provided ASD learners with VR-based design-problem solving tasks. They examined whether and how the tasks promoted design-oriented interpersonal discussions to develop ASD children's perspective taking skills and RF. Despite the emerging uses of VR-based interventions for ASD youths, there is a lack of empirical research on VR-based learning assessment. Because VR-based learning interventions are dynamic, it is vital to track students' real-time behaviors. Considering ASD adolescents' developmental features, they are likely to experience dynamic cognitive-affective states during VR-based training. Automatic assessment will then help to drive adaptive learning support.

Data fusion in education research

Research has increasingly proposed the usage of data analytics to track students' learning. Research demonstrated a variety of computational techniques for the automatic assessment to track behavioral evidence of learning. For example, Moon et al. (2020) developed a prediction model that detects ASD adolescents' RF development using supervised machine learning. They collected ASD adolescents' verbal utterances related to RF facets and trained a classification model. Several other studies used computer logs to build a prediction model. However, there is a limitation with the current prediction models tracking learner states. They relied on mostly a single data source. Considering that VR is designed to foster students' multimodal interactions, predicting students' learning states from a single data channel appears limited. Research reported the advantage of multimodal learning analytics (MMLA) to track students' behaviors in highly-interactive digital learning environments (Worsley & Martinez-Maldonado, 2018). MMLA aims at leveraging and predicting student learning by merging and interpreting multiple data inputs with computational techniques (Worsley & Martinez-Maldonado, 2018). Among many approaches in MMLA, multimodal data fusion is a method systematically integrating more than two different data sources. Henderson, Rowe, Paquette, Baker, and Lester (2020) conducted multimodal affect detection by collecting and fusing different types of student trace data in game-based learning for medical training. However, little research explored the feasibility of multimodal data fusion design, integration, and implementation in VR-based training.

Method

Data

We used a total of 178 audio- and screen-recorded 1-1.5 hour VR training sessions of eight ASD adolescents. Study participants participated in VR-based training (Moon et al., 2020) that contains multiple design quests (i.e., elevation bridge design and non-player character design) aimed to promote ASD adolescents' RF development. We sampled students' behavior data from two VR-based training modules (Figure 1). In the first module the participants were requested to build a mechanical bridge that allows island residents to move their cargoes without ships. In the second module the participants developed interactive NPCs by editing block-based computer scripts. The participants joined multiple rounds of training sessions and their behaviors were automatically logged in the virtual environment. In each training session, students had to investigate the surrounding natural and social contexts in the virtual scene, decompose design problems, prototype 3D design solutions, and conduct iterative tests. We collected two types of data: (1) video recordings of students' avatar behaviors during VR-based training, (2) computer logs that recorded students' training actions.

Data Wrangling

We carried out multimodal data fusion by blending two different types or modalities of data when predicting the states of RF enactment. Specifically, we used a late fusion approach (Meng, Jing, Yan, & Pedrycz, 2020) that classifies each modality results before fusing the outcome results. A late fusion approach merges the average confidence values of sub-decisions on classification and then determines the final classification result.

There are four data-wrangling steps for the multimodal data fusion. Figure 2 portrays the data fusion process implemented in this study. First, we collected two types of data: (1) speeches and (2) behavior logs collected from study participants. Student speech data was their verbal utterances in relation to RF development during VR-based 3D design activities. To collect students' speech data, we audio- and screen-recorded every training session. Computer logs of students' behaviors in VR were also automatically recorded. Second, we

conducted expert labeling to create benchmarking classification results of students' RF enactment prediction. There are four facets of RF enactment: (1) attention switching/cognitive shifting, (2) alternative representation, (3) pattern development, and (4) pattern contextualization (Table 1). We used a coding scheme that was iteratively tested and validated through multiple studies (Moon et al., 2020). The coders independently labeled RF facets, then compared and discussed their results until reaching 100% interrater agreement. Third, we converted students' speech and behavior data to a dataset for the training of the prediction model. Using a speech-to-text converting application, we transformed students' entire speeches to text data. For data conversion, we also used the LightSIDE that conducted text vectorization (Mayfield & Rosé, 2013). In terms of behavior logs, we converted students' behavior data to the frequency of each behavior feature. Based on the expert-labeling results, we conducted separate machine-learning classifiers with the two data sources (i.e., speeches / behavior logs) to compute the estimated probability scores of RF facets. Throughout candidate classifier evaluation, we chose random forest because it showed the best average prediction performance than the other classifiers. Fourth, we arranged the metadata of the collected data sources by time interval during VR training. Students' entire training session data was divided by the time interval, resulted in a total of 1,441 data instances for model development. We then implemented the classifiers using confidence-based fusion from respective data sources at sub-decision level. We then computed the final prediction results of RF by averaging the confidence scores from the sub-decision classifiers of two data sources. We pre-set a threshold condition as higher than 50%. Last, we evaluated the prediction results between the two respective data sources and the fused one to investigate whether multimodal data fusion improved the prediction performance. We evaluated each classifier's performance using the metrics as follows: AUC, F1 score, and precision. AUC is a performance metric to check whether a model can accurately distinguish between positive and negative classes. F1 score is a weighted average value of the precision and recall. Precision is the ratio between the number of positive cases correctly classified and the total number of positive cases. We have also tested several methodological features to refine the classifier settings—data imputation and splitting when training and testing a model. In terms of data imputation, we use the algorithm k-nearest neighbor (kNN). The goal of data imputation was to replace missing values of the input data in the prediction models. We set the ratio of training (80%) and testing (20%) data for model training. During the data fusion process, we found a potential imbalanced data issue in the training data set. Data imbalance indicates that data distribution is skewed so it is necessary to deal with imbalanced features through a computational technique. We used a synthetic minority over-sampling technique (SMOTE) that performs resampling by creating new data points of minority class.

Figure 1

Training Module Examples (Left: Elevation bridge design, Right: NPC design)

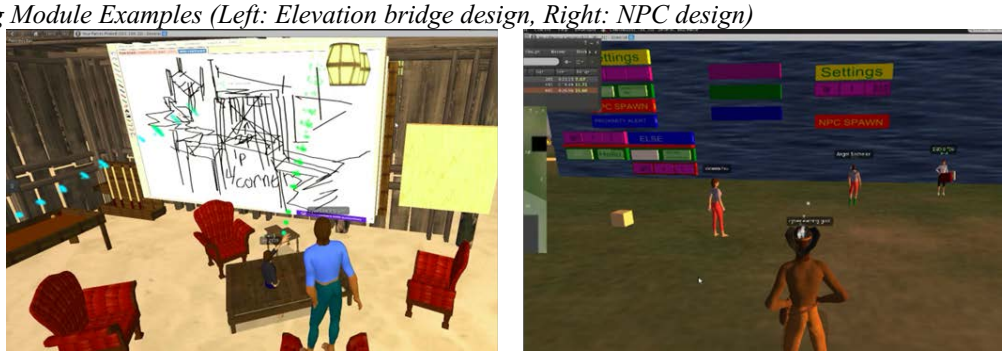

Figure 2

Multimodal Data Fusion Implementation

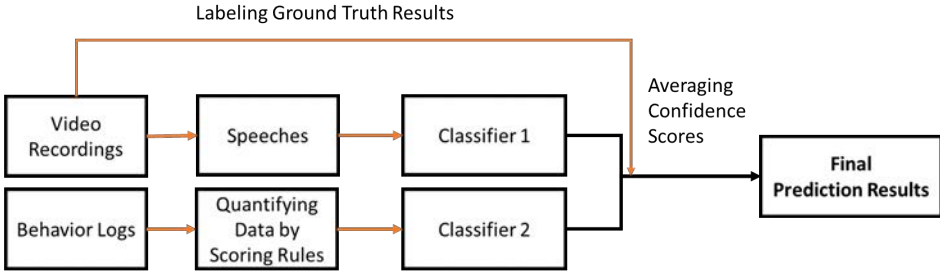

Table 1

RF Facets (Moon et al., 2020)

RF Facets	Definition
Attention Switching / Cognitive Shifting	Ability to switch attention or action based on changed rules and contextual demands
Alternative Representation	Ability to identify and apply multiple representations
Pattern Development	Ability to identify and delineate a pattern / rule during design problem analysis and solving
Pattern Contextualization	Ability to identify an implementation context of the endorsed pattern or customize the pattern based on a novel implementation context

Results

The results show that multimodal data fusion improved the overall performance results of the fused classifiers. Specifically, the fused classifier yielded the best performance scores (i.e., AUC, F1 Score, and Precision) in tracking all RF facets. The fused model performance in the NPC design module was generally better than that of the elevation bridge design module. A possible reason of this result is that the training data set in the NPC design module contains more student speech and behavior log data than that in the elevation bridge module. When examining the methodological features of the selected classifiers, we found the optimized number of trees in random forest classifiers (n = 20), pruning condition (confidence level = 30%), and oversampling parameters (the number of neighbors = 20) yielded the best prediction performance.

Conclusion and Future Research

The result of this study suggests the usefulness of multimodal data fusion in tracking RF during VR-based training. This study finding should inform on the design and implementation of MMLA in immersive learning environments. There are multiple future research directions. First, we will examine the applicability of dimension reduction techniques in developing a prediction model. Although the current prediction model has integrated multimodal data fusion, we did not evaluate which data features are best predictive of different RF facets. Therefore, it is worthwhile to implement dimension reduction to avoid data noises to make a prediction model efficient. Second, the present prediction model of this study only focused on detecting the positive occurrence of RF facets. Future research will build a prediction model that tracks both positive and negative cases of RF in VR-based training.

Analyzing the Influence of Student Problem Solving Approaches on Learning Through Teaching in Mathematics Education

Abstract: While previous research has examined what students learn as they agentically solve mathematics problems, less is known about what teachers learn through this process. We use this paper to address this oversight by analyzing interviews, lesson plans, and video observations of five novice elementary and middle school math teachers as they taught between six and eight lessons each. Findings reveal that teachers who rely on prescripted approaches more regularly developed knowledge related to classroom management and climate. Alternately, teachers who allowed students to agentically solve problems more routinely developed a deep understanding of students' mathematical thinking. This study therefore contributes to extant learning through teaching literature by illustrating how pedagogical choices directly affect what teachers learn within these approaches.

Introduction

As Nieminen et al. (2021) and others argue, allowing students to solve well-designed mathematics problems on their own (rather than teachers frontloading solution processes for students) leads to deep and meaningful student learning related to both mathematical content knowledge and socioemotional skills. However, less is known about what teachers learn when engaging students in this process. In response, we use this paper to address the following research question: what types of knowledge do teachers develop when using prescripted or open-ended pedagogical approaches? To address this question, we present empirical data from a study of early-career elementary and middle school math teachers. Our emergent analysis of this data reveals that teachers who employ student-driven problem-solving approaches more frequently develop knowledge related to the mathematical thinking of students while teacher-driven approaches primarily result in knowledge development related to general pedagogical concerns. This paper therefore contributes to extant learning through teaching (LTT) literature by providing a nuanced understanding of learning that occurs through these divergent pedagogical approaches.

Theoretical context

According to Sherin (2002), LTT exists as a critical and at times intractable aspect of developing as a teacher. Previous studies have uncovered a wealth of value within LTT as teachers have developed both discipline specific content knowledge (CK) (Elmendorf, 2006; Leikin, 2006;) and pedagogical content knowledge (PCK) (Perkins et al., 2015; Zazkis & Mamolo, 2018) through this learning process. In terms of the mechanisms through which LTT occurs, Schön (1987) describes a simple three-part framework that encompasses LTT: planning some sort of lesson or learning experience, implementing that plan with students, and then reflecting on the results. Since its publication, multiple scholars have elaborated on these three steps and provided a greater sense of detail within each element. Simon (1997), for instance, describes the planning stage as one in which teachers produce prospective learning trajectories for students that involve learning goals, proposed tasks, and hypotheses as to how the learning process will unfold.

Focusing on mathematics education specifically, LTT research has interrogated all phases of Schön's process to better understand how math teachers develop both CK and PCK when teaching. In doing so, Leikin (2010) notes that not all pedagogical tasks embody the same potential for LTT. Instead, some math lessons, especially those that create space for students to respond in new and unexpected ways, create significantly more opportunities for teachers to learn through the act of teaching. Additionally, Leikin (2006) found that teachers often develop both CK and PCK by creating new lessons and anticipating students' responses. These two practices within the planning process enable teachers to deeply engage with content in often unexpected ways. Yet despite these findings, what teachers learn when enacting lessons that rely on either student-driven problem solving or whole-group instruction, and how that learning compares, remains under explored in the literature. In response, we turn towards new empirical findings related to LTT within both pedagogical modes.

Methods

We collected the data used in this study for a larger project that investigated how novice middle school and elementary mathematics teachers' PCK develops through teaching (see Table 1 for demographic information).

 © ISLS

The teachers created 3 to 4 sets of 2-day lesson plans to teach a math concept. This 2-day lesson plan included teaching and assessment tasks, anticipated solution strategies from students, the underlying mathematical thinking for these strategies, and expected instructional strategies. By asking for these components, we aimed to capture teachers' knowledge of students' mathematical thinking and their mathematics teaching, two important elements of pedagogical content knowledge (e.g., Ball et al., 2008; Shulman, 1986). We then conducted a set of three structured interviews for each cycle of 2-day lesson plans (one pre interview and another interview after each lesson) as a means of investigating teachers' learning from their teaching. Additionally, we asked teachers to videotape themselves teaching one of the planned lessons. By including lesson plans, interviews, and videos of classroom practice, we were able to check the alignment between the planned lesson and the enacted lesson and ensure validity of our analysis through triangulation (Denzin, 2012).

Table 1
Background Characteristics of Participants

Teacher ID	Gender	Race	Years of Math Teaching Experience	Years of Teaching Experience	Lesson Plan Cycles Included in Study
Xavier	Male	Black	2	2	3
Daniella	Female	Multiracial	2	3	3
Linda	Female	White	1	3	4
Hanna	Female	Multiracial	0	0	3
Mike	Male	White	2	2	3

Once collected, we coded all of the data using the coding scheme developed by Fredericksen et al. (1998). In their analysis of teacher assessment practices, the authors divided the criteria for high quality teaching into four broad categories: pedagogy, climate, management, and mathematical thinking. For the purposes of this initial analysis, we consider teacher knowledge and self-reported learning related to each of these (for instance, do the teachers show evidence that they possess knowledge of their student's mathematical thinking?). Additionally, we coded for evidence of student-driven problem solving and teacher-driven instruction (i.e. the teacher shows the entire class how to solve the problem). Definitions of each code can be found in Table 2. To ensure reliability, we employed the consensus building process described by Harry et al. (2005): all data was coded by both members of the research team independently and then any disagreements on code applications were "debated and clarified until the group agreed on appropriate usage of the set of codes" (p. 6). Although we do not include analysis of the lesson plans or video observations here, we used these other forms of data to verify our coding of the interviews. More specifically, we looked for both moments of alignment and disagreement between what teachers were describing and what they showed in their lesson plans and while they were teaching. No significant disagreements were found. We therefore believe that the interview data accurately represents participant knowledge.

Table 2
Code definitions and examples

Code Name	Definition	Example
Knowledge codes		
Pedagogy	"The teacher shows a mastery of different instructional techniques and adapts them to students' backgrounds and abilities." (Frederiksen et al., 1998, p. 233).	"The solutions are presented to build upon students' conceptual understanding of the relationship between multiplication and division. The first solution is most accessible to students because it provides a visual model and as the solutions build upon each other, they eventually lead to the learning goal of explaining the relationship between multiplication and division and applying it to fractions."
Climate	"The social environment of the class empowers learning" (Frederiksen et al., 1998, p. 233).	"We talked about perseverance with difficult problems, and always trying to learn more. In their reflection, they drew little blobs, like 'fixed mindset: it's like a burned out-lightbulb,' and then 'growth mindset: it keeps on shining.'"
Management	"The class runs smoothly and efficiently." (Frederiksen et al., 1998, p. 233).	"I was walking around the room while they were doing the partner activity in addition to redirecting. I was also watching what they were doing. And I was seeing if they were setting up their ratios correctly and I also collected their work as well."

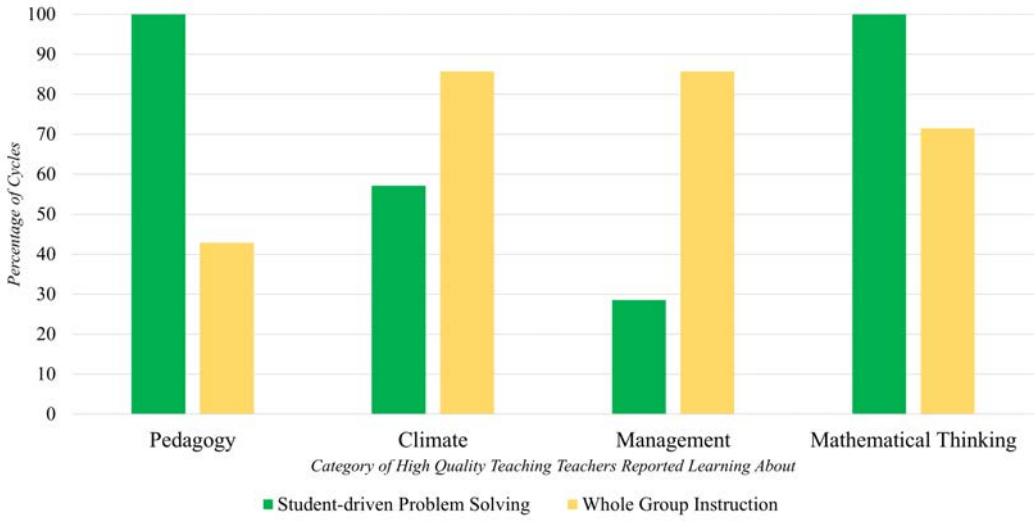
Mathematical Thinking	"A central goal of the class is to promote mathematical thinking among all participants" (Frederiksen et al., 1998, p. 233).	"Regrouping is really hard for 5th graders. I'm still learning how difficult it is for them to connect the same concept across different types of numbers. They can explain regrouping with whole numbers brilliantly and they can even do that with decimals. I think just because it's not a set place, like the fractional part, they're just not making that connection.
Problem solver codes		
Student-driven problem solving	When working on a new problem, students are able to try and solve the problem however they see fit.	"I like them to see what they know on their own and really investigate before I tell them how to do it. It just kind of lets them make connections on their own then."
General teacher-driven problem solving	The teacher shows the entire class how solve the problem presented to the class.	"The biggest thing is the process and multiplication. Are they following the process? Are they doing it exactly the way we have it on our note sheet? When we reference those notes, all they have to do is put in their numbers."

Findings and discussion

Through this analysis, we found evidence of teacher's knowledge development related to all four criteria for high quality instruction defined by Fredericksen et al. (1998) (see Table 2 for examples). Additionally, we found that 2 of the teachers (Linda and Hanna) overtly relied on student-driven problem solving while the other 3 teachers (Xavier, Daniella, and Mike) primarily used whole-group instruction in each class. In comparing these two sets of codes, however, we also discovered that how teachers reported learning related to Frederiksen et al.'s (1998) four categories were not evenly distributed (see Figure 1). In particular, the teachers who structured their classes around student-driven problem solving reported learning about pedagogy and mathematical thinking during all 7 of the 2-lesson cycles they taught during this study (100%). By contrast, teachers who focused on whole group instruction only reported learning about pedagogy during 3 of their 9 cycles (42.857%) and mathematical thinking during 5 of their 9 cycles (71.429%). In considering the other two categories, the relationship reversed. Teachers who focused on whole-group instruction reported learning about both management and climate during 6 of their 9 cycles (85.714%). The student-driven teachers only reported learning about management during 4 of their 7 cycles (57.143%) and climate during 2 of their 7 cycles (28.571%).

Figure 1

Evidence of Self-reported Learning by Pedagogical Approach



Based on these findings, we contend that a teacher's choice to position either the student or the teacher as the problem solver within a classroom environment could hold significant implications for what teachers learn when teaching. This study then builds on Leiken's (2010) assertion that teachers have greater opportunity to learn when students can respond to problems in new and unexpected ways. Specifically, our analysis provides a focus to previous research by unearthing the kinds of knowledge that teachers construct (and recognize as learning) in

these interactions: by allowing students to complete tasks on their own (and guiding students through that process), teachers more frequently develop PCK and learn how students think about mathematics. Conversely, the teachers who relied on whole group instruction more prominently recognized the learning they did related to general pedagogical concerns (management and climate). One possible cause of this diversion may be that teachers who merely present solution processes to students do not engage in interactions related to mathematical CK (or do so with lesser frequency) and instead focus on general pedagogical processes unrelated to content.

Taken together, these findings extend the work of Schön (1987) and Simon (1997) by considering how the act of planning not only engages teachers in LTT but shapes future contexts where LTT occurs. In choosing between a teacher-driven and student-driven approach to problem solving, teachers also decide between what they can expect to learn. In future iterations of this project, we will continue to refine our analysis by further specifying the types of knowledge teachers gain in different teaching contexts while simultaneously unearthing learning mechanisms that allow for this development. Future research should also continue to develop a nuanced understanding of the relationship between pedagogical models and LTT.

Investigating Students' Memory for Feedback in a Naturalistic Classroom

Shelby Weisen, Ashley Hufnagle, Martin Van Boekel
weise207@umn.edu, hufna011@umn.edu, vanbo024@umn.edu
University of Minnesota, Twin Cities

Abstract: The purpose of the present study was to examine students' memory for academic feedback in a naturalistic classroom setting. We investigated whether introductory applied psychology students had differential recall for four types of feedback. Students completed an activity, were given authentic feedback on their assignment, and recalled that feedback one week later. Findings suggest that students had the lowest recall for the two types of feedback that theoretically stand to benefit them most. Overall, students' recall across all feedback categories was very low compared to the amount of feedback units given by the instructor. We also saw a pattern of students "transforming" the more generalizable feedback they originally received to more task-specific feedback at recall. Practical implications of these findings are discussed.

Introduction

Feedback is an integral part of the academic process. Its purpose is to provide students with information that can propel them forward from their current state of knowledge/skills to a superior goal state (Hattie & Timperley, 2007). Literature in this area has highlighted the factors that may impact the cognitive and affective responses to different types of feedback and, consequently, the uptake and implementation of that feedback (e.g., Fyfe et al., 2015; Reeve et al., 2014). Even though such studies on feedback are plentiful, little is known about students' *recall* of the feedback they receive. This is surprising, especially as learners' memory of their feedback could influence whether the feedback is ultimately implemented, modified, or ignored (see Winne & Butler, 1994).

In their systematic review of the literature, Hattie and Timperley (2007) identified four main types of feedback students can receive: *Task Feedback (FT), Process Feedback (FP), Self-Regulation Feedback (FR), and Praise/Self Feedback (FS)* (See Table 1 for defining features and examples). Because *Process Feedback* is more generalizable and encourages deeper learning, it is seen as more beneficial and longer-term than *Task Feedback*. Arguably, the most beneficial type of feedback is *Self-Regulation Feedback* because it instructs students on how to self-assess their work and develop the skills necessary to become better self-regulators. *Praise/Self Feedback* can have ironic consequences for future motivation because it does not encourage students to invest further effort. Thus, it tends to be the least effective at improving academic performance.

Overall, Hattie and Timperley (2007) conclude that feedback's efficacy depends heavily on the level at which it was aimed. In the current study, we use this framework to categorize the feedback that students receive and recall receiving on a *real classroom assignment*. Much of the previous research on feedback has been done in laboratory settings, where feedback is manufactured and unrelated to the actual performance of the student on a given task (e.g., randomly providing positive/negative feedback to participants *without* considering their actual performance). The current study, which follows up on preliminary results from one lab section, aimed to fill these gaps in the literature by examining how much feedback students remember from an actual classroom assignment and whether students' memory differed as a function of feedback type.

Methods

Participants

The present study was conducted in a first-year introductory applied psychology college course. The class had an enrollment of 102 students, 76 of whom consented to participate in the study (M_{age} = 18.98, SD = 1.36). The students were split into four different lab sections, where they completed weekly projects in groups of 3-4.

This IRB-approved study was designed to blend into the course with minimal disruptions to its natural flow. Students completed an applied activity on the human body's response to stress in their groups. After submitting their assignment, the course instructor and four teaching assistants (TA) met to discuss grading procedures, ensuring consistency in grading and making sure the same detail of feedback was provided across labs. All assignments were graded before the following laboratory session. At the beginning of that lab session, students were given 10 minutes to individually read through their group's assignment feedback. This was the one

 © ISLS

major modification to the course (i.e., typically students did not get class time to review assignment feedback). One week after the feedback read-through in the lab, all students were given a surprise free recall task.

Materials

Students' recall of feedback

Participants were asked to complete an online survey about their thoughts and attitudes towards academic feedback and recall as much of the feedback given to them on the stress activity as possible. This was an open-ended question with no additional prompts about the activity or what type of information should be included in their response. From informal conversations with students, we learned that many were unlikely to revisit their previous feedback before starting a new assignment, even if they knew it had the potential to be beneficial. Therefore, we opted to avoid recall cues because their unsupported recall of the feedback would best represent their awareness and "use" of past feedback in a typical classroom situation.

Codebook

Feedback and recall of the feedback were broken into units. Feedback units were defined by a comment/recall that contained one unique idea about the work submitted (see Table 1). Feedback provided by the TA and students' recall of that feedback were coded into the four types of feedback presented in Hattie and Timperley's (2007) paper. In the instances that a piece of feedback could not be placed into one of the four categories, it was assigned to "Other." Responses were then examined for similarities; no patterns within the "Other" category emerged. All authors created and refined the codebook as well as co-coded all of these data, reaching a consensus for each unit.

Results

The average number of feedback units for each feedback category were calculated at the classroom level for both TA comments and student recall (see Table 2). As stated above, the course instructor and TAs met to discuss grading procedures, ensuring consistency in the quality and focus of the feedback. TAs in all lab sections gave feedback that represented all four feedback types outlined by Hattie and Timperley (2007). However, the amount of feedback provided differed significantly across the lab sections, therefore we could not collapse the data. On average, TAs gave FT and FP most often and an approximately equal number of feedback units in both categories (although this varied slightly by TA), whereas FS was given least often. In line with this, FT and FP were recalled most frequently by students, on average. However, students were more than twice as likely to recall FT than FP, despite being given both types in almost equal measure. FR was recalled least often by students, on average. Notably, students' recall (across all feedback categories) was very low compared to the amount of feedback units received from the TA. Overall, findings suggest that students have differential recall for the four types of feedback.

Discussion

This study demonstrates a noteworthy discrepancy between the types of feedback that educators *give* and the way students *understand, classify,* and *remember* that feedback. We observed that students recalled little of the feedback they received, and when they did, it was primarily the marginally beneficial task-based feedback. Theoretically, it would be most beneficial for students to remember FP and FR feedback, as these types have the greatest ability to generalize and be useful on future, novel learning tasks. Findings suggest that even if students are *receiving* the types of feedback that have the potential to be most impactful, they may not be drawing out the key elements to understand and remember their feedback in the ways that stand to benefit them most long-term. We saw examples of this "*transformation process,*" where students received process-based feedback but actually remembered it in a specific, task-based way. Due to space constraints of the current paper, we have provided only two examples (see Table 3).

Prior research demonstrates that critical constructive feedback, which scaffolds students to improve on tasks, often remains untapped (Tärning et al., 2020). Our findings begin to shed light on *why* this might be. Students may not be purposefully ignoring or not implementing feedback; instead, it might be a product of not understanding it in the same way that educators intend for them to, altering how they store and recall feedback. Additionally, Máñez and colleagues (2019) observed that sixth-grade students spent more time attending to feedback after failure than after success. Therefore, future analysis of our data could explore whether students were differentially remembering positive versus negative feedback.

Practically, these results beg the question: *how can we train students to better locate, remember, and use self-regulatory feedback (or at least prevent students from transforming useful, generalizable process-based feedback into more specific task-based feedback in their long-term memory)?* If we successfully accomplish these aims, we stand to better prepare students for future learning and improve course performance outcomes.

Table 1
Defining Features and Examples of the Four Types of Feedback

Feedback Type	Defining Features	Examples of Teaching Assistant Feedback	Examples of Student Recall of Feedback
Task (FT)	Provides task-specific information: ● Clarifies whether information in assignment is correct or incorrect ● Offers directions to get to correct information for the specific task (i.e., not intended to generalize) ● Direct text-level edits without explanation (e.g., track changes)	"You should add more information here." "Correct." "This is a helpful explanation for how this strategy directly addresses stress."	"I remember that my TA told us that one of our previous Biological processes, the Thalamus is does not really relate or affects our body when being stress." "Make sure we were citing correctly was a key point."
Process (FP)	Aimed at improving students' understanding of the learning processes required for successfully or more thoroughly completing the task (or similar future tasks - i.e., potential to generalize) ● Offers a strategy to create a product, find a resource, or complete a task more effectively	"...I recommend choosing one main idea for each paragraph. Make the main idea of that paragraph the first sentence (aka "topic sentence") of the paragraph. Then flesh out the main idea with relevant definitions, explanations, and examples…. Using this technique should help you to identify where you are being repetitive or adding unnecessary detail."	"I remembered the feedback talking about how some paragraphs needed to be split into two paragraph for a more coherent flow." "We needed to unify our conversations more in order to show more of a flow in our writing."
Self-Regulation (FR)	Feedback aimed to help students self-assess and, subsequently, boost confidence and motivation to engage further by investing effort to clarify or incorporate suggestions ● Reassures a successful previous procedure/process or demonstration of students' relevant content knowledge to motivate their further expansion on the topic ● OR feedback demonstrates how their writing might be interpreted by an outside reader, asking them to clarify and self-correct	"Make sure to relate these [definitions] back to the context (such as you do in paragraph 2)." "For reference, it sounds to me like stress is experienced through external factors that enact defense systems. Is this what you mean? Do you mean that these external factors trigger defense systems?"	"What I could recall is that our feedbacks for the biological process is a bit bad for we did not fulfill the require thing." (*Note*: In this case, the "require thing" was referring to the assignment rubric, knowledge that the student could/should use the rubric will allow them to self-assess in the future)
Self/Praise (FS)	Personal evaluation directed at the student (can have a positive or negative valence) but *without* a direct connection to task performance ● Typically does *not* motivate students to invest further effort	"Well done!" "Great effort"	"Overall, good job" "Written well"
Other (O)	Any instance of feedback that did not fit into the categories above	"If you would like to revise and resubmit, please do so by lab on Tuesday, 2/18/2020."	"Unfortunately, as I write this down, the only feedback I can really remember was 'negative.'"

Texas A&M University

Abstract: This study examines the design thinking process as a structure for collaborative project-based learning in undergraduate courses ranging from biomedical sciences to teacher education. Our aim in this design-based research study was to understand how design processes are experienced and to develop a set of design principles. Individually written reflection papers were coded in categories including design aspects that worked well as well as student struggles. Code co-occurrence correlations were calculated and a network map created. Findings in each set of relationships were translated into design moves. One important finding was that learning through design thinking requires truly collaborative work where team members work collectively throughout the design process. The learning experience should also be designed to emphasize building relationships of interdependence. The innovative analytical process used provides valuable insights to improve the use of design thinking for collaborative project-based learning in multiple disciplines.

Background

Project-based learning and collaborative learning are generally acknowledged in the literature as evidence-based high-impact practices (National Academies, 2018). However, there are a number of issues educators face when attempting to implement these practices in their own courses. A common issue is lack of scaffolding structure, leading to inconsistency of effectiveness, students trying to do all the work at the last minute, and breakdowns in interpersonal communication within student groups (Barron et al, 1998). Furthermore, many projects are structured such that the teacher determines the problem, process, and nature of the solution rather than helping students develop skills in problem identification, creative problem solving and managing productive failure through focused tinkering and exploration (Svihla & Reeve, 2016). Finally, project-based learning in academia often involves designing artifacts or solutions which are only seen by the teacher and peers within the course rather than pushing students to interact with real-world stakeholders and design solutions for real-world problems (Kincheloe, 2008). To address these and other related issues, we have been conducting design-based research study across multiple university courses in which students engage in the design thinking process.

In the current study we are using the Design Thinking for Engaged Learning model (Donaldson & Smith, 2017) which consists of a 10-stage process broken down into 5 phases, with each stage intentionally crafted such that students develop skills in designerly ways of knowing (Cross, 2006). For instance, in order to help students develop the "wicked problem framing" designerly way of knowing, small groups of students identify and frame a wicked problem within the disciplinary scope of the course (Donaldson et al, 2022). To help them develop the cognitive, affective, and conative empathy designerly ways of knowing, students go into real-world contexts in which their wicked problem exists and conduct observations and interviews to understand stakeholders' experiences of the problem—especially the experiences of those at the margins (Jamal et al, 2021). In order to facilitate truly collaborative (Chi, 2009) learning, groups are expected to complete all stages of the process together rather than splitting up tasks to be accomplished by individual members (Odom et al, 2021). In this study, we were seeking to understand how such design processes are experienced by students and to develop a set of principles for using design thinking as a structure for collaborative project-based learning in higher education.

Methodology

This design-based research study (Sandoval & Bell, 2004) investigated the use of design thinking for collaborative project-based learning in the second iteration in undergraduate courses. Students in agricultural leadership, bioenvironmental sciences, tourism studies, animal sciences, and teacher education courses engaged as small groups in the design thinking process over a period ranging from 10 to 14 weeks. The process was broken down into 5 design thinking phases. For analysis of the first iteration (not reported here) we used simple frequency analysis of weaknesses and strengths of the design found in 381 reflection papers. For analysis of this second iteration we developed an innovative analytical process through which to leverage multiple statistically significant

 © ISLS

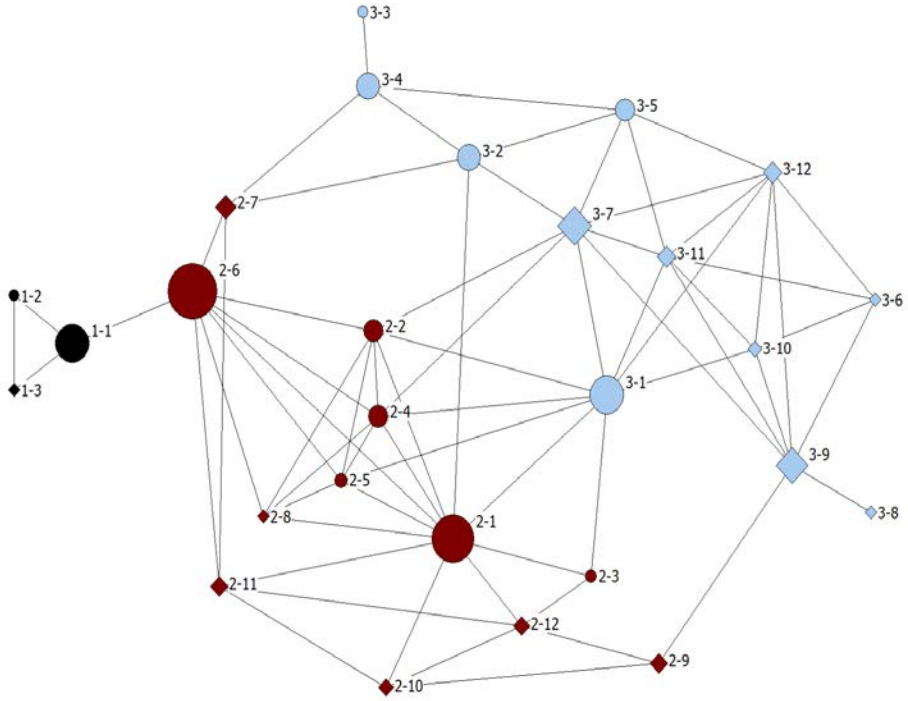
correlations between student struggles and design strengths as a means of developing data-driven design moves for improving the third iteration. Throughout the second intervention, students individually wrote reflection papers which were collected for data analysis (163 documents). We coded the data in MAXQDA Analytics Pro for emergent themes in a number of categories including design aspects that worked well as well as student struggles, resulting in 174 codes covering 2,257 coded segments. We then calculated code co-occurrence correlations to create symmetrical matrices which we imported into the UCINET and NetDraw network analysis software to create a network map of struggles and design features that worked with correlations of $p<0.001$. We used Girvan-Newman cluster analysis (Girvan & Newman, 2002) to identify clusters, calculated eigenvector values, and set node sizes according to betweenness centrality measures to identify the most salient strengths and weaknesses of the design. Because this is the second iteration in a design-based research study, we were primarily interested in crafting design moves to improve the next iteration. To do so, we selected the category of student struggles to indicate aspects of the design that were weak and the category of design aspects that worked well to suggest possible solutions which leverage strengths to address weaknesses. We analyzed the relationships between each of the student struggles and the related design strengths, and translated findings in each set of relationships into design moves.

Findings

In our network analysis of correlations at $p<0.001$ we found 3 clusters with Q=0.372 through Girvan-Newman analysis (see Figure 1) indicating the network of relationships between student struggles and aspects of the design that worked well. We set the node size such that nodes with higher betweenness centrality measures were larger. Diamond-shaped nodes are student struggles, and circles are aspects of the design that students experienced as beneficial.

Figure 1

Network Map of Design Strengths and Student Struggles



In the red cluster in the middle of Figure 1 we found that students who struggled with logistics (node 2-11) also tended to struggle with technology use (node 2-7), understanding what to do (node 2-8), divergent thinking (node 2-12), idea generation and coming up with new ideas (node 2-10). What worked for these students included interacting and developing relationships with team members (node 2-1), collaborative documents and technologies (node 2-5), teamwork times (node 2-6 - recurring meetings devoted to the team project), and idea generation (node 3-1). What these students also found beneficial was rehearsing and sharing projects with peers (node 2-2), and the development process (node 2-4). This suggested that a potential solution for the struggle with technology was to have teams hold workshop times with their teams during team work time where time was set aside specifically for troubleshooting problems. This design move was supported by the connection to the team work times, which worked well. A final design move this analysis suggested was to address student struggles with

logistics by providing students with opportunities to obtain feedback from outside perspectives on logistics of the projects.

There also appears to be a connection between students' personal struggles (Figure 1 - red cluster: node 2-9) and their struggles with divergent thinking (node 2-12), ideation (node 2-10), and collaboration, interpersonal interactions, and relationships in the group (node 3-9). These struggles were addressed with a design move of advising students to seek new perspectives and to be open to new perspectives outside of their group. Another design move that was developed and implemented was to emphasize the value of self-reflection and helping students recognize their own assumptions regarding a challenging team, team member, or situation. For this we added a prompt to a reflective assignment that asked students to think about managing personal and interpersonal relationships for optimal teamwork.

In the blue cluster on the right of Figure 1 we found that student struggles with time management (node 3-7) were connected to struggles with collaboration and relationships (node 3-9), adapting to change (node 3-12), and following instructions (node 2-11). What worked for students who struggled with time management was interest alignment in teams (node 3-5) and increased communication (node 3-2). To leverage these strengths to address the time management weakness, a potential solution is to encourage students to include timing expectations and status updates in their existing communications with each other so that they can leverage their current strengths with communication frequency. Modeling this behavior may be necessary to augment assignment instructions as these students also expressed struggles with following instructions in general.

There is also a connection between those who struggled in time management and success in generating a large number of ideas (Figure 1 - blue cluster: node 3-1). This suggests that they started the design process off well in generating many ideas (possibly because they had aligned interests within teams), but then struggled with collaboration and relationships (node 3-9), following instructions (node 2-11), and adapting to change (node 3-12). A design move and potential solution for this struggle was to add specific instructions for each of the team activities to instruct teams to spend only 40 minutes working collaboratively in the activity, complete the activity within the allotted time, and not delegate other outside individual work after the team meeting.

In the small black cluster on the left of Figure 1 we found that student struggles in problem finding (node 1-3) were related to strengths in scientific and conceptual understanding (node 2-1), and project framing and orientation activities (node 1-1). This led to the development of two design moves. First, the project framing and orientation activities were revised to include discussion of the scope (boundaries) delimiting what types of problems were within the disciplinary scope of the course (guided by the course learning outcomes) and what problems were outside the scope of the course. Second, the problem finding activity instructions were changed to ask groups to have discussions in which they narrowed the scope of their problem while discussing the ways in which the range of problems they were considering tied in with the scientific and conceptual material they had been studying thus far in the course and in previous courses in the discipline.

Using network analysis of correlations between student struggles and design strengths (aspects of the design which students found beneficial) not only allowed us to identify the multiple interdependencies between struggles and strengths in order to leverage those relationships to develop design moves, but also allowed us to identify overall leverage points in the data. Because betweenness centrality measures indicate the degree to which a node is "important" in connecting other nodes, we were able to interpret larger betweenness centrality measures of particular nodes as leverage points. In other words, changing that aspect would impact many other aspects. The design feature of requiring groups to set up weekly teamwork times (Figure 1: node 2-6) had the highest betweenness centrality measure (79.73 with an eigenvector of 0.27). Interacting and developing relationships with team members (node 2-1) had the second highest betweenness value (65.74 with an eigenvector of 0.36). Coming up with many ideas (node 3-1) had the third highest betweenness (48.97 with an eigenvector of 0.34). These three leverage points were design strengths. One area of student struggle had a high betweenness value (46.78 with an eigenvector of 0.28): time management (node 3-7). Taken together, this suggests—as supported by the earlier data-grounded design moves described earlier—that design thinking projects will be most powerful if we place an emphasis on building team relationships through regular working meetings in which all team members work collectively and collaboratively (rather than splitting up tasks and letting members work individually) over an extended period of time. This group functioning will further be optimized if we provide specific guidance and structures for time management.

Discussion and Implications

Design thinking can be used to structure collaborative project-based learning (Carroll et al, 2010). This study investigated the details of how to optimize such structuring of the design thinking process in learning contexts through analysis of the second iteration of a design-based research study. We hope to gain deeper insight in

subsequent iterations. One of our most important findings was that learning through design thinking requires truly collaborative work in which members of each team work together collectively to engage in all aspects of the design process, and that the learning experience should be designed such that it emphasizes building relationships of trust and interdependence within the team. We also found that it may be beneficial for design thinking teams to routinely share and discuss their work with peers outside their teams, as well as with others outside the educational context with an emphasis on reflection, perspective taking, and questioning assumptions. Another strategy suggested by our analysis was that learning through design thinking may be most effective if teams are taught and encouraged to engage in frequent metacognitive practices such as reflection-in-action (Schön, 1992), so that their discussions are not only focused on completing the task at hand, but also focused on review and refinement of logistical and technical issues, processes, and ways of thinking about the task at hand. Finally, the innovative analytical process we developed provided valuable insights grounded in the data, which we then leveraged to develop design moves to improve the implementation of design thinking for collaborative project-based learning. We believe that this analytical method may be applicable in a wide range of design-based research projects in multiple disciplines.

Teachers' Use of Resources for Equitable Integration of Computation in Science Classrooms

Abstract: While computation is a crucial aspect of modern science, students rarely have opportunities to engage in such work. In this study, we designed a series of professional learning opportunities for 12 physics teachers to support their enactment of equitable computational pedagogies. We asked how and why teachers utilized two primary resources of the PLS when making decisions about computational pedagogies. We analyzed multiple data sources using lenses from a situative learning perspective to examine teachers' critical pedagogical discourses. We discuss how teachers' critical discourses shaped the way the resources were utilized when designing computational learning opportunities for their students and the implications for future equity-oriented computational professional learning opportunities for teachers.

Purpose of the Study

Modern science increasingly rely on computation to explore and to understand the natural world; however, computation is largely absent in many high school science courses. Science teachers, then, must plan, enact, and reflect on opportunities for students to engage in computational practices. However, two challenges arise when considering how to support science teachers in designing opportunities for computational practices. First, current high school science teachers have likely not engaged in computational practices, nor have they considered how to plan, enact, and reflect on students' participation in computation. Second, merely providing students with opportunities to engage in computational practices does not necessarily result in equitable participation (Ensmenger, 2012).

Both challenges demonstrate that science teachers need support to provide equitable computational opportunities for students. In this study, we report on a series of professional learning opportunities for 5 secondary physics teachers. In this professional learning series, we provided teachers with a suite of resources to support their enactment of equitable computational pedagogies. By resources, we mean physical and intellectual commodities that teachers use to solve problems of practice (Stroupe, 2016). For this study, we asked:

1. *How did teachers attend to equity when planning, enacting, and reflecting on computation practices?*
2. *What resources were useful in supporting teachers' planning, enacting, and reflecting on equitable computation practices?*

Theoretical Framing

The above research questions are informed by sociocultural theories of teacher learning. When using resources, teachers engage in complex forms of intellectual activity that might otherwise be too difficult without some form of assistance. Note that teachers do not use resources absent of a context. As teachers use resources in their school, the community reciprocally reshapes the resources and their function to better serve valued goals (Cole & Engeström, 1993). While most science teachers use students' ideas, and other resources, to shape instruction, how and why they use the resources could vary. Therefore, we wanted to understand how teachers recognized and used resources to make decisions in concert with multiple voices from various instructional settings.

To unpack how and why teachers recognized and used resources, we examined their *critical pedagogical discourses* (hereafter, critical discourses). Critical discourses describe an individual's developing personal theories about what counts as productive teaching and learning (Flores, 2006; Rex & Nelson, 2004; Thompson et al., 2013). What makes these internal discourses critical is that they are consequential to an individual's actions and learning. Such discourses mediate learning and can influence how teachers think about practice and resource use across contexts (Sfard & Prusak, 2005). For this study, we used critical discourses to understand teachers' resource recognition and use, and we argue that teachers' instructional decisions using resources depends on what they see as problems or opportunities in

 © ISLS

practice. The explanatory power of critical discourses can broaden when the field understands why science teachers select particular resources to reason with and about, how their personal theory of teaching and learning shapes their resource use, and why their personal theory of teaching and learning helps them mediate contextual pressure to teach in specific ways.

Methods

The Professional Learning Sessions and Participants

With the goal of equitable integration of computation in secondary science classrooms, our professional learning sessions (PLS) had three major components: (1) a week-long workshop held in the summer, (2) workdays that occurred every two months during the school year after the initial workshop, and (3) informal communication between teachers and different workshop facilitators. The participating teachers were White with roughly even gender distribution. Over the course of the PLS, we introduced multiple resources to support teachers' implementation of equitable computational pedagogies. In this study, we focus on two primary resources (Table 1) from the PLS, minimally working code (MWC) and Equity QUantified In Participation (EQUIP, Reinholz & Shah, 2018). From the start of the week-long workshop, we introduced computation using MWC to make computational tasks accessible to both the teachers and students with minimal background in coding (Caballero, Kohlmyer, & Schatz, 2012). Together with teachers, we used EQUIP (Reinholz & Shah, 2018), a participation tracking tool, to analyze video recordings of students' small group collaboration on computational tasks. During workdays, each teacher debriefed the EQUIP analytic with a teacher educator.

Data and Analysis

To examine how the teachers took up these resources, we drew from two data sources. First, we interviewed six teachers who consistently participated in the PLS for two years. The semi-structured interview focused on the use of resources shared/promoted during the PLS, intended to provide insight into resource use (e.g., which were framed as useful/not useful, what resources were used by most teachers). Second, we analyzed recordings of debrief sessions. These recordings allowed us to see how resources were used with students (teachers talked about their resource use throughout the debrief session), particularly in terms of resources related to equity.

Based on thematic analysis, we identified how and why the two primary resources were used by teachers and each teacher's critical discourses. We triangulated our findings by drawing on both interviews and debrief data. Similarly, we identified each teacher's critical discourse that is consistent across their interviews and debriefs. These themes were specific to particular teachers, although there were some similarities across some of the teachers. In findings, we focus on two primary resources (MWC and EQUIP) and present teachers' critical discourses.

Findings

Our analysis showed that depending on teachers' critical discourses, they took up MWC and EQUIP differently. We compare and contrast how pairs of teachers applied these resources.

Responding to Students' Frustration with MWC

When the teachers talked about using MWC for their lessons, one salient theme was managing students' frustration because of students' unfamiliarity with computational tasks. More detailed analysis showed that the teachers managed this issue differently by either prioritizing *comfort* or *perseverance*.

> I don't mind that the students get frustrated. But I don't want them to spend the hour on that same frustration. Because they don't. They give up. They turn to another group or something like that. (Ms. Miller, interview)

> It feels good. And I think that's a really valuable thing to expose students to. Remember the last time you were frustrated at the beginning, and you just kept at it, and you kept working, kept working, let's try that again. Let's see if you can't do it again. (Mr. Ross, interview)

Although both Ms. Miller and Mr. Ross attended to students' level of frustration, the teachers interpreted the high level of frustration differently. Ms. Miller, based on her critical discourse of comfort, talked against the prolonged frustration that students might experience. On the other hand, Mr. Ross, based on the critical discourse of perseverance, spoke positively about students experiencing challenging computational tasks.

Their contrasting critical discourses also shaped different instructional decisions. Ms. Miller used the comment features (texts followed by # in VPython, computation-related pedagogical technique) to guide students during the task.

> It was too big of a jump for them. They needed, I have already gone in and done a bunch of commenting because there was no commenting in there. (Ms. Miller, interview)

Mr. Ross on the other hand allowed students to struggle for a longer period of time and presented his solution toward the end of the lesson when his students ran out of time to complete the task.

> I'd love to be able to spend time with this, but we've got to move on. And let me just show you a couple of – I'll show you the approach that I used. And so, I'll take a minute and do that. (Mr. Ross, interview)

Interpreting Inequitable Participation Using EQUIP

Teachers' critical discourse shaped how they interpreted disproportionate participation patterns shown in EQUIP analytics. We found two broad critical discourses of *individual mindset* and *systemic influence*.

When the facilitator asked Mr. Taylor about the marginalized pattern of participation for Manny, a male Latinx student, Mr. Taylor shared his explanation about the perceived fixed mindset that Manny held.

> Facilitator: So there are times when Manny is brought in there, but maybe it's just a sampling that happens to be [showing] this extreme pattern...or do you think that's more normal?
> Mr. Taylor: I've been fixated on growth versus fixed mindsets lately...encouraging students, kids to adopt a growth mindset because it's true. The idea that we can continue to grow throughout our life is true. ... So I am very much focused on the fixed mindset that Manny has, that all of us can adopt at a moment's notice. ... So it's not surprising to me that he gets into that fixed mindset quite often, and he isn't trying to grow, and become better, and accept the challenge, and work through the difficulties, and come out the other side being better because of the struggle that he goes through. So it's not surprising to me at all. (Mr. Taylor, debrief)

Mr. Taylor consistently portrayed Manny as not trying to grow and challenge himself, rather than considering how his race (i.e., a systemic influence) may be affecting Manny's opportunities to participate in small group learning settings.

Ms. Collins below shared an alternative critical discourse of systemic influence. When the facilitator asked Ms. Collins about equity-related patterns before reviewing the EQUIP report together, Ms. Collins offered her gendered experiences as a woman being positioned as the secretary in a small group setting, and she applied her critical discourse of systemic influence to interpret why she might see disproportionate participation by her marginalized students.

> I guess I expect that my minority students, whether that's in their academic level or their ethnicity or things, I'm sort of expecting to see that those are the students that are gonna end up asking questions more than they're gonna be doing explanations and answers. ... I'm expecting a lot of the time that those are the students who are gonna get put in the, "Here, just calculate this for us, run the calculator." … And not the ones who are reasoning. Mostly because I'm thinking about my time, when I was in college, as one of the few girls in the group, do I get relegated to the secretary position all the time? So I'm wondering if it's a similar thing in terms of my students of color and my lower academic-achieving students. Is that the same thing happening to them? (Ms. Collins, debrief)

Her critical discourse also shaped what she attended to in EQUIP analytics, such as who is asking questions or explaining and answering questions.

 © ISLS

Contributions of the Study

Our analysis showed how the teachers took up two primary resources (MWC and EQUIP) differently based on their critical discourses. This leads to three main contributions of the study. First, the range of how the teachers managed students' frustration with computational tasks highlights the importance of supporting teachers to meaningfully navigate the tension. Offering too much scaffolding nor leaving students in a helpless position would not be ideal. Explicit discussions on what and how much teacher support would encourage students to engage in disciplinary practices is a critical component of integrating computation in science.

Second, the contrasting interpretation of disproportionate participation by minoritized students showed that offering an equity-oriented tool is not enough. In particular, Mr. Taylor's interpretation of Manny's disproportionate participation concerns us because he attributed the issue to the perceived deficit of the marginalized student. His critical discourse also showed that the common frame of reference (e.g., growth mindset) could be twisted to place the blame on the marginalized students.

Lastly, the study largely highlighted the crucial role of teachers' critical discourses in the process of professional learning. Teachers' personal theories of teaching and learning represented in their critical discourses shaped the way they used two primary resources offered in PLS. We found that equity-oriented tools, such as EQUIP, may even be counterproductive when teachers' critical discourses reinforce deficit views on marginalized students. This warrants further research on how the computation- and equity-oriented professional learning contexts can be modified to explicate and reshape teachers' critical discourses.

Table 1: Two Primary Resources

Resources	Descriptions
Minimally Working Code (MWC)	Pre-made VPython codes that model particular science phenomena. The codes are working; meaning, they execute without an error. However, the codes need modifications to accurately represent the desired phenomena.
EQUIP Web App (EQUIP)	Classroom observation tool that generates quantitative analytics on student participation patterns based on students' social markers, such as gender and race (Reinholz & Shah, 2018; https://www.equip.ninja).

International Society of the Learning Sciences

A Dialogue on making use of constructionism in different scenarios as a leverage for empowerment, motivation, and learning.

Mariana L. Edelstein, TLT Lab, Columbia University and Instituto Singularidades, mariana.lederman@tltlab.org
Paola S. Ricci, TLT Lab, Columbia University and Instituto Catalisador, paola.ricci@tltlab.org

Abstract: The coronavirus pandemic forced Brazilian schools to move to an online environment rapidly. Consequently, many schools just took the traditional classroom approach to screens. This paper aims to reflect on our practices and share an innovative pedagogy that is adaptable to different scenarios and engages all learners. We will describe two cases to illustrate how a constructionist approach has sparked student agency and learning. We observed how a maker workshop contributed to a child with learning loss to complete his literacy process in the first one. In the second, we share the affordances of The Circle of Inventions practice, which allows for the implementation of constructionist moments in any learning environment. Ultimately, we aim to spark interest in more widespread constructionist practices in diverse learning contexts and leverage collaborations for new investigations, design, and implementation of innovative pedagogies in this field.

Introduction

This paper was born from an encounter at the Winter School of Learning Sciences in São Paulo, in August 2021. Exchanging experiences regarding our work as teachers, during the Covid-19 pandemic, in a private school, an afterschool maker program, and in a project designed to mitigate the problem of the lack of accessibility to online learning for students in a vulnerable community, led to the observation of a few patterns and the desire to think further and research issues regarding technology, making and the engagement in learning. Observing the clear need for adaptable strategies and routines to engage all students in education and seeing evidence that a constructionist approach, developed in these very diverse settings, has had a positive impact on students engagement, confidence and learning led us to ask ourselves, "how might we think together and design pedagogical innovations that allow for simple and purposeful constructionist learning opportunities in any learning environment?" With this question in mind, we began exchanging ideas. We decided to write this paper as a spark to an ongoing process of co-creation to develop, implement and test practices that promote more constructionist learning in any learning space. We use constructionist learning based on Seymour Papert's definition as a process where children are invited to create and construct meaningful and sharable objects to think with and play with. (Papert & Harel, 1991).

Like the rest of the world, the coronavirus pandemic forced Brazil to implement new forms of teaching and learning as schools rapidly moved online and to other forms of education according to connectivity and accessibility to technology. In this context, many schools just took the traditional classroom approach to the screens. Some tried to innovate and create engaging online learning. Others had to work around technology and deliver physical materials to students' homes. As Brazilian educators from different educational settings, this "new normal" has highlighted the need for innovative pedagogies that do not simply replicate the traditional classroom to screens. We also saw the need for learning strategies that are adaptable to different scenarios - online, blended, at school, or home - and that promote each learner's engagement. This paper will share two cases, that compose this dialogue, to illustrate how a constructionist approach has sparked students' agency, collaboration, and learning. In the first case, Edelstein observed how an afterschool maker lab workshop contributed to a child with learning loss completing his literacy process. The second, by Ricci, is regarding the practice of the Circle of Inventions, which allows for the implementation of constructionist moments in any learning environment. The ultimate goal of this paper, and this dialogue, is to spark interest in the topic to other teachers and researchers and leverage new investigations, design, and implementation of pedagogies that may support teachers in bringing more meaningful making into their classrooms no matter their context, access to technology, and curriculum.

The Constructionism of Seymour Papert (1991), the ideas of cultivating creativity in learners from Mitchel Resnick (2017), the concept of making in the classroom from Martinez and Stager (2019), the Agency-By-Design Project Zero framework (Clapp et al., 2017), the work on meaningful making developed by Paulo Blikstein and the Transformative Learning Technologies Lab (2019), the constructivism of Jean Piaget (1970), the critical pedagogy of Paulo Freire (1998), and the literacy process of Emilia Ferreiro (2011) are the main conductive threads and theoretical pillars that sustain and guide our work and the thinking behind this paper.

Intrinsic motivation as a necessary ingredient for the genuine engagement of children in learning processes is vital when thinking about the implementation of constructionist learning experiences. To reach such

 © ISLS

motivation, a sense of competence, autonomy, and belonging must be present, according to research in psychology and differentiation, and logically, the presence of meaning lies at the root of it all (Bondie, 2018). Constructionist learning, or maker-centered learning, is often connected to STEM (Science, Technology, Engineering, and Math) learning. In this paper, we will emphasize the importance of constructionist learning from the perspective of motivation and look at the positive impact generated in terms of social and emotional health for students involved. The Covid pandemic with the consequent social isolation of children highlighted, more than ever, the need for the design and implementation of learning experiences that have social and emotional wellbeing at the forefront. The cases that follow shed light on how constructionist learning experiences supported children in different contexts to be motivated and engage in learning and aim to provoke other educators and teachers to consider innovative strategies and routines to bring more constructionist learning into any learning environment in a way to trigger motivation, social and emotional safety, and learning.

The maker space as a facilitator for a child with learning loss

At the beginning of 2020, T., a 7-year-old male, a 2nd-grade student at a private school inspired by Reggio Emilia's approach and Paulo Freire's constructivism, found obstacles in his literacy process. T. was way behind his group, which worried his teachers. However, the family did not accept help for T. to participate in recovery classes offered within the school. At the same time, in a school of innovation and technology, T. attended maker workshops in weekly meetings. He was considered by the coordinator as highly capable, having already started his experience as a programmer. Faced with such different performances in these environments, I was interested in following him and understanding if maker education could collaborate with his literacy process. Therefore, I conducted interviews with the educators, with the management, did document analysis, observed the workshops, and experimented with the project carried out by T.

At first, I understood how the literacy assessment had been done at the School. The school was generous in its multiple probing resources and room configuration, free of tables and chairs. However, it is necessary to inquire and assess the development of each child to understand what the expectations are about them and the group. The school, aware of his learning gap, offered recovery classes. In this first moment, the family was resistant to the offer. Parallel to school activities, the starting point of the innovation and technology school for T. was different. The assessment process was formative, and the work developed individually, not depending on the pace of a group composed of so many children. Thus, it caught my attention that in an environment where assessments took the form of feedback, T. shows competence and realizes that he has resources and tools to develop his project, motivating and empowering him beyond that space.

The maker space is a literate environment, where its function is presented concretely through hands-on projects. Literacy begins with the process of understanding the world, so innovation, technology, and hands-on experience allow this reading to be concrete, with sense and sensitivity. Literacy needs to be understood as a personal project and the child's desire to access the world in which they are inserted. In this way, the involvement and path taken within the innovation and technology space should be analogous to the child's literacy project.

During the pandemic, T. was away from the school of innovation and technology for some time. Nonetheless, it was fascinating to observe the work he did when he returned. He elaborated his ideas and made them exist in his thoughts, despite the absence of hands-on experience in the makerspace. Upon returning, T. was full of ideas and desires. Although he did not realize that he already had enough knowledge to carry them out, these were quickly resumed with the help of his mediator, showing that the inner practice continued to take place, even if abstractly, during this period of absence. T. is a child who had difficulties with abstraction, as his teacher put it, but at this moment, he had the opportunity to notice that what he worked on in the abstract could be transposed to the concrete. This event empowered him and contributed to the development of the necessary abstraction for the literacy process. Such a fact demonstrates that we can work from a new perspective to empower the individual as a whole. Although there is no confirmation of any organic issue for T.'s difficulty, going through this experience helps him become more potent as an agent capable of learning and understanding that his difficulty is punctual.

The fact that T. successfully developed in the makerspace was also an opportunity for empowerment for the whole family. The space's coordinator, V., says that despite not having much contact with the family, "they are always very excited about T's projects. We always receive very positive feedback about his participation here in the lab, and the same is happening now with the brother, which reflects his great identification with our type of proposal". At first, the family told T's School that they trusted T.'s process in his own time, not understanding the need for the recovery class. I hypothesize that, by witnessing the growth through constructionist activities and by recognizing that T thrived in another environment, the family felt more comfortable accepting help to tackle T's difficulties related to literacy. In this way, the makerspace also acted as emotional support for the family.

T. is a child that does not give up on his desire to learn and gives importance to the space that school occupies in his life. With the help of the teachers, he understood he was capable of learning. This characteristic

of resilience also appeared in the makerspace. T. was deeply involved with his projects in a focused way. It was possible to see him devote hours to programming an Arduino, and in the end, when he saw that his result was not what he expected, he was satisfied with his learning and created new strategies for the following workshops. In the observations, it was clear that T. had a difficult time asking for help. However, the mediator in the makerspace made sure to prompt him and constantly asked questions and offered feedback, which he accepted. As he grew in the makerspace and learned from the modeling of the mediator, he felt confident to start helping a new classmate. From the maker's perspective, that the student may also occupy the position of teacher (Martinez and Stager, 2019), it is noticeable that T., as he began helping his new classmate, build his self-esteem, and understood himself as a mediator. When he understood that he could help his colleague with doubts, he started looking for a mediator to resolve his issues, leaving his passiveness behind.

At the end of 2021, T. was already successfully finishing his 3rd year at the elementary school. The difficulties in his literacy process had already been overcome. Within the makerspace, T. already occupied leadership roles and felt empowered and controlled his learning. Although not all fronts were in dialogue, for sure, it was a path of joint efforts between T., his family, his school, and the maker space.

The Circle of Inventions

Maker-centered learning promotes maker empowerment by developing a sensitivity to design through the creation of meaningful and shareable artifacts (Clapp et al., 2018). This path can be interesting for deep learning as children are actively involved in the learning process, are engaged in authentic real-world projects, have a chance to reflect on processes, articulate their understandings and collaborate with peers. However, implementing inclusive constructionist learning experiences that reach and engage all students can be a challenge for educators, especially in school contexts with time, material, professional development, curriculum, and technology constraints. This type of implementation made itself even more complex during the pandemic. In this section of the paper, we will share some examples of how the Circles of Inventions framework can help bring maker-centered learning into diverse classrooms, both online and in person. The Program Circles of Inventions (CoI), an initiative by the Brazilian non-profit Instituto Catalisador, began as a constructionist activity in public libraries in Brazil. After reading sessions, children engaged in the creation of meaningful personal narratives through the construction of artifacts to be played with and shared. Today, the program has evolved to include diverse non-formal educational spaces as well as schools. The framework developed for Circles of Inventions allows for a learning practice that fosters the thinking and sharing of narratives, ideas, and 3-dimensional drafts (artifacts) that are culturally responsive and meaningful. It may be integrated into different curriculum and pedagogical intentions (Camargo et al., 2019).

In March 2021, as we moved to online learning with less than a week to adapt and prepare for the "new normal", my goal was to continue with the constructionist learning experiences we were developing in the makerspace where I worked as a design thinking teacher in a private school in São Paulo. Due to the new context, the school reorganized the teaching teams into cohorts where all teachers would co-teach and support students' learning more integrally. The focus would be on literacy, math, and projects, especially in 2nd grade, where I was teaching. This new organization allowed me to partner with homeroom teachers in planning the writing workshops when we decided to adapt the writing workshops to the project we were developing and use the CoI framework as an opportunity for constructionists learning in the context of online learning. The framework, which includes a Circle of Reading, a Circle of Making, and a Circle of Narratives allows for multiple structures and thinking routines to be embedded into the practice, with the potential to scaffold group work, individual work, reflection, and articulation into realms that are meaningful for students. The core of the CoI is the creation of personal narratives after engaging in making a shareable artifact that translates thoughts and stories. The possibility of these personal narratives to emerge and find a safe space to be expressed is an essential aspect of this culturally responsive practice that fosters a sense of belonging. The CoI was an interesting and feasible way to spark motivation for writing workshops in an online context as: 1. The read-aloud (Circle of Reading) was possible, and children seemed to enjoy this moment, 2. Students could then move on to make artifacts (Circle of Making) sparked by a provocation born from the read-aloud with whatever materials they had access to at home, 3. They would later return to zoom to share their artifacts and stories (Circle of Narrative), a moment of high participation online. With this structure in place and children engaged, we would then give them the writing mini-lessons and send them to write inspired by their artifact and the narrative it generated. During journaling reflections, it became evident how much children had been engaged and were proud of the first book they managed to write throughout the term. The CoI that allowed for a constructionist learning moment, even online, seems like a practice that catalyzed more writing for this group.

Another example of the use of the CoI, in a different context, as a way to spark motivation and learning through constructionist experiences happened as an effort to continue the work of the maker-centered after school program of the Espaço Catalisador Pirituba, which works with students from a low-income community in São

Paulo. The student's lack of internet and device accessibility led the educators to organize maker kits for students' at home with guidelines for the activities. The app Whatsapp was something that most families managed to access on at least one family members' device, so this was the medium used for communication with students. Most activities proposed in the kits began with a story/narrative shared through Whatsapp, or in the Kit. Children were then provoked to make something and then share their creations and narratives via WhatsApp. Accounts by the team tell of high student engagement and family involvement, and where 80% of the children who were enrolled pre social isolation continued in the program.

In the Jd. Panorama community, a vulnerable housing settlement in the city of São Paulo, the CoI was also used online, thanks to a project to take the internet to students in the community. The goal was to give continuity to the work of the Creativity Studio, an afterschool program centered on art, making, and building agency in students. After receiving a kit with basic craft materials, the students of the Creativity Studio also engaged in a series of CoIs on zoom, one of which was a cycle of 4 encounters. The Circle of Reading used the book "What do you do with an idea" by Kobi Yamada (2013), which sparked a creative process that led the children to create innovative ideas regarding imagining the world after Covid. Students also gave each other feedback and submitted proposals to the Interaction Design and Children Conference Design Challenge. These examples show us how the CoI is a practice that may be used in different contexts to spark constructionist learning. It may take the form of a provocation for a project, as a community-building strategy, as the project itself, as a spark for a design process, and explore multiple contents depending on the books read, questions raised, and thinking routines implemented.

Conclusion

The cases exposed above reflect how a constructionist learning approach, that takes into consideration the student as a whole, that is culturally responsive and sensitive, where active listening by educators and peers is present motivates and engages students in such a way as to foster learning. In the first case, the possibility of the individual choosing his project, feeling able to carry it out and help his colleagues, collaborated to consolidate his literacy process. The whole experience gave him agency and empowered him to manage socio-emotional issues that previously paralyzed him. In the second case, the Circle of Inventions was a way to spark learning during social isolation in very different contexts, through read alouds, the making of meaningful artifacts, and, most importantly, the sharing of important personal narratives inspired by the artifacts created. This dialogue established by the authors through this paper reveals the relevance of constructionist learning experiences for meaningful and successful learning to occur. In light of the need for more motivation and consequent learning in diverse environments, constructionist possibilities designed to be easily implemented and culturally responsive, no matter the learning context, is a goal for us as educators. We take the opportunity of this paper to invite other educators and researchers to partner with us in the development of such innovative pedagogies, strategies, and routines that could facilitate the implementation of constructionist learning by any teacher in any environment, promoting agency in students, motivation, and learning.

Encouraging children to envision futures through learning in career development classes: Focusing on the case of Japanese elementary schools and "social scaffolding"

Ayaka Nakano, Graduate School of Education, the University of Tokyo, nakano@p.u-tokyo.ac.jp
Kunio Ushioda, Japan Society for Office Studies, k.ushi@snow.ocn.ne.jp

Abstract: This study analyzes what children in Japanese primary schools learn through career development classes carried out by volunteers who continuously participate in school-community partnerships, clarifying the influence of these classes. We analyze children's compositions describing their impressions of career development classes, utilizing a text mining tool (Tiny Text Miner βversion, or TTM) to analyze our data. Using TTM, we divide text data into words or phrases and analyze tendencies of word usage. Children, as a result, learn how long they will work during their lives, how society at present is constructed, what their future will be like, and what they work for in career development classes. Most children imagine what will happen in their future and future society, so these classes might provide them with the triggers to think about their future and offer "social scaffolding".

Major issues addressed

Education in schools is connected loosely to society, and children are always incorporated into it. Although many of them will work on it after graduating from high school or university, they cannot sufficiently learn the processes of viewing their future, thinking about their dreams, and realizing these future ideal perspectives. According to an investigation by the Japanese Cabinet Office, 60.6% of Japanese young people answered they had bright expectations for their future, which is the lowest rate among investigated countries (Japanese Cabinet Office, 2018). These results signify that it is difficult for Japanese young people to envisage a bright future and to form expectations about their future. To tackle these difficulties, in 2013, the Japanese government presented "4 Basic Directions about Educational Administration", and one of these directions signifies a "nourishing capability for surviving present society", which promotes career development. Career development in Japan, in general, is recognized as a way to nourish the ability to live. At the same time, career development aims to generate self-esteem and a sense of work based on children's curiosity, and to promote children planning their future and considering how they want to spend their lives.

Observing research on career development all over the world indicates that career development in the educational field can be seen to provide effective ways of nourishing children's perspectives on the future (e.g. Peila-Shustera et al., 2019). Previous research mentions that children must acquire the basic perspectives of career adaptability to envision their future and make educational or vocational decisions (Hartung et al., 2011). There is, however, not enough research on childhood career development, especially in non-Western cultures, despite studies on adolescence and adulthood (Liu et al., 2014). Career development is regarded as a way to promote children understanding their world, considering alternative goals, and planning courses of actions to meet goals (Magnuson & Starr, 2000). Children's aspirations and expectations for an occupation change dramatically during the elementary years (Auger et al., 2005). These results, however, do not specify how children concretely think or learn from career development classes, and they cannot clarify how children learn alongside career development providers or through comparing themselves at present to themselves in the future. Moreover, although the importance of connecting schools and society is recognized widely in Japan, there is not enough research about career development and about what children are learning through it. Regarding career development in elementary school, it is not an exaggeration to state that there is no analysis. This study thus seeks to analyze what children in Japanese primary schools learn through career development and to clarify the influence of it.

Methods

Participants and data collection

In this study, we investigate career development in Japanese public primary schools (called A school and B school). One volunteer in his 70s (called Volunteer O) engaged in conversation with A school and B school's principals, and they decided to hold career development in their schools. Volunteer O also participated in other activities held

 © ISLS

in these schools with fellow volunteers, so he continuously kept in touch with these schools, and he and the children knew one another. Ninety 5th grade children at A school and Fifty-eight 6th grade children at B school took career development classes in July 2021. These classes were held in such a manner as to prevent transmission of COVID-19, so Volunteer O consciously stood in front of the children while maintaining social distance, using PowerPoint and video (see Figure 1). He had been working at a company relating to communication, so he made presentations about 1) what his job was like, 2) why he began to work at that company, 3) how long we have to work, 4) what we work for, 5) how learning in schools can connect to our jobs, and 6) how to broaden our curiosity. This class contained Volunteer O's talking and videos relating to his jobs, showing a drone so that children would not be bored (see Figure 2). After finishing classes, teachers encouraged children to write what they learned when they participated. This study analyzed these children's compositions describing their impressions of the classes.

Figure 1
The situation of career development classes

Figure 2
How to introduce the story of the drone in classes

Method of analysis

Words and phrases that children often use can be clarified through text mining tool called Tiny Text Miner βversion (TTM), developed by Naohiro Matsumura and Asako Miura. Papers describing the impressions of career development classes of 148 children are analyzed. Before analyzing word usage, we designated the words that should be treated as noise in order to remove words not directly relating to children's impressions of career development classes. We also specified some words as synonyms that are combined through the analysis. We consequently filled the boxes of nouns, adjectives, and adverbs to designate objects of analysis. As part of the procedures stated above, we clarified 1) the tendency of word usage, and 2) relations between modification and re-modification through dependency parsing that can be ascertained by TTM. After clarifying the tendency of word usage and co-occurrence relation among words, we picked up some words or phrases from the analyzed results and observed concrete whole sentences containing these words or phrases. Through the above analysis, we tried to clarify how children learned and felt through career development classes.

Findings and implications

Tendency of word usage

As a result of analysis, 21 nouns, adjectives, or adverbs, which were abstracted more than 10 times, were designated: "job (noun)"= 73 times, "future (noun)"= 67 times, "movie (noun)"= 55 times, "interesting (adjective)"= 51 times, "drone (noun)"= 42 times, "class (noun)"= 29 times, "wonderful (adjective)"= 29 times, "study (noun)"= 27 times, "now (adverb)"= 26 times, "surprising (adjective)"= 24 times, "telephone (noun)"= 21 times, "school (noun)"= 18 times, "past (adverb)"= 18 times, "half (noun)"= 16 times, "development (noun)"= 16 times, "life course (noun)"= 16 times, " adult (noun)"= 13 times, "people (noun)"= 11 times, "dream (noun)"= 10 times, "society (noun)"= 10 times, and "like (noun)"= 10 times (see Table 1). These results refer to children who took career development classes and wrote about things relating to their jobs, their futures, their school lives, what they saw through the classes, and their feelings about the classes.

We then analyzed relations between modification and re-modification through dependency parsing. The results of analysis are as follows in descending order: "life course + half", "future + dream", "future + movie", "drone + manipulation", "class + interesting", "movie + interesting", "future + development", "drone + interesting", "job + like", and "job + money" (see Table 2). These results about relations among words signify that the words "half" and "life course", which were abstracted above, were used in relation to each other; we can predict that children mentioned something that happened through their half of the life course. The word "future" qualifies "dream", "movie", and "development", so children might imagine future developed society or their future dream through watching the movie, which was provided by Volunteer O, relating to future technologies. The word "drone" is often used in "manipulation" and "interesting"; thus, children may be surprised by the

manipulation of drones in the career development classes and find it interesting. These children also thought "class" or "movie" was "interesting", so they might experience a degree of interest, though there is the possibility that the impressions stated here are somewhat superficial. The word "job" is used in the same context as "like" and "money", so children may mention future jobs relating to their preferences or monetary conditions.

Table 1

Word usage: more than 10

job	73	study	27	development	16
future	67	now	26	life course	15
movie	55	surprising	24	adults	13
interesting	51	telephone	21	people	11
drone	42	school	18	dreams	10
class	29	past	18	society	10
wonderful	29	half	16	like	10

※1 Left sides: words

※2 Right sides: the number of words

Table 2

Relations of modifications and re-modifications

life course+half	movie+interesting
future+dream	future+development
future+movie	drone+interesting
drone+manipulation	job+like
class+interesting	job+money

※ "modification"+"re-modification"

How children learned in classes: observing concrete contexts

The results of dependence parsing, as stated above, clarified how some words are related to one another; nevertheless, they cannot signify the concrete contexts of the word usage. In this study, we therefore focus on "life course + half", "future + dream", "future + development", "job + like", and "job + money", which might strongly relate to career development, but the nuances or contexts of which are still ambiguous. We analyzed the original data, which comprised 148 papers on which children wrote their impressions of career development classes, and checked how the words "life course + half", "future + dream", "future + development", "job + like", and "job + money" were used in the concrete sentences. 1) "life course + half": Most children who used this combination mentioned that they were surprised at how long they have to work through their lives. Some children were motivated by the length of commitment to their jobs; others, however, felt that length was very long, with this feeling potentially fostering negative images of jobs (concrete sentences as follows).

> Boy 1: I was surprised that I have to work at a company for more than half of my life course, even if I have something that I want to do.
> Boy 2: I want to do the job which I like because I will be bored if I work for getting money.

2) "future + dream": Most children who used this combination mentioned their future dream. Some of them said that they had already decided on their future dream, and others said that they had not decided yet. Many of them found that career development classes had become triggers for imagining their future dreams.

> Girl 1: I have a dream that I want to do this job. People who were mentioned in the movie and classes today realized their dreams, so if I do not give up my dream and do my best to achieve it, my dream will come true. I therefore want to realize my dream, which I have had since I was a little child, and I want to feel that my job is very interesting.

3) "future + development": Most children who used this combination mentioned their curiosity about future development, and they imagined what would happen in their future.

> Girl 2: What I had the strongest impression of today was future development. Our society gradually develops, so it will become a different one in the future. I felt that this social change from present to future is very curious.

4) "job + like" and "job + money": Most children who used these combinations mentioned that they want to embark on their jobs because they want to continue their work for a long time and have a great life. Moreover, they expressed that they want to do their jobs not only to earn money but also to utilize their abilities.

> Boy 3: I thought about how important working and studying are though this class. Before taking the class, I thought people work only to get money. Taking this class enabled me to realize another purpose of working, so I will sometimes recall things that Volunteer O taught today when I am working in the future.

Conclusion

Children who participated in career development classes, in this study, were surprised at the reality of what a job entails, and were impressed by the reason for work. This very simple awareness can be said to be characteristic of career development in elementary schools because children in this age rage have a tendency to look to the near future according to development stages. These children's purity of perspectives about the future may enhance their feelings that these classes were very interesting. Children, as a result, learned how long they will work during their lives, how society at present is constructed, what their future will be like, and what they work for in these classes. Most children imagined what will happen in their future and future society, so these classes might provide them with triggers to think about their future perspectives, which inevitably contain positive and a few negative images of the future. Some tools used in these classes—for example, movies or drones—could offer a medium for children to look at the future. In addition, this study signified the possibility of collaboration between teachers, school counselors, and volunteers to realize career development classes, which broadens the range of jobs that children can learn.

Of course, the career classes analyzed in this study could not provide children with instructions on how to realize their futures; these classes could, however, illuminate children's futures and potential life courses. Providing young people with role models in the future encourages them to produce their ideal futures or to consider ways to realize their future. This process can be called "social scaffolding" in this study and may be related to intergenerational learning (Nakano, 2021). Children learned through relationships with volunteers or people who provided career development classes, and the behaviors of these people and the classes themselves became "social scaffolding" for children because career development, in this study, provided children with opportunities to learn and consider their future, promoting role modeling of children's futures and envisioning ways for children to achieve their dreams (see Figure 3). This study has importance in highlighting that career development classes present children with triggers for learning how study at school could connect to their futures and imagining more concrete images of these futures.

How the Learning Sciences Can Help Improve Corporate Training

Matthew Duvall, The University of Pennsylvania, mduv@upenn.edu

Abstract: This conceptual paper describes contemporary issues in one corporate professional development program. Culture, practices, modes of delivery, and external influences are all factors that contribute to the lack of innovation in corporate training. Although the learning sciences community does address learning in many contexts, including corporate training, this area is also underserved in research and the literature. This paper describes how the learning sciences might have a greater impact on corporate training by preparing learning and development practitioners to create more effective learning experiences and communicate more effectively about those experiences. Instructional designers in the corporate world must be able to efficiently create technology-enhanced learning experiences, while still advocating for the adoption and inclusion of relevant theories of how people learn.

Introduction

Many businesses in the United States have an employee training and development program. Typical categories of training include new employee orientation, compliance or regulatory training, job-specific skills improvement, and "soft skills" training (Colman, 2020). Research has shown a connection between employees' satisfaction with training and their overall job satisfaction (Jaworski et. al., 2018; Schmidt, 2007). However, these studies also found that employees are often dissatisfied with training options and companies can be reluctant to offer any training to part-time employees or those who are lower in the corporate hierarchy.

Although learning scientists have long advocated for a shift in how businesses view training (Barab & Plucker, 2002; Schank et. al., 1999) to focus more on contextualized experiential learning, much of the work in this area continues to be centered on schools or programs that are education-adjacent, such as university-business-partnership training programs (Bergner & Farad, 2021; Mambrey et. al., 2002; Raes et. al, 2017).

This conceptual paper, using an example from my experience as an instructional designer at a clinical service organization, argues that the learning sciences can help instructional designers and other corporate training practitioners to re-envision training in the workplace and create better learning experiences for all employees, resulting in greater job satisfaction and more fulfilled workers.

Theoretical Perspectives

Broadly, I am arguing for the learning sciences to examine how we can prepare instructional designers to work in corporate, non-educational settings. Learning scientists could apply principled practical knowledge, in those settings, to create "a ladder leading to sometimes radical design improvement" (Bereiter, 2014, p. 4). In addition, I am suggesting that we need to train instructional designers who are also "learning sciences communicators," similar to the Data Communicators proposed by Wolff et al. (2016), to broadcast the benefits of LS theories of learning and design frameworks throughout the corporate world.

To make this argument less abstract, I will discuss a specific case using the Social Infrastructure Framework developed by Bielaczyc (2006, 2013) to both design learning experiences and evaluate those learning experiences. The SIF focuses on four dynamic and inter-related elements: culture, practices, socio-techno-spatial relations, and interaction with the outside world (Figure 1). Previously, this framework was used in a single instructional design (ID) project for corporate training at a service organization for individuals with moderate to severe autism (Duvall, 2020). Although the SIF was originally focused on schools, the elements can be repurposed and refined to provide an approach to improving corporate training experiences as well.

Methodology

In this conceptual paper, I seek to address the question "How can perspectives from the learning sciences help instructional designers in corporate training programs? To do this, I provide an example of an organization where I worked as an instructional designer. Since 2004, X Autism Services (XAS), located in the northeastern United States, has served individuals with moderate to severe autism. The business's programs include early intervention for children from one to six years old, an educationally integrated behavioral services program for K-12 students who cannot be adequately served in the public school system, outreach programs embedded in public schools, and community integration and employment services for adults. XAS uses an applied behavior analysis (ABA) approach for treatment. In the last five years, the company's number of employees has more than doubled, resulting in an initiative to reframe the corporate training program. The goals for restructuring were to improve

 © ISLS

training in terms of resources needed, availability of courses, and impact on employee and business performance. In the next section, I will explain how I applied the SIF to the company's training program.

Results

Analyzing the context using the Social Infrastructure Framework

Cultural beliefs

Corporate learning programs often include discussions of adult learning theories (Colman, 2021; Gutierrez, 2021), modes of delivery (Masalimova et.al, 2016), and effectiveness (Strother, 2002). XAS is no exception. However, in practice there was little connection between theories of learning and practical implementation. In 2020, the business purchased and implemented a new learning management system (LMS) after evaluating several options. All of the systems touted individualized learning, peer-to-peer collaboration, and achievement recognition, but there was no discussion in the promotional materials about how these connected to various paradigms of learning. At XAS, as in many corporate training programs, there was not a well-defined overall paradigm for learning—especially surprising, given that the activities of the organization are centered on a behavioral approach to learning.

Often, training design and development requestors had little idea of which learners should be included or how learning should be assessed. There were also different categories of training: regulatory requirements, knowledge acquisition or "best practices," practical knowledge for specific jobs, and so-called "soft skills" training around interpersonal interactions.

Despite opportunities for innovation, the corporate training program at XAS often ended up focusing on things such as completion tracking, particularly for regulatory requirements, and return-on-investment versus costs (Rothman, 2002). There was also a focus on knowledge/learning as a product that could be purchased from others or, if developed internally, sold (Campbell, 2010; Taneja & Goel, 2014).

With the introduction of a Quality, Training, and Research (QTR) department in 2018, the organization indicated that it was attempting to shift its culture and training practices.

Practices

Because XAS began as a small company with fewer than 100 employees, corporate training most often occurred through direct instruction – lectures to all employees that were run by higher level employees in the organization. Typical materials included PowerPoint presentations and paper handouts. More informal training occurred on the job, in the moment and in context.

The goal of the QTR department was to implement an LMS and provide more streamlined instruction, including computer-based, self-guided training. However, early efforts merely replicated the existing practices, with videos of lecturers presenting PowerPoints.

Socio-techno-spatial relations

The practices of instructor-led training caused an issue as XAS grew. All-employee trainings for a company of 100 staff members require much fewer logistics and resources than for a company of almost 400. But initially there was no LMS to offer electronic delivery of training, which meant that other technology had to be adapted and repurposed. At the same time, the idea of "instructorless" training was such a cultural and practical shift that it impacted how employees, and executive leadership, viewed the relationship between learners/instructors/computers. Many discussions centered on how to ensure that learners were actually "doing" the learning. The most common questions were about how to prevent them from skipping ahead in videos or looking up answers for assessments.

Interactions with the outside world

The population that XAS serves, and the services it provides, means that there are significant regulations, particularly from the state government, that impact how its training programs operate. Yearly audits of each program require evidence of achieving training requirements. XAS also has consultants from private ABA practice and a graduate program at a local university who conduct professional development opportunities. These are primarily, but not singularly, offered to clinicians as opposed to direct support professionals or other support staff.

Instructional design using the Social Infrastructure Framework

Bielaczyc (2006) describes the elements of the SIF as interconnected, with the culture serving as the "substrate" (p. 306). That is, culture is infused throughout the practices, socio-techno-spatial relations, and interactions with

the outside world. Given this, to make significant changes in designing learning experiences, the culture also needs to change. There is a challenge here, because changing the culture requires both some form of intervention and the participation/acceptance of the members of the culture. It is a careful balancing act between pushing too far, and not pushing far enough, and requires communication tailored to the culture. Hallmarks of the learning sciences such as application of principled practical knowledge (Bereiter, 2014) and an iterative design-based approach can ameliorate these issues.

Next, I will discuss two ID projects and how they connect with the elements of the SIF as well as how the broad, corporate level understanding of the SIF elements, especially culture, informed these specific examples.

Software simulation training

In 2018, XAS adopted a new electronic health record software system. Executive leadership wanted to conduct training for all employees who would be entering client demographic and service records in the system. The original request was for an instructor-led session with an "I do – We do – You do" approach. I suggested an automated step-by-step simulator training, given that individuals often only need such training resources when they are actually using the system as novices. However, as a non-profit with limited financial resources, the only technology available to implement this training design was PowerPoint. Nevertheless, both the learners and executive leadership viewed the resulting "training module" favorably. This project involved and impacted culture (expectations of what comprised training), practice (method of training), socio-techno-spatial relations (use of software and how/when/where learners used it), and interaction with the outside world (knowledge of how to use PowerPoint to create a software simulator). As a result, it made a small but noticeable shift in how the company viewed training and helped make the case for investment in more advanced ID software. At the same time, an early suggestion that we needed no training at all – that users could learn how to use the system on their own from other employees and the materials available online from the software company itself—was unacceptable. Because of the ABA background of the company and its executive leadership, not having some XAS-developed form of a "task analysis" describing, step-by-step, how to complete data entry into the system was not viewed as a tenable solution.

Compliance and ethics training

One regulatory requirement was for employees to receive compliance and ethics training. While this is a pro-forma expectation at many companies, XAS wanted to customize its training due to the company's cultural precedents, as well as the unique population it served. The initial prototype was a brief welcome video from our compliance officer, followed by a recording of a PowerPoint presentation with a voice-over narration. The stated objective for the training was primarily to make employees aware of the compliance program and comfortable with identifying and reporting possible issues. I developed a second version of the training, a board game adapted from the classic Clue game. Learners would consider ethical principles through the lens of employees from the various program lines, generate ideas about what unethical behavior might look like, and discuss ways that they could report lapses (phone, email to compliance officer, website, and so on). In a trial of the two approaches, there was a statistically significant difference between the end-of-course knowledge assessments, with those who played the game performing better. In this case, one interesting feature was the socio-techno-spatial relations. The original request envisioned employees completing the training on their own with a computer, a departure from the corporate training culture. However, the game design allowed for sharing of multiple perspectives and discussions about ethics, which was more in line with the training's actual objectives. Another factor, related to interaction with the outside world, was that the compliance officer was in an external mentorship program on corporate compliance, which encouraged businesses to adopt novel approaches for their training programs. Finally, this case demonstrates how even "check the box" regulatory trainings can become more meaningful learning experiences if businesses want them to be.

Discussion

The SIF provides one example of how the learning sciences can improve corporate training. There are other theories (such as activity systems) or specific frameworks that could also be applied. Bereiter (2014) argued for the importance of principled practical knowledge in improving education. With corporate ID, practice is often emphasized, while principles – the theories underlying learning – are overlooked. Regardless of the aesthetic quality or technical aspects of corporate instructional materials, there is little connection between learning theory and practice.

At the same time, corporate training programs are a significant source of adult learning. They require businesses to invest resources and hopefully lead to more fulfilled and more competent employees, which benefits

both the employees and the company. However, corporate training often views learning as a product and focuses on metrics like time spent in training or multiple-choice questions answered correctly.

The learning sciences has much to offer corporations to improve learning. To achieve this potential, though, we must pay careful attention to factors that influence the acceptance of different approaches to learning. We must also equip practitioners, such as instructional designers, with research-based approaches to design that can facilitate their work. Most importantly, we must prepare them with the communication skills necessary to advocate for the use of learning theories and design frameworks that reflect what we know about how people learn.

Sources of difficulties in reading comprehension in adults with ADHD

Dorit Segal, Open University of Israel, doritse@openu.ac.il

Abstract: Academic success is highly dependent on students' ability to comprehend written texts. Students with Attention Deficit/Hyperactivity Disorder (ADHD) often struggle with reading comprehension, but the source of their difficulties is unclear. The current study compares reading comprehension, as well as linguistic and cognitive skills in adults with and without ADHD. Results show worse reading comprehension in adults with ADHD and an association between reading comprehension and sustained attention. Implications for reading comprehension instruction are discussed.

Introduction

Academic success is highly dependent on students' ability to read and comprehend written texts. Individuals with Attention Deficit/Hyperactivity Disorder (ADHD) often struggle academically (Barkley, 2000), and reading comprehension deficits, although not considered a primary deficit in ADHD, may contribute to these academic difficulties. It is currently unclear whether individuals with ADHD have reading comprehension difficulties and what underlies these difficulties if they exist. Some studies found that children and adults with ADHD have reading comprehension difficulties (Brock & Knapp, 1996; Samuelsson et al., 2004; Stern & Shalev, 2013), while others presented inconclusive findings (Ghelani et al., 2004). These inconsistencies may be related to individual differences in readers with ADHD, as well as to the tools that assess reading comprehension. Reading comprehension may vary as a function of cognitive and linguistic skills. In addition, the texts that assess reading comprehension differ in length, complexity, the degree to which they are meaningful and engaging, and their attentional demands, thus posing differential challenges to individuals with attention deficits. The type of reading comprehension questions can also affect the findings.

Most studies on reading comprehension in ADHD focus on identification of difficulties in reading comprehension. Little is known, however, about the nature of these difficulties. Reading comprehension is an active process in which the reader simultaneously extracts and constructs meaning from the written text, thus creating connections between the ideas presented in the text, and forming a coherent mental representation of the general message (Graesser et al., 1994). This process involves linguistic and cognitive abilities (e.g., vocabulary, memory, and attention), motivation (e.g., purpose of reading and interest in the content), and knowledge (e.g., topic knowledge and knowledge of comprehension strategies; Snow, 2002). Other critical components of reading comprehension are meta-comprehension, a special case of metacognition, and self-regulation. Meta-comprehension is the knowledge that readers have about their own comprehension (Flavell, 1979; Poissant, 2005). Self-regulation is the experiences, feelings, and thoughts that occur during reading, or any other ongoing cognitive activity. These experiences give individuals an internal feedback about their comprehension and allow them to use strategies to solve comprehension problems. Readers who are less confident in their comprehension may use more strategies to compensate for their poor understanding (Temelman-Yogey et al., 2020).

Individuals with ADHD have deficits in executive functioning (Pennington et al., 1993), and these deficits can affect each of the skills necessary for reading comprehension. For example, students with ADHD can struggle with remembering the text, with maintaining constant level of focus (i.e., sustained attention) during reading (Stern & Shalev, 2013), or with monitoring comprehension. Indeed, reading abilities of students with ADHD are often technical, with no deep semantic processing, and students may read an entire chapter but have no idea about its content (Levine, 1987). Students with ADHD may also be less motivated than students without ADHD, due to their earlier negative experience with reading comprehension. Understanding the cognitive mechanisms underlying reading comprehension will help create better assessment tools, and will help refine research-based instruction methods to promote the development of proficient comprehenders (Snow, 2002). The current study aimed to compare reading comprehension in students with and without ADHD and to characterize the source of reading comprehension difficulties in students with ADHD, if they exist.

Methods

Participants

Fifty-nine students from the Open University of Israel took part in an on-line study in exchange for course credit. Twenty-five participants (19 women, *M* age = 28.04 years, *SD* = 4.70) comprised the ADHD group, and 34 participants (*19* women; M age = 27.10 years, *SD* = 4.51) comprised the control group. All participants were born

 © ISLS

in Israel, they were native Hebrew speakers, and they reported no developmental or learning disabilities besides ADHD. The groups differed neither in age, t (57) = .78, p = .442, nor in years of education, t (57) = .22, p = .813.

Tasks

Neuropsychological testing

Participants answered some basic demographic questions and then completed a continuous conjunctive performance test (CCPT) to measure their sustained attention. In the CCPT, participants were presented with 320 geometric shapes and were asked to press the space bar when the target (a red square) appeared. The standard deviation of reaction times was used as a measure of the ability to keep a constant level of performance during the task, so that large SDs reflect poor sustained attention (Tsal et al., 2005). After completing the CCPT, participants performed the reading task, followed by an immediate recall task (Segal et al., 2019), as well as a Hebrew vocabulary test (Kavé et al., 2022). In the immediate recall task, participants named 12 pictures and were then asked to recall the names of the pictures. The memory score is the percent of items recalled correctly. In the vocabulary task, participants were asked to choose the correct meaning of 12 infrequent Hebrew words out of four alternatives. The vocabulary score is the percent of correct responses. Next, participants provided some more background information regarding their development and their language history, and then they rated the level to which seven ADHD symptoms characterized their behavior on a 1 (never) to 7 (very often) scale (Konfortes, 2010).

Reading tasks

Each participant read one of two informational texts: a text about the Taj Mahal (417 words) or a text about Babylon (426 words). Participants were asked to read the text and then to rate their comprehension ("how well did you understand the text on a scale of 1 (did not understand) to 4 (understood perfectly), as well as to judge their learning ("what are the chances that you will answer comprehension questions correctly on a scale of 25-100%?"). Then, they were presented with seven multiple-choice questions about the text. The accuracy score is the percent of correct answers to these seven questions.

Results

As shown in Table 1, participants with ADHD did not differ from control participants in memory and vocabulary, but they reported having higher levels of ADHD symptoms and their sustained attention was worse.

Table 1: Cognitive measures by group

	ADHD		control		t	p
	M	SD	M	SD		
Memory [a]	64.67	17.23	69.36	13.41	1.18	.244
Vocabulary [b]	48.33	22.18	54.17	21.64	1.01	.316
Sustained attention [c]	95.78	41.25	73.72	31.64	2.26	.028
ADHD symptoms [d]	21.00	5.07	15.85	3.69	4.51	<.001

[a] Percent of items recalled; [b] Percent of correct responses; [c] SD of reaction time to targets in milliseconds; [d] Level of reported symptoms.

Accuracy levels were similar across texts, t (57) = .46, p = .648, and therefore all further analyses were conducted for the two texts together. As shown in Table 2, participants with ADHD provided lower ratings of their comprehension than did control participants. They also judged their learning as less effective. Accuracy scores were lower in the ADHD group relative to the control group.

Table 2: Meta-comprehension and comprehension measures in the reading task, by group

	ADHD		Control				
	M	SD	M	SD	t	p	Cohen's d
Comprehension rating	2.92	1.04	3.38	.70	2.05	.045	.52
Learning judgement (%)	72.44	18.72	84.12	11.01	3.00	.004	.76
Accuracy score (%)	78.29	18.03	89.50	14.63	2.63	.011	.71

Table 3 presents the correlations between accuracy scores on the one hand and memory scores, vocabulary scores, sustained attention, and level of ADHD symptoms on the other hand. Sustained attention correlated significantly with accuracy scores as well as with ADHD symptoms.

Table 3: correlation analysis

	Memory	Vocabulary	Sustained attention	ADHD symptoms
Accuracy score	.23	.09	-.41**	-.07
Memory		.31*	-.04	-.20
Vocabulary			.05	-.10
Sustained attention				.36**

* $p < .05$, ** $p < .01$

Discussion

The present study explored whether adults with ADHD show difficulties in reading comprehension compared to age-matched students without ADHD, as well as the cognitive underpinnings of these difficulties.

Participants with ADHD reported higher levels of ADHD symptoms, they had significantly lower sustained attention, and their reading comprehension was worse relative to aged-matched controls. Participants with ADHD also rated the texts that they read as more difficult, and demonstrated lower confidence in their ability to answer comprehension questions than did participants without ADHD. The two groups did not differ in memory or in vocabulary.

These findings support previous reports of reading comprehension difficulties in adolescents with ADHD (Stern & Shalev, 2013), and suggest that reading comprehension difficulties persist into adulthood. These difficulties can also explain why students with ADHD often struggle academically (Barkley, 2000). Participants with ADHD have most likely dealt with reading comprehension difficulties since childhood, thus developing decreased confidence and increased awareness of their comprehension abilities over time. Nevertheless, they were probably unable to implement strategies to improve their reading comprehension.

Importantly, accuracy scores were not related to the level of ADHD symptoms, but to sustained attention, suggesting that inability to keep a constant level of focus impairs reading comprehension. Lapses of attention may impede the creation of connections between the ideas presented in the text, thus limiting the ability to understand the general message.

In the current study, there were no associations between memory and vocabulary scores and reading comprehension. This does not mean that memory and vocabulary are not important for reading comprehension. Instead, the findings suggest that these abilities do not suffice for reading comprehension and that sustained attention also plays a critical role in the process. Assessing sustained attention in poor comprehends will allow us to construct a more personalized educational plan for each reader according to the reader's specific cognitive functions, and to prevent frustration and increase confidence in reading and academic success.

International Society of the Learning Sciences

"It disrupts power dynamics": Co-Design Process as a Space for Intergenerational Learning with Distributed Expertise

Areej Mawasi, University of Colorado Boulder, armw7353@colorado.edu
Arturo Cortez, University of Colorado Boulder, Arturo.Cortez@colorado.edu
Ashieda McKoy, University of Colorado Boulder, Ashieda.Mckoy@colorado.edu
William R. Penuel, University of Colorado Boulder, william.penuel@colorado.edu

Abstract: This paper examines co-design as a space for collaborative learning with distributed expertise across generations and roles. We address a fundamental need in co-design spaces: to develop and surface expertise relevant to the design task across a team. We examine how knowledge building is experienced in a design process that has asymmetric expertise among youth, educators, and researchers. We used co-design to engage educators and youth in collaboration towards designing an Artificial Intelligence unit that centers equity and justice. We structured for joint inquiry to facilitate collective learning. We conducted interviews with participants to understand how they experienced codesign. We found our approach allowed for collaborative learning and interactivity among participants with different kinds of expertise.

Introduction and Background

Successful codesign requires a range of expertise and perspectives; just how to do so in a way that disrupts and transforms existing practice presents every co-design team with a challenge. Two motives for co-design are (1) to create conditions for design where diverse expertise can be surfaced, leveraged, and transformed (e.g., Bang & Vossoughi, 2016) and (2) to redistribute social power (Huybrechts et al., 2017). Co-designers have devised different strategies to accomplish these aims, such as creating novel activity structures for eliciting multiple perspectives (Matuk et al., 2016), mapping values of co-designers (Ryoo et al., 2015), and structuring participation to center perspectives of marginalized groups and communities (Ishimaru et al., 2018).

We build on the need to address such issues in research on co-design within the context of an effort to broaden participation of historically marginalized communities in STEM through the design of a unit focused on the sociocultural, ethical, and political dimensions of artificial intelligence using a storyline approach (Reiser et al., 2021). This paper aims to contribute to literature of participatory design, by focusing on co-design process as perceived by participants, towards understanding how we might design intentionally towards creating a collaborative learning where distributed expertise is developed in an intergenerational context that includes youth, educators, and researchers and where there was limited domain knowledge across all role groups.

Organizing for Intergenerational Codesign to Build Shared Expertise

To support codesigners in building expertise that could be distributed across the team, we created multiple specialized activity structures within the context of a week-long design workshop and the preparation for it (see Table 1).

Table 1
Co-Design Workshop Activities Aim and Structures

Aim	Activity Structures
Clarifying purposes	Engaging with everyday technologies Unpacking the AI goals together (subgroup)
Organizing for intergenerational design	Course to learn how to write storylines Organizing small groups where youth worked together as a group
Learning about AI	Identifying AI experts to join space Stations for learning

In this paper, we present the analysis of interviews conducted with participants to investigate how participants experienced the distribution of expertise and being in an intergenerational environment in co-design.

 © ISLS

Methods

In this section we describe the context of this study and participants, procedures of activities, instruments we used to examine participants' experience in co-design activities using interviews as an instrument, and the analytical approach used to examine their experience. We addressed the following questions: *How were participants' values reflected in their experience of co-design? What relationships did this co-design process afford or constrain for participants? How did their experience compare to other experiences involving building with others and youth?*

Participants

In this co-design workshop, eight educators and five young high school students (TS = teacher and student participants) participated in a five-day co-design workshop aimed at developing and designing an artificial intelligence unit that centers issues of equity and justice in artificial intelligence. Teachers' backgrounds and disciplines varied, and included High School English Language Arts (ELA), Middle school World Geography, Middle School Math, History, and after-school education programs focused on Media Literary and Agency. We invited high school students to join this co-design process as we wanted to attend to young people's voices and at the same time co-construct knowledge with them. Two months after the co-design workshop was completed, we invited all TSes for interviews. Twelve of 13 TSes were interviewed for addressing the research questions of this study. We also invited AI and AI Education experts to share their expertise in the workshop, two representatives from the district partner and four AI researchers who are experts in technology and artificial intelligence education. Four facilitating researchers led the co-design workshop to develop a storyline.

Data source

To address questions raised in this paper, one researcher conducted 12 interviews with teachers (n=7) and high school students (n=5) two to three months after the completion of the workshop. The protocol included questions designed to elicit participants' experience of the workshop, how it compared to other activities like it, key moments of the workshop, and the ideas they were exposed to or developed as part of the workshop. In addition, we asked participants about needs for teaching and learning if the units were used in their classrooms. All interviews conducted using an online conference application due to COVID-19. The interviews were recorded and transcribed using professional transcription services. One researcher reviewed the transcription for accuracy.

Analytical approach

To address our primary research question, we centered our analysis of interviews on (1) values participants reflected about their experience, (2) relations they described as were afforded or constrained in the co-design workshop, and (3) how this experience compared to other experiences they had in relation to work with others and building collaboratively. We conducted an inductive analysis that aimed at identifying themes and categories related to the three research questions.

Findings: Participants' Experience of Co-Design Workshop

Values and care in co-design

Throughout the workshop participants and researchers discussed norms and guiding equity-oriented principles in the co-design process and the ends towards which this learning space was organized (e.g., designing ethical AI literacies curriculum). We found that values and acts of care were enacted in different ways by teachers, researchers, and students, according to interviews with participants.

Multiple participants described that the co-design space was one where participants *showed respect for one another, felt welcomed, and positioned as valued co-designers.* Participants said that care and respect were values evident among teachers, researchers, and young students in ways that ideas were taken into consideration and invited in the space, and participants' backgrounds and prior experiences even as non-experts in the subject matter were respected. For example, one teacher mentioned "we were treated like professionals the whole time....it felt like it was leaning into everyone's different expertise." Notably, this teacher was someone who did bring significant expertise as a technology instructor in their school, specifically related to AI.

Relationality in co-design

Participants observed that relationships evolved in the space, and they said that co-design was a safe space to build relationships across people with different kinds of expertise and ages. These relationships developed between participants also included thinking collectively and individually about communities they work with (e.g, teachers, parents, students, communities of color).

When *building relations* in the space, participants said facilitators encouraged and designed for communication among all participants. Such interactions supported participants to learn about one another and build relations with one another. For example, a student asserted, said "I really liked how we could interact with other people and learn more from them [working together in groups]." Participants said that the co-design workshop was a *safe space* where they could "take risks without feeling embarrassed." A key part of that for participants was that participants felt they could seek help and pose questions, without the risk of judgment. One teacher who acknowledged they do not have expertise in AI, said "it gave space for everybody else who didn't know and knew they didn't know and felt uncomfortable by the fact they didn't know, to kind of grow."

As described earlier, the space brought participants with diverse and varied expertise and experiences to the space. We found that this diversity and variety allowed for fluid positionalities to be enacted and at the same time disrupted relations between teachers, students, and researchers. In other words, *the positionality of participants in relation to others* took different forms depending on type of activities and discussion topics, that is, participants described their role in relation to others in different ways taking different positionalities.

Uniqueness of experience: comparing this experience with other experiences

In analyzing how participants compared co-design to other experiences, we focused on how participants experienced the redistribution of power in the context of knowledge building compared to other experiences. Participants' experience of the co-design process and outcomes was described as different from other experiences in educational settings or professional settings (like curriculum design, professional development) when it comes to who is involved in the co-design process (e.g., diverse people including students) and the intentionality in co-design method (e.g., using storyline approach).

Participants described co-design as offering an opportunity to think about educational possibilities that were different from their previous experiences. For them, the co-design process was *disrupting the status quo* for what counts as design of curriculum and learning environments. For example, one teacher said, when asked if they would recommend this session to other educators, "Because it disrupts...it disrupts power dynamics. It disrupts our notion of what curriculum can be and look like. And then I think ultimately it infects the K-12 space with something that actually seats or has the potential to seat young people as co-conspirators in developing their own learning." This alternative possibility was also shared by students, who experienced the opportunity to build with teachers and have a say on the curriculum design process as a unique learning opportunity in which, "they [the teachers] were learning from us as we were learning from them" reflecting on the difference between power dynamics they often have with teachers versus during the co-design session.

Building collaboratively as a process and outcome

Participants described the co-design space as one where they were *building together*. Participants described the co-design space as affording collaborative building and thinking with others and building relations among participants through interactions during activities. Interviewees recognized that the process of building together involved them exchanging and navigating their varied expertise, experiences, and voices towards engaging in activities. Importantly, building together connected to who is in the room is enriching to the teachers and students experience. That is, the presence of participants of color who shared common cultural practices as expanding of what counts as diversity beyond the expertise in the space. One teacher, for example, described that an essential aspect of building with other participants was having people with varied expertise yet also a representation of people of color, "I also think, there were quite a few people of color in the room. I personally, as a person of color like when I'm designing, I like to be around other people who look like me and who have other experiences like me and it always enriches the session just like immediately." One student described an example where participants constructed an idea when exchanging perspectives and discussing, this example not just illustrate the notion of building together, but also building together with youth ideas in particular, "The discussion boards we did on the Jamboards, we all put our thoughts into it and we could see clearly our different perspectives of it. When we were saying stuff, the adults branched off what we were saying. So they understood where we were coming from and they started discussing more about it, so we added more into the conversation."

Participants described different types of ideas that were constructed with other participants and researchers. The participants described content related ideas (e.g., learning about racism in games), learning about co-design structure and process as a methodology, and ways to use materials and tools used in activities. One idea that resonated with multiple participants is learning about sociocultural dimensions of AI, such an idea was constructed in discussions among participants and researchers. For example, one teacher said, "the way there was that woman who did this research about how the facial recognition software mostly only worked on white faces, because of the data set was from only white faces and things like that. The way because the data that the AI uses

is from our racist history, it is reproducing that racism in a way that's neutral, because it's a computer program, that was a big take away from me."

Conclusion and Future Work

Several intentionally designed activity structures supported the development and elicitation of expertise in an intergenerational context. We found that these activity structures helped create a "safe space" for collaboration and knowledge building among participants around justice centered topics that matter to participants. In addition, positioning all participants as "not expert" in AI facilitated participation across generations and across the research-practice divide. For young people, the intentional design of the space did not require youth to think like adults; rather, intentionally designing spaces where they can maintain who they are, and assert their childhood/youth-hood as to express their perspectives (e.g., Cortez & Lizárraga, 2020).

Such findings are an invitation for co-design researchers to attend to equitable participation and ethics in structuring collaborations in co-design processes. Such a lens can disrupt power dynamics among participants and create a possibility for varied positionalities and ways of knowing and being to build knowledge collaboratively. In this paper we attended to the experience of educators and young participants in the co-design process as it is narrated by them. Future work we aim for will be centered on identifying and connecting between participants perceived experience and the actual engagement in situ.

Students' changing understanding of psychological evidence: Integrating evidence evaluation in psychology instruction

Abstract: This study extends the prevailing emphasis on evidence in the natural sciences by offering a novel fine-grained analysis of how undergraduate students evaluate psychological evidence. The study employs the Grasp of Evidence framework to explore psychology students' epistemic ideals and processes for evaluating popular psychological evidence, and examines how these change following a course that included collaborative evidence evaluation and design tasks. Analyses of pre and post evidence evaluation assessments reveal three key shifts in students' grasp of evidence: in perception of the sources of psychological knowledge, in views of scientific objectivity, and in definitions of psychological phenomena.

Introduction

To date, the majority of research on evidence evaluation practices has focused on the natural sciences (e.g., McNeill & Berland, 2017), and relatively little attention has been given to how students engage with evidence from the social sciences in general, and psychology specifically. This is particularly problematic because such evidence has become a staple of popular accounts of human behavior, and often informs public policy (e.g., Einfield, 2019). Moreover, evidence in psychological research has unique attributes as it is based on studying complex and unobservable everyday phenomena in ways that are amenable to empirical examination and replicable by other scientists (Elmes et al., 2011). Attentiveness to these characteristics is particularly challenging as psychology students often struggle to appreciate the scientific foundations of psychology (Balloo et al., 2018). However, we currently know little about how undergraduate psychology students' competence to evaluate psychological evidence can be fostered. Accordingly, this study examined if and how psychology students' ideals and processes for evaluating popular psychological evidence change following an introductory psychology course that provided opportunities for engaging in collaborative online evidence evaluation and design tasks.

Evidence evaluation poses unique challenges to students and laypersons because they lack the extensive disciplinary and methodological knowledge that is needed to understand and evaluate study designs and measures (Duncan et al., 2018). Thus, lay understanding of scientific evidence is inevitably bounded. Accordingly, Duncan et al. (2018) proposed a theoretical framework, called the Grasp of Evidence framework, which unpacks the dimensions of evidence that are relevant for preparing students to engage with evidence as outsiders to science. Duncan et al. (2018) argue that to meaningfully engage with science, laypersons need to grasp two aspects of evidence. The first aspect is experts' evidentiary practices – how experts gather, understand, evaluate, interpret, and integrate evidence. The second aspect is laypersons' evidentiary practices, that is, of how laypersons can use evidence despite their bounded understanding of science.

Within each of these aspects, Duncan et al. (2018) identify specific epistemic aims, epistemic ideals, and reliable epistemic processes for reasoning with and about evidence (Chinn et al., 2014): *(a) Epistemic aims* are the epistemic products or outcomes that people set to achieve. *(b) Epistemic ideals* are the criteria or norms that are used to evaluate whether epistemic aims have been achieved and the quality of epistemic products. For example, some of the epistemic ideals of expert evidence evaluation are the appropriateness of the methods and measures and the validity of the conclusions. *(c) Reliable epistemic processes* are the procedures, strategies, or methods that people can use to successfully achieve epistemic aims. Reliable processes of expert evidence evaluation involve, for example, scrutinizing the appropriateness of the study design. (Duncan et al., 2018).

Though there is a dearth of research on how students evaluate psychological evidence, researchers have identified some overarching challenges for evidence evaluation in psychology. First, students often fail to appreciate, or even actively doubt, the scientific basis of psychology as the study of human behavior (Balloo et al., 2018). Second, students often perceive objectivity in psychology as the negation of subjectivity: science is objective to the extent that it remains value-free (Douglas, 2009). However, objectivity does not require rejecting values, but arises from the using trustworthy processes for interacting with the world, and from social processes of validation, agreement formation, and debate. Third, students struggle to grasp how psychological knowledge is defined and evaluated through the use of valid operational definitions of subjective and complex phenomena.

Introductory psychology courses could provide an opportunity for cultivating such disciplinary epistemic practices. However, such courses are commonly lecture-based and have prioritized the coverage of content

 © ISLS

knowledge in the various domains of psychology at the expense of active engagement with epistemic practices (Gurung & Hackathorn, 2018). Researchers have stressed the importance of explicating the psychology's scientific and offering experiences that illustrate how research findings are underpinned by research methods.

Accordingly, this study set out to examine the following research questions: (1) How do undergraduate students' epistemic ideals and processes for evaluating popular psychological evidence change following an introductory psychology course designed to foster evidence evaluation competence? (2) How are students' evolving evidence evaluation ideals and processes reflected in collaborative evidence evaluation and design tasks?

Methods

Participants and Course Design

The study was conducted in a first-year undergraduate introduction to psychology course in a large university in Israel. The sample included 120 students (24 groups of 5 students, 70% female, 30% male). The course consisted of eight video lectures covering the basic domains of psychology. In addition, to facilitate engagement with psychological evidence, three collaborative online evidence evaluation tasks, and face-to-face meetings that centered around students' experiences in these tasks, were added to the course. The synchronous online tasks were conducted in the chat application on the course's Moodle platform. In each task, students were asked to evaluate popular accounts of psychological evidence and to formulate more scientifically rigorous ways to study these phenomena. The information sources (a newspaper piece, a TED talk, and a podcast) and the subjects discussed (e.g., emotions, approaches to psychotherapy) were intended to reflect psychological evidence students are likely to encounter online in their everyday life.

Data Sources and Analysis

Data sources included an evidence evaluation assessment, administered at the beginning and end of the course, and students' written discussions in the synchronous online group tasks. In the evidence evaluation assessment, participants read three popular reports that presented psychological evidence of varying quality ranging from low quality anecdotal evidence to a detailed report of a well-designed study. The pre- and post-assessments addressed different popular psychological topics (pre: child rearing; post: sleep), but the reports had highly similar source and evidence features and quality. Participants were asked to rate the trustworthiness and quality of each piece of evidence and to justify their evidence ratings in writing. The analysis focused on identifying epistemic ideals and processes of evidence evaluation in participants' justifications of their evaluations. We iteratively developed a coding scheme relying on the Grasp of Evidence framework (Duncan et al., 2018). Interrater reliability for all codes was higher than Cohen's Kappa > 0.78 ($M = 0.90$, $SD = 0.07$), which is a substantial level of agreement.

The goal of our qualitative analyses of students' discourse was to elaborate and refine the quantitative findings. Hence, we first quantitatively identified codes in which there were significant changes between the pre- and post-assessment. We then qualitatively analyzed episodes in which these codes were discussed by paying attention to the meaning of the codes in students' discourse and how this meaning was negotiated.

Findings

Theme I: Shifts in sources of knowledge – Decreasing reliance on personal knowledge

There was a significant decrease (from 69% to 52%, $p = .005$) in students' reliance on the ideal of *personal coherence with experience and intuition* to evaluate evidence ("Conclusions align with the reader's personal knowledge, experiences, or intuitions."). The decrease in personal coherence may reflect a growing recognition of the limitations of lay knowledge and a greater sensitivity to the division of cognitive labor between experts and laypersons. Yet, this decrease could also be due to increased disciplinary skills for evaluating evidence, which may have taken the place of reliance on personal judgments. Despite this decrease, even after the course, half of students still relied on personal coherence when evaluating evidence.

Analysis of the group discussions revealed that students rarely relied on personal information. Moreover, in contrast to the explicit reliance on personal knowledge or experience in the pre- and post-assessment tasks, in the group discussions personal information was auxiliary and implicit. We could not find examples in which students openly appealed to personal experience or knowledge in order to justify their proposals or arguments. This position was reserved for disciplinary knowledge about psychological theories and research methods.

Theme II: Shifts in views of objectivity – Towards procedural objectivity

There was a significant decrease (from 41% to 17%, $p < .001$) in appeals to the ideal of objectivity ("Conclusions are not influenced by researchers' subjective experiences, preferences, or values."), accompanied by increases in

use of the processes of replicating results ("Researchers attempt to confirm the results by running the study again with additional samples etc."; from 24% to 55%, $p < .001$) and using appropriate instruments ("The use of research instruments that can accurately and reliably measure the phenomenon at hand."; from 13% to 23%, $p < .05$). Taken together, we suggest that these shifts indicate changes in students' understanding of objectivity. Pre-instruction, students leaned towards depicting objectivity as achieved when scientific inquiry is unaffected by researchers' subjective judgments, preferences, and perspectives. Following instruction, students appeared to develop a more procedural view of objectivity, with increased mentions of measurement processes. In addition, students attended more to the social process of replicating results.

The collaborative tasks required evaluating evidence and proposing more rigorous means of studying psychological phenomena, which led students to discuss procedural aspects of objectivity. Consider, for instance, one group's discussion on which research instruments could be used to study emotions:

Speaker	Time	Utterance
John	08:33	Using questionnaires?
Dana	08:34	If we identify faces, we can analyze emotions, no?
George	08:35	Measuring brainwaves, measuring heartbeat, and measuring facial expressions could give us some something. If we use a large enough sample it could be quite accurate.
Sara	08:35	Yes, we need to combine different measures because emotions are really complex, and change from person to person.
Dana	08:36	And to construct experiments that include a verbal description and see if they align.

The group wrestles with the question of how to scientifically study emotions via a dialogical process in which they construct and critique each other's ideas. Throughout this discussion, notions of objectivity are not attributed to researchers, but rather to research instruments. Hence, this discussion is underpinned by an effort to identify procedurally objective (Douglas, 2009) ways to measure emotions, i.e., ways that would enable researchers to measure emotions in a systematic, quantifiable, and consistent manner. Nonetheless, issues related to replicating results were infrequently mentioned in the group tasks, which could reflect the fact that students focused on evaluating and designing a single study.

Theme III: Shifts in definitions of psychological phenomena – Towards operational definitions

The third shift involved changing views of the conceptualization of psychological phenomena. Specifically, students focused less on the nature of psychological phenomena and more on how these phenomena can be studied empirically. This shift was reflected in a decrease in the clarity of definitions ideal ("The phenomenon studied, and the variables, should be clearly and precisely defined."; from 44% to 18%, $p < .001$), together with an increase in mentions of valid methods ("Reliance on methods and study design that appropriately represent the phenomenon the researchers wished to study."; from 2% to 38%, $p < .001$). We suggest that these changes expose a shifting understanding of the interplay between evidence and phenomena. Instead of placing the onus on precisely conceptualizing the phenomenon itself, the focus shifts to finding valid ways to empirically study and measure these phenomena – formulating operational definitions that describe phenomena in measurable terms.

In the group discourse, students increasingly discussed the need to develop conceptually clear operational definitions. This was most salient in the third task, in which participants were asked to devise a scientific way to examine which therapeutic approach is "deeper". For example, consider this excerpt:

Speaker	Time	Utterance
Ben	09:05	We need to define "depth" and find a quantifiable way to measure it.
Merriam	09:06	Wait one second, what do we mean by depth? Therapy in which the therapist and patient have a deep relationship?
Ana	09:06	Maybe we can conduct an experiment that will examine whether patients know what the sources for their negative thoughts are.
Merriam	09:07	Therapy that discusses the deep aspects of an individual- the unconscious, events that took place in the past.
Ben	09:07	In my opinion, depth is the "meta-feeling" of the patient towards their own therapy. And not necessarily the outcome.
Merriam	09:07	But can we really know?
Ben	09:07	Maybe we can design a questionnaire.

 © ISLS

The group formulates and criticizes attempts at defining "depth" in treatment (deep relationship, sources of thoughts, unconscious events, etc.). This discussion is tied to quantifiable ways to measure depth. Hence, the request to collaboratively design experiments that test ill-defined psychological phenomena ("depth" of treatment) led to meaningful discussions of how to clearly define and operationalize constructs in valid ways.

Discussion

To the best of our knowledge, this is the first study to map in detail the epistemic ideals and processes are used by students to evaluate psychological evidence. Participants exhibited three main shifts in their evidence evaluation practices. First, there were shifts in views of sources of knowledge, with a significant decrease in reliance on personal knowledge. Nonetheless, even post-instruction, about half of the students appealed to their personal experience to evaluate evidence, suggesting that what develops is the ability to coordinate personal and disciplinary knowledge. Second, we identified shifts in students' views of objectivity – the emphasis shifted from objectivity as a lack of subjective bias to a more procedural view of objectivity, according to which scientific evidence is justified through the social processes underpinning its production (Douglas, 2007). The need to formulate precise and replicable means of studying psychological evidence in groups tasks, led to an emphasis on procedural aspects such as using reliable research instruments. Third, there were shifts in definitions of psychological phenomena, as students paid more attention not to the phenomenon itself, but rather to how it is conceptualized in a way that renders it amenable to scientific study. In the group tasks, students engaged with the challenge of translating everyday psychological phenomena into operational definitions. The necessity to do so in a group, led students to both explicate their own thinking, and to critique and develop the definitions and measures suggested by their group members.

These observations lead us to suggest three emerging design principles for engaging students with psychological evidence. First, providing students with ample opportunities to evaluate psychological evidence from a disciplinary perspective. This positioning encourages students to rely on disciplinary norms and standards rather than personal knowledge. Second, students' evaluation practices could be honed when they encounter evidence of diverse quality such as popular accounts, which include variations both in the evidence's quality and the rigor of its presentation. This may support a more refined understanding of the scientific work due to the need to disentangle unclear and partial accounts of evidence. Third, students stand to gain when they have opportunities to engage in collaborative evidence critique and design: not only explicating their thinking and critiquing others', this process is highly reflective of the nature of psychological research – simulating the processes scientists engage in when aiming to critique and improve existing operational definitions and measures.

Future research could address these issues while also tackling the limitations of the current study. First, as it did not include a control condition (for ethical reasons), we cannot evaluate the contribution of the different components of the course's design. Further, students did not have opportunities to integrate evidence from different sources or engage with more comprehensive bodies of evidence, which would have allowed them to explore more deeply the social and procedural nature of scientific evidence. Also, the tasks' emphasis on positioning students as experts came at the expense of paying more attention to lay evidentiary practices.

Affordances and Constraints of Online Museum Experiences for At-Home Science Engagement During the COVID-19 Pandemic

Catherine L. Dornfeld Tissenbaum, University of Illinois Urbana-Champaign, catdoti@illinois.edu
McKenna Lane, University of Illinois Urbana-Champaign, mllane2@illinois.edu

Abstract: Online museum experiences, or OMEs, expand access to museums beyond physical buildings. With limited visitation during the COVID-19 pandemic, many museums increased OME offerings, including those marketed toward families. However, as most OMEs are developed for K-12 audiences, we have yet to understand how OMEs support–or fail to support–families' engagement with science. To investigate how OMEs facilitated or constrained families' engagement with at-home science learning, we conducted semi-structured interviews with parents and used quantitative discourse analysis to identify emergent affordances and constraints. These findings can inform the design of OMEs that effectively support families' at-home engagement with science.

Introduction

During the COVID-19 pandemic, many museums developed distance learning programs to support visitors' engagement and learning in lieu of physical visits (Ennes, 2021). With limitations on physical visits, online programs offered alternative avenues for connecting visitors with museums. These programs, which we refer to as online museum experiences (OMEs), range from digitized collections to recorded tours and live investigations of phenomena (Chong & Smith, 2017). Over 1,200 OMEs are available through an online database curated by the American Alliance of Museums (AAM), with filters for content area, age range, and more (AAM, 2021).

While OMEs are available to the public, including families, we have a limited understanding of the ways that OMEs support families' engagement with science learning. Pre-pandemic, most OMEs were designed for use by K-12 students and teachers (Ennes, 2021). However, the pandemic incentivized development of OMEs for broader audiences (Ennes, 2021). Given the relatively new development of OMEs for families, we have yet to identify how OMEs support families' engagement and learning, including with science topics. We focus on this issue for two reasons. First, parents/guardians (hereafter "parents") play a pivotal role in supporting remote learning during the pandemic (Budhrani et al., 2021; Garbe et al., 2020). Second, designers cannot assume that what works in physical museums will automatically translate to OMEs, or that OMEs should aim to replicate physical visits given the unique affordances of online environments (Din, 2015; Ennes, 2021). In response, OME designers must identify key factors that support ease of use, learning, and enjoyment for families (Lin et al., 2012).

To this end, we analyzed 11 families' participation in science-focused OMEs for at-home learning during the COVID-19 pandemic. Our research questions were: *which characteristics of OMEs facilitated families' engagement with at-home science learning, and which characteristics constrained engagement?* We used quantitative discourse analysis (Mercer, 2004) to develop a coding scheme that identified emergent affordances and constraints of OMEs based on parents' feedback as shared during semi-structured interviews. This paper reports on affordances and constraints for at-home science learning among families, with the potential to inform future design of effective, engaging OMEs.

Theoretical Background

Pre-pandemic, most digital programs designed by museums were intended for K-12 audiences (Ennes, 2021). Virtual field trips (VFTs) are designed as multimedia-rich experiences that reduce financial and logistical barriers, generate access to experts, and emphasize learner-centered pedagogies (Klemm & Tuthill, 2003; Lacina, 2004; Zanetis, 2010). Yet, VFTs can unintentionally recreate barriers to access, such as by requiring English fluency, Internet access, and quiet environments (Klemm & Tuthill, 2003; Stylianou-Lambert & Stylianou, 2010). Also, VFTs differ in quality of design, including alignment to educational standards (Klemm & Tuthill, 2003; Zanetis, 2010). While VFTs offer alternative means of accessing museums globally, they are not without drawbacks.

The pandemic incentivized adaptation of existing digital programs and creation of new programs for wider audiences as delivered through synchronous meetings, social media, websites, and email (Ennes, 2021; Mitchell, 2019). These programs could supplement subject areas de-emphasized by remote learning, such as the arts and physical education (Budhrani et al., 2021). Yet, this benefit was less available to families without resources and/or self-efficacy to use technology (Garbe et al., 2020). Given families' status as a relatively new audience for digital programs, program designers must work with families to identify their needs and establish value, especially for families overwhelmed by remote learning (Flaccus & Gecker, 2020; Garbe et al., 2020).

 © ISLS

To understand how OMEs impacted families' engagement in at-home science learning, we used Gibson's (1986) conceptualization of affordances and constraints to identify positive and negative OME characteristics that affected families' engagement. Gibson (1986) described how the properties of people and their environment allow or prohibit certain actions or interactions (i.e., affordances and constraints0. People must be able to perceive affordances to act on them, including in digital environments where people must interpret the meaning of symbols, text, and multimedia to engage in learning (Greeno, 1994; Norman, 1999). This paper investigates the perceived affordances and constraints of OMEs that impacted families' engagement with at-home science learning toward the goal of informing designs for online informal learning experiences that effectively engage families.

Methods

This study focused on families' use of OMEs during the COVID-19 pandemic, with "family" referring to adults and children in the same household. We studied families because of parents' important role in supporting emergency remote learning (Budhrani et al., 2021; Garbe et al., 2020). We recruited 11 families through social media and e-newsletters and interviewed one parent per household (n = 11). Of 11 parent interviewees, seven identified as female, three as male, and one as genderqueer. Ten parents were white, and one was South Asian. Parents' mean age was 41 years old. Most parents (82%) had completed at least a master's degree. Children included 11 male children, six female children, and one non-binary child. Seventeen children were white, and one was South Asian. Children's mean age was 6 years old. Dependent on age, children experienced remote learning and/or parent-supervised activities in lieu of school or daycare. All families had Internet access at home.

Data sources included 11 semi-structured interviews with parents conducted from Dec. 2020 – Mar. 2021 by the first author. Each parent reflected on at least one self-selected, science-focused OME during the interview. Interviews included the following questions: (1) How would you describe the OME you shared with your child(ren)? (2) What kinds of goals did you have, broadly, when you started that experience? (3) What kinds of science learning goals did you have when you started that experience? (4) What do you remember from your experience? (5) How did you see your children learn during the experience? (6) Have your children mentioned the experience since? (7) Would you recommend this experience to others? (8) In your opinion, what tools in this experience were the most useful for learning? (9) Did you continue to investigate this topic afterward? If so, what other resources did you use? (10) What kinds of experiences or resources would you like to use in the future? Probes to elaborate were used when appropriate. Interviews lasted from 12 to 45 minutes (mean = 23 minutes).

We analyzed interviews using quantitative discourse analysis (Mercer, 2004) to develop an emergent coding scheme from parents' responses. We watched interviews independently to generate possible codes, then developed a coding scheme based on overlapping observations. We checked interrater reliability through independent coding of over 20% of the data (249 turns of 1,004 total turns of talk). Global Cohen's kappa was 0.90, which is considered "strong" (McHugh, 2012). Any differences were resolved through discussion. We independently coded remaining turns, then calculated the percentage of families mentioning each code and the percentage of individual codes within total turns of talk. Details of the coding scheme (including individual kappa values, descriptions, and examples) can be found here: https://bit.ly/3Jj3uHB.

Findings

During interviews, all parents shared their motivation for choosing to interact with a specific OME. Families were most often motivated by content or subject area (91% of families), followed by place or geographic location (64%). Five families mentioned that the study itself motivated them to interact with an OME (45%), while two families (18%) selected OMEs based on school or homeschool assignments.

Parents mentioned 14 characteristics of OMEs that facilitated their engagement (see Table 1 below). All identified affordances were emergent, not predetermined. Parents most frequently described the multimodal, interest-driven, and entertaining nature of OMEs. Four affordances specifically focused on support for engagement with science, such as exposing children to science topics and developing interest. Most parents thought OMEs could promote science and engineering practices, such as developing experiments and making predictions. Parents also saw OMEs as pedagogical supports that helped them to support their children's learning. Several parents reflected on their own experiences with K-12 science education. We observed variety in parents' science backgrounds; one parent received little K-12 science instruction while another had been a science teacher.

Parents also described constraints of OMEs for supporting at-home learning (see Table 2). Many families preferred physical activities and felt that OMEs were lacking compared to physical or outdoor activities. Also, OMEs were not considered to be as good as the "real thing" when visiting museums. Some parents preferred books over OMEs when supporting children's learning about science. Others mentioned concerns over screen time required by digital programs, especially in addition to remote learning, and wished to limit screen time even while recognizing potential benefits of OMEs. Parents also noticed when OMEs provided insufficient instructions,

follow-up resources, or support for varying background knowledge. Last, parents noted when topics were interesting to some, but not all, family members.

Table 1
Relative Frequency of Affordances Mentioned by Parents

% Families	% Turns	Affordances for Participation & Science Engagement
91%	5.6%	Multimodal; OMEs incorporated text and multimedia
91%	5.0%	Interest-driven; OMEs reflected parents' or children's interests
91%	3.2%	Entertaining; OMEs were enjoyable to interact with
82%	3.8%	Accessible; OMEs promoted access to people and places and incorporated everyday resources
73%	3.3%	Hands-on; OMEs featured hands-on activities or experiments
73%	1.9%	Educational; OMEs offer educational content and/or activities
64%	2.7%	Attention-sensitive; OMEs were developmentally appropriate for children's attention spans
64%	2.1%	Flexible; OME topics were switched quickly and easily
64%	1.6%	Shared; OMEs fostered interaction among family members
45%	0.8%	Vetted; OMEs offered research-based information
91%	3.6%	Exposure; OMEs exposed children to science concepts and possible interest
72%	3.7%	Inquiry; OMEs helped children to ask questions about phenomena
72%	2.2%	Parent support; OMEs helped parents to talk about science
45%	1.7%	Parent reflection; OMEs helped parents to reflect on relationships with science

Table 2
Relative Frequency of Constraints Mentioned by Parents

% Families	% Turns	Constraints on Participation
64%	1.2%	Physical activities preferred; OMEs lack the feeling of a physical museum visit.
27%	0.9%	Insufficient instructions; OMEs did not provide enough instructions or resources.
36%	0.7%	Books preferred; books are better sources of information than OMEs.
27%	0.5%	Conflicts over screen time; OMEs increase screen time beyond comfort level.
18%	0.2%	Split interests; OMEs do not reflect the whole family's interests.
9%	0.7%	Lack of parent support; OMEs lack sufficient background content

Discussion & Conclusion

We aimed to understand how OMEs impacted families' engagement with at-home science learning during the COVID-19 pandemic. By analyzing semi-structured interviews, we identified 14 affordances that facilitated families' engagement, with four focused on science, along with six constraints on engagement. These findings have implications for the design of OMEs that support informal learning about science in home settings.

Science content played a major role in families' selection of a particular OME, which we expected based on prior research about families' motivations for visiting museum websites (Lopatovska, 2015) and the general interest-driven nature of informal learning. This study also revealed that a museum's geographic location played a major role in families' selection of OMEs, with OMEs allowing families to virtually travel to places that could not be accessed during the pandemic. Further investigation of the geographic appeal of OMEs is warranted to understand how OMEs can be designed to teach science from both nearby and distant locales. We were initially surprised by the schooling motivation, given our focus on informal learning, but we found that homeschooling families already used OMEs on a regular basis to support their self-directed learning goals.

This study expands on earlier research about museum practices during the pandemic (e.g., Ennes, 2021) by analyzing emergent feedback from parents, rather than predetermined characteristics (e.g., Lin et al., 2012), with attention to constraints, too. Identifying both affordances and constraints expands the field's understanding of "good" design for family-friendly OMEs, with insights for genuinely supportive digital experiences that avoid common pitfalls. Our findings reiterate prior research about family-friendly characteristics, both digital (Lin et al., 2012) and physical (Borun et al., 2008), in that experiences should be multimodal, fun, and social. However, the ways in which physical affordances extend to online environments must be carefully considered, as OMEs present unique possibilities and limitations beyond replication of physical exhibits (Ennes, 2021). As the pandemic introduces new technologies for self-directed learning, designers of informal and/or online learning may benefit from research about technology-specific affordances and their impacts on science education.

This study is limited by a small, narrow sample of parents (who were mostly white and educated with Internet access at home) despite our efforts to recruit a more diverse sample (e.g., advertising free Internet Hotspots). Parents with access to education and resources may be more inclined to engage in learning activities such as OMEs during leisure time (Hood, 1983). To investigate this connection between parents' education and interest in OMEs, we plan to analyze surveys collected during this study about families' use of OMEs before and during the pandemic and their attitudes toward teaching and learning about science. We noted that two demographically similar families had very different experiences with OMEs; we plan to analyze their experiences as contrasting cases. We also plan to examine videos of families' interactions for evidence of scientific reasoning and/or learning. We would like to expand this study with a greater diversity of families, including more homeschooling families, to learn more about OMEs' role in self-directed learning.

In conclusion, this paper contributes emergent insights about the affordances and constraints of online museum experiences for at-home science learning. While families engaged with different OMEs, their interviews revealed common observations about the design of OMEs that facilitated or constrained engagement. This paper also emphasizes the role of families as relatively new and unique users of OMEs. Together, these insights can inform designs for OMEs that effectively support family-friendly engagement and learning.

A Path Analysis of Gender Differences in Social Presence in Online Course Discussion Forums

Amos Jeng, Hannah Valdiviejas, Michelle Perry
amosj2@illinois.edu, hsv@illinois.edu, mperry@illinois.edu
University of Illinois Urbana-Champaign

Abstract: *Online social presence*—the degree to which individuals project their identities and personalities into a web-based community—plays an essential role in fostering a connected and satisfying learning environment. The present study's aim was to explore gender differences in behaviors related to social presence in an online course. Using path analysis, we found that students identifying as women or non-binary were more likely than men to use indicators of mood, feeling, and emotion when posting to an online college course discussion forum, holding posting frequency constant. These results have implications for instructional strategies aimed at facilitating social presence in online learning environments.

Introduction

Social presence theorists aim to provide insight about online social interactions by examining the degree to which individuals "project themselves socially and emotionally" in online spaces (Garrison et al., 1999, p. 99). When online learners are socially present, they are perceived as real individuals with histories and fully formed personalities (Kehrwald, 2008). Social presence allows students to overcome feelings of loneliness or isolation typical to online settings by identifying with others (Kehrwald, 2008), which in turn leads to improved course satisfaction and learning (Swan & Shih, 2005). Thus, social presence often makes the difference between an online environment characterized by coldness and isolation, and one characterized by connectedness and interpersonal contact.

However, although social presence can be a critical component of any online learning community (Rovai, 2002), it is possible that not all students contribute to and experience social presence in the same way. As such, "it is unwise to presume that one particular online instructional strategy would affect all students equally" (Rovai & Baker, 2005, p. 32). Thus, to target all students' interpersonal needs, we need to improve understanding of online communicative behaviors from diverse students.

In this research, given our interest in the relationship between identity and technology in learning environments, we examine how online behaviors related to social presence may differ along gendered lines because gender is "created, maintained, and changed through communication" (Houser et al., 2019, p. 36). Survey studies have found that compared to men, students identifying as women perceive the online environment as having greater levels of social presence (Richardson & Swan, 2003), feel more connected to other students (Rovai & Baker, 2005), and are more likely to see the Internet as a tool for interpersonal communication (Jackson et al., 2001). Thus, it is possible that socially constructed conceptualizations of gender that associate strength and independence with masculinity and emotion and dependence with femininity (Morgan, 2021) yield differences in online behaviors that impact social presence.

Existing studies typically measure social presence using self-report scales, which are often inconsistent in their definitions of social presence (Lowenthal, 2010) and unable to assess behaviors relevant to social presence in real time. Therefore, our research is "concerned not just with how people perceive each of the presences *but also with what people … actually do during online courses*" (Lowenthal & Dunlap, 2014, p. 27, emphasis added).

The present study

Our investigation explores gender differences in three defined categories of social presence (affective, interactive, and cohesive) when posting to an online course discussion forum because each of these plays a role in creating a connected learning community (Garrison et al., 1999). *Affective* social presence is "the expression of emotion, feelings, and mood" (Rourke et al., 1999, p.6); *interactive* social presence is evidenced by attentiveness, acknowledgement, and reinforcement from one's peers (Rourke et al., 1999); and *cohesive* social presence is shown by "activities that build and sustain a sense of group commitment" and unity (Rourke et al., 1999, p.8).

This research is significant because students' behaviors when interacting via forums impact perceived social presence (Tu & McIsaac, 2002). Thus, it is important to understand how student behaviors are related to social presence in such settings. Our research question is: *Are there gender differences in the use of affective, interactive, or cohesive indicators of social presence in online course discussion forums?*

 © ISLS

Method

Participants

We analyzed three semesters' worth of discussion forum data in fully online sections of an introductory statistics course at a large public university in the midwestern United States. Data come from the 287 students who voluntarily posted to the discussion forum (1,674 initially enrolled; we removed the 1,381 students who did not post to the discussion form, 1 student with missing gender data and 5 students who enrolled multiple semesters). Our sample included 86 students (30.0%) who identified as men, and 201 (70.0%) who identified as women or non-binary. While we acknowledge that identifying as non-binary is not the same as identifying as a woman, the number of students identifying as non-binary was too small to analyze separately while protecting the privacy of their records (per the Family Educational Rights and Privacy Act).

