# Motivation

- Left-movers (LMs):
  - Pose a significant forecasting challenge
  - Are perceived as frequent producers of large hail
- There is little research on LMs:
  - Most research are case studies, radar analysis, and basic environmental analysis
    - Largely hodograph and storm motion focused
    - Small datasets
      - <100 LM cases with some exceeding >400 cases
  - No broader research on LM environments and parameter space.

# Data

- 889 observed LMs:
  - Manually identified and assigned a mesocyclone strength
    - WSR-88D
      - Maximum mesoanticyclonic rotational velocity in low or mid-levels
      - Storm structure
        - » Strongest gradient on the left flank
        - » Leftward motion relative to nearby convection
    - Manually quality-controlled
- 867 RUC/RAP sounding profiles:
  - Nearest storm inflow region
  - 22 contaminated profiles
- Mesocyclone strength:
  - Strong: 74 cases (8.54%)
  - Moderate: 296 cases (34.14%)
  - Weak: 461 cases (53.17%)
  - Marginal: 36 cases (4.15%)

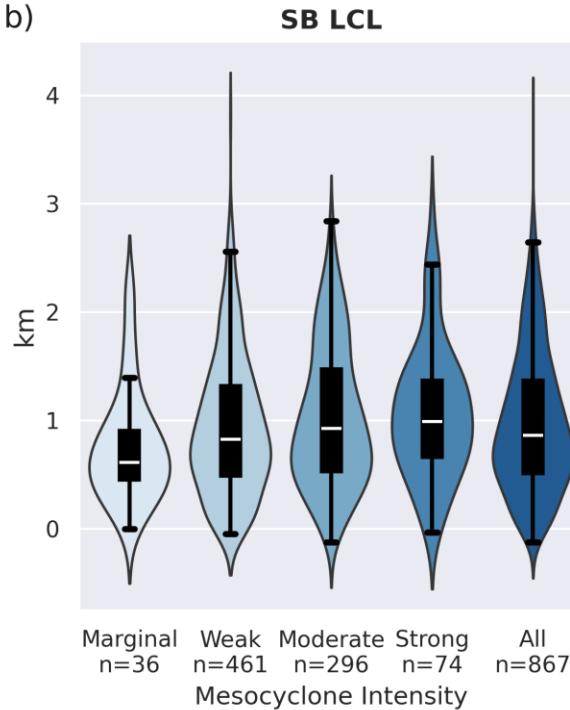

# Results: Thermodynamics

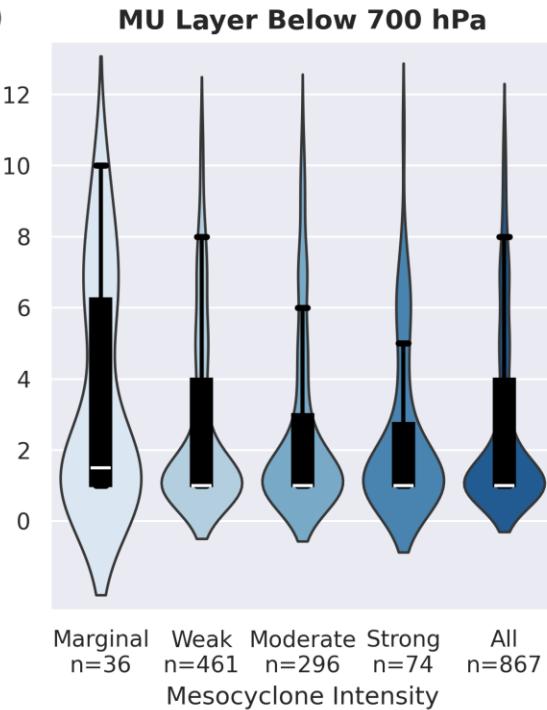

a)

b)

c)

