18 A challenge instructors face is developing and accurately assessing technical communication skills to ensure students can
19 apply and transfer the skills from the academic context into the context of engineering practice. By intentionally balancing
20 teaching transferrable communication skills relevant to engineering practice and evaluating student understanding,
21 engineering educators can foster competence and prepare students for the expectations of their professional careers. This
22 study addresses two questions: (1) how can chemical engineering instructors reliably and consistently assess student
23 communication skills, and (2) are instructor expectations aligned with those of practicing engineers? The use of well-
24 designed rubrics is important for setting clear expectations for students, providing constructive feedback, and in team
25 taught courses, grading consistently. This study discusses how a rubric for assessing technical communication skills in
26 senior-level chemical engineering laboratory reports was validated and demonstrated reliability across five chemical
27 engineering instructors. Additionally, five industry partners evaluated student reports for comparison to instructor rubric
28 scores. Expectations and perceptions of the quality of student work align between instructors and practicing engineers, but
29 practicing engineers prioritized safety and abstract clarity, while instructors prioritized the students' abilities to interpret
30 results and draw conclusions.

31 **Keywords:** lab reports; industry; rubrics; chemical engineering; multi-instructor
32

35 1. Introduction

36 Professional skills such as communication are
37 highly valued within the engineering profession [1,
38 2], as reflected by the key chemical engineering
39 ABET outcome for engineering graduates of “an
40 ability to communicate effectively with a range of
41 audiences” [3]. Surveys indicate that practicing
42 engineers spend a large portion of their time engag-
43 ing in technical communication [4] and that tech-
44 nical communication training has been shown to
45 correlate with increased success in the workforce
46 [5]. Despite this, feedback from industry partners
47 speaks to a lack of technical communication skills
48 in engineering graduates entering the engineering
49 profession [4, 5]. Engineering educators have long
50 endeavored to effectively incorporate technical
51 communication instruction and assessment into
52 engineering curriculums [6, 7], with the goal to
53 build skills in engineering students that are trans-
54 ferable into their work. As research has shown,
55 engineering communication is situated and rhetor-
56 ical [2]. This presents a challenge for educators
57

35 who are teaching within an academic context while
36 simultaneously preparing students for an engineer-
37 ing practice where expectations may differ [4].

38 To address this challenge, the use of well-
39 designed rubrics has been shown to help instructors
40 effectively assess technical communication skills [8]
41 and to serve as useful resources for students by
42 making expectations explicit, which may result in
43 improved performance [9] and possibly lower stu-
44 dent anxiety [10, 11]. In addition, rubrics may be
45 used as diagnostic tools, helping to identify gaps in
46 student knowledge and as vehicles for effective
47 feedback [12]. Previous literature has presented
48 rubrics for scoring undergraduate engineering
49 work based on group presentations [13], design
50 projects [11], and soft skills in general [14]. All of
51 those rubrics have constructs based on communica-
52 tion with the goal of fairly assessing student work
53 and providing students with a roadmap to success.
54 While undeniably useful, rubrics do have limita-
55 tions. Rubrics attempt to assign numerical values to
56 perspectives on writing quality that are inherently
57 subjective, meaning that varying interpretations of

1 criteria could occur by different instructors [8, 15].
2 In engineering courses, technical skills are likely
3 being assessed in parallel with communication
4 skills, making design of the rubric criteria poten-
5 tially more complicated [12, 16]. Careful consider-
6 tion is necessary to minimize inconsistency of
7 scoring, to accurately assess communication skills
8 and align rubrics with the standards of engineering
9 practice.

10 In the present study, a rubric was developed to
11 assess technical communication skills demon-
12 strated in a technical report written for a senior
13 level chemical engineering laboratory course. The
14 rubric was then validated for reliability among
15 course instructors using a two-way mixed, consis-
16 tency, average-measures intraclass correlation
17 (ICC). In addition, practicing engineers from indus-
18 try were tasked to score sample student work.
19 Scores were compared between instructors and
20 practicing engineers to evaluate whether expecta-
21 tions and perceptions of the quality of the student
22 work were consistent.