Measures

The 287 students produced 801 discussion forum posts. We adapted Rourke et al. (1999)'s coding scheme to assess the three social presence categories in students' messages; see Table 1.

Table 1
Indicators of Social Presence (adapted from Rourke et al., 1999)

Category	Indicator	Example	Interrater reliability (Cohen's κ)
Affective	1. Expression of emotion	"IS ANYONE GETTING 'C'?"	.89
	2. Use of humor	"I had 3 tries and 4 options. I got the question wrong. Rip"	1.00
	3. Self-disclosure	"I am beyond lost, even with that video"	.71
Interactive	4. Continuing a thread	Software dependent (e.g., "Subject:Re")	–
	5. Quoting or referring explicitly to others' messages	"what do you mean by 'skewed to the left'?"	.74
	6. Explicitly requesting help	"Can someone explain question 3?"	.86
	7. Complimenting or expressing appreciation	"That helped immensely!"	.89
	8. Expressing (dis)agreement	"I agree, question 7 sounds misleading"	.74
Cohesive	9. Using vocatives	"Thanks, Pal"	.91
	10. Using inclusive pronouns	"We unfortunately all have different numbers"	.97
	11. Using phatics, salutations	"Hi all"	.75

For each forum post, we assigned a value of "0" (i.e., the indicator is absent in the message) or "1" (i.e., the indicator is present in the message). The first and second authors each coded the same 20% of the data and obtained substantial agreement (Landis & Koch, 1977). The remaining forum posts were coded by the first author. To determine students' *affective*, *interactive*, and *cohesive score*, we calculated each student's average number of indicators used per post for each social presence category. To account for the possibility that students who were more engaged in discussion forums were also more likely to use social presence indicators in messages, we also assessed each participant's posting frequency, defined as one's total number of posts written duuring the semester. Gender information was obtained from course data and coded as "0" (man) or "1" (woman or non-binary).

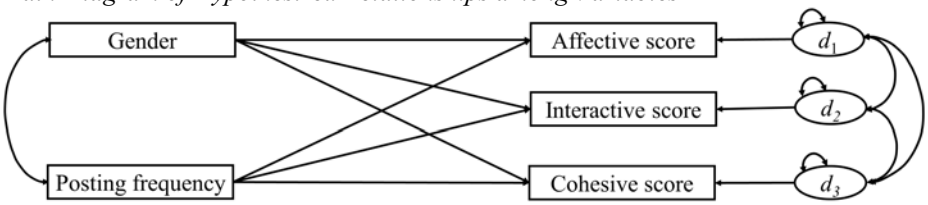
Analysis

We used path analysis to evaluate the direct effects of gender and posting frequency on affective, interactive, and cohesive score using the *lavaan* package in R (Rosseel, 2012); see Figure 1. Gender and posting frequency were hypothesized to have direct effects on affective score, interactive score, and cohesive score. Disturbances were included in our model to represent influences on outcome variables unaccounted for by our predictors. Gender and posting frequency were allowed to correlate, as were the disturbances corresponding to outcome variables.

Results

Interactive indicators were the most utilized category of social presence indicators among participants ($M = 1.00$, $SD = 0.38$), followed by affective indicators ($M = 0.38$, $SD = 0.44$), and lastly by cohesive indicators ($M = 0.16$, $SD = 0.33$). In total, participants used an average of 1.54 social presence indicators (across all categories) per post.

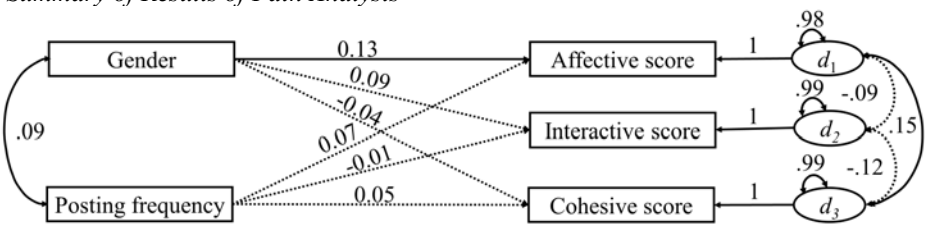
Figure 1
Path Diagram of Hypothesized Relationships among Variables



We used maximum likelihood estimation to estimate path model parameters; robust standard errors were used to correct for bias introduced by non-normal distributions in outcome variables (Browne, 1984). Because our model was just-identified, assessment of overall model fit was not relevant (see Yang, 2018).

Of the estimated direct effects, only the effect of gender on affective score was significant (β = 0.13, p = .02, 95% CI = [0.019, 0.240]), where students identifying as women or non-binary used a higher number of affective indicators per post than men. The effects of gender on interactive (β = 0.09, p = .19, 95% CI = [-0.035, 0.176]) and cohesive score (β = -0.04, p = .50, 95% CI = [-0.121, 0.058]) were non-significant, as were the effects of posting frequency on affective (β = 0.07, p = .11, 95% CI = [-0.002, 0.017]), interactive (β = -0.01, p = .66, 95% CI = [-0.006, 0.004]), and cohesive score (β = 0.05, p = .24, 95% CI = [-0.002, 0.010]). Figure 2 summarizes our results in the form of a path model, with fully standardized estimates reported for all parameters.

Figure 2
Summary of Results of Path Analysis



Note. Solid lines represent significant parameter estimates at p < .05. Dotted lines represent non-significant parameter estimates at p > .05. Variances associated with disturbances represent the proportion of variance in an outcome variable unexplained by our predictors (see Yang, 2018).

Discussion

Our aim was to contribute to ongoing conversations regarding the relationship between identity and technology in learning environments. Towards this end, we explored gender differences in students' contributions to three distinct categories (i.e., affective, interactive, and cohesive) of social presence in an online college course discussion forum. Our findings revealed that students identifying as women or non-binary were more likely than men to express mood, feeling, and emotion when posting online.

This result aligns with previous reports of gender differences in the online expression of emotion (Guiller & Durndell, 2007). We also build on earlier studies by using path analysis to compare the relative effects of gender on three social presence categories, as well as controlling for students' level of engagement in discussion forums. Our results suggest that gender differences in behaviors related to social presence primarily manifested themselves as differences in contributions to affective social presence, rather than to interactive or cohesive social presence.

This study complements previous research reporting that gender may be related to perceived social presence in online courses (Richardson & Swan, 2003; Rovai & Baker, 2005). That is, it is possible that in addition to perceiving other students as being more socially present, women and non-binary students also made more of an effort to be socially present themselves, in part by projecting their affective self into online forum posts. This interpretation is supported by previous research demonstrating that those who perceive greater levels of social presence in online communities are also those who project their personalities into online communities to a greater degree (Swan & Shih, 2005). Future research should simultaneously assess perceptions of and contributions to social presence within a single sample to test this hypothesis.

Furthermore, we can interpret this work through the lens of constructionist theories that see gender as "constructed through communication … cultivated by social institutions" (Houser et al., 2019, p. 34). Specifically, gendered patterns of socialization that identify intimacy and vulnerability as feminine values may have influenced how students chose to enact their gender identity in the discussion forum setting and thus resulted in disparities

in contributions to social presence (Rovai & Baker, 2005). Thus, to foster greater social presence in online learning commnunities, it may be important for educators and students to interrogate cultural norms that conceive of affective social presence as an intrinsically feminine quality.

In conclusion, this work contributes to conversations surrounding identity and learning technologies by exploring social presence in more nuanced ways than past studies. We believe that a promising avenue for future research would be to explore how educational and cultural institutions cultivate gendered communicative practices that in turn yield disparities in students' tendencies to project their identities in a web-based learning community. Such work could play an important role in informing conceptualizations of online social presence, challenging stereotypical gender roles, and informing the development of strategies designed to facilitate social presence in online learning environments.

Abstract: This study uses positioning theory to understand *how students come to construct their own and others' mathematical authority.* The study took place in the context of a classroom teaching experiment with 22 first-grade students in a demographically and academically diverse school. We coded the interactions of the eight students who had the most whole class airtime. We also determined airtime for these participants, which involved total talking time during whole class discussions, total utterances spoken during whole class discussions, and the number of times they were talked to. Findings show how one student's airtime contributed to her establishing undue authority and in turn having an incorrect idea endorsed by another student. Findings also reveal some of the interactions that contribute to authority construction over time.

In this study, we explore the following research question: *In what ways do students come to construct their own and others' mathematical authority?* Mathematical authority is "the degree to which students are given opportunities to be involved in decision making and whether they have a say in establishing priorities in task completion, method, or pace of learning." It is specific to math, or "who's in charge" of making mathematical contributions (Gresalfi & Cobb, 2006, p. 51). The question we pose stemmed from our observation of an interaction among a group of first grade students in Lesson 12 out of a total of 16 from an 8-week classroom teaching experiment (CTE).

The interaction occurred during Lesson 12 when a group of students were discussing how to represent two sisters' ages (Janice and Keisha), using variables. In the situation being discussed, Keisha is three years older than Janice. One student, Leo, proposed that Janice's age could be represented with j and Keisha's with k, indicating that these are the first letters of their names. Another student, Nyah, then proposed j for Janice's age and m for Keisha's age, using the order of the letters of the alphabet (e.g., $a = 1$; $b = 2$, etc.) and counting on three more from j. This approach has been documented elsewhere (e.g., MacGregor & Stacey, 1997) as a strategy students use when representing variable quantities. A third student, Zyla, then proposed representing Keisha's age as $j + 3$. A fourth student, Tia, disagreed with Zyla and instead proposed l for Keisha, counting three but including j in her counting (i.e., *j, k, l*). About a minute later, another student, Azaiah, stated that he agreed with Tia and that "I think it's l." When asked why, he referred to a moment earlier in the same lesson, when: "Tia was the right one because she put three on there (indicating that Tia had written "+3" on the shared classroom poster) and that was—and Leo needed help." Tia's mathematical authority and Azaiah's assessment of her idea based on his experience of her past expertise is at the crux of this paper. To investigate this dynamic, we use positioning theory (Anderson, 2009) and build on authors who have used this framing to explore related questions about authority (e.g., Langer-Osuna, 2016; Langer-Osuna et al., 2018), along with Engle et al.'s (2014) influence framework.

Methods

This paper draws data from a larger study carried out in a demographically and academically diverse public school in the Northeast region of the United States. The participants included 22 first grade students who participated in a CTE. The CTE involved eight weeks of classroom instruction organized into two 4-week cycles (with two 40-minute lessons taught per week). Each lesson was video recorded with two cameras and transcribed. The tasks designed for the CTE were based on field-tested tasks developed in previous research by the project researchers. The overarching goal was to engage the students in algebraic thinking, or to support them in

 © ISLS

generalizing, representing, justifying, and reasoning with mathematical relationships (Blanton et al., 2011; Blanton et al., 2015). Students were encouraged to share their ideas and to discuss among themselves the merits of their ideas, to agree or disagree, and share their reasoning. Our goal was to have a distributed sense of authority among all participants in the classroom, and, as teacher-researchers, to share with students both the sources of ideas proposed as well as the decision making around whose ideas should be taken up. Lessons typically began with a whole class (WC) discussion before students broke into small groups (3-5 students) to work on mathematics tasks at their table, and then wrapped up with another WC conversation.

All CTE lessons were videotaped and all written student work was collected. All classroom lessons, from Lesson 1 to Lesson 12, were transcribed verbatim. Lesson 12 includes the interaction in which Tia's incorrect idea was accepted. We are not including Lessons 13-16 in this paper because our study was focused on investigating how, from Lesson 1 to Lesson 12, mathematical authority was constructed. Additionally, while we coded all participants' utterances, we report on eight of the 22 students because these students had the most airtime and in turn had more opportunities to contribute in ways that shaped their positions. If we included data for the remaining students, the frequencies and percentages for each code for these students would be significantly low. Moreover, the five students who were at the center of the Lesson 12 interaction that motivated us to focus on the construction of authority are a subset of the eight focus students. We further selected from the dataset and only include the interactions that occurred in a WC setting because the eight students were present in this setting, whereas these students were separated when working in small groups and cameras did not capture all small group conversations.

We developed our coding scheme by a line-by-line review of the Lesson 12 transcript. We selected this lesson because of the interaction in which Azaiah accepted Tia's incorrect idea. In our line-by-line review and using the constant comparative method (Glaser & Strauss, 1967), we identified lines in which ideas were proposed and how they were responded to because these moments appeared to be linked to how participants were positioned. We define an idea as a thought or suggestion, which can be articulated orally or in writing. Ideas may vary depending on the task and situation at hand and are not necessarily stable or unitary (see Brizuela et al., 2015). Some utterances include one or more ideas, while some utterances do not.

Proposing an idea is a bid, or an opportunity for someone else to respond to your idea. The response typically comes from the teacher and is either neutral, positive (idea was accepted), or negative (idea was rejected). Sometimes the teacher's or student's tone led us to believe their response was neutral, positive, or negative, not the words they said. For example, "okay," said enthusiastically could indicate an idea is accepted whereas "okay" said flatly could indicate a neutral response. In addition to coding transcript lines, we kept track of the total airtime for each one of the students in each lesson, number of utterances spoken by each individual, and the number of times an individual is talked to. We use Langer-Osuna's (2015) definition for an utterance: "what was stated by a speaker when the speaker held the floor, regardless of whether the utterance was interrupted or was a completed turn. In the case of an interrupted utterance, if the speaker gained the floor again to complete the turn, the two turns were each coded as separate utterances" (p. 59). We found the totals for each of these codes across the 12 lessons for the eight focus students. We then ranked students based on the totals for each code. For example, we counted the number of times an individual proposed an idea across the 12 lessons, and then ranked that student in relation to the other eight students. If a student proposed the most ideas they were ranked as the highest for proposed ideas. Since some codes were associated with a negative responses (e.g., an idea is rejected), we reversed the ranking system when necessary. For example, if a student had the fewest instances of an idea being rejected, they were ranked the highest for ideas rejected. To ensure the reliability coders overlapped on 20% of the data. We calculated values for both percent agreement and Fleiss's Kappa to ensure agreement beyond chance agreement. The percent agreement was over 90%, and the resulting Kappa range was 0.58 – 0.71 for all videos.

Findings

In the following we describe observations of the eight students as they interacted over the course of the first 12 lessons in the CTE. The codes we focus on here fall into two overarching groups: airtime in a WC discussion (i.e., airtime, number of utterances, and times an individual is talked to; see top three rows in Table 1) and the number of ideas they propose and the ways in which their ideas are responded to (i.e., number of ideas proposed, responded to neutrally, accepted, explicitly rejected, and not taken up; see bottom rows in Table 1).

Table 1 shows the frequencies for the eight focus students in the two groups of codes described above. For each code, frequency is measured as the number of times a code is observed, except for airtime, which is reported in minutes. The grayscale of Table 1 shows how students compare *across each code* using the ranking method: darker colors indicate a higher ranking. Note that the fewer times an idea was rejected is associated with more authority, so the ranking is reversed for the ideas explicitly rejected and not responded to codes.

Table 1
Heatmap comparing frequencies for students in different categories that relate to authority

	Student							
Category	Azaiah	Leo	Nyah	Syd	Taya	Tia	Tye	Zyla
WC Airtime (in minutes)	8	7	10	7	7	15	9	10
Utterances in WC Discussion	61	55	72	48	53	120	57	86
Times Talked To WC Discussion	84	80	94	71	62	141	83	103
Ideas proposed	50	50	83	49	57	96	45	77
Ideas responded to neutrally	27	32	32	28	23	53	25	37
Ideas accepted	15	8	24	15	21	23	14	24
Ideas not taken up	3	3	3	0	1	3	7	7
Ideas explicitly rejected	0	4	4	0	2	2	3	3

Looking down the columns and across the rows in Table 1, we notice a higher number of darker cells for Tia, indicating her influence based on airtime, utterances, sharing of ideas, and neutral responses to her ideas. Zyla is the next highest in the airtime categories, followed by Nyah. In general, we observed the students who proposed more ideas also have higher frequencies for codes of how their ideas were responded to because in order to have an idea responded to, one must first propose an idea. For example, Tia, who proposed the most ideas, also had the most ideas responded to neutrally; we assume this is because as she proposed more ideas, there were more opportunities for her ideas to be responded to.

To better understand how students' ideas were responded to comparatively we provide percentages in Table 2. The percentages were calculated by taking the total for each idea response category (ideas responded to neutrally, accepted, explicitly rejected, and not taken up) and dividing it by the total number of ideas proposed by each individual. For example, Azaiah had 54% of his ideas responded to neutrally (see Table 2). We found that percentage by dividing the 27 instances of Azaiah's ideas being responded to neutrally (see Table 1) by the 50 ideas that Azaiah proposed (see Table 1). Table 2 is also a heat map that shows how students compare in each category using the ranking method: darker colors indicate a higher ranking. In this case students are ranked based on the percentage, not on the frequency for each category. Note that, once again, the fewer times an idea was rejected is associated with more authority, so the ranking is reversed for this code.

Looking down the columns and across the rows, we notice that, when focusing on percentages, Tia's prevalence in the WC discussions is not paralleled in terms of the percentage of her ideas responded to neutrally, accepted, or rejected. That is, in spite of standing out in terms of the amount of airtime during WC discussions, the number of utterances she made during WC discussions, the number of ideas she proposed, and the number of her ideas that were responded to neutrally (see Table 1), other students' ideas were responded to neutrally or accepted in higher proportions, and another students' ideas were rejected in a lower proportion compared to Tia's. When focusing on percentages, it is Leo who had the highest percentage of his ideas responded to neutrally; Taya had the highest percentage of ideas accepted; Azaiah had no ideas explicitly rejected; and Syd had no ideas explicitly rejected or not taken up (i.e., the lowest percentage). In Tia's case, she had the fourth highest percentage of her ideas neutrally responded to, the seventh highest percentage of her ideas accepted, the second lowest percentage of her ideas explicitly rejected, and the third lowest percentage of her ideas not taken up.

Table 2
Heatmap comparing students in the ideas responded to categories that relate to authority, using percentages

	Student							
Category	Azaiah	Leo	Nyah	Syd	Taya	Tia	Tye	Zyla
Ideas responded to neutrally	54%	64%	39%	57%	40%	55%	56%	48%
Ideas accepted	30%	16%	29%	31%	37%	24%	31%	31%
Ideas explicitly rejected	0%	8%	5%	0%	4%	2%	7%	4%
Ideas not taken up	6%	6%	4%	0%	2%	3%	16%	9%

Conclusion

 © ISLS

By looking at both the frequencies of airtime, utterances, and ideas, as well the ways in which ideas were responded to as a percentage of proposed ideas, we can see that Tia stands out in terms of amount of airtime, utterances, and ideas proposed. However, there were other students who stood out proportionally more than Tia in the ways in which their ideas were responded to.

The incorrect information that Tia provided in the lesson 12 exchange is noteworthy because from her and Azaiah's perspective it was logically sound. Tia was arguing that since Keisha is three years older than her sister, and her sister's age is represented with *j*, that Keisha's age should be represented with *l*. She is actually correcting another student who suggests *m* for Keisha's age. To Azaiah, Tia's argument is intuitive. Relatedly, Lane and Harris (2015), who worked with three to eight year olds, found that children are more likely to accept intuitive claims. Thus, we conclude that the content of that particular claim may have played a role in why it was accepted as valid and in turn resulted in granting Tia undue authority.

Understanding the construction of authority has implications far beyond the first-grade mathematics classroom in which our study occurred. Supporting students in developing a positive perspective on mathematics and their mathematical abilities is deeply intertwined with understanding mathematical authority in a classroom. As we think about how to cultivate positive mathematical mindsets among our students, in which they view themselves as sources of mathematics knowledge, we must better understand students' perceptions of themselves and others as sources of mathematical knowledge.

Abstract: The purpose of this study was to examine the relations between motivational beliefs, academic delay, and academic achievement in an online science course. The sample included one hundred and sixty-eight undergraduate students. We extracted data on timestamps for assignment submissions from the learning management system to capture students' behavioral delay for each assignment over the course of the semester. Using multilevel modeling, the results showed that the relation between academic delay and academic achievement was moderated by motivational beliefs. The negative effect of momentary delay on academic achievement depended on academic self-efficacy, while the negative effect of habitual delay on academic achievement depended on emotional cost. These findings point out that academic delay is not always harmful. Lateness in online courses is particularly detrimental to demotivated students but less consequential for motivated counterparts. Simply focusing on academic delay without considering who is engaging in the dilatory behavior could be misleading for intervention.

Major issues

Academic delay is a common phenomenon experienced by college students. Delay can be understood as behavioral postponement of one's own work and could signify the act of task avoidance (Ferrari et al., 1995). Academic delay is composed of two distinct components. Habitual delay refers to the extent to which an individual has a greater tendency than others to postpone coursework across various situations, while momentary delay refers to the extent to which an individual is engaged in postponement more than usual within a given situation during a certain period of time (Kljajic & Gaudreau, 2018). According to some reports, between 70 to 90 percent of college students engage in unnecessary delay in their coursework (Steel, 2007). This number is daunting given that meta-analyses have consistently shown that irrational tendency to postpone work is negatively correlated with all types of academic achievement, including course grade, quiz, and GPA (Steel, 2007). This tendency can be even more prominent in online learning environments. Although online courses feature autonomy, flexibility, and convenience, students are expected to learn with fewer regulatory cues from instructors and peers and need to override lower and distracting processes often occurring in self-paced learning environments that are competing with long-range goals (Levy & Ramim, 2012). In addition, students may be prone to delaying tasks until the last minute, owing to their frustration and emotional distress from technical difficulties in online courses (Cheng & Xie, 2021). For these reasons, academic delay in online courses is an area worthy of investigation.

Owing to the affordances of school and learning management systems (LMS) to capture various learning analytics, scholars are interested in determining valid measures of academic delay that are consistently associated with student achievement in online courses (Elvers et al., 2003; McElroy & Lubich, 2013). This inquiry is of great value in that it could offer stakeholders and instructors a clear idea in identifying problematic dilatory behaviors in real time and in a less intrusive manner. Although several measures have been examined in the literature, findings are mixed and inconsistent at times. In some instances, a behavioral measure, such as date of first posting in class or days between assignment submissions, was related to student achievement (McElroy & Lubich, 2013). In other instances, it was not (Lim, 2016). As Balkis (2011) has found, the relation between irrational postponement and academic achievement is quite complex and can be moderated by students' motivation. However, this complicated relation has been overlooked in the literature on academic delay. In addition, most of the previous studies have dominantly focused on the relation between students' habitual delay and academic achievement (Lim, 2016; You, 2015); therefore, whether students' momentary delay is related to academic achievement is under-examined and still unclear. For online instructors in particular, it is important and useful to know if and under what condition students' habitual and momentary delay are associated with academic achievement. The goal of the present study is to answer these major issues through a longitudinal data analysis.

Theoretical perspectives

 © ISLS

Academic delay and academic achievement

Several studies have been conducted to explore if academic delay is negatively related to academic achievement. Elvers et al. (2003) found that the difference between the date of first access to course content and the date of exams was negatively correlated with exam scores in an online class. However, in some cases, academic delay is not consistently related to academic achievement. For instance, McElroy and Lubich (2013) showed that although date of registration for class and date of first posting on discussion boards predicted students' grade earned-letter, they failed to predict grade earned-percent. Similarly, a study by Romano et al. (2005) indicated that although exam scores were related to the extent to which students completed learning sessions in one learning unit, this relation was not significant in the other learning units. These studies highlight that academic delay has been operationalized in different ways. In addition, these findings suggest that the association between academic delay and academic achievement is not consistent and, hence, is inconclusive.

Motivational beliefs and academic achievement

Motivation can be defined as "the process whereby goal-directed activities are instigated and sustained" (Schunk et al., 2014, p. 5). This process encompasses different subjective beliefs about engaging in a task, including academic self-efficacy (perceived competence), task value (reasons for engaging in a task), and cost (negative evaluations of what is required to engage in a task) (Eccles & Wigfield, 1995). Research has consistently shown that these motivational beliefs have a significant association with students' academic achievement. Komarraju and Nadler (2013) found that college students' academic self-efficacy and task value were significantly correlated with GPA. Jiang et al. (2018) also found that academic self-efficacy, task value, and cost were significantly correlated with midterm exam scores among 8th graders.

Methodological approach

The design of this study is guided by one central question: What is the relation between motivational beliefs, academic delay, and academic achievement in an online science class?

Sample and procedure

A total of 168 undergraduate students enrolling in an entomology course at a mid-western university participated in this study. About 74% of the participants were female and 26% were male. Eight percent of the participants were African American, 62% were White, 19% were Asian American, 2% were Hispanic, and 9% were other races. On average, participants were 21.23 years old. In terms of academic standing, 8% of participants were freshmen, 17% were sophomores, 34% were juniors, and 41% were seniors. During the second section of the Spring 2019 semester, students enrolled in this course were invited to complete an online survey on their demographic information and motivational beliefs and grant the authors permission to access their learning analytics and course grades.

Measures

Motivational beliefs

Five five-point Likert scale items (1 =not at all true; 5 =very true) adapted from the Patterns of the Adaptive Learning Survey (PALS; Midgley et al., 2000) were used to assess students' academic self-efficacy. A sample item is "I'm certain I can master the skills taught in this course." Cronbach's alpha is 0.93. Six seven-point Likert scale items adapted from the Motivated Strategies for Learning Questionnaire (MSLQ; Pintrich et al., 1993) were used to assess students' task value. A sample item is "It is important for me to learn the course material in this course." Cronbach's alpha is 0.95. Six nine-point Likert scale items (1 =completely disagree; 9 =completely agree) adapted from Flake et al. (2015) were used to evaluate students' negative emotional reaction to putting forth effort to completing academic tasks in a course, such as stress, frustration, anxiety, and worry. A sample item is "This course is emotionally draining." Cronbach's alpha is 0.95.

Academic delay

Timestamps for assignment submissions extracted from the LMS were chosen as the indicator of academic delay. In the present study, timestamp was defined as the difference in days between the submission time and the deadline for a graded assignment. Each timestamp was computed by subtracting the submission time from the deadline. For instance, if a student submitted an assignment on March 6, 2021 at 19:17 PM and the deadline was set on March 6, 2021 at 23:59 PM, then the timestamp for this assignment would be 0.20 days. Since there were 11 assignments in total, each student had a total of 11 timestamps if there was no missing assignment.

 © ISLS

Academic achievement

Academic achievement refers to students' grades for each assignment. Since there were 11 assignments in total, each student had a total of 11 grades.

Statistical analyses

Multilevel tobit regression analysis was employed to assess the relation between motivational beliefs, academic delay, and academic achievement. The tobit model was used considering the ceiling effect of student achievement data in our sample (Twisk & Rijmen, 2009). The strategy for model building was developed in line with Hoffman's (2015) recommendations. Person-mean-centering was implemented for the level-1 predictors to separate the habitual and momentary effects of academic delay (Hoffman, 2015). Fixed effects were evaluated using Wald tests.

Major findings

The results of multilevel tobit regression showed that the relation between momentary delay and academic achievement depended on academic self-efficacy (b = .86, p = .01). Also, the relation between habitual delay and academic achievement depended on emotional cost (b = -.47, p = .004). We further probed the interaction using the pick-a-point approach. The result showed that when academic self-efficacy was at or below the mean level, the relation between momentary delay and academic achievement was significantly negative (see Table 1). The lower academic self-efficacy was, the more negative the relation would be. On the contrary, when academic self-efficacy was one or two standard deviations above the mean, the relation was not significant. Also, the relation turned significantly positive when academic self-efficacy was three standard deviations above the mean. In terms of emotional cost, the result showed that when emotional cost was two standard deviations below the mean, the relation between habitual delay and academic achievement was not significant. On the contrary, when emotional cost was one deviation below the mean or higher, the relation was significantly negative. The higher emotional cost was, the more negative the relation would be.

Conclusions and implications

The present study examined the relations between motivational beliefs, academic delay, and academic achievement. The current findings have important implications for online instructors and the design of course analytics to support online learning. Most of the course analytics currently provided by learning management systems only present a student's timestamp for each assignment submission, which possibly conflates the effects of momentary delay with habitual delay, and, hence, may not be a reliable indicator for early intervention. Our findings suggest that future course analytics should also provide information on 1) whether a student postpones more than usual at a given time and 2) whether a student postpones more, on average, than other students in the

same course. These pieces of information need to be integrated with measures of motivational beliefs to effectively identify at-risk students in an online course. As the present study shows, academic delay is particularly detrimental to demotivated students but less consequential for motivated students. Simply focusing on academic delay without considering who is engaging in the dilatory behavior could be misleading for intervention.

LF-LKT: A logistic regression knowledge tracing model integrating learning and forgetting

Ting Zhang, Bo Jiang*
51204108032@stu.ecnu.edu.cn , bjiang@deit.ecnu.edu.cn
East China Normal University

Abstract: In the process of learning, learning behavior and forgetting behavior are interwoven, and students' forgetting behavior has great influence on Knowledge Tracing(KT). In order to accurately model learning and forgetting behaviors, this paper proposes a learning-forgetting logistic knowledge tracing(LF-LKT) model that integrated students' forgetting factors. Three factors affecting knowledge forgetting, including the time interval of KC, KC presentation sequence (that is, the recency effect), learning opportunities of KC, and students' response of KC are considered in this paper. We also give different level of weights to time interval. The proposed model is compared with other four models on three dataset. Results shows LF-LKT improves the predictive performance as compared to AFM, PFA . Moreover, the ablation study was conducted to investigate the influence of different factors and the result suggest the combination of three factors results in performance improvement.

Introduction

As the "brain" of the adaptive learning system, the learner model undertakes the important responsibility of self-adaptation. Specifically, in the process of learners' learning, the system relies on learners' historical learning data to construct learners' models. Based on structured subject knowledge and diversified learning resources, adaptive learning system provides students with the most suitable learning resources, paths and modes by collecting interactive data of students' learning process and utilizing technologies such as cognitive diagnosis, machine learning and personalized recommendation. The system can also feedback the knowledge mastery level of learners for educators, so that educators can identify the needs of learners, so as to better adjust teaching strategies. Therefore, learner modeling plays an important role in realizing personalized education. How to build a better learner model, how to combine the learner model with the design of teaching environment, and how to use the learner model in the learning environment to achieve personalized education are the core technical problems in the next stage.

Knowledge Tracing, builds the knowledge state model of learners through accurately modeling students' mastery level of a knowledge component over time based on their historical learning trajectories. KT is the earliest and most concerned learner modeling technology, which can provide learners with adaptive teaching support and push personalized learning resources, so as to improve learning effect and efficiency (Wang,2013).The knowledge tracing model is based on the interactive data of learners and the learning system. The theory of educational psychology and the theory of Ebbinghaus forgetting curve(Ebbinghaus,2013; Murre,2015) put forward that students forget what they have learned, and the impact of forgetting is the decline of knowledge mastery. Recent studies have considered students' forgetting behavior. However, how to adopt classical theories in traditional education, such as forgetting curve to predict knowledge state, is still in its infancy. Moreover, there are few studies considering recency effect. Inspired by the recency effect of psychological theory, this paper integrates factors such as the presentation of knowledge component into the model to predict students' knowledge state.

Proposed model

LF-LKT is based on Logistic Regression (LR) model(Kleinbaum,2002), which uses one or more continuous or discrete independent variables to analyze and predict discrete dependent variables. Logistic regression is one of the common methods of data mining and machine learning. LR model converts the dependent variable into correct and wrong binary logical variables (1 is correct, 0 is wrong), and the relationship between the probability of learners' correct response and the independent variable can be expressed as:

$$\mathrm{P}(Y_{ij} = 1|z) = \frac{1}{1+e^{-z}} \quad (1)$$

$$Z = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \cdots + \beta_n x_n \quad (2)$$

Where, Y_{ij} represents learner i's response to question j; Z represents the sum of linear weight values after superposition of independent variables; x_n represents each influence factor, and β_n is the coefficient of

*as the corresponding author of this paper

 © ISLS

logistic regression. P represents the probability of students correct response under various influencing factors, ranging from 0 to 1.

Students' historical learning trajectories will affect their knowledge mastery, and if the time interval is too long, they will forget. According to Ebbinghaus forgetting curve theory (Ebbinghaus ,2013;Murre,2015), the number of repeated learning knowledge component and the time interval since the last learning knowledge component will affect the degree of forgetting of students. According to the psychological theory of recency effect(Martin ,1991), the order in which information appears has an impact on students' cognition, and recency effect will lead to a deep impression on the recently learned content. Therefore, the following factors affecting knowledge forgetting are considered in this paper:

T: Time interval from the same knowledge component; N: the times of repetitions of knowledge component; θ: Students' response of a knowledge component. It can be divided into correct answers (C) and wrong answers (I).

Historical learning trajectories $x_1, x_2, \ldots, x_t$ in a group of learning tasks containing a specific knowledge component ($x_t$represents the answer situation of the t time step). Assuming that the knowledge component involved in the t-i time step and the t time step are the same, the time interval from the t-i time step to the t time step can be expressed in the following equation:

$$T = \sum_{i=1}^{n-1} \omega_i \cdot t_i \tag{3}$$

Where, ω_i represents the weight of the t-i time step distance from the t time step; t_i represents the time interval between the t-i time step and the t time step; n represents the answer sequence of learning the same knowledge component with the t time step; T is the weighted sum of ω_i and t_i.The weight mechanism stipulates that the model assigns a certain degree of weight value to the answer sequence of the same knowledge component as the t time step. The weight mechanism is based on the power law attenuation function, and the closer the answer sequence is to the t time step, the greater the influence is. Therefore, the weight mechanism can be expressed as the following equation:

$$\omega_i = {t_i}^{-x} \sum_{j=1}^{n-1} \frac{1}{{t_j}^{-x}} \tag{4}$$

The Predictive performance equation (PPE) model holds that the impact of repeated knowledge component and time interval is correlated, so the combined effect of repeated knowledge component and time interval can be expressed by the following equation(Jastrzembski &Gluck, 2009; Walsh et al., in press):

$$M_n = N^c \cdot T^{-d} \tag{5}$$

Where, c and d represent learning rate and decay rate respectively.Considering the three factors affecting forgetting, we can transform the Logistic Regression model according to equation(2) - (5) and the model formula proposed in this study was obtained:

$$P(Y_{ij} = 1 | M_n, C, I) = \frac{1}{1+e^{-(\beta_0+\beta_1 M_n+\beta_2 C+\beta_3 I)}} \tag{6}$$

To sum up, LF-LKT is based on logistic regression function, and comprehensively considers the interval of students' repeated learning of knowledge component, the presentation order of knowledge component (recency effect), the number of repeated learning of knowledge component and students' mastery of knowledge component.

Experimental design and analysis

In order to verify the performance of this model, the test performance of the model was compared with the AFM model, PFA model and R-PFA model PFA-decay model based on logistic regression model on public data set. The results are shown in Table 1(see Table 1):

Table 1

model prediction performance

dataset	performance indicators	AFM	PFA	R-PFA	PFA-Decay	LF-LKT
Fraction	precision	0.848	**0.915**	0.865	0.869	0.870
	recall	**0.981**	0.976	0.971	0.964	0.958
	F1	0.910	**0.915**	**0.915**	0.914	0.912
Tone	precision	0.835	0.836	0.839	0.839	**0.841**
	recall	**0.977**	0.974	0.968	0.962	0.964
	F1	**0.900**	**0.900**	0.899	0.897	0.898
Cloze	precision	0.770	0.779	0.779	0.785	**0.796**
	recall	0.767	0.761	0.755	0.766	**0.772**
	F1	0.768	0.770	0.767	0.775	**0.784**

It can be seen from the experimental results that, on the basis of comprehensive consideration of all evaluation indexes, the LF-LKT model proposed in this paper performs better than other models on Cloze data set, with the prediction accuracy of 0.784, precision of 0.796, recall rate of 0.772 and F1 value of 0.784. It's the

highest in all the models. Comparatively speaking, the prediction effect of LF-LKT on the other two data sets is not ideal, and the value distribution on each evaluation index is not balanced. Furthermore, taking Cloze data set as an example, the factors affecting forgetting are considered separately. The ablation study result is shown in Table 2. It can be seen that the combined effect of each factor is better than the simple effect.

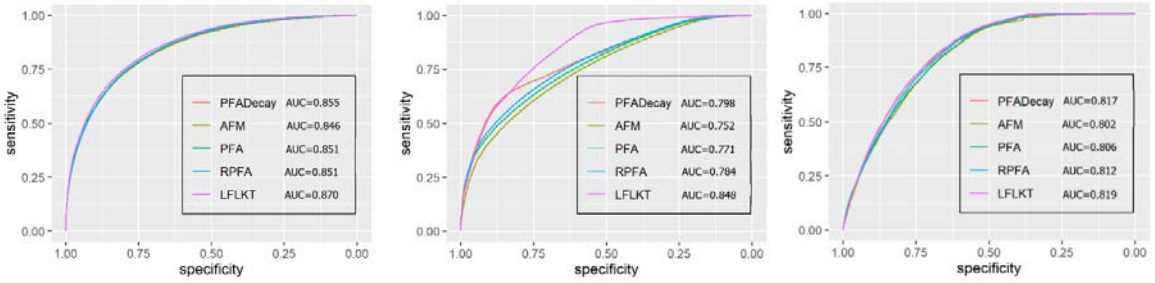
Table 2

ablation study of each forgetting factor

performance indicators	LF-LKT(N,T,θ)	LF-LKT(N,T)	LF-LKT(θ)
accuracy	**0.784**	0.779	0.771
precision	**0.796**	0.782	0.780
recall	0.772	**0.784**	0.764
F1	**0.784**	0.783	0.772

Figure 1

ROC curve



1-a ROC curve on Cloze *1-b curve on Fraction* *1-c curve of all models on Tone*

Table 3

Comparison of AUC values and R2 predicted by the model

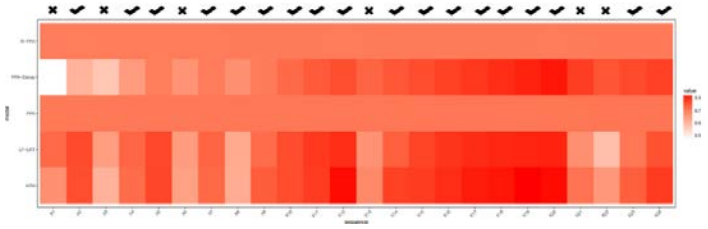
	R^2			AUC		
	Fraction	Tone	Cloze	Fraction	Tone	Cloze
LF-LKT	**0.275**	**0.228**	**0.352**	**0.848**	**0.820**	**0.870**
AFM	0.156	0.203	0.299	0.752	0.802	0.847
PFA	0.186	0.212	0.306	0.771	0.806	0.852
R-PFA	0.201	0.217	0.311	0.784	0.812	0.851
PFA-Decay	0.227	0.220	0.329	0.798	0.817	0.858

One of the basic tasks of knowledge tracing is to predict students' current performance on the next candidate exercise. By comparing the prediction results of the model with the real answer results of the students, the prediction performance of the model was compared (see Figure 1 Table 3).The AUC index of the model proposed in this paper is superior to the original AFM model, PFA model, extended R-PFA model and PFA-decay model on public data set, and the model fitting effect is better than other knowledge tracing models based on logistic regression model. The results show that LF-LKT model is superior to existing models in predicting students' future performance. From the experimental comparison results, it can be seen that AFM has the lowest prediction performance in the data set, which indicates that AFM has limitations in considering students' prior probability at the same time.

Another basic task of knowledge tracing is to output students' mastery of each knowledge component. This paper intercepts a student's learning record in the data set Chinese_tone study over a period of time, and uses five models to track the change of students' mastery of a knowledge component, as shown in Figure 1.In the figure, the abscissa represents students' learning history, the top is students' answers, and the ordinate represents students' mastery of the knowledge component predicted by the model.

The experimental result shows that the tracing effect of PFA and R-PFA model is not obvious. The tracing results of PFA-decay model changed slightly. At the 14th moment, after students correctly answered the exercises corresponding to knowledge component, LF-LKT and AFM models improved the tracing results of students' knowledge component mastery (the output value increased). At the 21st moment, after students made mistakes in the exercises corresponding to knowledge component, the tracing results of LF-LKT and AFM model on students' knowledge component were decreased .The above results showed that PFA-decay, LF-LKT and AFM models would update the corresponding knowledge component according to the answers obtained by students, so as to model the learning process of students.

Figure 2
heatmap of Chinese_tone study dataset



Discussion

In this paper, the time interval of KC, KC presentation sequence (that is, the recency effect), learning opportunities of KC, and students' response of KC are considered. A knowledge tracing model LF-LKT based on logistic regression model is proposed, which takes into account both learning and forgetting factors. The result shows that LF-LKT model improves the predictive performance as compared to traditional knowledge tracing models based on logistic regression model, such as AFM,PFA,R-PFA and PFA-decay models. Moreover, the ablation study was conducted to investigate the influence of different factors and the result suggest the combination of three factors results in performance improvement.

Personalized Automated Formative Feedback Can Support Students in Generating Causal Explanations in Biology

Moriah Ariely, Tanya Nazaretsky and Giora Alexandron
moriah.ariely@weizmann.ac.il, tanya.nazaretsky@weizmann.ac.il, giora.alexandron@weizmann.ac.il
Weizmann Institute of Science

Abstract: The ability to formulate scientific explanations is considered a major goal in science education. However, explaining scientific phenomena is a challenging task, and research has shown that many students are unable to construct proper explanations. And while personalized formative feedback can greatly assist students in closing the gaps between their current and the expected level of reasoning, teachers rarely find the time that is required to provide it. We present a novel framework for designing and providing formative feedback on causal explanations in biology, which can be generated *automatically* using NLP-based algorithms. Results from a controlled experiment showed that applying this framework led to significant improvement in student explanations. Based on these findings, we believe that our framework provides an effective approach for aligning between automated NLP-based analysis and formative assessment of biological explanations in the science classroom.

Introduction

Enhancing students' ability to formulate scientific explanations is considered a major goal of science education (National Research Council (NRC), 2012). However, research has shown that many students are unable to construct proper explanations (e.g., Nehm et al., 2012).

Constructed-response (CR) items are an important tool to elicit students' in-depth understanding of scientific concepts (Nehm et al., 2012), and students were found to benefit from guidance on their explanations and the opportunity to revise them (Ryoo & Linn, 2014; Tansomboon et al., 2017). However, proper assessment of CR items is a costly, time-consuming process, which requires developing grading rubrics and applying them to student responses. Teachers are struggling to find the time to devote to this process, leading to considerable delays in the feedback students receive on their CRs, and affecting its quality (Ariely et al., 2022).

Technology holds much promise for improving this process. Research on automated assessment in science education has shown that machine-learning (ML) and Natural Language Processing (NLP) can be used to construct scoring algorithms and provide immediate feedback to teachers and students (Zhai et al., 2020). However, few studies have attempted to leverage the power of automated scoring techniques for providing feedback on CR items. Moreover, research on the educational impact of formative assessment with automated scoring technologies in real classrooms – where most of the learning occurs – is scarce (Zhu et al., 2020). Our research aims for this gap.

Causal explanations in biology

The majority of explanations in the science classroom are attempts to provide an account that specifies what happened and how it occurred, namely, constructing causal accounts of phenomena (Osborne & Patterson, 2011). Causal explanation should include the sequential stages from input to output of the underlying causal event leading to a phenomenon, and also how one or more factors behave to give rise to a phenomenon (Krist et al., 2019). Depending on the phenomenon to be explained and the context in which it occurs, the underlying causality can be a simple linear relation between contiguous events, or it can consist of complex relations, with several causal factors interacting with each other (Grotzer, 2003). Studies show that students have difficulties in presenting the causal story in which event results from interactions among multiple components (Grotzer, 2003).

Automated formative assessment

Automated formative assessment of CR items in science education is typically based on invoking feedback that aims to close the gap between the expected and observed performance as identified using content-based scoring rubrics (e.g., Tansomboon et al., 2017). Application of ML and NLP are increasingly applied to automated content scoring of CR items (Zhai et al., 2020). Automated scoring techniques have many advantages for assessment such as objectivity, standardization and efficiency (e.g., Nehm et al. 2012; Tansomboon et al., 2017). Also, ML based assessment was found to promote significant learning gains (e.g., Tansomboon et al., 2017; Zhu et al., 2020). This makes ML-based assessment a cost-effective way for assessing students' explanations.

 © ISLS

Research goals and questions

In this study, we present a novel approach and method for designing and providing formative feedback on causal explanations in biology. Our method "breaks down" the expected explanation and reveals the components of the causal explanation. These components are then used to build fine-grained analytic rubrics that are designed for formative assessment purposes and aimed at capturing conceptual understanding.

We recently showed that NLP-based ML scoring models, that were trained on student response data that were human-labeled according to our analytic grading rubrics, can reach a high level of agreement with human experts on the task of scoring scientific explanations (Ariely et al., 2022). In the present study, we applied the automated scoring models to provide personalized feedback to students based on their performance in an authentic classroom scenario. While performed on a case study, our approach is directly applicable to causal explanations in other subjects in biology, and may be relevant to other disciplines as well.

The research questions that we seek to answer are: (1) how do students' responses to open-ended questions change after receiving personalized feedback and- (2) if our feedback on students' response to one item affects their response to a *different* item that measures the same concepts in a different context?

Methods

Participants and data collection

The main data set included 10th-grade students from five classes in the same urban school at the center of Israel (N=115). Due to ethical regulations, answers were collected anonymously, and students were requested to fill only their grade, gender, and geographic location. When needed, the class teacher numbered her students so that she could provide each student their personalized feedback, and track their performance.

Procedure

The constructed response items

Two constructed response items were presented to the students as part of their regular biology studies, and deal with the effect of anemia and smoking on physical activity (hereafter referred to as Anemia and Smoking items). Both items are typical open-ended questions in biology and require a causal explanation to explain the phenomena.

Groups description

The data set (N=115) included two groups as follows: One group included three classes in which the students submitted their responses to the Anemia item, and received personalized feedback on their response ~24 hours after submission. Then, the students were asked to submit their responses to the same item again, and also to another item- the Smoking item. Seventy-three students answered the Anemia item, but 19 of them did not submit their answer to the Anemia and Smoking item after receiving feedback, and were, thus, excluded from the analysis. Therefore, the final sample for this group was N=54 (hereafter the "Treatment group"). A second group included two classes in which the students answered both items one after the other, in a random, unknown order, submitted the items together, and did not receive any feedback on their responses (N=61; hereafter the "Control group").

Automated scoring models and analytic grading rubrics

The students' responses to the Anemia and Smoking items were *automatically graded* using automated scoring models, developed for these items in prior research (Ariely et al., 2022). Analytic grading rubrics were developed by the first author (a domain expert) and validated by a second domain expert and five experienced biology teachers. The rubrics decompose a correct explanation into a collection of binary categories, each representing an essential property that the student explanation should include (see Table 1). A detailed description of the development and performance of the automated scoring models can be found in Ariely et al. (2022).

Personalized feedback on students' responses

The feedback on students' responses (in case they were not fully correct) included a short paragraph followed by a figure that visualizes what is missing from the student's explanation and the student's score out of 5 points. The content of the feedback was predefined according to the different types of reasoning that are revealed by the analytic grading rubric. The feedback was sent to the class teacher who sent it to her students, and also provided a short explanation about the feedback format.

After the students in the Treatment group submitted their responses (following receiving the feedback), they answered a short questionnaire about how they used the feedback, and what part of the feedback was most

useful to them. This questionnaire served two purposes: First, characterizing what the students perceived as being most useful for them. Second, it also provided evidence that students actually read the feedback handed to them.

Table 1.
The categories of the analytic grading rubrics for the Anemia and Smoking items. The (+) and (–) signs represent which category is relevant to each item.

Category – present (+) not present (-)		Anemia item	Smoking item
a	CO-Oxygen competition	–	+
b	Oxygen is transported to the cells by RBC	+	+
c	Change in cell oxygen levels	+	+
d	Oxygen is a reactant in cellular respiration	+	+
e	Change in cellular respiration rates	+	+
f	Use of term (cellular respiration)	+	+
g	Energy is produced in cellular respiration	+	+
h	Change in energy production rates	+	+
i	Use of term (energy/ATP)	+	+
j	Energy is consumed by muscles/cells	+	+

Data analysis

To evaluate the impact of the feedback, we analyzed students' performance in a real classroom situation, by assessing their performance in two different, but conceptually similar, open-ended questions, before and after receiving feedback. This relies on the fact that our assessment and analytic grading rubrics allows us to compare items that measure the same concepts in different contexts.

The students' responses were automatically scored 0 or 1 for each category in the analytic grading rubric, and then these scores were combined to form a composite, holistic score for each item (out of 100%). We analyzed students' performance on the Anemia and Smoking items by comparing their holistic scores for each item. We used the Wilcoxon signed-rank test (for dependent samples), and Mann-Whitney U-test (for independent samples) to analyze differences between students' average holistic scores (followed by a Bonferroni correction, as the Anemia item was compared twice for the Treatment and Control groups).

Results

We analyzed students' performance on the Anemia and Smoking items by calculating their holistic score. We found that while both groups performed similarly on the pretest (Anemia items; two-tailed Mann-Whitney U-test, $z = 0.35305$, $p = 0.72634$, Table 3), the control group did not improve on the posttest (Anemia vs. Smoking item, two-tailed Wilcoxon signed-rank test, *z-score* = -1.2039, $p = 0.2301$, Table 3). However, the treatment group improved compared to its pretest results; the students' performance in the Anemia item improved significantly after they received personalized feedback on the *same* item (Anemia item pre vs. post, two-tailed Wilcoxon signed-rank test, $z = -5.3527$, $p < .00001$; Table 2), and also on a *different* item (Anemia vs. Smoking item, two-tailed Wilcoxon signed-rank test, *z-score* = -2.809, $p = 0.005$, Table 3). Moreover, the treatment group (with feedback) performed better than the control group (no feedback) on the posttest (Smoking items; two-tailed Mann-Whitney U-test, $z = -2.1491$, $p = 0.031$, Table 3).

Table 2.
The Treatment group's average scores in the Anemia item before and after feedback

	Anemia item (before feedback)	Anemia item (after feedback)	Wilcoxon signed-rank test (Anemia pre vs. Anemia post)
Treatment group (N=54)	51.9	80.0 (after feedback)	*z-score* = -5.3527, p <.00001*

Table 3.
The Treatment and Control groups' scores to the Anemia vs. Smoking items before and after feedback

	Anemia item	Smoking item	Wilcoxon signed-rank test (Anemia vs. Smoking)
Treatment group (N=54)	51.9	66.3 (after feedback)	*z-score* = -2.809, p <.01*
Control group (N=61)	54.1	57.2 (no feedback)	Not significant
Mann-Whitney U- Test (Treatment vs. Control)	Not significant	*z-score* = -2.1491, p <.05	

*Bonferroni correction (significant if $p < .025$)

Discussion

In this study, we present a novel approach and method for designing and providing automated formative feedback on causal explanations in biology. Our analysis shows that after receiving feedback on their response to one item (the Anemia item), students improved their responses to the *same item*, but also to a *different* item that measures the same underlying biology concepts (the Smoking item).

Studies on formative feedback stress that in order to be effective, the feedback should be immediate, individualized, and offer concrete guidance for improvement (Tansomboon et al., 2017). As presented in this study, machine learning algorithms that automatically score scientific explanations can be used to identify gaps in students' reasoning and provide them with timely and individualized feedback. In addition, our grading rubrics were specifically designed for providing *personalized* guidance based on the students' performance, which we believe assisted in students' revisions of their constructed responses.

More importantly, our approach for assessment can provide teachers and students with insights about how to generate and evaluate scientific explanations, because it makes the rationale of the scientific explanation and its components explicit, which can promote students' learning of scientific explanations. It is claimed that crafting complex causal explanations for biological phenomena, promotes students' understanding of the phenomenon and the underlying ideas (Grotzer & Bell Basca, 2003). Also, when students are involved in identifying causal explanations for a phenomenon they are prompt to infer about the underlying causes and to discover the structural connections of phenomena in the world (de Andrade et al., 2019).

Our approach can also provide researchers with a method for developing rubrics and models for automated formative assessment. Nevertheless, as the main limitation of this research is that it is based on a case study with two items on a certain biological phenomenon, further research is required to validate the generalizability of this approach to larger sets of items and of other topics within the biology curriculum.

Performing Algorithms: Weaving as Promising Context for Computational Learning

Anna Keune, Technical University of Munich, anna.keune@tum.de

Abstract: An important aspect of diversifying STEM fields, including computing, is to better understand how tools and materials that are associated with socio-historical practices of underrepresented populations are aligned with disciplinary concepts and what these materials contribute to teaching and learning. Taking a constructionist stance, this study builds on the precedent of electronic textiles in the learning sciences to investigate the alignment of non-electronically augmented fiber crafts with core computer science concepts through the idea of epistemological pluralism. Through an artifact analysis with computer science instructors, the study found that weaving and manipulating fabric are aligned with core computational concepts and that one craft activity requires multiple approaches to computational concepts. The work points to a particular instance of epistemological pluralism and the potential of fiber crafts as a context for understanding transfer of computational concepts across multiple representations.

Introduction

International communities are calling for more sustainable STEM and digital education (European Commission, 2021). One important aspect of this is to diversify STEM fields and to ensure underrepresented groups, including women, persist. Women's persistence in computing can be supported by fostering a sense of belonging that expands dominant computing cultures (Lewis et al., 2017). An opportunity for expanding computing cultures are tangible manipulatives–especially those that consist of materials that are associated with socio-historical practices of underrepresented populations in computing. For example, educational research on electronic textiles, which augment the feminized practice of sewing with electronic components (Buechley, 2006), demonstrated new leadership opportunities for girls (Buchholz et al., 2014), improved learning outcomes for all students (Peppler & Glosson, 2014), and inroads for rupturing dominant computing cultures (Kafai et al., 2021).

Yet, it remains underexplored how fiber crafts in their own right–without electronic components–align with core computational concepts and whether they present relevant contexts for further inquiry of computational learning while fostering a sense of belonging. Building on the precedent of educational research on e-textiles, the present study investigated weaving and manipulating fabric as a context for performing computational concepts, and asked: How do fiber crafts (i.e., weaving and manipulating fabric) align with computational concepts?

The present study builds on constructionist approaches to learning that posit that disciplinary concepts can be practiced through a range of expressive creations of personally meaningful artifacts (Papert, 1993). It also builds on design studies that call attention to the material relationships of digital things (Dourish, 2017). To begin to understand fiber crafts as contexts for computational learning, this qualitative study analyzed artifact analyses sessions with computer science instructors of middle school students' projects. The findings align fiber crafts with computational concepts (i.e., algorithms, variables, control structures, modularity, and troubleshooting) and show that fiber crafts require multiple approaches to computational concepts within the same craft activity (i.e., syntax-oriented, spatial, and performative approach). The work has implications for the design of interventions for computational learning of and with fiber crafts and points to an instance of epistemological pluralism and the potential of fiber crafts as a context for understanding transfer of computational concepts.

Potential of fiber crafts for inclusive computer science learning

To counter the trend of early drop-out of women in computer sciences, researchers have called for the recognition of women's leadership skills (Saavedra et al., 2014) and specialized computer science programs for girls (e.g., Pinkard et al., 2019). The movement toward identity-based groups frames computing as a form of community empowerment (Abbate, 2018) and presents a response to research that shows that women's persistence in computing can be supported by fostering a sense of belonging (Lewis et al., 2017).

The relationship of fiber crafts to women and computing promises a starting point for fostering computational belonging. For centuries, fiber crafts have been centrally positioned in the life experience of women (Barber, 1995). In a girl's education, fiber crafts were used to prepare her for domesticity while some women have used their needle work for socio-political expression (Parker, 1984). In early computing, the socio-historical relations of fiber crafts and domestic work were used to recruit women (Abbate, 2012) who went on to profoundly contribute to technology innovation (Essinger, 2004). For instance, the woven memory of Apollo Mission computers was produced by women and derogatively dubbed "little old ladies' memory" (Rosner et al., 2018).

 © ISLS

Within educational research, electronic textiles (Buechley, 2006) have consistently proven to be a cogent context for introducing youth—especially girls—to STEM ideas (e.g., Buchholz et al., 2014). Yet, despite research linking textiles to computing, computing with fiber crafts is frequently focused on adding (programmable) electronic components to textiles. How textile production is in and of itself computational remains an underexplored yet promising starting point for contributing to computational belonging.

A material dimension of epistemological pluralism

The constructionist idea of *epistemological pluralism* theorizes multiple ways of getting to know an idea as a key to domain learning (Turkle & Papert, 1992). Particularly productive for the present study is an underlying ontological dimension of epistemological pluralism. Turkle and Papert (1992) showed that technological innovations of computational materials, such as changes from command-line interfaces to object-oriented graphical interfaces, facilitated relationship-forming and expressive approaches to computing.

This resonates with research related to technology design that calls attention to the underlying material relationships of digital things (Eglash et al., 2020). For example, although often de-materialized, digital concepts, such as bits, are bound to an underlying tangible materiality (Dourish, 2017). Focusing on the materials and the practices they bring to learning, can teach about how materials "contribute to forms of learning and collaborating that are unexpected but that may be fruitful if developed further" (Sørensen, 2010, p. 7).

For example, when looking at weaving as a form of algorithmic doing, the process of programming, in which writers determine the outcome, becomes closer to live coding that produces an unfolding algorithm of person and loom combinations (Griffiths & McLean, 2017). In this case, the socio-material practices of loom and people frame the typical programming approach to algorithmic doing as something very different yet valuable. The ontological threads within constructionist ideas of epistemological pluralism and technology studies prompted the present study to consider what fiber crafts materials bring to computational learning.

Methods

This qualitative study investigated the alignment of computational concepts with fiber crafts. The study facilitated artifact analysis sessions with computer science instructors at research focused universities on whether and how they saw computational concepts in youth fiber craft projects. Computer science instructors were engaged because of their expert understanding of computing and their experience teaching computing to beginners. While this risks to position textiles in a supporting role, the instructors presented a starting point for aligning textiles with computing concepts all along being able to inform understanding of what textiles do that is typically not done in introductory courses. Recruiting happened through snowball sampling and systematic search of university websites. The projects were produced by middle school students during a fiber crafts course (Keune, 2021).

The data sources consisted of artifact analysis sessions and photographs of youth projects. The *artifact analysis sessions* (average 60 minutes long) introduced instructors to the crafts and facilitated analysis of youth projects. The instructors were presented with youth-created projects and were asked to identify how the craft require the use of computational concepts. *Close-up photographs of youth projects*, taken after each course session, captured the project plans and fiber-craft projects from a range of angles to capture project dimensionality. On average, this resulted in 20 photographs per youth per session (1886 photographs in total). The photographs showed details of youth-produced artifacts, including stitches and weaving techniques.

The *analysis of the artifact analysis sessions* followed iterative thematic coding related to K12CS framework (2016) core concepts (i.e., algorithms, variables, control structures, modularity, and troubleshooting) to align computer science concepts with fiber crafts. Descriptive codes built on language that the instructors used to capture expressed nuances. To collapse the descriptive codes, the codes were related to core concepts of the K12CS framework and subcategories of core concepts. The codes were discussed for agreement with a fellow researcher and presented for discussion to a research team. This approach made it possible to focus on descriptions by the instructors that elaborated what fiber crafts could bring to computing education.

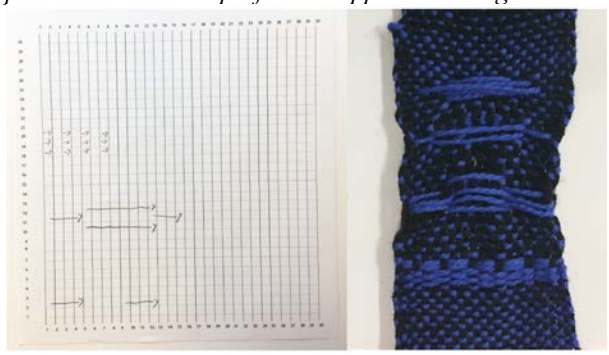
Findings

The analysis of the artifact analysis sessions identified that computer science instructors aligned fiber crafts with five computational concepts (i.e., algorithms, variables, control structures, modularity, and troubleshooting). While the research aligned all five concepts with both weaving and manipulating fabric, in the interest of space, this paper focuses on showing the alignment of algorithms with weaving and what this alignment contributes.

Algorithms are routines that can be performed by people and computers to accomplish tasks. Algorithms require effective communication with a computer by sorting algorithmic tasks and sub-tasks for computers to read and respond to. Across both crafts, instructors mapped algorithms directly onto crafts because of the crafts'

reliable artifact transformation. Artifact transformation consisted for both crafts of opportunities for three types of approaches to algorithms: 1) Syntax-oriented, 2) spatial, and 3) performative approaches to algorithms (see Figure 1 for weaving). Instructors highlighted the need to translate across approaches within the same activity.

Figure 1
Spatial-material and performed approach to algorithms in weaving



For weaving, 92% of instructors (n=11) highlighted the repetitive process of changing heddle positions paired with shuttle directions in a plain weave as algorithmic. A heddle is a flat piece with long and short openings for lifting threads. A shuttle is a carrier of yarn. For example, to create a plain weave pattern, weavers had to lift the heddle to part lengthwise threads and draw the shuttle with yarn between the threads in one direction. Then, to weave another row, weavers had to lower the heddle and draw the shuttle with yarn between the threads in the opposite direction. This pairing of heddle positions and shuttle directions remained for the duration of the weave.

Instructors connected the algorithmic aspects of weaving to a syntax-oriented approach of instructing a computer, like a programming language. One said: "It seems very algorithmic. You could (...) write instructions that [are] pretty robust that could be used to describe the behavior." The instructor's quote leads to the idea that weaving patterns can be described in a formal language, for instance, by writing a pattern down on paper, creating an interactive representation, or automating the functions of the loom through a computer program.

Rather than considering syntactic programming languages as the only way to engage with algorithms, the instructors suggested that algorithms are anchored with coordinate systems. One instructor said:

> Coordinates [in the computer] correspond to the states of the algorithm. To implement [an] operation on a computer, you have to think in terms of coordinates and where [to] put that number eventually (...). This is how the computer thinks.

Instructors also connected weaving with spatial approach to algorithms through the project plans on coordinate paper that youth drew (Figure 1, left). The coordinate grid paper showed warp threads of the loom as vertical lines and youth drew weft threads as horizontal lines. All warp and weft threads were numbered so they could plan personal patterns. Such coordinate patterns graphically represented the steps that would result in the woven fabric. One instructor said: "You just follow it very graphically (...) It's basically a line of code where you do right to left then you just follow it. Right to left, top to bottom." Through its position on the coordinate paper that corresponded to the weft threads of the loom, each drawn line was spatially anchored and could be located on the loom.

Instructors further connected weaving with a performative approach to algorithms. The algorithmic performance (i.e., the repetitive process of changing heddle positions paired with shuttle directions done by the loom and the youth) translated coordinate patterns on fabric into fabric. Instructors recognized the youths' process of weaving yarn into a matrix of warp threads as the way a computer would process a program (see Figure 1, right). Youth performed the algorithm, like how a computer would process a program, rather than communicate it in a machine-readable form for a computer to perform.

Discussion and Implications

Looking across the three approaches to algorithms in weaving, suggests that weaving is a context worth investigating for computational learning. Additionally, because weaving includes different approaches to algorithms in one activity, the craft presents a unique context for transfer. The research highlights the utility of supporting all three approaches (i.e., syntax-oriented, spatial, and performative) within one activity. For example, to foster the syntax-oriented approach to algorithms, activities could include opportunities to articulate the tasks and subtasks of weaving or opportunities to correct or complete pseudocode translations of common patterns. Where the first would be aligned with established weaving practices, the pseudocode activity could highlight

intersections among weaving and computing.

The relationships among approaches to algorithms were nonlinear. Rather than one leading approach, the translations across approaches to algorithms inform each other. For example, while a graphed plan could be implemented one to one by performing the illustrated algorithm, changes to the pattern can happen on the go, resulting in edits to the graphed plan. The fact that weaving fabric can involve multiple nonlinear approaches to algorithms within the same craft presents a particular instantiation of epistemological pluralism. Where weaving provides several ways of engaging with a domain idea that weavers can select from, weaving also makes it possible to engage with more than one approach to algorithms. This leads to considering epistemological pluralism in terms of recognizing multiple ways to approach a domain conceptual understanding simultaneously by one person. Along with the socio-historical promise of fiber crafts as fostering computational belonging for women in computing, the expanded understanding of epistemological pluralism further warrants additional studies that explore the utility of fiber crafts as context for computational learning.

Silly or Substantive?: How Video Club Can Help Science Teacher Candidates See Strengths in Students' Contributions

Blue, Laura, Pierson, Ashlyn
bluele75@gmail.com, ashlyn.e.pierson@gmail.com
The Ohio State University

Abstract: Teacher learning occurs at the intersection of practice, critical discourse, and reflection. Yet, the fast-paced nature of teaching makes stepping back to see students' ideas as resources difficult for teacher candidates. Video club (Barnhart & van Es, 2020) affords a collaborative space for teacher candidates to slow down so that they can uncover and challenge underlying assumptions about students and their contributions. This study explores video club as a tool for helping teacher candidates see strengths in students' contributions. We analyze data from science methods courses for teacher candidates, finding that video club can help them to see value in students' contributions that they initially perceived as "silly."

Objectives and significance

Equitable science teaching requires noticing students' strengths (Louie et al., 2021) and building upon students' multiple ways of knowing (Warren et al., 2020). While research has explored how to help teacher candidates (TCs) notice students' disciplinary resources (e.g., Robertson et al., 2015), less is known about how to help TCs take up students' questions and ideas when they do not align with the pathway prescribed by the curriculum (e.g, Reiser et al., 2021). This paper illustrates the power of video as a reflective tool for TCs to notice, value, and leverage student contributions. Specifically, we focus on how video club (Barnhart & van Es, 2020) can help TCs reframe students' "silly" questions and ideas as generative resources for science learning, positioning students as competent inquirers (Keifert & Stevens, 2019). Ultimately, this shift can contribute to an inclusive classroom community where a teacher transitions from "the-one-who-teaches, to one who is taught in dialogue with the students" (Freire, 2018, p. 80). To this end, we ask: How can video clubs help science teacher candidates see strengths in students' "silly" contributions?

Theoretical background

What teachers notice about students' contributions (e.g., questions, ideas, actions) is shaped by the sociopolitical frames through which teachers see their students (Louie et al., 2021). Pervasive deficit ideologies shape teacher noticing (Louie, 2020), constraining opportunities for learning (Horn, 2007) as teachers position students' contributions as not being relevant or appropriate (Flores & Rosa, 2015). Moreover, science education typically draws on exogenous understandings of inquiry, valuing classroom forms of professional practices (NRC, 2012) rather than taking students' contributions seriously (Keifert & Stevens, 2019). As a result, generative resources like students' playful interactions are often dismissed or overlooked in science classrooms (Keifert et al., 2021). Thus, there is a need for teacher educators to understand how deficit perspectives of students' contributions can be surfaced, challenged, and rearticulated (Philip, 2011) in order to help teachers attend to issues of equity and inclusion and see students' resources as strengths (Louie et al., 2021). We propose that video club could be used as a tool to help teacher candidates reframe student contributions (e.g., reframe contributions that they had initially dismissed as "silly" instead as substantive). In video clubs, teachers share and analyze short video clips of their own classrooms (van Es & Sherin, 2007). Through repeated viewing and discussion, video clubs support teachers to consider classroom discourse, curricular materials, and teaching strategies in the context of rich and complex classroom interactions (Borko et al., 2008). We propose that specific affordances of video club (watching videos repeatedly, pausing for discussion), when paired with anti-deficit framing (Louie et al., 2021), could help TCs see students' contributions as resources integral to science learning and notice resources that may have been overlooked as they were teaching. In addition, these reflective discussions could enable TCs to collectively imagine how they could cultivate students' strengths in the context of the lesson they are watching or in their future teaching.

Method

This study was conducted in two methods courses at a large university in the midwestern US that took place virtually using Zoom in Autumn 2021. One course focused on middle childhood science (grades 4-8) and included 15 TCs; the other focused on secondary science (grades 7-12) and included 7 TCs. We use pseudonyms that were

chosen by TCs to represent themselves. We focus our analysis on video clubs, which took place 3 times during each course. We use interaction analysis (Jordan & Henderson, 1995) and inductive coding (Charmaz, 2006) to explore how this design supported teachers to see strengths in students' contributions, focusing on how they reframed students' contributions as substantive rather than "silly."

During video clubs, TCs selected, watched, and discussed short video clips of their teaching (3-4 minutes) in small groups with four of their peers and a facilitator from the research team. TCs shared clips from their field placement as well as from their "microteaching" assignments (a mini-lesson planned and taught by TCs to their peers). To build toward an anti-deficit frame, before beginning video clubs, TCs read a case excerpt from Warren et al. (2020) about Jonathan, an African American boy who argued that the sun is living – an idea that aligns with contemporary systems-based perspectives in science, but that was initially dismissed by Jonathan's teacher. TCs discussed the case from the perspective of the teacher and the student, then reflected on connections to their own experiences as teachers and learners. Video club was introduced as a way to help TCs practice seeing students' strengths that might similarly be overlooked during teaching. Video club discussion was guided by three prompts: (1) How *does* the teacher or activity make space for students' ideas, (2) How *could* the teacher or activity make space for students' ideas, (3) What strengths do you notice in students' contributions?

Findings and discussion

Our analytic focus on "silly" questions and ideas emerged from a tension initially raised in the secondary science class. In her video club, Fairygirl explained that only "genuine" questions or ideas (rather than "silly" questions or ideas) were welcome in her classroom: "I think that that's really important to talk about in your classroom to make it a safe and respected environment for everybody to bring their own opinions. Not silly opinions or silly facts, but genuine questions, genuine ideas should always be welcomed." Here, Fairygirl distinguished between "genuine" and "silly." Yet, in reality, there are no objective criteria that can help teachers distinguish between these categories. Moreover, resources like children's play that might be constructed as silly (Keifert & Stevens, 2019) or otherwise inappropriate (Flores & Rosa, 2015) can be generative for classroom inquiry and science learning (Keifert et al., 2021; Pierson & Brady, 2020). Based on this interaction, when video clubs were introduced in the middle childhood science class, we attended specifically to how TCs constructed students' contributions as "silly" (or inappropriate) versus "genuine" (substantive or generative). Below, we present examples from the middle childhood class, focusing on two sessions: (1) the "practice" video club, where the whole class participated in a video club using a video of the instructor, Pierson, teaching in a 6th grade classroom, and (2) the first video club in which TCs shared videos of their own instruction. We show how video club helped TCs surface and challenge tensions related to "silly" questions in science classrooms, reframing students' contributions as substantive rather than "silly." We propose that slowing down and collaboratively seeking out students' strengths in their video clubs supported TCs' shifts from constraining to expansive perspectives of students' contributions.

Reframing "silly" in instructor's examples

Before the "practice" video club, Pierson asked TCs if they had experienced tensions like those experienced by the student and the teacher described in the "Jonathan and the Sun" reading. Margaret shared that her Spanish teacher "yelled at a student for asking what color a pumpkin was and he was colorblind," adding that it is important that teachers "not make assumptions that students are trying to cause problems." In response, in the Zoom chat, Shoobop wrote "that's not funny, but also a really funny question." This led into a conversation about what Shoobop described as students' "bravery" and "courage" to share risky questions and ideas, including ideas that might seem "funny" or "wrong" to the teacher and other students.

Building on this idea, Pierson intentionally highlighted in her teaching clip (students participating in an embodied model of an ecosystem with algae and guppies, see Pierson & Brady, 2020) student contributions that could be perceived as "silly." Early in the video, Shoobop picked up on one student comment that he saw as funny: a student's suggestion that "maybe if the guppies would communicate" they would survive longer in the ecosystem. Pierson asked him to "talk a little bit more about this quote." In the exchange that followed, the student's idea was reframed; rather than being "funny" it was seen as generative and appropriate for science learning:

> **Shoobop**: I honestly thought it was a funny sounding idea. I like that you [Pierson], like, kind of went with it though. Like it's kind of like a silly idea that like, I mean I don't know if [guppies] communicate with each other… but the idea of them, like, talking to each other just kind of made me smile.

> **Pierson:** That's interesting, because I, I think you're pulling out like, "okay, so a student is saying something, but if you take it seriously, where does it go?" Is that kind of what you're getting at?
> **Shoobop**: Yeah, like, I guess, well, I like the way you were like taking what they said and, like, rolling with it and, like, yeah, "let's imagine what might be different if the guppies were communicating."
> **Pierson**: Why would it be helpful, to talk about how different organisms communicate?
> **Margaret**: Yeah, so like, obviously, we talk a lot. Talking is how we communicate. But, like bees communicate though, like, shaking their butts. I think that's how they do it… there are certain things that like communicate through smells.

In this interaction, the TCs and Pierson worked together to reframe the student's contribution as a generative resource for exploring ideas critical to the biological and ecological phenomena the students were studying (whether and how organisms communicate), valuing and legitimizing a contribution initially described as "funny." At the end of the video, when students were dancing, Pierson referenced the interaction above again. After describing how dancing became a resource in this classroom, Pierson said, "so even things again like Shoobop was saying that seem kind of silly in the moment can be really great resources." Slowing down to imagine possible trajectories for students' ideas in this example laid the groundwork for TCs to later reframe and value students' "silly" contributions in their own video clubs.

Noticing and responding to students' contributions

The framing above helped TCs consider how they could invite and cultivate students' contributions in their own teaching, even if their students were afraid of being "wrong" or "silly." When sharing his own teaching video, Shoobop paused to highlight a moment when he says "There's no wrong answers in this classroom." Margaret commented on this statement, saying "it's important to open up the floor to the idea that nothing is off the table." With this comment, Margaret affirmed that all students' contributions could be valuable for learning. To encourage Shoobop to share his perspective, the facilitator asked: "so what were you thinking?" He explained:

> One of my favorite things to do in the classroom is just kind of like, if it feels like one angle isn't working, where, like, as before I was trying to go, like, there head on, like, let's talk about the content, I was, like, "well if we try to think outside any context, like, what we think is right or wrong answer, like let's discuss, like, what could be." I don't know. I don't think I'd go so far as to say like, "what would this look like in a parallel universe," but, like, "why don't we talk about that?" and then whatever we end up talking about we can then draw back to more, like, the actual meat and potatoes of the lesson.

This response echoes themes from the "practice" video club: that it is important to hear students' ideas because they can connect to the "actual meat and potatoes of the lesson." Yet, it also positions students' contributions as supportive of the curricular pathway, rather than an opportunity to open new lines of inquiry. In this sense, Shoobop's explanation indicates openness to students' ideas, but does not offer students epistemic authority (Haverly et al., 2020; Miller et al., 2018). Other students expressed similar stances. Ren said, "He was ready to go with it. He just kept the train rolling and encouraging that line of thought. I think that gave a great opportunity for students to share their thoughts." Billy added "He doesn't necessarily tell them if their ideas are right or wrong, but he does tell them, 'yeah, that's a great idea' and he still uses the ideas to just continue on that conversation." Once again, TCs positioned students' ideas as either "correct" or "incorrect" (even if the teacher withholds this information), which could lead to deficit perspectives of students' ideas. Still, these statements illustrate a shift in the TCs' stance away from narrowly focusing on ideas represented in their standards and curricula and toward inviting and valuing students' ideas. Later in the discussion, TCs discussed challenges with this approach. They said it can be difficult to respond to students' ideas in the moment. Shoobop shared a strategy that he used to slow down during instruction: repeating students' contributions (to allow himself time to process). He explained: "I think that's something that generally makes me uncomfortable in the classroom is like I very much so want to be the expert, which I think every teacher should be, and from time to time, when I'm like 'OK well I actually like need to think about what that person just said,' because I'm also a literal human being and need to think about things." Slowing down in this way allowed Shoobop to create space for himself to notice and respond, which in turn contributes to a classroom community where students' ideas are valued.

Conclusions and implications

Our findings have implications for the design of science methods courses that aim to support equitable teaching. Our data demonstrate how video club can help TCs see strengths in students' contributions. Here, we focus on the contrast between framing students' contributions as silly versus substantive, but we propose that this lens could be applied to other student contributions seen as "inappropriate" for science learning. Video clubs allow TCs time to pause and reflect on students' contributions and imagine generative possibilities in their responses. Over time, this could lead to shifts toward anti-deficit approaches that value and take seriously students' contributions. We conjecture that as these TCs continue with video club, they could shift toward seeing students' contributions as valuable in their own right (rather than only as means to the "meat and potatoes" of the lesson).

Study on Evaluation Indicator System of Interdisciplinary Problem-solving Ability for Pre-service STEM Teachers

Jie Xu, Department of Educational Information Technology, East China Normal University, xjhbsfdx@163.com
Haoxin Xu, Shanghai Institute of AI for Education, East China Normal University, xingyezn@163.com
Xianlong Xu, Department of Educational Information Technology, East China Normal University, xlxu@eec.ecnu.edu.cn

Abstract: With the advent of the era of artificial intelligence, the problems that students need to solve are more diversified and integrated. Therefore, it is very necessary to cultivate interdisciplinary problem-solving (IPS) ability for students. Pre-service STEM teachers play a very important role in interdisciplinary education, the analysis and evaluation of IPS ability of pre-service STEM teachers is helpful to understand the current ability level. Based on the literature review and the Delphi method, an evaluation indicator system for pre-service STEM teachers' IPS ability is constructed. Expert consultation and Analytic Hierarchy Process (AHP) method are used to determine the weight of indicators. 98 surveys from 10 colleges are collected, results indicated that the evaluation indicator system has high validity, pre-service STEM teachers' IPS ability is generally average. Finally, directions are also provided for evaluating and improving the IPS ability of pre-service STEM teachers.

Introduction

With the constant development of innovative technology, the problems that students need to solve are more diversified and integrated, the social demand for student is becoming more comprehensive. Cultivating learners' interdisciplinary problem-solving (IPS) ability have gradually become one of the key training objectives in the educational reform of most countries. In order to improve IPS ability of pre-service STEM teachers, the Australian and UK governments have issued corresponding policies towards providing high-quality special training and learning support. The Chinese government has also taken measures to construct specialist teacher groups with outstanding IPS ability through multi-school collaborative interdisciplinary teaching and research activities (Ministry of Education, 2019). IPS ability is important to students, however, pre-service STEM teachers as the ones who develop this ability in students, must also possess IPS ability (Ming & Sha, 2019). Researchers have evaluated middle school students' IPS ability (Feng, 2019). However, there are little research on teachers' IPS ability. Existing research mainly focus on the orientation of STEM instruction (Günbatar & Bakırcı, 2019), improving pre-service teachers' STEM knowledge and problem-solving skills ((Berisha & Vula, 2021; Özçakır Sümen & Çalışıcı, 2021). It has been an urgent need to cultivate IPS ability of pre-service STEM teachers. Previously, the concept of pre-service STEM teachers' IPS ability is needed to be clarified. Secondly, a corresponding indicator framework is necessary to estimate the ability. Therefore, in order to understand the current situation of IPS ability of pre-service teachers, it is necessary to establish the corresponding indicator framework that can diagnose pre-service teachers' IPS ability level.

Theoretical framework

IPS ability of pre-service STEM teachers is mainly discussed in this article. STEM teacher refers to teachers of subjects related to STEM such as mathematics, science and information technology. Pre-service teachers majoring in Educational Technology are good at STEM education and science education (Ming & Sha, 2019). IPS ability means that when pre-service STEM teachers encounter interdisciplinary problems in teaching, based on the attitude of facing the problem, combine the methods and strategies of multidisciplinary knowledge when dealing with problems, as well as the quality of interdisciplinary problem solving in exploring and integrating different disciplines.

Construction of evaluation indicator system

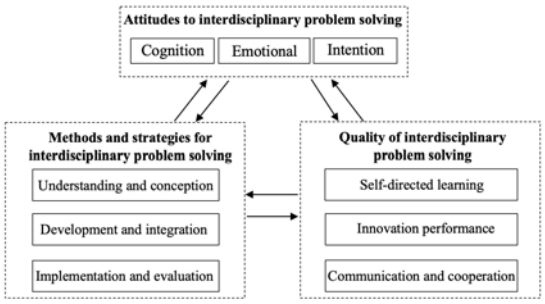
The cultivation of IPS ability is the trend of the times and one of the goals of current education. In this study, we refer to the outline of STEM teacher ability indicator system issued by China Institute of Education Sciences. The dimensions of problem-solving are referred to relevant literature as well (Huang Maozai & Chen Wendian, 2004). Then, an evaluation indicator system is constructed initially to evaluate the IPS ability of pre-service STEM teacher combining with the characteristics of pre-service teachers. Expert consultation questionnaire is designed

 © ISLS

to further determine evaluation indicator system. Finally, pre-service STEM teacher' IPS ability evaluation indicator system includes 3 first-level indicators and 9 secondary indicators (see Figure 1).

Figure 1

Evaluation Indicator System of Pre-service STEM Teachers' IPS Ability



The attitude dimension of interdisciplinary problem solving can be divided into three aspects of cognition, emotion and intention. “Attitude" refers to individual's stable psychological tendency and response to others or things, including cognition, emotion, and intention, which are usually manifested in beliefs, feelings, and behavioral tendencies (Shi, 2012). "Cognition" refers to the understanding and problem-solving beliefs of pre-service STEM teachers. "Emotion" is an emotional experience from the inside. "Intention" is the behavior of the pre-service STEM teacher’s sense of responsibility and mission to solve interdisciplinary problems, which is manifested by cognitive and emotional factors.

Interdisciplinary problem-solving methods and strategies dimension refers to the use of interdisciplinary thoughts and knowledge to solve problems. In this study, methods and strategies are divided into three parts (Su, 2017). The understanding and conception part indicates pre-service STEM teachers' understanding of knowledge involved in interdisciplinary problems and their conception of knowledge performance. The development and integration part indicates pre-service STEM teachers’ competence to obtain materials through multiple channels when developing teaching resources, integrate resources from the perspective of cultivating students' abilities in various aspects. The implementation and evaluation part refers to the methods and strategies used by pre-service STEM teachers to solve interdisciplinary problems in teaching organization and teaching implementation, it also can evaluate and optimize the process of solving interdisciplinary problems.

The quality dimension of interdisciplinary problem solving refers to the active learning, innovative performance and communication and collaboration abilities of pre-service STEM teachers in the process of solving interdisciplinary problems (Huang Maozai & Chen Wendian, 2004). Firstly, pre-service STEM teachers can recognize interdisciplinary problems, use appropriate methods to solve problems, improve the solutions and promote professional development. Secondly, pre-service STEM teachers need to show a unique way of thinking at all times, discover problems creatively. Finally, the development of pre-service STEM teachers emphasizes teamwork spirit, which stand for a harmonious atmosphere to share resources, communicate with each other, and jointly complete solutions to problems in cooperation.

Research questions

Based on the above construction of the evaluation indicator system, the current study mainly focuses on two questions:

(a) How to verify the effectiveness of the pre-service STEM teacher’s IPS ability evaluation indicator system?
(b)What level do the study objects perform in each dimension of IPS ability?

Research Design

Determine indicator weight

In the study, the expert consultation questionnaire of the indicator weight is designed after the construction of the evaluation indicator system. Then, the average (Likert five-point scale) is used to express the degree of the importance of each evaluation indicator, and the concentration of expert opinions is expressed by median and majority. Experts' opinions on each indicator are collected to delete indicators with low support. After two rounds of consultation by 12 experts, the evaluation indicator system is also determined.

The Analytic Hierarchy Process (AHP) is a decision-making method and proposed by the American operations researcher Saatty T.L. Firstly, an analysis structure model of the pre-service STEM teacher's IPS ability

evaluation indicator system is established in the yaahp software. Secondly, the 1-9 ratio scale method is introduced to compare and analyze the factors of each layer in pairs, distinguishing which element is more important. Finally, the judgment matrix is constructed. The weight of the pre-service STEM teacher's IPS ability rating indicator system is established through calculation and analysis of the experts' scoring of the importance of each indicator in the judgment matrix at the last (see Table 1).

Table 1
Pre-service STEM teacher's IPS ability evaluation indicator weight

First-level indicators	Weight	Secondary indicators	Weight
1. Attitudes to Interdisciplinary problem solving	0.28	1.1 Cognition	0.22
		1.2 Emotion	0.30
		1.3 Intention	0.48
2. Methods and strategies for interdisciplinary problem solving	0.33	2.1 Understanding and conception	0.29
		2.2 Development and integration	0.33
		2.3 Implementation and evaluation	0.38
3. Quality of interdisciplinary problem solving	0.39	3.1 Self-directed learning	0.25
		3.2 Innovation performance	0.35
		3.3 Communication and collaboration	0.40

Questionnaire design

The questionnaire is developed by using the pre-service STEM teacher's IPS ability evaluation indicator system constructed in this research. The questionnaire is a Likert five-point scale. The first part is the basic information of the survey objects, including gender, grade, major, and college level, etc. The second part is the current situation of survey objects' IPS ability, including 3 first-level indicators and 9 secondary indicators.

Participants

The survey objects cover senior undergraduate in educational technology and postgraduate in modern education technology from 10 normal colleges in China. The participants have mastered professional knowledge and teaching skills, and have participated in educational internships for 3-6 months in primary and secondary schools. However, they haven't entered the teaching field formally, lacking educational practical experience.

Procedure

A total of 104 questionnaires are collected in this survey and 98 are valid questionnaires, with an effective rate of 94.23%. Through SPSS analysis of the overall validity of the questionnaire, it is concluded that the overall KMO coefficient of the questionnaire survey is 0.885, the overall Alpha reliability coefficient is 0.954 and the Alpha reliability coefficient of each dimension type is greater than 0.7, which proves that the reliability of the questionnaire is relatively high.

Results

RQ1: How to verify the effectiveness of the pre-service STEM teacher's IPS ability evaluation indicator system?

Firstly, the pre-service STEM teacher's IPS ability evaluation indicator system is based on literature analysis and the Delphi method, more importantly, it is determined after two rounds of expert consultation. Secondly, the indicators weights at all levels are determined according to the analytic hierarchy process (AHP). Thirdly, the questionnaire is developed by using the pre-service STEM teacher's IPS ability evaluation indicator system. Finally, the result shows that the IPS ability levels of the research objects are normally distributed, the overall IPS ability is average level. In addition, some research objects claimed that the allocation of the evaluation indicator system is relatively reasonable, reflecting the requirements for specific abilities such as subject knowledge and operational skills at each stage of IPS. Therefore, the IPS ability evaluation indicator system designed in this research has high scientific and use-value.

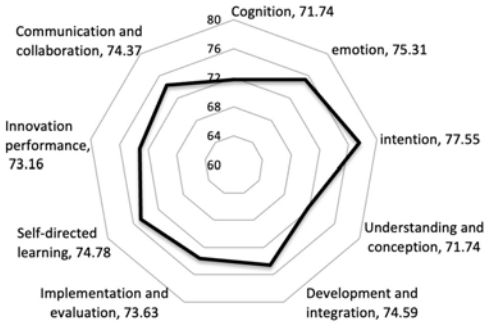
RQ2: What level do the research objects perform in each dimension of IPS ability?

The total score of pre-service STEM teachers' IPS ability is 74.27. According to the classic grade classification standard (Juan, 2016), the result indicates that the pre-service STEM teachers' IPS ability is generally average. The score of attitudes to IPS is 75.60. The methods and strategies of interdisciplinary problem solving and the quality of interdisciplinary solving are a little lower than average score, 73.40 and 74.05 respectively.

From the perspective of secondary indicators, the performance of the pre-services STEM teacher's intention and emotion, development and integration, self-directed learning, communication, and collaboration are better than that of other secondary indicators. While the level of cognition, understanding and conception, implementation and evaluation, innovation performance are relatively low. Especially the cognition, understanding and conception lag behind the level of development of other indicators (see Figure 2).

Figure 2

Pre-service STEM teachers' IPS ability secondary indicator score



Conclusion

The evaluation of pre-service STEM teachers' IPS ability is the prerequisite for STEM education. The localized design and development of the evaluation indicator system is a necessary way to evaluate the training effect of pre-service STEM teachers. In this study, the Delphi method is used to construct an evaluation indicator system for pre-service STEM teachers' IPS ability, the analytic hierarchy process (AHP) is also used to calculate the weights of indicators at all levels. The practical result shows that the evaluation indicator system can diagnose the pre-service STEM teachers' IPS ability levels and existing shortcomings to some extent. However, it's a complex system engineering to construct a scientific and reliable localized evaluation indicator system, which needs to be continuously revised and improved based on the evaluation object and the educational environment. In the future, the evaluation indicator system should be expanded in such aspects as the survey scope of regions and grades.

Emotional engagement assessment: self-reports versus facial expressions

Ilana Dubovi, Tel-Aviv University, ilanadubovi@tauex.tau.ac.il

Abstract: Current research utilizes self-reports and facial expression recognition analysis to provide a more continuous and objective insight into how students' emotional engagement unfolds and impacts learning. Analysis of nursing students learning with virtual reality simulation revealed that only the facial expression data channel, compared to self-reports, was sensitive to fluctuations in engagement which varied throughout the different learning session phases. In addition, findings show that learning achievements were negatively associated with facial expressions of anger and positively associated with positive self-reported emotions. Hence, this study demonstrates that the methodology of using multimodal data channels which encompass different types of measures, can provide insights into a more holistic understanding of engagement in learning and learning achievement.

Introduction

Engagement is a multidimensional construct that refers to an individual's active involvement in a learning activity (Christenson et al., 2012). This study explores only the emotional aspect of engagement. The *emotional engagement* focuses on states that are related to students' emotional involvement during learning activities (Christenson et al., 2012). Positive emotions include enthusiasm, interest and enjoyment while learning (Renninger & Bachrach, 2015). Whereas, negative emotional components include boredom, sadness, and frustration in the classroom (Skinner et al., 2008). Theories of motivation, including the self-determination theory, and the control-value theory (CVT) of academic emotions (Deci & Ryan, 1985; Pekrun & Linnenbrink-Garcia, 2012), emphasize the role that both positive and negative emotions have on students' involvement in learning activities, and underscore how affective dynamics sustain or disrupt learners' engagement to impact learning performance. The CVT predicts that positive activating emotions (e.g., curiosity and enjoyment) positively influence learning outcomes, whereas the inverse is true for negative-deactivating emotions (e.g., boredom) (Pekrun & Perry, 2014). Given the importance of emotional engagement, it is therefore crucial to capture how emotional engagement unfolds and what initiates and diminishes emotional experiences with the long-term goal of helping leaners to re-engage. So far, the most predominate measures of emotional engagement were self-reports and observations (D'Mello et al., 2017). This study suggests evaluate the additive value of the multimodal approach, using both, subjective self-reports and objective facial expression recognition analysis.

Facial expression recognition is a fully automated measure which it is based on artificial neural networks that can match varying sets of action unit activities to different discrete emotions (Ekman & Rosenberg, 1997). Facial expression analysis allows identification of changes in facial movements at very short time intervals, and can therefore provide an unobtrusive detailed view of students' emotions transitioning throughout a learning session (Dindar et al., 2020). Importantly, it has been suggested that self-report measures mainly reveal emotions a person has become consciously aware of, whereas an automatic facial expression analysis captures fast changing emotions in the implicit dimension of the subconscious (van Bommel et al., 2020). As such, incorporating the traditional measures of engagement, such as self-reports, with fully automated measures of engagement, can capture the grain size of engagement dynamics and provide both objective microlevel and subjective macrolevel perspectives (D'Mello et al., 2017).

Research questions

(1) How do students' emotional engagement unfold while they learn, as revealed by their self-reports and by facial expression analysis; and (2) What is the synergistic effect of this emotional engagement, as measured by the multimodal data streams of self-reports and facial expressions, on the students' learning achievements?

Methods

Participants

In total, 65 freshmen nursing students at an Israeli university volunteered to participate in the study. Due to technological issues of data collection (e.g., calibration errors), data of four participants was excluded, resulting in a final sample size of 61. Most participants were female (n=44), and the mean age was 23±5.1 years.

The study was conducted following the approval of the university's ethics committee (#0001776-2).

Research design and procedure

This study is part of a more extensive study (Dubovi, 2022). This was a prospective study with a pre-test – post-test design. The students' demographics and prior content knowledge were assessed via a pre-test paper-and-pencil survey. Each participant was then asked to sit in front of a computer and a calibration of their facial expression tracking was performed. Following this, participants were offered to learn with a desktop virtual reality simulation. The VR simulation incorporated the architecture of a 3D hospital (Dubovi et al., 2017). Playing the role of a nurse-avatar, participants were asked medication administration procedures. Emotional engagement characteristics were captured during the entire learning experience using facial expressions recognition algorithm. In addition, students were asked on three occasions by the VR simulation to complete the Positive and Negative Affect Scale (PANAS) questionnaire (Watson et al., 1988): Time 1, before the intro phase; Time 2, after the intro phase; and Time 3, after the last phase of the summing-up video. After the learning session, participants completed a paper-and-pencil content knowledge post-test. The iMotions 9.0 Biometric Research Platform (https://imotions.com) was used to setup the experimental design and to collect the data.

Data Collection Instruments

Facial expression recognition

The Affectiva Affdex algorithm provided by iMotions 9.0 (https://imotions.com) was used to obtain in real-time the 7 basic emotion likelihoods for joy, anger, surprise, contempt, fear, sadness, and disgust at a 30 Hz frequency. The algorithm uses the Facial Action Coding System to identify and categorize facial expressions based on specific facial 'action units' and was shown to be reliable (Ekman & Rosenberg, 1997; Kulke et al., 2020). The metrics can be thought of in terms of probability; as the emotion or facial expression occurs and intensifies, the score rises from 0 (no expression) to 100 (expression fully present). Then a thresholding for time and for absolute amplitude probability was carried out based on the iMotions guidelines (https://imotions.com/blog/facial-expression-analysis/) to extract emotion percentage metrics. Facial expressions were collected for the overall learning experience.

Positive and Negative Affect Scale (PANAS) questionnaire

The PANAS is a list of 20 adjectives used to describe 10 positive emotions and 10 negative emotions (Watson et al., 1988). The positive affect captures the feelings of being attentive, active, alert, excited, enthusiastic, determined, inspired, proud, interested, and strong. Negative affect includes the feelings of being hostile, irritable, ashamed, guilty, distressed, upset, scared, afraid, jittery, and nervous. The order of questions in the questionnaire was mixed between positive and negative affect scores. Respondents are required to indicate the extent to which they feel these emotions "at this moment" on a 5-point scale. Cronbach alpha yielded a good internal consistency score of .86 for the global positive affect and 0.82 for the global negative affect.

Content knowledge test

The Medication Administration Test (MAT) assessed the nursing students' understanding and practical applications of the medication administration guidelines. The test was validated in a previous study (Dubovi et al., 2017). The test consists of 13 multiple-choice items. Analysis of the MAT using Cronbach alpha yielded a good internal consistency score of .74.

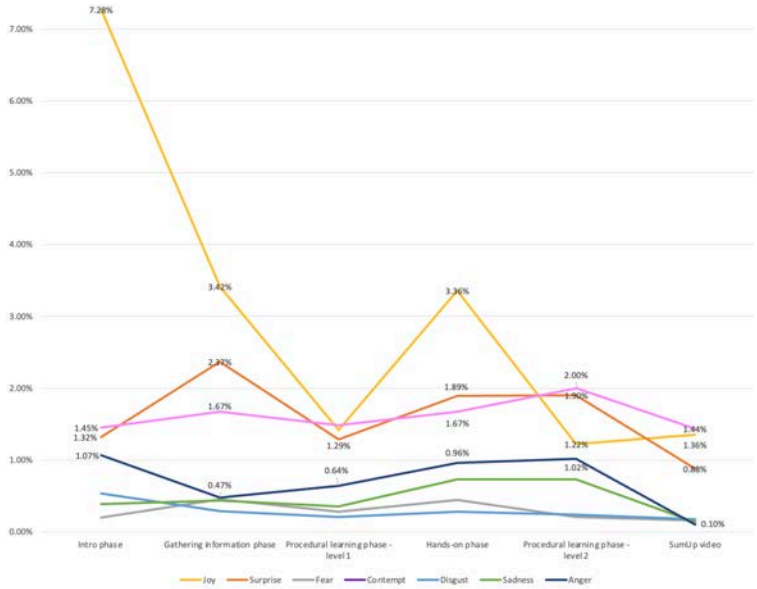
Results

Emotional engagement throughout the overall learning experience was captured via facial expressions extraction and PANAS self-reports. The Kruskal-Wallis H test of facial expressions revealed that participants experienced significantly more joy 4.0±3.6% than other emotions, such as surprise 1.7±2.6%, fear 0.3±0.9%, contempt 1.5±2.5%, disgust 0.3±0.6%, sadness 0.4±1.2%, and anger 0.8±1.6%; ($\chi 2(6) = 314.710$, $p < .001$). Furthermore, a linear mixed effects model (LMM) for repeated measures showed a significant interaction between the type of expressed emotions and the VR simulation phase ($F(30, 420.699) = 7.545$, $p<0.001$). Post-hoc analysis showed significantly more joyful expressions for the intro phase ($p < 0.001$) and for hands-on phase ($p < 0.001$; Figure 1). In addition, facial expressions of anger and surprise were expressed significantly less during the final sum-up video phase ($p < 0.005$).

While facial expression analysis captured the fluctuation of the students' implicit and fast changing emotions, the PANAS self-report detected the students' explicit emotions at three different time-points. Similarly to the facial expression analysis, the PANAS analysis revealed that students experienced significantly higher levels of positive emotions than negative emotions ($F(1, 3658)=6882.5$, $p<0.001$; 3.8±1.1 vs. 1.3±0.7, Table 1). The most predominant emotions while interacting with VR were interest (4.5±0.4), attentiveness (4.5±0.5) and alertness (4.3±0.5). A non-significant change in emotions was demonstrated by an LMM for repeated measures throughout the three times that the PANAS was administered ($F(38, 2239.068) = 0.964$, $p=0.533$).

Figure 1

Changes in students' emotions according to the VR simulation sequence phase.



The MAT content knowledge post-test scores were significantly higher than the pre-test scores (paired $t=-6.422$, $p<0.001$; 90±9 vs.78±16). To further understand the impact of emotional engagement on the students' knowledge gain, a bivariate intercorrelation analysis was performed (Table 1). The analysis revealed a significant negative correlation among anger facial expressions and post-tests scores ($r=-0.323$, $p < 0.1$; Table 1); as well as positive correlation of PANAS positive self-report emotions to post-tests scores ($r=0.294$, $p < 0.1$; Table 1).

Discussion

The main goal of this study was to identify the synergistic impact of the multimodal metrics on the students' learning achievements. The facial expression continuum revealed that joy (i.e., enjoyment) was the most predominant emotion that was expressed by students. It became evident that the frequency of the joy expression changed across the different VR learning phases. Although facial expressions of joy were the most frequent emotions expressed by students, there was no significant impact of joy on post-test learning achievements. In contrast, although facial expressions of anger were expressed at a relatively low frequency with no significant changes across the different phases of the learning session, they did show a significant association with post-test learning achievements. Interestingly, the subjective perception of their emotional experience, a PANAS self-report, demonstrated the significant impact of self-reported positive emotions on learning achievements. This study demonstrates that it is crucial to integrate both automated objective channels with subjective methodologies to provide a more holistic and comprehensive perspective on complex learning processes and learning outcomes.

Abstract: Maker-centered learning engages students in the creation of tangible artifacts. We focus on the edges of this intentional design process, where mundane materially entangled practices that are not driven merely by human intention happen. We build on theoretical perspectives that consider practices as assemblages and matter as active, relational, and dynamic. Together with teachers, we conducted an invention project in Finland. Students aged 14 to 15 designed and built smart products in small teams. To understand the continuity of details, we analyzed video recordings of three teams' design sessions on three levels: the macro, intermediate, and micro. The analysis framed the learning process as a balancing act. In addition to performing the learning task, students simultaneously created functional artifacts and adapted their creative flow to the institutional rhythm of the school classroom. Materiality created messiness and unpredictability but also provided tangible boundaries that allowed for action amidst this uncertainty.

Introduction

A key aspect of maker-centered learning is idea materialization, the transformation of abstract ideas into tangible forms. Working with tangible artifacts has been found to support learning that is multimodal and transactive across settings (Peppler et al., 2021). With our background in craft, design, and technology education, we perceive the idea materialization process as an entanglement of designer and matter, where the human maker learns from matter and thinks with it (Heimer, 2016). However, much activity takes place at the edges of this intentional design process, such as spontaneous play, matter that is entangled with sociopolitical questions (Vossoughi et al., 2016) or knowing beyond traditional academic skills (Kuby et al., 2015). We focus on these edges and mundane materially entangled practices that are not driven merely by human intention, but also affected by, for example, materials and technologies (Bodén et al., 2019).

Sensitizing ourselves to details and more-than-human relations does not offer universal facts. Instead, such a perspective helps us to recognize issues that call for response (Haraway, 2016). A focus on the wider connections between details can make actors hiding in mundanity, such as commercial corporations, visible (Decuypere, 2019). Appreciating moments of uncertainty and nonlinearity can help us to notice opportunities to support learning that places learners as part of the world, not outside observers, which is crucial in future education (Common Worlds Research Collective, 2020). To better understand the multiple fluid practices (Mol, 2002) that take place in a maker-centered learning project, we ask: How is the idea materialization process enacted in classroom practices?

Theoretical approaches

We understand idea materialization as an iterative and nonlinear process that includes constructing, evaluating, and revising various material models, such as sketches, mock-ups, prototypes, and final artifacts (Kangas et al., 2013). Our longstanding research in craft, design, and technology education helps us to avoid blindly adopting branded definitions of making, which, as Vossoughi et al. (2016) argue, can limit maker-centered learning to technological innovation aimed at contributing to economic growth. Our understanding of making emphasizes aspects such as embodied knowledge (Heimer, 2016) and wide-reaching material connections (Latour, 2005).

Widening the scope of our inquiry to the edges of intentional design allows us to explore the unverbalized practices that emerge during idea materialization. This approach helps us to understand the multiple realities that take shape in the classroom (Bodén et al., 2019). Placing special emphasis on acknowledging material agency as part of sociomaterial entanglements, we build on theoretical perspectives that consider practices as assemblages and matter as active, relational, and dynamic (Bodén et al., 2019; Haraway, 2016; Mol, 2002).

We begin by acknowledging that matter matters; it can transform situations (Latour, 2005). However, this material agency is not a static attribute but is instead enacted in relations (Mol, 2002). Therefore, instead of single actors, our focus is on the heterogeneous entanglements of human- and nonhuman actors and sociomaterial encounters in which humans and nonhumans transform each other (Latour, 2005). These transformations and

 © ISLS

effects of encounters are not predetermined; thus, we do not seek to establish fixed or stable roles of matter. Instead, we consider the practice of materialization to be fluid assemblage, which is constantly changing (Mol, 2002). We purposefully do not predetermine who or what participates in enacting the materialization. The more-than-human relations that constitute materialization cannot be clearly formulated in a neat network, as reality is not always logical (Mol, 2002). Thus, we do not seek universal epistemic claims but theoretically grounded situated knowledge (Haraway, 2016; Decuypere, 2019).

Methodology

For several years now, we, together with teachers, have conducted co-invention projects in elementary and secondary schools as part of regular curricular activities. This study focuses on a project that took place in spring 2019 in a Finnish upper secondary school. Students aged 14 to 15 designed and built smart products in small teams. The project lasted for 8 weeks and involved 17 sessions, lasting 75 minutes each. The orientation phase (three sessions) included a coding workshop, a lecture from a professional designer, and a visit to a design museum. During the initiative ideation phase (three sessions), students oriented themselves toward problems in their everyday lives and the artifacts involved in those problems. Teachers formed teams of three to four students, and these teams chose one initial idea to be developed and materialized, first as a mock-up and then as a functioning prototype (10 sessions). Finally, teachers organized an in-class invention fair, where students presented their inventions and gave and received constructive feedback (one session).

The first two authors were present at the school throughout the process. After orientation, we video recorded the 14 design sessions of three student teams. The inventions of these teams were named (by the students themselves) the Magic Bunny (a smart piggy bank that counts the money inserted), the Light-Up-Shirt (a garment with decorative LED lights that adjust to the environment), and the Pussi Cat (a smartphone bag that heats up if the temperature drops). To understand the context of the making process and the continuity of details, we analyzed video recordings (approximately 44 hours) on three levels: the macro, the intermediate, and the micro.

On the *macro level*, we engaged with the data by weaving a "Making-Process-Rug" (Riikonen et al., 2020). We went through the video recordings systematically and coded the main verbal and embodied design activities in 3-minute segments. This allowed us to create a visualization of the intentional design process (Figure 1). The Making-Process-Rug acted as a basis for the next level of analysis as well as provided a background for reflecting the relations among multiple aspects of idea materialization.

On *the intermediate level,* we unraveled dichotomies between classification and wonder (MacLure, 2013) by allowing the productively slow (Ulmer, 2017) coding process to guide our attention toward the edges of the intentional design process. We sought events that did not quite fit in the coding scheme but appeared still to be related to the idea materialization. On *the micro level*, we focused on details. We paid attention not only to the words, talk, and gestures of the students but also to the material aspects of the process by considering sounds, space, rhythm, and movement.

Finally, we considered these three levels along with complementary data. We reflected on how the micro-level details were present in student interviews, portfolios, and our field notes. This wider perspective enabled us to analyze how the materialization was enacted in nonlinear trajectories across the entire process. This thinking process was guided by theoretical concepts of material agency (Bodén et al., 2019; Latour, 2005) and fluid assemblage (Mol, 2002).

Findings

In this paper, we focus on three aspects of the idea materialization process. For all student teams, the process was simultaneously a learning performance, the emergence of a functional artifact, and an adaptation to an institutional rhythm.

The material constraints of the process affected and refined the nature of the *learning performance*. All details of abstract flowy ideas had to be concretized while coding. For example, blinking lights and the sounds of the microcontroller gave feedback on coding actions (Figure 2, Magic Bunny), demanding precise and detailed actions. The functionalities of commercial coding software (Microsoft MakeCode for Adafruit Circuit Playground) constrained the ideas that could be materialized and how they were materialized. When combined with the constraints of time, knowledge, and material resources, the materiality of coding required students and teachers to simplify the idea to make it an appropriate learning performance that was challenging enough but not unachievably difficult.

Technology actively shaped the process (Latour, 2005), and students had to think together with matter (Heimer, 2016). This allowed knowledge to emerge without verbalization (Kuby et al., 2015). However, the effect of technology was unpredictable and occurred regardless of preplanned process structures (Bodén et al., 2019); it was not merely a consequence of intentional design experiments. The central role of software and educational technology obscured the dichotomy between local mundane practices and global commercial actors (Decuypere, 2019). When the idea was adjusted to match the material resources, the multiplicity of the process was momentarily coordinated into a whole (Mol, 2002), resulting in a balancing act between ambitions and skills.

In addition to a learning performance, the process was also the emergence of a *functional artifact*. For example, the Light-Up-Shirt team mostly focused on making shirts that would complement their existing wardrobes or duplicate existing favorites (Figure 2, Light-Up-Shirt). These tangible objects were connected to the students' everyday lives beyond school. The open-ended design task allowed students to create artifacts that were meaningful for them, not merely to complete prefixed tasks. Sewing the smart LED lights onto a detachable piece of fabric allowed the students to fulfill the requirement to use digital technology with minimal effort. This balancing act between learning performance and personal interests illustrated how different aspects of the process were able to co-exist and interact (Mol, 2002).

The idea to be materialized was not abstract nor merely human to begin with but was instead informed by qualities of existing artifacts. The presence of artifacts embedded the process within wider society and cultural phenomena, such as fashion and consumer culture. Although these issues were not deliberately or verbally addressed, they were present in the artifacts (Latour, 2005).

The process was an adaptation to an *institutional rhythm*. The materialization process had to be adjusted in accordance with predefined school schedules, resources, and practices. Neither teachers nor students could have known beforehand how much time making the artifact would take; materials provided surprises. Even though the Pussi Cat team often engaged in non-task-related chat during design sessions, their making process flowed faster than anticipated. To make use of the allocated time, the team added decorative elements to their invention (Figure 2, Pussi Cat). The fragmented nature of the process, determined by the school schedule, demanded practices to facilitate transitions, such as routines for organizing the required materials in specific places after use and tracking the process with portfolios. In addition, the tempo of movement within the classrooms thickened toward the ends of the sessions, when students worked to finish their ongoing tasks.

Learning with matter (Heimer, 2016) extended from making design choices to balancing creative flow with institutional resources through material actions. Formal and informal aspects were allowed to co-exist by distributing them to different modalities (Mol, 2002), for example when progressing the learning performance by embodied means while verbally discussing informal issues.

Conclusions and implications

The coexistence of multiple aspects of idea materialization made the learning process a balancing act. The aim was not only to materialize design aspirations but also to cope with local resources, such as school schedules, the societal connections of objects, and the functionalities of the technologies of making. This materiality turned students' general inventions into situated artefacts, embedding abstract issues within tangible details at hand.

Furthermore, the open-ended design task and unscripted making sessions gave students space to act on their own terms. Much of this action took place on the edges of the intentional design. The material details of the designed artefacts were able to serve multiple, even contradictory purposes simultaneously. Non–task-related activities were neither opposed nor alternatives to task-related activities. Instead, the mundane activities provided opportunities for learning to cope with local requirements.

Methodologically, becoming sensitive to such multiple realities in the classroom requires that researchers acknowledge the agency of materiality and eagerly follow even surprising trains of thought prompted by data. In our case, going systematically through the video data gave us space to wonder at the ordinary and zoom in on what did not quite fit into predetermined categories. Instead of being deterministic explanations, theories acted as sensitizing devices, guiding the gaze toward fluid assemblages.

We have suggested an approach that examines classroom practices happening at the obscure boundaries of on-task and off-task activity. The aim is to evolve the understanding of the purpose of learning from mastering the world to cultivating responsible, situated action. In practice, such a perspective could be implemented by exploring how craft practices, which provide enabling constraints, could be utilized in various educational settings beyond maker-centered learning.

International Society of the Learning Sciences

Using hierarchical logistic regression analysis to investigate equity in classroom discourse

Aviv Orner, Ben-Gurion University of the Negev, avivorner@post.bgu.ac.il
Adam Lefstein, Ben-Gurion University of the Negev, lefstein@bgu.ac.il

Abstract: This paper presents a novel methodology for examining equity in classroom discourse. Coding discourse data at the level of the exchange (rather than the utterance) affords investigation of the relationships between teachers' expectations, teaching patterns, students' social backgrounds and participation patterns. Using a hierarchical logistic regression model, we found that the likelihood of students' answers being developed by the teacher in this particular classroom was greater for Jewish students, for boys, for students from higher socio-economic backgrounds, for answers given following teacher nomination, and for relevant responses. In contrast to previous studies, the teacher's perception of the student's learning ability and the type of question posed had no statistically significant effect on the likelihood of the teacher developing the student's answer. The study contributes to our understanding of the mechanisms of educational injustice, to the development of methods for investigating equity in classroom discourse, and – thereby – to its rectification.

Theoretical framework: Participation and equity in classroom discourse

Studies of classroom interaction drawing on sociocultural theory (Vygotsky, 1978) stress students' active participation as a necessary component for fostering learning opportunities and outcomes (e.g. Snell & Lefstein, 2018; Black, 2004; Howe, Hennessy, Mercer, Vrikki, & Wheatley, 2019; O'Connor, Michaels, & Chapin, 2015). Applying this lens, other studies showed there are differences in students' participation in terms of frequency and quality, based on socio-economic background (Black, 2004), ethnicity (Kelly, 2008), and gender (Myhill, 2002). Differences in student participation could be the result of personal qualities, such as cognitive abilities, intrinsic motivation, attitudes towards school, etc. (Jurik, Gröschner, & Seidel, 2014).

A complementary perspective sees variations in participation levels as caused by the teachers' differential behavior towards students from different backgrounds (Sedova & Salamounova, 2016). Thus, teachers' expectations from their students likely affect the ways in which they interact with their students and influence how and what they teach, which may in turn shape students' learning processes and outcomes (Wang, Rubie-Davies & Meissel, 2018). Such differentiated teaching likely has negative consequences, especially when based upon students' social background, perceived ability and/or prior achievement (Black, 2004; Kelly, 2008). Teachers' implicit biases have been shown to influence their expectations of their students (Adair, Colegrove & McManus, 2017), leading to differential treatment and differential learning opportunities (Black, 2004; Snell & Lefstein, 2018). The above-quoted studies focused on teacher actions. However, Calarco (2018) argued that children are not the passive victims or beneficiaries of teachers' biases. Studies of teachers' expectations cannot, in most cases, explain whether teachers' responses are shaped by students' behaviors or by their demographics, because they rarely discuss how students' behaviors may shape differentiated teaching (Calarco, 2018). A few qualitative studies have combined teachers' expectations and behavior with student behaviors, but focused on case studies of individual students, which are telling but unsystematic (Black 2004; Orner & Netz, 2021; Snell & Lefstein, 2018; Sedova & Salamounova, 2016). Similarly, Wang, Rubie-Davis and Meissel's (2018) recent systematic review of quantitative studies on teacher expectations suggests that studies of students' classroom behaviors as both an outcome and a mediating factor of the effects of teachers' expectations have received limited scholarly attention. Only four quantitative studies of this question were identified during the past decades, with inconsistent findings. Based on their review they argue that it is necessary to examine quantitative variables (e.g., how often and for how long students speak) alongside qualitative variables (e.g., utterances' content, immediate context, and identity work).

One problem limiting current efforts to bridge the gap described is the lack of a suitable methodology. Addressing this methodological gap, the present study proposes a new methodology for examining equity in classroom discourse. This methodology involves expanding the unit of analysis from the utterance to the exchange, which enables examination of the inter-relationships between multiple identity categories (e.g., gender, nationality, socio-economic status, the teacher's perception of the student's abilities) and discourse forms (means of attaining the floor, type of question addressed, relevance of the response). Such expansion of the unit of analysis allows us to use hierarchical logistic regression analysis to address complex issues such as: Does the teacher

 © ISLS

develop (through elaboration moves) more answers from boys because they are viewed as more capable or because they tend to answer open questions and their answers are viewed as more relevant?

To understand such gender differences, a model that controls the various variables is required. Understanding the fine-grained workings of this and similar mechanisms is a crucial step towards their rectification. To illustrate the methodology, we address the following research question: How do background characteristics, perceived learning ability and patterns of students' participation affect the likelihood of the teacher developing students' answers? Teacher development of student answers is critical to learning processes because it takes students' ideas seriously, either by challenging them or building on them. Examples of teacher development include probing the student to elaborate their (usually, his) response, or posing an uptake question: that is, a new initiation that incorporates the student's answer. Previous studies have found these questions to be "optimal patterns" that increase participation and thus increase learning opportunities (e.g., Howe et al., 2019).

According to the research hypothesis, the likelihood of developing an answer will be higher among boys, Jews, students from high socio-economic status, with high perceived abilities who answer open-ended questions, receive permission to speak with the teacher's approval, and provide relevant answers. We hypothesize that patterns of students' participation (means of attaining the floor, relevance of the response) and perceived learning ability will shape the likelihood of teachers' developing student responses. Moreover, we hypothesize that these variables will not be sufficient to explain the correlation between student background variables (gender, nationality, socio-economic status) and the likelihood of teachers' developing student responses. Rather, we expect that demographic variables will have an impact above and beyond student behavior.

Research setting

This illustrative case study is part of a design-based research project conducted in 21 Israeli Hebrew-speaking secular state schools and designed to promote academically productive talk. One of the issues we investigated, in a focused study in a sub-set of two schools, is how students' social backgrounds shape their educational experiences and learning. The current study was conducted in one of the schools participating in these two projects. The class was composed of 24 fifth graders, aged 10-11: 15 boys and 9 girls, from middle to low socioeconomic backgrounds, and their language arts teacher. Four of the students were Arab, which was out of the ordinary in the relatively segregated Israeli education system, in which students from each sector (secular Jewish, religious Jewish, ultra-orthodox Jewish, Arab and Druze) study separate curricula in separate schools. We chose to focus on this classroom due to the diverse backgrounds of the students who study in it. The data were collected during the 2019-2020 school year. All participants and their parents or guardians gave informed consent.

Data collection and analysis

Data analysis is based on a subsample of eight lessons that were observed, videotaped and transcribed in full. The transcripts were arranged in a database (Figure 1), with each line representing an event, which we defined as a sequence that opens with the teacher's initiation, proceeds to a student response and concludes with teacher feedback (adapted from IRE – Initiation, Response, Evaluation (Mehan, 1979)). The arrangement of events requires the exercise of judgement that may affect the findings – for example, when the teacher's request leads to several overlapping responses and one feedback that is difficult to characterize for whom it is intended. In this case, one researcher segmented all the events. After segmenting the data set, we coded each event (N=1142) according to categories developed and adapted from previous studies of class discourse (Table 1). Although we coded other variables, we only report here the variables included in the regression. We used Cohen's *kappa* test to calculate inter-rater reliability of the coding. We estimated a hierarchical logistic regression model to predict the likelihood that the teacher would develop the student's response given background characteristics, perceived learning ability, question type, the form of the student's bid for participation and the relevance of the response.

Findings

Variables shaping the likelihood of a student's answer being developed by the teacher

Our macro unit is the students, within which are nested interactional events (micro-level). Because we are interested in the differences between students as well as the differences within each student from interaction to interaction we chose the random slope model where each student has his/her own slope. Table 2 summarizes the coefficients and standard errors of the hierarchical logistic regression model predicting the likelihood of the student's answer being developed by the teacher.

Table 2
Hierarchical logistic regression model predicting the likelihood of a student's answer being developed by the teacher (N=1142)

The findings of this study present a complex picture in relation to the effect of background characteristics, perceived learning ability, and students' participation on the likelihood of this teacher developing their answers. On the basis of previous studies we expected to find statistically significant effects for gender, nationality and socio-economic status on the likelihood of the teacher developing students' answers. Indeed, the likelihood of developing a girl's answer was 78% lower on average compared to boys while controlling the other variables; each increase of a unit in socio-economic status increases the likelihood of the answer being developed by 1.04 points on average while controlling the other variables; and the likelihood of Jewish students' answers being developed is 4.6 times greater on average compared to Arab students while controlling the other variables. However, in contrast to previous studies, we were surprised to find that the regression model of the learning ability perceived by the teacher has no statistically significant effect on the likelihood of the answer being developed by the teacher. This can probably be explained by the relationship of the ability variable with the additional background variables – a relationship that requires further examination in a broader sample. Regarding the question characteristics, the findings also contradicted the research hypothesis that the likelihood of developing answers to open-ended questions would be higher. In fact, the effect of the type of question (open/closed) was not statistically significant. This surprising finding requires qualitative examination beyond the scope of this work. Moreover, the likelihood of a student contribution that was offered not in response to a question being developed is 47% lower on average compared to an answer to a closed question while controlling the other variables. In accordance with our hypothesis, the probability of answers given with the teacher's approval to be developed is 3.2 times higher on average compared to answers given without explicit permission while controlling the other variables. In addition, the likelihood of a relevant answer to be developed is 2.06 points greater on average compared to irrelevant answers while controlling the other variables. Finally, the variance of the random slope, i.e. the variance between each student's mean value of responses being developed is almost zero (4.19e-33). Also, the fact that there is not necessarily a need for a random slope, that is, that the dependence between the observations for each student is not high, contradicted our hypotheses.

Limitations

Although the model findings are not the focus we will note that there are limitations to the sample which limit the validity of the findings. First, the analysis is based on observations of eight lessons in only one classroom that deviates from the normal distribution. In order for the chosen model to be valid it is necessary to expand the sample so that it meets the normality assumption. Second, the homoscedasticity assumption, according to which the variance in each of the random components is the same throughout different values of the explanatory variables, does not appear to hold for the following variables: gender, nationality, socio-economic status, perceived academic ability. However, the assumption does hold, i.e. the variance is fixed, for the different modes of the teacher's question, the manner of obtaining permission to speak and the relevance of the answer. Another limitation is that this study of one teacher in one classroom is in no way representative of other teachers and other classrooms. We build here on Shaffer and Serlin's (2004) use of intra-sample statistical analysis as a technique for using quantitative tools to support qualitative inquiry. As such, our findings "don't 'generalize' in the

traditional quantitative sense, but they do justify drawing statistically based conclusions about observations in a qualitative context" (p.3).

Regarding the methodology, the arrangement of events according to the IRE structure imposes upon the discourse a teacher-led structure that may not always be appropriate and obscures, for example, interaction between students that is not mediated by the teacher (though this was not a problem vis-à-vis the current data set). In addition, the model does not take into account the cases of silent students, who did not participate at all. Similarly, we included in the analysis only events in which students actually spoke. A more complete picture would include students who bid for turn but who were not nominated and did not speak without permission. We intend to address these limitations in future research.

Significance of the study

Expanding the unit of analysis from the utterance to the exchange in the methodology we developed helps bridge the gap in the literature in relation to the mediation process between teachers' expectations and perceptions of learning ability, teaching patterns and students' participation patterns. In this case we presented a model that predicts teacher elaboration moves on the basis of student background variables and participation, but many other predictive models can be constructed, for example, for predicting students' participation patterns based on background characteristics and teaching patterns. Exposing these patterns and power relations enhances our understanding of existing mechanisms in classroom discourse that promote or hinder learning opportunities, advancing us towards their rectification, and its conclusions may be used in designing a teaching strategy that promotes equitable participation among learners. As noted above, the contribution of this paper is methodological; realizing the potential of this methodology requires using it in examination of a broader, ideally representative sample.

Intertwined Development of Interest Pursuits

Jael Draijer, Larike Bronkhorst, Sanne Akkerman
j.m.draijer@uu.nl, l.h.bronkhorst@uu.nl, s.f.akkerman@uu.nl
Utrecht University

Abstract: Whereas interest research has long focused on one specific interest within one context (e.g. mathematics interest in class), students pursue multiple interests in parallel. As such, development of interest pursuits can become intertwined. The current study explores such intertwined developments by using a qualitative ESM smartphone application and interviews with 30 students (aged 14-25 years) in different educational programs. Analysis of the interviews shows three main intertwined developments: 1) *object genesis*, where one interest develops out of another, 2) *parallel engagement*, i.e. two interests co-occur or their engagement is mediated by similar skills or knowledge, and 3) *related meaning-making*, i.e. two interests have a similar meaning or gain meaning in relation to each other. Whereas interest theory typically speaks of interest development as a process of deepening of a single interest, the results of the current study reveal how interest development can also reflect broadening and connecting of multiple interests.

Introduction

Whereas interest research has long focused on one specific interest within one context (e.g. mathematics interest in class), in recent years there is increasing attention for multiplicity of interest (Akkerman & Bakker, 2019; Hofer, 2010; Krapp, 2002). Small-scale studies such as Akkerman and Bakker (2019) have demonstrated how adolescents pursue multiple interests in parallel, which concern a high variety of domains (academic and nonacademic) and encompass topic-, activity- and event-based objects of interest. Given this multiplicity, as a student moves through daily life, they take with them all their previous (interest) experiences into the current moment (Dewey, 1938; Roth & Jornet, 2014). As such, connections between interests are likely to arise, whether unintentionally or prompted by others, and these interest pursuits may (temporarily) become intertwined and develop in parallel.

Not much is known about the way interests develop in relation to each other, although case-studies have provided some initial conjectures. For instance, Azevedo (2011) investigates amateur model rocketeers and observes links with other objects of interest. Amateur rocketeer Bill, in this study, is also a movie fanatic and often specifically seeks out movies about rockets. His friend George has a computer engineering background and consequently experiments with incorporating electric machinery in his rockets. Similar examples can be found in work of Ito and colleagues (2019), e.g. a girl makes crochet designs associated with her interest in Harry Potter. Next to such intertwined interest pursuits, Slot and colleagues (2020) report on alternation of interest based on their investigation of how school is reflected in students' interest experiences. They find that students sometimes deliberately alternate school-related interests with leisure interests (e.g., gaming or watching series) in order to process their school work or rejuvenate after a long day. These articles together show some initial examples of intertwined developments, and demonstrate the need for a more systematic investigation of intertwined development of interest pursuits over time. As such, the present study aims to extend understanding of interest development as not just the deepening of a single interest, but also the broadening and connecting of multiple interests. By explicating the ways in which adolescents relate their interest pursuits in daily life, we hope to aid educators in recognizing and amplifying existing connections between objects of (potential) interest for adolescents within classroom settings and beyond.

In the current study we describe interest development from a comprehensive person-objects-contexts perspective such as proposed in earlier work by the last author (i.e., P-O-Cs perspective, Akkerman & Bakker, 2019), a perspective that assumes persons to continuously pursue and shape multiple idiosyncratic interests across multiple social contexts throughout their everyday lives. We explore the development of interest pursuits in daily life by answering the following research question: *What intertwined interest development do adolescents report?* A better understanding of the developmental processes of multiple interest pursuits can extend interest theories beyond a single interest and support theorizing multiplicity. This in turn can add to the practical understanding of interest developments which may seem unexpected when just looking at a single interest. In addition, explicating the intertwined development of adolescents' interests can aid approaches that aim to connect education to adolescents' daily life experiences (e.g., Ito et al., 2019), by demonstrating how these connections naturally take shape and develop in daily life.

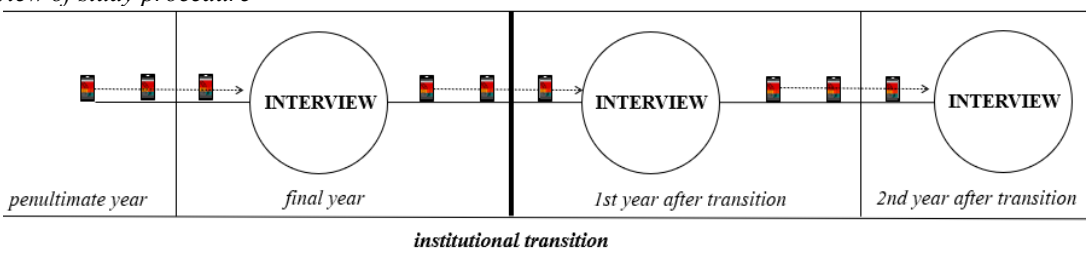
 © ISLS

Methods

In order to explore the multidirectional developments in parallel interests, we employed a qualitative longitudinal approach using interviews informed by qualitative ESM (Experience Sampling Method) data collected using a smartphone application called *inTin*. The timeline of this study is outlined in Figure 1. The participating students were interviewed three times, with one year in between each interview. Preceding the interviews, students reported on their interests in inTin during three intermittent weeks (three to four months in between each week). Data was collected between March 2018 and December 2020, the last two inTin weeks and the last interview took place during the COVID-19 pandemic.

Figure 1

Overview of study procedure



Participants

Thirty students participated in the interviews and ESM study. Participants were enrolled in diverse educational tracks in the Netherlands, including (pre-)vocational education, general (professional) and (pre-) university education (in Dutch: *mavo, havo, vwo, mbo, hbo, wo;* five participants per track) and were aged 14-25 years at the start of the study, with 63% female. This diverse sample was chosen to capture a large variety of complex interest experiences across different educational settings and life-wide situations. The first interview took place in the final year of the students' study program. Respondents volunteered to participate and were offered financial compensation for taking part in the study. All participants signed an informed consent form and for participants who were younger than 16, a parent or caregiver signed an additional permission form. Ethical approval for this study was given by the Ethics Committee of the Faculty of Social Sciences.

Materials

The methods employed in this study concern interviews informed by qualitative ESM data. An ESM application was used to capture (changes in) daily-life interests of the participating students. Students used this application to log their existing and novel (incidental) interests that they experienced within a week. Following from our person-centered perspective, participants were free to give any name to their objects of interest instead of choosing from pre-existing categories, doing justice to the idiosyncratic nature of interest (Akkerman & Bakker, 2019).

Each participant was interviewed three times, with one year in between each interview. The interview scheme contained semi-structured questions that were adapted to the interests that the participants reported in the ESM application during the three weeks of using the application preceding the interview. In the first interview, participants were asked about the history, value and forms of engagement for several of their interests, aiming at a variety of different interests (e.g., asking them to talk about an interest they had pursued for a long time and an interest that was rather new). These questions were aimed at one interest at a time, but participants often mentioned other interests that they considered related. In addition, participants were asked to think about next year, and to predict which of their objects of interest they would still be interested in and why, which probed them to consider any foreseen trade-offs between interests. In the second and third interview, the students were asked about any changes in their objects of interests that occurred since the preceding interview. Each experienced change was discussed in more detail using semi-structured questions, asking about the experienced origin of the change, and about the current value and form(s) of engaging. In answering these, participants regularly related these changes to (changes in) their other interests.

Analysis

The second interview is the main focus of analysis. In this interview we detected relations between interests by marking passages where the student, when talking about one interest, mentions one of their other objects of interest. For example, when asked about their interest in hiking, a participant describes how they also listen to music while hiking, which is one of the other objects identified as interest. For each interest-relation that is identified in this way, passages about the associated interests are selected in all three interviews. When reading these interview

 © ISLS

excerpts, we selected for further analysis only those relations where a) the relation between the interests is object-based and b) the interests are involved in each other's development. This means we did not include relations where the described connection was generic (e.g., when reading a book is mentioned in relation to soccer because they both take up leisure time), nor relations without indication of intertwined development.

For each selected interest relation, we made short descriptions of all involved interests and their relation at each interview timepoint. These descriptions were further synthesized in one summary per relation that reflected the core of the intertwined development. We then contrasted and grouped together all interest relations that showed comparable intertwined development, until exhaustive and meaningful categories were reached. Half of the sample is used for initial explorative analysis, and after the categories were determined we examined whether these were supported by data of the remaining fifteen adolescents**.**

Results

Results demonstrate notable inter- and intraindividual varieties in development of associated interests. Whereas some adolescents experience many connections between their parallel interests, others seem to experience or talk about their interests in more isolated ways and mention only few notable relations between their various interest pursuits. Below we describe the three intertwined developments that we observed in the data.

Object genesis

Firstly, adolescents described how novel objects of interests arose from engagement with their longstanding objects of interests. For example, Ronald has been interested in "playing videogames" with friends for a long time. In the interview, when asked how his interest in "programming" started, he mentions: "My brother bought an Xbox when I was six, or eight, the very first one and then we started gaming together. So that's how the interest in those devices started actually. It was quite a logical step for me, it's just fun." In this case it seems that the content of playing videogames and programming are close enough together that simply playing games sparked Ronald's interest in programming. Ronald pursued a study program and career in IT, which shows that this interest that initially arose from a leisure interest becomes a long-lasting theme in his educational and professional life.

Further examples show the mediating role that other people can play in this process. This is evident for Steve, who was interested in "badminton" for a long time, training multiple times a week and being very competitive. In the first interview he says he definitely wants to continue playing badminton, but preceding the second interview two of his teammates quit the sport. His remaining teammate then said he was going to play tennis instead, and Steve tells us: "So then I said: 'great, I'll do that too'." Despite his initial plans to continue playing badminton, he switches to tennis rather impulsively. During the third interview he still became increasingly more skilled at and enthusiastic about his new interest in "tennis". Other people within a certain interest-related practice can thus suggest ideas that become identified as new objects of interest, which can subsequently last for a long time.

Parallel engagement

A second intertwined development regards parallel engagement of interests. The most predominant way in which we observed this to happen is *co-occurrence*, wherein an adolescent recognizes and appreciates multiple objects of interest within the same moment. For example, Piper is interested in "music", and enjoys listening to all kinds ranging from classical music to heavy metal. She describes how she sometimes recognizes and appreciates music when watching movies, which for her is another interest: "If I hear something in a movie, … if I hear something somewhere that really grabs my attention, then I immediately turn on Shazam and then I link it right to Spotify and I have it right there and then, yeah, I can study it a little bit, listen to it a little bit more often." She also describes how, when watching certain movies, she can really feel the music inside and it makes her feel strong emotions. In Piper's case, these objects of interest co-occur because they are combined in societal structures (i.e., films generally contain music), which she then both recognizes within one situation. In some cases the objects of interest even seem to be nested, meaning they cannot be separated but co-occur by default of the social activity (e.g., "science" and "Medicine", "judo" and "giving judo training"). This is contrasted with cases where co-occurrence is not imposed by (societal) structures but emerges from daily life or from personal initiatives.

Notably, we also found instances where participants described parallel engagement without the interests co-occurring in a situation. These engagements were connected through skills, knowledge or resources by which engagement of both interests developed in a similar way, which we term *mediated engagement*. This can be illustrated by Nicky, who is interested in the "news", which she reads daily and discusses with her parents. She feels it is important to know what is going on in the world and it makes her realize how good her own life is. After completing secondary school she starts studying "Medicine" and there learns to read scientific articles critically. She observes that this has changed the way she reads the daily news as well, looking at news articles more

critically (especially when this concerns scientific findings). In this way, the adolescent describes how the development of these interests is intertwined by skills that are used in both practices, or transported from one practice to another.

Related meaning-making

A third intertwined development concerns adolescents relating the meaning they ascribe to their interest, to another interest. A first exhibit of this concerns interests pursuits whose meaning is similar to each other, i.e. *comparable meaning*. Nicky talks about this in the context of her interest in "childcare", her side job, which decreased when she started studying Medicine: "I have always liked taking care of people, I can't explain it, but I used to get that satisfaction from childcare. But now I'm pursuing a study where actually caring for people is central, so that's where I kind of get that satisfaction now". Although she still likes to work at the daycare, it has become less important to her and she talks about looking for another job closer to her university. In this way, the comparable meaning of both interests has consequences for the continuity of her interest in childcare: it seems less necessary than before. It should be remarked that comparable meanings were often observed for multiple sport-related interests, which often had a similar meaning in an adolescents life (e.g., maintaining a healthy lifestyle) and thus were seen as interchangeable.

Whereas the above describes a stable relation between the interests, we also observed many instances where an interest gains a different meaning in relation to another interest pursuit, which we call *transformed meaning*. For example, Hilbert becomes increasingly interested in what he calls "personal development": learning new things in general and setting goals for his future. In light of this interest and his desire to do useful things with his time, he reconsiders the value of other interests, such as "Netflix" and "gaming": "If you look at what gaming brings me, then it is not as much as three hours invested in watching YouTube videos on how I can achieve my goal or … whether I want to become smarter in a way or whatever. So that's why certain traits have been toned down or left out altogether, like gaming and Netflix." In other words, Hilbert looks at his interests in "gaming" and "Netflix" through the lens of his interest in "personal development", and increasingly regards playing games and watching series on Netflix as a waste of time compared to activities that allow him to develop as a person. Hence, Hilbert compares and contrasts his interests, which leads to one of them decreasing in value and possibly disappearing altogether.

Discussion

The aim of the present research was to explore intertwined development of interest pursuits. By studying what connections adolescents themselves make between their interests, we have demonstrated how intertwined development can be described in terms of object genesis, parallel engagement and related meaning-making. Whereas interest theory typically speaks of interest development as a process of deepening of a single interest (e.g., Hidi & Renninger, 2006; Renninger & Hidi, 2015), the results of the current study demonstrate how interest development can also reflect broadening and connecting of multiple interests through these three developments.

Processes of object genesis, parallel engagement and related meaning-making were observed for objects of interest that can be considered close in terms of domain (e.g., food/health and cycling), but also for objects that are societally further apart (e.g., food and music). Hence, even when connections seem unlikely given societal distance, in daily life different objects of interests can connect. This goes not only go for leisure interests, but also for school related interests. Hence, educators that want to connect their learning materials to students' daily life, may start by being open to the connections that students themselves already naturally see.

Exploring Focused Responsiveness as an Approach to Facilitation in Professional Learning

Jennifer Richards, Northwestern University, jrichards@northwestern.edu

Abstract: Meaningful professional learning (PL) for teachers needs to center their assets, aims, and needs while also bringing them into conversation with research-based instructional approaches that support student learning. In service of facilitating meaningful PL, this study introduces and aims to develop characterizations of focused responsiveness in PL. I draw on multiple literature bases and interviews with science teacher leaders who facilitated professional learning communities to build understandings of what focused responsiveness to teachers may entail and look like in PL, and associated tensions. Deeper understanding of this approach has the potential to contribute to the design and enactment of PL environments that value teachers as highly knowledgeable professionals and experienced co-generators of their own learning.

Introduction

Formal K-12 educational settings in the United States are heterogeneous and ever-evolving landscapes of initiatives, priorities, and local constituencies. In science education, the field is amid ongoing reforms with the *Framework for K-12 Science Education* (NRC, 2012) and the Next Generation Science Standards (NGSS); calls to address "deep and enduring disparities in K-16 science education" (NASEM, 2021, p. 8); and liberatory efforts to center richly diverse student and educator repertoires (e.g., Warren et al., 2020). To meaningfully engage teachers within such landscapes, PL needs to focus on research-based instructional approaches shown to support student learning, while also centering teachers' assets, aims, and needs.

This study aims to develop characterizations of an approach to PL facilitation aligned with the vision above—focused responsiveness. Broadly speaking, focused responsiveness refers to facilitation that provides opportunities for teachers' voices to be valued in and shape PL (being *responsive*), echoing recent calls in PL literature for increased responsiveness and opportunities for teacher agency (e.g., Buxton et al., 2015; Cavendish et al., 2020), while also building toward broader goals for teacher learning (shaping *focus*). Responsive and goal-oriented facilitation can be mutually supportive but may also give rise to tensions common to PL that brings local actors and broader initiatives into conversation (e.g., Allen & Heredia, 2020).

Here, I draw on multiple literature bases and interviews with teacher leaders (TLs), who facilitated PL with science teachers, to stitch together initial contours of focused responsiveness as an approach to PL facilitation. Generating deeper understandings of focused responsiveness has the potential to contribute to the design and enactment of PL environments that support more localized, meaningful teacher learning opportunities and value teachers as the professionals and people they are.

Theoretical underpinnings of focused responsiveness in PL facilitation

Facilitation matters for effective PL but is often an understudied component (Borko et al., 2014). Some studies exploring the nature of PL facilitation have identified generative sets of facilitation moves and practices linked to specific goals, such as promoting collaborative learning among teachers (e.g., Gibbons et al., 2021; Zhang et al., 2011). However, few studies have focused on how facilitators navigate being responsive to teachers. The work of Koellner et al. (2011) and Remillard and Geist (2002) are notable exceptions here, and the present conceptualization of focused responsiveness builds on insights from these studies and broader literatures on 1) responsiveness to student thinking in K-12 settings, 2) adult and teacher learning, and 3) features of effective PL. Together, these literature bases point toward several key facets of focused responsiveness.