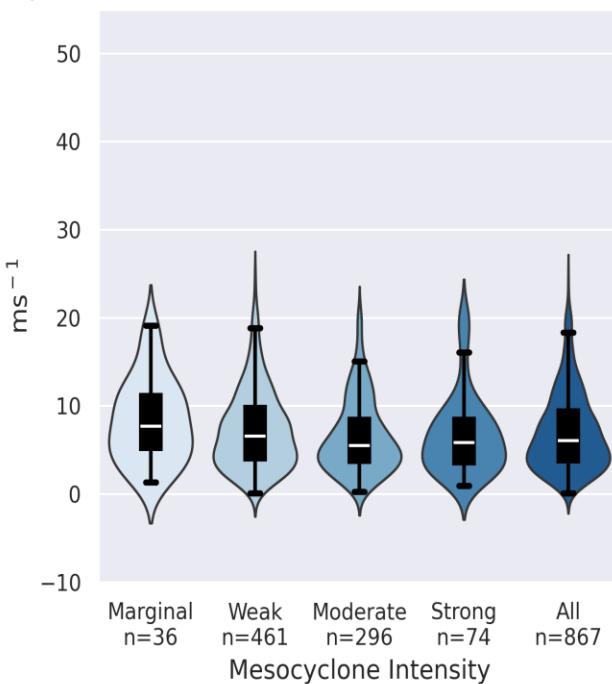

- With increasing mesocyclone strength:
  - Higher CAPE
  - Higher LCLs
  - Decreasing likelihood of being elevated

# Results: Kinematics

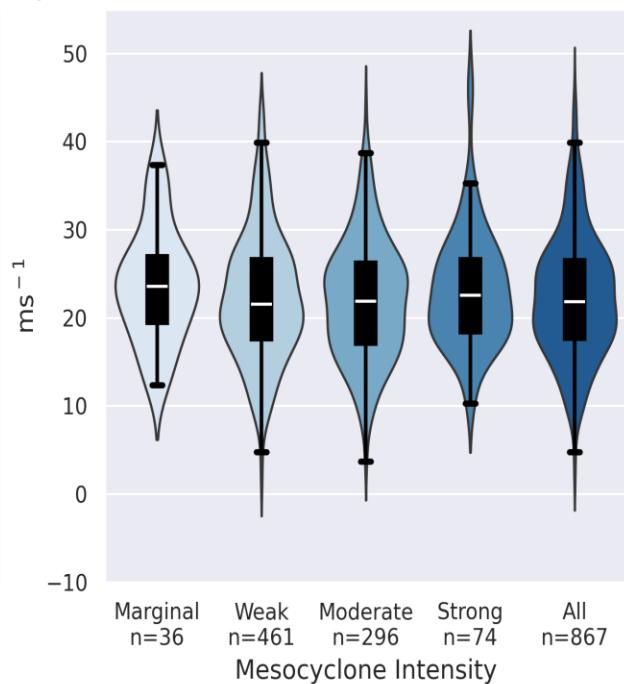

a)

0-1 km Shear

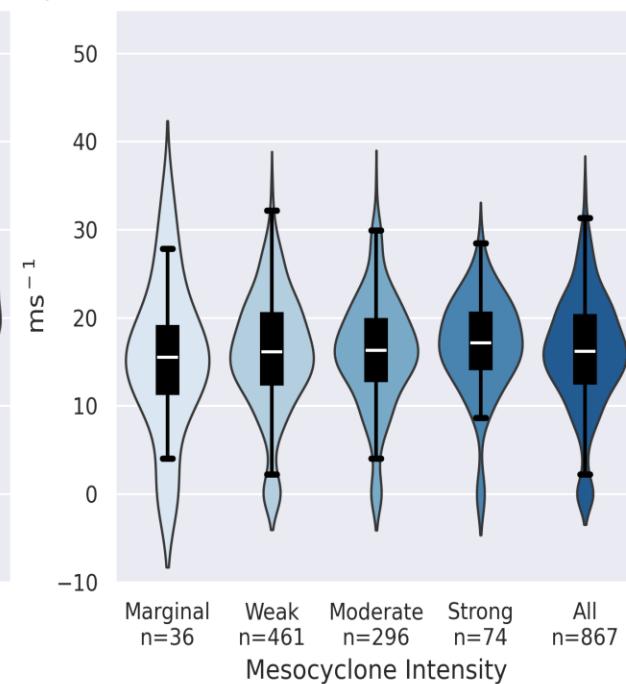

b)

0-6 km Shear

c)

