#### Abstract

Let R be a non-commutative field. We prove that generic triples of flags in an m-dimensional R-vector space are described by flat R-line bundles on the honeycomb graph with  $\frac{(m-1)(m-2)}{2}$  holes.

Generalising this, we prove that the non-commutative stack  $\mathcal{X}_{m,\mathbb{S}}$  of framed flat R-vector bundles of rank m on a decorated surface  $\mathbb{S}$  contains open dense substacks, identified with stacks of flat line bundles on certain bipartite graphs  $\Gamma$  on  $\mathbb{S}$ .

We introduce non-commutative cluster Poisson varieties related to bipartite ribbon graphs. They carry a canonical non-commutative Poisson structure. The result above just means that the space  $\mathcal{X}_{m,\mathbb{S}}$  has a structure of a non-commutative cluster Poisson variety, equivariant under the action of the mapping class group of  $\mathbb{S}$ .

For bipartite graphs on a torus, we get the non-commutative dimer cluster integrable system.

We develop a parallel dual story of non-commutative cluster  $\mathcal{A}$ -varieties related to bipartite ribbon graphs. They carry a canonical non-commutative 2-form. The dual non-commutative moduli space  $\mathcal{A}_{m,\mathbb{S}}$  of twisted decorated local systems on  $\mathbb{S}$  carries a cluster  $\mathcal{A}$ -variety structure, equivariant under the action of the mapping class group of  $\mathbb{S}$ . The non-commutative cluster  $\mathcal{A}$ -coordinates on the space  $\mathcal{A}_{m,\mathbb{S}}$  are expressed as ratios of Gelfand-Retakh quasideterminants. In the case m=2 this recovers the Berenstein-Retakh non-commutative cluster algebras related to surfaces.

For any split reductive group G with connected center, we prove that all stacks of framed G—Stokes data carry a cluster Poisson structure, equivariant under the wild mapping class group. Therefore these stacks can be equivariantly quantized.

The similar stacks of decorated G-Stokes data carry an equivariant cluster  $\mathcal{A}$ -variety structure. We introduce admissible dg-sheaves, and define non-commutative stacks of Stokes data as stacks of admissible dg-sheaves of certain type.

# 1 Introduction

**Summary**. Section 1.1 is a selfcontained exposition of several key results of the paper. All of them but Proposition 1.7 are equipped with complete proofs. Computations proving Proposition 1.7 are presented in Section 6.3. They show how Gelfand-Retakh's quasideterminants [GR] appear from the geometric considerations, making many of their properties obvious.

In particular, we prove in Section 1.1 the following. Take a surface S, possibly singular and non-orientable, obtained by gluing triangles and deleting their vertices. Then generic local system of m-dimensional vector spaces over a skew field R on S, equipped with a flat section of the associated local system of flags near each deleted vertex, can be described by a flat line bundle on a certain graph  $\Gamma$ .

One can glue a surface from triangles in various ways. Different gluing patterns lead to different graphs  $\Gamma$ . The main question not resolved in Section 1.1 is how to relate flat line bundles on different graphs  $\Gamma$  describing the same generic local system on the surface. To address this question we introduce in Sections 2 & 4 non-commutative cluster varieties of two flavors, related to bipartite ribbon graphs. They carry, respectively, a non-commutative Poisson structure and a closed non-commutative 2-form. In Sections 5 & 6 we define these cluster structures on moduli spaces of R-local systems on surfaces of two flavors, depending on the type of flags near the vertices. The crucial role play bipartite graphs on the surface called  $GL_m$ -graphs [G]. A preview can be found in Section 1.2.

 $GL_m$ -graphs appear in the description of local systems on surfaces out of the blue. In Section 7 we present another approach, which explains the role of  $GL_m$ -graphs, and proves the main results in a bit stronger form. We start from any collection  $\mathcal{H}$  of smooth coordinated curves with disjoint Legendrians on

an oriented surface. We assign to  $\mathcal{H}$  a finite type stack  $\mathcal{M}(\mathcal{H}, \mathbf{1})$ . We show explicitly that deformations of the collection  $\mathcal{H}$  leaving its components smooth and their Legendrians disjoint lead to equivalent stacks.

Here is an example. Let S be a surface S with a finite set of punctures. Draw m small simple non-intersecting loops around each puncture s. Denote by  $\mathcal{H}_m$  their union. Then  $\mathcal{M}(\mathcal{H}_m, \mathbf{1})$  is the the stack  $\mathcal{X}_m(S)$  of m-dimensional local systems on S with a complete flag near each puncture, invariant under the monodromy around s. On the other hand, zig-zag paths of any bipartite graph  $\Gamma$  on S provide a collection  $\mathcal{Z}_{\Gamma}$  of cooriented curves on S. We show that  $\mathcal{M}(\mathcal{Z}_{\Gamma}, \mathbf{1})$  contains as an open subspace the space  $\text{Loc}_1(\Gamma)$  of flat line bundles on the graph  $\Gamma$ . By the very definition of a  $\text{GL}_m$ -graph, the collection of its zig-zag paths is isotopic to the collection of loops  $\mathcal{H}_m$ . Such an isotopy provides an open embedding

$$\operatorname{Loc}_1(\Gamma) \subset \mathcal{M}(\mathcal{Z}_{\Gamma}, \mathbf{1}) \stackrel{\sim}{=} \mathcal{M}(\mathcal{H}_m, \mathbf{1}) = \mathcal{X}_m(S).$$

So we embed the non-commutative torus  $Loc_1(\Gamma)$  as an open part in  $\mathcal{X}_m(S)$ . The union of these tori for all  $GL_m$ -graphs on S is a cluster Poisson atlas in the sense of Section 2, equivariant under the mapping class group action. See the preview in Section 1.3.

In Section 8 we construct a wide supply of stacks with a similar cluster description. We start from a split reductive group G over  $\mathbb{Q}$ , and pick any collection  $\{\beta_s\}$  of elements of the cyclic envelope of the Artin braid semigroup  $\mathrm{Br}_{\mathrm{G}}^+$ , assigned to the punctures s of S. We introduce a stack  $\mathcal{X}_{\mathrm{G}}(S,\{\beta_s\})$  of G-local systems on S with a pattern of flags near each puncture s determined by the  $\beta_s$ . When  $\beta_s = e$  is the unit for all s, and  $\mathrm{G} = \mathrm{GL}_m$ , we get the stack  $\mathcal{X}_m(S)$ . When  $S = S^2 - \{0, \infty\}$  and  $\beta_0 = e$ , we recover the cluster Poisson varieties introduced in [FG3]. Using this and [GS19] we show that, skipping  $S^2 - \{0\}$ , any stack  $\mathcal{X}_{\mathrm{G}}(S,\{\beta_s\})$  carries a cluster Poisson structure equivariant under the action of the wild mapping class group for the pair  $(S,\{\beta_s\})$ . We get similar results for any surface S glued from triangles, decorated in addition to the  $\{\beta_s\}$  at the punctures s by the elements of the braid semigroup  $\mathrm{Br}_{\mathrm{G}}^+$  at the corners.

These stacks are of independent interest. For example, any stack of Stokes data for holomorphic G-bundles with meromorphic connections on a Riemann surface is holomorphically equivalent to one of them. However unless G is of type  $A_1$ , many stacks  $\mathcal{X}_G(S, \{\beta_s\})$  do not appear this way.

We describe non-commutative analogs of stacks  $\mathcal{X}_{GL_m}(\mathcal{S}, \{\beta_s\})$  and prove that they carry a non-commutative cluster Poisson structure, equivariant under the wild mapping class group action.

Section 3 contains an application of the constructions of Section 2 to non-commutative cluster integrable systems. It is entirely independent of the rest of the paper.

### 1.1 Spectral description of generic triples of flags

Let R be a *skew field*, i.e. a non-commutative division algebra. An m-dimensional R-vector space is a free rank m left R-module. If m = 1, we call it an R-line.

A flag  $\mathcal{F}$  in an m-dimensional R-vector space V is a filtration by R-vector spaces

$$V = \mathcal{F}^0 \supset \mathcal{F}^1 \supset \mathcal{F}^2 \supset \dots \supset \mathcal{F}^{m-1} \supset \mathcal{F}^m = 0, \quad \text{codim } \mathcal{F}^i = i. \tag{1}$$

We associate to a flag  $\mathcal{F}$  a collection of m lines  $\operatorname{gr}^i\mathcal{F}:=\mathcal{F}^i/\mathcal{F}^{i+1},\ i=0,...,m-1.$ 

The group of automorphisms of the R-vector space V acts transitively on the set of all flags in V.

In Section 1.1 we describe generic triples of flags in an m-dimensional R-vector space via flat line bundles on the bipartite graph  $\Gamma_m$ , shown on Figures 1, 2. It is a self-contained part of the paper, describing the simplest, and at the same time crucial result with all details. Let us start with generic pairs of flags.

<sup>&</sup>lt;sup>1</sup>Here stack means traditional stack used in algebraic geometry.

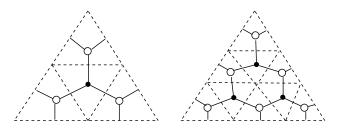

Figure 1: The bipartite graphs  $\Gamma_2$  and  $\Gamma_3$ , shown by solid lines.

**1. Generic pairs of flags.** A pair of flags  $(\mathcal{A}, \mathcal{B})$  in an m-dimensional R-vector space V is generic if for any integers  $a, b \geq 0$  such that a + b = m the projections  $V \longrightarrow V/\mathcal{A}^a$  and  $V \longrightarrow V/\mathcal{B}^b$  induce an isomorphism

$$V \xrightarrow{\sim} V/\mathcal{A}^a \oplus V/\mathcal{B}^b$$
.

Given a generic pair of flags  $(\mathcal{A}, \mathcal{B})$ , let us set

$$L^{b+1} := \mathcal{A}^a \cap \mathcal{B}^b, \quad a+b = m-1, \ a, b > 0.$$

The embeddings  $L^a \hookrightarrow V$ , a = 1, ..., m, give rise to a canonical isomorphism

$$L^1 \oplus \ldots \oplus L^m \xrightarrow{\sim} V.$$

**Lemma 1.1.** Assigning to a generic pair of flags (A, B) in an m-dimensional R-vector space V the ordered collection of m lines  $(L^1, \ldots, L^m)$  we get an equivalence of groupoids:

Groupoid of generic pairs of flags in m-dimensional spaces 
$$(V, \mathcal{A}, \mathcal{B}) \xrightarrow{\sim}$$
  
Groupoid of ordered collections of m lines  $(L^1, \dots, L^m)$ .

*Proof.* The inverse functor  $(L^1, \ldots, L^m) \longrightarrow (V, \mathcal{A}, \mathcal{B})$  is given by

$$V := L^1 \oplus \ldots \oplus L^m, \quad \mathcal{A}^a := L^1 \oplus \ldots \oplus L^{m-a}, \quad \mathcal{B}^b := L^{b+1} \oplus \ldots \oplus L^m.$$

2. Spectral description of the groupoid of generic triples of flags. A triple of flags (A, B, C) in an m-dimensional R-vector space V is generic if for any non-negative integers (a, b, c) with a + b + c = m, the following map is an isomorphism:<sup>2</sup>

$$V \longrightarrow V/\mathcal{A}^a \oplus V/\mathcal{B}^b \oplus V/\mathcal{C}^c, \qquad a+b+c=m.$$
 (3)

Let us describe generic triples of flags in an m-dimensional R-vector space.

Let us assign a triple of flags  $(\mathcal{A}, \mathcal{B}, \mathcal{C})$  to the vertices of a triangle t, labeled by A, B, C.

We introduce a bipartite graph  $\Gamma_m$ , shown in Figures 1-2 for  $m \leq 4$ . Recall that a bipartite graph is a graph with vertices of two types,  $\bullet$ -vertices and  $\circ$ -vertices, such that each edge has a vertex of each type.

To define the graph  $\Gamma_m$ , take an m-triangulation of the triangle t, shown by punctured lines on Figure 1. It subdivides each side of the triangle into m equal segments, and tessellates the triangle into little triangles of two types: the  $\bullet$ -triangles, and the  $\circ$ -triangles. The bipartite graph  $\Gamma_m$  is the dual graph for this tessellation.

Recall that a flat line bundle L on a graph  $\Gamma$  is given by the following data:

<sup>&</sup>lt;sup>2</sup>Note that a flag in V gives rise to the dual flag in  $V^*$ , but the dual to a generic triple of flags may not be generic.

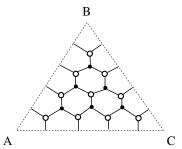

Figure 2: A bipartite graph  $\Gamma_4$  for a generic triple of flags  $(\mathcal{A}, \mathcal{B}, \mathcal{C})$  in a 4-dimensional space.

- 1. A line  $L_v$  for every vertex v of  $\Gamma$ .
- 2. An isomorphism  $t_{w,v}: L_v \to L_w$  for each edge of  $\Gamma$  with the ends v, w, with  $t_{v,w} = t_{w,v}^{-1}$ .

**Theorem 1.2.** There is a canonical equivalence between the following two groupoids:

- 1. Groupoid of generic triples of flags in an m-dimensional R-vector space.
- 2. Groupoid of R-line bundles with connections on the bipartite graph  $\Gamma_m$ , see Figure 4.

Proof. 1. The functor  $\mathcal{L}$ : {Generic triples of flags}  $\longrightarrow$  {Flat line bundles on the graph  $\Gamma_m$ }. Given a generic triple of flags  $(\mathcal{A}, \mathcal{B}, \mathcal{C})$ , let us define a flat R-line bundle  $\mathcal{L}(\mathcal{A}, \mathcal{B}, \mathcal{C})$  on the graph  $\Gamma_m$ .

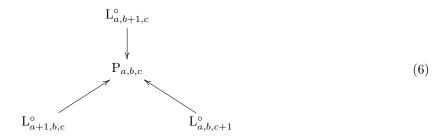

1. The  $\circ$ -vertices of the graph  $\Gamma_m$  are parametrized by the triples of non-negative integers (a, b, c) such that a + b + c = m - 1. We assign to each  $\circ$ -vertex a one dimensional subspace:

$$L_{a,b,c}^{\circ} := \mathcal{A}^a \cap \mathcal{B}^b \cap \mathcal{C}^c, \qquad a+b+c = m-1.$$
(4)

2. The  $\bullet$ -vertices of the graph  $\Gamma_m$  are parametrized by the triples of non-negative integers (a, b, c) such that a + b + c = m - 2. We assign to each  $\bullet$ -vertex a two dimensional subspace:

$$P_{a,b,c} := \mathcal{A}^a \cap \mathcal{B}^b \cap \mathcal{C}^c, \qquad a+b+c = m-2.$$
 (5)

The plane  $P_{a,b,c}$  assigned to a  $\bullet$ -vertex b contains three lines assigned to the  $\circ$ -vertices incident to b:

Indeed, the embedding  $\mathcal{A}^{a+1} \hookrightarrow \mathcal{A}^a$  induces the embedding  $\mathcal{A}^{a+1} \cap \mathcal{B}^b \cap \mathcal{C}^c \hookrightarrow \mathcal{A}^a \cap \mathcal{B}^b \cap \mathcal{C}^c$ . Condition (3) just means that for each plane  $P_{a,b,c}$ , the three lines (6) are disjoint. We define a line  $L_{a,b,c}^{\bullet}$  as the kernel of the natural map from the sum of the three lines in (6) to the plane:

$$L_{a,b,c}^{\bullet} := \operatorname{Ker}\left(L_{a+1,b,c} \oplus L_{a,b+1,c} \oplus L_{a+1,b,c} \longrightarrow P_{a,b,c}\right). \tag{7}$$

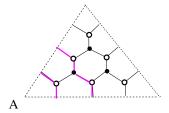

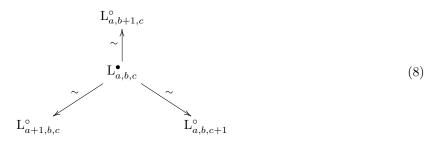

Figure 3: Vertices of the graph  $\Gamma_3$  on the distance  $\leq 2$  from the vertex A are on the two (purple) zig-zags.

Then there are three maps, induced by projections of the subspace  $L_{a,b,c}^{\bullet}$  onto the summands:

These three maps are isomorphisms if and only if the three lines in the plane  $P_{a,b,c}$  are disjoint.

So we get a flat line bundle on the graph  $\Gamma_m$ : its fibers at the vertices are given by the lines  $L^{\circ}$  and  $L^{\bullet}$ , and the parallel transport along an edge  $\bullet \to \circ$  is given by a map  $L^{\bullet} \longrightarrow L^{\circ}$  in (107).

**Remark.** If R = K is commutative, the moduli space of flat line bundles on a graph  $\Gamma$  is identified with  $H^1(\Gamma, K^*)$ . So flat line bundles on the graph  $\Gamma_m$  are described by their monodromies around the  $\binom{m-1}{2}$  holes in the graph. These are literally the canonical coordinates from [FG1], called the *triple ratios*. If R is non-commutative, we no longer have canonical coordinates describing generic triples. For example, the isomorphism classes of flat R-line bundles on the graph  $\Gamma_3$  are described by the elements of  $R^*$  considered modulo the conjugation. For m > 3 we need to pick a base point and paths to get a collection of elements of  $R^*$  defined up to a common conjugation.

2. The reconstruction functor  $\mathcal{R}$ : {Flat line bundles on  $\Gamma_m$ }  $\longrightarrow$  {generic triples of flags}. Given a flat line bundle  $\mathcal{L}$  on the graph  $\Gamma_m$ , we get a map from the direct sum over all internal  $\bullet$ -vertices {**b**} of the graph  $\Gamma_m$  to the direct sum over all  $\circ$ -vertices {**w**} of the graph  $\Gamma_m$ :

$$K_{\mathcal{L}}: \bigoplus_{\text{internal } \bullet - \text{vertices } \mathbf{b}} \mathcal{L}_{\mathbf{b}} \longrightarrow \bigoplus_{\text{o-vertices } \mathbf{w}} \mathcal{L}_{\mathbf{w}}.$$
 (9)

We define a vector space  $V_{\mathcal{L}}$  as the cokernel of this map:

$$V_{\mathcal{L}} := \operatorname{Coker}(\mathbf{K}_{\mathcal{L}}). \tag{10}$$

Let us define three flags in this vector space, assigned to the vertices of the triangle t. Given a vertex A, consider a function  $d_A$ : {vertices of the graph  $\Gamma_m$ }  $\longrightarrow$  {1, ..., m}, given by the distance from a vertex to the A, see Figure 3.<sup>3</sup> The function  $m - d_A$  induces a decreasing filtration on the complex (9).<sup>4</sup> So it induces a filtration on Coker( $K_L$ ). We define the flag  $\mathcal{A}_L^{\bullet}$  as the space (10) with this filtration. Explicitly:

$$\mathcal{A}_{\mathcal{L}}^{a} := \operatorname{Coker}\left(\bigoplus_{d_{A}(\mathbf{b}) \leq m-a} \mathcal{L}_{\mathbf{b}} \longrightarrow \bigoplus_{d_{A}(\mathbf{w}) \leq m-a} \mathcal{L}_{\mathbf{w}}\right), \qquad a = 0, ..., m-1.$$
(11)

<sup>&</sup>lt;sup>3</sup>That is the distance to A from the zig-zag strand containing the vertex on the graph  $\Gamma_m$  and parallel to the side BC. <sup>4</sup>That is a filtration on each of the spaces, preserved by the operator  $K_{\mathcal{L}}$ .

This way we get a functor

$$\mathcal{R}: \mathcal{L} \longrightarrow (\mathcal{A}_{\mathcal{L}}^{\bullet}, \mathcal{B}_{\mathcal{L}}^{\bullet}, \mathcal{C}_{\mathcal{L}}^{\bullet}). \tag{12}$$

By the definition, the functors  $\mathcal{L}$  and  $\mathcal{R}$  provide the equivalence of categories. Theorem 1.2 is proved.  $\square$ 

3. Reconstruction functor revisited. Denote by  $\Gamma'_m$  the graph obtained from the graph  $\Gamma_m$  by adding  $\bullet$ -vertices at the endpoints of external edges, see Figure 4, pictured on the sides of the triangle.

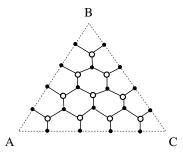

Figure 4: The bipartite graph  $\overline{\Gamma}_4$  includes the  $\bullet$ -vertices on the sides of the triangle.

A flat line bundle  $\mathcal{L}$  on  $\overline{\Gamma}_m$  provides three m-dimensional R-vector spaces assigned to the sides of the triangle as follows. For example, take the side AB. Let  $V_{\rm AB}^{\bullet}$  be the direct sum of the fibers of  $\mathcal{L}$  at the  $\bullet$ -vertices on the side AB, and  $V_{\rm AB}^{\circ}$  the direct sum of the fibers of  $\mathcal{L}$  at the  $\circ$ -vertices closest to the side AB. The parallel transport along the edges from  $\bullet$ -vertices on the side AB to the closest  $\circ$ -vertices provides a canonical isomorphism  $V_{\rm AB}^{\bullet} = V_{\rm AB}^{\circ}$ . So we set

$$V_{\mathrm{AB}} := V_{\mathrm{AB}}^{\bullet} = V_{\mathrm{AB}}^{\circ}.$$

Denote by  $V_{\mathcal{L}}^{\bullet}$  (respectively  $V_{\mathcal{L}}^{\circ}$ ) the direct sum of the lines  $\mathcal{L}_{\mathbf{b}}$  over all  $\bullet$ -vertices  $\mathbf{b}$  (respectively the lines  $\mathcal{L}_{\mathbf{w}}$  over the  $\circ$ -vertices  $\mathbf{w}$ ) of the graph  $\Gamma_m$  on Figure 2. Then there is a canonical map, induced by the embedding  $V_{AB}^{\circ} \hookrightarrow V_{\mathcal{L}}^{\circ}$ , followed by the projection to the quotient  $V_{\mathcal{L}}$ , defined in (10):

$$\psi_{AB}: V_{AB} \longrightarrow V_{\mathcal{L}}.$$
 (13)

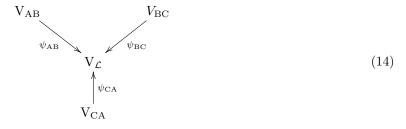

**Lemma 1.3.** One has  $\psi_{AB} = \psi_{BA}$ . The map  $\psi_{AB}$  is an isomorphism.

*Proof.* The first claim is the tautology. The second is equivalent to the statement that

$$V_{\Lambda B}^{\circ} \cap K_{\mathcal{L}}(V_{\mathcal{L}}^{\bullet}) = 0.$$

Let  $\widetilde{V}_{\mathcal{L}}^{\circ}$  be the direct sum of  $\mathcal{L}_{\mathbf{w}}$  over all but the ones closest to the side AB  $\circ$ -vertices. So  $V_{\mathcal{L}}^{\circ} = V_{\mathrm{AB}} \oplus \widetilde{V}_{\mathcal{L}}^{\circ}$ . Note that the map  $K_{\mathcal{L},\mathrm{C}} : V_{\mathcal{L}}^{\circ} \stackrel{\sim}{\longrightarrow} \widetilde{V}_{\mathcal{L}}^{\circ}$  given by the parallel transport from each  $\bullet$ -vertex along the edge towards the vertex C is an isomorphism. There are increasing filtrations of the spaces  $\widetilde{V}_{\mathcal{L}}^{\circ}$  and  $V_{\mathcal{L}}^{\bullet}$ , given by the codistance from the  $\circ/\bullet$ -vertices to the vertex C of the triangle, such that the map  $\mathrm{gr}K_{\mathcal{L}}$  of their associated graded induced by the map  $K_{\mathcal{L}}$  is the map  $K_{\mathcal{L},\mathrm{C}}$ . This implies the claim.

Therefore we have three canonical isomorphisms  $\psi_{AB}$ ,  $\psi_{BC}$ ,  $\psi_{CA}$ :

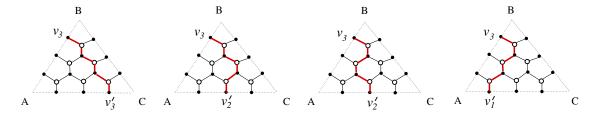

Figure 5: There are four A-paths from the vertex  $v_3$  on the side AB to the side AC.

Our next goal is to calculate the composition

$$\psi_{\rm AC}^{-1} \circ \psi_{\rm AB} : V_{\rm AB} \longrightarrow V_{\mathcal L} \longrightarrow V_{\rm AC}.$$
 (15)

To present the answer, we define explicitly an isomorphism

$$\varphi_{A,B\to C}: V_{AB} \longrightarrow V_{AC}.$$
 (16)

Namely, we define an A-path as a path on the graph from a vertex on the side AB to a vertex on the side AC, which always go towards AC. So given a vertex  $v_i$  on the side AB on the distance i from A, and a vertex  $v'_j$  on the side AC on the distance j from A, there are  $\binom{i-1}{j-1}$  A-paths  $\gamma: v_i \longrightarrow v'_j$ , see Figure 5. Then we set:

$$\varphi_{A,B\to C} := \sum_{\gamma} (-1)^{i-1} t_{\gamma}, \tag{17}$$

where the sum is over all A-paths  $\gamma: v_i \longrightarrow v'_j$  from AB to AC, and  $t_\gamma: \mathcal{L}_{v_i} \longrightarrow \mathcal{L}_{v'_j}$  is the parallel transport in the local system  $\mathcal{L}$  along the path  $\gamma$ .

**Proposition 1.4.** The map (15) coincides with the map (16):

$$\psi_{\mathrm{AC}}^{-1} \circ \psi_{\mathrm{AB}} = \varphi_{\mathrm{A,B} \to \mathrm{C}}.$$

Proof. Let f be a  $\bullet$ -vertex of the graph  $\Gamma_m$ . Denote by a,b,c the  $\circ$ -vertices next to f, so that they are in the natural bijection with the vertices of the triangle, e.g. the a is north of f and matches A. Pick a non-zero vector  $f \in \mathcal{L}_f$ . Denote by  $e_a, e_b, e_c$  its parallel transports to the fibers at the vertices a,b,c. Denote by  $e'_a,e'_b,e'_c$  their projections to  $V_{\mathcal{L}}$ . Then  $e'_a=-e'_b-e'_c$ . Note that  $e_b$  and  $e_c$  are parallel transports of the vector  $e_a$  to the fibers of  $\mathcal{L}$  at the vertices b and c. Then apply the same procedure to  $e_b$  and  $e_c$  and so on. In the end we express the vector  $e'_a$  as a linear combination of the vectors at the vertices on the side AC. Applying this to the  $\circ$ -vertices closest to the side AB we prove the formula.  $\square$ 

The space  $V_{AB}$  carries flags  $\mathcal{F}_{AB}^{\bullet}$  and  $\mathcal{F}_{BA}^{\bullet}$ , assigned to the orientations of the side. Namely, let  $\mathbf{b}_1, ..., \mathbf{b}_m$  be the  $\bullet$ -vertices on the side AB, oriented A  $\to$  B. Then the subspaces of the flag  $\mathcal{F}_{AB}^{\bullet}$  are

$$\mathcal{F}_{AB}^{a} := \mathcal{L}_{\mathbf{b}_{1}} \oplus \ldots \oplus \mathcal{L}_{\mathbf{b}_{m-a}}.$$
 (18)

It is clear from the definitions that the following three flags in the space  $V_{\mathcal{L}}$  coincide

$$\psi_{AB}(\mathcal{F}_{AB}^{\bullet}) = \psi_{AC}(\mathcal{F}_{AC}^{\bullet}) = \mathcal{A}_{\mathcal{L}}^{\bullet}. \tag{19}$$

So we can define a variant  $\mathcal{R}'$  of the reconstruction functor  $\mathcal{R}$  as follows.

Take the three spaces  $V_{AB}$ ,  $V_{BC}$ ,  $V_{CA}$  assigned to the sides of the triangle. There are six explicitly defined isomorphisms between them: the isomorphism  $\psi_{A,B\to C}$  given by (17), and the ones obtained by permuting  $\{A,B,C\}$ . Proposition 1.4 implies that

$$\varphi_{A,C\to B} \circ \varphi_{A,B\to C} = Id.$$

$$\varphi_{B,C\to A} \circ \varphi_{C,A\to B} \circ \varphi_{A,B\to C} = Id.$$
(20)

Similar identities are obtained by permuting {A, B, C}. Therefore we can identify the three vector spaces, and transform the flags to one of them, getting a configuration of three flags. These flags are in generic position. Finally, it is clear from the construction that we have the following Proposition.

**Proposition 1.5.** The two reconstruction functors  $\mathcal{R}$  and  $\mathcal{R}'$  coincide.

The functor  $\mathcal{R}'$  is a variant of the snake algorithm [FG1, Section 9.7] in the commutative case. We use it to prove in Theorem 1.9 an analog of the Laurent phenomenon in the non-commutative case.

**4. Spectral description of decorated triples of flags.** A decorated flag is a flag  $\mathcal{F}^{\bullet}$  as in (1) with a choice of a non-zero element  $f_i \in \operatorname{gr}^i \mathcal{F} := \mathcal{F}^{i-1}/\mathcal{F}^i$  in each successive quotient.

A zig-zag path, or simply a zig-zag, on a ribbon graph  $\Gamma$  is a path turning at every vertex either left or right, so that the left and right turns alternate. Zig-zags on a bipartite ribbon graph are oriented so that they turn right at  $\circ$ -vertices. The graph  $\Gamma_m$  carries 3m oriented zig-zags, see Figure 6.

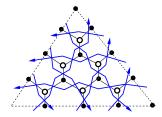

Figure 6: Nine zig-zag paths on the bipartite graph  $\Gamma_3$ . We push zig-zags a bit out of the vertices.

**Theorem 1.6.** There is a canonical equivalence between the following two groupoids:

- 1. Groupoid of generic triples of decorated flags in an m-dimensional R-vector space.
- 2. Groupoid of R-line bundles with connections on the bipartite graph  $\Gamma_m$ , trivialised on every zig-zag.