First, focused responsiveness as an approach to PL facilitation foregrounds taking an asset- or resource-based view of teachers and their contributions—presuming that what teachers bring to bear is valuable and generative. This stance is evident in work on responsiveness to students' contributions in K-12 settings (e.g., Campbell et al., 2016; Hammer et al., 2012) and work on teacher learning that treats teachers' knowledge and experience as assets (e.g., Horn & Kane, 2015; Remillard & Geist, 2002). For instance, Remillard and Geist explored how facilitators navigated "openings" in an elementary mathematics PL curriculum when teachers raised challenges or questions, and they ultimately framed such contributions as opportunities for learning. Second, focused responsiveness involves inviting and pursuing teachers' contributions and participation in direction-setting. This facet is evident across the identified literature bases, including perspectives on adult learning that emphasize the importance of adults determining the direction of their own learning experiences (e.g., Knowles, 1973). Pursuing teachers' contributions may occur in the moment within interactions, and/or over time when

 © ISLS

shaping lines of inquiry and associated structures (e.g., Hammer et al., 2012; Koellner et al., 2011). Third, focused responsiveness seeks to bring teachers' contributions into conversation with goals that matter for supporting student learning and experiences within classrooms. In other words, like responsiveness in K-12 settings that maintains connection with disciplinary ideas and practices (e.g., Hammer et al., 2012) and consistent with research on effective PL (e.g., Darling-Hammond et al., 2017), focused responsiveness in PL maintains connection with identified goals for teacher learning. The remainder of this paper explores these facets in the rich perspectives of teacher leaders (TLs) who facilitated science professional learning communities (PLCs) described below.

Study context and methods

This study took place in the context of a partnership to support science teacher learning with a large urban district. Since adopting the NGSS, the district science office has emphasized two main instructional goals—enhancing 1) rigor and 2) educational equity in science instruction. Briefly in this context, rigor refers to learning opportunities that integrate the three dimensions outlined by the NGSS within cognitively demanding tasks and responsive and collaborative talk (e.g., Tekkumru-Kisa et al., 2019). Educational equity refers to learning opportunities that connect to and leverage diverse assets and ways of knowing (e.g., Warren et al., 2020) and work towards justice. The district is cultivating PLCs with foci connected to these goals, such as supporting student discourse or connecting to students' cultures. In 2020-21, sixteen high school science teachers were selected and supported in serving as TLs. PLCs led by these TLs met virtually six to eight times and engaged in inquiry cycles connected to teachers' aims within the PLCs' focus areas. Thus, PLCs and TLs have latitude to be flexible and responsive to teachers, *and* they are expected to advance rigor and equity in students' opportunities for science learning—making this a rich context for exploring focused responsiveness.

At the end of the 2020-21 school year, I conducted semi-structured interviews with six TLs who facilitated PLCs. Interviews invited TLs to share motivations for and experiences of leading PLCs, facilitation practices, and examples in which they felt they were able to be responsive to teachers or found it challenging to do so. I foregrounded responsiveness rather than focused responsiveness in my questioning as something more recognizable to TLs. All interviews lasted between 25 and 45 minutes and were audio recorded and transcribed.

I engaged in grounded, qualitative analysis (Charmaz, 2008) to explore characterizations of responsiveness from TLs' perspectives. I began by identifying examples and non-examples of responsiveness that TLs described. Examples involved a TL foregrounding or responding to teachers' contributions in the PLC, either in real-time or across sessions. Non-examples involved a TL explicitly depicting not being, feeling able, or feeling successful in being responsive. There were 19 examples and five non-examples of responsiveness across the interview corpus. For each, I drew on TLs' wording to characterize the nature of the responsiveness (or desired responsiveness, for non-examples), what the TL was responding to, whether the TL drew connections to PLC foci, and evident tensions. Finally, I looked across examples and non-examples to identify patterns in the data.

Major findings: TLs' characterizations of responsiveness in PL facilitation

Each TL reported enacting multiple ways of being responsive to teachers in the PLCs. Table 1 summarizes several characterizations of responsiveness that crosscut examples and TLs. (All TLs' names are pseudonyms.)

Table 1

Teacher Leaders' Characterizations of Responsiveness in PL Facilitation

Characterization: Responsiveness as…	Prevalence	Tied to PLC focus?	Indicative quote
Providing resources to meet teachers' aims or needs	5 examples 1 non	Often	*Liza:* "Like responding to people's [PLC focus] needs, in terms of ideas for what to do in certain scenarios… we tried to be responsive… to provide ideas for them, new things to try, and we tried to bring in based on where they were at… what they said they needed..."
Changing structures to meet teachers' aims or needs	4 examples 2 non	Not often	*Veronica:* "… we decided to shift to more of a focus each session… whoever the focus person was was really bringing their problem of practice that they want to work on and everyone could collaborate with them. So, that was one way we were trying to be responsive…"

 © ISLS

Participating and co-constructing with PLC colleagues	4 examples	Often	*Jake:* "I wanted to position myself as sort of another participant in a way, and I mean honestly a lot of that comes from identified need. Like I really think I could do a better job of… meeting the goals of the PLC in my instruction… all the teachers… have really interesting ideas and insights that I certainly don't… we're all just kind of professionals- a community of professionals trying to tackle these things."
Addressing challenges in teachers' contributions	6 examples 2 non	Mixed	*Clara:* "I had a teacher who expressed that they were in the PLC so that they would understand… but that they really didn't need to do or get the work done because they had a co-teacher… I was trying to do that experience for [them]… to internalize that it's not I'm just here to see what you guys do..."

Depictions of responsiveness as *providing resources to meet teachers' aims or needs* shared several similarities. As in the example described by Liza, TLs depicted providing resources, ideas, or feedback typically specific to the PLC focus in response to what teachers brought up or requested. TLs pursued teachers' requests and direction-setting in this characterization, though TLs often took responsibility for providing resources themselves (rather than, for instance, drawing out resources from the group). Tensions arose for several TLs with respect to understanding and balancing teachers' requests and being responsive when they felt they did not have the requisite content or instructional knowledge; these were exacerbated by COVID and remote learning.

Another characterization of responsiveness described by TLs was *changing structures to meet teachers' aims or needs*. Structural forms of responsiveness included being flexible with protocols and timing or shifting activity structures (as described by Veronica). In another example, Clara intentionally integrated different kinds of structures in response to teachers' reported learning preferences. This characterization tended to be less connected to the PLC focus and more about process, and tensions arose when TLs felt unsure of teachers' aims or desires. One TL also reported a "self-imposed" tension of wanting to "get through the program."

TLs also depicted a responsive practice and framing of *participating and co-constructing with teachers in the PLC*. Here, TLs explicitly noted rich assets from teachers with respect to the PLC's inquiry, and they positioned themselves as co-learners in pursuing those together. Few tensions were noted here.

A final characterization was responsiveness as *addressing challenges in teachers' contributions*. As depicted in the name of this characterization, TLs did not focus on assets but rather what they perceived as challenges or issues to resolve. They tended to do so through providing targeted guidance or, as Clara described above, designing specific learning experiences for teachers. Responses were sometimes at odds with the PLC focus, depending on the nature of the challenge. TLs expressed tensions in how to address issues collegially, and again how to do so when they felt they did not have the knowledge or tools required.

Conclusions and significance

This study articulates the initial contours of focused responsiveness as an approach to PL facilitation, contributing to needed understandings of how PL can be more responsive to teachers (Buxton et al., 2015; Cavendish et al., 2020). In conceptualizing focused responsiveness, multiple literature bases highlighted the importance of taking an asset- or resource-based view of teachers' contributions and attending to their participation in direction-setting, while seeking to bring teachers' contributions into conversation with goals that matter for supporting student learning and thriving. TLs' interviews added to and complicated this general conceptualization by illuminating numerous characterizations of responsiveness, in which TLs took certain kinds of actions (e.g., providing resources, changing structures) to respond to different aspects of teachers' contributions (e.g., teachers' aims, perceived challenges). The range of characterizations identified in this study add to the landscape of what focused responsiveness might look like in PL practice.

TLs' varied characterizations also demonstrated different facets of the literature-based conceptualization of focused responsiveness. For instance, in many cases, TLs demonstrated attention to and pursuit of resources like teachers' ideas and aims, but *addressing challenges in teachers' contributions* was less aligned with the asset-based facet of focused responsiveness. Additionally, characterizations ranged in the degree of focus on matters of science teaching and learning. Characterizations that centered the instruction-oriented substance of teachers' contributions often connected to the focus of the PLC, but examples of responsiveness that were more structural or process-oriented did not tend to emphasize the PLC focus directly. While such examples may ultimately be in

service of supporting the PLC's focused work, as some TLs noted, there were sometimes tensions in when and how to respond if not directly aligned with the PLC's focus.

Moving forward, future work could explore instances of focused responsiveness *in situ* in PL facilitation contexts and impacts on teachers' experiences in PL and on their learning and practice. Building on findings from this study, research could also examine ways of reinforcing asset-based perspectives with facilitators and the role(s) of facilitators' knowledge in focused responsiveness—including when "not knowing" may be an affordance, as potentially in the characterization of *participating and co-constructing with teachers*. Focused responsiveness in facilitation has the potential to contribute to the design and enactment of meaningful PL environments that center teachers as highly knowledgeable and experienced co-generators of their own learning.

Historians' criteria for appraising historiography: An interview study

Mikko Kainulainen, University of Turku, mikain@utu.fi
Marjaana Puurtinen, University of Turku, marjaana.puurtinen@utu.fi
Clark A. Chinn, Rutgers University, clark.chinn@gse.rutgers.edu

Abstract: Developing and applying epistemic ideals or criteria is a core component of epistemic practices. In history education, epistemic criteria have been included in approaches to teaching history as well as in theoretical frameworks for investigating the learning and understanding of the domain. One justification for these frameworks is in the epistemic practices of expert historians; however, empirical evidence about historians' epistemic criteria is scarce. Thus, we set out to explore epistemic criteria historians use to determine quality in their own and others' work through an analysis of interviews with 26 Finnish historians. We identified over 80 criteria that we placed in categories such as internal characteristics of works; connections to past and present knowledge and practices; connections to future knowledge and practices; proxies; connections to non-epistemic use; and emotions. These findings open up possibilities for better developing criteria in history education and considering their connections to those of experts.

Introduction

Epistemic criteria are a central component of epistemic practices: They are ideals or standards for determining when and why inquiries have reached their goals, or when and why some epistemic products might be preferred over others (Chinn & Rinehart, 2016). The use and need for epistemic criteria is well recognized within philosophy and practice of historiography (Jordanova, 2019; Kainulainen et al., 2019; Kuukkanen, 2015). In history education too, epistemic criteria are relevant for many approaches to learning and teaching history. These include, for instance, modeling and supporting historical reading skills, employing historical evidence, classroom argumentation, and broadly methods that involve students in evaluating and interpreting products of historiography (Fogo, 2014; Herrenkohl & Cornelius, 2013). Epistemic criteria also play a crucial role in the study of learners' understanding of the nature of history or their epistemological beliefs (VanSledright & Maggioni, 2016). In recent decades much of history education has indeed centered on simulating the practices of historiography and has emphasized the educational aim of "the development of an understanding of how historical knowledge is constructed and evaluated" (Voet & De Wever, 2017, p. 312).

We propose that the part of history education that involves appraising products of historiography should build more strongly upon an evidence-based understanding of the ideals or criteria that domain experts themselves use in such tasks; however, research on this topic is still scarce. As one exception, Gottlieb and Wineburg (2012) studied religious historians' use of epistemic criteria in evaluating historical claims presented in curated sets of short document extracts, and they identified criteria applied by the historians such as trustworthiness of evidence and intertextual references. They also found that historians applied different epistemic criteria depending on whether the documents related to their religious commitments or not.

We explored this topic by conducting interviews in which historians at length presented and discussed their own research as well as some research by others. We used the AIR model of epistemic cognition (Chinn & Rinehart, 2016) as one framework guiding our methods and analysis. According to this model, epistemic cognition refers to people's ways of knowing. The model analyzes epistemic cognition into three components—epistemic Aims and value, epistemic Ideals, and Reliable epistemic processes. Epistemic aims refer to the goals people set for knowing and understanding. We have documented a range of epistemic aims relevant for expert historians; these include critiquing existing ideas, gaining understanding, popularizing research, and developing their own epistemic competences (Kainulainen, et al., 2022). Epistemic ideals are the criteria or standards that people use to appraise whether they have achieved their aims and to evaluate epistemic products. In science, epistemic ideals for good explanations can include fit with evidence, fruitfulness, and simplicity. Chinn and Sandoval (2018) proposed possible differences between scientists and historians in the ideals that are commonly used; in this paper, we explore what historians' epistemic ideals are. Finally, reliable epistemic processes are the individual or community strategies, activities, or methods that people use to achieve their aims. (1)

Research Question

In this paper, we analyze the ideals that historians describe as important to their epistemic practice. We ask: What ideals (criteria or standards) do historians use for appraising quality in historiography?

 © ISLS

Methods

Participants

The participants were 26 volunteer Finnish historians, who were recruited by contacting various history departments and writing an invitation to a national online forum for humanities scholars. The historians represented a variety of different faculties and traditions of historical research. All had earned a PhD degree, but their career lengths varied from post-doc researchers to emeriti professors. All of the participants were somehow affiliated with at least one Finnish university. In order to secure the confidentiality of the participants, we only refer to the participants as "Historian [nr]" and exclude their universities, degrees, and details of research topics in all of the excerpts below.

Procedure

The first author conducted semi-structured interviews with the historians in Finnish language. The length of interviews varied from less than one hour to almost three hours, averaging 90 minutes. The full interview scheme included questions related to all components of the AIR model as well as other topics, and the historians discussed their research in detail and at length. In terms of identifying historians' epistemic ideals, key questions in the interview included: "What is your best work, and why?"; "What about someone else's best work, and why?"; "When reviewing papers, books, or presentations, which criteria do you usually use to evaluate such work?"; and "What are your common critiques regarding methods in such review situations?" The full interview scheme is available from the authors.

Data Analysis

The transcribed interviews were analyzed by means of a qualitative content analysis (Schreier, 2012) that proceeded through various iterative and collaborative stages. In the beginning, codes were developed extensively. Later on, when it became apparent that some of these codes did not prove useful in characterizing the data, they were either removed or merged with another similar enough code. Hence, in a way, the coding scheme from the earlier stage of research can be considered a self-made analytic tool, which we then used, tested, and further developed during the analysis. The final coding scheme is available from the authors.

Results

Our analysis of historians' epistemic criteria identified over 80 different criteria (or codes), divided into to eight categories. Below, due to the short length of this paper, we limit our discussion to six of the categories (2), focusing on those criteria that (a) were mentioned by several historians, and (b) we consider especially relevant for history education and its practices.

We begin with the category titled "internal characteristics of historiography"—i.e. criteria that refer mainly to features of the products (e.g., articles, books, conference presentations) themselves. All historians mentioned ideals assigned to this category, including 26 different ideals. The most frequently mentioned ones can be roughly grouped into ideals for evaluating the output's literary or rhetorical quality and ideals for evaluating its methodological quality. These groups have clear implications for history education: Both should be accounted for. Regarding the first group, historians spoke of *internal coherence* (whether the work fits together); *quality of argumentation*; *readability*; *communicativeness*; and, as in this excerpt, *style of text and presentation*:

> [A] fluent writing style that moves one's own argumentation forward is important. So even though the topic might be interesting as such, if it is written in a dull and bland way, it is not a good article. (Historian 9)

The methodological quality of the products of historiography could be assessed based on the *perspectival* aspects of the work (whether there is a perspective; whether it is brought forth; and whether it is interesting or important); *scope and quality of sources*; *amount of theory, analysis and narration*; and *transparency of processes* (whether and how the frameworks and methods of the study are presented). As an example of the last, one historian (13) criticized some work for not "explicating their methods" and considered the experience of reading such work irritating and "an unfair game, because you are not telling what you do, and why."

The second category—also one that all historians referred to—was "connections to past and present knowledge and practices." This category reflects Kuhn's (1977) famous notion of the 'essential tension' between tradition and invention in scholarship. In this category, some of the mentioned ideals—namely *contextualization*; *timeliness*; and *positioning the work in relation to ongoing discussions*—are already incorporated in some history

education practices; however, they might not be explicitly discussed as ideals of the domain. Other ideals, however, require considerable domain expertise. These include *originality, exceptionality and innovativeness*; or *methodological originality*, the last being exemplified below:

> It combined the kind of things that had not been done before; read sources in a whole new way. And by studying a small detail he was able to say something about a very wide thing, by generalizing something that nobody had noticed before. (Historian 16)

Third, historians also highlighted "connections to future knowledge and practices." This implies that historiography should not just build on or challenge existing understandings, but also be fruitful in opening up vistas for new work. This appears something that the tasks and practices typical to history education do not always allow. The specific codes in this category include ideals such as *connections to future theory and knowledge*; *connections to future methods and practice*; *ability to promote future research;* or *interdisciplinary value*. Exemplifying the last, one historian (15) considered their work valuable to the research field because "it not only contributes to historical research, but it could also have use for researchers in other fields." In educational applications, it is possible that students could come to appreciate the value of ideas that open up new questions for inquiry.

Fourth, when assessing historiography, the interviewed historians also referred to "proxies" in determining quality in their own and others work. This category refers to externalizing or outsourcing (part of) the criteria to others. The category can be further divided into expert and lay proxies. Thus, in educational applications, students could also learn the value of expert and lay audience evaluations as central to how historical work is appraised. Expert proxies include ideals such as the very act and process of *experts publishing* the work; more generally, *reliance on expert commentary and evaluation;* and *experts' acceptance or engagement* in or with the work. The last is exemplified below (in a statement that also resonates with the previous category):

> Well, the criteria comes through that discussion that is presumably formed after the publication of this book, and it has already formed in many workshops and conferences. Through that, I can then see how well it works. (Historian 22)

Some historians also referred to *lay visibility* (the extent and nature of public visibility); or, as exemplified below in a statement related to engaging local communities with one's studies, *lay excitement and interest*:

> I don't use any criteria [to determine whether aims have been reached]. I don't, like, sit and think with some criteria how they [the aims] are fulfilled. […] It is not rational to think of criteria, even though perhaps I should. But one sees it through the echo given by teaching, whether students are excited. Once or twice a week I go to talk to different [groups and organizations], so in a way that is the criteria: the interest the research raises in others than colleagues. (Historian 6)

Fifth, historians also referred historiography's "connections to non-epistemic uses," in terms of whether the work had *societal impact*. What differentiates this from lay or expert proxies is influence on societal changes and political debates (and not only interest in or acceptance of the work). For example, one historian (20) wrote a history of a profession, and mentioned as an important feedback from contemporary practitioners of the same profession how they "considered it as an empowering book […] that meant a lot to their professional self-perception." It is possible to envision historical inquiries among students in which students consider community applicability of ideas as one of the criteria for evaluating them (see, Goldenberg, 2019).

Finally, historians referred to their "emotions and affects" that works of historiography raise. These include *happiness, fun, and satisfaction*; and many historians mentioned *excitement and interest* related to historiographic output. While many referred to their own interest upon engaging with others' work, some also referred to the excitement of other historians producing and presenting the work:

> Also, if it seems that a person is somehow themself not at all excited about it; If someone comes to a conference and does a terribly mechanical paper, then you cannot pick up the important things from there, even though there may be some. (Historian 12)

Incorporating such ideals into historical inquiries in educational settings could enrich these inquiries with the epistemic emotions that help animate professional historical work.

Discussion

In sum, the interviewed group of Finnish historians working in the contemporary academia mentioned tens of different epistemic ideals they use as criteria for evaluating historiography. These ideals range from the characteristics of the (literary) output to its significance both scientifically and societally, and to historians' own affective responses to the work in question. Our observations have at least two general implications for the development of history education. First, we should explicate not just learning goals or teaching practices, but also the epistemic ideals of the domain related to them, since they apparently play a role in how experts in the field conduct their work. Second, the sheer number of epistemic ideals identified in this study makes one hesitate to claim that we are even now grasping any full scope of them. It is, then, no wonder that teachers are not all that familiar with the range of epistemic criteria in history (e.g., Koutsianou & Emvalotis, 2021). However, it still seems apparent that experts apply a wide range of ideals; therefore, why should educators expect students to operate with only a few? And even if only a few, which few? To be sure, not all epistemic ideals we identified are as useful in designing learning and teaching as others, but, at the minimum, awareness of the scope of expert epistemic ideals in history seems necessary, if educators aim to bring history learning closer to what the practice of historiography entails.

Endnotes

(1) In an ongoing investigation, we are also exploring historians' epistemic processes.
(2) In addition to the ones discussed here, there were also the categories of *negative ideals* and *other ideals*

Biology teachers' re-designed eLearning units: The relationships between knowledge types and scientific practices

Carmel Bar, Weizmann Institute of Science, carmel.bar@weizmann.ac.il
Merav Siani, Weizmann Institute of Science, Herzog College, sianimerav@gmail.com
Anat Yarden, Weizmann Institute of Science, anat.yarden@weizmann.ac.il
*Carmel Bar and Merav Siani contributed equally to this paper

Abstract: Lately, eLearning has substituted traditional forms of teaching and learning. However, little is known about the possible link between eLearning, addressing epistemic knowledge and scientific practices. We aimed to analyze teachers' re-designed eLearning units and examine the extent to which high school biology teachers address epistemic knowledge and scientific practices in the Personalized Teaching and Learning, PeTeL platform. We qualitatively mapped the re-designed ecology and evolution eLearning units according to knowledge types and scientific practices. We found that a few teachers addressed epistemic knowledge in their re-designed eLearning units, and that questions that include only content knowledge, mostly lacked scientific practices. Thus, it seems that most of the teachers find epistemic knowledge difficult to address.

Introduction

In the past 25 years, eLearning has substituted traditional forms of teaching and learning in schools, higher education and companies (Herden, 2011). During the COVID-19 pandemic, when educational institutions were closed all over the world, eLearning has become necessary, facing the challenges of preserving the process of learning while ensuring that it is still valuable (Mailizar et al., 2020). Designing eLearning units and incorporating them into the students' curriculum might increase student motivation and the use of these techniques will probably be needed in the future as well (Mystakidis et al., 2021).

Teachers report an increase in ownership, agency and professional development when they re-design eLearning units (Penuel et al., 2007). In this study, as part of a 30 hours professional development (PD) course of in-service teachers, teachers re-designed eLearning units in an eLearning platform, called PeTeL (*PeTeL*, 2022). The main aim of this study was to analyze teachers' re-designed eLearning units and trace the epistemic knowledge and scientific practices that the teachers had implemented into their units.

Theoretical background

Scientific literacy and types of knowledge

A central goal of science education is preparing students for their roles as future scientifically literate people, as reflected in many policy documents worldwide (National Research Council., 2012). In this paper, we follow the definition suggested by the OECD PISA Framework (*PISA 2018 Science Framework*, 2019), which defines three components of scientific literacy: (a) content knowledge - knowledge of the theoretical concepts and ideas of the discipline; (b) procedural knowledge - knowledge of the standard procedures that underlie the methods and practices used to establish scientific knowledge; and (c) epistemic knowledge - understanding the rationale of scientific inquiry, how scientific knowledge has been derived; and the degree to which such knowledge is justified by evidence or theoretical explanations. We shall concentrate specifically on this type of knowledge and the way it is reflected in the eLearning units that teachers had re-designed since it has been found that students' interest in science learning was positively correlated to their understanding of the epistemic knowledge of science (Ho & Liang, 2015). Additionally, when students actively engage in the practices of science, it means that teachers believe that their students are capable of thinking in an epistemic manner (Stroupe, 2014). Students who view that scientific knowledge changes and that experiments are needed to prove it, are more likely to hold constructive conceptions of learning science (Ho & Liang, 2015).

Scientific practices

The National Research Council (2012) defined eight science and engineering practices which follow behaviors that scientists engage in as they investigate and build models and theories about the natural world (Next Generation Science Standards, 2013): a) Asking questions; b) Developing and using models; c) Planning and carrying out investigations; d) Analyzing and interpreting data; e) Using mathematics and computational thinking;

 © ISLS

f) Constructing explanations; g) Engaging in argument from evidence; and h) Obtaining, evaluating, and communicating information.

The PeTeL platform and teachers as re-designers

The PeTeL platform, developed by the Weizmann Institute Department of Science Teaching, is an interactive online Learning Management System (LMS) that allows educators to manage their classroom materials and individual curricula in a single platform. The vision of PeTeL is to enable science, technology, engineering, and mathematics (STEM) teachers in Israel to teach science accompanied by a single, collaborative, digital platform, rich in interactive units that enable diagnostic and evaluation processes integrated into the LMS.

When designers design learning units, the content is usually developed from scratch. Yet, in many cases, it is possible to use existing course materials such as written books, exercise sheets, instructions for laboratory lessons and so on, as a basis for developing eLearning units (Herden, 2011). In these cases the teachers are called re-designers and we shall use this term when relating to the teachers who participated in the PD course.

Research goal and research question

The link between usage of epistemic knowledge, scientific practices and re-designing of eLearning units in the context of high school biology in general and in ecology and evolution in particular, has not been previously investigated. In this study, we attempt to analyze biology teachers' re-design of eLearning units during a PD course and trace the epistemic knowledge and scientific practices that the teachers had implemented into these units. Accordingly, we aim to answer the following research question: To what extent do high school biology teachers address epistemic knowledge and scientific practices in the eLearning unit they re-designed?

Methods

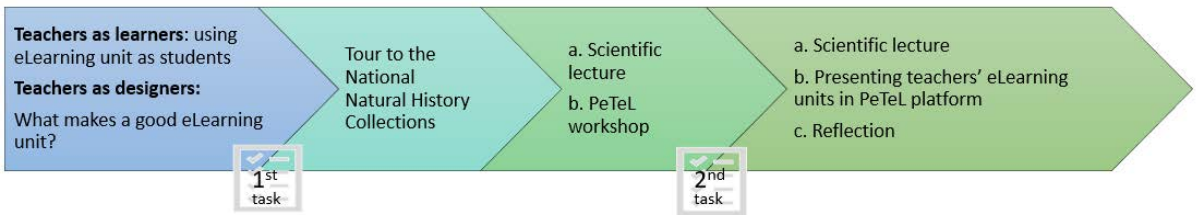
Research design

During summer 2021, a 30 hours PD course "Ecology, evolution and datasets - from the researcher's desk to classroom teaching" was offered to high school biology teachers in Israel. The participants of this study were 20 experienced high school biology teachers. The teachers voluntarily chose to participate in the PD course and in the accompanying research.

PD course description

The course was designed to help high-school biology teachers incorporate eLearning to their instruction in the context of ecology and evolution. The PD course was carried out as a hybrid course due to the COVID-19 outbreak restrictions. The 30 teaching hours, included online sessions, a guided tour and asynchronous meetings dedicated to two tasks (Figure 1). The first day of the course was dedicated to introducing an ecology eLearning unit in the PeTeL platform from a student's point of view, a review of techno-pedagogy in science education and collaboratively establishing criteria for good eLearning instruction units. Following this session, a task was assigned to the participants, in which they were asked to re-design an instruction unit based on either a textbook, a simulation or a dataset (Figure 1, 1st task). Later, they received personal feedback from the authors based on the pre-established criteria. The second day of the course was dedicated to a tour at the National Natural History Collections with an emphasis on the fish, reptiles and the paleontological collections. The third day included a scientific lecture on evolution, and a further look into the interactive PeTeL platform. On the last day, following a lecture on ecology, the teachers presented their eLearning units (Figure 1, 2nd task), received feedback from their peers and reflected on the process of re-designing their unit.

Figure 1
Professional development time line



Data collection and analysis

During the PD course, each teacher or small group of teachers re-designed an eLearning unit. The data sources of this study were 14 eLearning units in the PeTeL platform. Each question of each unit was coded according to the knowledge components of scientific literacy (*PISA 2018 Science Framework*, 2019) and NGSS science practices (Next Generation Science Standards, 2013) using ATLAS.ti Scientific Software. Each question received multiple codes. This paper refers to the analysis of a total of 176 questions included in the 14 eLearning units.

The data sources were coded by the two first authors. First, two units were coded together. Then, each author coded half of the units herself and the units were swapped. The degree of consent was 95%. The differences were discussed until a 100% agreement on all encodings was reached.

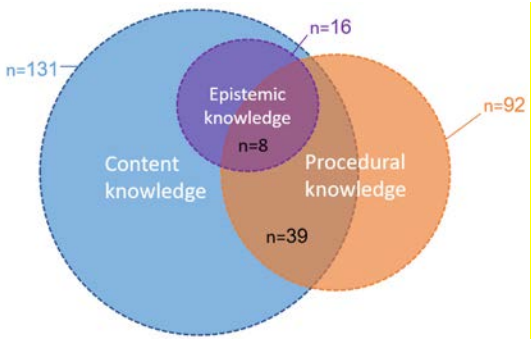
Results

Distribution of knowledge types in the teachers' eLearning units

The distribution of the scientific knowledge needed to answer the questions that were included in the eLearning units that the teachers re-designed is shown in Figure 2. Out of 176 questions, 131 questions required the use of content knowledge (blue), 92 procedural knowledge (orange) and 16 epistemic knowledge (purple). Thirty-nine questions required both content and procedural knowledge. All 16 epistemic knowledge questions included content knowledge, and eight of them included all three knowledge types (Figure 2). While all 14 units included content and procedural questions, only four units included epistemic knowledge questions.

Figure 2

Distribution of knowledge types in eLearning units' questions (n=176)



Do teachers link types of knowledge and scientific practices in their questions?

When teachers use questions that include only content knowledge, a large proportion of the questions do not include any scientific practice (n=50/76). On the other hand, when re-designing questions which require the use of epistemic and/or procedural knowledge, they always use scientific practices. An example of a question which includes all knowledge types and uses the 'planning and carrying out investigations' practice is as follows: "*Design a controlled experiment with which you will try to prove which of the theories, Darwin's or Lamarck's, is correct. For the experiment you are given mice that are genetically identical. Describe the course of the experiment*." (Teacher NK)

Discussion

In this study we present an analysis of biology teachers' re-design of eLearning units through which we investigated the teachers' use of knowledge types in these units, dealing with ecology and evolution. Our main findings are that teachers use mainly content knowledge in eLearning units they re-design, then procedural and the least epistemic knowledge. This finding is in line with PISA's target distribution of score points by knowledge type, which states that the proportions of content, procedural and epistemic knowledge would be 55-66%, 19-31% and 11-22% respectively (*PISA 2018 Science Framework*, 2019 table 4.9). However, our results meet this distribution only in the overall analysis, since we found that only a third of the teachers contributed to the epistemic components and most of the teachers did not relate to epistemic knowledge at all.

Although it is known that epistemic knowledge is important for students to become future educated citizens that can judge misinformation, understand scientific claims and make informed decisions (Hofer, 2020), usually students engage in a rather small amount of epistemic knowledge during their science lessons (Erduran &

Garcia-Mila, 2015). Despite the importance of this issue, some teachers do not refer to it during their teaching, maybe since some teachers do not have enough confidence with epistemic knowledge, and find it difficult to deal with NOS in class (Leach et al., 2003). This might explain our finding that only a relatively small percentage of teachers dealt with epistemic knowledge in their units.

It was recently shown that there is a hierarchy between knowledge types, when high-school students are using a molecular viewer for answering questions about protein structure and function. It was shown that the use of epistemic knowledge is not possible without the use of content knowledge and procedural knowledge (Levkovich & Yarden, 2021). The analysis of the units described here has also shown this pattern. Thus, epistemic knowledge is difficult for teachers to include in their units not only because they might not fully understand it, but also because prior content and procedural knowledge, are needed as a basis for students to engage in epistemic knowledge.

Every Glass Ceiling Has a Floor (of Interaction): Studying Body Position During Floor-based Activities in Kindergarten Classrooms

Deborah Silvis, Jody Clarke-Midura, Jessica Shumway

Victor R. Lee, Stanford University, vrlee@stanford.edu

Abstract: Classroom environments have been hot spots for studies of conversational "floor maintenance," or the ways in which people establish interactional rights and obligations through turn-taking or topical cohesion. We know less about how the physical floor of interaction is negotiated when activities literally take place on the floor, as in Kindergarten classrooms. In floor-based learning activities, body movements, body positions, and proximity are key modalities for establishing rights and obligations for participating in tasks. This paper analyzes video of Kindergarteners engaged in a floor-based learning activity, where children moved around and positioned themselves (and others) to participate. We found that while children often leaned in to the task-space, there were occasions where they sat back, but were nonetheless productive. Referring to these latter forms of participation as "zones of productive exclusion," we analyze how body positioning indexed children's rights and obligations in-task. We discuss implications for analyses of the powered relations between differently-positioned bodies.

Introduction

Classroom environments have been hot spots for studies of conversational "floor maintenance," or the ways in which people establish interactional rights and obligations through turn-taking or topical cohesion (e.g., Erickson, 2005; Macbeth, 1992; Philips, 1983; Shultz et al.,1982). Rights and obligations to initiate a topic, respond, change topic, or extend topics are involved in negotiating conversational floors (Shultz et al., 1982). Collaborative sense-making requires maintaining the conversational floor, or as Erickson (1982) put it, "topics require floors to be in" (p. 47). Local discursive ordering entails both talk's floor and the physical, "custodial" floor of the classroom (Macbeth, 1992, p. 126); however, typically, studies of conversational floor maintenance focus on *talk* that takes place while children and teachers are "carpentered to the desk" (McDermott, 1976, p. 43, as cited in Davies & Hunt, 1994). This paper explores how topics are also physically instantiated and examines body position as a means of floor maintenance in the context of floor-based Kindergarten learning activities.

Like conversations, floor-based learning activities have their own collaborative norms, rules that govern how, when, whether, and to what ends people are supposed to move around, interact with materials, or position themselves with respect to others. Just as it is usually improper to "turn-shark" during classroom conversations (Erickson, 2005, p. 54), in floor-based group learning activities that are the subject of this analysis, it was not customary to take other people's materials out of their hands, nor to crisscross your body over someone else's to assert an idea or course of action. However, breakdowns in conversational and collaborative task norms *do* routinely occur, presenting a question: *How do children's body positions establish rights and obligations to maintain the floor of interaction when tasks literally take place on the floor?* We addressed this question in the context of a Kindergarten classroom activity, analyzing how talk-in-interaction and arrangement of materials shaped how people positioned themselves and each other to have particular rights or access. Tracing dynamic body movements of people within collaborative tasks showed how they managed the floor of interaction, even when they were excluded from the task-space. We focus on exclusion as a form of body positioning that accomplished floor management and argue that *body* position can index *social* position in floor-based activities.

Perspectives on body position in maintaining floors of interaction

We draw on perspectives within traditions of interaction analysis (IA), focusing on embodied ways of establishing "patterns in the allocation of interactional rights and obligations among all the members who are enacting a social occasion together" (Shultz et al., 1982, p. 94). In verbal exchanges, people adopt metaphorical floor-management strategies (i.e., "taking the floor," "holding the floor," "yielding the floor," etc.) according to standard practices. Managing conversational floors in interactions means establishing "who's got the floor" (Edelsky, 1981), which entails conventional rights and obligations vis-à-vis topical change, cohesion, and extension. Learning environments have been ground zero for studies of interactional floors (Macbeth, 1992; Philips, 1983; Shultz et

 © ISLS

al., 1983), and negotiation of rights and obligations in the physical space of a classroom's "custodial floor" (Macbeth, 1992, p. 126) has received some attention (e.g., Erickson, 2005). However, prominent examples of research on positional dynamics focus on physical arrangements of people seated around tables (e.g., tables, desks, Shultz et al., 1982) or standing (e.g., cocktail parties, Kendon, 1990). And while research on untethered learning designs explores how the body is an important resource for sense-making and establishing a social order (e.g., Danish et al., 2020; Lee, 2015; Marin et al., 2020), often these designs involve groups of people standing or moving around on foot. We know less about how the floor of interaction is negotiated when activity literally take place *seated* on the floor, as is customary in early childhood classrooms. Negotiating rights entails relations of power, and this analysis also builds with studies that theorize learning, bodies, and power together, and as always in relation (Goodwin, 2006; Ma & Munter, 2014; Marin et al., 2020; Stevens, 2012; Vossoughi et al., 2020).

Methods of data collection and analysis

The teaching and learning described in this paper was part of a design-based study set in the Mountain West region of the US and designed to investigate young children's STEM learning. Data analyzed were collected over one month in a rural elementary school classroom that was part of a grant-funded program providing full-day Kindergarten to support English Language Learners, students who had an Individualized Education Plan (IEP), and students identified by their entrance assessment. Fifteen students participated at this site in 4 groups of 3-4 children. We analyzed three groups with equal numbers of boys (n=2) and girls (n=2) per group, because we were also exploring social categories like gender as potentially relevant for participation. Lessons were video recorded and taught by research team members who had formal experience teaching young children. In the STEM tasks we designed, a tangible programming robot typically needed to go on some adventure, travel to a series of locations, or avoid obstacles placed in its path. Materials included a large floor grid; a collection of directional arrow cards that serve as codes or commands; one template per group for organizing codes that we call a "program organizer;" and a mechanical robot with buttons for each of four directional commands (Figure 1). This paper does not analyze children's programming per se; however, materials used in-task help contextualize interactions.

Nine hours of video-recorded lessons were first reviewed and content logged (Jordan & Henderson, 1995). We then conducted iterative rounds of open coding and a series of group video viewing sessions. We coded interactions according to how children were positioning themselves to use or access materials, and we thematically grouped types of positional configurations around the floor in broad categories that describe diametrically opposed positionings: *comporting/contorting* and *leaning in/sitting back*. In the latter categories, sitting back was much less common than leaning in. We decided to focus on the smaller subset of instances of children sitting back to understand how they were participating when they assumed these positions. We focus the following analysis on a specific form of sitting back we call "zones of productive exclusion" in which children were positioned away from the "mainline" activity but nonetheless stayed engaged in the task from the sideline.

Establishing a zone of productive exclusion

While it was entirely possible to participate in tasks from a distance (and many children did so), leaning in and extending the body into the toy's grid-space (see grid in Figure 1, Frame 4) was a pervasive form of interaction across tasks and groups. Therefore, it was quite noticeable when someone sat back or was denied access to the floor grid and materials. Most tasks were designed for children to have a mainline focus with a front-row vantage point towards the grid; however, because of the size and configuration of the physical environment and materials, there was often someone left out, displaced to a marginal position off to the side or on a corner of the mat. Sometimes, the person in the excluded position started off the task sitting back or offset from the rest. Other times, despite starting off with mainline access, they were progressively or systematically elbowed out by eager programmers.

Figure 1 *Bowen leans on Hazel (1) and reaches across her to select his codes and place them on the program organizer (2). Hazel finds space for her counter-idea in the air (3) and off to the side (4).*

 © ISLS

When Hazel and her partner Bowen began a task for programming their robot's route, Hazel was in an optimal, mainline position to access the critical materials and had an ideal vantage point for visualizing the robot's path. However, as they started programming, Bowen immediately leaned on Hazel's body (Figure 1, Frame 1), stretching over her to reach the materials (Frame 2). Hazel first looked for alternative spaces to place her codes, because Bowen was quickly filling up the program organizer without consulting her. After making a bid to modify the program, Hazel tried to find space to express her idea. First, she tried to place the code cards on the floor grid.

Then she tried to hold a sequence of codes aloft in her hand (Frame 3). When she could no longer hold any more cards, she turned at a ninety-degree angle to the grid and programmed off to the side, sitting back from the mainline and periodically looking over her shoulder at the codes and the robot in order to determine its next move (Frame 4). When their teacher brought the pairs of children together to test their programs, Hazel claimed that the program Bowen had made was "not her program." She explained quietly that she "did not have enough room." Hazel's sidelined programming, conducted in a zone of exclusion, established a floor space for programming, still on topic, but not within the same floor of interaction where her partner performed his activity. We now turn to a discussion of interactional floor maintenance, and discuss this instance in terms of patterns of exclusion we observed and implications for the organization of floor-based activities.

Processes of exclusion for establishing floors of interaction

Whereas cohesion in conversation requires speakers to extend or change topics, collaboration in floor-based learning activities involved children using their bodies to maintain the floor of the activity. We found that for some children, maintaining the floor of interaction in coding tasks involved processes of exclusion, whereby sitting back from or being forced out of the mainline activity established an alternative space for engaging in the task. For Hazel, establishing a "zone of productive exclusion" was important so that she could build the program she had in mind. When Bowen dominated their programming, Hazel took the task in her own direction on the physical floor. When the interactional floor fell out from under her, and her partner obstructed her participation in the mainline programming, Hazel's sidelined orientation created her own zone of exclusion, a space where she could think through the program without needing to justify her thoughts or jockey for position.

We noted earlier how leaning-in was a frequent form of embodied participation; this was true for boys and girls. It is also worth noting that in the more infrequent instances in which children sat back, it was typically girls who were positioned away from the group or the grid. Girls in these marginal positions often engaged in peripheral activities like exploring or organizing unused coding materials, producing utterances to themselves about coding, or programming their own path; such tasks, while not mainline, were nonetheless productive for their sense-making. To be clear, we are not advocating a model of separating certain children from the group. Nor do we believe "sitting back" should be valued over "leaning in." These practices represent ways of disciplining difference and perpetuating classroom regimes in which quiet children do well, and active children are deemed out-of-line or off-task. Leaning in and sitting back are not proxies for disruption and docility. Rather, *we see children's own positionings of themselves and each other as agentive forms of producing spaces for sense-making*.

These marginal positionings represent potentially beneficial learning arrangements, in that they produced the sort of spaces that support children's diverse forms of participation, particularly for those who are systematically excluded in STEM, such as children who identify as girls or children from minoritized backgrounds. Analyzing physical dynamics of floor-based activities prompts us to think more critically about the social dynamics operating in classroom spaces. How are body position and social position co-constituted through intersectional identities where gender, language, race, age, or ability are "omnirelevant" to interactional rights and obligations (Stokoe & Smithson, 2001, p. 251)? Exploring this question will involve interrogating *exclusions entailed by our methods of interaction and conversation analysis*. We conclude with a few methodological implications we anticipate for future interactional studies of body positioning, learning, and relations of power.

Implications for future analysis of body positioning

CA and IA have not tended to treat gender and other social categories as relevant to interactions unless participants index them through talk or orient to them in-task (Stokoe & Smithson, 2001; cf. Schegloff, 1997). Yet, as analysts of interactions which are always powered, we observe that positioning in relation to member categories is not always explicit in interaction, and "what we call categories of gender, race, ethnicity, etc., are shorthand for a set of structures that position persons" (Young, 2005, p. 19). Seeing social positionings through body positioning means recognizing ways that power is instantiated in bodies, and how "conversely, these spatial configurations of bodies and actions index membership categories relevant to the activity in progress" (Takanashi & Den, 2019, p. 270). We urge learning scientists to continue to strengthen impoverished treatments of both gender divorced from other salient categories of difference like race (e.g., Patel, 2021), and gender defined as binary, sex-based

difference (e.g., Dennis et al., 2019). Finally, we encourage analysts to consider how theories not only describe what is possible for some bodies and not others, but what is actually experienced *as differently-positioned bodies* in physical environments. In that spirit, we conclude with Ahmed (2017), whose queer theorizing concerns not only theoretical spaces of possibility, but real, physical spaces constructed by whiteness and sexism in academic settings. She writes, "walls are how some bodies are not encountered in the first place. Walls are how other bodies are stopped by an encounter" (p. 145). Classrooms are made up of walls as well as doors that are more open to some bodies than others. Classrooms also have floors, and for every glass ceiling, there is a floor (of interaction).

Emphasizing the role of coordination class theory on the study of student learning with representations

Sidney Spurgeon and Mike Stieff
sspurg2@uic.edu, mstieff@uic.edu
University of Illinois at Chicago

Abstract: Visual representations are a core feature of teaching and learning in STEM disciplines. In all STEM fields, visual representations are used to describe phenomena, support problem solving, and aid communication. A significant body of research has documented that STEM students face challenges interpreting, generating, and translating representations across STEM curricula resultant from deficits in students' "representational competence" skills. In this paper we examine the theoretical underpinnings of representational competence (RC) and argue that the constraints of RC can be remedied by instead applying coordination class theory. Considering two examples of students' problem-solving with representations, we illustrate how developing coordination classes better explain the observed challenges students face with external representations in STEM disciplines.

Introduction

The teaching and learning of visual representations are key parts of education, particularly in STEM fields. How students understand representations is inextricably linked to their development of content knowledge since a common way of communicating conceptual information is through external modes of visualization (e.g., images, videos, simulations). Typically, the analysis of students' learning with representations is related to their conceptual understanding through the correct use of disciplinary representations (Nitz et al., 2014; Stieff, 2011). The theoretical construct that often frames such research is known as representational competence (RC) and is a presumed barrier for learning in STEM (Kohnle et al., 2020; Kozma & Russell, 2005; Nitz et al., 2014). RC assumes that as students develop their ability to utilize disciplinary representations their learning of associated conceptual knowledge is facilitated. However, such an assumption neglects the myriad ways that novice learners interpret and understand the features of external representations. We propose that reconceptualizing representational competence as developing coordination classes will effectively address the shortcomings of RC. Coordination class theory (diSessa & Sherin, 1998) offers a perspective on student learning with representations that considers internal cognitive processes beyond demonstrated skills that better characterize the ways students employ their prior knowledge to make meaning out of representational features. While we do not present an empirical study that directly tests our claims, we do utilize some exemplar cases from prior research conducted by the authors that demonstrate the application of coordination class theory as opposed to representational competence. By doing so we provide researchers with an alternative approach to studying external representations that may provide more productive outcomes for research and instruction.

Theoretical framework

The representational competence construct was developed from work by Kozma and Russell who studied the ways novices and experts interpret, generate, and transform chemistry representations (Kozma & Russell, 1997). Invoking the Knowledge-in-Pieces framework (KiP; (diSessa, 1993), Kozma and Russell argued that chemistry learners develop a fragmented understanding of chemistry concepts because they lack prior knowledge based on observable phenomena in their everyday lives (Kozma & Russell, 1997). While intuitive knowledge elements originate from direct experiences in domains such as physics (e.g., p-prims), chemistry instruction relies more heavily on visual representations to describe the sub-microscopic nature of phenomena. Therefore, Kozma and Russell argued that conceptual change in chemistry is inhibited by students' difficulty interpreting representations and inability to apply representations in problem-solving contexts. Their observations led them to develop a set of representational skills they believed necessary for the advancement of novices to expert-level conceptual understanding in chemistry.

While the RC construct leverages several aspects of KiP, Kozma and Russell are unclear on how these elements function through the RC skills to promote conceptual change. Additionally, much of the scholarship that invokes RC as a theoretical construct and dimension of analysis only consider whether students demonstrate RC skills. This leads to binary classifications of whether students "have" or "do not have" RC, which narrows the scope of interpretations and useful insights from such research. Without considering *how* and *why* students engage

 © ISLS

with visual representations in particular ways there is little value in instructional methods that simply promote the correct use of representations. Coordination class theory (diSessa & Sherin, 1998) provides a perspective that can answer these *how* and *why* questions while also characterizing the connections students make between features of external representations and their prior knowledge.

While diSessa and Sherin explored the implications of KiP in physics, they recognized that there was a common issue of how concepts are discussed and studied in education research that fails to account for how learners establish an understanding of a concept across representations or phenomena. They argued that conceptual change for some core concepts in STEM is better conceived as the development of coordination classes that include two structural components. First, readout strategies describe how students interpret information from the external world; second, causal nets describe how students create meaning based on their interpretations and develop connections to their prior knowledge. The readout strategies students use to extract information from the world and their assumptions involving underlying knowledge elements that comprise causal nets are integral to understanding how students progress from novices to experts. Additionally, students can coordinate information through their readout strategies in two ways: integration and invariance. The former describes how one must attend to different pieces of information within a situation to formulate a comprehensive understanding. The latter refers to how an idea can be presented in different ways across multiple situations. With respect to representations, a student must come to recognize how one representation communicates information about underlying phenomena through various features (integration), as well as how different representations may describe the same information but in different ways (invariance).

When comparing representational competence to coordination classes, the former lends itself to representational skills being distinct yet related to content knowledge. It is ambiguous whether Kozma and Russell truly contest that RC is separate from content knowledge, yet later research that invokes the construct has come to treat RC and conceptual change as independent outcomes (e.g., Nitz et al., 2014; Stieff, 2011; Stieff & DeSutter, 2021). By considering the inherent connections made between representations and the concepts they communicate, coordination class theory allows us to better understand how students develop content knowledge through the use of disciplinary representations. Since the connections novice students make between knowledge elements and representational features are less likely to be as straightforward and canonical as the connections we see experts create, it requires deeper consideration of the ways in which students reason. As such, coordination class theory provides a more fine-grained approach by considering what the student interprets from a visual representation together with how they apply their prior knowledge.

Reframing representational competence as coordination class theory

In proposing this alternative to understanding how students engage with visual representations, we present a set of exemplars that demonstrate how researchers might apply coordination class theory. We describe how students interpret pre-existing disciplinary representations as well as how they generate their own representations through sketching. These examples are from prior research conducted by the authors to gain a better understanding of how students engage with chemistry representations, however, coordination classes were not a framing theory or approach to analysis. Importantly, the discussion of these examples is not intended to be a developed methodological approach for the application of coordination class theory. Rather we seek to broadly describe how coordination class theory could be invoked in research on external representations and the resultant implications.

The first example is from the first author's dissertation research that included semi-structured interviews with thirty first-semester general chemistry students. These interviews were conducted to understand how students use different chemistry representations when introduced to a novel topic area. Students were provided with instructional materials that included a short reading passage introducing the topic of molecular geometry along with a chart of all fifteen molecular geometries with example molecules in one of three different representations (ball-and-stick, dash-wedge, or Lewis dot). The second example stems from a larger project involving high school students' engagement with a design-based chemistry curriculum that employs workbook activities in conjunction with sub-microscopic simulations (Stieff et al., 2012). This specific activity prompted students to draw what they thought water would look like on macroscopic, microscopic, and sub-microscopic scales and modalities.

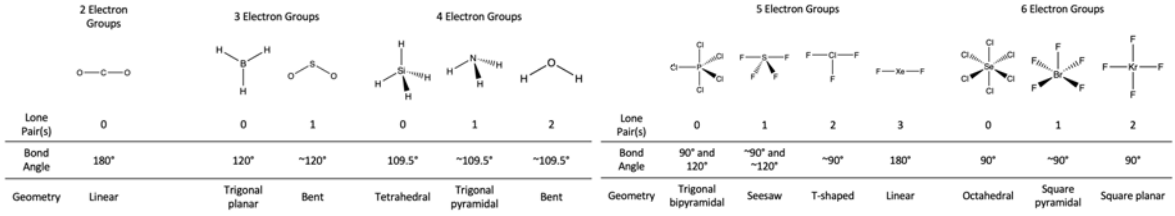
Example 1: Inferences about dash-wedge diagrams

When considering coordination class theory, we see that students apply several different readout strategies in congruence with connections in their causal net to understand a novel concept (molecular geometry) using unfamiliar representations like dash-wedge perspective formulas (see Figure 1).

 © ISLS

Figure 1

Dash-wedge perspective formulas provided to students as part of instructional materials.



When presented with this form of representation, students would first focus on familiar features they learned from chemistry instruction. For instance, students would utilize readout strategies to recognize that the letters in the representation communicated information regarding the elements involved. From here, they would take advantage of connections in their causal net between the element symbols and information from the periodic table. When prompted, students would try to explain additional formalisms of the representation such as the dashed and wedged lines. Students applied additional readout strategies to collect further information about the representational features (e.g., that the dashed and wedged lines form triangles; the wedged line is bolder/darker; the dashed line is more dispersed). Unlike the element symbols, many students did not have developed connections in their causal net between the dashed and wedged lines and spatial orientation, therefore they invoked other knowledge elements to form connections. In this case, they often related the dashed and wedged lines to relative bond strength or different types of bonds (e.g., covalent, ionic, single or double bonds).

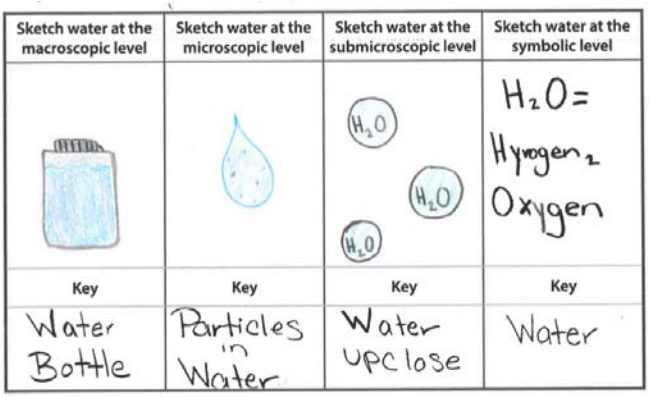
Analyzing these student responses from the lens of representational competence, we would only be interested in whether the students could correctly identify the conventional meanings of the dashed and wedged lines. When considering the responses from the perspective of coordination class theory, we can see how the familiarity of representational features and the related causal nets influence students' attention and their interpretation of the representation.

Example 2: Understanding different scales

The second example involving high school students' sketching gives us insight into how students make connections between knowledge elements, which in turn leads them to generate sketches with a focus on particular features. Figure 2 is a student artifact from a workbook activity in which students were asked to draw water at three different scales. We can see that the student has a rich causal net based on frequent engagement with water at a macroscopic scale, yet they are less familiar with the microscopic and sub-microscopic, so they attempt to apply similar representational features based on readout strategies from the macroscopic. Across panels in the figure, the student still draws water at a macroscopic scale as a droplet, and they conflate symbolic features in their sketch of water at a sub-microscopic scale.

Figure 2

Student-generated sketches of water at the macroscopic, microscopic, and sub-microscopic scales as well as in the symbolic form.



While prior studies around representational competence might simply deem these two sketches as incorrect due to their non-canonical forms, coordination class theory provides us with a more detailed

 © ISLS

understanding of the possible reasoning behind these sketches. We can see that the student has continued to use the color blue in both their microscopic and sub-microscopic sketches, which may indicate that they are trying to demonstrate invariance in their drawings based on the causal net they have developed for water at a macroscopic scale. The student is also likely unfamiliar with the conventions utilized in disciplinary chemistry representations at these two scales, so they invoke prior knowledge to integrate how they understand water in other situations (e.g., using the chemical formula for water in the sub-microscopic sketch).

Conclusion

This paper demonstrates the theoretical power of applying coordination class theory to the study of students' engagement with disciplinary representations. Rather than taking the narrow focus of whether students can correctly use and interpret representations, coordination class theory emphasizes the ways in which students understand external representations and link them to underlying phenomena. Moreover, coordination class theory provides a more detailed understanding of how students engage prior knowledge that other frameworks, such as diagram comprehension (Zhang, 1997), do not investigate closely.

Researchers may use this information to develop interventions and targeted instructional practices that redirect the focus in learning with representations to the connections formed between representational features and the concepts they communicate, rather than the procedural use of disciplinary representations in specific contexts. Additionally, it would be of interest to investigate how different forms of instruction influence the development of readout strategies and causal nets around the use of representations. Specifically, how instruction that emphasizes and describes the connections between representational features and underlying phenomena would help engage students in useful readout strategies that will allow them to make further connections and inferences in their causal nets. In doing so, students may be better equipped to identify aspects of invariance and integration in disciplinary representations as well as generating representations in novel contexts.

Abstract: Neuroimaging studies show that expertise in math shapes brain functions. To understand the brain processes behind complex math tasks and manipulation of large abstract concepts, we need to study the brain with naturalistic stimuli. Such stimuli are, for example, long math demonstrations that evoke simultaneous and overlapping cognitive and metacognitive processes. In our EEG study, we compared math experts and novices while they actively processed long math demonstrations in sitting and standing. Experts had an enhanced delta (0.5-4 Hz) phase synchrony over the centro-parieto-occipital electrodes compared to novices. Internal concentration and engagement may play a role in such enhanced delta synchrony.

Introduction

Behavioral studies have shed light on cognitive mechanisms and concepts arising during mathematics and cognition. Brain research aims to understand, on a neuronal level, these mental transformations related to math processing. Thus far, neuroscientific studies in children, adults, and math experts have focused on relatively simple mathematical processing in the brain.

Until now, brain research of mathematical cognition is accomplished with very quick mathematical tasks such as single- or double-digit arithmetic, or a short sentence describing a mathematical concept (e.g. Amalric & Dehaene, 2019; De Smedt et al., 2009). All of these studies are made with a strictly still body posture, due to noise sensitivity of the imaging methods and artifacts caused by body movement. Problems may emerge when simplified models, based on such short and artificial tasks in isolated and static settings, are applied to complex psychological phenomena, like mathematical cognition. Complex cognitive phenomena are exceedingly difficult, perhaps impossible, to describe through the data of their building blocks alone, since these phenomena are greater than the sum of their parts (Zaki & Ochsner, 2012). Our study aims to contribute to the naturalistic leap in brain research of math, the path of which is already being developed by interesting studies, such as Dikker and collaborators (2017) on STEM learning in a classroom measured by EEG.

In our study, we focus on the brain processes of math experts and novices over three oscillation frequencies: delta, theta, and alpha. We study the cortical synchrony with EEG when the participants actively processed longer math demonstrations with a duration from 13 to 68 seconds. By active processing, we refer to the mental activity we do when we read notes, proofs, and worked examples. Therefore, active processing is not restricted to solving problems. The math demonstrations are presented in symbolics and geometric manner when the participants are sitting and standing. We expect the math experts to show stronger activation over the parietal electrodes than novices when processing math demonstrations (Grabner & De Smedt, 2012), possibly due to the expected activation of the domain-specific number network (Amalric & Dehaene 2019).

Methods

Participants

In the math expert (bachelor and master students in math or math-related disciplines) and novice (no university-level math studies) groups, there were 23 participants (6 female and 17 male; 6 female and 17 male, respectively).

The age of the participants ranged from 19 to 24 years (mean 21.0 years, standard deviation 1.82) among math experts and from 19 to 35 years (mean 23.6 y, std 3.89) among novices. All participants in both groups were right-handed. No participants reported hearing loss or history of neurological illnesses. The experiment protocol was conducted in accordance with the Declaration of Helsinki and approved by the local Ethics Commission.

 © ISLS

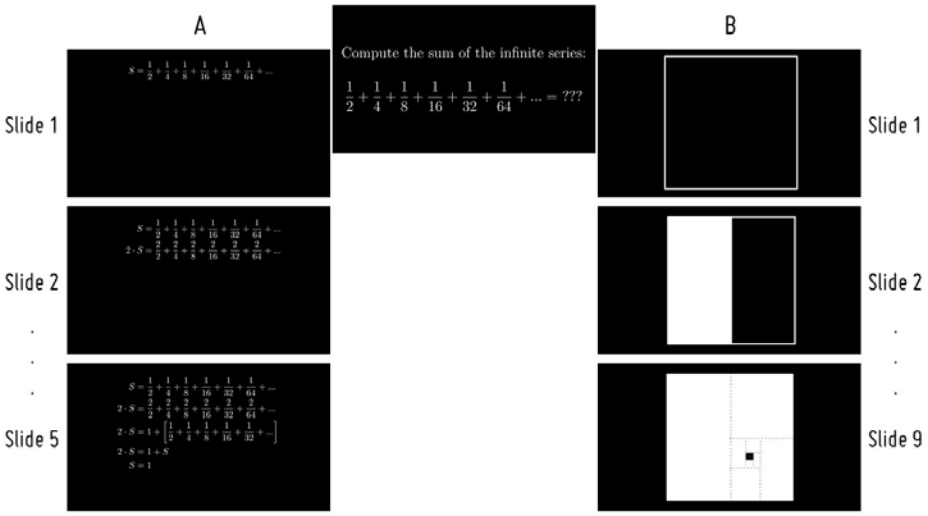
Stimulus

Participants watched 16 math demonstrations in a pseudorandomized order knowing that after watching them, they are asked to explain them to the experimenter. After each demonstration they were asked three self-evaluation reflections to which they answered by pressing a button in a 4-button response box. Each set of trials contained 4 excerpts of the same presentation style (symbolic or geometric) in two conditions (sitting or standing). One out of 8 math demonstrations is shown in Figure 1, both in a symbolic (Figure 1A) and in a geometric form (Figure 1B). The self-evaluation reflections (SER), which were presented after each demonstration, were the following: *I had enough of time to follow the math demonstration* (SER1), *I was familiar with the math demonstration* (SER2), *I understood the math demonstration* (SER3), and *I found this math demonstration engaging* (SER4). The options for the answers given via the response box were the following: 1 = *Completely disagree*, 2 = *Somewhat disagree*, 3 = *Somewhat agree*, and 4 = *Completely agree*.

Each math demonstration consisted of several slides, varying from 4 to 12 slides (6.9 slides on average) depending on the complexity of the demonstration. The total duration of math demonstrations varied from 13 seconds to 68 seconds (33.1 seconds on average). The timing of each slide was fixed and was defined based on a previous online screening with math experts and novices who did not participate in the actual study.

Figure 1

One out of 8 math demonstrations shown in symbolic (A) and geometric (B) form. The first slide (image in the middle) was the same in both symbolic and geometric presentation and was not used in the data analysis.



Equipment and procedure

The stimuli were presented to the participants with the MATLAB version R2019b via PsychToolbox version 3. The total length of the experiment material was approximately 15 minutes. The data were recorded using Ant Neuro eego mylab electrode caps with active 128 EEG channels and 4 external electrodes for eye movements.

Data analysis

The average of all the EEG electrodes was set as a reference meaning taking the average of the signal at all EEG electrodes and subtracting it from the EEG signal at every electrode for every time point. The data were treated with independent component analysis (ICA) decomposition with the *runica* algorithm of EEGLAB to detect and remove artefacts related to eye movements and blinks. The data were split into the frequency bands of 0.5-4 Hz (delta), 4–8 Hz (theta), and 8–13 Hz (alpha) with high-pass and low-pass filtering.

We calculated the phase synchrony values (PSV; Tass et al., 1998) of the EEG data to the math demonstrations. The PSV value was calculated for 5-second segments with 50% overlapping for each math demonstration excluding the first two seconds and last second of the presentation. We conducted the synchrony analysis over the 12 electrodes of F3 (5), Fz (6), F4 (7), FCz (42), Cz (16), CP3 (48), CP4 (49), P1 (51), Pz (26),

 © ISLS

P2 (52), PPO1 (92) and PPO2 (93; the 128-channel Ant Neuro EEG cap gap). Many of these fronto-parieto-occipital electrodes are traditionally used in EEG studies of mathematical cognition and show modulations in oscillation over memory retrieval, procedural strategies, and math training (e.g. De Smedt et al., 2009; Grabner & De Smedt, 2012).

The statistical analyses were conducted with MATLAB. The statistical analysis, repeated-measures ANOVA with a between-subject factor Group (Experts and Novices) and within-subject factors Posture (Sitting and Standing for math demonstrations), and Stimulus (Symbolic and Geometric), was conducted separately for each electrode pair (66 electrode pairs), each frequency band (delta, theta, and alpha). pGG indicates the Greenhouse-Geisser adjusted p-values of the repeated-measures ANOVA. For false discovery rate (FDR) correction, we employed a q-value threshold of 0.05. In the results section, we report only the statistically significant results in which both the pGG and the pFDR are < 0.05.

Results

Behavioral results

Self-evaluation reflections are an important indicator of how well the participants understood the math demonstrations (SER3) and how deeply they felt engaged with each demonstration (SER4). We also screened familiarity (SER2), and whether the participants had sufficient time to follow the steps of the demonstrations (SER1). For SER1, SER3 and SER4 experts reported significantly higher scores than novices, pGG=8.2e-06, pGG=8.2e-06, and pGG=0.0042, respectively. For SER2, there was no group difference, pGG=0.63.

EEG results

EEG results related to the Group differences and their interactions are reported and discussed in this paper The only statistically significant Group differences and their interactions occurred over the delta band (Table 1).

Table 1

Repeated measures ANOVA was calculated individually for each frequency band with between factor Group (Experts, Novices) and within-factors Stimulus (Symbolic, Geometric) and Posture (Sitting, Standing). This table presents the significant group main effects and interactions and in all of them Experts have stronger synchrony than Novices (Experts > Novices).

Delta: 0.5 – 4 Hz	Electrode pair	pGG value	pFDR	Multiple comparison (Bonferroni)	Difference	Standard error
Group main effect	Cz – PPO1	0.015	0.0097		0.12	0.046
	Pz – P2	0.020	0.0067		0.14	0.056
	CP3 – P1	0.049	0.0080		0.10	0.051
Group*SitStand interaction	Cz – Pz	0.014	0.00035	Standing: (p= 0.035)	0.11	0.049
	Cz – P1	0.020	0.00035	(p= 0.034)	0.11	0.052
	CP4 – PPO1	0.049	0.00048	(p= 0.046)	0.11	0.052

Discussion

In our study, we compared math experts to novices when they were actively watching long and complex math demonstrations in an EEG laboratory in sitting and standing body posture. Our main finding is that the math experts have a stronger delta phase synchrony over the centro-parieto-occipital electrode pairs than novices when watching math demonstrations. Our results refer to enhanced internal concentration (Harmony, 2013), and/or activity related to the number network in experts in comparison to novices (Amalric & Dehaene, 2019).

Internal concentration

When processing long and complex math demonstrations, internal concentration is crucial bringing the focus to the task at hand. Simultaneously, brain processes related to other external stimuli or task-irrelevant internal thoughts need to be suppressed. Harmony and colleagues (Harmony, 2013) showed that left parietotemporal

cortices have an increased activation on the delta band (3,9 Hz) during an arithmetic calculation in comparison to control tasks. After other results from their laboratory, Harmony and colleagues (2013) reasoned this increase in the delta band to occur due to enhanced internal concentration required to solve the arithmetic problem. Also in our study, the enhanced delta phase synchrony in experts over the centro-parieto-occipital electrodes may reflect their deeper internal concertation in comparison to novices. The self-evaluation reflections would also support this interpretation since experts reported stronger engagement and a better understanding of the math demonstrations than novices.

Sitting and standing body posture

Most of the group differences in delta synchrony in experts and novices occurred during both body postures, sitting and standing. However, some synchrony differences, expanding to the right hemisphere, emerged only during the standing position. To our knowledge, our study is the first one that investigates complex math in a standing body posture. Visuospatial working memory seems to function faster and more precisely when standing than when sitting down (Dodwell et al., 2019). However, sustained upright posture seems to require constant attentional engagement (Woollacott and Shumway-Cook, 2002). In our study, potential attentional interference between standing and math tasks appears to challenge math novices more than experts, who might have more automatic mathematical processing and thus require less attentional effort (Jeon et al., 2019).

Conclusions

Our novel study setting with long and complex math stimuli revealed enhanced delta synchrony in math experts in comparison to novices over the centro-parieto-occipital electrodes. Over some electrode pairs, the group differences were shown only when standing but not while sitting. Taken together, these results indicate a deeper internal concentration in experts and/or potentially a stronger activation of the number network in comparison to novices when actively processing math demonstrations. Our results encourage future study of the brain with naturalistic stimuli, such as long and complex math tasks, in naturalistic setting including different body postures to understand how the brain functions in the real world in which continuous and overlapping stimuli are encountered and interacted with, evoking several simultaneous sensory, cognitive and emotional brain processes.

Personalized Instruction to Teach Secondary Students to Deeply Comprehend and Build Knowledge from Science Texts.

Donna Caccamise, Peter W. Foltz
donna.caccamise@colorado.edu; peter.foltz@colorado.edu
University of Colorado, Boulder

Abstract: eBRAVO is a unique, theory driven, web-based teaching tool that simultaneously provides advanced reading comprehension assessment and skill development, knowledge building skills, combined with a standards-based science curriculum in ecology. The instruction is individually paced, has whole classroom activities to aid classroom pacing, teacher and student dashboards demonstrating progress, and is open source. We describe the approach to theory-driven development, co-design and evaluation in the project and the implications for supporting reading comprehension in STEM.

Introduction

In order to be successful in school, students need to be able to read content-area texts well enough to learn and remember new content, and they must be able to apply what they know in future reading and learning situations, as well as apply the knowledge in novel contexts. Comprehension instruction is intended to give students specific tools that expert readers use, to be applied in situations where comprehension breaks down (e.g., Biancarosa & Snow, 2006; Goldman, 2012; Kim, Vaughn, Wanzek, & Wei, 2004; Pilonieta, 2010; Pressley, 2000). However, in the middle school years this instruction typically consists of isolated strategy or skill development taught in remedial reading and English/language arts classes and often ignores the goal of cumulatively building knowledge from texts (e.g., Duke, Pearson, Strachan, & Billman, 2011).

The eBRAVO project targeted this well-documented weakness in reading comprehension (particularly for expository texts) that typically persist and significantly impact students' further academic progress (e.g., Anonymous, 2017; Chen & Ho, 2012; Norris and Phillips, 2003). It addresses the problem with current practices in comprehension instruction by embedding explicit comprehension instruction in a content-area context that improves reading comprehension skills in middle school readers. The approach is designed to provide scaffolded support to help students understand difficult content-rich, informational text, teaching them how to overcome misconceptions, understand the text meaning, and build knowledge.

Developing eBRAVO

For the project, researchers developed and pilot tested the eBRAVO intervention aimed at helping middle school students develop deep comprehension skills necessary to read, comprehend, and build knowledge from informational texts. This project used a novel approach to translating theory to practice by simultaneously addressing parallel learning processes in actual learning settings: skillfully reading challenging texts to achieve deep understanding while also building knowledge about a complex content area from the content in the reading. At the same time, this project worked iteratively with stakeholders—teachers and students—to design a tool that works practically in both classroom and individual learning settings (e.g., Penuel, Fishma, Cheng & Sabelli, 2011).

The eBRAVO development used a theory-driven adaptation and enhancement of a previously-developed paper-based intervention (BRAVO; Fostering Comprehension and Knowledge-Building in Middle-School Struggling Readers), shown in prior work to have promise for improving students' reading comprehension outcomes (Foltz, Littrell-Baez, & Kintsch, E, 2018). eBRAVO, like BRAVO, is aimed at improving the reading comprehension skills of middle school students who have adequate reading fluency but still have trouble learning from informational text as they read. The intervention, embedded in a STEM curriculum, teaches students how to implement reading comprehension strategies and how to actively build knowledge.

Moving from a paper-based to an online curriculum afforded multiple changes in design to permit individualized comprehension strategy instruction within a curriculum with contextualized texts at different levels of reading difficulty. eBRAVO was developed as a web-based reading application that contained a complete ecology curriculum. A design-based implementation research (DBIR) approach was used to carry out the project (Penuel, Fishman, Cheng, & Sabelli, 2011). This approach consisted of co-design meetings which allowed researchers and instructors to interact as full partners in developing and evaluating materials and instruction.

 © ISLS

The eBRAVO curriculum is an adaptive reading experience with embedded formative assessments on web-enabled devices in which students work through a twelve chapter ecology curriculum. It is designed to allow students to proceed through the lessons at a self-paced rate, rather than as a class. To accommodate this personalized learning experience in an intelligent tutoring approach, we adapted the five class-level lessons from BRAVO into videos and a practice problem personalized for each chapter, creating 119 lessons. As students work within eBRAVO, they first read a short chapter of 3 to 11 paragraphs of ecology reading content connected to what they have read so far in the curriculum. These readings incorporate in-text highlighting and clickable definitions for key vocabulary, along with embedded figures including images of important components or diagrams of certain systems. Once students have completed their readings, they proceed directly to open-ended writing asking them to record the big ideas found in the text. eBRAVO then probes their deep comprehension with multiple choice questions that target both issues brought up directly in the text as well as inferences and connections to greater ideas from previous texts. The open-ended writing is assessed using NLP-based approaches to measure content and inferences that were learned (Foltz et.al.2020; Foltz, 2017). The system assess multiple literacy skills and if the system determines a student should see subsequent reading lessons based on their comprehension scores, it then gauges which type of reading support (linking ideas, gist, summary, graphic organizer, or inference) with which the student needs help and sends them to the appropriate lesson for that chapter and content, The lessons further incorporate two to five minute videos that outline the key comprehension strategy that is targeted and demonstrate how to apply this comprehension strategy to parts of the chapter that the student has just completed.

Taken together these features provide students with just-in-time instruction on needed skills to better understand and learn from the text *as they are reading it* (Foltz et.al. 2020; Foltz, 2017). The process of development of eBRAVO for one STEM domain further resulted in a more general curriculum framework that may be applied to new content areas and that will allow more individualized scaffolding to better meet the needs of a variety of classrooms, students, and instructors in both Language Arts and content area classrooms.

Evaluation

The first two years of this project involved iterative development of the eBRAVO interactive, web-based tool, in collaboration with teachers and students. Researchers began by identifying and adapting previously developed and studied BRAVO curriculum components into a format that could be delivered online through eBRAVO. Participants in this study included approximately 288 students in 6th through 9th grades in suburban school districts in the Denver, Colorado area.. Data were collected from teachers and students via surveys, interviews, and focus groups to examine usability and feasibility as well as data from embedded formative assessments. The eBRAVO system also collected user data (e.g. click streams), and the researchers collected student performance data pre- and post-intervention. During this project, revisions were made to eBRAVO from iterative design with teachers and students as collaborators, followed by field testing of the upgraded system based on user feedback, use and performance. We implemented additional important features including an online concept map activity used to consolidate knowledge, and to more deeply understand the "Big Ideas. Additionally, scenarios were developed to bring students together in teacher-led classroom activities and to "catch up" students who engaged individually at a slower pace. Our small classroom efficacy study was impacted, however, by the pandemic, so due to school shutdowns this team pivoted and made design changes to make the intervention available nationwide over the internet, while preserving IRB protocols.

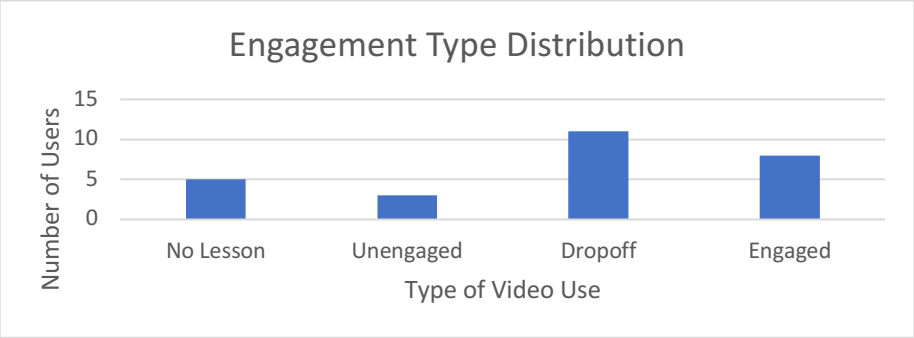
Proximal outcomes of the eBRAVO intervention included assessments embedded within the eBRAVO system, such as quick quizzes and writing prompts targeting deep comprehension of the ecology curriculum (Behrens, DiCerbo & Foltz, 2019). Researchers assessed student education outcomes a pre/post text recall task designed to assess their ability to extract/learn information from any novel informational text on a subject that was unfamiliar. In addition, click streams and other student behaviors using the eBRAVO intervention were collected to aid in usage and usability analyses. (e.g., Quigley, Caccamise, Weatherley, & Foltz, 2020).

Sample results

As an example of the results from the evaluation of eBRAVO, click stream data was used to sort out students demonstrating different levels of effort. In a pairwise t-test analysis of students' comprehension scores within eBRAVO, a significant difference was found when comparing Engaged & Dropoff with "No Lesson" and

Unengaged groups (p = 0.0405). This indicated that some exposure to the lessons had some positive effect (see Figure 1.)

Figure 1.



This project resulted in eBRAVO v1, a fully functional, interactive intervention that is open source and ready for use by educators, parents, and researchers. Key features of the intervention include the following: eBRAVO is an online reader that jointly provides standards-based middle school Ecology content AND a reading comprehension assessment, tutor, and knowledge-building assistant on a personalized instructional basis. Internal skilled reading components addresses local cohesion, global cohesion, inference, and knowledge integration. Each just-in-time lesson includes brief videos with comprehension and metacognitive strategies modeled for students. Content chapters combine to build a body of knowledge about ecology similar to any science text, but in eBRAVO there are activities for students to practice comprehension strategies on an individualized, as-needed basis, using this adaptive technology.

Outcomes and lessons learned

The main features of the intervention and findings of the project's pilot study are as follows:

- We developed a unique approach to comprehension instruction with an open access online instruction aid assisting students while they build knowledge from text using a personalized, interactive approach.
- We discovered and addressed a need to incorporate periodic whole-classroom activities to allow teachers to more fully assess what knowledge building had occurred and to adjust the curriculum to catch up the slower learners.
- We created an online concept mapping activity designed to help students process the information in the eBRAVO texts to promote deeper learning and knowledge building.
- We developed and evaluated NLP and Machine Learning based methods that allowed automatic scoring of the concept maps to measure the student knowledge representations and methods for assessing student summaries to measure the amount of information gained from the reading activities.
- We developed and evaluated machine learning algorithms to assess individual comprehension skills on the fly as students needed to use them to build knowledge. If they demonstrated a lack of needed skills in a given instance, they were directed to a short interactive tutorial about the deficient skill.
- eBRAVO was presented in the Ed Games Expo, 2021, a national showcase hosted by the Department of Education to demonstrate the latest in educational games, tutors, and electronic teaching tools whose development IES has supported.
- **Additional online resources and information:** Youtube video for Ed Games Expo, 2021. https://www.youtube.com/xxxxxxxxxxxxxxX (skip the ad that occurs before the video)
    - BRAVO website (xxxxxxxxxxx)

Conclusion

The research team adapted eBRAVO from the existing paper-and-pencil **B**oulder **R**e**A**ding inter**V**enti**O**n (BRAVO). By adapting BRAVO for electronic delivery, the researchers worked to make the curriculum framework and content more flexible while making delivery more accessible and workable for classroom teachers and their students. eBRAVO offers an automated, online curriculum that includes baseline assessments of students' comprehension skills, as well as formative and summative assessments throughout the curriculum. eBRAVO simultaneously combines comprehension instruction with content instruction in an as-needed basis to enhance learning and knowledge building as a student reads a challenging text for that purpose. We developed a

robust, commercial grade version and included features that enables automated scoring of concept maps and open-ended writing activities. Automating scoring of such learning activities allows teachers to incorporate these critical concept formation components that are normally not scalable in secondary classrooms. With broader exposure, this tool that teaches critical knowledge building skills used by skilled readers can be made available to anyone via the internet, dramatically increasing inclusion and potential equity for students nationwide who don't receive this sort of instruction through their school districts.

Abstract: The COVID-19 pandemic destabilized the prevailing grammar of schooling and forced schools to rely on digital technologies to create new routines and practices. This offers a unique opportunity to examine the interplay between digital technologies and the temporospatial features of schooling, and how these relations were mediated via contextual features. Based on semi-structured interviews with principals and teachers in Muslim-Palestinian and secular-Jewish schools in Jerusalem, this paper qualitatively analyzes the main technological tools used by educators: instant messaging (WhatsApp), video-conferencing (Zoom) and school-wide platforms (Google Classroom). Our findings stress how technological affordances varied according to socioeconomic status and diverging perceptions of schooling. Specifically, we found that lower-SES Palestinian schools, who faced more acute challenges, utilized digital technologies to restabilize the grammar of schooling in order to monitor and support students' basic needs, whereas average-SES Jewish schools focused on facilitating informal interactions that catered to students' emotional wellbeing.

Introduction

Digital technologies are often presented as nurturing "anytime-anyplace" learning – open, flexible, individualized and student-led learning – that would allow overcoming the staleness of conventional schooling (Selwyn, 2013). In practice, research shows that novel technologies have not had a substantial impact on the overall structure of schooling and have been mostly integrated within the prevailing "grammar of schooling": "the regular structures and rules that organize the work of instruction… standardized organizational practices in dividing time and space, classifying students and allocating them to classrooms, and splintering knowledge into 'subjects.'" (Tyack & Tobin, 1994; p. 454). However, during the COVID-19 pandemic, technology-mediated remote schooling (TMRS) had become compulsory and widespread almost overnight. Educators had to quickly negotiate how to rely on online learning tools to create a fully-fledged alternative to physical schooling. Therefore, digital technologies were now used to mediate the basic temporospatial facets of the grammar of schooling, thus potentially reshaping it. While it is still early to appreciate the long-term implications of the transition to TMRS, it is clear that it temporarily destabilized the prevailing grammar of schooling, requiring schools to prioritize and choose among competing goals and structures (Reich et al., 2020). The need to pursue such drastic changes therefore offers a rare opportunity to explore how digital technologies inform reconstructions of the "grammar of schooling".

Inquiries into the use of technologies in education often rely on the implicit assumption that technological devices have fixed affordances and will reproduce the same modes of conduct within and across educational settings, while ignoring the social and political features of technology-use (Davis, 2020). However, technological affordances are not inherent to tools nor are they static, but rather depend on users' needs, aims and associated meanings (Dishon, 2021). This is particularly pronounced during TMRS as it relies on having the necessary access to computers and the internet, a home environment conducive for learning, and caretakers who can support students (Williamson et al., 2020). Accordingly, this qualitative study examines the experiences, choices and perceptions of principals and teachers in socioeconomically diverse Muslim-Palestinian and secular-Jewish primary schools. We set out to examine the main technologies educators relied on during TMRS, how these different technologies shaped the temporospatial features of TMRS, and how they were mediated through socioeconomic and cultural characteristics. Our aim is not to offer a representative description of schools' use of digital technologies, but rather to offer theoretical contributions concerning how educational technologies reorganize key aspects of schooling, and how this function is mediated via contextual features.

Methods

The study was conducted in three Muslim-Palestinian and three Jewish-Secular primary schools in the Jerusalem school district. Studying Muslim-Palestinian and Secular-Jewish schools allows examining how the transition to TMRS was mediated by socioeconomic status and cultural and political characteristics, due to glaring disparities

 © ISLS

between the two populations in terms of access to physical infrastructure and education (Shtern & Rokem, 2021). All three Palestinian schools had students from very low SES status, whereas Jewish schools were characterized by an average SES population, with pockets of very lower SES students (e.g., refugees.). Schools were chosen based on a purposive sampling, which strived to offer socioeconomic and cultural variation within each of the populations.

Collecting and analyzing data

We conducted semi-structured in-depth interviews with school principals, head of ICT departments (if the school had one), and 2-3 teachers. The interviews were conducted October-December 2020 via the Zoom platform and were recorded and transcribed verbatim. Interviews focused on the transition to TMRS: the challenges and dilemmas schools faced, their responses, and participants' explanations for their choices. Thematic analysis was used to identify the main themes emerging from our data (Braun & Clarke, 2006). Each interview was read and analyzed by at least three team members, and discussed by the whole team, which allowed multiple perspectives to emerge (Cornish et al., 2014). While our analyses explored various aspects of schooling, in this paper we focus solely on those themes that had to with the temporospatial features of TMRS.

Findings

We identified three digital technologies that were central to TMRS: instant messaging (WhatsApp); video conferencing (predominantly Zoom); and schooling-platforms (Google Classroom). These technologies were not only the most prevalent, but they emerged as a common aspect of the organization of TMRS: teachers and principals attributed great significance to these technologies, explicating pros and cons for each tool, and further discussing their ramifications on the practices of schooling. While educators also mentioned the use of educational apps tailored for specific content knowledge and other generic tools used in classes (e.g., Padlet), these were mentioned far less frequently, and were mostly brought up in the more limited context of teaching and learning. Thus, beyond the more detailed uses of different technologies, it is vital to note the dominance of *commercial tools*. In what follows, we describe the key themes that emerged for each technology in terms of the temporospatial structures of schooling (table 2). In our discussion, we highlight key variations in technology use across schools.

Technology	Themes
Instant messaging	*Porous*: Rapid simultaneous interactions at different levels
	All-day schooling: unclear temporal limits to the school day
Video conferencing	*Familiar class routines*: approximating the temporal structure of schooling
	Breaking spatial barriers: blurring differences between the school and the home
Platforms	*Comprehensive school structure*: complex organization of children and classes

WhatsApp

WhatsApp is the most common messaging app in Israel, and a central tool for sharing information in schools pre-pandemic, mostly through class-wide chat groups with parents or students. As such, WhatsApp gained a primary role early in TMRS, serving as a means of communicating decisions regarding school operations during lockdown, and sharing educational material and tasks. Two key temporospatial themes emerged from participants' interviews: WhatsApp's *porous* nature, and its role in the establishment of *all-day schooling*.

The main temporospatial characteristic of WhatsApp was its *porous* nature. Due to its use to facilitate various formal and informal communicational contexts, it blurred and undermined demarcations within schools and between schooling and individuals' personal lives. Beyond personal use, WhatsApp was used to disseminate information to teachers, for teacher communication with parents, and as a tool for sharing and receiving educational materials, often for different classrooms. This blurring was not only temporal in nature. In more affluent populations, new personal connections were made between teachers and older students who had their own phones. While the class WhatsApp group was used mainly for sharing information, private chats were conducted in a new, amicable manner. This had rendered WhatsApp a liminal technological space, in which the division between personal and professional life was blurred. This also has to do with the blurring of the temporal structure of schooling. As teachers and students were often chatting during what is normally considered off-hours, the tone and content also geared towards informality.

The second theme centers on the blurring of the temporal distinction between school and home, described by interviewees as *all day schooling*. Each student could access materials on WhatsApp and react at various times throughout the day, which altered the temporal rhythm of schooling: instead of the uniform routine, students and families interacted with teachers at different paces and at different times. Moreover, as teachers often had to

function as "tech-support' for children and families, they felt they had to be "on-call" way past what was previously expected. Consequently, teachers reported very long work hours during TMRS, many of those spent on WhatsApp. As WhatsApp blurred the temporal boundaries on communication, teachers noted that its centrality led to a norm of *all-day schooling*, which was described as leading to a sense of burnout.

Zoom and video-conferencing apps

Shortly after school closings, video-conferencing applications (predominantly Zoom) were being introduced as core aspects of TMRS. While some schools integrated Zoom very quickly into their daily routine, others encountered difficulties stemming from scarcity of end-devices, unstable network connections, and poor staff and parents' technological literacy. In lower SES and Palestinian schools, families had to allocate their technological devices between children at specific times. In some cases, this led schools to organize different Zoom times for different age groups as to prevent overlaps within families. Two key temporospatial themes emerged with respect to the centrality of Zoom: *familiar class routines*, and *breaking spatial barriers*.

The strongest impact Zoom had on remote schooling was that it reintroduced *familiar class routines*: fixed timetables in which Zoom sessions were allocated according to disciplines. These familiar routines were also apparent in terms of the dynamics of each lesson: Zoom was perceived as a teacher-centered virtual space. Building on such capacities, it was often depicted as online frontal teaching, with slideshows serving the teacher as whiteboard. According to many teachers, the Zoom class schedule reinstated structure in students' lives and calmed their worried parents. At the same time, Zoom had brought back some familiar challenges of appropriate classroom conduct. In several schools, rules of participation and conduct were restated – cameras had to stay on, no eating was allowed during class, school uniform became mandatory and so on.

Though Zoom reintroduced familiar temporal routines, it concurrently *broke spatial barriers,* changing interaction patterns between teachers and students. First, due to the virtual presence in each other's home, Zoom was perceived as allowing a better understanding of students' experiences and emotional states, compared to a-synchronous tools. In higher-SES schools, Zoom was explicitly used for creating emotional affinity, ranging from shared breakfasts to more elaborate cases of joint cooking classes. Zoom created a new situation of blurred boundaries between private familial life, and professional educational life. In lower-SES schools catering for families living in dire situations, teachers reported that Zoom enabled supervision of familial life and the wellbeing of students, thus serving schools' pastoral role in the community. Second, the breaching of personal space was at times a challenge. In more religious Palestinian schools, participants noted issues of privacy due to the exposure of religious Muslim women in their home. In higher-SES Jewish schools, Zoom opened the classroom to the scrutinizing gaze of parents. Parents had interrupted teachers during lessons, asking questions, requesting attention to their children, and even correcting the teacher's grammar.

Schooling Platforms

School-wide platforms (e.g., Google Classroom) offer a panel of tools incorporated into tailored profiles both at class and student level. These platforms were described as requiring the greatest effort: creating dedicated email accounts, opening in-platform profiles for all students and staff, and teaching teachers and students how to operate them. Consequently, some schools did not attempt to integrate such platforms: one Palestinian school that did not have the required infrastructure, and two higher-SES Jewish schools, where principals explained that this would require a level of effort (from teachers and families) they thought was unrealistic during the pandemic.

School-wide platforms offered a hybrid of both task-centered and teacher-centered learning, organizing links to tasks, materials, and live video lessons. In this respect, they provide a digital representation of the *comprehensive school structure*: students can navigate in and out of lessons, teachers can coordinate Zoom teaching hours between classes, and management can consider which grades get which sessions at what time. Thus, the platform had served to create a coherent organizational structure. The personalized aspect of such platforms – connecting each student to a personal profile – allowed principals, teachers, and parents to keep track of students' progress. Hence, in terms of the temporospatial organization of schooling, platforms add another layer in that they enhance the summative and quantifiable tracking of students' and teachers' actions within the school, in ways more elaborate than were used before.

Discussion

The exodus to TMRS in light of the COVID-19 pandemic serves as a unique opportunity to examine the potential interplay between digital technologies and the grammar of schooling. Whereas above we focused on shared themes that emerged across schools, we now focus on how technology-use was mediated through contextual factors. Specifically, we examine how the temporospatial organization of schooling facilitated by the various technologies along two main issues: inequalities in access, and diverging perceptions of schooling.

Contrary to the adulation of the "anytime-anyplace" capacities of digital technologies, participants discussed to challenges characteristic of such modes of learning. First, schools serving minoritized populations were limited to relying on digital technologies "at very specific locations, in very specific times", i.e., when students have electricity, available end-devices and a stable network connection. Thus, in Palestinian schools, who faced both challenges in terms of access and organizational capacities (e.g., none had a designated ICT department), educators asserted that TMRS required closely monitoring and supporting students and families. This led lower-SES and Palestinian schools to adopt a more structured approach to schooling. This could explain the somewhat surprising finding that Palestinian schools were much faster to integrate school-wide platforms, although they were facing much more dire circumstances to begin with. Principals explained that without a structured organization of TMRS it would be too challenging for them to keep track of students' situation and offer the needed support. Second, across all schools, anyplace-anytime learning (mostly via WhatsApp) was perceived not as an opportunity, but rather as a burden. Teachers argued that all-day availability led to a sense of burnout, and highlighted the social nature of schooling, which required gathering teachers and students in a shared synchronous space. Accordingly, better-resourced schools opted for structured synchronous lessons via Zoom.

Besides issues of access, diverging definitions of the aims of remote schooling also shaped the functions of technological tools. Notably, the relatively higher-SES Jewish schools focused less on academics and social supervision, and more on how digital technologies allow establishing informal modes of interaction that cater to students' social-emotional needs (personal interactions, "extra-curricular" activities), which were deemed more urgent in light of the turbulences of the pandemic. These differences were reflected in diverging use of WhatsApp, but were most apparent in the perception of Zoom's role. Palestinian interviewees, that stressed the academic responsibilities of school to its struggling population, portrayed Zoom as the digital extrapolation of frontal teaching, intended to maintain academic progress. In contrast, Jewish interviewees highlighted how Zoom was used to facilitate emotional bonds. These differences might serve an explanation for why lower SES schools managed to introduce school-wide platforms in spite of the effort it required, while higher SES schools did not – such platforms were less relevant to their focus on the informal and intimate modes of teacher-student interaction.

Conclusion

In summary, our analysis revealed that schools mainly relied on free commercial technologies as the pillars of TMRS (Williamson et al., 2020): WhatsApp (instant messaging), Zoom (video conferencing), and Google Classroom (school-wide platforms). These played a different role in reshaping the temporospatial grammar of schooling: WhatsApp facilitated a flexible and porous school structure, where schooling was enmeshed with other aspects of teachers' lives. Zoom, in contrast, was mainly integrated into the familiar grammar of schooling (Selwyn, 2013). Yet, its blurring of the spatial separation of home and school (a separation often described as a key drawback of conventional schooling), was interpreted very differently according to context. Palestinian interviewees described this as an impediment to their responsibility towards families in dire need, while Jewish interviewees also depicted this as an opportunity to focus more on social-emotional aspects. Finally, schoolwide platforms, the only tools specifically tailored to education, created a virtual version of the grammar of schooling, which facilitated increased centralized control of learning and the collection and analysis of student data.

Technocentrism in Visitors' Views of Computing and Computing Education in Informal Spaces

Stephanie Hladik; Stephanie.Hladik@colorado.edu; University of Colorado Boulder
Pratim Sengupta; pratim.sengupta@ucalgary.ca; University of Calgary

Abstract: In this paper, we investigate how technocentric discourse shapes interactions between visitors, facilitators, and a computational science exhibit in a Canadian science museum. Technocentrism can lead both educators and learners to centre the production of technical artifacts (e.g., code, simulations) or the hardware and software of a learning environment in ways that ignore the social, cultural, and political aspects of learning. Drawing on video-recorded interactions of visitors with a computational science exhibit, we highlight the emergence of technocentric frames of both code/coding and computing education, and how they may impact visitor engagement (or non-engagement) with the exhibit and reify hegemonic notions of computing . Rather than letting computational learning environments "speak for themselves," explicit conversations about what computing is or should be are necessary to counteract technocentrism in computing education.

Introduction and purpose

Technocentrism was defined by Papert (1987) as the fallacy of referring answers to all questions about technology to the technology itself, rather than the social, cultural, and political supports that shape the use and meaningfulness of that technology. The pragmatic implications of technocentrism are of direct concern to us in the realm of computing education, given that technocentric discourses and pedagogies may hide the complexity of learning and teaching experiences that extend far beyond the computer (Sengupta et al., 2021) and may even further marginalize students who have been historically oppressed (Margolis et al., 2017; Vossoughi et al., 2016). Given this context, our work arises from the concern that the nature and role of technocentric discourse in computing education, especially in informal spaces, remains under-investigated. In this article, we draw from empirical data collected at a computational science exhibit in a Canadian science museum to highlight the ways in which technocentrism can impact visitor perceptions of computing education environments – even (or especially) those which purport to challenge technocentrism in their design.

Background: Technocentrism and informal computing education

Our work arises from a concern that despite attention to designing learner-centered environments and pedagogies, technocentric discourses and practices reduce complex educational challenges to a matter "of buying into the right technology and creating structures that standardize and routinize [its] use" (Burch & Miglani, 2018; p. 610). We view technocentrism as an ideological position (Philip & Gupta, 2020) that also shapes epistemological, axiological, and methodological approaches in computing education research. Ideologically, technocentrism positions computing education in a way that centers the production of technical artifacts (e.g., computer code, models, simulations, etc.) over the complexity of human experiences (Sengupta et al., 2021). Technocentric views have also been shown to be instrumental in shaping post-secondary students' perspectives of what should count as "real engineering" (Niles et al., 2020), potentially leading them to ignore the value of innovative learning experiences. Methodologically, this restricts research on the design of new technologies or environments to questions of efficacy of design, rather than attempting to understand the complexity of the experiences of learning and teaching (Sengupta et al., 2021). Axiologically, technocentric approaches can lead us to position historically marginalized learners using deficit lenses (Vossoughi et al., 2016; Kayumova & Sengupta, 2022). At the same time, given the difficulty of talking about a specific form of technology without referring to the technology itself (Sengupta et al., 2021), as well as a vast body of research in computing education and popular media representations of coding that promote the "charisma" of the computer over social interactions essential for computing (Ames, 2019) we believe that technocentric discourses may be shaping learning experiences of computing in both formal and informal spaces. This paper offers a preliminary exploration of this phenomenon in the context of informal computing education.

Research design

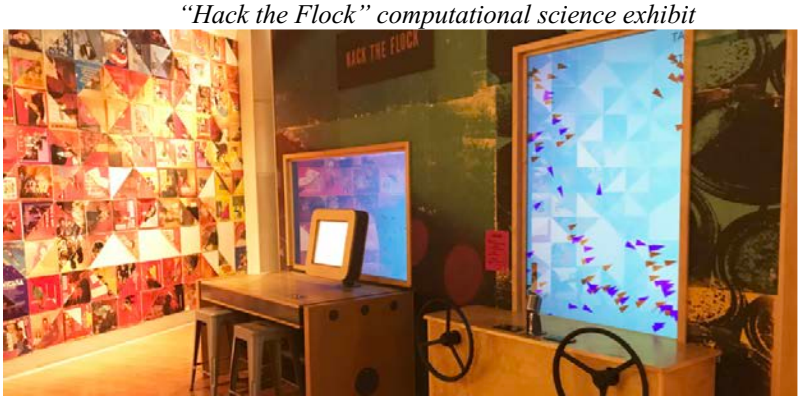
Setting and goal

 © ISLS

Hack the Flock, pictured in Figure 1, is a public computing environment (Sengupta & Shanahan, 2017) located in the Open Studio area of a science museum located in a Western Canadian city. Public computing environments are "open-ended, public learning environments, in which visitors can directly access, modify and create complex and authentic scientific work through interacting with open source computing platforms" (Sengupta & Shanahan, 2017, p. 1124). Our goal in this study is to explore technocentric discourses may be shaping visitors' interactions with Hack the Flock, especially given that the design of the exhibit explicitly seeks to decenter the technology (here understood as the programming language, the simulation code and the simulation display) in ways that may create tension with technocentric expectations (Sengupta et al., 2021) by supporting visitors through facilitation to center their own voices.

The simulation used in this exhibit is based on Reynolds' (1987) flocking algorithm in which Boids (bird-droids) flock around the screen according to three parameters: alignment, cohesion, and separation. Visitors can use the computer terminal to directly change those parameters in the code as well as, for example, change their colour, shape, speed, and size, and even add images of bees and monkeys onto the screen. The computer code is written in P5, a professional text-based programming language which is based on Javascript and Processing. The exhibit is intended to include facilitation, either live (a human facilitator at the exhibit) or in the form of comments or instructions embedded in the code itself.

Figure 1
"Hack the Flock" computational science exhibit



Data collection and analysis

We video and audio recorded visitor interactions at the exhibit, which captured discourse, physical movement, and changes made to the code. A total of 86 interactions were recorded, ranging in length from 50 seconds to 71 minutes (median length of 15:06). Each of these interactions included between 1-4 visitors of various ages (almost always including at least one child), one facilitator, and occasionally, a researcher (to answer questions as needed). We wish to be explicit that these videos of visitor/facilitator interactions were conducted in a naturalistic manner. Neither the facilitator nor the researcher explicitly asked the visitor(s) for their views on computing or the exhibit. However, during the interactions, some visitors made comments about computing education or the purpose of the exhibit, and a few specifically struck up conversations with the facilitator and/or the researcher on these topics. The first author watched all 86 interactions and flagged time periods in which visitors made comments about how the exhibit promoted, reified, or challenged their personal views of computing/computing education. This resulted in very few segments being flagged – 11 conversation segments across only 6 videos, possibly due to the young age of visitors (leading facilitators to focus on procedural aspects of working with the exhibit), and the fact that facilitators did not specifically ask visitors about their thoughts of computing/computing education. These segments were coded inductively using thematic analysis (Miles & Huberman, 1994) and constant comparison (Glaser, 1965). We compared the emergent codes against known perceptions and approaches in computing/computing education literature in terms of technocentrism (Papert, 1987; Sengupta et al., 2021). Our analysis focused on how visitors positioned code (i.e., assumptions about "real" code) coding (i.e., what coding in professional contexts looks like), and computing education (i.e., what computing education looks like).

Findings

Technocentric frames of code and coding: "Real" code must be complex

The use of a text-based programming language at Hack the Flock was a deliberate choice to break down growing divides between professional computing (which typically uses text-based languages) and computing education for children in the form of block-based challenges. While our exhibit uses the original flocking code from Reynolds (1987), it is split into different files, one of which includes easy-to-change variables and functions as well as extended commenting that can act as instructions. This design choice resulted in two men questioning whether the code with which they were interacting was "actual code":

> Visitor 1: What I'd really like to know is, [is] this the actual code behind something?
> Facilitator: Well [..] I mean, I guess this is the pretty version.
> Visitor 1: - simplified. Anyways. This is the pretty version.
> Facilitator: A version with instructions.
> Visitor 2: [sarcastically] What are you talking about, I am now officially a coder by coding this.
> Facilitator: Yes. To be honest, I am not a coding expert by any means. I know the extent of how to do this…
> [the facilitator and men spend several minutes working at the exhibit]
> Facilitator: Thanks for experimenting. You learned how to code. [laughs]
> Visitor 2: [sarcastically] We're basically coders now.

The visitor's sarcastic comment showed that since this code had been reorganized (simplified) and included instructions, it was not the same as real coding and therefore he implied that someone working with this code would not be a "real" coder. Despite the fact that the code was originally authored by computational scientists using a professionally used, text-based programming language, even something as minor as the code's organization and presentation diminished its authentic value. This is a technocentric view that emphasizes the technical work of *writing* code, ignoring the expertise that comes with *reading* and *commenting* code as well. In particular, commenting code is a socially valued practice in the discipline of computing, and has been shown to be an effective pedagogical practice for teaching and learning coding (Vieira et al., 2019), so the fact that the inclusion of comments or "instructions" is seen to diminish the authenticity of the computing education environment is in conflict with best practices from both computing education and the computing profession.

Technocentric frames of computing education: Erasure of human-human interaction

Western popular media has also promoted the idea of computing as an individual, anti-social endeavour (Lagesen, 2008). Along these lines, a woman remarked to the facilitator that while she thought the exhibit was a cool idea, there was no way that children under the age of 10 would spend more than three minutes at the exhibit (an assertion that our research has proved false). When the facilitator challenged that by pointing out that children spend more time when she is at the exhibit to help them understand it, the young woman argued:

> Young woman: But that's not the point of an exhibit right? Like, it's like human-exhibit interaction. I mean, human-human interaction is great. I honestly would've been like, "Oh cool," tried to change something, done nothing, walked away. So I like, appreciated this. But at the same time, I think that if it was a bit more clear...

While the visitor appreciated the help that she received from the facilitator and acknowledged that her interaction at the exhibit would have been much shorter without it, her words showcase a belief that human-exhibit interaction should be prioritized over human-human interaction at the exhibit. Her argument relies on a technocentric account of computing, in which the exhibit should "stand on its own" and the technology (the code, the hardware, etc.) is what determines whether or not a visitor can learn computing. The young woman in this section is advocating for a deliberate removal of "people" from the evaluation of an exhibit, that the need for a human facilitator is in fact a design flaw to be fixed. In fact, Hack the Flock is unable to "stand on its own" in the way that the young woman suggests. Even if visitors are simply able to sit down and start working at the exhibit, it is inherently tied to people through the values and visions of its designers, the history and perceptions of computing that are held on individual and societal levels, and of course, in the actions and words of the facilitators who enliven it. Without facilitators to challenge exclusionary perceptions of computing (i.e., it is only for "tech-savvy" white men) by explicitly inviting all learners to engage with the exhibit ("try changing a number!") visitors who would otherwise have novel, playful, and exploratory experiences with computing may walk by the exhibit without even trying it – perpetuating issues of equity in computing education.

Discussion and Conclusion

While several facets of technocentrism are evident in the visitors' interactions, perhaps most notable is the notion that facilitation is not the "point" of an exhibit, as noted by several visitors in our study. This stands in direct contrast with our observations as well as research on the role that facilitators play in promoting enjoyable learning experiences for visitors in science museums and other informal learning spaces (Dawson, 2019; Roque, 2016; Tran, 2007). For Hack the Flock specifically, we believe that the human-human interaction of facilitation is a key factor deepening visitor engagement (median of over 15 minutes), evidenced by the fact that without facilitation, visitors typically spent less than a couple of minutes at the exhibit, or even walked by it altogether.

Our wider concern is that technocentric notions of visitors may limit their participation in computational work. It is possible that visitor comments did not entirely stem from technocentric viewpoints and may have been influenced by other factors, such as uncertainty in the tone of a facilitator (in Finding 1), or their direct experiences working with particular segments of this exhibit's code and not others. But from an ideological perspective (Philip & Gupta, 2020), their implicit assumptions of what "real coding" looks like were also clearly shaping their experiences, which in turn has implications for the power relationships between visitors, facilitators and computing. Future work should involve more in-depth discussions and interviews with visitors around what computing has been, how it is currently viewed, and what it could or should be. These conversations should explicitly discuss design and pedagogical decisions including choice of programming language, the role of facilitators, and the expected types of interaction, in order to address hegemonic notions of computing as anti-social, necessarily difficult, and only appropriate for privileged learners.

Iterative, Reflexive, and Generative Processes of Participatory Design of Arts: Interrogating Racial Ideologies in Design

Shima Dadkhahfard, Miwa Aoki Takeuchi
shima.dadkhahfard@ucalgary.ca, miwa.takeuchi@ucalgary.ca
University of Calgary

Abstract: Set in the context of our study that used digital illustrated stories to evoke the power of artistic renderings for public communication of research, we investigate underlying racial ideologies of the artist/researcher in the illustrations. We transformed our ethnographic findings around subjugated embodied disciplinary knowledge into artistic renderings to initiate discussion with teacher candidate participants on equity in school mathematics teaching. In the process of participatory design of arts, the artist/researcher engaged in multiple conversations with the teacher candidates through iterative redesigns centered on these discussions. Based on video data, interview data and the artist/researcher's reflexive accounts, we examined whether and how the collaboration between the artist/researcher and teacher candidate participants could open spaces for ideological expansion. Our findings demonstrate that iterative cycles of participatory redesign of arts, focusing on racial ideologies, can be generative toward ideological expansions toward equity.

Background

Design is never neutral. From benches in the park to illustrations in picture books, design can discriminate (Benjamin, 2019). Picture book illustrations that children encounter in the early years of their lives can carry problematic racial ideologies such as color blindness, white gaze, and objectifying racialized people through representation (Rogers & Christian, 2007). These ideologies are not static or rigid; rather they are "sense making that stabilizes, challenges, and/or transforms the distribution of material and symbolic resources in society" (Philip et al., 2018, p. 184). From this perspective, ideologies can dynamically change in the course of interactions.

Our study used digital illustrated stories to evoke the power of artistic renderings for public communication – in the context of this study, public communication of critical views on embodiment in mathematics education with teacher candidates. In the normative disciplinary spaces of mathematics, bodies marginalized due to gender, race, and other dimensions of histories of oppression can be subjugated (Takeuchi, 2018). The design of the digital illustrated story was carried out in iterative cycles, by attending to lived experiences shared by the teacher candidate participants, being mediated by the illustration. In this paper, we focus on the negotiation of ideologies enacted in the process of design. Our study was participatory design wherein we critically attended to the power, historicity, and relational dynamics, as provoked by Bang and Vossoughi (2016). Inspired by socially engaged arts (Dewhurst, 2010), we tried to design a visual artifact to open up the conversations on equity in school teaching and learning by depicting lived bodily experiences of schooling (Takeuchi & Dadkhahfard, 2019) previously shared by migrant children. Dimensions of race, power, and politics should be fully accounted for, in the process of participatory design (Vakil et al., 2016). By attending to ideologies that manifest in the process of design, we question the neutrality of designed artifacts and unveil the politics in the design process.

Methodology

Our study was carried out in three interrelated phases. In Phase I, we identified the themes around disciplinary norms in mathematics classrooms, based on our ethnographic findings. The main theme we decided to illustrate involved racialized bodily experiences of migrant children that were censored in the context of institutionalized, in-school mathematics learning (as depicted in textual form by Takeuchi, 2018). In Phase II, in order to challenge such disciplinary norms of the mathematics classrooms, Author 1 (Dadkhahfard) used her graphic design skills to digitally illustrate ethnographic findings described in our earlier works. We decided to make the illustrated story book "wordless" to communicate with audiences from diverse linguistic backgrounds and diverse age groups and the book was repeatedly re-designed. We then used the designed illustrated story in Phase III in the context of teacher education. Interrogating racial ideologies in illustrations was done through iterative cycles of design within Phase II and III. We repeatedly revisited initial illustrations by focusing on racial ideologies (Philip et al., 2018) that are inscribed in multiple versions of illustrations. Reflexivity in the process of participatory design research should be critical. Therefore, we attended to ideologies perpetuating intersectional histories of oppression while also reflecting on "how we see, and how we move differently based on new forms of perception and understanding"

(Bang & Vossoughi, 2016, p. 181). Arts can invite the emergence of reflectivity, but this process could be experienced with emotions including discomfort as designers/artists deeply examine their taken-for-granted perspectives, and ideologies (Skukauskaite et al., 2021). We treat this discomfort experienced by the designer in the iterative process of co-creating arts with the participants as potential resources for ideological expansion (Philip et al., 2018). In our study, we see this reflexive process as potential spaces for value sharing and challenging power hierarchies between artist/researcher and the participants.

We used the illustrated story designed in Phase II in a teacher education course and facilitated conversations about mathematics, equity, and power. The study in Phase III on which this paper is based was conducted in a teacher education program located in a Canadian city and each teacher candidate was specialized in early childhood and elementary school education. A total of 22 teacher candidates participated in the study and five were racialized teacher candidates. Written responses were collected during in-class activity and follow-up interviews were conducted with five teacher candidates. Interviews elicited how teacher candidates interpreted the illustrated story and whether and how they connected or did not connect with the story. They were also asked to discuss mathematics pedagogy depicted in the illustrated story in relation to their future teaching. During the interview, teacher candidates also draw images of how they would continue the story. Each interview was audio and video-recorded. Video was mostly used to capture gestures and drawings and did not capture the faces of the teacher candidate participants to ensure their privacy. After each interview, we wrote detailed field notes and interview data was fully transcribed. After Phase III, Author 1 engaged in the redesign of illustrations iteratively, based on the conversations she had during the interviews. For the purpose of this paper, we use data from Phase II and III and versions of digital illustrated stories designed by Author 1. We ask the following research questions: 1) How did racial ideologies change in the iterative process of participatory art design? 2) How did the collaboration with the participants help facilitate this change? In our findings, where appropriate, we use the first-person account of an artist/designer to address these questions, along with thematic analysis from video and interview data. Analysis was collaboratively done between the two authors to unveil and reflect on potential underlying racial ideologies perpetuated through illustrations.

Findings

Initial racial ideologies

In the initial design, the illustrated story represented the experience of marginalization and differences in slightly abstract ways and did not explicitly depict race by assigning skin colors to migrant students. To show race implicitly and distinguish between migrant students and their peers, instead of representing explicit racial aspects of the characters by skin colors, I (Dadkhahfard, the artist/researcher) assigned two color themes (blue and pink) to migrant students, their parents, and their homes (Figure 1; Panel 1 & 2). I then used black and white for other students to create a clear contrast (Figure 1; Panel 3). By making characters somewhat abstract for their countries of origin or racial backgrounds, I thought that audiences could have more space to come up with diverse interpretations of the difference and marginalization. This might allow them to construct stories related to their own experiences of mathematics learning, inspired by the illustrated story. By making characters without specificities of their countries of origin or racial backgrounds, I also tried to avoid reproducing stereotypes. As an illustrator, I struggled to represent race in my design. Historically, stereotypical, and simplified images of racialized people have been perpetuated in illustrations and picture books (Edmonds, 1986). In this struggle, I chose the color that was "neutral" to me. However, in this process, I perpetuated racial ideologies of color blindness and white gaze in illustrations (as pointed out by Rogers & Christian, 2007).

Figure 1

Abstract Depiction of Race in the First Version of the Illustrated Story Book

Interactions with teacher candidates

We used the illustrated story book in Phase III to facilitate conversations about mathematics teaching, equity, and power with the teacher candidate participants. Some of the racialized teacher candidates talked implicitly about the role of race in mathematics learning and pointed out a problem of the lack of representation on race in the initial illustration. For instance, Betty said "If there's more, like color involved … Looking at it [pointing at the designed illustrated stories], I wouldn't have guessed that the two students were, like, Filipino. You can tell that they're different than the students." Similarly, Dana said, "Students that are reading this wouldn't understand 'Ooh, you're different than me because you're Black.'" In their conversations with me, racialized teacher candidates suggested that I as the designer should make race more explicit in the illustrations to bring forth discussions on equity in mathematics classrooms. They pointed out that the abstract color schemas highlighting migrant students' experiences were interpreted as indicators of differences, but not as representations of racial dynamics. The depiction of race in the form of visual art and its relationship to the evoking conversation around race has received relatively little attention (Dewhurst, 2010). However, the conversations with teacher candidates suggest that explicit racial representation was essential for advancing the discussion on race and inequity in mathematics classrooms. After the conversations with teacher candidates and the deepening of our understanding around depictions of race, we, the Authors, started to engage in iterative inquiry of what it means to illustrate race and racialized experiences.

The redesign process

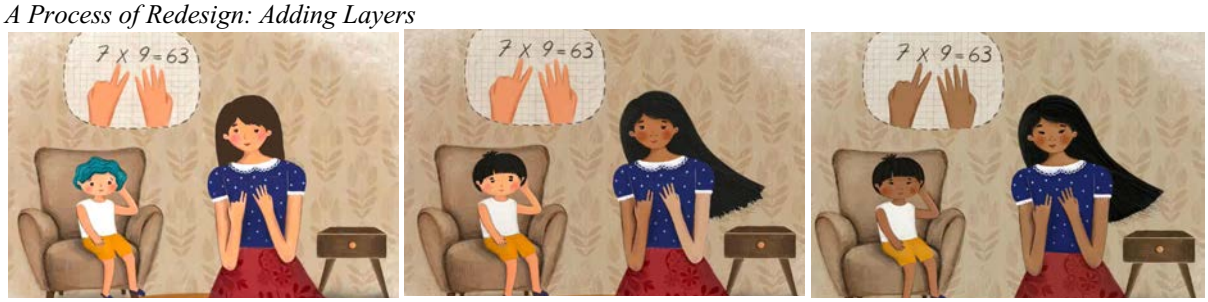
In the second cycle of designing the illustrated story, we started testing different racial representations in the illustrated story. After several back-and-forth attempts at modification, I engaged in watching videos of the participants who were depicted as protagonists in the illustrations with a focus on understanding more about the lived history of these people. I did not focus on skin colors of racialized migrant students but tried to add more complex layers of meaning-making that could depict these students' experiences in the mainstream mathematics classroom (e.g., representing the history of mathematics methods used at home more fully – Figure 2). In the modified illustrated story, I chose to assign color to the characters' skin in complex ways with multiple layers (See the process of adding layers in Figure 3) that were closer to their skin color. However, in this process, we were mindful of not reducing race to skin color. I came to the profound understanding that illustration of racialized experiences in institutional spaces of school should be at the core of the image. In the revision, I focused on racialized migrant children's experiences of being forced to erase and hide intergenerational mathematical knowledge passed on in home environments. I also tried to depict the experiences of subjugation and agency inscribed in racialized bodies.

Figure 2

Depiction of Race in the Modified Version of Illustrated Story Book

Figure 3

A Process of Redesign: Adding Layers



Other considerations for the design to depict racialized experiences are illustrating mothers of color teaching mathematics to their children. This is to counter the history of mathematics that has been constituted as a masculine discipline (Mendick, 2006) that mostly excluded women of color (Leyva, 2016). To counter this hegemonic norm, I described what mothers passed on mathematically to their children (also to be aligned with findings from Takeuchi's (2018) original ethnographic study that was depicted in illustrations).

Scholarly significance of the study

Our study focused on reflexive accounts of an artist/researcher to critically examine her taken-for-granted values, perspectives, and ideologies through her collaboration with participants. Interrogating racial ideology in design can possibly challenge discriminatory design (Benjamin, 2019). Our paper highlights that collaboration with the teacher candidate participants in the iterative process of design can challenge taken-for-granted values, perspectives, and ideologies manifested in the processes. In Phase II, we had to question the neutrality in ideology in our design-based research. Design-based research in the learning sciences were never neutral (Vakil et al., 2016); instead, it can either reinforce or challenge racial ideologies.

Our study depicts iterative, reflexive, and generative processes of designing and redesigning the illustrated story, in order to critically interrogate racial ideologies (Philip et al., 2018) in the process of design. Through ideological expansion afforded in the process of participatory design, we can also move towards designing *tertiary artifacts* that are alternative representations of the world to help us envision the possibilities that are not presently achieved (Wartofsky, 1979). Gutiérrez (2016) discusses the possibilities of designing tertiary artifacts with historical epistemology – the tertiary artifacts that help our "learning to see historically, to imagine new futures for people and their communities" (p. 190). Tertiary artifacts play a significant role in mediating the ways in which influential people like teachers envision the world in new ways. While the scope of this paper was limited to teacher candidates, our future research will depict how racialized parents and children engage in the iterative process of co-designing arts as a way of challenging normative ideologies manifested in mathematics classrooms. This can lead to an envisioning of a more equitable pedagogy in school and beyond.

Argumentation with Summary Tables in Geoscience Learning

Kathryn M. Bateman, Michigan State University, batema34@msu.edu
Brandin Conrath, The Pennsylvania State University, bmc395@psu.edu
Scott McDonald, The Pennsylvania State University, smcdonald@psu.edu
Amy Pallant, The Concord Consortium, apallant@concord.org

Abstract: In this study, we examine the interactions and discourse of a middle school classroom as they use a Summary Table to scaffold the generation of scientific arguments during the implementation of an online plate tectonics curriculum. Creating time and space for scientific discourse provided students with sense-making opportunities around complex science ideas to support their explanations of the phenomenon. The Summary Table scaffolded the development of increasingly sophisticated explanations by structuring students' observations to connect with the driving question of the unit. Specifically, the Summary Table supported small and whole group discussions positioning students to argue and partake in open critique of their claims and evidence in increasingly public ways as they develop sophisticated science explanations.

Introduction

The fundamental vision of Ambitious Science Teaching (AST) is to support students from all backgrounds in understanding core science ideas, participating in authentic science practices and problems, and developing students' ability to learn alone (Windschitl, Thompson, & Braaten, 2018). To achieve this vision, the AST framework incorporates four sets of teaching practices for teachers to invest in as they attempt to make pedagogical shifts in their teaching. One central set is designed for supporting students' evolving thinking, often grounded in public discourse events. Here, the AST framework introduces the Summary Table as a tool to support students' ongoing scientific sensemaking (Windschitl et al., 2018). Summary Tables provide students with a way to structure and organize their thoughts based on classroom discourse regarding an anchoring phenomenon (Windschitl et al., 2018). Students can engage in conversation where they compare ideas in reflective critiques to refine and build new science ideas as they work to complete the Summary Table.

We view this collective critique as a form of argumentation, a subset of discussion with a persuasive nature and necessity of reasonable critics as participants (Shemwell & Furtak, 2010). Students naturally engage in arguments in everyday life, but the AST framework scaffolds students' development of scientific arguments inclusive of talk moves around claims, evidence, rebuttals, and counterclaims (Windschitl et al., 2018). We argue that the framing of the Summary Table includes critical discourse of these talk components that can be instrumental in developing students' explanations and arguments of scientific phenomena. It is with these ideas in mind we ask: In what ways does the use of Summary Tables influence student argumentation?

Methodology

Context

Our study took place in a middle school classroom in the northeastern US, where veteran teacher, Keith (all names used are pseudonyms), taught 82 seventh grade (12- and 13-year-old) students across six classes. Keith was experienced in AST and argumentation, having had ongoing professional learning opportunities in both areas over the past decade through his local college. The summer prior to the study, he participated in a week-long professional learning workshop to support the use of a digital plate tectonics curriculum part of the Geological Models for Explorations Of the Dynamic Earth (GEODE) project. The workshop, designed and facilitated by the authors, centered the Summary Table as a tool for teachers and students to use in developing an explanation of the driving question, "What will Earth look like in 500 million years?" Keith used the Summary Tables in his classroom in iterative phases of small group and teacher-led whole-class discussion. The whole class discussions included negotiating students' ideas into an agreed-upon statement for the class Summary Table which students copied into their science notebooks.

Data and Analysis

Specifically, this study analyzes the classroom discourse associated with the use of a Summary Table during the implementation of GEODE. We captured audio and video recordings of whole-class interactions, audio recordings of small group table talk, video and screen capture of pairs of students using the curriculum, and artifacts produced

 © ISLS

by students, including their Summary Tables and summative scientific arguments (CERs) in their science notebooks throughout 13 90-minute class periods.

To understand how students' interaction with the Summary Table influenced the students' final explanation, we analyzed data from one class period ($N = 24$ students) in four phases. In the first phase, we created event maps (Kelly & Chen, 1999) of the curriculum's implementation to identify the sections of instruction in which the class discourse centered around their Summary Table, resulting in three 90-minute class periods for further analysis. In the second phase, we expanded the event maps; we transcribed discussions to create units of analysis for discrete discourse events in which students discussed a specific scientific idea related to the Summary Table task. We transcribed both whole class and small group talk derived from the conversations of three focus groups of four students who had consented to participate. In the third phase, using grounded theory (Charmaz, 2014), we identified salient themes of ideas that occurred during these discourse events, such as public argumentation and refinement of ideas. Finally, we traced the emergence of these ideas in the discourse through small and whole group talk, students' Summary Tables, and final arguments located within CER Journal entries.

Findings

In this section, we follow the narrative evolution of students working to develop explanations and arguments using the Summary Table. Students collectively refine an observation for the Summary Table, increasing in sophistication during each iteration. Next, the teacher uses talk moves to re-focuses a pair's idea which led to open critique and argumentation in small groups before being brought up during the whole-class discussion. The findings here focus on four students and their teacher, Keith, negotiating an explanation for why some mountains have volcanoes and others do not, one step in explaining the phenomenon of plate tectonics. By following the evolution of this idea through its use in the Summary Table and associated discourse, we see students' explanations increase in sophistication. The structure of the Summary Table document kept track of the different stages of ideas as the students progressed through different activities, instead of requiring them to memorize key observations and claims. We argue that multiple iterations of critique, aided by the structure and documentation of the Summary Table (Figure 1), support the development of students' later arguments.

In a previous class period, students had oscillated between small and whole group discussions to arrive at a class-wide claim of "Everywhere that a volcano forms, you will find earthquakes, but you can find earthquakes alone." Captured in the students' Summary Tables at the end of the lesson, this statement is built upon in the following discussions as part of the patterns and evidence that supports claims about plate boundaries. Here, we illustrate the further evolution of this idea through a case of one small group (Eden, Emily, Cal, and Anna) navigating the relationship between earthquakes and volcanoes through the Plate Tectonics curriculum.

During the Summary Table discussions, students' public thinking was subjected to critique and guidance from other actors in the classroom (peers and teachers) as they argued communal explanations. As the class accepted the observation between volcanoes and earthquakes into the Summary Table, Keith guided students to search for more observations to add to it, building on the relationship between active volcanoes and earthquakes. In their small groups, students split into dyads to explore and discuss. Anna and Eden began looking for connections between the three locations they had explored through the curricular tools (Andes Mountains, Himalayas, and Aleutian Islands), eventually noting that the volcanoes and earthquakes in the Andes are near water (Pacific Ocean) as seen with a data visualization tool. They called Keith over to their table to share the idea. He focused the pair on the types of plates near the Andes and stated there is an ocean plate and a land (continental) plate. Keith then asked about the types of plates near the Aleutians and Himalayas, to which the pair responded with "ocean and ocean" and "land and land" respectively. Although scientific vocabulary around plate tectonics used in this discourse event may be considered unsophisticated, they were building ideas that would likely increase in sophistication (McDonald et al., 2018).

The two pairs at the table were brought back together as Anna interrupted the other dyad (Emily and Cal) at her table, "Emily! You know how in the Aleutians you have ocean and ocean plates? But in the Himalayas, you have land and land. That's why there's not volcanoes [in the Himalayas]!" The foursome then briefly discussed the location of the Aleutian Islands before Cal said, "Wait a second, why does it [the type of plate] matter? 'Cause shouldn't it-." Anna interrupted him and argued, "No, because remember land and land don't cause [volcanoes] because remember when we did the plate (a reference to a simulation in the module), where [we] had two [plates] come together? There were just mountains, there were no volcanoes." Cal then stated that he remembered now and accepted Anna's idea. Anna and Eden's discovery enabled the group to elicit Cal's ideas about plate types, as well as provide Anna with the opportunity to connect her claims to evidence from the module.

When Keith brought the class together to discuss what to place in the Summary Table from their discussions, Anna was the first student to publicly offer an idea, exuberantly waving her hand in the air. She claimed,

> Okay, so what we noticed is that most of the volcanoes are near water. So, then when we did the globe thing [simulation of plates interacting], where we tried to make the Aleutians, we did an ocean and ocean plate, which caused islands of volcanoes. But then we did a land and a land coming together, it didn't [form volcanoes].

In response to this, Keith pressed the whole class to develop a grounded claim for the Summary Table based on Anna's idea, specifically thinking about each of the observed plate interactions. Eden said, "Well for the Andes it's land and water plates but for the Aleutians, it's water and water." Keith began to document these ideas as generalized claims within the Summary Table. As he continued to revoice Anna's ideas, Keith moved away from the use of phrases like "water ones" using the more scientific term, oceanic plates. He documented these refined ideas into the Summary Table's overall claim for the activity (see Figure 1), which served as a connection to the driving question of the unit. Rather than discussing their reasoning as a class, each student used the class claim from the Summary Table as a claim within their CER Journal (see Figure 2), giving them a chance to make an individual argument for the activity while collecting additional evidence from the module.

Figure 1

Summary Table entry for Activity 2

Activity	What patterns did we observe? What observations did we make?	What is causing those patterns or observations?	How does this help us understand the earth and what it will look like in the future?
Module 2 - Interrupting Earth's clues	Everywhere that a volcano forms you will find earthquakes **but** you can find earthquakes alone Trenches occur next to volcanic islands Trenches occur next to volcanic mountains Earthquakes occur shallow near trenches and deeper under the volcano as they move farther inland Earthquakes occur at depths less than 200 in the Himalayas		When plates converge (come together) earthquakes and mountains occur. • oceanic and continental results in volcanic mountains and a trench • oceanic and oceanic results in volcanic islands and trench • continental and continental results in **NON** volcanic mountains no trench

Figure 2

Anna's CER Journal – Students annotated their reasoning using the following color codes: Green indicates new science terms, blue indicates thoughts related to the driving question, red indicates questions students have, and purple is where edits/additions were made in later lessons. The yellow highlight added by the student was not part of the class color coding.

Claim	Evidence	Reasoning
When plates come together (converge) earthquakes and mountains occur. • Oceanic and continental results in Volcanic mountains and a trench • Oceanic and Oceanic results in Volcanic Islands and trench • Continental and Continental **NON VOLCANIC** Mountains, and **NO TRENCH**		The elevation goes up when you have an oceanic plate and a continental plate or if you have two oceanic plates. We see this in the Andes mountains and the Aleutian islands because one plate goes on top of the oher one and the other plate goes in a downward way which causes a trench and a mountain. When you have continental plate and a continental plate it won't just push up it like crumbles. In the pictures the ones where you see more of the volcanoes it is near water. The earthquakes are more deeper closer inland or under the volcano and the ones that are more near the water and the trench are more shallow and you can tell because of the colors of the dots. The picture of the Himalayas only has one volcano. Since there is only one volcano in the himalayas it is probably not active any more. How come you don't have as many volcanoes when there is two land plates? When two plates are **Converging** one plate is going under the other and that process is called **Subduction**.

Throughout the evolution of this idea, we saw that students participated in open argumentation around their ideas. Within small group talk, we saw an instance of hesitation when Cal did not agree with Anna's idea, to which Anna argued her position citing direct evidence from the module (Shemwell & Furtak, 2010). As Anna

 © ISLS

argued her position, Cal was able to gain insight into Anna's conceptions and reasoning, seeing a different perspective to establish the communal idea. Anna's ideas then were critiqued in her interaction with Eden, their sharing with Keith, and her debate with Cal, before sharing with the whole group. The Summary Table, scaffolded by Keith's classroom discourse culture, provided three opportunities for Anna to express her idea, receive feedback, and develop a deeper understanding.

We also highlight that Keith served a critical role in focusing and revoicing the students' developing ideas as he used AST teacher talk moves to focus the students' talk to his intended curricular goal of completing the Summary Table (Windschitl et al., 2018). First, we see him situate students to engage in peer-to-peer talk in dyads. When he visits the small groups, he presses students to expand their ideas in pattern finding to bring the notion of types of plates to their explanation. Finally, in the whole group discussion, Keith uses revoicing to bring students' everyday language together with scientific language, such as connecting "water ones" with "oceanic plate." Together, Keith's use of talk moves and the Summary Table supports students' development of scientific explanations for the phenomenon.

Conclusion

Our findings illustrate that creating time and space for scientific discourse provided students with sense-making opportunities around complex science ideas to support their explanations of the phenomenon. The Summary Table scaffolded development of increasingly sophisticated explanations by providing a structure for students to discuss and connect ideas with the driving question of the unit (Windschitl et al., 2018). Specifically, the Summary Table supported small and whole group discussions positioning students to both construct and critique ideas in diverse public ways (Ford, 2008). Ideas which were made public (small or whole group) were able to be debated to improve upon the idea before it became part of students' explanations at the end of the activity (Duschl & Osborne, 2002). Furthermore, the process of publicizing thoughts provided students with access to the conceptions and reasoning of the teacher and students in the class (Windschitl et al., 2018). This allows them to experience unfamiliar perspectives of complex ideas and develop communal explanations of scientific phenomena. However, talking in small groups does not eliminate the non-normative explanations from arguments, as students may not have the knowledge and skills to recognize the inconsistencies in their peers' arguments. Using the findings of Berland and Lee (2012) we see this as less concerning, as students have multiple opportunities for construction and critique of ideas in the iterative classroom discussions supported by the organizational of the Summary Table. This study shows the importance of critical talk between students and teachers framed by the Summary Table. We argue that the Summary Table scaffolded classroom discourse around complex phenomena in ways that supported the development of increasingly sophisticated scientific explanations.

The Effect of Weekly Writing and Peer Reviewing Upon Students' Writing Competence

Min Hae Song, Jaeseo Lim, Jooyong Park
suru0224@snu.ac.kr, jaeseolim@snu.ac.kr, jooypark@snu.ac.kr
Seoul National University

Abstract: The importance of writing competence is being emphasized in society. One way to enhance undergraduates' writing competencies is to increase the number of WID (Writing in the Disciplines) classes. In order to introduce more WID classes and give students more opportunities to write, Park (2017) proposed a class method that utilizes writing and peer reviewing as a preparatory activity. The aim of this study was to find out whether Park's method can improve students' writing competence. Writing performances of thirty-three undergraduates in ten writing assignments were assessed by two raters based on two criteria of 'insight' and the 'flow of writing'. The results showed that the writing performance of students at the end of the semester was significantly higher than that of the students at the beginning of the semester. We hope this study provides a rationale for the expansion of writing education.

Introduction

Writing is an effective tool that allows people to share their events, or feelings, and thoughts with others. Since most of the work conducted in an organization is carried out in teams, the importance of writing, which enables clear communication, is being emphasized. For example, employees spend more and more time on using email and messages, and Amazon holds executive meetings based on six-page reports instead of using presentation slides (Cross & Gray, 2013). In this context, universities endeavor to enhance the writing skills of their students through writing education. Nevertheless, the writing skills of college graduates still do not meet the standards expected in society (National Association of Colleges and Employers, 2010).

In order to enhance students' writing competencies, improving the quality of current writing education as well as providing students with more opportunities to write is needed. One way to do this is increasing the number of WID (Writing in the Disciplines) classes, which are classes that teach writing skills within academic disciplines. This is because increasing the number of classes that teach only writing skills increases the burden on students and makes it difficult to teach appropriate writing for each discipline. Introducing more WID classes in universities can overcome this problem and allow students to organize what they learned in classes in writing, thereby helping them acquire knowledge and develop thinking skills in a balanced manner (Carter et al., 2007).

The reason why WID classes are seldom used despite their high learning effect is a greater burden on the instructors compared to lecture-centered classes. In WID classes, instructors are required not only to teach the learning material but also to select appropriate writing assignments and to assess and give proper feedback. Evaluating and providing feedback to students' writing assignments require more time than other assignments or tests because the content as well as the flow and the structure of the writing needs to be assessed (Herrington & Cadman, 1991). Therefore, some instructors in WID classes either fail to provide appropriate feedback promptly or only give minimum writing assignments to students (Kellogg & Whiteford, 2009).

One way of providing students with frequent writing assignments and feedback in WID classes by reducing the burden on the instructors is to introduce peer-assessment. The effectiveness of the peer-assessment was confirmed through several studies. The quality of the final writing assignments improved when they revised based on feedback from peers. (Liu & Carless, 2006). Also, another study showed that students who received feedback from their peers wrote a similar or better final report than students who received feedback from one expert only (Cho et al., 2008). Another advantage of peer-assessment is that it helps students understand the class content more deeply (Falchikov, 1986). Therefore, introducing peer-assessment to WID classes can reduce the burden of instructors while also enhancing students' learning (Liu & Carless, 2006).

Peer-assessment is usually used in WID classes in which students are required to write four to six-page long essays two or three times per semester. Two or three peer assessments per semester are helpful for students. However, providing only two or three writing tasks and peer-assessments per semester leaves a wide interval in between assignments, which makes it difficult for students to relate the content learned in class to their writings. In this context, Park (2017) proposed a WID class method in which students are required to write essays related to the content to be learned in the next class and to review each others' essays as a preparatory activity every week.

The WID class method developed by Park (2017) has a high learning effect since it includes the three components of effective learning, repetition, spacing, and retrieval (Yeung et al., 2021). Park's WID class method

 © ISLS

makes students learn a topic iteratively with moderate timing through a series of activities: reading, writing, and reviewing others' writings before class, discussing and taking a lecture during class, and finally revising their essays. These whole activities enable frequent retrieval and can also help enhance students' writing skills. However, whether this class can enhance students' writing skills has not yet been verified empirically. In this study, we tried to confirm this possibility by analyzing students' writing assignments from the actual class.

WID Class Method

The Park (2017)'s class method consists of three activities: a preparatory activity including writing and peer-assessment, a class activity with lectures and discussions, and a review activity through revising. First, a week before the first class of the week the instructor provides a writing assignment based on a part of the textbook to be covered in class and related learning materials such as recent research papers or articles. Criteria for peer-assessment, are also given. Students are required to upload a one-page essay along with the questions they had, to the online peer-review system until the night before class. The essays are distributed anonymously to all students, with each student allocated with four other students' essays. Students are required first to assess and provide feedback to the four essays anonymously, then to assess their own essay.

After completing the preparatory activity, students attend 75-minute classes, which are held twice a week (Monday and Wednesday). On Monday, the instructor gives a detailed lecture on the content covered in the preparatory activity. On Wednesday, students have a discussion on the questions selected by the instructor from the whole uploaded questions. To ensure that all students actively participate in the discussion, the instructor divides students into small groups of three or four. The discussion lasts for 50 minutes, and for the remaining time, the instructor asks students to share what they discussed and gives answers to questions that were not solved. From the end of the class on Monday to Friday evening, students evaluate how helpful the feedback they received was, while also revising their own essay based on what they learned from class and the feedback. The above process is repeated every week for a total of thirteen weeks, excluding the weeks for midterm and final exams.

Method

Participants

Thirty-three undergraduates in a university in Seoul, Korea participated in this study. All participants were from "Introduction to Psychology" course in the spring semester of 2018 and consented for participation before the study, which was approved by the university's Institutional Review Board (IRB No. 1805/002-006).

Writing assignment

In this study, ten out of the thirteen writing assignments written by thirty-three participants were analyzed. In the "Introduction to Psychology" course, students were required to write a one-page essay as a preparatory activity every week for a total of thirteen weeks during a fifteen-week-semester. The writing assignment required not only understanding the given papers and textbooks, but also high-order thinking. For example, in the week teaching educational psychology, textbooks explaining the principles of educational psychology and papers related to gamification were provided. Students then summarized the content and presented their ideas and opinions about what psychological points need to be supplemented for gamification to be more effective. Among thirteen assignments, three assignments (assignments for week 1, 8, and 13) were excluded from the analysis. The reason for the exclusion was that in week 1, 8, and 13, more than half of the students did not submit the writing assignment, making a comparison between such assignments and assignments from the other ten weeks difficult.

Evaluation criteria

Both the peer-assessments by the students during preparatory activity and measurement of writing performance of students in this study used the same evaluation criteria: 'insight' and 'flow of writing' on a 7-point Likert scale. The 'insight' criterion measured the novelty of the ideas and criticisms presented in the essays. The 'flow of writing' criterion assessed how well the essay was organized and how well it was easily readable.

Analysis

In order to find out whether the WID class method proposed by Park (2017) was effective in improving writing competencies, the writing performance from the ten writing assignments was analyzed. The writing performance was evaluated by two raters based on the two criteria and then the average score of two assessors was used in the analysis. All evaluation was conducted after the end of the semester without any knowledge regarding who the writer is. Also, in order to prevent the order effect, raters evaluated the writing assignments in

a random order, so that neither the order of students nor the order of the week the assignment was given was repeated. Also, the assessors' agreement measured by ICC was higher than .7 which means that the results of the two assessors' ratings can be sufficiently trusted. Therefore, we used the average score of two assessors to confirm the change in the writing performance of each week, and then conducted a t-test to compare the difference between the writing performance in the first two weeks (week 2 and 3) and that in the last two weeks (week 11 and 12).

Method

Table 1

Mean and Standard Deviation of Writing Performance, 'Insight' and 'Flow of Writing' Score of Each Week

	Number of Essays	Writing Performance	Insight	Flow of Writing
Week 2	29	8.034(*SD*=1.700)	4.069(*SD*=1.132)	3.966(*SD*=1.117)
Week 3	30	8.121(*SD*=1.139)	4.071(*SD*=.825)	4.125(*SD*=.824)
Week 4	28	8.625(*SD*=1.425)	4.464(*SD*=.962)	4.161(*SD*=.695)
Week 5	30	8.367(*SD*=1.852)	4.267(*SD*=1.065)	4.1(*SD*=.968)
Week 6	29	8.371(*SD*=1.323)	4.081(*SD*=.828)	4.290(*SD*=.656)
Week 7	31	8.375(*SD*=1.442)	4.0(*SD*=.833)	4.375(*SD*=.751)
Week 9	29	8.45(*SD*=1.700)	4.101(*SD*=1.321)	4.34(*SD*=.942)
Week 10	29	9.257(*SD*=1.704)	4.657(*SD*=.856)	4.6(*SD*=.976)
Week 11	30	9.086(*SD*=1.396)	4.603(*SD*=.828)	4.483(*SD*=.726)
Week 12	28	9.304(*SD*=1.853)	4.643(*SD*=.922)	4.661(*SD*=1.046)

The mean and standard deviation of the students' writing performance for each week are shown in Table 1. As can be seen from Table 1, students' writing performance in week 2 and 3 was about 8.2 points, which was close to the average. However, in week 11 and 12, which were almost at the end of the semester, the writing performance improved to 9.3 points. Also, the average scores of 'insight' and 'flow of writing' were about 4 points in the beginning, but they improved to 4.6 points at the end. In order to figure out whether the students' writing performance has improved through this WID class, the difference between the writing performance at the beginning and those at the end of the semester was analyzed by the t-test. Before comparing the writing performances of students at the beginning with those at the end of the semester, the difference in scores between the two weeks at the beginning of the semester and the difference in scores between the two weeks at the end of the semester were analyzed first. A t-test revealed that there were no significant differences ($t(55) = .377$, $p = .708$, $d = .060$; $t(49) = .267$, $p = .791$, $d = .133$). This shows that the students performed the writing tasks at a similar level in the first two weeks and the last two weeks respectively, even though topics for each week were all different. Then, we compared the average writing performance of the first two weeks and that of the last two weeks to verify the effectiveness of the WID class method. The results showed that the average writing performance of the last two weeks was significantly higher than that of the first two weeks ($t(112) = 3.559$, $p < .001$, $d = .667$; $M = 9.193$ vs. 8.114). We also conducted a t-test on each criterion: 'insight' and 'flow of writing'. 'Insight' and 'flow of writing' scores of the last two weeks were significantly higher than those of the first two weeks ($t(110) = 3.181$, $p = .002$, $d = .596$; $t(111) = 2.998$, $p = .003$, $d = .562$). These results show that the whole series of processes of the suggested class method can help enhance students' writing competencies.