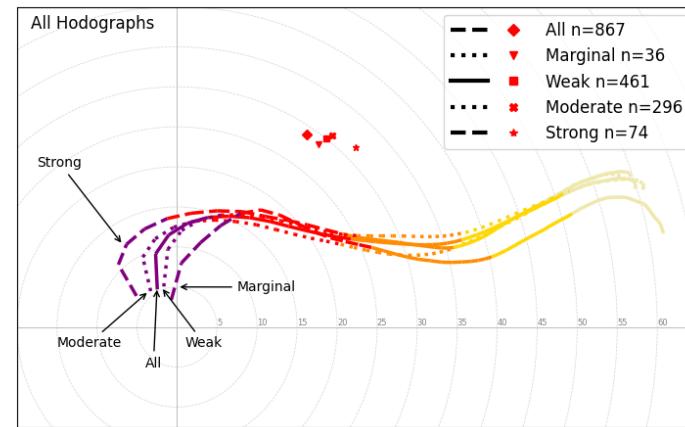

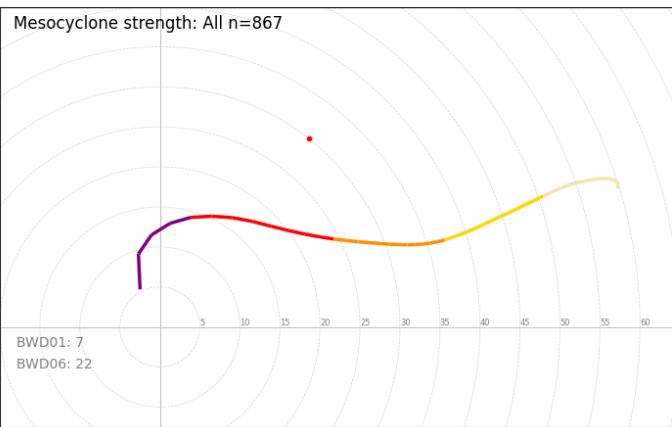

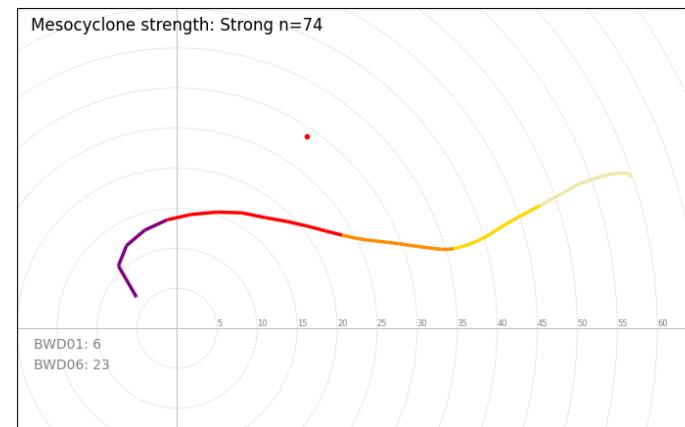

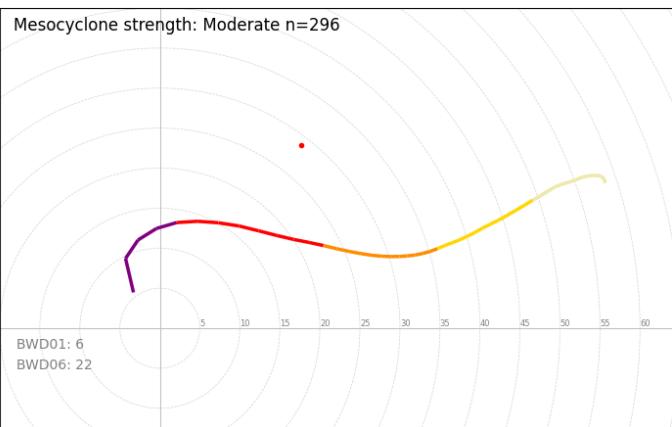

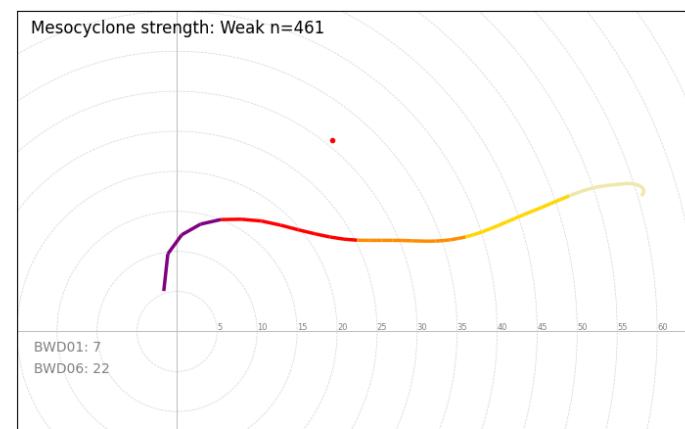

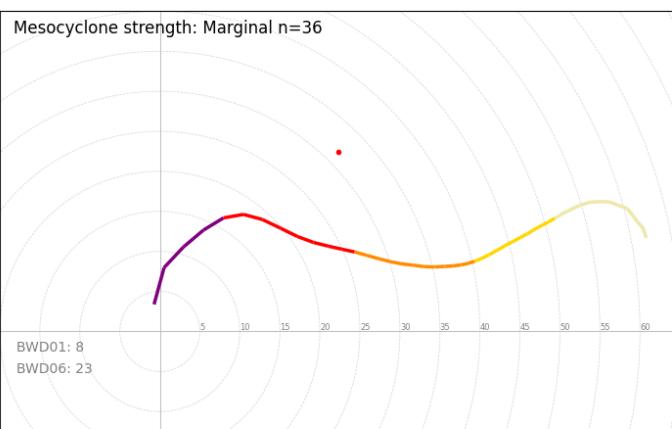

EBWD

- With increasing mesocyclone strength:
  - Decrease in 0-1 km shear
  - Increase in EBWD