2. Methods

2.1 Experimental Course

27 In the chemical engineering curriculum at Montana
28 State University, students are required to complete
29 ECHM 442: Unit Operations Senior Laboratory I
30 and ECHM 443: Unit Operations Senior Labora-
31 tory II. The objectives of these senior-level labora-
32 tory courses are to provide students with hands-on
33 experience with unit operations commonly found in
34 industry, to develop their communication skills and
35 require them to work collaboratively in teams. The
36 curriculum does not include a technical writing
37 requirement, and therefore, oral and written com-
38 munication training occurs primarily through these
39 courses, along with capstone design. Both courses
40 are team taught, with one lead instructor who
41 coordinates the course, gives lectures, grades any
42 homework and supervises one of six experiments.
43 The other instructors each supervise one of the
44 other six experiments and complete all the grading
45 for students performing that experiment.

46 In the semester prior to taking ECHM 443,
47 students learn about technical writing and the
48 structure and format of the required writing assign-
49 ments as well as review statistics through a series of
50 10 lectures in the ECHM 442 course. The students
51 also complete two well-defined laboratory experi-
52 ments in groups of 3–5. Then, ECHM 443 course
53 builds upon the foundation of ECHM 442, provid-
54 ing further technical communication instruction
55 and practice. The experiments in the ECHM 443
56 course are also less well-defined, providing more
57 opportunity for experimental design and agency in

1 analysis. The course consists of three 50 min lec-
2 tures that cover course format, schedule and struc-
3 ture, give instruction for peer feedback and provide
4 instructor feedback on technical reports. Students,
5 in groups of 3–5, perform two lab experiments
6 related to fundamental chemical engineering unit
7 operations. The available experiments include heat
8 exchangers, a continuous stirred tank reactor
9 (CSTR), an enzyme kinetics experiment, and a
10 friction and fluid flow experiment. Each student
11 group is assigned two of the experiment types to
12 complete and performs the two experiment rota-
13 tions on a 5-week schedule. Over the course of the 5
14 weeks, the group prepares a written experimental
15 plan, orally presents the plan to their instructor for
16 approval and performs the experiment. Then the
17 students, individually analyze the data and write a
18 technical report or executive memo. Students also
19 provide peer feedback on rough drafts of the
20 reports. Assignments for the course include two
21 group experimental plans, two group oral presenta-
22 tions of the experimental plan, two individual
23 technical reports, one individual executive memo
24 and two instances of peer feedback.

2.2 Instructor Grading

25 Five chemical engineering instructors of the ECHM
26 442 and ECHM 443 senior-level chemical engineer-
27 ing courses were provided with four samples of
28 student work, technical reports on the topic of
29 heat exchangers. The samples of student work
30 were randomly selected from the Spring 2019
31 ECHM 443 course. Work was selected from the
32 Spring 2019 semester to remove any association by
33 instructors to current students. This semester was
34 also chosen as it occurred prior to the COVID-19
35 shutdown, which altered the structure of the
36 courses. The technical report was approximately 8
37 pages long and is expected to include: a cover page,
38 abstract, introduction/background/theory, objec-
39 tives, methods, results and discussion, conclusions
40 and recommendations, and appendices. Instructors
41 were asked to score the reports using the ECHM
42 443 technical report rubric, which was developed in
43 collaboration with the university's Writing Center
44 [17]. The rubric had a maximum total score of 30
45 points and consisted of six constructs with point
46 values ranging from 1-to-4 or 1-to-7 (partial rubric
47 shown in Table 1). In addition, to help students
48 better understand the point values, point values
49 correspond to traditional letter grades, "A", "B",
50 "C", "D" and "F" level work such as for a 1–4 scale
51 the point values are 4 for "A" work, 3.5 for "B"
52 work, 3 for "C" work, 2.5 for "D" work and 0 for
53 "F" work. For each level, a detailed description of
54 what was required to obtain the corresponding
55 grade was explicitly included on the rubric.

1 **Table 1.** Technical report rubric constructs, maximum point value of each construct and explicit detailed description of “A” level work
2