Theorem 1.6 is immediately deduced from Theorem 1.2 and the description of the reconstruction functor, which turns trivializations of the local system on zig-zags into decoration vectors of the flags.

The notable difference is that in the decorated setting there is a coordinate description. Indeed, for each edge E of the graph  $\Gamma_m$  there are two zig-zags  $\gamma_1, \gamma_2$  containing E. They provide two trivialisations  $s_{\gamma_1}$  and  $s_{\gamma_2}$  of the restriction of a flat line bundle to E. We assume that the oriented zig-zag  $\gamma_1$  goes along the edge E in the direction  $\circ \to \bullet$ . We define an edge coordinate  $\Delta_E$  as their ratio:

$$s_{\gamma_1} = \Delta_E \cdot s_{\gamma_2}, \quad \Delta_E \in R^*. \tag{21}$$

Elements  $\{\Delta_E\}$  satisfy the following monomial relations. For each internal vertex of  $\Gamma_m$ , the counterclockwise product of the elements  $\Delta_E$  over the edges incident to the vertex is equal to 1, see Figure 7. There are no other relations between elements  $\{\Delta_E\}$ .

Recall that, given an  $n \times n$  matrix M over a non-commutative skew field R, Gelfand and Retakh [GR] defined quasideterminants  $M_{ij}$ ,  $1 \le i, j \le n$ . If R is commutative, then the quasideterminant  $M_{ij}$  is, up to a sign, the ratio of the determinant of M by a minor obtained by deleting the row i and the column j of M. See (140) for examples of quasideterminants of  $2 \times 2$  matrices.

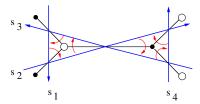

Figure 7: Writing  $\Delta_E = s_1/s_2$  etc. where  $s_i$  are flat sections on zig-zags, the counterclockwise products are:  $s_1/s_2 \cdot s_2/s_3 \cdot s_3/s_1 = 1$  near the  $\circ$ -vertex, and  $s_2/s_3 \cdot s_3/s_4 \cdot s_4/s_2 = 1$  near the  $\bullet$ -vertex.

**Proposition 1.7.** Given a generic triple of decorated flags, the invariants  $\{\Delta_E\}$  at the edges of the graph  $\Gamma_m$  are ratios of two Gelfand-Retakh quasideterminants.

See a detailed discussion of the simplest m=2 case in Section 6.3.

In the commutative case, assuming that the space V carries a volume form, the invariants  $\Delta_E$  are ratios of the  $\mathcal{A}$ -coordinates  $A_f$  [FG1], assigned to the faces of the graph  $\Gamma_m$ . Precisely, each edge E is shared by two faces  $f^+$  and  $f^-$ , where  $f^+$  is to the left of the  $\circ \to \bullet$  oriented edge E, and  $\Delta_E = A_{f^+}/A_{f^-}$ .

5. A generalization for surfaces glued from triangles. Theorem 1.2 and 1.6 have the following immediate generalizations. Take a finite collection of triangles, glue them edge-to-edge in an arbitrary way, and delete the vertices of the glued triangles. The obtained "surface"  $\mathcal{S}$  is singular along the edges where more then two triangles meet. It might be non-orientable. Its boundary is the union of the edges which are not glued to other edges. It has corners, also referred to as special points, and punctures provided by the deleted vertices. The punctures correspond to those deleted vertices whose neighborhoods are topologically non-trivial. We call the union of the corners and punctures marked points. These are precisely the points which has been deleted. It comes with a triangulation  $\mathcal{T}$ .

Let us consider the following groupoids.

- 1. Groupoid  $\mathcal{X}_{m,\mathcal{S}}$  of local systems of m-dimensional R-vector spaces on  $\mathcal{S}$ , equipped with a flag in a fiber near each special point s, invariant under the monodromy around s, such that for each triangle of  $\mathcal{T}$  the triple of flags obtained by moving the flags near the vertices to one point is generic.
- 2. Groupoid  $\mathcal{A}_{m,\mathcal{S}}$  of local systems of m-dimensional R-vector spaces on  $\mathcal{S}$ , equipped with a <u>decorated</u> flag in a fiber near each special point s, invariant under the monodromy s, such that for each triangle of  $\mathcal{T}$  the triple of flags obtained by moving the flags near the vertices to one point is generic.

We call the local systems with the data as in 1) framed local systems, and as in 2) the decorated ones.

If S = t is just a triangle,  $\mathcal{X}_{m,t}$  is the groupoid of triples of flags in generic position an m-dimensional R-vector space. Indeed, any local system on a triangle is trivial, so the triple of flags at the vertices is the only data left. Similarly,  $\mathcal{A}_{m,t}$  is the groupoid of triples of decorated flags in generic position in an m-dimensional R-vector space.

The graphs  $\Gamma'_m$  are glued into a bipartite graph  $\Gamma_m(\mathcal{T})$ : gluing the triangles along the sides we glue the matching black vertices on the sides.

**Theorem 1.8.** Denote by S such a possibly singular and possibly unorientable triangulated surface.

- 1) The groupoid  $\mathcal{X}_{m,\mathcal{S}}$  is equivalent to the groupoid of flat line bundles on the graph  $\Gamma_m(\mathcal{T})$ .
- 2) The groupoid  $\mathcal{A}_{m,S}$  is equivalent to the groupoid of flat line bundles on the graph  $\Gamma_m(\mathcal{T})$ , trivialized on each ziq-zaq path.

Proof. 1) Take triangles with the vertices (a, b, c) and (b', c', d) and glue them along the bc-sides, matching the b and c vertices, getting a rectangle abcd. The  $GL_m$ -graphs  $\Gamma_{abc}$  and  $\Gamma_{b'c'd}$  assigned to these triangles are glued into a  $GL_m$ -graph  $\Gamma_{abcd}$  for the rectangle abcd. Given flat line bundles  $\mathcal{L}_{abc}$  and  $\mathcal{L}_{b'c'd}$  on the graphs  $\Gamma_{abc}$  and  $\Gamma_{b'c'd}$ , Theorem 1.2 provides generic triples of flags (A, B, C) and (B', C', D) in m-dimensional R-vector spaces  $V_{abc}$  and respectively  $V_{b'c'd}$ . Each of the two spaces is decomposed into a direct sum of m lines, provided by the pair of flags BC and B'C'. The sets of these lines are identified. So there is a collection of isomorphisms of R-vector spaces  $i_{bc}: V_{abc} \longrightarrow V_{b'c'd}$  which identifies the lines and the flags  $\{B, C\}$  and  $\{B', C'\}$ . These isomorphisms form a right  $(R^{\times})^m$ -torsor. Indeed, an isomorphism  $i_{bc}$  is defined uniquely up to the composition with an R-linear map  $\varphi'$  preserving the lines assigned to the flags B', C'. So we get an  $(R^{\times})^m$ -torsor of configurations of four flags A, B, C, D. Given such an isomorphism  $i_{bc}$ , there is a canonical way to glue the flat line bundles  $\mathcal{L}_{abc}$  and  $\mathcal{L}_{b'c'd}$  into a flat line bundle  $\mathcal{L}_{abcd}$  on the graph  $\Gamma_{abcd}$ . The obtained line bundles form a  $(R^{\times})^m$ -torsor. Conversely, we can start from gluing the flat line bundles  $\mathcal{L}_{abc}$  and  $\mathcal{L}_{b'c'd}$ . This way we get a canonical equivalence between the two torsors. Performing this equivalence for each pair of glued triangles, we prove the claim.

- 2) The same arguments plus Theorem 1.6 provide flat line bundles on the graphs  $\Gamma_m(\mathcal{T})$  trivialized on zig-zag paths.
- **6.** The non-commutative Laurent phenomenon. Take a generic framed local system  $\mathcal{V}$  of m-dimensional R-vector spaces on  $\mathcal{S}$ . Denote by  $\mathcal{L}$  the associated flat line bundle on the graph  $\Gamma_m(\mathcal{T})$ . Take an edge e of the triangulation  $\mathcal{T}$ . Recall the reconstruction functor  $\mathcal{R}'$ . The local system  $V := \mathcal{R}'(\mathcal{L})$  is isomorphic to  $\mathcal{E}$  by Theorem 1.2 and Proposition 1.5. Its fiber  $V'_e$  over e is the direct sum of the fibers  $\mathcal{L}_{\mathbf{b_i}}$  of the flat line bundle  $\mathcal{L}$  over the  $\bullet$ -vertices  $\mathbf{b}_i$  on the edge e:

$$V_e' = \bigoplus_{\mathbf{b}_i} \mathcal{L}_{\mathbf{b}_i}.$$

So the monodromy of V along any closed path  $\alpha$  on  $\mathcal S$  interseting the edge e provides a linear map

$$M_{\alpha}: \bigoplus_{\mathbf{b}_i} \mathcal{L}_{\mathbf{b}_i} \longrightarrow \bigoplus_{\mathbf{b}_i} \mathcal{L}_{\mathbf{b}_i}.$$

It is described by the matrix elements  $\mu_{ij}: \mathcal{L}_{\mathbf{b}_i} \longrightarrow \mathcal{L}_{\mathbf{b}_j}$ .

Given a decorated local system  $\mathcal{F}$ , the lines  $\mathcal{L}_{\mathbf{b}_i}$  carry non-zero vectors. Therefore the monodromy is described by a matrix  $\mu_{ij}$  with the entries in  $R^{\times}$ . Recall that in this case there are elements  $\Delta_E \in R^{\times}$  assigned to the edges E of the bipartite graph  $\Gamma_m(\mathcal{T})$ , called the  $\mathcal{A}$ -coordinates of  $\mathcal{F}$ .

**Theorem 1.9.** The matrix elements  $\mu_{ij}$  of the monodromy of a framed local system V on S along a loop  $\alpha$  are finite signed sums of the monodromies of the associated flat line bundle  $\mathcal{L}$  on the graph  $\Gamma_m(\mathcal{T})$  along certain paths from  $\mathbf{b}_i$  to  $\mathbf{b}_j$  on the graph, homotopic to  $\alpha$ .

The matrix elements of the monodromy of a decorated local system  $\mathcal{F}$  on  $\mathcal{S}$  are finite signed sums of the products of the associated  $\mathcal{A}-$ coordinates or their inverses:

$$\mu_{ij} = \sum_{\gamma} \pm \Delta_{E_{\gamma,1}}^{\varepsilon_1} \cdots \Delta_{E_{\gamma,k}}^{\varepsilon_k}, \qquad \varepsilon_j \in \pm 1.$$
 (22)

The sum is over certain paths  $\gamma$  on the graph from  $\mathbf{b}_i$  to  $\mathbf{b}_j$ , and  $E_{\gamma,j}$  are the consecutive edges of the  $\gamma$ . The sign  $\varepsilon$  in  $\Delta_E^{\varepsilon}$  is determined by the direction of the edge E on the path  $\gamma$ : from  $\circ \to \bullet$ , or  $\bullet \to \circ$ .

*Proof.* The loop  $\alpha$  intersects edges  $e_1, e_2, ..., e_n$  of  $\mathcal{T}$ , ordered by the intersection points  $e_i \cap \alpha$  on the  $\alpha$ . The reconstruction functor  $\mathcal{R}'$  for the triangle provides explicit isomorphisms defined by formula (17):

$$V_e \xrightarrow{\mathcal{R}'} V_{e_1} \xrightarrow{\mathcal{R}'} \dots \xrightarrow{\mathcal{R}'} V_{e_n} \xrightarrow{\mathcal{R}'} V_e.$$

The monodromy  $M_{\alpha}$  is their composition. This proves the first claim. The second follows from this since for the decorated local system each map  $\mathcal{R}'$  is described explicitly by a matrix, whose entries are given by the signed sums over paths, and each path provides a monomial in  $\mathcal{A}$ -coordinates or their inverses.  $\square$ 

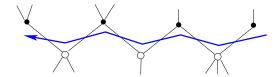

Figure 8: A zig-zag on a bipartite graph, naturally oriented, and pushed out of the vertices.

Formula (22) is the non-commutative analog of the Laurent phenomenon for the monodromies.

When S is smooth and orientable, it is the surface glued from triangles into a decorated surface. Recall that a decorated surface S is a smooth oriented surface with a finite set of punctures inside and special points on the boundary, considered modulo isotopy. We assume that each boundary component has special points. A marked point is either a special point or a puncture.

We described generic framed/decorated local systems on a decorated surface  $\mathbb S$  via flat line bundles on the graph  $\Gamma_m(\mathcal T)$  for an ideal triangulation  $\mathcal T$  of  $\mathbb S$ . The mapping class group  $\Gamma_{\mathbb S}$  of  $\mathbb S$  acts by automorphisms of the space of local systems on  $\mathbb S$ , preserving the data at the marked points. We want to see how its action affects the above description. For this we need, for each  $\gamma \in \Gamma_{\mathbb S}$ , to relate the flat line bundles on the graphs  $\Gamma_m(\mathcal T)$  and  $\Gamma_m(\gamma(\mathcal T))$  corresponding to a generic local system on  $\mathbb S$ . Recall that a flip of a triangulation  $\mathcal T$  is a new triangulation  $\mathcal T'$  obtained by flipping the diagonal in one of the rectangles of  $\mathcal T$ . Since any two ideal triangulations are related by a sequence of flips, we have to solve the problem for a single flip. However if m > 2, a flip  $\mathcal T \to \mathcal T'$  results in a complicated transformation of the bipartite graphs  $\Gamma_m(\mathcal T) \to \Gamma_m(\mathcal T')$ . In [G] this transformation was decomposed into a composition of  $(m-1)^2$  elementary moves, known as two by two moves, of bipartite graphs of special kind, called  $\mathrm{GL}_m$ -graphs. So to relate the flat line bundles on the graphs  $\Gamma_m(\mathcal T)$  and  $\Gamma_m(\mathcal T')$  assigned to a generic framed/decorated local system on  $\mathbb S$  we generalize the main constructions of Section 1.1 to  $\mathrm{GL}_m$ -graphs. We discuss this in Sections 1.2 - 1.3.

## 1.2 Describing noncommutative local systems on surfaces

1. Spectral description of local systems on decorated surfaces via  $GL_m$ -graphs. For a decorated surface S there are two more flexible variants of Theorem 1.8 described below.

Let us recall few more facts about bipartite ribbon graphs, see also Section 5.1. A bipartite ribbon graph  $\Gamma$  gives rise to a decorated surface  $\mathbb{S}_{\Gamma}$  homotopy equivalent to  $\Gamma$ , obtained by gluing the ribbons. The graph  $\Gamma$  is embedded to the surface  $\mathbb{S}_{\Gamma}$ . A bipartite ribbon graph  $\Gamma$  gives rise to the conjugate bipartite ribbon graph  $\Gamma^*$ , obtained by altering the cyclic order of the edges at each  $\bullet$ -vertex. The surface  $\Sigma_{\Gamma}$  associated with the ribbon graph  $\Gamma^*$  is called the *spectral surface*. The collection  $\mathcal{Z}_{\Gamma}$  of oriented zig-zags of  $\Gamma$ , being pushed to  $\mathbb{S}_{\Gamma}$ , is well defined up to an isotopy. It allows to reconstruct the graph  $\Gamma$ . There are elementary transformations of bipartite ribbon graphs, called the two by two move.

A special type of bipartite graphs on  $\mathbb{S}$ , called  $\mathrm{GL_m}$ -graphs,  $m \geq 2$ , was introduced in [G]. They are characterized the way their zig-zags relate to the marked points. Precisely, (on a finite cover of  $\mathbb{S}$ ,) each zig-zag path goes around a single marked point on  $\mathbb{S}$ , and for each marked point s on  $\mathbb{S}$  there are exactly m zig-zag paths going around s. There is also a technical condition: no parallel bigons, see Figure 30.

Any ideal triangulation  $\mathcal{T}$  of  $\mathbb{S}$ , i.e., a triangulation with vertices at the marked points, gives rise to a  $GL_m$ -graph  $\Gamma_m(\mathcal{T})$  on  $\mathbb{S}$ . The  $GL_m$ -graphs  $\Gamma_m(\mathcal{T})$  and  $\Gamma_m(\mathcal{T}')$  assigned to the triangulations  $\mathcal{T}$  and  $\mathcal{T}'$  related by a flip of an edge can be connected by a sequence of two by two moves [G, Section 1.2].

A flat connection on an R-vector bundle induces a flat connection on the bundle of flags in its fibers.

**Definition 1.10.** A framed R-local system on a decorated surface S is a local system of finite dimensional R-vector spaces on S with a framing, given by flat sections of the restriction of the associated local system

of flags to the neighborhoods of the marked points.

**Theorem 1.11.** Let  $\Gamma$  be a  $GL_m$ -graph on a decorated surface  $\mathbb{S}$ , homotopy equivalent to  $\mathbb{S}$ , and  $\Sigma_{\Gamma}$  the spectral surface. Consider the following two groupoids:

- 1. Groupoid  $\mathcal{X}_{m,\mathbb{S}}$  of m-dimensional framed R-local systems on  $\mathbb{S}$ ;
- 2. Groupoid  $Loc_1(\Sigma_{\Gamma})$  of flat R-line bundles with connection on the spectral surface  $\Sigma_{\Gamma}$ .

Then there is a canonical open embedding<sup>5</sup>

$$\varphi_{\Gamma}: \operatorname{Loc}_{1}(\Sigma_{\Gamma}) \hookrightarrow \mathcal{X}_{m,\mathbb{S}}.$$
 (23)

The spectral surface  $\Sigma_{\Gamma}$  is homotopy equivalent to the graph  $\Gamma^*$ . So local systems on  $\Sigma_{\Gamma}$  are the same thing as local systems on the graph  $\Gamma^*$ . Note also that  $\Gamma = \Gamma^*$ . So there are canonical identifications

$$Loc_1(\Sigma_{\Gamma}) = Loc_1(\Gamma) = Loc_1(\Gamma^*). \tag{24}$$

Theorem 1.11 is proved in Section 7. The main idea is outlined in Section 1.3. It is based on the interpretation of each of the moduli spaces as a moduli space of *admissible dg-sheaves*. We use only a combinatorial description of admissible dg-sheaves, and elementary linear algebra, valid over a skew field.<sup>6</sup>

An elementary proof of a slightly weaker version of Theorem 1.11 is given in Theorem 5.4. Namely, we restrict to bipartite graphs which can be obtained by compositions of two by two moves from the graphs  $\Gamma_m(\mathcal{T})$  related to ideal triangulations, and give a simple construction of a functor assigning to a generic local system on  $\mathbb{S}$  a flat line bundle on the spectral surface  $\Sigma_{\Gamma}$ , providing a birational equivalence of the groupoids 1) and 2). Theorem 5.4 is all we need to describe explicitly the action of the mapping class group  $\Gamma_{\mathbb{S}}$  on the space of all framed local systems, discussed in the end of Section 1.1.

We show in Section 2.1 that any two by two move of bipartite ribbon graphs  $\mu: \Gamma \to \Gamma'$  gives rise to a non-commutative birational isomorphism  $\mu$  intertwining  $\varphi_{\Gamma}$  and  $\varphi_{\Gamma'}$ :

$$\mu: \operatorname{Loc}_1(\Gamma) \xrightarrow{\sim} \operatorname{Loc}_1(\Gamma').$$
 (25)

Therefore the natural action of the mapping class group of  $\mathbb{S}$  on the non-commutative moduli space  $\mathcal{X}_{m,\mathbb{S}}$  can be presented by compositions of birational isomorphisms (25).

Theorems 1.11 & 5.4 are closely related to the Gaiotto-Moore-Neitzke abelianization of vector bundles with flat connection on a Riemann surface via flat line bundle on the associated spectral curve [GMN].<sup>7</sup>

When R = K is commutative and  $\Gamma$  is a bipartite ribbon graph,  $\operatorname{Loc}_1(\Gamma)(K) = H^1(\Gamma, K^*)$ . Any loop  $\gamma$  on  $\Gamma$  defines a function on  $\operatorname{Loc}_1(\Gamma)$  given by the monodromy around the loop. Given a  $\operatorname{GL}_m$ -graph  $\Gamma \subset \mathbb{S}$ , the birational isomorphism (23) is nothing else but the cluster Poisson coordinate system on the space  $\mathcal{X}_{\operatorname{GL}_m,\mathbb{S}}$  of framed  $\operatorname{GL}_m$ -local systems on  $\mathbb{S}$  [G]. The  $\operatorname{PGL}_m$ -version of the story was done in [FG1].

Going back to a skew field R, the monodromy of a flat R-line bundle over a circle is described by an element of  $R^*$  modulo conjugation. So it does not give rise to a well defined rational function on

<sup>&</sup>lt;sup>5</sup>In particular, they are birationally equivalent.

<sup>&</sup>lt;sup>6</sup>We do not use constructions involving tensor products of vector spaces. The latter are not defined as R-vector spaces. <sup>7</sup>Following the request of the referee, let us elaborate this. Gaiotto-Moore-Neitzke [GMN] start from the spectral cover  $\pi: \Sigma_{\rm an} \to C$  related to a point of the Hitchin base of a Riemann surface C, and assign to it a spectral network on C. Given a flat line bundle  $\mathcal{L}$  on  $\Sigma_{\rm an}$ , they define, using the spectral network, an n-dimensional flat bundle  $\mathcal{E}$  on C. The construction in general involves infinite formal sums. When n > 2, it is not clear (and probably not always true) that the topological spectral covers corresponding to ideal webs can be realized as the analytic ones  $\Sigma_{\rm an}$ . However when the ideal web comes from an ideal triangulation of S, [GMNs] defines the spectral network bypassing the spectral curve, and the flat bundle  $\mathcal{E}$  is given then by a finite sum construction. It is not clear how to do this for more general ideal webs. In particular, it is not clear how to prove using this approach that flips of triangulations give rise to non-commutative cluster transformations, or to describe the action of the mapping class group of S on the non-commutative moduli space  $\mathcal{X}_m$  S.

non-commutative space. The analogs of cluster Poisson coordinate systems are non-commutative birational isomorphisms (23). The analogs of cluster Poisson transformations are non-commutative birational isomorphisms (25) intertwining the ones (23).

Let us introduce the non-commutative analog of the Poisson structure in a more general setup of non-commutative cluster Poisson varieties assigned to arbitrary bipartite ribbon graphs. Here Theorem 5.4 is sufficient for the development of the theory, and all its applications discussed in the paper.

2. Non-commutative cluster Poisson varieties. In the commutative case, a cluster Poisson variety is defined by starting from a quiver, and considering a collection of quivers related by sequences of mutations. We assign to each quiver a cluster Poisson torus, and glue them by using birational isomorphisms between the tori assigned to mutations.

A special class of quivers and mutations is provided by bipartite ribbon graphs and two by two moves between them [GK]. A cluster Poisson torus assigned to a bipartite graph  $\Gamma$  is given by  $H^1(\Gamma, \mathbb{G}_m) = \text{Loc}_1(\Gamma)$ . It has the following Poisson structure. Recall that the graphs  $\Gamma$  and  $\Gamma^*$  coincide - only their ribbon structures are different. On the other hand, the graph  $\Gamma^*$  is homotopy equivalent to the spectral surface  $\Sigma_{\Gamma}$ . So the intersection pairing on  $H_1(\Sigma_{\Gamma}, \mathbb{Z})$  induces a Poisson structure on  $H^1(\Gamma, \mathbb{G}_m)$ . Birational transformations (25) in the commutative case are cluster Poisson transformations.

In the non-commutative case, the analogs of quivers are bipartite ribbon graphs. The analogs of mutations are two by two moves. The non-commutative cluster Poisson torus assigned to a bipartite graph  $\Gamma$  is the moduli space  $\text{Loc}_1(\Gamma)$ . Consider a collection of bipartite ribbon graphs  $\{\Gamma'\}$  obtained by a sequence of two by two moves from the original graph  $\Gamma$ . Then groupoids  $\text{Loc}_1(\Gamma')$  are related by birational transformations (25). We show in the end of Section 2.1 that they satisfy the pentagon relations. Therefore we get a non-commutative analog of a cluster Poisson variety  $\mathcal{X}_{|\Gamma|}$  by gluing them according to these birational isomorphisms.

To introduce a non-commutative analog of the Poisson structure, consider the free abelian group  $L(\Gamma)$  generated by the loops on the graph  $\Gamma$ . It has a Lie algebra structure, provided by the bipartite ribbon structure on  $\Gamma$ . Since the graphs  $\Gamma$  and  $\Gamma^*$  coincide, there is another Lie bracket on the same vector space, provided by the bipartite ribbon structure of  $\Gamma^*$ . We denote by  $L(\Gamma^*)$  the latter Lie algebra.

The commutative algebra given by the symmetric algebra of  $L(\Gamma^*)$  has a unique commutative Poisson algebra structure extending the Lie bracket on  $L(\Gamma^*)$ . It is the non-commutative analog of the Poisson structure on  $H^1(\Gamma, \mathbb{G}_m)$ . We prove that it is preserved by non-commutative birational isomorphisms (25).

We conclude that the moduli spaces of m-dimensional R-local systems on decorated surfaces carry a non-commutative cluster Poisson variety structure.

Another class of interesting examples are non-commutative Grassmannians, parametrising the m-dimensional subspaces in a standard N-dimensional R-vector space, and their strata.

Finally, a few words about "non-commutative spaces". We say that X is a non-commutative space if for any skew field R there is a set X(R) of R-points, depending functorially on R. We say that X is a non-commutative stack if there is a non-commutative space  $\mathcal{X}$  such that for each skew field R the group  $\mathrm{GL}_n(R)$  acts on  $\mathcal{X}(R)$ , and  $X(R) := \mathcal{X}(R)/\mathrm{GL}_n(R)$ . For example, for the non-commutive space  $\mathrm{Loc}_m'(S)$  of m-dimensional local systems on a surface S, trivialized at a point  $x \in S$ , the  $\mathrm{Loc}_m'(S)(R)$  is the set of m-dimensional R-local systems on S, trivialized x. For the non-commutative stack  $\mathrm{Loc}_m(S)$  we have  $\mathrm{Loc}_m(S)(R) := \mathrm{Loc}_m'(S)(R)/\mathrm{GL}_m(R)$ . Non-commutative spaces/stacks in the paper, e.g. the ones  $\mathcal{X}_m(\mathbb{S})/\mathcal{A}_m(R)$  of framed/decorated m-dimensional local systems on a decorated surface  $\mathbb{S}$ , are understood this way.

Quite often one can define points of a non-commutative space X with values in the  $N \times N$  matrices  $\operatorname{Mat}_N(K)$  over a field K, and there are commutative spaces  $X_N$  such that  $X(\operatorname{Mat}_N(K)) = X_n(K)$ . For example,  $\operatorname{Loc}'_m(S)(\operatorname{Mat}_N(K)) := \operatorname{Loc}'_{mN}(S)(K)$ . Then a non-commutative space gives rise to a collection of classical moduli spaces parametrized by positive integers N. The non-commutative differential forms,

and symplectic or Poisson structures on such a non-commutative space X are defined so that they provide the usual differential forms, symplectic or Poisson structures on  $X(\text{Mat}_N(K))$ .

3. An application: Non-commutative cluster integrable systems. In Section 3, in the special case when  $\Gamma$  is a bipartite graph on a torus, we define a non-commutative generalisation of the dimer models, and a non-commutative analog of the dimer cluster integrable system constructed in [GK]. After the definition of cluster Poisson varieties is given, the construction of the Hamiltonians and the proof that they Poisson commute follows literally the commutative case. In the simplest example we recover the non-commutative integrable system from [K].

Since the dimer cluster integrable systems is equivalent to the relativistic Toda systems studied by Fock and Marshakov [FM], this also gives a non-commutative analog of the latter for  $GL_m$ .

**4. Spectral description of <u>twisted</u> local systems on decorated surfaces.** Let T'S be the complement to the zero section of the tangent bundle on S.

**Definition 1.12.** A twisted local system on  $\mathbb{S}$  is a local system on  $T'\mathbb{S}$  with the monodromy -1 around a loop generating  $\pi_1(T'_s\mathbb{S})$ .

We consider twisted framed local systems of R-modules of rank m on  $\mathbb{S}$ . Notice that the -1 monodromy around a loop generating  $\pi_1(T_s'\mathbb{S})$  preserves the framing flags.

**Theorem 1.13.** Let  $\Gamma$  be a  $GL_m$ -graph on a decorated surface  $\mathbb{S}$ , homotopy equivalent to  $\mathbb{S}$ , and  $\Sigma_{\Gamma}$  the spectral surface. Consider the following two groupoids:

- 1. Groupoid of m-dimensional <u>twisted</u> framed R-local systems on  $\mathbb{S}$ ;
- 2. Groupoid of flat twisted R-line bundles with connection on the spectral surface  $\Sigma_{\Gamma}$ .

Then there is a canonical open embedding of the second groupoid to the first.

Theorem 1.11 is the "untwisted" version of Theorem 1.13, with the underlined words "twisted" deleted. We can identify untwisted and twisted local systems on  $\Sigma_{\Gamma}$  since the obstruction lies in  $H^2(\Sigma_{\Gamma}, \mathbb{Z}/2\mathbb{Z}) = 0$ .

5. Non-commutative cluster  $\mathcal{A}$ -varieties. In the commutative set-up, cluster varieties come in pairs, as cluster Poisson varieties, and cluster  $K_2$ -varieties, also referred to as cluster  $\mathcal{A}$ -varieties [FG2]. Moreover, there are two dual variants of moduli spaces of local systems on decorated surfaces, which carry an equivariant cluster variety structure of either Poisson or  $K_2$ -flavor. We show that in the non-commutative set-up the story is similar. Let us discuss now the non-commutative cluster  $\mathcal{A}$ -varieties.