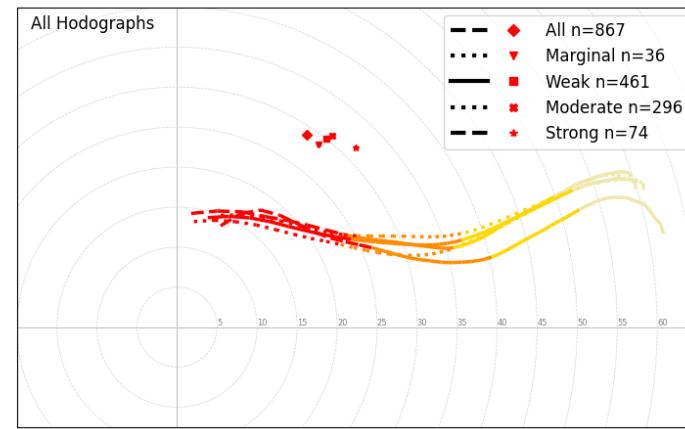

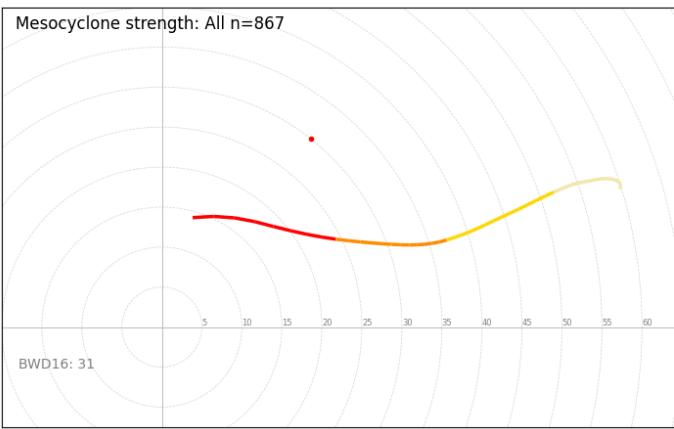

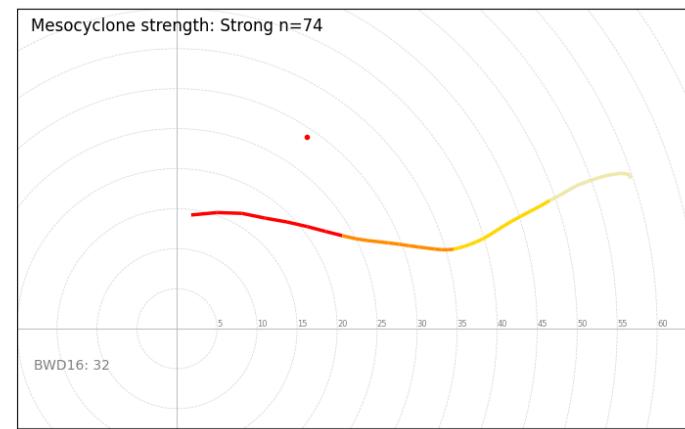

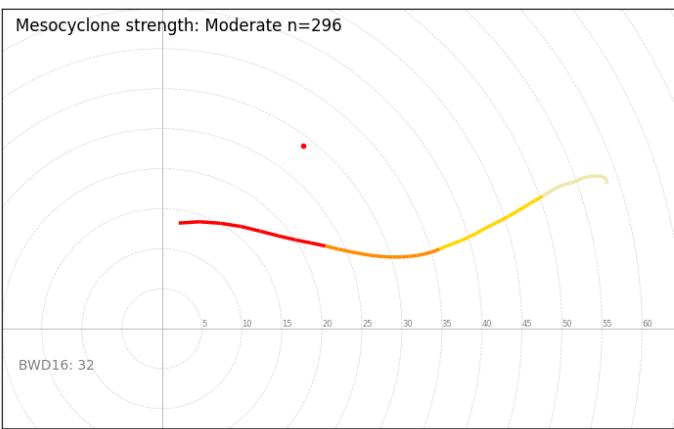

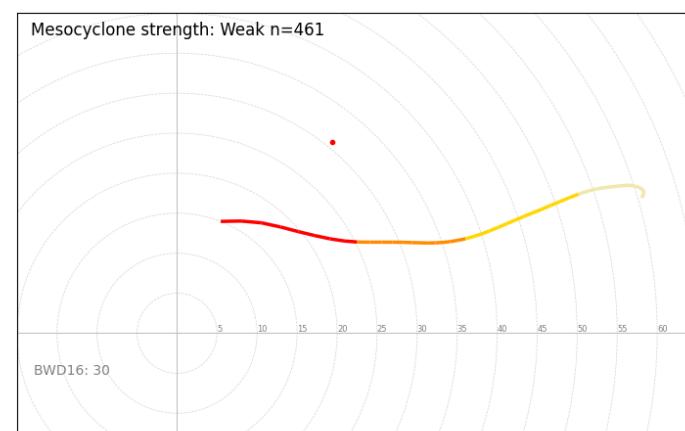

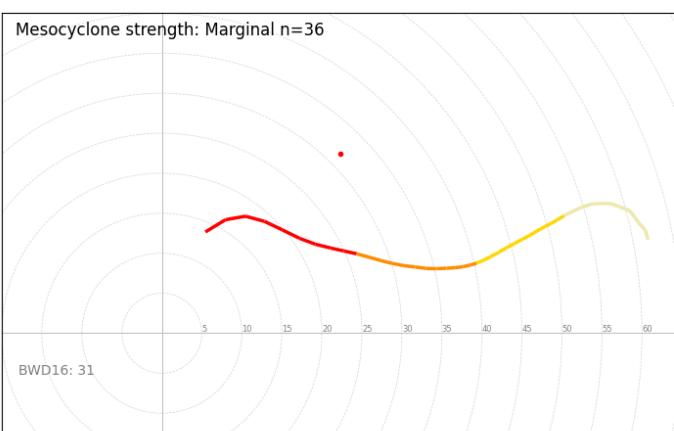

# LM Composite Hodographs

— 0-1 km   — 1-3 km   — 3-6 km   — 6-9 km   — 9-12 km

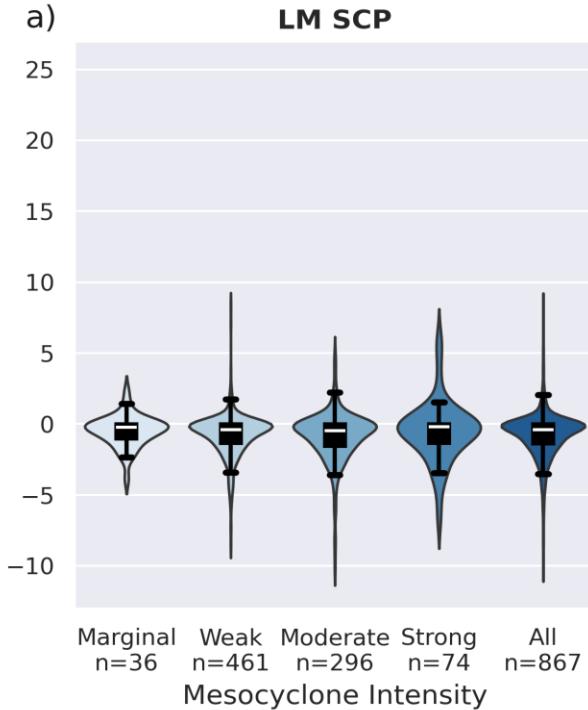

# LM Composite Hodographs

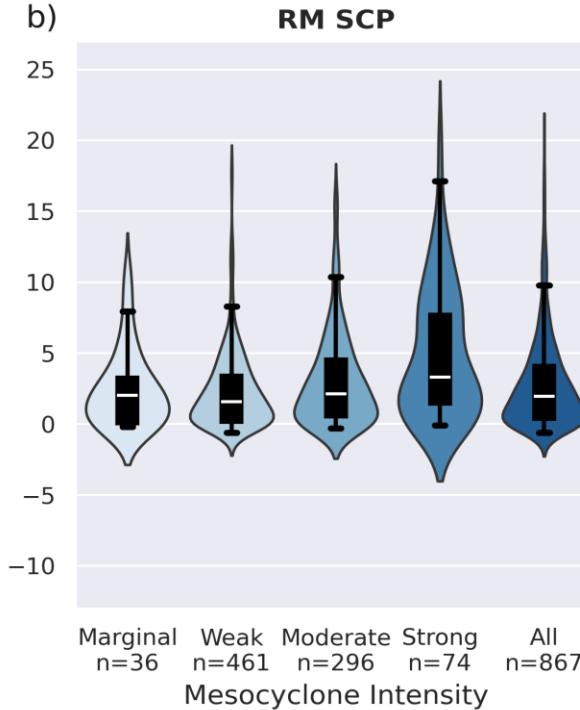