3	Construct	Max Point 4 Value	Description for “A” work
5	1 Context and Purpose	4	Demonstrates a thorough understanding of who you’re writing for and what you’re trying to accomplish with the report. All information is relevant for the context of the report and connected to the overall objective.
6	2 Technical Content and Analysis	7	Uses appropriate, accurate and relevant content to demonstrate clear understanding of the objective as related to engineering concepts, experimental methods and results. Clearly demonstrates ability to interpret results and draw conclusions.
7	3 Organization and Formatting	4	The technical report follows the organizational structure taught. It includes all required components/sections and each component is complete and formatted correctly, including proper citation. Under the 8 page (not including references and appendices) limit.
8	4 Figures, Tables and Schematics	4	All schematics, tables, and figures are correctly formatted, labeled, cited, and contain accurate and meaningful information.
9	5 Precise and Concise Technical Writing	7	The technical content is communicated clearly and succinctly with short and simple sentences. Precise and accurate technical language is readily understood by the intended audience. Sentences flow smoothly, are structurally correct and convey the intended meaning without wordiness so that the reader understands what was done.
10	6 Language Execution	4	Skillfully communicates using correct grammar and spelling with little to no distracting errors that interfere with reader understanding.

22

2.3 Instructor Inter-Rater Reliability (IRR)

23 Inter-rater reliability (IRR) was assessed using a
24 two-way mixed, consistency, average-measures
25 intraclass correlation (ICC) for each of the six
26 constructs on which students were rated. The ICC
27 is a descriptive statistic used to assess the level of
28 consistency in ratings from two or more raters on
29 the same construct across participants. The ICC
30 works well with multiple raters who have used
31 ordinal data for their ratings. The ICC can range
32 from 0, random agreement, to +1.0, perfect agree-
33 ment, with higher ratings indicating higher consis-
34 tency among raters. For example, a rating of 0.80
35 would indicate that 80% of the variance among
36 raters was due to true consistency among raters,
37 and 20% was due to unexplained error.

38

2.4 Industry Grading

39 Industry participants were recruited to evaluate
40 whether instructor expectations aligned with those
41 of practicing engineers. The authors reached out to
42 members of their departmental advisory board and
43 five agreed to participate in the study. Participants
44 were chemical engineers at various stages in their
45 career and working in sectors ranging from energy
46 (WBI Energy) to oil and gas (Cenex, Conoco
47 Phillips), semiconductors (Micron) and materials
48 science (3M Corp.). One participant was recently
49 retired, three were senior level managers and two
50 were process engineers. The five industry partici-
51 pants were provided four technical reports, three of
52 which were the same as the instructors and one
53 alternative report. The replacement of one report
54 was made due to the high level of complexity in the
55 instructor-graded report and therefore, was

56 replaced with a more typical report. While the
57 replaced report was not graded as part of the
58 instructor validation, it was graded by five chemical
59 engineering instructors at a later date. A document
60 was also provided that described the course context,
61 assignment context, objective of the technical
62 report, and a brief refresher on heat transfer
63 theory, which was the topic of the reports. The
64 following feedback guidelines were also provided
65 that were adapted from Sheffield et al. [16]:

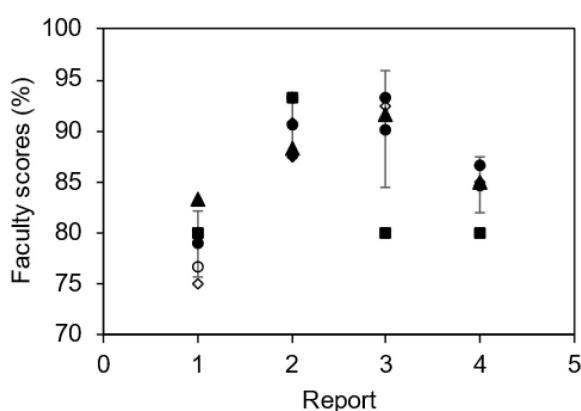

- 66 • (High A work) Work earning this score is ready
67 to be passed on to a real client. In every way, it
68 meets audience needs. Major points are clear and
69 well supported with evidence; technical content is
70 correct. Document is formatted and organized to
71 guide to major points. Clear and interesting
72 visuals and prose contribute to professional-
73 level quality.
- 74 • (A/A-) Work earning this score is strong and all
75 technical content is correct. If I were your super-
76 visor on an internship, I’d suggest minor changes
77 before sending it on to a real client. Those
78 changes might include slight changes to prose,
79 visuals, or formatting to increase clarity and
80 readability. The suggestions are truly minor,
81 and if the document were sent on without the
82 requested changes, I wouldn’t be too concerned.
83 None of the errors are so large that they would
84 affect our company’s or your relationship with
85 the client.
- 86 • (B+/B) Work earning this score is good. If I were
87 your supervisor on an internship, I’d consider
88 this a strong draft but suggest changes before
89 sending it on to a real client. Either because of

1 **Table 2.** Example of the scoring table that the industry participants completed for each report
2

Student 1	Grade based on Guidelines above:
Comments regarding the quality of writing (i.e., what was good, what needs to be improved).	
What overall feedback would you provide the student?	