A bipartite ribbon graph  $\Gamma$  gives rise to a non-commutative torus  $\mathcal{A}_{\Gamma}$  - the moduli space of twisted flat R-line bundles on the associated spectral surface  $\Sigma_{\Gamma}$ , trivialized at the boundary. It comes with a canonical collection of  $\mathcal{A}$ -coordinates  $\{\Delta_E\}$ , parametrised by the edges of the graph  $\Gamma$ , and satisfying monomial relations parametrised by the vertices of  $\Gamma$ .<sup>8</sup> For a two by two move  $\mu: \Gamma_1 \longrightarrow \Gamma_2$ , we define in Section 4.1 a non-commutative birational isomorphism

$$\mu: \mathcal{A}_{\Gamma_1} \longrightarrow \mathcal{A}_{\Gamma_2}.$$
 (26)

It serves the role of a non-commutative cluster  $\mathcal{A}$ -transformation. We show that transformations (26) satisfy the pentagon relations. Therefore we can glue them into a non-commutative space  $\mathcal{A}_{|\Gamma|}$ , which we call a non-commutative cluster  $\mathcal{A}$ -variety.

<sup>&</sup>lt;sup>8</sup>Note that boundary components of the spectral surface  $\Sigma_{\Gamma}$  are in natural bijection with zig-zags on the original surface  $\Sigma_{\Gamma}$ . So this description match the one in subsection 3, except that now we can talk about the twisted flavor of the story.

We prove that a non-commutative cluster  $\mathcal{A}$ -variety carries a canonical non-commutative 2-form  $\Omega$ . Precisely, given a bipartite ribbon graph  $\Gamma$  we introduce a non-commutative 2-form  $\Omega_{\Gamma}$  on the torus  $\mathcal{A}_{\Gamma}$ . It has a simple expression in the cluster  $\mathcal{A}$ -coordinates. Birational isomorphisms (26) preserve them:

$$\mu^*\Omega_{\Gamma_2} = \Omega_{\Gamma_1}.$$

This feature of non-commutative cluster  $\mathcal{A}$ -varieties is quite non-trivial. Its proof Section 9 leads to a version of the Steinberg relation for non-commutative 2-forms, see Theorem 9.4. In the commutative case, we recover the 2-form associated with cluster algebras/cluster  $\mathcal{A}$ -varieties [GSV], [FG2].

Just as in the commutative case, there is a canonical map of non-commutative cluster varieties

$$p: \mathcal{A} \longrightarrow \mathcal{X}$$
.

It has Hamiltonian properties similar to the ones in the commutative case, where it is the projection along the null-foliation of the canonical 2-form on  $\Omega$  on A.

We stress that in sharp contrast with the commutative case, non-commutative cluster Poisson varieties do not carry any cluster coordinates. Therefore cluster Poisson considerations require new language.

On the other hand, the non-commutative cluster  $\mathcal{A}$ -varieties come with a canonical collection of functions. Although we refer to them as cluster  $\mathcal{A}$ -coordinates, unlike in the commutative case, cluster coordinates in each cluster are not independent; they satisfy certain monomial relations.

6. Spectral description of the non-commutative <u>decorated</u> local systems on S. In the commutative case there is the dual moduli space  $\mathcal{A}_{\mathrm{SL_m},S}$  parametrised twisted  $\mathrm{SL_m}$ -local systems on S equipped with a *decoration*: a choice of an invariant decorated flag near every marked point of S. It has a cluster A-variety structure [FG1], which is a geometric incarnation of the Fomin-Zelevinsky upper cluster algebras [FZI]. There are cluster A-coordinate systems on  $A_{\mathrm{SL_m},S}$  parametrised by ideal triangulations [FG1] or, more generally,  $\mathrm{SL_m}$ -graphs [G].

The noncommutative analog is the moduli space  $\mathcal{A}_{m,\mathbb{S}}$  parametrised twisted decorated rank m R-local systems on  $\mathbb{S}$ . Note that there is no non-commutative analog of  $\mathrm{SL}_{\mathrm{m}}$ . Its generic points parametrise twisted flat line bundles on the spectral surface  $\Sigma$  which are trivialized at the boundary of  $\Sigma$ . The trivilalisations allow to construct rational functions  $\Delta_E$  on the moduli space  $\mathcal{A}_{m,\mathbb{S}}$  parametrised by the edges E of the graph  $\Gamma$ . These functions are analogs of the cluster  $\mathcal{A}$ -coordinates. As we stressed above, the functions  $\Delta_E$  do not form a coordinate system: they satisfy non-trivial monomial relations. There is no natural way to select a subset of the generators. A similar phenomenon occurs already for the commutative moduli space  $\mathcal{A}_{\mathrm{GL}_{\mathrm{m}},\mathbb{S}}$  [G].

7. Berenstein-Retakh non-commutative cluster algebras related to surfaces. In Section 6 we show that in the case of two dimensional twisted decorated non-commutative local systems the obtained coordinate description recovers the non-commutative cluster functions decribed as ratios of  $2 \times 2$  quasideterminants by A. Berenstein and V. Retakh in [BR]. In our approach formulas for these functions were obtained by geometric considerations, which made their properties evident.

In general the functions  $\Delta_E$  on the moduli spaces  $\mathcal{A}_{m,\mathbb{S}}$  are ratios of the Gelfand-Retakh quasideterminants [GR]. This way we get a geometric approach to quasideterminants.

# 1.3 Non-commutative cluster varieties and stacks of admissible dg-sheaves

Given a bipartite ribbon graph  $\Gamma$ , we take stacks  $Loc_1(\Gamma')$ , where graphs  $\Gamma'$  are obtained from  $\Gamma$  by any sequences of two by two moves, and glue them via birational isomorphisms (25) into a space  $\mathcal{X}_{|\Gamma|}$ .

Then a question arises: can we assign to each bipartite ribbon graph  $\Gamma$  a finite stack  $\mathcal{M}_{|\Gamma|}^{\circ}$ , whose equivalence class is invariant under two by two moves, and which contains  $\operatorname{Loc}_1(\Gamma)$  as a Zariski open

substack? Equivalently, we want to have a Zariski open embedding of  $\mathcal{X}_{|\Gamma|}$  into an an priori defined stack:

$$\mathcal{X}_{|\Gamma|} \subset \mathcal{M}_{|\Gamma|}^{\circ}.$$
 (27)

To approach this question, we introduce stacks of admissible dg-sheaves on manifolds. This allows to answer the question in many interesting situations, discussed below, although not in full generality yet.

1. Admissible dg-sheaves. Given a cell complex C, we define in Section 7.1 a dg-category of dg-sheaves, a dg-version of the derived category of complexes of sheaves constructible for the stratification of C.

Recall that the microlocal support of a constructible complex of sheaves on a manifold X is a complex of sheaves on a conical Lagrangian in the cotangent bundle  $T^*X$  [KS]. A cooriented hypersurface in a manifold X gives rise to a Lagrangian in  $T^*X$ , and a Legendrian in its spherical bundle  $ST^*X$ . They are given, respectively, by the conormal vectors/rays in the direction specified by the coorientation.

Let  $\mathcal{H}$  be a collection of <u>smooth</u> cooriented hypersurfaces in a manifold X with <u>disjoint</u> Legendrians. We consider a subcategory of  $\mathcal{H}$ -supported dg-sheaves. These are dg-sheaves whose microlocal support is given by complexes supported at the zero section and Lagrangians assigned to the hypersurfaces of  $\mathcal{H}$ .

Then we consider a dg-subcategory of  $\mathcal{H}$ -admissible dg-sheaves. Its key features are the following.

- 1. Admissible dg-sheaves on a manifold X are concentrated in the degrees [0,1].
- 2. The microlocal support of an  $\mathcal{H}$ -admissible dg-sheaf is supported on the union of the zero section of  $T^*X$  and a Lagrangian  $T^*_{\mathcal{H}}X$ , given by the union of conormal bundles to the cooriented hypersurfaces of  $\mathcal{H}$ . For each component  $\mathcal{C}$  of  $\mathcal{H}$ , the microlocalisation along  $T^*_{\mathcal{C}}X$  can be identified with a local system on  $\mathcal{C}$ .
- 3. Stacks of  $\mathcal{H}$ -admissible dg-sheaves are invariant under deformations of  $\mathcal{H}$  on X, called below admissible isotopies, which keep each component of  $\mathcal{H}$  smooth, and their Legendrians disjoint.

We demonstrate property 3) directly in Section 7.2 in the dimension 2. We stess that we allow in the process of deformation non-transversal intersections, e.g. three lines intersecting in a point. Note that a smooth Hamiltonian isotopy of a Legendrian curve can develop a cusp, which we do not allow.

Note that according to [GKS], the derived category of all constructible sheaves with a given microlocal support is invariant under Legendrian isotopies. However this does not imply that admissible isotopies preserve  $\mathcal{H}$ -admissibility, and not all Legendrian isotopies preserve  $\mathcal{H}$ -admissibility.

Since local systems on the conormal bundle to a cooriented hypersurface are pull backs of local systems on the hypersurface, we abuse terminology by referring to them as local systems on the hypersurface. Therefore below we refer to the microlocal support on  $T_{\mathcal{H}}^*X$  as the Legendrian microlocal support.

Since  $\mathcal{H}$ -admissible dg-sheaves are concentrated in degrees [0,1], not all complexes of constructible sheaves with Legendrian microlocal support in  $T^*_{\mathcal{H}}X$  are  $\mathcal{H}$ -admissible. Stacks of  $\mathcal{H}$ -admissible dg-sheaves are of finite type, while stacks of complexes of constructible sheaves with the Legendrian microlocal support in  $T^*_{\mathcal{H}}X$  are not: the latter contain local systems on X placed in arbitrary degrees.

Let  $\Gamma$  be a bipartite ribbon graph. Denote by  $\mathcal{Z}_{\Gamma}$  the collection of oriented zig-zags on the decorated surface  $\mathbb{S}_{\Gamma}$  associated to  $\Gamma$ , well defined up to isotopy. Since the surface  $\mathbb{S}_{\Gamma}$  is oriented, zig-zags are cooriented. The complement  $\mathbb{S}_{\Gamma} - \mathcal{Z}_{\Gamma}$  is a union of domains of three types, depending on the orientation types of their boundary segments, see Figure 9 & Section 7.3.

**Lemma 1.14.** The stack  $Loc_1(\Gamma)$  of flat line bundles on a bipartite ribbon graph  $\Gamma$  is canonically equivalent to the stack of  $\mathcal{Z}_{\Gamma}$ -admissible dg-sheaves on  $\mathbb{S}_{\Gamma}$  satisfying the following conditions:

1. They are acyclic on mixed domains - note that this is an open condition.

<sup>&</sup>lt;sup>9</sup>The condition that a complex does not have cohomology in two neighboring degrees is an open condition. In particular the conditions that a complex is acyclic, or has a single non-trivial cohomology group, are open conditions. The latter are precisely the conditions we impose in Lemma 1.14.

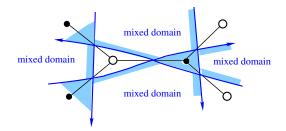

Figure 9: Zig-zag paths for a bipartite graph  $\Gamma$  on a surface  $\mathbb{S}$  cut the surface into  $\bullet$ ,  $\circ$ , and mixed domains. Each zig-zag path is coorientated by a shaded area to the right of the path.

2. Their Legendrian microlocal support is given by flat R-line bundles at every curve of  $\mathcal{Z}_{\Gamma}$ .

Our construction of the functor from the sheaves on the surface to flat line bundles on the graph  $\Gamma$  uses dg-sheaves: the connection on the line bundle on  $\Gamma$  is given by "homotopies between morphisms", absent in the classical description of the derived category. In the commutative setting, another construction of the functor follows from [STWZ].<sup>10</sup>

Denote by  $\mathcal{M}(\mathcal{H}, \mathbf{1})$  the stack of  $\mathcal{H}$ -admissible dg-sheaves on a surface satisfying property 2) of Lemma 1.14 for every curve of  $\mathcal{H}$ . It is a finite type stack. Then By Lemma 1.14 there is an embedding

$$Loc_1(\Gamma) \subset \mathcal{M}(\mathcal{Z}_{\Gamma}, \mathbf{1}).$$
 (28)

We define  $\mathcal{M}_{|\Gamma|}^{\circ}$  as the component of  $\mathcal{M}(\mathcal{Z}_{\Gamma}, \mathbf{1})$  containing  $Loc_1(\Gamma)$ . We show that in many interesting cases we get this way Zarisky open embeddings (27).

2. Examples of stacks of  $\mathcal{H}$ -admissible dg-sheaves. They include the stacks of Stokes data, which are the Betti side of stacks of flat connections with irregular singularities on Riemann surfaces, see Sections 8.1 - 8.2. This way we get non-commutative stacks of Stokes data stacks as well.

Let us explain how to get the Betti stack of framed flat connections in the case of regular singularities. For each marked point s of  $\mathbb{S}$ , in a small punctured at s disc/half disc, consider m non intersecting and non selfintersecting circles/arcs ending on the boundary, cooriented out of s. Denote by  $\mathcal{I}_{\mathbb{S},m}$  their union, see Figure 10. Its isotopy class is determined uniquely by the surface  $\mathbb{S}$  and the integer m.

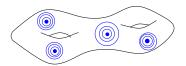

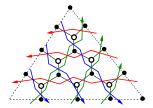

Figure 10: A collection of curves  $\mathcal{I}_{\mathbb{S},3}$  on a genus two surface  $\mathbb{S}$  with four punctures.

The following observation is an immediate corollary of the definition of  $\mathcal{I}_{\mathbb{S},m}$ -admissible dg-sheaves.

**Lemma 1.15.** The stack  $\mathcal{X}_{\mathbb{S},m}$  of m-dimensional R-local systems on a decorated surface  $\mathbb{S}$  with complete filtrations near marked points is canonically equivalent to the stack of  $\mathcal{I}_{\mathbb{S},m}$ -admissible dg-sheaves on  $\mathbb{S}$  satisfying the following two conditions:

<sup>&</sup>lt;sup>10</sup>Namely, as was pointed out by the referee, in [STWZ] a Lagrangian L with the topology of the spectral surface of  $\Gamma$  is constructed; it fills the Legendrian of the zig-zag curves. Let  $\widetilde{L}$  be its Legendrian lift to  $J^1(S) \subset T^*S \times R^1$ . By Guillermou's quantization theorem [G12], [GKS], Loc<sub>1</sub>(L) can be identified with the sheaves which are zero at  $S \times -\infty$ , and pure of microlocal rank one along the conormal to  $\widetilde{L}$ . Restricting the sheaves to  $S \times \infty$  we get the functor.

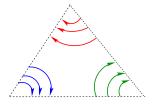

Figure 11: Zig-zag paths on the bipartite graph  $\Gamma_3$  on the left can be admissibly deformed to concentric arcs around the vertices, shown on the right.

1. They are acyclic near the marked points.

2. Their microlocal support is the union of the zero section and flat R-line bundles at every curve of  $\mathcal{I}_{\mathbb{S},m}$ .

Lemmas 1.14 - 1.15 provide a non-commutative cluster Poisson structure on the stack  $\mathcal{X}_{\mathbb{S},m}$ . Indeed, by Lemma 1.15,  $\mathcal{X}_{\mathbb{S},m}$  is realized as the substack  $\mathcal{M}_0(\mathcal{I}_{\mathbb{S},m},\mathbf{1}) \subset \mathcal{M}(\mathcal{I}_{\mathbb{S},m},\mathbf{1})$  given by condition 1):

$$\mathcal{X}_{\mathbb{S},m} = \mathcal{M}_0(\mathcal{I}_{\mathbb{S},m}, \mathbf{1}) \subset \mathcal{M}(\mathcal{I}_{\mathbb{S},m}, \mathbf{1}).$$

Consider a bipartite  $GL_m$ -graph  $\Gamma$  on  $\mathbb{S}$ . By its very definition [G], there is an admissible isotopy of the collection  $\mathcal{Z}_{\Gamma}$  of its zig-zags to the collection of curves  $\mathcal{I}_{\mathbb{S},m}$ , see Figure 11:

$$i_{\Gamma}: \mathcal{Z}_{\Gamma} \longrightarrow \mathcal{I}_{\mathbb{S},m}.$$
 (29)

By property 3), isotopy (29) provides an equivalence of the related stacks of  $\mathcal{H}$ -admissible dg-sheaves

$$i_{\Gamma*}: \mathcal{M}(\mathcal{Z}_{\Gamma}, \mathbf{1}) \xrightarrow{\sim} \mathcal{M}(\mathcal{I}_{\mathbb{S},m}, \mathbf{1}).$$

By Lemma 1.14, the stack  $Loc_1(\Gamma)$  is realized as the Zariski open substack  $\mathcal{M}_{mix=0}(\mathcal{Z}_{\Gamma}, \mathbf{1})$  of  $\mathcal{M}(\mathcal{Z}_{\Gamma}, \mathbf{1})$  defined by condition 1):

$$\operatorname{Loc}_1(\Gamma) = \mathcal{M}_{\operatorname{mix}=0}(\mathcal{Z}_{\Gamma}, \mathbf{1}) \subset \mathcal{M}(\mathcal{Z}_{\Gamma}, \mathbf{1}).$$

Indeed, the acyclicity on mixed domains in Lemma 1.14 is an open condition. Acyclicity on mixed domains implies acyclicity near marked points since marked points are contained in the mixed domains, see Figure 11 when  $\mathbb S$  is a triangle. The general case reduces to this since we can get a  $\mathrm{GL}_m$ -graph on  $\mathbb S$  by amalgamating the graphs  $\Gamma_m$  on triangles of an ideal triangulation of  $\mathbb S$ . Therefore  $i_{\Gamma *}$  induces an open embedding  $j_{\Gamma}: \mathcal{M}_{\mathrm{mix}=0}(\mathcal{Z}_{\Gamma}, \mathbf{1}) \subset \mathcal{M}_0(\mathcal{I}_{\mathbb S,m}, \mathbf{1})$ . Summarising, we get the commutative diagram

$$\operatorname{Loc}_{1}(\Gamma) = \mathcal{M}_{\operatorname{mix}=0}(\mathcal{Z}_{\Gamma}, \mathbf{1}) \xrightarrow{\subset} \mathcal{M}(\mathcal{Z}_{\Gamma}, \mathbf{1})$$

$$\downarrow_{\Gamma} \mid \cap \qquad \downarrow_{\Gamma_{*}} \mid \sim \qquad (30)$$

$$\mathcal{X}_{\mathbb{S},m} = \mathcal{M}_{0}(\mathcal{I}_{\mathbb{S},m}, \mathbf{1}) \xrightarrow{\subset} \mathcal{M}(\mathcal{I}_{\mathbb{S},m}, \mathbf{1}).$$

In particular, for any  $GL_m$ -graph  $\Gamma$  on  $\mathbb{S}$ , we have, as was promised in (27),

$$\mathcal{M}^0_{|\Gamma|} = \mathcal{X}_{\mathbb{S},m}.\tag{31}$$

For example, the bipartite graph  $\Gamma_m$  on Figure 11 allows to recover the whole stack of all triples of flags as the stack  $\mathcal{M}^0_{|\Gamma_m|}$ , rather than describing its generic part, as Theorem 1.2 does.

The stack  $\operatorname{Loc}_1(\Gamma)$  is a non-commutative Poisson torus. So open embeddings  $j_{\Gamma}: \operatorname{Loc}_1(\Gamma) \subset \mathcal{X}_{\mathbb{S},m}$  for bipartite  $\operatorname{GL}_m$ -graphs  $\Gamma$  on  $\mathbb{S}$  define a non-commutative cluster Poisson structure on the stack  $\mathcal{X}_{\mathbb{S},m}$ . The action of the mapping class group  $\Gamma_{\mathbb{S}}$  of  $\mathbb{S}$  preserves the class of  $\operatorname{GL}_m$ -graphs on  $\mathbb{S}$ . Any two of them are related by a sequence of two by two moves [G], providing admissible isotopies of their zig-zags.

Therefore we get a  $\Gamma_{\mathbb{S}}$ -equivariant non-commutative cluster Poisson structure on the stack  $\mathcal{X}_{\mathbb{S},m}$ .

In Section 8.3 we describe stacks of framed Stokes data via admissible dg-sheaves, and show that

Stacks of (framed) Stokes data are shadows of non-commutative (framed) stacks of Stokes data: (32)

**Theorem 1.16.** For any stack of framed Stokes data S on a decorated surface S, there is a non-commutative stack  $S^{nc}$  over  $Spec(\mathbb{Z})$ , whose restriction to commutative fields is the stack S. Assume that  $S \neq S^2 - \{\infty\}$ . Then the stack  $S^{nc}$  carries a non-commutative cluster Poisson structure equivariant under the wild mapping class group.

The argument is based on the observation that, similarly to Lemma 1.15, stacks of Stokes data can be realized as stacks of  $\mathcal{L}$ -admissible dg-sheaves on  $\mathbb{S}$  vanishing near the punctures, where  $\mathcal{L}$  is the union of certain local collection of curves  $\mathcal{L}_p$  around the punctures p.

When  $\mathbb{S} = S^2 - \{0, \infty\}$ , with one regular and one irregular point, these stacks are identified birationally with cluster Poisson varieties assigned in [FG3] to the cyclic closures of elements of the braid semigroup. Thanks to [FG3, Section 3.10], their quivers are described by bipartite graphs. The general case is reduced to this one plus the regular triangle case. The case when  $\mathbb{S} = S^2 - \{\infty\}$  requires a different technology, and is not considered in the paper. Yet the result is true in this case as well.

3. Stacks of framed G-Stokes data, their cluster Poisson structure & quantization. Stacks of G-Stokes data provide the Betti realization of stacks of G-bundles with meromorphic connections with arbitrary singularities on a Riemann surface  $\Sigma$ . We introduce stacks of *framed* G-Stokes data, and prove that they carry a cluster Poisson structure, equivariant under the wild mapping class group action.

**Theorem 1.17.** Assume that  $\mathbb{S} \neq S^2 - \{\infty\}$ . For any split reductive group G over  $\mathbb{Q}$  with connected center, the stack of framed G-Stokes data on  $\mathbb{S}$  has a cluster Poisson structure, equivariant under the action of the wild mapping class group. Stacks of plain G-Stokes data carry compatible Poisson structures.

The Poisson nature of the moduli spaces of Stokes data was studied by P. Boalch [Bo11]. Theorems 1.17 - 1.18 are valid for a much larger class of *ideal* Legendrian links  $\mathcal{L}$ , see Section 8.2.

Theorem 1.17 is proved in Section 8.4 using the following key ingredients.

- 1. If  $\mathbb{S} = S^2 \{0, \infty\}$ , with one regular and one irregular point, the stacks of G-Stokes data are identified birationally with the cluster Poisson varieties assigned in [FG3] to the cyclic closures of certain elements of the braid semigroup  $\mathrm{Br}_{\mathrm{G}}^+$  related to G.
- 2. When S = t is a triangle, the cluster Poisson structure of the related space  $\mathcal{P}_{G,t}$  of configurations of triples of flags with pinnings was described in [GS19]. The key point is its cyclic invariance.
- 3. If  $S = S^2 \{\infty\}$ , the stacks of Stokes data are given by certain cyclically ordered configurations of flags. The cluster Poisson structure for sufficiently generic cyclic configurations follows from [GS19].

The general case is built from these ones, except for single irregular point - that is  $\mathbb{S} = S^2 - \{\infty\}$  - of rather degenerate type, which requires different technique, and is omitted.

Combining Theorem 1.17 with the cluster quantization machine [FG4], we get the following.

**Theorem 1.18.** Under the same assumptions as in Theorem 1.17, the stacks of G-Stokes data, plain or framed, admit a cluster Poisson quantization, equivariant under the wild mapping class group action.

Precisely, we apply the cluster quantization to the cluster Poisson space of framed G-Stokes data. Then we use the fact that forgetting the framing we get a map to the space of plane G-Stokes data, which is finite Galois map over a generic point. Its Galois group, given by a product of the Weyl groups of G, acts by cluster Poisson transformations. This allows us to pass to its invariants.

Theorem 1.18 completes the program of cluster quantization of the moduli spaces of flat connections on Riemann surfaces. In the regular case this was done in [FG1] for  $G = PGL_m$ , and in [GS19] in general.

4. Cluster A-varieties via stacks of admissible dg-sheaves. The analogs of cluster A-varieties in this set-up are given by stacks of (twisted)  $\mathcal{H}$ -admissible dg-sheaves with the following extra condition:

Local systems on all components of the microlocal support but the zero secion are trivialized. (33)

In particular, given a bipartite ribbon graph  $\Gamma$  we recover non-commutative cluster  $\mathcal{A}$ -varieties discussed in Section 1.2. Indeed, zig-zags on the surface  $\mathbb{S}_{\Gamma}$  match boundary curves on the spectral surface  $\Sigma_{\Gamma}$ . So the trivialization of the local systems on zig-zags on  $\mathbb{S}_{\Gamma}$ , describing the microlocal support of an admissible dg-sheaf, amounts to the trivialization of the local system on the spectral surface  $\Sigma_{\Gamma}$  on the boundary of  $\Sigma_{\Gamma}$ . The cluster  $\mathcal{A}$ -coordinates are assigned to the edges of  $\Gamma$ . They are obtained by comparing trivialisations of the local systems on the two boundary components by using the parallel transport along the canonical up to isotopy path connecting two boundary components.

**Remark.** The stacks of Stokes data are the geometric analogs of (families of) wildly ramified representations of the absolute Galois group, see [DMR]. So Theorem 1.18 should be useful in various flavors of the geometric quantum Langlands correspondence.

- 5. CY<sub>3</sub>-categories assigned to stacks of Stokes data. Description of the cluster Poisson structure on stacks of Stokes data via webs of zig-zags for certain bipartite graphs on the surface S has another important application. Recall that any bipartite graph gives rise to a canonical quiver with potential, which determines a combinatorially defined 3d CY  $A_{\infty}$ -category. The categories assigned to bipartite graphs related by two by two moves are equivalant. Therefore we arrive to a combinatorially defined 3d Calabi-Yau  $A_{\infty}$ -category assigned to any topological Stokes data  $(\mathcal{L}, d)$ . This category should describe the Fukaya category of the family of open complex CY threefolds assigned to the same data  $(\mathcal{L}, d)$ . This story in the regular case is described in [G]. The m=2 case is established in [BS], [S].
- **6. Comments.** Sections 7 and 8.3 are very closely related to the series of works of Shende-Treumann-Williams-Zaslow [STZ14], [STWZ], [STZ16], where they studied extensively, in the commutative setting, moduli spaces of rank one microlocal sheaves, including the ones related to bipartite surface graphs. They usually work with all constructible complexes of sheaves with given microlocal support rather than with finite type stacks of admissible ones. The restrictions on constructible sheaf categories to cut down to finite type stacks appear in [STZ14, Proposition 5.20], [STWZ, Proposition 5.20]. The admissibility condition appears in [STWZ, Proposition 5.3]. We use the very existence of the category of sheaves with given microlocal support [KS]. Other than that, our exposition is selfcontained and very elementary.

Our work also relates to some aspects of the Gao-Shen-Weng program [GSW]. In particular, non-commutative Plucker relations appear in their approach as well.

7. Acknowledgments. We are grateful to A. Berenstein and V. Retakh for useful discussions during the Summer 2011 in IHES, when the project was started, and all results of Section 1.1 were obtained. The hospitality of IHES was crucial for the developing of the project. We are very grateful to the referee, who read the paper very carefully, and made many comments, incorporated in the text, which improved and clarified the exposition.

A.G. was supported by the NSF grants DMS-1059129, DMS-1564385, DMS-1900743, DMS-2153059. He was a Fellow of the Simons Foundation in 2019 and 2023. He is grateful to the NSF, Simons Foundation, and IHES for hospitality and support.

 $<sup>^{11}\</sup>mathrm{We}$  are grateful to the referee for the last two comments.

# 2 Non-commutative cluster Poisson varieties

### 2.1 Two by two moves for non-commutative flat line bundles

Definition 2.2 for the action of two by two moves on flat line bundles is dictated by the example provided by configurations of four lines in a two dimensional space given in Section 1.1.

Recall that a ribbon graph is a graph with a cyclic order of the edges at every vertex. We allow ribbon graphs with external, that is 1-valent, vertices. A ribbon graph  $\Gamma$  is the same thing as a graph on a decorated surface  $\mathbb S$  which is homotopy equivalent to the graph.

A face path on  $\Gamma$  is a path turning right at every vertex. There is a bijection

$$\{\text{face paths on }\Gamma\} \longleftrightarrow \{\text{marked points on }S\}.$$
 (34)

Face intervals correspond to special points on  $\mathbb{S}$ . Face loops correspond to punctures of  $\mathbb{S}$ .

A zig-zag path on  $\Gamma$  is a path turning at every vertex either left or right, so that the left and right turns alternate. A zig-zag path on a bipartite ribbon graph  $\Gamma$  is oriented so that it turns right at the  $\circ$ -vertices, and turns left at the  $\circ$ -vertices, see Figure 29.

#### 1. Two by two moves.

**Definition 2.1.** Let  $\Gamma$  be a bipartite ribbon graph containing a subgraph  $\alpha$  on the left of Figure 12. A two by two move  $\mu_{\alpha}: \Gamma \to \Gamma'$  at  $\alpha$  produces a new bipartite graph  $\Gamma'$ , obtained by replacing  $\alpha$  by the subgraph  $\alpha'$  on the right of Figure 12.

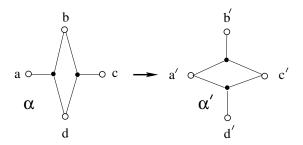

Figure 12: A two by two move  $\alpha \to \alpha'$ .

Given a two by two move  $\mu_{\alpha}: \Gamma \to \Gamma'$ , let us define a birational isomorphism of the moduli spaces of non-commutative flat line bundles on the graphs:

$$\mu_{\alpha}: \operatorname{Loc}_{1}(\Gamma) \longrightarrow \operatorname{Loc}_{1}(\Gamma').$$
 (35)

Consider a two by two move at  $\alpha$  shown on Figure 12:

$$\mu_{\alpha}: \Gamma \to \Gamma'$$
.