— LCL-3 km   — 3-6 km   — 6-9 km   — 9-12 km

# Results: Composite Parameters

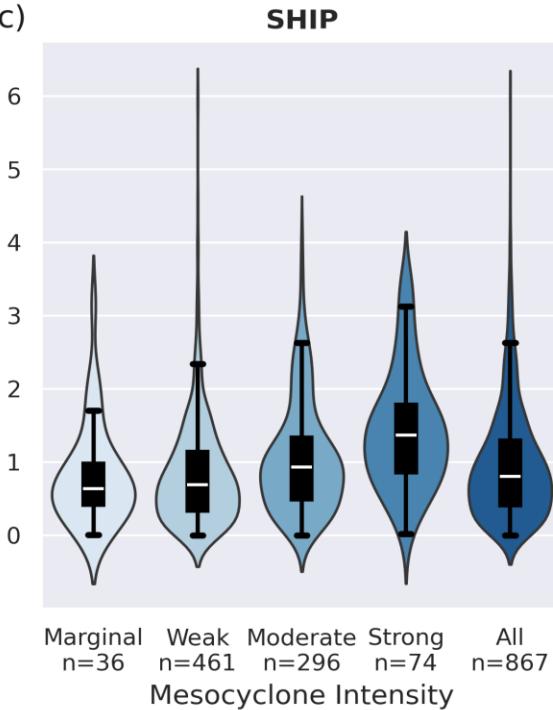

a)

b)

c)

- The current LM supercell composite parameter has no skill in predicting LMs
  - Environments supportive of both LMs and RMs tend to overlap
- SHIP increases with increasing mesocyclone strength

# Key Takeaways

- LMs have different inflow regions than RMs
  - S-shaped hodographs with clockwise curvature in low levels
  - Once restricted to LCL height, the shear profile becomes more favorable
  - LMs rarely have low-level mesocyclones
    - Weak, transient, updrafts with little to no tornado production
- CAPE, LCL height, and hodograph shape (above LCL) may be good predictors of LM strength.
- Commonly used metrics of shear are not useful predictors, and LM SCP has no skill for operational usage.
- Ongoing work is looking at environments to better anticipate LM supercells, particularly those that are severe.