7 severity of a single issue (perhaps errors or
8 missing evidence for technical content), or sig-
9 nificant issues with prose, I would be concerned if
10 this document went to a client without those
11 changes made.

- 12 • (B-/C+) Work earning this score shows some
13 promise, but it lacks much-needed polish and/or
14 includes technical errors. If I were your super-
15 visor on an internship, I would require substan-
16 tive revision to the majority of the document
17 before it could be passed on to a client. Though
18 evidence of good ideas and/or solid engineering
19 work is present, I am certain that a client would
20 be too distracted by the many problems and/or
21 technical errors to form a positive impression of
22 you or our company.
- 23 • (C/C-) Work earning this score requires signifi-
24 cant revision before it can be passed on to a real
25 client. These changes include improvements in
26 clarity and readability as well as in major content
27 (perhaps content is missing, unclear, or wrong). I
28 would panic if this document were sent directly to
29 a client without significant revision, as I believe it

44 **Fig. 1.** The overall scores for four reports for each of the five
45 instructors (as indicated by different symbols). Also shown are
46 the average scores across all instructors for each report (●) and
47 error bars represent standard deviations.

48 **Table 3.** Averages and standard deviations of report scores
49 graded by instructors

50 Report	Instructor Average Scores (%)	Instructor Standard Deviation
51 1	52 79.0	53 3.2
54 2	55 90.7	56 2.7
57 3		5.7
4 4	84.7	2.7

5 could affect our company's relationship with the
6 client.

- 7 • Scores lower than C- are uncommon (and
8 usually the result of incomplete work).

9 For the industry participants, to simplify the grad-
10 ing process and reduce grading time they were given
11 a more general score sheet (Table 2) asking for a
12 letter score rather than scoring with the rubric.
13 Then, in order to compare industry partner scores
14 to instructor scores, the letter grades were con-
15 verted to numerical scores using standard percent
16 to letter grade conversions (e.g., A = 95, A/A- = 93,
17 A- = 91, B+ = 89, etc.) for analysis.

22 **3. Results and Discussion**

23 *3.1 Instructor Scored Reports (Rubric-based)*

24 To assess the quality of student work, five instruc-
25 tors graded four reports using a rubric consisting of
26 six constructs (Table 1). All instructors had prior
27 experience teaching chemical engineering labora-
28 tory courses with technical report assignments. As
29 can be seen in Fig. 1, instructor scores were largely
30 consistent, approaching or within standard devia-
31 tions for reports 1, 2, and 4 of less than 3.5% (Table
32 3). Report 3 had a higher standard deviation of
33 5.7%, resulting from one instructor grading the
34 report significantly lower than the other three
35 graders, which is shown as the square in Fig. 1.

36 To further explore report 3, Fig. 2 shows the
37 points given for each rubric construct with each
38 marker type representing a different instructor
39 (other than the filled circle, which is the average
40 score). It can be seen that the instructor represented
41 by the square gave lower scores for three of the
42 constructs. The square grader scored significantly
43 lower for constructs 2 (Technical Content), 5 (Pre-
44 cise and Concise Technical Writing), and 6 (Lang-
45 uage Execution). During a discussion meeting that
46 followed the scoring, this instructor (square) felt
47 that report 3 contained extraneous information and
48 was missing necessary analysis. This decreased the
49 scores in both Technical Content and Concise and
50 Precise Technical Writing categories relative to the
51 other instructors (Fig. 2). Due to the report score
52 being 30 points, each point is equivalent to 3.33
53 percentage points. Since that grader was approxi-
54 mately 3.8 points below the average of the other
55 instructors, that resulted in an over 12% lower
56 overall score.