Let  $\alpha_0$  be the graph  $\alpha$  without the  $\circ$ -vertices, and similarly  $\alpha'_0$ . By the definition,  $\Gamma - \alpha_0 = \Gamma' - \alpha'_0$ . Denote by  $b \bullet a$  the arc t on the graph  $\alpha$  going from the  $\circ$ -vertex a to the  $\bullet$ -vertex, and then to the  $\circ$ -vertex b - see Figure 13. We use a similar notation for the graph  $\alpha'$ .

Starting from a flat line bundle L on  $\Gamma$ , we produce a new flat line bundle L' on  $\Gamma'$  as follows:

Let  $M_v: L_v \to L_v$  be the <u>minus</u> of the operator of counterclockwise monodromy around the simple loop on  $L_\alpha$ , acting at the fiber at v, see Figure 14.

• The restriction of L' to  $\Gamma' - \alpha'_0$  is defined as the restriction of L to  $\Gamma - \alpha_0$ .

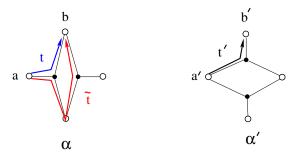

Figure 13: The two by two move action on the parallel transform:  $t' := t + \tilde{t} = (1 + M_b)t$ .

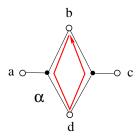

Figure 14:  $M_b$  is the negative of the counterclockwise monodromy around the loop  $\alpha$ .

• The restriction of L' to  $\alpha'$ , denoted by  $L_{\alpha'}$ , is defined in Definition 2.2.

**Definition 2.2.** Given a flat line bundle  $L_{\alpha}$  on the graph  $\alpha$ , we define a flat line bundle  $L_{\alpha'}$  on the graph  $\alpha'$  by setting the parallel transports along the arcs between the  $\circ$ -vertices on  $\alpha'$  to be:

$$t_{b' \bullet a'} := (1 + M_b) t_{b \bullet a}, \quad t_{c' \bullet b'} := t_{c \bullet b} (1 + M_b)^{-1}, t_{d' \bullet c'} := (1 + M_d) t_{d \bullet c}, \quad t_{a' \bullet d'} := t_{a \bullet d} (1 + M_d)^{-1}.$$
(36)

We glue the flat line bundle  $L_{\alpha'}$  to the restriction of the flat line bundle L to  $\Gamma - \alpha_0$ .

Let  $\widetilde{t}_{b,a}$  be "the other way around  $\alpha$ " parallel transport from a to b, see Figure 13. Then

$$t_{b'\bullet a'} \stackrel{(36)}{=} (1 + M_b) t_{b\bullet a} = t_{b\bullet a} (1 + M_a) = t_{b\bullet a} + \widetilde{t}_{b,a}. \tag{37}$$

It is a sum of the two different simple paths from a to b on  $\alpha$ .

**Lemma 2.3.** Monodromies of the local systems  $L_{\alpha}$  and  $L_{\alpha'}$  at each of the four  $\circ$ -points coinside:

$$M_a = M'_a, \quad M_b = M'_b, \quad M_c = M'_c, \quad M_d = M'_d.$$

*Proof.* We have

$$M'_{a} = t_{a' \bullet d'} t_{d' \bullet c'} t_{c' \bullet b'} t_{b' \bullet a'} = t_{a \bullet d} (1 + M_{d})^{-1} (1 + M_{d}) t_{d \bullet c} t_{c \bullet b} (1 + M_{b})^{-1} (1 + M_{b}) t_{b \bullet a} = t_{a \bullet d} t_{d \bullet c} t_{c \bullet b} t_{b \bullet a} = M_{a}.$$
(38)

Next, using  $M_a = M'_a$  we have

$$M_b' = t_{b' \bullet a'} M_a' t_{b' \bullet a'}^{-1} \stackrel{(36)}{=} t_{b \bullet a} (1 + M_a) M_a t_{b' \bullet a'}^{-1} = t_{b \bullet a} M_a (1 + M_a) t_{b' \bullet a'}^{-1}. \tag{39}$$

The first two equalities in (37) imply:

$$t_{b'\bullet a'}^{-1} \stackrel{(37)}{=} (t_{b\bullet a}(1+M_a))^{-1} = (1+M_a)^{-1}t_{b\bullet a}^{-1}.$$

Substituting this to (39), we get:

$$M_{b'} \stackrel{(39)}{=} t_{b \bullet a} M_a (1 + M_a) (1 + M_a)^{-1} t_{b \bullet a}^{-1} = t_{b \bullet a} M_a t_{b \bullet a}^{-1} = M_b.$$

The last two equalities follow from the cyclic shift by two symmetry of the picture.

Corollary 2.4. i) We can rewrite Definition 2.2 as follows:

$$t_{b'\bullet a'} := (1 + M_b)t_{b\bullet a}, \quad (1 + M_{c'})t_{c'\bullet b'} := t_{c\bullet b}, t_{d'\bullet c'} := (1 + M_d)t_{d\bullet c}, \quad (1 + M_{a'})t_{a'\bullet d'} := t_{a\bullet d}.$$

$$(40)$$

ii) One has  $\mu_{\alpha'} \circ \mu_{\alpha} = \operatorname{Id}$ .

*Proof.* i) Indeed, using Lemma 2.3,

$$t_{c' \bullet b'} = t_{c \bullet b} (1 + M_b)^{-1} = t_{c \bullet b} (1 + M_{b'})^{-1} \implies t_{c' \bullet b'} (1 + M_{b'}) = t_{c \bullet b} \implies (1 + M_{c'}) t_{c' \bullet b'} = t_{c \bullet b}.$$

The identity  $(1 + M_{a'})t_{a' \bullet d'} := t_{a \bullet d}$  follows by the cyclic shift by two symmetry.

- ii) Since the cyclic shift by one of  $\alpha'$  is isomorphic to  $\alpha$ , this implies  $\mu_{\alpha'} \circ \mu_{\alpha} = \mathrm{Id}$ .
- 2. Configurations of lines and two by two moves. To prove that transformations (35) satisfy the pentagon relations we need the following comparison result. Our construction from Section 1.1, see Theorems 1.2 and 1.8, provides a birational equivalence of groupoids, see Figure 12 for the notation:

{Quadruples of lines in a 2-dimensional 
$$R$$
-vector space  $V$ , at the  $\circ$ -vertices of  $\alpha$ }  $\longleftrightarrow$  {Flat  $R$ -line bundles on the graph  $\alpha$ }. (41)

**Proposition 2.5.** The transformation in Definition 2.2 is characterised by the condition that it commutes with equivalence (41), providing a commutative diagram

{Line bundles 
$$\mathcal{L}$$
 on  $\alpha$ }
$$\xrightarrow{Definition \ 2.2} \qquad \qquad \{Line \ bundle \ \mathcal{L}' \ on \ \alpha'\}$$

$$(42)$$

$$(A, B, C, D) \subset V$$

*Proof.* We start with a configuration of four generic lines (A, B, C, D) in V. We assign them to the  $\circ$ -vertices (a, b, c, d) of the graph  $\alpha$ , and to the  $\circ$ -vertices (a', b', c', d') of the graph  $\alpha'$ .

We abuse notation by denoting by the same letter a a vector in the line A, etc.

The two  $\bullet$ -vertices provide us five vectors in the lines (A,B,C,D), defined uniquely up to a common left  $R^*$ -factor by the condition that the sum of the three vectors at the  $\circ$ -vertices incident to any  $\bullet$ -vertex is zero. These are the vectors illustrated on the left of Figure 15:

$$(a, b, b_1, c, d),$$
 So  $b_1 = Xb, X \in \mathbb{R}^*.$ 

The counterclockwise monodromy around  $\alpha$  acts on any of them by the left multiplication by X. Indeed,

$$t_{a \bullet b}(b) = a, \quad t_{d \bullet a}(a) = d, \quad t_{c \bullet d}(d) = c, \quad t_{b_1 \bullet c}(c) = b_1 = Xb. \tag{43}$$

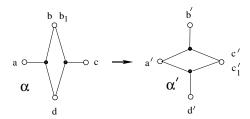

Figure 15: Calculating the two by two move for twisted configurations of lines in  $V_2$ .

There are similar five vectors in V related to the graph  $\alpha'$ , illustrated on the right in Figure 15:

$$(a', b', b'_1, c', d')$$
, So  $b'_1 = Yb'$ ,  $Y \in \mathbb{R}^*$ .

The counterclockwise monodromy around  $\alpha'$  acts on them as the left multiplication by Y. One summarises definition of these vectors by the following relations, one per each  $\bullet$ -vertex:

$$a+b+d=0$$
,  $d+c+b_1=0$ ;  $a'+b'+c'=0$ ,  $a'+d'+c'_1=0$ . (44)

Notice that  $b_1 = Xb$  and  $c'_1 = Yc'$ . So the equations read now as

$$a+b+d=0$$
,  $d+c+Xb=0$ ;  $a'+b'+c'=0$ ,  $a'+d'+Yc'=0$ .

These vectors are related as follows.

#### Lemma 2.6. One has

$$a' = a,$$
  $b' = (1 - X)b,$   $c' = -c,$   $d' = (1 - X^{-1})d.$  (45)

*Proof.* Each pair of the vectors  $(a', a), \ldots, (d', d)$  is collinear, so  $a' = \lambda_a a$ ,  $b' = \lambda_b b$ ,  $c' = \lambda_c c$ ,  $d' = \lambda_d d$ . Let us solve these equations. First, let us express c, d via a, b, and respectively c', d' via a', b':

$$d = -a - b$$
,  $c = (1 - X)b + a$ ,  $c' = -a' - b'$ ,  $d' = -(1 - Y)a' + Yb'$ .

Next, the identities  $\lambda_c c = c'$  and  $\lambda_d d = d'$  give:

$$\lambda_c((1-X)b+a) = -\lambda_a a - \lambda_b b, \qquad \lambda_d(a+b) = (1-Y)a - Y\lambda_b b.$$

Set  $\lambda_a = 1$ . Then we get the following equations:

$$\lambda_b = 1 - X$$
,  $\lambda_c = -1$ ,  $\lambda_d = 1 - Y$ ,  $-Y\lambda_b = \lambda_d$ 

From the first and last equations we see that  $Y = X^{-1}$ , and therefore we finally get

$$\lambda_a = 1, \quad \lambda_b = 1 - X, \quad \lambda_c = -1, \quad \lambda_d = 1 - X^{-1}.$$

Lemma 2.6 together with (43) implies

$$t_{b' \bullet a'} = (1 - X)t_{b \bullet a}, \quad t_{c' \bullet b'} = (1 - X^{-1})^{-1}t_{c \bullet b_1},$$
  

$$t_{d' \bullet c'} = (1 - X)t_{d \bullet c}, \quad t_{a' \bullet d'} = (1 - X^{-1})^{-1}t_{a \bullet d}.$$
(46)

Recall that  $M_a$  is the negative of the counterclockwise monodromy around  $\alpha$ .

Lemma 2.7. Formulas (46) are equivalent to formulas (36).

*Proof.* The first line in (36) is equivalent to the second one by the cyclic shift by two argument. The right formula in each line in (36) is equivalent to the left one, applied to the two by two move  $\mu_{\alpha'}: \Gamma' \to \Gamma$ . So we need to check only one of the four formulas in (36).

In the top left formula in (46) the variable X, by its definition, is the action of the counterclockwise monodromy along  $\alpha$  on the vector b. So it can be written as  $t_{b'\bullet a'} = (1 + M_b)t_{b\bullet a}$ , which is just the top left formula in (36).

Proposition 2.5 is proved  $\Box$ 

### 3. The pentagon relation.

**Theorem 2.8.** The fifth power of "two by two move followed by the non-trivial symmetry of the triangulated pentagon" for the two by two moves on Figure 16 acts as the identity on flat line bundles.

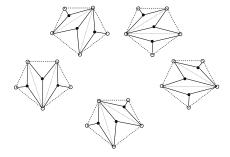

Figure 16: The pentagon relation.

*Proof.* Let  $\{\Gamma_i\}$ , where  $i \in \mathbb{Z}/5\mathbb{Z}$ , be the sequence of bipartite graphs on Figure 16. They are assigned to triangulations of the pentagon. The two by two move  $\Gamma_i \to \Gamma_{i+1}$  corresponds to a flip of the triangulation. For each of the graphs  $\Gamma_i$  there is an equivalence of groupoids

{Generic flat line bundles on the graph 
$$\Gamma_i$$
}  $\longleftrightarrow$  (47)

{Generic 5-tuples of lines in a two dimensional space V, assigned to  $\circ$ -vertices of a pentagon.}

Thanks to Lemma 2.7 the mutation of flat line bundles corresponding to a two by two move intertwines these equivalences. Indeed, a two by two move corresponding to a flip of a triangulation of the pentagon keeps intact one of the triangles of the triangulation, and does not affect the restriction of the flat line bundle to the graph inside of that triangle.

### 2.2 Non-commutative cluster Poisson varieties

In this Section we define a non-commutative analog of the Poisson algebra assigned to a bipartite ribbon graph in [GK]. The output is still a *commutative* Poisson algebra. We prove that two by two moves give rise to homomorphisms of Poisson algebras.

**1.** The algebra  $\mathcal{O}_{\Gamma}$ . Let  $\Gamma$  be a graph. An oriented loop  $\alpha$  on  $\Gamma$  is a continuous map  $\alpha: S^1 \to \Gamma$  of an oriented circle. A vertex of the loop  $\alpha$  is a point  $v \in S^1$  which is mapped to a vertex of  $\Gamma$ .

Denote by  $l_{\Gamma}$  the set of all oriented loops on  $\Gamma$ , considered modulo homotopy. Let

$$L_{\Gamma} := \mathbb{Z}[l_{\Gamma}]$$

be the free abelian group generated by the set  $l_{\Gamma}$ . Let  $\mathcal{O}_{\Gamma}$  be its symmetric algebra:

$$\mathcal{O}_{\Gamma} := S^*(L_{\Gamma}). \tag{48}$$

Let  $Loc_{N,\mathbb{C}}(\Gamma)$  be the moduli space of all N-dimensional complex vector bundles with connections on  $\Gamma$ . Denote by  $\mathcal{O}(Loc_{N,\mathbb{C}}(\Gamma))$  the algebra of regular functions on this space. There is a canonical map of commutative algebras

$$r: \mathcal{O}_{\Gamma} \longrightarrow \mathcal{O}(\operatorname{Loc}_{N,\mathbb{C}}(\Gamma)).$$
 (49)

Namely, a loop  $\alpha$  on  $\Gamma$  give rise to a function  $M_{\alpha}$  on  $\operatorname{Loc}_{N,\mathbb{C}}(\Gamma)$  given by the 1/N times the trace of the monodromy along the loop  $\alpha$ . Homotopic loops give the same function. Since  $\mathcal{O}_{\Gamma}$  is the free commutative algebra generated by the set  $l_{\Gamma}$ , the map  $\alpha \longmapsto M_{\alpha}$  extends uniquely to a homomorphism (49). The trivial loop maps to the unit.

**2.** The Goldman bracket for a ribbon graph  $\Gamma$ . Let us define a Lie bracket  $\{*,*\}_G$  on  $L_{\Gamma}$ . A valency m vertex v of a ribbon graph  $\Gamma$  gives rise to a free abelian group  $\mathbb{A}_v$  of rank m-1, given by  $\mathbb{Z}$ -linear combinations of the oriented out of v edges  $\stackrel{\rightarrow}{E}_i$  at v, of total degree zero:

$$\mathbb{A}_v = \{ \sum n_i \stackrel{\rightarrow}{E}_i \mid \sum n_i = 0, \ n_i \in \mathbb{Z} \}.$$

It is generated by the "oriented paths"  $\overrightarrow{E}_i - \overrightarrow{E}_j$ , where  $-\overrightarrow{E}_j$  is the edge  $E_j$  oriented towards v.

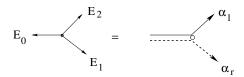

Figure 17: One has  $\delta_v(\alpha_r, \alpha_l) = \frac{1}{2}$ .

**Lemma 2.9.** Given a vertex v of  $\Gamma$ , there is a unique skew symmetric bilinear form

$$\delta_v: \mathbb{A}_v \wedge \mathbb{A}_v \longrightarrow \frac{1}{2}\mathbb{Z}$$

such that for any triple  $E_0, E_1, E_2$  of edges as in Figure 17 one has

$$\delta_v(\alpha_r \wedge \alpha_l) = \frac{1}{2}, \qquad \alpha_r := \stackrel{\rightarrow}{E_1} - \stackrel{\rightarrow}{E_0}, \quad \alpha_l := \stackrel{\rightarrow}{E_2} - \stackrel{\rightarrow}{E_0}.$$
 (50)

Take two loops  $\alpha$  and  $\beta$  on a ribbon graph  $\Gamma$ . Let  $\alpha_v \in \mathbb{A}_v$  be the element induced by the loop  $\alpha$  at the vertex v. Set  $\delta_v(\alpha, \beta) := \delta_v(\alpha_v, \beta_v)$ . Given a pair (v, w), where v is a vertex of  $\alpha$ , w is a vertex of  $\beta$ , and  $\alpha(v) = \beta(w)$ , consider a new loop  $\alpha \circ_{v=w} \beta$  obtained by starting at the vertex  $\beta(w)$ , going around the loop  $\beta$ , and then around the loop  $\alpha$ . We define a bracket  $\{\alpha, \beta\}_G$  by taking the sum over all such pairs of vertices (v, w):

$$\{\alpha, \beta\}_{G} := \sum_{v=w} \delta_{v}(\alpha, \beta) \cdot \alpha \circ_{v=w} \beta.$$

This is a ribbon graph version of the Goldman bracket. It is easy to check the following.

**Theorem 2.10.** The bracket  $\{*,*\}_G$  provides  $L_{\Gamma}$  with a Lie algebra structure. So it extends via the Leibniz rule to a Poisson bracket  $\{*,*\}_G$  on the commutative algebra  $\mathcal{O}_{\Gamma}$ . The map (49) is a map of Poisson algebras.

3. The Lie bracket  $\{*,*\}$  on the space  $L_{\Gamma}$  for a bipartite ribbon graph  $\Gamma$ . Let  $\Gamma$  be a bipartite ribbon graph. We apply the previous construction to the conjugate graph  $\Gamma^*$ .

**Definition 2.11.** i) The Lie bracket  $\{*,*\}$  on  $L_{\Gamma}$  is induced, via the isomorphism  $L_{\Gamma} = L_{\Gamma^*}$ , by the Lie bracket on  $L_{\Gamma^*}$ , for the conjugate graph  $\Gamma^*$ .

ii) It induces, via the Leibniz rule, a Poisson algebra structure  $\{*,*\}$  on  $\mathcal{O}_{\Gamma}$ .

Let  $\alpha, \beta$  be two oriented loops on a bipartite surface graph  $\Gamma$ . Then

$$\{\alpha, \beta\} = \sum_{v} \operatorname{sgn}(v) \delta_v(\alpha, \beta) \cdot \alpha \circ_v \beta.$$

The sum is over all vertices  $v \in \alpha \cap \beta$ , and  $\operatorname{sgn}(v) = 1$  for the  $\circ$ -vertex, and -1 for the  $\bullet$ -vertex.

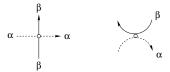

Figure 18: On the left:  $\delta_v(\alpha, \beta) = 1$ . On the right:  $\delta_v(\alpha, \beta) = 0$ .

To calculate the bracket  $\{\alpha, \beta\}$  between two loops  $\alpha, \beta$  on  $\Gamma$  we have the following two cases:

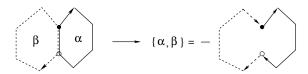

Figure 19: One has  $\{\alpha, \beta\} = -\alpha \circ \beta$ , where  $\alpha \circ \beta$  is the loop on the right.

- A vertex  $v \in \alpha \cap \beta$  is an isolated intersection point. Then its contribution is  $\pm 1, 0$  depending on the geometry of the intersection, as depicted on Figure 18.
- A vertex  $v \in \alpha \cap \beta$  lies on an edge  $vw \subset \alpha \cap \beta$ . Then its contribution is  $\pm 1, 0$  depending on the geometry of the intersection, as depicted on Figures 19, 20.

Figure 20: The total contribution of the  $\circ$  and  $\bullet$ -vertices to  $\{\alpha, \beta\}$  is zero.

Changing the orientation of the surface amounts to changing the sign of the Poisson bracket. Interchanging black and white we change the sign of the Poisson bracket.

Let us consider the formal completion  $\widehat{L}_{\Gamma}$  of  $L_{\Gamma}$  by the length of the loop on the graph  $\Gamma$ , counted as the total number of edges in the loop. Then we make sense of  $(1+M)^{-1}\gamma$  as  $(1-M+M^2-M^3+...)\gamma$ .

**Theorem 2.12.** Let  $\Gamma \to \Gamma'$  be a two by two move of bipartite ribbon graphs. Then the map induced by Definition 2.2 is a Lie algebra homomorphism of completed Lie algebras:

$$\mu_{\Gamma \to \Gamma'}: \widehat{L}_{\Gamma} \longrightarrow \widehat{L}_{\Gamma'}.$$

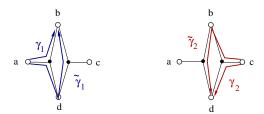

Figure 21: The sum of the contributions of the edges  $\bullet b$  and  $\bullet d$  to  $\{\gamma_1, \widetilde{\gamma}_2\} + \{\widetilde{\gamma}_1, \gamma_2\}$  is zero. Thus  $\{\gamma_1, \widetilde{\gamma}_2\} + \{\widetilde{\gamma}_1, \gamma_2\} = 0$ . One has  $\{\widetilde{\gamma}_1, \widetilde{\gamma}_2\} = 0$  since the paths are enter and exit at the common edges  $b \bullet$  and  $d \bullet$  in the same direction. So  $\{\gamma_1 + \widetilde{\gamma}_1, \gamma_2 + \widetilde{\gamma}_2\} = \{\gamma_1, \gamma_2\}$ .

*Proof.* Denote by  $\gamma_{b \bullet a}$  a loop on  $\Gamma$  containing the segment  $t_{b \bullet a}$ , etc. Consider the following three identities:

$$\{\gamma_{b'\bullet a'}, \gamma_{d'\bullet c'}\} = \{\gamma_{b\bullet a}, \gamma_{d\bullet c}\},$$

$$\{\gamma_{b'\bullet a'}, \gamma_{c'\bullet b'}\} = \{\gamma_{b\bullet a}, \gamma_{c\bullet b}\},$$

$$\{\gamma_{b'\bullet a'}, \gamma_{c'\bullet b'}\} = \{\gamma_{b\bullet a}, \gamma_{c\bullet b}\}.$$
(51)

Theorem 2.12 follows from them. Indeed, we have twelve identities like this to check. Using the skew-symmetry of the Poisson bracket, we reduce their number to six. These six can be reduced to the three identities (51): two identities are reduced by the rotation by 180° of the graph, and one by changing the plane orientation. Relation 3) in (51) is reduced to 1) by changing the plane orientation. Let us check identities 1) and 2).

1) We have the following, where the first equality is Definition (36), and the second is explained on Figure 21:

$$\{\gamma_{b'\bullet a'}, \gamma_{d'\bullet c'}\} = \{(1+M_b)\gamma_{b\bullet a}, (1+M_d)\gamma_{d\bullet c}\} \stackrel{\text{Fig}}{=} 21 \{\gamma_{b\bullet a}, \gamma_{d\bullet c}\}.$$

2) The second boils down to

$$\{(1+M_b)\gamma_{b\bullet a}, (1+M_c)^{-1}\gamma_{c\bullet b}\} \stackrel{?}{=} \{\gamma_{b\bullet a}, \gamma_{c\bullet b}\}.$$

$$(52)$$

П

So we need to prove that

$$\{M_b \gamma_{b \bullet a}, (1 - M_c^{-1} + M_c^2 - \dots) \gamma_{c \bullet b}\} \stackrel{?}{=} \{\gamma_{b \bullet a}, (M_c^{-1} - M_c^2 + M_c^3 - \dots) \gamma_{c \bullet b}\}.$$
 (53)

This is checked by using the following general identity, where  $X_{c \bullet b}$  is a loop containing the segment  $c \bullet b$ :

$$\{M_b\gamma_{b\bullet a}, X_{c\bullet b}\} = \{\gamma_{b\bullet a}, M_cX_{c\bullet b}\}.$$

This identity proved by a calculation illustrated on Figure 22.

Corollary 2.13. A two by two move gives rise to a birational isomorphism of Poisson algebras:

$$\mu_{\Gamma \to \Gamma'} : \widehat{\mathcal{O}}_{\Gamma} \longrightarrow \widehat{\mathcal{O}}_{\Gamma'}.$$

Conclusion. Groupoids  $Loc_1(\Gamma)$  assigned to bipartite graphs  $\Gamma$  and related by birational transformations (35) form a non-commutative analog of a cluster Poisson variety, with the Poisson bracket on the algebra (48) given by Definition 2.11.

# 3 Dimers and non-commutative cluster integrable systems

In Section 3 we apply the general results about non-commutative cluster Poisson varieties from previous Sections to produce non-commutative cluster integrable systems, which in the commutative case were studied in [GK]. Section 3 will not be used anywhere in the rest of the paper.

$$\{ \begin{array}{c} \\ \\ \\ \\ \\ \end{array}, \begin{array}{c} \\ \\ \\ \end{array} \\ = \begin{array}{c} \\ \\ \\ \end{array} \\ + \cdots$$

Figure 22: Calculating the Poisson brackets  $\{M_b\gamma_{b\bullet a}, X_{c\bullet b}\}$  and  $\{\gamma_{b\bullet a}, M_cX_{c\bullet b}\}$  we get the same result.

**1. Dimer covers.** A dimer cover of a bipartite graph  $\Gamma$  is a subset of edges of  $\Gamma$  such that each vertex is the endpoint of a unique edge in the dimer cover. Given a dimer cover M, we assign to each edge E of  $\Gamma$  the weight  $\omega_M(E) \in \{0,1\}$  such that  $\omega_M(E) = 1$  if and only if the edge E belongs to M. Let [E] be the edge E oriented as  $\bullet \to \circ$ . Then we get a 1-chain

$$[M] := \sum_E \omega_M(E)[E].$$

Here the sum is over all edges. We define sgn(v) := -1 for the  $\bullet$ -vertex v, and sgn(v) := 1 for the  $\circ$ -vertex. The condition that M is a dimer cover just means that

$$d[M] = \sum_{v} \operatorname{sgn}(v)[v].$$

Here the sum is over all vertices v of  $\Gamma$ . So if  $M_1, M_2$  are dimer covers,  $[M_1] - [M_2]$  is a 1-cycle.

- 2. Zig-zag paths revisited. Recall that a zig-zag  $\gamma$  on a bipartite ribbon graph  $\Gamma$  is oriented so that it turns right at the  $\circ$ -vertices, and turns left at the  $\bullet$ -vertices. For every edge there are exactly two zig-zag paths containing the edge. They traverse the edge the opposite ways.
- 3. A reference dimer cover  $\Phi$  for a bipartite graph on a torus [GK]. We consider from now bipartite graphs  $\Gamma$  on a torus T. A bipartite graph  $\Gamma$  on a torus is minimal if it does not have parallel bigons, see the left picture on Figure 30. Homology classes of oriented zig-zag paths on a bipartite graph  $\Gamma \subset \Gamma$  form a collection of vectors  $e_1, ..., e_n$  of the rank two lattice  $H_1(\Gamma, \mathbb{Z})$ . We order them cyclically by the angle they make with a given direction. Their sum is zero. So they are oriented sides of a convex polygon  $N \subset H_1(\Gamma, \mathbb{Z})$ , called the Newton polygon of  $\Gamma$ . The set  $\{e_1, ..., e_n\}$  is identified with the set of primitive edges of the boundary  $\partial N$  of N. Alternatively, N is the convex hull of  $0, e_1, e_1 + e_2, ..., e_1 + ... + e_{n-1}$ .

Let X be the set of circular-order-preserving maps

$$\alpha: \{e_1, \dots, e_n\} \to \mathbb{R}/\mathbb{Z}. \tag{54}$$

Let E be an edge of  $\Gamma$ . Denote by  $z_r$  (respectively  $z_l$ ) the zig-zag path containing E in which the  $\circ$ -vertex of E precedes (respectively follows) the  $\bullet$ -vertex. Then a map  $\alpha$  provides a function

$$\varphi_{\alpha} = \varphi : \{ \text{Edges of } \Gamma \} \longrightarrow \mathbb{R}, \qquad \varphi(E) := \alpha_r - \alpha_l.$$
 (55)

Here we use the identification of zig-zag loops with their homology classes  $e_i$ . Then  $\alpha_r$  (respectively  $\alpha_l$ ) is the evaluation of the map  $\alpha$  on the zig-zag path  $z_r$  (respectively  $z_l$ ) crossing the edge E, and  $\alpha_r - \alpha_l$  denotes the length of the counterclockwise arc on  $S^1 = \mathbb{R}/\mathbb{Z}$  from  $\alpha_l$  to  $\alpha_r$ .

**Theorem 3.1.** [GK, Theorem 3.3] For any map  $\alpha \in X$ , the function  $\varphi_{\alpha}$  satisfies

$$d\varphi_{\alpha} = \sum_{v} \operatorname{sgn}(v)[v].$$

Take a map  $\alpha$  which sends all  $e_i$  to 0 and assigns 1 to the arc between  $e_i$  and  $e_{i+1}$ , and 0 to all other arcs. Then  $\varphi_{\alpha}$  is a dimer cover of  $\Gamma$ . We denote it by  $\Phi$ . It corresponds to a vertex of the Newton polygone, perhaps a degenerate one, i.e. located on a side.