The above results suggest that the WID class method using writing and peer-assessment as a preparatory activity improves students' writing competencies. Although there was little feedback on the writing assignments from the instructor in this class, the writing performance improved significantly by just providing opportunities to write and review each others' writing assignments. In conclusion, the WID class method of Park (2017) can help improve the writing competencies of students while reducing the burden of evaluation on instructors.

Discussion

The importance of writing, a useful tool for developing thought and sharing ideas, is being emphasized in education as well as in organizations. However, it is difficult to witness major changes aimed at improving writing education. This study introduced a new WID class method proposed by Park (2017), which utilizes peer reviewing as a preparatory activity, and verified its effectiveness. The WID class method proposed by Park incorporates the three components confirmed to be effective in achieving higher learning effect, repetition, spacing, and retrieval. Every week, students study the learning material, write an essay, ask questions, and review other writings before class. During class time, students take a lecture and then discuss with other students. After class, students are required to revise their essays. In order to verify whether the process of this proposed WID class method could improve the writing skills of students, we analyzed the essays from the actual class.

The analysis of ten different writing assignments each performed by thirty-three students showed that the students' writing performance improved significantly at the end of the semester compared to the beginning of the semester. Not only did the 'insight' scores related to class content but also the 'flow of writing' scores related to writing skills improved. Although an absolute comparison of writing performance was difficult since each writing assignment had a different topic, nevertheless the result showed that making students write essays and review peers' essays as well as their own every week throughout a semester helps students write better. Also, considering that such results were obtained with minimal feedback from the instructor, the proposed WID class method can be easily adopted in the educational scene.

The effectiveness of the Park's WID class method can also be supported by the lecture evaluation conducted by students at the end of the semester. More than half of the students stated in the lecture evaluation that the weekly preparatory activity helped them become more accustomed to writing and improve their writing skills. The results of this study may be self-evident, which is that students' writing competencies improved after they wrote essays every week and reviewed each other's essays. However, a point worth noting is that the aforementioned result was achieved with minimal intervention from the instructor.

However, further studies are needed before introducing the Park's method to various educational fields. First, more objective methods for evaluating the writing performance of students are needed. For example, comparing the results from group who were taught with the Park's WID class method with results from a control group taught with a different method can re-verify the effectiveness of the proposed class method. Another room for further development is to increase the credibility of peer-assessment. Some students pointed out in their lecture evaluation that they could not fully trust the evaluation and feedback given by other students. Thus, methods to improve the credibility of peer-assessment should be developed to apply Park's method in various fields.

Despite the above, this study revealed that improving writing competencies via frequent writing and peer reviewing can be achieved without intervention from the instructor. If the effect of the WID class method proposed by Park is re-verified through further studies, we expect that it can be adopted in various educational fields. In conclusion, we hope that this study and follow-up studies will contribute to the development of the proposed class method, and that students' writing skills are improved as universities widely adopt the method.

Investigating the Relationship Among Solution Quality, Group Variability in Science Confidence, and Reciprocal Participation in Online Science Collaborative Problem-Solving Tasks

Arif Rachmatullah, Nonye M. Alozie, Mindy Hsiao, Hui Yang, and Anirudh Som
arif.rachmatullah, maggie.alozie, mindy.hsiao, hui.yang, anirudh.som@sri.com
SRI International

Abstract: The current study examines how group variability in science confidence interacts with perceived reciprocal participation to influence group's solution quality. Thirty-five groups of four adults worked collaboratively on nine science tasks in an online synchronous setting. Surveys were used to gather data on each member's science confidence level and perceived reciprocal participation. We found a significant interaction effect of group variability in science confidence and reciprocal participation on solution quality. Further analyses showed that for groups with low variability in science confidence, the more variability in reciprocal participation, the lower the solution quality they generated. However, the finding for the groups with high variability in science confidence was the opposite – the more variability in reciprocal participation, the better solution quality they generated. The current study underscores the importance of science confidence in collaborative problem-solving activities.

Introduction

Research has suggested the importance of exposing students to numerous collaborative problem-solving tasks in science classrooms. Such activities positively influence learning outcomes (Bungum et al., 2018) and other crucial skills, such as metacognitive self-regulation (Chen & Chiu, 2016) and scientific argumentation (Nichols et al., 2016). However, several studies have acknowledged the challenges of implementing effective collaborative problem-solving because it relies on several factors. Research has indicated that enabling effective collaborative problem-solving relies on (a) group composition (e.g., Kallery & Loupidou, 2016); (b) students' individual and shared learning regulation (Järvelä & Hadwin, 2013); (c) relational and communication skills (Kutnick & Blatchford, 2014); and (d) levels of scaffolding provided for students (Chen & Chiu, 2016). In the current study, we focused on how group composition— particularly the heterogeneity of group members' science-confidence levels—interacts with perceived reciprocal participation (i.e., group members' perceptions of their contribution in providing and receiving clarification, feedback, and help during collaborative problem-solving) during collaboration to influence the groups' quality of solutions.

Several studies have explored heterogeneity's influence on group performance (e.g., Kallery & Loupidou, 2016). However, little is known about the interaction effect of group variability in science confidence and perceived reciprocal participation on the quality of solutions generated collaboratively. Based on the socio-cognitive theory of learning, confidence in an academic subject or content area influences and is influenced by cognitive ability or prior knowledge (e.g., understanding of scientific concepts). Consequently, in a science collaborative problem-solving setting, productive scientific argumentation and discussion are desired and have been found to depend on prior knowledge, confidence, and familiarity with science topic areas (Grooms et al., 2018). Thus, members' science confidence is integral in such a collaborative setting.

In the current research, we conducted a clinical study with 35 groups of four adult individuals working collaboratively on nine science tasks in a synchronous online environment. We aimed to gain more evidence on how heterogeneity in science confidence interacts with reciprocal participation to influence solution quality. The three research questions guiding this study are as follows: (1) To what extent does group variability in science confidence correlate to solution quality generated through collaboration?; (2) To what extent does group variability in perceived reciprocal participation correlate to solution quality generated through collaboration?; and (3) Does the interaction of group variability in science confidence and perceived reciprocal participation affect the solution's quality generated through collaboration?

Methods

Participants and Context. A total of 35 groups with four members each participated in the current study. We recruited these adult participants (age M = 30.88, SD = 11.88) via email. They comprised a broad range of occupations: graduate students, freelancers, engineers, teachers, attorneys, and retirees. Demographically, 60% of the participants were female, 26% male, and 14% identified as non-binary. In addition to gender, 40% of the

 © ISLS

participants were White, 31% Asian, 21% Hispanic/Latinx, 6% Black/African American, 1% Native American, and the remaining 1% identified as Other. Of these participants, 37% reported speaking one or more languages other than English at home. Regarding group information, 60% of the groups were mixed gender, and 69% were multi-racial. In addition, 71% of the groups had at least one multilingual member. The groups collaborated for a total average of 45 minutes to solve nine science tasks. Each group collaborated in a synchronous online environment through the video conferencing platform Zoom.

Scoring Solution Quality and Instruments. The participants completed two surveys: one before collaborating and another when finishing. The science-confidence data of each participant were collected as part of the pre-collaboration survey, and the perceived reciprocal participation data were collected as part of the post-collaboration survey. **Science Confidence**. We asked participants to rate their confidence in five science concepts: photosynthesis, cellular respiration, energy and matter, ecosystem, and earth and space science. **Perceived Reciprocal Participation**. We adopted an instrument developed by Dewiyanti et al. (2007) to measure each participants' perceptions of their reciprocal participation during collaboration. An example item included "I asked for an explanation if other group members gave unclear feedback." The instrument had a Cronbach's alpha value of .841, indicating satisfactory reliability. To obtain the data on group variability in science confidence and perceived reciprocal participation, we calculated the standard deviation (*SD*) based on the four participants' average scores. We used this *SD* value for each group to define the group variability in science confidence and perceived reciprocal participation. **Scoring Solution Quality**. We developed a rubric, and two coders scored the solution quality together. Any disagreements were discussed until they reached a consensus. Hence, we did not compute any inter-coder reliability. **Covariate: Variability in Group Working Opinion**. We wanted to control for group variability in the group working opinion. Participants' group working opinions were measured with an instrument using developed by Dewiyanti et al. (2007). Scale item included "Working in a group is motivating" and "Working in a group is challenging" (reversed item). This instrument had a Cronbach's alpha of .848.

Data Analysis. Pearson's correlation test was run to observe the associations among the variables. The results from these correlation tests were used to answer RQ1 and RQ2. We used multiple regression tests to answer RQ3. Two regression models were tested. Model 1 consisted of all variables without an interaction effect. Model 2 consisted of all variables in Model 1 and an interaction effect of group variability in science confidence and perceived reciprocal participation. If we identified an interaction effect, we then used Model 2 to generate the graph of interaction effect on the dependent variable (i.e., group solution quality score).

Table 1

Full Regression Models: with and without an Interaction Effect

Variable	Model 1: Without Interaction Effect			Model 2: With Interaction Effect		
	b	*t*	*p*	*b*	*t*	*p*
Intercept	85.60	17.90	< .001	95.54	19.44	< .001
GV in Age	0.03	.20	.842	0.11	0.78	.444
Group Mixed Gender Status^S	-2.54	-1.68	.105	-2.54	-1.89	.070
Group Ethnically Diverse Status^S	2.99	1.89	.070	3.66	2.56	.017
Multilingual Member(s) in Group^S	-0.36	-0.23	.821	-0.04	-0.03	.980
GV in Science Confidence	-1.76	-0.45	.656	-21.04	-2.77	.010
GV in Group Working Opinion	3.06	0.56	.581	3.62	0.74	.465
GV in Perceived Reciprocal Participation	-5.81	-2.22	.035	-21.35	-3.61	.001
GV in Science Confidence x GV in Perceived Reciprocal Participation	-	-	-	37.11	2.85	.008
R (R_{adj})	.28 (.10)			.45 (.29)		
F-value *(df)*	1.53 (27)			2.71 (26)		
p-value	.201			.026		
ΔF (Δdf)	-			1.18 (1)		
p-value for ΔF	-			.391		

Findings

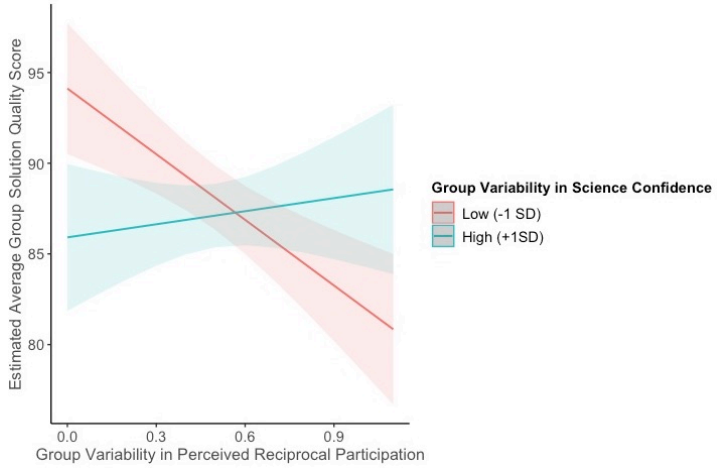
Based on the correlation tests, we found that group variability (GV) in Science Confidence did not significantly correlate with the Group Solution Quality Score (r = .09, p > .05). However, we found that GV in Perceived Reciprocal Participation significantly correlated with Group Solution Quality Score (r = -.34; p = .045), and the

 © ISLS

correlation coefficient was negative. These findings hence answered the first and second research questions. Following these results, regression tests were run, and the results are presented in Table 1. First, a regression model without interaction effect (Model 1) was performed first to investigate the main effect of each predictor, including the covariates. Based on Model 1, only GV in Perceived Reciprocal Participation was the significant predictor ($p < .05$) of Group Solution Quality Score. In Model 2, we found a significant interaction effect of GV in Science Confidence and GV in Perceived Reciprocal Participation on Group Solution Quality Score. We also found that Group Ethnically Diverse Status positively predicted Group Solution Goal, indicating that the more ethnically diverse a group, the better the group's solution quality. Figure 1 illustrates that for a group with low variability in science confidence (i.e., group members have relatively similar science confidence), the greater the variability in perceived reciprocal participation (i.e., group members had differing perceptions of their own reciprocal participation), the lower group-solution quality the group generates. However, these variability results did not show whether participants had high vs. low science confidence—low variability could be attributed to two cases: all group members had high science confidence, or they all had low science confidence. Thus, we investigated further by calculating the aggregate mean of group scores on science confidence. The result was 1.96 out of 3 ($SD = 0.25$), indicating that most groups had relatively moderate-high science confidence.

Figure 1

The Interaction Effect between Group Variability in Science Confidence and Group Variability in Perceived Reciprocal Participation on Group Solution Quality Score (Based on Model 2)



Regarding the group with high variability in science confidence, we found that the greater the variability in perceived reciprocal participation (i.e., group members had differing perceptions of their own reciprocal participation), the better solution quality the group generates. In addition, based on Figure 1, the results also implied that groups with low variability in science confidence (i.e., all group members have relatively similar science confidence) and low variability in perceived reciprocal participation (i.e., all group members have relatively similar perceptions of their own participation during collaboration) would generate the best solutions. Again, low variability in perceived reciprocal participation can consist of two cases: either all group members think they actively participated, or all group members do not think they actively participated. Thus, we followed up by calculating the aggregate mean of group scores on perceived reciprocal participation. The average was 3.75 out of 5 points ($SD = 0.33$), indicating that most participants believed they actively participated during the collaboration. Therefore, for the context of the current study, both low group variability in science confidence and perceived reciprocal participation can be interpreted in the context of high confidence and high reciprocal participation groups.

Discussion and conclusion

The current study's primary purpose aimed to uncover the interaction effect of GV in science confidence and perceived reciprocal participation on solution quality generated in a series of science collaborative problem-solving activities. Our study findings suggest two types of group configuration that can be adopted to maximize the solution quality generated collaboratively. The first configuration is when all students in a group have the same level of science confidence (particularly, relatively high) and when all students also have relatively similar chances to participate during the collaboration process (clarifying and providing feedback). Such a group would

be the one that generates a better-quality solution. This type of group composition may also create what González et al. (2003) called group cohesion characterized by social and task cohesion.

The second group configuration that may maximize the solution quality is when a group comprises members with different levels of science confidence and when the members have different chances to participate. This configuration allows group tutoring. Thus, members with higher science-confidence levels (presumably higher science knowledge) have more opportunities to explain and clarify concepts to members with lower science-confidence levels (and presumably lower science knowledge). Therefore, in this kind of group configuration, a relatively steep learning curve arises for the members with lower science confidence, which allow the groups to engage in activities that maintain productive struggle events leading to a better solution quality.

Although the current study was situated in a laboratory setting, we believe that our findings have implications for both K–16 and professional education. For instance, when science teachers implement collaborative learning in a formal K–12 setting, they tend to create student groups based on students' varying levels of science knowledge. Although assessing student science knowledge at the beginning of units is sometimes logistically feasible, teachers often lack sufficient time to gather students' conceptual understanding; diagnosing students' knowledge is labor-intensive. Instead, teachers can use one simple question that asks them to rate their confidence in the science concepts to be learned. Student groups can then be formed based on this confidence level. If students form their own groups after teachers gather confidence-level information, the teachers can also guide these student groups to ensure cohesion is maintained.

We urge the readers to carefully interpret the findings due to several limitations. These limitations include but not limited to study's context, which is situated in a laboratory setting, and small sample size. For future studies, we believe that conducting qualitative analysis and presenting episodes of how members of a group based on science confidence interact during science collaborative problem-solving activities. We believe such data and analysis can substantiate the current study findings.

Surfacing Collective Pedagogical Content Knowledge for Data Literacy: An Exploratory Study with High School Science Teachers

Katherine M. Miller, Susan Yoon, and Jooeun Shim

University of Pennsylvania

Abstract: There is a need for greater focus on the critical aspects of data literacy at the high school level. However, data literacy requires explicit integration between math and science, which high school teachers often aren't experienced with. Thus, teaching data literacy may require different PCK than that typical for high school science. This study adds to underrepresented research on PCK for data literacy by engaging a group of experienced teachers in collaboratively attempting to define PCK for data literacy through discussing their experiences implementing a unit designed to support the development of data literacy in students. Three components of PCK for data literacy are surfaced and examined.

Introduction

In our data-rich world, there are strong calls for greater focus on data literacy as increasingly, 21st century jobs require some level of data literacy (e.g., Gould et al., 2016). Rubin (2020) identifies five critical aspects of knowledge for working with data: a) *data in context*, b) *variability of data*, c) *data in aggregate*, d) *data visualization*, and e) *inferences with data*. For the purpose of this study, a sixth critical aspect highlighted by Kjelvik and Schultheis (2019) has been added: f) *complexity of data sets*. These six critical aspects of data literacy serve as a foundation for what students should know about how to work with authentic data. There has been limited research on pedagogical best practices for teaching data literacy, especially through authentic, complex, messy data (Gould et al., 2016; Mike, 2020). However, Nadelson and Seifert (2017) discussed the importance of highlighting the interdisciplinary nature of data, with connections between math and science classes made explicit. This sort of content integration is not something that high school teachers are often experienced or supported in doing (Kelley & Knowles, 2016), especially when it comes to engaging students with complex authentic data (Kjelvik & Schultheis, 2019). Thus, teachers need support in identifying the pedagogical content knowledge (PCK) required to support student learning with and about data (Kelley & Knowles, 2016). Though some research has been done on PCK for STEM integration (e.g., Vossen et al., 2020), PCK for data literacy is an under-explored concept (Mike, 2020). This study builds on a larger study on integrating bioinformatics lessons into high school science classrooms using student-collected data. We work with a small group of experienced teachers to collaboratively examine their understanding of PCK for data literacy using established methods of surfacing PCK (i.e., content representations and video reflections). This exploratory study seeks to answer the question: what are some components of PCK for data literacy in high school science classrooms?

Background

High school science teachers often have not been given the time or resources to engage students in full authentic investigations which address the interdisciplinary nature of data and as such they may need support in determining the best pedagogical strategies (Gould et al., 2016; Nadelson & Seifert, 2017). Currently very little is known about what PCK for teaching with and about data looks like and what sort of experiences are needed to support it (Gould et al., 2016; Mike, 2020). PCK is defined as the "special amalgam of content and pedagogy that is uniquely the province of teachers" (Shulman, 1987, p. 8) and has been shown to be subject and even topic specific (Smith & Banilower, 2015). As such, PCK for data literacy may require knowledge that is distinct from that which science teachers already hold. The science education community has outlined a model for PCK that identifies three levels of PCK that interact with each other: collective, personal, and enacted, where collective PCK encompasses the common knowledge held by a group of teachers made up of an amalgamation of their personal knowledge and experiences with enaction (Carleson & Daehler, 2019). Additionally, PCK has been shown to be composed of distinct components (e.g., Park & Chen, 2012), the two most commonly studied of which are *knowledge of student understanding*, and *knowledge of teaching strategies*.

Studies have shown that working collaboratively allows teachers to surface deeper and more nuanced PCK (Nilsson & Loughran, 2012; Vossen et al., 2020). Research that has supported teachers in successful identification and growth of PCK often uses one or both of two methods: content representations (CoRes) and video reflections. A CoRe is a template which prompts a teacher or group of teachers to think about teaching a particular topic through big ideas with questions such as: *Why is it important for students to know this? What else*

 © ISLS

do you know about this idea that you do not intend students to know yet? What is your knowledge of students' thinking which influences your teaching of this idea? Studies have found that enabling teachers to make their practice, and their thinking on their practice visible allowed them to then reflect effectively on that knowledge (e.g., Vossen et al., 2020). Using a CoRe as an artifact allows teachers to develop a shared language around the content knowledge and the PCK for teaching a particular topic (Nilsson & Loughran, 2012). Engaging in video reflections prompts teachers to examine and make visible their thinking while enacting a lesson. By combining CoRes and video reflections on data literacy lessons, this study hopes to support a small group of experienced science teachers in surfacing PCK for data literacy.

Methods

Context

This exploratory study exists within the larger context of an intervention designed to support teachers in implementing a STEM-integrated problem based learning unit on bioinformatics in their science classrooms. The unit uses mobile learning through portable air quality sensors connected to a phone app to engage students with active collection of real-world data to address the provided problem of asthma rates in urban areas. The intervention included a summer professional development which took place over four weeks during July 2021, conducted asynchronously on the edX testing platform called Edge. After the summer course, four participating teachers were invited to participate in a PCK Extension Workshop Program which would focus explicitly on PCK. The extension program consists of approximately 20 hours of workshops spread over fall and winter 2021 while teachers are actively engaged in implementing the bioinformatics unit. The series of workshops includes virtual synchronous meet ups with some asynchronous work to support preparation for these meetings. During the workshops, teachers collectively build CoRes on the different critical aspects of data literacy while learning about PCK as a concept and how it can be identified and measured. Additionally, teachers conduct video reflections of their implementation in which they identify examples of enacted PCK and discuss how they support student learning. As the workshop program is still in progress, this paper focuses on initial findings on how participating teachers are conceptualizing PCK for data literacy.

The four participating teachers in this study work in three different public schools in a large urban school district in the northeastern United States in which over 90% of students qualify for free or reduced lunch. The three schools represent typical schools within the district, with large populations of minority students, English as a second language learners, and students who are socioeconomically disadvantaged. The four teachers consist of three who identify as female and one who identifies as male, three who identify as white and one who identifies as South Asian. They have an average teaching experience of 12.75 years with the most experienced teaching for 22 years while the least experienced is only in her second year of teaching in a formal classroom after a number of years working in informal education. All four teachers are implementing the bioinformatics unit in a high school science classroom.

Data sources and analysis

The data sources for this study consist of three CoRes built collaboratively during the extension workshops focused on the critical aspects of *data in context*, *data visualizations*, and *inferences with data*, written reflections completed by teachers after watching two videos of themselves and their colleagues teaching data literacy lessons that focused on those three critical aspects, and transcripts of the sessions during which the CoRes were created and the video reflections discussed. Five sessions, each 90 minutes in length (or 450 minutes total) were used for this analysis. A constant comparative analysis (Glaser, 2008) was conducted on the transcripts of the sessions and the written artifacts to identify emerging themes on PCK for data literacy.

Findings

Teachers have begun to surface an initial set of components of PCK for data literacy. These include two aspects of *knowledge of students' understanding* of data as well as *knowledge of a teaching strategy* that can be applied to help engage those student understandings.

Knowledge of students' understanding of data

Two initial themes that have arisen from teachers discussions of PCK for data literacy are that students: a) are not used to questioning data and b) struggle with the ambiguity of real-world authentic data. Concerning the first theme, while high school science does often use data, students are usually asked to interpret it without being asked to interrogate it, however a primary component of data literacy is being able to place data in its context and

understand how the context might affect the results and interpretations. In order for teachers to effectively teach the context component of data literacy, it is important for them to have strong knowledge of how and why students' predisposition to data may hinder that learning. To surface and build on that component of teacher PCK, the teachers were asked to explicitly identify what they knew and understood about student thinking. In response to a prompt in the CoRe on *inference with data* about student thinking, the teachers wrote, "Students will see "expert" conclusions and assume the expert must know - so why would they need a different conclusion." In the discussion around this understanding Mary stated that, "the whole point of [students] learning data literacy is so that they are not stuck believing that three or four out of four dentists means something really magical." This is revealing knowledge about student understanding, that students are "stuck" seeing data as truth without training to question it or even the knowledge that they can. Hallie added that though students are "able to see the 'what' they don't go for the 'so what'" which is referencing students' tendency to read data, but not question it. The knowledge that students are not used to questioning data also came up while teachers were building a CoRe on *data visualization* and discussing how easily people can be manipulated by "pretty" graphs. Mary said, "[students] are mostly on the receiving end of data and that is a place they can get manipulated by beautiful fonts and fancy bright red." In using the word 'manipulated' to talk about how students interface with data visualizations, she is again revealing knowledge of how students are unused to questioning data and instead accept it as is. By revealing this knowledge, the teachers are making visible a component of PCK which will help them better address students' preconceptions.

With respect to the second theme of struggle with ambiguity, while students are usually conditioned to accept data they see externally as fact and are not experienced in questioning it, they often take an opposite approach with their own data in that rather than accepting data they collect, they assume there is a "right" answer and their data needs to match that. Again, this is important knowledge for teachers to have in order to engage their students with data literacy, specifically with the component of building inferences with data and creating data visualizations to display their findings. When completing a CoRe on *data visualization* teachers wrote that creating data visualizations can "feel wishy-washy for students who are accustomed to 'only one of the choices is correct'" and that when creating data visualizations "students can be overly cautious with taking intellectual/design risks, to the point of paralysis. Many won't start until they know they are doing it 'right'" In further discussions about this understanding that students have about working with data, Manisha brought up the phrase "integrity of data" and how when it comes to their own data students are uncomfortable with ambiguity being okay. Additionally, while building the CoRe on *inference with data* teachers discussed ways to engage this student understanding through having them collect data on tangible objects so that they can see that "data is real and personal" to combat students' need for data to be "right" as measured by an arbitrary authority. Surfacing the knowledge that students struggle with ambiguity of data allowed teachers to verbalize this component of PCK and apply it to strategies for teaching data literacy.

Knowledge of instructional strategies for teaching with and about data

While teachers were building the CoRes and discussing their implementations of the data literacy lessons, they began to identify one particular instructional strategy to work with students' understanding of data as needing to be "right" and unquestionable. The idea of data as a story, or as having a story to tell, surfaced during many of the teachers' conversations. It was discussed as a way to support students in shifting the way they interface with data by thinking about a data set as a text and using text-analysis tools to deconstruct the 'story' the data is trying to tell. One of the big ideas they collectively chose while building the CoRe for *data visualization* was "Data visualizations tell a particular story about a set of data at a particular point in time." Additionally, while discussing the CoRe for *data in context,* Will said, "[students] are looking at one set of data, but there's this whole other world of data that you're choosing to ignore to fit your story and that's what I want them to understand, is you can use data to properly to support any position that you want."

When teachers were discussing a video of Hallie teaching a data literacy lesson, the instructional strategy of unpacking data as if it's a text and using literary analysis tools to support students in gaining experience and confidence critiquing data began to take shape. Hallie explained her emergent thinking on this saying, "If we were reading a short story and we say [...] what's the background we can assume this character might have had because of the way that they speak or whatever." She then connected that to analyzing a data visualization with, "There is a story that it's telling. [...] so, using a kind of text analysis [the students] can ask questions like who were these people? Why were they asking [these questions]?" This led to a larger conversation about different ways that students could be introduced to this process with Mary suggesting, "Offer a data set and invite groups of students to use the same data to tell various stories - don't tell each group what the others were asked to do - and then have students present their visualizations to the larger group." Manisha then added a suggestion to use the sugar refinery association's involvement with the diabetes association as a way to show students competing stories and "not to tell them the other side [at the beginning] and then just drop one bomb of a perspective and make them rethink

everything that they believed before that." Both of these examples are methods of introducing students to thinking about data as telling a story. While Mary's suggestion engages with students' understanding about data being unambiguous, Manisha engages with their tendency to accept data at face value without interrogating or questioning it. The strategy of treating data like a literary story can be used to engage both student understandings addressed in the previous section.

Implications

This paper reports on the initial findings of an ongoing study that investigates the surfacing of collective PCK for data literacy in high school science. As the research wraps up, a more robust analysis of the data will be conducted in order to achieve validity on these initial findings. Additionally, extensive interviews with the participating teachers will be conducted at the end of the workshop series to explore the processes used in the workshop and their effectiveness in supporting teachers to surface and expand their PCK for data literacy. However, the initial findings show that experienced high school science teachers hold some PCK for teaching with and about data and that, in support of previous research on developing PCK (e.g., Nilsson & Loughran, 2012, Vossen et al., 2020), PCK can be surfaced through collective discussion of the critical aspects of data literacy as mediated by CoRes and video reflections. This research hopes to continue to add to the burgeoning literature on teaching for data literacy at the high school level (e.g., Mike, 2020) by working with experienced teachers to understand what PCK for data literacy looks like, how it may or may not be different from traditional PCK for science, and how teachers can be supported to make this PCK visible and accessible. This study will contribute to identifying the supports needed to improve students' knowledge of the critical aspects of data literacy through identifying PCK for teaching with and about data.

Does Problem-Solving Before Instruction Reduce the Minoritized Student Achievement Gap?

Shannon N. Derkson and Marci S. DeCaro
shannon.derkson@louisville.edu, marci.decaro@louisville.edu,
University of Louisville

Abstract: Despite equal ability, racially-minoritized students disproportionately underperform and drop out of STEM courses. Active learning methods have been shown to help reduce this gap. We examined whether exploratory learning, a type of active learning, has similar benefits. Exploratory learning reverses traditional instruct-then-practice approaches by giving students a novel activity prior to instruction. Undergraduate students (*N*=354) were randomly assigned to learn concepts of statistical variance in explore-first (activity then instruction) or instruct-first (instruction then activity) conditions. Posttest scores improved overall in explore-first compared to instruct-first conditions. However, underrepresented students had lower scores than non-underrepresented students in both conditions. Although effective overall, exploratory learning did not decrease the underrepresented student achievement gap. Certain one-time active learning methods may not be sufficient to promote inclusivity and reduce barriers to underrepresented students' learning.

Introduction

Racially-minoritized students are underrepresented (UR) in Science, Technology, Engineering, and Mathematics (STEM) disciplines (Curry & DeBoer, 2020; PCAST, 2012). Yet, these students are essential for the STEM workforce, and enter colleges and universities aspiring to major in STEM at the same rate as non-underrepresented students (non-UR) (Malcolm & Feder, 2016). UR students show disproportionate underperformance and dropout rates from STEM disciplines (Ballen et al., 2017; PCAST, 2012). Disproportionate retention of UR students in STEM is thought to be due to various factors, such as social isolation, "chilly" classrooms (i.e., instructor dominated lectures that involve little student participation in large introductory classes), low confidence, and stereotype threat (Ballen et al., 2017). Active learning may help to reduce this gap (Saunders & Kardia, 2011).

The current study more closely examined the role a specific type of active learning can play in decreasing the UR student achievement gap in STEM fields. *Exploratory learning* adds a problem solving (exploration) phase before lecture (DeCaro & Rittle-Johnson, 2012), often improving students' conceptual understanding and knowledge transfer to related concepts (Darabi et al., 2018; Loibl et al., 2017). No prior studies have examined whether exploratory learning also helps reduce the UR student achievement gap. Active learning includes multiple instructional methods targeting students' understanding (e.g., in-class activities, low-stakes quizzes) and classroom climate (e.g., collaborative learning; Bauer et al., 2020). Examining how one specific type of active learning impacts UR student learning may provide insight into what factors help to reduce achievement gaps.

Active learning

Multiple studies have shown that UR students are interested, and as capable to excel, in STEM as much as non-UR students (Malcolm & Feder, 2016; Steele & Aronson, 1995). The U.S. Federal Government has called for action to increase representation in STEM (National Academies Press, 2011). One solution is to employ more inclusive instruction in STEM curricula. *Inclusive instruction* is a pedagogical approach that promotes the idea that all students in the classroom belong and possess the ability to be successful (Johnson, 2019). In an inclusive classroom, instructors and students all take responsibility for students' learning. Instructors create a space where students feel supported and encouraged (Saunders & Kardia, 2011).

One way to implement inclusive instruction is to use active learning (Saunders & Kardia, 2011). *Active learning* engages students through activities, collaborative learning, and/or in class discussion, as opposed to passively listening to lectures (Brame, 2016). Active learning encourages students to analyze and critically think about concepts, improving student outcomes such as grades (Ballen et al., 2017; Freeman et al., 2014). Ballen and colleagues (2017) showed that active learning, compared to traditional lectures, closed the UR student achievement gap in an introductory biology course. After adding active learning to the course curriculum, UR students' assessments and grades increased to the level of non-UR students. UR students' science self-efficacy—confidence in their capability to do science—also increased. Similar results have been found in other studies (e.g., Eddy & Hogan, 2014; Haak et al., 2011).

Exploratory learning

More work is needed to determine which active learning methods lead to these benefits. The current study examined *exploratory learning*, a specific type of active learning in which students explore a novel concept prior to instruction on that topic. Exploratory learning encompasses several methods (DeCaro & Rittle-Johnson, 2012), including problem-solve-instruct methods (e.g., Loibl et al., 2017), productive failure (e.g., Kapur, 2012), and preparation for future learning (e.g., Schwartz & Martin, 2004). A growing number of studies have shown that exploratory learning generally improves students' understanding of concepts; rote problem-solving procedures are learned equally well in explore-first and instruct-first methods (Loibl et al., 2017).

Exploratory learning is thought to benefit understanding through several learning mechanisms (Loibl et al., 2017). First, solving novel problems helps students activate relevant prior knowledge, integrating what they know with the new instruction (Newman & DeCaro, 2019). Second, students realize where they have gaps in their knowledge, calibrating their metacognition, and alerting them that the instruction can help fill those gaps (Loibl et al., 2017). Third, students begin to discern what features of the problem are key, and which are less important, deepening their understanding of the concepts (DeCaro & Rittle-Johnson, 2012; Schwartz & Martin, 2004).

Current Study

We examined whether exploratory learning, as a type of active learning activity targeting conceptual understanding, would help to reduce the UR student achievement gap. We combined data collected for other studies in psychological statistics courses with lab studies using the same materials, and conducted a secondary analysis. Participants were randomly assigned to one of two conditions. Students in the *explore-first condition* explored a standard deviation problem and "invented" an equation to solve it. Then they read instruction on the concept and procedures of standard deviation. Students in the *instruct-first condition* viewed the materials in the opposite order (instruction, then problem). Either immediately after (lab sessions) or one week later (classroom sessions), students completed a posttest that assessed conceptual understanding of standard deviation.

We hypothesized that students in the explore-first condition would score higher on the posttest overall, compared to students in the instruct-first condition. We also hypothesized that any difference in posttest scores between UR and non-UR students in the instruct-first condition would be reduced in the explore-first condition. However, another possibility is that the cognitive benefits of exploratory learning are insufficient to increase inclusive instruction, especially in a one-time intervention in which students work individually. This experiment therefore tested whether exploring alone is a sufficient method to reduce the UR student achievement gap.

Methods

Participants

Participants (N=354) were undergraduate students enrolled in introductory psychology statistics courses (n=263) or who participated in a lab study at the same university (n=91). Students were categorized as UR (n=94; 26.4%) based on their reported race/ethnicity, including African-American/Black, Hispanic/Latinx, Native American, Hawaiian/Pacific Islander, or biracial/"mixed" (Curry & DeBoer, 2020). Non-UR (n=262; 73.6%) participants indicated that they were Caucasian/white. Participants from other racial/ethnic groups (e.g., Asian) were not included in analyses, as they are not typically considered to face the same academic challenges as other minoritized groups (Curry & DeBoer, 2020).

Participants were included in the dataset if they completed both the intervention and posttest. Participants were excluded if they had experience with the learning materials, or if they reported previously learning about standard deviation and scored above 97% on the posttest. Participants were also excluded if they reported that their primary language was not English, due to the large reading component of the study (this variable was not collected from 174 participants; all were included in the dataset).

Materials

The **intervention packet** (adapted from Kapur, 2012; Wiedmann et al., 2012) consisted of three sections that varied in order depending on condition: instruction, activity, and survey (demographics). The **instruction section** included a written text passage giving direct instruction on the concepts and procedures for calculating standard deviation, with two short practice questions. The **activity section** included a problem asking students to determine the consistency of antioxidants in tea produced by three different tea growers over six years (Newman & DeCaro, 2019). Students viewed a table designed to facilitate contrasting cases, to help students ascertain the relevant problem features (e.g., the importance of sample size; Schwartz et al., 2012). Students in the *explore-first condition* were asked to "Come up with a formula for consistency to show which tea grower has the most consistent levels of antioxidants…" Students in the *instruct-first condition* were instead asked to use what they

just learned about standard deviation to calculate consistency. The **posttest** included four essay questions that targeted conceptual and procedural aspects of standard deviation, drawn from Newman and DeCaro (2019) (interrater reliability: Cronbach's alphas > .80).

Procedure

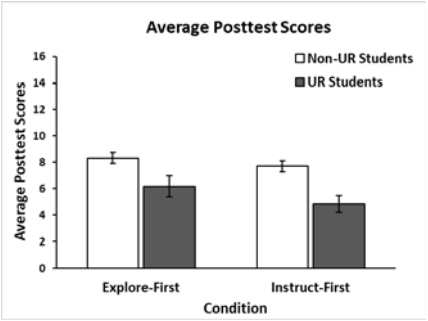
Students were randomly assigned to condition based on the intervention packet given. Students in the *explore-first condition* (*n*=174) completed the activity, then the instruction. Students in the *instruct-first condition* (*n*=180) completed the instruction then activity. Students were given 15 minutes for each section of the packet and 35 minutes for the posttest. Students in the psychology statistics lab classes completed the posttest one week after the intervention. Students in the lab (non-classroom) study completed both packets in one session. Students in classroom studies were debriefed via email and given the option to remove their data from the study. Students in the lab study completed a consent form at the beginning and were given psychology research credit for participation. All procedures were approved by the university Institutional Review Board.

Results

A preliminary analysis showed that the difference between conditions (explore-first, instruct-first) was statistically significant without including representation status as a factor, $F(1,356)=4.25$, $p=.040$, $\eta_p^2=.012$. Posttest scores were higher in the explore-first (M=7.88 out of 16, SE=0.37) than the instruct-first condition (M=6.80, SE=0.37).

Posttest scores were then analyzed using a 2 (condition: *explore-first*, *instruct-first*) × 2 (representation status: *UR*, *non-UR*) between-subjects factorial ANOVA. No main effect of condition was found, $F(1,356)=2.67$, $p=.103$, $\eta_p^2=.008$. A main effect of representation status was found, $F(1,356)=17.83$, $p<.001$, $\eta_p^2=.048$. There was no condition × representation status interaction, $F<1$, $p=.566$, $\eta_p^2=.001$. As shown in *Figure 1*, UR students scored lower on the posttest than non-UR students in both the explore-first condition (UR: M=6.17, SE=0.80, CI[4.59–7.74]; non-UR: M=8.32, SE=0.41, CI[7.52–9.13]) and instruct-first condition (UR: M=4.86, SE=0.64, CI[3.61–6.11]; non-UR: M=7.71, SE=0.43, CI[6.85–8.55]). Exploratory learning did not reduce the achievement gap.

Figure 1 *Average Posttest Scores as a Function of Condition and Underrepresentation (UR) Status (Error Bars=SEs)*



Discussion

This study examined whether exploratory learning would reduce the UR student achievement gap when learning about a statistics concept and procedure across undergraduate classroom and lab settings. Compared to an instruct-first condition, students in the explore-first condition scored higher on a posttest, although the effect was weak. UR students performed at a lower level than non-UR students across both instruct-first and explore-first conditions, demonstrating that exploratory learning did not significantly reduce the UR student achievement gap.

This finding contrasts prior studies showing that using active learning techniques can reduce the achievement gap between UR and non-UR students in STEM courses (e.g., Ballen et al., 2017; Haak et al., 2011). However, these studies included multiple active learning methods used over an entire semester. Thus, it is unclear which specific methods drove these benefits or whether a single lesson using active learning may be sufficient to demonstrate additional learning benefits for UR students. The current results demonstrate that a single exploratory learning lesson—at least as used in this study—is insufficient to reduce the achievement gap.

Several factors may have limited our ability to differentially improve UR students' learning. Our results may be limited by weak implementation of exploratory learning. In addition, students only experienced this learning method once. Perhaps repeated exposure to learning methods known to improve students' conceptual understanding is necessary to have more widespread benefits. Given the challenges of exploratory learning, instructions aimed at a growth mindset may need to be included (e.g., Bauer et al., 2020). Finally, students worked individually in our study, but collaborative learning may be key to an inclusive learning environment. Collaboration encourages relationships between students and instructors, and may be necessary to reduce a "chilly" climate.

Our findings underscore the importance of continuing to discern the key ingredients of active learning that do increase inclusivity and academic performance for UR students. For example, Bauer et al. (2020) argue that instructional methods should target both cognitive and affective aspects of learning. Others (e.g., Lorenzo et al., 2006) focus primarily on the social aspects of an inclusive teaching environment. Exploratory learning may

be useful, but insufficient, without being combined with other aspects of inclusive teaching, to help promote equitable learning for all students.

Rural Teachers' Computing Attitudes in their Classrooms

Melissa P. Mendenhall, Colby Tofel-Grehl, David F. Feldon
sciencemmendenhall@gmail.com, colby.tg@usu.edu, david.feldon@usu.edu
Utah State University

Abstract: The purpose of this multiple case study is to explore teacher attitudes toward and engagement with technology as they participate in STEM professional development and subsequently enact instruction. Using the lens of cultural historical activity theory (CHAT), we examine the ways in which two middle school teachers in a rural community shifted their perspectives on technology during this process. Findings suggest that teacher attitude toward technology can be moderated through the means of a more knowledgeable other who scaffolds teacher learning and integration of technology, providing insights into the professional development needs of rural teachers.

Teachers and technology in STEM education

As seen in new fields such as chemometrics and computational biology, computing is increasingly required in STEM careers (Weintrop et al., 2015). Further, computational thinking is conceptualized as a foundational literacy for the 21st century (Grover & Pea, 2013). Because of this, students need the support of educators in scaffolding computing understanding that will help them prepare for STEM career success in the future. Accordingly, all teachers of young students need preparation to teach computing skills. Unfortunately, current computing experiences in education tend to not include authentic and meaningful integration that is relevant to STEM problems (Pitman & Gaines, 2015). Furthermore, the pedagogical content knowledge that teachers need to engage students authentically in integrated STEM computing projects is lacking. Thus, the teaching of skills necessary to support student interest and learning in STEM is not occurring (Kafai & Burke, 2014) .

Implementing computational thinking tasks into instruction requires that teachers have familiarity with technology, computer science, and the pedagogy needed to support students in making sense of it (Tofel-Grehl et al., 2018). However, teachers often report that they do not have enough competence to engage students in STEM learning around computing (Tofel-Grehl et al., 2021). Thus, additional professional development is needed.

By building in professional development time for teachers to learn, reflect, and apply knowledge and skills related to computing and technology into instruction, teachers are supported to make the shifts necessary to change instruction to more authentic and meaningful STEM learning (Avci et al., 2020). Furthermore, research suggests that knowing teacher attitudes is critical for professional development, because teachers teach what they believe is important (Pajares, 1992). Additionally, knowledge of educator attitudes toward a practice "is critical for understanding teachers' thought processes, classroom practices, [and] change" (Smith, 2002, p. 42). Therefore, to improve STEM learning and career outcomes for students, we must improve STEM instruction to thoughtfully integrate computing and teacher attitudes about such integrated teaching. Gaining this understanding can inform professional development designers in the creation of professional learning experiences that scaffold educators to include technology in STEM education for their community of students. Accordingly, we pose two research questions:

1. What attitudes do teachers express toward technology and computing within their classrooms?
2. How do teachers approach and engage with technology both during professional development and during classroom instruction?

Theoretical framing

Through the lens of cultural historical activity theory (CHAT; Engeström, 1999), this research conceptualizes professional development as activity systems within which teachers (subjects) and professional development (means) jointly endeavor to enrich teachers' understanding of technology implementation in instruction, particularly teachers' attitudes toward, approaches to, and engagement with technology (object). Integral to this activity structure are the tools and signs used to mediate the relation of subject to object. In this case these tools include teacher understanding of STEM instruction and pedagogical skills and strategies used in STEM instruction. The tools of teacher understanding of STEM and pedagogical skills are developed from within the

 © ISLS

activity system but, they can also draw them in from other activities or experiences (Greeno & Engeström, 2014). Thus, teachers may draw on their experiences with technology and other pedagogical constructs as tools to increase their abilities to incorporate technology. Further, as members of the activity system community, teachers are likely to adopt and transform these tools and representations over time (Schwarz & Hershkowitz, 2001) as ways to support future students in their pursuit of learning outcomes. As such, teachers are likely to be more reflective about encounters with these conceptual tools as constructions of meaning new to their instructional design (Koschmann et al., 1998).

Methods

To explore teacher attitudes toward, and engagement with technology, this research uses a multiple case study design to analyze field notes and memos for themes in the data responsive to the research questions. These themes are then explored through reflective interviews with the participating teachers to enhance understanding.

Participants

On the Big Island of Hawaii, the rural town of Nui Huna is located halfway between the two cities on the island and has a 70% free/reduced lunch rate in public schools. The two teachers participating in this study were selected for their prior teaching experience. Amy (pseudonym) is a white woman who moved to the island eight years ago, is certified in multiple subjects, and has been teaching for over 15 years. Jill (pseudonym) is also a white woman who has lived on the island her whole life and has taught middle school for 10 years.

Professional development

Teachers were engaged in a faded scaffold of support for learning and practicing, working with students using STEM and computing skills and competencies. This approach emphasizes the importance of tracing, commenting, and explaining code as a means for developing understanding of these constructs as tools and signs (Lopez et al., 2008; Murphy et al., 2012). Working within the structures of a summer school schedule following initial workshop training, teachers experienced three different roles within the classroom whenever possible. During the first period of the day, teachers were observer learners, making projects alongside students. In the second period of the day, teachers stepped into the role of teacher with the support of the PD provider. At the close of the school day, teachers and PD providers debriefed on the day as well as previewed the coming day. This approach towards training teachers provided them both with the knowledge they need to engage these practices in their classrooms and immediate opportunities to practice teaching with supportive team members standing by. Because teachers often express anxiety or fear at engaging these new approaches (Howell et al., 2016), scaffolding their first coding teaching experience with their PD provider present allows teachers to professionally take risks and expand their abilities without fear of failure.

Design and data sources

This research utilizes a case study design to explore teacher attitudes and engagement with technology in an authentic situation as experienced with learning and implementing coding and computing into instruction.

Analysis

We analyzed fieldnotes, interviews, and audio recordings from professional development and classroom instruction. Data sources were open coded to explore the study's research questions. As themes emerged through open coding, we recorded these to creating memos. Follow up interviews were then conducted to member check or explore further emerging themes found within the data. After completing initial coding analysis, follow up interviews were conducted with both participants to dive deeper into the initial themes.

Findings

The initial codes from the field notes were listed sequentially to identify patterns. The patterns were then described as possible themes. For example, patterns of multiple codes in Amy's personal learning and co-teaching data (e.g., Teaching insecurities, Anxious focus on planning, Anxiety over learning about technology) pointed out an overwhelming concern or anxiousness during learning and instruction. This theme is Anxiety.

A second theme surfaced from the data for Jill. Specifically, the codes Learns quickly, Independent learner, Independent teacher with own ideas, "Frills free and efficient", and Lack of attention to detail all converged around the notion of autonomy in learning. This theme is Independent Learning.

Additionally, when analyzing the code patterns for both teachers, the code Technology is lower priority seemed to precede the code Disconnect between teacher and students. This theme is labeled:

Disengagement.
Hence, the following initial themes emerged in relation to the teachers' attitudes toward, approaches to, and engagement with computing:

1. **Anxiety**: Overwhelming concern toward learning and instruction. In the initial codes, despite her many years of experience, Amy demonstrated patterns of teaching insecurities. She was anxious with a focus on planning. She articulated anxiety regarding learning coding and was anxious about approaching and engaging with technology during instruction.
2. **Independent Learning**: Desire for autonomy in learning. Jill shared ideas of independence to choose the speed of learning and independence to choose her focus during instruction.
3. **Disengagement**: Disengagement with technology precedes disengagement with students. Despite their interest and willingness to engage technology within their classrooms, Amy and Jill also both demonstrated a disengagement from technology or seeing themselves as teachers of technology.

Interview data analysis

Findings from the data analysis of the interviews with both teachers consistently confirmed both the anxiety and independent learning themes. For example, during the interview, Amy responded: "I've always had a hard time conceptualizing coding…the idea that I had to learn this and then, and then like possibly have to answer questions in like help [of students]" and "You're presented with new things and asked to do new tasks that you don't know how to do, you're anxious about it", which confirmed the anxiety theme. Also, the independent learning theme was observed through comments like when Jill said: "I have low exposure [to technology], but I'm kind of comfortable fiddling. I mean, I feel bad if I do something wrong, but like I'm not scared of it" and "I like to have time working independently through something…just because I don't like the pressure of like going too slow, going too fast, that kind of stuff." Of note, through interview the teachers did not perceive their own disengagement but rather focused on the value of the professional development.

When considering the attitudes expressed by teachers both in general and within their classrooms, it appeared that the relationship between the teacher (subject) and their attitudes toward computing with technology (object) were moderated by a specific means (professional development). Amy's initial attitude toward computing and technology was one of anxiety. However, during the interview, she relaxed and was optimistic when discussing time spent in professional development. Specifically, she expressed that the professional development provider was able to answer her questions and provide her with the tools she needed to be successful teaching.

Jill's expression of independent learning also appeared to moderate when discussing the idea of implementing computing into her classroom instruction. She expressed her desire to have help learning how to integrate computing into her curriculum. She felt this could be accomplished by means of professional development. Jill's independence was observed most robustly in the projects during which she engaged most carefully within the professional development. In other words, her independence was mediated by the professional development and her attention to it.

In both cases, the professional development served as means to moderate teacher attitudes by supporting teachers as they developed their knowledge of computing. The dynamics of this moderation resembled action as a more knowledgeable peer that supports others in developing through what Vygotsky (1978) termed the zone of proximal development. For both teachers, their ultimate desire was to enhance and deepen their content knowledge. They approached and engaged with technology from the perspective of using it to effectively teach content. Integration was a critical reason for their engagement with technology, which prompted the creation of a new theme- *Integration*. This replaced disengagement as a theme because it better explained teachers' reasoning. Specifically, computing was an instructional approach that provided these teachers a way to further student understanding of their content knowledge.

Overall, all three themes suggest that getting teachers to engage with the tools (computing and technology) required or will require a more knowledgeable other (Vygotsky, 1978). This allowed Amy to feel confident and secure in integrating computing and technology into instruction and can allowed Jill to see how to integrate computing and technology more fully into her instruction in ways that deepen and enhance the content. It appears the most important moderating factor for teachers to consume and produce with computing during professional learning experiences was the professional development provider (mean). This person provided the means for helping teachers feel confident, capable, and able to implement the new strategy into instruction.

Discussion

This paper showcases the beliefs and experiences of teachers seeking to engage in teaching with technology. Of all the means engaged by the teachers in this study, it was their experiences of the professional development that drove their beliefs about technology. Specifically, we see shifts from anxious and avoidant behaviors to accepting and engaging behaviors that manifest as a function of relational interactions that shift the distribution of labor from isolated engagement with technology on the part of the teacher to a cooperative effort between the teacher and the professional development provider. When asked, the teachers felt that this shift was possible for them because of the support of the professional development provider. This speaks to the value and importance of slow and tailored professional learning for rural teachers.

By meeting teachers where they are *and* fostering their ability through engagement with their interest, professional development provides a unique opportunity to serve as both peer and more knowledgeable other within the space of their own learning. While the beliefs and attitudes experienced by teachers are often shifting, finding means that can facilitate shifts in belief can better support technology engagement and adoption within classrooms.

"Design for Co-Design" in a Computer Science Curriculum Research-Practice Partnership

Victor R. Lee, Stanford University, vrlee@stanford.edu
Jody Clarke-Midura, Jessica Shumway, & Mimi Recker, jody.clarke@usu.edu, jessica.shumway@usu.edu, mimi.recker@usu.edu
Utah State University

Abstract: This paper reports on a study of the dynamics of a Research-Practice Partnership (RPP) oriented around design, specifically the co-design model. The RPP is focused on supporting elementary school computer science (CS) instruction by involving paraprofessional educators and teachers in curricular co-design. A problem of practice addressed is that few elementary educators have backgrounds in teaching CS and have limited available instructional time and budget for CS. The co-design strategy entailed highlighting CS concepts in the mathematics curriculum during classroom instruction and designing computer lab lessons that explored related ideas through programming. Analyses focused on tensions within RPP interaction dynamics and how they were accommodated when RPP partners were designing for co-design activities, a critical component that leads to curricular co-design itself. We illustrate these tensions with examples of clusters of activity that appeared repeatedly among the research and practice team members when "designing for co-design".

Introduction

Research-practice partnerships (RPP) are gaining traction as a model for supporting practice-driven lines of inquiry and educational improvement in the learning sciences. While this represents an encouraging development for those interested in working on persistent problems of educational practice, Coburn and Penuel (2016) have also observed that "given new investments in RPPs, we need parallel investments in research on the dynamics and outcomes of partnerships. Studies of partnership dynamics are crucial to enable new partnerships to learn how to do this work and for existing partnerships to learn from each other's experiences" (p. 52). In this paper, we report on early empirical work designed to heed Coburn and Penuel's call to intentionally study partnership dynamics. Specifically, we examine one type of RPP, the design research partnership (Coburn et al., 2013), and specifically the curricular "co-design" model (Penuel et al., 2007; Voogt et al., 2015). Our goals in this paper are to illustrate some of those partnership dynamics interactionally – through actual descriptively analyzed researcher and practitioner conversations - and argue more broadly that a part of that partnership dynamic research should attend to the meta-design work involved in RPP teams designing for co-design.

Framework: Design for Co-Design

While the RPP structure is key to our endeavor, our emphasis is on the work that surrounds the co-design activity itself. As a genre of curriculum development, co-design and related collaborative approaches (e.g., work circles; Shrader et al., 1999) are intended to be activities in which educators and design-oriented education researchers jointly do the ideational and prototyping work of curriculum improvement (Arce-Trigatti et al., 2018), rather than following a more typical sequence of late-term educator involvement using researcher-created curriculum and post-hoc feedback. This co-design configuration can serve to disrupt perceived and common imbalances between researchers and practitioners. However, there are a number of challenges to navigate in co-design because it brings together different communities with distinct histories, norms, and commitments to engage in joint work. Parts of this will ultimately be negotiated during the co-design activity itself, but that opportunity to do that negotiation is itself designed. Thus, we assert that there is an additional layer of design work that takes place to prepare for the co-design activities. We refer to this additional layer of work as "designing for co-design" and show how it is also a critical component that contributes to successful curricular co-design (see Figure 1).

For our partnership (funded by National Science Foundation Grants 2031382 and 2031404), design for co-design was necessary work because the co-designing educators (e.g., teachers) became involved after the grant supporting this RPP had been awarded. However, we contend that designing for co-design is necessary and common work done by RPP teams with longer partnership histories, particularly when new members (e.g., new teachers, district personnel, research assistants) are invited to join and take on active roles following natural turnover. In similarly-oriented work, this type of effort to open up space for full participation in co-design work has been characterized as organizing for teacher agency (Severance et al., 2016) and has lent itself to retrospective

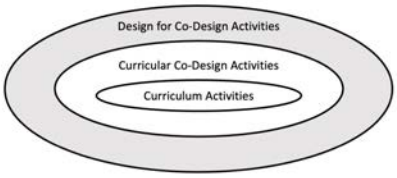
analyses of field notes and artifacts from co-design sessions. The present study complements and is informed by Severance et al., although it examines a different geographical context, a different subject matter and age group, and paraprofessional educators in addition to classroom teachers. Moreover, we articulate in this paper the conditions and constraints that were managed during this case's design for co-design.

Figure 1
Concentric circles of design involved in curriculum design research-practice partnerships.



RPP Context: An Integrated Math-Computer Science Co-design Project

The study context comes from an RPP that seeks to support and co-develop elementary school computer science (CS) instruction that involves paraprofessional educators (whose position title in the district is "computer lab specialists") and classroom teachers in a rural-serving U.S. school district. A key problem of practice addressed in this RPP is that very few elementary school teachers have backgrounds in or comfort with teaching CS. The computer lab specialists were newly being asked to provide the CS instruction. The strategy being pursued by this RPP was to identify and highlight CS concepts in the already adopted mathematics curriculum and then structure the computer lab lessons as activities for exploring the same related mathematical ideas through a computational medium (i.e., Scratch). Adequately supporting the professional learning of paraprofessionals represents another set of persistent problems of practice.

Data, Interpretive Methods, and An Illustration

Our project was designed to study partnership dynamics from conception. Project personnel were assigned to lead an empirical study of the interactional dynamics within the RPP itself. This was in addition to other team members conducting research on educator learning and student experience with the newly designed learning activities. This self-examination component provides the data for this study, which took place during the COVID-19 pandemic when social distancing and remote work measures were in place. As such, virtually all activities up until this writing had taken place via Zoom, and video recordings of these meetings serve as the primary data source. In addition, the team members leading the RPP dynamics research conducted interviews with all participants and collected artifacts such as agendas and common documents. Data included 14 recorded weekly meetings (each 1-1.5 hours) involving 7 university-affiliated researchers (Principal Investigators and Graduate Researchers) from two institutions and 2 school district central office employees (Curriculum Leads). In addition, there were three, hour-long co-design meetings that included three classroom teachers and one computer lab specialist.

The analysis essentially involved recording RPP interactions, coding and curating them, and then engaging in more detailed descriptive analysis of the content of the curated interactions. These analyses were vetted by the larger group. This bears some resemblance to interaction analysis (Jordan & Henderson, 1995), which involves obtaining recordings and iteratively engaging in group analysis and argumentation of clips to forming an interpretation that is justified by evidence apparent in the record (e.g., specific utterances or words used by a speaker).

To illustrate, an example excerpt that was coded as **DESIGNING CO-DESIGN** and curated from the corpus appears below. This example excerpt, while long, is presented to give a sense of the type of interactional speech data that were examined and also to illustrate how **DESIGNING CO-DESIGN** episodes fit the following criteria: 1. The conversation had contributions from members of both the research and practice organizations, 2. The topic of conversation was related directly to how to structure the curricular co-design activities, and 3. From review of other meeting records and artifacts, the conversation ultimately led to a decision about the organization of the co-design activities themselves. In this excerpt, the first co-design meeting was scheduled to take place. It was the first time the classroom teachers and computer lab specialist explored how to design integrations between classroom mathematics content and computer lab instruction. In thinking about this meeting, researcher M raised the concern that it was unclear how to introduce the goals of the planned co-design. Researcher J offered a suggestion, and then district leader B offered her support for J's suggestion. Then B and district leader S voiced constraints: there was a lack of crossover content knowledge between the teachers and computer lab specialist.

University Researcher M: *You know, thinking about this first meeting, and, you know, the teachers as partners, but not overwhelming them. I mean, yeah -- I'm just trying to envision how we can talk about sort of the objectives here and get meaningful input on what units makes sense to them. Any suggestions?*
University Researcher J: *They don't know anything about Scratch or what the capabilities are, it may be hard for them to envision that. So I wonder if there's a way we can kind of, without too much information, but to give them some kind of like overview of some examples in Scratch or something, maybe this other curriculum that you mentioned -- something that gives them an idea, something to kind of think about, they can envision it.*
District Leader B: *I was gonna say, I think that that would really help our teachers, especially where they do have limited exposure to computer science, giving them a kind of a -- an idea of what it looks like, would be helpful for sure. And I know with this team, too, they have interest in computer science, but they haven't had a lot of experience with it. With the classroom teachers, for sure. So I think that would be a great idea.*
District Leader S: *And how much is the computer specialist going to need to understand about the math concepts to teach it properly? That's also going to be a potential constraint.*

In this segment, a common underlying question explored by all four speakers was how to make the work of co-design feel tractable and approachable for the teachers and lab specialist who would, at a designated and time-limited future meeting, begin this work for the first time. Following Severance et al (2016) in wanting to "present the vision" for innovative learning activities as stimulus for curricular co-design, researcher M questioned how the co-design could be presented to "get meaningful input". This question led to articulation of two fundamental challenges for the planned co-design. First was the unfamiliar end goal of integrated lessons needed to be envisioned but the team wanted it to be rooted in the ideas of the co-design team. They did not want to overly constrain the co-design team's thinking nor provide examples that already solved the design problem nor provide poor examples that did not encourage ambitious integrated instruction. Utterances from M and J expressed this, as did other utterances during the meeting. Second was how to negotiate two different content areas while recognizing what knowledge was necessary to teach integrated lessons. On the one hand, CS as a focal topic was unfamiliar to the classroom teachers (speaker B). On the other, the specialists were not assumed to have the degree of mathematical knowledge for teaching that the classroom teachers would have (speaker S).

It ended up taking several additional RPP planning meetings to get there, but a decision was eventually reached to introduce a Scratch programming sample and view it together in addition to a small set of practitioner-facing examples from practitioner publications to express that there were numerous viable possibilities that could be developed. Regardless, this excerpt serves to model the challenge, show the data used, and illustrate how our analysis worked to maintain accountability to the transcript data as we analyzed interactions.

Additional Examples of Design for Co-Design Challenges

As a short paper reporting on a project that is still in progress, our goal is to argue that design for co-design is a component of RPP co-design structures and that it contains worthwhile design questions for learning scientists to explore. While longer post-hoc analysis will come in the future, we consider it worthwhile for the learning sciences community to already begin recognizing and discussing this design for co-design space that many RPPs already have and are encountering. Given that, the remaining empirical examples are illustrative to name some design for co-design challenges. These were derived and analyzed in the fashion briefly modeled above.

Negotiating Technological Infrastructure Across Partners

One recurring set of concerns we have seen across "designing for co-design" meetings, especially leading up to the first co-design session, was how to manage digital systems. A concern among partners was that the university team might appear as having the greatest amount of influence. This extended to what technologies were used and how co-design engaged with those technologies. The university had contracts with various vendors including Box.com, and the university's institutional review board (IRB) required that Box be used for security purposes with human subjects data. This led to the university defaulting to Box for its online storage infrastructure. However, a district team member expressed that Box was not familiar to district personnel: "*I just think it needs to be easy for teachers -- Box is not intuitive by any means. And I think it, you know -- teachers are used to Google drive*." The university team was bound by IRB rules to use Box, yet opted to maintain both Box and Google-based volumes, with Google Drive used exclusively for co-design so that district partners would not feel like they were encumbered with needing to use 'the university's preferred tools'. While this is one decision, there were several others. For instance, the project created a design group email list through Google groups so administrative control and email names did not have the university's address in them, further detaching those aspects of co-design

communications from the university's tools. Elsewhere, it extended to questions about calendaring systems and Zoom accounts to use as those could represent influence in the partnership.

Moving Away from Researcher-favored Dialects

Another topic that came up in "designing for co-design" work was what language to use. While education researchers are currently enthusiastic about RPPs, it is unclear how widely known the term is among practitioners and how enthusiastically it is endorsed. To illustrate, district team member S, who had been part of writing the grant referred to the entire endeavor in a meeting as: "*You know the design, you know the practice design practice partnership*". While we were confident this person valued and enthusiastically supported the partnership, the RPP term itself was not one that seemed of great importance to S. One of the university project leaders was sensitive to this and explicitly acknowledged it during a meeting and at one point mentioned "*the things I'm planning to say -- I'm trying to avoid too much jargon – 'research-practice partnership' would certainly be under the umbrella of jargon*". Thus, the point here is that there are different language communities coming together where terms are bestowed different status. Forcing or policing these could inadvertently signal power or influence on the partnership and in designing the co-design, decisions were made to recognize and avoid giving those signals.

This question of terminology even extended to the terms 'design' and 'co-design'. Researchers, and especially learning scientists, value design and treat it as agentic and generative activity. However, a district partner commented that "design" implied a lot of time and effort. For example, many teachers do not think of their work leading up to classroom instruction as "designing" their lessons but rather "planning" their lessons. This was illustrated by the following comment during a meeting about what to call the team of (what we as learning scientists call) curriculum co-designers.

> District Member B: *I do think that, from the teacher's perspective -- going to the word adapting makes the challenge less overwhelming, because when you're talking to a teacher about designing units -- that's a long-term time-intensive process -- but adapting I think is a better word for that.*

As we, the authors of this paper, are participants in and are addressing the learning sciences community where "design" is discussed, we comfortably use the term here. However, the RPP team that was designing the co-design elected to leave this determination to the co-design team. "Design" was offered as a descriptor, but the teachers and specialist viewed it as "integration". This became part of the collective identity that emerged, and that group even gave themselves the name "Code Math integration group" that did not use the "design" term.

Conclusion

RPPs and co-design have been proposed as newer vehicles for joint work between researchers and practitioners. There is a need and call (i.e., Coburn & Penuel, 2016) to not only study RPP outputs but also their internal dynamics. Among those, we argue, are the steps taken within a design RPP to design for co-design activities. We believe and sought to illustrate that this additional layer of work is productive and that such work is quite common but unstated. Our examples in this paper show what some of this work looks like, and we invite the learning sciences community to further explore this space so that more generative and equitable RPPs can be developed and maintained in the future.

Feeling Irregularly White: The Role of Emotions in Activist Learning

Yang Hsun Hou and Niral Shah
yhhou@uw.edu and niral@uw.edu
University of Washington

Abstract: Building on learning sciences literature that centers emotions, this paper explores the interplay between learning emotions and learning cross-racial allyship. Research in the learning sciences has often set aside the role of emotions in learning. In recognition that learning to counter White supremacy typically involves a wide range of emotions—from compassion and righteous anger to fear and denial—we explore the affordances of analyzing emotions around activist learning. For this purpose, we analyze a memoir written by Mab Segrest, a White anti-racist activist who learned to become a cross-racial ally with Black activists in the Southern United States. We incorporate affect theory with situated and sociocultural learning theories to conceptualize emotions as both social practices and cultural artifacts. The findings describe how cross-racial allyship learning involves the negotiation of one's own emotions alongside the emotions in one's community.

Introduction

> *I had begun to feel pretty irregularly White. Klan folks had a term for it: race traitor. Driving in and out of counties with heavy Klan activity, I kept my eye on the rearview mirror, and any time a truck with a Confederate flag license plate passed me, the hair on the back of my neck would rise. (Segrest, 1994, p. 80)*

Emotions are core to human experience (Ahmed, 2013). As learning is a fundamental human activity, this means that the relationship between learning and emotions requires attention. This is particularly true in learning how to counter social injustice, as learning scientists have begun to consider the emotional dimensions of learning to be an activist (see Vea, 2020). Specifically in the context of racism, learning to counter White supremacy (i.e., anti-racism) typically involves a wide range of emotions: from compassion and righteous anger to fear and denial. Understanding the complex ways people negotiate this constellation of emotions can shed light on how people learn anti-racism.

This paper focuses on the life of Mab Segrest, a White anti-racist activist who became a "traitor" to White supremacy through grassroots organizing in the 1980s. This work derives from a larger study of how people learn anti-racism. Elsewhere, we have begun developing a methodology for characterizing anti-racism learning, particularly along long timescales (Shah & Hou, in press). Here we focus on the emotional entailments of anti-racism learning—in this case, as Mab learned to become a cross-racial ally with Black activists in the Southern United States. Specifically, we draw on situated and sociocultural perspectives on learning to analyze Mab's shifts from sympathy *for* the Other, to sympathy *with* the Other, as well as the myriad of racialized emotions that followed and expanded beyond empathy (Bonilla-Silva, 2019). The following research question oriented the study: *What emotions mediated Mab's understanding of herself as a White person, and how did they facilitate her learning of cross-racial allyship?* Our findings contribute to learning sciences research by illustrating the affordances of conceptualizing emotions both as social practices (see Vea, 2020) and as sociocultural artifacts. We conclude by discussing how a perspective that accounts for multiple emotions, as opposed to one-dimensional approaches to racial healing, can lead to better designs for learning racial justice activism.

 © ISLS

Conceptual Framework

Here we explore the interplay of learning emotions and learning cross-racial allyship, with an emphasis on emotions specific to racialized societies (Bonilla-Silva, 2019). We use the term "Whiteness" to describe a form of discourse and ideology, rather than individuals with white skin. In other words, Whiteness denotes "the structural valuation of [lighter] skin color, which invests it with meaning regarding the overall organization of society" (Leonardo, 2009, p. 92). We examine Mab's personal and activist journey as she questions the validity of Whiteness and engages in anti-racism.

Our claims around Mab's learning attempt to describe emotions through the perspective of situated and sociocultural learning theories, particularly the concepts of social practices (Lave & Wenger, 1991) and cultural artifacts (Vygotsky, 1978; Wertsch, 1998). The field of learning sciences has often set aside the role of emotions "through outright exclusion or through ways of thinking that separate emotion as an external force on learning" (Vea, 2020, p. 314). However, addressing emotions is imperative if we want to comprehensively understand learning. For this purpose, we incorporate aspects of affect theory with situated and sociocultural learning theories. Through affect theory, emotions become a lens through which to understand human behaviors (Ahmed, 2013). Drawing on situated learning theory, we conceptualize emotions as "[producing] the effect of surfaces and boundaries of bodies" (Ahmed, 2013, p. 194), thereby acting as social practices that bound specific communities together (i.e., communities experiencing joy or grief or other emotions). Through Vygotskian sociocultural learning theories, we incorporate Ahmed's (2013) concept of "stickiness", describing how "the work of emotion involves the 'sticking' of signs to bodies: for example, when others become 'hateful', then actions of 'hate' are directed against them" (p. 13). By extension, emotions convey how different cultural artifacts "stick" to different racialized bodies. We add here to Vea's work on viewing emotions as a form of social practice, "of expression/emoting and emotional management" (2020, p. 315), and explore the parallel affordances of viewing emotions as artifacts.

Method

Our qualitative approach attempts to understand, interrogate, and deconstruct the emotional dimensions of lived experiences (Bhattacharya, 2017). We specifically employed methods designed to analyze emotions from written text. By treating a memoir as data, we examined emotions on an individual scale but also connected to the people and historical events shaping a person's life. We chose Mab's memoir, *Memoir of a Race Traitor* (1994), from a collection of 20th-century U.S.-based anti-racist activist memoirs, which was generated from a larger study of how people learn anti-racism (Shah & Hou, in press). Given the necessary role of White people in anti-racist struggle, we were especially curious about Mab's identification as a "race traitor," and we analyzed a specific excerpt of the memoir where the emotions around being a race traitor were prominent (e.g., Mab's emotions around White individuals and in relation to her mother) (Segrest, 1994, p. 80-82). Our racial positionalities as Han Taiwanese (Hou) and as Brown (Shah) also informed our perspectives around cross-racial allyship.

Set in the 1980s when Mab joined North Carolinians Against Racist and Religious Violence (NCARRV) and participated in anti-Klan activity, our selected data describe Mab's shifting emotions, perspectives, and behaviors as she gradually understood herself as a race traitor. In other words, Mab began to recognize herself (and observe how others recognized her) as a White person who acts against White racial interests. In our analysis, we identified Mab's emotions by focusing on explicit emotion words used by Mab (e.g., fear, sorrow, self-hatred, suspicion). While we recognize that memoirists might not fully disclose all that they are feeling, we believe that using in vivo text provided valuable insight into Mab's emotional landscape.

Findings

First, we analyze events from Mab's life through a lens of emotions as social practices, and then we analyze other events through a lens of emotions as cultural artifacts. Together, the findings show that while emotions are racialized

and situated within racialized societies, emotions evolve alongside a fluidity of racial subjectivities (Bonilla-Silva, 2019, p. 5). That is, in Mab's case, although her emotions were situated in her position as a White lesbian woman, her emotions diverged from White folks around her as she continued her anti-Klan work.

Emotions about Whiteness as Social Practices

> I often found myself hating all white people, including myself. As I took on racism, I also found its effects could be turned on me. The possibility of overt violence or the reality of subtle ostracism gave me a sense of shared risk, not the same as the dangers faced by my friends of color, but close enough. I began to feel more uneasy around other whites and more at ease around people of color. ... Could I find ways to share and appreciate other cultures without mimicking or appropriating them, without denying my continuing white privilege? (Segrest, 1994, p. 80)

As Mab continued to participate in anti-Klan activity with NCARRV, she began to interpret Whiteness differently. Emotionally, she described feeling a growing sense of suspicion towards White strangers, seeing them as threatening and keeping her guard up around them. For example, in restaurants with predominantly White customers, she would sit with her back against the wall and eye White strangers with suspicion (p. 80). As a social practice, her emotion of suspicion described a sense of shared risk with her friends of color and established boundaries between her and White strangers, resonating with the ways that affect "...produces the effect of surfaces and boundaries of bodies" (Ahmed, 2013, p. 194). Mab's participation in suspicion created distance between herself and White strangers and, by extension, Mab noted feeling more comfortable around Black, Indigenous, and other people of color (BIPOC) rather than White individuals. Overall, we view Mab's suspicion towards other White people as a social practice central to the NCARRV community, which in turn bound her away from White people in other communities.

Emotions about Whiteness as Circulating Artifacts

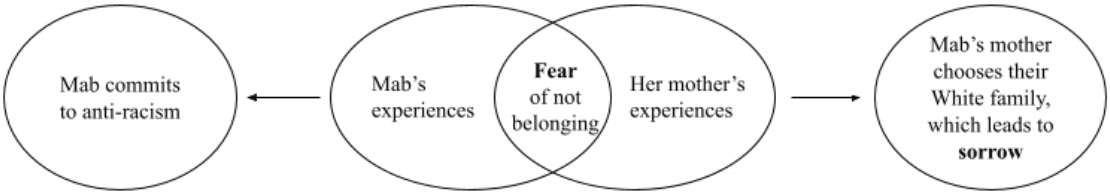
Mab also began to interpret her own Whiteness as a target for self-hatred. She described how her hate for White people began to extend towards herself. Resonating with literature on the "stickiness" of affect (Ahmed, 2013), this newfound self-hatred can be understood in terms of Mab's appropriation of cultural artifacts as she grappled with viewing Whiteness as something to reconstruct or abolish (Leonardo, 2009). That is, she began wondering if it was possible to acknowledge White privilege while reclaiming her Whiteness. For Mab, Whiteness was no longer something that is benign and ignorable, but rather something that necessitated profound change.

As Mab moved about the world as a race traitor, she experienced difficulty finding belonging in either White or BIPOC communities, which led to fears around her safety and belonging (p. 80). We argue that her fear can be viewed as a cultural artifact, made available by Mab's position as a race traitor. Further, appropriating fear allowed Mab to forge an important connection: with her mother and her mother's emotions. Before Mab was born, Mab's mother had been in a similar situation: she had received a job offer as a registrar to *oppose* racist voter suppression but decided to turn it down and maintain her family ties. In reflecting on this life event, Mab's mother said, "When people have to choose, they will go with their own race," (p. 81). This particular experience generated considerable sorrow for Mab's mother, which she later confided to Mab: "My mother was a woman deeply torn by the racism into which she was born. She shared her sorrow with me, often telling me stories of how she and a friend had stopped a Klan rally on the courthouse steps by protesting to the mayor" (p. 81). This sorrow, as a cultural artifact, was available across time and between bodies (see Figure 1). Specifically, when Mab began to feel the fear of not belonging to either White or BIPOC communities, she recalled her mother's similar experiences, which took place years ago. She said, "I had inherited from my mother an awareness of the deep schisms in our culture, and I suspected that it was her attempts to negotiate them that eventually destroyed her. When push came to shove, could I make a different choice?" (p. 82). As Mab negotiated with her fears and her mother's sorrows, she wondered if she could make a different choice

from her mother. In a certain sense, Mab's appropriating the artifact of her mother's sorrow eventually led to a participation shift in social practices, as she furthered her commitment towards anti-racism in comparison to her mother.

Figure 1

Emotions as cultural artifacts in Mab and her mother's lives.



Discussion

This study has explored the affordances of analyzing emotions around activist learning as both social practices and cultural artifacts. We concur with Vea's (2020) prior work highlighting the value of analyzing emotions as social practices. We build on that work by bringing into focus the possibility of examining emotions as artifacts. In particular, we have described how emotions (as cultural artifacts) pass between bodies, traverse time, and shift one's participation in social practices. In relation to cross-racial allyship and anti-racism, this work also shows how such learning involves the negotiation of emotions beyond empathy and the negotiation of one's own and one's community's emotions. In recognition of the role of emotions, we raise several questions for the learning sciences community. With respect to theory, what might an integrated theory that incorporates emotions into learning theories look like? With respect to methodology, when should we choose to examine emotions as artifacts or as social practices? With respect to practice, how do we respond to these shifting emotions in order to create a more supportive environment for anti-racism learning? We believe further research into the role of emotions would be critical to promote better designs for supporting the learning of anti-racism.

SRI International

Collaboration is an important learning process. During collaborative learning, students engage in group activities where they converge on goals, solve problems and make joint decisions. To understand the process of collaboration, we focused on how behavior and interaction patterns contribute to the social-relational space of collaboration. We have designed a multilayered conceptual model for the collaboration process and an observation rubric that identifies behaviors and interactions during collaboration that serves as the foundation for machine learning models that can provide behavioral insight into the process of collaboration. This study reports results on several validation studies performed to establish a validation argument for our collaboration conceptual model and collaboration rubric. Through disconfirming evidence, interrater reliability testing, expert reviews, and focus group interviews, we found that our stratified architecture of collaboration and rubric provide valid accounts and descriptions of human behavior and interactions that can be used to substantiate the collaboration process.

Introduction

Collaborative learning experiences involve interactive peer-to-peer interactions as students solve problems and converge on decisions (Roschelle, 1992) and is comprised of speech-based and behavior-based interactions that intersect for successful product outcomes. Collaboration is a central component of how students learn but presents challenges when determining its role in the learning process. Teachers use speech, namely, discourse and the quality of group products to determine how students negotiate solutions to problems as part of the collaboration process (Roschelle & Teasely, 1995; Guo, Saab, Post, & Admiraal, 2020). For this work, we use machine learning to delve deeper into the behavior-based interactions that students exhibit when collaborating because it is important for students to be mindful of how speech *and* behavior work together for the creation of high-quality group products (Steinbock, 2008). To explore the feasibility and challenges of using behavior to explain the process of collaboration, we have designed a stratified conceptual model for collaboration and rubric that uses nonverbal behaviors and interactions to identify patterns of collaboration to train machine learning models that can provide behavioral analytics for collaboration.

We performed various validation studies of our collaboration conceptual model and rubric to derive a validation argument for valid, reliable, and objective constructs of collaboration. To demonstrate a construct validity argument, we present evidence from disconfirming approaches, interrater reliability testing, expert reviews, and focus groups interviews. Our validation research questions are as follows: (1) How does our concept of collaboration accurately represent theoretically based constructs of collaboration? (2) To what extent do individual key behaviors demonstrate collaboration competencies needed in group settings? (3) To what extent does nonverbal behavioral information from each level of collaboration provide teachers with adequate information for understanding how well students collaborate?

Literature Review

Collaboration As a Process

We describe collaboration as a complex process through which a group of students interdependently and constructively explore ideas to search for solutions, construct new knowledge, and create a socio-cognitive space to generate and share goals, ideas, plans and tools (Roschelle, 1992; Grosz & Kraus, 1996; Child & Shaw, 2015). Our work focuses on two components of collaboration: 1) the process of collaboration (Roschelle & Teasely, 1995), and 2) the nonverbal gestures and behavioral interactions exhibited during collaborative group work.

 © ISLS

Our collaboration conceptual model (Alozie et al., 2020) is based on theoretical models that bring together research on social factors (i.e., behaviors, social cohesion), cognitive science (i.e., social-cognitive systems), and education research (i.e., problem-solving strategies). We broke collaboration down into four building blocks. (1) *Gestures*, where students move their bodies to express an idea or meaning. (2) *Individual awareness,* where students build a community through their understanding of self. (3) *Social and cognitive awareness,* where students engage in cooperative interactions (Johnson & Johnson, 2008), interdependance, and build an understanding of "other" in a group space. (4) *Shared interactive culture*, where students share plans, intensions, goals and tools and work as a team.

Automating Collaboration Assessment Using Speech-based and Behavior-based Analytics.

The use of multimodal learning analytics offers insights into how students learn when performing unstructured tasks like problem solving in the digital and physical world (Blikstein, 2013). Emerging work in speech and textual analytics has shown promise in using machine learning to observe group interactions. Online collaboration assessment has been done through the analysis of peer discourse (Erkens & Janssen, 2008). Other research has collected speech-based data of students working face-to-face to assess collaboration quality (D'Angelo et al., 2015). Behavior analytics for collaboration has made great gains in isolating gestures, sounds, and interactions that can indicate the quality of collaboration (e.g., Subburaj et al., 2020). Visual behavior analytics have focused on evaluating individual facial expressions, group interactions, affect, and task success (D'Mello, 2020). Some studies combined speech and behavior analytics to assess collaboration (Martinez-Maldonado et al., 2013).

Addressing Bias in Artificial Intelligence and Human Interactions

Biased data will create biased machine learning models. If the training data is more representative of some behaviors than others, then the model's predictions would systematically be biased against the under-represented behaviors, and vice-versa (Roselli, Matthews, & Talagala, 2019). We understand that eradicating all bias is difficult and use vetting of the training data to decrease the occurrence of biased annotations (Roselli, Matthews, & Talagala, 2019). To address potential bias due to unequal amounts of data, we perform controlled mix-up data augmentation (Som et al., 2020) which creates additional training samples that use features from existing samples. To expand our sample variation, we recruit students that are diverse in race and gender identification and provide anti-bias training for human observers and analysts. We also use a modular annotation approach to avoid propagating bias across samples and to increase the explainability of each machine learning model.

Methods

Validating the Collaboration Conceptual Model and Rubric Using Disconfirming Evidence and Interrater Reliability Testing. We used discomfirming evidence (Booth et al., 2013) to establish validity of our collaboration conceptual model (RQ1); a procedure whereby the researcher looks for areas of disagreement and for divergent data (Roselli, Matthews, & Talagala, 2019). Two education researchers with expertise in learning science, classroom studies, and STEM education examined the collaboration conceptual model, looking for areas of disagreement. Six different researchers also watched and annotated videos (Barron & Pea, 2013) to establish inter-rater reliability (Cohen's Kappa above 0.6; Landis & Koch, 1977) and look for areas of disagreement. When disconfirming evidence was found, the researchers discussed their responses, came to a consensus, and refined the collaboration rubric.

Validating the Collaboration Rubric Using Participant Focus Groups. To determine the authenticity of our collaboration rubric (RQ2), we convened 9 focus groups that demonstrated diversity in age, race, gender, and occupation. Participants were asked several questions about collaboration. For example, *How do you define collaboration?* and *What do you think are the characteristics of a good collaborator?* We used open coding and selective coding processes to analyze the transcriptions of focus group interviews.

Validating the Collaboration Conceptual Model and Rubric Through Expert Reviews. We conducted expert reviews of the collaboration conceptual model and rubric using a survey and open-ended questions (RQ2 and 3). The expert review was a questionnaire consisting of Likert scale questions about the alignment of the collaboration building blocks to theory-based descriptions and constructs. For example, experts were asked questions like "*To what extent do the building blocks [of collaboration] align with the descriptions [of collaboration]?*" and given choices ranging from *Does not align* to *Aligns very well*. Using qualitative thematic analyses of the open-ended responses and calculating reliability scores of the ratings, we checked for consistency across reviews and then determined a set of revisions based on recommendations.

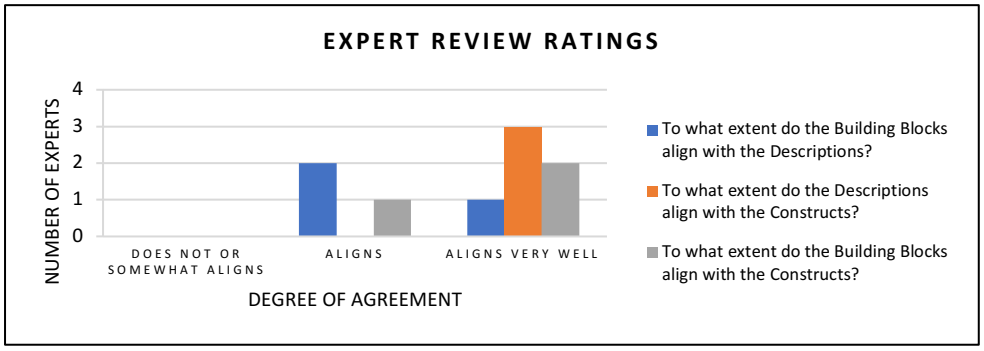
Findings

Definition of collaboration. Most participants stated that collaboration can be defined as shared goals, diversity, inclusivity of behaviors and interactions, distributed responsibilities and roles, an intersection of talents, and opportunities to participate. For example, one participant from Group 7 said, "The bare bones definition of collaboration is just a group working towards a common goal, and everyone bring their own ideas, background and experience in achieving that goal, whether it be through for school or for a personal project or for work." Another participant in said, "Inherency of the intersection of multiple people towards a common goal," and added, "Yeah, and it has to include progress." Similarly, a participant from Group 11 said, "In an ideal world, I would say that a collaborative task is one where you get meaningful efficiencies from having multiple people work on something," then added, "One opportunity for that is differentiated skills, knowledge, expertise, but not necessarily." Common themes among participants about the components of effective collaboration were 1) clear communication, 2) well assigned roles and division of labor, 3) trust and respect among team members, and 4) having shared goals and norms.

Collaboration Conceptual Model. According to the expert responses, our collaboration conceptual model showed alignment with theory and had internal consistency (see Figure 1). However, they commented that the conceptual model should be less linear to show that there is a network of movement between levels.

Figure 1

Construct alignment results from expert review



Collaboration Rubrics. The human annotators achieved above 0.6 Cohen's Kappa inter-rater reliability, showing a convergence in judgement while maintaining variation. However, the experts suggested that a wide range of behaviors would help reduce bias and suggested that the use of descriptions, rather than ratings would be more informative. For example, one expert wrote, "The demeanor codes are unlikely to have all students fitting the description. The codes are fine, but the descriptions are not detailed enough." Our experts pointed to differences in the kinds of interactions that are exhibited among neurodiverse individuals. For instance, one reviewer wrote, "Looking at screen: 'looking at speaker or activity' places significance on one's social interactions. Those who are neurodivergent may not be completing these activities with the same regularity as the neurotypical learners. This is true also of "sustained fidgeting" as well as "sitting still." The experts also recommended measuring heterogeneity of the group using percentage, to allow for group size variation.

Behaviors and interactions of a good collaborator: Emergent themes showed that participants identified a good collaborator as someone that is open-minded and driven, open to critiques, accepting of different perspectives, and welcoming of challenges. Themes also indicated that participants thought that an effective collaborator is considerate and attentive. For instance, a participant in Group 9 said, "[A good collaborator] doesn't just decide on, like, what they want to happen and how they want it to happen and just go for it. With the project, I think people who, like, work to help others express their ideas." Participants also highlighted good communication as important for collaboration. A participant in Group 2 said, "I think good communication from each team member; open mindedness and willingness to share ideas and to discuss other ideas and not force your own opinion based on, like, what you know. So, it's about open mindedness and communication for me." Additional interaction patterns identified by the participants were the ability to provide and follow directions and manage the group dynamics to achieve the articulated shared goal.

Conclusions and Next Steps

Our validation studies provided an effective validation argument for our collaboration conceptual model and rubric. Findings from our studies showed that (1) our concept of collaboration accurately represents theoretically based constructs of collaboration, (2) individual behaviors identified in our rubric effectively measure the

collaboration competencies needed in group settings, and (3) nonverbal behavioral information from each level of collaboration can provide teachers with insightful information for understanding how students collaborate. We found alignment to our working definition of collaboration (e.g., shared goals, co-construction of knowledge, and sharing of tools) and used the recommendations to revise our collaboration conceptual model.

Ultimately, our collaboration conceptual model and rubrics will be used to inform the development of machine learning models that can be used to capture behaviors and interactions in group settings and provide behavioral insights about the collaboration process. Our next steps will be to examine the social structures using epistemic and social network analysis and explore the relationship between talk and gesture. We will also perform machine learning validation tests to explore the consistency, accuracy, and explainability of the machine learning models. Behavior analytics is intended to inform the teacher's exploration of group dynamics- not replace it.

Learning from Teachers' Concepts of Dialogic Pedagogy

Matan Barak, Hebrew University of Jerusalem, barakmatan@gmail.com

Abstract: Advocates of dialogic pedagogy advance a certain set of ideas about productive classroom talk. Associated research processes usually begin with researchers' concepts of what dialogue should look like and then examine whether teachers understand and enact them. Following Vygotsky's ideas that concepts are formed primarily through social interaction and that learners are never *tabula rasa*, I investigate teachers' concepts of dialogic pedagogy as they emerged during a professional development workshop. I use thematic analysis to identify seven teachers' concepts, examining whether and how they were advanced during the workshop and investigate the broader contexts that shape them. My examination of teachers' concepts shows that (a) teachers have an eclectic and flexible approach toward dialogic pedagogy, pointing to conflicting pedagogical needs and pressures; (b) teachers' concepts are embedded within classroom affordances and constraints, pointing to their potential role in bridging between researchers' concepts and the realities and limitations of classroom practice.

Objectives

A growing body of evidence points to the potential of dialogic pedagogy for improving thinking and learning in the classroom (e.g., Resnick et al., 2015). Advocates of dialogic pedagogy promote ideas about productive classroom talk (e.g. Alexander, 2020; Mercer et al., 2019) and try to persuade teachers to adopt and enact them. Associated research processes usually begin with researchers' concepts of what dialogue should look like and then examine whether teachers understand and enact them. The following paper aims to examine *teachers'* understandings, assumptions and objectives – their own concepts – of dialogic pedagogy. This investigation builds on Vygotsky's (2012) and his follower's ideas regarding concept formation (e.g., Wertsch, 1991). According to Vygotsky, concepts are formed primarily through intermental processes, grounded in and mediated by social interaction. Importantly, learners do not arrive *tabula rasa* to such processes but have already accumulated experiences, developed ideas and objectives which bound their learning and their appropriation of new concepts. Investigating teachers' perspectives and understandings of dialogic pedagogy, as they emerged during professional development (PD) interaction, would benefit the field in several ways. First, such exploration may help recognize the disparities between researchers' and teachers' concepts. Second, teachers' concepts are embedded within classroom and institutional contexts, giving insights into the challenges of disseminating and enacting researchers' concepts of dialogic pedagogy. Third, teachers' concepts may shed light on shortcomings and blindspots of researchers' conceptual and practical tools and point to directions and sites for future research.

Theoretical perspectives

In recent decades numerous researchers have suggested various conceptual approaches to dialogic pedagogy (e.g., Lefstein & Snell, 2014; Kim & Wilkinson, 2019). In the PD processes investigated here, facilitators presented dialogic pedagogy mostly in general principles as teaching that affords opportunities for students to express their thoughts and ideas, to inquire, challenge, or build upon others' ideas and to reason about and critically weigh multiple arguments and solutions (e.g., Alexander, 2020; Resnick, et al., 2015). Which of these ideas resonated with the teachers? How did teachers relate them to their existing experiences and perspectives? Following Vygotsky, Wertsch (1991) elucidates that a process of concept formation "results in a mastery of abstract forms of reasoning… units are abstracted from their communicative contexts and become objects of reflection" (p. 29-30). Vygotsky indicates that a mastery of new concepts requires addressing the differences, and sometimes conflicts, between learners existing concepts acquired in their everyday experience and the corresponding academic concepts. Following a Vygotskian framework to teacher professional learning (e.g., Grossman et al., 1999), in this paper, instead of beginning with the principles or concepts of what researchers believe productive dialogue should look like, I map teachers' concepts of dialogic pedagogy as they emerged during PD processes, and endeavour to understand them on their own terms. I discuss how teachers' concepts relate to the PD processes they emerged in, the contexts that influence them and what lessons can be learned to advance research and practice in the field.

Methods

Research Contexts

 © ISLS

This research was conducted within a yearlong PD workshop in Israel focusing on dialogic pedagogy in language arts lessons. The process included eight language arts teachers, five instructional coaches and four researchers learning and working together to codesign and develop dialogic instructional units. During the 2018-2019 academic year, I video-recorded 20 biweekly meetings (70 hours total), collected materials and resources, and summarized events in reflective memos. The PD process included iterative cycles of codesigning, enacting, inquiring, reflecting, and refining dialogic instructional units in the language arts (Barak & Lefstein, 2021). Facilitators led the group meetings in line with these different stages, usually not allocating time for directly advancing or deliberating concepts of dialogic pedagogy. However, beyond presenting dialogic pedagogy in general terms as mentioned in the theory section above, during the sessions the facilitators explicitly highlighted three central ideas: (a) that productive discussions involve prompting students' thoughts, ideas and reasoning; (b) that teachers should connect between different lines of inquiry that emerge during discussions and (c) that assuming critical stances is a central facet of dialogic teaching.

Data Analysis

To identify and map teachers' concepts I investigated the workshop data thematically. This analytic process included the following stages:

a. Reviewing the whole data set. This review included moving slowly through the video-recordings of the meetings, identifying interesting episodes and interactions (Rampton, 2006) relating to conceptualizations of dialogic pedagogy.
b. Identifying preliminary codes (Braun & Clarke, 2012) for teacher utterances that relate to classroom talk, noting different purposes and functions that teachers attribute to dialogue.
c. Reviewing the data corpus again, in search of recurring themes that shed light on the teachers' views, ideas and understandings. This process included identifying episodes in which different ideas and views about classroom dialogue were directly discussed by teachers during the PD sessions (a total of 26 episodes of about 15-30 minutes each were identified).
d. Assembling the emerging themes into seven categories that reflect distinct concepts of dialogic pedagogy.

After mapping the concepts, I reviewed the data set to examine pedagogical assumptions and tensions and how the teachers' concepts relate to ideas that the facilitators advanced. I integrated into my analysis also written material produced in the workshop context, against the backdrop of the broader ethnographic data, such as material from the curriculum and other national education resources.

Findings

By following the four-stage process described above, I identified seven teacher concepts expressed during the PD program.

1. **Getting students to talk.** The core of this concept is that getting student to talk is important feature *in of itself*, irrespective of the content or the quality of discourse. While regularly stressing the importance of increased student participation, teachers acknowledged that opening the floor for students is not without its challenges, such as balancing student talk with other pedagogical needs (e.g., lesson structure, teacher authority or educational purpose).
2. Encouraging students to talk among themselves. This concept highlighted the importance of allowing students to talk autonomously, without teacher guidance. The underlying assumption of this stance is that teachers should consciously relinquish the floor and reduce control over topics, structure and purposes of the discussion.
3. **Developing speaking skills.** This objective relates to the first concept – getting students talking – but highlighted a specific focus and justification: getting students to talk to hone their oral language skills. On many occasions, teachers related these skills to formulations outlined in official guidelines for classroom discussions (e.g., Ministry of Education, undated).
4. **Cultivating polite discussion norms.** Teachers claimed that classroom discussions involve establishing a respectful classroom environment. An underlying assumption of this perspective is that teachers and schools are responsible for imparting prosocial behaviors, and indeed teachers agreed that maintaining polite norms is a basic, unambiguous requirement of classroom interaction.
5. **Students arguing their points of view and offering reasons.** Teachers assumed that meaningful classroom discussions involve students expressing ideas, arguments and reasoning together. They stressed that learning to lead such discussions, and being granted the legitimacy to do so, was a significant aspect of the PD program.
6. **Creating interpersonal encounters.** Some teachers related to classroom discussion as an opportunity for encounters on a personal, emotional level. While teachers expressed the notion that such

communication cultivates inclusive classroom environment, they also raised pedagogical tensions it brings about, pointing to difficulties in maintaining focused classroom activity and meeting institutional requirements.

7. **Assuming critical stances.** This concept underlines the notion that assuming critical stances toward texts promotes productive discussions and enhances students' engagement. Interestingly, teachers related to this idea mostly by invoking their own experiences as learners in the PD workshop, especially following sessions that included interpreting, criticizing and questioning texts as preparation for classroom dialogue.

Note that even though some of these concepts interrelate, they point to different underlying purposes and functions of classroom talk and are thus mutually exclusive. Table 1 outlines the episodes in which different concepts were directly expressed and the number of teachers that expressed them.

Table 1

Distribution of teacher concepts

Concept	Total times concept directly expressed	Number of episodes in which concept expressed (from total of 26 episodes)	Number of *different* teachers who expressed concept (out of 8 teachers)
1. Getting students to talk	7	5	3
2. Encouraging students to talk amongst themselves	5	5	3
3. Developing speaking skills	5	3	3
4. Cultivating polite discussion norms	12	7	7
5. Students arguing their points of view and offering reasons	19	9	7
6. Creating interpersonal encounters	3	3	2
7. Assuming critical stances	6	4	4

Notably, some concepts were more prominent than others in the numbers of times they were expressed, the numbers of episodes they emerged in and the number of teachers expressing them. For example, many different teachers expressed concept 5 (students arguing their points of view and offering reasons) as it was central to the PD program and was raised repeatedly by facilitators. Concept 6 (creating interpersonal encounters) was expressed on very few occasions and only by two teachers. On the other hand, concept 1 (getting students to talk), emerged on several occasions but was expressed only by three teachers who repeatedly voiced this idea.

Some of the concepts the teachers expressed, namely concepts 5-7, resonate quite closely with ideas facilitators tried to promote and the research literature. However, at times the teachers ignored some of the notions the facilitators underlined. For example, the facilitators recommended that when students argue their points of view and offer reasons (concept 5) the teacher's role is to bring together the different lines of inquiry – and that aiming for such coherence is fundamental to productive classroom dialogue. The teachers hardly echoed the latter notion during the sessions. This may be explained by the fact that teachers need to simultaneously take on multiple roles as managers of classroom discussions, as evident in the multiple concepts and tensions they expressed. Adding yet another role of connecting between students' ideas may seem an excessive load.

Concepts 1-4 echo also requirements, pressures and educational discourses that relate to classroom talk. For example, the goal of increasing student talk during lessons (concepts 1) resonates with recent reform efforts in Israel to promote a more constructivist pedagogy (Ministry of Education, 2014). The facilitators did not advance this concept in of itself, but acknowledged it as a basic, implicit condition for leading productive classroom discussions. On the other hand, the facilitators encouraged the teachers to avoid concentrating on students' formulations as means for developing their speaking skills (concept 3), instead to try and recognize their thinking and arguments, even when they seem ill-structured or confused. The teachers associated this concept with institutional expectations to appropriate students into academic language and formulations that reflect adequate disciplinary vocabulary and ways of thinking.

Scholarly significance

The premise of this study, following Vygotskian insights into processes of concept formation, is that teachers have important pre-existing concepts with regards to the pedagogical agenda they encounter; that it is important to study and understand (rather than evaluate) teachers' concepts if we wish to introduce them to new ones; and that a crucial site to investigate teachers' concepts, and the negotiations about them, is social interaction (for example, during PD processes). Three central insights can be derived from the above investigation into teachers'

concepts of dialogic pedagogy, their emergence during the PD workshop and the broader contexts influencing them.

First, thinking about dialogue through the concrete classroom lens allows (and indeed in many cases, demands) teachers an eclectic approach. The multiple concepts teachers expressed, and the pedagogical tensions they raised about them, indicate their acute awareness of classroom intricacies. Their approach indicates, in-effect, that leading classroom discussions demands of teachers to take on multiple roles, stances and to lead diverse, at times contradictory, practices. To better understand teachers' possible adoption of researchers' ideas and recommendations, more studies should focus on the nitty gritty interactional realities within the classroom and promote dialogic pedagogy taking these realities and limitations into consideration. Second, teachers' concepts are flexible. Many of the teachers readily espoused different concepts during different sessions, reflecting the contradictions and tensions inherent in school realities. Two central questions for investigation are, what are the conditions that promote particular concepts over other? And how can promoters of dialogic pedagogy enhance teachers' dialogic repertoires?

Third, teachers' concepts relate to broader educational discourses and agenda. In recent decades, classroom talk is receiving more attention from decision-makers who have begun to target it as a lever of instructional change. Ideas and policies, translated and filtered through PD processes and resources influence teachers' understandings and perspectives regarding dialogic pedagogy. This paper points to diverse resources, such as reforms (e.g., Ministry of Education, 2014), official guidelines for classroom discussion (e.g., Ministry of Education, undated) and other national programs, as resonating in teachers' concepts of dialogic pedagogy. The findings presented here calls for more trans-contextual studies in the field, to investigate how different discourses shape and bound classroom talk, and for promoters of dialogic pedagogy to engage more closely with these educational trends.

Biology teachers' reflections on the benefits and challenges of using scanning electron microscopes in a biology classroom

Bat-Shahar Dorfman, Anat Yarden
Bat-shahar.dorfman@weizmann.ac.il, Anat.Yarden@weizmann.ac.il
Weizmann Institute of Science, Israel

Abstract: Calls have been made to give K–12 teachers and students access to current methods used in biological research, including advanced microscopy. The scanning electron microscope (SEM) is a powerful tool that can be used for either remote or onsite inquiry experiences for students. To use this microscope in a way that promotes students' understanding of biological concepts, teachers should be informed about its capabilities, benefits and limitations as an instructional tool. Therefore, we introduced SEM to in-service biology teachers through a teacher-training workshop where they experienced activities using the SEM. We then assessed their views on the possible benefits and challenges of the SEM in high-school biology class, and particularly while teaching the relationships between structure and function. The participants' insights are described and discussed here, shedding light on what biology teachers should take into consideration while planning and engaging their students in activities using the SEM.

Introduction

Scanning electron microscopy in biology and science education

The scanning electron microscope (SEM) is a powerful tool used by scientists from various disciplines to observe and chemically analyze the surface and near-surface regions of specimens down to the nano level. Similarly, the SEM may allow teachers and students to investigate the finest details of biological structures, thereby facilitating exploration of the relationships between structure and function—a central concept in many biology curricula worldwide (reviewed in Zer Kavod, 2018). Unfortunately, there are many structural aspects pivotal for the understanding of biology that cannot be observed directly by teachers and students, as they are at the micro level. Scanning electron microscopy can reveal the micro (and even nano) structures, enabling an exploring of their possible relationship to function. This can enrich the teachers' toolbox and allow them to provide their students with more complete information. For example, concrete observations of real cells followed by a modeling process enabled students to explore the different functions of the cellular structures and complex interrelations within the cell (e.g., Verhoeff et al., 2008). Direct observations of biological structures by scanning electron microscopy may also allow students and teachers to experience authentic scientific practices, which is one of the goals of many policy documents worldwide (e.g., European Commission, 2011; National Research Council, 2012).

Like other authentic scientific research technologies, the SEM is usually not available to school teachers. With the ease of use and reduced size and cost of the newer SEMs, together with a higher awareness of the value of such authentic technologies to science teaching, scanning electron microscopy is finding its way into high-school programs. However, despite various projects aimed at using SEMs to acquire content knowledge, most of the published papers discussing them refer to chemistry and earth science activities, and only a few to biology (e.g., Cady et al., 2015). Furthermore, most of the published papers report only the affective gains of using the SEM, such as increased engagement, motivation and interest in science, or increased inquiry skills (e.g., Cady et al., 2015; Childers & Jones, 2017). There is a lack of information on the SEM's possible contributions to teaching biology or on the challenges of using it. Providing teachers with opportunities to experience a certain technology first-hand, learn about it, and observe its pedagogical benefits can help shape their attitudes and views toward applying that technology in their classroom (Mishra et al., 2019). We therefore exposed biology teachers to the SEM so that they could gain first-hand familiarity with this technology and evaluate its pedagogical potential. We assessed their views regarding the SEM—its benefits and the challenges that it poses. This is particularly important considering the lack of information in the literature regarding these aspects of using the SEM.

Goals of the study

The main goals of this exploratory study were to introduce the SEM to biology teachers, and to assess these teachers' views on the potential benefits and challenges of using the SEM as an instructional tool for teaching biology in high school, following their own experience with the SEM.

 © ISLS

The context of the study

Participants and workshop description

Participants included 10 high-school biology teachers (6 females, 4 males) who participated in a teacher-training workshop on scanning electron microscopy. The teachers came from different schools in Israel and had 5 to 31 years of teaching experience. All the teachers voluntarily chose to participate in the workshop and in the accompanying research.

The workshop was part of a more comprehensive 4-day, 30-hour professional development (PD) course during the summer vacation (2019). The 4-day course was designed to expose 10 high-school chemistry and 10 biology teachers to the SEM as an instructional tool, and to involve them in developing SEM activities for students (Yonai et al., 2022). On the first day, all of the teachers familiarized themselves with the SEM (the Thermofisher Phenom desktop SEM). Each day they experienced a different workshop with a different activity. Some of the activities were chemistry-oriented and one was biology-oriented. After experiencing each activity, the teachers were asked to provide their inputs and to suggest how to adapt the activity to high-school students. The current study refers only to the 10 biology teachers' insights following the biology-oriented activity.

The rationale of the biology-oriented activity

The activity was developed by a team of life scientists and science education researchers. The goal of the activity was to investigate the motility of the emmer wheat's seed-dispersal unit, based on research by Elbaum et al. (2007), which demonstrated structure–function relationships. In their study, using scanning electron microscopy, Elbaum et al. (2007) identified the mechanism underlying the unit's movement, as the awns move in response to the day–night changes in humidity, thereby dispersing the seeds.

The activity was designed to address the major obstacles to implementing new technologies in the educational system: lack of teachers' familiarity with the technology, and the need for teachers' recognition of its contribution to their work (Mishra et al., 2019), and following the guidelines suggested by Luft & Hewson, 2014. We constructed the SEM activity while taking into consideration the following design principles: (1) Choosing a biological phenomenon that can be observed at the macro level, but whose underlying structure is only observable at the micro level; (2) choosing a topic that would be new and intriguing to the teachers, even the more experienced ones, yet can be related to the biology curriculum; (3) making the SEM an essential tool for exploring the phenomenon (observing the micro-level structures with another tool would not provide a complete explanation); (4) making room for teachers' own ideas, based on their pedagogical experience and the context of their schools; and (5) creating an activity that the teachers could perform with their students in a biology class (after adaptations to suit students' cognitive abilities and knowledge). The activity included four different hands-on tasks, each of which was a key to understanding an aspect of the explored phenomenon. Each task was accompanied by a set of instructions and questions designed to evoke the participants' thinking about the likely relations between the structures they were observing and their possible contribution to the seed's motility (function). Two tasks included macro-level observations, and two tasks focused on micro- and nano-level observations, using binoculars and the SEM. The process was guided by a scientist, who showed the participants how to operate the SEM, and when needed, where to look and what they were seeing. In the summary session, the conclusions from the different tasks were brought together to create the complete picture of the motility of the wheat's seed-dispersal unit. The scientist also discussed the implications of the phenomenon for current research and challenges faced by society.

Data collection and analysis

Open-ended pen and paper questionnaires were used to assess the participating teachers' views on using the SEM as an instructional tool for teaching biology in high school. The questions, adapted from Margel et al. (2004), asked the teachers: Based on your experience in the PD and in class, (1) what is the unique value (benefits) of using the SEM as an instructional tool for teaching biology: (a) for the teacher? (b) for the students? (c) for teaching the relationships between biological structure and function? (2) what difficulties (challenges) could students encounter while working with the SEM? The questionnaires were voluntarily filled out by all of the biology teachers (n=10) in the summarizing session of the course. The teachers' answers to each question were categorized, and the categories were counted to identify the most prevalent themes. In order to anonymize the analysis of the questionnaires, each teacher was assigned an identifying serial number (#1-10). When we refer to statements of teachers, we follow those teachers' statements with their serial numbers, within parentheses.

Results

Teachers' views of the SEM as an instructional tool for teaching biology

SEM's unique value and benefits for teachers and students

When describing the possible benefits of using the SEM for their teaching, the most prevalent theme was that the SEM is valuable for the teaching of biology, as it enables visualizing biological structures that are otherwise abstract or only visualized in pictures. Some teachers (#2, 3, 6, 8, 9) wrote that seeing objects in "real time" would make the data more credible for the students and would help them understand the learned biological phenomena better. The following frequent theme was that the SEM allows teachers to deepen or expand their explanations of phenomena. For example, a discussion about structures and mechanisms involved in the phenomenon at hand, referring to the chemicals involved (using SEM's ability to perform chemical analyses). Some referred not only to content knowledge but also to describing past and current research. Several teachers wrote that using the SEM may allow them to engage their students with cutting-edge, authentic technology (#5,7,9,10). They wrote that this, and the ability to see the real biological structures, can help them evoke their students' curiosity and excitement (#2,3,7,8,10). When asked about the value of the SEM for the students, most of the teachers wrote that using the SEM may allow students to better understand the learned phenomena and the relationships between structure and function. It may allow them to form a more coherent view of the content knowledge, to connect the pieces of data in a more realistic way. They attributed this to the ability to observe the structures with their own eyes, not only through models or learning about them theoretically (#3,6). Some teachers referred to high engagement of students, in contrast to passive learning (#3,5,8,10), and the affective gains of using the SEM (these were referred to as benefits both for the teachers and for the students).

All of the teachers wrote that use of SEMs in a structured activity is important for a deep understanding of structure–function relationships. They wrote that in the activity, the structures and their relationships to function become observable and therefore more vivid. For example, teacher #9 wrote that "many properties are not observable using a light microscope. Students compensate for this by learning from pictures or videos, but it is not in real time, like scanning electron microscopy observations, and therefore less effective for understanding the structure–function relationships." Nevertheless, three teachers restricted their answers by noting that scanning electron microscopy may contribute to this understanding only with proper direction from the teachers, and that using scanning electron microscopy is beneficial, but not necessary. Some suggested exploring the structure–function relationships underlying specific processes, mostly plant-science related, such as the way the unique microstructure of each pollen contributes to its distribution.

The challenges of using the SEM – possible student difficulties while learning biology with the SEM

Describing the challenges of using the SEM for their teaching, the majority of the teachers wrote that their students may experience technical and technological difficulties operating the SEM or preparing the samples. All of the teachers referred to difficulties resulting from the highly detailed images produced by the SEM: Some wrote that the image contains too much information (#2, 4). Most of the teachers anticipated that students would be confused and disoriented by the visual overload and would not be able to understand what they are seeing without guidance (#2, 4, 5, 6, 8, 9). According to the teachers, this may distract them from the structure and phenomenon that are the focus of the lesson. Some teachers (#3, 5, 10) referred to difficulties in understanding orders of magnitude and scale. A few teachers (#8, 9) wrote that students may have difficulties relating the structures they observe at the micro level to the observations and phenomena at the macro level. Teachers wrote that considering these challenges, it is important to prepare the students in advance as to what they are expected to see, to provide them with particularly accurate instructions for the activity, and to closely guide them through the process.

Discussion and implications for practice

In view of the calls for using technology in biology class, many initiatives aim to provide students with access to cutting-edge technologies, including SEMs. Our findings imply that while biology teachers see the unique value and contributions of the SEM as an instructional tool, they also predict several challenges for using it in their classroom. These challenges are not often discussed in the literature, and thus this study may assist in filling this gap. The main benefits that biology teachers attributed to the SEM suggest that teachers can harness its visualization abilities to increase their students'—and their own—better understanding of biological phenomena. Particularly of the relationships between structure and function, and topics for which there are not enough opportunities for hands-on activities, or which are typically less interesting for students, such as plants (Krell & Schmidt, 2020). However, based on the challenges that the teachers themselves experienced during the activity, our findings indicate potential challenges for students working with the SEM, which may inhibit their learning

process. This stresses the importance of using the SEM only if its benefits are substantial and necessary for the learning process. Otherwise, it may not contribute, or may even inhibit students' understanding, due to cognitive overload (Sweller, 1994). Therefore, it is recommended that the teachers and other activity developers make the SEM essential for discovering the discussed biological phenomena. For example, when teaching about a biological phenomenon involving structures that can only be seen by the SEM. Teachers can use scanning electron microscopy for concepts that they have already discussed with their students but lacked the means of visualization, or compare the images obtained from the SEM with the simplified models. To minimize the difficulties and increase the educational gains from activities with the SEM, the teachers expressed their need to construct accurate and detailed instructions and be able to offer close guidance to their students. Teachers' guidance throughout the process is pivotal to preventing student confusion or disorientation. Teachers should explicitly communicate to the students the aim of the activity and what it is that they are seeing, and discuss the relationships between the structures seen by the students and function. Thus, this study reaffirms the teachers' central role in exposing and mediating technologies and their uses to their students (e.g., Waight & Abd-El-Khalick, 2018). Therefore, teachers should be trained to use the SEM, both technically and pedagogically, while explicitly discussing the possible benefits and challenges, such as those presented above. Teachers can also take part in designing activities and adapting them to their students' needs, to their teaching goals, and to their curricula (Luft & Hewson, 2014). The insights from this study can give teachers a better view of the benefits and the challenges of using it from their peers' point of view, which may encourage teachers to use the SEM and support their teaching practice.

Abstract: Despite the potential advantages of using Augmented Reality (AR) in education, most of the existing AR studies have failed to analyse the impact of pedagogical approaches as well as the pedagogical strategies of implementing AR in teaching and learning. An inquiry-based learning framework, coined QIMS, was proposed in this study by considering AR affordances. Through a quasi-experimental design, this study compared three conditions for science learning in a primary school. Results indicated that though students did not demonstrate statistically significant improvement in their academic performance when AR was used, students' self-directed learning and creative thinking skills did significantly improve via experiencing the QIMS inquiry-based learning activities. The use of AR played a more significant role in enhancing students' critical thinking and knowledge creation efficacy. Integrating QIMS and AR was more effective for students with lower abilities. The study provided suggestions on how to integrate AR with inquiry-based learning in science learning.

Introduction

Augmented Reality (AR) technology, with its current advances, has become readily available in education. While technology can be a catalyst for transforming the nature of teaching and learning, it needs to be utilised with appropriate pedagogies, as pedagogy is a crucial component in the employment of AR technology (Chadeea & Prinsloo, 2019). Inquiry-based learning (IBL) is one of the most common pedagogies in AR interventions (Wen & Looi, 2019; Garzón, et al., 2020). AR-enabled inquiry activities could engage learners in an immersive context that enhances scientific investigations –where students can collect data outside the classroom, interact with an avatar, or communicate face-to-face with peers in a more authentic setting (Dunleavy et al., 2009). Despite the potential advantages of using AR in education and its suitability for supporting science learning through simulation activities, AR's concrete uses are relatively not as well understood as that of other technologies (Wu & Wen, 2020). Most existing studies have failed to analyse the impact of pedagogical approaches as well as the pedagogical strategies of implementing AR in teaching and learning (Garzón, et al., 2020). To respond to this need, this study works on investigating how the IBL approach can be integrated with AR-supported formal science learning and if and how it can help to improve students' academic performances and 21st century skills.

AR-based Inquiry-based Learning Activity Design

QIMS inquiry framework for guiding AR activity design

In this study, we articulated a framework for science learning leveraging AR technologies: Questioning, Investigating, Making and Synthesising (QIMS). With reference to Kolb's cycle (2014) in the comprehension and transformation dimensions, students learn in the AR environment to address our proposed QIMS framework. (1) Questioning: Students are guided to raise questions in a topic; (2)Investigating: They will have a concrete experience of the phenomenon through AR simulations and reflect on that experience; (3) Making: They will apply the formation of abstract concepts (analysis) and generalisations (conclusions) which are then used to test hypotheses, resulting in new experiences and inquiries; (4) Synthesising: They conclude their findings to summarise knowledge to capture both comprehension and transformation dimensions.

Learning package of plant reproduction

The learning package on the topic of plant reproduction was designed based on the QIMS framework, meant for grade 5 students. It is centred on a story where a group of aliens need help in growing plants, as their planet is in

 © ISLS

trouble and their plants are unable to thrive there. The students were tasked to help the aliens, with their acquired knowledge on plants. The QIMS cycle includes (1) Questioning: Students ask questions about the alien's planet and on the topic of plants; (2) Investigating: Students concretise their experience of the phenomena by using AR tools and conduct experiments related to the topic. They also note down their reflections and complete some worksheets on the subject; (3) Making: Students create a plant to save the aliens' planet. They develop hypotheses on why their creations can save the planet by applying the concepts they had learnt; (4) Synthesising: They conclude by presenting their plant creations with supporting explanations on why their plants are feasible.

The Plant Lifecycle AR App was developed for the topic of plant reproduction, built using the Unity3D engine, with AR functionality provided by the Vuforia plugin. The Plant Lifecycle AR app comprises three activities: (1) Flower Anatomy, (2) Seed Dispersal, and (3) Plant Engineer.

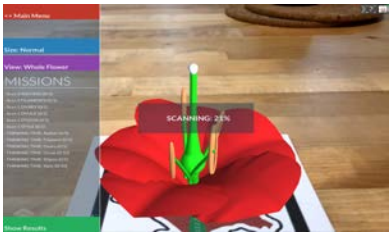

Fig. 1a. Flower anatomy activity

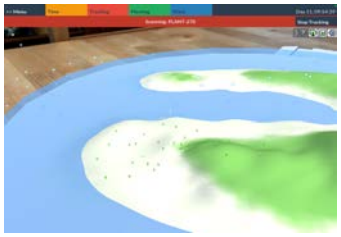

Fig. 1b. Plants dispersed by wind in a characteristic pattern

Fig. 1c. Example of a completed plant model

Fig. 1 the developed Plant Lifecycle AR App

Methodology

A quasi-experimental design method was used to set up an experiment that lasted for 2 weeks to determine whether AR-supported IBL significantly improved pupils' science learning performance and learning competencies better than inquiry-based learning without AR or non-inquiry-based learning. Two research questions were proposed to investigate the students' academic performance and 21st century skills in different learning design conditions. They are: (1) Did AR-supported inquiry-based science learning generate a more positive impact on pupils' learning outcome? (2) Did AR-supported AR-based inquiry-based science learning have a more positive impact on pupils' 21st skills? Which aspects were these reflected in?

Participants

Student participants in the study were 117 grade 5 students from a Singapore government primary school (see Table 1). They belonged to 3 different grade 5 classes and were of similar academic abilities.

Table 1: Participants and learning design conditions.

Class	No. of students	Learning design conditions	Teacher involved
Class A	39	AR + QIMS framework	Teacher A
Class B	38	QIMS framework without AR	Teacher B
Class C	40	No AR, No QIMS	Teacher C

For class A, the teacher introduced the story with a problem scenario – aliens had visited the students' for help. Upon setting the context, the teacher got students to ask questions that they were curious about (Q-questioning). For (I-investigating), the students were given various tasks and encouraged to "think like a scientist". Students learnt about the structure of plants independently, through The Flower Anatomy activity (Fig. 1a) of the Plant Lifecycle AR App. There was little formal instruction from the teacher. The AR app allowed students to self-direct their own learning through self-discovery and active participation instead of just relying primarily on the teacher for information. Students had to examine a virtual flower using the app, identity and scan parts of the flower according to "missions". After successfully scanning the correct flower part, the app displayed pop-up descriptions of the plant. The teacher also brought actual flowers to the class to review and "verify" that the virtual plant had the same structure as a real-life plant.

The second activity was framed through the same problem scenario, illustrating the concept of seed dispersal. Students learnt about the methods of seed dispersal via a simulation activity, the Seed Dispersal activity (Fig. 1b). Students could control the direction and speed of wind by manipulating AR markers. These tasks were designed to be open-ended and intended for students to explore and investigate independently before the teacher gave them the answers and explanations.

The last activity was to review and consolidate what students had learnt (S-synthesising). Students related what they had during learnt during the plant reproduction lessons to a previous topic, Plant transport systems and explained how the two topics were connected. With the AR app, students designed a hybrid plant that could survive and reproduce in the harsh conditions of the aliens' planet (Fig. 1c) (M- making and S - synthesising). Thereafter, the students presented their plant to their classmates and were encouraged to be as creative as they could.

Similarly, the teacher in class B framed the lesson with the same story of the aliens. She did not use the AR app but led students in a cycle of questioning and investigating. She brought different types of seeds for students to touch and feel, guiding them to think about why and how the seeds could help the aliens learn more about pollination and seed dispersal. After investigating, the teacher recapped all the concepts and related it back to the story of the aliens, as well as to the previous topic of plant transport systems. The teacher in class C did not relate the story of the aliens, nor did she make use of AR or QIMS. As in traditional classes, she employed a more teacher-led and direct instructive approach. The students did conduct experiments but were given more explicit instructions.

Instruments

The pre-test checks students' existing conceptual knowledge of the topic of plant reproduction before the intervention. It was a pen-and-paper test with a total score of 16 marks. The test had ten questions and the students were given about 20 mins to complete it. The survey questionnaire, adapted from Chai et al. (2015) measuring students' perceptions of 21st century learning practices, was administered to students after the intervention. The post-survey, consisting of 5 scales, was administrated online in the week of the last intervention. A total of 112 students' responses were collected and analysed. The Cronbach's alpha reliability coefficients for the survey was 0.966, and the Cronbach's alpha reliability coefficients of each scale are above 0.8.

We also conducted online interviews with teachers. The three teachers were interviewed individually via zoom. Each interview lasted about an hour. The teachers' interviews were conducted in a semi-structured format including questions such as – how they perceived students' attitudes towards the use of AR; their opinions on the use of the QIMS framework.

Results

Impact on learning results

We performed an analysis of covariance (ANCOVA) to examine the significance of the mean differences among the three learning design conditions. The post-test score was used as the dependent variable and the pre-test score was used as covariance. The results indicated no significant difference in learning outcomes among the three conditions, F (2,111) = 0.303, p = 0.739. Though the estimated marginal mean of the class using AR with the QIMS framework was higher than the other classes, the LSD post-hoc comparisons showed that there were no significant differences among 3 classes.

Impact on students' 21st learning skills

To interpret whether and in which aspects AR and QIMS had an impact on students' 21st learning skills, we conducted separate analyses of variance (ANOVA) for each scale. As shown in Table 2, there are significant differences among classes in **self-directed learning** [F (2,109) = 4.040, p = 0.020], **critical thinking** [F (2,109) = 3.142, p = 0.047] and **creative thinking** [F (2,109) = 4.079, p = 0.020], but no significant differences among classes could be found in other scales.

LSD Post-hoc tests further revealed that there were no significant differences between the experimental classes with or without using AR in all the scales. However, the pairwise LSD comparisons revealed that there were significant differences in mean values between the class using AR with QIMS and the control class in self-directed learning (p= 0.012), creative thinking (p = 0.007), critical thinking (p = 0.018), and knowledge creation efficacy (p= 0.036). There were also significant differences in mean values between the class using AR without QIMS and the control class in self-directed learning (p= 0.021), creative thinking (p= 0.048), and authentic problem-solving (p= 0.021).

The findings suggested that there was little difference between the class using AR with QIMS and the class without using AR but with QIMS. Yet integrating AR with QIMS had a more significant effect on students' self-directed learning, creative thinking, and critical thinking skills, especially for the low progress learners. This is consistent with the findings drawn from the teachers' interviews. According to the teacher B who used QIMS, the activities based on QIMS provided students the opportunity to be creative, as they were able to do their own questioning and generate their own ideas on how to solve a question or problem. Though IBL was emphasised in

the curriculum, the teachers pointed out that the QIMS was more student-led. Teacher A using AR also mentioned that "with the use of AR, we need to be able to give students autonomy for their own learning."

It was worth noting that the use of AR did not affect students' perceptions on authentic problem-solving. On the one hand, this finding might indicate that the immersion of paper-based AR was not sufficient. On the other hand, this might suggest that instead of replicating real-world experiments or being limited in the classroom, our subsequent AR activity design should further strengthen the link with the living environment. Besides, although the experimental Class A had a higher self-rating in the scale of collaborative learning, there was no significant difference among the three classes. This might indicate that the collaboration script embedded in the AR and QIMS-based learning activities could be further improved.

Discussion and Conclusion

The aim of the study was to investigate how to integrate IBL with AR in science learning to improve students' learning performance and 21st century skills. This paper presents an inquiry-based learning framework (QIMS) that consists of interactive processes of questioning, investigating, making and synthesizing. Instead of approaching inquiry as purely discovery on one's own, Mayer (2004) has stated that there should be guidance, structure and objectives stated in the inquiry-based activities. The paper reports an empirical study to demonstrate how the QIMS framework was used to guide AR learning activity design, and the impact on grade 5 students' learning outcomes and development of soft skills. The findings indicate that the class using AR did not outperform the class following QIMS without AR. However, the two classes engaging in QIMS activities outperformed the class without QIMS. Though students did not demonstrate statistically significant improvements in their academic performance, their self-directed learning and creative thinking skills did significantly improve via experiencing the QIMS inquiry-based learning activities.

This study has several important limitations. The main drawback is the limited time of intervention. Secondly, as the AR app is self-developed, the user interface and 3D animations can still be further polished to better engage learners. Our initial hypothesis is that the class using both AR and QIMS could outperform the other two classes. However, this is not supported by the data of this study. It may be caused by the intervention time and/or the AR app design. The AR app will be further updated, and relevant work has been planned and will be conducted in more schools. The following studies will also explore the impact of AR-based QIMS learning packages on different topics. Besides, future research will pay attention to how students interact during the learning processes to further explain how individual differences influence on the success of the AR activities and how to design AR activities to benefit diverse learners.

Identifying productive reflection in ill-structured problem solving

Aditi Kothiyal, Swiss Federal Institute of Technology Lausanne (EPFL), aditi.kothiyal@epfl.ch
Jennifer K. Olsen, University of San Diego, jenniferolsen@sandiego.edu

Abstract: Ill-structured problems are common in the workplace but difficult for undergraduate students to learn. Within engineering, one ill-structured problem is engineering estimation, which involves determining an approximate value for a physical quantity in a system. Researchers have developed multi-phase modeling-based learning environments to support the learning of estimation. Although this software scaffolds the steps involved in estimation for students, it is still an open question as to how students engage in these learning processes. In this work, we analyze the interaction sequences of students during the engineering estimation process and how they relate to performance. High performing students engage in significantly more patterns of evaluation and planning concurrently with modeling, compared with lower performing students. These findings highlight the importance of additional interventions to trigger the evaluation and planning processes among learners.

Introduction and Related Work

Consider this problem*: "You have to design a light aircraft of maximum take-off weight of 15000 kg. It should be able to take off in 1000 m and less than 30 seconds. Its air speed at 40000 ft above sea level should be about 750 km/hr. Estimate the power of the engine you need to design such an aircraft."* This is an example of an ill-structured problem as it has multiple solutions, solution approaches, uncertainties and evaluation criteria (Jonassen, 2000). Such ill-structured problems are common in engineering when there is incomplete information about the exact operating conditions and the features of the machinery (Linder, 1999). In these situations, experts solve problems by understanding the problem space, making assumptions and scoping the problem, generating possible solutions and selecting one, and implementing and monitoring the solution (Jonassen, 1997). Monitoring their progress and intermittently evaluating their goals is an integral part of the expert problem-solving process (Kothiyal, Murthy & Chandrasekharan, 2016). Students have difficulties with ill-structured problems because solving them requires students to regulate their cognition by planning and evaluating their goals, and monitoring their progress (Shin et al., 2003). Scaffolding these processes can help students learn ill-structured problem solving (Ge & Land, 2004). Researchers have developed learning technologies to scaffold these problem-solving processes (Tawfik et al, 2018), but less is known about how students use these tools for effective learning.

For scaffolds to be effective at supporting student learning, we need to understand whether and how students engage with these scaffolds. Previous work has begun to investigate these learning processes and researchers have found that successful students are able to connect task activities to domain knowledge (Wen et al., 2018), follow incremental approaches (Blikstein et al., 2014), and use more cycles of testing and pausing (Perez et al., 2017) compared with less successful students. These examples support that students who engage in more reflection while problem solving may have higher learning. However, it is an open question of how these results may transfer to another ill-structured problem-solving context, as the frequency of reflection required may vary for different kinds of problems. Therefore, an analysis of students' learning processes is necessary to better understand the interplay between problem-solving and reflective activities within a scaffolded ill-structured problem-solving context, and how that relates to learning. Such an analysis can support our understanding of when to intervene in the learning process to effectively support student learning.

The goal of this work is to investigate the differential sequential action patterns of students who succeed vs those who do not at engineering estimation problem-solving, which is an ill-structured problem where engineers need to determine an approximate value for a quantity (such as power required by the aircraft in the example above). To investigate the sequences of actions that students engage in during learning, we used the modeling-based estimation learning environment (MEttLE) which divides the learning of estimation problem solving into six phases (Kothiyal & Murthy, 2018) with scaffolds to support every phase of the problem solving such as question prompts and hints (Ge & Land, 2004). We address the research question, what are the sequential action patterns of learners as they learn estimation problem-solving, and how do they relate to performance? Specifically, we are interested in how learners engage in problem understanding and reflective actions during problem solving and revisit previous phases. We hypothesize that students who have higher performance would interplay more frequently between modeling and reflection activities, and revisit previous phases more as they reflect on past actions.

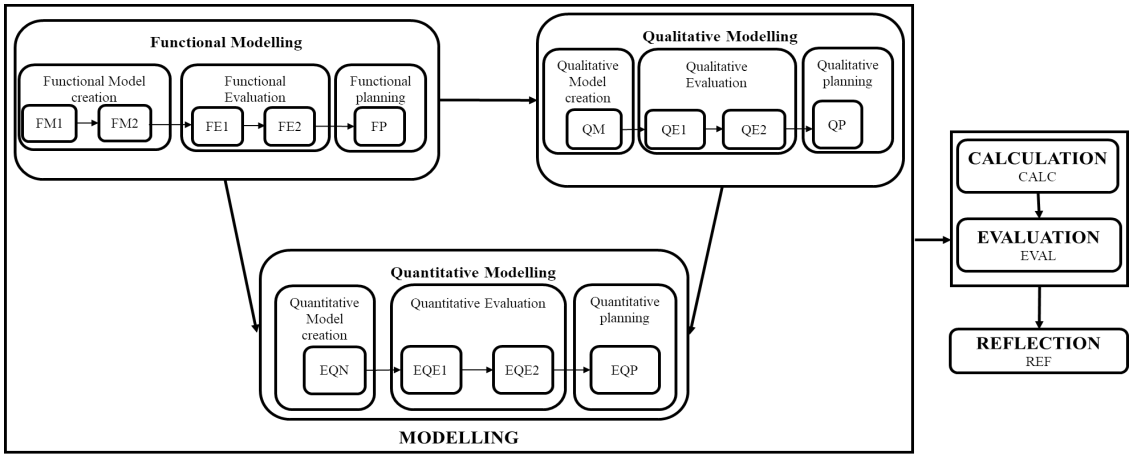
 © ISLS

Methods

Learning Activity

MEttLE structures engineering estimation problems into six tasks (three modeling tasks, a calculation task, a final evaluation task and a reflection task) with the modeling tasks being further divided into three subtasks, and some subtasks having multiple steps (Figure 1). The three modeling tasks, based on the expert estimation process (Kothiyal, Murthy & Chandrasekharan, 2016), are called functional, qualitative and quantitative modeling. Within each modeling task, students have model creation, evaluation and planning subtasks (details and screenshots of the software are available in Kothiyal and Murthy (2018)) that include questions for triggering the metacognitive processes of monitoring the model, evaluation and planning such as *"While estimating power for a design, would you determine the maximum, average or instantaneous power required? Why?"*. The functional and qualitative model creation together constitute problem understanding. The final evaluation task includes questions for triggering the evaluation of the calculated estimate. The problem is considered complete when the estimate passes given evaluation criteria. After solving the problem, students complete a reflection task which includes questions asking them to reflect on the estimation process. MEttLE is an open-ended intervention in which students can do a task/subtask at any time, use the affordances as they see fit and do the (sub)tasks as many times as they wish. During the process, all actions are logged by the system.

Figure 1.
Task flow showing the sequence of the engineering estimation learning tasks, subtasks, steps and their codes within MEttLE



Participants and Data Collection

We analyzed data from a field study in an engineering college with 72 second year students (50 mechanical and 22 electronics engineering) who solved a problem in MEttLE as part of a workshop. The average age of the learners was 20 years. The study began with informed consent being gathered from all participants. Afterwards, participants individually solved one problem in MEttLE, namely, *"You are participating in an electric car race in which you are required to design an electric car of weight 5kg with wheel diameters of 4" that can traverse a track of 50m in less than 5 seconds. Estimate the electrical power needed to achieve this performance."* While solving, students were not allowed to use the internet but could use all the resources in MEttLE and ask the researcher for technical help. As a posttest, participants individually solved an estimation problem on paper similar to the one in MEttLE, without any additional resources or help. We collected logs of participants' interactions in MEttLE, including entered data with timestamps. Owing to technical issues, we were able to recover the logs of only 22 participants, which are used in our analysis.

Analysis Approach

We graded the posttests using the rubric for assessing estimation given in Kothiyal & Murthy (2018). For every criterion that was satisfied, we awarded one point, for a total of three points. Participants who scored three points were classified as high performing students and all others were classified as low performing students. We had three learners in the high performing group and nineteen learners in the low performing group.

To identify interesting behaviors that are associated with the engineering estimation process and can be used to differentiate high and low performing students, we used differential sequence mining (DSM) (Kinnebrew

et al., 2013). DSM identifies sequences of actions that are common within a group of students and by comparing these action sequences between groups, we can better understand how they are associated with performance. To perform the DSM, we used the log data from MEttLE to get all student actions and coded each action as the step the student was working on to align with the flow seen in Figure 1. For example, the functional model creation subtask is split across two steps and any student action in step 1 is coded FM1 and any action in step 2 is coded FM2. Thus, the action coding corresponds exactly to the problem-solving step the student is at. Some steps have multiple questions that require inputs leading to sequences such as "FE2 -> FE2 ->FE2", which indicate either that a student entered responses to different questions on the page or revised their previous response. These sequences of coded student actions serve as the input to the DSM algorithm that identifies the most frequent patterns. We implemented the algorithm using the LASAT tool (Mishra et al., 2019) with the s-support set to 0.5, which means that the algorithm returns all patterns that are 1) present in at least 50% of the teams in at least one group, high or low performing and 2) whose frequency of occurrence in a team (i-support) was statistically significantly different between the two groups.

Findings

Table 1

Top-10 frequent patterns of high and low performing students

No.	Pattern	S-Frequent Group	t-test (p value)	I-Support (Hi)	I-Support (Lo)	Effect Size
1	FE2 -> FE2 -> FE2 -> FP -> FP	High	6.85E-06	1	0.32	1.51
2	FM1 -> FE1 -> FE1	High	2.95E-04	1	0.47	1.08
3	QP -> QP	BOTH	7.94E-04	1	0.53	0.97
4	FP	BOTH	0.0012	2	1.16	0.93
5	FE2	BOTH	0.0018	3	1.8	0.89
6	QE1 -> QE1 -> QE1 -> QE2 -> QE2	BOTH	0.002	1	0.58	0.87
7	QE2	BOTH	0.0045	1	0.63	0.78
8	EQN	BOTH	0.02	1	0.74	0.61
9	QE1	BOTH	0.02	1	0.79	0.61
10	FE1	BOTH	0.03	1	0.84	0.58

From our sequence analysis, we found six main findings related to our research question of how learners engage in reflective actions during problem solving. *1)* High performing group shows significantly more sequences of functional model creation, evaluation and planning than the low performing group (see Table 1, rows 1-2). *2)* High performers had more attempts at the functional evaluation questions (rows 5, 10), and immediately after the functional model creation (row 2). *3)* High performers attempted the questions on the functional planning (row 4), and did so immediately after the functional evaluation (row 1). *4)* High performers had more sequences of qualitative evaluation and planning than low performers, meaning that they attempted the qualitative evaluation questions (rows 6, 7, 9) and the qualitative planning (row 3), although it is not clear when they did the planning questions. *5)* High performers attempted quantitative model creation (row 8) more frequently, but we did not find any frequent sequences of quantitative evaluation and planning or final evaluation and reflection among either group. *6)* Contrary to what we hypothesized, we found that there are no revisits to previously completed tasks by learners in either group that meet the s-support criteria.

Discussion and Conclusion

In this work, we investigated the estimation learning processes of students, a kind of ill-structured problem commonly encountered in engineering education. Specifically, we used differential sequence mining with data from students working with the MEttLE learning software to investigate how high and low performing students use reflection and revisiting actions in their engineering estimation learning process. Experts tend to spend more time exploring and re-representing the problem, and intermittently evaluate their work (Wankat & Oreovicz, 2015; Kothiyal, Murthy & Chandrasekharan, 2016), and we found similar problem-understanding and reflection patterns with our high performing students. These actions are promising to find within the engineering estimation process, as these behaviors are known to be productive for ill-structured problem solving (Wankat & Oreovicz, 2015; Shin et al. 2003; Jonassen, 1997). More concerning is the fact that these same actions were present to a significantly lesser extent with low performing students as these actions were explicitly scaffolded inside of MEttLE. The students were provided with question prompts at frequent intervals to trigger the problem-understanding (functional and qualitative model creation) and reflection (model evaluation and planning) processes. However,

only high performers used the scaffolds and performed problem-understanding, evaluation and planning. These results are interesting because it is not that low performing students tried to engage in these types of actions and still did not perform well; this makes it much more likely that the lack of problem-understanding and reflection actions may be directly connected to the low performance. It may then be the case that providing scaffolding in an open-ended intervention is not enough. More meta-cognitive scaffolding may be needed to guide students to do these problem-understanding and reflection actions at regular intervals until they are able to build these processes into their implicit problem-solving process.

Although there are several limitations to our study, the work shows promising results in understanding the impact of students' problem-understanding and reflective actions and the role that learning scaffolding plays in this process. First, we did not find that students engaged in reflective quantitative modeling and final evaluation, and cycles of modeling, evaluating and planning, which may be due to students not having enough time. Additionally, we had a small sample size of 22 students and a skew with 3 high performers and 19 low performers. All of these factors may have had an impact on our results. However, these results add to the current literature by both replicating the importance of problem-understanding and reflective actions within ill-structured problem solving, and extending the literature by showing the limitations of scaffolding this process without explicitly providing support for students who may not have the skills to know when and how to engage in these productive problem-solving processes. Future work is needed to explore how additional guidance should be incorporated to ensure that students do the problem-understanding, evaluation and planning tasks.