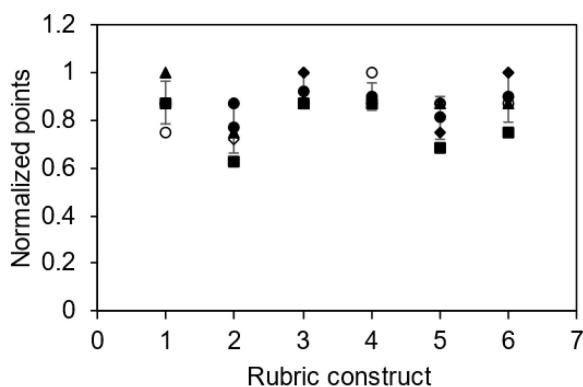

Fig. 2. Report 3 scores for each individual rubric construct (as defined in Table 1) for each instructor (correspond to same symbols as in Fig. 1). Also shown are the average scores for each construct (●) with error bars representing standard deviations.

Table 4. ICC on scores for the four randomly selected student sample technical reports graded by five instructors

Rubric Construct	ICC Value	Rating
Context and Purpose	0.79	Excellent
Technical Content and Analysis	0.63	Good
Organization and Formatting	0.75	Excellent
Figures, Tables and Schematics	0.61	Good
Precise and Concise Technical Writing	0.94	Excellent
Language Execution	0.55	Fair
Overall Score	0.90	Excellent

To further explore the consistency of grading between instructors, inter-rater reliability (IRR) was assessed where intraclass correlations (ICCs) of less than 0.40 are considered poor, between 0.40 and 0.59 are fair, between 0.60 and 0.74 are good, and above 0.75 are excellent. Some caution must be used in interpreting the ICCs reported here mainly because only four reports were rated; however, the ICCs do provide a general sense of how consistent the instructors were. It was found with the exception of the Language Execution construct, the instructors provided good or excellent consistency in their ratings (Table 4). The high ICCs indicate that the instructors had a high degree of agreement and a minimal amount of error leading to consistent report scoring.

Although there was high agreement in other constructs, the Language Execution construct, which evaluates the grammar and spelling quality within the report, was rated as “fair.” When looking at the scores between graders for this construct, Fig. 3 shows that overall, the grading was fairly consistent, with only the square instructor providing a lower score due to the perceived excessive information. Since the standard deviations only ranged from 0.01–0.10 for each report, the Language Execution construct was deemed acceptable.

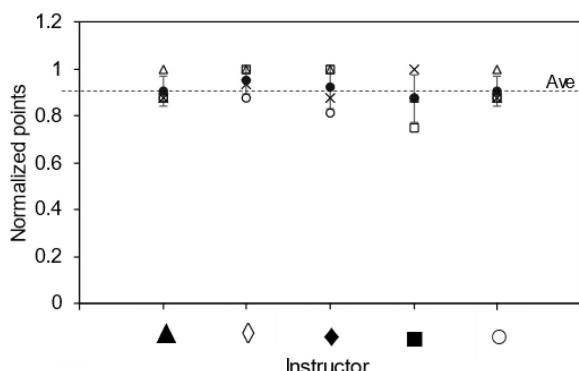

Fig. 3. The normalized points received for the rubric construct Language Execution by instructor (●, ▲, ◆, ■, and ○) for each of the four reports (○, □, △, and ×). Instructor averages are indicated by the filled circle (●) with an overall average of 0.91 indicated by the dashed line. Error bars represent standard deviations.

3.2 Industry Scored Reports (Letter grade-based)

To determine whether technical communication standards are similar for chemical engineering instructors and practicing chemical engineers, the latter were given four reports where reports 1–3 corresponded to the same reports numbered 1 through 3 that were scored by the instructors and discussed in the previous section. Report 4 was not provided to industry participants as it contained confusing, complex theory and likely would have imposed a significant time investment. Instead, industry partners were provided a report selected to be more standard, labeled report 4I. This report was not graded as part of the instructor validation of the rubric discussed above but was graded by chemical engineering instructors at a later date.

Fig. 4 shows the scores for each of the reports from the five industry participants, including the averages and standard deviations, which are also listed in Table 5. Report 1 had the highest variability with a standard deviation of 6.4% and scores that ranged from C/C– to B+/B. This is similar to the instructor scoring which ranged from a low of 75% (C) to a high of 83% (B). Reports 2 and 3 had lower variability with standard deviations of 4.3% and 4.8% respectively. Interestingly for report 3, one industry partner also highlighted the same extraneous information as one instructor (square grader) and correspondingly, gave a lower score (B+/B) than three of the other four industry participants (High A; A–; B+/B; A/A–). Note that some differences, particularly in standard deviation, would be expected as the industry partners used a letter-based grade system compared to the numerical rubric the instructors used. Overall, when combining the reports scored by both instructor and industry (reports 1–3), the industry partner scores were largely in agreement with instructor