**4. The commuting Hamiltonians.** Since M and  $\Phi$  are perfect matchings, the 1-cycle  $[M] - [\Phi]$  is a union of non-intersecting and nonselfintersecting loops. Considered modulo homotopy on the graph  $\Gamma$ , it defines an element

$$(M) := [M] - [\Phi] \in L(\Gamma).$$

**Definition 3.2.** Let  $\Gamma$  be a bipartite graph on a torus. The non-commutative partition function  $\mathcal{P}_{\Phi}$  is an element of  $L(\Gamma)$  given as the sum over all dimer covers M of  $\Gamma$ 

$$\mathcal{P}_{\Phi} := \sum_{M} \operatorname{sgn}(M)(M). \tag{56}$$

The element  $[M] - [\Phi]$  defines a class in  $H_1(T, \mathbb{Z})$ , denoted by  $h_T(M)$ . The set of homology classes for different dimer covers M of  $\Gamma$  coincides with the set of internal points of a shift of the Newton polygon N. Take the sum over the dimer covers M with the same homology class a:

$$H_a := \sum_{h_{\mathcal{T}}(M)=a} (M) \in L(\Gamma). \tag{57}$$

Furthermore, for any nonzero integer n, we define a new element

$$H_{na} \in L(\Gamma)$$
.

Namely, if n > 0, it is obtained by travelling n times each loop of  $H_a$ . If n < 0, we reverse the orientations of the loops of  $H_a$ , and then travel each obtained loop |n| times.

**Definition 3.3.** The elements  $H_{na}$  are the Hamiltonians of the dimer system.

**Remark.** A map  $\alpha$  related to another vertex of the Newton polygon leads to another collection of Hamiltonians which differ from  $\{H_a\}$  by a sum of zig-zag loops, which lies in the center of the Poisson algebra  $\mathcal{O}(\Gamma)$ . Therefore the Hamiltonian flows do not depend on the choice of  $\alpha$ , and on each symplectic leaf any two collections of Hamiltonians differ by a common factor.

**Theorem 3.4.** Let  $\Gamma$  be a minimal bipartite graph on a torus  $\Gamma$ . Then the Hamiltonians  $H_{na}$  commute under the Lie bracket on  $L(\Gamma)$ . Therefore they Poisson commute in  $\mathcal{O}(\Gamma)$ .

*Proof.* We prove that  $\{H_a, H_b\} = 0$ . The proof almost literally follows the proof of [GK, Theorem 3.7]. For the convenience of the reader we indicate the main steps. The claim that  $\{H_{na}, H_{mb}\} = 0$  follows from this.

Take a pair of matchings  $(M_1, M_2)$  on  $\Gamma$ . Let us assign to them another pair of matchings  $(\widetilde{M}_1, \widetilde{M}_2)$  on  $\Gamma$ . Since  $[M_1] - [M_2]$  is a 1-cycle, and  $M_1, M_2$  are dimer covers, it is a disjoint union of non-itersecting and non-selfintersecting loops. So  $[M_1] - [M_2]$  is a disjoint union of:

- 1. homologically trivial on the torus loops,
- 2. homologically non-trivial loops,
- 3. edges shared by both matchings.

For every edge E of each homologically trivial loop we switch the label of E: if E belongs to a matching  $M_1$  (respectively  $M_2$ ), we declare that it will belong to a matching  $\widetilde{M}_2$  (respectively  $\widetilde{M}_1$ ). For all other edges we keep their labels intact. Switching the labels of a homologically trivial loop we do not change the homology classes  $[M_1] - [\Phi]$ ,  $[M_2] - [\Phi]$ . Clearly  $\widetilde{M}_i = M_i$ .

Lemma 3.5. [GK, Lemma 3.8] One has

$$\{(M_1), (M_2)\} + \{(\widetilde{M}_1), (\widetilde{M}_2)\} = 0.$$
(58)

*Proof.* Let us write (58) as a sum of the local contributions corresponding to the vertices v of  $\Gamma$ , and break it in three pieces as follows:

$$\varepsilon(\mu_1, \mu_2) + \varepsilon(\widetilde{\mu}_1, \widetilde{\mu}_2) = \left(\sum_{v \in \mathcal{E}_1} + \sum_{v \in \mathcal{E}_2} + \sum_{v \in \mathcal{E}_3}\right) \left(\delta_v(\mu_1, \mu_2) + \delta_v(\widetilde{\mu}_1, \widetilde{\mu}_2)\right).$$

Here  $\mathcal{E}_1$  (respectively  $\mathcal{E}_2$  and  $\mathcal{E}_3$ ) is the set of vertices which belongs to the homologically trivial loops (respectively homologically non-trivial loops, double edges).

For any  $v \in \mathcal{E}_1$  we have  $\delta_v(\mu_1, \mu_2) + \delta_v(\widetilde{\mu}_1, \widetilde{\mu}_2) = 0$  since the elements  $l_v(\mu_1) \in \mathbb{A}_v$  provided by  $\mu_i$  coincides with the  $l_v(\widetilde{\mu}_2)$ , and similarly  $l_v(\mu_2) = l_v(\widetilde{\mu}_1)$ . So the first sum is a sum of zeros.

The third sum is also a sum of zeros by the skew symmetry of the bracket.

It remains to prove that

$$\sum_{v \in \mathcal{E}_2} \left( \delta_v(\mu_1, \mu_2) + \delta_v(\widetilde{\mu}_1, \widetilde{\mu}_2) \right) = 0.$$

Let  $\gamma$  be an oriented loop on  $\Gamma$ . The bending  $b_v(\gamma;\varphi)$  of the function  $\varphi$  at a vertex v of  $\gamma$  is

$$b_v(\gamma;\varphi) = \sum_{E \in R_v} \varphi(E) - \sum_{E \in L_v} \varphi(E) \in \mathbb{R}.$$

Here  $R_v$  (respectively  $L_v$ ) is the set of all edges sharing the vertex v which are on the right (respectively left) of the oriented path  $\gamma$ . Lemma 3.5 now follows from Lemma 3.6 below.

**Lemma 3.6.** [GK, Lemma 3.9] For any simple topologically nontrivial loop  $\gamma$ , and for any  $\alpha \in X$ , see (54), the corresponding function  $\varphi_{\alpha}$  satisfies,

$$\sum_{v \in \gamma} b_v(\gamma; \varphi_\alpha) = 0.$$

<sup>12</sup>Contrary to this, switching the labels of homologically non-trivial loops in  $[M_1] - [M_2]$ , we do change the homology classes  $[M_i] - [\Phi]$ .

# 4 Non-commutative cluster A-varieties

# 4.1 Non-commutative cluster A-varieties from bipartite ribbon graphs

Convention. Dealing with <u>twisted</u> local systems on a decorated surface  $\mathbb{S}$ , we alter  $\mathbb{S}$  by cutting out a little disc near each marked point m on  $\mathbb{S}$ . Abusing notation, we denote the obtained surface by  $\mathbb{S}$ . The tangent vectors to each boundary component of  $\mathbb{S}$ , positively oriented for the boundary orientation of  $\mathbb{S}$ , form a homotopy (semi)circle  $S_m^1$  in the bundle of non-zero tangent vectors to  $\mathbb{S}$ . We perform a similar procedure with the marked points on the spectral curve  $\Sigma$ . Talking about a flat section of a twisted local system near a marked point m of  $\mathbb{S}$  or  $\Sigma$ , we mean a flat section of its restriction to the (semi)circle  $S_m^1$ .

The definition of a framed local system on a decorated surface in Definition 1.10 easily extends to the case of a twisted framed local system on  $\mathbb{S}$ . So by the monodromy of a twisted local system near a puncture we mean the monodromy of its restriction to the oriented homotopy circle near the puncture.

Figure 23: An edge E of a ribbon graph  $\Gamma$  determines two faces of  $\mathbb{S}_{\Gamma}$ , denoted  $f_E^+$  and  $f_E^-$ . There is a canonical homotopy class of path  $p_E$ , connecting boundary components  $f_E^+$  and  $f_E^-$ , shown by a blue arc.

Pick a vector field tangent to the boundary of each face of a decorated surface, following the boundary orientation, see Figure 23. A trivialization of a twisted flat line bundle  $\mathcal{L}$  on the surface at the boundary is given by a choice of a non-zero section of the fiber of  $\mathcal{L}$  over the tangent boundary vector field. Recall the surface  $\mathbb{S}_{\Gamma}$  for a ribbon graph  $\Gamma$ , and the spectral surface  $\Sigma_{\Gamma}$  for a bipartite ribbon graph  $\Gamma$ . Given a bipartite ribbon graph  $\Gamma$ , consider the groupoid, defined in either of the following two ways:

$$\mathcal{A}_{\Gamma} := \{ \text{Twisted flat line bundles on the spectral surface } \Sigma_{\Gamma}, \text{ trivialized at the boundary} \}.$$

$$= \{ \text{Twisted flat line bundles on the surface } \mathbb{S}_{\Gamma}, \text{ trivialized at the zig-zag strands} \}.$$
(59)

These definitions are equivalent since there are canonical identifications:

$$\Gamma = \Gamma^*, \quad \Sigma_{\Gamma} = \mathbb{S}_{\Gamma^*}, \quad \{\text{zig-zags on } \mathbb{S}_{\Gamma}\} = \{\text{boundary components of } \Sigma_{\Gamma}\}.$$

Let us give a coordinate description of the non-commutative tori  $\mathcal{A}_{\Gamma}$  in terms of the  $\mathcal{A}$ -coordinates.

#### 1. A-coordinates on ribbon graphs.

**Definition 4.1.** Let  $\Gamma$  be a ribbon graph. The A-coordinates on  $\Gamma$  are the elements  $\{\Delta_E \in R^*\}$  assigned to the oriented edges E of  $\Gamma$ , satisfying the following monomial relations:

• Let E be an oriented edge, and  $\overline{E}$  the same edge with the opposite orientation. Then

$$\Delta_E \Delta_{\overline{E}} = -1. \tag{60}$$

• Let  $E_1, ..., E_n$  be the edges incident to any vertex v of  $\Gamma$ , oriented out of the vertex v, whose order is compatible with their cyclic order. Then

$$\Delta_{E_1} \Delta_{E_2} \dots \Delta_{E_n} = -1. \tag{61}$$

Calling the elements  $\Delta_E$  "coordinates" is an abuse of terminology since they are not independent. We use the name  $\mathcal{A}$ -decorated ribbon graph for a ribbon graph with a collection of  $\mathcal{A}$ -coordinates.

**Lemma 4.2.** Given a ribbon graph  $\Gamma$ , the A-coordinates on  $\Gamma$  parametrise the isomorphism classes of twisted flat line bundles on the surface  $\mathbb{S}_{\Gamma}$ , trivialized at the boundary.

*Proof.* We start from a twisted line bundle on the oriented decorated surface  $\mathbb{S}_{\Gamma}$ . An edge E of  $\Gamma$  determines two faces  $f_E^+$  and  $f_E^-$  of  $\mathbb{S}_{\Gamma}$ . There is a canonical homotopy class of path  $p_E$ , connecting boundary components  $f_E^+$  and  $f_E^-$ , see Figure 23. The parallel transport along the  $p_E$  acts on the trivializations  $s_E^\pm$  at the boundary components  $f_E^\pm$  as follows, defining elements  $\Delta_E \in R^*$ :

$$\operatorname{par}_{p_E}: s_E^+ \longrightarrow \Delta_E s_E^-, \quad \Delta_E \in \mathbb{R}^*.$$
 (62)

Going around any edge, or any vertex along the cyclic order at this vertex, as on Figure 23, we rotate the tangent vector by  $2\pi$ , getting both relations (60) and (61). For example, for a 3-valent vertex we get

$$s_{E_1}^+ \longrightarrow \Delta_{E_1} s_{E_1}^- = \Delta_{E_1} s_{E_2}^+ \longrightarrow \Delta_{E_1} \Delta_{E_2} s_{E_2}^- = \Delta_{E_1} \Delta_{E_2} s_{E_3}^+ \longrightarrow \Delta_{E_1} \Delta_{E_2} \Delta_{E_3} s_{E_3}^- = -\Delta_{E_1} \Delta_{E_2} \Delta_{E_3} s_{E_1}^+.$$
(63)

Here the arrows are induced by the parallel transports (62)  $\operatorname{par}_{p_{E_i}}$ ,  $i \in \mathbb{Z}/3\mathbb{Z}$ . The = signs mean canonical identifications provided by the parallel transport along the arcs  $\alpha_i$  between  $E_i$  to  $E_{i+1}$ , see Figure 23, identifying  $s_{E_i}^-$  with  $s_{E_{i+1}}^+$ . The – sign in the end results from the fact that going around the circle amounts to the monodromy -1.

Conversely, picking a section s over a tangent vector to a boundary component, and using elements  $\Delta_E$  satisfying the monomial relations (60) and (61), we recover the twisted flat line bundle on  $\mathbb{S}_{\Gamma}$ , trivialized at the boundary. Changing s we get an isomorphic object.

# **2.** Conventions on $\mathcal{A}$ -coordinates on <u>bipartite</u> ribbon graphs. Given a bipartite ribbon graph, its edges are orientated $\circ \longrightarrow \bullet$ .

Using this convention, the set of  $\mathcal{A}$ -coordinates on any bipartite ribbon graph can be given by a collection of elements  $\{\Delta_E\}$  assigned to *nonoriented* edges E, assuming their default  $\circ \longrightarrow \bullet$  orientation, subject to the following relations, where *antycyclic* means the order opposite to the cyclic order:

The cyclic product of the elements on the edges sharing any  $\circ$ -vertex is equal to -1.

The antycyclic product of the elements on the edges sharing any  $\bullet$ -vertex v is  $(-1)^{\operatorname{val}(v)-1}$ .

Indeed, given a  $\bullet$ -vertex v, we have, using  $\Delta_{\overline{E}_i} = -\Delta_{E_i}^{-1}$ :

$$-1 = \prod_{i=1}^{\text{val}(v)} \Delta_{\overline{E}_i} = \prod_{i=1}^{\text{val}(v)} (-\Delta_{E_i}^{-1}) = (-1)^{\text{val}(v)} \left(\prod_{\text{val}(v)}^{i=1} \Delta_{E_i}\right)^{-1}.$$
 (65)

We apply this convention to the bipartite ribbon graph  $\Gamma^*$ , since the spectral surface where the twisted flat line bundles live, is  $\mathbb{S}_{\Gamma^*}$ .

Note that the bipartite ribbon graphs  $\Gamma$  and  $\Gamma^*$  are identical as graphs. Thinking about the graph  $\Gamma$ , e.g. drawing Figures, we depict the cyclic order on  $\Gamma$  as the counterclockwise one, and use below and in Section 6.3 a different convention:

The counterclockwise product of the elements on the edges sharing a  $\circ$ -vertex is equal to -1.

The counterclockwise product of the elements on the edges sharing a  $\bullet$ -vertex v is  $(-1)^{\text{val}(v)-1}$ .

Figure 24: The relations between the coordinates  $a_i$  and  $b_i$  are  $a_i a_{i+1} = (b_i b_{i+1})^{-1}$ ,  $\forall i \in \mathbb{Z}/4\mathbb{Z}$ . The cases i = 1, 3 are checked using Figure 25, the cases i = 2, 4 are similar.

# 3. The action of the two by two moves on A-coordinates on bipartite ribbon graphs. Recall the two by two moves of bipartite ribbon graphs, shown on Figure 24, see also Definition 2.1 below.

We define a birational isomorphism  $\mathcal{A}_{\Gamma} \longrightarrow \mathcal{A}_{\Gamma'}$  corresponding to a two by two move  $\Gamma \longrightarrow \Gamma'$ , serving the role of an elementary non-commutative A-cluster transformation. Let us assign the coordinates  $\{a_1, a_2, a_3, a_4\}$  and  $\{b_1, b_2, b_3, b_4\}$  to the internal edges on the graphs on Figure 24. Let us set

$$A_i = a_i a_{i+1} a_{i+2} a_{i+3}, \quad B_i = b_i b_{i+1} b_{i+2} b_{i+3}, \quad i \in \mathbb{Z}/4\mathbb{Z}.$$
 (67)

Consider the following transformation of the coordinates illustrated on Figure 24.

$$b_{1} = (1 + A_{3}^{-1})a_{3} = a_{3}(1 + A_{4}^{-1});$$

$$b_{2} = (1 + A_{4})^{-1}a_{4} = a_{4}(1 + A_{1})^{-1};$$

$$b_{3} = (1 + A_{1}^{-1})a_{1} = a_{1}(1 + A_{2}^{-1}).$$

$$b_{4} = (1 + A_{2})^{-1}a_{2} = a_{2}(1 + A_{3})^{-1};$$
(68)

To check the second equality in each line, note that  $a_i a_{i+1} a_{i+2} a_{i+3} a_{i+4}$  can be written in two ways:

$$a_i A_{i+1} = A_i a_i, \quad \forall i \in \mathbb{Z}/4\mathbb{Z};$$
 (69)

**Lemma 4.3.** The square of the two by two transformation (68) is the identity transformation.

*Proof.* This can be proved, by using the calculation of the coordinate transformations for the space  $\operatorname{Conf}_{4}^{\operatorname{df}}(V_2)$  of four decorated flags in Section 6.3. Since the direct check is easy, let us elaborate it.

Going from b's to a's, the analog of the first formula in (68) is the following formula:  $a_2 = b_4(1 + B_1^{-1})$ . Since  $B_1^{-1} = A_3$ , it is equivalent to  $b_4 = a_2(1 + A_3)^{-1}$ , which is indeed the case by (68).

Similarly, the analog of the second formula in (68) is the following:  $a_3 = b_1(1 + B_2)^{-1}$ . Since  $B_2^{-1} = A_4$ ,

it is equivalent to  $b_1 = a_3(1 + A_4^{-1})$ , which is indeed the case by (68).

**Lemma 4.4.** We have for any  $i \in \mathbb{Z}/4\mathbb{Z}$ :

$$b_i b_{i+1} = (a_i a_{i+1})^{-1},$$
  

$$A_i = B_{i+2}^{-1}.$$
(70)

*Proof.* We have

$$b_3b_4a_3a_4 = a_1(1+A_2^{-1})(1+A_2)^{-1}a_2a_3a_4 = a_1A_2^{-1}a_2a_3a_4 = A_2^{-1}A_2 = 1.$$

$$b_4b_1a_4a_1 = a_2(1+A_3)^{-1}(1+A_3^{-1})a_3a_4a_1 = a_2A_3^{-1}a_3a_4a_1 = A_3^{-1}A_3 = 1.$$
(71)

Since transformation formulas (68) are invariant under the cyclic shift  $i \mapsto i+2$ , the first formula in (70) follows. The second formula follows from the first.

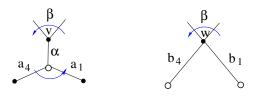

Figure 25: Using conventions (66), we have:  $a_4a_1\alpha = -1$ ,  $\alpha\beta = (-1)^{\text{val}(v)-1}$ ,  $b_4b_1\beta = (-1)^{\text{val}(v)}$ . Therefore  $a_4a_1 = (b_4b_1)^{-1}$ .

Figure 25 shows that formula (70) is consistent with the condition that the counterclockwise product of the coordinates around a  $\circ$ -vertex is 1, and around a  $\bullet$ -vertex is 1.

In Section 6.3 we define  $\mathcal{A}$ -coordinates for  $GL_2$ -graphs on a decorated surface  $\mathbb{S}$ , parametrising the moduli space  $\mathcal{A}_{2,\mathbb{S}}$ . The change of these  $\mathcal{A}$ -coordinates under a flip of a triangulation, studied in Section 6.3, motivated the definition of the  $\mathcal{A}$ -cluster coordinate transformations in (68).

**Theorem 4.5.** The coordinate transformation (68) for a two by two move satisfies the pentagon relation.

The proof can be obtained by a long calculation. Instead, we give a simple proof based on Theorem 6.5 in the end of Section 6.3.

Theorem 4.5 allows to define the non-comutative cluster variety  $\mathcal{A} = \mathcal{A}_{|\Gamma|}$  assigned to a bipartite ribbon graph  $\Gamma$ . Its clusters are parametrised by the bipartite ribbon graphs which can be obtained from  $\Gamma$  by two by two moves and the elementary transformations given by shrinking a two-valent vertex. We assign to each cluster the non-commutative torus  $\mathcal{A}_{\Gamma}$ , and glue them using the coordinate transformations (68) corresponding to the two by two moves. In Section 4.2 we will show that there is a canonical non-commutative 2-form  $\Omega_{\mathcal{A}}$  on the cluster variety  $\mathcal{A}$ , preserved by the two by two moves of the graphs.

# 4.2 The canonical 2-form on a non-commutative cluster A-variety.

**1. The non-commutative analog of**  $d \log(a_1) \wedge \ldots \wedge d \log(a_n)$ . Recall the cyclic envelope of the tensor algebra  $\mathrm{T}(V)$  of a graded vector space V. It is spanned by the elements  $(v_1 \otimes v_2 \otimes \ldots \otimes v_n)_{\mathcal{C}}$ , which are cyclically invariant:

$$(v_1 \otimes v_2 \otimes \ldots \otimes v_n)_{\mathcal{C}} = (-1)^{|v_1| \cdot (|v_2| + \ldots + |v_n|)} (v_2 \otimes v_3 \otimes \ldots \otimes v_n \otimes v_1)_{\mathcal{C}}.$$

Below, if it can not lead to a misunderstanding, we use a shorthand

$$v_1v_2\ldots v_n:=(v_1\otimes v_2\otimes\ldots\otimes v_n)_{\mathcal{C}}.$$

Given a graded algebra A, denote by  $\Omega_A$  the  $\mathbb{Q}$ -vector space<sup>13</sup> generated by the symbols da where  $a \in A$ , modulo the following relations:  $d(\alpha a + \beta b) = \alpha da + \beta db$ ,  $\alpha, \beta \in \mathbb{Q}$ , and the Leibniz rule  $d(ab) = da \cdot b + (-1)^{|a|} a \cdot db$ . Here |da| = |a| + 1, where  $|\cdot|$  denotes the degree in A. Denote by  $\mathcal{C}T(A \oplus \Omega_A)$  the cyclic envelope of the tensor algebra of the graded  $\mathbb{Q}$ -vector space  $T(A \oplus \Omega_A)$ .

**Definition 4.6.** Given any graded algebra A, and any invertible elements  $a_i \in A^{\times}$ , the cyclic product

$$\{a_1, \dots, a_n\} := da_1 \dots da_n a_n^{-1} \dots a_1^{-1} \in \mathcal{C}\mathrm{T}(A \oplus \Omega_A)$$

$$\tag{72}$$

is the noncommutative analog of  $d \log(a_1) \wedge \ldots \wedge d \log(a_n)$ .

For example, the non-commutative 2-form generalizing  $d \log(a) \wedge d \log(b)$  is given by:

$$\{a,b\} = da \ db \ b^{-1}a^{-1}. \tag{73}$$

Note that  $\{\alpha a, \beta b\} = \{a, b\}$  for any  $\alpha, \beta \in \mathbb{Q}^{\times}$ . In particular, we often use below that  $\{\pm a, \pm b\} = \{a, b\}$ .

<sup>&</sup>lt;sup>13</sup>Characteristic p would be fine as well, but we do not need this in the paper.

**Theorem 4.7.** For any elements  $a_0, \ldots, a_n$  we have the Hochshild cocycle property:

$$\{a_1, ..., a_n\} - \sum_{i=0}^{n-1} (-1)^i \{a_0, ..., a_{i-1}, a_i a_{i+1}, a_{i+2}, ..., a_n\} + (-1)^n \{a_0, ..., a_{n-1}\} = 0.$$
 (74)

For example:

$$\{a\} - \{ab\} + \{b\} = 0, 
 \{b, c\} - \{ab, c\} + \{a, bc\} - \{a, b\} = 0.$$
(75)

*Proof.* Each of the following terms appears in the sum (74) twice, with the opposite signs

$$da_0 \dots da_{i-1} da_i \ a_{i+1} da_{i+2} \dots da_n a_n^{-1} \dots a_0^{-1}$$
.

Lemma 4.8. i) One has

$$\{a,b\} = -\{b^{-1}, a^{-1}\}. (76)$$

ii) Suppose that  $abc = \pm 1$ . Then (77) implies that  $\{a,b\}$  is cyclic invariant:

$$\{a,b\} + \{b,c\} + \{c,a\} = 3 \cdot \{a,b\}. \tag{77}$$

*iii)* We have  $\{x, 1+x\} = \{1+x, x\}.$ 

*Proof.* i) Recall the identity  $c dc^{-1} = -dc c^{-1}$ . Using this, we have

$$\{a,b\} = da \ db \ b^{-1}a^{-1} = a^{-1}da \ db \ b^{-1} = da^{-1} \ a \ b \ db^{-1} = -db^{-1}da^{-1} \ ab = -\{b^{-1},a^{-1}\}.$$

ii) Since  $\{a,b\} = \{a,-b\}$ , we may assume that abc = 1. Then we have to show that

$${a,b} + {b,(ab)^{-1}} + {(ab)^{-1},a} = 3{a,b}.$$
 (78)

Let us write the second identity in (75) for  $c = (ab)^{-1}$ :

$${a,b} - {a,a^{-1}} + {ab,(ab)^{-1}} - {b,(ab)^{-1}} = 0.$$
 (79)

By (76), we have  $\{a, a^{-1}\} = -\{a, a^{-1}\}$ . So  $\{a, a^{-1}\} = 0$ . So

$${a,b} = {b,(ab)^{-1}}.$$
 (80)

Using (76) we have:  $\{a,b\} = -\{b^{-1},a^{-1}\} \stackrel{(80)}{=} -\{a^{-1},ab\} = \{(ab)^{-1},a\}$ . This and (80) imply the claim.

iii) One has 
$$\{x, 1+x\} = dxdx(1+x)^{-1}x^{-1} = dxdxx^{-1}(1+x)^{-1} = \{1+x, x\}.$$

2. The non-commutative 2-form  $\Omega_{\Gamma}$  for an  $\mathcal{A}$ -decorated bipartite ribbon graph  $\Gamma$ . Recall that an edge of a graph  $\Gamma$  is called an *external edge* if one of its vertices is univalent.

For simplicity, we do not consider graphs which have a component given by a single external edge.

We start from a trivalent ribbon graph  $\Gamma_v$  with a single-vertex v, decorated by  $a_1, a_2, a_3$  in the order compatible with the cyclic structure at v, such that  $a_1a_2a_3 = \pm 1$ . Then we set, using notation (73):

$$\Omega_v := \{a_1, a_2\}. \tag{81}$$

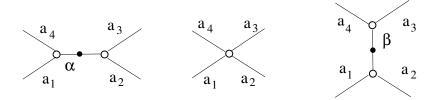

Figure 26: The cocycle condition guarantees that the 2-form  $\Omega_{\Gamma}$  is well defined.

It depends only on the cyclic order of the edges. Indeed,  $\{a_1, a_2\} = \{a_2, a_3\} = \{a_3, a_1\}$  since  $a_1a_2a_3 = \pm 1$ . Given a ribbon graph  $\Gamma_v$  with a single vertex v of valency > 3, we expand this vertex by adding two-valent vertices of the opposite color, as shown on Figure 26, producing a bipartite ribbon graph  $\Gamma'_{ij}$ with trivalent vertices of the original color, and two-valent vertices of the opposite color. We set

$$\Omega_v := \sum_{x \in \Gamma'_v} \Omega_x. \tag{82}$$

By default, the contribution of the 2-valent vertex is zero. <sup>14</sup> The sum is over trivalent vertices of the graph  $\Gamma'_v$ . To see that it does not depend on the choice of  $\Gamma'_v$ , it is sufficient to check this for the graphs on Figure 26. This boils down to the cocycle condition for  $\{a, b\}$ :

$$\{a_2, a_3\} + \{\alpha, a_4\} = \{a_1, a_2\} + \{\beta, a_3\} \longleftrightarrow \{a_2, a_3\} + \{a_1, a_2a_3\} = \{a_1, a_2\} + \{a_1a_2, a_3\}.$$

$$(83)$$

Now we introduce the non-commutative 2-form assigned to an any decorated bipartite ribbon graph  $\Gamma$ . Recall the  $\mathcal{A}$ -decorated ribbon graph, see Definition 4.1.

**Definition 4.9.** Given an A-decorated bipartite ribbon graph  $\Gamma$ , we set

$$\Omega_{\Gamma} := \sum_{w \in \Gamma} \Omega_w - \sum_{b \in \Gamma} \Omega_b. \tag{84}$$

Here the first sum is over all  $\circ$ -vertices of  $\Gamma$ , and the second over all  $\bullet$ -vertices.

We assign to each edge E of an A-decorated ribbon graph  $\Gamma$ , decorated by an element  $a_E$ , the following 3-form

$$\omega_E := (a_E^{-1} d a_E)^3. (85)$$

**Theorem 4.10.** For an A-decorated bipartite ribbon graph  $\Gamma$ , the  $d\Omega_{\Gamma}$  is a sum is over all external edges E of  $\Gamma$ :

$$d\Omega_{\Gamma} = \sum_{E} \omega_{E}.$$
 (86)

The 2-form  $\Omega_{\Gamma}$  assigned to an  $\mathcal{A}$ -decorated ribbon graph  $\Gamma$  without external edges is closed:  $d\Omega_{\Gamma}=0$ .

*Proof.* Clearly the first claim implies the second.

**Lemma 4.11.** Let abc = 1. Then

$$3d\{a,b\} = -(a^{-1}da)^3 - (b^{-1}db)^3 - (c^{-1}dc)^3.$$
(87)

14This is consistent with  $\{a,a^{-1}\} = 0$  since the decorations of a 2-valent vertex are  $a, \pm a^{-1}$ .