Student Engagement in Collaborative Problem Solving through Media Arts Production

Anna Jordan-Douglass, Makefully, anna@makefullystudios.com
Jessie Nixon, Utah State University, jessie.nixon@usu.edu

Abstract: Collaborative problem solving skills are essential skills for young people that can be gained through artistic media production, yet many educators do not feel prepared to assess media projects. We draw upon examples from two case studies in media arts production to examine collaborative problem solving skills. Building on the PISA framework for collaborative problem solving skills, we demonstrate where and when different skills take place during media production creating directions for classroom assessments.

Major Issues Addressed

To cultivate equitable education systems for the 21st Century, it is essential to teach young people collaborative problem solving skills (Ito et al., 2020; Graesser et al., 2017). Media arts productions can be integrated into classrooms to help students concurrently gain collaborative skills through the act of solving problems with peers (Lee et al., 2015). Yet, teachers often do not know how to assess media productions (Reilly & Atkins, 2013). To address this obstacle, we examine collaborative problem solving at different stages of the production process creating direction for classroom assessments.

Collaborative problem solving through artistic media production

Media production projects often require the collaboration of individuals in assigned roles with specific duties (Barron et al., 2014). Collaborative learning creates positive results for learners' cognitive, meta-cognitive and social aspects of learning (Johnson & Johnson, 2009) and helps learners achieve higher learning outcomes (Chen et al., 2018) and develop teamwork skills (Curşeu et al., 2012). We adopt Roschelle and Teasley's (1995) definition of collaborative learning as "a coordinated, synchronous activity that is the result of a continued attempt to construct and maintain a shared conception of a problem" (p. 70) as media arts production creates an iterative set of problems to be solved. Well-structured, collaborative problem solving tasks require distinctive roles and interdependency of the group members (Graesser, et al., 2017). Media arts productions create prime opportunities for collaboration as students concurrently gain collaborative skills through the act of solving problems with peers (Lee et al., 2015).

Learning through arts production processes are inherently deep and robust constructivist learning experiences (Halverson, 2013), providing students with opportunities to construct meaning of content while simultaneously gaining exposure to skills gained through the instruction of these art forms (Gullatt, 2008). Production also lends itself to interdisciplinary learning, where creators make sense of a specific domain or topic while also acquiring literacy practices across domain areas, including: new media literacy, technology fluency, artistic expression, traditional computer courses, or media education (Peppler, 2010).

Pulling from our combined experience in media production and our research in two creative production classrooms, we set out to answer our research question: What collaborative problem-solving processes do students engage in through artistic media production?

Assessing artistic media production

While many educators today integrate media production into their classroom, they often feel unprepared to assess media (Reilly & Atkins, 2013). As a result, they either do not assess the assignments or assess production based on the acquisition of factual content creating a decoupling of production practices and assessment (Silseth & Gilje, 2017; Aagaard & Lund, 2013). With the demands of the formal classroom environments, it is difficult to assess media production as it should be: both embedded into the process and product (Halverson, 2012). Through evaluating collaborative media arts production, educators can create assessments that will help shape what students see as valuable to learn (Silseth & Gilje, 2017).

In this paper, we demystify assessment for media arts production by demonstrating what collaborative problem solving skills to assess throughout the production process. We use the definitions from the PISA collaborative problem solving framework, which guides assessment of an individual working with a group rather than the group as a whole (Graesser et al., 2017). The PISA framing assesses students' collaborative problem solving along two dimensions: collaboration (first horizontal column) and problem solving (top row), resulting in

 © ISLS

12 specific skills (see Table 1). The PISA framework allows us to map particular moments of production to the collaborative, problem solving processes and quantify the acts taking place during the production process.

Table 1
Adapted PISA Matrix with color-coding system for production stages. Red: Pre-production; Yellow: Production; Green: Post-production; Purple: ongoing in all three stages. Original source: Fiore, S.M. et al. (2017).

	1) Establishing and maintaining shared understanding	2) Taking appropriate action to solve the problem	3) Establishing and maintaining team organization
A) Exploring and understanding	A1) Discovering perspectives and abilities of team members	A2) Discovering the type of interaction to solve the problem, along with goals	A3) Understanding roles to solve the problem
B) Representing and formulating	B1) Building a shared representation and negotiating the meaning of the problem (common ground)	B2) Identifying and describing the tasks to be completed	B3) Describing roles and team organization (communication protocol/ rules of engagement)
C) Planning and executing	C1) Communicating with the team members about the actions to be/ being performed	C2) Enacting plans	C3) Following rules of engagement (e.g. prompting other team members to perform their tasks)
D) Monitoring and reflecting	D1) Monitoring and repairing the shared understanding	D2) Monitoring the results of action and evaluating success in solving the problem	D3) Monitoring, providing feedback and adapting the team organization and roles.

Production Process Stages

Media production involves the process of turning one's ideas, knowledge, and skills into a digital representation, from the initial spark to a final product (Jocson, 2012; Halverson & Gibbons, 2010). While production is an iterative practice, most practices fit into three stages: pre-production, production, and post-production (Jocson, 2012). Table 1 reflects the collaborative problem solving skills tied to the three stages of production.

Pre-production involves conceptualization from brainstorming, storyboarding, and creating a plan of action. Initial planning creates direction while students set goals (A2), determine tasks to be completed (B2), and assign roles (A1, B3). During production, students collect materials and lace together all of the elements, often readjusting their initial ideas (Jocson, 2012). Students communicate with group members (C1), negotiating and renegotiating roles and plans (C2, C3) to meet their larger goal (B1). Post-production involves refining and modifying the artistic representation toward the final goal (D1, D2). As production is an iterative process, monitoring, providing feedback and adapting the team organization and roles can occur throughout (D3).

Methodological Approaches

Data Sources

Our research examines two case studies from unrelated media arts productions in public schools in the Midwest region of the United States. In both cases, we individually served as participant-observers engaging and collaborating with teachers and students throughout the production process. We both used ethnographic field notes from classroom observations and semi-structured interviews with teachers and students to understand more about group roles in these two collaborative productive experiences.

Collaborative Video Production

One study took place in a 9th grade high school introductory video production class in a small project-based, public charter high school in the United States. This case study follows Marty, Chris, Sigrid, and Mariah as they produced their silent film. "Anxiety". The film is about a young woman who suffers from social anxiety and is unable to leave her apartment. The film shows the character struggling to leave, confronting their own anxiety, and eventually leaving their apartment to join their friends at a party.

Collaborative Puppet Documentaries

The second study took place in a 2nd grade classroom participating in a STEAM residency program in the United States. The researcher worked as a teaching artist with two classroom teachers who co-taught 48 students. Students worked in production groups to create puppet-hosted mini documentaries about weathering and erosion, while learning about the digital media production process, puppet building and performance.

Data Analysis

To understand what collaborative problem solving processes students engage in through artistic media production, we used a multiple-case study approach to determine how the production processes compared in these to very different productions (Yin, 2003). We broke down the two cases into three stages: pre-production, production, and post production (Jocson, 2012). Through deductive coding using each of the categories of the PISA matrix, we determined where and when collaborative problem solving activities took place. We then triangulated data by jointly reviewing the two cases using the PISA matrix adding a color-coding system to the matrix based on production stages.

Major Findings

In this section we use examples from the video production project and puppet documentary to demonstrate the collaborative problem solving skills found in the pre-production, production, and post-production stages. We tie moments of each stage to particular skills in the PISA framework, labelling each with the corresponding letter and number from the matrix (see Table 1).

Pre-production

In the second grade classroom, while the students were skilled at using technology for project-based learning, they were novices to the media production process and being part of a production team. The teachers and teaching artist worked collaboratively to devise production roles for the students. Roles were assigned based on input from students on their preferences and interests, as well as the teacher 's perspectives of abilities and group balance (A1). Crews were formed of six students made up of two partners to each role: puppet designer, set/prop designer, and writer. These were structured to be interdependent roles to support their collaboration while meeting all the needs of the production (A2, A3). The students each had their own tasks to work on to bring the creative vision together (B2). Adult guides helped in supporting alignment to a single vision as well as group communication. However, the need for alignment and communication became readily apparent to the students; as they collected resources and began writing, they realized the need to communicate and work together to a shared creative vision - for example, the writers needed to be on the same page as the puppet designers to write the character properly (B3).

Production

Marty, Chris, Sigrid, and Mariah set out with inspirational goals of overlapping two videos in order to see the same character directly behind the other character. Their process included trials, revisions, and reshooting as nobody in the group had attempted this before. They started by filming the actor once in front wearing all white and again in the back wearing all black, but they realized two problems (B1): 1) the set of the two videos was inconsistent and 2) the two films were inconsistently shaky making it more difficult to match up the two videos. To remedy this, they discussed the actions needed to remedy the inconsistencies (C1) and enacted these plans (C2): they had to refilm, figure out a way to stabilize their iPad without a tripod, and re-examine the set to make sure everything was consistent. Marty, the director, helped direct the other group members in their roles from directing the actor’s movements to prompting others to move parts of the set to create more consistent backgrounds (C3).

Post-production

Marty, Chris, Sigrid, and Mariah had to figure out how to overlay video footage to create the impression that the two characters were in the same room. First, they had to learn how to use new software to create the complicated shot using online tutorials and seeking assistance from their teacher. During editing, the group had to return to production and refilm a few shots for consistency (D2). The group also participated in critique with their classmates where they received feedback that conflicted with their shared vision. The most significant feedback they received was that their peers felt the character in the film seemed angry or indecisive rather than anxious. The group therefore returned to refilming, editing, and added additional music and filters to portray the feeling of anxiety (D1).

Significance of Work

This work has important implications for teachers integrating media arts production into their curriculum. First, by designating specific collaborative problem solving skills into particular stages of production, teachers can pinpoint moments in production to assess specific skills creating more direction for those teachers who are unsure of how to assess media (Reilly & Atkins, 2013). Second, recognizing that media arts production involves the social construction of knowledge (Silseth & Gilje, 2017), our work provides direction for assessing collaborative problem solving as a process.

University of Maryland

Abstract: Learning within videogames is often examined using pre-test and post-test, and/or by evaluating players' responses within the design of the game. This study examines young players' perceptions of learning within an educational videogame by analyzing their reactions and responses captured during gameplay and in an interview after the gameplay session. Our findings indicate that different players perceived different elements to be learning outcomes of playing the game. We argue that educational game designers should consider having different elements such as storyline, content-based puzzles, strategy, social skills, and problem-solving to engage players with diverse interests and prior experiences within the educational game design.

Introduction & Theoretical Grounding

The videogame industry is one of the fastest growing entertainment sectors. Games are also increasingly recognized as effective environments for learning (Clark et al., 2016; Dindar, 2018). A significant body of research has found the positive effects of playing videogames focusing on four main domains: cognitive, motivational, emotional, and social (Granic et al., 2014). Game based learning (GBL) literature includes accounts of several studies designed to test games' affordances for learning and skills development. For example, Shute et al. (2015), showed playing a puzzle game could improve players' problem solving, spatial skills, and persistence. Barr (2018) studied how undergraduate students perceived commercial game for developing skills and found a broadly positive perception of the games' efficacy for development of skills such as communication skill, resourcefulness, and adaptability. The literature shows that videogames can be a powerful tool for learning; however, there are two related gaps: 1) there is a lack of focus on micro-level interactions that players have with GBL; and 2) there is no work that ties designed elements to the perceived learning experiences of games. Thus, there is a need for empirical work about what players perceive as learning within a game designed for learning which we address in this study by examining the following research question: *What game mechanics are recognized as learning elements by players?*
Our study contributes by expanding prior work on game-based learning in two ways: 1) understanding players' perceptions of learning within a game, i.e., to identify what players view as learning and 2) providing implications for designing an educational videogame to increase the engagement of players coming from a diverse set of experiences.

Method

Data was collected from 17 participants between the ages of 11 to 14 (7 females, 10 males), recruited through a list-serve associated with the University of Maryland as well as advertisements sent via the local library. 3 participants identified as African American or Black, 4 as Asian or Pacific Islander, 6 as White or Caucasian, and 4 participants didn't report their

 © ISLS

racial identities in the demographic survey.

The data was collected using a Zoom interface where each participant shared their camera and microphone as well as their screen during the gameplay session. Each gameplay session was recorded. Each of the data collection sessions were approximately an hour long including ~40 minutes of gameplay and ~20 minutes of follow-up interview. During the follow-up interview, participants were asked about their impressions about the game and its possible learning outcomes of playing the game. The open-ended questions allowed the participants to discuss what they perceive as learning in videogames, specifically our game, *HEX of the Turtle Islands* (*HEX)*. All procedures were approved by University of Maryland Institutional Review Board.

A constructivist grounded theory approach guided the data analysis process (Charmaz, 2014). Our analysis took place over an iterative process using open, focused, axial coding, and memoing throughout the data analysis process (Strauss & Corbin, 1990).

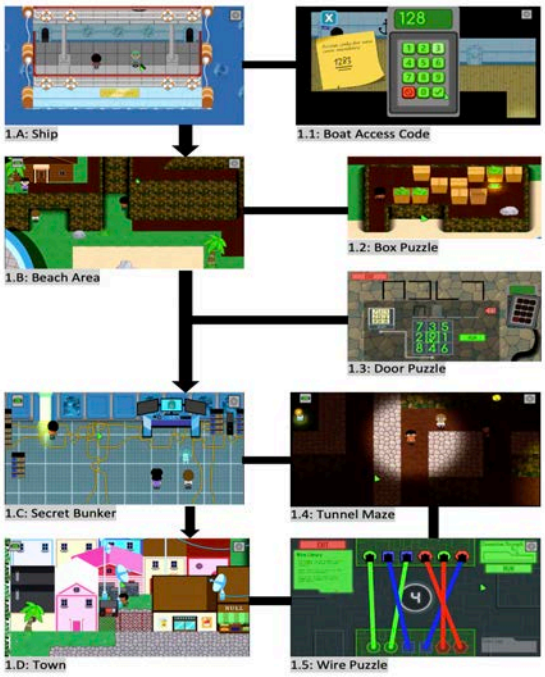

Figure 1: A map of action through the game. Labels A, B, C, and D represent locations that the player explores throughout the game (the Ship, Beach, Bunker and Tunnel, and Town). Labels 1, 2, 3, and 4 represent puzzles that the player encounters in each location (the access code, cipher, box pushing, and wire puzzles).

HEX of the Turtle Islands

HEX is an under-development game designed to introduce youth (11-14 years) to the domain of cybersecurity. The version of the game used for this paper represents an early prototype of the first level of the game which was being tested with players to get feedback for the larger design process. *HEX* is a single player, two-dimensional videogame that combines rich narrative through exploration of scenarios and puzzles rooted in cybersecurity concepts. The player takes on the role of a student investigating a larger conspiracy involving an evil corporation known as *HEX*. Throughout the gameplay, the player encounters cybersecurity scenarios that they must solve to find out what is happening, rescue the crew, and help to save the world in the process. The sequence provided in Figure 1 is roughly the intended pathway through the game for a player.

FINDINGS

Our analysis revealed five main learning themes that emerged from responses about what players thought the game was designed to teach – ecological storyline (one thread of narrative in addition to a larger cybersecurity related plot), content specific puzzle, strategy, social skills, and problem solving. These perceived learning outcomes are not mutually exclusive as some players reported more than one learning outcome of playing *HEX*.

Ecological storyline:

This theme refers to players identifying the narrative elements of *HEX.* For example, Adam recognized the ecological storyline as such, "*In the beginning, there was a little bit about [sea turtles–] ... the depth of the water with time the sea creatures came out*..." Here Adam is responding to hints that are placed in the game world about the impact that *HEX* is having on local sea turtle populations. Three players reported that they identify the learning outcome of playing *HEX* is to learn about the ecology on the islands.

Content Specific Puzzles:

The content specific puzzle theme emerged from six players' responses indicating specific content (e.g., code, logic, etc.) related to the domain of the game to be the learning element. For instance, Daniel shared, "*I learned about the logic gates and things from the puzzles* (Refer to Fig 1.5)." Another player, Maya, mentioned in her interview, "*I definitely think the [cipher] code* (Refer to Fig 1.3)." Daniel's response indicates that he recognizes the logical content involved in the wire puzzles whereas Maya's response emphasized the cryptography content involved in the cipher puzzle. These responses indicate that players pay attention to the content of the puzzles especially if they can identify the objective of having those puzzles in the game.

Problem solving:

Players' responses indicated that problem solving was the most prevalent learning outcome of playing *HEX*, nine players' responses indicated reference to the different elements of problem solving. For example, Matthew shared that, "*I think it was designed to help you to solve different problems*." Another player, Susan, responded that the learning outcome of playing the game is "*how to solve problems – Critically*." The problem solving was a larger theme with implicit references to high level concepts involved in problem solving such as 'critical thinking', 'logical thinking', 'decision making', and 'remembering' things to apply those later in the game.

Strategy:

The responses where players refer to applying strategy to make efficient use of available resources was labelled as strategy. This category was distinguished from problem solving because responses in problem solving referred to a collection of high order thinking skills whereas strategy was referenced to a specific form of ability. For example, Ben responded that "*Probably learning to use your resources and figure out what you could do with your situation with what you had*." His response indicates that while playing, players are required to use strategy to figure out how to make efficient use of the available resources. This theme points to a broader implication of what players do in the game environment can apply in their real-life scenarios.

4.5 Social Skills:

The responses where three players refer to social skills such as being friendly, interacting with people, and seeking help from others were labelled as social skills. For example, Ethan perceived the learning outcome of playing *HEX* is "*to be friends with people or ask for help.*"

This response indicates being social in the game can lead to being social in the real world.

Discussion & Conclusion

We found that players perceive learning within *HEX* in reference to different mechanisms involved in the *HEX* design: ecological storyline, content specific puzzles, strategy, social skills, and problem solving. These findings signify that different players attend to different mechanisms while playing a game. Even though there are similarities in some players' perceptions of learning outcomes associated with playing the game, differences in their responses indicates the 'emergent experience' of the gameplay (Squire, 2006). Our findings suggest that as designers of educational games we cannot assume that every player will have a similar learning outcome while playing a particular game.

The findings of this study are limited in certain ways. The potential learning outcomes emerged from this study are not an objective measure of all possible learning that happened to the players during gameplay. These learning outcomes are situated in the designed elements of *HEX*. Different videogame genres provide different kinds of affordances to players in the game. Future research needs be conducted to study how players perceive learning happening in other videogames to address these limitations. Our study is an initial step to understand learning in game-based learning from young players' perspectives, but we need more empirical studies to see effects of gameplay experiences on a player's perception of learning outcomes.

To conclude, our study findings indicate that different players identify different game mechanics to be associated with learning within the game. Thus, we argue that educational games should have multiple elements such as storyline, content-based puzzles, strategy, social skills, and problem-solving to engage diverse learners in the gameplay.

Abstract: Simulated learning environments have the potential to significantly enhance engagement and conceptual understanding for all students, including students with learning disabilities and difficulties. Dream2B, a web-based video game designed with the Universal Design for Learning framework to maximize access, advancement, and power, includes for fourth through sixth grade students in supplemental mathematics instructional settings. Considerations for Dream2B's design and development are shared as well as planning for and results of feasibility testing in 4th grade classrooms.

Keywords: mathematics, universal design, supplemental instruction, gam-based instruction, fractions, learning disabilities, equity

Promoting diversity in the workforce is paramount for U.S. innovation in Science, Technology, Engineering, and Mathematics (STEM) and Information and Communications Technology (ICT) fields. Individuals with disabilities are underutilized members of the STEM and ICT workforce (e.g., National Science Foundation's National Center for Science and Engineering Statistics, 2019), even though these individuals exhibit unique traits and skills that are particularly beneficial in these careers (Dreaver et al., 2020). For example, Scott et al. (2019) noted these individuals often exhibit: 1) sustained attention to detail, 2) systematic procedural knowledge and skills, and 3) the ability to conceptualize outcomes and solutions to complex problems. The underutilization leads to an inverse relationship between worker supply and workforce demand and perpetuates disparities, especially for underrepresented groups.

Students with learning disabilities (LD), in particular, are one of the largest subgroups of individuals with disabilities and receive supplemental services to remediate areas of difficulty, such as fractions and rational numbers. Yet, this group exhibits reduced engagement and attendance in mathematics and science courses when compared to their peers in tier 1, often due to boredom (Sparks, 2015). The reduced engagement is likely an issue of access. Students with disabilities often require access to different tools to learn or express their STEM knowledge (Author). They also benefit from problems that allow for novel solutions because of the unexpected prior knowledge they bring to the classroom (Author). Both instructional design elements position students' knowledge as important and valuable. Unfortunately, many learning environments afford students with disabilities a one-size-fits-all procedural instruction with little opportunity to engage in and express their unique reasoning (Lambert & Tan, 2017).

In this paper, we report on the design, development, and initial testing plan of Dream2B, a game enhanced supplemental mathematics curriculum. Developed using the Universal Design for Learning (UDL) framework, Dream2B is designed to maximize accessibility and engagement by providing fraction conceptual understanding challenges rooted in authentic STEM careers. Tutorials, action adaptive prompting, and authentic formative and summative assessments are included within the user interface. Game-based problem-solving and after-game play discussion activities promote connections and strategically link to academic curriculum standards. The research questions are: (a) What were student perceptions of the Dream2B intervention?, (b) What were teachers' perceptions of the educational value of the curriculum?, and (c) What was the impact of the Dream 2B intervention on student outcomes (i.e., mathematics engagement/conceptual understanding/STEM Interest)? Below, we unpack Dream2B's core components. Then, we discuss our ongoing usability and feasibility testing of Dream2B in three fourth grade classrooms. Data collection is ongoing. Completed results will be shared in session.

Access, advancement, and power: Dream2B

Dream 2B is a narrative-based mathematics game where students play the role of "Bunny" who helps various STEM/ICT career specialists complete tasks by demonstrating their conceptual understanding of fractions. The

 © ISLS

game narrative describes how Bunny attends career day at school and is introduced to five different careers in STEM and ICT fields. Bunny returns home, goes to sleep, and begins to dream about the different careers discussed that day. In the dream, Bunny is introduced to different career specialists who are each encountering an issue at work and are seeking Bunny's help to fix it. Therefore, Bunny's role in the dream (or game) is to solve these challenges. Each challenge requires Bunny to engage in problem tasks (see below) that can be completed by solving fraction problems.

There are six worlds in the game, with the first five worlds corresponding to the different STEM/ICT careers: wind technician, solar engineer, fire inspector, photogrammetrist, and programmer. These five careers were chosen based on projected career increases over the next 10 years by the U.S. Bureau of Labor Statistics. Each of the first five worlds corresponds to a specific career; world six is a combination of tasks from all careers. The use of game narratives have yielded mixed findings about their effectiveness on learning outcomes (e.g., Clark et al., 2016). However, introducing a narrative has also been found to positively impact learning and motivational outcomes (Plass et al., 2015; Wouters et al., 2013). Therefore, we believe that providing a base narrative in Dream 2B will positively impact learning aligned with the mathematics curriculum we included (see below) and interest in STEM/ICT careers.

We take an innovative approach to the design and development of supplemental math interventions by integrating the following core components into Dream2B: (a) Game Tasks along a Fraction Learning Trajectory, (b) Universal Design for Learning, (c) Action Adaptive Self-Regulation Prompts, and (d) After Game Concept/Skill Connections.

Understanding dream2B's usability and feasibility

Our project is collecting and analyzing data related to the feasibility of Dream2B. This work is supported by a concurrent mixed methods design with one phase of data collection and analysis. Qualitative data will be embedded into the quantitative design. Data and analyses from this year will be used to inform a final revision to the supplemental curriculum before pilot testing.

Recruitment and training. We recruited three fourth grade teachers and their students to implement the Dream2B curriculum. Teacher and student participant selection was purposive in that inclusive math classrooms were selected that include 5-10% of students with disabilities for the feasibility testing. Participating teachers attended four one-half day training sessions on implementation of the curriculum. Day 1 of training opened with the purpose of the study, the logic model, and the target population. Teachers will become familiar with the design of the new curriculum, its features, and the overall learning trajectory that grounds the task sequence, prompts, and teacher talk moves. Over the second and third day of training, each task category and its written lessons acted as structural guides. The guides were designed to help teachers deepen their understanding of how students might think within the tasks and understand how the core components are used to bolster student learning. Teachers worked with each other to discern possible nuances in students' reasoning and prompts that are embedded into the game and curriculum. On the 4th and final day of training, teachers practiced using Dream2B through role playing. Teachers formed a small group with their peers and the research team, rotating between teaching roles and student roles, hypothetically engaging in the tasks, and implementing mocked student strategies. Teachers then engaged in discourse and used identified talk moves taught during the training to facilitate a sample student conversation.

Data collection. We are collecting five kinds of data to gauge the feasibility of the curriculum to answer the research questions (student perceptions, teacher perceptions, student outcomes). Each area is addressed below.

In terms of student and teacher perceptions, we will meet with our teachers in a 1.5 hour long semi-structured focus group to gather feedback on STEM career characters, guides, and motivational game components (i.e., resource management, narratives, character unlock). We will discuss how content is currently taught in classroom instruction, difficulties students may be experiencing with the content, and teacher familiarity with pedagogical moves used in the curriculum (e.g., worked examples, number strings; game prompts and task sequencing) and the extent to which, if at all, these design components were being used in their classroom. Finally, we will meet with 4th grade students with and without LD to conduct semi-structured interviews to gauge students' strengths (i.e., what students already know about ratio and proportion; what gestures they may already employ as they solve problems). We will also gain feedback on the preliminary list and design of STEM careers, game characters, and elements to align the game to preferences of elementary school students.

In terms of student learning outcomes, defined as engagement/conceptual understanding/STEM Interest, we will use several measures. First, the *Engagement in Science Learning Activities* survey, written for use with 10 to 14-year-old students immediately after an in-class or informal activity, will be used to measure student engagement with the curriculum. The survey measures a student's cognitive, behavioral, and affective engagement. Participants respond on a Likert-type scale ranging from 1 (*YES!*) to 4 (*NO!*). Both Cronbach's α and the polychoric coefficients yielded acceptable reliability when using all eight scale items (0.80 and 0.85, respectively). In addition to the survey, click trails will be used to determine in-game engagement. We will use 60 second game intervals without activity as the basis for engagement based on Author's prior research.

Conceptual understanding will be measured before and after the intervention using the Test of Fraction Schemes (Wilkins et al., 2013) and problem solutions generated during the games. The Fraction Schemes test is a proximal measure of the effects of the intervention on students' fraction conceptions. It consists of 12 items; 4 items for each of the following fraction concepts: unit fraction concept, partitive fraction concept, and splitting that underlies the recursive fraction and iterative fraction concepts. Internal consistency reliability for the test was reported as 0.70 for the unit fraction concept and splitting. Criterion-related validity with an associated clinical interview score was reported with coefficients of 0.52 ($p < 0.01$) for splitting and 0.58 ($p < 0.01$) for the unit fraction concept. Following Wilkins et al.[89], test scores will be supplemented by student interviews with an additional six items to assess the nature of students' pre-post fraction concepts.

Students' STEM interests will be measured with the Upper Elementary School (4-5) and Middle High School (6-12) Student Attitudes Toward STEM (S-STEM) (Friday Institute for Educational Innovation, 2016). It contains 56 items across six constructs: math attitudes (8 items), science attitudes (9 items), engineering and technology attitudes (9 items), 21st century learning attitudes (11 items), interest in STEM career areas (12 items), and 7 "About You" items that measure short-term expectations for course success and exposure to STEM careers. Responses are supported by a five-point Likert scale, with response options ranging from "strongly disagree" (1) to "strongly agree" (5). Higher scores reflect the greater perceived value of participants. Cronbach's α of the S-STEM ranged from 0.84 to 0.86 for the grade 4-5 subscales and 0.89 to 0.91 for the middle high school subscales.

Feasibility data analysis. We will take various strides to ensure the credibility, transferability, and dependability of the collected data. The prolonged engagement with teachers and students, persistent observation of problem-solving strategies, self-regulation utterances, and discourse representations, language, and observable operations), triangulation (i.e., 3 coders, 3 sources of data, 3 methods to collect data - video, student work, field notes) and member checking with teachers and students will address credibility of the data. Describing not just the behavior of students in the intervention but also the context supports transferability; we will also report examples of our coding processes and rationale for what codes were clustered together to form the basis of a theme to ensure dependability. We will also organize and analyze collected process and product data utilizing an array of tools. We will transcribe (verbatim) all video recordings that capture students' self-regulatory utterances during problem solving ("Think"), their discourse ("Pair" and "Share"), and teachers' employed talk moves ("Share"). We will also use Excel to organize students' self-reported use of checklist prompts, student and teacher self-regulation survey data, and pre- and post- test (product data) scores on the paper and pencil tests.

We will conduct 3 sets of data analysis: (1) assess teacher and students' perceptions of the curriculum, (2) assess pre-mid-post changes in self-reported engagement, conceptual understanding, and self-reported STEM and ICT interest, and (3) assess within-student fluctuations in time stamped behaviors over the learning sessions. To understand student and teacher perceptions of Dream2B, we will qualitatively analyze the focus group data. Specifically, we will transcribe and qualitatively code the data for recurring themes.

To investigate changes in students' reported engagement, their conceptual understanding, and reported STEM and ICT interest from pretest, mid-study, to posttest between conditions, we will conduct a series of repeated measures ANOVAs with time as the within-subjects factor and teacher as the between- subjects factor. We will examine the main effect of time (pre vs. mid. vs. post), the main effect of condition (teacher), and the interaction between time and condition on engagement scores, conceptual understanding scores, and STEM/ICT interest scores. We will also run linear regressions (single and multiple) to determine if engagement, conceptual understanding, and STEM and ICT interest at pretest are predictive of these measures at mid-study or posttest, or if measures at mid-study are predictive of measures at post-test.

To investigate the trace data (i.e., click trails during the game) and how they fluctuate across sessions or games, we will conduct multilevel modeling and educational data mining analyses. As the study includes a nested design (students within teachers), we can investigate the between- and within-student or teacher variance in time spent engaging in game activities or game levels, and their association with our posttest measures. The trace data will generate a stacked dataset with multiple rows of data per participant, where one row can represent a game session or game level, as opposed to aggregating all this information into a single row (i.e., mean game session duration). In addition, we will use sequential pattern mining to examine if we can detect sequences of in-game actions that are common across participants, and then determine the frequencies of those sequential patterns per student and compare those frequencies using chi-square analysis differential sequence mining. In addition to examining overall group differences between test times, we can examine processes of engaging in-game behaviors across class sessions or game levels.

Final interpretation. Results of each analysis will then be merged to compare and interrelate the feasibility of implementing Dream2B in fourth grade classrooms. Once the data are analyzed and organized, results will be used to make necessary adjustments to the curriculum. In session, we will report on the analysis and curriculum revisions.

The Effects of Domain-specific Knowledge on (Re)reading a Literary Short Story

Kathryn S. McCarthy, kmccarthy12@gsu.edu
Davis M. Whaley, dwhaley4@student.gsu.edu
Georgia State University, USA

Abstract: This study was designed to address the issue that student readers often struggle to generate the interpretive inferences needed for successful literary comprehension. Participants (n = 60) thought aloud as they read a short story. They were assigned to a 2(instruction: control, literary information) × 2(think-aloud: first pass, rereading) design. Providing readers with information about how to engage with a text in a literary way as well as an opportunity to reread and reexamine the story showed modest benefits for increasing interpretive inferencing. These findings have implications for how to help students to develop and use strategies that can support their understanding and enjoyment of literary works.

Introduction

Literary reading invites the construction of *interpretive inferences* about the deeper meanings of the work and reflection on the literary or aesthetic qualities of the work (e.g., McCarthy, 2015; Levine, 2019). However, students rarely make interpretive inferences as they read and often find literary foregrounding (i.e., stylistic variations) that experts appreciate to be dense and confusing (e.g., Claassen, 2012; Graves & Frederiksen, 1991; Peskin, 1998; Zeitz, 1994). In order to develop effective interventions to support the use of literary-appropriate reading strategies, there needs to be a better understanding of the domain-specific literary knowledge that supports the construction of interpretive inferences (Lee & Goldman, 2015).

McCarthy (2015) drew upon empirical studies of literature and theories of discourse comprehension to argue that literary experts possess not only knowledge that literary reading invites interpretation (e.g., a domain-appropriate reading goal), but also knowledge of relevant conventions and themes that support the construction of interpretive inferences. Rabinowitz (1987) refers to the shared knowledge between author and reader as literary rules: knowledge of conventions reflect *Rules of Notice* and knowledge of themes reflect *Rules of Signification.* Prior work has demonstrated that providing short background readings that describe relevant Rules of Notice and/or Rules of Signification prior to reading a story can improve their literary reading strategies. More specifically, these manipulations decrease student readers' reliance on close-to-text paraphrasing and encourage more interpretive inferencing (McCarthy & Goldman, 2019). Further, readers given information about the literary rules report higher ratings of enjoyment and appreciation of the story. These studies suggest that introducing novices to domain-specific literary knowledge can support more literary-appropriate interpretive processing.

The current work builds upon these studies to further examine ways to support novice literary readers in producing interpretive inferences. In the current study, we reduce the number of pre-reading conditions to include only the extremes (no information vs. information about both literary rules) and increase the sample size afford the use of inferential statistics. Critically, we also included a rereading manipulation. Rereading was assumed to support interpretive inferencing for two reasons. The first reason comes from research in discourse processing examining how readers construct mental models of what they read. Millis and colleagues (1998) demonstrated that comprehension processes during first reading are dedicated to constructing a textbase or gist representation of the text; whereas, upon rereading, resources are shifted to construction of inferences that support a more robust situation model. By the same logic, some have argued that novice readers may refrain from generating interpretive inferences during their initial readings of a text because they need to first construct literal aspects of the mental model before they are able to consider nonliteral meanings. The second reason comes from literary theory which suggests that rereading, or multiple readings, can allow readers to reexamine and appreciate literary qualities of the text (e.g., Dixon et al., 1993). In either case, the opportunity to reread should enhance readers' propensity to engage in more literary-appropriate processes, especially if they are given information that can support the generation of interpretive inferences. Thus, the current study aims to answer two research questions: (RQ1) *To what extent does providing information about literary rules change readers' processing of a literary short story?*

 © ISLS

Based on prior think-aloud studies (e.g., Burkett & Goldman, 2016; Claassen, 2012; Graves & Frederiksen, 1991), we predicted that students in the no information control condition would produce think-alouds dominated by paraphrasing. We predicted providing students with pre-reading information that informed them of relevant *Rules of Notice* and *Rules of Signification* would decrease the amount of paraphrases and increase the generation of interpretive inferences. We also anticipated that increased knowledge of how to make sense of the text would enhance their enjoyment and appreciation of the story. (RQ2) *Does a rereading opportunity augment the effects of providing literary information?* We hypothesized that an opportunity to read the text through once prior to thinking-aloud would allow readers to allocate more resources to complex inferences. Thus, readers may be better able to leverage the literary information on a second pass of the story. We also predicted that the opportunity to reread would increase readers' enjoyment and appreciation of the story (Kuijpers & Hakemulder, 2018).

Method

Design & Procedure

Students (n = 60, M_{age} = 27.18, *SD* = 7.18) from an urban university in the southeastern United States read and thought aloud about the short story *The Elephant* by Slowomir Mrozek. Participants completed the study one at a time in a one-hour session. Due to continued social distancing protocols, data were collected via videoconference. Participants were given a think-aloud instruction to verbalize as if they were "turning up the volume" on their thoughts as they read (e.g., Peskin, 1998). The experimenter modeled a think-aloud and then participants were given the chance to practice until they felt comfortable thinking aloud. Participants were randomly assigned to a 2(instruction: control, rules) × 2(think-aloud: first pass, rereading) between-subjects design. In the *control* condition, participants were only given the title of the story. In the *Rules* condition, participants were given information about relevant Rules of Notice (deviation from the norm, disruption, juxtaposition) used in the story and Rules of Signification (participants were told that the text was a satire and were given an explanation of what satire is). Participants in the *first pass* condition were prompted to think-aloud during their first reading of the story. Participants in the *rereading* condition were instructed to read the text silently before being prompted to think-aloud during their second reading. After reading, participants answered three appreciation items. Participants rated (1-7) the extent to which they agreed with the following statements: "Is this story an example of good literature?", "Did you enjoy reading this story?", and "Would you recommend this story to someone else to read?" (Dixon et al., 1993). Participants then completed a 20-item true/false comprehension test designed to measure readers' literal understanding of the story. Finally, the participants completed the Author Recognition Task (ART; Acheson et al., 2008) which is designed to measure print exposure.

Procedure

Think Aloud Coding

Participants' think-alouds were transcribed and parsed into idea units and coded using a simplified rubric from Whaley and McCarthy (2020). The rubric includes four categories. *Paraphrases* reflect restatements of content that is explicit in the text. *Text-based inferences* reflect a broad range of statements in which the participants are generating inferences to maintain a story-world representation of the text (e.g., "he obviously is trying to cut corners and use the money for himself or use to basically boost his ego", "So it sounds like because the director misled the kids […] seeing it disappear made them believe that elephants just aren't real"). *Interpretive inferences* are statements that go beyond the story world to identify nonliteral meaning ("it makes me think that maybe this is metaphorical for something else") and to understand the author's possible intention or meaning about the world at large ("There is some definite political statements that are being made through the subtext"). All other kinds of statements, including metacognitive monitoring statements ("Okay I'm a little confused") and personal associations ("I have rabbits at my backyard") were collapsed into an *other* category. Two researchers coded a random subset of 20% of the think-alouds, achieving good interrater reliability (weighted kappa = .75) and then independently coded the remaining think-alouds.

Results

Preliminary Analyses

ART scores (*M* = 10.46, *SD* = 9.28) reveal low print exposure relative to prior reports of undergraduate samples (Acheson et al., 2008 report *M* = 22.70 of 65), but consistent with their status as non-experts. An analysis of variance (ANOVA) test revealed no significant differences in ART score across the conditions, *F*s < 1.00,

indicating no *a priori* differences in readers' print exposure. Comprehension score was calculated as proportion correct. Participants scored highly (M = .90, SD = .07) and the ANOVA revealed no differences in comprehension score across the conditions, all Fs < 1.00.

On average, participants' think-alouds included less than 1000 words (M = 944.28, SD = 390.71). An ANOVA revealed no significant differences in think-aloud length, although the effect of rereading approached significance, $F(1,56) = 3.59$, $p = 0.06$. This pattern suggested that those who had already read the text once silently prior to thinking aloud (reread condition) generated slightly longer think-alouds (M = 1039.33, SD = 422.76) than those who were asked to think-aloud on their first pass of the text (M = 849.23, SD = 336.39).

Think-Aloud Processes

The omnibus 2(instruction: control, rules) × 2(think-aloud: first pass, reread) × 3(process: paraphrase, text-based inference, interpretive inference) mixed ANOVA revealed a significant three-way interaction, $F(2,112) = 6.45$, $p < .01$ (Figure 1). To follow up this significant effect and to address RQ1, we first examined participants who thought aloud during their first pass of the story. Consistent with prior work, there was a main effect of process type, $F(2, 56) = 46.86$, $p < .01$, such that participants generated significantly more paraphrases than text-based inferences and more text-based inferences than interpretive inferences (Tukey HSD test ps < .03, Figure 1, left). However, there was no main effect of instruction condition, $F(1, 28) = 2.24$, $p = .15$, and the process by instruction interaction failed to reach significance, $F(2,56) = 2.54$, $p = .09$.

To address RQ2, we then examined the effects of the instruction manipulation for the reread condition, who were given an opportunity read silently before thinking aloud. Consistent with the first pass participants, there was a significant main effect of process type, $F(2, 56) = 41.60$, $p < .01$, such that there were significant differences across all three types of processes (Tukey HSD tests, ps < .01). There was, again, no main effect of instruction condition, $F < 1.00$. However, these results were qualified by a significant process by instruction interaction, $F(2, 56) = 3.93$, $p = .03$. A t-test indicated significant differences in the proportion of paraphrases in the predicted direction such that participants given literary rules prior to reading and thinking aloud generated a smaller proportion paraphrases than those given no information, $t(28) = -2.13$, $p = 0.04$. There was no effect of information condition on the proportion of text-based inferences, $t(28) = 1.14$, $p = 0.26$. Finally, a t-test for the proportion of interpretive inferences as function of information condition failed to reach significance, $t(28) = 1.88$, $p = 0.08$. However, the low overall rates suggest a possible floor effect. Taken together, these results suggest that the opportunity to familiarize themselves with the text prior to thinking aloud increased the predicted effects of the literary information instructions.

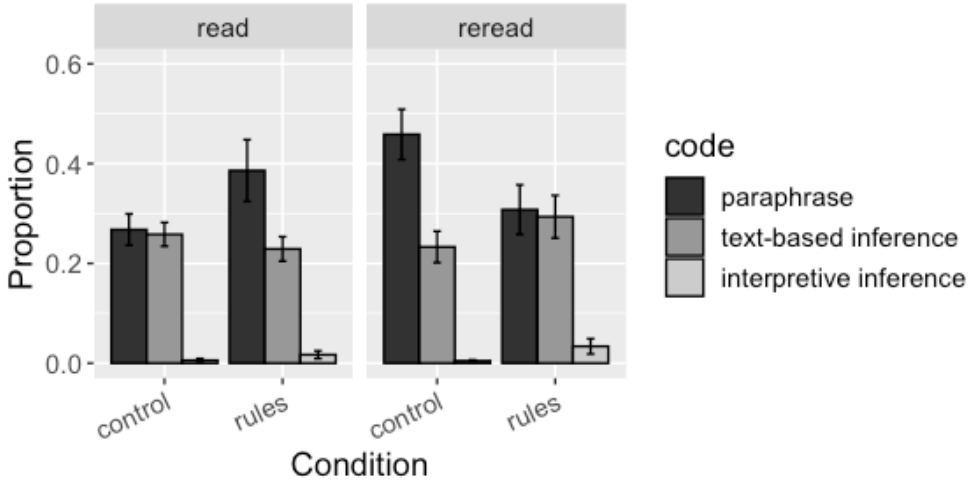

Figure 1
Think-Aloud Processes as a Function of Literary Rule Information and Rereading Condition

Appreciation Measures

The omnibus ANOVA indicated a significant three-way interaction, $F(2,110) = 4.33$, $p = .02$. Follow-ups indicated no effects for whether the story is good literature (Q2) or whether they would recommend the story to a friend (Q3; all ps > .10). By contrast, there were significant differences across conditions for ratings of enjoyment

(Q1; Table 1). More specifically, there was a significant main effect of information condition $F(1, 17.07) = 9.52$, $p < .01$, such that readers given literary rules information prior to reading found the story more enjoyable than those given no pre-reading information. These findings partially support our prediction related to the effect of literary instruction, but not rereading (e.g., Dixon et al., 1993; Kuijpers & Hakemulder, 2018).

Table 1
Appreciation Ratings as a Function of Literary Rule Information and Rereading Condition

	Did you enjoy reading this story? (Q1)		*Is this story an example of good literature? (Q2)*		*Would you recommend this story to someone else to read? (Q3)*	
	Control ***M* (*SD*)**	Rules ***M* (*SD*)**	Control ***M* (*SD*)**	Rules ***M* (*SD*)**	Control ***M* (*SD*)**	Rules ***M* (*SD*)**
First Pass	5.00 (1.41)	5.53 (1.19)	4.00 (1.31)	4.47 (1.55)	4.13 (1.64)	4.47 (1.64)
Rereading	3.93 (1.62)	5.43 (1.02)	4.00 (1.56)	4.36 (1.22)	5.07 (1.33)	4.57 (1.40)

Discussion

This study replicated previous work showing that knowledge of literary conventions and themes 1) affects how readers approach the text, such that they engage in less paraphrasing and slightly more interpretation and 2) increases enjoyment of the story. The study also extends this research by demonstrating that novice readers may be better able to leverage this domain-specific knowledge when given the opportunity to reread. These findings are consistent with the idea that rereading allows readers to focus their efforts on higher-order comprehension processes once an initial foundation has been laid and that revisiting a story gives a reader the opportunity to reexamine their understanding and gain new insights. Future research should examine reader processes in more fine-grained ways to better understand what drives these rereading effects and future development of instructional activities and interventions should consider emphasis on and opportunities to reread stories to help students to leverage their literary-specific knowledge and enact relevant comprehension processes.

Expanding Teacher Transformative Agency: An Activity-theoretical Formative Intervention Research in School-based Dialogue Sessions toward Future Making

Katsuhiro Yamazumi, Kansai University, kyamazum@kansai-u.ac.jp

Abstract: Drawing on cultural–historical activity theory and expansive learning theory, this paper focuses on methodologically reexamining and transforming the linear interventions incorporated in traditional standardized pedagogy and educational research. To achieve this, the present study investigates strategies for generating formative interventions in teacher learning and development in an attempt to engage teachers in collaborative interventions to facilitate expansive learning. Teacher transformative agency can be generated and exercised through collaborative formative interventions. During this process, teachers become responsible activity agents who collaborate to independently reshape their activity systems. This paper presents the findings of a formative intervention study of teacher learning and development in school-based research involving teachers at a municipal elementary school in Japan. The participating teachers' school-based research can be characterized as expansive learning through which they collaboratively formed complex concepts, giving rise to a new vision of schooling.

Introduction

In the field of school reform, traditional standard intervention studies are reduced to linear causality, wherein a top-down view regards teachers as entirely passive agents of policies, while policymakers and researchers create a grand design that teachers then apply or revise, resulting in more positive change for students. Conversely, the basic principle of *formative intervention studies based on cultural–historical activity theory* is that teachers themselves gain the agency to control the intervention and take charge of the process. Thus, teachers become change agents. *Activity theory* studies how agents collaboratively redesign, change, and transform their collective activity systems, which have been culturally and historically constructed (Engeström, 1987/2015, 2008, 2016, 2018; Leont'ev, 1978, 1981; Sannino et al., 2009; Sannino & Ellis, 2013; Yamazumi, 2021). Here, the focus is on triggering and sustaining expansive transformation led and owned by teachers.

Moving beyond the limitations of linear intervention, activity–theoretical formative interventions in teacher learning and development attempt to facilitate teachers' *expansive learning*, as theorized by Yrjö Engeström (1987/2015, 2016)—that is, expanding the object of teachers' collaborative learning from below to change the broader structure of an entire school as a collective activity system. These *collaborative interventions* engage teachers in creating their own interventions to independently transform their activity systems (Yamazumi, 2021). Through such interventions, teacher *transformative agency* can be generated and exercised. In other words, collaborative formative interventions based on activity theory enable teachers to become responsible activity agents who collaborate on shared inquiry into desired objects, forms, and patterns of practice, resulting in the redesign of schools.

Drawing on the abovementioned frameworks, this paper focuses on methodologically reexamining and transforming the linear interventions incorporated in traditional standardized pedagogy and educational research. To achieve this transformation, this paper investigates strategies to generate formative interventions in teacher learning and development in an attempt to engage teachers in collaborative interventions to facilitate expansive learning. Reporting on an activity–theoretical case study, this paper presents the findings of a formative intervention study of teacher learning and development in teachers' school-based research at Jōetsu Municipal Ōmachi Elementary School, Jōetsu City, Japan, by analyzing the process involved in the teachers' expansive learning in dialogue sessions that combine classroom newsletters and activity reports.

Formative intervention methodology to expand transformative agency

Today, a form of intervention research based on activity theory geared toward people's expansive learning in social practices, work, and organizations is being promoted worldwide. This intervention research has evolved remarkably through a methodological principle called formative intervention, which is founded on the attitude embedded in concepts such as a "joint venture" (Engeström, 1987/2015, p. 22) between practitioners and researchers, premised upon practitioners becoming the collective subjects of an evolving new activity system with respect to which they collaborate, analyze, and intervene in it themselves as agents. In doing so, their joint

 © ISLS

intervention does not follow a predetermined course but instead seeks an expansive transition to "what is not yet there" (Engeström, 2016, p. 9).

Based on the framework of activity theory, which captures collective human creation of activity systems, expansive learning theory is a new theory of learning that considers agents' collective design of activities and practical involvement in transformations as their learning process (Engeström, 1987/2015, 2016). Expansive learning goes beyond the level of learning to solve a given problem and instead reaches the level of creating the problem or task itself, equivalent to what Gregory Bateson (1972, p. 119) calls "Learning III." Expansive learning also generates "what is not yet there"—in other words, "novel material forms of collective life, not merely construction of novel ideas in the minds of the learners" (Engeström, 2016, p. 9).

The expansive learning approach to school change through formative intervention focuses on methodologically reexamining and transforming linear perspectives of interventions that have been incorporated into traditional standardized pedagogy and educational research. The essential concern with expansive learning in and for the creation of new forms of pedagogical practices in schools is that people involved in schooling can "design and implement their own futures as their prevalent practices show symptoms of crisis" (Engeström, 1991, p. 256). In the area of school reform, the expansive learning approach is not based on the idea of "benevolent reform from above" (p. 257).

Therefore, even in its methodological principles, formative intervention differs fundamentally from the traditional top-down linear intervention that policymakers and researchers monopolize. From the viewpoint of formative intervention that facilitates participants' expansive learning, new forms of education should be reconceptualized as dialogically negotiated activities in which various agents produce new collaborative interventions while transforming their activity systems.

School-based dialogue sessions as collaborative formative interventions

Drawing on the abovementioned theoretical framework and methodology of formative interventions, this section considers school-based research at Jōetsu Municipal Ōmachi Elementary School, Jōetsu City, Japan, by analyzing teachers' expansive learning process in dialogue sessions that combined classroom newsletters and activity reports. In the 2020 academic year, 33 school-based dialogue sessions were held at the Ōmachi Elementary School and attended by all teachers. At the end of each session, the participating teachers wrote individual reflective essays, which all participants read.

It is relevant here to focus on the difference between what Mikhail Bakhtin (1975/1981, p. 342) calls "authoritative discourse" and "internally persuasive discourse" in order to gain a clear understanding of the dialogical, responsible, and reflective nature of the sessions at Ōmachi Elementary School. Bakhtin describes authoritative discourse as the "tendency to assimilate to others' discourse" (p. 342). In contrast to authoritative discourse, internally persuasive discourse evokes new ways of thinking. It allows one to acknowledge one's innermost feelings, thus bestowing the power of creative self-expression.

Having analyzed teachers' statements, the dialogue sessions at Ōmachi Elementary School can be considered a place for teachers to directly engage with internally persuasive discourse. In other words, dialogue sessions are creative and productive activities that encourage teachers to acknowledge others' internally persuasive discourse. Engaging in these interactive relationships awakens "new and independent words" within shared educational practice. This invites us to reveal "ever newer *ways to mean*" (Bakhtin, 1975/1981, p. 346).

Hence, the dialogue sessions at Ōmachi Elementary School resemble the so-called indigenous thinking that arises from below through the teachers themselves. This involves their everyday practice of educating and thorough reexamination and requestioning of the collective life of collaboration between teachers and children. In other words, this is tightly interwoven with the concept of "one's own word," as Bakhtin states. The aim is to generate a common ground and language. As one teacher stated, the dialogue sessions inspire indigenous, sensuous, and wild cognition, thoughts, and expressions rooted in the everyday lives of teachers' work with children. In connection with this, they are heading toward the creation of new common images of children and schools. Here, where school-based research is considered to be the model of a collective activity system (Engeström, 1987/2015, p. 63) for making a school, the dialogue sessions seem to act as instruments mediating internally persuasive discourse among the participants.

The emergence of teacher transformative agency through collaborative concept formation toward future making

The in-school research activity at Ōmachi Elementary School is also a form of expansive learning for teachers, ecnouraging the collaborative formation of a new concept that is "not yet there." This concept concerns the genesis of the school's future. The aim of this level of concept formation is as follows:

> The Things Considered in the Form of a Third Semester's Initiative (Issues): Constructing New Visions of the Child and the School
> It is essential we have a common concept (words) concerning views of children and education if we are to perceive, recognize, and expand the learning and growth of children as a whole school and by "everyone." The third semester will be used to inductively gather and analyze individual concrete "activity" in the first and second semester; while raising the level of abstraction, we wish to explore and assemble a shared concept (words) that expresses and directs the intended vision of the child and of the school. Into this we wish to include the school management policies of the managerial staff as well as the wishes of guardians and local communities.
> This research activity in the third semester can be considered to be linked to the creation of a grand design for the school in the new academic year, the resetting of educational and priority goals, the way school evaluations, and the organizing the curriculum. (Jōetsu Municipal Ōmachi Elementary School Research Promotion Department, "The Proposal for the 29th School-based Dialogue Session [Revised and Annotated]," January 7, 2021)

The shared concept (words) that the teachers formed through the dialogue sessions at Ōmachi Elementary School is not among those "stable, well-defined and neutral concepts" (Engeström et al., 2005, p. 48) with which only the "standard cognitive theories of concept formation" have been preoccupied. Rather, it belongs among "unstable and contradictory complex concepts" (p. 48) that teachers seek and spin out as expansive concepts that are "not yet there." In this sense, these "complex concepts" give the subject the power of creative expression by awakening "new and independent words" (Bakhtin, 1975/1981, p. 345), and they are invited to reveal "ever newer *ways to mean*" (p. 346). Engeström and his colleagues (2005) have stated that complex concepts are formed during creation. This represents the externalization and generation of culturally new concepts.

Mr. Eisuke Takahashi (2020, p. 19), head-teacher of research at Ōmachi Elementary School in 2020, understood the teachers' dialogue sessions in school-based research that combined classroom newsletters and activity reports as opportunities to collectively listen to "children's ways of living and episodes from 'activity with children.'" In other words, the dialogue session is a performance of "*anchoring down*," based on "experiential and descriptive language" or "cases, feelings, and ethnography," as referenced by Engeström (2004, pp. 98–99). In this anchoring down, teachers ask "how" questions (Engeström, 2016, pp. 95–96). Moreover, by asking "who, what, when" questions, teachers also perform "*anchoring sideways*." However, the dialogue sessions at Ōmachi Elementary School were not limited to anchoring down and anchoring sideways; they also aimed at collaborative concept formation, as described above. This means that they also strive toward "*anchoring up*." Therefore, these are dialogue sessions in which teachers asked "why" questions about the origins of the problem and contradictions in educational practice, as well as "where to" questions about the future of the entire school activity system and the network of activity systems. Engeström (2004) states that when these different types of questions act as "second stimuli" (instruments as mediating artifacts), as Lev Vygotsky (1930/1999) emphasized in his "double stimulation" principle, in workplace meetings, the following is important: "[T]he key is in complementarity, interplay, and transitions among the different types of questions" (Engeström, 2004, p. 101).

Thus, expansive learning in which practitioners themselves design and transform their own activity systems can be characterized as the "construction and use of dynamic multi-level conceptual instrumentalities" (Engeström et al., 2005, p. 59). In doing so, two-way movements, namely bottom-up and top-down, fill the gaps between situational "what" and technical "how" conceptualizations and spatial–systemic "why" and historical–visionary "where to" conceptualizations. At that point, the agent uses multi-level questions as mediating artifacts and second stimuli, whereby they themselves invent, use, and mediate, thus controlling their actions from outside and redefining the circumstances. When they actively intervene in the situation, transformative agency emerges, triggering intentional transformative actions (Engeström, 2016, pp. 224–225).

Of the 33 school-based dialogue sessions held in the 2020 academic year at Ōmachi Elementary School, the 32nd session titled "Session on School Making," in which all teachers participated, was held on February 25, 2021. The session focused on exploring ideas for shaping the school's future and legacy. Based on the school's grand design proposal for the upcoming academic year, discussions were held about the school's new image, the image of the child, the curriculum, concrete initiatives, and research directions. In other words, the "Session on School Making" was an attempt to collaborate and collectively perform epistemological work in which teachers tackle "where to" questions through the invention and use of mediating artifacts. This work explores and assembles a shared concept that expresses and directs the intended vision of the child and of the school. The "where to" concept that the teachers formed collaboratively was "making together."

Conclusions

Teachers' school-based research at the Ōmachi Elementary School can be characterized as expansive learning that fostered the collaborative formation of concepts and future making toward a new vision of the school. Such concept formation and future making does not occur in the dimension related to the method or technique of discrete teaching, but rather in the dimension of asking "why" and "where to" questions pertaining to an entire school as a collective activity system and the future of the school. School-based research helps formulate "where to" concepts such as "making together," which is a useful living instrument (mediating artifact) that teachers can use to develop a vision for their school's future activity system and redesign its present activity system.

Modeling the school's future strongly suggests the adoption of a school learning activity based on mutual aid and care as an alternative to schooling linked to the creation of a post-capitalist degrowth society. With this alternative, the use value of school learning is geared toward people living side by side and creating joy, common good, and well-being for everyone. To achieve this, the school is perceived as working on rediscovering and expanding sharing and as a place where learning is concrete, unique, and useful to each person.

Online platforms as sites for Learning: Exploring the use of online resources in Computer and Software Engineering education

Andrés Arturo Araos Moya, University of Oslo
Crina Damşa, University of Oslo
Dragan Gašević, Monash University

Abstract: This study investigates how online platforms are used as sites for learning by undergraduate students in computer and software engineering (CSE). The study combined different methods and data types to explore the resource infrastructure available to 73 CSE students as they used several online platforms to learn software development over a period of three months. Our findings reveal that students combined multiple platforms in different ways, providing access to a wide variety of resources, and across learning contexts that extend beyond the boundaries of the formal curriculum. The study contributes empirical evidence about learning with platform-based resources and suggests that future research should focus on how platforms can be considered as resources for learning in undergraduate education.

Introduction

Students in undergraduate education engage increasingly with online platforms such as Google or Udemy to support their learning activities, included or not in the design of their curricular tasks (Zlatkin-Troitschanskaia et al., 2021; Henderson et al., 2017). Research shows that students use such platforms also to learn study-related content outside the context of curricular tasks (Brown et al., 2016). Online platforms can offer support for student learning in multiple ways (Manca, 2020), but research has mostly focused on examining learning in curricular contexts and through social networking platforms (e.g. Facebook or Twitter) or in instant messaging platforms (e.g. WhatsApp or WeChat). Other platforms, many of them domain-specific, have received less attention. In domains such as computer and software engineering (CSE), where professional work has become rich in online resources and practices (Storey et al., 2017), platforms are especially relevant. CSE professionals use a wide variety of platforms for their work (e.g. GitHub or Stack Overflow), and some studies have shown CSE students using those same platforms to support their learning during their studies, both formally (Tushev et al., 2020) and informally (Damşa & Nerland, 2016). Nonetheless, the understanding of how students learn using platforms in specific disciplinary domains is still limited (Zlatkin-Troitschanskaia et al., 2021), constraining teachers' efforts to support students during their studies. This study sheds light on this matter, by exploring the infrastructure of resources provided by online platforms as CSE students learn software development during their studies. To address this aim, we used a mixed methods research design, in order to answer the following research questions:
RQ1: How do CSE students combine online platforms across curricular and online, non-curricular contexts to learn software development?
RQ2: What learning resources are made available to students when online platforms are used?

Conceptual Framework

To examine students' use of online platforms, this study builds on two conceptual underlays. Firstly, the use of platforms is seen as contextual, as actions students carry out involving the use of platforms are not isolated but bound to specific situations and circumstances taking place over time (Zheng & Yano, 2007). Secondly, platforms are conceptualized as online software infrastructures that are characterized by the resources they provide access to, and which play a mediational function by linking students with different people and types of information (Bruce & Levin, 1997). Analytically, we focus on the performance of students' actions over time involving the use of platforms. These actions are represented by the access to different platforms over time, characterized by different configurations of platforms used. Configurations determine which resources are at students' disposal as they move across boundaries of curricular and online, non-curricular contexts. Configuration is a variable consisting of different combinations of platforms that are assembled in specific situations and provide access to different types of resources, shaping the infrastructure of resources students have access to as they use online platforms.

Methods

The study was conducted by inviting undergraduate students from CSE programs from four major universities in Norway to participate voluntarily in the Fall 2020 and Spring 2021 semesters through their course teachers, limited to courses related to software development. The identity of the participants was protected following national and

 © ISLS

GDPR regulations. In total, 73 students participated, 33 in the Fall 2020 and 40 in the Spring 2021. The dataset collected consists of students' web-browsing history and self-reports, as well as 27 individual stimulated recall interviews (Dempsey, 2010). A custom-made software was used to collect self-reports and web-browsing history, which surveyed students about actions directed at learning software development and the platforms used to carry them out. The software also retrieved information about every time those platforms were accessed during a three-month period back from the moment the survey was submitted. During the interviews, carried out using an online video conference service, students were shown the platforms they selected in the survey and the monthly frequency of access to each platform, to prompt reflections about when, how and why online platforms were used. The interviews were audio recorded and later transcribed verbatim. The dataset was analyzed, firstly, through a sessionization, in which the events in the web-browsing history were aggregated into smaller aggregated units (i.e. sessions), defined based on a maximum separation between events (Kapusta et al., 2014). A subset of sessions was selected for analysis based on the self-reports. Secondly, a descriptive mapping was carried out to identify and group the resources within each platform, in order to define distinct types of platforms. Thirdly, a latent class analysis (LCA) (Muthén, 2001) of the types of platforms used during the sessions was performed, with the best model selected based on the lowest BIC criteria. Finally, a thematic analysis of the interview transcripts (Braun & Clarke, 2012) identified learning contexts involved in the use of platforms.

Findings

The sessionization resulted in 12,799 sessions characterized by platforms accessed, of which 3,336 sessions were selected based on the actions carried out with the platforms involved. The descriptive mapping resulted in eight different types of platforms being used by the students, with search engine (SE) and video repository (VR) platforms being the most frequent in the sessions, identified in more than half of the sessions. Tutorials and courses (T&C), questions and answers (Q&A), source code repository (SCR) and communication (COMM) platforms were present in about 30-40% of the sessions, while text library (TL) and SN platforms were the least used, present in less than 30% of the sessions. The analysis of the interview data revealed that the sessions took place mainly in the context of curriculum-based tasks, although some of the students also reported using them to develop software outside their study-related work. The curriculum-based tasks were mostly recurrent software development tasks part of specific courses, and students used platforms both during these tasks as well as to prepare in advance for them. In a few cases, students used platforms also to prepare in advance for lectures. Outside the context of their studies, some of the interviewees reported using online platforms to master and implement new programming methods, either as leisure or for entrepreneurial purposes.

The LCA resulted in a five-class model being chosen after following the minimum BIC criteria, and assessing results from likelihood ratio tests and the entropy of the models, which reached 0.906, suggesting a good class assignment (See Table 1).

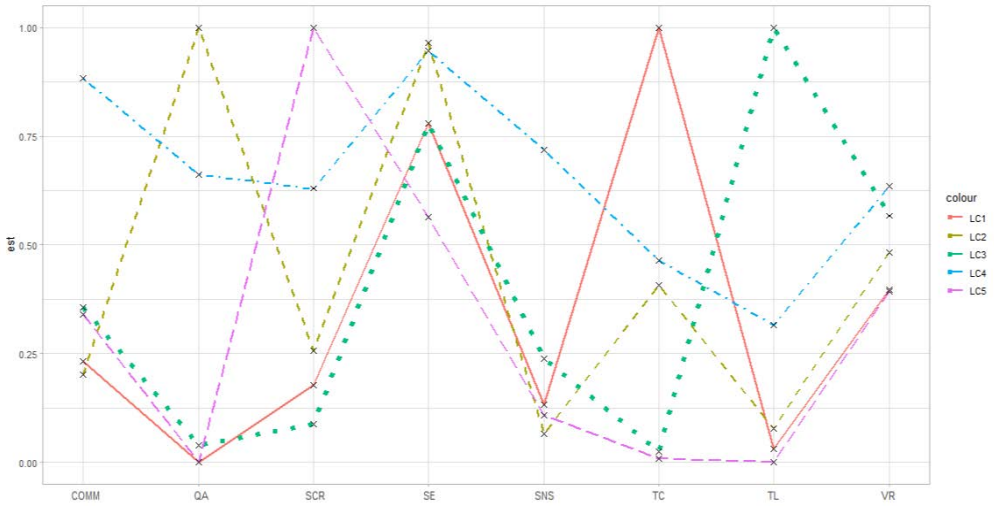
Table 1
Latent Class Analysis - Information criteria indexes

Classes	AIC	BIC	aBIC	VLMR	LMR	BLRT	Entropy
2	31263.3	31367.3	31313.2	0.000	0.000	0.000	0.888
3	30243.1	30402.0	30319.4	0.000	0.000	0.000	0.871
4	29448.5	29662.4	29551.2	0.000	0.000	0.000	0.979
5	**29222.8**	**29491.7**	**29351.9**	**0.000**	**0.000**	**0.000**	**0.906**
6	29180.7	29504.7	29336.3	0.089	0.0919	0.000	0.845

Each one of the latent classes in the selected model were found to be characterized by at least one distinctive type of platform. This is visible in Figure 1, where the x-axis lists the types of platforms involved and the y-axis the conditional probability of class membership for each type of platform. **Latent class 1** (LC1) accounted for 19% of the sessions after assigning the most likely class to the sessions, and distinguished itself from the rest due to a high conditional probability of having T&C and SE platforms. This configuration suggests that students accessed an infrastructure of resources characterized, firstly, by web-search, present in SE platforms. This enabled searching for information in other platforms based on terms introduced by the user. In addition, this infrastructure also provided access to knowledge summarizations and representations, as well as procedural models, mostly related to software development, as well as visualization software that enables running code to check its output, all present in T&C platforms. **Latent class 2** (LC2) accounted for 33.3% of the sessions once the most likely class was assigned. These sessions showed a high conditional probability of having Q&A and SE platforms present. This configuration suggests students had access to web search, like in LC1, but also to discussions directed at solving specific programming problems and functionalities for publishing text and code

components in such discussions, present in Q&A platforms. In addition, these platforms offer access to resources that enable public profiling and making connections with other users on the platforms. **Latent class 3** (LC3) accounted for 21.7% of the sessions, and distinguished itself from the rest by a high conditional probability of having TL and SE platforms in the configuration of the sessions associated with it. Similar to LC1 and LC3, this configuration suggests an infrastructure characterized by web search, but also by knowledge summarization related to a wide arrange of topics, resources that are present in TL platforms. **Latent class 4** (LC4) accounted for 6.4% of the web-browsing sessions once the most likely latent class was assigned. LC4 distinguished itself for having a high conditional probability for COMM, SN and VR platforms, as well as a moderately high probability of having Q&A, SE and SCR platforms present. This configuration suggests a large resources infrastructure involved. COMM platforms were characterized by functionalities that enable asynchronous and synchronous audio and text messaging, videoconferencing and screen sharing. SN platforms offer access to social networking resources, such as public profiling and features for making and managing connections with other people, but also resources for publishing information in different formats such as text or video. VR platforms were characterized by digital libraries of videos related to a wide variety of topics, but also by features that enable publishing text comments next to the videos, public profiling and managing connections. SCR platforms were characterized by digital libraries of source code and by functionalities that enable working with other people in source code asynchronously, by modifying and managing changes made in the code in different ways. Finally, **latent class 5** (LC5) accounted for 19.7% of the sessions, and distinguished itself from the rest by a high conditional probability of having SCR platforms present. Thus, the resource infrastructure students had access to was mainly characterized by the resources available in these platforms, which are described above, and that enable working and managing asynchronously in source with others.

Figure 1
Probability of Types of Platforms in each Latent Class



Discussion and Conclusions

With regard to *how do CSE students combine online platforms across contexts to learn software development,* the findings revealed that students' use of online platforms took place across both curricular (Manca, 2020; Henderson et al., 2017) and non-curricular contexts (Brown et al., 2016), primarily during performing software development tasks. Our findings add to previous studies by showing that, in both types of contexts, students used multiple platforms that were combined in different ways, presumably to address different aspects of the tasks they engage in. Students constantly crossed curricular boundaries to informally use resources they deemed relevant for their learning, and even used platforms to work in their own projects. Moreover, the platforms accessed by students were, in some cases, domain-specific, highlighting the importance of taking into account disciplinary contexts to understand how students learn using online platforms (Damşa & Nerland, 2016).

With regard to what *learning resources are made available for students when online platforms are used*, the findings show that, although the resources available to the students varied significantly across sessions, clear patterns emerged related to the configurations of platforms used by them to support their learning. For instance, while some of the resources infrastructures observed are similar, important differences emerged with regard to what specific resources were available across these configurations. Moreover, the infrastructures accessed not

only involved resources related to the use of information, but also those that connected students with different people and that enabled different ways of relating with them. Such differences, found as a result of the LCA and the descriptive mapping, suggest students act purposefully to address different aspects of the tasks they engaged in, suggesting that the use of platforms not only is situated in nature but also relational.

These findings are in line with previous studies that argue that students purposely shape the resource infrastructure they use to support their learning by moving across multiple contexts and that this infrastructure is domain specific (Damşa & Nerland, 2016; Tushev, 2020). Furthermore, the current study adds by providing empirical evidence of such processes, showing the specific resources and contexts shaping such infrastructure and that students use multiple platforms in combination to shape it.

This study makes an empirical contribution, by shedding light on students' learning that involves the use of online platforms. Students act purposely to assemble different resource infrastructures as a response to the learning context in which platforms are used, but also enclosed in larger learning contexts that involve both the curriculum as well as specific disciplinary domains. The current study also makes a methodological contribution, by showing how different types of data and new analytical techniques, such as the sessionization process in combination with the LCA, can provide valuable insights into students' learning practices. Future research should focus on how online platforms can respond to specific disciplinary domains, and examine in-depth how students combine multiple platforms purposefully in order to access the resources they deem as necessary for specific learning needs. This research should further explore how the resources within platforms are used by students, what relevant learning affordances these provide and what purposes drive students to use platforms. Higher education institutions should also take such considerations into account, as the informal use of platforms seems to play a determinant role in what learning resources shape student learning.

Situating Socio-Scientific Representations in Artistic Transformations

Maria Kolovou, Ji Shen, Jennifer Kahn
mxk1058@miami.edu, j.shen@miami.edu, jkahnthorne@miami.edu
University of Miami

Abstract: The current study aims to link artistic practices with STEM learning by documenting a case study of five 6th graders who navigated multiple artistic representations to interpret an article about a social scientific issue. Analysis of interviews, observations, video clips, and students' artifacts point to a set of factors (personal, social, cultural, material, and embodied) that mediated students' construction, transformation, and communication of multiple artistic (including embodied) representations.

Conceptual framework

Research in STEM education has widely focused on the role of student-generated representations for deepening and communicating learning (Cox, 1999; diSessa, 2004; Greeno & Hall, 1997). Little research has built on these findings to expand and include explorations of how students engage in representations for Socio-Scientific Issues (SSI) explorations. SSI are controversial issues of public interest that are related to science, such as topics related to climate change. Considering that SSI interventions address controversial problems that could have multiple solutions, the study of SSI is important for grasping the complex and contested nature of science. (Tytler, 2012). The present study aims to fill this gap, including understanding how students transform representations at the intersection of SSI and arts and how they connect mental and external representations with embodied representations, which engenders new forms of learning and representing (Pande & Chandrasekharan, 2017).

The study follows an activity (1.5h duration) during a STEAM elective course in which 6th graders were framed as artists working in a museum and were asked to construct multiple artistic representations to communicate their interpretation of an SSI article. The article raised the question: "Is a person's fate a matter of nature or nurture?" with references about the influence of the environment and genes on a person's traits. Students transformed the article (sentential representation) to drawings (pictorial representations), used their bodies to collaboratively transform the drawings to "static sculptures" (embodied representations), and added sound and short movements to transform the static sculptures to "interactive sculptures" (dynamic embodied representations). The guiding research question of the study was: *How do middle school students construct, transform, and communicate various artistic representations to make meaning out of an SSI article?*

Conceptual framework

Representations as distributed and embodied

Our theoretical framework is informed by current shifts in cognitive science, namely *distributed* and *embodied* cognition theories, that stress the role of the material environment, context, motor actions, perception, embodiment, imagination, analogy, and metaphors for cognition (Barsalou, 1999; Hutchins, 2010; Johnson, 2017). Within the distributed perspective, the competences that individuals display are distributed among the tools, the environment and other people (Hutchins, 2010). Particularly for collaborative activities, participants share their representational skills and use the tools of their local environment (Cole & Engeström, 1993). From this perspective, individuals' capacities to represent need to be understood in context, that is in relation to the local setting, including the tools in use and social and cultural factors (situated perspective, Lave & Wenger, 1991). Embodied and enactive theories highlight the relation between action, perception, and experience (Barsalou, 1999; Varela et al., 2017). Embodiment is "the premise that the particular bodies we have influence how we think" (Hutchins, 2010, p. 428). Enaction is "the idea that organisms create their own experience through their actions" (Hutchins, 2010, p. 428). Hutchins (2010) applied the enactive perspective into representations by arguing that humans integrate perception, action, and imagination and "make material patterns into representations by *enacting* their meanings" (p. 434). Moving and experiencing the body affect how people perceive the represented world, a world that depends on the affordances and constrains of the bodily experiences (Hutchins, 2010; Varela et al., 2017).

 © ISLS

Methods

We followed a case study research design (Merriam & Tisdell, 2015), in which we developed a curriculum to foster middle school students' integrated STEM, arts, and literacy practices. Thirty-nine students participated in the elective course (18 female students and 21 male students), and 18 students consented to take part in the study and allowed for video recordings and photos. The current study focuses on a group of five students. All students of the group identified as Hispanic, and three of the students were female while the rest two were male. In the activity explored in this paper (week 4 of the curriculum; 1.5h duration), learners, in groups of 4-5, took on the role of artists who drew paintings inspired from an article about genetics and engaged in a series of representational transformations.

To ensure credibility and increase the trustworthiness of the study we collected a variety of data (Lincoln & Guba, 1986): Video records of the focus group's activities, intensive 30-min individual interviews with two of the participants, informal conversations with the group, students' artifacts (drawings, photos), and ethnographic observations (field notes and memos). We fully transcribed the interviews and the video records. For the analysis of the interviews, we conducted open coding and constant comparison (Corbin & Strauss, 2014). For the video analysis, we attended both to verbal (talk) and non-verbal (gestures, bodily postures, tone of voice, etc.) ways of communication (Goodwin, 2007). We also created matrices to examine each student-generated representational transformation (Miles & Huberman, 1994). Each matrix included a summary of observations, researchers' notes/interpretations, students' quotes from their discussions and interviews, and description of students' artifacts.

Findings

First Transformation: Article to Drawing

Students used the affordances of drawing to communicate their interpretations of the article. Their creations reveal a variety of perspectives and strategies (e.g., color, symmetry, pictorial metaphor, narrative metaphor). All students reasoned about their choices by connecting their pictorial representations with references from the text, although sometimes they distorted textual references to accommodate their choices (see Figure 1).

Students incorporated cultural norms, their preferences, and previous experiences into their drawings. For instance, Camila transformed a linguistic metaphor ("a cosmic dice rolling into one's favor") into pictorial cultural symbolism. She used a cultural inference that the best value shown in dice is six and the worst is one, as commonly agreed in boarding games. She also used the symbolism of color, dark color for representing the poor and bright color for representing the rich.

Figure 1

Photo of the Static Sculpture and Students' Drawing

Sofia created a pictorial metaphor to communicate her interpretation of success and failure. She drew a tree with some of its roots "colored all the way to show fulfilled lives" and some of the roots not "colored all the way" to show that some "lives could have been more fulfilled, but they weren't" (Sofia's interview). Sofia said in her interview that she always liked drawing trees and now she thought that "maybe, a tree could incorporate in here like a family tree." Sofia merged her preference in drawing trees with a cultural norm according to which trees symbolize "family trees." With her choice to "fill" some of the roots and not others, Sofia also created her own symbolism: the level of extension of the roots' color (not the color itself) symbolized a person's fulfillment in life. Sofia mistakenly thought that "somewhere in the article it said that some people have fulfilled lives" (Sofia's interview). Sofia was possibly referring to the article's "successful lives," but she transformed the word

 © ISLS

"successful" into the word "fulfilled" and this transformation aligned with her choice to "fill" with color some roots and not others. Here, she turned something abstract (i.e., "successful lives") to a concrete pictorial metaphor (i.e. tree roots filled with colors).

Second transformation: Drawing into static sculptures

The case of Sofia: From the "tree of life" to "DNA dancing"

Initially, Sofia agreed to represent a tree for the collaborative representation. When the members of the group positioned themselves in space, she tried to move like a tree and after 15 seconds, she said to her peers that she did not want to depict a tree (video records). Carlos suggested that she should represent DNA instead, and Sofia tried this option by "cross[ing] [her] arms and legs to make it look like [she] was coiled as a DNA," as she had seen in drawings of DNA (Sofia's interview). Sofia reported her "DNA dance" (our term) as fun to do during her interview, and she attributed her movements to her experience as a ballet dancer: "it's just after you start doing this sort certain dance for like months and months, then you start picking up your hands and your positions to be a bit more inclined to that position on how you are." The dynamic form of the DNA, as compared to the more static tree, aligned with how she preferred to move as a dancer. Sofia also reasoned about representing DNA, saying that "DNA is important" and that the group would not be able to relay any message to the audience without it (Sofia's interview). For Sofia, the change of the representational medium also led to different representational tools at her disposition.

Third transformation: Static sculptures into dynamic sculptures

In the initial frozen posture, Isabella put both her hands on her neck, as if she touched an imaginary necklace. Her face was frozen in an expression that showed excitement. Camila sat on Isabella's left, and her hands were positioned as if she counted money. Carlos stood next to Camila. He held his palms projecting his hands, as if he threatened someone with an imaginary gun. Next to him sat Luis. Luis sat in a curved position, holding a pencil case, pretending this was a case for people to put money in. Sofia stood in the middle, crossing her hands, as if these were the strands of DNA. When the "sculptures" became interactive, Isabella took her hands off her neck and took a red sharpener, pretending it was a mobile phone that she used to text her friends about her new necklace. Camila used her pencil case as an imaginary phone. "Hi," she said, and she froze in an expression of excitement. Carlos put his hands behind his back as if he got arrested, and he turned his face on the wall. Luis revealed a paper that wrote "needs money" from his jacket and he spoke in a weak voice: "Money, money." Sofia moved her hands and froze in a position with her right hand up and her left hand down. In the following, we present Sofia's and Luis case.

The case of Sofia: Hand down for downfall

During the group's rehearsal, Sofia moved her whole body in something that seemed like a DNA dance, and ended in a posture in which she had "one hand down on the side that Carlos and Luis were and the other hand up on the side that Camila and Isabella were" (Sofia's interview). She explained that she wanted to show "that Carlos and Luis had a bit more of a downfall than Isabella and Camila." The rehearsal video shows that Sofia "discovered" the gesture through experimenting with her body first, rather than first thinking of this idea and then applying it to her body. Sofia was using an embodied metaphor. According to Lakoff and Johnson (1980), humans understand abstract concepts using their bodily experiences and this is mirrored in the metaphors they use when they talk. Lakoff and Johnson suggest, for example, that our familiarity with the upright position produces the "up/down" conceptual metaphors; "up" is unconsciously perceived as "having control" while "down" is considered as "being subject to control" (e.g., *upper* social class, she has the *upper* hand, I am feeling *down* today, etc.). Interestingly, at this point Sofia's gesturing of some people's "downfall" and other's good fortune indexed her first metaphor (the tree with some roots colored all the way and others non-colored). Just as Sofia had transformed the article's word "successful lives" to "ful*fill*ed lives" in alignment with her choice to *fill* the roots, she now transformed the article's word "failure" into "*down*fall," in alignment with her choice to gesture *down*wards.

Discussion

Overall, participants devised and enacted creative strategies for generating, transforming, and communicating representations that supplemented the verbal-representations which dominate in traditional schooling. They created and used different kinds of metaphors to communicate their intended message, infused their previous experiences and personal preferences to their representations, considered the audience, reasoned about their decisions, and adapted their strategies to the constraints and affordances of the different

representational media. Particularly embodied collaborative representations and use of the surrounding objects in imaginative ways supported non-verbal communication and creative collaboration among the members of the group and enforced the use of embodiment that is rarely encouraged in conventional science classrooms. Therefore, students were able to construct and share meaning among themselves and their audience by using multiple rather than only propositional forms of representations, challenging a dominant schooling assumption that meaning making relies mostly on words.

The present study confirms that learners already possess rich resources for representing (Azevedo, 2000; Danish & Enyedy, 2007). Students used color to create symbolisms in the representational medium of drawing, created symmetry and contrast in space with their bodies, and communicated meaning with non-verbal ways, such as gestures. Embodied representations both facilitated students' collaborative interactions (verbal and non-verbal) and provided different possibilities of constructing meaning. This aligns with embodied cognition theories that suggest that humans express abstract concepts through movement, without the need for verbal representations (Lakoff & Johnson, 2008). Students' experiences and movements affected not only their transformations during the representations, but also their word choices when they reasoned for their decisions (Sofia's case when talking about "fulfilled" lives and "some peoples' downfall" being the most obvious example).

Identifying Associations between Expansive Framing and Transfer through Learning Analytics in an Online Context

Joshua D. Quick, Daniel T. Hickey
jdquick@iu.edu, dthickey@indiana.edu
Indiana University

Abstract: This study presents preliminary work in social learning analytics by identifying instances of expansive framing and their relationship with transfer in an online course iteratively designed using the situative principles of productive disciplinary engagement and expansive framing. This analysis occurred in two stages. First, through a discourse analysis of fifteen students who completed the course in summer 2020, a mixed-effects logistic model was constructed to understand the relationship between students' use of expansively framed speech and transfer strategies. Second, a mixed-effect linear model of students' transfer strategy use and student performance on three summative exams was constructed. While a clear link between students' expansively framed discourse and transfer strategy use was detected, no significant relationship between students' transfer strategy use and exam performance was detected. We interpret these findings in relation to the role of expansive framing, transfer in of knowledge, and the transfer out of knowledge.

This research was conducted in an online, graduate level course on educational assessment that has been iteratively refined (see Hickey et al., 2020) from the starting point of the design principles for *productive disciplinary engagement* (PDE; Engle & Conant, 2002) and *expansive framing* (Engle, Lam, Nix, & Meyer, 2012). These principles were adopted to provide multiple beneficial processes for learners to engage with the disciplinary content of the course. PDE describes a set of principles for learners to engage in authentic disciplinary problems by "problematizing" instructional content from their own perspective and publicly being held accountable for developing disciplinary norms and practices. Expansive framing is intended to increase the likelihood of transfer to subsequent contexts by extending learners' use of linguistic frames beyond the course context (i.e., outside *people*, *places, topics, and times*) to be positioned and position themselves as authors who are accountable to disciplinary norms and practices.

The principle aim of this study is understanding the relation between expansive framing and transfer as proposed by Engle et al., (2012) within an online teaching and learning context intended to promote such practices. A recent review of published research on PDE and expansive framing (Hickey et al., 2021) revealed little evidence documenting the relative impact of expansive framing on transfer in authentic teaching and learning contexts other than Engle et al. (2011). As such, this study fits within both an existing design-based research project of online teaching and learning and a larger framework for understanding the relationship between expansive framing, productive disciplinary engagement, and transfer.

An agenda for researching expansive framing within an online context

Engle et al., (2012) advanced five specific explanations of why expansive framing should lead to more generative learning and increased transfer, compared to more "bounded" curricular routines. These explanations are (a) connecting settings promotes an expectation of transfer; (b) connecting settings means prior contexts continue to be relevant in potential transfer contexts; (c) authorship and connecting to prior settings during learning leads to transfer-in of ways that support later transfer out; (d) authorship promotes accountability in particular contexts; (e) authorship as a practice generalizes practices of accountability and adaptation in transfer contexts. Engle et al. indicate that an explanation of transfer could incorporate one, a combination, or all of these hypothesized mechanisms. The current course design seeks to enable learners to expansively frame their interaction with curricular routines in terms of an actual or aspirational aim and evaluate educational assessment practices through repeated connections and revisions of these aims. This feature is intended to promote greater intercontextualities and authoritative positioning in the course context. Thus, our primary focus in the current study is to understand the relationships more fully between transfer in of knowledge introduced through expansive framing and the taking up of authoritative positions on disciplinary knowledge as introduced by the course design. This focus is chosen in part to explore whether the course mechanisms to support transfer-in actually do so, which is presumed to help explain whether transferring out knowledge also obtains. This focus further reveals if and how the establishment of intercontextuality in the form of numerous connections to outside contexts that are further expected to support transfer actually does so.

 © ISLS

Research question and methods

This analysis focused on the following research question: Does encouraging students to expansively frame their engagement lead to greater transfer in of prior knowledge through the use of transfer strategies of generating examples, making comparisons, and generalizations that more frequently connect to frames beyond the current course context. If so, do these transfer strategies support transfer out as estimated by exam performance?

We frame this analysis as social learning analytics (Buckingham-Shum & Ferguson, 2012) in that rather than focusing on automated, computational processes from data generated from networked systems we are attending to the social processes that are stored and represented within these systems. Specifically, we attend to the discourse stored within the course management system. As such, we approached this analysis as an initial exercise in labeling said discourse and identifying associations through a mixed method design.

Methods, participants, and data sources

A total of 15 students who took the course in Summer 2020 were eligible as participants. Only students who completed the course and did not opt out of the study were included in the analysis. These criteria did not exclude any student. Observations from these participants included student responses to wikiflolio and reflection prompts in relation to students' self-selected educational assessment problems. Wikifolio prompts asked students to evaluate their interaction with a particular element of educational assessment with their problem; whereas reflections encompassed five prompts that asked students to consider how their prior engagement in the wikifolio and their peer and instructor interactions influenced their understanding of educational assessment. Excluding missing responses, this resulted in a total of 1,597 observations. Each student's three modular exams were also used to assess the extent students' transferred out knowledge.

Our analysis incorporated quantitative methods of qualitative codes (see Chi, 1997). The analysis occurred in two stages. First, a coding of these wikifolio and reflection responses was conducted. Second, two statistical analyses were conducted. This analysis involved a mixed-effect logistic regression model constructed from coded observations to identify the relationship between expansive framing, authorship, and each transfer strategy and a linear mixed-effect model of student transfer strategy use within each module and their modular exam performance was constructed. All analysis codes, coding discussions transcripts, and R cleaning and analysis scripts are available in an Open Science Framework (OSF) repository (https://osf.io/dqfap/).

Coding procedures

Expansive framing and authorship & accountability codes were adopted from Andrews et al. (2019) and transfer strategy codes were adapted from general strategies that have been identified as effective in promoting learner transference of knowledge (see Bransford et al., 2000). All codes were binary and coding was conducted openly and transparently by the first author. Three audit sessions (see Cresswell & Miller, 2000) between the second author and two peers were held to discuss their findings and elaborate further directions in coding analysis.

Mixed-effect models

Mixed-effect models describe a family of statistical approaches that used both random and fixed parameters to deal with clustered and repeated measure data (see Raudenbush & Byrk, 2002). For the first, model each observation was used as "trial" for whether expansive framing occurred and whether corresponding use of a transfer strategy was also observed. The second model was constructed from student's modular exam scores and the frequency of transfer strategy use within the wikifolios and reflections within that module for each student.

Results

Table 1 confirms that multiple instances of expansively framed elements increased the odds that students engaged in transfer strategy use. For example, students' who framed their engagement using *time past* increased the odds that they generated examples by a factor of 5.61. However, different transfer strategies coincided with different components of expansive framing and productive disciplinary engagement. For instance, framing engagement using *time future* led to a statistically unlikely increase in the odds of making generalizations but was not significant for students' generation of examples. For comparisons, demonstrating *authorship* (making authoritative claims) and framing with *topics* (beyond educational assessment) increased the odds of making comparisons by a factor of 2.09 and 3.32, respectively (both significant). Notably whether expansive framing was specifically encouraged by the prompt did not significantly relate to the odds of using transfer strategies. Also, the type of prompt appeared to have varying influence on the extent to which a particular transfer strategy was employed. For instance, engagement in reflections indicated a reduction in the odds of students generating examples and generalizing but increased the odds of students making comparisons. This is possibly due to students

making more comparative actions on their work at different times and in relation to other participants. Taken as a whole, then, these results suggest that students were likely to use these strategies to transfer in previous knowledge as Engle et al., (2012) suggested. As such, the course appears to be functioning as intended. Of course, this raises the question on whether there was a substantive relationship of students' transfer-in and transfer out as measured by course exams.

Relation between transfer strategy and course exams

Table 2 shows that, there were no significant effects of any of the transfer strategies and exam performance. In other words, the transference out was too subtle for detection within these selected response measures and that the variation between transfer strategy did not discriminate enough to detect differences in the relatively high exam performances (the respective exam medians were 9.5, 9, and 8 out of a maximum of 10) and was not able to identify the subtle variations of transference of knowledge entailed by these strategies. Taking stock, then, we have observed that the course design facilitates and supports the transfer in of knowledge through repeated engagement routines, but we have not found a corresponding effect of students' capacity to transfer out due, in part, to the limitations of these exam measures. Namely, the exams were entirely selected response and displayed little variation.

Table 2:
Relation Between Transfer Strategy Use and Exam Scores

	exam_score

Discussion & conclusion

These preliminary results suggest that the course design effectively encouraged the development of students' transfer strategies through expansively framing engagement and increasing students' transfer in of previous knowledge and experience. As such, the evidence that intercontextuality was established supports Engle et al's (2012) explanation that expansive framing is likely to encourage students to transfer in prior knowledge. Similar links were observed between students taking up of authoritative positions and the transfer in of their prior knowledge. We did not observe, however, a clear indication of learners' ability to transfer out this knowledge. This may have been due to a ceiling effect in the exams as little variation in student performance scores was observed. This suggests a need for refining the exams to enable students' to more readily display their knowledge within these assessments through constructed response items. Such a revision could also assess whether there is a cost to the contextualizations produced in these courses since ongoing discussions indicate a trade-off between contextualization and likelihood of transfer (see Day et al., 2015; Goldstone & Son, 2005).

Abstract: Integration of computational thinking (CT) within STEM subjects is common, although not often at the elementary school level where teachers have minimal experience with CT. We have designed and are refining INFUSECS, a narrative-centered digital learning environment to support upper elementary students' CT and science knowledge construction as they create digital stories. We used orchestration as our theoretical framework, to examine how elementary teachers planned to approach this multidisciplinary implementation. Through a series of three focus groups, we learned that teachers planned for their students to take notes or utilize other graphic organizers to align the science content with the narrative planning, to engage in collaborative sense-making, and to observe the teacher modeling use of the INFUSECS system. Ultimately, the results have informed the next phase of our research design as we collect teacher and student level data as INFUSECS is utilized in authentic classroom settings.

Introduction

Researchers and practitioners increasingly acknowledge the importance of computational thinking (CT) in supporting students' problem-solving skills across learning contexts and subject areas (Yadav et al., 2016). Although the integration of CT among other academic disciplines is both practical and effective (Voogt et al., 2015), this integration is complex at the elementary school level as US teachers have minimal experience with CT (Code.org Advocacy Coalition, 2018). The overlap between CT and STEM subjects (Basu et al., 2016) supports the integration within such subjects. Many elementary teachers incorporate reading, writing, and discussion practices into their daily teaching, making it a feasible space to integrate CT; however, there are fewer findings around how to blend CT and language arts. As such, deep multidisciplinary work, designed specifically for elementary contexts, can help us better understand how to integrate CT into these grade levels.

We have designed and are iterating upon a narrative-centered digital learning environment that utilizes a block-based programming language to foster upper elementary students' (ages 8 to 11) CT and science knowledge construction as they create digital stories. Digital storytelling permits the creation of effective and engaging learning experiences that support diverse individual needs (Smeda et al., 2014), including learning science concepts in elementary grades (Smith et al., 2020). It also helps teachers weave CT into elementary settings without requiring the need for separate courses. What is not yet known is how elementary teachers approach such multidisciplinary implementations that integrate CT, science, and language arts.

Theoretical framework

Orchestration has been proposed by educational technology researchers as a useful heuristic for understanding how teachers facilitate technology-enhanced learning environments to support student learning experiences (Dillenbourg et al., 2018). The framework supports understanding of how novel instructional technologies are implemented in the classroom by acknowledging the integral role of the teacher as they manage the complexity of these environments and their students' varied learning needs (Dillenbourg et al., 2018). We recognize that central to the technology integration process are the decisions that teachers make with regards to planning and designing for the optimal use of technology to meet intended learning objectives, and that as students use those technologies, teachers adapt and modify (Roschelle et al., 2013).

 © ISLS

The orchestration process for technology-enhanced learning environments often unfolds with developers initially designing curricula and resources for teacher and student use (Kollar & Fischer, 2013). Teachers then adapt the designed curriculum to fit their classroom constraints and contexts. The ways teachers intend to modify the curriculum can help researchers and developers be more efficient and practical when designing new classroom learning technologies (Wang et al., 2018).

Methods

Data collection

We conducted a series of three focus groups with elementary school teachers during the spring and summer of 2021. In the spring of 2021, two focus groups were held, each with three participating teachers. These 75-minute focus groups were conducted virtually and recorded with video conferencing software. All video sessions were transcribed verbatim. We utilized a semi-structured protocol that consisted of three parts: 1) an introduction to the learning environment; 2) teacher experimentation with the learning environment; and 3) post-experimentation focus group questions. During the experimentation phase, the participants individually joined a breakout room, shared their screens, and engaged in a think-aloud interaction with the learning environment. An example probe included, "What did you learn today that will help you teach INFUSECS curricular materials and use the learning environment?" The final focus group occurred at the conclusion of an eight-hour summer workshop on INFUSECS. The participants from this final focus group were asked questions such as, "Where do you see INFUSECS best fitting into your curriculum and what you already teach?"

The INFUSECS learning environment

The INFUSECS learning environment has two components: 1) a Science Explorer where students learn about energy sources and conversion via multimedia content and a simulation (Figure 1); 2) a Narrative Designer where students develop interactive stories using a block-based programming language (Figure 2). The goal is for students to integrate scientific understanding as they solve a problem-based learning scenario (e.g., shipwrecked scientists on a deserted island must power up their village) depicted through their narrative.

Figure 1

Screenshot from Science Explorer

Figure 2

Screenshot from Narrative Designer

Data analysis

Three researchers individually open coded the transcripts from each of the sessions. The researchers focused on thematic elements related to how teachers planned to implement INFUSECS with students. Subsequently, the researchers met collectively to determine where their identified themes converged across the sessions and reached consensus on the thematic elements of the results. The thematic findings highlight our teacher participants' perspectives on how they intend to implement and adapt INFUSECS for their students' benefit. Such orchestration efforts reflect their understanding of the complex physical and digital learning environments in their classrooms.

Findings

Strategies for connecting science to the problem scenario

Teachers were concerned with how well their students would connect and integrate the science concepts and ideas presented within the Science Explorer into their narratives. Such disciplinary literacy highlights the need to read and write well across the content areas. The teachers suggested two ways this could be supported throughout the learning experience. First, teachers commented that they would encourage their students to take notes on key

 © ISLS

science concepts presented to them throughout the Science Explorer. One teacher advised that, "All the vocabulary that you know [the students] are going to need [should be] accented in some manner and having them be able to take some notes… on paper and pencil or putting a little notepad on the screen."

Second, teachers noted that students would benefit from using a storyboarding process with graphic organizers for notetaking and planning of their stories. This strategy would simultaneously scaffold the integration of science concepts from the Science Explorer into their narratives. One teacher mentioned, "If you want them to write a story on a deserted island with all of the science concepts that they've just learned, you have to tell them that, and having a piece for them to pre-organize themselves, you have to do that for them."

Collaboration and discussion for sense-making

All teachers noted the potential that collaborative discussion—a CT skill—could offer for fostering successful student experiences with INFUSECS. They shared ideas of how they would embed collaborative opportunities to facilitate the sense-making process (e.g., whole-class, small group, dyads), and where in the learning process it would best occur (e.g., interactions with the Science Explorer, planning their stories). In describing the utility of peer collaboration in small groups for connecting the science concepts to the story building process, one teacher commented that small group collaboration would be beneficial for ideation, noting, "I just think they'd need to work either in pairs or in a group to come up with some ideas first and then put it in [their narratives]."

Other teachers noted that whole-group discussion would stimulate brainstorming and connecting the ideas from the Science Explorer to the problem-based scenario. One teacher suggested prompting discussion with "*If you were on an island, what could you do?,*" so all students could think through and discuss different responses before encountering the science concepts and writing their narratives. Others suggested going through the Science Explorer as a class and discussing the scientific concepts as they appeared could help to mitigate potential misconceptions and stimulate the process of scientific inquiry.

Teacher modeling and pacing

Due to the unfamiliarity of the learning environment for students, as well as the novel approach to generating science-rich narratives that it supports, teachers felt strongly that some degree of teacher modeling throughout the *entire* learning experience was necessary. This finding was somewhat in contrast to what we anticipated. We believed that teachers would primarily be interested in demonstrating the Narrative Designer portion to alleviate their stated concerns about students who would not have prior experience with a block-based programming environment. However, teachers offered ideas for teacher modeling during all the system's learning components. One commented, "I would want to go through it with my students, so they really got it. Then if there were other ones that they did later, they would get the whole process."

Further, teachers offered valuable insight into how they would pace the instruction and student exploration of the INFUSECS learning environment for optimal learning outcomes. The teachers believed that by demonstrating the learning environment first for students as a class, the time needed for students to get accustomed to the system would decrease. As such, several teachers noted the need to plan for more time at the outset of using INFUSECS. One commented, "Anytime you use something for the first time, it takes you three days to get through it. The next time, it's not going to be as much."

To create an optimal learning experience for her students, one teacher noted how she would balance and pace different instructional strategies throughout the various components of the INFUSECS system:

> "I could see teaching each of the [energy] sources, showing it in [INFUSECS], working through the slow process of how does it work, doing it in here, then playing with it, and then simultaneously, we're also starting to create that storyboard … [in] small groups … Then their final project would then be to do it themselves."

Discussion, conclusion, and future directions

Our thematic findings indicate that, even with limited background in teaching CT and block-based programming, elementary school teachers have clear and pragmatic intentions for how they propose to implement a narrative-centered digital learning environment such as INFUSECS in their classrooms. Using orchestration as a guide, we highlighted from our three teacher focus groups the ways teachers indicated they planned to modify and ultimately implement INFUSECS for the benefit of student learning outcomes.

This work foregrounds that regardless of the specific educational technology, the role of the teacher is instrumental in shaping student learning experiences. Teachers possess deep expertise about their students' needs, as well as the cultural and contextual constraints in which these learning environments will be used.

Acknowledging teachers' expertise in the classroom, we note that their desired modifications, what Kollar and Fisher (2013) call 'arranging,' in service of what is best for their students, bears out in the literature (Dillenbourg et al., 2018). Recall that teachers mentioned wanting their students to take notes or utilize other graphic organizers to align the science content with the narrative planning, to engage in collaborative sense-making, and to observe the teacher modeling use of the INFUSECS system. Listening to our teacher participants' suggested modifications will drive our research and development work moving forward.

Although INFUSECS was not explicitly designed for students to work together, teachers who create intentional opportunities for students to engage in collaborative learning throughout the scientific inquiry and narrative design process can increase student learning outcomes (Chen et al., 2018). Thus, we will document teachers' strategic use of collaborative learning with INFUSECS during implementation to determine its effectiveness. The teachers in our work noted an extensive amount of modeling they intended to utilize. Wood et al. (1976), the originators of the term *scaffolding* in education, suggest that the purpose of scaffolding is to control learners' frustration, guide learners' actions in support of their learning, and model the problem-solving process. We intend to assess teachers' varied levels of in-class scaffolding and students' learning outcomes.

Ultimately, we found orchestration, in particular documenting how teachers would "arrange" the use of INFUSECS in their classrooms, a helpful lens to plan future professional development and design support for teachers as they learn to integrate it in their classrooms. The results have also informed the next phase of our research as we collect teacher and student level data as INFUSECS is utilized in authentic classroom settings.

Qualitative Research as the Co-construction of Knowledge: Designed and Emergent Opportunities for Equity in Data Collection

Jonathan Tunstall, Kailea Saplan, Andy Stoiber
jtunstall@wisc.edu, saplan@wisc.edu, acstoiber@wisc.edu
University of Wisconsin, Madison

Abstract: Power imbalances are often operationalized in traditional qualitative research when participants are seen as having "settled" thoughts or truths that a researcher can extract by objectively limiting bias. Like scholars who have advanced humanizing and dignity-sustaining approaches to research (Paris & Winn, 2020), we instead see research as an opportunity to co-construct knowledge and scholarship through building relationships and conversing as co-authorities. In this paper, we critically reflect on the methodology used in a recent study on community-based, out-of-school time (OST) youth arts programs across the United States, highlighting the ways we designed the study to subvert traditional roles and assumptions about meaning making in qualitative research.

Major issue addressed

Conducting interviews and focus groups in qualitative research through an equity lens is about much more than including participants from diverse backgrounds. It requires researchers to adapt data collection methods to meet the needs of the communities they engage with, and to approach interviewing as a process of co-constructing knowledge (Vossoughi & Zavala, 2020). Equitable methods require researchers to intentionally reflect on and mitigate power dynamics that may be present (e.g., between researcher and participant, or between multiple participants in a focus group), and interrogate the assumed roles played by all interlocutors involved. Power imbalances are often operationalized in traditional interview protocols when the participants are seen as having "settled" thoughts or understanding that a researcher can extract by objectively limiting bias (Vossoughi & Zavala, 2020). Like scholars who have advanced humanizing and dignity-sustaining approaches to research (Denzin, 2015; Paris & Winn, 2020), we instead see research as an opportunity to co-construct knowledge and scholarship through building relationships and conversing as co-authorities. With that approach, interviews and focus groups become bi-directional pedagogical encounters between agents with porous roles whose meaning making is ever-developing and mutually influenced (Vossoughi & Zavala, 2020).

In this paper, we critically reflect on a methodology used in a recent study on community-based, out-of-school time (OST) youth arts programs across the United States. Taking a Critical Qualitative Inquiry (CQI) perspective on research methodology (Cannella et al., 2015), we highlight the ways in which traditional power dynamics in qualitative research were subverted through intentional design that guided the project. Our reflection is guided by the following questions: (1) How did design features allow for participants and researchers to co-construct the research experience? (2) What meaning making opportunities emerged as a result of that co-construction?

Theoretical and methodological approaches

Critical Qualitative Inquiry

The history of racism and exclusion in the scientific community, in both the natural and social sciences, is undeniable (Gould, 1996; Bonilla-Silva & Zuberi, 2008). For instance, writers and philosophers like Zora Neal Hurston, W.E.B. Dubois, James Baldwin, and many others who put forward Black scholarship anyway they could, are rarely credited for shaping social thought. However, in an attempt to counteract centuries of discrimination, scholars have been making an effort to operationalize these philosophers' work as methodological precedents that inform decolonial perspectives in research (Grant, 2021). In other words, they are returning to writing from the past to inform scholarship today, and filling the gaps in literature left by racism and settler-colonialism.

Additionally, scholars are exploring new ways to conduct research that move away from discriminatory and paternalistic traditions. The national project we reflect on in this paper is one such example, which was developed in the paradigm of Critical Qualitative Inquiry. Denzin describes CQI as a paradigm within qualitative inquiry that attempts to interrupt dominant methodology by taking both an interpretivist and activist role in research, and by "[making] a difference in the lives of socially oppressed persons" (Denzin, 2015, p. 32). That is to say, CQI interrupts the Eurocentric lineage of academic research when scholars interrogate and expose oppressive practices and intentionally break from norms that continue to yoke the field to intellectual elitism and

 © ISLS

white supremacy (Cannella et al., 2015). Because repressive structures of colonialism often operate invisibly in education and educational research (Kao-mea, 2004, p. 22, as cited in Cannella et al., 2015), the project was designed to (a) subvert power imbalances that result from traditional researcher-participant relationships, and (b) create opportunities for methodological flexibility that can resist oppressive practices as they emerge and embrace a malleable meaning-making process.

Critical Indigenous Research Methodology

The specific methodology that grounded the national project in CQI comes from Critical Indigenous Research Methodology (CIRM) (Brayboy et al., 2012). CIRM is described as a reclamation of the Indigenous thought world (Brayboy et al., 2012); it moves away from the assumptions that limiting researcher voice makes it possible to objectively extract meaning from participants' responses, and that it should be the central goal of qualitative research. A CIRM framework for research is founded on relationship building, respect, and reciprocity (Brayboy et al., 2012). Intentionally fostering relationships with the goal of taking responsibility, showing respect, and enacting reciprocity was central to the design of the national project. To build relationships, the foremost priority during the research conversations was to nurture trust among all participants present. This approach was in direct contrast to positivist traditions of science that primarily seek to uncover the objective truth from participants' observed behavior and elicited responses. Here, espousing a constructionist epistemology (Denzin, 2015; Brayboy et al., 2012), researchers and interview participants are understood as generating knowledge in conversation with one another.

Project methodology

The study we reflect on in this paper consisted of a series of research conversations akin to interviews and focus groups with a variety of stakeholders in out-of-school time (OST) arts organizations. The research goal for the national project was to understand the needs, struggles, and successes of community-based youth arts programs across the United States. Arts organizations known for their work with Black youth, Indigenous youth, and youth of color (BIPOC youth), and who themselves have deep roots in the community they serve, were purposely selected to participate. Rather than follow a traditional snowball sampling method (Merriam & Tisdell, 2016), "which implies "rolling up" relevant participants into our work in a linear fashion, as one person nominates the next, we describe our approach as more like a "boat down the river"' (Halverson et al., in press, p. 13). Starting with suggestions from our research advisory board, we followed leads to stakeholders, "guiding our boat down particular river branches based on the types of communities and art forms we thought it important to collaborate with based on what we were learning along the way" (Halverson et al., in press, p. 13).

In all, 72 stakeholders participated in the study, including 9 policy makers, 8 researchers, 28 organization leaders/ directors, 17 teaching artists, and 10 youth artists. Our data set included 25 research conversations: 12 one-on-one conversations, 6 small group conversations with cultural-geographic regions, and 7 small group conversations with specific OST arts organizations. The conversations were semi-structured and mirrored a loosely organized dialogue where the interview protocol was more of a guideline than a script. Almost all conversations took place over Zoom, with the exception of one participant who preferred to speak over the phone. Analysis for the national project was an iterative process of (a) emic coding (Saldaña, 2016) that described both the topic and content of stakeholders' responses, (b) analytic memo writing (Merriam & Tisdell, 2016) to draw connections across responses and explicitly document meaning making as it occurred, and (c) regular analytic meetings to build consensus on the meaning that was emerging from responses.

Critical reflection methodology

After conducting the original study, five mini-projects were developed in which sub-groups of the research team re-analyzed the data following new inquiries. In this mini-project, we reviewed the data collection methods, the research conversation transcripts, the analytic memos, and the raw video footage in an attempt to understand how design features allowed researchers' and participants' to build relationships and co-construct knowledge and the research process together. We re-analyzed the data by coding for moments when (1) either the researcher or the participant took agency in the conversation, (2) where a researcher offered their own perspective or understanding based on what was said, or (3) where participants pushed back against a researcher's offering, against each other, or against an underlying assumption inherent in the questions being asked. Additionally, we looked for moments where interlocutors shared personal reflections or memories, erupted into laughter, and seemed hesitant or uncertain in their responses; we investigated these moments as possible examples where trust was being built or had been built.

Critical reflection

Flexible engagement

Data collection for this project took place the summer after the pandemic hit the United States in March 2020. During a time when home and work boundaries were being upended, we made it a priority to invite participants to engage in the study however they were most comfortable. Before each conversation took place, a research team member would connect with an individual expert or point person for the small groups and discuss their preferences. For instance, one participant did not feel comfortable having their video recorded, and another chose to talk over the phone instead of over Zoom. If one holds that research is meant to extract "objective" truths by controlling for discrete variables that might affect a participant's response, then this anomaly might have been thought to detract from the consistency of the research or from the reliability of the project's findings. However, centering CQI in this work meant embracing the anomaly as a feature of the collective expertise we were gathering, not a flaw. Additionally, though we did not expect that being flexible meant offering a phone interview instead of a recorded Zoom call, we quickly adjusted to suit the desires of this participant, pointing to adaptability as a necessary condition for this design feature.

We also designed flexibility around what was discussed during research conversations. As is common with semi-structured interview and focus group protocol, all conversations were not conducted identically. We wanted to remain flexible with how conversations unfolded and to prioritize whatever themes OST organization leaders thought was most important for the field to know. For example, it became clear in conversations with Indigenous experts and organization leaders who work with Indigenous youth that the separation between OST and school-based programs does not always exist, particularly in rural locations where some youth access art supplies through their schools. Instead, they chose to talk about the ways in which artmaking is both deeply embedded in some tribal culture and difficult to access through formal educational environments. Designing for flexibility allowed participants to share information that was most relevant to the work they do and take ownership over their participation in the study. Moreover, the flexibility in design also highlighted the importance of adaptability on the part of researchers, which emerged as a critical feature alongside flexible engagement.

Honoring expertise

Participants' expertise is not always valued in research, but we perceived all stakeholders as experts in the field of OST youth arts and experts of their own lived experiences as artists, youth workers, and members of the community they served. In other words, the role of "authority," which is usually reserved for scholars, became porous as everyone who participated in a conversation was considered an authority. We honored participants' expertise when we invited organization leaders to direct the program-centered, small group conversations after sharing with them the general themes the research team was interested in. Additionally, organization leaders were encouraged to tailor the conversation questions for the group depending on what would be most salient to the group based on their insider knowledge.

This design feature was included as a way to subvert traditional roles between researcher and participant, and empower participants to guide the study. Ultimately, we realized this feature also allowed us to highlight and tap into the trust, rapport, and shared knowledge that was already established between organization leaders, teaching artists, and youth artists. Some of the most powerful moments occurred when the OST organization leaders guided the conversations themselves. Moreover, because everyone was an authority in their own right, the conversations were not one-sided in favor of either the researcher or the participant. Approaching meaning-making in research as a collective process transformed the research conversations into bi-directional pedagogical encounters whereby all interlocutors could learn from another. Framing research as an opportunity for both researchers and participants to learn and evolve subverts the expectation that interlocutors' thoughts and understanding is settled and static.

Nurturing relationships

Building trust was a key component of fostering meaningful relationships with participants over the span of 40-90 minute conversations. As we mentioned above, one way we built trust was to tap into relationships where it already existed and allow those bonds to guide the research. Another way we built trust, particularly in the small group conversations, was through the inclusion of a theatre improvisation game. At the beginning of each small group conversation, the researchers led everyone through an activity known as Gift Giving (though it probably has many names), in which one person pantomimes handing another person a gift (in our case, through the Zoom screen). Then the person receiving the gift replies something to the effect of, "Thank you for the gift! How did you know that I needed this [fill in the blank] in order to get through the rest of my day?" The person receiving

the gift then pantomimes using whatever they improvised. This type of warm up game or icebreaker is a common ritual among theatre ensembles. By dedicating 10 minutes to this activity, it was our intention to begin building a connection that would be the foundation of the group conversation. We hoped the activity would provide everyone a point of joyful, silly, and meaningful connection through a common experience (if they did not already have one), and a chance to learn a little about each other prior to opening up in conversation. Ultimately, the activity invited participants and researchers to acknowledge and reflect on their current state of mind in a fun, whimsical manner that seemed to create space for vulnerability and more candid conversation.

Conclusion

Although more research is necessary to understand how the design features impacted participants' experiences, we believe these features allowed participants to co-construct the research experience and play an integral role in directing the outcomes of the study. Participants were encouraged to take agency over the study and their participation in it. Their expertise was honored, allowing the roles of "researcher" and "researched" to be porous and in flux (Vossoughi & Zavala, 2020) and encouraging everyone in conversation to learn from one another. They were met with flexibility, respect, and a genuine opportunity to foster relationships through trust. Opportunities for joy and silliness were specifically designed into this study in a way that invited participants to speak candidly during conversations. In watching the video recordings, we noticed an air of familiarity and uncertainty among the interlocutors, an atmosphere where they are simultaneously commingling, building relationships, and co-constructing knowledge. Analyzing and understanding the relationship between researcher and participant is not usually a core component of qualitative research even today. Although taking such an approach to research is complex and somewhat nebulous, it is an important step to developing new visions of qualitative research as we endeavor to honor and gain insight from communities in equitable ways.

Facilitating productive struggle in science education: The possible benefits of managing scientific uncertainty during sensemaking

Jongchan Park, Emily Starett, Ying-Chih Chen, Michelle Jordan
jpark366@asu.edu, estarret@asu.edu, ychen495@asu.edu, michelle.e.jordan@asu.edu
Mary Lou Fulton Teachers College, Arizona State University

Abstract: Utilizing students' scientific uncertainty as a resource for deep learning opportunities has been introduced for productive sensemaking in science education. However, productively managing the emerging uncertainty is challenging for teachers and students in that they are often frustrated by or ignore the uncertainty during sensemaking. It also remains unclear what drives or obstructs sensemaking when students are learning science concepts, and when the process advances or recedes. This paper aims to suggest a conceptual framework to understand how uncertainty management can facilitate students' sensemaking so that they can experience productive struggle. To develop the framework, this theoretical paper explores sources and types of scientific uncertainty, and how the management of these uncertainties does or does not promote the productiveness of students' struggle during sensemaking. Lastly, a framework is proposed to translate the theoretical constructs into classroom practices.

Introduction

An extensive research strand emphasizes the importance of struggling experiences in developing a deep understanding of science concepts, phenomena, or solutions. Among them, to name a few, are impasse-driven learning (VanLehn et al., 2003), productive failure (Kapur, 2008), and productive struggle (Warshauer, 2015). The underlying ideas across these theoretical approaches to confronting impasse are consistent regarding its prerequisite: the recognition or identification of the impasse, gap or inconsistency in the current knowledge structure offers opportunities to move one step forward, and then, the subsequent intentional and effortful struggling to overcome the challenges yields productive learning outcomes.

In a similar vein, utilizing students' scientific uncertainty as resources for deep learning opportunities has been explored in science education (Beghetto, 2017; Manz, 2018). Practices of science (e.g., Next Generation Science Standards [NGSS], 2013) inherently involve dealing with uncertainty. When students are required to engage in scientific practices to make sense of scientific phenomena, identifying and exploring what they are uncertain about can drive their process of sensemaking (Odden & Russ, 2019). However, recognizing and maintaining emerging uncertainty is challenging for students; they are often cognitively overwhelmed or even emotionally frustrated, and thus tend to ignore the uncertainty (Chen, 2022; Jordan & McDaniel, 2014). Instructional supports are thus needed to gear students' struggling toward productive management of their scientific uncertainty when engaged in sensemaking during science learning.

Researchers have explored the process of sensemaking in order to identify when and with what students may struggle and offered frameworks for how teachers can support the sensemaking process. They have identified a series of non-linear phases of sensemaking (e.g., inconsistency or gap recognition, generation of explanation, and resolution; Odden & Russ, 2019). However, it remains unclear what drives, obstructs, or resumes the process of sensemaking and when the process advances and recedes. To uncover this issue, this theoretical paper aims to suggest a conceptual framework to understand how uncertainty management can facilitate students' sensemaking process so that they can experience productive struggle.

Sensemaking and scientific uncertainty

Odden and Russ (2019) defined sensemaking as "the process of building an explanation to resolve a perceived gap or conflict knowledge" (p. 187) and identified what elicits and sustains the process of sensemaking (e.g., perceived gap as an entry condition, lack of discussion as constraints, or satisfactorily resolved gap as an exit condition). Building on this previous research, this paper suggests four phases of sensemaking: *phenomena representation, knowledge gap recognition, exploration*, and *application and evaluation* of potential resolution.

Along with the four phases of sensemaking shown in Table 1, this paper highlights iterative and effortful uncertainty management with which students are engaged during sensemaking and explains the (meta-)cognitive engagement involved in uncertainty management during each phase. In this manner, this paper advances an understanding of the role of students' uncertainty management in driving or impeding sensemaking related to scientific phenomena, and of when and how instructional strategies can be implemented during sensemaking.

 © ISLS

Table 1
The Four Phases of Sensemaking and the Students' Uncertainty Management

Phases	Sensemaking features	Students' uncertainty management
Phenomena representation	• Interpreting and representing situations • Prioritizing parameters • Generating initial thoughts	• Students raise uncertainty when they recognize and acknowledge uncertainty of interpreting and representing situations, otherwise it is ignored or vanishes
Knowledge gap recognition	• Prior knowledge alignment • Recognizing the gap between initial (naïve) thoughts and target knowledge • Specifying the knowledge gap	• Students reflect on uncertainty and recognize, acknowledge, and/or specify inconsistency between prior knowledge and the target knowledge
Exploration	• Observing and gathering data, information and ideas • Analyzing and interpreting data, information and ideas • Generating explanation and reasoning	• Students maintain uncertainty during the exploration of new data, information and ideas • New uncertainty may emerge in the exploration (i.e., situated uncertainty) while the old uncertainty is being managed
Application and evaluation	• Applying a new understanding to the represented phenomena to fill the gap • Evaluating the potential solution • Revising the initial thoughts and retaining the revised ones	• Students reduce uncertainty when the recognized gap appears to be filled, otherwise uncertainty may remain or be ignored • New uncertainty may emerge in the process of applying or evaluating the suggested solution

Uncertainty management for productive struggle

As suggested so far, it is not the uncertainty itself but the *management* of uncertainty that drives the sensemaking process in either productive or unproductive ways during science learning. To unpack the relationship between uncertainty management and productive struggle, this theoretical paper distinguishes desirable uncertainty from undesirable uncertainty and posits how managing the two types of uncertainty can cause either curiosity or frustration through productive or unproductive struggle as illustrated in Figure 1. In addition to the discussion on desirability of uncertainty for productive struggle, two major sources of scientific uncertainty, *content knowledge* and *epistemic knowledge*, are introduced.

Sources of scientific uncertainty

Uncertainty in learning is defined as a subjective experience of being aware that one has insufficient or incoherent knowledge, or ability to make sense of phenomena, situations, or solutions (Chen, 2022; Jordan & McDaniel, 2014). The feeling of uncertainty is subjective because it is experienced differently between individuals depending on the degree to which individuals react to novelty, complexity, unfamiliarity, ambiguity, and lack of clarity. Individuals' ability to understand the given topic also interacts with these causes of uncertainty to spark students' subjective uncertainty (Silvia, 2010).

In science classrooms, there are two major sources of scientific uncertainty against which students experience novelty, complexity, etc. during science learning: Content and epistemic knowledge. In other words, content and epistemic uncertainty can be distinguished in terms of what is known and how it is known. *Content uncertainty* can be defined as individual's subjective feeling that they are unaware of or unconfident about the terminology, principles, or theories being discussed (e.g., "What theory can explain why the small ball fall faster than the big one with the same weight?"), while *epistemic uncertainty* refers to individual's subjective feeling that they are unsure about "how we know what I know and why we believe it" (Duschl, 2008, p.269; e.g., "How can I know that the air makes the difference in the speed of falling balls?").

Types of scientific uncertainty

Additionally, content and epistemic uncertainty can both fall into additional categories determined by their desirability: Desirable and undesirable uncertainty. Regarding the types of uncertainty in this vein, researchers used different but similar terms, such as *good and bad uncertainty* (Beghetto, 2017) and *productive uncertainty* (Manz, 2018). The authors concur with these distinctions of uncertainty in that they address that not all uncertainty is detrimental or beneficial. Nevertheless, this paper prefers to frame uncertainty based on its desirability. This is in part because this paper distinguishes uncertainty from uncertainty management which Beghetto (2017) and Manz (2018) did not. It is the productive uncertainty management that can make even "bad" uncertainty desirable at some points. The desirable uncertainty is desirable because it concerns the knowledge which is crucial to

sensemaking of the topic and it emerges at an appropriate time (e.g., emerging during the phenomena representation rather than interrupting the process of reducing other crucial uncertainties).

Engaging in productive struggle through uncertainty management

While it is individual differences that makes uncertainty desirable or undesirable at the beginning of sensemaking during science learning as stated above, the productive management of both types of uncertainties can encourage students to engage in productive struggle and spark curiosity for learners to yield productive learning outcomes. *Productive struggle* involves the process where students grapple with their understanding of the presented information and actively work through the struggle to make sense of the problematized phenomenon and advance their own understanding (Warshauer, 2015). In this theoretical paper, we adapted the Fredricks's et al. (2004) framework of examining school engagement to represent student engagement at the level of a learning event. With this framework, this paper distinguishes productive struggle from unproductive struggle regarding three dimensions of engagement: *behavioral, emotional, and cognitive engagement* (See Figure 1). This framework not only helps construct a multifaceted understanding of individual differences during uncertainty management but also suggests instructional strategies for productive uncertainty management in multifaceted ways.

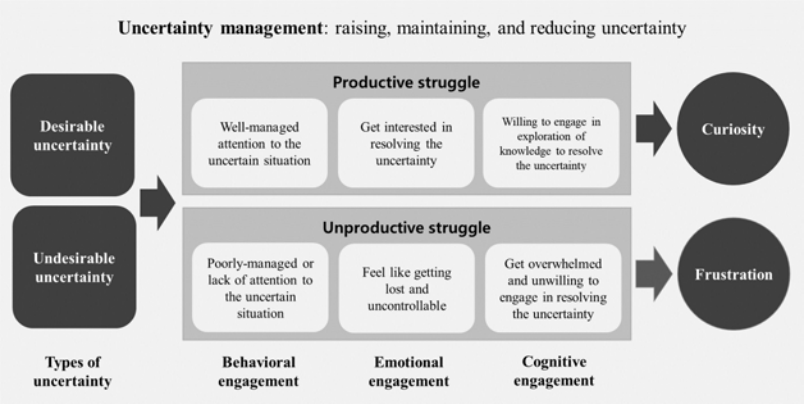
Gee (2017) emphasized that the combined effects of behavioral, emotional, and cognitive engagement facilitate the process of resolving the recognized uncertainty. For example, Gee identified a) well-managed attention to what students fail to make sense and b) interests to what they are paying attention to and c) intentional caring for the uncertainty as crucial factors of meaningful learning experiences (i.e., productive struggle). On the other hand, students may disengage in their learning when they lose their attention, feel uncontrollable, or get cognitively overwhelmed partially due to their perceived inability to understand or due to persistent failure (D'Mello & Graesser, 2012; Silvia, 2010).

Outcomes of uncertainty management

Desirable uncertainty can spark curiosity when it is productively managed, but it can also frustrate learners when it unnecessarily persists unresolved (D'Mello & Grasser, 2012). Similarly, undesirable uncertainty can also frustrate learners when it is, for example, too complex to resolve, but it can also lead to students' curiosity when it is strategically managed (See Figure 1). It should be noted that productive uncertainty management is not easily achieved and thus needs the combined effort of a strategic approach utilizing student, peer, and teacher support (Chen, 2022; Jordan & McDaniel, 2014). A strategic approach will include, for example, (collaboratively or individually) raising, maintaining, and reducing uncertainty through questioning, comparing, or generating explanations about issues of uncertainty at an appropriate time. One means of translating this approach into practice is discussed in the following section.

Figure 1

Productive and Unproductive Struggle through Uncertainty Management



Facilitating productive struggle in sensemaking

How students manage their uncertainty determines the processes and outcomes of sensemaking. Therefore, instructional supports are needed to help students productively manage their uncertainty for productive struggle in sensemaking. Understanding how (un)desirable uncertainty associated with epistemic or content knowledge can lead to (un)productive struggle sheds practical light on how teachers can support students' uncertainty management in each sensemaking phase. Table 2 shows some examples of instructional strategies that teacher can use based on the phase of sensemaking and knowledge type associated with students' scientific uncertainty.

Table 2
Managing Scientific Uncertainty During Sensemaking to Facilitate Productive Struggle

Sensemaking phases	Source of scientific uncertainty		Uncertainty management
	Epistemic knowledge	Content knowledge	Teachers' strategies for using desirable uncertainty to manage uncertainty
Phase 1: Phenomena representation	Knowledge used for representing and interpreting phenomena	Knowledge about scientific concepts associated with the phenomena	- Raising desirable uncertainty by problematizing, challenging initial ideas or opening up the problem space in ways that elicit curiosity
Phase 2: Knowledge gap recognition	Knowledge used for recognizing inconsistency between initial thoughts and the represented phenomena		- Reflecting on uncertainty to trigger prior knowledge and identify what knowledge needs to be explored - Expanding desirable uncertainty to other relevant uncertainties targeting the hypothesis, variables, and methods that students plan to explore
Phase 3: Exploration	Knowledge used for finding, collecting, and interpreting data to use as evidence and elaborate the potential solution		- Maintaining uncertainty by comparing conflicting ideas or data, or introducing alternative claims - Maintaining uncertainty by seeking variations of potential solutions while staying curious about options - Raising a new uncertainty when necessary
Phase 4: Application and evaluation	Knowledge used for applying the potential solution and evaluate the soundness of it		- Reducing uncertainty by helping to construct and determine the best solution - Reducing uncertainty by helping to reconstruct a new knowledge system that is not the same as Phase 1

Young children's use of spatial sensemaking practices as mediators of spatial skills during informal STEM programs

Abstract: While considerable research has examined when young children develop spatial skills and how these predict their success in STEM engagement, this study adds to the limited research on the processes through which young children learn to reason spatially during everyday learning environments. Through investigations of science and engineering programs for 3–5-year-old children, we provide evidence for how these programs engage children in a diverse range of spatial sensemaking practices, such as gestures, sketching, and object manipulation, which in turn engage their use of multiple forms of spatial skills. Our findings suggest children used spatial sensemaking to solve engineering problems and make sense of science phenomena, setting the stage for future STEM learning.

Introduction

Spatial thinking—the use of spatial concepts, spatial tools, and application of spatial reasoning— is fundamental to everyday life as well as advancing access to science, technology, engineering, and mathematics (STEM) pursuits (National Research Council, 2006). We apply the skills of spatial thinking when we use a map to navigate to a new location or use instructions to assemble furniture. Yet early differences in how children reason spatially have implications for their near-term and long-term opportunities in pursuing STEM interests. Research demonstrates that preschool-age children's spatial skills predict early success in mathematics (e.g., Gunderson et al., 2012) and has thus provides the link to later persistence in science (Wai et al., 2009). Spatial skills–application of cognitive processes to reason about spatial information—can be improved through a wide-variety of interventions, even among very young children (Uttal et al., 2013; Yang et al., 2020). However, what is needed is more information on how children's everyday learning contexts, such as museum settings and preschools, can provide *spatialized* experiences for children that embed training for spatial thinking alongside play-based STEM engagement (Newcombe, 2013). This study considers how STEM programs in a science center provide an opportunity for a spatialized experience where children enact spatial practices in order to engage in spatial skills.

Spatial Skills and Distributed Spatial Sensemaking

Literature on how people engage in spatial thinking often frames the process as a set of cognitive spatial skills (e.g., Uttal et al., 2013). One benefit of categorizing spatial skills is the identification of correlations between specific spatial skills and performance in STEM fields (Hegarty, 2014). Such findings suggest that supporting flexible use of a broad range of spatial skills might benefit children in their early learning experiences. We drew on a taxonomy which classifies spatial skills along two orthogonal dimensions: *intrinsic* to *extrinsic* and *static* to *dynamic* (Uttal et al., 2013). For example, the spatial skill mental rotation (the ability to rotate 2D or 3D objects in one's mind) is classified as *intrinsic* (within the object) and *dynamic* (active mental manipulation).

We also use a distributed spatial sensemaking framework to better examine how the learning environment support children's use of spatial skills. Distributed spatial sensemaking frames children's use of spatial reasoning as practices situated in context and drawing on social and material resources (Ramey, Stevens, & Uttal, 2020). This framework helps us better understand children's learning by situating spatial thinking in their everyday learning opportunities. Young children's spatial thinking is malleable (e.g., Yang et al., 2020) so it is important for research to identify the range of conditions that improve children's spatial thinking. The distributed spatial sensemaking framework was used to identify how and when the children used spatial sensemaking practices – defined as "strategies for making sense of spatial information that relied on communication with other individuals (learners or instructors) or interactions with external objects and representations" (Ramey & Uttal, 2017, p. 12). While this framework has been used to uncover the ways middle school students use spatial sensemaking (e.g., Ramey & Uttal, 2017), our research demonstrates the utility of this framework to understand the processes through which spatial thinking is learned, enacted, and leads to constructing explanations and solving problems in everyday learning contexts for preschool-age children. Drawing on these frameworks, we conducted a qualitative study of three preschool STEM programs, guided by the following research question: *In what ways do spatial sensemaking practices engage children's use of spatial skills during STEM programs?*

 © ISLS

Methodology

Our methodological approach drew on interaction analysis because it is grounded in a belief that "knowledge and action are fundamentally social in origin, organization, and use, and are situated in particular social and material ecologies" (Jordan & Henderson, 1995, p. 41). Gathering video-data is well-suited to interaction analysis because it allowed us to generate patterns from multiple sets of observations. Further, video analysis allowed us to consider the embodied nature of children's meaning-making with their hands, bodies, and material manipulations.

To investigate children's spatial sensemaking, we chose three preschool STEM programs at a science center located in a town in the North Eastern United States. The programs selected for their potential for prompting children's spatial thinking: a 5-day engineering camp, a 30-min program about lunar craters, and a 30-min program about shadows. Participants included the preschool-age (age 3-5 years) children attending each program: n=8, n=10, and n=6, respectively, and the early childhood educators who led each program. Each program was video recorded using multiple camera angles. We selected only the video sections from the engineering camp showing children working towards solving each day's main engineering challenge as our pre-coding suggested these would provide a rich source of data on young children's spatial thinking (~1.5 hrs / day) for analysis. We analyzed the full data sets from the other two programs (~30 min each).

Using *Vosiac* for video coding, we first broadly coded to identify events in which children and educators engaged in spatial sensemaking practices. Within these events, we applied three coding schemes. (1) We began with coding children's spatial sensemaking practices (SSPs) (Ramey & Uttal, 2017): spatial talk, gestures, object manipulation, body movement, and sketching. (2) We coded clusters of SSPs for spatial skills using Uttal et al. (2013)'s typology, with sub-codes defined in Ramey et al. (2020). The four spatial skills are: *intrinsic-static*: "Perceiving objects, paths or spatial configurations amid distracting background information," *intrinsic-dynamic*: "Piecing together objects into more complex configurations, visualizing and mentally transforming objects," *extrinsic-static*: "Understanding abstract spatial principles, such as horizontal invariance or verticality," and *extrinsic-dynamic* "Visualizing an environment in its entirety from a different position" (Uttal et al., 2013, p. 4). (3) We coded each event for social and material resources mediating their production: educators, other children, physical materials, sketches, and tools (Ramey et al., 2020). (4) We coded for preschool-age children's evidence-based explanations (e.g., Plummer & Ricketts, 2018) and engineering problem-solving (e.g., NRC, 2013).

To improve the validity of our coding, we used existing frameworks from the literature (e.g., Ramey & Uttal, 2017; Uttal et al., 2013; NRC, 2013). The first author coded the video data and then reviewed all coding with the second author to improve reliability. All codes were agreed upon after discussion. Working across our coded videos, we defined themes from patterns observed across the code groups (Braun & Clarke, 2006).

Findings

Our analyses resulted in three major themes. First, we demonstrated how the preschool-age children engaged in a range of spatial skills, during science and engineering activities, using multiple spatial sensemaking practices. Second, we identified the important role played by educators and the material resources provided to the children in how they engaged with spatial thinking. Third, the children used spatial sensemaking practices as an essential component of constructing evidence-based explanations in science and solving problems in engineering. Below, we provide excerpts from the programs illustrating these themes. Each science program and each day of the engineering camp engaged children in a few spatial sensemaking practices, which in turn supported one or two spatial skills. However, across all three programs, we found children engaged in a broad range of practices and three of the four spatial skill quadrants. And, individual spatial sensemaking practices (e.g., sketching, gesturing) engaged children in diverse spatial skills, depending on the program. Figure 1 shows the relationship we observed between the spatial skills and the range of spatial sensemaking practices children were using.

We include two excerpts to illustrate the relationship between spatial sensemaking practices and spatial skills in children's STEM learning as well as the important role played by the educators and materials. These practices, people, and resources came together to engage children in designing solutions to problems and constructing explanations for science phenomena. The first excerpt took place during Day 1 of the engineering camp. Initially, each child drew a design for their fort. Mia (5 years) drew a square base with a triangular roof and a chimney then worked with Sean (4 years), Adam (5 years) to build the fort's base using cardboard and tape. Just before the transcript below, Laura (Educator) placed a large flat piece of cardboard on as a roof for their fort.

Mia: (to Laura) Look at this. This is the chimney [points to her drawing] and this is the (unintelligible).

Laura: This isn't what you guys were drawing. My roof is flat [Laura rubs her hand across flat roof].

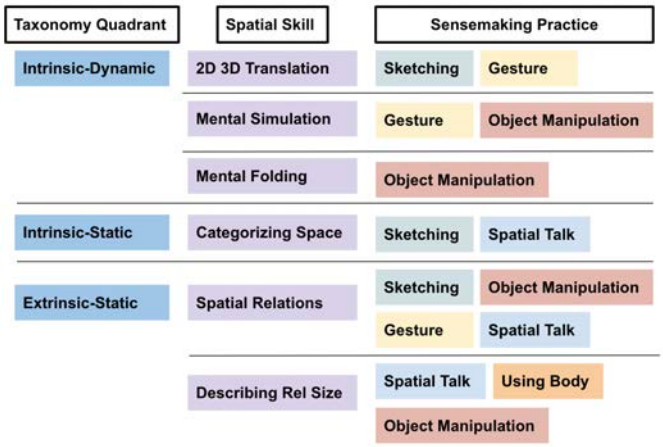
Mia: This is OK. [She rubs her hand across a spot on the edge of the roof.]

 © ISLS

Laura: You're OK with it flat?
Mia: Yeah, [she returns to point at her drawing] it's just that, we can make this the chimney [indicates chimney] -
Laura: Make the, so we're going to use [gestures with both hands a rough chimney shape] –
Mia: [Places hand back on the same spot on the roof] The chimney can be right here, I know – [spins back to grab her pencil and starts drawing on the roof] –
Laura: So how can we make a pretend chimney –
Mia: [Brings Laura back to her drawing] We'll make a hole in the roof. OK, [unintelligible but she is gesturing to her drawing for Laura to see].

After this, the group works to construct a cardboard chimney attached to the spot Mia indicated on the roof. Mia used spatial sensemaking practices of *gesturing* and *sketching* to support her use of the Intrinsic-Dynamic spatial skill of *2D to 3D translation*. This spatial skill involves moving between 2D representations (Mia's sketch) to 3D representations (locating and then creating the chimney on the fort). Mia used the spatial sensemaking practices––gesturing and sketching—to facilitate her engagement with *designing solutions* (NRC, 2013) – an important engineering practice – as she worked to communicate her ideas about the design (e.g., the location of the chimney) and negotiate the nature of the fort (flat versus peaked roof) with Laura.

Figure 1
Relationship between the spatial skills observed and children's use of spatial sensemaking practices



The second example is from the end of the shadow program. Earlier in the program, the children used flashlights and small bear figures to investigate ways to create shadows of different lengths and directions. At the end of the program, the educators, Nora and Tina, work with Mark (5 years) and the other children to draw a picture of the location of the Sun, Bear, and his shadow.

Mark: This is Bear's shadow [taps on his drawing of the shadow to get Nora's attention].
Nora: OK, so here is the Sun and here is Bear's shadow. Why did you draw it there?
Mark: (short, unclear comment)
Tina: Tell us what you figured out before.
Mark: So, when I holded it right here [points pen towards Bear drawing to indicate how he held his flashlight during the investigation] then his shadow when this way [gestures towards his drawing of the shadow on the opposite side of the Bear figure].
Nora: OK, that was your observation.

In the excerpt, Mark used the spatial sensemaking practices of *gesturing, sketching, object manipulation*, and *spatial talk* to support his use of the Extrinsic-Static spatial skill, *spatial relations*. This spatial skill involves visualizing or describing relations between objects, such as how Mark described the relationship between the light source, object, and shadow location using his sketch, pen, and gestures. In doing so, Mark used evidence he gathered (earlier in the program) while engaged in *object manipulation* to initially determine the relationship using a flashlight and a bear figurine. He referenced this ("*when I holded it right there*") as evidence for the *explanation* he constructed for the shadow phenomenon (Plummer & Ricketts, 2018).

We have described how the children used spatial sensemaking practices to facilitate their use of spatial skills when designing solutions or constructing explanations. But these episodes were also facilitated by children's access to the material resources provided in the learning environment (e.g., cardboard boxes, flashlights, sketch

paper and pens) and the supporting prompts and questions by the educators. Both Mia and Mark used the materials resources to facilitate their spatial reasoning; Mia used the cardboard fort to help her communicate spatial elements of the design to Laura while Mark reflected on embodied knowledge of the use of his flashlight when recounting spatial relations in his explanation. These, and the majority of episodes of spatial sensemaking we observed, were facilitated by educators' questions and guidance. In the engineering camp, Laura engages with Mia to negotiate a design solution for the chimney. In the shadow program, Nora prompts Mark to explain his shadow drawing which provides an opportunity for him to offer the evidence for how his reasoning supports his claim.

Discussion

Our analysis demonstrates the diverse set of practices preschool-age children used to apply spatial skills while engaging in solving problems and investigating science phenomena. Across a selection of STEM programs, we identified children's use of spatial skills within three quadrants of Uttal et al. (2013)'s taxonomy. Further, our analysis reveals that young children draw on both personal resources (spatial sensemaking practices) and external resources (educators and the materials provided in the workshop) to facilitate their application of those spatial skills to solve spatial problems. Thus, we make the following contributions to the literature on young children's spatial thinking. First, this study address gaps in the literature about how STEM education may engage young children's early spatial skills through participation in distributed spatial sensemaking, though more research on the efficacy of such programs is still needed. Second, our study provides insight into methods that may improve young children's spatial skills using alternatives to traditional models of spatial training or decontextualized instruction (e.g., Yang et al., 2020). While spatialized instruction is largely absent from formal early education curricula (Pritulsky et al., 2020), our findings suggest that play-based, STEM activities may engage children in distributed spatial sensemaking providing opportunities to develop spatial skills.

How Research-practice Partnerships Learn to Develop Goals for Math and Identify Local Problems of Practice

Benjamin Michael Superfine, Alison Castro Superfine, Craig DeVoto, Ahreum Han
bsuperfi@uic.edu, amcastro@uic.edu, craig.devoto@gmail.com, ahan21@uic.edu
University of Illinois at Chicago

Abstract: Research-practice partnerships (RPPs) are an efficacious and increasingly common organizational approach for educational improvement. However, as RPPs learn to effectively engage in instructional improvement, they go through various stages. Several factors can influence the development of organizational learning across these stages. We describe how RPPs at their earliest stages in two school districts in the United States learned to develop goals for improving math teaching and learning, and identify local problems of practice with respect to these goals. We also highlight how district history, the engagement of "boundary spanners," and other key factors influence this process.