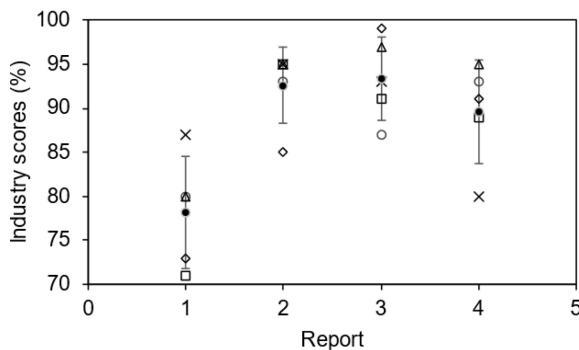

Fig. 4. The overall scores for reports 1–3 and report 14 for each of the five industry partners (as indicated by different symbols). Also shown are the average scores across all industry partners for each report (●). Error bars represent standard deviations.

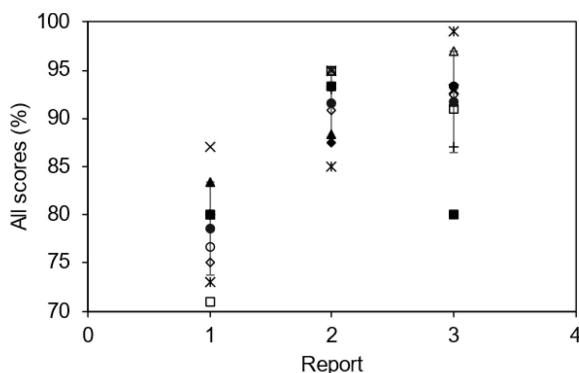

Fig. 5. The overall scores for reports 1–3 for both instructors and industry partners (as indicated by different symbols). Also shown are the average scores for each report (●). Error bars represent standard deviations.

Table 5. Average and standard deviations of report scores by instructors and industry partners and corresponding letter grades for reports 1–3, graded during the instructor rubric validation, and the report graded by industry and instructors outside of the rubric validation (4I)

Report	Instructor Average Scores (%)	Instructor Standard Deviation	Instructor Letter Grades	Industry Partner Average Scores (%)	Industry Partner Standard Deviation	Industry Partner Letter Grade
1	79.0	3.2	C+	78.2	6.4	C+
2	90.7	2.7	A-	92.6	4.3	A-
3	90.2	5.7	A-	93.4	4.8	A/A-
4I	84.9	2.1	B	89.6	5.8	B+

Table 6. Summary of the written feedback given by industry and instructor graders

Report	Industry Feedback	Instructor Feedback
1	<ul style="list-style-type: none"> Poorly written abstract Lacks professionalism Would “panic if a report of this quality was sent to a client” 	<ul style="list-style-type: none"> Poorly written overall report Technical writing needs improvement Results lack interpretation
2	<ul style="list-style-type: none"> Strong abstract, but could be more concise 	<ul style="list-style-type: none"> Abstract needs to include results interpretation
3	<ul style="list-style-type: none"> Well-written Contained excess information: “Less is more” and “scope creep,” which could lead to necessary costs for client 	<ul style="list-style-type: none"> Needs a clear conclusion and recommendation Contained superfluous details
14	<ul style="list-style-type: none"> Abstract needs improvement Inconsistencies in the results Incorrect word use Excellent safety section; “sets the bar for how these subjects should be conveyed” 	<ul style="list-style-type: none"> Noted deficiencies in each section of the report Abstract was weak Lacked clarity in the results and discussion Had technical errors

scores (Fig. 5; Table 5), indicating that the expectations and standards of the chemical engineering instructors were in alignment with those of practicing engineers. Although overall scores were in alignment between instructors and the industry partners, further analysis was done on the comments provided by both to determine if the noted deficiencies were similar.