*Proof.* Straightforward calculation, using  $c^{-1}dc = -d(c^{-1})c$  shows that the right hand side is

$$-(a^{-1}da)^3-(b^{-1}db)^3+\left((ab)^{-1}d(ab)\right)^3=3dadbd(b^{-1})a^{-1}+3d(a^{-1})dadbb^{-1}=3d\{a,b\}.$$

Therefore for each  $\circ$ -vertex w of  $\Gamma$  the differential of the 2-form  $\Omega_w$  assigned to w is

$$d\Omega_w = -\sum_{w \in E_i} \omega_{E_i}. \tag{88}$$

Here the sum is over all edges  $E_i$  sharing the vertex w.

On the other hand, for each  $\bullet$ -vertex b of  $\Gamma$  the differential of the 2-form  $\Omega_b$  assigned to b is

$$d\Omega_b = \sum_{b \in E_i} \omega_{E_i}. \tag{89}$$

Here the sum is over all edges sharing the vertex b. Then evidently

$$d\Omega_{\Gamma} = \sum_{v \in \Gamma} d\Omega_v = -\sum_{E \subset \Gamma} \omega_E + \sum_{E \subset \Gamma} \omega_E = 0.$$
 (90)

For the convenience of the reader, we reproduce the picture illustrating the change of the coordinates under the two by two move, which we refer to in Theorem 4.12.

Figure 27: The right picture is obtained from the left one by the clockwise rotation by 90°, followed by the cyclic shift  $a_i \mapsto b_{i+1}$ ,  $i \in \mathbb{Z}/4\mathbb{Z}$ .

**Theorem 4.12.** The 2-form  $\Omega_{\Gamma}$  assigned to a decorated bipartite ribbon graph  $\Gamma$  is invariant under the two by two moves. This just means that the following identity holds, using the notation (68):

$$\{a_4, a_1\} - \{a_1, a_2\} + \{a_2, a_3\} - \{a_3, a_4\} = \{b_1, b_2\} - \{b_2, b_3\} + \{b_3, b_4\} - \{b_4, b_1\}.$$
 (91)

*Proof.* Denote by  $\Gamma$  and  $\Gamma'$  the two ribbon graphs related by a two by two move. Then we claim that

$$\Omega_{\Gamma} - \Omega_{\Gamma'} = \left( \{a_4, a_1\} - \{a_1, a_2\} + \{a_2, a_3\} - \{a_3, a_4\} \right) - \left( \{b_1, b_2\} - \{b_2, b_3\} + \{b_3, b_4\} - \{b_4, b_1\} \right). \tag{92}$$

Indeed, the contribution of the left  $\bullet$ -vertex on Figure 27 is equal to  $-\Omega_{\alpha} - \Omega_{\beta}$ , where  $\alpha$  and  $\beta$  are the two  $\bullet$ -vertices on the left graph  $\Gamma$  on Figure 28. The contribution of the  $\bullet$ - and  $\circ$ -vertices  $\gamma$  and  $\delta$  on the right graph  $\Gamma'$  on Figure 28 is equal to  $-\Omega_{\gamma} + \Omega_{\delta}$ . Since, as Figure 28 shows,  $\Omega_{\alpha} = \Omega_{\gamma}$ , the total contribution of the left vertices on Figure 27 to  $\Omega_{\Gamma} - \Omega_{\Gamma'}$  is equal to  $-\Omega_{\beta} - \Omega_{\delta}$ . Note that by defolt the contribution of thie two-valent vertices are zero. Similar analysis for the top, right and bottom vertices on Figure 27 shows that their total contribution to the left hand side of (92) is equal to the right hand side of (92). On the other hand, the contributions of all other matching vertices of the graphs  $\Gamma$  and  $\Gamma'$  evidently coincide.

Therefore it remains to prove the identity (91). This is done by a tedious calculation in Section 9. Note that, as we show there, the identity follows from a more elementary identity from Theorem 9.4. The latter is the non-commutative analog of the Steinberg relation  $d \log(1+X) \wedge d \log(X)$ .

**Remarks.** 1. The right picture on Figure 27 can be obtained from the left one by the clockwise rotation by 90°, followed by the cyclic shift  $a_i \mapsto b_{i+1}$ . The right hand side of relation (91) is obtained from the left hand side by the same cyclic shift.

2. Figure 28 shows that the identity  $a_3a_4 = (b_3b_4)^{-1}$  is crucial to check that the invariance of the 2-form  $\Omega_{\Gamma}$  under two by two moves is equivalent to the identity (91).

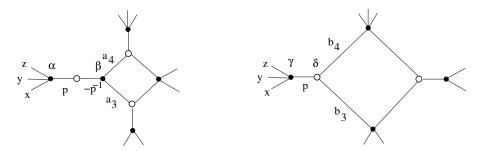

Figure 28: Contributions of vertices  $\alpha$  and  $\gamma$  to, respectively,  $\Omega_{\Gamma}$  and  $\Omega_{\Gamma'}$  coincide:  $\Omega_{\alpha} = \Omega_{\gamma}$ . We use the identity  $a_3a_4 = (b_3b_4)^{-1}$  to see that the decorations of right edges of vertices  $\alpha$  and  $\gamma$  are the same: p. We use sign convention (66). The signs of  $\mathcal{A}$ -decorations do not affect the 2-forms since  $\{\pm a, \pm b\} = \{a, b\}$ .

**A variant.** Take any ribbon graph  $\Gamma$ . Assign to its oriented edges **E** elements  $a_{\mathbf{E}}$  such that denoting by  $\overline{\mathbf{E}}$  the edge **E** with the opposite orientation, we have  $a_{\mathbf{E}}a_{\overline{\mathbf{E}}}=1$ . For each vertex  $v \in \Gamma$  we define  $\Omega_v$  using the edges are oriented out of the vertex, and set take the sum over all vertices  $v \in \Gamma$  of valency > 1:

$$\Omega_{\Gamma} := \sum_{v \in \Gamma} \Omega_v. \tag{93}$$

### 5 Spectral description of framed local systems on surfaces

In Section 5.1 we start from recalling some material from [G]: a class of bipartite ribbon graphs called  $GL_m$ -graphs, and their spectral surfaces. Then we describe non-commutative framed local systems on a decorated surface  $\mathbb S$  via framed flat line bundles on the spectral surface  $\Sigma$  of a bipartite graph on  $\mathbb S$ . Namely, we show that the main construction of Section 1.1 can be generalized to any  $GL_m$ -graph.

In Sections 5.2 and 5.3 we consider the <u>twisted</u> variant: describe non-commutative <u>twisted</u> framed local systems on  $\mathbb S$  via <u>twisted</u> framed flat line bundles on the spectral surface  $\Sigma$ .

In Section 5.2 we consider the key example, when S is a triangle t.

In Section 5.3 we consider the general case.

### 5.1 Spectral description of non-commutative framed local systems

1. The  $GL_m$ -graphs and spectral surfaces [G]. Given a bipartite ribbon graph  $\Gamma$ , the *conjugate ribbon graph*  $\Gamma^*$  introduced in [GK] is obtained by changing the cyclic order of the edges at every  $\bullet$ -vertex. There is a bijection:

$$\{\text{zig-zag paths on }\Gamma\} \longleftrightarrow \{\text{face paths on }\Gamma^*\}.$$
 (94)

The conjugate ribbon graph  $\Gamma^*$  provides a topological surface  $\Sigma$  with holes, whose boundaries are the face paths on  $\Gamma^*$ , described as follows. Let us add to the ribbon graph  $\Gamma^*$  its punctured faces  $F_{\gamma_i}$  bounding the face paths  $\gamma_i$ . Precisely, if  $\gamma_i$  is a face loop, then  $F_{\gamma_i}$  is a disc bounded by this loop, punctured inside. If  $\gamma_i$  is a face interval, then  $F_{\gamma_i}$  is a disc; the half of its boundary is identified with the path  $\gamma_i$ , and the

rest becomes boundary of  $\Sigma$ . It is handy to puncture it at the marked point. We arrive at a topological surface, called the *spectral surface* [G]:

$$\Sigma = \Gamma^* \cup \cup_{\gamma_i} F_{\gamma_i}. \tag{95}$$

Let  $\mathbb{S}$  be a decorated surface with marked points  $\{s_1, ..., s_n\}$ . A strand on  $\mathbb{S}$  is either an oriented loop, or an oriented path on  $\mathbb{S} - \{s_1, ..., s_n\}$  connecting boundary points. Let  $\gamma$  be a strand such that  $\mathbb{S} - \gamma$  has two connected components:

$$S - \gamma = S_{\gamma}^{\circ} \cup S_{\gamma}^{\circ'}. \tag{96}$$

They inherit orientatations from  $\mathbb{S}$ . The domain  $S_{\gamma}^{\circ}$  is the one whose orientation induces the original (clockwise) orientation of  $\gamma$ . We denote by  $S_{\gamma}$  the closure of  $S_{\gamma}^{\circ}$ .

Let  $\mathbb{S}$  be a decorated surface associated with a bipartite ribbon graph  $\Gamma$ , so that  $\Gamma \subset \mathbb{S}$ . Given a zigzag path  $\gamma$  on  $\Gamma$ , the shape of the domain  $S_{\gamma}$  near a vertex v of  $\Gamma$  depends on the vertex type. Namely, the intersection  $S_{\gamma} \cap U_v$  with a neighborhood  $U_v$  of v is a single sector if v is a  $\circ$ -vertex, and a union of  $\operatorname{val}(v) - 1$  sectors if v is a  $\circ$ -vertex, see Figure 29.

Figure 29: A (green) oriented zig-zag strand  $\gamma$  near a vertex v, deformed slightly off the vertex.

Pushing a bit zig-zag paths out of the vertices as on Figure 29, we get zig-zag strands on  $\mathbb{S}$ . Let  $\{\gamma\}$  be the collection of zig-zag strands on S. We assume that for each zig-zag strand  $\gamma$ 

•  $\mathbb{S} - \gamma$  has two connected components, and the domains  $S_{\gamma}$  are discs.

Using bijection (94), we construct the spectral surface  $\Sigma$  as follows. Denote by  $F_{\gamma}$  a copy of the disc  $S_{\gamma}$ . We attach the disc  $F_{\gamma}$  to every zig-zag path  $\gamma$  on  $\Gamma$ . Since the  $F_{\gamma}$  are discs, we get a surface homeomorphic to surface (95). Canonical maps  $F_{\gamma} \longrightarrow S_{\gamma}$  provide a ramified map:

$$\pi: \Sigma \longrightarrow \mathbb{S}.$$
 (97)

**Definition 5.1.** The degree m of the map  $\pi$  is called the rank of the bipartite ribbon graph  $\Gamma$ .

The map  $\pi$  has the following properties:

- The ramification points of π are the ◆-vertices of Γ of valency ≥ 3: the ramification index of a
   ◆-vertex equals its valency minus 2: this is clear from Figure 29.
- For every marked point  $s \in \mathbb{S}$  there is a bijection

$$\varphi_s: \{1, ..., m\} \longrightarrow \pi^{-1}(s). \tag{98}$$

Indeed, the set  $\pi^{-1}(s)$  is identified canonically with the set of zig-zag loops/arcs going around the point s. Each of the latter is the boundary of a disc/angle containing s, which are ordered by the inclusion.

**Definition 5.2.** Let  $\Gamma \subset \mathbb{S}$  be a bipartite graph associated with a decorated surface  $\mathbb{S}$ .

- (i) A zig-zag strand  $\gamma$  on  $\mathbb S$  is <u>ideal</u> if the domain  $S_{\gamma}^{\circ}$  in (96) contains a single marked point s. We say that  $\gamma$  is associated to s.
  - (ii)  $\Gamma$  is a strict  $GL_m$ -graph if its rank is m > 1, all zig-zag strands are ideal, and:
  - There are m zig-zag strands associated with each marked point.

Figure 30: No parallel bigons (left) and half-bigons (right; the boundary of S is punctured).

- There are no parallel bigons and parallel half-bigons, see Figure 30.
- (iii)  $\Gamma$  is a  $\operatorname{GL}_m$ -graph if for some finite unramified cover  $\rho: \widetilde{\mathbb{S}} \to \mathbb{S}$ ,  $\rho^{-1}(\Gamma)$  is a strict  $\operatorname{GL}_m$ -graph.

For example, the bipartite ribbon graph  $\Gamma_m(\mathcal{T})$  assigned to an ideal triangulation  $\mathcal{T}$  of S just before Theorem 1.8 is a  $GL_m$ -graph.

For a strict  $GL_m$ -graph  $\Gamma$  on  $\mathbb{S}$ , the *codistance*  $\langle x, s \rangle$  from a point  $x \in \mathbb{S}$  to a special point s is the number of zig-zag strands  $\gamma$  associated with s such that x belongs to the <u>open</u> disc  $S_{\gamma}^{\circ}$ . For example, the codistance to a special point s from a point s very close to s is m.

**Lemma 5.3.** Let  $\Gamma$  be a strict  $GL_m$ -graph on  $\mathbb{S}$ . Then zig-zags associated with a marked point s form m concentric (half-) circles, going counterclockwise around s.

For any point  $x \in \mathbb{S} - \Gamma$ , the sum of codistances from x to the marked points is equal to  $\operatorname{rk}(\Gamma)$ :

$$\sum_{s} \langle x, s \rangle = \operatorname{rk}(\Gamma). \tag{99}$$

*Proof.* Formula (99) is equivalent to the definition of rank as the degree of the covering  $\pi$ .

Alternatively, formula (99) is evident for a point x close to a marked point: in this case all codistances but one are 0, and the non-zero one is m. When x moves, crossing an edge E in an internal point, we alter codistances as follows: one of them increases by 1, another decreases by 1, the rest stay intact.  $\square$ 

2. Spectral description of non-commutative framed local systems. Given a decorated surface  $\mathbb{S}$ , recall the notion of a *framing* on a local system of finite dimensional vector spaces over a skew field R, see Definition 1.10. A framing is a choice of a flat section of the associated local system of flags near each marked point. A local system on  $\mathbb{S}$  is framed if it is equipped with a framing.

The monodromy of an m-dimensional framed R-local system  $\mathcal{V}$  on  $\mathbb{S}$  around a puncture p is an operator N in the fiber  $\mathcal{V}_x$  over a nearby point x preserving the framing flag  $\mathcal{F}$  in  $\mathcal{V}_x$ . The triple  $(\mathcal{V}_x, \mathcal{F}, N)$  determines m operators, called the *monodromy eigenvalue operators* at p:

$$N_i: \operatorname{gr}^i \mathcal{F} \longrightarrow \operatorname{gr}^i \mathcal{F}, \quad i = 0, ..., m-1.$$

If R is commutative, these are the eigenvalues of N, which determine the semisimple part of N. The points of  $\Sigma_{\Gamma}$  projecting to the marked points of  $\mathbb{S}$  are the marked points of  $\Sigma_{\Gamma}$ .

**Theorem 5.4.** Let  $\Gamma$  be a  $\operatorname{GL_m}$ -graph on a decorated surface  $\mathbb S$ , homotopy equivalent to  $\mathbb S$ . We assume that it can be related by a sequence of two by two moves to a  $\operatorname{GL_m}$ -graph  $\Gamma_m(\mathcal T)$  assigned to an ideal triangulation of  $\mathbb S$ .<sup>15</sup> Then the following two groupoids are canonically birationally equivalent

- 1. Groupoid of m-dimensional framed R-local systems on  $\mathbb{S}$ ;
- 2. Groupoid of flat R-line bundles with connection on the spectral surface  $\Sigma_{\Gamma}$ .

 $<sup>^{15}</sup>$ We do not know whether any  $GL_m$ -graph on a decorated surface  $\mathbb S$  has this property. This is the case when  $\mathbb S$  is a polygon by [G, Section 3]. Since the collection of  $GL_m$ -graphs with this property is equivariant under the action of the mapping class group of  $\mathbb S$ , Theorem 5.4 is sufficient for all our purposes.

The equivalence identifies the monodromy eigenvalue operators of the connection on V around a puncture p with the monodromy operators of  $\mathcal{L}$  around the punctures on  $\Sigma_{\Gamma}$  over p, so that the eigenvalue operator  $N_i$  is the monodromy of  $\mathcal{L}$  around the point  $\varphi_p(i) \in \pi^{-1}(p)$ , see (98).

*Proof.* Flat line bundles on the spectral surface  $\Sigma_{\Gamma}$  are the same thing as flat line bundles on the graph  $\Gamma$ . Follow the proof of Theorem 1.2, adjusted to the graph  $\Gamma$ , let us define a functor

$$\mathcal{L}: \{\text{Generic } m\text{-dimensional framed local systems } \mathcal{V} \text{ on } \mathbb{S}\} \longrightarrow \{\text{Flat line bundles on } \Gamma\}.$$
 (100)

Given a vertex v of  $\Gamma$  and a marked point s on  $\mathbb{S}$  with the codistance  $\langle v, s \rangle > 0$ , there is a unique zig-zag  $\gamma$  containing v such that  $s \in S_{\gamma}$ . Since  $S_{\gamma}$  is a punctured disc, and the flag  $\mathcal{F}^{\bullet}(s)$  near s is monodromy invariant, there is a canonical parallel transport of the flag  $\mathcal{F}^{\bullet}(s)$  to a flag  $\mathcal{F}^{\bullet}_{v,s}$  in the fiber  $\mathcal{V}_v$  of  $\mathcal{V}$  at v.

1. Let **w** be a  $\circ$ -vertex of the graph  $\Gamma$ . Denote by  $a_1, ..., a_n$  the codistances from the **w** to the marked points  $s_1, ..., s_n$  on  $\mathbb{S}$ . Then

$$a_1 + \dots + a_n = m - 1, \quad a_i \ge 0.$$

We assign to the  $\circ$ -vertex **w** a one dimensional subspace in the vector space  $\mathcal{V}_{\mathbf{w}}$ :

$$L_{\mathbf{w}}^{\circ} := \mathcal{F}_{\mathbf{w},s_1}^{a_1} \cap \ldots \cap \mathcal{F}_{\mathbf{w},s_n}^{a_n}. \tag{101}$$

2. Let **b** be a k-valent  $\bullet$ -vertex of the graph  $\Gamma$ . Denote by  $b_1, ..., b_n$  the codistances from the **b** to the marked points  $s_1, ..., s_n$  on  $\mathbb{S}$ . Then

$$b_1 + \ldots + b_n = m - k + 1, \quad b_i \ge 0.$$

We assign to the k-valent  $\bullet$ -vertex **b** a (k-1)-dimensional subspace in the vector space  $\mathcal{V}_{\mathbf{b}}$ :

$$P_{\mathbf{b}} := \mathcal{F}_{\mathbf{b}, s_1}^{b_1} \cap \ldots \cap \mathcal{F}_{\mathbf{b}, s_n}^{b_n}. \tag{102}$$

The condition that for a configuration of flags the intersections (101) and (102) have given dimensions (1 or 2) is an open condition. To check that the collection of flags satisfying this condition is non-empty, we note that this follows by Theorem 1.2 for the bipartite graphs  $\Gamma_m(\mathcal{T})$ . Since two by two moves provide birational isomorphisms, the claim follows.

The plane  $P_{\mathbf{b}}$  contains the k lines  $L^{\circ}_{\mathbf{w}}$  assigned to the  $\circ$ -vertices  $\mathbf{w}$  incident to  $\mathbf{b}$ . Indeed, the codistances  $(a_1, ..., a_n)$  and  $(b_1, ..., b_n)$  from the vertices  $\mathbf{w}$  and  $\mathbf{b}$  are related as follows:  $0 \le a_i - b_i \le 1$ , and  $a_j = b_j + 1$  for exactly k indices j. For any such an index j the embedding  $\mathcal{F}^{b_j+1} \hookrightarrow \mathcal{F}^{b_j}$  induces the embedding  $i_{\mathbf{w}\to\mathbf{b}}: L^{\circ}_{\mathbf{w}} \longrightarrow P_{\mathbf{b}}$ .

We define a line  $L_{\mathbf{b}}^{\bullet}$  as the kernel of the sum of these maps over all  $\circ$ -vertices  $\mathbf{w}$  incident to the  $\mathbf{b}$ :

$$L_{\mathbf{b}}^{\bullet} := \operatorname{Ker}\left(\bigoplus_{\mathbf{w}=\mathbf{b}} L_{\mathbf{w}}^{\circ} \stackrel{i_{\mathbf{w}\to\mathbf{b}}}{\longrightarrow} P_{\mathbf{b}}\right). \tag{103}$$

Then there is a canonical map, induced by projections of the subspace  $L_{\mathbf{b}}^{\bullet}$  onto the summands:

$$L_{\mathbf{b}}^{\bullet} \longrightarrow \bigoplus_{\mathbf{w}} L_{\mathbf{w}}^{\circ}.$$
 (104)

So we get a flat line bundle  $\mathcal{L}_{\mathcal{V}}$  on the graph  $\Gamma$ . Its fibers at the vertices are given by the lines  $L^{\circ}$  and  $L^{\bullet}$ , and the parallel transport along an edge  $\bullet \to \circ$  is given by a map  $L^{\bullet} \longrightarrow L^{\circ}$  in (104).

**Remark.** If R = K is commutative, the moduli space of flat line bundles on a graph  $\Gamma$  is identified with  $H^1(\Gamma, K^*)$ . The latter include the monodromies around the holes in the graph. These are the coordinates from [G], generalizing the coordinates [FG1] to ideal bipartite graphs on  $\mathbb{S}$ .

If R is non-commutative, we no longer have canonical coordinates.

Let us show that the functor  $\mathcal{L}$  is an equivalence. Pick an ideal triangulation  $\mathcal{T}$  of  $\mathbb{S}$ . Recall the  $\mathrm{GL}_m$ -graph  $\Gamma_m(\mathcal{T})$  related to  $\mathcal{T}$ . By Theorem 1.8, applied to the surface  $\mathcal{S}$  glued from the triangles of  $\mathcal{T}$ , which is just the decorated surface  $\mathbb{S}$ , the functor (100) is an equivalence of groupoids, where "generic" means that the triple of flags for each triangle of  $\mathcal{T}$  is generic in the sense of Section 1.1. Then the claim for a graph  $\Gamma$  related to  $\Gamma_m(\mathcal{T})$  by a sequence of two by two moves follows from results of Section 2.1.  $\square$ 

### 5.2 Spectral description of generic twisted triples of flags

Let us replace a triangle t by an oriented circle  $S^1$  with three marked points A, B, C. Twisted framed local systems on  $(S^1; A, B, C)$  are the same thing as the flat line bundle on  $S^1$  with the monodromy -1, and flags  $(\mathcal{A}, \mathcal{B}, \mathcal{C})$  in the fibers over the tangent vectors  $v_A, v_B, v_C$  to  $S^1$  at the points A, B, C, following the orientation of  $S^1$ . We call such data twisted triples of flags. There is a canonical one-dimensional local system  $\varepsilon$  on  $S^1$  with the monodromy -1. Multiplying by  $\varepsilon$ , we identify the usual and twisted triples of flags. So there is almost no difference between the two notions. The distinction between the two will be important when we move to decorated twisted configurations of flags.

Take a generic triple of flags  $(\mathcal{A}, \mathcal{B}, \mathcal{C})$  in an m-dimensional R-vector space. We assign the flags to the vertices of a triangle t. The bipartite ribbon graph  $\Gamma_m$  on Figure 4 assigned to t gives rise to the spectral surface  $\Sigma_m$ . Namely, each zig-zag  $\gamma$  on  $\Gamma_m$  determines a smaller triangle  $t_{\gamma}$ , given by the component of  $t-\gamma$  containing a single vertex of t. Take the disjoint union of all triangles  $t_{\gamma}$ . Then, for each edge E of the graph  $\Gamma_m$ , glue the triangles  $t_{\gamma'}$  and  $t_{\gamma''}$  assigned to the zig-zags  $\gamma'$  and  $\gamma''$  containing E over the edge E. We get the surface  $\Sigma_m$  and the projection  $\Sigma_m \longrightarrow t$ , ramified over the  $\bullet$ -vertices. To avoid confusion, we denote by  $F_{\gamma}$  the triangle  $t_{\gamma}$  when it sits on the spectral surface.

**Theorem 5.5.** There is a canonical equivalence between the following two groupoids:

- 1. Groupoid of generic triples of flags in an m-dimensional R-vector space.
- 2. Groupoid of flat <u>twisted</u> R-line bundles with connection on the spectral surface  $\Sigma_m$  of the graph  $\Gamma_m$ .

*Proof.* 1  $\longrightarrow$  2. A triple of flags  $(\mathcal{A}, \mathcal{B}, \mathcal{C})$  in an m-dimensional R-vector space V gives rise to 3m lines

$$\operatorname{gr}^{a} \mathcal{A}, \operatorname{gr}^{b} \mathcal{B}, \operatorname{gr}^{c} \mathcal{C}, a, b, c = 0, ..., m - 1.$$
 (105)

Given a zig-zag  $\gamma$  on the graph  $\Gamma_m$  going around of the vertex A, we assign to the face  $F_{\gamma}$  of the spectral surface the line  $\operatorname{gr}^{a_{\gamma}-1}\mathcal{A}$ , where  $a_{\gamma} \in \{1,...,m\}$  is the codistance from  $\gamma$  to A. Abusing notation, we denote by  $\operatorname{gr}^{a_{\gamma}-1}\mathcal{A}$  the twisted flat line bundle on  $F_{\gamma}$  whose restriction to oriented tangent vectors to the oriented side BC is given by the line  $\operatorname{gr}^{a_{\gamma}-1}\mathcal{A}$ . We do the same for the vertices B, C. Let us glue these twisted flat line bundles on the 3m faces  $F_{\gamma}$  to a twisted line bundle on the spectral surface.

Note that the edges of the graph  $\Gamma_m$  are parametrised by the following data:

- i) A triple of non-negative integers (a, b, c) such that a + b + c = m 1, plus
- ii) A choice of two of the three numbers (a, b, c).

The faces of the graph  $\Gamma_m$  are labeled by the triples of non-negative integers (a,b,c) with a+b+c=m.

Given a data  $(\underline{a}, \underline{b}, c)$  assigned to an edge E, where the chosen pair in ii) is the pair (a, b), the two faces  $F_{\gamma'}$  and  $F_{\gamma''}$  of the spectral surface sharing the edge E are labeled by the triples (a, b + 1, c) and (a + 1, b, c), accordantly. Then the faces  $F_{\gamma'}$  and  $F_{\gamma''}$  carry the line bundles

$$\mathcal{L}_{\gamma'} := \operatorname{gr}^a \mathcal{A}, \qquad \mathcal{L}_{\gamma''} := \operatorname{gr}^b \mathcal{B}.$$

We assign to the edge E the line

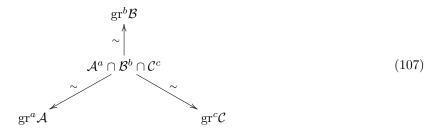

$$\mathbf{L}_E := \mathcal{A}^a \cap \mathcal{B}^b \cap \mathcal{C}^c.$$

Then there are canonical isomorphisms, obtained by projecting along  $\mathcal{A}^{a+1}$  and  $\mathcal{B}^{b+1}$ :

$$\operatorname{gr}^a \mathcal{A} \stackrel{\sim}{\longleftarrow} \mathcal{A}^a \cap \mathcal{B}^b \cap \mathcal{C}^c \stackrel{\sim}{\longrightarrow} \operatorname{gr}^b \mathcal{B}.$$
 (106)

They allow to glue the twisted flat line bundles over the faces  $F_{\gamma'}$  and  $F_{\gamma''}$  along their common edge E. Let us extend the obtained twisted flat line bundle on  $\Sigma_m$  – {the vertices of  $\Gamma_m^*$ } to the spectral surface. In order to do this, we make the following observations.

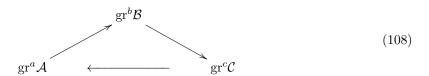

For any triple (a, b, c) such that a + b + c = m - 1 there are three canonical isomorphisms:

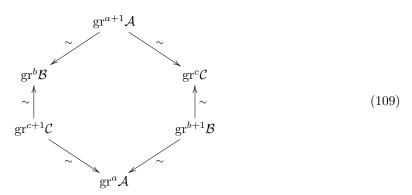

The first is the composition  $\mathcal{A}^a \cap \mathcal{B}^b \cap \mathcal{C}^c \hookrightarrow \mathcal{A}^a \to \mathcal{A}^a/\mathcal{A}^{a+1}$ . The others are similar.

**Lemma 5.6.** There are the following relations between the isomorphisms (107):

1. For any integers  $a, b, c \ge 0$  such that a + b + c = m - 1 there is a commutative triangle, i.e. the composition of the three isomorphism is the identity:

2. For any integers  $a, b, c \ge 0$  such that a + b + c = m - 2 there is a sign-commutative hexagon, i.e. the composition of the following six isomorphisms/their inverces is equal to -1:

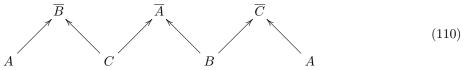

*Proof.* 1) Starting with a pair of isomorphisms  $\operatorname{gr}^a \mathcal{A} \stackrel{\sim}{\longleftarrow} \mathcal{A}^a \cap \mathcal{B}^b \cap \mathcal{C}^c \stackrel{\sim}{\longrightarrow} \operatorname{gr}^b \mathcal{B}$ , and composing the inverse of the first one with the second, we get an isomorphism  $\operatorname{gr}^a \mathcal{A} \stackrel{\sim}{\longrightarrow} \operatorname{gr}^b \mathcal{B}$ . The other two are similar. This makes the first claim is evident.

2) Intersecting with the plane  $\mathcal{A}^a \cap \mathcal{B}^b \cap \mathcal{C}^c$ , we reduce the claim to the following. Let A, B, C be three different lines in a plane P. Consider the quotient lines

$$\overline{A} := P/A, \quad \overline{B} := P/B, \quad \overline{C} := P/C.$$

Projecting the line A to the quotient line  $\overline{B}$  we get an isomorphism  $A \longrightarrow \overline{B}$ . There are six such line isomorphisms:

We compose them to a map  $A \to A$ , where going against an arrow means inverting the isomorphism. We claim that the composition is the minus identity map. Indeed, choose a triple of non-zero vectors  $x \in A, y \in B, z \in C$  whose sum is zero:

$$x + y + z = 0. (111)$$

Such a triple exists, and is defined uniquely up to a multiplication from the left by a non-zero scalar. Condition (111) just means that x+z projects to zero in  $\overline{B}$ . So the map  $A \longrightarrow C$  provided by the diagram  $A \stackrel{\sim}{\longrightarrow} \overline{B} \stackrel{\sim}{\longleftarrow} C$  is given by  $x \longmapsto -z$ . Therefore the composition  $A \longrightarrow C \longrightarrow B \longrightarrow A$  is given by  $x \longmapsto -z \longmapsto y \longmapsto -x$ .