Introduction

RPPs are an efficacious and increasingly common organizational approach for educational improvement. They engage researchers and practitioners in joint work around local problems of practice and promote evidence-based inquiry into how such problems might be addressed (Penuel et al., 2011). RPPs can also be a productive approach for developing the capacities of its participants and respective organizations if they are deliberately designed with this goal in mind (Fishman et al. 2013). However, RPPs are different; they develop over time, across various stages, and require different types of organizational learning. Preliminary or initial developmental stages, in particular, have a significant impact on the life of RPPs (e.g., Law & Liang, 2019).

In this paper, we describe how RPPs at their earliest stages in two school districts in the United States learned to develop goals for improving math teaching and learning, and identify local problems of practice in relation to these goals. We also examine factors that potentially influenced such goal development and problem identification. As part of the CASPIR (Collaborating around Structures, Processes, and Instructional Routines) Math Project (referred to hereinafter as CASPIR), university researchers and professional developers formed an RPP with each school district. The goals of CASPIR are to co-develop and co-implement a multi-component professional development intervention designed to improve teachers', teacher leaders', and administrators' understanding of effective math teaching and learning, and to enhance the organizational capacities of schools and districts to support such instructional improvements in math. CASPIR employs a design-based implementation research (DBIR) process involving collaboration between researchers, professional developers, and district and school personnel. In the cases of both districts, district math leadership teams (DMLTs), in collaboration with the university team, constitute the organizational unit responsible for identifying the problems of practice and where CASPIR's efforts at developing structures for ongoing RPP work were focused.

The CASPIR Math Project Model

The CASPIR model is aimed at using a DBIR process to enhance organizational and stakeholder capacities to identify local problems of practice related to math teaching and learning and develop and implement strategies to address these problems. The model includes three components enacted across teacher, school, and district levels. First, DMLTs are formed with teachers, district/school administrators, and the university team. DMLTs then regularly meet and collaborate to co-develop a robust vision for math teaching and learning at the district level, which contributes to a "coherent instructional system" (Cobb et al., 2018, p. 11-12). Once the vision is articulated, the DMLT analyzes the district's strengths and needs, and develops district math goals and strategies to support math improvement in relation to local problems of practice. Second, professional development is co-designed and co-implemented by the DMLTs, and aimed at teachers, school leaders, and district leaders. This PD can attend to a range of issues, depending on the vision for math teaching and learning initially developed, and on the specific local problem of practice chosen by the DMLT. Third, iterative cycles of design and redesign are implemented annually—whereby data is collected, goals are set, strategies are implemented, strategies are assessed, and the cycle begins anew. This paper describes the initial stages of CASPIR.

Theoretical and Empirical Background

The key features of a DBIR approach include: (1) focusing on user-centric problems of practice; (2) iterative, collaborative design; (3) developing a theory of improvement through systematic inquiry; and (4) developing

 © ISLS

capacity for sustaining change in systems (Penuel et al., 2011). Such an approach recognizes that "achieving successful change in complex work systems means recognizing that one cannot predict ahead of time all of the details that need to be worked through nor the negative consequences that might ensue" (Bryk et al., 2015, p. 7). Meanwhile, RPPs are directly aimed at learning to do such work not simply from an individual perspective but also organizationally. Routines and processes, shared insights and understandings, and information processing abilities, are foundational elements for building organizations that can effectively engage in DBIR (Basten & Haamann, 2018). However, RPPs do not simply work "out of the box." Rather, they develop over time and through various stages. For example, it can be efficacious for RPPs learning to engage in DBIR to begin their work by focusing a central team of researchers and practitioners on a discrete and user-centric problem of practice, like student skills and knowledge in a particular content domain (Fishman et al., 2003). Emphasizing the importance of shared understandings, Henrick et al. (2015) highlight the utility of specifying explicit, high-quality visions or goals for teaching and learning at the outset of DBIR work to serve as a target for learning. Grounded in this vision, a theory of action about supports for teacher learning in relation to this goal can be articulated and ultimately implemented. As RPPs participating in such a process mature, they engage in design, analysis, and feedback cycles, potentially guided by tools, routines, and procedures that are instituted to develop capacities to engage in such work sustainably. These early moves are key steps for organizations learning to engage in DBIR.

A key element of organizations developing such capacities at their earliest stages and learning to conduct such work are evaluators/researchers. Indeed, they can leverage practitioners' experiences to better understand local problems of practice (Dozios et al., 2010) by framing key issues and problems, introducing frameworks to guide meaning-making, identifying key indicators to guide data collection, and building stakeholder consensus. Conversely, several interrelated factors can influence how RPPs develop and learn to engage in DBIR over time. For instance, local district context and history constitute key factors, as they can drive the emergence of different problems of practice and make scaling up challenging across different contexts (e.g., Bryk et al., 2015). Certain elements of the RPP itself are also key factors influencing RPP development. Notably, boundary spanners (or brokers) are individuals that can help bridge differences across researchers and practitioners, such as goals, expectations and routines (Hopkins et al., 2019). Boundary objects (i.e. shared resources and ideas that facilitate coordination of activities) can promote productive researcher-practitioner communication (Hopkins et al., 2019).

Methods

Drawn from a larger multiple-embedded case study involving several school districts (Yin, 2013), data for this study come from DMLTs in two districts—Washington and Hamilton (pseudonyms). Washington has four primary schools, and Hamilton has three. During the 2020-21 school year, we collected two data sources across both DMLTs: semi-structured interviews with all DMLT members (N = 64), and observations of all DMLT meetings to-date (N = 53). All data sources were recorded and transcribed.

We developed a different analytic procedure for interviews and observations, followed by triangularization across both data sources. Beforehand, training and interrater reliability (IRR) were conducted. For the semi-structured interviews, we first developed an inductive coding scheme based on extant research that captured perceptions about instructional improvement, role of the DMLT, and data-driven decision making. After achieving a Cohen's Kappa of 0.80 or higher, a group of eight researchers from the university team live coded all interviews. DMLT meetings were scored using a graded rubric across various elements including membership, roles/responsibilities, mission/vision, and data-driven decision making to track DMLT progress towards goal development for math improvement/learning.

Findings

Washington DMLT

Washington had a history with the university team prior to the start of CASPIR. For the five years prior, the district participated in extensive teacher and administrator professional development activities, and received regular instructional coaching support. With the exception of one of these years, the district had a DMLT that met between 2-3 times during the school year, generally discussed teacher professional development efforts, and had ongoing discussions about how to support peer classroom observations among teachers in the district. However, the DMLT did not engage in any systematic data collection or iterative cycles of instructional improvement.

CASPIR began its collaboration with Washington in AY20-21. At the first meeting, the CASPIR team introduced CASPIR as well as its goals related to supporting the district in learning how to engage in data-driven improvement cycles. To prepare the DMLT for defining a problem, CASPIR personnel facilitated DMLT discussions on articulating a vision of math teaching and learning in the district. They started with a vision board and then generated descriptive statements. DMLT members generated descriptions of their idealized visions of

what teachers and students should be doing in schools and classrooms. They categorized and connected these statements into a web depicting a draft of the Washington vision for math teaching and learning. The district vision includes statements about students engaging in productive struggle and using tools such as manipulatives and high-quality tasks, and teachers creating learning environments in which students are respected. The DMLT's analysis of the vision determined that the least well-developed category included "tools"—i.e., written materials and tasks that support high-quality instruction. Using interview data collected from DMLT members, there was significant consensus around how to describe a high-quality task that aligned well with what research says.

After identifying tasks that support high-quality instruction as a potential focus for a first improvement cycle, the DMLT designed and implemented an exploration of the problem space related to such tasks. This exploration resulted in a list of potential problems presented as questions. At the same time, several DMLT members had concerns about how the district would determine and agree to which tasks would be deemed as supporting high-quality instruction. This led to the DMLT's use of various research sources (e.g., math standards, educational research articles) to build from DMLT members' interview comments and develop a draft framework for analyzing tasks. This process occurred over the last four DMLT meetings. At the end of Year 1, the DMLT was developing a plan to collect data on the types of math tasks present in the math curricula, and a plan to improve teachers' and administrators' understanding of different types of tasks. Overall, in Year 1, the Washington DMLT developed a robust, research-based vision for math teaching and learning. The team then used this vision to identify a potential focus are for a first improvement cycle.

Hamilton DMLT

Hamilton had an uneven history with the university team prior to the start of CASPIR. In the two years prior to CASPIR, the district initiated a DMLT that met between 2-3 times during the school year that generally discussed a vision for math teaching and learning, reviewed math curriculum materials, set a teacher professional development plan for the year, and explored curriculum analysis tools. The DMLT meetings were facilitated by district representatives, with some support provided by the university, and consisted of only math teachers. The DMLT did not engage in any systematic data collection or improvement cycles.

CASPIR began its collaboration with Hamilton in AY20-21. At the first meeting, the CASPIR team introduced CASPIR and its goals related to supporting the district in learning how to engage in data-driven improvement cycles. The team also discussed the need to build a collaborative vision for high-quality math teaching and learning across the districts, and possible areas of focus to inform the math improvement cycles. However, the district math lead on the DMLT pushed back on the need to develop a vision for math teaching and learning beyond the current version, citing "We already have a vision." At subsequent DMLT meetings, the district math lead proposed a possible focus area for math instructional improvement, namely number sense. As she stated, "We can be pretty confident in saying our students have struggled with number sense." While this decision was not based on any systematic data collection, there was general agreement from other district representatives on the team, and the DMLT agreed on this focus area for a first improvement cycle. As another member reiterated, "I am one hundred percent behind [number sense]. I have felt there is a huge deficit in our district."

For the remainder of the DMLT meetings in Year 1, the team drew from various research-based documents related to students developing number sense (e.g., math standards, research articles from practitioner journals). As part of these discussions, the CASPIR math coach presented a framework for the multiple dimensions of students' number sense that ultimately served as the guiding framework for how the DMLT defined number sense. The focus of the last four DMLT meetings of Year 1 involved developing a shared understanding of number sense according to this framework and discussing the development of a common assessment system for number sense that could be used across schools and grade levels. At the end of Year 1, the DMLT developed a plan to revise existing assessments for the common assessment system over the summer, with the goal of administering the revised assessments in the next school year. So, in contrast to Washington's DMLT, Hamilton's DMLT quickly narrowed its focus to a problem of practice without devoting significant attention to goal development and understanding associated evaluative frameworks.

Discussion

Although the Washington and Hamilton DMLTs were both RPPs at their earliest stages engaging in similar work, their learning about goal development and problem identification took very different trajectories. Where Washington's problem was grounded in strongly articulated goals for teaching and learning and primed for systematic data collection, Hamilton's problem was not and mainly anecdotal. Looking across both cases, our initial analyses highlight key factors influencing the trajectory of both DMLTs (see Table 2).

Table 2
District Trajectories in Early RPP Stages

District	History	Visioning Process	Vision	Identified Problem and Approach
Washington	Long history with professional developers, no specific perceived area of teaching and learning need	Long and focused	Strongly articulated, robust focus on teaching and learning, operationalized by framework	Improvement of math tasks using vision and systematic data collection supported by framework
Hamilton	Uneven history with professional developers, perceived need to focus on number sense	Short and superficial	Vague and not directly tied to teaching and learning	Improvement of students' number sense without vision or systematic data collection

There are likely several factors that influenced how Washington and Hamilton learned to engage in goal identification and problem identification in their RPPs. Our early analyses highlight the importance of district history. Washington had a long history with professional developers who focused on math teaching and learning in ways reflected by the visioning process. These professional developers served as key boundary spanners who were core members of the university team. In contrast, Hamilton had an uneven history with these professional developers, and their boundary spanning was not as effective at focusing the RPP on learning to develop high-quality goals for math teaching and learning. Moreover, members of the Hamilton DMLT came into the RPP with a belief that number sense was a key area for instructional improvement.

AI-Supported Scaffolding for Writing Academic Arguments

Min Kyu Kim, Georgia State University, mkim120@gsu.edu
Nam Ju Kim, University of Miami, namju.kim@miami.edu

Abstract: Despite the importance of writing academic arguments, instructors often lack enough time and knowledge to provide prompt support adaptive to individual students' discipline-specific arguments. AI techniques can enable automated and adaptive educational scaffolding. In this study, we created a test version of the Artificial Intelligent-Supported Scaffolding (AISS) system that provides scaffolds in the form of alternative writing examples that human experts would write. Our mix-methods data gathered from 14 students enrolled in two sections of the same graduate-level online course revealed that the students leveraged AI-generated scaffolds to build a more substantial claim with elaborated ideas in a cohesive text structure. The current study's findings demonstrated the potential of AI to provide personalized scaffolding for writing academic arguments.

Introduction

Competent writing capabilities are required for tertiary students because they are often tasked with communicating in a scientific manner through written arguments (Pelger & Nilsson, 2016). Students must utilize discipline-specific knowledge, integrate various information from multiple sources, and construct compelling arguments (Goldman et al., 2019). Despite the importance of academic argumentation, due to the complexity of writing arguments, writing arguments often remains as a demanding task even for proficient learners. However, students rarely receive formative and prompt support due to instructors' lack of time and skills to teach individuals' discipline-specific argumentation topics (McNamara et al., 2019; Passonneau et al., 2017).

Scholars have explored the use of AI that may assist or substitute for expert human tutors (Puri & Mishra, 2020; Yang, 2021). For example, Yang (2021) demonstrated that an AI system as a teaching agent guided students to deploy good processes and strategies in writing. However, the current AI's ability tends to focus on well-structured domains (e.g., algebra) and therefore is not enough to understand ill-defined and complex problems such as individual students' domain-specific written arguments (Koedinger & Corbett, 2006; Goel & Joyner, 2016).

Admitting that the use of AI in education is in its infancy, we attempted to leverage AI techniques to help students to write academic arguments. To this end, we developed a pilot application named the Artificial Intelligent-Supported Scaffolding (AISS) system. In this initial investigation, we deployed a mixed-methods approach to examine how AI-provided scaffolding drove students to revise their arguments. Specifically, the following questions guided this study.

- To what extent did the AI-enhanced scaffolding help students to improve the quality of their arguments?
- How did students draw on the AI-based scaffolding to revise their arguments?

Background

Academic argumentation and AI-Enabled Scaffolding

A skilled writer leverages domain knowledge and the source of ideas they have learned to support a claim and articulate a process of argumentation in cohesive and coherent ways to persuade others. One effective way that helps students improve argumentation skills may provide them with good examples pertaining to individuals' argumentation topics and use examples as scaffolds to articulate their arguments (Westby et al., 2010). Given scaffolds, students may learn about more appropriate languages, ideas, and professional tones and manners to write a strong argument.

We focused on the role of AI to provide automated scaffolds adaptive to individuals' arguments. Scaffolds– is a broad range of instructional support that enables students to perform beyond their current capacity can take various formats, including prompts, feedback, guidance, hints, and expert models (Wood et al., 1976). In this study, we regarded expert modeling as the most effective way to support students' argument development because expert models can serve as a conduit through which students consider better ideas and sound evidence (i.e., conceptual scaffolding), learn about writing strategies (i.e., strategic scaffolding), and evaluate the quality of their arguments against given experts' examples (i.e., metacognitive scaffolding (Anderson et al., 1997).

We drew on the current Natural Language Processing (NLP) AI techniques that can make sense of the complex disciplinary textual data (Goel, 2019) and provides individualized and prompt scaffolds in the forms of computer-generated written examples that human experts would write. Therefore, augmented by AI, personalized

 © ISLS

support for individuals' argument development can be scalable to many students from diverse disciplines and backgrounds.

Lexical features, text cohesion, and argument quality

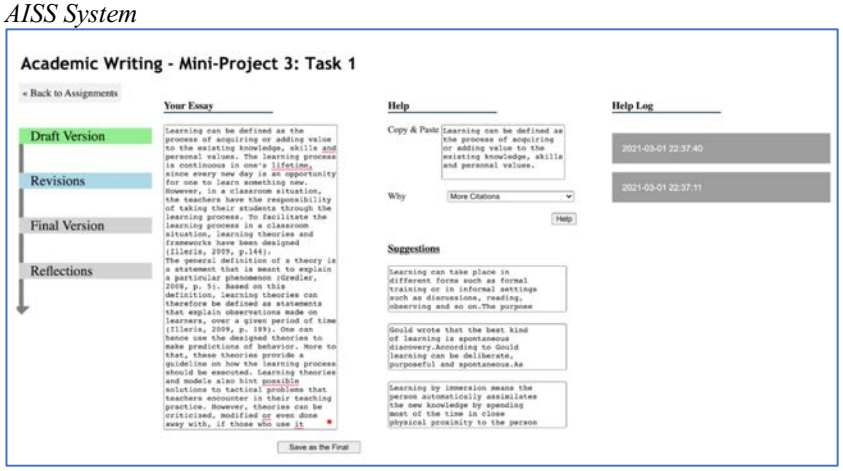
Academic writing consists of developments at various interconnected competencies across different levels of words, phrases, clauses, intra-sentential, inter-sentential, paragraph, and textual levels of analysis. Accordingly, an argument is structured with lexical items—typically nouns, verbs, adjectives, adverbs, etc.—that build their syntactic expressions and semantic relations together (Williams, 2015). Therefore, understanding an argument's lexical elements and syntactic structure is critical to determining the quality of arguments. Scholars have agreed that lexical features contribute to both construction and comprehension of semantics of a text and therefore relate to the quality of arguments (Morris & Cobb, 2004; Vogelin et al., 2019). In this study, we focus on four aspects of text cohesion, as follows:

- Lexical diversity indicates the extent to which unique words are used in the text.
- Lexical density describes the extent of using content words (i.e., nouns, verbs, adjectives, and adverbs) in text.
- Sentence overlap indicates the number of text items repeated across sentences.
- Semantic overlap indicates the extent of underlying semantic relations in the text.

AI-supported scaffolding system (AISS)

We developed a prototype of the AISS system that supports students to practice argument writing skills. As depicted in Figure 1, AISS's NLP AI algorithms generate examples as expert models (suggestions) for the part students like to improve (Help). Referring to expert models, students can learn new/correct vocabulary and citations for their arguments (i.e., conceptual scaffolding) and improve the ways to write cohesive and coherent paragraphs (i.e., strategic scaffolding). A process of revisions is stimulated by students' self-evaluation of what they have written against given examples (i.e., metacognitive scaffolding). On AISS, such an argument development is guided by the process of planning, drafting, and revising (i.e., procedural scaffolding),

Figure 1
AISS System



Methods

Research context and participants

Participants were 14 students enrolled in two sections of the same graduate-level online course, which allowed us to have more cases and compare two cohorts. Cohort 1 included 6 students who consented to the study participation out of 13 students enrolled in a spring semester section. Cohort 2 consisted of 8 students out of 12 enrolled in the following summer semester. During Week 9 of the course, as part of the assignment, on AISS, students developed their arguments for the question: "Is the constructivist learning approach better? Choose your position. If YES, what is a constructivist learning environment, and what effects are intended? If NO, are there downfalls in using the constructivist teaching approach?"

Data collection and analysis

We analyzed draft and final versions of the students' arguments, using the Tool for the Automatic Analysis of Cohesion (TAACO; Crossley et al., 2016) that provides hundreds of indices at the word, sentence, and document level leveraged to evaluate linguistic features of students' written arguments. Scholars have used TAACO to evaluate discourse-level cohesion–the degree to which information is connected across the text (Skalicky, 2019). In this study, we selected 17 indices corresponding to the four text cohesion categories (see Table 1). Also, we conducted visual inspections of the written arguments to examine how students used the feedback to revise their arguments.

Findings and Discussion

As described in Table 1, in both cohorts, final versions showed a decrease in the values of lexical diversity indices. Results indicate that the students tended to use selected words (i.e., concepts), including their synonyms, rather than bringing in more new languages in their revisions. It seems that students became aware of and focused on key ideas supported by the AI scaffolding. Contrarily, indices of lexical density increased from drafts to final versions, meaning that the students more frequently used content words in their final arguments that contribute to the meaning of the text. Taken together with lexical diversity, it appears that students developed their arguments containing more words possessing semantic content while centering on key ideas.

Table 1

Average Differences between the Final and Draft Arguments

Category	Index (Final – Draft)	Cohort 1 (N = 6)	Cohort 2 (N = 8)	Total (N = 14)
Lexical Diversity	Lemma_ttr	(0.052)	(0.047)	(0.049)
	Noun_ttr	(0.035)	(0.036)	(0.035)
	Verb_ttr	(0.095)	(0.018)	(0.051)
Lexical Density	lexical_density_tokens	0.003	0.002	0.002
	lexical_density_types	0.032	0.023	0.027
Sentence Overlap	adjacent_overlap_all_sent	(0.001)	(0.000)	(0.001)
	adjacent_overlap_2_all_sent	(0.039)	(0.017)	(0.026)
	adjacent_overlap_binary_all_sent	0.002	0.001	0.001
	adjacent_overlap_binary_2_all_sent	0.000	0.000	0.000
	adjacent_overlap_CW_sent	0.004	(0.003)	(0.000)
	adjacent_overlap_2_CW_sent	(0.036)	(0.024)	(0.029)
	adjacent_overlap_binary_CW_sent	0.031	0.012	0.021
	adjacent_overlap_binary_2_CW_sent	0.036	(0.016)	0.006
Semantic Overlap	lda_1_all_sent	0.004	(0.000)	0.002
	lda_2_all_sent	0.003	0.002	0.003
	word2vec_1_all_sent	0.011	0.014	0.012
	word2vec_2_all_sent	0.018	0.016	0.017

Note. A number contained within parenthesis is a negative number. Content words (CW) include nouns, lexical verbs, adjectives, and adverbs derived from adjectives. Lexical diversity indices: Measure of lexical diversity of the ratio of unique (type-lemmas, nouns, and verbs, respective) to all words (tokens-lemmas, nouns, and verbs, respectively). Lexical density indices: the proportion of the text that consists of content words (tokens or types). Sentence overlap: The amount of text items that repeated in text. Adjacent overlap 1 and 2 sent indicate the number of lemma types (or any CW lemmas) that occur at least once in the next sentence and the next two sentences divided by the number of words considered, respectively. Adjacent overlap _binary 1 and 2 sent indicate the number of any lemma types (or any CW lemmas) that occur at least once in the next sentence and the next two sentences divided by the number of sentences considered, respectively. Semantic overlap: Underlying semantic relations in texts through computational models. Ida_1 and_2 indicate average latent Dirichlet allocation divergence score between all adjacent sentences with one and two-sentence span, respectively. Word2vec_1

and_2 indicate average word2vec similarity score between all adjacent sentences with one and two-sentence span, respectively.

As to sentence overlap, both one sentence and two sentences adjacent overlap indices for all lemma types and content words lemma types tended to decrease while their overlap binary values increased, indicating that the students attempted to avoid a redundant use of the same languages (overlap indices) but tried to properly use main ideas across adjacent sentences (overlap binary indices), resulting in a more cohesive argument. In the same vein, semantic overlap indices showed an increased overlap in the students' arguments, indicating that the students used languages within similar topics (i.e., LDA indices) and contexts (i.e., Word2vec indices).

Besides, visual inspection of students' arguments showed that students used examples to add new ideas and paraphrase AI-generated texts. Such additional activities entailed restructuring the logical flow of the arguments (examples of visual inspections will be presented at the conference).

The findings of this exploratory study demonstrated the potential of AI to provide personalized scaffolding for writing academic arguments. The AISS scaffolding appeared to help students to locate relevant and most current literature. Students leveraged AI-generated scaffolds to build a stronger claim with elaborated ideas in a cohesive text structure. However, the current study revealed several limitations. NLP AI techniques need be fine-tuned to are still at the infancy stage, requiring further articulation. The original AI algorithms in AISS have not been tuned to educational use, especially for scientific argumentation. For example, the AI sometimes generated thematically irrelevant suggestions. Also, we need to detect whether students just copy and paste the suggestions without learning how to formulate their own responses to improve text.

Teachers' use of augmented reality in the classroom: reasons, practices, and needs

Josef Buchner*, Jule M. Krüger*, Daniel Bodemer, Michael Kerres
josef.buchner@uni-due.de, jule.krueger@uni-due.de, bodemer@uni-due.de, michael.kerres@uni-due.de
University of Duisburg-Essen
*These authors contributed equally to this work

Abstract: Research on augmented reality (AR) in education shows various advantages and challenges for learners while research on teachers is scarce. In practice, teachers drive the implementation of AR in classes, and it is important to examine current practices and requirements to be able to effectively support their efforts. $N = 16$ teachers who had used AR in their classes took part in a survey with open-ended questions focusing on reasons for, current practice of, and needs when using AR in education. The answers were classified into different (sub-)categories. As reasons for usage, different instructional and non-instructional purposes are mentioned. In the current practices various technologies, design-platforms and educational materials are described, and needs include content availability, pedagogical integration, and technical infrastructure. The results are discussed with a focus on unexpected outcomes and the potentials of collaboration between researchers, practitioners, and other stakeholders to support teachers AR classroom integration.

Introduction

In this study, we examine teachers' use of augmented reality (AR) in the classroom. AR is an emerging visualization technology defined by the simultaneous presence of real and virtual objects that are geometrically aligned and enable real-time interactions (Azuma et al., 2001). Previous research identified several opportunities of AR for the purpose of teaching and learning. For example, AR can support the understanding of complex science concepts by visualizing the invisible (Yoon & Wang, 2014), scaffolds inquiry-based learning (Kyza & Georgiou, 2019), and reduces cognitive load leading to increased performance (Buchner et al., 2022). Krüger et al. (2019) describe three major characteristics that distinguish AR learning environments from other technology-enhanced learning scenarios and entail advantages when purposefully implementing AR for appropriate learning goals: *contextuality*, i.e. placing virtual elements in a real-world context; *interactivity*, i.e. combined physical and virtual manipulation; and *spatiality*, i.e. spatial positioning and dimensionality of virtual objects. In addition to promoting learning and comprehension, researchers mention motivational and affective factors as central outcomes when using AR in education (Akçayır & Akçayır, 2017; Ibáñez & Delgado-Kloos, 2018). However, along with the opportunities, research shows that implementing AR in the classroom is challenging. Most often, technical issues are reported in the literature, like the lack of devices, weak internet connection or problems during the representation of the AR visualization (Akçayır & Akçayır, 2017). Another matter concerns instructional design, including the identification of learning objectives that can be effectively achieved using AR or the prerequisites for learners to successfully engage with the AR learning environment. In their review, Buchner et al. (2022) distinguished between declarative and procedural knowledge acquisition and found that AR is better suited to promote procedural knowledge.

As the research presented shows, scholars have so far focused their investigations on learning and the role of the learners. Research that focuses on teachers is scarce. However, as for any other technology, teachers have a key role here as they are responsible for an effective and efficient use of the technology, like AR, in class. Alalwan et al. (2020) provide in their study a developing country perspective of AR usage in science education. The authors interviewed 29 primary school teachers revealing that lack of competency and resources (among others) were common challenges. In da Silva et al. (2018), results from Brazilian teachers and their use and experience with AR are reported. The authors conclude that AR is still something new for the teachers and a major limitation for further use of AR in school is the lack of content creation tools. Other studies exploring the AR experience of teachers under real classroom conditions are lacking. Hence, several questions regarding the use of AR in schooling remain open. For example, do teachers use AR in their lesson for the same reasons found in the research literature, which specific implementations do they use, and is the lack of resources also true for the European context? In this study, we aim to address these questions and contribute to the limited research base regarding teachers' use in educational practice. Therefore, we investigate teachers' reasons for and current practice of using AR in their classes. Furthermore, we examine what teachers require to overcome challenges linked to the usage of AR in education and to make the use of AR in practice more effective and efficient.

 © ISLS

Methods

A semi-structured survey was addressed to German-speaking teachers who had used AR in education. A convenience sampling approach was used and $N = 16$ teachers, age 26 to 56 ($M = 37.80$, $SD = 8.74$), from different school forms and course areas took part. Six were male, nine female, and one did not disclose.

Five open-ended questions should trigger word-based, open responses in three categories, inquiring about teachers' reasons to use AR, their current practice of implementation, and their requirements to overcome challenges they come across. We added different sub-questions to elicit elaborate, detailed answers, for example specifying the question on how AR was used by asking for the specific methods and technologies and triggering a description of requirements by asking for what went wrong in the implementation. The specific questions in their original German and translated English form can be found here: https://osf.io/yqux4/.

The teachers were contacted especially through posts and messages on Twitter directed towards relevant audiences. A link to the online questionnaire was provided and participants gave their consent for data collection at the beginning. They then answered general questions about the context of their AR use. On the next page, the open-ended questions were given. At the end, the demographics were inquired, and a short debriefing was given.

Because the goal of the survey was to learn more about teachers' reasons to use AR, their current practice of implementation, and their requirements to overcome challenges they come across, these categories were also focused during data analysis when classifying the participants' answers. The authors classified answers and individual text-snippets into the three question-categories: (1) "Why do teachers use AR in instruction?"; (2) "How do teachers use AR in instruction?"; (3) "What do teachers need to overcome challenges of using AR in instruction?". Further, in a joint negotiation of two authors, answer-categories and -subcategories were developed.

Results and Discussion

The structure of the established categories will be described in more detail in this section. For example quotes per (sub-)category, see https://osf.io/yqux4/.

Why do teachers use AR in instruction?

Regarding the question why teachers use AR in their lessons, we found that most of the statements address a kind of instructional purpose with the sub-categories learning from AR, learning with AR, and learning about AR. Most of the teachers stated that they use AR to visualize content and invisible phenomena. As a result, the teachers expect the visualization to more effectively support comprehension of the content compared to other illustrations, e.g., 2D pictures (learning from AR). The use of AR to visualize the invisible is also reflected in the research literature on AR in education and the opportunity to illustrate complex and abstract content and information is described as a main benefit of AR usage. The possible advantage of 3D (like used in AR applications) over 2D is also reported by teachers in da Silva et al. (2018). The next most frequently mentioned instructional purpose represents a learning with AR perspective. Here, teachers used AR technology to involve the learners in a design process. For example, teachers reported that the students created videos to orally practice a foreign language. As shown in the literature, involving learners in a design process can be an effective learning approach. In the Brazilian context (da Silva et al., 2018) teachers also described AR content creation by students. In the developing countries perspective reflected in Alalwan et al. (2020) this purpose is missing because of lacking authoring tools. AR was also mentioned as a purpose on its own, representing a learning about AR perspective. For example, one teacher used AR in computer science education showing the learners how the technology works. Interestingly, this aspect is novel for our study. However, researchers point out the importance of learning about new digital technologies like AR due to an increasing demand for people with skills in this area (Fominykh et al., 2020).

We identified three categories not fitting into the instructional purpose category. Teachers implemented AR in the classroom because they themselves were interested in the technology and wanted to test it. Others mentioned that they wanted to design a learning experience beyond the curriculum to create memorable events for the learners. Another aspect concerned sustainability. One teacher stated that AR helps to provide further information without printing masses of paper sheets. While personal interest and providing experience beyond the curriculum is mentioned similarly in da Silva et al. (2018) and Alalwan et al. (2020), using AR for sustainable reasons is an aspect not reported in the literature so far. Another interesting result of our study is that none of the teachers quoted motivational aspects as a reason for AR use. This is contrary to the literature as authors indicate motivation as an important advantage of using AR in educational settings (Akçayır & Akçayır, 2017).

How do teachers use AR in instruction?

The questions of how teachers used AR in their lessons including which technologies and materials they implemented were answered very differently. The answers could be classified into three categories, namely

instructional approaches, technologies, and educational materials used. The instructional approaches mentioned in or implied from the description of the procedures include teacher-led approaches like demonstration and augmentation of available physical curricular materials. This is supported by the often-mentioned instructional purposes of illustration or concrete visualization of material in the previous section (Yoon & Wang, 2014). Further, student-centered instructional approaches were described, including inquiry, project-based and problem-based learning, and collaborative experimentation. Inquiry, project-based and collaborative learning were described as important approaches that can be achieved with AR (Garzón et al., 2020), which may be a reason the teachers used them. The implementation of the student-centered approach of design-based learning is furthermore connected to the above-mentioned instructional purpose of learning with AR instead of from AR.

Concerning the different technologies used, a distinction can be made between hardware and software, or more specifically design-platforms used. Most teachers stated that they used mobile devices like tablets and smartphones, which are ubiquitous and less expensive than the less-mentioned AR-glasses. One teacher described projecting the screen of a tablet onto a beamer, probably to enable every student to see the material. This shows that creative approaches can be born if, for example, there are not enough devices available. Many different design-platforms were mentioned, including Areeka Studio, Blippar and HP Reveal, which was also mentioned in da Silva et al. (2018). While this diversity in available and used software may be enriching because different use cases can be addressed, the incompatibility between different platforms might be a problem for sharing materials. Many of the teachers mentioned more than one platform, which shows that they either had to switch due to different use cases, or that they switched because they have not found the perfect platform, yet. Either way, there seems to be some effort involved in choosing the appropriate application.

Concerning educational materials, some of the participants describe materials that they developed themselves, while other participants described having used available materials. Own materials were often developed with easily usable authoring tools like HP Reveal or Blippar, although more elaborate content-creation including the design of a booklet and a specific application were also mentioned by a participant. The educational material that was already available could be split into the marker-based, marker-less, and location-based AR technologies, where marker-based materials were described more often, e.g., in the form of Areeka animal cards or the MergeCube. A few marker-less materials, like GeoGebra, were mentioned. Location-based material was described only in one case, namely with the platform Actionbound. This prevalence towards marker-based materials may be based on their higher availability due to less technological requirements for devices. While marker-less applications require a device that can scan surfaces which is, for example, possible through ARkit and ARcore technologies in most new IOS and Android mobile devices, marker-based applications mostly only need a functioning camera for target detection.

What do teachers need to overcome challenges of using AR in instruction?

Regarding the perceived challenges and needs to overcome them, we found three main categories. The first category concerns content - self-created and existing. For content creation, teachers complain about the lack of easy-to-use and cost-free authoring tools. For example, some teachers mentioned that they used the HP Reveal AR studio, which is now no longer available. Additionally, the teachers call for training on how to create AR objects, especially 3D models, and more time to prepare AR-enriched lessons. For existing AR materials, teachers report that these do not align with curriculum goals and lack of interactivity. Furthermore, the applications are not inclusive (e.g., usable on different devices) and not freely available. In sum, more high-quality AR educational materials are needed. The results in the content category are like those found in da Silva et al. (2018) and Alalwan et al. (2020), indicating that the problem of content is independent of the country. A detail stressed by the teachers in our study is that they request more materials in German.

Second, teachers experienced pedagogical issues during the AR classroom integration. These can be summarized as a lack of ideas for purposeful usage and perceived pitfalls that should be avoided. For example, teachers observed a so-called *wow-effect* that did not translate into more effective learning. To overcome this issue, training on how to purposefully use AR in class was suggested. This might also help to avoid the observed pitfalls like a distracting effect in terms of technical problems during the use. This issue is also reflected in the literature (Akçayır & Akçayır, 2017).

Third, technical issues like poor internet or the complete lack of devices that can easily display AR were also listed as problems by the teachers in our study. It is particularly interesting that one teacher pointed out that the use of students' smartphones can also cause problems. Some devices would simply no longer meet the requirements and have too little computing power for AR. The small display of smartphones was also mentioned as a limiting factor. Thus, teachers in the European, German-speaking context are struggling with the same technical shortcomings as the teachers in da Silva et al. (2018) and Alalwan et al. (2020).

Conclusion and implications

In summary, European (here: German-speaking) teachers face similar challenges when using AR as, for example, teachers in developing countries. To facilitate teachers' use of AR, different recommendations can be made.

School authorities, such as policy makers, need to provide a technical infrastructure so that the use of AR can take place smoothly and teachers can focus on instructional design considerations. Here, there is a need for trainings from teacher education institutes and continuing education providers that convey both the technical and pedagogical fundamentals for the use of AR in class. One concern of the teachers surveyed was that they would like to exchange ideas with others. Hence, it would be desirable to establish a networking platform that allows the exchange of AR materials, instructional designs, and experiences. It also became apparent that previous research has not yet been sufficiently successful in sustainably anchoring developed AR applications in practice. Future educational AR research should therefore integrate experimentally gained knowledge and technological approaches even more closely within practice. By directly involving teachers in these research and development processes, this can result in applicable, freely available, and reusable AR materials. Moreover, research can develop free and user-friendly AR design platforms to help harness the potential of teachers as a significant resource for content creation. Companies developing or willing to develop AR learning materials should also collaborate with both practitioners and researchers. As shown, the quality of many existing materials is considered poor. Collaboration among AR developers, educational technology researchers, and practitioners would certainly be able to contribute to more effective, efficient, and high-quality AR educational media in this regard.

To conclude, it was found that some teachers are in general willing to employ AR in the classroom for several reasons and with different instructional approaches, although these teachers still have to endure various challenges. To overcome these challenges, collaboration with research and other stakeholders is necessary to make AR an integral part of teachers' instructional toolbox.

Designing STEM Classes for Hawaiian Youth's Rightful Presence

Colby Tofel-Grehl
Colby.TG@usu.edu
Utah State University

Abstract: This paper shares the process of designing a summer school science and technology class focused on youth advocacy and the development of youth *rightful presence* (Calabrese Barton & Tan, 2019) for students in Hawaii. We examine students' changing perspectives and connections to STEM through their engagement in projects that center their own geography and life experiences. Findings indicate that youth sense of agency and autonomy were greatly improved by engaging in a space where science and technology were tools serving their own goals of protecting the island from further development and tourist abuse.

Introduction

Students entering the STEM workforce must be both trained and motivated to do so. However, the ability of school instruction to impart the necessary knowledge is largely dependent upon a solid foundation of motivation and prerequisite skills developed earlier (Akerson et al., 2011). Low levels of participation in STEM have been traced back to a lack of effective preparation and a lack of interest from students; without prior exposure and interest, students are unlikely to choose STEM as a focus of future pursuits (Hall et al., 2011). As such, it is essential that youths' skills and interest be developed prior to the secondary level. Minoritized communities and individuals have long found themselves excluded from legitimated access to STEM classrooms, careers, and communities. In order to support student STEM interest within the context of rural Hawaii, this research explores the development and design of a culturally responsive computing and making class specifically designed to support youth *rightful presence* in STEM (Calabrese-Barton & Tan, 2019).

Background

Making and specifically targeted inclusive maker activities offer a context that can support the development of *rightful presence* (Calabrese Barton & Tan, 2019). The tools, materials and processes of making can disrupt stereotypes around who can and does engage in STEM by affording youth the opportunity to engage in projects and activities of their own design (Fields & King, 2014). The duality of low and high tech materials used in making can provide a novel entry point for youth into STEM as often young people already see themselves as capable in using crafting supplies (Kafai et al., 2014). This is especially true for individuals who already craft or have family members who craft (Tofel-Grehl et al, 2017). Many making activities, such as electronic textiles (e-textiles) have been shown to integrate handcrafts and cultural funds of knowledge not often engaged in school classrooms (González, Moll, & Amanti, 2005). This has shown some promise in bringing historically marginalized groups into STEM (Kafai et al., 2014). Further, e-textiles are highly personalizable, providing opportunities to express oneself and connect with others through STEM. For instance, youth may use e-textiles materials to tell a story about a meaningful moment in their life or to build something to address an issue in their community (Greenberg & Calabrese Barton, 2017). Research in culturally responsive computing has also shown that narrative and place-based approaches to making are especially promising for bringing historically marginalized or excluded groups into STEM (Searle et al., 2020). Therefore, by engaging youth in STEM activities through making rooted in a particular place and support the sustained development of interest and personal belonging in STEM, further inroads may be made into how youth perceive who does STEM.

Theoretical Framework and Research Questions

Our goal for this work was to support the development of better STEM identity and youth agency among Hawaiian youth. To that end, we engage Calabrese-Barton & Tan's *rightful presence* framework to guide this work. Rightful presence is "legitimate membership in a classroom community because of who one is (not who one should be), in which the practices of that community work toward and support restructuring power dynamics toward more just ends through making injustice and social change visible" (Calabrese Barton & Tan, 2019, p. 618). Rightfullness of presence requires youth to fully occupy the disciplinary space within their classroom in such a way that they are able to restructure and reimagine their learning space for themselves. Rightful presence calls for a deconstruction of the power structures fundamental to schools in three core ways. First, the notion of a choice to extend rights to all parties inherently requires a brokering of power wherein those with power choose to extend rights to those without it. This structure makes the rights of some contingent upon

 © ISLS

the benevolence of others—something that inherently undercuts rightful presence. Secondly, rightful presence requires the acknowledgement that science cannot be divorced from the political. Rightfully present spaces recognize and make visible the political struggle of minoritized individuals central to their history as related to science. Third, rightful presence requires the active deconstruction and disruption of normative power processes that marginalize students. This disruption of structural oppressions creates visibility, and recenters the responsibility on the beneficiaries of power. For youth in Hawaii a rightfully present STEM class centers around issues and questions of great importance to communities on the island, such as the impact of tourism.

With this framework and a design-based research approach in mind, we ask the following research questions:

1) How can educators design opportunities to support youth's sense of rightful presence?
2) Does youth's rightful presence manifest into action or agency within a classroom setting?

Methods

We engaged a phenomenographic lens for qualitative data collection and analysis during the course design and planning, the teacher professional development, and the ten day class sessions. Data collected include audio recordings of the class, curriculum design notes, fieldnotes, interviews, and photographs of artifacts.

Context & participants

Ten youth from around the local town enrolled in the middle school participated in the maker class, which met four hours a day for two-weeks. Youth were from various cultural and social backgrounds. The participating teacher is national board certified in science and social studies and has been teaching for over 20 years. She has been teaching at this public charter school for the past 8 years since moving from the mainland to Hawaii.

Description of the class

The class was co-designed in collaboration with the participating teacher. Her focus was on finding ways to engage science and technology to support youth awareness and activism with indigenous issues on the island. The class included two place-based field trips to sacred sites on the island. Youth engaged in three Hawaii focused maker projects. The first project tasked youth with engaging in making a paper circuit plaque that shared information about themselves and their passions (see figure 1). In the top left corner, they were asked to share an area of science that was of interest to them. In the top right corner, they were asked to share a place they want to visit. In the bottom right corner, they were asked to share a hobby or interest and in the bottom left corner they were asked to share a social or community issue they were passionate about.

Figure 1. Example of Name Placard, 3D Printed Volcano Map, and Advocacy App

The second project (figure 1) saw youth using 3d printed topographical maps to build computational circuits that explored the geology and history of the island's volcanos. This project let students engage with both the geography and geology of their island. Students investigated topics such as volcanic age, activity, or height. With this information in hand, students picked three volcanoes and determined how to visually represent the data they had on a single aspect of the geologic information gathered about their island's volcanoes.
The final project engaged youth in the design and coding of "advocacy apps." During the place-based fieldtrips, youth were tasked with interviewing land caretakers about the behaviors and actions of tourists as they visited important places around the island. These interviews were used to generate class derived codes of conduct for sacred spaces. Youth then built apps to support tourists engaging in appropriate behaviors (see figure 1).

Data

A member of the research team took fieldnotes and kept daily reflections during and after class. In addition to the collection of qualitative fieldnotes, table microphones were used to collect audio recordings of the groups. A

total of 40 hours of class time were recorded and transcribed. At times youth were interviewed to follow up on conversations that emerged organically at tables. Daily photographs were taken to capture the process of making and youth engagement with designing projects that engaged their identities. Of specific interest in tracking shifts in youth identity were localized projects focused on various places on the island.

Findings

In seeking to develop youth's sense of agency and rightful presence the class needed to support youth in finding contexts and content that was both meaningful and applicable in their daily lives. With the rising resentment across the island towards tourist vandalism, the collaborating teacher felt that engaging youth in learning and thinking about how they could affect behavioral change on their island was essential to students on Hawaii.

The first project was designed as both an ice breaker and key point of contact for us to be able to collect information about what was of value to the youth in the class. Designed by the collaborating teacher, the activity asked youth to share their names, pronouns, and four facts. Students were asked to share a passion, a place they love, a hobby, and a science interest. As she conceptualized the activity, the teacher noted:

> I like this name card activity because it lets us learn about the kids and what is important to them… If we combine it with the paper circuit, the kids can learn that part of the science while we learn what matters to them. When the kids can tell us what matters to them, they get a lot more into it.

By allowing youth to share their interests and passions, we were able to open up dialogues in the class with the specific goal of creating greater rightful presence for youth. For example, when one student, Leilani, shared her passion for protecting the Maunakea volcano from further development and destruction by scientists who were seeking to put up another large telescope, we pivoted the conversation to talk about why this conflict between Indigenous Hawaiians and scientists was important for all citizens of the island.

Figure 3. Leilani's name card showcasing her care for the Maunakea and disinterest in science.

With the conflict on the island having been the source of great angst for some students like Leilani, who spent her weekends with her family camped on the mountain seeking to stop impending bulldozers, other students made clear their lack of knowledge about the conflict. When Leilani explained the importance of the site, classmates began to discuss why it was important for everyone to help solve the problem. Marcus commented "Yesterday I did not even know about this. But now I can understand why Leilani is upset. I would be mad too if someone bulldozed my church. So, like, helping stop this is really important."

In Marcus we see the beginnings of an awareness at the injustices around him and the urge to help his friend make better a problem that was important. This marks the beginnings of a more rightfully present classroom as students uncover and address injustices, one of the core tenets of rightful presence. This dialogue continued as students engaged in their second project, the 3D printed volcano. After learning about the ages, activity, and relative heights of all the volcanos on the island, they selected three to create a computational circuit with actuators to model features of the volcanoes. Students programmed microprocessors to help tell the geologic story of their island. Tying the scientific information about the volcano into her display, Leilani shared some of her knowledge about how its great height was explained in Hawaiian culture because it was the child of the sun and earth. This bridging of scientific understanding with her Hawaiian epistemology brought Leilani to the idea that "geology isn't so bad." Her softening towards science was noteworthy because of her belief that science was at war with her people.

During the class students took two field trips to Hawaiian sacred sites. The first field trip took youth to the Wai'pio valley to interview and learn from the land's caretakers. The second field trip brought youth to the

Pu'ukohola Heiau, a national historic site and holy site to Indigenous Hawaiians. Through their conversations with the land caretakers students learned about the many problematic behaviors of the visitors to these sites. After these two field trips, the class began to brainstorm ways they could help people learn about the rules and regulations they needed to follow to have a respectful visit to these spaces. Youth engaged in a design and coding project entitled Advocacy Apps. Using MIT's App Inventor, a visual programming environment designed to facilitate app building for novice programmers, youth designed and built apps that explained the importance of respecting Hawaiian spaces and appropriate codes of conduct.

Students were eager participants in the design and coding processes for their apps. As one youth commented "These apps are good because I think people could really use them. They might work." The project marked a turning point for several youth in the class. Rather than observing and worrying about the injustices they discussed as a class, participants were able to engage with a problem and work to bring attention to the issue. In doing so, several youth commented on how they could see the value and applicability of the project. As Manzina said "I really like this because I feel like I can do something. In school I can't do anything with what I learn." Manzina's comment highlights precisely why designing for rightful presence in STEM is so important.

Conclusion and Discussion

Designing projects in support of youth rightful presence can be challenging but offers unique links between youth home identity and school identity. Making can provide youth a meaningful, culturally relevant way to engage with science learning around issues important to them. We see in this class experience that teachers are able to bring together content knowledge they need to teach with projects that engage student interest on a personal level. This integration of science into their daily lives and concerns creates a space in which science is personally and politically meaningful. Rightfully present science teaching not only makes science more accessible, but it also works to dismantle historic notions of what science is and who does the work of science. Culturally relevant making and rightfully present science go hand in hand to redefine what science is, who does science, and what science can bring to the lives and experiences of communities across the globe.

Innovate to Mitigate: Analysis of student design and rationale in a crowdsourcing competition to mitigate global warming

Gillan Puttick, Brian Drayton, Santiago Gasca
gillian_puttick@terc.edu, brian_drayton@terc.edu, santiago_gasca@terc.edu

TERC, Cambridge, MA

Abstract: The Innovate to Mitigate project adapts crowdsourcing to support project-based STEM education, posing design challenges for secondary-school students to design feasible innovative strategies to mitigate CO_2 emissions and thus global warming. The paper presents evidence that the web-mediated communities of practice support learning of STEM concepts and practices and provides an account of how student and scientist discourse support that learning. Productive talk deployed by community members elicited greater levels of reasoning than was originally manifest in student work and resulted in improved student products.

Introduction

Global warming is increasingly seen to affect everyone's lives and many young people are eager to respond (e.g., Thunberg et al. 2020). Engaging the issue constructively ("active hope") can counteract the anxiety and depression such an overwhelming problem elicits (Hayes et al., 2018). The Innovate to Mitigate (I2M) project poses design challenges in climate change mitigation for middle- and high-school students. Our initial research (Puttick & Drayton 2017; Drayton & Puttick, 2018) suggests that an open but well-structured challenge to develop mitigation strategies can galvanize creativity and engagement among young people, and support "3-D learning" (NRC, 2012).

Crowdsourcing for STEM learning

Crowdsourcing and social media are increasingly common media for participation in society (Hossain & Kourainen, 2015; Arelas & Ladrón-de-Guevara, 2011). The crowdsourcing communities in Innovate to Mitigate (I2M) (students, teachers, scientists) are designed as learning environments in which students can collaborate to iteratively improve design ideas and STEM knowledge. Such heterogeneous communities of practice offer a diversity of inputs, including insights about practice from more experienced participants (Wenger, 1998). Dialogic knowledge- construction and design, facilitated by the division of labor within the team (Puttick & Drayton 2017; Drayton &Puttick, 2018), is strengthened by collaboration among competitors in the challenge. This open integrative process is central in our adaptation of crowdsourcing. Students' discourse can provide insight into students' reasoning and understanding of STEM concepts and practices, and evaluation of each other's comments (Ketonen et al., 2020; Samarasekara et al., 2020; Cheng & Tsai, 2012). Other impacts may include growth in quality and depth of student argumentation, and in metacognitive effects such as students' capacity to evaluate their own reasoning and evidence (Anker-Hansen & Andrée, 2019).

Dialectical learning in science education

"Discourse" in science classrooms has taken on great importance under the influence of research in the sociology of science. The Frameworks argue that the true aim of science is to create and critique evidence-based causal accounts of natural phenomena (NRC, 2012). On this view, science moves forward in important measure by its discourse within a community of practitioners. One genre or mode of discourse is “narrative” (Kvernbekk, 2003). A second, strongly advocated approach is “argumentation,” structured around making and defending claims that propose explanations for phenomena (Allchin & Zemplén, 2020; Boğar, 2019).

A further refinement, "productive talk," developed and characterized by learning scientists in recent decades, places a key emphasis on collaborative knowledge building and on the ways that teachers can facilitate (but not direct) the use of "talk moves" that help students make theory- or data-based claims, seek or evaluate evidence for or against the claims, and elaborate the implications of their work. A further intent is the adoption of "talk moves" by students into their dialogue with each other within teams, in large-group critique and collaborative sense-making (Michaels & O'Connor 2021; Resnick et al. 2015).

We conjecture that a collaborative/competitive design challenge such as I2M will not only offer an

 © ISLS

opportunity for students to engage in STEM practices, but also to engage in sense-making and knowledge-building discourse related to their designs, which will shape how resulting products are reshaped. In this paper we ask: (i) What evidence is there that crowd sourcing led to changes in students' design artifacts and rationales, generated during an I2M challenge? (ii) How are these changes related to students' science discourse with each other and with scientists giving feedback on the project designs?

Methods

Student teams propose a design abstract, based on a mitigation strategy such as energy conservation, alternative energy generation, or social/behavioral change. Since abstracts scaffold the whole investigation, students are asked to describe their idea, how they consider it an innovation, and how feasible it might be to implement. Teams post their abstract to the project's online page. All students and TERC scientists post questions and comments. After two weeks of discussion, teams post revised abstracts, using comments received. The teams conduct their project over the next 3 months and produce a final paper and a short video presentation.

Participants

For this paper, we analyze the data generated by five I2M teams during the abstract phase of the 2021-2022 competition: Eco Warriors (5 students in 10th grade), Team Imoto (2 in 12th grade), Wolf Pack (2 in 9th grade), Dream Team (2 in 9th and 2 in 11th grade), Carbon Cancelling Cougars (2 in 10th grade).

Data sources and Analysis

The data in this case study include: (i) The teams' initial abstracts, (ii) All discussion posts from students and scientists, and (iii) The revised abstracts.

Data were coded by three researchers to identify technical/science content, proposed design elements, categories of rationale, evidence adduced, and talk moves (Table 1).

Table 1 *Coding Scheme*

Code	Description
Say more	Asks for clarification of a statement or claim
Rephrasing	Restatement of what commenter thinks they read Ask for evidence
	Asks for evidence in support of a statement/claim Ask for reasoning/rationale
	Asks for description of thinking about a claim
Rationale: Authority	Explicitly cites an authority, (e.g., teacher, article) Rationale: Causal
	Relies upon an explanatory theory or concept
Rationale: Empirical	Based on empirical data, or absence thereof Rationale: Factual
	Asserts a claim as fact
Rhetorical	Aims to persuade, engage Challenge/counterexample
	Describes an exception to an idea Agree/disagree (and why)
	Asks others to agree/disagree with their point Add on
	Asks others to provide more information
New idea	Provides an additional new idea
Affect	Expresses approval, liking

Coded data were discussed by researchers. After coding was stable, a researcher wrote an interpretive research narrative about each team. Narratives were discussed by the research team to test inferences, identify issues requiring further analysis, and maximize the value of the data. Finally, cases were compared to identify differences and similarities of interest in relation to the research questions.

Results

Three of the five initial abstracts that the teams posted provided a rationale for their proposed designs that relied on statements of fact and unsubstantiated claims. For example, Team Imoto, proposing an innovation related to renewable energy generation, wrote, “Renewable energy can be produced from a multitude of ways, wind, solar, or even something as grand as nuclear. But something overlooked is the use of gravity in generating electricity. Using the force of the Earth’s gravitational pull, we want to create some device that will generate electricity by a turbine that is pushed by a flow of water from a rain gutter.”

In the discussion of abstracts, coding of statements from competition **participants** yielded (a) “Affect,” (b) “Add on,” or “Say More," and (c) “Ask for Evidence” as the most frequent codes. For example, Pranav

commented on Team Imoto's abstract, "Very unique idea. (Affect) 1. What materials will have to go into building this device? How accessible is it for people to obtain said materials?" (Add on, Say more). Ned, commenting on the same abstract, asked, "How would gravity be used to generate electricity? How much would the device cost? Would it be relatively simple? […] How would this collect drinkable water?" (Add on, Ask for Evidence). Commenting on Dream Team's abstract proposing to innovate on textile dyeing, Micah Red asked, "Some of your words are a little hard to understand. Could you please explain what a super-degrading microorganism is? Or give an example?" (Say more).

Scientists, on the other hand, tended to suggest new but related ideas, and to ask for reasoning. For example, Gina commented on Team Imoto's abstract as follows, "I wonder how you're thinking about its possible impact on reducing emissions. Will you measure the current produced, then do a calculation […] to come up with an overall guesstimate of greenhouse gas reduction?" (Add on, New Idea, Ask for Evidence and Reasoning). Commenting on the textile dyeing abstract, Benny asked, "Does it make a difference whether the dyes being used are plant- or mineral-based, as opposed to synthetics? I know weavers and spinners in my area […] believe these dyes are better for the environment. I am not sure it's true, though." (Add on, Ask for Evidence, New Idea, Ask for Reasoning).

Regardless of how probing the comments and questions were, the conversational exchanges between teams and commenters uniformly revealed productive reasoning and development of science practices. For example, the following exchange occurred in discussion of the Carbon Cancelling Cougars design, which was to find, and test overlooked hydrocarbons, e.g., household waste, as biofuels:

Brody: Great idea! Do you have any specific materials in mind for initial testing?

Ned: one of our chief areas of interest was the "reuse" part of the classic "reduce, reuse, recycle" mantra. This means that instead of disposing of things like cooking grease (often a waste product), one could use that to produce a fuel to use to cut down on gasoline usage. Not only does this reduce carbon emissions, it also cuts down on waste.

Benny: do you have a combustion system […] to test the different fuels with, or will you use a calorimeter and other sensors to evaluate heat output and emissions, or what?

Ned: the calorimeter would be a great tool for testing the output. We'll also be actually testing the different fuels in an engine (not sure of exactly what yet) to test efficiency, as that is also a priority (if the alternative is less efficient than the status quo, it's unlikely to be implemented).

Gina: I'm curious how you plan to do this critical piece of research [ID'ing wasted fuels] before you get to testing the candidates you've chosen. What criteria do you think you will use to make the decision?

Ned: To find such materials, we could ask around and take a survey (perhaps students/teachers/parents of our school?) to find what kinds of products are commonly wasted in everyday life. We would then compare what we know from the EPA of the chemical composition of these products to the goal of what is necessary for a biofuel.

Parag: Do you have an estimate (in pounds/tons) of the amount of greenhouse gas emissions that can be reduced with your idea? Moreover, how will you measure efficiency with regards to biofuels?

Ned: The estimate would be extremely variable based on how large implementation could be, as well as what metric we are going on, e.g., "how much does a gallon of biofuels reduce emissions?" As far as efficiency, what I'm talking about there is how useful the biofuel is compared to conventional sources.

In these exchanges we notice commenters asking for clarification, additional information, evidence, and elaboration of reasoning. Comments in turn elicited a series of elaborated statements that were empirical, causal, rhetorical and authoritative rationales that would contribute to a reshaped design.

The revised abstracts showed quite extensive elaboration of detail and reasoning. For example, the revised abstract from Team Imoto included the same idea of generating "hydro-power" from generators positioned in household gutters but the team elaborated the proposed mechanism thus, "The water will then be stored in a tank and with the help of a small pump, like the one used at UNITEC, will help to generate the electricity. The water can then be used, alongside a pump, to turn a microturbine and generate electricity. The type of generator so far that we are looking at is a cylindrical power generator which we thought about thanks to the idea from Benny." The rationale for their design was buttressed by citing an authority, and an explanatory concept. The team also provided a causal rationale, in connecting their device to mitigation, "Bringing it to a wide scale […] will help people in the fight against climate change because it will bring people energy independence from major fossil fuel companies and in turn reduce greenhouse gas emissions."

Likewise, the revised abstract from the Dream Team remained focused on innovations in textile dyeing but included more depth in detail and reasoning. For example, describing how untreated wastewaters are often dumped into nearby water bodies, the team explained that "Leftover dye water hinders penetration of light into affected bodies of water, impairing photosynthesis rates." Prompted by one commenter, they

provided a causal rationale for their design in linking impaired rates of photosynthesis to climate mitigation, "...carbon is sequestered in the world's bodies of water and the lifeforms that live in them such as fish and marine plants. Therefore, the overall health of these ecosystems is critical to combat climate change."

Discussion and significance

This paper provides preliminary evidence that a crowd-sourced challenge, situated in a heterogeneous community whose conversations are scaffolded by a shared purpose, can enable substantive STEM learning. As the exchanges between commenters and responders show, the abstracts gained empirical and theoretical strength as participants practiced "productive science talk." Research has shown that student uptake of productive talk moves generally only increases after the moves have been modeled in the classroom by a teacher (e.g., Murphy et al., 2018; Sedova et al., 2016), yet this type of discourse emerged without coaching in the I2M community. Furthermore, our findings show that this productivity – in discourse, in reshaped abstracts - was made possible by the diversity in expertise central to learning in a community of practice. Future research will focus on the impact of including additional crowdsourcing opportunities in the course of future competitions and on the microgenesis of concepts and practices in an extended, discourse-mediated design project.

Abstract: This paper examines an online professional learning intervention to develop teachers' pedagogical design capacity to develop five-dimensional (5D) learning and assessment opportunities, which involve integrated use of science and engineering practices, disciplinary core ideas, and crosscutting concepts in science to make sense of phenomena and problems that are interesting to students and support students as knowers, doers, and users of science. We present findings from our design study, which suggest both the promise of such an approach and some of the challenges and tensions experienced by teachers as they chose and used phenomena to support 5D learning opportunities for students.

Introduction

An important focus of professional learning is to support teachers' development of pedagogical design capacity (PDC), that is, their capacity to create and adapt materials that can deepen their practice and improve student learning (Brown, 2002). Supporting this development is an intensive, iterative process that requires preparing teachers to choose, adapt, and create materials to align with instructional goals (Brown, 2009). This approach to professional learning acknowledges that teachers are in fact *designers* of learning opportunities for students, not just implementers of others' designs (DeBarger et al., 2013).

The purpose of this design study was to develop and test an online professional learning intervention for teachers to support them in designing and using assessments that are aligned to the vision of science teaching and learning articulated in *A Framework for K-12 Science Education* (National Research Council, 2012). Assessments that align with this vision are quite different from those typically used in science classrooms: they demand tasks that are compelling to students and require them to use science and engineering practices (SEPs), disciplinary core ideas (DCIs), and crosscutting concepts (CCCs) in science to make sense of phenomena and problems (NASEM, 2019; National Research Council, 2014). Bell et al. (2016) argued that the *Framework* presents a five-dimensional (5D) vision of instruction and assessment that not only includes a three-dimensional (3D) vision of science, involving the integration of DCIs, SEPs, and CCCs, but also two additional dimensions: engaging student interest and supporting students' identity development as knowers, doers, and users of science.

A particularly vexing challenge for science curriculum and assessment designers and teachers alike is choosing phenomena for instruction and assessment. Phenomena are observable events that students can explain using science knowledge and practices and are key to realizing the vision of the *Framework*, because they provide contexts for students to use the dimensions together to engage in science (NASEM, 2019). It is challenging to choose phenomena for instruction and assessment, because it is possible to choose phenomena that are interesting to students but that do not provide opportunities for students to develop and demonstrate understanding of 3D standards. Similarly, it may be possible to choose phenomena whose explanations address 3D standards, but do not connect with students' interests, experiences, and identities. What designers in any role need is a type of "design know-how" (van den Akker, 1999) for choosing and using phenomena that support students' 3D understanding, while also accounting for their interests and identity development. This paper explores how we supported the development of this "design know-how" or PDC with rural teachers in the context of an online professional learning intervention.

Description of our intervention

Our intervention is an online adaptation of a two-day, face-to-face workshop series to help teachers design assessment tasks aligned with the NRC (2012) *Framework*. Penuel et al. (2019) found that teachers who participated in these workshops improved the quality of their designed tasks. Building on this work, we identified five PDC areas that teachers need to develop 5D instruction and assessments, namely their capacity to 1) "unpack"

 © ISLS

the targeted 3D understandings found in the standards, 2) learn about their students' interests and prior experiences with science, 3) understand what phenomena are and how they can be used to frame instruction and assessment, 4) choose phenomenon contexts that are engaging and productive for students to develop and demonstrate targeted understandings, and 5) develop assessments that prompt students' integrated use of the 3Ds to explain phenomena. These areas are interconnected, as teachers' unpacking of standards and understanding of their students' interests influence how they choose phenomena and design prompts that support student sensemaking and identity development. In this paper, we explore how our intervention supported teachers in understanding the purpose and value of using phenomena and the challenges involved when choosing appropriate phenomena to frame instruction and assessment opportunities.

We used a storyline approach (Reiser et al., 2021) to design three sets of lessons and tools to support the development of teachers' PDC. Teachers engaged in 25 hours of synchronous, online learning over nine afterschool sessions during Fall 2021, with additional asynchronous work and opportunities for feedback between sessions. In Lesson Set 1, we co-developed with teachers a 5D, *Framework*-aligned vision of instruction and assessment. We introduced teachers to tools designed to help them elicit information about their students' interests and science-linked identities and unpack the targeted 3D understandings from the standards. In Lesson Set 2, we co-developed with teachers characteristics of phenomena that would help students achieve the targeted 3D learning goals, engage student interest, and support students' science identity development. Using these characteristics and tools, teachers identified and evaluated candidate phenomena and developed assessment scenarios that included data to present these phenomena to students. In Lesson Set 3, teachers collaboratively analyzed examples of phenomenon-driven assessments from different grade bands and content areas and developed and administered their assessments to their students. Using evidence from student work and surveys, teachers developed rubrics to make claims about students' 3D understanding and provide feedback.

Methods

This design study involved three middle and eight high school science teachers from two rural districts and two facilitators. All teachers were beginning to implement their state's 3D standards. To analyze how our intervention supported teachers in understanding, choosing, and using phenomena, we analyzed data sources from the second lesson set (Sessions 4-6, 7.5 hours), when teachers began integrating the PDC areas named above: (1) field notes, which synthesized detailed descriptions of the facilitation and teachers' engagement with the ideas and tools, (2) virtual artifacts that documented shared thinking, and (3) exit tickets, where teachers shared how each activity met the session's learning goals. Analysis of data sources involved identifying each instance where teachers discussed or wrote about phenomena. In the context of the intervention's designed learning trajectory, we characterized teachers' ideas about phenomena and the "rules of thumb" they developed for choosing phenomena. Since teachers were new to 5D instruction and assessment design, we identified challenges that teachers named or encountered when designing with phenomena. We created and discussed analytic memos and identified themes about how teachers understood and began to use phenomena and the 5Ds in design.

Findings

Our paper focuses on the shifts and tensions observed in teachers' considerations when choosing phenomena.

Teachers deepened their understanding of the role of phenomena

The intervention's planned trajectory was designed to deepen teachers' understanding of the considerations that they needed to think about when choosing and using phenomena. Teachers posted their initial definitions and characteristics of phenomena on a digital interactive whiteboard (i.e., Jamboard). Teachers focused initially on two aspects of phenomena: (1) they should be "observable" and involve "real world" situations and (2) they should be "engaging" and prompt students to wonder or ask questions. These aspects of phenomena aligned with two dimensions: engaging student interest and creating authentic situations that could support the development of practice-linked identities. However, only two of the initial 29 characteristics connected the use of phenomena to the development of scientific understanding. Leveraging these initial ideas, facilitators engaged teachers in an activity to use these characteristics to evaluate candidate examples of phenomena. These examples varied in intentional ways to allow teachers to distinguish between phenomena, which foregrounded observations for student sensemaking, from non-examples, which included concepts or "big ideas" (e.g., evolution) or components of an explanation that could be used to explain a phenomenon. Through this activity, teachers clarified and iterated upon their ideas to develop "rules of thumb" for identifying phenomena and lenses for making examples more "phenomenon-like". For example, teachers clarified that phenomena were not "scientific facts" for explaining a phenomenon. One teacher shared that a card that read, "Chlorophyll causes plants to appear green" was a "scientific fact" that could be used as part of "a good explanation of a phenomenon," but was not a phenomenon

 © ISLS

(Session 4 Field Notes, 9/21/21). Upon reflection, a teacher shared why it made sense for phenomena to focus on what was observable rather than components of an explanation, "when you explain it in detail, it's just spitting out facts - not leaving space for the students themselves to question and figure it out. It needs to not be fact, but something that leaves room for learning" (Session 4 Field Notes, 9/21/21). Thus, this teacher connected her understanding of what phenomena are to the role that phenomena play in inviting students to wonder and support student sensemaking in service of the desired learning goals.

Although teachers could articulate what phenomena were *not*, teachers continued to encounter challenges with describing phenomena as observations to be explained. After discussing our rules of thumb for identifying phenomena, one teacher desired to apply what they had to learned to describe what the phenomenon was from that session, where teachers watched a time-lapse video showing a badger decomposing on the side of the road. When describing what the phenomenon was in the video, the teacher described the explanatory processes involved ("the multiple stages of decomposition the badger include"), while another focused on the medium used to present the phenomenon ("the time lapse video of a dead badger") (Jamboard, 9/21/21). In response, the facilitator pressed teachers to think about what the students observed, which helped teachers to describe the phenomenon as the disappearance of the dead badger over three days. Thus, deliberating on our description of the phenomenon helped teachers refine their rules of thumb for describing phenomena, which was an important stepping-stone for designing 5D learning opportunities for students to make sense of phenomena.

Teachers experienced design tensions when choosing phenomena

The intervention used three key tools to support teachers in developing 5D, phenomenon-driven learning opportunities for students: 1) the *Student and Community Interest Inventory* to elicit understanding of students' interests and science-linked identities, 2) the *Unpacking Tool* to analyze the targeted 3D understandings at grade band, and 3) the *Choosing Candidate Phenomena Tool*, which used findings from the first two tools to evaluate the appropriateness of phenomena and choose data sources that invited student sensemaking using the targeted 3Ds. While teachers made progress with considering how phenomena could frame 5D leaning opportunities, teacher required additional support, even with the support of tools, when developing their own assessments. We describe some of these challenges and tensions below.

Weighing student interest with 3Ds when choosing phenomena

In the course, teachers considered how students' explanations of phenomena could support students in developing and demonstrating an understanding of the target DCIs. At the same time, teachers were expected to consider student interest and identity as well. Several teachers came to appreciate the design challenge of designing for all 5Ds and not just the 3Ds foregrounded in standards documents. For instance, one teacher wrote, "It is actually harder than it seems to come up with compelling phenomena that can be used to both grab students' attention and get at a deeper understanding!" (Session 6 Exit Ticket, 10/5/21). Facilitating conversations around these tensions helped to develop teachers' lenses for evaluating and enhancing phenomena. In one task, teachers chose between two phenomena to help students demonstrate a high school chemistry standard (HS-PS3-4), "Plan and conduct an investigation to provide evidence that the transfer of thermal energy when two components of different temperature are combined within a closed system results in a more uniform energy distribution among the components in the system". One teacher in a small group discussion argued for using hot springs as the phenomenon, since she felt it was *better aligned with the target DCIs*. In contrast, another teacher argued for melting polar ice caps, because she thought it would be *more compelling and relevant to students*. She contended, "That's going to get the interest of the kids! […] If my aunt is affected because she lives in Key West, they're going to say, 'The scientists need to monitor it!'" (Session 5 Fieldnotes, 9/28/21). In response, the first teacher offered ideas for enhancing the DCI alignment of the melting polar ice phenomenon by foregrounding the contact between warmer ocean water and the polar ice to show how "the transfer of thermal energy when two components of different temperature are combined" (HS-PS3-4) could explain the phenomenon (Session 5 Fieldnotes, 9/28/21). In this small group discussion, we observed tensions when considering a phenomenon's 3D alignment and its interest to students. However, the group found a way to consider both lenses to enhance the 5D-alignment of phenomena and the importance of content expertise when choosing and enhancing phenomena.

Weighing authenticity of data sources for assessment scenarios with 3D learning goals

Facilitators intended to focus on the use of scientific data as one of several ways to present a phenomenon to students when designing assessment scenarios. Some teachers became overwhelmed by the search for data. For example, one teacher shared, "I had to stop halfway through and do some deep breathing, because it overwhelms me. Do you know how long I spent searching for data, local data - searching, searching, searching for an entire day. It's just a lot of time" (Session 6 Fieldnotes, 10/5/21). Teachers analyzed an example assessment that used

modified scientific journal data to support student sensemaking, which may have contributed to feelings that the inclusion of scientific data was essential to scenario development. In conversations with teachers, facilitators recognized that some teachers lost sight of the purpose for using the data, which was to present the observations or information needed to support student sensemaking of the phenomenon. To alleviate this tension, facilitators attempted to broaden teachers' vision for the type of data that would be needed to meet their targeted 3D goals and pointed them to resources for finding data or phenomena that could be adapted.

Conclusion

Phenomena are key to realizing the vision of the *Framework;* but, choosing phenomena that align with targeted 3D learning goals, engage student interest, and support students as knowers, doers, and users of science is an ambitious and complex design task. The lack of examples of high quality, phenomenon-driven assessments highlights the need for interventions to develop teachers' capacity to design 5D assessments. Our intervention has designed tools to help mediate this work, and our initial findings suggest that teachers improved in key PDC areas that can support them as designers and adaptors of existing materials. Although our research surfaced challenges and tensions that teachers face when engaging in this work, our intervention created time and space for teachers to process and apply what they learned with support. All instructional and assessment examples used in the intervention came from freely available materials, so that teachers could have a model from which to base their designs and consider ways to implement what they have learned in instruction. To summarize, our initial findings suggest that when used in a collaborative context, the intervention tools can foster the development of teachers' capacities to act as designers of 5D learning opportunities for students.

Balancing Agency and Accountability to Support Learning in Playful, Embodied Science Activities

Selena Steinberg, Indiana University, ssteinb@iu.edu
Joshua Danish, Indiana University, jdanish@indiana.edu

Abstract: Student agency is important to support in learning environments, as it enables students to control their learning and can lead to new understandings of content. Yet, there are many questions about when and how to hold students accountable for content learning while still fostering their agency. This paper examines data from a first-grade classroom, in which students embodied bees in the STEP (Danish et al., 2020) mixed-reality environment in order to learn about nectar collection and pollination. We analyze the ways in which student agency and accountability interacted in the embodied learning space and led to engagement with science content. We describe patterns in how student agency can support sensemaking as students navigate different sources of accountability and we discuss productive ways to balance agency and accountability in embodied learning environments.

Introduction and framing

Student agency has long been seen as an important part of science learning. It provides new roles and voice to students (Barton et al., 2010), and enables students to actively generate disciplinary knowledge (Cavagnetto et al., 2020). While agency has been defined in several ways across education and psychology, we find it productive to view agency from a sociocultural perspective. We build on sociocultural theories of learning, which highlight how cultural ideas and artifacts mediate learning (Engeström, 1987; Vygotsky, 1978) to view student activity as individuals-operating-with-mediational-means (Wertsch, 1993). Agency, then, is not something that students possess or do not, but instead can be conceptualized as the mediated actions that students have opportunities to, and choose to, enact within a classroom activity system. In this view, it is important to consider what features of the classroom environment support or limit students' ability to exercise agency and how they do so. In our work on embodiment, we have found that activities where students use gestures, body positions, and movement to represent and explore their ideas can provide new opportunities for, and constraints on, student agency (Danish et al., 2020). Students often have the freedom to move however they want, yet their peers' motion or the software environment also constrain the impact that their movement has on the system being explored.

The goal of this paper is to examine the ways in which particular features of an embodied learning activity influenced student agency and supported student learning. We focus specifically on understanding the role of *accountability.* Agency and accountability are often dichotomized as opposites, in which agency is good and accountability, structure, or teacher authority should be minimized. However, in an academic setting, students often need to be held accountable to disciplinary practices and content, and so the question shifts to how agency and accountability should be balanced in the classroom in order to foster learning (e.g. Danish & Enyedy, 2006). In embodied environments in particular, students act and interact in ways that are different from many science classrooms (Danish et al., 2020; Lindgren & Johnson-Glenberg, 2013), which necessitates new understandings of how agency and accountability function. Therefore, we ask the following research questions:

1) How do students take up agentic roles in embodied learning experiences?
2) How do interactions between agency and accountability in embodied activities influence the learning of scientific content?

Methods

Participants and data sources

This work examines data from the Science through Technology Enhanced Play (STEP) project (Danish et al., 2020). In this project, 11 students from a small public school in the midwestern United States participated in collective embodied activities in a mixed-reality environment, in which motion tracking software captured student movement and depicted students on a screen as bees in a field (see Figure 1). This analysis focuses on the group of students participating in a series of eight lesson plans focused on understanding honeybees, nectar collection, and pollination (see Danish et al., 2020 for similar studies). The classroom teacher and several researchers served as instructors of the unit.

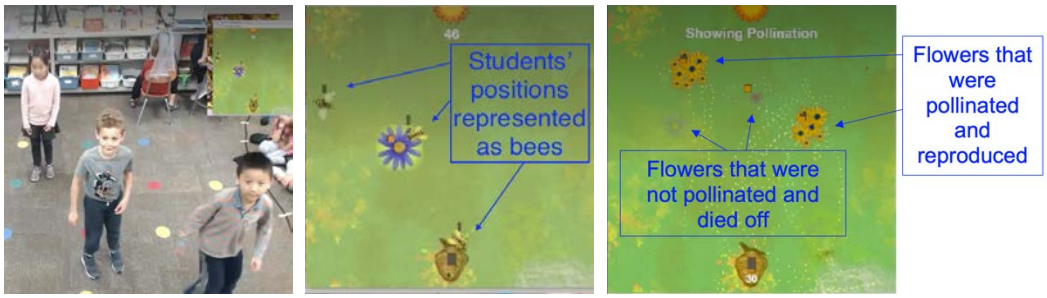

Figure 1. Students tracked by STEP (Image 1) and the projected STEP simulation (Images 2, 3)

Analysis

We began by reviewing video footage including screen recordings of the STEP simulation of the whole lesson sequence, and logged moments where agency or accountability were salient. Based upon this first pass, we selected moments for further analysis in which interactions between accountability and agency seemed to be productive for the learning of scientific content. We iteratively reviewed these moments by articulating and refining conjectures about the role of agency and accountability in supporting learning. In the present analysis, we present patterns that we observed across the lessons, and then focus on one activity that occurred on the sixth day of the sequence where students learned about pollination. We selected this illustrative example, in which student agency seemed to positively impact learning, because we were interested in highlighting the potential value of student agency in this kind of embodied design. Note that while episodes had varying levels of student agency, many had similar moments and we selected this particular episode because of the many interactions between agency and accountability that were concentrated in one sequence. We use interaction analysis (Jordan & Henderson, 1995) to consider how students interacted with each other, the instructors, and the simulation, and the ways that the activity oriented students to behave in agentic ways or notice different sources of accountability.

Findings and discussion

Patterns across the lesson sequence

Our first research question asked how students take up agentic roles in embodied learning experiences. Across activities and days, we noticed a stark contrast between the limited agency that students were afforded in teacher-led discussions about content (where students could choose to answer a question or not), and the more flexible agency that they were afforded in the embodied activities (where students had agency to act, speak, and model in ways that they decided). In the embodied activities, one way that students acted agentically was by making decisions about where and how to move in the space. In some cases, students' movement choices were influenced by the way that the system responded to their behaviors. For example, some students chose to crouch down, but when they did so, they lost the nectar that they had collected because the system could no longer see them. As a result, students stopped choosing to behave in this way and stood up tall. In addition to the ways in which students decided to move, they also had agency to call out and direct other students' actions. That is, as students watched others engaging in movement, they often took it upon themselves to hold their peers accountable to the content, particularly through comments like "get the nectar to the hive!" Students that were directed by other students had agency to listen or not, prompting them to navigate sources of accountability in relation to their own goals.

Our second research question asked how interactions between agency and accountability influenced the learning of scientific content. In this designed space, we found that there were several competing sources that students needed to be accountable to, including the instructors' suggestions, other students' suggestions, and the software. The presence of these competing accountabilities gave students the agency to determine which ones to follow, and why. We argue that in exercising this agency, students explored and made sense of the underlying rules that are a part of accountability, leading to learning of the target content.

Illustrative case: Agency, accountability, and learning about pollination

In this case, we focus on the agency on one particular student, Tom (though other students also acted in agentic ways), and how that agency enabled the class to learn more about the process of pollination. Prior to this episode, students had just finished a round of embodied activity in which they acted as bees to visit flowers, and then saw that the next spring, most of the flowers died, but one was replaced with many other flowers because it had been pollinated. Students held many diverse ideas about the ways that bees pollinate flowers, including that the one flower grew back the next spring because it had more nectar left, because it got the least pollinated, because visiting multiple flowers pollinates them, and because flowers get pollinated when bees go to the same type of

 © ISLS

flower (to which another student disagreed). The current episode began after Tom exercised agency by suggesting that to pollinate the flowers, the bees needed to visit the big yellow flower on the right and then the big yellow flower on the left. An instructor took up Tom's suggestion and engaged the class in testing that hypothesis. Tom was the first student to enter the field as a bee and he went straight to the yellow flower to collect its nectar:

(1) Instructor 1: Okay, so now go to the other one.
(2) Instructor 2: You can go to the other one, Tom.
(3) Tom: Wait, I'm full though, so I can't go anywhere. *(walks backwards towards the hive)*
(4) Caleb: Yeah you can.
(5) Instructor 2: Okay, come back quick.

In this interaction, Tom encountered competing sources of accountability: being accountable to the instructor for the pollination plan that he created, and being accountable to the software for the behavior of bees (when the bee is holding the maximum amount of nectar that it can, it needs to drop it off at the hive). In line 3, Tom exercised agency by deciding to behave as a bee would by moving back towards the hive, instead of adhering to his pollination plan. Another student argued that Tom could actually move wherever he wanted (line 4), while an instructor gave him permission to enact agency by following his choice of accountability source. In doing so, Tom was able to engage in sensemaking around the behavior of bees.

After Tom returned to the hive, an instructor sent Jade into the embodied space. While instructors served as one source of accountability for students, reminding them of Tom's idea throughout the embodied experience, Tom also had agency in holding his peers accountable to his idea, who also had agency in how they followed up:

(1) *(Jade walks out to a purple flower)*
(2) Instructor 2: We're going to the yellow ones, Jade.
(3) Jade: Oh. *(moves to a yellow flower)*
(4) Instructor 2: The two big yellow ones are the ones we're going to. That was what Tom had suggested.
(5) Instructor 2: Drop it off, you've got to pay attention.
{33 seconds pass with other students entering and leaving the space}
(6) Tom: Try the other yellow one, I'm the only one who's went there.
(7) Instructor 1: Yeah, make sure you go from one to the next. You could fill up a little bit on one.
(8) Caleb: You're filling up all on just one. They're just filling up on one!

Accountability played a positive role in this exchange in that reminders to follow the rules ensured that students would be able to see the results of Tom's plan. In line 4, an instructor held Jade accountable to the original plan, and specifically positioned Tom's ideas as a valuable contribution. In addition to instructors enforcing accountability, Tom and Caleb made suggestions to the embodied participants. The instructor's comment on line 7 reinforced the norm that students have agency to make suggestions by ratifying Tom's comment from line 6.

There were several components of students' agency in relation to accountability that led to engagement with the scientific concepts. Tom's agency to suggest an idea, to choose to be accountable to the rules of the simulation rather than to the teacher, and to hold students accountable to trying his idea all helped students to learn about how pollination works. When the embodied experience ended, students were successful in pollinating the yellow flowers and were able to articulate what bees needed to do for pollination to occur:

(1) Instructor 1: Okay, so let's see what happens the next spring. *(Figure 1 Image 3 is displayed)*
(2) Students (overlapping): Ooohhhh! That's awesome!
(3) Instructor 1: So what'd you notice?
(4) Tom: That you have to go to the same flower.
(5) Diana: No!
(6) Tom: No, that you have to go to the same type of flower.
(7) Instructor 3: So Diana, what do you think?
(8) Diana: It helped going to different flowers. But it would help if we would go to the purple flowers. If there was like two purple flowers, you could go to both of them, and two yellow ones.

Not only did students articulate that their method, going from one yellow flower to another, was successful in pollinating the yellow flowers, but in line 8, they extended their explanation to say that if they had also visited two purple flowers (a different kind of flower), those flowers also could have been pollinated, suggesting that they

had begun to recognize the importance of visiting flowers of the same species as indicated by color. Students continued to discuss what happened and their theories of pollination. The episode concluded:

(1) Instructor 1: So do bees plan like that, you think, or it just happens?
(2) Students (overlapping): It happens.
(3) Instructor 1: Yeah, but what about flowers makes bees want to go to them to make that happen?
(4) Tom: Cause they want to get nectar, but they accidentally pick up pollen and they go to different flowers, the same bees.
(5) Instructor 1: Good, so lots of good nectar is what will draw bees to the flowers.

Tom articulated that bees' primary goal is nectar collection, and that pollination is a byproduct of that process. Perhaps his desire to drop off his nectar rather than visit the next flower during the embodied activity helped to prompt this realization for the class. A multiple-choice assessment provided additional evidence that students learned about how pollination works. Students participated in a pre and post test before and after the series of eight lessons, in which four questions about pollination were posed. Students scored significantly better on this set of questions on the post-test as compared to the pre-test, $t(9)= -2.058$, $p < 0.05$, one-tailed. Note that one student declined to participate in the multiple-choice assessment.

Implications and conclusion

In our analysis, we found that embodied activities broadened the types of agency available to students as compared to traditional teacher-led discussions. That is, students enacted agency through choosing where and how to move, holding their peers accountable to ideas and content, and navigating competing sources of accountability. This work suggests that accountability does not necessarily have to limit student agency. Having multiple sources to be accountable *to* (instructor(s), the other students, and the rules of the software/technology) and being accountable *for* multiple ideas (in this case, for enacting a pollination plan and for collecting nectar) enables students to understand that rules are not just for following, but for making sense of. When students had agency to make sense of competing sources of accountability, they gained nuanced understandings of content. Therefore, designers of learning activities should consider how to create an environment where multiple, competing sources of accountability are present, and where students are given agency to both act as and to navigate these sources.

Constructing a Mathematical Identity as an Adolescent Black Girl

Sophia Raymond, Tufts University, Sophia.Pompilus@tufts.edu

Abstract: Recent literature within mathematics education has begun to focus on identity and its effect on students' self-perception as mathematical learners and doers, as it shapes every part of a students' life, including their relation to mathematics. This study investigates the construction of mathematical identity for a middle school Black female mathematics student, Crystal, over the course of her sixth grade year. The student was observed in her online and in-person classroom and interviewed after school to gain insight into her mathematical identity. Selected interview data centered on discussions of identity were analyzed to generate an understanding of how her mathematical identity was crafted, and how this influenced her as a mathematician. This study emphasizes the importance of voice scholarship (Ladson-Billings, 1995) in spotlighting an oft-forgotten group to broaden research about their mathematics education experiences.

This case study considers the following research question: *What are the factors associated with Black girls' mathematical experiences, and how do they inform the construction of their mathematical identities?* I ground my research on McGee's (2015) construct of fragile and robust identities, a framework the author used to survey the intersection of mathematical and racial identities relative to the mathematical experiences of Black undergraduates. Mathematical identity construction involves the intersection of a plethora of factors including students' personal experiences, and McGee (2015) argued that for Black students in particular, mathematics education researchers should also consider race as a dominant factor. Black students arrive at school with their own knowledge (Freire, 1968), and for them, this includes knowledge of racialized experiences and events they encounter, all of which contribute to their mathematical identity.

For Black girls like Crystal, mathematical identity research is critical because their self-perceptions about their mathematical competence are highly related to their social identity as members of two minoritized identity groups. Evans et al. (2011) emphasized the importance of examining multiple identities jointly, as one's identity is a conglomeration. They claimed that even if identities may be hierarchically ordered, intersectionality, rather than additivity, must be the focus. In comprehending how Black girls craft their mathematical identities, it is crucial to understand what it means to learn mathematics while being both Black (Martin 2012) and a girl (Kurtz et al., 2008).

Methods

I engaged in a year-long study of Crystal in her mathematics classroom at a public suburban middle school in the Northeastern United States. This school was composed of approximately 71% White, 13% Black, 6% Asian, 5% Hispanic, 4% multiracial and non-Hispanic, 0.2% Native American, and 0.1% Native Hawaiian and Pacific Islander students. Nearly 11% of students are economically disadvantaged. Potential participation was limited to all Black girls who volunteered and whose parents consented across three sixth grade mathematics classes. Due to difficulties in recruiting during the first full academic year during the COVID-19 pandemic, as well as having to withdraw a student for inconsistent participation, Crystal was the single study participant. She identified as a Black girl with parents who immigrated from Nigeria, and she attended sixth grade through the full remote model up until mid April 2021, when she switched to being fully in person, per State and District orders for all students to return to K-12 schools.

There were three rounds of observations and interviews from February to June 2021, and following each one of these rounds of observations were interviews after school that lasted up to 30 minutes. In total, there were 10 interviews conducted. In these interviews, Crystal was asked follow-up questions related to classroom lessons, as well as questions about her identity more broadly. Due to limitations of online class observations (e.g., Crystal's choice regarding camera and microphone usage) to examine Crystal's interactions with her peers or teachers, there was nominal data relevant to her identity in the classroom data. Conversely, much of the interview data related specifically to identity, the focal point of this study. As a result, only the interview data were selected for analysis. For one of the 10 interviews, I used a guided protocol, the Multidimensional Model of Black Identity (MMBI; Sellers, 2013) which included statements related to identity. This interview was not selected for analysis as the questions' central focus on identity influenced Crystal's answers, providing less spontaneous responses on her part.

 © ISLS

I then transcribed each of the nine remaining interviews. In order to further pare down my dataset, I used a grounded approach (Glaser & Strauss, 1967) using ideas in formation (Charmaz, 2006) to identify emerging themes in the transcripts, highlighting those themes which repeated throughout all transcripts (see Data Analysis section). Identity was an obvious theme, but others emerged throughout my analysis. Thus, I decided to select only the interviews in which Crystal conveyed or explicitly suggested identity in our conversations at least once. In total, there were nine interviews selected.

Along with two other coders, we developed a coding scheme through a line-by-line review of the interview transcripts. We noted themes that were referenced in the transcript lines, which were the following: (1) affect, (2) expectations, and (3) identity. Using Merriam-Webster Dictionary's definitions, affect is defined as: "the conscious emotion that occurs in reaction to a thought or experience." Expectations are social norms around what others consider "reasonable, due, necessary" or expected of someone. I define identity by extending McCarthey and Moje's (2002) definition: it is comprised of social and/or personal constructions about self that can vary over time and contexts that shape or are aspects of how humans understand the world around them and how they too are understood.

I coded every line of the transcripts to identify these themes, and used an utterance as my unit of analysis, focusing only on Crystal's utterances. I define an utterance to be a single line of verbal discourse by a speaker, bound on each side (i.e., beginning and end of an utterance) by utterances from another speaker. Utterances could be coded for multiple themes and sub-themes (see below). To ensure the reliability of my coding, a second training coder with a PhD in mathematics education and I each independently coded 20% of the transcript data (i.e., two interview transcripts) for the three themes; this also accounted for 20% of the total interview time (1). The second coder and I had an 84.71% agreement.

I then returned to the nine interview transcripts to identify sub-themes (Saldaña, 2013) to gain a deeper understanding of how all of the themes materialized and shifted over time. The respective sub-themes, which all fall under the expectations theme, shown in Table 1, are: (a) personal expectations, (b) parental expectations, and (c) societal expectations.

Table 1.
Sub-themes used in coding of data.

Sub-themes	Definition	Example
Personal expectations	Personal beliefs about what is considered "reasonable, due, necessary" or expected (using Merriam-Webster Dictionary definition of "expect").	*"Math is one of those things that you just have to do."* ***February 4, 2021, Line 71***
Parental expectations	Messages parents/guardians convey to children relative to their beliefs regarding what is considered proper and necessary (Parsons et al., 1982).	*"And my parents kept-, kept on telling me, 'make math your friend'."* ***April 30, 2021, line 179***
Societal expectations	Normative beliefs fostered by others in the social environment (Joseph et al., 2020).	*"They just portray [school] as a horrible place that you should never wanna go to."* ***February 4, 2021, line 139***

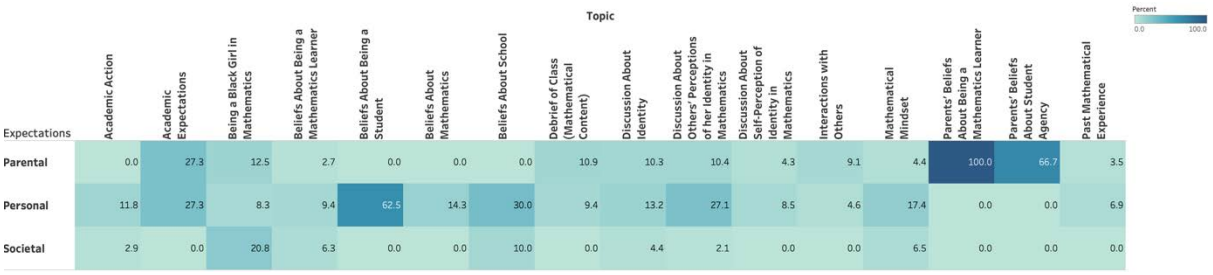
After refining the sub-themes, I shifted my attention towards identifying what may have prompted Crystal to answer my questions in particular ways, to learn more about Crystal's relationship to mathematics. For example, were there types of questions associated with specific sub-themes, and could any shifts identified be explained? I considered each coded utterance in context to explore this, looking at how these themes shifted across the three rounds of data collection. I did this by first identifying the topics covered during our discussion, and calculating the percentages of each sub-theme in her discourse about the topics. These shifts were used to then construct my study's claims.

Findings

Figure 1 displays a heat map of all nine interviews in which Crystal participated over the course of her 6th grade year that had utterances coded for expectations. On the top of the heat maps are the different topics discussed across all interviews, which were identified from examining the questions from the interview protocol. These

topics are alphabetically ordered. Gaps in the heat maps are a result of the lack of topic and sub-theme overlap. Cell shading corresponds to the intersection of sub-themes and topics. The lightest shade denotes lower percentages of these occurrences, while the darkest shade denotes higher percentages. For example, 62.5% in the personal expectations row means that 62.5% of the utterances across the nine interviews had an overlap between personal expectations mentioned by Crystal and a question from her about her beliefs about being a student. The column width of the topics do not denote the length of interview time spent on them.

Figure 1 *Heat map comparing Crystal's utterances coded for expectations for all the three rounds of data collection.*



Of her utterances about beliefs about being a student, 62.5% of them were coded as her personal expectations. For instance, Crystal leans into perfectionism, believing that mistakes are a negative mark on one's competence. She reflected on her negative 5th grade mathematical experience:

> 98 Crystal: All I know that, is that in 5th grade, I kinda varied. But most of the time, what I [inaudible]. I didn't really like 5th grade [inaudible] is that oftentimes I would, I would get in this habit of pouting during math class.
>
> 101 Crystal: Uh, most of it because of a bad score, or I felt as though I was, you know, low self-esteem. I thought I was dumb, I was getting things wrong. I thought everyone knows this but I don't. So, what's wrong with me? (*April 30, 2021 Interview*)

She continues this thinking in sixth grade:

> 134 Crystal: Like, some people accept their mistakes, except I'm just one of those people that don't like them.
>
> 135 Sophia: Mhm. What-, what do you think-, what don't you like about your mistakes?
>
> 136 Crystal: Well, I don't know. I just-, I just hate, uh. [inaudible]. OK, so bottom line, I'm the kind of person that likes to be right.

Though initially this understanding may seem to be isolated as her own expectation, it was in fact connected to her familiarity and interpretation of societal and parental expectations. Joseph et al. (2019) claimed this is true for all students, as their academic identities are a mix of how they, their families, and others see them. Crystal's parents wield momentous power in her understanding of what it means to be Black and learning mathematics. She acknowledged that despite her parents informing her that "Black people are really, really smart" (February 23, 2021 interview, line 204), "[Black people] have to work twice as hard as a White person might work" (June 8, 2021 interview, line 49). Crystal had a keen awareness of societal expectations about mathematics which implies that mathematics learners are not typically perceived to be Black or female. In speaking about the lack of Black women in the mathematics field, Crystal said this:

> 237 Crystal: Maybe they-, maybe th-, they want to get into the math field, except-, e-, e-, except all the-, all these White people th-, th-, that-, all these White people th-, th-, that are part of the math field are like, "you can't do this. You can't be in the math field. Get out of here!" (*February 23, 2021 Interview*)

Crystal's parents' expectations themselves are rooted in societal expectations for Black students and subsequently, a desire for Crystal to achieve well. This undoubtedly affected her own personal expectations. As evidenced by the heat map above, in addition to her beliefs about being a student, Crystal's utterances related to her personal expectations were centered on topics related to ideas she had conceived about school (30%), academic expectations (27.3%), and discussion about others' perceptions of her identity in mathematics (27.1%). And yet, 100% of her utterances across the interviews about her parents' beliefs about being a mathematics learner were coded as her parents' expectations. Contrastingly, 0% of her utterances about the same were coded as her own personal expectations. I contend that this is because Crystal's own expectations were actually rooted in her interpretation of her parents' expectations for her.

Conclusion

In McGee's (2015) three-component framework, a fragile mathematical identity is based on the "delicate" (McGee, 2015, p. 604) relationship between a Black student's mathematical achievement and their constant racialization sustained in doing mathematics. Contrastingly, a robust identity centers on the resilience and fortitude these students develop and exhibit in spite of racialized mathematics experiences to maintain the necessary motivation for mathematical achievement. Crystal was extrinsically motivated to achieve highly in mathematics due to her parents' expectations, which were based on societal expectations for Black students. According to McGee (2015), this means her mathematics identity is fragile.

There are several limitations to this study, one of which is the fact that this is a single case study, which is not generalizable. Nonetheless, for students like Crystal, their attitudes about mathematics cannot be examined as existing in a silo, but in combination with external factors, especially race, which is often a dominant factor for identity. Next, Crystal's identity as a child of immigrants adds a different dimension to identity construction that my study does not address. This would certainly be a unique experience that cannot necessarily be extended to other Black girls.

Endnotes

(1) The total interview time was 3 hours, 53 minutes, and 20 seconds, and 20% of this time was 37 minutes and 47 seconds.

Organizing Outreach for Cultural Transformation: The Design of a STEM Education Learning Pathway

Trang C. Tran, Joseph L. Polman, Daniel Knight
Trang.Tran@colorado.edu, Joseph.Polman@colorado.edu, Daniel.Knight@colorado.edu
University of Colorado Boulder

Abstract: This case study leverages the Nasir et al. (2020) *learning pathways* framework to examine the relationship between learning environments, activities, roles and responsibilities, as well as social interactions taking place in a collegiate STEM outreach program. Using observational, survey, and interview data collected from three groups of instructors and learners in both university and high school settings, we identify how the course participant structure and distributed system of activities helped to engender university students' participation, identification, and transformation. We highlight how students embarked on a transformative identification process with STEM fields and broader intellectual identities as they undertook multiple roles and responsibilities in different learning sites and timescales. Our study suggests an innovative model to enhance the design and enactment of university-based outreach efforts to support alternative, culturally transformative pathways in STEM.

Overview and significance

Like many STEM fields, engineering seeks to attract a diverse population into the field. But becoming an engineer is complicated and dehumanizing endeavor for many identity groups, who experience being marginalized and pushed out (Adams et al., 2011; Stevens et al., 2008). Cultural change is needed to create more just, equitable, and humane learning environments. In this paper we examine two linked environments—one in higher education and STEM education settings in rural high schools. Rural US settings are under-resourced and under-researched (Lavalley, 2018), and have challenges in recruiting teaching staff (DeFeo & Tran, 2019), and in preparing students for engineering (DeUrquidi, 2019). We describe the organization of a university outreach program based in a college of engineering, who partners with high school STEM teachers. This program has tools and cultural practices to support learning pathways (Nasir et al., 2020) for two groups: (1) higher education graduate and undergraduate engineering students (whom we call "mentors") interested in educational outreach; (2) high school students taking STEM education courses (whom we call "students"). This paper focuses on the university mentors.

Literature review and conceptual framing

The program utilizes a *project-based learning (PBL)* approach that seeks to promote students learning by doing as they collaboratively pursue endeavors that are authentic to them and to disciplinary practices, while teachers facilitate students' investigations (Boardman et al., 2021; Miller & Krajcik, 2019).

We employed Nasir et al.'s (2020) *learning pathways* conceptual framework to guide our analysis. Learning pathways are culturally organized trajectories of positioning, participation, and identification. The framework advances two key ideas: a) how access, resources, and experiences of learning, while multidimensional and intersectional, are socially and institutionally driven and b) how learning as a process of navigating and interacting with cultural practices and values always evolves in relation to identities. The framework takes as a unit of analysis *cultural activities*, encompassing practices, interaction, artifacts, and objects that support how an individual is "socialized into navigating and understanding" their learning and development (p. 205). We applied three characteristics of learning from the framework: (1) how *identification* is based on relationality, affect, and motivation, (2) how *learning* is accomplished through cultural practices and routines distributed across persons, time, and space, and (3) how *privilege and marginalization* are enacted within structures.

To understand how *learning* is accomplished through cultural practices and routines distributed across persons, materials, time, and space, we utilize the concepts of participant structures, activity structures, and hybridization. Philip (1972) described *participant structure* as the organization of roles and responsibilities in a learning environment, which is one aspect of division of labor (Engeström, 2001) widely taken up in learning sciences (Sandoval, 2014). Within a participant structure, *role assignment* influences learners' social, linguistic, and cognitive development (Herrenkohl & Guerra, 1998). *Distributed activity structures* delineate sequences of activities, milestones, and artifacts, all tying to disciplinary goals (Polman, 2004); this perspective describes how students appropriate the tools they use during activities as their own, thus learning and developing new identities, under the guidance of teachers (Polman, 2004). In *hybridized learning,* people carry out hybrid cultural (Gutiérrez et al., 2019) and boundary-spanning (Buxton et al., 2005) practices. Examples of successful hybridized learning

space include the Fifth Dimension (Cole & The Distributed Literacy Consortium, 2006) and related efforts (DiGiacomo & Gutiérrez, 2017) which have bridged university teacher education and learning sciences coursework, and many more in museums, libraries, and communities.

Context and Methods

This analysis is drawn from a university-based science and engineering outreach program, AirProject (all proper names are pseudonyms), in a mountain west US state. The collegiate course is in an engineering department at a large US public university which serves almost 33,000 students in its graduate and undergraduate programs; 70% identify as white, 13% receive federal Pell grants, and 30% take out loans (NCES, 2020). The high school students served by this program are in 9 rural schools and are 71% white and 52% economically disadvantaged; 40% would be first generation college students (Colorado Department of Education, 2020).

Mentors' learning is structured into a yearlong course, offered to both undergraduates and graduates. The fall focuses on (1) technical objectives around air quality science and engineering, (2) scientific communication, and (3) mentoring skills. Specifically, mentors conduct a small research project of their choice, in which they pursue air quality questions in their local environment; collect data with a monitoring device (yPod); analyze the data and communicate results. They also practice teaching. In the spring, with support from university instructors and partner teachers, mentors guide HS students through a three-month air quality monitoring project. They meet once a week with instructors and classmates to reflect, discuss, and strategize teaching tips and problem solving.

Study participants include 12 mentors enrolled in the AirProject course, 3 university course instructors, and 3 high school teachers. 7 mentors identified as female and 5 male; 10 mentors identified as white, 1 Hispanic or Latinx, and 1 white and Asian American. High school classroom activities involved 86 students. Our data is drawn from three sources: 1) classroom observation notes; 2) mentor surveys; and 3) a focus group interview with 12 mentors at the end of the spring. We coded these data using the conceptual framework described above, along with axial emergent sub-themes within each category (Corbin & Strauss, 2019).

Findings

The AirProject *participant* and *distributed activity structure* prompted mentors to conduct air quality research throughout the fall and then teach these content and skills to their high school students during the spring. Thus, mentors have opportunities to rotate among different conventional and unconventional roles within a familiar curriculum. We identified two key themes: a) how the AirProject learning ecology shaped mentors' culturally transformational learning pathways and b) how mentors enacted learning as identification and becoming.

The learning ecology shapes culturally transformational learning pathways

Learning with multiple, responsive instructors and supportive high school teachers. In this small-size, learner-focused university course, the instructors worked together and supported one another in facilitating the lessons as well as responding to student inquiries. Ava appreciated "different angles that each instructor brought to the table." Ava's impression was concurred by all mentors. Participant structures incorporating multiple instructors are not novel, but it was notable how the three instructors, each with unique expertise, worked together to facilitate a multi-level scientific and engineering learning environment. In addition to appreciating the learning experiences in their university-based class, mentors reflected on their interactions with the high school teacher. Due to COVID-19, mentors had to call in for remote teaching while their partner teachers were in the room with students. Teachers skillfully helped mentors to stimulate students' learning through compliments, encouragement, and lighthearted jokes. Lucas said: "Our teacher was phenomenal… knowing the students, he would say … 'This person is probably going to have good work, we can volunteer them to go as an example." In between lessons, teachers were the main source of immediate assistance for students. They coordinated a schedule to lend out yPods and helped answer questions and troubleshoot. While leaving mentors autonomy to execute their lesson plans, teachers modeled productive, engaging communication.

Learning with multiple purposes. What was unique in the design of AirProject was that as mentors participated in the course, they had just-in-time learning to facilitate teaching HS students. Mia noted, "I didn't know very much about [air quality engineering] going into the course, so a lot of what we ended up teaching to the students I'd learned like a month or so beforehand … [I] immediately transferred that knowledge to someone else." Positioned as a mentor, Mia not only noted information relevant for lesson plans, but also handpicked materials that she believed to be engaging for students, drawing from her personal experience with those materials. Ben, Lucas, and Sophie recognized how they took on *facilitating, scaffolding, and mentoring* roles the ways that mirrored what their instructors did in the fall. In our observations, we frequently corroborated the synergy between the university-based instructors' guidance and how mentors positioned themselves as facilitators in high school

classrooms. Mentors carried themselves more like "knowledgeable partners" as opposed to merely claiming a position as authoritative sources of knowledge (Tabak & Baumgartner, 2004).

Mentors' participation in the AirProject reflected how they motivationally, relationally, and affectively (Nasir et al., 2020) operated in a system of learning pathways generative to their identity development. Like many of her peers who came to the course without much familiarity with air quality, Amelia pushed herself to study unfamiliar concepts and terminologies. Similarly, Noah was motivated to further his curiosity; he explained how he appropriated previous knowledge of scientific reasoning and sensemaking to his AirProject experience. Mentors also noticed generative relational patterns in their participation. Noah described how the collaborative mindset and the "peer community" learning experience rippled into the HS classrooms; he detailed how mentors rotated responsibilities, so they had one person focusing on the main curriculum and the other more "focused on managing time and interactions" and served as "the backup on curriculum topics and content." As Ava taught, she related more to her professors' work, and found herself willing to pay more attention in class to reciprocate the professor's effort. Mentors were transitioning from positions of novice learners to more knowledgeable peers; they appropriated relevant skills to advance disciplinary proficiency and at the same time actively moderated their own participation. Finally, at the end of the year mentors discussed *emotion and affect*. Emma described her overwhelming "imposter syndrome" and "lack of confidence" had made her feel the experience was at first "terrifying." Emma then noted improvements in how she handled questions and facilitated learning each time she came back to visit her students, which was "affirming," as was seeing her students skillfully presenting their projects. Other mentors concurred with "joy" and "pride" in seeing students present their research.

Learning as identification and becoming

Eleven of 12 mentors self-identify and are socially positioned as white, but the focus group interview revealed their non-monolithic identity positions. Working alongside peers and mentees prompted mentors to revisit their personal and social awareness. Liam recalled that as a "first-generation student, … without my middle school and high school teachers finding me to be excelling in math and science, I probably would never [have] become interested in engineering." Emma noted that "as a high school student I didn't think engineering was an option due to [my] lack of confidence." A student from a rural part of the state and a student whose pathway was through the community college system shared similar sentiments. These examples characterize how mentors' learning pathways included enactment of both privileges, for having racially privileged backgrounds and enrolling in a predominantly white institution and discipline—ones that persistently favored their racial identity—and marginalization, ones defined by their first-generation status, gender, geographic location, and age.

Mentors' self-identifications situated how they identified with *mentoring and role modeling*. Mia was adamant, "I do see myself as a role model because I came from a similar background as many of these kids, and now as a college student, I feel like I could be an example of where hard work can get you." Meanwhile, Emma saw *mentoring and role modeling* in her students connecting with her through the experience of "someone who doesn't have all the answers, because I think that feeling of not knowing all the answers is relatable," and referred to her interactions with students as a way to together disrupt stereotyping in their STEM pathways. Mia's identification reveals how notions of relationality can be blended in the dominant discourse of meritocracy. Emma's identification reflects a more holistic and reflexive imagination, emphasizing that mentoring is as much about building relationships and connection with students as sharing domain-specific knowledge.

Mentors' transition of roles, engendered by the AirProject activity structure, contributed to their emergent identities. We noted changes in how mentors saw themselves as STEM persons. Reflecting on the impacts of the AirProject experience on their STEM identities, some mentors shared an enhanced sense of confidence in educational and career trajectories in becoming an engineer. Participation in the AirProject prompted mentors to reconsider commitment for becoming a STEM educator, which for many of them is a renewed learning pathway. Charlotte is "thinking a lot more creatively about what I could do with my degree that might involve education and STEM together." As mentors participated in learning and teaching air-quality subjects in a collaborative, transformative context, they forged new identities, focusing on being able to "build shared understanding of what is happening and what will happen next" (Nasir et al., 2020, p. 198).

Discussion

Despite the strong interest that universities, faculty, and schools have in outreach and engagement, it is not simple to organize or to effectively implement. Our study has implications for how educators could employ innovative participant and activity structures in designing for productive STEM learning pathways, and consequently, ways to explicitly enhance the design and enactment of university-based educational outreach efforts. Our research contributes to describing how such systems can be mutually supportive of the various participants and the roles they need to play. The AirProject participant-activity structure provides an ecology that supports the learning and

development of participants along multiple pathways across roles and sites. University students learned air quality science and monitoring technology engineering; they also had the opportunity to learn how to teach within a context highly supported by university instructors and high school teachers. Mentors' learning pathways were situated in multiple sites, as they moved across university classes, self-selected sites for data collection, and high school settings. This ecology provides the time, place, context, scientific tools, and milestone events for evolving interactions, inquiries, and practices, all of which facilitated mentors' developmental pathways. Besides its benefits in concurrently scaffolding STEM learning for two communities of learners, the AirProject also prepares for a rippling effect of role modeling (Hinojosa, 2018). University instructors acted as role models to mentors as more advanced engineers and experienced educators; mentors acted as role models to high school students; and teachers acted as role models to mentors as educators. The design of this distributed activity system across university and rural high school settings provides one example of how learning pathways can be supported to provide more equitable access and participation in engineering, a field that has historically marginalized many.

Less is More: Balancing Tradeoffs in an Engineering Design Task During a Teacher Workshop

Matthew M. Johnson, Penn State University, mmj125@psu.edu
Minyoung Gil, Penn State University, mgil@psu.edu

Abstract: Despite the recent emphasis on the importance of K-12 students engaging in engineering content and practices, there has been little research done about how teachers learn engineering practices through teacher workshops and even less on how they utilize those experiences to teach engineering in their classes. Using methods of interactional ethnography, we analyzed data from an online teacher workshop in which elementary teachers engineered solutions to a multi-criteria problem in which balancing tradeoffs was a key practice. We found that teachers tended to focus on one criterion rather than both and lacked strategies to consider balancing these tradeoffs. We also found that a second iteration afforded all groups to demonstrate learning through improvement. Implications are discussed related to the importance of a focus on balancing tradeoffs in teacher learning and on pedagogy of engineering projects.

Engineering practices in Elementary Science Settings

Using engineering practices to teach K-12 science concepts is a relatively new paradigm (NRC, 2012) but offers many potential benefits as reviewed by Cunningham and Carlsen (2014), such as enhanced motivation to learn science, cognitive gains resulting from iteration (Capobianco, 2011), and enhanced problem-solving skills. Cunningham & Carlsen (2014) also advocated better understanding of how the practices manifest differently in science and engineering. A review of studies about engineering led Cunningham and Kelly (2017) to propose sixteen *epistemic practices of engineering* that are used to propose, communicate, assess, and legitimize knowledge. Among these practices are persisting and learning from failure, envisioning multiple solutions, and **making trade-offs between criteria and constraints** (Cunningham and Kelly, 2017).

Teachers trained before the *Framework for K-12 Science Education* (NRC, 2012) have no engineering experience, so they require professional learning opportunities. Particularly in engineering, it is recommended that teachers first experience design activities as a learner (i.e. "the student hat") and then have time to reflect on the problems and opportunities teaching it may present (i.e. "the teacher hat") (Sargianis et al., 2012). Changes in teacher practice have been demonstrated when science professional development has been focused on pedagogy (Enderle et al., 2014). Increases in teachers' learning about nature of science, self-efficacy for teaching and improvements in teaching have also been shown when teachers engage in the science practices (Sadler et al., 2010). However, teacher learning of the practices of engineers has so far been understudied.

Theoretical Framework

We approach this study with a sociocultural understanding of classroom work. It is guided by empirical studies of professional scientists and engineers. We also view the teacher learning through the lens of professional vision, where they learn to teach through interactions with instructors and as they get practice in the classroom.

Studies looking closely at the professional practice of STEM professionals (i.e. "science studies") give us insight into the ways in which disciplinary experts create knowledge. These epistemic practices are constructed socially, are situated in activity, rely on prior discourse and/or artifacts, and matter to what counts as knowledge (Cunningham & Kelly, 2017). Teacher learning is also sociocultural as they develop a professional vision. Goodwin (2015) describes how members of a profession learn discursive practices by observing phenomenon in a specific context, then marking or highlighting the specific aspects that are salient and producing representations of these practices. In learning to teach, teachers must first notice what is important in a teaching situation and understand why it is important. Particularly as these teachers learn new content and practices, they must consider these interactions in classroom environments and reflect on them as they gain experience teaching. Our r**esearch question was,** How and in what ways did the teachers collectively **balance the trade-offs between criteria and constraints of a multi-criteria engineering problem**?

Methods

This is the first study of a larger funded project that seeks to understand how teachers from rural school districts learn about engineering through professional learning opportunities and how they utilize local funds of knowledge

 © ISLS

to help their students make connections between their own lives and engineering. For this study, four pairs of teachers from three different buildings within two small, rural school districts in the mid-Atlantic region (~80 students per grade level) were observed engaging in engineering practices during one four-hour session of a 16 hour long professional development series. These teachers were selected for the study because they attended the school district in which they now teach, have at least 5 years' experience in teaching elementary school, and had not previously taught engineering.

Due to the COVID-19 pandemic, the workshops were changed from two days in-person to four remote, half-day sessions covering the same topics. The teachers were in pairs in a school conference room with the materials they needed to construct and test their prototypes. However, the workshop was conducted over Zoom, using Google Classroom for distributing the course materials (other than the physical material, which were delivered) and for collecting evaluation data, photos, and videos from the teachers. Our data collection and analysis are described below, but can be read in greater detail (Johnson, 2021).

On Day 1, teachers engaged in an activity called, "Perspiring Penguins" (Schnittka & Bell, 2010) to introduce them to engineering practices. The teachers designed an enclosure given a variety of materials to protect a penguin ice cube from mass loss during a five-minute exposure to a heat box, attempting to **minimize cost** and **minimize percentage of mass (of the penguin ice cube) lost**. The materials that can be more easily used to protect the penguin cost more money. Trying to minimize both cost and mass loss are in direct conflict and require balancing tradeoffs. The cost and percent mass loss were graphed, and teachers went through a second design iteration after discussing how to improve their designs. They then reflected on the steps they took to design the best enclosure possible through discussion and in an engineering journal given the criteria and constraints to consider engineering practices.

We chose to use interactional ethnography (IE) as an approach to study our research question. IE is an approach that borrows from sociolinguistics, cultural anthropology, ethnomethodology, and critical discourse analysis and is used to study cultures-in-the-making to consider the use of discourse, and actions in the co-construction of the participants' reality (Kelly & Green, 2019). This is useful in addressing socially situated talk and action, and is also a systematic approach to observational data collection that enables the analysis of locally defined and enacted roles and responsibilities that are difficult to identify using experiments, pre/post, or other techniques (Watkins et al., 2014).

To analyze, we made event maps (Kelly et al, 2001; Author, 2019) to understand the overall activity of the teachers and to identify episodes for more detailed analysis. Then transcripts were compiled by using the transcription capabilities of Zoom and YouTube and then cleaning the word-by-word transcripts by fixing mistakes and assigning speakers to the lines of text. Using the event maps to identify the interactions of interest, we then compared the interactions between the four groups to find patterns and differences. As participant observers, we got to understand the norms of the groups and typical interactions, and using audio-visual recordings, we were able to reduce the dependence on premature interpretation and reducing the importance of the observer. Discourse analysis of this type is useful for not only generalizing classes of phenomena, but also about the unique properties of individual instances (Lemke, 1998). A more detailed description of methodology can be found (Author, 2019).

Findings

Based on the interactions we analyzed relating to balancing trade-offs, we argue two potentially important claims.

1. In the first iteration, none of the groups demonstrated strategies for, or an emphasis on balancing tradeoffs, as they focused either on cost or performance, but not both.
2. In the second iteration, they were able to compare their designs to others, and all demonstrated improvement through a focus on balancing tradeoffs between criteria and constraints.

Designing an enclosure for an ice cube penguin that prevents melting but minimizes cost is fundamentally at odds. We were interested in how the teachers approached this challenge and which strategies they used to balance these competing criteria. During the initial design, the four groups exhibited three distinct approaches. Nikki and Heather focused almost exclusively on keeping cost as low as possible. They decided they only wanted to use a reflective "roof" to protect the ice. They tested each of the materials to see which would be the most effective at reflecting the incoming radiation from the heat lamps. After comparing aluminum foil and mylar, they decided to compare the relative value of adding a second layer of foil. In this interaction with the facilitator (Walter), Nikki emphasizes this point:

> 24:11 – Heather: So one liner is 125 [dollars] and two for 250 [dollars]. So if one layer is best, that's what we want to go with.

After testing, they determined that there was minimal value to a second layer and used one layer for a total of $125.

> 27:44 – Walter (facilitator): Alright, so you're going with a pretty minimal design trying to benefit most on cost, right? And that was based on the evidence you collected?
> 27:54 – Nikki – Yes. Less is more.
> 27:56 – Walter – Less is more in your test. Okay.

However, in the group from the other school in the same district, Jared and Bea emphasized the criteria of preventing the penguin from melting. Their design cost $700 (compared to the first group's cost of $125).

> 35:45 – Jared – You want a piece on the box. Something on the bottom because that felt that's in there is going to be hot and we're going to set it [the device] on it [the felt]. So you don't want a piece of foam or something on the bottom. Yeah, maybe this is going to be pricey. We're going to be expensive, but we're going to save our penguin!

The other two groups focused more on function than Nikki and Heather, but more on minimizing cost than Bea and Jared. In fact, an interesting conversation between Paris and her facilitator Wendy arose about the relative cost of their device. (Note: It is important to keep in mind that there was no maximum cost of the device, and the groups were in different locations so they were unable to compare their costs.)

> 46:55 – Paris – We're expensive. Yeah. 192[$] Okay, so we were. We just had to measure everything and calculate everything out and we're expensive!
> 47:07 – Wendy (facilitator) – It's ok, sounds good. I don't know. You'll like compare your costs versus how much your penguin lives and you'll see that there's like a balance and then you'll try to improve your balance when you get to the next iteration, so it's all good.

After testing the four initial prototypes and plotting them on a scatterplot (Fig 1), groups were given the opportunity to improve their design. Three of the groups focused on finding ways to decrease the cost of their original design without sacrificing much in its ability to save the penguin. Group 2 from Athens focused on ways to decrease the cost by identifying expensive materials while still providing insulation for the ice cube. Jared described the process:

> 56:50 – Jared – So, um we're going to try to eliminate the things that we think probably were not as effective, but also the things that were expensive. We lined the bottle on the bottom with the cotton balls. We put 10 cotton balls in the bottom to try to keep some of that heat from coming up. Uh, but they're 30 dollars a piece so we ten of those so that's three hundred dollars, so if we can get rid of a few cotton balls maybe, and maybe make our base that [the penguin] is sitting on a little smaller that could decrease our cost.

Figure 1 is a graph showing the changes for each of the four groups. With a multi-criteria problem like this with even emphasis placed on both cost and percent loss, improvement is shown by any movement that decreases the distance to the origin of the graph (i.e., $0 and 0% is the theoretical best score). All four groups improved, although Athens2 improved the least. The arrows point from the first iteration to the second.

Conclusions and Implications

Our findings suggest that without an emphasis on and strategies for balancing tradeoffs in teacher workshops, both teachers and their students will miss a key practice of engineers (Cunningham & Kelly, 2017; Madhavan, 2015). Three of the four teacher groups focused on cost, and three of those groups thought their designs were "expensive" because they did not know what the other groups spent and were not given a maximum cost. However, when given the opportunity to improve, each of the groups' designs better balanced the tradeoffs, a demonstration of learning. This strengthens the argument that learning can be demonstrated through improvement in engineering (Capobianco, et al, 2011; Author, 2019), and that this learning should be assessed because most engineering education projects do not provide reliable evidence of learning (Svihla & Petrosino, 2008)

Among the many engineering practices outlined by Cunningham and Kelly (2017), the idea of balancing tradeoffs is among the most consequential from a pedagogical standpoint. As opposed to scientific inquiry, where the goal is progress toward "truth" (Cunningham & Carlsen, 2014), the contextual nature of engineering design means that there is not one correct answer. Further, the teacher or curriculum designer can completely change the activity by altering the criteria/constraints. Performance can be weighted more heavily than cost. Cost can be limited by a maximum amount in which students might use extraneous materials as long as they don't reach that maximum, but cost can also be minimized. However, to be able to lead engineering activities in elementary settings, teachers need to first experience this practice, reflect on it as a teacher, and develop strategies to support student learning (Sargianis et al., 2012). Our next analyses will investigate closely these workshop teachers as they teach engineering and help their students navigate the engineering practices like balancing tradeoffs.

Figure 1
Each group improved in the second iteration because the points are closer to the graph's origin

Care and Complexity: Designing for Holistic Understandings of and within a Pandemic

Abstract: The COVID-19 pandemic spans multiple systems and dimensions – social, scientific, emotional, and axiological. This paper describes the collaborative design process of an elementary-age program addressing COVID-19, systems thinking, and photography from this multi-dimensional perspective. With the COVID-19 pandemic as both curricular content and design context, an educational design emerged that includes care as the centerpiece of both design structure and process. Using an ethnographic approach, we outline the evolution of the curricular theme – from relationships, to protection, to care – and how this theme is realized in our design. Through a perspective of care, we consider what it means to include socio-emotional elements in systems thinking, specifically axiological considerations. This paper contributes to the need for educational designs that consider COVID-19 from multiple dimensions, to understandings of how collaborative processes can shape design, and to (re)theorizations of systems thinking in the learning sciences.

Introduction

The effects of COVID-19 have cascaded throughout nearly all aspects of our lives – some anticipated, others unpredictable. Global and local systems are responding to the pandemic's effects on the economy, healthcare, education, and individual well-being. To think critically and adapt in the pandemic necessitates systems thinking to make sense of the interrelated and emergent phenomena arising from COVID-19. The pandemic reaches into social, scientific, emotional, and, we argue, axiological (i.e., pertaining to ethics and values) spheres. This paper describes the collaborative design process of an elementary-age (8–11-year-old) informal curriculum addressing COVID-19, systems thinking, and photography from this multi-dimensional perspective.

The Care and COVID curriculum attempts to weave together multiple dimensions of the COVID-19 pandemic – spanning from individual to global systems. Care and COVID was designed during the pandemic, almost entirely over Zoom, a context that fostered unique perspectives for design that shifted with the collaborators' personal reflections of relationships, protection, and care in the pandemic. The inclusion of zoonotic disease science concepts, multi-dimensional systems thinking, and photography intends to engage learners with concepts of agency, ethics, and care. Care and COVID underwent three thematic shifts in our collaborative design process, outlined in this paper, that refocused the curriculum from what and how we protect from COVID-19 to why we should protect ourselves and others from COVID-19. The curriculum has not yet been implemented with students, with plans to do so in Spring and Summer 2022.

The goals of this paper are to describe the evolution of the Care and COVID design, how the contribution of multiple voices led to the theme of care, and to describe our emergent design conjecture, that attending to care in design may bring socio-emotional, and axiological dimensions into systems thinking. This paper presents the design process and elements of our first iteration of Care and COVID that reflect a multi-dimensional approach to systems thinking, offering a possible (re)theorization of systems thinking within the learning sciences as well as an understanding of how collaborative processes may shape such design.

Theory

The COVID-19 pandemic and our potential entry into a "viralocene" (Kristensen, 2020) present urgent imperatives for us to make sense of the complex relations and interconnections involved in emerging disease systems while imagining new forms of resilience with/in them. The pandemic reminds us of the intricate, mutual inextricabilities among environmental destruction, viral mutation, and multi-species relations, to name a few. The learning sciences have long attended to such forms of biological complexity and relationality in terms of *systems thinking*. Diverse approaches to systems thinking within the field share a general commitment to investigating and supporting reasoning about complex phenomena in ways that attend to multiple factors interacting across a wide variety of micro- and macro-scales (e.g., Hmelo-Silver & Azevedo, 2006; Penner, 2000; Resnick, 2006; Sabelli, 2006). Most approaches to systems thinking focus on rational-cognitive forms of understanding emergent processes (Resnick, 1996), system elements and dynamics (Chandler & Boutilier, 1992), and structure-behavior-function relations (Hmelo-Silver & Azevedo, 2006). While these remain important, the lived poignancies of the current pandemic – as both context and content of our design project – have made visible some of the affective and axiological lacunae within predominant approaches to systems thinking.

The pandemic's impacts on education have brought into frame fundamental questions about the relationship between learning and what it means to care for one another. Because of this, we also theorize our

 © ISLS

emerging curriculum design in terms of *care* as described by Hobart and Kneese (2020) as "strategies for enduring precarious worlds" composed of an "affective connective tissue" formed by "a relational set of discourses and practices between people, environments, and objects that approximate… 'empathy,' 'sympathy,' or 'fellow feeling'" (p. 2). This turn toward theorizing care beyond the strict locus of the individual to "span a breadth of localities: selves, communities, and social worlds" (Hobart & Kneese, 2020, p. 2) resonates with the cross-scalar holism of the systems turn in learning sciences while better disclosing the socio-emotional and axiological dimensions of complex systems.

Methods

The designers of *Care and COVID* co-developed the curriculum within the context of a broader participatory-design partnership (Bang & Vossoughi, 2016; DiSalvo et al., 2017). The partnership includes racially, geographically, and professionally diverse formal and informal educators serving rural, historically non-dominant communities, as well as university educators and researchers. We aim to contribute to the diverse and emerging approaches to participatory work in the learning sciences by responding to the research question of how the curriculum's core thematic focus has developed and refined over time through co-design. We aim to provide an ethnographic account (Erickson, 1984) of the curriculum's history (and imagined future) that interrelates: (1) analysis of records and artifacts from our design process, (2) our own evolving theoretical perspectives on what it means - or could mean - to support the development of systems thinking about the pandemic, and (3) reflections on the evolution of our own collaborative relationships and processes. Our data include collaboratively produced notes and written reflections spanning nearly a year, as well as fieldnotes and Zoom recordings of design meetings.

Members of the *Care and COVID* design team met for one hour weekly between February 2021 and April 2022 and completed asynchronous tasks outside of meetings. Early stages of design included consultation with teaching artists, medical practitioners, and advisory members. Over this period, the design team was tasked with developing a 10-hour curriculum. From initiation, the design team believed that centering the curriculum around a systems-focused theme may support elementary-aged learners to elucidate systems thinking. The development of this theme – beginning with relationships, then evolving to protection, and ultimately coalescing around care – highlights a shift in our design team's thinking about the intersection of photography, systems thinking, and the COVID-19 experience. We describe the evolution of our design below, a process that leads us to conjecture that attending to care may bring socio-emotional and axiological dimensions into systems thinking and that photography may engage students in acts of caring.

Design evolution: Relationships, protection, and care

Relationships

Early design sessions of Care and COVID, beginning in February 2021, included open brainstorming around photography, visual literacy, and the COVID-19 experience. The social heteroglossia (Bahktin, 1981) was evident as the six initial design team members had a wide variety of professional and educational backgrounds, spanning K-12 education, adult education, science and art education, research, and healthcare. Participants were excited to leverage the arts to engage learners in acts of storytelling, especially in regard to the inequities of healthcare and COVID-19. Each weekly meeting was abuzz with ideas, constructed from the diversity of voices and personal pandemic experiences. Challenged to include COVID-19 disease science, photography, and systems thinking in the curriculum, the design team grappled with how to connect these topics in a way accessible to elementary-aged learners. Our own emotional and relational experiences with COVID-19 surfaced and revealed the many ways we tried to relate to one another. As a result, relationships became the beacon not only for our work as a team, but for our curriculum as well.

We saw the theme of relationships as one that could bridge curricular needs across photography, systems thinking, and COVID-19. We viewed relationships as a potential way to include multiple dimensions of COVID-19 systems, including socio-emotional perspectives. Specifically, the design team included a focus on students' relationships with their own bodies, families, and communities, as well as their trust and distrust of healthcare and information. We then employed photography as a way to elicit and communicate relationships and emotions. By March 2021, initial drafts of the curriculum included three segmented foci – relationships with self, relationships with communities, and relationships globally – specifically attending to how COVID-19 interplays within and across these scales. This curriculum structure - having students consider relationships at varying scales - became a fixture in Care and COVID that remained throughout design. At each level, photography became the anchor

through which learners could explore COVID-19 relationships in both affective and scientific ways, and a medium to express, compare, and contrast their lived experiences with their peers. An activity at this stage of design prompted students to take photographs of playgrounds in the pandemic to explore their personal and their community's relationship to these shared spaces.

Protection

In June 2021, the *Care and COVID* design team shifted from six to four members as two community educators opted not to extend their involvement beyond the initial commitment. The remaining four team members included the principal investigator, two graduate students, and one community educator with expertise in arts education. At this time, the *Care and COVID* curricular theme shifted from relationships to an agentic focus on protection. The shift to protection was prompted by a desire to move into action surrounding COVID-19, rather than only analyzing COVID-19 connections and impacts. We wanted to empower students as agentic members of their communities and society with valued stories about protection to be shared through photography. For example, the design team co-designed a lesson positioning students as community protectors. Here, students take self-portraits as protectors in their community, tapping into their own stories and understandings of what protection looks like. Prior design work around relationships ensured that the theme of protection was not exclusively scientific (e.g., learning about how masks reduce transmission), but also included social elements of resilience around COVID-19 (e.g., examining healthcare access in rural communities). We viewed protection from COVID-19 as relational, encompassing the previous theme, with individuals relating to themselves, their communities, and society through protective action. We embraced protection as an expansive concept, reflected in our design by moving students from activities about individual protection, to community protection, to societal protection – keeping the structure originally implemented with the theme of relationships. For example, a curricular feature on the societal scale has learners create photo narratives of protection (or lack thereof) to tell stories of systemic assets or barriers to protection. These stories come from their own notions and ideas of what protection can and should be, and allows for the overlapping of individual, community, and social protections.

Care

In October 2021, *Care and COVID* underwent its most recent thematic shift when the design team collectively reflected on the essence of the overall curriculum. Initially focusing on relationships, and then protection, the notion of care ultimately solidified as the curricular theme. We view the current theme of care as a transition to not only explore *what* and *how* we protect, but also *why* we should protect ourselves and others from COVID-19. This axiological shift in the curriculum encourages students to value their own lives and the lives of others and to consider which actions represent care. For example, one activity has students write, act out, and photograph skits depicting what it looks like to care for the preciousness of their lives, specifically the preciousness of their health, bodies, and families. Throughout the curriculum, students explore acts of care through theatrics, self-portraits, and photo narratives. *Care and COVID* positions art as an empowering, accessible, physical, and emotional way to care for others, to engage in multi-scalar systematic care through photography and storytelling.

The design team also notes care as integral to our co-design process. The design of *Care and COVID* has occurred during the COVID-19 pandemic; care for ourselves and for each other has been imperative. We ask and listen to each other, we adapt to the needs of team members, and we bring empathy to the forefront of our design conversations. Maintaining the heteroglossia of our team has become a collective act of care throughout our design process. The focus on care within our design team has allowed each of us an opportunity to voice our passions and diverse expertise in design.

Conclusion

The evolution of *Care and COVID*'s design theme, from relationships to protection to care, represents an expansion from solely cognitive to also include socio-emotional and axiological dimensions of COVID-19 systems. Our team is exploring how these dimensions, when integrated into systems thinking, can give learners a holistic understanding of a phenomenon, in this case, protection from COVID-19. Through our co-design process, we identified care, focusing on the protection of oneself and others on multiple scales, as one way to bridge the many dimensions of COVID-19. Using photography, we are exploring the integration of the arts as an act of care; we are exploring how to support learners with tools to personally make sense of COVID-19 and to care for themselves, and others, through their art.

Future work will investigate the implementation of *Care and COVID*. We will examine how the curriculum does or does not support learners in considering COVID-19 systems from multiple dimensions. We

wonder: How does the inclusion of care in design support multi-dimensional understandings of systems thinking across socio-emotional and axiological spheres? What role does arts-integration play in expanding the dimensions through which students understand systems? We conjecture that design centered around and within care, utilizing strategies of arts-integration, may support students in developing holistic understandings of systems on multiple scales and in multiple dimensions.

Abstract: One way to help develop foundational computational literacy skills for K-12 students is to integrate computational thinking (CT) into science and math, but teachers have struggled to implement CT. This work investigates secondary science and math teachers' CT outcomes as they engaged in a four-week summer institute. This study uses conjecture mapping to inform iterative design, implementation, and evaluation of the institute over two years. This paper characterizes teacher learning outcomes and the specific aspects of the institute design that led to those outcomes. Findings suggest the institute's design led to increased CT knowledge and confidence in CT. Specifically, teacher outcomes were supported by teachers' engagement as learners in discussion, reflection, and interaction with computational tools. Challenges encountered were used to inform redesign and a second implementation.

Purpose

Computational tools and methods are increasingly important in STEM disciplines. As such, it has become important to include computing in K-12 science education, both to enable students to understand the science, and to develop foundational computational literacy (Wilensky et al., 2014). One way to achieve this is to integrate computational thinking (CT) into core classes, such as science and math. CT, as conceptualized by Papert (1980), described the process of thinking about a phenomenon through using, creating, and constructing computational tools. While the potential benefits of CT integration with science and math are evident, teachers have struggled to design and implement CT in their classrooms. Several barriers impede CT's uptake such as lack of appropriate technology and infrastructure, teachers' limited experience with CT and computing, limited time to teach content, and limited professional development resources (e.g., Aljowaed & Alebaikan, 2018). Thus, it becomes increasingly important to support teachers in learning about and implementing CT. Our research team has worked with teachers to integrate CT into science and math classes for several years. Our approach has evolved from researcher-designed units to complete co-design with teachers. This co-design took place in 2019 during a four-week summer institute (CTSI), which also included workshops to support learning about CT, how to integrate CT, and how to teach CT. The research is guided by the following research questions. After a four-week summer institute where teachers engaged in workshops and co-design, 1) What were the teacher learning outcomes? And 2) How did the summer institute's design mediate teacher outcomes?

Framework

Table 1
Initial PD Conjecture Map About the Design of the 2019 PD

Conjectures	Embodiment	Mediating Processes	Outcomes
Teacher engagement in workshops and co-design will lead to learning about CT and how to integrate CT.	Workshops in which teachers participate in lessons about CT. Co-design in which teachers worked with researchers.	Interacting with computational tools Designing and creating computational tools	Learning about CT & computational tools Learning about how to integrate CT

Conjecture mapping was used to investigate how the design of the summer institute led to teacher learning outcomes (Sandoval, 2014). Elements of a conjecture map specify how the design of a learning environment enables desired outcomes. Conjecture maps consist of high-level conjectures (initial ideas about supporting learning through the learning environment), embodiment (the learning environment design elements), mediating processes (the activities and/or interactions connecting the embodiment and desired outcomes), and outcomes (the

 © ISLS

desired outcomes of the learning environment). Project researchers made an initial conjecture map before data analysis, which was then used to test design ideas, and data was used to refine the conjecture map. Table 1 depicts the initial conjecture map of hypothesized connections between design and outcomes.

Methods

The summer institute

The summer institute was four weeks with eight teacher participants. During the first week, teachers participated in workshops aimed to help them understand CT and its integration. Workshops included engaging the teachers as learners in several exemplar CT integrated lessons. The subsequent three weeks were dedicated to co-design where each teacher worked with one researcher to design new CT-integrated science and math units. More details about the summer institute are described elsewhere (Wu et al., 2022).

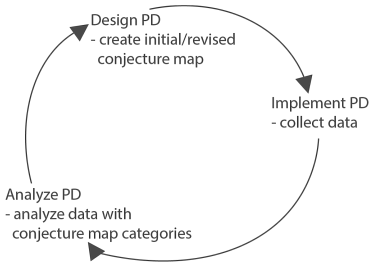
Data sources

Multiple data sources were collected throughout the summer institute. At the end of each week, the teachers filled out a reflection form to provide feedback. The group also discussed aspects that went well, aspects that were challenging, and goals for the next week, which was followed by a weekly exit ticket that each teacher filled out. At the end of the summer institute, teachers completed a post survey and a 45-minute semi-structured interview where they discussed their experiences. Audio and video recordings of the workshops were also collected.

Analysis

We utilized conjecture mapping design cycles to first identify desired professional learning outcomes and then to guide the design, implementation, data collection, analysis, and revision of the learning experience (Figure 1). We developed an initial conjecture map to plan and design the learning experience (Table 1). This qualitative study to investigate the how the learning experience contributed to outcomes took place through several rounds of inductive and deductive coding with triangulation between data sources (Miles et al., 2014). In the first round of coding, we investigated data sources to identify outcomes. Next, authors one and two coded data for connections between the identified outcomes and specific design elements (embodiments) and how they led to the outcome (mediating processes). These findings were used to modify the conjecture map to represent the actual learning experience implementation. A third round of coding was implemented to identify issues and areas for improvement that arose during the learning experience implementation. The refined conjecture map based on implementation data was used to redesign the learning experience.

Figure 1
Conjecture Mapping Design Cycle



Results

Teacher learning outcomes

Three categories of teacher self-reported outcomes were identified through the qualitative analysis: 1) Learning about and how to use CT tools, 2) Learning about pedagogy to support CT integration and scaffolding, and 3) Changes in values and attitudes regarding CT. Table 2 shows examples coded for each outcome. These results indicate the summer institute led to positive outcomes in teacher learning and shifts in values and attitudes.

Table 2
Teacher Learning Outcomes

 © ISLS

Outcome	Quotation Example
Learning about and how to use CT tools	"I learned a lot about how to program NetLogo, as well as how to use various computational tools effectively in instruction" (Derick, Post CTSI Survey).
Learning about pedagogy to support CT integration and scaffolding	"Brainstormed new ideas for modeling the unit, interesting ideas for models that I wouldn't have thought of, like pulling in the data snapshots to model and having students place sensors" (Lacey, Post CTSI Survey).
Changes in values and attitudes regarding CT	"I have really learned a lot and will be more confident using CT with the students. I think I may even be able to do a little trouble-shooting and be less reliant on the team that observed my classes." (Tracy, weekly reflection 7/25)

Design mediated outcomes

The initial conjecture map was refined based on teacher responses, and then used to investigate the connections between outcomes and the summer institute design (Table 3). The Embodiment column describes the workshops and co-design teachers engaged in during the summer institute. The Outcomes column shows the outcomes identified from the data in the prior section. The Mediating Processes column describes the processes teachers engaged in during the embodiment that led to the outcomes. For example, when teachers engaged as learners in a workshop session (embodiment), they interacted with computational tools (mediating process), which led to learning about CT and computational tools (outcome).