Two instructors provided detailed written feedback and all five industry partners gave some comments on reports 1–3. The general themes of comments were largely consistent, particularly between the instructors and then between the industry participants, although industry partners and instructors tended to focus on slightly different aspects (Table 6). In general, industry partners placed a high emphasis on the quality of the abstract, professionalism and on safety, while instructors focused more on technical writing, the results and analysis, and the technical content. Instructors did comment on the need for improved technical writing but did not use the word “professionalism.” Industry participants noted that upper-level managers often do not read past the abstract, and hence, why there was more focus on it. Additionally, having good grammar and word selection “are important in building the trust of the reader in your technical abilities.” Finally, safety was a theme overall for the industry participants as several, but not all, made comments regarding safety, either complimenting the safety considerations or recommending improvements. The instructors did not

1 comment near as much on the safety section but felt
2 that this was an important section to emphasize
3 going forward.

4 3.3 Limitations

5 There are some limitations for this validation study.
6 Although there were five raters involved in the
7 rubric validation to determine the IRR of the
8 rubric, the raters examined only four technical
9 reports that were on the same topic in order to
10 reduce the amount of topic reviewing that the
11 industry partners needed to do. Ideally, more
12 reports from different experiments would be used
13 to determine if there are differences in report topics.
14 One other limitation is that the industry partners did
15 not use the rubric to grade the technical reports, but
16 instead just assigned a letter grade that was con-
17 verted to a percentage. Having the industry partners
18 use the rubric could provide further validation that
19 the rubric is robust although would require more
20 time. Additionally, this rubric was only validated
21 across instructors in two different chemical and
22 biological engineering courses at one institution.
23 Expansion to other courses, departments, and
24 even institutions could provide insight as to whether
25 this rubric would be of value for other courses.

26 4. Conclusions

27 This study sought to address two questions: (1) how
28 can chemical engineering instructors reliably and
29 consistently assess student communication skills
30 and (2) are instructor expectations aligned with
31 those of practicing engineers? A rubric was
32 designed to assess technical skills, using a technical
33 content and analysis construct, and communication
34 skills using constructs that assess particular aspects
35 of technical writing such as context and purpose
36 and precise and concise technical writing. Instructor
37 scores evaluating technical reports using the
38 rubric were consistent between instructors as
39 shown by the close ranging average scores, low
40 standard deviations, and high ICCs. These rubrics
41 could be utilized broadly in engineering laboratory
42 courses with a technical writing component with
43 minor adjustments to accommodate differences in
44 course structure, disciplinary variations, and industry
45 expectations in various cultural contexts. As

46 instructor discussion about the scoring process
47 yielded valuable insights on what instructors
48 valued and why, an instructor ‘training’ or ‘orienta-
49 tion’ for new instructors or team-taught courses
50 would be beneficial to ensure alignment of expecta-
51 tions and consistency of scoring. Such a training
52 could include discussion on interpretation of rubric
53 constructs, how to provide clear feedback tied to
54 the rubric, and practice with the rubrics prior to the
55 course.

56 In addition, expectations of quality were, on
57 average, similar between instructors and practicing
58 engineers, the industry partners. When looking
59 qualitatively at comments, some differences
60 emerged. Industry partners placed a high emphasis
61 on the issue of safety and a concise, yet summative
62 abstract while the instructors had a more holistic
63 view, with an emphasis on interpretation of results,
64 discussion and drawing of conclusions. Taking into
65 account this knowledge, instructors should put
66 more emphasis on the abstract and safety. Given
67 the academic context and learning objectives of the
68 course, however, instructors should still hold high
69 standards for the students on technical analysis.
70 Industry partners have an assumption of com-
71 petence once a student has graduated, and focused less
72 on the technical content, assuming it was accurate.
73 As educators, it is our job to get students to that
74 point of competency and to teach transferable
75 communication skills relevant to engineering prac-
76 tice. This work provides insight into the necessity of
77 balancing teaching within an academic context with
78 preparing students for the practice of engineering.
79 With the framework provided by the rubric,
80 instructors could adjust the rubric to align with
81 industry expectations within their context and also
82 use the understanding gleaned from the validation
83 process in instructor orientations to emphasize how
84 to assess student skills through both the academic
85 and industry lens.

86 *Acknowledgements* – This work is supported by the National
87 Science Foundation under grant number 2120775. Any results
88 expressed are those of the authors and do not necessarily reflect
89 the views of the National Science Foundation. Additionally,
90 funding for preliminary work was provided through a Bryan
91 Innovative Instructional Grant from MSU’s NACOE and an
92 Integrating Writing into STEM grant from the MSU Writing
93 Center. The authors thank the MSU Writing Center for guidance
94 and insight on rubric design and effective feedback.