The part i) of Lemma 5.6 allows to extend the twisted flat line bundle to the  $\circ$ -vertices. Indeed, although the composition of the three maps on Figure 31 is the identity map, the tangent vectors are rotated by  $2\pi$ , thus resulting the -Id map.

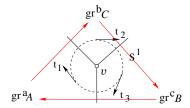

Figure 31: Let a + b + c = m - 1, and the line  $\operatorname{gr}^a \mathcal{A}$  sits over the tangent vector  $t_1$ , etc.. By (108), the composition  $\operatorname{gr}^a \mathcal{A} \to \operatorname{gr}^b \mathcal{B} \to \operatorname{gr}^c \mathcal{C} \to \operatorname{gr}^a \mathcal{A}$  is the identity map. The tangent vector  $t_1$  rotates by  $t_1 \to t_2 \to t_3 \to t_1$  by  $2\pi$ .

Similarly, the part ii) of of Lemma 5.6 allows to extend the twisted flat line bundle to the  $\bullet$ -vertices. Indeed, although the composition of the six maps (109) is -Id, the tangent vectors are rotated by  $4\pi$ , thus still resulting the -Id map.

 $2 \longrightarrow 1$ . The functor  $\mathcal{R}$ : {Twisted flat line bundles on  $\Sigma_m$ }  $\longrightarrow$  {generic twisted triples of flags}. Take a twisted flat line bundle  $\mathcal{L}$  on the spectral surface  $\Sigma_m$  of the bipartite ribbon graph  $\Gamma_m$ . It contains the graph  $\Gamma_m^*$ . For each vertex  $v \in \Gamma_m^*$ , restrict  $\mathcal{L}$  to the positively oriented tangent vectors to an oriented circle  $S_v^1 \subset T_v \Sigma - \{0\}$ , getting a flat line bundle  $\mathcal{L}_{S_v^1}$  on  $S_v^1$  with the monodromy -1.

Then the flat connection on  $\mathcal{L}$  provides a natural map

$$K_{\mathcal{L}}: \bigoplus_{\text{internal } \bullet - \text{vertices } \mathbf{b}} \mathcal{L}_{S_{\mathbf{b}}^{1}} \longrightarrow \bigoplus_{\circ - \text{vertices } \mathbf{w}} \mathcal{L}_{S_{\mathbf{w}}^{1}}.$$
 (112)

We identify all circles  $S^1_{\mathbf{w}}$  with a circle  $S^1$ , and define the vector space  $V_{\mathcal{L}}$  as the cokernel of this map:

$$V_{\mathcal{L}} := \operatorname{Coker}(K_{\mathcal{L}}). \tag{113}$$

It is a flat bundle on the circle  $S^1$  with the monodromy  $-\mathrm{Id}$ . Let us define three flags in the fibers of this local system over the points A, B, C. The distance functions  $d_A$ ,  $d_B$ ,  $d_C$ , see the proof of Theorem 1.2, induce three filtrations in the fibers of complex (112) over the points A, B, C. They induce filtrations on  $\mathrm{Coker}(K_C)$ , providing a twisted triple of flags. The functor  $\mathcal{R}$  is the inverse to the one defined before.  $\square$ 

**Remark.** Let us compare constructions of the connection in the proofs of Theorems 1.2 and 5.5. The key point is that given three vectors x, y, z in a two dimensional vector space with x + y + z = 0, we can define a connection either by  $x \to y \to z \to x$ , as we did proving Theorem 1.2, or by  $x \to -y \to z \to -x$ , getting a twisted connection.

### 5.3 Spectral description twisted local systems on surfaces

Below we use the notation  $\Sigma$  for the spectral surface  $\Sigma_{\Gamma}$  since the bipartite graph  $\Gamma$  is fixed.

**Theorem 5.7.** Let  $\Gamma$  be a  $GL_m$ -graph on a decorated surface  $\mathbb{S}$ , and  $\Sigma$  the corresponding spectral surface. Then the following two groupoids are canonically birationally equivalent:

- 1. Groupoid of m-dimensional twisted framed R-vector bundles with flat connections V on S.
- 2. Groupoid of flat <u>twisted</u> R-line bundles with connection  $\mathcal{L}$  on the spectral surface  $\Sigma$ .

The equivalence identifies the monodromy eigenvalue operators of the connection on V around a puncture p with the monodromy operators of  $\mathcal{L}$  around the punctures on  $\Sigma$  over p just as in Theorem 5.4.

*Proof.* Let  $\mathcal{V}$  be an m-dimensional twisted framed R-local system on  $\mathbb{S}$ . Let us construct a twisted flat line bundle  $\mathcal{L}$  on  $\Sigma$ . Let  $\mathcal{F}(s)$  be a flat section of the local system of flags in  $\mathcal{V}$  defining a framing near a marked point  $s \in \mathbb{S}$ . For each zig-zag  $\gamma$  going around s, it provides a flat section over the punctured disc  $S_{\gamma}$ . Recall the punctured face  $F_{\gamma}$  of the spectral surface  $\Sigma$  assigned to  $\gamma$ . By the very construction of the spectral surface, there is a canonical identification:

$$F_{\gamma} = S_{\gamma}$$
.

We use it to transport the flat section of the local system of flags on  $S_{\gamma}$  to  $F_{\gamma}$ , and denote it by  $\mathcal{F}(s)$ . We assign to a zig-zag  $\gamma$  a number  $a_{\gamma} \in \{1, ..., m\}$  - the codistance from a point of the open disc  $S_{\gamma}^{\circ}$  close to  $\gamma$  to the marked point associated with  $\gamma$ . Then there is a twisted flat line bundle on the face  $F_{\gamma}$  of  $\Sigma$ :

$$\mathcal{L}_{F_{\gamma}} := \operatorname{gr}^{a_{\gamma} - 1} \mathcal{F}(s) \tag{114}$$

Let us glue them into a twisted flat line bundle  $\mathcal{L}$  on  $\Sigma$ .

**Lemma 5.8.** Let  $s_1, \ldots, s_n$  be the marked points on  $\mathbb{S}$ . Let y be a point of  $\Sigma$ , and  $x := \pi(y) \in \mathbb{S}$ . Let  $0 \le a_j \le m$  be the codistance from x to  $s_j$ . Then we have:

1. Let  $y \in \Sigma - \Gamma^*$ . Then

$$a_1 + \ldots + a_n = m. \tag{115}$$

2. Let  $y \in \Gamma^* - \{\bullet - vertices\}$ . Then

$$a_1 + \ldots + a_n = m - 1. (116)$$

3. Let y be a k-valent  $\bullet$ -vertex of  $\Gamma^*$ . Then

$$a_1 + \ldots + a_n = m - k + 1. (117)$$

*Proof.* 1. When a point x is inside of a face, the claim follows from (99).

- 2. When a point x' moves and hits an inside point x of an edge E, just one of the codistances  $a_i$  decreases by 1. Namely, it is the one corresponding to the marked point  $s_{\gamma}$  surrounded by the zig-zag  $\gamma$  containing E, such that the open domain  $S_{\gamma}^{\circ}$  containes x'. Same thing happens when x is a  $\circ$ -vertex. Indeed, take a small disc  $U_x$  containing x. Let  $\gamma_1, \ldots, \gamma_k$  be the zig-zags containing x. The domains  $S_{\gamma}^{\circ} \cap U_x$  are disjoint, and their closures cover  $U_x$ , as shown on the left in Figure 29.
- 3. When a point x' moves and hits a  $\bullet$ -vertex x, the k-1 of the codistances  $\{a_i\}$  decrease by 1. They are the ones corresponding to the zig-zags  $\gamma$  containing the vertex x such that  $x' \in S_{\gamma}^{\circ}$ .

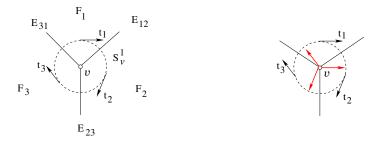

Figure 32: On the left: the edges  $E_{i,i+1}$  and faces  $F_i$  of  $\Gamma^*$  near a  $\circ$ -vertex v.

Gluing over an edge E of  $\Gamma$ . Let  $\gamma_1$  and  $\gamma_2$  be the two zig-zags passing through E, and  $s_1$  and  $s_2$  the related marked points of  $\mathbb S$ . Faces  $F_{\gamma_1}$  and  $F_{\gamma_2}$  on  $\Sigma$  intersect along the edge (identified with) E. We denote by  $\mathcal F^{a_i}$  the codimension  $a_i$  subspace of the flag  $\mathcal F(s_i)$ . Then, thanks to (116),  $a_1 + a_2 + \ldots + a_n = m-1$ , and so there is a twisted flat line bundle near the edge E on  $\mathbb S$ :

$$\mathcal{L}_E := \mathcal{F}^{a_1} \cap \mathcal{F}^{a_2} \cap \mathcal{F}^{a_3} \cap \dots \cap \mathcal{F}^{a_n}, \qquad a_1 + a_2 + \dots + a_n = m - 1. \tag{118}$$

Note that there are canonical projections

$$\mathcal{F}^{a_1} \longrightarrow \operatorname{gr}^{a_1} \mathcal{F}(s_1), \qquad \mathcal{F}^{a_2} \longrightarrow \operatorname{gr}^{a_2} \mathcal{F}(s_2).$$

Restricting them to intersection (118) we get isomorphisms of twisted flat line bundles near the edge E:

$$\mathcal{L}_{F_{\gamma_1}} \stackrel{\text{(114)}}{=} \operatorname{gr}^{a_1} \mathcal{F}(s_1) \stackrel{\sim}{\longleftarrow} \mathcal{L}_E \stackrel{\sim}{\longrightarrow} \operatorname{gr}^{a_2} \mathcal{F}(s_2) \stackrel{\text{(114)}}{=} \mathcal{L}_{F_{\gamma_2}}. \tag{119}$$

Here the very left and right isomorphisms come from the fact that the codistances from a generic point of  $S_{\gamma_1}^{\circ}$  close to the zig-zag  $\gamma_1$  are given by  $(a_1 + 1, a_2, \dots, a_n)$ , and for  $S_{\gamma_2}^{\circ}$  they are  $(a_1, a_2 + 1, \dots, a_n)$ . Using isomorphisms (119), we glue twisted flat line bundles (114) on faces  $F_{\gamma}$  into a twisted flat line bundle

$$\mathcal{L}^{\times}$$
 on  $\Sigma$  – {vertices of  $\Gamma^*$ }.

**Proposition 5.9.** The twisted flat line bundle  $\mathcal{L}^{\times}$  extends to a twisted flat line bundle  $\mathcal{L}$  on  $\Sigma$ .

*Proof.* Take a small circle  $S_v^1$  around a vertex  $v \in \Gamma^*$  on the spectral surface  $\Sigma$ . Restrict the  $\mathcal{L}^{\times}$  to a section of the bundle of non-zero tangent vectors on  $S_v^1$ . We get a flat line bundle  $\mathcal{L}_v^{\times}$  over the circle  $S_v^1$ .

**Lemma 5.10.** The monodromy of the flat line bundle  $\mathcal{L}_v^{\times}$  around every  $\circ$ -vertex v is equal to -1.

Proof. Denote by  $E_{i,i+1}$  the edge of  $\Gamma^*$  shared by the faces  $F_i$  and  $F_{i+1}$ , see Figure 32. Take a non-zero tangent vector  $t_i$  at a point of  $S_v^1 \cap F_i$  in the clockwise direction. Denote by  $\mathcal{L}_{t_i}$  the fiber of the twisted local system  $\mathcal{L}_{F_i}$  over  $t_i$ . To define the parallel transform  $\mathcal{L}_{t_i} \to \mathcal{L}_{t_{i+1}}$ , we move tangent vectors  $t_i$  and  $t_{i+1}$  towards each other to the tangent vector  $t_{i,i+1}$  at the point  $S_v^1 \cap E_{i,i+1}$ , and use isomorphisms (119). Denote by  $\tilde{t}_i$  the tangent vectors at the vertex v parallel to the tangent vectors  $t_i$ , see the red vectors on the right picture on Figure 32. We have canonical isomorphisms  $\mathcal{L}_{t_i} = \mathcal{L}_{\tilde{t}_i}$  provided by the parallel transform of tangent vectors  $t_i \to \tilde{t}_i$ . After these identifications, the parallel transform of the vector  $t_i$  around the circle  $S_v^1$  amounts to the parallel transform  $\mathcal{L}_{\tilde{t}_i}$  for the rotation of the tangent vector  $\tilde{t}_i$  by 360°, resulting the -1 monodromy.

Lemma 5.10 implies Proposition 5.9 a ∘-vertex.

Now let  $\bullet$  be a  $\bullet$ -vertex of  $\Gamma$ . Let  $v_1, \ldots, v_k$  be the  $\circ$ -vertices incident to  $\bullet$ , whose order is compatible with the cyclic structure at  $\bullet$ . A zig-zag  $\ldots v_i \bullet v_{i+1} \ldots$ , where  $i \in \mathbb{Z}/k\mathbb{Z}$ , passing via the vertex  $\bullet$  determines a  $\bullet$ -cosector, see Figure 33:

$$C_{v_i \bullet v_{i+1}} := U_{\bullet} \cap S_{\gamma}.$$

The flat line bundle over this  $\bullet$ -cosector is denoted by  $\mathcal{L}_{C_{v_i}\bullet_{v_{i+1}}}$ . Next, for each  $\circ$ -vertex  $v_i$  consider the domain  $C_{v_i}$  given by the intersection of  $U_{v_i}$  with an angle formed by the two edges at  $v_i$  on the left and on the right of the edge  $\bullet v_i$ , see Figure 33. Denote the twisted flat line bundle over this domain by  $\mathcal{L}_{C_{v_i}}$ .

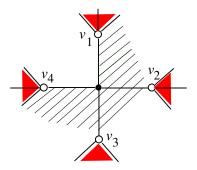

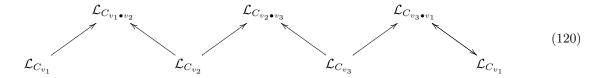

Figure 33: The shaded domain is the cosector  $C_{v_4 \bullet v_1}$ . The red ones are domains  $C_{v_i}$ .

For each i = 1, ..., k the twisted flat structure of  $\mathcal{L}$  provides a pair of isomorphisms

$$\mathcal{L}_{C_{v_i}} \longrightarrow \mathcal{L}_{C_{v_i \bullet v_{i+1}}} \longleftarrow \mathcal{L}_{C_{v_{i+1}}}.$$

They combine into a diagram of 2k line isomorphisms. For example, for k=3 we get

The same argument as in the proof of Lemma 5.6(ii) shows that the composition is  $(-1)^k$ .

Moving around the circle  $S^1_{\bullet}$  on the spectral surface  $\Sigma$  we rotate the projection to  $\mathbb S$  of the tangent vector to the circle by  $(\operatorname{val}(\bullet) - 1)2\pi$ . The composition of  $2\operatorname{val}(\bullet)$  line isomorphisms in (120) is  $(-1)^{\operatorname{val}(\bullet)}$ . Since  $\operatorname{val}(\bullet) - 1 + \operatorname{val}(\bullet)$  is odd, the result is multiplied by -1. So we can extend the twisted flat line bundle  $\mathcal{L}^{\times}$  across the  $\bullet$ -vertex. Proposition 5.9 is proved.

To prove that the constructed map is a birational equivalence of groupoids, we proceed similarly to the proof of equivalence in Theorem 5.5. Theorem 5.7 is proved.

## 6 Spectral description of twisted decorated local systems

### 6.1 The spectral description

We use the same conventions about twisted local systems on S as in Section 5.3. We recall decorated flags, defined in Section 1.2.2.

**Definition 6.1.** A twisted decorated R-local system on a decorated surface S is a twisted local system of finite dimensional R-vector spaces on S with a flat section of the associated local system of decorated flags over each marked boundary component.

Let  $\Gamma$  be a  $GL_m$ -graph on  $\mathbb{S}$ , homotopy equivalent to  $\mathbb{S}$ . Denote by  $\Sigma$  its spectral surface.

**Theorem 6.2.** Given a  $GL_m$ -graph  $\Gamma$  on  $\mathbb{S}$ , homotopy equivalent to  $\mathbb{S}$ , there is a birational equivalences of groupoids of non-commutative local systems:

$$\{m\text{-}dimensional \ \underline{twisted \ decorated} \ local \ systems \ \mathcal{V} \ on \ \mathbb{S}\} \longleftrightarrow \{Flat \ twisted \ line \ bundles \ \mathcal{L} \ on \ \Sigma, \ trivialized \ on \ the \ boundary\}.$$
 (121)

*Proof.* Equivalence (121) is obtained by applying the equivalence from Theorem 5.7 to twisted framed local systems on  $\mathbb{S}$ , equipped with an extra data: a decoration.<sup>16</sup> The description of the eigenvalue monodromy operators in Theorem 5.7 implies that the twisted flat line bundle  $\mathcal{L}$  on  $\Sigma$  assigned to  $\mathcal{V}$  has the following property:

• The restrictions of  $\mathcal{L}$  to punctured discs around the marked points in  $\pi^{-1}(s)$  are identified with the twisted flat line bundles  $\operatorname{gr}^a \mathcal{A}$  associated to the decoration of  $\mathcal{V}$  near s.

So a choice of a decoration on  $\mathcal{V}$  near a marked point s is equivalent to a choice of trivializations of the restriction of  $\mathcal{L}$  to the homotopy circles near the marked points  $\pi^{-1}(s)$ .

A coordinate description. Recall that  $\Gamma = \Gamma^*$  as graphs, and faces of  $\Gamma^*$  match zig-zags on  $\Gamma$ . By Theorem 4.2, the isomorphism classes of <u>twisted</u> flat line bundles on the spectral surface  $\Sigma$ , trivialised on the marked boundary, are described by a collection of invariants  $\Delta_{\mathbf{E}} \in \mathbb{R}^{\times}$  at the oriented edges  $\mathbf{E}$  of  $\Gamma$ , subject to the monomial relations (61).

Since the edges have canonical orientation  $\circ \to \bullet$ , given a  $\operatorname{GL}_m$ -graph  $\Gamma$  on  $\mathbb S$ , we get a collection of elements  $\Delta_E \in R^\times$ , assigned to the edges E of  $\Gamma$ . They describe generic twisted decorated local systems of m-dimensional R-vector spaces on  $\mathbb S$ . They are non-commutative counterparts of the ratios of the cluster  $\mathcal A$ -coordinates [FG1], introduced in the context of  $\operatorname{GL}_m$ -graphs  $\Gamma$  in [G].

Precisely, in the commutative case, for the twisted  $SL_m$ -local systems, the A-coordinates  $\{A_F\}$  are assigned to the faces F of the graph  $\Gamma$ . Then  $\Delta_E = A_{F_+}/A_{F_-}$ , where  $F_+$  and  $F_-$  are the two faces sharing the edge E, with the face  $F_+$  on the right of the oriented  $\circ \to \bullet$  edge. However the functions  $\{\Delta_E\}$  do not form a coordinate system: they satisfy monomial relations (61).

In Section 6.2 we elaborate the m=2 example.

### 6.2 Gluing spectral surfaces for GL<sub>2</sub>-graphs from hexagons

The spectral surface  $\Sigma$  of a  $GL_m$ -graph  $\Gamma$  was discussed in Section ??. Below we revisit the case of a  $GL_2$ -graph from a more elementary perspective, and use this to describe non-commutative twisted decorated  $GL_2$ -local systems on a decorated surface  $\mathbb S$  via flat line bundles on the spectral surface. Then in Section 6.3 we elaborate this description in detail in coordinates, relating to the Gelfand-Retakh quasideterminants and algebraic relations between them.

1. The spectral surface for the triangle. Let  $\Gamma$  be the  $GL_2$ -graph associated to the triangle t, see Figure 36. The spectral surface of  $\Gamma$  is a hexagon  $h_t$  providing a 2:1 cover of the triangle t, ramified at the central  $\bullet$ -vertex. The map  $h_t \to t$  can be realized by the map  $z \to z^2$  sending a regular hexagon in the complex plane z with the vertices at the sixth roots of unity onto a triangle with vertices at the cubic

<sup>&</sup>lt;sup>16</sup>Note that a decorated local system is unipotent.

roots of unity. The vertices of the hexagon  $h_t$  are labeled by elements of the set  $\{1,2\}$ , so that going around the hexagon the labels alternate. For each vertex v of t there is a bijection

{The vertices of the hexagon 
$$h_t$$
 over  $v$ }  $\stackrel{\sim}{\longrightarrow}$  {1, 2}.

The sides of the hexagon inherit a " $1 \rightarrow 2$ " orientation.

- 2. Gluing the spectral surface from hexagons. Let  $\mathcal{T}$  be an ideal triangulation of  $\mathbb{S}$ . For each triangle t of  $\mathcal{T}$  choose a hexagon  $h_t$  over t with the vertices labeled as above. Let us glue the hexagons  $h_t$  into a complete smooth topological surface  $\Sigma$ . Given an edge E of  $\mathcal{T}$ , there are two triangles t and t' sharing E. Let h and h' be the hexagons covering these triangles. We identify the vertices of the hexagons with the same labels, projecting onto the same vertex of  $\mathcal{T}$ . Then we glue two edges whose vertices are identified. For example, gluing two hexagons assigned to a triangulation of a rectangle we get an annulus. Denote by  $\mathbf{S}$  a complete surface obtained by filling the punctures on  $\mathbb{S}$ . Gluing hexagons  $h_t$  we get a surface  $\Sigma$  with the following properties:
  - There is a 2:1 map  $\pi:\Sigma\to\mathbf{S}$  with one ramification point in every triangle of  $\mathcal{T}$ .
  - For every marked point  $s \in \mathbf{S}$  there is a bijection  $\pi^{-1}(s) \longrightarrow \{1, 2\}$ . Moving around a triangle of  $\mathcal{T}$  we get a permutation  $\{1, 2\} \longrightarrow \{2, 1\}$ .

The spectral surface  $\Sigma$  is obtained by deleting the vertices of the triangles from  $\Sigma$ .

3. The twisted decorated flat line bundle on  $\Sigma$ . Let  $\mathcal{V}$  be a twisted decorated local system of two dimensional R-vector spaces over  $\mathbb{S}$ . So there is an invariant decorated flag  $\mathcal{A}_s$  near each marked point s. For every ideal triangle t there are decorated flags  $\mathcal{A}$ ,  $\mathcal{B}$ ,  $\mathcal{C}$  assigned to the vertices of t. We assign to the vertices of the hexagon  $h_t$  the following six trivialised lines

$$A := \mathcal{A}^{1}, \qquad B := \mathcal{B}^{1}, \qquad C := \mathcal{C}^{1},$$

$$\overline{A} := \mathcal{A}/\mathcal{A}^{1}, \quad \overline{B} := \mathcal{B}/\mathcal{B}^{1}, \quad \overline{C} := \mathcal{C}/\mathcal{C}^{1},$$
(122)

so that going around the hexagon we get the lines  $(A, \overline{B}, C, \overline{A}, B, \overline{C})$ . We denote by  $a_1$  the vector trivializing the line A, by  $a_2$  the vector trivializing the line  $\overline{A}$  etc.

The map  $h_t \to t$  sends the vertices labeled by  $A, \overline{A}$  to the vertex a, and so on, see Figure 34. We get a twisted flat line bundle  $\mathcal{L}_{h_t}$  over the hexagon, trivialised at the tangent vectors to the boundary near the vertices by the vectors provided by the decorations. For example, the line bundle near the vertex A of the hexagon is trivialised by the vector  $a_1 \in A$ . The parallel transports along the oriented edges are defined by the following maps/their inverses:

$$\varphi_{a_1,b_2}: A \longrightarrow \overline{B}.$$
(123)

Given an ideal triangulation of  $\mathbb{S}$ , and gluing the hexagons  $h_t$  into the surface  $\Sigma$ , the twisted flat line bundles  $\mathcal{L}_{h_t}$  are glued into a twisted flat line bundle  $\mathcal{L}$  on  $\Sigma$ , trivialized near the marked points.

We construct  $\mathcal{A}$ -coordinates by assigning to each edge E of the hexagonal tessellation of  $\Sigma$  an  $\Delta_E \in R^{\times}$  as follows. Let A and  $\overline{B}$  be the lines over the vertices of E, trivialized by non-zero vectors  $a_1 \in A$  and  $b_2 \in \overline{B}$ , provided by the decorations. The parallel transport  $\varphi_E : A \to \overline{B}$  along the E acts by  $\varphi_E(a_1) = \Delta_E b_2$ . For every hexagon  $h_t$ , the alternated product of the six functions  $\Delta_E$  assigned to its consecutive edges is equal to -1. There are no more relations between the functions  $\{\Delta_E\}$ .

Let us elaborate this, to see what happens when we alter a  $GL_2$ -graph  $\Gamma$  by a two by two move.

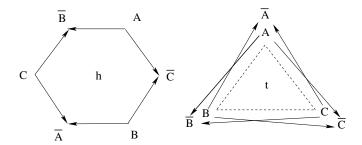

Figure 34: The twisted flat line bundle on a hexagon assigned to a triple of flags.

## 6.3 Coordinates for twisted decorated non-commutative 2-dimensional local systems on $\mathbb S$

1. Twisted triples of decorated flags. We define them as collections of decorated flags

$$\{\mathcal{F}_i\}, i \in \mathbb{Z}/6\mathbb{Z}, \text{ such that } \mathcal{F}_{i+3} = -\mathcal{F}_i \ \forall i \in \mathbb{Z}/6\mathbb{Z}.$$

**Lemma 6.3.** A twisted triple of decorated flags  $\{\mathcal{F}_i\}$  is the same thing as a twisted decorated local system on the triangle t.

*Proof.* We consider t as a disc with three marked points  $x_1, x_2, x_3$ . Pick a non-zero tangent vector  $v_i$  at the point  $x_i$ , which follow the boundary orientation. There is the unique twisted local system  $\mathcal{L}$  on the disc. We identify the fibers  $\mathcal{L}_{v_i}$  of  $\mathcal{L}$  at the vectors  $v_i$  by the parallel transport from  $v_1$  to  $v_2$  and to  $v_3$  along the boundary circle, following the circle orientation, depicted as counterclockwise on the pictures.

Set  $V := \mathcal{L}_{v_1}$ . We assign to a triple of decorated flags  $\{\mathcal{F}_i\}$  in V a pair  $(\mathcal{L}, \alpha)$ , where the decoration  $\alpha$  is given by the flag  $\mathcal{F}_i$  at the fibers  $\mathcal{L}_{v_i}$  for i = 1, 2, 3, identified with V as above.

A triple of decorated flags  $(\mathcal{A}, \mathcal{B}, \mathcal{C})$  gives rise to a twisted triple, setting

$$(\mathcal{A}, \mathcal{B}, \mathcal{C}) \longmapsto (\mathcal{A}, \mathcal{B}, \mathcal{C}, \mathcal{A}', \mathcal{B}', \mathcal{C}'), \quad \mathcal{A}' = -\mathcal{A}, \quad \mathcal{B}' = -\mathcal{B}, \quad \mathcal{C}' = -\mathcal{C}. \tag{124}$$

2. Describing twisted pairs of decorated flags in a two dimensional space. Let  $\mathcal{A}$ ,  $\mathcal{B}$  be two decorated flags in a two dimensional R-vector space  $V_2$ . Let

$$A := \mathcal{A}^1, \qquad B := \mathcal{B}^1,$$
  
 $\overline{A} := \mathcal{A}/\mathcal{A}^1, \quad \overline{B} := \mathcal{B}/\mathcal{B}^1$ 
(125)

be the pairs of associate graded lines of these flags. Each of the lines is equipped with a non-zero vector. We can describe decorated flags by these vectors, using the notation

$$\mathcal{A} = (a_1, a_2), \quad \mathcal{B} = (b_1, b_2).$$
 (126)

Projecting the line A to the quotient line  $\overline{B}$  we get an isomorphism of lines

$$\varphi_{a_1,b_2}: A \longrightarrow \overline{B}.$$
(127)

Since the lines are equipped with non-zero vectors, it is described by an element  $\Delta(a_1, b_2) \in R^*$ :

$$\varphi_{a_1,b_2}: a_1 \longmapsto \Delta(a_1,b_2)b_2. \tag{128}$$

The inverse map  $\varphi_{b_2,a_1}:\overline{B}\longrightarrow A,\ b_2\longmapsto \Delta(b_2,a_1)a_1$  is described by the invariant

$$\Delta(b_2, a_1) := \Delta(a_1, b_2)^{-1}. \tag{129}$$

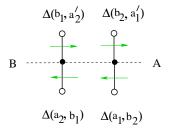

Figure 35: Invariants of a twisted pair of decorated flags (A, B, -A, -B) at the edges of a (disconnected) bipartite ribbon graph.