Table 3

Conjecture Map for the design of the 2020 PD

Conjectures	Embodiment	Mediating Processes	Outcomes
Teacher engagement in workshops as learners followed by explicit reflection leads to learning about CT and changes in perceptions of CT.	Workshops in which teachers engaged as learners.	Answering questions in the CT-STEM units	Learning about and how to use CT Tools
	Workshops in which teachers reflected on pedagogy, CT content, science content, and planned their unit design.	Interacting with computational tools	Learning about pedagogy to support CT integration and scaffolding
Co-design allows for learning about CT and changes in perceptions of CT.	Feedback from other teachers and STEM experts.	Discussions	Changes in values and attitudes regarding CT
	Co-design in which teachers worked with researchers.	Designing and creating computational tools	CT-integrated units

Four mediating processes were identified within the data: 1) Answering questions in the CT-STEM units, 2) Interacting with computational tools, 3) Discussions, and 4) Designing and creating computational tools. The video data provided evidence of connections between mediating factors and outcomes, thus triangulating the various data sources. The connections between mediating processes and outcomes suggest the design of the summer institute led to teacher learning and changes in values and attitudes regarding CT. The overall conjecture map led to the development of two major conjectures about the design of the summer institute. First, teacher engagement in workshops as learners followed by explicit reflection leads to learning about CT and changes in perceptions of CT. Second, co-design allows for learning about CT and changes in perceptions of CT.

Although the 2019 summer institute led to several important outcomes, teachers did experience challenges and tensions. Some teachers felt unprepared to pick a unit topic after the first week. Teachers felt that workshops and design time could have been better interwoven to allow for reflecting on how to incorporate the ideas in their context. The red text in Table 3 represents new additions to the PD for the following year (2020). To address challenges, we began co-designing and planning earlier in the PD and allowed for reflection and planning with each workshop. To facilitate discussion and feedback, we added several sessions where teachers discussed their units with each other and with STEM professionals outside the project.

Findings presented elsewhere showed the 2020 teacher participants experienced similar outcomes, such as learning about CT practices, CT tools, and how to teach with integrated CT (Wu et al., 2021). Teacher's 2020 workshop reflections indicate they appreciated receiving feedback from STEM professionals. "Loved the feedback from the three-four people I spoke with. Loved connecting with a post-secondary professor to discuss some missing pieces when vertically building awareness in skill and content planning" (Matthew, 2020 Workshop Reflection). Similarly, teachers valued feedback from other teachers in the institute. "The team feedback and cross-team feedback were incredibly valuable" (Kathy, 2020 Post CTSI Survey). After the first week of the institute teachers were asked what went well, and several teachers indicated the time spent brainstorming along with workshops was beneficial. "I feel very accomplished with the brainstorming that [Jack] and I have begun. Looking forward to getting started next week!" (Jeremy, Week 1 Exit Ticket). These responses indicate the modification to include planning time earlier in the institute was helpful for teachers. Teacher participants in both summer institutes (2019 and 2020) successfully co-designed and implemented CT-integrated science and math units. Full units are available on the project website (ct-stem.northwestern.edu).

Discussion

Our research builds on and extends existing literature (Hestness et al., 2018, Yadav at al., 2014) by connecting the design of a learning environment with teacher outcomes through specific embodiments and mediating processes, adding to the literature knowledge about how to support teachers in learning about CT and feeling confident with teaching CT. Significant outcomes identified in this research also suggest that the summer institute addressed some of the barriers to implementing CT in schools, such as limited computing experience and limited professional development resources. Findings suggest the workshop design (engaging as learners, discussion, reflection, interaction with computational tools) led to increased CT knowledge and confidence in CT, which prepared the teachers for co-design. Co-design of new CT integrated units supported learning about CT tools and how to integrate them and increased confidence with CT through discussions, interactions with computational tools, and the design and creation of computational tools. Co-design pathways and cases of specific co-design approaches are detailed elsewhere (Kelter et al., 2021).

Navigating Moments of Tension and Uncertainty in Co-Design of University Curriculum

Sharon Lin, California State University, Fullerton, sharonlin1129@csu.fullerton.edu
Gavin Tierney, California State University, Fullerton, gtierney@fullerton.edu

Abstract: Student co-design promotes an alternative educational structure where students are involved in the classroom design process, honoring students' agency in their learning. However, co-design differs from other design processes because it is a largely collaborative and symbiotic process where groups of designers and facilitators are required to work collectively while navigating disagreements and tension. Due to the unique nature of the co-design environment, moments of tension and uncertainty are common in the design process and can potentially interfere with group productivity. Common examples of tension that often impede designers from progressing include uncertainty of how to move forward or disagreements in creating the design product itself. Through data gathered from a co-design journey involving college students working on redesigning an undergraduate education course, this paper illustrates the design processes needed to navigate moments of uncertainty and tension during co-design to ultimately achieve a collaborative and authentic design outcome.

Major issues addressed

Co-design is a design process in which designers collaborate as participants in the creation of a design product. Our paper focuses specifically on student co-design, a design process involving university student designers redesigning an undergraduate university course curriculum. The collaborative nature of co-design allows for the potential of designers' experiences and insights to be equally valued and heard, disrupting the usual hierarchies that exist in curriculum design (Iversen, Smith, & Dindler 2017; Tierney, Horstman, & Tzou, 2021). Such a process not only creates a product that is reflective of the most important components of the course curriculum but also one that is also most authentic to the designers (Pitt, et al., 2019; Tierney, Horstman, & Tzou, 2021; Yip et al., 2017). However, because co-design relies on group work and healthy collaboration to be successful, unity and productivity among the designers is crucial. Yet, it is unrealistic to expect disagreements and uncertainty to never arise in group work, creating a need for processes to navigate these scenarios. Our research questions for this work are: In moments of tension and uncertainty, what are the different ways designers and facilitators resolve tension or uncertainty? In what ways does tension positively and/or negatively impact educational co-design (put another way, is tension in co-design necessarily a bad thing)?

Potential significance

Other studies of co-design have acknowledged its effectiveness in education and design (Camino & Zeldin, 2002; Tierney, Horstman, & Tzou, 2021; Yip et al., 2017). However, despite the praise that co-design receives, there is a lack of research regarding its processes. Specifically, there is a need for research that outlines the processes required for successful co-design to occur. While this paper contributes to education research in general, it specifically contributes to literature in Learning Sciences focused on design stakeholders and design processes. This paper highlights the nuanced practices of facilitation and group work during co-design. Through the approach to co-design used in this study, participants' perspectives and experiences are incorporated in ways that impact the design and redesign of learning environments. Without attuning to how facilitators and groups operate during co-design, student co-design can run the risk of reifying hierarchical power dynamics when students are involved in performative ways that do not incorporate their voice or remediate the historically marginalized roles within education (Camino & Zeldin, 2002; Giroux, 2009; Kirshner, 2015; Tierney, Horstman, & Tzou, 2021; White & Wyn, 2013). Through our data, we identified some critical components in the actions of designers and facilitators in navigating moments of tension and uncertainty. We also examined whether all tension is a disruptive force and found that productive tension can be an asset that design groups should not try to avoid. These findings offer guidelines for both facilitators and designers to resolve moments of tension and uncertainty.

Theoretical approaches

In our design work and in this paper, we take a sociocultural perspective on student co-design, in that we view participation and learning as an interaction between individuals (in this case university students and faculty) and the contexts in which they participate (Holland, Lachicotte, Skinner, & Cain, 1998). The process of learning, while a different conceptual category, cannot be separated from the process of emotion, belonging, or identity development (Nasir, Roseberry, Warren, & Lee, 2006). We also used communities of practice (Wenger, 1998) as a theoretical frame of how individuals participate within learning communities, examining the ways in which participation shifts over time in a community of practice.

Goals, values, and practices are in part inherited from the history of the group and its domain of practice, both from the individual histories of its members across various social worlds and through their ongoing negotiation within a community of practice. Different members of a community have different positional identities, with different kinds and levels of influence over the group's activity (Holland et al., 1998; Holland & Lave, 2001). So too, the identity and learning of the community, as a collective, shifts over time. We used Wenger's (1998) concept of "joint enterprise" to capture ongoing negotiations of a co-design group's sense of itself, what binds members to the group, and what they accomplish together. Group members' participation in the group both determines and is influenced by this sense of "what we are about." To this we add the construct of *productive friction* which Ward et al. (2011) defined as "dissonance… when two or more social worlds conflict that leads to more sophisticated practice" (p. 14). In our analysis, we use productive friction to understand moments of tension in the design process, negotiating new practices, and directions in joint enterprise.

Methods and data sources

This work was set in the context of a university aiming to transform its education courses by centralizing just, equitable, and inclusive education. Due to the pandemic, all design sessions were conducted online over the conferencing application, Zoom. All documentation of the design process was also recorded virtually, using Zoom audio and video recordings. The designers also used Miro, an online whiteboard that was captured and saved after every design session. The design team consisted of six main designers (Katherine, Jeff, Mitch, Hannah, Vanessa, Chrissie), three feedback groups (in which Author one, Sharon, participated), and one facilitator (Author two, Gavin). All designers, including those in the feedback groups, had taken the Adolescent Development course with the facilitator, Gavin, as their professor in the past two years. This paper examines the behaviors of the six main designers and the facilitator as they redesign the undergraduate Adolescent Development course.

Because all meeting sessions occurred over Zoom, ten sessions of video and audio data were collected. Miro, the virtual whiteboard the design team used, was also documented at the end of every session. Qualitative data analysis occurred in four coding phases: open coding, focused coding based on research questions, writing analytic memos looking in and across codes and data, and generating hypotheses. We used initial qualitative coding and analytic approaches that are inductive and abductive – grounded theory (Corbin & Strauss, 2008). Open coding of participants' own words was conducted to examine how participants co-constructed the design space and the norms and practices within. The videos that were analyzed were chosen based on the amount of significant changes that occurred on the Miro whiteboard. The sessions where the most changes occurred on the whiteboard signified shifts in practice (compared to refining already established practices) and so were chosen to examine potential tension during those shifts. The videos were also analyzed in chronological order to preserve the linear co-design process. Video and audio recordings of the design sessions were analyzed by looking for recurring themes or actions taken by members of the design team. Those themes and actions were translated into codes, grouping similar moments together. These moments in the design process were then reanalyzed through the lens of tension and uncertainty, pinpointing moments where disagreement and confusion arose.

Major findings

Through data gathered during the design sessions, we identified three processes that focused on addressing tension and uncertainty in the co-design environment: 1) Facilitator Guidance, 2) Community Building, 3) Productive Tension. Two of these findings deal with the resolution of tension and uncertainty, while the third relates to the nature of tension and uncertainty, assessing whether these moments are necessarily unproductive.

Facilitator guidance

Facilitator guidance is an integral part of navigating tension in co-design due to the facilitator's ability to act as a guide for the designers. How facilitators provide guidance is essential in moments of tension or uncertainty because they are usually the person with the most knowledge on both the subject matter and the co-design process. As such, this kind of *deeper knowledge of content and design process* can help designers find their way out of tension. One example of this occurs when the design group is introduced to some changes that a feedback group had made on their Miro board in design session five. The feedback group had previously left comments on the group's Miro whiteboard for them to consider. Gavin offers the group multiple ways to alter the Miro board based on their feedback. Ultimately, Gavin leaves the final decision up to the designers. This example demonstrates the benefit of experience and knowledge in the design process. Because Gavin has more insight in the design process and the subject matter, he can guide the group, giving them options on how they should proceed. With his expertise, the design group is shown possible routes to incorporate new information into their design, aiding the group in finding the best way forward. This moment is also significant due to Gavin's leaving the decision up to the designers, providing a space for the design team to negotiate their joint enterprise. Here, he demonstrates that facilitators should be involved in the design process, but that designers should make the final decision to ensure an authentic design product.

Another form of facilitator guidance is their *perspective as a meta-designer*. Student designers often become so involved in the design process that they can no longer see the bigger picture or produce new ideas capable of pulling them out of disagreements and confusion. Facilitators can thus bring new perspectives, aiding the designers in pivoting their thinking. An instance where the facilitator uses their perspective as a meta-designer occurs when the design group is introduced to the idea of equitable and inclusive education (JEIE) in session six. As the designers take some time to look over both the ideals of JEIE and their Miro board, they struggle to combine them. When Gavin asks the group how they would merge these ideals into their Miro whiteboard, he is met with no response. Eventually, Hannah asks, "Um, do you mean incorporating JEIE towards the principles that you've brainstormed and added, or towards what we've done already?" Then Katherine comments on the challenges that connecting JEIE to their Miro board might pose: "I feel like we will struggle less putting JEIE into some constellations, whereas others like Biological Development…we might struggle a little more." Noticing their confusion, Gavin offers the designers a question to redirect them: "Are the ideals of equitable and inclusive education central in the Adolescent Development course, or are they only present?" This instance demonstrates the importance of having a facilitator who is "out of the weeds" and has a "bird's eye view" of the design process. In this instance, Gavin identifies the group's struggle between incorporating and centralizing equitable education, naming space that they are experiencing tension, something the designers may not have caught themselves. The facilitator's unique perspective led the design group to rethink their trajectory, providing an opportunity for productive friction and negotiation, eventually clearing up group uncertainty and giving them a direction to pursue.

Community building and temporary leadership

Community building primarily deals with designers feeling comfortable around each other. The goal is for the designers to feel safe offering opinions, challenging ideas, and questioning one another. Community building is vital in co-design because it increases designers' willingness to step into certain roles to guide the design group out of tension. Often, the group requires temporary leadership, allowing designers to step into roles they may not always be in, and lead the group out of tension or confusion. Feeling comfortable and safe in a creative environment also allows designers to take risks, leading to more creative and innovative design outcomes.

A moment that illustrates how roles centered in community building can be used to reduce tension or uncertainty occurs in session six when the design group struggles to organize their sticky notes in the constellation "classroom environment" while also incorporating the ideas of JEIE. The six main designers were in the process of incorporating JEIE into each of the main constellations from the original curriculum. However, uncertainty arises when the group struggles to organize their Miro board in a way that connects "Classroom Environment" with JEIE. Jeff offers his opinion and says, "I was just thinking we could take the JEIE stickies that we had and make a more direct correlation between the subject matter and JEIE." After going into more depth about his idea, he asks if anybody in the group has any ideas that may be different from his: "As long as that works for everyone else, because I don't want this to just be my own thing. Does anyone else have, like, a way they think would be better at going at it?" This moment is significant because it demonstrates how stepping into leadership roles can provide the group with direction when confronted with uncertainty. By shifting his positional identity and taking on a leadership position, Jeff changes the dynamics within the group, allowing designers to collaborate differently. Jeff also

demonstrates that leadership is not limited to decision making. Rather, Jeff opens the floor to other designers, illustrating how embodying both the leadership role and the team member role allows for more collaboration and negotiation of the group's joint enterprise. We are currently in the process of further analyzing data to identify specific processes and tools to support designers building community and taking on temporary leadership roles.

Productive tension

Productive tension refers to moments of disagreement or friction in design where the outcome does not detract from the design process but rather enhances or improves the final design product. These moments should be seen as meaningful disagreements that push the design process forward rather than obstacles. One moment that illustrates productive tension occurs in session six. Hannah brought up an alternative redesign method that works backwards to centralize equitable and inclusive education in the badge design. Hannah asks the group "I wonder, because the goal of this is to make JEIE, like, the central part, right? If we relate the JEIE stickies to the concept, and then to the stickies that we've already made?" Here, Hannah is referring to the existing "stickies" or sticky notes that the rest of the design group have previously made on the Miro board. The rest of the group reacts positively to the idea but are unsure of how to execute it. After a moment of silent thought, Jeff introduces a proposal to the group: "We kind of did that at first with the stickies we have to the side of Educator Role. We do it in a similar way in terms of putting down quick ideas of JEIE to the whole thing while we're thinking about it in a broader scope." Although Hannah's proposal led to even more confusion and uncertainty, the group acknowledged the idea had merit and worked through how they could possibly implement this process into their design. This moment is significant because it demonstrates how not all conflict or tension is unproductive. While Hannah's idea spurred more uncertainty among the designers, she also added a better method for the redesign, demonstrating how uncertainty and tension have the potential to improve the design process. Designers should not actively seek to minimize all moments of tension but instead embrace them as they arise. Risk and discomfort are spaces where original ideas come from, and we should not seek to reduce them (Heath & Smyth, 1999). However, productive tension is most effective if it is related to the design work and designers feel supported by the design group. In addition, feelings of support among the designers are essential for this type of risk-taking in productive tension to occur, which is why community building and facilitator guidance are so crucial. These aspects of the design process build meaningful relationships, increasing designers' willingness to take risks and enter spaces of discomfort and tension.

Unpacking Iteration: Exploring Forms of Iterative Practice in Physics Labs

Jason M. May, University of Utah, jason.may@utah.edu

Abstract: Iteration is pervasive in current perspectives of student reasoning, but it is also often assumed, backgrounded, or minimized in favor of other empirical interests and results, despite being foundational to reasoning processes and inquiry. This paper forefronts iterative practice while examining student reasoning in a reform-based undergraduate physics lab course. We present an instrumental case study analysis of a single student group, documenting how they engaged in micro- and macro-levels of iterative practice at the nexus of experimental activity and sensemaking throughout their experimentation. These results illustrate the nuance in students' iterative practice at different levels and prompt new questions about how different forms of iterative practice may impact student learning.

Background and Theoretical Perspectives

In the Learning Sciences, there is widespread recognition of the importance of iteration. Iteration occurs as part of student reasoning within engineering design (e.g., Smith & Tjandra, 1998), scientific modeling (e.g., Windschitl et al., 2008), makerspaces (Ramey & Uttal, 2017), argumentation (e.g., Herrenkohl & Cornelius, 2013), and experimental physics (e.g., Holmes & Wieman, 2016). However, iteration is often assumed without extensive definition or backgrounded in favor of other empirical results. For example, Windschitl et al. (2008) describe an iterative framework for scientific modeling but do not empirically investigate the iterative elements of the framework in learning contexts. Thus, we have limited knowledge about the structure of iteration and its relationship to larger reasoning processes. This paper aims to shed new light on iterative practice in student reasoning by presenting an instrumental case study analysis of students' iterative practice at the nexus of experimental activity and sensemaking in a reform-based undergraduate introductory physics laboratory course. We highlight how a focus on iterative practice may serve as a conducive mechanism for analyzing complex student reasoning in scientific learning environments.

Experimental Activity and Sensemaking in Physics Labs

We define iteration as a successive process that builds and improves upon previous outcomes of theory, design, or experimentation (e.g., Elliott, 2012). While many forms of iterative practice abound, we rely upon experimental and epistemic iteration, the processes by which scientists repeat experimental steps to improve empirical results or protocols (Collins, 1992) and successively alter and refine scientific knowledge to improve accuracy or explanatory power (Chang, 2004). These constructs help conceptualize how iteration might be prevalent in students' experimental activity and sensemaking.

We conceptualize experimental activity as a hierarchical process composed of macro- and micro-level activities. At a macro-level, experimental activity involves students carrying out broad experimental actions, such as making predictions, data collection, troubleshooting, and data analysis, in the lab setting to complete experimental goals (e.g., Wieman, 2015; Zwickl et al., 2015). These macro-level actions are composed of micro-level experimental actions, such as preparing apparatus and adjusting software parameters. Each hierarchical level can evoke iteration, whereby students repeat experimental steps to increase accuracy or explanatory power. For example, at the macro-level, students can experimentally iterate between making predictions, collecting data, and comparing measurement results to predictions to produce more accurate scientific models. At the micro-level, students engaging in troubleshooting can iterate between identifying issues with apparatus, generating and testing causes, and repairing apparatus or procedures (Dounas-Frazer et al., 2016). While prior research has documented these experimental activities in physics labs (e.g., Wieman, 2015; Zwickl et al., 2015), they often minimize iteration and implicitly obscure authentic accounts of student experimental activity.

We conceptualize sensemaking as a process of iteratively constructing and critiquing explanations and procedures to resolve inconsistencies through developing a knowledge framework, recognizing an inconsistency, and enacting sensemaking moves such as mechanistic reasoning and analogy building (Odden & Russ, 2018; 2019). Students frequently engage in sensemaking processes during both macro- and micro-level experimental activity. For example, troubleshooting involves iterating between the micro-level actions to identify and resolve procedural inconsistencies. Similarly, students often iterate between conceptual and experimental elements while

 © ISLS

sensemaking at the macro-level to recognize and resolve inconsistencies between experimental evidence and hypotheses. We suspect that students' iterative practice is simultaneously experimental and epistemic, allowing improvement of experimental results and generation of new conceptual knowledge.

We ask the following research question: In what ways do undergraduate students engage in iterative practices at the nexus of their experimental activity and sensemaking in undergraduate physics lab settings? To answer this, we examined thirteen student groups' experimentation in a reform-based undergraduate physics lab course. To provide a detailed analysis, we present an instrumental case study of a student group, highlighting their iterative practice at the macro- and micro-levels of experimental activity and sensemaking.

Research Methods

This study was conducted in an Introductory Physics for Life Sciences (IPLS) laboratory course at a large, research-intensive university in the western United States. The course was recently reformed to prioritize students' autonomous engagement in authentic scientific experimentation. Enrolled students were predominantly life science majors who planned on attending medical school. The student population was majority upper-division (86%), white (67%), and male-identifying (53%). In the course, students work in groups to complete multi-week investigations by developing research questions and experimental designs to model a biological phenomenon, conducting the experiment, and developing and presenting a scientific argument to their peers and instructors.

Data from 13 groups across four labs included screen capture data of their computers and external video and audio. We first identified macro-level categories of students' experimental activity composed of micro-level actions; for instance, macro-level data collection composed of micro-level actions of adjusting experimental equipment, reviewing technical documentation, or preparing biological samples. These categories were used to code random selections of the video data, and we refined the categories until reaching saturation. Two authors then conducted interrater reliability measurements, achieving near-perfect agreement (κ=0.83) after a single round of coding changes. The first author then coded the remaining data. Next, we reviewed the coding to identify the entry (inconsistencies) and exit conditions (resolutions) in students' sensemaking. We identified sensemaking episodes related to both micro-level procedural and macro-level conceptual inconsistencies and then examined how students worked towards resolutions. We focused on both direct sequences of actions and iterative cycles across multiple actions and searched for instances where students iterated between collecting evidence, analyzing data, engaging in mechanistic reasoning, or constructing explanations (e.g., Odden & Russ, 2018).

To provide an in-depth analysis of students' iterative practice, we present an instrumental case study analysis of iterative practice from a group of four students (Lisa, Chloe, Margo, and Edmund; pseudonyms) whose iterative practice broadly represented the data corpus. This group was chosen via intensity sampling (Creswell, 2007), as it had rich, but not extreme, evidence of iterative practice. The group's experimental activity focused on investigating whether the concentration of microspheres housed within a fluid impacted their rate of Brownian motion (i.e., random motion of particles suspended in a fluid). Specifically, the group collected and analyzed video data of microsphere samples moving in fluids to determine how the concentration of microspheres impacts their rate of Brownian motion to model how medical drugs diffuse within and between human cells.

Analysis

Micro-level Iteration

Throughout their experimentation, the case study group engaged in multiple iterations of micro-level experimental activity cycles while sensemaking to resolve inconsistencies in their experiment. These micro-level iterations typically involved four steps: *proposing causes* for an inconsistency, *planning* micro-level experimental actions to work towards resolution, *carrying out* these actions, and *assessing* the action's outcomes against desired resolution. We highlight an example from early in their investigation when the group encountered a micro-level procedural inconsistency during data collection that sparked a sensemaking process.

When preparing a microsphere sample for video collection, the group recognized a procedural inconsistency: the second sample (labeled 500x) had fewer microspheres than the first (labeled 100x), contradicting their expectation that the 100x sample had a lower concentration. This inconsistency recognition initiated the group's iterative micro-level sensemaking process, where they enacted multiple iterations of micro-level experimental activity actions in direct sequence. In Step 1, the group *proposed causes* for the inconsistency, including inconsistent mixing (Chloe: "Did I shake it too much?") or microsphere settling (Chloe: "It might have just settled."). In Step 2, the group *planned* micro-level experimental actions to resolve the inconsistency. They planned to collect a new sample of their microsphere solution more carefully from the bottom of a properly mixed vial (Edmund: "Maybe closer to the bottom … not touching the bottom necessarily but just the closest you can get without touching."). In Step 3, the group *carried out* this micro-level experimental action, preparing their new

sample according to their plans. In Step 4, the group *assessed* the outcome of this micro-level experimental action, identifying that the new microsphere sample looked "weird" and "squished" rather than evenly dispersed and spherical. Without resolution, the group completed additional iterations with similar experimental actions to resolve the inconsistency and move forward, reaching resolution with instructor assistance. When comparing this case to others in the data corpus, we found that most observed groups engaged in multiple iterations of micro-level experimental activity cycles while sensemaking about procedural inconsistencies, with variation in the sequence of steps, the role of instructor support, and the nature of the formal resolution.

Macro-Level Iteration

At a macro-level, we found that the group iterated between four steps that involved experimental activity and sensemaking to construct an explanation that accounted for experimental evidence. In Step 1, the group engaged in *experimental activity to collect evidence*, either through qualitative observation or through quantitative analysis. In Step 2, the group *compared their collected evidence to their initial experimental hypothesis*. In Step 3, students *recognized an inconsistency* between their collected experimental evidence and their initial experimental hypothesis, initiating a period of sensemaking. In Step 4, students *engaged in sensemaking* to attempt to resolve the inconsistency. After most iterations, the group would determine that additional evidence was needed for their explanation and then collect new evidence, initiating a new iteration.

Early in their experiment, the group engaged in the four macro-level steps while collecting videos of their microsphere samples, shifting from experimental activity to sensemaking through recognizing an inconsistency between their evidence and hypothesis. In Step 1, the group *collected experimental evidence* about speed and concentration by looking at the microsphere sample via the microscope camera and computer. In Step 2, the group *compared their observational evidence with their initial experimental hypothesis*; shortly after their initial observations, Lisa said: "Just eyeballing it, I don't think the one with more spheres was moving more." We infer that her phrasing "I don't think" suggests she had an initial expectation, from the group's hypothesis, that the sample with a higher concentration of microspheres would have faster Brownian motion, contrary to their observations. This statement leads directly to Step 3, where the group formally *recognized an inconsistency* between their observational evidence and hypothesis (Lisa: "I mean, our hypothesis could be incorrect, you never know."). Lisa recognized an inconsistency between their observational evidence and their initial hypothesis, though she was hesitant to argue outright that their hypothesis is incorrect based solely on qualitative evidence ("The data will confirm."). In Step 4, the group *enacted sensemaking moves* to resolve the inconsistency. Following Lisa's comment, Edmund and Chloe engaged in mechanistic reasoning to develop an explanation of the mechanisms that could support their initial hypothesis, even though it does not account for their preliminary evidence. Edmund incorporated his understanding of diffusive processes ("if there are more spheres in an area … they are going to want to move out.") to support the group's initial hypothesis. Chloe added description that higher microsphere concentration should result in more collisions, which she equates to more overall Brownian motion ("They're colliding with each other … so, they should be moving more."). At this stage of their experimentation, the group seemed to be confident in using their initial hypothesis for their final explanation, but they were open to revising it based on additional evidence (e.g., "The data will confirm."). After Edmund's last statement, the group shifted back to collecting additional evidence.

The group iterated through this four-step cycle several times during subsequent experimentation. For example, later, the group computed diffusion coefficients (a quantity representing the rate of Brownian motion) during several rounds of quantitative data analysis (Step 1), compared their data to their initial hypothesis (Step 2; "Just eyeballing your number, so far it doesn't look like it's bigger than eleven."), recognized the inconsistency between their evidence and hypothesis (Step 3; "I thought it was supposed to be … bigger."), and engaged in sensemaking to resolve the inconsistency through constructing new explanations (Step 4). In Step 4, the group used mechanistic reasoning to construct an explanation that reinforces their initial hypothesis. Edmund recognized that the conceptual elements of the group's hypothesis cannot support a formal explanation of their results: "Technically, similar equilibrium … they should all be distributed somewhat equally, even though there's more spheres in one or the other, how they're spaced … it's not like, in one video there's a bunch in one spot and not another, and in another video they're all …" The group recognized that developing an explanation to reinforce their hypothesis may not resolve the inconsistency since the explanation does not account for experimental evidence or align with their studied system. The group then decided to collect additional evidence.

After collecting and analyzing their final evidence, the group shifted to a final sensemaking period to explain their results and the underlying mechanisms at play. The group built multiple analogies to address elements of their system, including equating microsphere Brownian motion to "when you're in a crowded elevator" and contrasting this phenomenon with billiard ball collisions ("If you just had microspheres but got rid of the fluid, like a bunch of billiards balls that interacted with each other, that's not [your system]."). Through additional

sensemaking discussion, the group eventually developed a consensus explanation (e.g., Lisa: Because when [a microsphere] bumps into a fluid particle … it's just gonna change its course versus, like, stop it from moving. When it runs into something with its same size, it's kinda gonna stop moving.").

In summary, the group frequently shifts between four macro-level steps throughout experimentation, iterating between collecting experimental evidence, comparing their evidence to initial hypotheses, recognizing an inconsistency, and engaging in sensemaking. We found that most groups in the data corpus enacted similar macro-level iteration to construct explanations, though there was variety in the iterative sequence, flexibility of initial hypotheses, and reliance on experimental evidence during explanation construction.

Discussion

This study utilizes a theoretical lens of iterative practice to analyze student reasoning at the nexus of experimental activity and sensemaking. The results highlight two distinct forms of iteration within micro- and macro-level experimental activity. While the experimental activity observed here has been documented elsewhere, focusing on students' iterative practice begins to shed new light on the progression of student reasoning during experimental activity in ways minimized in other literature. This work sheds light on how iterative practice exists at different scales within multi-dimensional learning environments; future research can explore how iterative practice may be prevalent at different cognitive and procedural levels within student learning in other contexts. As well, while this study broadly focuses on experimental and epistemic iteration, other forms of iterative practice may be more ubiquitous in other learning environments, such as course-based undergraduate research experiences (CUREs). Beyond empirical studies, these results reinforce our knowledge that student learning in science is often nonlinear and iterative, further stressing the need for new pedagogical approaches in science education.

Abstract: Some forms of movement, such as rocking, are common means of sensory self-regulation yet are discouraged in classroom contexts. We analyze the ableist underpinnings of this approach, and ask instead: could sensory-attractive activities such as rocking instead be solicited to serve content learning? Our design-based research project, Balance Board Math, fosters sensory–cognitive opportunities for the regulatory movement of rocking to serve as an intrinsic interaction resource for exploring mathematical graphical representations, with a focus on properties of sinusoidal functions such as frequency and amplitude. We analyze the role of balance/vestibular activation in pilot participants' exploration of graphing before, during, and after Balance Board Math activities.

Theoretical framework and design objective

Research on the relationship between bodily movement and learning flourishes in the learning sciences separately from fields such as psychology and occupational therapy (OT). While learning sciences researchers, inspired by the embodied turn in the cognitive sciences (e.g., Newen et al., 2018), are actively evaluating interactive designs that recruit bodily movement to enact concepts (Lee, 2015; Zhong et al., 2021), psychologists and occupational therapists advocate the maintenance of optimal alertness levels by engaging sensory stimuli that are of an adaptive intensity for one's neurological sensory processing profile (Dunn, 1997). As such, embodied cognition and sensory regulation paradigms currently offer distinct implications for understanding and fostering learning. Embodied cognition views of education construe movement as a means of exploring concepts (e.g., walking along a number line); sensory regulation construes movement as a means of regulating one's arousal state to sustain engagement (e.g., bouncing on an exercise ball). These two bodies of literature remain disparate due to the assumption that regulation and cognition are independent processes. We ask: might these siloed theoretical perspectives mutually inform each other towards a more holistic understanding of movement in learning? What if students' spontaneous regulatory activity, such as rocking or fidgeting, were resources for novel forms of instruction? We investigate these questions by creating a math instructional context where the sensory regulatory behavior of rocking is invited to participate in math conceptual exploration: Balance Board Math (BBM).

Self-initiated sensory-regulatory movements, such as pacing or rocking, are often read as disruptive, and such readings are compounded by the divergent sensory practices of many learners with disabilities (for example, learners on the autism spectrum; see Nolan & McBride, 2015) as well as racialized readings of students' bodies (Annamma et al., 2013). Situated within the Special Education Embodied Design (SpEED) design-based research framework (Tancredi et al., 2022), BBM sets out to deconstruct ableist norms of bodily engagement in schools, legitimizing learners' diverse sensory regulatory movements within the classroom. Inspired by the ubiquity of spontaneous vestibular-activating movement such as rocking and pacing, we imagine vestibular-driven mathematical conceptualizations that could offer new resources for inclusive instruction. Acknowledging the spectrum of sensory profiles (Dunn, 1997), BBM seeks to offer children the opportunity to engage their vestibular sense at an intensity adapted to their specific neurological thresholds and needs.

Design

Balance Board Math (BBM) (Figure 1) is a motion-graphing learning environment (Duijzer et al., 2019), where learners explicitly recruit and refine their capacity to attend through their vestibular sensory modality as their means of mathematical exploration. BBM establishes a whole-body relation to graphs, mirroring observations of skilled graphers "being the graph," not just "seeing the graph" (Gerofsky, 2011). In BBM, a sensor detects the board's angular shifts. As learners rock on the board, they draw a live graph representing properties of their rocking which is projected on a screen in front of them (Figure 1).The speed and sensitivity of the graph is

 © ISLS

calibrated at the onset to each student's comfort. Learners' left/back rocking correlates to an upwards trajectory and right/forward correlates to a downwards trajectory. BBM activities focus on sinusoids to solicit the rhythmic and repetitive rocking patterns that are characteristic of sensory regulation. BBM's discovery-based learning activities explore different aspects of a function: graphing, amplitude, and frequency (Figure 2). Learners are tasked with figuring out how to generate and maximize a focal color (here: green) within each activity. In Function Exploration, the user's line turns green if they trace a function displayed on the screen (Figure 2, left). In Amplitude Exploration, the graph turns green when they rock at a target amplitude (Figure 2, center). In Frequency Exploration, only periods of a focal length turn green (Figure 3, right). Users come to identify and control different parameters of their graphs. The specific focal amplitude, frequency, or function can be modified, serving primarily as a context to guide users to attend to different aspects of their rocking.

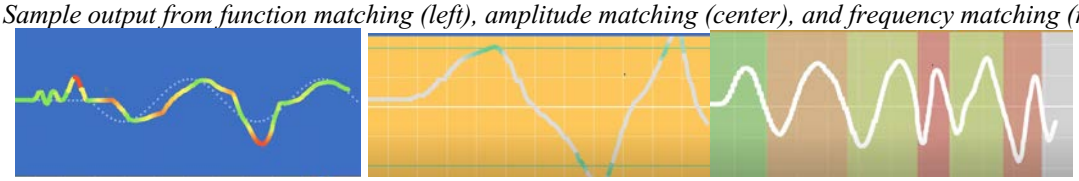
Sample output from function matching (left), amplitude matching (center), and frequency matching (right)



Research questions

1. What roles do vestibular-stimulating movement play in learning when invited into math instruction?
2. Does BBM change children's perception of graphs, as expressed through their speech and gestures? If so, how?

Methods

BBM was piloted through semi-structured clinical interviews with six children grades 2-6 individually or in pairs in a lab or after-school learning center. Upon trying each activity, participants were prompted to ideate on what made green and offered to try again until they were satisfied with their explanation and outcome. Before and after the interviews, participants were prompted to describe three static images of sinusoidal graphs using gestures and words. We transcribed and coded video for rocking pattern, task strategy, and regulatory activity, and two raters blinded to pre/post order coded graph gestures quantitatively for the "seeing" vs. "being" the graph criteria in Gerofsky (2011). For a more in-depth description of methods and analysis, see (Tancredi et al., in press). Here, we draw examples from the case of one 6th-grade boy, Kyle, for whom we had the most complete data.

Results

Balance Graphing Interactions

Participants rocked to explore each BBM activity. Participants expressed a range of vestibular sensory preferences during these activities, from gentle rocking with limited amplitude to intense rocking across the board's full range of movement. Our focal case student, Kyle, explored the three activities together with a peer, Cory, for several rounds, continuing after Cory departed. Kyle generally rocked with greater intensity than Cory. The pair were able to identify and control the focal parameter in each activity through cycles of graphing and reflection, and to communicate about their products across their different rocking styles.

Consistent with a sensory regulation perspective (e.g., Dunn, 1997), during activities like listening that entail less inherent vestibular stimulation, the children spontaneously rocked on the board. Children informally identified as highly sensory-seeking by their parents or instructors exhibited a higher frequency and intensity of such rocking. In one instance, Kyle was engaged in such rocking when the interviewer commented, "you mentioned earlier something about the distance between each hill." With the words "distance between each hill,"

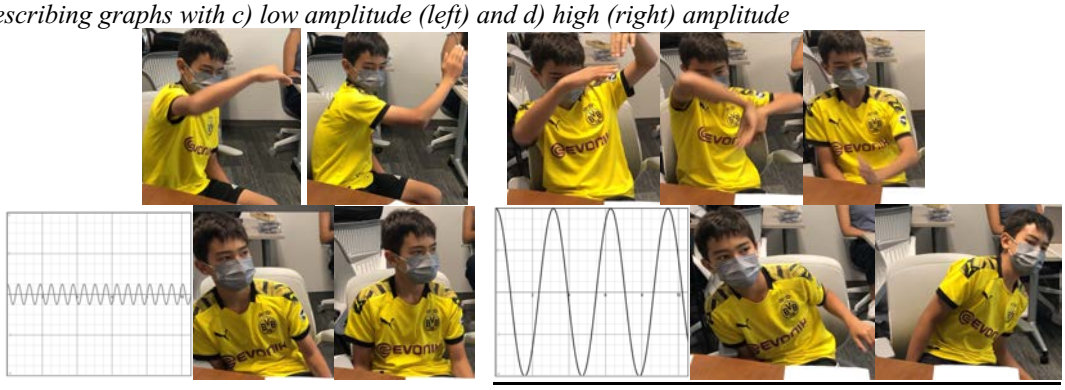
Kyle's rocking suddenly shifted to slow, sweeping rocks, corresponding with how he would have created spaced out graphical features earlier. What would traditionally be interpreted as background movement-for-regulation fluidly transformed into movement-as-thinking as Kyle acted out the conjecture raised by his interlocutor. At times, such rocking seemed to participate directly in his thought process. For example, when asked, "what did you notice this time about green?" Kyle responded, "Maybe it's not how far it is, but… [rocks right, left, right, left, slows to a stop in the center]. I don't really know." Rocking was enfolded within his sense-making utterance, perhaps reanimating the actions that produced his graph, perhaps expressing a thought not yet verbalizable, as observed in gesture–speech mismatch (Church & Goldin-Meadow, 1986). What would traditionally be interpreted as sensory-regulatory behavior in this context fluidly interacted with the meaning-making process.

Pre and Post Graph Interviews

Across participants, there was a statistically significant increase in mean being-the-graph gesture index scores from pre to post ($t = -2.19$, $d.f.=11$, $p < 0.05$) (see Tancredi et al., in press), reflecting progress from "seeing" towards "being" the graph on Gerofsky's (2011) scale. For example, during all three pre-interview graphs, Kyle positioned his gestural graph's *x*-axis at roughly shoulder height and spanned from nose/forehead down to heart for the *y*-axis (Figure 3a). During the post-interview, his gestures covered a broader span, with the *x*-axis falling at heart level and the y-axis spanning from the top of his head to his waist (Figure 3b). Kyle also showed newfound core-muscle and spine engagement in the post interview. Furthermore, during the post-interview, Kyle exhibited rocking movements accompanying his speech descriptions: he he rocked his upper body left to right as he described one graph as "quicker," and another as "slower um but like rocking a lot farther" (Figure 3c, 3d). Kyle's rocking gestures also reflected graphs' relative amplitudes. When describing a low amplitude graph (Figure 3c), he rocked about 15 degrees from vertical, whereas for a high amplitude graph, (Figure 3d), he rocked about 25 degrees from vertical. Kyle's rocking motions during verbal descriptions suggest that applying the balance board instrument as a means of drawing graphs has shaped his *utilization scheme*: he perceived graphs as affording rocking (Vérillon & Rabardel, 1995).

Figure 3

a) Kyle gestures sin(x) (pre, upper left) and b) cos(x) (upper right); Kyle rocks while verbally describing graphs with c) low amplitude (left) and d) high (right) amplitude



Discussion

These preliminary findings suggest that dynamic/interactive/whole body experiences with BBM may residually affect how students perceive traditionally static graph displays even when off the balance board, enriching their enactive landscape (Kirsh, 2013). They also suggest that BBM could be a rich context to study the intersection of regulatory and mathematical movement. This design-based research project offers a prospective proof-of-concept for recruiting regulatory activity into mathematical discourse, as well as for the viability of vestibular experiences in conceptual learning. Future work will further evaluate the interaction between different sensory profiles and BBM activity and seek to evaluate BBM in inclusive education settings across profiles. To this end, BBM will expand into multi-user activities and other access modalities such as sonification.

Conclusion

BBM not only provides enhanced opportunity for vestibular sensory regulation, but also positions vestibular experience as integral to mathematical exploration. The project seeks to bridge previously disparate research on sensory regulation and math education and ultimately contribute evidence to elaborate upon embodied cognition theory through a sensory perspective. Embodied design (Abrahamson et al., 2020) calls for instructional design

to embrace and build from learners' embodied resources. Grounding in these preliminary results, we propose that to do so, instructional design must 1) offer students access to a range of sensory stimulation to support regulation, and 2) think beyond the restrictive norms of classroom bodily engagement and the narrow focus on dominant instructional modalities like vision and audition. BBM focuses on rocking and the vestibular sense, but implications may carry over to other senses commonly engaged for sensory regulation such as the tactile and proprioceptive senses. Legitimizing sensory regulation within educational practice can help deconstruct ableist instructional norms that disadvantage sensorially minoritized learners and introduce new entry points into academic concepts for all learners.

Abstract: Analogical reasoning is critical in debugging. Still, the literature is unclear on how non-CS major novice programming learners draw inferences from previous debugging tasks when attempting to understand the present debugging task. We addressed the research question *How do novice programming learners discover relational commonalities across debugging tasks in which block-code contains structural relations within itself and with a corresponding robot?* We used a theory-informed coding scheme to analyze interviews and screencasting data. We found that (a) noticing similarities in *function* between the target task and the source task(s) guided learners to discover *relational commonalities within block code* between the source task(s) and the target task, (b) functional analogy was not necessary for discovery of every relational commonality between the target task and the source task in block code, and (c) noticing and using relational commonalities did not always lead to successful debugging.

Introduction

Strategies to facilitate analogical mapping between a source context and a target context have been studied in many domains. In programming learning contexts, strategies tend to involve analogies connecting unfamiliar programming concepts and rules to familiar ones (Muller & Haberman, 2008). But there has been less attention paid to how non-CS majors draw inferences from their previous debugging task when attempting to understand the present debugging task. Doing so requires that multiple relations be highlighted to make analogical comparisons within debugging. That is, comparisons are not just between one structure (of a source task) to another structure (of a target task) (e.g., leaves : a tree :: petals : a flower) but also for one set of structures from multiple relations within a source debugging task to another set of structures from multiple relations within a target debugging task. In this study, debugging tasks contain both virtual and physical objects and their relations. For example, comparing *block code* in a source debugging task to *block code* in a target debugging task is part of analogical reasoning, but so is comparing *relations between block code and the robot* in a source debugging task to *relations between block code and the robot* in a target debugging task. As shown in the figures below, there are common relational structures between virtual objects, Figure 1 (the source) and Figure 2 (the target). The relation between the repeat # times block A and the movement blocks B is that B is repeated # times indicated in A. There are relational structures also between the block code (the virtual object) and the robot (the physical object) in that the robot is moved by the block code (the robot moves # times depending on the parameter in the repeat function), which also creates parallel connectivity between the source debugging task and the target debugging task.

Figure 1
Source Task (Tracing a Square Once)

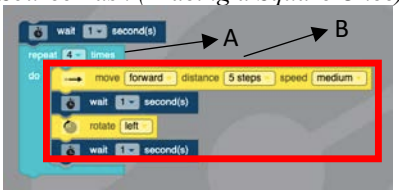

Figure 2
Target Task (Tracing a Rectangle 3 Times)

Research shows that people can recognize relational commonalities even with "conflicting object matches" between two tasks (Gentner & Smith, 2013, p. 4). For example, when given one picture showing a tow truck towing a car and the other picture showing a car towing a boat, people are highly likely to choose the boat in the second picture as a corresponding object to the car in the first picture due to the common structural relation between towing and being towed (Gentner & Smith, 2013). Block code in the present study was not an object as familiar as daily objects like vehicles to our participants and also contained symbolic, visual, and material forms. Thus, our research question was: *How do novice programming learners discover relational commonalities across debugging tasks in which block-code contains structural relations within itself and with a corresponding robot?*

 © ISLS

Conceptual framework

Our conceptual framework was grounded in the analogical reasoning (e.g., Gentner & Smith, 2013) and computer programming (e.g., Clement, Kurland, Mawby, & Pea, 1986) literatures but also design studies that investigated analogical reasoning during design (e.g., Ahmed & Christensen, 2009; Chai, Cen, Ruan, Yang, & Li, 2015; Cheong, Hallihan, & Shu, 2014; Gero & Kannengiesser, 2004). Our framework includes three perspective angles. Analogical reasoning *processes* include the encoding, inferring, mapping, applying, and verifying phases (Gentner & Smith, 2013; Sternberg & Rifkin, 1979). Analogical reasoning *foci* include visual, functional, behavioral, and structural analogies (Chai et al., 2015; Gero & Kannengiesser, 2004). Analogical reasoning *forms* include analogical comparisons in virtual objects, physical objects, and relation between virtual and physical objects. Our framework defines small, large, and mixed analogical reasoning distances between the source and target tasks, meaning a small distance having greater superficial similarities (Ahmed & Christensen, 2009; Muller, 2005).

Methods

Participants and context

Participants were 19 undergraduates who engaged with a robotics and play unit in a required three-credit play-based activities course in an early childhood and elementary education program of a large public university in the northeastern United States. The unit was for 90 minutes per week for eight weeks. All but two participants had completed field experience at the preschool, kindergarten, and/or lower elementary grades. All but one participant indicated no to little programming knowledge prior to the unit. Both members of the pair reported in this proposal - Judith and Anne - were female and juniors. All names have been changed.

Debugging tasks

Participants were invited to debug a series of buggy code segments given along with descriptions that explained expected behaviors of robots in an early childhood's play and learning context. In total, nine debugging tasks with increasing difficulties were given, five of which were done in class as paired debugging tasks and four of which were done as homework individually. Three practice tasks were given between debugging tasks. In this proposal, we present one debugging task called "Cleaning the Playroom" as the target task (Figure 4), and its similarities and dissimilarities with one of the source tasks called "Color Game" (see Figures 3 and 4).

Figure 3
Code for the Color Game Task

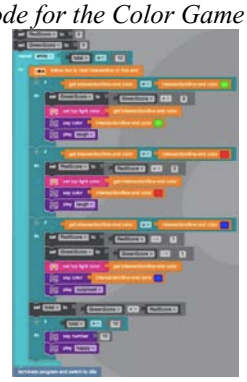

Figure 4
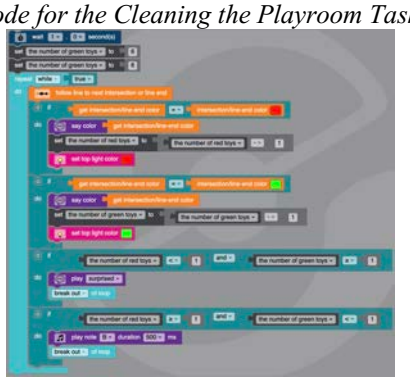
Code for the Cleaning the Playroom Task



Data collection

Participants' computer screens were recorded during debugging. Their reflections and final code were collected during the unit and interviews were conducted after the unit ended. The total length of all screen-recordings was about 33 hours. Anne and Judith's screen-recording was about 3.5 hours. They were also video-recorded.

Data analysis

We developed a coding scheme based on our conceptual framework grounded in the analogical reasoning literature (Chai et al., 2015; Clement et al., 1986; Gentner & Smith, 2013; Gero & Kannengiesser, 2004, 2014; Gero & McNeill, 1998; Ruppert, 2013; Sternberg, 1977; Sternberg & Rifkin,1979). The coding scheme included encoding and inferring, mapping, applying, and verifying as high-level nodes. All nodes had sub-nodes for small distance, large distance, and mixed distance. *Mapping* sub-nodes were used to code visual, functional, behavioral, and structural analogies. Applying sub-nodes were used to code correct and incorrect uses of relevant or irrelevant similarities and dissimilarities. We first pilot-tested the coding scheme by applying it to

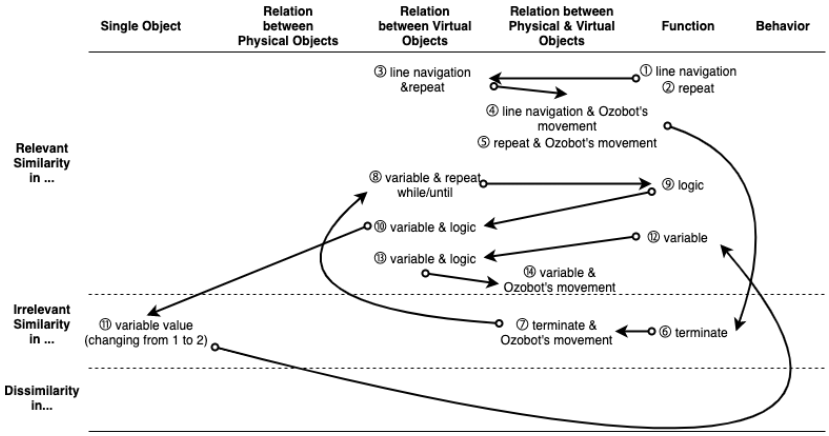
 © ISLS

data from two participants' debugging tasks (Octagon and Hexagon). After coding independently, we met to reach consensus and address discrepancies in coding. Then, we independently coded two other participants' data from debugging the Energy versus Obstacle task. We met again to reach consensus and address discrepancies in coding. Then, we did another round of independent coding for data from Anne and Judith's debugging the Energy versus Obstacle task. Upon completion of the third pilot coding task, we again met to discuss coding, and decided to add mixed distance to the coding scheme. Then, we recoded using the revised coding scheme independently and reached consensus. Finally, we coded Anne and Judith's data from their Cleaning the Playroom debugging in NVivo. The average interrater reliability ICC score was 0.849.

Findings and Discussions

Figure 5

Summary of Anne and Judith's Analogical Comparisons during Debugging



Noticing similarities in *function* between the target task and the source task(s) guided learners to discover *relational commonalities within block code* between the source task(s) and the target task. For example, analogical comparisons that Anne and Judith went through from ① to ② and ③ in Figure 5 depict that they did not begin seeing ③ the *relational commonality* between the target task (the Cleaning the Playroom task) and the source task (the Color Game task) in the structural relation between the line navigation and the repeat blocks until they noticed ① ② the functional commonalities of line navigation and repeat blocks between the target and source tasks. The role of such a functional analogy, in this case, is productive considering that it eventually led to the discovery of ④ ⑤ *relational commonalities* between the block code and the robot in the target and source tasks. Such a productive role of functional analogy is contradictory to findings in analogical reasoning literature in which functional comparisons were found to limit reasoners' capacity to identify relevant analogy (Cheong et al., 2014). The multimodal forms of objects in the present study may have impacted this finding. Due to symbolic, visual, and material forms used in debugging tasks and relational structures embedded within and between the multiple forms, understanding function of objects was critical to understanding objects and structures within them and associated with other objects. It seems natural to use tangible analogies ① ② to visualize analogies that are not immediately visible ③. Table 1 shows the pair's discourse and actions during analogical comparisons.

Functional analogy was not necessary for discovery of every relational commonality between the target and the source tasks in the structure within block code. As shown in ⑧, the participants were able to map the relation between the repeat while and the variable blocks in the target task to that in the source task. Noticing this relational commonality led to attention to ⑨ functional commonalities of logic blocks in the target and source tasks. While functional analogies were used again to understand the logic blocks and their structures in ⑨, as in ①, this could be attributed to less familiarity with logic blocks compared to more familiarity with repeat blocks built through analogical comparison from ① to ⑤.

Noticing and using relational commonalities did not always lead to successful debugging. For example, when Anne and Judith noticed ⑩ the relational commonality between the target and the source tasks in the structural relation between the variable and the logic blocks, they then fixated on ⑪ analogical comparison of the numeric value in the math block between the target and source tasks. This analogy was unrelated to bugs in the target task, thereby leading to studying ⑫ the function of variable blocks.

Implications for research and practice

The present study contributes to advancing the analogical reasoning literature by adding empirical findings of novice programmers' learning processes that involve tasks with complex relational commonalities. It also enriches research on debugging through the lens of analogical reasoning. Its practical contribution is to CS education in that understanding of non-CS majors' reasoning during debugging can be used in broadening participation in CS.

Table 1

Part of Anne and Judith's Debugging Episode

Debugging scene	Source task	Target task	Analogical comparisons
Judith: Why do you think the Ozobot did what it did? Anne: Because this [follow line to next intersection or line end] block wasn't here [in the repeat block] like this if statement (*She pointed out the if/do condition for red intersection to indicate the correct place for the follow line to next intersection or line end block)* ① ②	Line navigation block was within repeat block before logic block, which made the robot move continuously.	Line navigation block was out of the repeat block in the buggy code.	They focused on the location of line navigation block in the target task: outside of repeat block, not inside repeat block. The pair noticed similarities in function of line navigation and repeat blocks between the target and the source tasks ① ②, which made the robot move continuously.
Judith: What is a rule? Anne: but like a movement [line navigation block] before the if statement ③. I don't know.	Line navigation block was within repeat.	Line navigation block should be within the repeat block to make line navigation block work repeatedly between intersections.	They began noticing similarity in relation between line navigation block and repeat block between the target and source tasks ③.
Judith: All right. What if we put a follow line or line navigation block underneath of a repeat block ③ in order for it to follow a grid [on the map]? ④ ⑤ *(She indicated the rule by highlighting the correct place of line navigation block within repeat and its relation with the robot's movement)*	The robot moved on the map because line navigation block was within the repeat block.	The robot did not move on the map because line navigation block was outside of repeat block.	They developed a rule indicating the relationship between line navigation block and repeat block ③. They then noticed similarity in relation between line navigation block within repeat block and the robot's movement on the map in the target and source tasks ④ ⑤.

The Tensions of Making Space: How Teachers Work Toward Heterogeneous Science Sense-Making

Abstract: As science education navigates the tensions between convergence-seeking and heterogeneity-seeking images of science, this paper investigates how elementary science teachers work within and around these tensions as they make space for student sense-making. We focused on two teachers who participated in a multi-year professional development and analyzed moments when they engaged in both responsive and culturally responsive teaching practices. The first teacher used distributed scaffolds (i.e., zooms) to expand participation in science activities and foreground students' prior knowledge about the phenomenon, but often toward canonical or dominant cultural knowledge. Our second teacher showed a shift in her practice by restructuring a categorization activity from a pre-determined worksheet to having students determine the categories. We argue that making space practices that align more with culturally responsive and sustaining pedagogies could help teachers pursue students' ideas towards heterogeneity-seeking images of science.

Motivation and research questions

According to one of our teacher participants: "The process of [science] is really organic, not as static as we make it...we just have this really narrow vision of what science has been." The "we" refers to teachers and stakeholders with power (e.g., district leaders, policy makers) to enforce standards that K-12 science teachers feel immense pressure to cover. The most recent science standard reforms represent an important paradigm shift from focusing on knowledge attainment to authentic practices (NGSS Lead States, 2013). This paradigm shift is often implemented in convergence-seeking ways: students work to collaboratively build shared understandings and knowledge, drawing from their diverse initial ideas towards an accepted set of understandings represented in state standards (e.g., "storylines;" Reiser et al., 2021). This image of science is fundamental to making scientific progress, though it can often overlook the messiness, uncertainty, and multiple existing theories about science phenomena common in professional science practice (Pickering, 1995). Therefore, a heterogeneity-seeking image of science, where divergent explanations and processes for pursuing ideas about scientific phenomena are valued, is a lens used to validate students' multiple ways of knowing (Warren et al., 2020) moving towards more equitable sense-making and science learning. As we re-imagine how these two images of science (convergence-seeking, heterogeneity-seeking; Pierson et al., 2020) inform science lesson planning and enactment, we ask: How do science teachers navigate working within—or around—the tension between accountability to standards and to equitable sense-making?

Theoretical framework

In response to our teachers' desire to broaden the vision of what science can be, we built on the work of Haverly et al. (2018) and asset-based pedagogies (Warren et al., 2020) to contribute to conceptualizations of how teachers can *make space* for equitable sense-making—collaboratively constructing knowledge with students' diverse epistemic resources—in classrooms. Our PD design also built on *responsive teaching* (Robertson et al., 2015) and *culturally responsive teaching* (Gay, 2018). In our PD, we tried to support teachers to see students' disciplinary strengths from a responsive teaching lens, but this pedagogical approach often assumes science is neutral or objective and that the goal of science education is conceptual change, usually toward a specific learning objective. At the same time, we saw examples of our teachers enacting culturally responsive and *culturally sustaining pedagogies* (Alim & Paris, 2017). As we continue to make space for students' diverse ideas to be added to collective scientific sense-making, we must also consider: "the ways in which young people are enacting race, ethnicity, language, literacy, and their engagement with culture is always shifting and dynamic" (Alim & Paris, p. 7).

 © ISLS

In this paper, we explore how teachers, supported by both responsive teaching and culturally sustaining approaches, navigated tensions between convergence-seeking and heterogeneity-seeking images of science that made space for and successfully sustained a greater range of children's sense-making resources and prior experiences. To examine our research question (How do teachers navigate the tension between accountability to standards and to equitable sense-making?), we present two cases that elucidate some ways teachers navigated both *within* and *around* tensions between these two images of science.

Methods

We focused on two of nine teachers who were all part of a larger, multi-year project in a Southeast city of the US. Our first case study (Yin, 2014) follows Anne, who taught first grade and was in her second year of teaching. Soren is our second case study teacher, who taught kindergarten, and was in her 14th year of teaching. We collected video data from two to three lesson observations per teacher and four video club professional development meetings each academic year where teachers presented a recorded clip from their classroom practice to collectively reflect on representations used in cross-grade-level groups (Sherin & van Es, 2005). We present data from classroom (observations and recorded clips) and video club data in our findings. Our research team then engaged in iterative video analysis using interaction analysis (Jordan & Henderson, 1995). We (1) time indexed and content logged videos (Derry et al., 2010); (2) wrote memos and timestamped episodes when teachers made space (e.g., validated student thinking, adding zooms on diagrams); and (3) collectively viewed episodes to refine our hypotheses (Engle et al., 2007) about how teachers worked within or around the tensions between convergence- and heterogeneity-seeking images of science.

Findings

Our first case study showed Anne used common distributed scaffolding practices (Tabak, 2004; e.g., zooms on diagrammatic representations) to make space for broadened student participation. We argue space was made for students from historically minoritized backgrounds to contribute to the science storyline, but towards an image of science that was mostly convergence-seeking. Our second case study (Soren) represented an example of how a teacher's making space and distributed scaffolding practices shifted from convergence-seeking to more heterogeneity-seeking images of science, presenting more and different opportunities for sense-making. These examples will show the variety of perspectives teachers may be operating under in respect to the paradigm shift we propose, and how there was still room for teachers to push forward toward authentic epistemic heterogeneity and validating students' epistemic agency to author their own sense-making processes.

Anne: A zoom that prompted a teacher reflection on epistemic authority

In Anne's classroom, she used diagrammatic representations to help first graders understand the relationships between heat and energy. Specifically, the tool Anne used was a *zoom*. The zoom was introduced during PD as a learning scaffold that "lets us see something that is not really observable." Using this tool as "microscope eyes," students can make visible something that was not seen before. This analysis centers on Anne sharing a clip of her classroom teaching during a video club with other teachers.

In the classroom video, Anne followed one student's idea to add a zoom coming from a stick figure's foot. Then, the student suggested adding "red stuff" to the foot inside the zoom because "your feet will be red if they burn." Anne used the color red as a convergence-seeking scaffold to highlight relationships between heat transfer and the sun. Pivoting to the whole class, she took up the student's comment about red burns asking, "Does anyone else know anything about burns? Anyone ever had a sunburn?" When only one student replied "yeah," Anne responded, "Maybe? Maybe?" After a beat, Anne called on the student who replied and continued her line of questions about sunburns. "What happens to your skin when you get a sunburn?" Anne asked. "It—it turns red," the student replied. From this affirmation, Anne turned to the representation on the board, added a zoom, and drew a foot inside it—toes and all. When the video was paused, Anne explained to the video club group that mentioning the sunburn "was an 'uh-oh' moment" because as "a white teacher when I think later, I was talking about a sunburn… And, I was like, 'Well that was a privileged moment of me.'" In this moment, Anne recognized that her assumption that all students could relate to having a red sunburn was based on the notion that everybody had experienced red sunburns, when "not all of [her] kids get a red sunburn." From this "uh-oh moment," Anne pressed on in the video. "What color do you think we should color that foot?" Anne asked. In response, she got two answers from her students, "red" *and* "brown." In this moment the tension became fully realized and Anne had to navigate between the lived reality of students' different races (of which a majority were non-white), and the color red that had surfaced as a scaffold for the transfer of energy as heat. To reconcile this tension, Anne offered one student a skinny brown marker to "scribble-scrabble" in the color of the foot, while at the same time, Anne leaned over to color in spots on the foot with a skinny red marker to signify a "burn on [the] foot from [the]

sun." Overall, this episode portrayed the tensions teachers navigate between convergence- and heterogeneity-seeking images of classroom practices particularly as teachers attend to experiences different than their own.

Soren: Evolution of an activity

We now compare two instances of Soren teaching a similar lesson in Year 1 and Year 3 (Y1 and Y3).

Activity Structure

In the Y1 video, Soren designed an activity for students to record properties of materials at each of several stations; in the Y1 classroom video students were at the wood station. Soren constrained students' observations of wood objects by directing students on what part of the spatula to draw on their papers: "Draw the stick part, that's the wood part." In contrast, in the Y3 classroom video, Soren asked students to explore "different ways that we can sort" putting them in groups with bags including a mix of materials. In the Y3 video club, Alexis (3rd) noted she liked how Soren gave "them the space to pick out what things they see…it's like a mix of different reasons that they had to sort it." Alexis emphasized opportunities Soren designed to allow students' onto-epistemic authority (Warren et al., 2020) to define how to sort and what were reasonable sorting decisions. Indeed, Soren's design made space for students to sort by color, use, material, and sound. In Y1, Soren worked to ensure that students recorded information on their worksheet towards the convergence-seeking image of science where the standards correct answers were treated as the only right answers. In contrast, Soren in Y3 worked to create space for students' onto-epistemic agency and drew upon their contributions as part of meaningful disciplinary sensemaking.

Interactional Patterns

There were significant shifts in interactional patterns from Y1 to Y3. In Y1, Soren emphasized a one-on-one in series interactional pattern (Keifert, 2015) in which a teacher talked to one student, and then the next without other children talking (though they could observe). This is visible in Y1 when Ben wanted to connect the sharp point on his pencil to the sharp points of the pinecone that another student had identified, Soren responded "Oh, I'm asking [another student] but I like your connection. If you hold onto that connection, we'll talk about it." In contrast, in Y3, Soren emphasized collaborative discussion when one of the three students in the group described their decision making for their sorting, she responded, "Orange Tiger, do you agree with that?" and "Blue Cheetah, I like your thinking, but you need to share it with your group," to support students to learn how to engage with one another. In the Y3 video club, Regina (K) acknowledged developing this practice as a challenge and noted the practice of supporting shared sense-making between students could be difficult because they are still learning how to "verbalize their thinking." Regina emphasized to Soren, "You checked in with each kid in the group. Like 'You shared this, did you hear what he said? Do you agree? Do YOU agree?'" The Y3 shifts to encourage students to speak to each other was valued by teachers but also acknowledged as a challenge.

Feeling Phenomena

In Y1, Soren directed students towards what they should be noticing with their eyes, hands, and ears. For instance, when a child was struggling to describe the texture of a stick, Soren provided significant guidance when she said "Look. Is it smoo-oo-ooth (rubs hand slowly over surface of the floor) or bumpy (lifts hand and moves it in a wave-like gesture)?" and then repeated the question and gesture several more times before responding to the student with, " Good job! It's bumpy! Excellent! That's how it feels. You can write that down." In this exchange, Soren pushed the student towards describing what he felt to match her expected answer. In Y1, Soren also supported a student in attending to sound as he tapped a block of wood: "I saw you hitting it with your hand (*Soren hits her own hands together)*. What are you trying to discover?" and affirmed that the wood was hard. In Y3 when a child knocked two plastic items together, she asked: "What were you doing? Show us again what you were doing with them." This time the student replied, "Because they sound the same so I put them together." Soren affirmed saying, "Oh, you were testing…how they sound and that helps you know what they were made of?" Even though she affirmed students' reasoning in both cases, in Y1 Soren dictated what kinds of properties should be used while in Y3 Soren focused on revoicing student thinking. Thus, in Y1 Soren directed what to sense while in Y3 she followed students' reasons for their ways of investigating the materials.

Discussion and Implications

These case studies help answer the question of what happens after space is made for student sense-making, by showing how elementary science teachers navigated tensions within and around the convergence-seeking and heterogeneity-seeking images of science education. With Anne, she embodied the attribute of culturally sustaining teaching as comprehensive and inclusive. Even though her lesson used a collective model that our PD unknowingly communicated as a convergence- or consensus-seeking tool, Anne welcomed an unexpected piece

of cultural knowledge to the class model. Soren also showed us how culturally sustaining teaching can be empowering: she redesigned her activity from Y1 to Y3 so that the children directed and decided the rules of the categorization activity, allowing them to use an expansive set of sense-making resources (e.g., matching colors, hitting materials and comparing the hardness or sounds). As researchers, we are continually learning alongside our teachers as we pursue a heterogeneity-seeking image of science in our classrooms. While these examples are not an exhaustive list of ways to promote culturally sustaining and heterogeneity-seeking pedagogies in the classroom, we do want to highlight these moments as starting points to continue studying what making space and validating multiple ways of knowing look like in classrooms where there is still tension and immense pressure to meet predetermined convergence-sought standards. In future PD meetings, we hope to design resources more intentionally to promote heterogeneity-seeking images of science.

Abstract: As new technologies proliferate our world, many well-meaning efforts seek to expand access to and broaden participation in STEM education and careers, yet many of these efforts disregard the fact that science, technology, and design are cultural processes. Building on a growing body of work, we examine how families experience and design together at the intersection of culture and technology. Drawing on Indigenous science and culturally sustaining/revitalizing perspectives, we investigate the ways in which families engage with culture and technology during a plant walk led by Tribal Elders that included a Tribally-designed virtual reality (re)interpretation of the experience. Insights from our findings highlight ways in which one Tribal Nation balanced culture and technology in ways that reclaimed their uses to maintain technological sovereignty and self-determination as designers.

Objective

One persistent challenge to broadening participation in and access to STEM is that the majority of these efforts operate from the assumption that science is acultural resulting in deep epistemological tensions (Bang & Medin, 2010; Brayboy & Maughan, 2009). Not only does this ignore the cultural, historical, and political roots of science, but it also marginalizes Indigenous peoples, who take an ecological approach to science and recognize it as inextricable from culture (Aikenhead, 1997; Bang & Medin, 2010). From this stance, we argue that the perpetuation of technological disparities is rooted in (mis)representation and lack of representation of Indigenous culture, education, and science. As a result, emerging technologies do not support or engage Indigenous ways of being and knowing and often they harm, silence, or further traumatize Indigenous peoples (Litts et al., 2020).

In response and resistance, scholars push for "technological self-determination and sovereignty" (Winter & Boudreau, 2018). We further posit that *who designs* matters as it inherently determines the cultural process of design and therefore the product of what is designed. To contribute to this ongoing conversation, in this paper, we share a four-day community workshop, *Shoshone Plant Experience*, designed with the Northwestern Band of the Shoshone Nation (NWBSN) to support engagement with culture, science, and art through digital and "original technologies" (Barajas-López & Bang, 2018). Our inquiry is guided by the research question: *how do culture and technology intersect in a community workshop?* Drawing on Indigenous science and culturally sustaining/revitalizing perspectives (McCarty & Lee, 2014), we investigate the *forms of relating* to culture and technology that families engage during a plant walk led by Tribal Elders and through creating digital (re)interpretations to share with the broader Tribal community. Given the tenuous history of technology with Indigenous peoples, our goal is to understand the ways Indigenous communities relate with digital technologies.

Perspectives

Indigenous Science

At the forefront of our work is Indigenous knowledge systems, science, and storywork. Indigenous knowledge systems are epistemologies rooted in science and storywork (Battiste, 2002; Brayboy, 2005). Indigenous science is a "culture-dependent collective rational perceiving of reality" (Ogawa, 1995, p. 588) often shared within communities through narrative experience and oral histories (Archibald, 2008; Kawagley, 2006). Indigenous stories frequently include narratives of origination and shared community experiences, and should be viewed as the equivalent of western theory and practices (Brayboy, 2005). In particular, storywork is the act of bringing Indigenous storytelling experiences into educational contexts (Archibald, 2008). In our work, Indigenous storywork as science is understood an inherently social process shaped by culture, history, and politics that is relationally intertwined with land and place.

 © ISLS

Culturally sustaining/revitalizing

We take a culturally sustaining/revitalizing approach (McCarty & Lee, 2014) to our work. Culturally sustaining/revitalizing pedagogy builds on Paris' culturally sustaining pedagogy (Paris, 2012) and focuses on understanding and conceptualizing educational practices specific to Indigenous learners. Culturally sustaining/revitalizing pedagogies are shaped by a deep recognition of Tribal sovereignty and need for decolonizing learning toward sustaining/revitalizing identities of Indigenous learners (McCarty & Lee, 2014).

Methods

Methodological approach

In our broader project, we adopt a community-based design research (Bang et al., 2016) approach, which consists of "design efforts that work from within the "ongoingness" of communities" (p. 11). Specifically, we take a *community-driven design research* (Litts et al., 2021) approach, a collaborative design process in which Indigenous partners maintain sovereignty as designers, to our partnership work. This methodological orientation recognizes the historical, cultural, and political nature of partnering with Indigenous communities, as well as embraces the needs for inviting community-wide, intergenerational participation and addressing systemic and historical challenges. From this stance, we take up an *intrinsic case study* (Stake, 2008) approach where we seek to understand the *Shoshone Plant Experience* itself as a case. Thus, the case is bound by the four days of the workshop. In this paper, we focus on moments where culture and technology intersect.

Setting and participants

The NWBSN is a community of about 575 enrolled members most of whom are dispersed across urban and rural areas in Northern Utah and Southern Idaho. Historically, NWBSN are a nomadic people without a designated reservation land. We held a four-day workshop, *Shoshone Plant Experience*, which consisted of one day of exploring native plants with Tribal Elders in a local canyon and three days of developing (re)interpretations of the plants' stories using a variety of media. As part of the workshop, Tribal community members also developed a virtual reality (re)interpretation of the plant walk (see: daigwade.org/shoshoneplants) to share cultural and experiential knowledge with the broader Tribal community. Family participation varied across days, but we had 20 participants throughout the workshop who consented to the research.

Data Collection and Analysis

In this paper, we present findings from a range of qualitative data collected throughout the *Shoshone Plant Experience*. Data include fieldnotes from four researchers, audio and video recordings, design work, and semi-structured interviews throughout the workshop. Across data, we developed the *Shoshone Plant Experience* as a case by tracing the ways in which families engage culture and technology through descriptive and in-vivo coding (Saldaña, 2009). We then examined the ways in which families experienced, described, and reflected on their relationship with culture and technology in moments where they intersected. Kimmerer (2013) explains how land is woven into storywork practices: "our relationship with the land cannot heal until we hear its stories" (p. 9). It is this act of relating that frames our analyses. We share Bang and Marin's (2015) commitment to "relational epistemologies," which is rooted in the belief that all things are "connected in dynamic, interactive, and mutually reciprocal relationships" (p. 534).

We collaboratively developed analytic insights through oral sharing and reflection in weekly meetings. Tribal Elders of the research team reviewed written accounts of these oral meaning-making sessions to establish resonance. With this collaborative meaning-making process, we collectively triangulate interpretations and claims (Creswell, 1998) across partners, perspectives, and data types.

Findings

While analyses are ongoing, we present here three *forms of relating* (reciprocity, preservation, and experiential) with the intersection of culture and technology that families shared through the *Shoshone Plant Experience*. Analytic contributions from Tribal Elders are presented as direct quotes.

Reciprocity of learning culture and technology

In the Shoshone Plant Experience workshop, we noted several demonstrations of the "mutually reciprocal relationships" (Bang & Marin, 2015) between cultural knowledge and digital technology. Tribal Elder Rios Pacheco (Author 2) unpacks how Raymond, a 13-year-old Tribal member, illustrated this relationship: "When her boy came and he came and asked you know quietly and… and I told him you know okay lets go over here and

look at these plants. So we went through and looked at them and said well we'll take this one… and I told him to watch out because of all the thorns on that plant. So we took a sample of that plant and we kept on going and then we found another one and I asked him how it felt and what it was for… so he had that contact of one-on-one. Then he turns around and when we were ready to leave, you asked if he wanted to help Jake with the drone, so now he's able to have contact with a complete circle… So what happens is we have that contact with one-on-one and then now we have this interest in technology of how he can show that one-on-one. Not just by being there in person and seeing that plant, but also using technology to see that plant 3D and see the whole valley in 3D. So that's what the future of technology is: bringing what you see in life into a better understanding to someone that doesn't have that opportunity to see it in life." (Data Analysis Meeting, 07/05/2021).

In this example, the cultural knowledge exchange between Rios and Raymond prompted Raymond to craft a (re)interpretation using virtual reality technologies, which in turn prompted deeper exploration of cultural knowledge and so forth. We found that families who attended the in-person plant walk experienced the plants and learned about their uses and then re-experienced that learning in their interpretations with digital technologies.

Preservation of culture with technology

Through the *Shoshone Plant Experience* workshop, families expanded the ways in which culture can be preserved with and through technology, especially as designers. Family participants who continued with the three workshop days at the Tribal Offices, developed their own interpretations of cultural knowledge that they learned on the plant walk. These took the form of digital stories or movies, informational graphics or videos, and more. Tribal Elder Patty Timbimboo-Madsen (Author 3) reflects on the impact of developing these interpretations: "... to me in the end, I can see it giving us an easier way for preservation to retain the information and to be able to pass that on to the people of the Tribe. It's in our words and through our eyes and to me it's a gift giving back to the people of the Tribe" (Data Analysis Meeting, 07/08/2021). Building on this point, Tribal Elder Gwen Davis (Author 4) contributes, "Well technology is something that we have to embrace, because it's here… I believe it's going to be a way in which we learn how to use it to preserve ourselves, whether it's our culture or whether it's how we learn how to do things. It's a way of teaching…" (Data Analysis Meeting, 07/08/2021).

Moreover, when considering the traditional oral ways of preserving culture, Tribal Elders grappled with the tradeoffs of using technology for cultural preservation. Patty explained, "Oral histories are good because you can tell it anyway you want. Is there a wrong way or a right way? But once it's cemented on paper, or on a computer or on a tape or whatever, it's more permanent instead of trying to make the story up again. I think any time you try to elaborate it more or make it more funny or add your two cents to it, it kind of changes." (Data Analysis Meeting, 07/08/2021).

Rios further expounds, "Yeah I don't think technology is going to change anything, it's just like oral history. You carry on what you heard, but you also have that opportunity to add to it and you have the opportunity to take away from it. Same way with technology. You're not going to say everything word for word, because you have the capability of changing those words… The only ones that will stay the same are the ones that are true to what they're saying and what they want to convey… But [technology is] also good, because you can have a thought and it [moves] all the way throughout the world. But your oral thought can only be conveyed with that small group that's around you. That's the big difference."

Experiencing culture through technology

Using virtual reality to recreate the *Shoshone Plant Experience* is aligned with how the Tribe hopes to use technology to preserve and share culture, yet it does have limitations in the relationship between their storywork and the land. Tribal Member Alicia Martinez (Author 6) describes the loss of human essence as a limitation of this technology stating, "I don't know I mean just even technology itself, separate from culture, you know I think one of some of the complaints, maybe or the criticism of it is the loss of the human essence" (Data Analysis Meeting, 07/05/2021). She further argues that we need to restore the human/more than human essence by maintaining space for the relational connections between technology, culture, and the land. Curiously, we did note all of this woven together in one key moment, which we share here as an illustrative example.

The use of this technology was initially a pragmatic solution to engage people who could not participate on the workshop days, which became one of its key affordances. During the three design workshop days, NWBSN community members put on Oculus Go headsets to view the VR footage we captured from the plant walk day. This became an intergenerational learning experience where Ruby, a 10-year-old Tribal Member, quickly became the go-to teacher for how to use the Oculus Go. In exchange, many of the NWBSN community members immediately began sharing stories and memories based on what they viewed through the headset. For example, Garry, a Tribal Leader, exclaimed, "Oh whoa… Holy Moly!!... That is awesome!" Once oriented to the Oculus Go, he began sharing his own cultural knowledge and stories based on what he saw in the virtual canyon as if we

were all standing there together. In addition to providing insights for how the intersection of culture and technology facilitated Elder-youth interactions and exchanges of knowledge, this example also demonstrates the unique affordance of experiential or immersive technologies in prompting deepening and furthering of relational sharing of cultural knowledge. This also reinforces the *reciprocity* of culture and technology previously discussed.

Insights & Significance

Insights from our findings highlight three forms of relations (reciprocity, preservation, and experiential) that the NWBSN community engaged with at the intersection of culture and technology. These forms of relations were illustrative of the collective move in the community to reclaim their uses of technology by maintaining technological sovereignty and self-determination as designers (Winter & Boudreau, 2018). Specifically, the reciprocal relationships that emerged in the *Shoshone Plant Experience* workshop sheds light on how Indigenous communities can build new relationships with technology when maintaining sovereignty and self-determination over their engagement with it. To this end, as we continue to grapple with the early findings of our work, we persistently wonder about the significant and complex role of *land* in our work, particular for the NWBSN. Our work builds on and contributes to existing efforts to center Indigenous science and culture and expand current notions of *who* counts as designers of technology.

Abstract: Relationships are at the core of doing community-based research that works and matters. However, the process through which university researchers learn to engage in relational work is often *presumed* to be understood rather than explicitly articulated. Building on approaches that conceptualize relationality and critical historicity as central to the success of equity-oriented approaches in education, we present a polyvocal autoethnography where researchers in a RPP featuring YPAR elements learned to engage in what we call *substantive relational work* (relational work with commitment to *caretaking relations* and *critical bifocality*) with community partners. By analyzing everyday moments, we highlight the invisible learning process of a scholar-in-training working alongside a university researcher, program staff, and youth leads at a non-profit organization. We discuss how relational work is both work necessary to move equity-oriented community-based research forward, as well as work that matters in itself for researchers to reconceptualize discursively and materially.

Introduction

Scholars studying research practice partnerships (RPP) have written on the importance of building relationships with community partners (Coburn et al., 2016) in doing "work that matters" (Penuel et al., 2015) toward educational improvement. However, given the often-extractive history of research within communities, RPP scholars face the multifaceted, abstract task of "avoid[ing] perpetuating existing systems of injustice" in not only their research foci, but also their relational approach with communities (Denner et al., 2019, p. 2). We hope to expand on RPP scholarship centering relational work as key to doing community-based research that disrupts systems of inequity on practical and structural levels. We examine two otherwise "invisible" (Jurow, 2016) elements of relational work: building substantive relationships, and learning how to do so effectively within the academy. We build on the insights of participatory design research, which "attends to the ways in which (a) critical historicity, (b) power, and (c) relational dynamics shape processes of partnering and the possible forms of learning that emerge in and through them" (Bang & Vossoughi, 2016, p. 173-174).

In this paper, we present a scholar-in-training's apprenticed learning around what we refer to as *substantive relational work*. To define this concept, we draw on *critical bifocality* (Weis & Fine, 2012), and *caretaking relations* (TallBear, 2019) from critical and decolonial perspectives. Rooted in indigenous ways of knowing, caretaking relations represents a narrative based in "relations and obligations in the here and now" (TallBear, 2019, p. 25)—alternate to a settler-based society that "objectifies the land and water and other-than-human beings as potentially owned resources" (p. 32) for relentless "American dreaming" of production and progress (p. 24). At the same time, critical bifocality requires researchers' responsiveness to the ways higher-level structures and inequities hold "attendant consequences for the local level with regard to lived-out social and economic practices of individuals and collectivities" (Weis & Fine, 2012, p. 3). At the core of substantive relational work is therefore the idea that centering caretaking relations in research is not an abstract point of sentimentalism detached from real world concerns—it is a quotidian political stance centering connection and wellbeing in the face of the demands of White supremacy and exploitative capitalist structures.

We situate our study within the first cycle of a youth participatory action research (YPAR) project in a two-year RPP with a non-profit organization. The RPP goal is to understand through a YPAR approach—which positions youth as researchers with expertise/agency (Caraballo et al., 2017)—how youth voice shapes improvement of out-of-school career pathway programs. Authors 1 and 2 joined as adult co-researchers supporting youth leads in this project. We approached our inquiry with the exploratory question: **What does it look like in practice for a scholar-in-training researcher to learn to engage in substantive relational work alongside university researchers, youth, and program staff in a YPAR-infused RPP?** Overall, we hope to contribute to

 © ISLS

scholarship which highlights relational work as an "expert educational practice" with "unarticulated assumptions" to be honored, made explicit, and mentored (Bevan & Penuel, 2017, p. xxii).

Methods

Distinct from conventional autoethnographies, this apprenticed autoethnography is a polyvocal piece that weaves between first and third person perspectives to capture personal and shared learning reflections. Through the lens of the researcher as an instrument of data collection (Denzin & Lincoln, 2003), we collected field notes and memos from Authors 1 and 2 throughout the 14-week YPAR project cycle to capture everyday interactions and learning (Holmes & Hall, 2020). Authors 1 and 2 wrote field notes/memos during and following each session with each other, program staff (Chloe and Khat), and youth leads (Emily and Michelle). Memos were guided by the following prompts: What's coming up for me after this [event, session, meeting etc.]?; Are there any highlights/healthy tensions?; What am I noticing about the relationship or the project this week? The final data corpus consisted of 32 single-spaced pages of university researcher field notes and memos.

Throughout a month-long series of discussion, Authors 1 and 2 analyzed these documents and identified pivotal points of relational work. Using these moments as a way "in" to the relationships, we coded for critical bifocality and caretaking relations among the selected excerpts and wrote analytic memos to demonstrate how the learning of substantive relational work mapped onto everyday moments. All partners' names have been replaced with pseudonyms.

Findings

In this section, we shift to a first-person perspective to walk through reflective vignettes which guided my (Author 1's) learning of substantive relational work as apprenticed by community practice experts. Our findings 1) show the interconnection of critical bifocality and caretaking relations in the quotidian learning of substantive relational work and 2) illustrate the importance of language, informality, and recommitment as areas with the potential to rupture bifurcated roles and asymmetry in power. We emboldened segments within each vignette which demonstrated researchers' consciousness of critical bifocality (in blue) and caretaking relations (in red).

At the start: Learning to navigate language, history, and power in research

We demonstrate how navigating historicized dynamics through language served as an opportunity for relational learning in the initial phases of the RPP. The following excerpt reflects on an initial meeting where program staff and researchers introduced themselves and their roles in the project. My (Author 1's) use of technical domain-specific language in explaining university researchers' roles and inviting our partners to engage as co-researchers—especially when understood alongside extractive histories of research in communities—visibly confused and unsettled program staff members Khat and Chloe. Through mentorship from Author 2, I reflected on the role of language and immediacy in relational work:

> Talking to Chloe **I realized that I was talking [like] how I'm used to talking in academia.** [...] Like Author 2 told me [...] **it's important to know who we are talking with and how the language we're using can affect the way that the people we're trying to build relationships can feel…especially since Khat said this was the first time they were working with researchers who wanted to learn more about what they're doing and actually try to integrate into it.** [Author 2 and I] both stayed on after Chloe left (I think he could tell I was feeling some sort of way about the exchange) and we talked it out. I appreciate [Author 2] being there. **I'm starting to see how this big deal in the literature sometimes really can be as simple as noticing how someone's feeling and staying after to talk.**

Working through these tensions with Author 2 provided me with the space to practice critical bifocality by processing and reconciling into local context the structural and historicized implications of research language—namely how it has been used to reinforce hierarchies of expertise and stifle non-researcher voices (Bevan & Penuel, 2017). As aware of these tensions as I was in the moment, I found myself unable to escape or resolve them. Through discussion and reflection, I came to see the nuanced perspective-taking and awareness of structural dynamics required to navigate how I position myself in relationships with partners through quotidian means like language. Additionally, the immediacy with which Author 2 addressed these tensions demonstrated elements of caretaking relations. Through this interaction, I realized that in addition to prioritizing relational obligations in the "here and now" (TallBear, 2019, p. 25), it was of equal importance to consciously expand who I considered as part of my spatial web in relational work. Until this point, I had conceptualized relational work in RPPs as an endeavor directed toward community partners, not fellow university researchers. Author 2 showed me

that substantive relationality is an ongoing stance—regardless of roles within a project—that pushes back on exploitative rhythms and hierarchies of work.

In the thick of it: Learning to cultivate affective connections through informality

RPP scholars detail the importance of establishing collaborative ways of work to advance relationships, but are less explicit about how this process might unfold. In the following excerpt, I (Author 1) reflected on the importance of informal interactions between program staff and youth leads in fostering collaborative routines:

> Emily, a youth lead, sat in [a YPAR session planning meeting] (totally of her volition after a check-in with Chloe where Chloe casually invited her to the meeting) and gave great feedback. **It's because of those moments of connection between people outside of meetings that so much is shared, and new doors and routines open which further cement the heart of the work we're trying to do—in this case, incorporating youth input in more of the planning.**

I learned that Chloe met with youth leads and participants individually outside of sessions to hear youths' personal updates and programmatic input, positioning them as fellow contributors and stakeholders. Just as Author 2's choice to attend those around him was rooted in critical bifocality, Chloe's commitment to caretaking relations "outside of meetings" created informal spaces for affective connection to intentionally rupture conventional hierarchies between youth and adults. This vignette demonstrates how informal moments—despite often being under-documented, undervalued, and invisible, especially in task-oriented environments—can be critical to establishing deeper routines of collaboration within RPPs.

Seeing how committing time to informality and affective connection could transform relationships, I texted Michelle, the youth lead I was paired with, to ask if she was free in the upcoming week to check in. This one-off meeting quickly became joyful weekly working sessions where we shared life updates and spirited suggestions for project directions. Throughout our relationship, I saw Michelle step into her role as a caring and passionate team lead who energized and drew out the strengths of our group members to craft an inspired youth-led project. From a critical bifocal lens, I saw how taking initiative to carve out informal, affective spaces in the RPP served as a local opportunity to push back on structures that neglect the voices of marginalized youth in social change (Caraballo et al., 2017). This instance highlights how seemingly small actions rooted in caretaking, such as reaching out and cultivating spaces for affective connection, is relational work which can transform relationships and make more democratized, synergistic work in RPPs possible.

Reprise: Learning to recommit to substantive relational work as a political stance

Part of the challenge of relational work is its nonlinear nature, which requires re-commitments and renegotiations between competing priorities and challenges. In this section, we draw attention to an everyday moment of tension between sanctioned, often rewarded markers of progress, and invisible relational work. Although not mutually exclusive, these moments of tension can serve as opportunities to engage in the unlearning and relearning required to make intentional decisions that align with who we aspire to be as researchers—amidst the backdrop of settler notions of production/progress (TallBear, 2019) which have infused social science research.

As the end of the cycle drew near, university researchers and youth leads grew increasingly conscious of the tensions between the varied academic and domestic commitments of marginalized youth and the time needed to execute their ambitious YPAR projects. Following discussion, youth leads gave their teams the option to scale down their project deliverables (i.e., fewer interviews and smaller scale surveys). In the following reflection which was crucial to my own learning regarding relational work, Author 2 reflected on his relational recommitments throughout the last few weeks of the cycle, how youth lead Emily's approach catalyzed this process, and how this decision led to new possibilities in the YPAR project space:

> I feel like I've let go of most of the impulses around scientific validity that I was struggling with in past weeks and **have tried to focus on the interpersonal and political foundations of participatory research. Being paired with Emily, who is a college student and a youth lead, I've appreciated their approach to prioritizing relationship building by building in substantial check-ins during our breakout sessions.** A few weeks ago, **I suggested integrating appreciations at the end of our group meetings as a way to build community amongst our groups.** I feel like these small gestures have helped to facilitate more engagement from everyone, but especially the younger and more quiet high schoolers in our group. Currently, we are planning the presentation. [...] **There seems to be some energy around designing a presentation that isn't an "academic" presentation, but one that integrates a**

bit more creativity and interactivity since we have several artists in the group. I think it's a great way for our group to continue to unsettle the professionalized and "scholarly" modes of research.

Through critical bifocality, Author 2 sensed the tacit obligation to commoditize the group's time and effort toward fulfilling the project to an intangible standard reflective of larger settler notions of "American dreaming" ingrained in our systems and psyches (TallBear, 2019). Reinvigorated by Emily's commitment to caretaking relations, Author 2's suggestions demonstrate a conscious decision to subvert settler mindsets of productivity (TallBear, 2019). Furthermore, this vignette demonstrated how recommitting to relationships created moments of rupture that further rebalanced asymmetries in power while pushing RPP work in innovative directions. Through deep discussion with Author 2, I realized that choosing to balance on the one hand, project deliverables and the dreams of progress they represent, and on the other, relational work with the people in front of me—despite the time commitments, emotional labor, and discomfort that came with it—was one way to unlearn these notions and disrupt systems of inequity on local and structural levels.

Conclusion, limitations, and implications

By foregrounding substantive relational work and its learning, we emphasize the importance of not reducing relationality to a broad discussion about methods, partners, or milestones— "but rather [seeing it as] a way of living and interacting with the world" (Ritterbusch 2019, p. 1300) that dictates and enables the different forms, methodologies, solidarities, intimacies, and trajectories social change projects might take. For RPP researchers committed to addressing complex issues of equity, substantive relational work in daily practice is critical to doing community-based research that both works and matters—as well as work that matters in itself.

A limitation of this paper is its focus on researcher learning. Our insights were possible in large part to the relational sensibilities each of our partners came into the space with, likely influenced by their prior work and community organizing experiences. A future direction is the amplification of community partners' rich expertise surrounding the dynamics of language, informality, and recommitment in substantive relational work. Additionally, we acknowledge that structural dynamics within the academy may incentivize particular timelines and interpretations of community-based research that may dilute substantive engagement with communities, encouraging "lite pedagogies" of relationality (Ritterbusch, 2019). As such, our insights prompt a push to design RPPs around relationally sensitive timelines and epistemologies, mentorship, and reflection opportunities to allow for substantive relational work and its learning. As equity-oriented educational improvement continues, we look to perspectives from the margins to deepen our commitments to such work with communities.

From Queer Feminism to Anti-racism: A Sociocultural Analysis of Activist Learning Across the Lifespan

Niral Shah, niral@uw.edu
Yang Hsun Hou, yhhou@uw.edu
University of Washington, Seattle

Abstract: Learning scientists have begun to spotlight social movements as important sites of learning. In this paper, we build on this growing literature by analyzing how a White lesbian activist came to learn anti-racism through her participation in the queer feminist movement. Although researchers recognize the longitudinal nature of activist learning, due to resource constraints ethnographic studies often last no longer than a couple of years. Here we respond to this challenge by presenting an analytical approach for tracing the learning of anti-racism over *extended* timescales (e.g., decades). Specifically, we suggest the potential of memoirs to illuminate learning processes across social settings and across the lifespan.

Introduction

Scholarship in the learning sciences has shown that racism, particularly White supremacy, remains a modern societal problem (Nasir, 2011). After George Floyd's public murder in the United States in 2020, people across the globe engaged in new forms of anti-racist activism. However, few studies have investigated anti-racism as a *learned* phenomenon. This is significant because empirically grounded theories of anti-racism learning have the potential to make educational efforts more effective, thereby bringing us closer to a racially just world.

In this paper, we argue for a lens on this problem that examines learning across settings and across the lifespan. To that end, we analyze the anti-racism learning processes of a grassroots organizer named Mab Segrest (hereafter referred to as Mab), as narrated in her book *Memoir of a Race Traitor* (1994). Mab's story is compelling because after growing up with a racist family in deeply segregated Alabama, this White lesbian woman became active in queer feminist movements and eventually came to identify as a "race traitor," resisting White supremacy and committing herself to deep forms of anti-racist activism. Drawing on situated and sociocultural perspectives on learning (Lave & Wenger, 1991; Wertsch, 1998), we explore the following research question: *What aspects of anti-racism did Mab learn, and how can that learning be described in terms of the relative availability of sociocultural artifacts related to race, identity, and activism across her lifespan?*

With this study we aim to make two main contributions to research on learning in social movements (Curnow & Jurow, 2021). First, we offer the beginnings of an analytical approach designed to trace activist learning across *extended* timescales. Specifically, we explore the unique affordances of memoirs as a data source for analyzing learning. Second, our findings reveal novel insights about activist learning, particularly how some activists might learn to accept the risks associated with grassroots activism.

Prior Research

In recent years, researchers have begun to conceptualize social movements as important sites of learning (Curnow & Jurow, 2021). Regarding anti-racist activism specifically, several studies have drawn on sociocultural perspectives to document anti-racism learning processes in a range of settings (e.g., environmental justice movements—see Curnow et al., 2019). Methodologically, learning scientists in this area have recognized that learning is distributed across both space (i.e., social setting) and time (Jurow & Shea, 2015). Understanding the full complexity of how, where, and when people learn to be activists requires an analytical approach that traverses what Erickson (2021) calls the "fuzzy boundaries" of people's lives: how learning travels between people's personal and professional lives, as well as between childhood and adulthood. With respect to time, Erickson (2021) has argued for researchers to employ a "diachronic approach to ethnography—ethnography in time depth" (p. 156). Whereas many prior studies have taken a longitudinal approach, due to resource constraints they can often only trace people's learning over a couple years at most. What is needed is a methodology that can capture the longitudinal, nuanced quality of activist learning.

Conceptual Framework

Anti-racism entered mainstream discourse in Europe in the wake of World War II. Since then, the field has neither settled on a single definition of anti-racism, nor does it seem wise to seek one given the adaptable nature of racism across geographic locales and social settings (Gillborn, 2004). Still, there is consensus that anti-racism goes

 © ISLS

beyond awareness to involve concerted *actions* (Paradies, 2016), and that anti-racism is intersectional with efforts to resist related oppressions (e.g., ableism, homophobia) (Dei, 1996).

To theorize anti-racism as a *learned* phenomenon, we draw on situated perspectives that characterize learning as shifts in participation in social practices (Lave & Wenger, 1991), as well as Vygotskian sociocultural theory, which emphasizes the cultural artifacts people deploy to accomplish goals and thereby mediate human activity (Wertsch, 1998). Artifacts come in material forms (e.g., a book that changes one's understanding of racism) or non-material forms (e.g., relationships with others that facilitate participation in anti-racist practices).

A key idea in the forthcoming analysis is the notion of *availability*. That is, people's thoughts and actions are mediated by those artifacts that are available to them within their lifeworld. Imagine a child who was raised in a certain type of White supremacist household: the artifacts primarily available to them would include racist narratives about White superiority, family members spouting those narratives, and racist signs like the Confederate flag. Even if the child rejects White supremacy later in life (i.e., as anti-racist artifacts become more available), we can speculate that legacy racist artifacts from their past may still exert a gravitational pull on their identities and how they live their lives. Thus, as we conceptualize anti-racism learning in terms of shifts in the relative availability of artifacts, we ask: how do various artifacts available in a person's life—across both time and setting—create the conditions for learning anti-racism?

A Brief Chronology of Mab's Life

Mab Segrest was born in 1949 in Alabama, a place with deep roots in slavery and a history of violent commitment to White supremacy. During her teenage years in the 1960s, Mab's own town became a national flashpoint of the Civil Rights movement as her school was being desegregated. Mab's discomfort with the treatment of Black people during this time led to tensions with her pro-segregation family. And while she did not identify then as queer, Mab's sexual identity further contributed to her feeling like an "outsider."

After completing graduate school in North Carolina, Mab decided to join a Southern queer feminist group that published a journal called *Feminary*. In part, this decision was driven by the break-up of her relationship with a woman named Pat, which led Mab to seek community with other lesbians and greater acceptance of her sexual identity. This period was crucial to Mab's eventual uptake of anti-racist organizing as a member of a Black-led group called North Carolinians Against Racist and Religious Violence (NCARRV).

Methods

We follow Jurow and Shea (2015) in using ontogenetic analysis to trace individual development over longer timescales. To that end, we explored the value of memoirs as data for making claims about learning. Not only do memoirs zoom in on micro-interactions (e.g., conversations between key actors), but they also often narrate events connected across many years. For this study, we searched for memoirs written by U.S.-based anti-racist activists since the turn of the 20th century. We chose Mab's memoir because of the critical role White people must play in resisting White supremacy. Additionally, Mab's intersectional identities as a lesbian woman in the South made her story particularly compelling.

Our analysis focuses on her time with *Feminary* (1976-1983; p. 37-47) because this was a significant pivot in Mab's life, as she learned ideas and practices related to queer feminist activism that set the stage for her work with NCARRV. We began by segmenting this memoir excerpt into episodes and identified each by interactions or activities that Mab was engaged in (e.g., leading an anti-racist workshop, attending a protest). We then tagged segments and clustered them thematically (e.g., intersectionality, coalition building). Finally, we independently made lists of material and non-material artifacts relevant to the activity in each segment, wrote memos and made visual representations, and met several times to compare and reconcile. Our identification of artifacts was informed in part by previous schemes for identifying sociocultural artifacts (e.g., Nasir, 2011).

We note that our positionalities—Shah (straight Brown man) and Hou (queer Han Taiwanese)—informed our highlighting of timescales, given the longitudinal nature of our anti-racism learning since childhood.

Findings

From a situated perspective, we found evidence of several shifts in the quality of Mab's anti-racism during this time (e.g., uptake of intersectionality; coalition-building across multiple social marker groups). Here we focus on one: Mab's shift towards high-risk, on-the-ground organizing. Specifically, the form of Mab's activism changed from a mostly ideological form of activism to a more grassroots form focused on direct action:

> With Feminary, our battle had been largely interior, a psychic confrontation with the lethal forces of the culture as we had internalized them. It was an intense, revealing, but sometimes

> insular process…By 1983, I had hit the limits of this internal work…Guided by the people who eventually incorporated North Carolinians Against Racist and Religious Violence, I set to work to learn to organize. (p. 52)

Outside her ideological training and writing at Feminary, Mab had begun to participate in several protests and civil disobedience actions. But what this quote highlights is the centering of grassroots organizing in her activism, which then precipitated in her move to NCARRV. Still, *how* did Mab learn this aspect of anti-racism?

Anti-racist organizing in the 1980s, in one of the historical hearts of Klan activity (North Carolina), was dangerous work. Sustainable activism requires a high risk-tolerance and sophisticated organizing skills. Next, we analyze how changes in the relative availability of certain artifacts mediated Mab's security in her sexual identity and her understanding of activism itself. In turn, we argue that these shifts facilitated Mab's learning of this aspect of anti-racism.

Self-acceptance affords greater risk tolerance

In 1976, Mab was at a low point in her personal life. For years, the position of "outsider" was a cultural artifact that took up considerable space in Mab's lifeworld (e.g., family tensions over race; uncertainty over her sexual identity). As a young adult, this narrative of being an "outsider" was temporarily assuaged after falling in love with Pat, her first serious lesbian partner. But in the loneliness and vulnerability that opened after Pat left, Mab redeployed the "outsider" narrative as an identity marker. It was under these conditions Mab joined *Feminary*.

Several new artifacts related to queer identity become available to Mab through various experiences in *Feminary*. In addition to material artifacts in the form of written histories of feminist and queer feminist movements, Mab was suddenly surrounded by lesbian women committed to empowering their communities. We can infer that these new relationships afforded Mab a model of queer people more firmly rooted in their sexual identities. About these friends and colleagues Mab wrote: "Their feminism was the language of my freedom, the necessary antidote to all my years of loneliness, self-hatred, and fear" (p. 44).

Alongside her growing acceptance of her sexual identity, Mab was also re-establishing a sense of safety and belonging in her personal life. Moving in with Carl and Allan—who she refers to as "gay brothers"—and with her friend and lover, Barb, helped Mab re-establish a sense of home that was lost when Pat left. This "alternative family," as she calls it, brought more stability into her life.

Overall, we argue that the stability Mab found through her queer feminist activism and home life laid a foundation for Mab to participate in higher-risk forms of activist practice. Of course, being a queer person in that time and place already took tremendous courage. However, anti-racist organizing represented a new level of risk. Our argument is this: when you feel like you belong, you are more likely to feel capable of participating in the collective work of high-risk organizing. The artifact of "outsider" became less available, or as Mab puts it: "Lesbian-feminism was my door into the possibility of belonging and self-acceptance…it was not long before the other issue basic to my identity—race—began to surface" (p. 46).

New artifacts shape Mab's perspective on the forms of activist work

In parallel with changes in Mab's feelings of personal acceptance and community belonging, new artifacts were also emerging that changed how she understood the work of activism itself. One formative experience in Mab's professional life was an anti-war protest she attended with thousands of women at the Pentagon in Washington, D.C. During the Pentagon protest, some of her fellow organizers were arrested, and Mab connects this to the desegregation battles during her childhood in Alabama:

> The armed guards at the Pentagon felt like the armed force that George Wallace had sent to surround my school. Its stone walls radiated the same coldness as the marble of the Alabama capitol. As I waited that night outside the jail in support of the last of our crew to emerge, I knew I was finally deciding to put my power against the power of the state." (p. 49)

There are several important sociocultural dynamics in play here. First, in recognizing "the power of the state," Mab is re-mediating how she understands her own activism and what it should be. The experience of watching her friends jailed at the Pentagon—the ultimate symbol of U.S. militarism—made available a new artifact in the form of a narrative about the high-stakes nature of anti-oppressive work. Second, the lines between Mab's past and present appear to blur, as she analogizes State-sponsored resistance at the Pentagon protest to her childhood experience of watching her community in Alabama resist desegregation. The common thread is the realization that activism transcends local conflicts—that both feminist and anti-racist activism must contend with State-level power.

 © ISLS

Another experience that re-shaped Mab's perspective on activism involved anti-racism workshops she facilitated with a colleague. Typically, these workshops consisted of participants personally reflecting on race in their lives and engaging in role plays, which afforded them opportunities to practice intervening on racism in authentic situations. These roleplays were intended to culminate in discussions of activism, but as Mab noticed, this rarely happened: "We found that participants became so absorbed in the interpersonal issues that we never got to the activism. Were we starting at the wrong end of the process?" (p. 49). In suggesting that grassroots activism might require higher priority, Mab was re-evaluating the nature of her own work. It appears that a greater urgency for direct action was becoming centered in Mab's activism, and NCARRV would offer Mab an opportunity to realize that urgency.

Discussion & Future Considerations

This paper contributes to research on learning in social movements by offering the beginnings of a methodological approach that attends to learning at both micro and macro timescales. In response to Erickson's (2021) call for greater "time depth" in such work, we have argued here for the potential of memoirs as data, which to our knowledge have not been used to analyze learning. Like all data, memoirs have limitations, but we believe they resonate with more established ethnographic approaches to studying learning.

In Mab's case, our analysis reveals that her learning did not hinge on a single epiphany about racism or a particular moment of clarity, but that instead it unfolded over long stretches of time in nonlinear fashion. We showed how fluctuations in the availability of different artifacts over many years help explain her eventual move to anti-racist organizing. The foregrounding of new artifacts (and backgrounding of others) created the conditions for new and deeper forms of learning. More broadly, we suggest that this study highlights the value in applying learning theory to questions of anti-racism.

We close with two questions for future consideration. With respect to research, if people's motivations for and learning of anti-oppressive activism is mediated by forces across the lifespan, then how can we design research that surfaces the historical nature of these learning processes? And relatedly, with respect to practice, how should anti-racism education initiatives account for the long timescales of anti-racism learning?

Use of Crosscutting Concepts as Epistemic Heuristics

Lori Andersen, University of Hawai'i at Mānoa, lori.andersen@hawaii.edu

Abstract: Drawing from analyses of teaching and learning and a framework for epistemic thinking, I use four levels of epistemic thinking (practical, epistemic cognition, epistemic metacognitive knowledge, epistemic metacognitive strategy) and an implicit-explicit dimension to distinguish among uses of and supports for the crosscutting concepts. This work has implications for the design of learning environments that can promote students' metacognition about the crosscutting concepts.

The issue addressed

One critical aspect of engaging all students in science learning is to prepare them to guide their own scientific intellectual work (Nordine et al., 2021). Metacognition refers to students' awareness and understanding of their own thought processes (New Oxford American Dictionary). Epistemic heuristics are rules for guiding one's scientific work (Knorr Cetina, 1999; Krist et al., 2019), such as the tacit rules that scientists use to develop explanations for how and why phenomena happen (i.e., Anderson, 2018). However, the epistemic heuristics that guide this work in school science have generally not been made clear to students, which prevents many students from developing metacognition. The crosscutting concepts (CCCs) in the Next Generation Science Standards can be interpreted as a representation of these epistemic heuristics (Anderson, 2018; Krist et al., 2019; Rivet et al., 2016) and there is agreement that the CCCs should be made clear to students, but there is a lack of consensus on how and why to do so (Miller & Shelton, 2021; Nordine et al., 2021). I present an equity argument to explain why it is necessary to make CCCs clear to students and a two-dimensional model (implicit-explicit, practical-epistemic) with four levels of epistemic thinking to describe how to make the CCCs clear to students.

Potential significance of the work

A lack of clear epistemic heuristics can prevent members of marginalized communities from fully engaging in science (Cooper, 2020), which is an equity issue. There is a need for clear teaching of epistemic CCC use so students can move toward self-regulation and direct their own scientific sensemaking. Teaching and learning that provides all students opportunities to learn how to use the epistemic heuristics will increase equity (Cooper, 2020; Fulmer et al., 2018; Nordine et al., 2021). Fick et al., (2020) introduced axes of support (practical-epistemic and implicit-explicit) with four categories of CCC supports. In this paper, a three-level epistemic thinking model describes three subcategories of epistemic CCC uses that are learning goals. Each subcategory of CCC use corresponds to specific instructional supports. This new two-dimensional model provides a more detailed framework for improving our understanding of the nuances of CCC use and how to provide instructional supports.

Epistemic thinking and epistemic heuristics

In general, *thinking* includes both the use of mental processes (i.e., cognition) and the knowledge and regulation of one's own mental processes (i.e., metacognition; Barzilai & Zohar, 2016). In the context of science teaching and learning, *epistemic* means related to the development of scientific knowledge. *Epistemic thinking* encompasses epistemic cognition and epistemic metacognition (Barzilai & Zohar, 2016). Epistemic cognition is a students' ability to use a mental process to develop scientific knowledge, while epistemic metacognition is a students' ability to monitor and control the use of a mental process to develop scientific knowledge.

Epistemic heuristics are mental processes for guiding scientific intellectual work (Knorr Cetina, 1999; Krist et al., 2019), such as the unwritten rules that scientists use to develop explanations for how and why phenomena happen (i.e., Anderson, 2018). The crosscutting concepts (CCCs) in the Next Generation Science Standards are statements of these epistemic heuristics (Krist et al., 2019; Rivet et al., 2016). In this paper, the term CCCs refers to their use as epistemic heuristics, which is important because how the CCCs are presented in instruction may result in non-epistemic use by students (Andersen, 2021; Fick et al., 2020). For example, students may look for patterns without knowing how or why they are doing so, which is an example of non-epistemic use. On the other hand, students can be supported to know how to use the patterns CCC, why to use the patterns CCC, and how to self-regulate the use of the patterns CCC, which are different aspects of *epistemic* use.

Describing CCC use with levels of epistemic thinking

A two-dimensional model (implicit-explicit, practical-epistemic) with three levels of epistemic thinking can help science educators distinguish among different kinds of CCC use and provide appropriate instructional supports.

 © ISLS

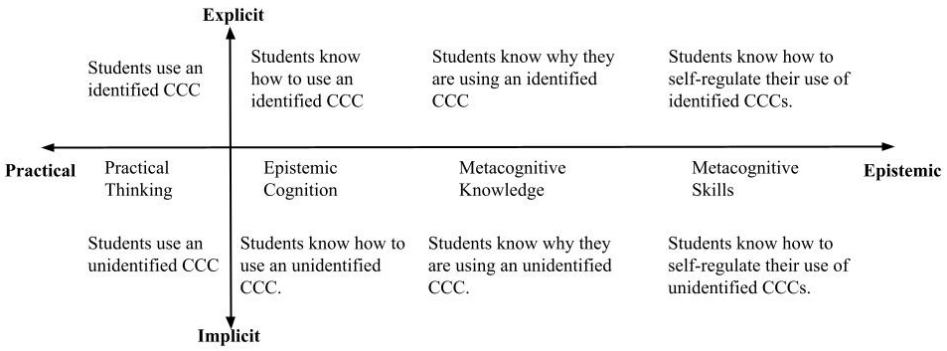
Prior theoretical work established axes of support based on two continua, implicit–explicit and practical–epistemic (Fick et al., 2020), which described four quadrants that represent four categories of CCC supports. The practical–epistemic axis was described as a continuum, but specific criteria to meaningfully compare and contrast levels of epistemic CCC supports on the continuum were not provided. I have modified the practical-epistemic axis using a practical-epistemic continuum with four levels—practical thinking, epistemic cognition, epistemic metacognitive knowledge, and epistemic metacognitive skill—to resolve the issue. In addition to providing defined levels of epistemic supports, this model also uses a modified definition of explicit. The definition Fick et al. (2020) used overlaps with the extant definition for epistemic thinking (i.e., Barzilai & Zohar, 2016), which made the two axes interdependent. The new model uses a revised definition that removes the overlap and improves alignment with the educational psychology literature. These modifications are explained in more detail in the next section.

Defining the implicit-explicit and practical-epistemic continua

Figure 1 is the new two-dimensional model of CCC use. The vertical axis represents the implicit-explicit dimension. *Implicit* use of a CCC is use without knowing you are using that particular CCC (Fick et al., 2020), such as when students use their intuitive ideas about CCCs (e.g., Goggins et al., 2021). However, in contrast with the prior definition of *explicit* as "including supports for students to know *how and why* to use the CCC..." (Fick et al., 2020, p. 854), I define *explicit* as including supports for knowing *that* you are using a particular CCC, removing the how and why component because the defined levels of epistemic thinking (e.g., Barzilai & Zohar, 2016) already account for that component. The lowest level of epistemic thinking, *practical thinking*, is use of a CCC based on intuition. The other three epistemic thinking levels make important distinctions between epistemic cognition and two levels of metacognitive thinking. *Epistemic cognition* refers to knowing how to use a CCC, while *metacognitive knowledge* refers to knowing why to use a CCC. In this way, how and why to use a CCC are addressed by epistemic cognition and metacognitive knowledge. *Metacognitive skills* are the ability to regulate one's own use of the CCCs (Barzilai & Zohar, 2016) and this highest level extends the Fick et al. (2020) practical-epistemic continuum to support students' agency and the engagement with multiple CCCs. Figure 1 indicates eight types of possible CCC uses or supports that provide a way to distinguish among different kinds of epistemic uses of CCCs, which was not possible with the Fick et al. (2020) model.

Figure 1

Two-dimensional Model of CCC Use



Example

In this section, an example of metacognitive knowledge support for CCC use from a fifth-grade science curriculum unit is examined. In the example, the teacher leads a discussion about the use of data from an investigation to figure out what happens to materials in our garbage over time (NYU SAIL, 2019).

> *To answer our question, we will record change in the properties of the garbage materials and the weight of the landfill bottle systems*. Direct students to look at the property and weight data tables in Investigation 2-1: Landfill bottles. Ask students to describe how the data tables are organized and how the data tables may be helpful in answering the investigation question. (The first data table allows us to record the properties of the materials at each time point. This will help us figure out whether the materials change over time. The second data table allows us to record the weight of the materials at teach time point. This will help us figure out whether the materials vanish over time. The second data table also has separate columns for the open and

> closed systems so that we can make comparisons between these conditions. (NYU SAIL, 2019, Lesson 2-1 p. 8)

This example supports students' metacognitive knowledge use of CCCs because the purpose of the discussion is for students to understand why they are using specific CCCs. Some of the CCC supports are implicit because the CCCs are not called out formally (e.g., patterns), while other CCC supports are explicit (change). The purpose of the discussion is to help students use multiple CCCs to develop a causal explanation for the changes they will observe in the landfill bottle. The discussion develops knowledge about each CCCs contribution to the causal explanation, which is why that CCC should be used (i.e., metacognitive knowledge). Later, when students construct explanations independently, they will need to have metacognitive skills to self-regulate their use of many CCCs. Providing all students with greater opportunity to learn why they to use specific CCCs and develop self-regulation is an equity strategy because typical instruction has denied such opportunities to students from underrepresented groups (Cooper, 2020).

Discussion: Interpreting the continua

Based on document analyses of a curriculum unit using the two-dimensional model (Andersen, 2022), I identified examples of the levels of epistemic thinking. Practical thinking is when students use their personal resources to access CCCs in science. One support for practical thinking with the cause-and-effect CCC was

> Say, *now that we have recorded our first set of data, we have to wait. What do you think will happen to the different garbage materials over time? Why do you think that?* Have students talk in partners about their predictions. Then tell students to write their predictions and reasons for their predictions... (NYU SAIL, 2019, Lesson 2-1 p. 11)

In this example, the teacher is asking students about their ideas for what will happen and why, which is a practical thinking support for students to use the cause-and-effect CCC in their own practical thinking. Practical thinking is an opportunity for students to use their home-based resources in science learning, which can increase equity (Goggins et al., 2021). Later in the unit, we see practical thinking support for the same CCC that is made explicit by calling out the CCC.

> How will you show what ***causes*** changes in the landfill bottles? Also, remind students about the process of microbes, In our model, it is important to think about the process. The ***cause*** is microbes. The ***effect*** is decomposition of food materials. (NYU SAIL, 2019, Lesson 4-2 p. 11)

Building directly on the knowledge that all students bring to school helps to build science identity and increase engagement in science for students from underrepresented groups, which is an equity strategy (Goggins et al., 2021). In this next example, we see epistemic cognition support for the systems and system models CCC.

> What we are doing today is different than a drawing you might do in art class. In art class, we might focus on making the drawing exactly like what we see. In science, we focus on details that are important to our investigation. We use symbols and a key to represent components of the ***system***. For example, in art class we would draw a real looking banana, but in science we could use a symbol of a circle to represent a banana and a symbol of a square to represent the aluminum foil. (NYU SAIL, 2019, Lesson 2-1 p. 11)

This example shows support for students to know how to use the CCC as they identify the system components (epistemic cognition). Andersen (2021) identified 290 examples of CCC supports through document analysis of the NYU SAIL (2019) curriculum, including supports for all four levels of epistemic thinking (practical, epistemic cognition, epistemic metacognitive knowledge, epistemic metacognitive strategies). These supports strategically facilitate learning experiences, or ***metacognitive experiences***, in the curriculum including discussion that describes the goals, concepts, and processes that scientists use to produce knowledge (Chinn et al., 2020), such as the examples provided above. In other words, the teachers' guide included many explicit supports that teachers could use to facilitate students' epistemic use of the CCCs (Andersen, 2021), which is different from the findings of similar studies of teaching and learning that showed mostly implicit supports (e.g., Fick et al., 2021; Markwordt et al., 2022). Providing explicit supports that facilitate students' epistemic thinking broadens students' access to science and can make science teaching more equitable (Cooper, 2020; Goggins et al., 2021).

Conclusion

Instructional supports can provide metacognitive experiences for the CCC uses represented by the eight regions in Figure 1. These supports are needed to help students move from practical use to epistemic cognition and eventually to metacognitive skill. Equitable science curriculum must provide intentional, strategic supports that allow all students to develop their epistemic thinking abilities, rather than relying on students to understand and internalize tacit norms, which has historically yielded inequitable results (Goggins et al., 2021). Epistemic thinking should begin with practical use of CCCs, then build to three levels of epistemic thinking—epistemic cognition, metacognitive knowledge, and metacognitive skills. I hypothesize that students epistemic thinking moves through the epistemic thinking levels as they engage in learning experiences, or metacognitive experiences, that require them to use CCCs at corresponding levels of epistemic thinking. Those metacognitive experiences are facilitated by teachers via curricular supports. Metacognitive experiences are relevant learning activities that develop the elements of epistemic thinking (Barzilai & Zohar, 2016). The eight distinct types of CCC use (Figure 1) suggest directions for future research to examine how curriculum and teaching can strategically and systematically support students' emerging use of the CCCs as epistemic heuristics. This work has implications for equitable science teaching and learning because without intentional supports many students will not take up these epistemic heuristics, particularly those who are members of marginalized groups.

Shifts in high school students' conceptions of sensor-based devices and toys

Gayithri Jayathirtha
gayithri@upenn.edu
University of Pennsylvania

Abstract: Advancing conceptions of computing system internals—structural composition and dynamic behavior— is key to learning computing and critically engaging with it. However, novices' informal ideas challenge their engagement. In this study, I conducted and qualitatively analyzed ten students' interviews about a pair of functionally similar computing artifacts before and after a 14-week-long online electronic textiles unit. The analysis revealed that, post-unit, students had developed advanced conceptions of computing systems, both structurally and behaviorally. They frequently accounted for computing and explained internal dynamics in terms of data and control flow. I discuss implications of the findings for future computing education research and designs to promote critical computing learning.

Keywords: Computing learning, student conceptions, physical computing, electronic textiles.

Introduction & Background

A primary objective of introductory computing education is to help learners develop a conception of layers of abstractions between software and hardware that make everyday computing systems functional (CSTA, 2017). With devices such as automatic soap dispensers and facial recognition software critiqued for biases against marginalized peoples (e.g., Costanza-Chock, 2020), understanding the internal dynamics of computing systems is important. But, we barely know how learners think about computing devices and their internal workings.

Student conceptions of physical computing artifacts consist of structure, behavior, and function (Bhatta & Goel, 1997). The physical parts of the system and interconnections make the structural composition; roles of different elements cover the functional aspects; and the underlying logic causing outcomes through control and data flows accounts for the behavior. For sensor-based devices: (1) the *structural* aspects include microcontrollers, sensors, lights, and the physical interconnections; (2) the *functional* aspects consist of lights as outputs and sensors as inputs; and (3) the *behavioral* aspects include the underlying program logic that causes outcomes.

In prior studies, learners have been interviewed about coffee makers, stoplights, and smartphones to capture their conceptions (e.g., Przybylla & Romieke, 2014). Across, novices' limited understanding about these systems stands out. With only input and output components visible, learners develop naïve notions about the inner structural composition of these systems. A few studies (Cederqvist, 2020; Jayathirtha & Kafai; 2021) have noted how even students within computing courses have a limited understanding of these computing devices. Concepts of control and data flow—how inputs such as touch and light intensity cause different outcomes—were almost inaccessible to novices (e.g., Cederqvist, 2020). In this paper, we conducted and qualitatively analyzed student interviews (Creswell & Poth, 2016) before and after an introductory e-textiles unit within a high school online class. We asked: How did student conceptions, particularly their structural and behavioral understanding, of physical computing systems shift at the end of the unit?

Methodology

Context and participants

The study was conducted at a public charter high school located in a U.S. west coast city. An experienced high school computing teacher was teaching online an e-textiles unit within the *Exploring Computer Science* course (Kafai et al., 2019). To highlight the internal dynamics of physical computing systems, the teacher infused a variety of additional explanations and learning activities throughout the unit. In this paper, we focus on analyzing shifts in student conceptions about physical computing systems pre- and post-unit. The teacher chose ten of the 24 consenting students (5 male, 5 female; all except one identified as non-White) for interviews. All students were formally learning to program for the first time and had ~10 weeks of *Scratch* programming.

Data collection and analysis

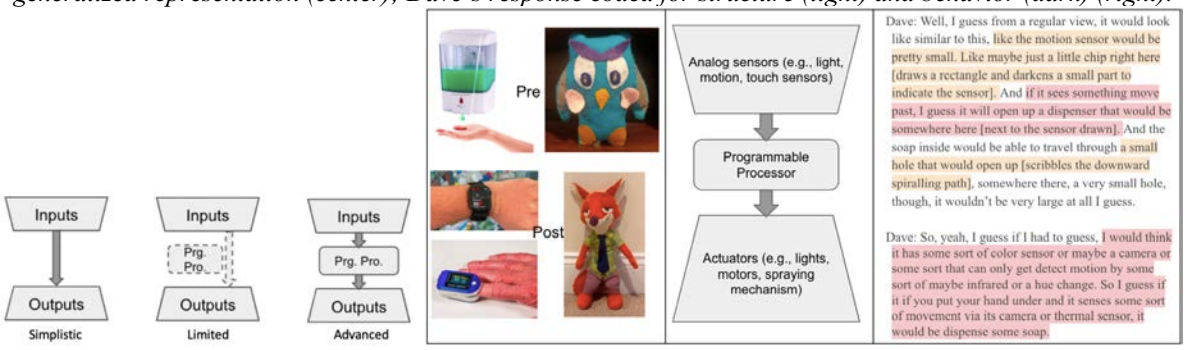
 © ISLS

I interviewed students pre- and post-unit to capture their structural and behavioral understanding. Each interview (~20-30 mins each) had two sets of questions: one about the working of a sensor-based everyday device (automatic soap dispenser pre-unit and pulsometer post-unit) followed by another about an interactive toy (see Figure 1, center). All four artifacts were functionally similar, i.e., involved analog sensors and outputs but differed aesthetically (see Figure 1, center). The everyday technologies were not discussed in class and the toys were similar to student e-textile projects but more sophisticated. Students were given the functional description of the artifacts during the interviews and asked questions such as: "what do you think is inside? How do you think it works?". They were encouraged to draw and explain.

Student responses across pre- and post-unit interviews were thematically analyzed for structural and behavioral details (see Figure 1, right). Based on earlier work (Figure 1, left; Jayathirtha & Kafai, 2021), I deductively generated a codebook to identify structural and behavioral details and qualitative distinctions (*simplified, limited, advanced* in Figure 1, left). For instance, structural and behavioral aspects were separated in Dave's response (light and dark shades in Figure 1, right), and each was further classified as *simplistic* since there was no mention of any computation mediating inputs and outputs in the structural or behavioral explanations. Structural explanations that included a computing component but lacked apparent interconnections between parts were categorized as *limited.* Explanations with clear interconnections between computing, input, and output devices were coded as *advanced*. Within behavioral explanations, the mere mention of computing without further details about its role was coded as *limited*, and explanations with any further elaboration about how computing mediates the system behavior were categorized as *advanced*. I, along with another researcher, discussed the codebook and analyzed two students' (20% of the dataset) pre- and post-unit interviews. We agreed upon 15 out of 16 (93.75%) codes and resolved the discrepancy through discussion. We analyzed the rest of the interviews independently, verified their responses (~90% agreement), and clarified discrepancies.

Figure 1

Representation of categories of student conceptions (left), Pre- and Post-interview artifacts and their generalized representation (center); Dave's response coded for structure (light) and behavior (dark) (right).



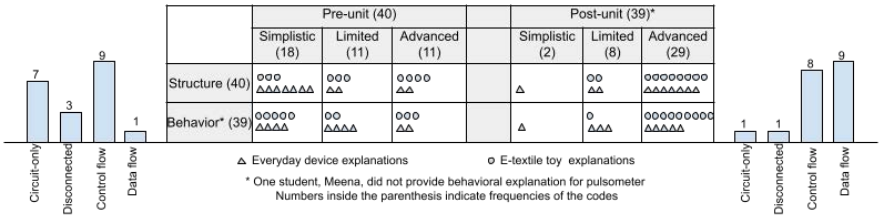
We further inductively analyzed (Creswell & Poth, 2016) behavioral explanations and captured four key themes: (a.) behavioral descriptions which involved only circuit-based mechanisms; (b.) explanations that treated programs and circuits as disconnected; (c.) explanations that only accounted for control flow (such as basic conditional logic) within the systems; and, (d.) descriptions that include both control and data/information flow between programs and circuits during program execution. The first two closely overlapped with *simplistic* and *limited* explanations. The latter two themes were evident within the *advanced* category, i.e., accounted for computing but by highlighting different aspects of its dynamic nature. The same researcher was presented the themes and example excerpts from student responses who agreed with most of them (85% agreement). Disagreements were resolved through discussion.

Findings

Overall, students' structural and behavioral understanding of sensor-based devices and toys shifted from simplistic or limited pre-unit to advanced post-unit (see Figure 2, central table). Pre-unit, structural explanations were mainly limited to input and output devices. Behavioral explanations either involved only electronic interactions between circuit elements or accounted for control flow similar to conditional logic in *Scratch.* However, post-unit, structural explanations included computational components and clearer interconnections. Further, behavioral explanations included data flow details involving sensor values and their processing.

Figure 2

Distribution of student responses across structural and behavioral details (table) and themes and frequencies within behavioral explanations pre- and post-unit (graphs either sides).



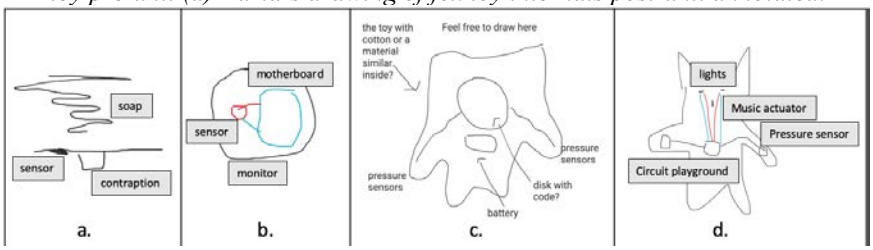
Towards advanced structural understanding

Most structural explanations pre-unit missed computing, more so in the case of automatic soap dispensers (Figure 2, Simplistic column along Structure row). Although the toy's structural composition was more accessible pre-unit, most responses still lacked interconnections between different components (14 out of 20). However, post unit, students' structural explanations across artifacts involved a computational component and interconnections (table in Figure 2, Structure row). Most descriptions included computing-related components such as "motherboard" and microcontrollers, and drew interconnections between input, output, and processing unit.

Across both interview artifacts, explanations about structural composition got more sophisticated post-unit. Pre-unit, more than half of the explanations (14 out of 20) missed any computing component or included one without a clear role. For instance, in pre-unit, Dave described the internals of the soap dispenser as involving only a sensor and a mechanical "contraption" for letting the soap out (Figure 4, a.; 020521, pre-unit). These explanations are unlike Karla's pre-unit response that involved a "disk with code" connected to the "pressure sensors" at the hands of the toy bird, without any connections with the "disk" (Figure 4, c.). However, at the end of the unit, most descriptions (15 out of 20) involved a separate microcontroller connected to input and output devices. Besides structural composition, there was a significant difference in how students explained interconnections post-unit compared to pre-unit. Unlike mentioning different parts without interconnections pre-unit, students made more elaborate connections post-unit. For instance, in his description of how a pulsometer works, Dave clarified that the sensor and the screen will be connected to the "motherboard" to receive values and display them onto the screen. This is comparable to Karla's explanation post-unit involving microcontroller and actuators with definite interconnections (Figure 4, d.).

Figure 4

(a) Dave's annotated drawing of internal structure of an automatic soap dispenser pre-unit; (b) Dave's pulsometer internals post-unit annotated; (c) Karla's structural drawing of the bird toy pre-unit (d) Karla's drawing of fox toy internals post-unit annotated.



Towards advanced behavioral understanding

Unlike structural understanding, pre-unit, students' conception of both systems' internal behaviors was simplistic or limited (Behavior row in Figure 3). However, post-unit, this shifted to more advanced understanding within behavioral descriptions across the everyday technologies and e-textile toys, more pronounced in the case of the toy. Further, students included more data and control flow details in their internal working explanations post-unit.

Before the unit, most behavioral explanations (15 out of 20) were either simplistic or involved computing in a limited fashion. For example, Santos explained the underlying mechanism for the toy as "two pieces of wires, when squeezed, touch and send a signal to the light. They turn brighter when you squeeze them harder" (022421, pre-unit). However, post-unit, students' explanations involved more computational details, moving between the

different layers of abstractions between the hardware and the software. Most (15 of 19) descriptions had computing mediating data flow between the input sensors and the actuators such as LEDs or the display; only 5 of the 19 explanations were simplistic or limited. Overall, learners more often acknowledged the role of programs in controlling the behavior of the system post-unit.

Students' behavioral explanations, post-unit, moved from predominantly circuit-based or control-flow-based to more data-flow-based (see Figure 3, graphs on either side). Pre-unit, a majority either involved only circuit-related aspects (7 out of 20) or treated circuit and program as separate entities (3 out of 20) or explained in terms of conditional control flow, drawing from *Scratch* they had just learned (9 out of 20). However, post-unit, students better articulated the mediating role of computing within these artifacts, at least in one of their explanations. A majority of explanations (9 out of 19) included some form of computation with numerical values produced by the sensors and programs as comparing values to make decisions for outcomes or performing arithmetic operations on them such as counting or incrementing based on the pulses sensed. However, a small proportion of students (2 out of 10) struggled to explain the behavior of the pulsometer.

Discussion

Students moving towards constructing advanced explanations of the internal dynamics of everyday devices and interactive toys post-unit is promising in a few ways. Unlike prior studies that reported school students across a wide range of ages having difficulty unpacking everyday devices (e.g., Cederqvist, 2020), our results noted that high school students within physical computing unit shifted their conceptions. However, given that this was one of the first studies exploring changes in learner conceptions across a semester-long unit, more work is needed to examine the role of curricular projects, the curriculum, and the context of e-textiles in deepening student conceptions about the inner workings of physical computing systems.

Analyzing students' structural and behavioral conceptions illuminated specific aspects of this conceptual shift. Learners not only developed a more detailed understanding of the structural composition and connections, but they had also developed a language to talk about different layers of abstractions between the hardware and software. Such a trend can be considered a step towards understanding the underlying designs of everyday devices that embody social injustices (e.g., Costanza-Chock, 2020). Thinking about the internal dynamics of devices such as automatic soap dispensers or digital pulsometers in terms of sensor values and their processing makes room for critical questions such as who's data is included and excluded in the device design and what are the implications for different user groups. Such questions can lead to recognizing how social aspects such as race, gender, sexual identity, etc., intersect with the design of these devices and developing computing literacy required to advocate for actionable design changes within everyday computing systems (Costanza-Chock, 2020).

University of Louisville

Abstract: This study tested whether exploring with simulations before instruction offers the conceptual benefits of "productive failure," compared to a more traditional lecture-then-practice method. Undergraduate students (*N*=218) in introductory chemistry courses completed an activity using an online simulation about atomic structure. Students either completed the simulation activity before (explore-first condition) or after (instruct-first condition) a lecture on the topic. Students in both conditions scored equally on an assessment of basic facts taught in the instruction. However, students in the explore-first condition scored significantly higher on assessments of conceptual understanding and transfer to a new concept, compared to students in the instruct-first condition. Students in the explore-first condition also reported experiencing greater competence and curiosity during the learning activities. A guided simulation activity prior to instruction can have both motivational benefits and deepen students' understanding.

Introduction

Exploratory Learning

Exploratory learning reverses the typical lecture-then-practice order of instruction, by giving students an exploration activity prior to direct instruction on the underlying topic. A growing number of studies have demonstrated that exploring before instruction improves students' conceptual understanding (Darabi et al., 2018; Loibl et al., 2017; Sinha & Kapur, 2021). Studies have also shown that students who explore first are better prepared for "future learning"— transferring their understanding to a related topic (Schwartz & Martin, 2004).

Completing a novel activity before instruction can be challenging, but also beneficial to learning. This process is considered "productive failure" for several reasons (Kapur, 2016). First, students consider what they already know about the content area, better integrating prior knowledge with the new knowledge (Newman & DeCaro, 2019). Second, students realize that they have gaps in their understanding—increasing the accuracy of their metacognition (Glogger-Frey et al., 2015) and heightening curiosity (Lamnina & Chase, 2019). Finally, students discern what features of the problems are, and are not, relevant to solving the problem (DeCaro & Rittle-Johnson, 2012; Glogger-Frey et al. 2015; Loibl et al., 2017; Schwartz & Martin, 2004).

Although exploratory learning has been shown to improve conceptual understanding, not all studies show this benefit (e.g., Chase & Klahr, 2017). More research is needed, in order to demonstrate when an exploration activity will benefit student learning or not. Additionally, little is known about whether activities that do not involve problem solving also have conceptual benefits when used as exploration activities.

Current study

The current study examined whether an online, interactive simulation benefits students' conceptual understanding when used as an exploration activity before a lecture, as opposed to practice after a lecture. *Interactive simulations* are graphically visualized representations of events, processes, and systems, designed to allow students to engage in scientific inquiry (Moser et al., 2017). When using a simulation, students can test hypotheses by systematically adjusting parameters and manipulating objects. Simulations have been increasingly accessible and popular to use in STEM classrooms (Blake & Scanlon, 2007). Despite their differences from the problem-solving activities typically used in exploratory learning, simulations present many of the same features thought to be useful (Kapur, 2016). For example, completing a simulation before instruction is potentially challenging but engaging, students can use prior knowledge to work on them, they offer feedback that can help students discern important problem features, and they include a wide problem space for students to explore.

In a controlled experimental design, students in undergraduate chemistry courses were randomly assigned to condition. Each condition included the same materials in different order. Students in the *explore-first condition* completed an online simulation activity on atomic structure, then were lectured on this topic. Students

 © ISLS

in the *instruct-first condition* completed lecture, then the simulation activity. All students then completed a survey assessing their perceptions of the learning activities. Finally, students completed a posttest assessing knowledge of facts directly taught during the lecture, targeted concepts, and transfer of knowledge to a new, related concept.

We hypothesized that the benefits of exploring before instruction would not be found on assessment of the taught facts, but rather on the conceptual and transfer items (e.g., Loibl et al., 2017; Schwartz & Martin, 2004). We also explored whether general motivational factors (situational interest, curiosity, self-efficacy, competence, belonging) would increase in the explore-first condition. Some prior studies have shown evidence of improved interest, but results have been mixed (e.g., Weaver et al., 2018), and most studies have not examined these factors. Such results would demonstrate that simulations can be used effectively as exploration. Moreover, conceptual changes may arise from a technique that is easy to implement, even in large undergraduate STEM courses.

Methods

Participants

Participants (N=218) were all undergraduate students (M_{age}=18.7, SD=2.38, 44.5% female) enrolled in two sections of an introductory chemistry course who completed both the simulation activity and posttest. Additional students were excluded from analyses for not attending the full class session (5 students), or for illegible writing on the posttest that precluded scoring (1 student).

Materials

The class sessions included four phases that varied in order: simulation activity, lecture, survey, and posttest. Students in the *instruct-first condition* (n=116) completed the lecture, then the simulation activity. Students in the *explore-first condition* (n=102) completed the simulation activity, then the lecture.

In the *simulation activity*, students explored the *Build an Atom* Physics Education Technology (PhET) interactive simulation (https://phet.colorado.edu/en/simulations/build-an-atom) using their own devices. Students were given a worksheet to guide their exploration, and most students worked individually. The worksheet consisted of brief instructions on how to operate the simulation, followed by guiding questions (e.g., Place a neutron in the nucleus. What is the name of the element?"). In the *lecture*, the course professor gave direct instruction on the topic of atomic structure accompanied by presentation slides. The lecture began by introducing the basics of atoms, followed by description of atomic structure, isotopes, and atom identity.

Survey items assessed motivational factors related to the learning activities, using a 5-point Likert scale (1=*Strongly Disagree*, 5=*Strongly Agree*). Items assessed students' perceived *self-efficacy* (2 items, α=.72; adapted from Findley-Van Nostrand & Pollenz, 2017; e.g., "I feel confident in my ability to learn these kinds of topics"), *competence* (2 items, α=.37; Findley-Van Nostrand & Pollenz, 2017; e.g., Thanks to today's learning activities, I feel more competent in this topic area), *situational interest* (3 items, α=.62; Rotgans & Schmidt, 2014, e.g., "I enjoyed working on these activities"), *curiosity* (3 items, α=.60; Naylor, 1981; e.g., "I want to know more about what I was working on"), and *prospective belonging uncertainty* (4 items, α=.82; adapted from Walton & Cohen, 2011; e.g., "Sometimes I worry that I do not belong in college." The belonging items were reverse coded, so that higher scores reflected greater perceived belonging. Next, students completed the *Mental Effort Rating Scale,* a measure of cognitive load (1 item; Paas, 1992; "In completing the learning activities I invested…"). This item was rated on a scale from 1 (*very, very low mental effort)* to 9 (*very, very high mental effort*). Additional survey items were not included in the current report. Finally, students provided demographic information.

The *posttest* included 12 open-ended questions developed by two content experts (chemistry professors). Six items assessed facts taught during the lecture (6 points; α=.76; e.g., "What is the name of the particle that has no charge?"). Five items targeted conceptual knowledge (10 points; α=.31; e.g., "Explain the difference between an atom and an ion"). One item tested knowledge transfer (2 points; "What is the charge of an ion that has 12 protons and 13 electrons? Explain your answer").

Procedure

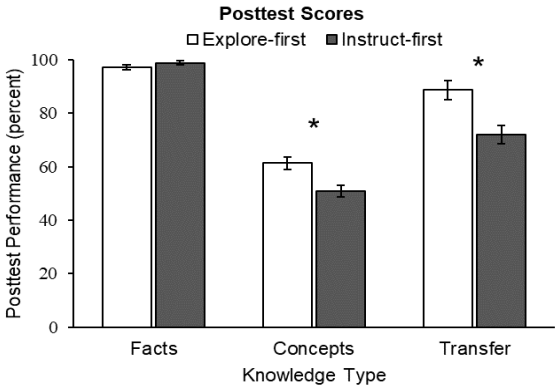
Students were enrolled in two sections of an introductory chemistry course, taught by the same professor in large lecture halls. Each course section was randomly divided into two groups and asked to attend on Wednesday (instruct-first condition; n=102) or Friday (explore-first condition; n=116), in a 50-min session. The explore-first condition began with the simulation activity (approximately 15 min), then the lecture (approximately 15 min). The instruct-first condition completed the lecture then simulation activity. Then, students completed the questionnaire (5 min) and posttest (10-15 min) on paper, without computers or notes. Students were told that responses would not be graded and assessed how they learned from the activities. Weeks later, the instructor sent a debriefing email with the option to withdraw data. All procedures were approved by the university IRB.

Results

Learning Outcomes

Posttest scores were examined using a 2 (*instruction order*: explore-first, instruct-first) × 2 (*knowledge type*: facts, concepts) mixed-factorial analysis of variance (ANOVA), with instruction order between-subjects and knowledge type within-subjects. A significant main effect of instruction order was found, $F(1,216)=5.63$, $p=.018$, $\eta_p^2=.03$. On average, posttest scores were higher for students in the explore-first condition ($M=79.22\%$, $SE=1.31$) than in the instruct-first condition ($M=74.94\%$, $SE=1.23$). There was also a significant main effect of knowledge type, $F(1,216)=649.82$, $p<.001$, $\eta_p^2=.75$, with higher scores on questions assessing basic facts ($M=97.96\%$, $SE=0.63$) than concepts ($M=56.20$, $SE=1.60$). These effects were qualified by a significant interaction, $F(1,216)=13.71$, $p<.001$, $\eta_p^2=.06$ (Figure 1). Follow-up ANOVAs revealed that fact knowledge scores were not significantly different between the explore-first ($M=97.06\%$ $SE=0.91$, *95% CI*[95.28, 98.86]) and instruct-first ($M=98.85\%$, $SE=0.86$, *95% CI* [97.16, 100.54]) conditions, $F(1,216)=2.05$, $p=.154$, $\eta_p^2=.01$. Concept knowledge scores were significantly higher in the explore-first ($M=61.37\%$, $SE=2.34$, *95% CI*[56.76, 65.98]) than the instruct-first condition ($M=51.03\%$, $SE=2.19$, *95% CI*[46.71, 55.36]), $F(1,216)=10.40$, $p<.001$, $\eta_p^2=.05$. A separate ANOVA demonstrated that students in the explore-first condition ($M=88.73\%$, $SE=3.63$) scored higher on transfer than those in the instruct-first condition ($M=71.98\%$, $SE=3.41$), $F(1,216)=11.29$, $p=.001$, $\eta_p^2=.05$.

Figure 1
Posttest scores as a function of knowledge type and order of instruction. Error bars = ± 1 SE.



Survey

Instruction order had no impact on reported cognitive load (Table 1), $F(1,209)=1.61$, $p=.207$; by the end of the class session, students in the explore-first condition did not perceive higher mental effort. To assess differences between instruction orders on the other survey items, a MANOVA was used. A significant overall effect of instruction order was found, $F(5,174)= 2.89$, $p=.016$; Wilks' $\Lambda=.923$, $\eta_p^2= .08$. On average, students in the explore-first condition rated these measures as higher than the instruct-first condition. Examining each scale, significant differences were found for curiosity, $F(1,178)=4.81$, $p=.030$, $\eta_p^2=.03$, and competence, $F(1,178)=6.04$, $p=.001$, $\eta_p^2= .06$ (Table 1).

Table 1 *Descriptive Statistics for Survey Subscales*

	Explore-First			*Instruct-First*		
	M	*SE*	*95% CI*	*M*	*SE*	*95% CI*
Cognitive Load	5.51	0.15	5.21–5.80	5.24	0.14	4.96–5.52
Self-efficacy	4.35	0.05	4.24–4.46	4.28	0.06	4.16–4.39
Belonging	4.04	0.08	3.88–4.20	3.98	0.09	3.81–4.15
Curiosity	**3.79**	**0.05**	**3.68–3.89**	**3.58**	**0.08**	**3.41–3.74**
Competence	**3.78**	**0.08**	**3.63–3.92**	**3.41**	**0.09**	**3.24–3.57**
Situational Interest	3.97	0.06	3.85–4.08	3.86	0.07	3.71–4.01

Note: Bold=statistically significant at p<.05. Cognitive load 9-point scale; all others 5-point scale.

Discussion

Students given a guided simulation activity before lecture in an undergraduate chemistry course scored higher on assessments of concept knowledge, and transfer to a new concept, compared to completing the same simulation activity after instruction. Students in the explore-first condition also showed motivational benefits, with higher ratings of curiosity and competence. Motivation often predicts desire to continue learning about a topic (Deci & Ryan, 2000). These results suggest that exploratory learning may have benefits for future learning and persistence.

These findings expand the exploratory learning literature by examining the impact of using simulations, rather than problem-solving activities, as exploration activities before lecture. These results also extend this research to an undergraduate chemistry course. This research used a controlled classroom experiment, manipulating only the order of the activity and lecture, demonstrating a causal effect. Materials were created and administered by chemistry professors, increasing ecological validity.

More research is needed to replicate these findings, with other types of simulations, learning domains, and other instructors. One limitation is that the instruct-first condition was given earlier in the week than the explore-first condition, thus the professor may have become more fluent in giving the lecture. However, the professor had taught this course for many years, reducing the likelihood of practice effects.

Simulations are becoming increasingly accessible in STEM courses. These results suggest that a minor change in the timing of these simulations—given before, rather than after, instruction—can deepen students' understanding and support their perceived competence and curiosity for the information.

Achievement Motivation in Writing: Exploring the Pursuit of Multiple Goals and Keystroke Behaviors During Writing Tasks

Allison M. Banzon, Michelle Taub, Joel Schneier
amacey@knights.ucf.edu, michelle.taub@ucf.edu, joel.schneier@ucf.edu
University of Central Florida

Abstract: Few studies have investigated the applicability of structured motivation frameworks across more subjective academic tasks such as writing. By using person-oriented analyses and fine-grained data channels to build upon existing theories of motivation in writing tasks, ongoing research can work towards capturing how motivation impacts students' writing processes as they unfold. As such, this study examined the occurrence of multiple goal orientation profiles in undergraduate writing students and if those goal profiles differed in the average duration students spent engaging in multiple writing processes. A *k*-means cluster analysis ($n = 60$) revealed three student clusters with distinct multiple goal profiles. A one-way MANOVA did not find significant differences in mean keystroke activity times across these profiles, bringing into question the applicability of traditional achievement goal frameworks in writing contexts.
Keywords: Achievement Goal Theory, Keystroke Analysis, Motivation, Writing Analytics

Achievement motivation in writing tasks

Achievement goal theories have been used to research learners' achievement motivation in educational settings (Elliot & Murayama, 2008), resulting in the development of self-report that are used to categorize students within a single achievement goal orientation. Previous research supports the relationship between students' pursuit of these goal orientations and beneficial academic outcomes such as increased academic achievement or content interest (Senko et al., 2011), however renewed attention to the impact of motivation within complex tasks like writing, has prompted researchers to apply these measures in context where measures of achievement are more subjective (Wormington & Linnenbrink-Garcia, 2017).

As such, it is important to expand beyond the current reliance on self-report measures and exclusive goal endorsement (Elliot et al., 2011). In contrast with more objective STEM disciplines, the 'right' answer in writing is often subjective and situated within dynamic cognitive and socio-cultural factors (Graham, 2018). This level of subjectivity, paired with limited understanding of how motivation interacts with students' writing processes may impact the relevance of a highly structured measure like the AGQ-R in writing contexts.

For this reason, achievement goal research must expland to better reflect the impact of less clearly delineated elements such as multiple goal profiles and contextual factors. While past studies examining the role of goal orientations in writing have found relationships between performance goals and increased academic achievement (Senko et al., 2011), as well as mastery goals and beneficial behaviors like revision (Kaplan et al., 2009), researchers investigating the role of achievement goals in writing have also noted the existence of multicollinearity between goal orientations and participant reports noting similar usage of revision strategies across goal profiles, muddying our understanding of how achievement goals impact motivation in writing contexts (Paul et al., 2021). By shifting towards the use of person-centered research methods and granular data channels, researchers may be able to examine individual motivation profiles more closely (Urdan & Kaplan, 2020; Wormington & Linnenbrink-Garcia, 2017).

Theoretical frameworks

Elliot and Murayama's (2008) 2x2 achievement goal questionnaire-revised, (AGQ-R) has been widely used to asess learners' achievement motivation across diverse educational contexts. Within the traditional 2x2 framework, learners are categorized into distinct achievement goal orientations, which Elliot and Murayama separate by both the definition of learners' achievement goals (mastery and performance) as well as the valence of those goals (approach and avoidance), resulting in four distinct goal profiles (2008). Previous research on these achievement goal profiles (i.e., mastery approach [MAP], mastery avoidance [MAV], performance approach [PAP], and performance avoidance [PAV]; see Elliot & Murayama, 2008) has found positively valenced approach goals like MAP and PAP to be linked with desirable student outcomes such as increased academic achievement and content mastery, while negatively valenced avoidance goals are largely viewed as less-beneficial (Elliot & Murayama, 2008).

 © ISLS

Graham's writer(s)-within-community model (WWC) provides a discipline-specific compliment to the achievement goal framework by giving attention to the role that motivation plays in the writing process (2018). Graham describes writing as a complex task that is influenced by both cognitive and sociocultural factors, positing that a writer's motivation or goals for the task are influenced by both internal (i.e., content knowledge) and sociocultural (i.e., community support) factors, which impacts learners' writing processes and behaviors (Camacho et al., 2021). Given the complex nature of writing texts, the WWC model provides important insight into contextual factors specific to writing tasks that may impact the writing process (Graham, 2018).

This study used these theories to interpret writers' achievement goals and writing processes, utilizing advances in analysis methods and fine-grained representations of participants writing processes to highlight the connections between participants' motivation and writing processes.

Current study

This study sought to examine first-year undergraduate writing students' self-reported achievement goals in relation to completing a self-reflective writing task, as well as the relationship between those goals and students' keystroke behaviors during the writing task.

The participants in this study were undergraduate students (n = 60) enrolled in a first-year writing course. Students were asked to *describe in as much detail the step-by-step process of how you complete a formal writing task* for 30 minutes. Students had no requirements (e.g., specified length, structure, etc.) other than to respond to the prompt for the allotted duration and were explicitly told their responses would not be graded.

Prior to the study, participants responded to a series of questionnaires that included Elliot and Murayama's (2008) AGQ-R. The AGQ-R contains four subscales (one for each of the achievement goal profiles) that consist of 3 questions for each subscale, for a total of 12 items. Participants indicated their agreement (from 1 = '*strongly disagree'* to 5 = '*strongly agree'*) to statements to measure their achievement goals in relation to the writing course. Each of the four subscales have also shown high levels of internal consistency (mastery approach [=.84], mastery avoidance [=.88], performance approach [=.92], performance avoidance [=.94]) (Elliot & Murayama, 2008).

Keystrokes were logged using InputLog (Leijten & Van Waes, 2013) to record students' input in Microsoft Word during the writing session (e.g., mouse movements, keystrokes, inter-key intervals, etc.) with its associated timestamp in milliseconds. Keystroke behaviors utilized within this study included the mean total time participants spent pausing, inserting, producing, and deleting text during the writing.

Results

Research question 1: Did undergraduate writing students' self-reported achievement goal endorsements suggest the occurrence of multiple goal profiles?

Given the presence of significant multicollinearity between participants' aggregate scores derived from the 2x2 AGQ-R, a cluster analysis was performed to identify multiple goal orientation profile types across participants.

Hierarchical clustering was applied to participants' raw aggregate scores for each of the achievement goal subscales using Ward's method, with changes in the agglomeration coefficients (AC) and assessment of the resulting visualizations (i.e., elbow technique) used to determine the ideal number of clusters (Wortha et al., 2019). *k*-means clustering was used to compare cluster centers and membership for the 2- and 3-cluster solutions. Given that the 3-cluster solution found large Euclidean distances between the final cluster centers and appropriate sample sizes for each cluster (n > 15), the 3-cluster solution was selected.

The 3-cluster solution was further categorized based on the goal profile labeling procedures outlined in Wormington and Linnenbrink-Garcia's 2017 meta-analysis. Cluster profile labels were based on each cluster's mean aggregate AGQ-R subscale scores (e.g., less than 6 on a 15-point scale indicates low goal endorsement, more than 12 indicates a high goal endorsement, and scores within that range are viewed as moderate goal endorsement), where average mean aggregate scores for each of the four subscales were used to label the 3 clusters.

Research question 2: What multiple achievement goal profiles did students pursue in relation to the writing task?

Cluster 1: High all goals

Students in Cluster 1 (n = 24) were classified as belonging to the *High All Goals* profile, with final cluster centers (see Figure 1) exhibiting high endorsement of all four achievement goal orientations, which suggests these students were highly concerned with both writing task mastery and their ability to appear as competent writers to others. While traditional achievement goal theories may interpret the pursuit of all four goal orientations as

inherently contradictory, Wormington and Linnenbrink-Garcia's meta-analysis found that students within High All Goals profiles displayed high levels of academic achievement, suggesting some benefits of multiple goal pursuit (2017).

Cluster 2: Average all goals

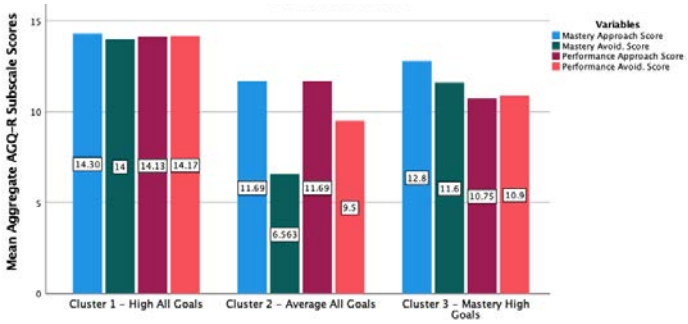
Students in Cluster 2 (n = 16) were classified as belonging to the *Average All Goals* profile, with final cluster centers (see Figure 1) exhibiting average endorsement of all four achievement goal orientations, which suggests these students were also concerned with both writing task mastery and their ability to appear as competent writers to others, but at a more moderate level. Wormington and Linnenbrink-Garcia found this goal profile to be the most prevalent, with students in Average All Goals profiles exhibiting lower scores on measures of engagement and well-being (2017).

Cluster 3: Mastery high goals

Students in Cluster 3 (n = 20) were classified as belonging to the *Mastery High Goals* profile, with final cluster centers (see Figure 1) exhibiting high endorsement of both mastery approach and mastery avoidance goal orientations, which suggests these students were most strongly motivated by an intrinsic desire to master the writing content. While the mastery avoidance cluster center (M = 11.60) fell below the established requisite score, its proximity to the cut off score (12) in addition to the overall high mastery approach score (M = 12.80) suggested Cluster 3 most closely fit the Mastery High goals profile described by Wormington and Linnenbrink-Garcia (2017). Wormington and Linnenbrink-Garcia (2017) found this goal profile to be common and generally associated with higher academic performance outcomes than other goal profiles included within studies of multiple goal orientations.

Figure 1

Final Cluster Centers for 3-Cluster Solution.



Research question 3: Was there a significant difference in students' keystroke behaviors between the resulting goal orientation profiles?

A one-way multivariate analysis of variance (MANOVA) was conducted to determine if participants' mean deletion, insertion, production, and pausing times (ms) captured within the keystroke logs significantly varied between the three established achievement goal profile clusters. Despite variation in keystroke behavior times across the clusters, there were no significant differences in mean keystroke behavior times across the three goal profile clusters (see Table 1).

Table 1

Means, Standard Deviations, and MANOVA Results for Keystroke Activity Times Across Clusters

Keystroke	Cluster 1		Cluster 2		Cluster 3		$F(2, 57)$	
Times (ms)	*M*	*SD*	*M*	*SD*	*M*	*SD*	*F*	*p*
Deletion	44573.42	22812.62	43197.31	18249.34	44526.85	19065.17	.026	.975
Insertion	142536.67	135310.16	140085.56	117000.28	169006.85	174162.17	.239	.788
Production	4000847.42	135896.80	365366.19	170528.41	339559.25	143882.99	.947	.394
Pausing	1761231.71	113013.01	1733557.38	102386.89	1745347.30	74019.01	.393	.677

Discussion and future directions

Given the presence of multicollinearity between goal profiles, a *k*-means cluster analysis used to answer research question one produced three student clusters, each with a distinct achievement goal endorsement profile. Results of research question two found that all three goal profile clusters exhibited high to moderate endorsement of two or more achievement goals simultaneously, supporting the occurrence of multiple goals and highlighting the complexity of students' writing motivation (Graham, 2018).

The third research question examined relationships between students' achievement goal profiles and writing behaviors measured through keystroke logging. Although the mean keystroke activity time differences across the established goal orientation clusters were not statistically significant, the discrepancy between these findings and the established linkages between achievement goal orientations and academic performance highlights the need for further exploration of achievement goals in writing tasks to include more granular data (i.e., keystroke input).

Through the inclusion of multiple data channels and person-orientated methods like cluster analysis, researchers can develop a deeper understanding of motivation in writing contexts, potentially challenging some of the long-standing assumptions regarding the achievement goal framework and its generalizability across more subjective tasks like writing.

Abstract: In this paper, we describe a study exploring cross-cultural differences in the game designs of middle school students from the USA and Argentina. Students created game design artifacts as part of the *WearableLearning* curriculum, which were coded to identify game aspects such as social and physical interactions, technology incorporation, and game characteristics and representations. We describe initial findings on how students' culture is potentially expressed in their game designs and discuss future directions for designing interactive learning environments that engage students in game design activities.

Keywords: learning technologies, game design, constructionism, culture

Introduction

The digital revolution has reshaped education and efforts to improve student learning outcomes. For example, individualized learning technologies have been found to improve learning outcomes and enhance student motivation (Hamada & Hassan, 2016). There is also a growing research focus on the intersections of culture, learning, and technology. Learning takes place in cultural contexts and learners' cultural backgrounds shape their learning habits (Ladson-Billings, 1995). Research on how culture influences learning suggests that instruction and learning environments should be consistent with learners' cultural experiences (Benson et al. 2017). Mohammed and Mohan (2011) argued that deficiencies in cultural awareness in digital learning platforms and instructional design cannot be ignored, given the rapid rise of digital learning. Some interactive learning environments (ILEs) have been expanded to account for the socio-cultural aspects of learners, such as the use of avatars that provide a sense of familiar cultural presence for learners (e.g., Arroyo et al., 2014).

In this paper, we explore how learners' culture is potentially expressed in their game designs within the context of *WearableLearning* (*WL*), a platform for children to learn mathematics by *playing*, *designing*, and *programming* physically active and social educational math games that use mobile phones to support players (Micciolo et al., 2018). *WL*'s accompanying curriculum engages students in the experience of *playing* games, and then later on *designing* and *building* their own games for peers to play. A key part of this process asks students to express game design ideas as drawings and narrations on booklets. These artifacts could mirror learners' cultural values, beliefs, and practices. Understanding the cultural constructs embedded in these designs and artifacts could help us identify ways to better support students' learning, and more broadly, improve the design of ILEs and understand the extent to which learning technologies can be "exported" to other geographies and communities. We present our initial findings on cross-cultural differences in game designs by middle school students from the USA and Argentina and discuss how these findings can be used to benefit the design of ILEs.

Related Work and Theoretical Framework

Our work is driven by key constructs including socio-cultural theory, constructivism, and constructionism.

Socio-cultural theory. Socio-cultural learning theory stresses that learning occurs within a social world and that learners' cognitive development is largely influenced by their surrounding culture, tools, beliefs, and attitudes (Vygotsky, 1978). In the *WL* context, game design artifacts such as written narratives, drawings, and diagrams on rules, physical objects and space, or physicality could mirror aspects of learners' culture, such as their beliefs, values, attitudes, perceptions of time, religion, and material possessions (Hofstede et al., 2005). In a similar vein, Kafai (1996) explored students' game designs and gender differences in them; we continue to build on such research through explorations of cross-cultural differences in the game designs of learners.

Constructivism and constructionism. *Constructivism* posits that learners construct their own knowledge and unique meanings for concepts (Elby, 2000). Related to this is *constructionism*, which states that learners are more deeply involved in their learning if they are constructing something that others will see, critique, and use (Harel & Papert, 1991). Leveraging constructivism and constructionism, *WL* facilitates mathematics and computing learning through learner-constructed math games (Micciolo et al., 2018). Through the *WL* curriculum, learners design and program phone-supported, physically active games, situating themselves within the context

 © ISLS

of a problem- and project-based game-design activity at the same time.

WearableLearning. *WL* is an ILE that enables learners to create and play mobile math games using a visual programming language based on *finite state machines* (FSMs). FSMs are typically used to teach computer behavior, concepts, and logic in terms of actions and reactions through visual FSM diagrams (FSMDs). The *WL* curriculum promotes computational thinking (CT) through game creation and play that integrate math, physical activity, multiplayer games, and programming. Prior work on *WL* has shown that middle school math teachers cultivated a deeper understanding of math concepts as game creators and players (Smith et al., 2020). Kafai and Burke (2015) noted that learning through game creation improves children's understanding of programming and math concepts. Our work expands *WL's* game design and play embodied learning portfolio through the lens of cross-cultural differences. Specifically, this study aims to answer the following research questions (RQs):

RQ1: What differences in *WearableLearning* game designs between students from Argentine schools and US schools exhibit, along the aspects of (a) social and physical interactions, (b) technology incorporation and dependence, (c) game characteristics, and (d) game representations?

RQ2: What do differences in game designs suggest about how students express their culture in their games?

Methodology

To explore cross-cultural differences in the game designs of students from Argentine and US schools, we analyzed *WL* game design artifacts using Ottmar et al.'s (n.d.) game design coding scheme.

Study design. We ran the six-stage *WL* curriculum with middle school students in US and Argentine schools. Students were introduced to the *WL* platform and were asked to create multiplayer games that use math, physical activity, and mobile phones (phones are used for game prompts and game inputs). The full curriculum is available at https://osf.io/yq49e/. In Stage 2 of the curriculum (a curriculum "stage" corresponds to a day), student teams brainstormed their own math games on paper to draw or map out game ideas. In Stage 3, students were given a short lecture on FSMs and then designed FSMDs on paper to represent the behaviors of mobile phones in their game. Students drew "state" boxes that correspond to game screens on the phone and arrows that specified concrete inputs (buttons, text, color sequences) that game players had to enter to move from one game state to the next. We analyzed game design artifacts from these two curriculum stages.

Participants and data collection. We collected data from a total of 172 students. Students from the US school were 21 seventh and eighth graders who attended a week-long game development summer camp. Students from three Argentine private schools were 151 sixth and seventh grade students who participated in our curriculum activities once a week for 6 weeks. In both cases, the activities were the same and each activity lasted for 60-90 minutes each day. The data collected includes the paper-based game ideation (Stage 2) and FSMD (Stages 3) sketches and the games programmed on the *WL* platform (Stages 4 to 6). Our analyses and discussions in this paper will focus on students' paper-based sketches from Stages 2 and 3 (Figure 1).

Analysis. We used a coding rubric designed by the *WL* research team specifically for analyzing game design artifacts produced by students through the *WL* platform and curriculum (full coding rubric available at https://osf.io/yq49e/). We coded for four game aspects: (1) social and physical interactions (*Collaboration, Competition,* and *Physicality Option*); (2) technological descriptors (*Dependence* and *Incorporation*); (3) game characteristics (*Game Descriptors, Progressive Levels,* and *End Goal*); and (4) game representation components (*FSMD Rules, Physical Objects, Physical Space,* and *Timing*). We used Between Subjects t-tests and Chi-Square tests to analyze differences between students from the US school and students from the Argentine schools.

Results and Discussion

We coded for ten game variables. Table 1 shows a subset of the results from coding the (1) *social and physical interactions* (*SP*), (2) *technological descriptors* (*TD*), (3) *game characteristics* (*GC*), and (4) *game representation components* (*GR*) from students' game design artifacts. We include only the four game variables with statistically significant results due to space constraints (full set of results available at https://osf.io/yq49e/): *Competition Between Teams* is the extent to which a game engages player teams in competition, *Technology Incorporation* indicates whether or not the designed game uses any form of technology (e.g., iPad, computers) within the gameplay, *End Goal* refers to the presence of an end goal for players or teams to win or finish the game, and *Timing* refers to expressions of time within the game (e.g., waiting time for turns). We found that the game designs of students from the US school depicted significantly more *competition* between teams than the game designs of students from the Argentine schools. Conversely, US students' game designs depicted less *collaboration* than Argentine students' game designs. These results suggest an expression of practices from the cultures of students' contexts: the Argentine students may be expressing the collectivist nature of Latin culture and the US students expressing the individualist culture of the US (Triandis & Gelfand, 2012). Game designs of the US students also

Figure 1
Examples of game design (left) and FSM diagram (right) sketches produced by Argentine students.

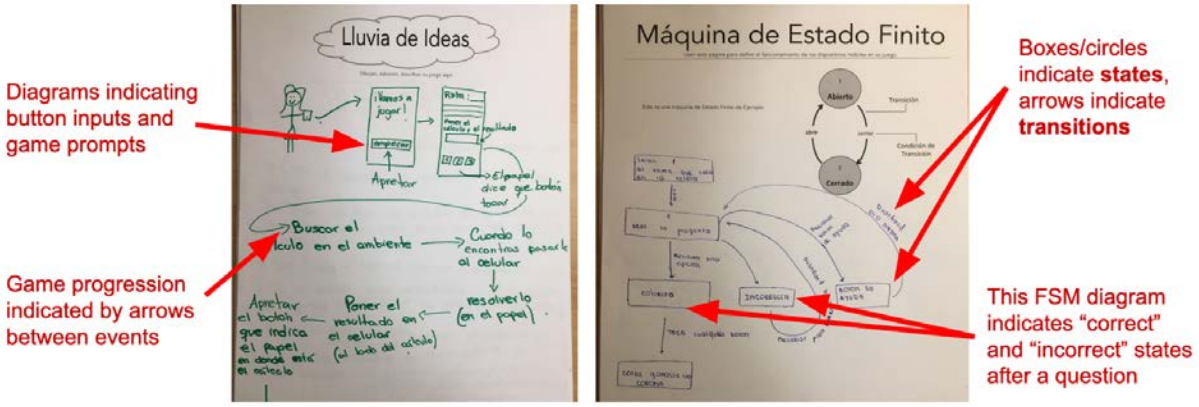

Table 1
*Count and % occurrence (in parentheses) for game variables coded for US (n=7) and Argentina (ARG) (n=41) games. (Chi-Square tests: * indicates significant difference, $p<0.05$; $^{+}$ indicates significant difference, $p<0.1$)*

Game Variables Coded	US-Stage 2	US-Stage 3	ARG-Stage 2	ARG-Stage 3
(*SP*) Competition Between Teams	3 (42.9%)*	3 (42.9%)	5 (12.2%)*	8 (19.5%)
(*TD*) Technology Incorporation	7 (100%)$^{+}$	5 (71.4%)	28 (68.3%)$^{+}$	22 (53.7%)
(*GC*) End Goal	5 (71.4%)$^{+}$	2 (28.6%)	15 (36.6%)$^{+}$	14 (34.1%)
(*GR*) FSMD: Timing		7 (100%)*		20 (48.8%)*

incorporated more technology than Argentine students' game designs. Reports (Auxier et al., 2020; Ravalli & Paoloni, 2016) indicate that children in the US and Argentina have access to technology at an early age, so early technology access does not explain the differences in technology incorporation in games. This, however, points to the need to better and more deeply understand our students' contexts. For example, we did not have data on students' use of technology outside of school settings.

In terms of game representations, all game designs of the US students had *timing* components compared to about half of the games from the Argentine students. The expression of timing in game designs may be related to the students' perception of time: Latin cultures tend to be flexible in their use of time, whereas US culture perceives time in a more rigid manner (White et al., 2011). With regard to *end goals*, in Stage 2 of the curriculum, there were more game designs by US students that had specific end goals for their games compared with Argentine students' game designs. These expressions of end goals dropped in Stage 3 in the game designs of both US and Argentine students. We suspect, however, that this drop had less to do with cultural factors, but rather the students' ability to translate from one design representation to another. Stage 2 required students to informally draw and sketch out their game design ideas on paper; Stage 3 required them to create a more formal representation of their game design sketches through FSMDs (also on paper). It is possible that when translating from one representation to another, students could have found that certain end goals they initially sketched out or conceptualized were difficult to formally represent in FSMDs. This hypothesis merits further exploration with bigger populations of students to better understand how expressions of game factors such as specifications of end goals are represented in game designs and potentially relates to students' cultures.

Conclusions, Limitations, and Future Work

Our results show that the game designs by students from a US school exhibited more technology incorporation, competition, specific end goals, and timing. Game designs by students from Argentine schools exhibited more collaboration, relatively consistent expression of game end goals, and less timing components. Aligning these with prior work on individualist and collectivist cultures, our work points to initial insights on how the culture of students' contexts (i.e., a US school and the three Argentine schools) could potentially influence how learners construct game design artifacts, specifically game designs constructed through the *WL* curriculum. This study could serve as a jump-off point for further research on exploring how ILEs and curricula supports, sustains, or hinders learners from expressing their cultural beliefs, attitudes, values, and practices in the artifacts they design and construct. Future work could address limitations in our study. For example, we used the geographic locations of the participating schools as a proxy for culture. This ignores the unique, multifaceted sociocultural identities

of the students themselves and does not account for how the cultural backgrounds of each student could contribute to and shape the game design artifacts that they co-constructed with their peers. Interviews or focus-group activities with the students could enable the collection and analysis of more nuanced data to more deeply understand the kinds of cultural expressions that students bring into the constructions of game artifacts. Furthermore, this can provide insights for designing curricula and ILEs (such as *WL*) that engage students in creative design and construction activities for learning that are also grounded in the students' needs and values. Additionally, our analyses are based primarily on our coding rubric, and this study is the first time it has been used on design artifacts beyond ones collected from the US. In future work, we aim to further explore and understand the extent to which our coding rubric can be used to encapsulate the nuanced characteristics of game design artifacts created by learners, especially across different cultures and contexts.

Abstract: In this paper, we explored young children's embodied representation of states of matter after engaging in a mixed-reality environment where students explored states of matter by acting as particles (Danish et al., 2020). To examine how embodiment may play a role in helping students' explanations, we analyzed students' performance in assessments to explore how embodiment helps young children represent their ideas and found they were able to use a combination of talk and embodiment to provide more detailed explanations. Then we further explored how students formed these conceptual understandings in the MR environment and applied interaction analysis to analyze how embodiment played a role in the process. The results showed that gestures students used in the post-assessment emerged through their collective embodiment in the classroom.

Introduction

Embodiment has been viewed as a crucial part of cognition and learning (Abrahamson & Lindgren, 2014), prompting scholars to explore how to use embodiment to support students' learning (Danish et al., 2020). Previous studies demonstrate how engaging with conceptual ideas through movement improves students' target content understanding. Embodied motion and gesture have also been shown to serve an important role in students' communication and knowledge construction (Broaders, et la., 2007). As the role of embodiment in learning and knowing continues to be studied, there remains little scholarship exploring the role of embodiment in assessment in addition to instruction.

Many studies use multiple choice questions or content-focused measures of learning after embodied activities that reflect traditional beliefs about learning and do not keep pace with our current understanding of the repertoires of embodied expression children utilize during learning. Novices, in particular, might have ideas about target science content that they cannot show in the traditional assessment context. Therefore, there is a need to incorporate embodiment into assessments that measure students' learning after engaging in embodied learning activities. Previous research also suggests that embodiment offers an alternative way for elementary students to explain their understanding of concepts that they're less familiar with (Salehet al., 2015). This suggests that embodiment can offer a broader picture of what concepts students understand and how deeply they understand them. However, questions remain about how to reliably draw out students' embodied understandings in an assessment context. Therefore, in this paper, we focus on students learning states of matter within the Science through Technology Enhanced Play (STEP) environment as a case study for how the body can play a role in supporting sensemaking across learning and assessment. In prior studies, we found that students were able to understand complex science concepts such as the particulate nature of matter while engaging in the STEP environment (Danish et al., 2020). In this study, we designed two forms of instruments to assess young children's understanding of states of matter: a multiple-choice test and an individual interview. In the interview, we encouraged students to use their bodies to show how particles behave in different states of matter. We also provided manipulatives for student's opportunities to "act out" ideas. We then explored the following two questions: 1) How did embodied prompts help students to represent their ideas in an assessment context? 2) How did students form a conceptual understanding of particles' behavior and connection to macro-level state within the STEP environment?

Design

This study was built in the Science through Technology Enhanced Play (STEP) environment (Danish et al., 2020), a MR environment that uses Kinect cameras to track students' movement and map them to digital avatars. As students move in the space, the simulation shows their movement as particles interacting and changing into solid, liquid, and gaseous states on a shared screen in front of the classroom. The learning targets were (a) understanding and demonstrating particle behaviors in three states of matter and (b) depicting the connections between microscopic and macroscopic representations of matter. While students moved to represent particles moving,

 © ISLS

STEP depicted particle speed, distance, attraction, and particle trajectory according to real-world physics, enabling students to discover these underlying rules through their collective movement.

Method

Participants and Data source

Twenty-two students from a first and second-grade mixed-age classroom in a mid-western elementary school in the U.S. participated in this study. Students participated in a 7-session STEP activity; each session included 30 minutes of activity in the STEP environment and 30 minutes of supplemental activities without the STEP software in another classroom. Students participated in multiple-choice pre-tests and then one-on-one interviews the week before the project started, and the multiple-choice post-test was followed by individual post-interviews after the class engaged with all STEP activities. The interview included 26 questions, and during the interview, students were encouraged to use body movements to demonstrate particle behavior. All classroom activities and interviews were video recorded for analysis.

Data analysis

We applied a paired t-test to examine students' overall understanding of particle behavior We coded the pre- and post-interviews with a coding scheme used in previous iterations of STEP (Danish et al., 2020). Three research assistants coded the interviews and achieve 81% agreement on coding. We also looked into the interview data to find how embodiment helped them to demonstrate their understanding of the particle's behavior. All authors re-watched students' interviews videos and focused on students' verbal and embodied responses in the videos to explore how they articulated their ideas in the interviews. Based on our review of the interviews, we found that students used gestures in the post-assessment to supplement their demonstration of understanding, especially for challenging ideas such as micro-macro connection. Then we went back to the classroom videos and applied interaction analysis (IA, Jordan & Henderson, 1995) to see how concepts explored in students' interviews were developed through their in-classroom activities.

Findings

We ran a paired t-test on students' performance on the multiple-choice test and found there was a significant improvement from the pre-test score (M = 5.5) to post score (M = 11.2), t = -8.72, p <.01, which showed that students' overall understanding of the target content improved after they engaged within the STEP environment.

To answer our question: "How did embodied prompts help students to represent their ideas in an assessment context?" We focused on two sets of interview questions related to the challenging multiple-choice questions: 1) questions that encouraged students to use their body to act like particles and 2) questions that asked them about the micro-macro connection. We found that more students were able to answer the interview questions in post-interviews accurately when encouraged to use their body to represent particles' movement. For example, 57% of students were able to describe at least one characteristics of particles in Question 4 "Let us pretend you are particles in that water, can you act out with your body how particles are moving in the water?". Then for questions 12-15, which covered micro-macro connections, we found thirteen of the twenty-one students (61%) were able to elaborate on the mechanisms of particles' behavior. This was quite a difference compared to the 2 students who were able to answer the multiple-choice question covering similar content correctly. This suggests that students benefited from using their bodies to explain their understanding.

We present an example of a student gesturing to answer the question about particles moving in water. These questions asked how particles behave when there is a macro-level change (Table 1). Lily explained that with a macro-level change, the liquid would turn to gas (line 2). Then in the next question, she described changes in the distance between particles and the speed of particles with gestures (Line 4). She mentioned that "they will go farther apart, and go faster and have more energy," while pulling her hands far apart horizontally to show the increasing distance between particles in liquid as they get more energy. Then she used another gesture to demonstrate the speed of particles by making her hands into fists and moving them quickly in the air (Table 1, Figure b). Then she used the same gesture to describe the distance between particles as far apart. In her responses, her gestures were consistent with demonstrating certain characteristics of the particles' behavior (e.g. distance). In addition, she was also able to describe the changes in particles' speed, which is the concept she failed to answer in the multiple-choice test. On looking across the interviews, we found that this pattern of gestures and embodiment supporting more elaborate descriptions was consistent across the interviews analyzed. Therefore, the interview helped students to demonstrate ideas by allowing students to use gestures to represent ideas.

Table 1

Lily gesturing to demonstrate particle behaviors to answer question 12 to 14.

Turn	Verbal	Embodiment
1 Author 2	if the plate is really hot, what will happen to liquid water? [Q12]	
2 Lily	It turn to gas. [MMC1, macro change]	Student used gesture to show the distance between particles (figure a). a
3 Author 2	So, if the plate is really hot, what will happen to the particles in the water [Q13]	
4 Lily	They will go farther apart, and go faster and have more energy [MMC4, Distance and Speed]	And then she used gesture to show particles will go "faster" (figure b) b
5 Author 2	More energy. Okay, so why do you think the particles will do that? [Q14]	
6 Lily	Um.. Because gas has more energy and it goes apart.	When students talk about the particles go part, she used the gesture in previous answer (a) again to show the distance between particles.

RQ 2 How does students' understanding of particles behavior form in classroom activity?

To answer our second research question, we analyzed how students' embodiment helped them to form their conceptual understanding in classroom activity. We focused on how students' understanding of 1) characteristics of particle behavior (e.g. distance), and 2) micro-macro connection, were constructed during class activity. We identified two classroom activities on 1) students exploring particles behavior in a tank, and 2) students explore particles with changes of temperature when the concepts we outlined above were discussed.

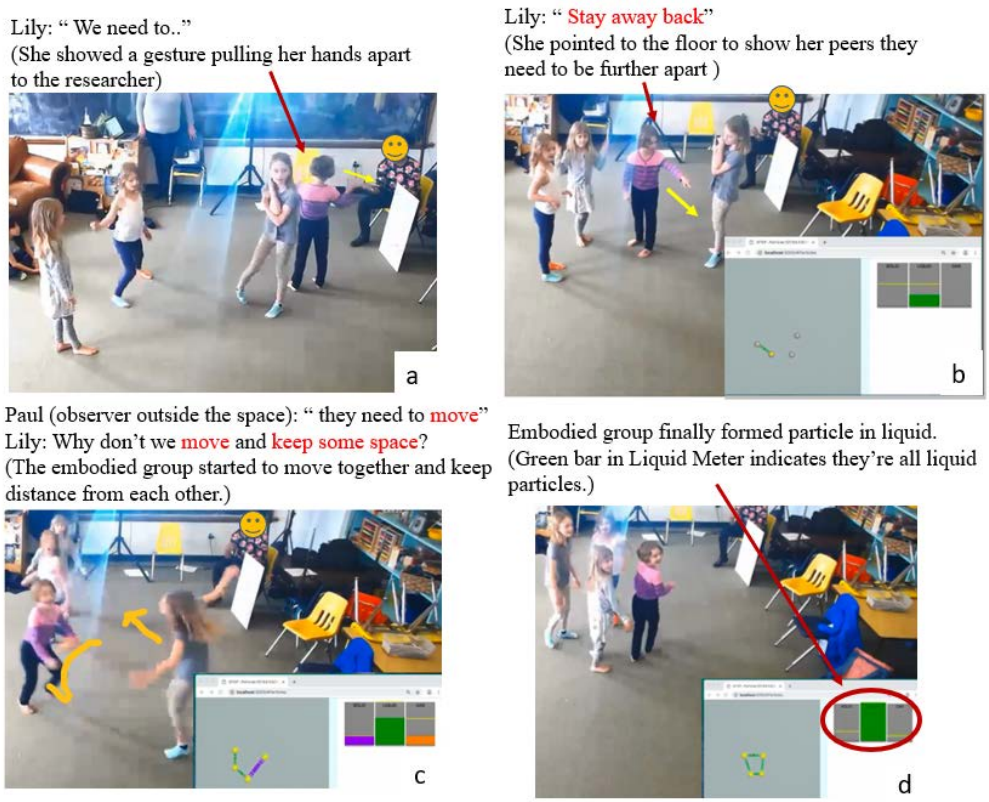
Exploring characteristics of particles in a tank

Our Day 3 activity focused on helping students to understand particle speed and distance in three states of matter. The physical positions of students were projected as particles on the shared screen and they needed to move collectively to form different states of matter. We present a segment of Lily's group collectively exploring how liquid particles move in Figure 1.

Lily's group went into the space with a goal to form liquid. They started moving freely in the space, and tried different motions (e.g., running, standing still) that would trigger the state meter in the simulation to indicate that they had achieved liquid state. Even though they were recognized as particles, there was no certain state shown in the state meter. So, the researcher in the space asked them what they needed to do to make liquid. Lily looked at the screen and used a gesture that pulling her hands far apart, indicating her group should be farther apart (Figure 1a). With encouragement from the researcher, Lily went back to the tracking area, pointed to the floor, and told her peers to stay away (Figure 1b). Here, Lily suggested the team to work collectively to adjust their relative *distance* between particles. Even though they moved away from each other, they were not recognized as liquid particles in STEP simulation. At this moment, Paul, an observer pointed out that the embodied group was not moving. Then the entire group started to move around without maintaining their distance from one another leading to no particular state of matter depicted by the state meter. Then Lily suggested, "why don't we move around and still keep some distance" (Figure 1c). At this moment, Lily was suggesting her team collectively adjust their *distance and speed*. In response, the embodied group walked in one direction to keep relatively the same speed and amount of space, and the team was recognized as liquid particles by the state meter (Figure 1d). In summary, this episode showed that students' understanding of liquid particles was formed through their collective embodiment. In post-assessment, when students were asked to demonstrate liquid particles, we also see a similarity between the gesture that Lily used here to represent particles' distance in the classroom and interview.

Figure 1

Lily's group exploring how liquid particles move.



Summary and Significance

In this study, we explored the role of embodiment in an assessment context contrasted with a more traditional multiple-choice assessment, and how students formed the conceptual understanding in classroom activities. We found that the individual interviews offered students opportunities to articulate their ideas with more detail through talk, gesture, and motion. Students frequently used gestures in the post-interview to demonstrate their understanding of particles' behavior. Then we analyzed classroom data to understand how young children made sense of the content when they embodied particles in the MR environment. By showing links between Lily's interview answer and her actions during classroom activity, we show how to construct embodied assessment questions that map to classroom learning. This suggests that, especially when students have learned concepts in an embodied learning context, assessments that capitalize on these embodied resources may provide greater insights into their emergent understanding of the concepts than traditional measures.

Focused Self-Explanations Lead to the Best Learning Outcomes in a Digital Learning Game

Bruce M. McLaren, Carnegie Mellon University, bmclaren@cs.cmu.edu
J. Elizabeth Richey, University of Pittsburgh, JER177@pitt.edu
Huy Anh Nguyen, Carnegie Mellon University, hn1@cs.cmu.edu
Michael Mogessie, Carnegie Mellon University, michaelmogessie@cmu.edu

Abstract: Prompted self-explanation, in which learners are induced to explain how they have solved problems, is a powerful instructional technique. Self-explanation can be prompted within learning technology by asking learners to construct their own self-explanations or select explanations from a menu. The menu-based approach has led to the best learning outcomes in the relatively few cases it has been studied in the context of digital learning games, contrary to some self-explanation theory. In a classroom study of 214 5th and 6th graders, in which the students played a digital learning game, we compared three forms of prompted self-explanation: menu-based, scaffolded, and focused (i.e., open-ended text entry, but with a focused prompt). Students in the focused condition learned more than students in the menu-based condition at delayed posttest, with no other learning differences between the conditions. This suggests that focused self-explanations may be especially beneficial for retention and deeper knowledge.

Introduction

Prompted self-explanation is used to promote learning by encouraging learners to self-explain what they are studying or how they have solved a problem (Wylie & Chi, 2014). As an instructional strategy, prompted self-explanation has proven to be one of the most robust and effective learning science principles (Pashler et al., 2007). Different forms of prompted self-explanation have been shown to be effective in a variety of studies with educational technology. Wylie and Chi (2014) cast the various forms of prompted self-explanation that have been used in learning technology along a continuum between what we describe as *unconstrained* and *highly constrained* self-explanations. Unconstrained self-explanations allow learners to freely create their own explanations, while presenting the highest cognitive challenge to learners (i.e., *open-ended self-explanations*). Highly constrained self-explanations, on the other hand, present the learner with a small set of options to choose from to self-explain and thus create the least cognitive challenge for learners (i.e., *menu-based self-explanations*). Between the two extremes are three other types of prompted self-explanation: *focused self-explanations*, which are constructive but focused in a specific way, such as prompting learners to identify relationships between mental models; *scaffolded self-explanations*, which provide support and/or feedback as learners construct explanations or fill in blanks of an explanation sentence; and *resource-based self-explanations*, in which explanations are selected by learners with the support of a resource, such as a glossary.

According to Chi and Wylie's (2014) Interactive-Constructive-Active-Passive (ICAP) framework for cognitive engagement, open-ended and focused self-explanations are constructive because the student must generate their own content. Scaffolded, resource-based, and menu-based self-explanations are active, because the student must actively select or manipulate information provided to them. The ICAP framework predicts that students should learn more from more cognitively engaging tasks, meaning constructive self-explanations should be more beneficial than active self-explanations. Only a limited number of studies have directly compared different types of self-explanation prompts. Evidence across these studies suggests that focused self-explanations may be the best, because they are constructive, yet direct students to ideas and explanations better than open-ended prompts, thus reducing cognitive load (Wylie & Chi, 2014) .

Self-Explanation in Digital Learning Games

Digital learning games are an interesting and important platform for exploring self-explanation, as they are now widespread in education, with a growing research base supporting their efficacy (Mayer, 2019). Despite contentions that prompted self-explanation within a digital learning game could disrupt game flow and induce extraneous cognitive processing (Adams & Clark, 2014), prompted self-explanation has been shown to support learning within games. For instance, Hsu and Tsai (2011) found that prompting learners to explain their errors from a menu of choices led to better learning gains than not prompting error explanations. However, not all studies have led to benefits of prompted self-explanations in digital learning games. For instance, Adams and Clark (2014) found no learning differences between two game conditions: menu-based self-explanation with explanatory feedback and a control condition with neither self-explanation nor explanatory feedback.

 © ISLS

We know of only one study that directly compared menu-based and open-ended self-explanations in learning games, and in that study Johnson and Mayer (2010) showed that menu-based self-explanations led to better transfer than open-ended self-explanations. While Johnson and Mayer argued that menu-based prompts likely led to better learning because they were less disruptive to game flow, Wylie and Chi (2014) argue that the open-ended prompts of the study may not have had the focus to direct students' attention in a game environment.

In light of the competing predictions that less disruptive self-explanations are best (Johnson & Mayer, 2010) and that more constructive self-explanations are best (Chi & Wylie, 2014), we decided to conduct a study with our learning game *Decimal Point* (McLaren et al., 2017) to investigate this issue. We hypothesized that constructive explanations could lead to deeper learning within a game context without disruption to game flow, provided that they are sufficiently focused.

A Self-Explanation Study with the *Decimal Point* Learning Game

Decimal Point is a single-player, non-competitive learning game based on an amusement park metaphor (McLaren et al., 2017). It is designed to help middle-school students practice their decimal knowledge. The student plays a variety of *mini-games* targeted at common decimal misconceptions within theme areas. Students make their way through the entire amusement park playing all of the mini-games in sequence. An example mini-game is "Rocket Science," which challenges the student to fill the gas of a rocket ship by choosing fuel canisters labeled with decimal numbers (e.g., 9.222, 9.3, 9.43, 9.2111) in the order from largest to smallest. If they make mistakes as they choose canisters, they are prompted to correct their solution by dragging and dropping the canisters into the correct order. The student continues playing the game until they correctly order the canisters. After correctly solving two problems within each mini-game, students are prompted to answer a self-explanation question, according to one of three different conditions and self-explanation formats.

The original version of the game employed a menu-based self-explanation approach and produced better learning outcomes compared to a non-game control (McLaren et al., 2017). In the current study we compared three forms of self-explanation to test competing hypotheses about the benefits of more constrained, active self-explanations (Johnson & Mayer, 2010) and less constrained, constructive self-explanations (Wylie & Chi, 2014) in digital learning games.

- *Menu-based self-explanations*: Students were presented with 3 or 4 explanation menu options, with the correct option being a conceptual description of the problem solution. We consider this form to be highly constrained and active according to the ICAP framework.
- *Scaffolded self-explanations*: Students were prompted to complete a fill-in-the-blank sentence, using a word bank of 4 or 5 words/phrases that could be inserted into the sentence. We consider scaffolded self-explanations to be moderately constrained and active according to the ICAP framework.
- *Focused self-explanation*: Students responded to focused self-explanation prompts about specific problems by filling in an open-text field. To assure that students would expend at least minimal effort, we required that their self-explanations contained at least four words with at least one of the words being from a relevant list (including common misspellings) that would legitimately be found in a correct explanation. We consider this form to be minimally constrained and constructive according to ICAP.

Across all conditions, students could not proceed to the next mini-game until they provided a correct self-explanation or, in the focused condition, an explanation that met the length and relevance requirements. The question prompts were written to align content across all three conditions. Our rationale for choosing these three prompted self-explanation approaches was to directly compare different levels of cognitive engagement (constructive and active), while also including the original menu-based approach used in previous versions of the game. Our research questions for the study were:

RQ1. Which form of prompted self-explanation – menu-based, scaffolded, or focused – leads to the best learning outcomes in the context of the Decimal Point learning game? Although prior results with self-explanation in digital learning games supported using menu-based prompts to avoid disrupting game flow (Johnson & Mayer, 2010), the theories proposed by other researchers suggest that constructive prompts are better than active prompts if they are sufficiently focused (Wylie & Chi, 2014; Chi & Wylie, 2014). Therefore, we predicted that focused prompts would be best.

RQ2. Which form of prompted self-explanation – menu-based, scaffolded, or focused – leads to the least enjoyment in the context of the Decimal Point learning game? This is an important question because one wouldn't want to lose the enjoyment aspect of game-based learning, given that engagement has been shown to explain the learning benefits of a game compared to the non-game equivalent (Richey et al., 2021). As less constrained prompts are likely to be more disruptive to game flow, we hypothesized that the order of enjoyment would be: menu-based self-explanation more enjoyable than scaffolded, which

would, in turn, be more enjoyable than focused.

Method and Materials

Four schools, 1 rural, 2 suburban, and 1 urban, with a total of 357 5th and 6th grade students participated in the study during regular class time. One hundred and forty-three (143) students were dropped due to (a) failing to complete part or all of the learning materials or any tests and (b) having participated in a similar study the previous year. (Note that the relatively high attrition rate was due, at least in part, to running the study during the COVID-19 period.) Of the remaining 214 students, 75 were in the menu-based condition (mean age: 11.6; girls: 39; boys: 35; 1 did not respond), 72 were in the scaffolded condition (mean age: 11.6; girls: 44; boys: 28), and 67 were in the focused condition (mean age: 11.6; girls: 31; boys: 36)

During 45-to-55-minute class periods for up to a full week, students worked on the Internet-based materials at their own pace to complete a decimal pretest, the game intervention according to condition (i.e., They played all of the mini-games, with two problems per mini-game, followed by a prompted self-explanation, according to condition), an immediate posttest, and a questionnaire. One week after the posttest, a delayed posttest was taken during one class period. Each test consisted of 43 items, designed to probe for decimal misconceptions and conceptual understanding, with 52 points possible across these items. We used three isomorphic test forms that were positionally counterbalanced across conditions. The questionnaire included 3 items each from the mastery, meaning, and challenge subscales of the Player Experience Inventory (PXI). We also included 3 items targeting affective engagement and 3 items targeting behavioral/cognitive engagement. Finally, we included 5 items adapted from an enjoyment subscale, the Achievement Emotions Questionnaire.

Results

RQ1. Which form of prompted self-explanation -- menu-based, scaffolded, or focused -- leads to the best learning outcomes in the context of the Decimal Point learning game?

A one-way analysis of variance (ANOVA) showed there were no differences in pretest performance based on condition, $F(2, 211) = 1.90$, $p = .15$, $\eta^2_p = .018$ An ANCOVA revealed a significant effect of condition on delayed posttest when controlling for pretest, $F(3, 210) = 3.08$, $p = .048$, $\eta^2_p = .028$. Pairwise comparisons with Bonferroni corrections indicated that the focused condition performed significantly better than the menu-based condition, $p = .042$. There were no significant differences in performance between the focused and scaffolded conditions, $p = .76$, or between the menu-based and scaffolded conditions, $p = .55$. There was no significant effect at immediate posttest, also when controlling for pretest, $F(3,210) = 2.25$, $p = .11$, $\eta^2_p = .021$. Thus, our hypothesis that focused self-explanations would lead to the best learning outcome was confirmed (at least with respect to the focused versus menu-based comparison).

To better understand the different conditions' effects on students' learning processes, we also analyzed time spent and errors made. An ANOVA indicated a significant condition effect on time, $F(2, 211) = 13.27$, $p < .001$, $\eta^2_p = .11$. Pairwise comparisons with Bonferroni corrections revealed that the menu-based condition took significantly less time than the scaffolded condition, $p < .001$, and the focused condition, $p = .001$, but there was no significant difference in time between the scaffolded and focused conditions, $p = .88$. There was no significant condition effect on the number of errors during gameplay, $F(2, 211) = 0.72$, $p = .49$, $\eta^2_p = .007$.

Table 1. The mean and standard deviation of different learning and game play metrics by condition.

	Menu-based (n = 75)	Scaffolded (n = 72)	Focused (n = 67)
Pretest	26.01 (10.47)	24.63 (10.03)	27.96 (9.69)
Posttest	30.12 (9.58)	30.58 (9.88)	33.69 (9.33)
Delayed posttest	30.55 (10.29)	30.97 (10.23)	34.81 (9.88)
Time (minutes)	62.65 (24.68)	83.76 (27.56)	79.12 (26.09)
Errors	75.07 (50.52)	73.22 (46.94)	65.63 (49.67)

RQ2. Which form of prompted self-explanation -- menu-based, scaffolded, or focused -- leads to the least enjoyment in the context of the Decimal Point learning game?

We applied a series of ANOVAs to assess the impact of condition on each of the factors analyzed in the questionnaire: player mastery, player meaning, player challenge, affective engagement, behavioral/cognitive engagement, and enjoyment. There was a significant effect of condition on player mastery, $F(2, 211) = 4.15$, $p = .017$, $\eta^2_p = .038$. Pairwise comparisons with Bonferroni corrections revealed that the focused condition led to significantly greater feelings of mastery than the menu-based condition, $p = .014$. There were no significant

differences in mastery between students in the focused condition and the scaffolded condition, $p = .19$, or between students in the scaffolded and menu-based conditions, $p = .96$. There was no significant effect of condition on any other questionnaire measure, $p = .16$, indicating that students' reported experiences of engagement, enjoyment, meaning, and challenge did not differ based on self-explanation condition.

Discussion and Conclusions

The central finding of this study is that focused self-explanations led to better learning outcomes than menu-based self-explanations in the context of a digital learning game. Although this is consistent with prior research comparing focused and menu-based prompts in interactive learning environments, it contrasts with the findings of Johnson and Mayer (2010), in which students playing a learning game attained a better learning outcome using menu-based prompts than students using open-ended self-explanations. An important difference between our study and the Johnson and Mayer study is that they used an open-ended prompt ("Provide an explanation for your answer in the space below"), while we used *focused* prompts that were specific to the values and misconceptions addressed by each problem. While Johnson and Mayer argue that less constrained prompts may be more disruptive to game flow than more constrained prompts, Wylie and Chi (2014) suggest that more constrained, constructive prompts can be beneficial in digital learning environments, including games, provided they are sufficiently focused. Our results appear to support the latter view.

The superior learning benefit of focused self-explanation was on a one-week delayed posttest, suggesting deeper, more conceptual learning. This further suggests that focused self-explanations may be especially beneficial for retention and deeper knowledge, consistent with the ICAP theory (Chi & Wylie, 2014) claim that this type of knowledge is better supported by constructive processes than active processes.

We also found that the learning benefit of focused explanations did not come at the expense of enjoyment. In particular, there were no differences in enjoyment across the three conditions. Thus, the benefits of enjoyment often claimed for digital learning games do not appear to have been undercut with less constrained self-explanations. Even though extra cognitive resources were likely expended by the students in the focused self-explanation condition, they enjoyed playing *Decimal Point* as much as the students in the other conditions and even expressed a greater sense of player mastery.

Determining the best way to infuse instruction into digital learning games, while maintaining the flow and enjoyment that is central to learning games, is an important research direction. While prior research indicated that menu-based self-explanations in games were superior to open-ended self-explanations in a game-based learning context, this study found that focused self-explanations led to a better learning outcome than menu-based self-explanations, suggesting that focused, constructive prompts can be effective in learning games.

Qualitative Observations of Metacognitive Tendencies of High and Low Foreign Language Anxiety Learners

Rebecca Paterson, Emmanuel Manalo
rebecca.paterson.62e@st.kyoto-u.ac.jp, manalo.emmanuel.3z@kyoto-u.ac.jp
Kyoto University, Japan

Abstract: Despite the ever-growing necessity to speak in a foreign language (FL), it remains a nerve-wracking task for many. Speaking in a FL, a cognitive task, is under the control of a learner's metacognition, and research in mathematics anxiety have pointed to metacognition's role in the possible onset and/or maintenance of negative affect. The link between foreign language anxiety (FLA) and metacognition, however, is currently unclear. To understand this link further, the authors combined the use of novel scenarios and a questionnaire to identify differences in metacognitive thoughts and behaviours between high (HA) and low anxiety (LA) participants. HA participants were found to write less relevant information and be more negative towards themselves, while LA participants mentioned more strategic choices and focused more on the task at hand.

Introduction

Foreign language anxiety (FLA), an affective condition that affects both a learner's desire to engage in speaking activities and their performance (Young, 1991), is a particularly pressing issue in our interconnected global society where many people are required to communication in a FL – English. While potential causes are plenty, such as negative past experiences (MacIntyre & Gardner, 1998) and study-abroad experience (Saito & Iida, 2015), there is also a possibility that a thinking element – a metacognitive element – may play a role in FLA.

Metacognition encompasses both the knowledge people have of themselves as learners, their strategies in a given task, as well as their planning, monitoring, and evaluation strategies (Wenden, 1999). Speaking is a skill that requires complex cognitive processes such as message planning, monitoring of oneself and others, and evaluating communication efficacy (Levelt, 1989), as well as a skill which is also subject to self-efficacy judgements (Wenden, 1999), thus influenced by metacognition. While somewhat dissimilar, mathematics is likewise a subject that requires complex cognitive and metacognitive skills, and in the context of mathematics anxiety, a lack of sufficient metacognitive skills, or an inability to apply them properly may cause or further exacerbate anxiety in the context of mathematics test-taking (Veenman et al., 2000). This same theoretical thread may also apply to FL speaking.

Currently, many studies in FLA rely on self-report questionnaires completed by large samples of learners to draw inferences about the nature of the issue based on statistical models and correlations. While this is often the most ethically sound and generalisable method available, there are obvious limitations. Due to this, there are still many questions unanswered about the cognitive – particularly the metacognitive – element of FLA. In this study, the authors apply a novel approach to answer the following questions:

1. Is there a relationship between metacognition and foreign language anxiety?
2. What metacognitive tendencies do anxious individuals show?

Method

Participants

Participants were 68 students (mean age: approx. 19 years) enrolled in both English major and non-English major courses at a women's university in Western Japan. Of these, high and low anxiety participants were selected for further qualitative analysis (see Results).

Procedure and Materials

The survey study comprised three parts which were administered online over the course of three weeks. In the first week, participants wrote, in free prose, answers to six scenarios each designed to elicit participants' metacognitive knowledge or strategy in a slightly stressful context where English should be used (Table 1). The six components of metacognition chosen were based on Wenden's definitions (Wenden, 1998). In the following two weeks, the Japanese version of two 5-point Likert-type scale questionnaires – the Foreign Language Classroom Anxiety Scale (FLCAS) (Yashima et al., 2009) and a double-back Japanese translation of the Metacognitive Awareness Inventory (MAI) (Schraw & Dennison, 1994) – were administered. These self-report

 © ISLS

questionnaires are designed to measure the extent of classroom FLA and awareness of metacognitive capabilities, respectively.

Table 1
Six Novel Scenarios Designed to Elicit Metacognitive Thoughts and Behaviours

Metacognitive component	Scenario
Planning	For your English class, you must give a 5-minute presentation in English about climate change. You have one week to prepare for this presentation. You can use notes, but you cannot read from a script. How would you prepare? List in order what you would do to prepare. Explain and provide details where necessary.
Monitoring	You are travelling in Singapore, a country that uses English, Mandarin Chinese, Malay and Tamil. However, you dropped your purse in a department store. It contains your credit cards, money, and hotel key. You go to the security office to get help. During this conversation, what would you be thinking about when explaining to the security guards?
Evaluation	Imagine you work in an international company. You have just given a presentation in English, but you do not think it went very well. List what aspects of your presentation would be important for you to consider in deciding how good or how poorly you did your presentation. Apart from what you think, how else can you find out how well you did?
Task knowledge	Imagine that you have been invited to participate in an international meeting to discuss university student experiences, in English. List what you would need to do to decide whether to participate. Explain briefly why those would be important in helping you decide.
Strategy knowledge	An international student from Senegal has just joined your course, but she cannot speak Japanese. One of the teachers recommended you look after her during her first few weeks in Japan. You are talking at lunch with the student and some other Japanese friends in English, however the conversation isn't going well and there is some tension. What will you do?
Person knowledge	Describe yourself as an English speaker/learner. What are your strengths and weaknesses? Why are these your strengths and weaknesses? What is important in speaking English?

Analysis

Data-driven thematic analysis was used to identify salient features of the sample's metacognitive behaviours and tendencies (Tsuchiya, 2016). Clauses expressing semantically similar ideas were extracted, then grouped and labelled under headings that captured the main theme. Correlational analysis was conducted on the questionnaire data to examine relationships between FLA and metacognitive awareness to clarify a possible link between these two concepts within the participants.

Results and Discussion

A significant correlation was found between the FCLAS and the MAI (r = -.39, p > .01), indicating a moderate relationship between FLA and metacognitive awareness. To select low and high FLA participants for further comparative qualitative analysis, the first and fourth quartiles (105 and 126, respectively) were calculated. Participants whose FLA score included or fell below 105 were considered "low anxiety" and likewise, those whose FLA score included or exceed 126 were classed as "high anxiety". These will be referred to as the LA (low anxiety) group (n = 17) and HA (high anxiety) group (n = 14, due to non-submissions, this group has fewer members), respectively. Qualitative differences between the two groups' metacognitive knowledge and strategies were identified, and these are outlined below where the percentages are the number of participants who fell under a given thematic category out of a total of 31. The quotations that follow each section begin with the group (HA or LA) and the participant's randomised 4-digit identification number, followed by text translated from Japanese.

Planning

Both groups showed a preference for general planning behaviours: researching necessary information prior to scripting (48%), the creation of a script in Japanese (31%) and subsequent translation into English (42%), and memorisation of the script (35%). Notably, many of the LA group showed further aptness of strategy choice that would make the hypothetical classroom presentation easier for them. They exclusively wrote that they would write the script in English first (8 responses) and would create bullet points/notes (7 of 10) and identify and focus on keywords (3). Members of this group were aware of the need to make the text easier to memorise while also being aware of the week time limit. Finally, only participants in the LA group wrote about strategies for reducing

anxiety during the presentation (2) and considered the needs of the audience (5). The HA group, on the other hand, tended towards more actual planning behaviours such as choosing topic areas (6 of 11) and making summaries (5 of 8) and lacked the same strategic decisions mentioned by the LA group (see example comparison below).

> LA (4103): I will write out the words and phrases I circled from my script on another piece of paper, and use them as presentation notes, in case I get nervous and forget everything.
> HA (2222): First I will write a report and summarise my points from that.

Monitoring

Hypothetical monitoring behaviours common to both groups were making sure they would explain the contents (48%) and features (65%) of the lost item, as well as the places they visited prior to its loss (58%). Like the above, few strategies were salient in the HA group but themes exclusive to this group were: favour confirming possible collection of the item (2 of 3) and the need to prepare themselves for the worst (2 of 3), while giving the reason that it may have been stolen or that the country is not as safe as Japan (example below). In contrast, the LA group mentioned how they would ask advice from the authorities (2 responses) and use gestures and visual aids to facilitate communication (5 of 7; example below). While shared by a small percentage of the HA group participants, use of visual aids (2 of 7) and the awareness of the need for easy communication categories (3 of 5) were occupied largely by LA participants, who, based on the above, seem to be aware of the authoritative listener in this task and the necessity to communicate effectively.

> LA (3509): When going abroad, the most important thing in addition to speaking, is to make sure you convey what you want to convey by using gestures.
> HA (7637): Even if the purse comes back, the contents might not, as Singapore isn't as safe as Japan.

Evaluation

The analysis for the hypothetical evaluation scenario also yielded similar qualities between the two groups: asking the audience directly for feedback (61%), reflecting on their performance by themselves (29%), comparing with others' presentations (13%), and using the evaluative information for further use (13%). Again, the HA group did not indicate any behaviours that were not seen in the LA group, although they did mention evaluation standards such as the need to be understandable from the perspective of the audience for their presentation (3 of 4). Themes occupied by the LA group participants were: the use of video (7 of 9), monitoring audience reactions (2 of 3), and the use of questionnaires (4 of 6). All of these indicate ease around actively engaging with their performance outcomes and the audience. Examples of comparing with others appeared in both groups; however, the tone of the HA group member is far more critical.

> LA (4802): I would look at presentations done by people who did well, compare what they did and why, and then see what I could learn from them.
> HA (9274): I would compare with others and think carefully about what parts were not good.

Task knowledge

Both groups mentioned the requirement of sufficient English (23%) and communication skills (31%) in helping to decide whether to participate in the event, although these were more common amongst those in the LA group (4 of 7 and 7 of 10, respectively). In line with the above results, the LA group were found to include other qualities in addition to the shared qualities. These were: mentioning of specific (4) and general (3 of 5) speaking skills, affect (2 of 3), and their ability to understand English well enough (5 of 6). Both groups responded incorrectly with *how they would prepare* for the event, but the difference here is the LA group's mentioning of linguistic (5 of 7) and vocabulary preparation (2 of 3) in contrast to the HA group's preference to write about specific content (4 of 7) and preparing hypothetical materials for the event (1), which would not likely be necessary. Below is a comparison between how two participants, high and low anxiety, responded in relation to language. The LA participant is more specific and relevant in her submission.

> LA (5252): I need to think about whether I can respond immediately during question time (because thinking and searching up information would hold up the conversation).
> HA (9285): Since I still don't know the right vocabulary, I would prioritise memorising them.

Strategy knowledge

In relation to the participants' strategy knowledge, both groups saw value in mixing English and Japanese in this scenario (13%), where communication breakdown had occurred. They also equally mentioned playing a game to ease tension (16%). In the HA group, one participant mentioned the use of external tools such as using a translator, while others mentioned introducing or talking about Japan (2 of 3; example below). To compare with the LA group, these participants focused more on the hypothetical exchange student in the moment and were more likely to mention asking her questions (4 of 5) and talking about her country (8 of 10; example below), rather than their own. Their responses were found under labels that showed more active group management strategies such as conversation manager, entering the conversation, and providing an alternative topic (total 12 of 18).

> LA (4802): For example, by sharing the differences between our two countries and trying to speak in each other's language, we can teach each other new things and reduce some tension.
> HA (0241): I would ask the exchange student about Japan and if she says something like "I like shrines" we'd talk about that together with the others.

Person knowledge

This section was a set of sub-questions that elicited details of learner beliefs. This yielded a particularly rich set of data which can be summarised as follows: the HA group viewed their *overall* English-speaking skills and self-impression negatively and especially in relation to others, with their most salient strength being compensatory body language. They were particularly harsh about their weaknesses in English grammar and pronunciation. In contrast, the LA participants mentioned *certain aspects* of themselves that they viewed as problematic such as a lack of confidence and symptoms of anxiety, but also noted some positive aspects of their overall impression as well, which was exclusive to this group. They were also more focused on their ability to communicate, both linguistically and with gestures. A comparison between the two participants' negative views of their vocabulary knowledge can be found below. Note the self-blaming tone of the HA participant.

> LA (4103): I can convey necessary information to the listener with a small number of words but I think this is also a weakness. I only use the words I know.
> HA (1395): I don't know any vocabulary at all and because I don't know anything there isn't much I can say, so I end up not being able to speak.

Conclusion

While both groups demonstrated necessary metacognitive skills that were relevant to each scenario, presumably facilitating hypothetical success, subtle differences existed between the LA and HA groups indicating that the LA group chose more effective strategies that matched the scenario more closely and were aware of not only themselves but the other people they would encounter in each scenario. From these results it appears that there is a qualitative difference in the metacognitive competencies of HA and LA learners, and further research should clarify whether there is a casual relationship between these competencies and its direction of influence.

Insights from Using a Systematic Design Process to Develop Classroom-based Assessment Resources for Measuring Elementary Students' Science and Literacy Proficiencies

Daniel Damelin, Concord Consortium, ddamelin@concord.org

Abstract: The *Framework* and NGSS bring to the forefront the role of language in doing science and in learning from doing science. Yet, most existing science assessments for elementary learners do not integrate or attend to aspects of scientific language and literacy that are essential components of science proficiency. Accordingly, there is a need for high-quality classroom resources capable of providing teachers with information on where students are in the process of developing proficiency in science and scientific-specific literacy. In this paper, we present our design process for developing assessment resources – tasks, rubrics, and teacher support materials – and describe initial insights from using the process to develop resources for elementary grade classrooms. We highlight challenges and opportunities that have emerged from our work attending to the role of literacy assessing multi-dimensional science learning, incorporating equity and inclusion considerations in assessment design, and embracing the affordances of technology.

Introduction

High-quality, classroom-based assessment resources can provide critical information that helps teachers in making informed instructional decisions to further student science learning (Shepard et al., 2018). However, the potential of classroom-based assessments to increase students' opportunities to learn can only be realized if students can access and engage with tasks productively and if accompanying resources provide teachers with insights on students' developing proficiencies. This sets a high bar for knowledge-in-use assessments that aim to measure students' multidimensional proficiencies as articulated in science education frameworks and standards such as the National Research Council's Framework for K-12 Science Education (henceforth *Framework*; NRC, 2012) and the accompanying Next Generation Science Standards in the United States (NGSS Lead States, 2013). The challenge is especially acute when designing assessment resources for early elementary students who are just beginning to develop the cognitive endurance, attention span, physical dexterity, and language and literacy skills they must have to demonstrate what they know and can do (Billman et al., 2021). For example, as young students use and apply their knowledge to understand and explain phenomena, they must learn science-specific ways of talking, reading, and writing to communicate findings and provide explanations (Billman & Pearson, 2018). Unfortunately, most existing science assessments for elementary learners do not integrate or attend to aspects of scientific language and literacy that are essential components of science proficiency. Accordingly, there is a need for classroom resources capable of providing teachers with information on students' developing proficiencies in science and science-specific literacy.

In this paper, we describe how we use the Next Generation Science Assessments for Young Scientists (NGSA-YS) design process to fill the need for equitable, technology-based assessment tasks that integrate science and literacy proficiencies appropriate for elementary students. The NGSA-YS process (Billman et al., 2021) was specifically developed to meet the challenge of measuring students' integrated science and literacy proficiencies by following the argumentative reasoning of evidence centered design (ECD; Mislevy & Haertel, 2006) to create classroom-based assessment tasks that support NGSS teaching and learning. In accordance with the principles of ECD, NGSA-YS is a systematic design and development process that builds from the Next Generation Science Assessment (NGSA) approach (Harris et al., 2019; Harris et al., in press). NGSA-YS aims to result in coherent assessments by unpacking the science and literacy dimensions to be measured, developing evidence statements that describe student performances, and creating tasks that measure specific knowledge and skills, which taken all together form a basis of an argument about what students know. After describing the design process, we highlight challenges and opportunities that have emerged from our work.

Theoretical framework

 © ISLS

Three-dimensional science learning and the integrated role of literacy

The vision of science learning in the *Framework* emphasizes three dimensions – disciplinary core ideas, crosscutting concepts, and science and engineering practices – and the idea of knowledge-in-use where students use and apply the dimensions to explain phenomena and/or design solutions to problems. Importantly, the *Framework* also brings to the forefront the role of language in doing and learning science. For example, students develop proficiency in scientific ways of talking, reading, and writing when they engage in the science and engineering practice of argumentation to construct claims based on evidence or to exchange ideas that advance, improve, and defend explanations. Likewise, applying the crosscutting concept of systems and system models requires students to generate coherent narrative accounts of science phenomena, linking ideas and describing relationships among components in systems. Recent research shows that integrated science and literacy instruction increases student learning in both domains (Billman & Pearson, 2018; Maarouf, 2019). It follows that classroom-based assessment resources should also attend to this integration to best support science instruction.

Equity and inclusion considerations in the design process

The *Framework* makes the call that science education must be for all students. The design of classroom-based, knowledge-in-use assessments must likewise heed that call, ensuring that assessments are inclusive of all students and are equitable in the measure of all students' proficiency (NRC, 2014). Recent guidance for designing knowledge-in-use assessments that attend to and promote inclusion of all learners includes recommendations that tasks use scenarios and phenomena that are likely to have interest or universal relevance for students, explicitly attend to accessibility of language, include scaffolds to make expectations explicit for students, and be accompanied by tools and routines to support teacher enactment (Furtak et al., 2020). This is an emerging area in NGSS-aligned assessment, where researchers are dedicating attention to how assessments can and should support meaningful science learning for a wide range of students.

Affordances of technology for high-quality formative assessment

Technology-delivered assessments can provide unique opportunities for students to demonstrate knowledge-in-use, exhibit emerging literacy proficiency, and can also provide equitable and inclusive ways for students to access and engage with tasks. Related to this last point, technology can provide options for students to use multiple modalities and representations, affording students with diverse abilities and language backgrounds opportunities to demonstrate their proficiencies that are not possible in print-based assessment (Henderson et al., 2021). For teachers, technology can make regular use of formative assessment more feasible by providing support for implementation, data collection, interpretation, and instructional next steps (Zhai et al., 2020).

The NGSA-YS design process

The NGSA-YS design process consists of four iterative steps (Figure 1). Each step includes activities that achieve coherence across the science and literacy proficiencies underlying an NGSS performance expectation (PE), that incorporate guidance for equity and inclusion, and tend to the design of technology-based affordances.

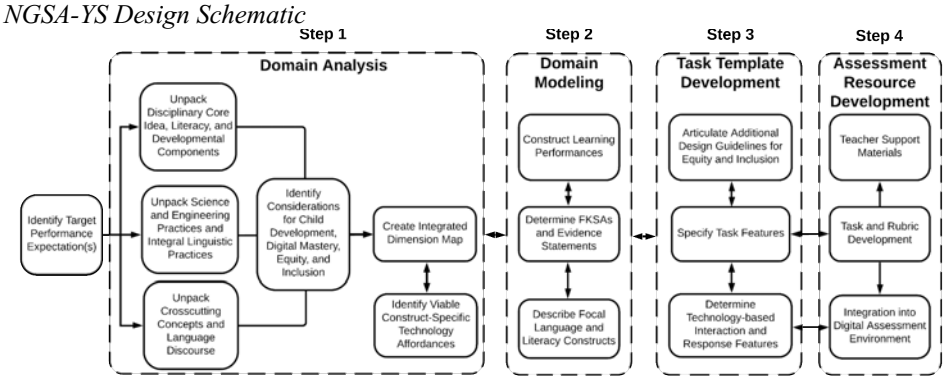
The first step is a purposeful analysis of the domain covered by a PE or PE bundle. In this step, we identify the focal components of each dimension including the science-specific language and aspects of literacy required to demonstrate proficiency as well as the aspects of language and literacy that may inhibit students' ability to demonstrate proficiency. Information obtained through the domain analysis is brought back together in an *integrated dimension map* (IDM) that illustrates relationships between each aspect of the three dimensions of the NGSS called out in the PE along with key elements of science-specific language and literacy. The IDM helps identify ways in which the three dimensions can work together to define proficiency and lays the groundwork for specifying the knowledge, skills, and abilities that will be measured. Alongside our IDMs, we set forth an identification of viable technology affordances specific to the constructs articulated in the mapping.

The second step, domain modeling, uses the IDM to articulate and refine the multiple sub-performances (referred to as learning performances) that students need to demonstrate to meet a PE or PE bundle. A single learning performance is crafted as a knowledge-in-use statement that is smaller in scope and covers a designated area of an IDM. Multiple learning performances are needed to fully cover the conceptual terrain of a PE. Learning performances are a keystone in the process of developing tasks that assess for building toward a PE.

The design goal of **the third step** is to develop task templates – detailed design tools that guide the creation of families of tasks and rubrics. Task templates articulate information about how the task is presented to the student, what content is covered in the task, options for how students can respond, and preliminary scoring guidelines. Templates also bring attention to language and literacy features, to equity and inclusion considerations, and to intended technology interactions such as how students will interact with any digital components as part of the task activities or response modes.

The final step involves operationalizing the assessment argument and specifications from the task template to develop tasks, scoring rubrics, associated digital assessment environments, and teacher resources. In general, each task consists of a set of prompts tied together by a common, developmentally appropriate scenario that establishes a relevant phenomenon or context for student problem solving aligned to the associated learning performance. The prompts embedded within the task ensure that there are opportunities for students to demonstrate integrated proficiency with the dimensions of the learning performance and with science-specific language and literacy. Rubrics target the science and science-specific literacy aspects of student responses that should be scored and show how they relate to proficiency with the learning performance. To complement the assessment tasks and rubrics, we develop materials to support teachers' use of the assessments and their facility with implementing formative assessment practices in the midst of science instruction. A key resource is a practice guide to support administration of the tasks, scoring and interpretation of student responses, and decision-making for instructional next steps.

Figure 1
NGSA-YS Design Schematic



Challenges and opportunities in using the NGSA-YS process

Our use of the NGSA-YS process revealed new challenges in addressing the needs of teachers and students. It also revealed new opportunities to push the assessment development field forward in attending to literacy and equity within multi-dimensional science assessment design while realizing the affordances of technology.

All students, especially in the early grades, benefit from opportunities to practice and develop a broad range of language and literacy skills in the context of engaging with the NGSS. In our work, we recognize that these opportunities must also extend to classroom-based assessment. Consequently, it is important in assessment design to identify measurable components of language and literacy proficiency that are essential elements of the target science performance. One challenge we wrestled with was determining the degree to which students can express their understandings with everyday language while recognizing that science has domain-specific words, some that are essential for engaging with an idea or concept, but which students are unlikely to encounter outside of the classroom (Osborne et al., 2016). For example, "push and pull" is sometimes sufficient for expressing ideas about forces, but the domain-specific use of "forces" can include additional meanings. We have found, too, that it is of value to identify general language and literacy proficiency targets. For example, student proficiency with writing within an organizational structure can be targeted (e.g., students' ability to describe the steps in an investigation). This adds new challenges in unpacking an NGSS PE, but also improves the instructional supportiveness of the assessment in both science and language arts domains.

Equity is interwoven throughout our work using the NGSA-YS process. In attempting to follow the emerging guidance on equity and inclusion, we have wrestled with early grade students' lived experiences and developmental profiles in relationship to expectations put forth in the NGSS. For example, providing students with different options when developing and using models without neglecting the conventions and expectations in the design and format of visual representations in the scientific community. Additionally, in identifying phenomena and constructing task scenarios that are relevant to students' lived experiences, we have wrestled with the tension between scenarios that have universal relevance and utility for a wide range of students and those that leverage the specific identities of learners.

As we work to design assessments that will be delivered on a digital platform, we have focused on affordances that fall into two categories: (1) general enhancements applicable to all tasks; and (2) interactive technology-based components directly related to an assessment target. General enhancements include building text-to-speech capabilities to facilitate students' reading of the assessment tasks and speech-to-text capabilities to

assist students in recording their responses in ways that do not require keyboarding skills. Interactive components include design patterns that allow students to express ideas in modalities other than writing and to engage in science practices in ways not possible with paper-based assessments. These might be simulations that students manipulate and annotate, tools that facilitate construction of a model diagram, or drag-and-drop interactives that provide a context-specific opportunity to express concepts and ideas with both words and images. Evaluating when affordances from these two categories are useful in a particular context has raised new questions regarding what elementary students can do within a digital system and what supports they need.

Conclusion

Our use of the NGSA-YS approach has contributed to our understanding of knowledge-in-use assessment design for the early elementary grades by focusing attention on the science-specific language and literacy practices that are integral parts of multi-dimensional science learning. Importantly, considerations of language and literacy inform the tasks, the rubrics, and the teaching resources we develop. New technology affords opportunities for students of wide-ranging proficiency to showcase what they know and can do. These insights fit into an emerging appreciation of the integrated role of science and literacy that push our assessment work forward in designing instructionally beneficial assessments for elementary teachers and their young students.

Students' Prior Knowledge of Disease Spread and Prevention

Siyu Wu, siyu.wu@aggiemail.usu.edu; Hillary Swanson, hillary.swanson@usu.edu; Utah State University
Bruce Sherin, bsherin@northwestern.edu; Uri Wilensky, uri@northwestern.edu; Northwestern University

Abstract: The COVID-19 pandemic has highlighted a need for students to learn about public health issues, including the transmission of disease and methods for the prevention of epidemics. This study presents data from a project focused on developing an emergent systems microworld to help middle school students learn about these topics. The microworld is designed to help students model and test their ideas about how a disease spreads through a population and how an epidemic can be prevented. The paper presents an analysis of students' prior knowledge of disease spread and prevention, which they shared during an activity preceding their exploration of the microworld. We present student ideas in categories of *disease transmission*, *recovery from disease*, and *disease protection strategies*. We describe their ideas and suggest how they may be integrated into the design of the microworld.

The COVID-19 pandemic has highlighted the need for a health-literate society. This means enhancing the public's knowledge of public health issues, including the transmission of disease and methods for the prevention of epidemics. Epidemiology is a branch of science that studies health-related behaviors and outcomes in populations. This includes subjects such as disease causation and transmission, outbreak investigation, and disease surveillance. At present, learning about epidemiology is primarily limited to graduate and undergraduate students. By comparison, few middle school students have access to courses in epidemiology (D'Agostino, 2018). Some scholars have found that developing material on epidemiology for middle school students is challenging (Hlaing, 2014). However, learning about epidemiological topics at a young age is essential for helping students make informed decisions regarding their health and having critical thinking regarding public health policy (Bracken, 2014).

To address this need, we are designing student-centered epidemiology education materials for middle school students. We use NetTango (Horn, Baker, & Wilensky, 2020), a block-based interface to the NetLogo modeling platform (Wilensky, 1999). NetTango blocks allow students to create, test, and debug models of disease spread based on their own ideas. Blocks in NetTango are not general-purpose programming primitives, but rather, are semantic blocks relevant to the modeled phenomenon. The approach engages students in the construction of an agent-based computational model of the spread of disease in the context of an emergent systems microworld (ESM) (Dabholkar, Anton & Wilensky, 2018). Students can develop ideas about disease spread and prevention at the level of a population by exploring individual agent behavior and multi-agent interactions.

Emergent systems microworlds and the value of their application have been investigated by many research studies, including studies that specifically examine the impact on students' understanding of scientific phenomena (Levy and Wilensky, 2009; Wilensky & Reisman, 2006; Wilkerson-Jerde, Gravel, & Macrander, 2015). We are investigating how to integrate students' prior knowledge into the design of the ESM, so that students can construct, test, and revise models that represent their thinking. Our aim is to build a computational modeling environment that very consciously meets students halfway. This means giving students programming blocks that allow them to work with ideas that closely match their intuitions, which in turn requires research into what these intuitions are. The present work investigates student intuitions about the spread of disease and based on these findings, makes recommendations for refinements to the primitive coding blocks in the microworld, so that students can model, test, and debug their thinking.

Theoretical Foundations

This research draws on a constructivist view of knowledge and learning called Knowledge in Pieces (KiP; diSessa,1993). KiP argues that knowledge is a complex system composed of knowledge elements. KiP instruction advocates that learning starts with eliciting students' prior knowledge and develops by reorganizing and refining the learner's knowledge networks. To our constructivist lens, we add the lens of constructionism (Papert, 1980). Constructionism is a theory of pedagogy, which posits that learning happens best through the construction of publicly shareable artifacts. Constructing a publicly shareable artifact helps students learn because they can gain knowledge and skills by creating, reflecting on, and discussing their artifacts. In the case of our project, the learning-by-modeling approach has students use computational models to refine their thinking through the building, testing, and debugging of models.

 © ISLS

Methods

In this paper, we ask "*What intuitions do students have about disease spread and prevention, and how can those be used to inform our microworld design?*" To address these questions, we employed a lab-based case study approach (Yin, 1998) and conducted one-on-one, 1.5-hour recorded interviews through Zoom with middle school students (ages 12-14). During the interview, students were asked questions about the spread and prevention of disease and then invited to model and test their ideas in the microworld shown in Figure 1.

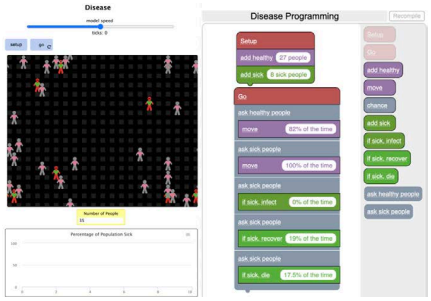

Figure 1. Screenshot of the *Disease Spread* microworld (Martin et al., 2021).

Figure 1 shows the microworld display. The box on the left represents the world, where agents interact with each other. The modeling space on the right of the interface has blocks including "setup," "go," "add healthy," "add sick," "ask healthy people," "ask sick people," "move," "chance," "if sick, infect," "if sick, recover," and "if sick, die." These blocks can be used to model the spread of disease by arranging them in the modeling space. The microworld is agent-based, meaning each agent is asked to behave, at each tick of the clock, according to the blocks assigned to them in the "go" procedure. For example, healthy agents might be asked to move randomly throughout the world and become infected with some probability if they cross paths with an agent who is sick.

The interviewer began the session by sharing their screen and presenting the student with a story about the spread of disease. The story was about Jack, who goes to a party and interacts with Mary, who has been sick. Jack gets sick the next day and then, having recovered, goes to play soccer with his friends. One of the friends gets sick the next day. The interviewer asked open-ended questions and probed for additional information after each explanation offered by the student. After answering the questions, the students were invited to model and test their ideas in the microworld.

This study focuses on interviews with three middle school students: Alex (13), Max (12), and Sam (14). The interviews were recorded and transcribed. A microanalysis (diSessa, Sherin, & Levin, 2016) was conducted to produce a list of the students' initial ideas about the spread and prevention of disease. The audio recording of each student's interview was reviewed, and times were noted during which they revealed their thinking. These episodes were then marked on the transcript, which was then read for evidence of their initial thinking.

Our analysis of the data was driven by the aim of refining the set of coding blocks used in the microworld, and our own intuitions about the appropriate grain size for these blocks. We began by paraphrasing the student explanations, and then looked across students for common ideas. The ideas were organized based on similarities and grouped into the following categories: 1) *disease transmission*, 2) *recovery from disease*, and 3) *disease protection strategies*. These students' ideas can help us get a sense of what intuitions students have about disease spread and prevention and how we might revise the emergent systems microworld by adding new blocks and adding parameters to existing blocks.

Findings

The analysis revealed 11 pre-instructional ideas across the three categories. We propose 6 corresponding revisions to the microworld, which would allow students to model and test these ideas. We present each knowledge category, listing student ideas (with illustrative segments of transcript) and proposed model revisions.

Disease transmission

Pre-instructional ideas belonging to this category emerged when the students explained why Jack took a day to develop symptoms after he played with Mary and transmitted the virus to others even though he had no symptoms. Table 1 organizes students' ideas about *disease transmission* and implications for the design of our ESM.

Table 1. Pre-instructional ideas about *disease transmission* and design implications.

Transcript	Pre-Instructional Ideas	Implications for Block Design
Sam: …You do not show symptoms right away, it takes time for you to start to feel it.	It takes time to get sick and show symptoms.	Add a "set incubation time" block, to cause a delay between being exposed and getting sick.
Max: Mary sneezed or coughed, the species, the sneeze or cough went into the body of Jack and took time to process and get into his body and get infected. Alex: The virus got on, for example, his hand. And then when he got home, he had to eat and touch the food. That was with his hand. So, he ate the food, so now it is in his stomach.	Agents of disease can transmit through the human mouth and nose when coughing and sneezing. Agents of disease can stay on objects and transfer through touch.	Add "cough," "sneeze," and "touch objects" blocks to the "ask sick people" and "ask healthy people" block sets. The parameters of each block could be varied with respect to probability of infection.
Alex: Maybe even Jack recovered from the virus. He still had something in his body when they were playing. Max: …it's like since he is lying on the bed for like a week, perhaps the disease stops working, but when Jack started to play, they started working again.	Agents of disease can still be in your body even when you are healthy. Viruses would "sleep" in a deactivated body and "wake up" when the body is active again.	Add a "show symptoms" block with a variable probability parameter, to allow agents to be sick with or without showing symptoms.

Disease Recovery

This category of pre-instructional ideas emerged when students explained what disease Jack caught. Table 2 organizes students' ideas about *disease recovery* and implications for the design of our ESM.

Table 2. Pre-instructional ideas about *disease recovery* and design implications

Transcript	Pre-Instructional Ideas	Implications for Block Design
Alex: …When he recovers from the normal flu, he can't affect it to someone else. [...] A flu. You get it once. Because after your body sees the virus, they will get rid of it right away.	A body can gain immunity when it gets used to a disease.	Add an "if recover, gain immunity" block, with an adjustable probability parameter.
Max: Probably COVID. Coronaviruses, however, our body can't identify them, so it takes a process for our body to notice that we are sick and clear the virus.	It takes time for our body to recover from Coronavirus.	Add the blocks "get flu" and "get COVID-19" to pair with the variable probability "if sick, recover" block.

Disease Protection Strategies

This category of pre-instructional ideas emerged when students were asked to explain which kind of protection strategies would be effective in protecting themselves from infection when vaccines are still in short supply. Table 3 organizes students' ideas about *disease protection strategies* and implications for the design of our ESM.

Table 3. Pre-instructional ideas about *disease protection strategies* and design implications

Transcript	Pre-Instructional Ideas	Implications for Block Design

Sam: I'm kind of staying at home and stuff. [...] I don't think wearing masks works. The virus would stay on the masks. Your mouth touches the masks, then the virus comes into your body. Alex: I think every time you go out, wear masks. Some people wear masks and facial to protect their eyes too. Wash hands often. Sanitize your clothes and shoes when back home.	Stay home more of the time. Wear masks and facial shields. Wash hands. Sanitize personal objects and the environment.	Add "wear masks," "wash hands," "wear facial masks," and "sanitize the environment and belongings" blocks to the "ask sick people" and "ask healthy people" sets of blocks. Each block could have different parameters for probability of infection. It would be possible to display the results of single or multiple disease prevention strategies by stacking or using them separately.

Discussion

Our larger research project aims to develop emergent systems microworlds that intentionally meet students halfway. We approach this by providing students with programming blocks that correspond to their intuitions, which requires investigating what those intuitions are. This study examined students' intuitions about disease spread and prevention. Findings suggest that students have many intuitions about the spread, recovery from, and prevention of disease. Our findings offer insight into what coding blocks a pandemic microworld should have so that students can build, test, and debug models that represent their thinking. We anticipate that adapting blocks to accommodate students' intuitions will help students build models that represent their thinking and allow those without programming experience to use agent-based modeling to learn about complex systems phenomena.

Investigating Student Learning about Disease Spread and Prevention in the Context of Agent-Based Computational Modeling

Siyu Wu, siyu.wu@aggiemail.usu.edu; Hillary Swanson, hillary.swanson@usu.edu, Utah State University
Bruce Sherin, bsherin@northwestern.edu; Uri Wilensky, uri@northwestern.edu, Northwestern University

Abstract: COVID-19 has brought increased attention to the importance of health literacy, including understanding of the transmission and prevention of disease. This study presents data from a project aimed at developing a computational modeling microworld to help middle school students learn about these topics. Specifically, the microworld is meant to help students model and test their ideas about how a disease spreads through a population and how an epidemic can be prevented. The paper analyzes one student's knowledge refinement through the building, testing, and debugging of a disease spread and prevention model. We model student refinement of thinking through steps of building initial models and predicting results, testing initial models and making sense of the results, debugging and retesting models, observing final models, and explaining results. Our findings suggest adolescents can learn about strategies for disease prevention through computational modeling.

Introduction

COVID-19 has brought increased attention to the importance of health literacy in society. This involves making the public aware of issues related to public health, such as disease transmission and epidemic prevention. Epidemiology is the study of population-level health-related behaviors and outcomes, including disease causation, transmission, and prevention. Castagno et al. (2020) found that computational models could support the teaching and learning of topics in epidemiology. Their study was limited to undergraduate and graduate students and there is therefore a need to study how adolescents learn about epidemiological topics through computational modeling.

Agent-based computational modeling microworlds are a powerful tool for helping students learn about complex systems phenomena, including the spread of disease (Wilensky & Abrahamson, 2006). The value of their application has been described in many research studies, including studies that specifically describe their impact on students' understanding of scientific phenomena (Levy & Wilensky, 2009; Wilensky & Reisman, 2006, Wilkerson-Jerde, Gravel, & Macrander, 2015). We aim to offer middle school students block-based modeling microworlds, which allow them to represent their ideas in the program code and refine their thinking as they debug their program. We lower the threshold of this type of coding by using NetTango (Horn, Baker, & Wilensky, 2020). NetTango makes the computational power of NetLogo (Wilensky, 1999) accessible to modelers by using a block-based programming language curated to a particular phenomenon. NetTango blocks are not a full programming language, but domain-specific blocks relevant to the modeled phenomenon. This paper examines how our *Disease Spread* microworld can support student learning about agent-level behaviors that can lead to the prevention of an epidemic. Specifically, we show how a middle school student refined his thinking about disease prevention strategies using an agent-based computational microworld.

Theoretical Foundations

Constructionism informed the development of the instructional environment for this study. Constructionism asserts that learning occurs best through the construction and refinement of publicly shareable artifacts (Papert, 1980). Constructionist pedagogy helps students gain knowledge and skills by creating, reflecting on, and discussing these artifacts. In the case of our study, students used a computational agent-based model to articulate their thoughts on disease spread and prevention. They refined their ideas as they tested, debugged and refined their models. The theory of Knowledge in Pieces (KiP; diSessa,1993) informed our analysis of the engagement and refinement of naive knowledge. Knowledge, according to KiP, is a complex system made up of knowledge elements. Learning happens through the reorganization and refinement of the learner's knowledge networks. KiP instruction is constructivist, focusing on eliciting and refining students' prior knowledge.

Methods

This paper draws data from a larger study focused on developing a computational modeling microworld to help students construct an understanding of the spread of disease (Figure 1). The present work investigates the question: "*How does the computational block-based modeling microworld help students move from their initial thinking to their later thinking, with respect to disease prevention strategies?"* In order to address this question, we employed

 © ISLS

a lab-based case study approach (Yin, 1998). We conducted a one-on-one 1.5-hour interview through Zoom with a 12-year-old student we call Max. During the interview, Max was asked questions about the spread and prevention of disease and then invited to model and test his ideas in the microworld (Figure 1).

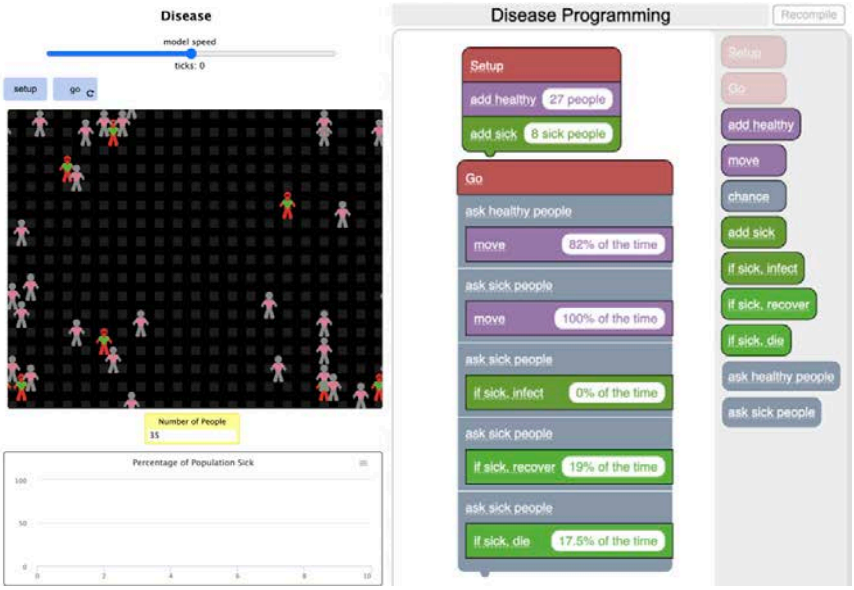

Figure 1: Screenshot of the *Disease Spread* microworld (Martin et al., 2021).

The box on the left side of Figure 1 represents a space where agents interact with each other. The modeling space on the right side of the interface has blocks including "setup," "go," "add sick," "add healthy," "ask healthy people," "ask sick people," "move," "chance," "if sick, infect," "if sick, recover," and "if sick, die." These blocks can be used to model the spread of disease by dragging and arranging them in the modeling space. The microworld is agent-based, meaning each agent is asked to behave, at each tick of the clock, according to the blocks assigned to them in the "go" procedure. For example, healthy agents might be asked to move randomly throughout the world and become infected with some probability if they cross paths with an agent who is sick. Sick agents might be asked to die or recover with some probability.

Max was invited to model and test his ideas in the microworld. Instead of writing text-based programs, he used blocks to build and test models and examine how emergent patterns arose at the system level from simple rules and interactions at the agent level. Specifically, he could build and test a model representing the spread of disease to explore how the individual-level interactions could give rise to a pandemic, and how individuals' different protection behaviors could make an impact on the overall health of the public.

We audio-recorded and transcribed Max's interview. We conducted a microgenetic analysis (diSessa, Sherin, & Levin, 2016) to produce a temporal decomposition of Max's trajectory of thinking with respect to disease prevention and protection strategies. First, we reviewed the recording of Max using the modeling microworld to build models of two different disease prevention strategies. We noted times during which he built, tested, debugged, and made sense of his models. These episodes were marked on the transcript, which was then analyzed to understand his process of knowledge refinement. This process included four steps: 1) building an initial model and predicting its results, 2) testing the initial model and making sense of its results, 3) debugging and retesting the model, and 4) observing the final model and explaining its results. We then tracked the shifts in Max's ideas over the course of these steps in order to understand how engagement in computational modeling helped Max refine his thinking.

Findings

We present an episode from Max's interview to illustrate how he refined his thinking as he refined his models. In the beginning, Max thought the best strategy for preventing a pandemic was for everyone to stay at home. By the end of the interview, in contrast, he had developed a sense that strict quarantine may not be more effective than allowing healthy people to move around with protection (such as masks), while sick people stayed at home most of the time. In this way, he may have developed his thinking and arrived at a more nuanced understanding of disease prevention.

The interviewer wanted to focus Max on two tasks toward the end of the interview and asked: "Could you arrange the blocks or modify the parameters of the blocks to create two situations? The first situation is the case where everyone stays at home, the second situation is the case where only sick people stay at home, but healthy people are free to move with protection." The steps below describe Max's trajectory through the modeling activity, highlighting his shifts in thinking.

The "Everyone stays at home" model

The interviewer asked Max to build a model of a strict quarantine, in which everyone stayed at home.

Step 1: Building the initial model and predicting its results

Max set up the world with 27 healthy people and 8 sick people. He asked healthy people to move with 82% probability and sick people with 100% probability. He set the probability of infection at 0%, the probability of recovery to 19%, and the probability of death to 17.5%.

> Max: …Basically like this. You can't infect anybody. Mmmm. [Max runs the model] Yeah. Nobody is dying. So basically, if they are quarantined, they can't touch each other, so they can't infect each other. Yeah, all the people would like to recover eventually.

He constructed the model to have a high rate of movement and a 0% chance of infection based on his initial assumptions about how strict quarantine would affect the rules of disease spread. Instead of lowering the rate of movement to represent a strict quarantine in which everyone stayed at home, he reduced the infection rate to zero to create a condition in which "no disease may spread among individuals." Even though this model did not accurately depict people's behavior, it was consistent with his prior belief that "strict quarantine would be the most effective way to safeguard the population." Before he tested his model, he predicted that no one would die. His initial thinking was: "Everyone stays at home is the most effective disease prevention strategy."

Step 2: Testing the initial model and making sense of the results

Max ran his model and watched five people die. He said he was surprised by the outcome of the model run. This reaction was evidence that he built this model with the expectation that a strict quarantine would be the most effective disease prevention strategy. He tried to understand what was happening at the agent level that would have caused the aggregate-level outcome, in particular, why five people died even when the infection probability was 0%.

Step 3: Debugging and retesting the model

In response to the interviewer's prompt, Max started debugging the model.

> Max: Hmmm. Oh, yeah, move! Move rate should be 0%. [Max decreased the probability of moving to 0]. I will try to increase this [Max increased the infection probability to 49.8%, then recompiled the code and tested the model].

Max decreased the probability of movement from 100% to 0% and increased the probability of infection from 0% to 45%. These two moves indicate that he debugged his thinking regarding how to use the blocks to represent a strict quarantine and the probability that a disease would actually transmit. His updated model represents a more normative way of modeling a strict quarantine, by more accurately representing the rules governing individual agents and their interactions.

Step 4: Observing and explaining the results

Max tested the effect of his modified parameter and watched as 6 sick people died, even though no one moved in this model. Max appeared to be surprised by this result, saying, "Oh no, more people died." This is evidence that the outcome of the model-run did not match his expectations. It suggests that he expected this modified model to work out differently, producing a result where fewer people died. It is interesting to note that Max did not continue to debug his model and find the cause of the unexpected deaths, which was the 17.5% chance of dying faced by every sick individual, each tick of the clock.

The "Sick people stay at home" model

Next, the interviewer asked Max to model a situation where only sick people were required to stay at home, while healthy people were allowed to move around the world freely, wearing protection such as masks. Max indicated

that he expected this approach to lead to more sick people and deaths ("So basically, healthy people can move 100% of the time so that more people would die"). As in the previous activity, he engaged in steps of model building, testing, debugging, and explaining his observations. He left most of the model from the previous activity intact, changing only the probability of movement for healthy people (increasing it from 0% to 100%). When he ran the model, four people died. He was surprised by this result, as he expected more people to be infected and die. When asked if he thought there were any issues with the parameters left over from his previous model (probability of infection, recovery, and death) he replied, "I don't think so."

His final thinking on the effectiveness of the two disease prevention strategies was "I am not sure now. I mean, the outcomes of healthy people moving around and staying at home is a tie." This is evidence that engaging in the modeling activity played a role in shifting his thinking about the relationship between agent-level interactions and aggregate-level outcomes. While at the start of the activity, Max expressed certainty in his assertion that strict quarantine would be the most effective prevention strategy, after modeling the two approaches, he felt less certain, hinting that there may be more to consider given the two approaches produced similar results. Though this is a small shift in thinking, it is still a shift, and it is possible that further exploration of the model would lead to more debugging of the model, and in turn, refinement of thinking.

Discussion

This study investigated how a middle school student refined his thinking about disease prevention strategies using an agent-based computational microworld. Findings suggest that computational modeling can help students refine their thinking through building models and predicting results, testing models and making sense of the results, debugging and retesting the models, observing models, and explaining results. Our findings offer insight into how adolescents can learn about disease prevention through computational modeling. A high-level goal of our work is to develop microworlds in which students build models using a language they understand. Analyses show that our representations work as expected. Though somewhat abstract, Max was able to build and refine his model based on ideas drawn from his everyday experiences of the phenomenon he was trying to model.

Evaluating a Framework for Learning Non-routine Problem-Solving in Mathematics

Huy Anh Nguyen, Yuqing Guo, Vy Nguyen, Carnegie Mellon University

Abstract: An important goal of mathematics education is supporting students' ability to tackle novel, non-routine problems. However, typical mathematics instruction in U.S. classrooms often places emphasis on rote learning, without exposing students to the process of deriving a formula or alternative solutions. We propose a framework, *Try-See-Tell-Do*, which combines several evidence-based learning strategies to help students develop non-routine problem-solving skills. Following the framework, a student would first *try* a non-routine problem on their own, *see* a worked example solution to the problem, self-explain (*tell*) the solution they saw, and finally practice with two novel non-routine problems (*do*). Through a series of eight think-aloud interviews, where high school students applied the framework to solve combinatorics problems, we found that students could recognize the instructional value of the learning activities. Additionally, we noted students' tendency to rely on memorized formulas and derived actionable insights on improving the framework to reduce this behavior.

Introduction

The ability to solve non-routine problems plays an increasingly important role in modern workplaces (Neubert et al., 2015), where well-defined routines are insufficient. However, in U.S. classrooms, non-routine problems are often viewed as targeting only high-performing students, and even with these students, there is a lack of empirical evidence for which instructional strategy, or combination of strategies, is most effective (Gavaz et al., 2021). Towards addressing this gap, we propose and evaluate an instructional framework, *Try-See-Tell-Do*, intended to develop non-routine problem solving skills by combining several evidence-based learning science techniques: solving a problem on one's own (*try*), seeing a worked example of this same problem (*see*), self-explaining a solution to the problem (*tell*), and finally practicing with related problems (*do*). These activities are based on well-established benefits of attempting to invent a solution to a new problem before receiving instruction on it (Schwartz & Martin, 2004), worked examples as a means of scaffolding (Paas et al., 2003), and self-explanation as a trigger of generative processing that supports deep learning (Chi et al., 1989).

While each component of the proposed framework has strong conceptual and empirical support, these learning science principles have rarely been applied to non-routine problems or in tandem. Thus, our goal in this research is to evaluate the effectiveness of the *Try-See-Tell-Do* framework as a whole. To this end, we formulated the conceptual strategies that students were expected to learn and designed learning activities based on these strategies and the framework pipeline. Then, we conducted think-aloud interview studies to record students' performance and feedback as they tried out the framework. In what follows, we describe each phase of *Try-See-Tell-Do* in greater detail and formulate the primary take-aways from our qualitative analyses.

Conceptualizing how students learn non-routine problem solving

In preparation for developing the *Try-See-Tell-Do* framework, we solved 70 non-routine mathematics problems from the textbook by Johnson & Herr (2011) and consolidated the techniques introduced in the textbook into eight strategies. Four strategies are for "preprocessing," used to create a mental representation of the problem: *Use Smaller Number*, *Specify*, *List Requirements* and *Identify Target Quantities*. Four strategies are "solving" strategies, used to come up with a solution: *List Number Sequence, Solve Smaller Subproblem, Solve Complementary Problem, Create Equations*. For example, the non-routine problem of finding the last digit in the number 2^{57} can be solved with the preprocessing strategy *Use Smaller Number,* followed by the solving strategy *List Number Sequence*. Specifically, one could list the final digits of smaller exponents of $2 – 2^1$ ends in 2, 2^2 ends in 4, 2^3 ends in 8, 2^4 ends in 6, 2^5 ends in 2 – to identify the recurring pattern 2, 4, 8, 6. Such a pattern in turn implies that 2^{57} should end in 2, without needing to directly compute this number.

In a practical setting, students would have the opportunity to experiment with different combinations of preprocessing steps and solving strategies to construct a solution. In the scope of this work, however, we wanted to first evaluate whether the framework pipeline is effective. Therefore, we only had students work with one preprocessing step, *Use Smaller Number*, and one solving strategy, *List Number Sequence*, in our study. We

 © ISLS

selected three problems from Johnson and Herr (2011)'s textbook that have distinct contexts and involve different number sequences, but can all be solved with this combination of preprocessing and solving strategies:

- **Q1**: You and your friends are organizing a tournament, where each person will play one match against each other. There are five players in total - A, B, C, D, E. How many matches will be played in total?
- **Q2**: Alexis, Bart, Chuck, Jerry, Timmy, Kim, and Dariah are all called in to a radio show to get free tickets to a concert. How many possible orders in which their calls could have been received are there?
- **Q3**: In a movie theater, there are ten rows of seats. The first row contains one seat, the second three seats, the third five seats, the fourth seven seats, and so on. How many seats are there in total?

One of the three problems (Q1) was assigned to the *Try, See,* and *Tell* stages, where students could make an attempt at solving (*Try*) before seeing the worked example (*See*) and explaining a solution (*Tell*). The remaining problems (Q2, Q3) played the role of near- and far-transfer practice problems in the *Do* stage, after students had learned from Q1's solution. We selected high school students as our interview participants since they may have had some, but probably limited, experience with combinatorics, which is typically covered in the first year of undergraduate study in the U.S. In this way, the participants were not expected to have prior formal exposure to the problems and would consider them as non-routine.

Methods

We recruited eight high school students (6 males, 2 females, aged 15-18) in the U.S. to participate in our online think-aloud interviews. Participation was completely voluntary and participants were compensated $25 after the interview. First, participants were asked about their math background, including their grade level, classes taken, and general experience with math. Then they were instructed on how the think-aloud process would be conducted, along with a think-aloud demo on a simple math problem, carried out by the interviewer. The interviews each proceeded based on the four stages of our instructional framework. In the *Try* stage, participants were asked to solve a non-routine problem (Q1) on their own. They then went to the *See* stage and saw a worked example solution to the same problem, Q1. To promote interactive learning, we presented each step as a multiple-choice question on a web interface (1). After answering each question, participants would see a feedback message about their correctness. Participants concluded the *See* stage by reviewing the entirety of the worked example solution, before moving to the *Tell* stage. Here, they were asked to treat the interviewer as a novice and tell them how to solve Q1, using either the solution they derived in the *Try* stage or the one they saw in the *See* stage. Next, the *Do* stage presented two more problems (Q2 and Q3) for participants to solve on their own to measure near and far transfer. Finally, we asked participants about their thoughts on the overall framework.

With permission from the participants and their parents, we recorded the interview audio along with the participants' draft work in each stage. Then we transcribed and performed a narrative inquiry among three researchers on the audio data, focusing on participants' self-reported math background, their feedback on each stage, and their evaluation of the overall framework. We also investigated whether the first three stages provided sufficient learning support for participants to tackle the near-transfer problem (Q2) and far-transfer problem (Q3) in the final *Do* stage, as well as any notable difficulties that participants encountered throughout the interview. From this point, we denote each participant with an anonymous ID, ranging from P1 to P8.

Analysis and Results

There were five rising sophomores and three rising juniors who took part in the study. Five participants had taken classes up to Algebra 2 and three up to Advanced Placement Calculus. All participants indicated that they enjoyed learning math because they liked to challenge themselves or because they had a positive learning experience.

Try stage

In this stage, participants solved the problem Q1 on their own. Five participants were familiar with the underlying combinatorial formula of the problem and were quick to point out the correct answer, "5 choose 2," which equals to 10. The remaining three did not mention any connection to combinatorics, likely because they were not exposed to this field. Among them, one arrived at the correct answer by listing out all the 10 matches. The other two attempted to visualize the problem by drawing the tournament layout in a graph; however, these participants incorrectly considered "A vs B" and "B vs A" as different matches, leading to an overestimation. When asked about the rationale for their chosen approach, participants either mentioned that they had seen a similar problem or that they felt the visualization and enumeration approach was the most natural.

See stage

In this stage, participants reviewed a worked example of the *List Number Sequence* strategy for Q1, accompanied by seven multiple-choice questions. The first question asked about whether it's better to consider all the participating teams at once, or start with a smaller number of teams. The expected answer is the latter, which reflects the *Use Smaller Number* preprocessing strategy, but seven out of eight participants selected the former, which aligns with their approach in the *Try* stage. P6 noted that both options could lead to the correct answer, so the question text should be clearer about why one option is preferred over another. After this point, all participants picked up on the spirit of the solution and were able to correctly answer subsequent questions. When asked about their preference, five participants preferred their original approach (applying the combinatorial formula), on the grounds that the worked example took longer to carry out than their original solution and may not work for more complicated problems. At the same time, they acknowledged that this bottom-up approach could be helpful to beginner students who have no knowledge of combinatorics – as P4 stated, "*It shouldn't be set as the be-all-end-all thinking process as people obviously process thoughts differently, but it's a great baseline to start off the process if people have no idea how to think of problems like this*." The remaining three participants were more welcoming of the worked example, noting that seeing the explanations helped them better understand the solution; P2 further compared this process to their online learning experience: "*Khan Academy shows the steps but doesn't force you to work through it, so this is more helpful*."

Tell stage

In this stage, participants were asked to teach a novice about solving Q1, using either their original solution in the *Try* stage or the worked example in the *See* stage. Five participants taught with their original solution because they were more comfortable with it (P1, P3) or because they believed it is more effective and generalizable (P6, P7, P8). The remaining three chose to explain the worked example, rather than their original combinatorial approach. When asked about their rationale for switching, P5 indicated that the worked example presented a new approach to them, so they'd like to teach it to understand it better. Likewise, P4 considered seeing the fine-grained worked example a new experience -- "*it shows you a process of how to teach others to think, it's a very streamlined process and very natural, but I wouldn't have thought of it before.*" When reflecting on their experience, all participants indicated that this *Tell* stage is the most helpful in the framework. P5 was very familiar with the combinatorial formula solution; thus, having to explain the solution to a novice forced them to think about why the formula works and delve more into the underlying principles. P2 also made a reference to the inductive process "*starting small, building big in a systematic way,*" which they found particularly useful.

Do stage

The first problem (Q2) in this stage was solved successfully by four out of eight participants (P5, P6, P7, P8). These participants were able to immediately point out the answer, which is 7! = 5040, as the problem context is naturally how permutation is defined. Notably, one participant, P2, realized that the problem is related to a combinatorial formula but could not recall the formula -- "*I just can't remember what I actually did with this problem because we had something like this before as well*." The remaining participants either proposed an incorrect answer (7 x 7 = 49) after some trial-and-error or gave up without a solution. The second *Do* problem (Q3) observed more success, where six participants (P2, P4, P5, P6, P7, P8) arrived at the correct answer but did not start from smaller cases, instead considering the whole problem setting. However, participant P5, after mentioning the general formula, also attempted a second solution that followed the *List Number Sequence* strategy from the *See* stage; P5 was the only participant that did so. The remaining two participants failed because they either made a calculation mistake or could not recall an appropriate formula.

When asked about whether the previous stages (*Try*, *See*, *Tell*) helped with their performance on the *Do* stage, P2 noted that these stages helped orient their thoughts and have a clear direction of what to do. The remaining participants indicated that the previous stages had little effect on them, either because they had already seen all three problems given in the interview (P5, P6, P7, P8), or because they didn't apply the strategy in the *See* stage to solve subsequent problems (P1, P3, P4). However, some participants felt that they could have learned from the previous stages if given more time to digest the problem and solution content: "*now that I'm thinking about it, it helped me just now realize that I could minimize the number*" (P1).

Discussion and Conclusion

This work explores a general framework for training high school students in solving non-routine problems. While the framework did not yield clear learning benefits as measured by performance on the practice problems, it reveals important insights into students' problem-solving behaviors and suggests potential future avenues.

Our first observation is that all participants had a strong tendency to appeal to formulas during their problem solving. When these attempts failed, they would then resort to solving the problem by brute force (i.e.,

list all possible configurations) and would give up if this approach was not fruitful. This behavior occurred most frequently in Q2, where there are too many configurations to manually enumerate. Consistent with our findings, Stigler et al. (2010) has reported that, when facing a novel problem that requires flexibility, U.S. students tend to apply memorized procedures or formulas incorrectly rather than develop new solutions.

To combat this issue, we devised the *Try-See-Tell-Do* framework to highlight a general strategy for discovering a solution to a problem, without relying on rote memorization. We hypothesized that the *See* stage, with its detailed worked example, would clarify the conceptual workflow for students, and that subsequent stages would reinforce this workflow through self-explanation, near-transfer and far-transfer practice. Our interview results showed that participants did find the worked example useful, especially for less experienced students, which is consistent with research showing worked examples are most beneficial for novices (Paas et al., 2003). However, most participants were not able to capture the underlying heuristic and apply them to new problems. On the other hand, the *Tell* stage was positively received by all participants, who indicated that it was a novel and helpful experience. Although students thinking an approach is helpful and actually *showing* it is helpful through actual use are two different outcomes, this finding does at least point to past research that shows self-explanation following a worked example is a powerful and robust mechanism to support learning (Chi et al., 1989). For our next experiment, we plan to improve the *See* stage with an interactive visualization of the worked example, which can be effective at maintaining engagement (Liang & Sedig, 2010), while also highlight the core take-aways. As observed from past studies on problem-solving (Arslan & Yazgan, 2015; Nguyen et al., 2020), the visualization approach aligns well with how students tend to explore the solution space when attempting novel problems

Finally, we remark that our interviews were conducted on a small sample of students who had either solid or excellent backgrounds in mathematics. To promote broader applicability, additional evaluation of the *Try-See-Tell-Do* framework is needed, especially with lower-performing students, for whom the multi-layered instructional support may be more beneficial. Nevertheless, we have uncovered students' reliance on formula application as a central issue in problem solving and identified room for improvement in the implementation of our learning strategies. We envision that, through iterative refinement, the framework can be deployed as a digital learning platform with support for personalized feedback to promote non-routine problem-solving skills at scale.

Responses of rural Chinese teachers to workshops on culturally relevant constructivist pedagogy

Weiying Li, Marcia C. Linn
weiyingli@berkeley.edu, mclinn@berkeley.edu
Graduate School of Education, University of California, Berkeley

Abstract: We analyzed the impact of two workshops that introduce Knowledge Integration and Culturally Relevant Pedagogy to rural Chinese science teachers. The workshops emphasized connecting science lessons to local, culturally-relevant contexts. Teachers developed written lesson plans to localize their instruction and implemented their plans in classrooms. We used inductive coding to identify five levels of localization in the lesson plans. We captured the creative plans that teachers generated in three classroom case studies. The workshops revealed ways to support rural Chinese teachers to connect complex science topics to culturally-relevant local examples and identified areas for improvement.

Introduction

Science education researchers and practitioners have long emphasized constructivist perspectives, including eliciting students' prior knowledge and related experiences to scaffold learning (Vygotsky, 1978; Linn & Eylon, 2011). In 2001, the Ministry of Education (MOE) in China embarked on a series of education reforms to shift from an exam-oriented to a student-centric and constructivist education system (MOE, 2001). Consistent with this shift we studied how teachers in a middle school in central rural China responded to two constructivist workshops. We investigated how teachers planned and enacted their lesson plans.

In China, rural areas include villages where people mainly engage in agricultural activities and rural towns that evolved from villages and function as educational, cultural, and economic centers (National Bureau of Statistics, 2008). Rural areas often preserve more traditional cultural practices, compared to urban areas (Oakes, 2013). Rural teachers in China rarely adopt constructivist teaching (Sang et al., 2009; Zhang & Liu, 2014) because they are socialized into norms of science teaching that reinforce exam results (Wu, 2016). And, teachers lack constructivist teaching professional development compatible with rural contexts (Rao & Ye, 2016).

Rural contexts offer a rich environment for learning science as students make scientific inquiries in family settings, community events, natural surroundings, and the agricultural activities in their lives (Avery & Kassam, 2011). Although social constructivists demonstrate that science is impacted by cultural values (Bingle & Gaskell, 1994), in school science classrooms where western science dominates, local practices and knowledge are seldom acknowledged. Researchers have begun to bridge the gap between local experiences and school science (Bang & Medin, 2010), and place-based education approaches (Bartholomaeus, 2006).

We investigated rural teachers' lesson plans and implementation of localized science learning contexts to answer the following research questions: 1) What kinds of localized learning contexts do rural Chinese teachers create? 2) What are the challenges of building localized contexts into science lessons?

Methods

Workshops and Participants

The two-day workshops were held in January 2021 and June 2021. The first workshop introduced the concepts of constructivist teaching and Knowledge Integration (KI) pedagogy. The KI pedagogy emphasizes that students develop multiple, varied ideas about the same scientific phenomena across their many experiences at school, at home, and when interacting with the natural world. By eliciting students' ideas, providing opportunities for students to discover more ideas, encouraging students to distinguish among these ideas, and asking students to reflect on their ideas, teachers help students develop a coherent account of the phenomena (Linn & Eylon, 2011). The second workshop introduced Culturally Relevant Pedagogy (CRP). By supporting learners to draw on their cultural identities and reflect on social inequalities, teachers can build identity as a science learner (Ladson-Billings, 1995). At the end of the second workshop teachers drew on KI and CRP to write a lesson plan that created a learning context to introduce a new concept to their students.

Participants were 20 science teachers who attended both workshops: 8 physics, 8 chemistry, and 4 biology teachers. All 20 teachers are rural residents who grew up in the area and have taught grade 7, 8, or 9 at the school for 4 to 40 years (M = 22.2 years, SD = 8.58). Three case studies involved teachers who consented to

 © ISLS

classroom observations and interviews. After observing each 45-min class, the first author interviewed the teacher and two to three students, asking, "How do you feel about this class?"

Data sources and analysis

The 20 teachers' written lesson plans, written in Mandarin, were analyzed. The first author used inductive coding (Thomas, 2006) to create categories for the localized contexts. The lesson plans were then translated into English. The case study observations were in Mandarin Chinese and the interviews were in local rural dialect Chinese. They were translated into Mandarin, coded, and translated into English.

Results

Each teacher made a detailed lesson plan and 18 of the 20 teachers included creative and relevant local contexts. Teachers were eager to incorporate local contexts in science teaching. Using inductive coding, 5 levels of localizations emerged in the teacher's written lesson plans (see Table 1).

Table 1

Levels of Localized Context Examples Generated by the Teachers

Score	Levels and Criteria	Examples
1	No context building	● I don't think giving examples is helpful in my classroom. It will weaken my teaching efficiency.
2	Irrelevant: Building contexts that are irrelevant to learning objectives	● I will play some music, videos, or pictures that are relevant to learning content to help students get into the learning status. ● When I teach *infectious diseases*, I will introduce a story about a Pacific Island in our biology history.
3	Partial Link: Teachers build contexts that have one of the characteristics: 1) relevant to learning objectives; 2) familiar to students; 3) shared within community culture; 4) have critique of inequities.	● When I teach *salt metathesis reactions*, I don't want students to just memorize the equation. I often introduce it with changing dancing partners while dancing in a ballroom. [In rural China, ballroom dancing is not common, especially among students.] ● I often use our real life events as my example. While I introduce the concept of solutions, I will ask students to predict the reason why the water in swimming pools is blue. [In rural China, swimming pools are not common]
4	Full Link: Students included **one link** between two characteristics listed above.	● When I teach *buoyancy*, there is a very widely used experiment in the textbook: we will ask students to wear plastic disposable gloves and then put their hands into a water tank. Many teachers will just describe to students about how they might feel, but I will ask students to share their feelings (e.g. the gloves will cling to their hands), and predict the reason. ● When I teach *voltage*, the concept is very difficult to understand. The textbook says that "electric current is the result of electric charges moving in a certain direction", but I think students are often confused by "Why charges move in a certain direction?", then I will show them a video about the formation of stream/water flow, and make analogies among flows, current, water pressure, and voltage.
5	Complex Link: Teachers provided **two links**	● When teaching *levers in simple machines*, I will prepare some really hard pieces of chalk and invite two male students to squash them. I can imagine that they will use all their strength to squash the chalk. After that, I will take my pliers, and ask them to try this tool which will easily squash the chalk. ● When I teach *purify*, I will introduce the concept with our Chinese slang "A speck of mouse dung spoils a whole pot of porridge". ● When I teach *Metamorphosis in amphibians*, I will use the story in our traditional fairytale 'The Tadpoles Look For Their Mommy' and ask students to predict the reason why tadpoles cannot recognize their mom.

 © ISLS

The level of implementation of localization did not depend on the science course taught or years of teaching experience. Two of the three CRP features were detected: creating contexts relevant to learning objectives and creating contexts that are interactive, familiar to students, and shared by the community. The lesson plans did not include critiques.

The teachers of each case study reported that their students became excited and engaged when they realized that they were using local knowledge in science. The cases were scored from Level 3 to Level 5.

Case 1 Combustion and Spring Lantern Festival (Level 5)

Teacher Ku is a chemistry teacher with 20 years of experience who was teaching 48 9th grade students about combustion. Ku showed a photo of the Spring Lantern Festival and asked students to rank the most important part of the lantern to keep it lit without burning. Students discussed in groups for 10 minutes and then shared their predictions. Many students raised their hands. Student A mentioned that the vent at the top of the lantern is important because otherwise the light will go out really fast. Student B shared making lanterns by using a special coating inside the paper to concentrate the heat to the center and reduce the chances of the paper burning. Student C's group believed that the material of the candle wick is crucial. After the whole class shared, Ku played a video introducing the functions of different parts in a lantern and asked students to revise their thinking based on the video. During the interview, Ku reported the lesson was a success because "everyone was participating and they also analyzed the combustion conditions by themselves". Student C was surprised that the creative lantern designs aligned with science ideas and described feeling like a "practitioner scientist". Student D didn't speak to the whole class, but drew on prior knowledge during group discussion, saying, "They are discussing the purpose of the vent. Some say it's left for our hand to light the candle, but I remembered that I covered the vent one time because I didn't want the wind to blow it off, but the fire went out immediately. I shared the story with them, and we started to talk about how this vent can be useful."

Teacher Ku's lesson followed the localized KI pattern: eliciting students' prior knowledge; helping students discover new ideas by comparing their experiences and by watching the video. Students spontaneously engaged in distinguishing ideas by comparing their first-hand experiences. Teacher Ku added a distinguishing activity where students ranked the elements of the lantern that controlled combustion. Students then reflected by reconsidering their rankings and explaining their reasoning.

Case 2 Phase Change and Laundry (Level 5)

Teacher Zeng, a physics teacher with 10 years' experience, was teaching 49 8th grade students about phase change. Teacher Zeng introduced the topic by lecturing about the heat transfer process and the changes of states for 20 minutes. Then Zeng showed a picture of laundry hanging in the rural courtyard in the summer (dryers are not common in rural areas) and asked students to predict the phase changes. Several students quickly answered loudly "evaporate!". Then Zeng discovered new ideas by asking if they ever used special methods to make the clothes dry faster. After 10 seconds, Student E said, "Yes, they usually dry faster on sunny days than on cloudy days." Zeng distinguished ideas by asking, "Based on what you've learned so far, can you predict the reasons why they dry faster on sunny days?" Student E then said, "Because of sunlight." Student F said, "Because it's warmer when the sun comes out." Zeng then asked, "What has this to do with the phase change?" Student E answered, "They need heat when they evaporate. The warm sunlight hastens this process." Zeng nodded his head and then asked for more answers. Student G raised hand and said, "They will dry faster if hung in the open courtyard than in the balcony, than indoors." Teacher asked for her reasoning. She said, "Because there is more wind in the open spaces. They can take away moisture." Student H said, "Expand the clothes instead of squeezing them together." Zeng tried to help her reflect on ideas and predict the reasons why her way is faster. Student H said with hesitation, "Maybe because I expose more moisture?" Teacher Zeng agreed with her and added more details, "you increase the surface contacting air, so the water can evaporate faster."

Teacher Zeng implemented the KI pattern while drawing on the students' local knowledge. During the interview, Zeng reported that students were engaged, especially the female students, remarking that in rural families, laundry is always the "women's business." Student G reported already knowing about phase change and learning the names of the phases and the mechanism of heat transfer. Student H reported that laundry methods that seemed like tricks, actually followed real science. Teacher Zeng selected relevant local experiences and was able to recognize female students for their scientific observations.

Case 3 Force and Pressure and Walking/Skiing in Snow (Level 3)

Teacher Zhang, a physics teacher with 28 years of experience, was teaching 46 8th grade students about "force and pressure." Zhang asked students to think about the differences between walking in the snow and walking in the snow with skis. When asked to share ideas, no student raised their hand. Teacher Zhang showed a picture of

a kid skiing and one kid walking in snow. He asked for observations. After 5 minutes there were no hands raised so the lecture continued. During the interview, Zhang said that the example achieved some level of success because students had time to think about the real-life example. However, Student I showed a slight disagreement: "I don't understand why the boy uses skis. How could he move?" Student J was also confused by the details in the picture, "I saw that the ski in the TV is a very large single board, why does this boy use two separate narrow boards? Does this have any difference with the single board?"

Although Teacher Zhang incorporated an example, since the school is located in central-southern China, few rural students have used skis. Students might have seen skiers on TV or the Internet but they didn't have first-hand experiences and were not able to take advantage of the example.

Conclusion and Discussion

These results illustrate the effectiveness of two workshops using KI and CRP to support rural teachers to localize their science instruction. In spite of years of experience with teacher-centered, western science dominated, exam-oriented instruction, many teachers were able to identify relevant local cultural practices and empower students to connect them to scientific phenomena. Some teachers selected textbook examples that were not familiar to their students and gained insight into the limitations of this approach. A few interpreted their students inability to interpret the examples as a weakness or underestimated the ability of their students to come up with examples. The workshops can be improved by increasing opportunities for teachers to collaboratively connect science to local examples. By enabling teachers to report on the successes in the case studies, teachers can enable others to recognize the strengths of rural students.

Detecting Cherry-Picked Evidence in Texts: Challenges for Undergraduate Students

Abstract: Authors of digital documents often seek to mislead readers by presenting *cherry-picked evidence*—e.g., a single study supporting a claim when most studies support a different claim. We report results of two experiments to examine whether undergraduate students adjust their epistemic judgments to account for cherry-picked evidence when they read multiple texts with conflicting claims. In Study 1, students adjusted their epistemic judgments when cherry picking was explicitly indicated with warnings called out in texts. In Study 2, however, with a different topic and four conditions that manipulated different degrees to which cherry picking of evidence was explicit, students did not adjust their epistemic judgments, even when evidence was blatantly cherry picked. In addition, very few students mentioned cherry picked evidence in explaining the grounds for their judgments, even when cherry picking was explicit but without such warnings in Study 1. These suggest that most students attend little to whether evidence is cherry picked, except the condition in which authors call out warnings of cherry-picking in texts.

Introduction

Citizens must often weigh information from multiple sources of information to make judgments on issues such as which medicine they should take for a health condition; much of the available information is unvetted and inaccurate. One way to attempt to determine which information to believe is to scrutinize the evidence presented for claims (Duncan et al., 2018). However, sources may intentionally or inadvertently mislead readers who seek to scrutinize evidence by presenting cherry-picked evidence; that is, they may selectively choose one or two studies that support a position, although the majority of studies support a different position. Accordingly, people need to develop their reasoning skills to judge whether evidence has been cherry picked and to reduce reliance on cherry-picked evidence. They should instead seek out information about what the larger bodies of evidence support. This is an important competence that can improve success in reasoning about conflicting evidence encountered online. However, researchers have not yet systematically investigated people's competence in recognizing cherry-picked evidence and in adjusting their beliefs in line with whether evidence has been cherry picked. In this paper, we report the results of two studies that investigate these competences.

Texts presenting cherry-picked evidence are pervasive in social media, and laypeople need to be able to recognize when it occurs and to adjust their conclusions accordingly (Levitan, 2017). However, sources who cherry pick evidence rarely make this clear: They may not realize it themselves, or they may conceal the fact that they have cherry picked the evidence that they present. Still, there may be signs that the evidence has been cherry picked. Authors may hint that they searched for evidence before finding any supporting evidence. Authors may betray cherry picking by not referring to what any larger body of evidence demonstrates, or by not giving any reason for choosing the evidence that they have highlighted. Further, authors of other sources of information may point out that an author has cherry picked evidence. They may also explicitly point out what positions are supported by larger bodies of evidence, highlighting possible cherry picking by those who tout unrepresentative studies. To detect such nuances in texts, readers need to be attentive to trying to find out what larger bodies of evidence say, not just what one or two studies say (Duncan et al., 2018). The purpose of the experiments reported in this paper is to explore whether undergraduates are attentive to these issues, and particularly if they are attentive to cherry-picked evidence when forming beliefs on scientific and social scientific issues.

Study 1. Comparison between Implicit and Explicit Signs of Cherry Picking

We conducted the first experiment to examine whether undergraduate students adjust two kinds of epistemic judgments in response to cherry-picked evidence: (1) beliefs about the claim that the cherry-picked evidence supports and (2) beliefs about the trustworthiness of the source that presents cherry-picked evidence. There were two conditions that manipulated how explicit the indicators of cherry-picked evidence were.

 © ISLS

We developed two documents that presented competing claims on the relationships of rewards, motivation, and performance in social science. Document 1, said to be written by a business journalist, presented evidence from a study that supported a pro-reward claim that "rewards increase workers' productivity" (pro-reward position) based on a lab study where 36 groups of business people in two conditions worked on personnel selection tasks with or without monetary rewards. The study supported the use of rewards to increase productivity. Document 2, said to be written by an author of five bestselling books on motivation research, presented an opposing claim that "rewards decrease workers' productivity" (anti-reward position) based on a field study with 87 participants working on 9 varied tasks and a relatively large reward worth several months' wages. The study's conclusion was that the higher monetary rewards led to worse performance in most tasks, except for very simple tasks that did not require much cognitive attention. These documents were based on actual positions taken by researchers and authors on this topic (e.g., Document 2 was based on the work of Pink, 2011).

Method

The design was experimental, with two conditions (**implicit** versus **explicit** expressions of cherry picking) that varied according to the content of the two documents. In the ***implicit*** cherry-picking condition, Document 1 explained the author's position, mentioning that "monetary rewards tell people that they are valued, and that their work is valued," and then introduced the study described above as evidence, after writing, "Here is *a study* that supports this view." The document then concluded, "It is well known rewards are a main motivator of human behavior…...This is *one study* that shows the efficacy of this approach." (All italics in excerpts from documents have been added to this report for emphasis to highlight differences.) Document 2 first explained the author's position, reporting that "*nearly all psychological studies* have shown that monetary rewards and prizes decrease motivation and performance." Then the document introduced the evidence of the study described above after pointing out a problem in other studies that had been conducted because of the relatively small rewards in those studies. In the ***explicit*** cherry-picking condition, Document 1 added one statement to the document that asserted that the author had searched through many studies until finding one study that supported their claim, thus straightforwardly acknowledging cherry picking. Likewise, another statement was added to Document 2 in which the author warns that if readers find documents that supports a pro-reward position, those documents ignore the large majority of studies that support an anti-reward position. Thus, two corresponding documents presented the same evidence in both conditions, but only the explicit condition contained explicit descriptions of cherry picking and warnings about cherry picking. In both conditions, Document 1 said nothing about the broader body of evidence, and Document 2 asserted that most studies support the anti-reward position.

Participants were 151 undergraduate students in an introductory education course at a public university in Japan; 41 were excluded due to technical problems with the online system, leaving 110 participants. Participants were randomly assigned to conditions. All participants first answered a pre-survey in which they rated (a) the degree of their agreement with the pro-reward or anti-reward positions on 7-point Likert scales (1 = strongly disagree and 7 = strongly agree) (*pre-position*). Next they read versions of the two documents that corresponded to their assigned condition. After this, on a post survey using the same Likert scales, they rated (a) their degree of agreement with the pro-reward and anti-reward positions (*post-position*), (b) the trustworthiness of each of the two documents (*post-trustworthiness*), and (c) the strength of evidence that the pro-reward and anti-reward claims were based on (*post-strength*). In addition, they were asked to report their judgment of the relative amount of evidence supporting the two positions (ranging from 1, indicating that all the studies support the anti-reward position, to 7, indicating that all the studies support the pro-reward position) (*post-amount*). Each pair of responses (on the pro- and anti-reward positions for pre-and post-position, post-trustworthiness, and post-strength) was merged into one variable by subtracting the anti-reward rating from the pro-reward rating, so that a larger value indicated a preference for the pro-reward position, document, and evidence.

Results

The results are summarized in Table 1. There was no significant difference in pre-position between the conditions (F (1,108) = 0.19, η^2 = 0.02), with both groups tending to favor the pro-rewards position equivalently. On the post surveys, the means for each variable were significantly different (post-position: F (1, 108) = 7.30, η^2 = 0.06; post-trustworthiness: F (1,108) = 6.33, η^2 = 0.06; post-strength: F (1,108) = 7.54, η^2 = 0.07; and post-amount: F (1,108) = 5.98, η^2 = 0.05). Participants in the explicit condition provided, on average, significantly lower scores on post-position, post-trustworthiness, post-strength, and post-amount for the pro-reward position. That is, the ***explicit*** markers indicating that the pro-rewards author was cherry picking evidence caused participants to lower their relative preference for the pro-reward position. Explicit markers of cherry picking to support the pro-reward position also led the participants to lower their relative trust in the pro-reward source's trustworthiness and to lower relative ratings of strength for the pro-reward source's evidence.

Table 1
Descriptive and ANOVA Statistics for Study 1

Variables	Implicit (n = 62)		Explicit (n = 48)		F (1, 108)	η^2
	M	*SD*	*M*	*SD*		
Pre-position	3.15	2.22	2.96	2.29	0.19 *n.s.*	0.02
Post-position	1.42	2.46	0.17	2.35	7.30 **	0.06
Post-trustworthiness	–0.26	2.18	–1.27	1.98	6.33 *	0.06
Post-strength	0.68	2.09	–0.50	2.41	7.54 **	0.07
Post-amount	4.34	0.75	3.94	0.98	5.98 *	0.05

* $p < .05$, ** $p < .01$

Study 2. Comparison among Different Signs of Cherry Picking

In Study 1, undergraduate students adjusted their epistemic judgments appropriately when (a) the evidence was explicitly cherry picked and (b) the cherry picking was called out by an opponent. Given this finding, we conducted the second experiment to examine how students responded to differing degrees to which the cherry picking was explicit or implicit.

Method

Two fictional documents were developed that presented opposing claims on the effectiveness of a nutritional supplement called Serenade. Document 1 was said to be written by a doctor who had reported research on nutrition problems for 22 years. It argued for the positive effects of Serenade on health and presented as evidence a recent study showing that Serenade had a positive effect on health (pro-Serenade position). In contrast, Document 2, written by a different doctor who had researched on health promotion by health foods for 21 years, presented an opposing claim with different evidence from another recent study that supported the conclusion that Serenade has a harmful effect on health (anti-Serenade position).

There were four experimental conditions, determined by variations in the content in these two documents. In the first condition (***none—no indication of cherry picking***), the two documents were presented as described above. Specifically, both authors reported "a recent study" as evidence. In the second condition (***hint***), the pro-Serenade Document 1 stated, "After some searching of typical recent research reports, I found a study that I would like to share with you." This statement provided a hint of cherry picking, whereas Document 2 just mentioned that the study presented as evidence was "one typical recent study." In the third condition (***explicit***), Document 1 stated, "There have been many typical recent studies done on the health effects of Serenade. I have looked at many of these studies and in my search, I found one that supports its positive effects, which I would like to share with you." This provided a blatant statement of cherry picking. Document 2 was the same as in the ***hint*** condition. In the last condition (***super explicit***), Document 1 included the same blatant statements as in the ***explicit*** condition, but also included as background information emphasizing that the author of Document 1 had searched many recent studies that supported his belief that Serenade has positive health benefits, and finally found one that supports his claim out of many studies that did not but that he did not report. Document 2 was the same as in the ***hint*** and ***explicit*** conditions, except that one statement was added as background information that the author of Document 2 had written the article after reviewing a variety of recent studies.