Generic pairs of flags (A, B) are described up to an isomorphism by the invariants  $\{\Delta(a_1, b_2), \Delta(b_1, a_2)\}$ . Let us consider now <u>twisted</u> pairs of decorated flags (A, B, -A, -B). Then the natural invariants are

$$\{\Delta(a_1, b_2), \Delta(b_1, a_2')\}, \quad a_2' := -a_2.$$

They are invariant under the twisted cyclic shift  $(\mathcal{A}, \mathcal{B}, -\mathcal{A}, -\mathcal{B}) \to (\mathcal{B}, -\mathcal{A}, -\mathcal{B}, -\mathcal{A})$ . Note that on the bipartite graph on Figure 35, consistently with (66), there are two more invariants:

$$\Delta(a_2, b_1)^{-1} = -\Delta(b_1, a_2'), \quad \Delta(b_2, a_1') := -\Delta(a_1, b_2)^{-1}.$$
(130)

3. Describing twisted triples of decorated flags in a two dimensional space. Let  $\mathcal{A}$ ,  $\mathcal{B}$ ,  $\mathcal{C}$  be three decorated flags in a two dimensional R-vector space  $V_2$ . Similar to (125), we set

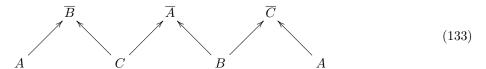

$$A := \mathcal{A}^{1}, \qquad B := \mathcal{B}^{1}, \qquad C := \mathcal{C}^{1},$$

$$\overline{A} := \mathcal{A}/\mathcal{A}^{1}, \quad \overline{B} := \mathcal{B}/\mathcal{B}^{1}, \quad \overline{C} := \mathcal{C}/\mathcal{C}^{1}.$$
(131)

We describe decorated flags by the vectors in these lines, using the notation

$$\mathcal{A} = (a_1, a_2), \quad \mathcal{B} = (b_1, b_2), \quad \mathcal{C} = (c_1, c_2).$$
 (132)

The three flags provide six such line isomorphisms, which we organize into a diagram:

We compose the six maps to a map  $A \to A$ , where going against an arrow means inverting the isomorphism. By Lemma 5.6 the composition is equal to  $-\mathrm{Id}$ . This just means that

$$\Delta(a_1, b_2)\Delta(c_1, b_2)^{-1}\Delta(c_1, a_2)\Delta(b_1, a_2)^{-1}\Delta(b_1, c_2)\Delta(a_1, c_2)^{-1} = -1.$$
(134)

Using the twisted triples of decorated flags (124), setting  $a'_1 := -a_1$ , etc., and using (129), we write this as

$$\Delta(a_1, b_2)\Delta(b_2, c_1)\Delta(c_1, a_2')\Delta(a_2', b_1')\Delta(b_1', c_2')\Delta(c_2', a_1') = 1.$$
(135)

In fact this is just equivalent to

$$\Delta(a_1, b_2)\Delta(b_2, c_1)\Delta(c_1, a_2)\Delta(a_2, b_1)\Delta(b_1, c_2)\Delta(c_2, a_1') = 1.$$
(136)

Let  $\Gamma$  be the GL<sub>2</sub>-graph associated to the triangle t, see Figure 36. The lines A, B, C are assigned to the sectors  $C_A$ ,  $C_B$ ,  $C_C$ . The lines  $\overline{A}, \overline{B}, \overline{C}$  are assigned to the cosectors  $\widehat{C}_A$ ,  $\widehat{C}_B$ ,  $\widehat{C}_C$ . The spectral

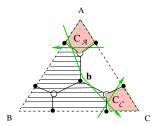

Figure 36: Sectors  $C_{\mathcal{A}}$  and  $C_{\mathcal{C}}$  (pink) and cosector  $\widehat{C}_{\mathcal{B}}$  (shaded).

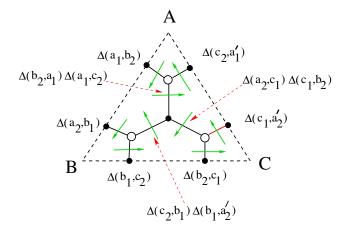

Figure 37: The  $\mathcal{A}$ -coordinates on the bipartite  $GL_2$ -graph assigned to a triangle. The coordinates at the side CA are assigned to the pair  $(\mathcal{C}, \mathcal{A}')$  where  $\mathcal{A}' := -\mathcal{A}$ , and  $(a'_1, a'_2) = (-a_1, -a_2)$ . Identity (135) means that the counterclockwise product of the coordinates at the edges at the central  $\bullet$ -vertex is 1.

surface of  $\Gamma$  is a hexagon  $h_t$  providing a 2:1 cover of the triangle t, ramified at the central  $\bullet$ -vertex.

Using this and notation (129), we assign the coordinates to the edges of the bipartite  $GL_2$ -graph related to the counterclockwise oriented triangle on Figure 37. Then we assign coordinates to the edges of a bipartite  $GL_2$ -graph associated with an ideal triangulation of the surface, as shown on Figure 38.

The cyclic product of elements at the edges incident to a  $\circ$ -vertex is -1, and for the  $\bullet$ -vertices  $(-1)^{\text{val}(v)-1}$ . For a  $\bullet$ -vertex this is the six-term identity (135), or, equivalently, (136).

The product of the two coordinates at the edges sharing a two-valent  $\bullet$ -vertex is -1. We shrink the edge containing a two-valent  $\bullet$ -vertex into a  $\circ$ -vertex. Then the cyclic product of the resulted coordinates at the edges of the new  $\circ$ -vertex is -1, as needed. The resulted coordinates for the two triangulations of a rectangle are shown on Figures 39 - 40.

**4.** In coordinates. Choose a basis  $(e_1, e_2)$  in the two dimensional R-vector space  $V_2$ . Then the three pairs of vectors  $(a_1, a_2; b_1, b_2; c_1, c_2)$  are described by a  $2 \times 6$  matrix with the columns given by decompositions

$$a_1 = a_{11}e_1 + a_{12}e_2, \quad a_2 = a_{21}e_1 + a_{22}e_2;$$
  
 $b_1 = b_{11}e_1 + b_{12}e_2, \quad b_2 = b_{21}e_1 + b_{22}e_2;$   
 $c_1 = c_{11}e_1 + c_{12}e_2, \quad c_2 = c_{21}e_1 + c_{22}e_2.$  (137)

The condition that  $a_1 - \Delta(a_1, b_2)b_2 = \lambda b_1$  for some  $\lambda \in \mathbb{R}^*$  just means that

$$(a_{11}e_1 + a_{12}e_2) - \Delta(a_1, b_2)(b_{21}e_1 + b_{22}e_2) = \lambda(b_{11}e_1 + b_{12}e_2).$$

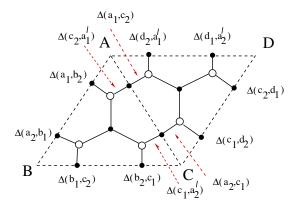

Figure 38: The  $\mathcal{A}$ -coordinates on the bipartite  $\mathrm{GL}_2$ -graph associated with a triangulated rectangle.

So we get a system of equations

$$\begin{cases}
 a_{11} - \Delta(a_1, b_2)b_{21} = \lambda b_{11}, \\
 a_{12} - \Delta(a_1, b_2)b_{22} = \lambda b_{12}.
\end{cases}$$
(138)

To solve the system, multiply the first equation from the right by  $b_{11}^{-1}$ , the second by  $b_{12}^{-1}$ , and subtract. We get the unique solution, which can be written in two slightly different ways:

$$\Delta(a_1, b_2) = (a_{11} - a_{12}b_{12}^{-1}b_{11})(b_{21} - b_{22}b_{12}^{-1}b_{11})^{-1} = (a_1, b_1)_{11}(b_1, b_2)_{21}^{-1}; 
\Delta(a_1, b_2) = (a_{11}b_{11}^{-1}b_{12} - a_{12})(b_{21}b_{11}^{-1}b_{12} - b_{22})^{-1} = (a_1, b_1)_{12}(b_1, b_2)_{22}^{-1}.$$
(139)

Here  $(x_1, x_2)_{ij}$  is the quasideterminant [GR] assigned to the (ij) entry of a 2 × 2 matrix  $(x_{ij})$ :

$$(x_1, x_2)_{11} := x_{11} - x_{12} x_{22}^{-1} x_{21}, \quad (x_1, x_2)_{12} := x_{12} - x_{11} x_{21}^{-1} x_{22}.$$

$$(x_1, x_2)_{21} := x_{21} - x_{22} x_{12}^{-1} x_{11}, \quad (x_1, x_2)_{22} := x_{22} - x_{21} x_{11}^{-1} x_{12}.$$

$$(140)$$

- **5.** Remarks. 1. Equations (138) reflect the parallel transform in the <u>twisted</u> flat line bundle, see Remark in the end of Section 5.2.
- 2. If R is commutative, formulas (139) look as follows. Pick a symplectic form  $\omega \in \det(V_2^*)$ . Then for any two vectors  $v, w \in V_2$  we have an invariant  $\omega(v, w)$ , and formula (139) can be written as:

$$\Delta(a_1, b_2) = -\omega(a_1, b_1)\omega(b_1, b_2)^{-1}$$
  
=\omega(b\_1, a\_1)\omega(b\_1, b\_2)^{-1}. (141)

**6. Flips of triangulations and non-commutative Plücker relations.** Given a basis  $(e_1, e_2)$  in the R-vector space  $V_2$ , the four pairs of vectors  $(a_1, a_2; b_1, b_2; c_1, c_2; d_1, d_2)$  are described by a  $2 \times 8$  matrix:

$$a_{1} = a_{11}e_{1} + a_{12}e_{2}, \quad a_{2} = a_{21}e_{1} + a_{22}e_{2};$$

$$b_{1} = b_{11}e_{1} + b_{12}e_{2}, \quad b_{2} = b_{21}e_{1} + b_{22}e_{2};$$

$$c_{1} = c_{11}e_{1} + c_{12}e_{2}, \quad c_{2} = c_{21}e_{1} + c_{22}e_{2};$$

$$d_{1} = d_{11}e_{1} + d_{12}e_{2}, \quad d_{2} = d_{21}e_{1} + d_{22}e_{2}.$$

$$(142)$$

Recall the Plücker identity for quasideterminants:

$$(a_1, c_1)_{11} = (a_1, b_1)_{11}(d_1, b_1)_{11}^{-1}(d_1, c_1)_{11} + (a_1, d_1)_{11}(b_1, d_1)_{11}^{-1}(b_1, c_1)_{11}.$$

$$(143)$$

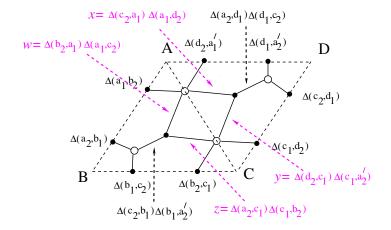

Figure 39: The A-coordinates for the triangulation AC of counterclockwise oriented rectangle ABCD.

**Proposition 6.4.** There is a non-commutative Plücker relation for the elements  $\Delta(*,*)$  from (139):

$$\Delta(a_1, c_2) = \Delta(a_1, b_2) \Delta(d_1, b_2)^{-1} \Delta(d_1, c_2) + \Delta(a_1, d_2) \Delta(b_1, d_2)^{-1} \Delta(b_1, c_2). \tag{144}$$

It is equivalent to the Plücker identity for quasideterminants.

*Proof.* We use formula  $\Delta(a_1, b_2) = (a_1, b_1)_{11}(b_1, b_2)_{21}^{-1}$  from (139). Then we have to check that

$$(a_{1}, c_{1})_{11}(c_{1}, c_{2})_{21}^{-1} \stackrel{?}{=} (a_{1}, b_{1})_{11}(b_{1}, b_{2})_{21}^{-1} \cdot (b_{1}, b_{2})_{21}(d_{1}, b_{1})_{11}^{-1} \cdot (d_{1}, c_{1})_{11}(c_{1}, c_{2})_{21}^{-1} + (a_{1}, d_{1})_{11}(d_{1}, d_{2})_{21}^{-1} \cdot (d_{1}, d_{2})_{21}(b_{1}, d_{1})_{11}^{-1} \cdot (b_{1}, c_{1})_{11}(c_{1}, c_{2})_{21}^{-1}$$

$$= (a_{1}, b_{1})_{11}(d_{1}, b_{1})_{11}^{-1}(d_{1}, c_{1})_{11}(c_{1}, c_{2})_{21}^{-1} + (a_{1}, d_{1})_{11}(b_{1}, d_{1})_{11}^{-1}(b_{1}, c_{1})_{11}(c_{1}, c_{2})_{21}^{-1}.$$

$$(145)$$

Multiplying this from the right by  $(c_1, c_2)_{21}$  we get precisely (143).

Preliminary comments. Recall from Lemma 4.2 that  $\mathcal{A}$ -decorated ribbon graphs  $\Gamma$  are in bijection with twisted one dimensional local systems on the corresponding spectral surface  $\Sigma = \mathbb{S}_{\Gamma}$ , trivialized at the boundary. By Theorem 1.8, proved in Section 1.1, the one dimensional local systems on the spectral surface inject into twisted decorated local systems on the base surface  $\mathbb{S} = \mathbb{S}_{\Gamma}$ . In the case considered in Theorem 6.5, the latter are just twisted configurations of quadruples of flags in  $V_2$ . In Theorem 6.5 below we consider the case when the ribbon graphs  $\Gamma$  and  $\Gamma'$  are dual to the two triangulations of the rectangle ABCD. If a certain quadruple of flags is in the image of both injections, for the graphs  $\Gamma$  and  $\Gamma'$ , then Theorem 6.5 tells how the corresponding  $\mathcal{A}$ -decorations of the graphs  $\Gamma$  and  $\Gamma'$  are related. Note that a quadruple of flags is described by 12 = 8 + 4  $\mathcal{A}$ -coordinates. We stress that they are not coordinates, since there are monomial relations between them.<sup>17</sup> The eight  $\mathcal{A}$ -coordinates at the external edges, see Figure 39, remain intact. So we have to explain how the  $\mathcal{A}$ -coordinates at the four rhombus edges change under a flip. The answer is given by formulas (146).<sup>18</sup>

<sup>&</sup>lt;sup>17</sup>The coordinate at the internal non-rhombus edge in each triangle is recovered by the monomial relation at its  $\circ$ -vertex. <sup>18</sup>Decorated flags in  $V_2$  depend on 3 parameters. So the space of isomorphism classes of quadruples of decorated flags in  $V_2$  depends on  $V_2$  dep

**Theorem 6.5.** The flip  $AC \to BD$  of the triangulated rectangle ABCD amounts to the following transformation of the A-coordinates, as explained in the comment above, depicted on Figures 39-40:

$$\overline{x} = (1 + (zwxy)^{-1})z = z(1 + (wxyz)^{-1}); 
\overline{y} = (1 + wxyz)^{-1}w = w(1 + xyzw)^{-1}; 
\overline{z} = (1 + (xyzw)^{-1})x = x(1 + (yzwx)^{-1}); 
\overline{w} = (1 + yzwx)^{-1}y = y(1 + zwxy)^{-1}.$$
(146)

Each of these formulas is equivalent to the non-commutative Plücker identity (144).

*Proof.* The clockwise products of the rhombus edge coordinates on Figure 39, starting from a  $\bullet$ -vertex, are given by:

$$yzwx = -\Delta(d_2, c_1)\Delta(c_1, b_2)\Delta(b_2, a_1)\Delta(a_1, d_2),$$
  

$$wxyz = -\Delta(b_2, a_1)\Delta(a_1, d_2)\Delta(d_2, c_1)\Delta(c_1, b_2).$$
(147)

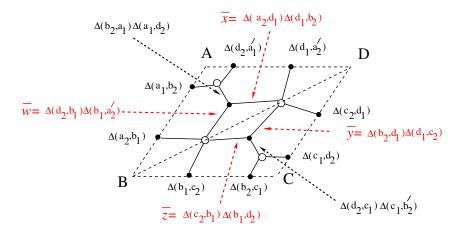

Figure 40: The  $\mathcal{A}$ -coordinates for the triangulation BD of counterclockwise oriented rectangle ABCD. We start with a configuration of 4 decorated flags  $(\mathcal{A}, \mathcal{B}, \mathcal{C}, \mathcal{D})$ . It induces triples  $(\mathcal{A}, \mathcal{B}, \mathcal{C})$  and  $(\mathcal{B}, \mathcal{C}, \mathcal{D})$ , which we promote to twisted configurations, and introduce the coordinates as on Figure 37.

Clockwise products of rhombus edge coordinates on Figure 40, starting from a ●−vertex, are given by:

$$\overline{x} \ \overline{y} \ \overline{z} \ \overline{w} = -\Delta(a_2, d_1) \Delta(d_1, c_2) \Delta(c_2, b_1) \Delta(b_1, a_2), 
\overline{z} \ \overline{w} \ \overline{y} = -\Delta(c_2, b_1) \Delta(b_1, a_2) \Delta(a_2, d_1) \Delta(d_1, c_2).$$
(148)

Now the proof is deduced easily from the following Lemma.

Lemma 6.6. We have:

$$y\overline{w}^{-1} = 1 + \Delta(d_2, c_1)\Delta(c_1, b_2)\Delta(b_2, a_1)\Delta(a_1, d_2) = 1 + yzwx;$$

$$w\overline{y}^{-1} = 1 + \Delta(b_2, a_1)\Delta(a_1, d_2)\Delta(d_2, c_1)\Delta(c_1, b_2) = 1 + wxyz;$$

$$z^{-1}\overline{x} = 1 + \Delta(b_2, c_1)\Delta(c_1, d_2)\Delta(d_2, a_1)\Delta(a_1, b_2) = 1 + (wxyz)^{-1};$$

$$x^{-1}\overline{z} = 1 + \Delta(d_2, a_1)\Delta(a_1, b_2)\Delta(b_2, c_1)\Delta(c_1, d_2) = 1 + (yzwx)^{-1}.$$
(149)

*Proof.* It is easy to see that we have the following:

$$w\overline{y}^{-1} = \Delta(b_2, a_1)\Delta(a_1, c_2)\Delta(c_2, d_1)\Delta(d_1, b_2),$$

$$z^{-1}\overline{x} = \Delta(b_2, c_1)\Delta(c_1, a_2)\Delta(a_2, d_1)\Delta(d_1, b_2),$$
(150)

and similar two identities obtained by the cyclic shift by two:  $(a, b, c, d) \mapsto (c, d, a, b)$ . Substituting the non-commutative Plücker identity (144) to formula (150) for  $w\overline{y}^{-1}$  we get

$$w\overline{y}^{-1} = \Delta(b_{2}, a_{1}) \Big( \Delta(a_{1}, b_{2}) \Delta(b_{2}, d_{1}) \Delta(d_{1}, c_{2}) + \Delta(a_{1}, d_{2}) \Delta(d_{2}, b_{1}) \Delta(b_{1}, c_{2}) \Big) \Delta(c_{2}, d_{1}) \Delta(d_{1}, b_{2})$$

$$= 1 + \Delta(b_{2}, a_{1}) \Delta(a_{1}, d_{2}) \Delta(d_{2}, b_{1}) \cdot \Delta(b_{1}, c_{2}) \Delta(c_{2}, d_{1}) \Delta(d_{1}, b_{2})$$

$$= 1 + \Delta(b_{2}, a_{1}) \Delta(a_{1}, d_{2}) \Delta(d_{2}, b_{1}) \cdot \Delta(b_{1}, d_{2}) \Delta(d_{2}, c_{1}) \Delta(c_{1}, b_{2})$$

$$= 1 - \Delta(b_{2}, a_{1}) \Delta(a_{1}, d_{2}) \Delta(d_{2}, c_{1}) \Delta(c_{1}, b_{2})$$

$$= 1 + wxyz.$$
(151)

Here to get the third equality we use the following identity, equivalent to (134), combined with (129):

$$\Delta(b_1, c_2)\Delta(c_2, d_1)\Delta(d_1, b_2) = -\Delta(b_1, d_2)\Delta(d_2, c_1)\Delta(c_1, b_2). \tag{152}$$

The identity for  $y\overline{w}^{-1}$  is obtained from this by the cyclic shift by two.

Similarly, to get formula formula (150) for  $z^{-1}\overline{x}$  we need the non-commutative Plücker identity

$$\Delta(c_1, a_2) = \Delta(c_1, d_2)\Delta(d_2, b_1)\Delta(b_1, a_2) + \Delta(c_1, b_2)\Delta(b_2, d_1)\Delta(d_1, a_2). \tag{153}$$

Substituting identity (153) to formula (150) for  $z^{-1}\overline{x}$ , we get

$$z^{-1}\overline{x} = \Delta(b_{2}, c_{1})\Delta(c_{1}, a_{2})\Delta(a_{2}, d_{1})\Delta(d_{1}, b_{2})$$

$$\stackrel{(153)}{=} \Delta(b_{2}, c_{1}) \Big( \Delta(c_{1}, d_{2})\Delta(d_{2}, b_{1})\Delta(b_{1}, a_{2}) + \Delta(c_{1}, b_{2})\Delta(b_{2}, d_{1})\Delta(d_{1}, a_{2}) \Big) \Delta(a_{2}, d_{1})\Delta(d_{1}, b_{2})$$

$$= \Delta(b_{2}, c_{1})\Delta(c_{1}, d_{2})\Delta(d_{2}, b_{1}) \cdot \Delta(b_{1}, a_{2})\Delta(a_{2}, d_{1})\Delta(d_{1}, b_{2}) + 1$$

$$= 1 - \Delta(b_{2}, c_{1})\Delta(c_{1}, d_{2})\Delta(d_{2}, b_{1}) \cdot \Delta(b_{1}, d_{2})\Delta(d_{2}, a_{1})\Delta(a_{1}, b_{2})$$

$$= 1 - \Delta(b_{2}, c_{1})\Delta(c_{1}, d_{2})\Delta(d_{2}, a_{1})\Delta(a_{1}, b_{2})$$

$$= 1 - \Delta(b_{2}, c_{1})\Delta(c_{1}, d_{2})\Delta(d_{2}, a_{1})\Delta(a_{1}, b_{2})$$

$$\stackrel{(147)}{=} 1 + (wxuz)^{-1}.$$

$$(154)$$

Here to get the fourth equality we use the identity similar to (152).

**7. Remark.** Formulas (146) imply that the monodromies starting at the ●−vertex are related as follows:

$$\overline{x} \ \overline{y} \ \overline{z} \ \overline{w} = (zwxy)^{-1}. \tag{155}$$

Indeed, the left hand side is equal to

$$z(1 + (wxyz)^{-1})(1 + wxyz)^{-1}wx(1 + (yzwx)^{-1})(1 + yzwx)^{-1}y$$

$$=z \cdot (wxyz)^{-1} \cdot wx \cdot (yzwx)^{-1} \cdot y = (zwxy)^{-1}.$$
(156)

It is also clear from Figures 39 - 40 that each side of (155) is equal to  $\Delta(a_2, d_1)\Delta(d_1, c_2)\Delta(c_2, b_1)\Delta(b_1, a_2)$ .

We say that a twisted decorated two-dimensional R-local system on  $\mathbb{S}$  is *generic*, if for any triangle t of any ideal triangulation of  $\mathbb{S}$  the decorations at the vertices of t are in generic position.

Corollary 6.7. The isomorphism classes of generic twisted decorated two-dimensional local systems on  $\mathbb{S}$  can be described by a collection of  $-3\chi(\mathbb{S}) - 1$  elements  $a_i \in R^{\times}$  which satisfy a countable collection of inequalities  $F_i(a_i) \neq 0$ , where  $F_i$  are non-commutative rational functions.

For example, generic quadruples of decorated flags in a two-dimensional R-vector space  $V_2$  are parametrised by  $f_1, ..., f_8, x, y, z, w \in R^{\times}$  where  $xyzw \neq -1$  satisfying four monomial relations.

#### 8. Proof of Theorem 4.5.

*Proof.* There are two ways to assign the non-commutative cluster  $\mathcal{A}$ -coordinates to generic quadruples of decorated flags in a two-dimensional R-vector space  $V_2$ . They correspond to the two bipartite  $GL_2$ -graphs assigned to the two triangulations of the rectangle. Formula (146) proved in Theorem 6.5 calculates the related coordinate transformation. Formula (146) is the same as the one (68).

Denote by  $\operatorname{Conf}_n^{\mathrm{df}}(V_2)^{\circ}$  the isomorphism classes of n generic decorated flags in  $V_2$ . Consider the cluster  $\mathcal{A}$ -coordinates on  $\operatorname{Conf}_5^{\mathrm{df}}(V_2)^{\circ}$ , assigned to the bipartite  $\operatorname{GL}_2$ -graphs provided by the five different triangulations of the pentagon. By Theorem 6.5, each flip of a triangulation of the pentagon is described by the transformation (68) of  $\mathcal{A}$ -coordinates for the corresponding bipartite ribbon graphs. By the construction, the composition of the five consecutive transformations describes the identity map on  $\operatorname{Conf}_5^{\mathrm{df}}(V_2)^{\circ}$ . Since the cluster  $\mathcal{A}$ -coordinates for a given triangulation of the pentagon provide an open embedding of  $\operatorname{Conf}_5^{\mathrm{df}}(V_2)$  to the cluster torus, this implies the pentagon relation for the  $\mathcal{A}$ -coordinates.

# 7 Admissible dg-sheaves on surfaces and non-commutative cluster varieties

### 7.1 Admissible dg-sheaves

1. DG-category of constructible dg-sheaves on a cell complex. Let X be a stratified topological space, such that the closure of each stratum is a ball. The strata form a partially ordered set. We write  $\sigma_1 < \sigma_2$  if  $\sigma_1 \subset \overline{\sigma}_2$  and  $\sigma_1 \neq \sigma_2$ . It determines a quiver Q, whose vertices are the strata  $\sigma$ , and vertices  $\sigma_1, \sigma_2$  are related by an arrow  $\sigma_1 \to \sigma_2$  if and only if  $\sigma_1 < \sigma_2$ .

The quiver Q determines a nonunital  $A_{\infty}$ -category Q whose objects are the strata  $\sigma$ , and

$$\operatorname{Hom}_{\mathcal{Q}}(\sigma_1, \sigma_2) := \begin{cases} \mathbb{Z} & \text{if } \sigma_1 < \sigma_2, \\ 0 & \text{otherwise.} \end{cases}$$
 (157)

The composition of Hom's is defined by the composition of arrows.

**Definition 7.1.** A constructible dg-sheaf on X is an  $A_{\infty}$ -functor from the  $A_{\infty}$ -category  $\mathcal{Q}$  to the dg-category Vect $^{\bullet}$  of complexes of R-vector spaces. Constructible dg-sheaves form a dg-category

$$\mathcal{C}_X := \operatorname{Fun}_{A_{\infty}}(\mathcal{Q}, \operatorname{Vect}^{\bullet}).$$

We consider it as a category linear over the underlying ground field - that is  $\mathbb{Q}$  if R is of characteristic zero, since  $\operatorname{Hom}_R$  and  $\otimes_R$  do not have a natural R-linear structure.

Elaborating this definition, an  $A_{\infty}$ -functor  $\mathcal{F} \in \mathrm{Ob}(\mathcal{C}_X)$  is given by the following data:

• For each nested collection of strata  $\sigma_0 < \sigma_1 < \ldots < \sigma_n$ , a map

$$f_{\sigma_0,\ldots,\sigma_n}: \mathcal{F}(\sigma_0) \otimes \operatorname{Hom}_{\mathcal{Q}}(\sigma_0,\sigma_1) \otimes \ldots \otimes \operatorname{Hom}_{\mathcal{Q}}(\sigma_{n-1},\sigma_n) \longrightarrow \mathcal{F}(\sigma_n)[1-n].$$
 (158)

These maps satisfy the well known quadratic equations.

Since the spaces  $\operatorname{Hom}_{\mathcal{O}}(\sigma_0, \sigma_1)$  are canonically identified with  $\mathbb{Z}$ , one can write (158) just as

$$f_{\sigma_0,\dots,\sigma_n}: \mathcal{F}(\sigma_0) \longrightarrow \mathcal{F}(\sigma_n)[1-n].$$
 (159)

One pictures a map (158) by a collection of points on the half-line, with the objects  $\sigma_i$  at the intervals between the points, and the object  $\mathcal{F}$  at the end point, see Figure 41. Then the terms of the quadratic equations match all the ways to collapse a collection of consecutive points.

Elaborating further, an object of the category  $\mathcal{C}_X$  is given by the following data:

$$f_{\sigma_0\sigma_1\sigma_2\sigma_3}$$
:
 $f_{\sigma_0\sigma_1\sigma_2\sigma_3}$ :
 $f_{\sigma_0\sigma_1\sigma_2\sigma_3}$ 
 $f_{\sigma_0\sigma_1\sigma_2\sigma_3}$ 
 $f_{\sigma_3\sigma_3}$ 

Figure 41: A map  $\mathcal{F}(\sigma_0) \otimes \operatorname{Hom}(\sigma_0, \sigma_1) \otimes \operatorname{Hom}(\sigma_1, \sigma_2) \otimes \operatorname{Hom}(\sigma_2, \sigma_3) \longrightarrow \mathcal{F}(\sigma_3)[-2]$ .

A complex  $C_{\sigma}$  assigned to each cell  $\sigma$ .

For each pair of strata  $\sigma_0 < \sigma_1$ , a map of complexes  $f_{\sigma_0,\sigma_1}: C_{\sigma_0} \longrightarrow C_{\sigma_1}$ . For each triple of strata  $\sigma_0 < \sigma_1 < \sigma_2$ , a homotopy  $f_{\sigma_0,\sigma_1,\sigma_2}: C_{\sigma_0} \to C_{\sigma_2}[-1]$ :

$$[d, f_{\sigma_0, \sigma_1, \sigma_2}] = f_{\sigma_1, \sigma_2} \circ f_{\sigma_0, \sigma_1} - f_{\sigma_0, \sigma_2}.$$

And so on.

Given two  $A_{\infty}$ -functors  $\mathcal F$  and  $\mathcal G$ , one defines a graded vector space

$$\operatorname{Hom}^{\bullet}(\mathcal{F},\mathcal{G}) := \prod_{n \geq 0} \prod_{\sigma_{0} < \dots < \sigma_{n}} \operatorname{Hom}^{\bullet} \Big( \mathcal{F}(\sigma_{0}) \otimes \operatorname{Hom}_{\mathcal{Q}}(\sigma_{0}, \sigma_{1}) \otimes \dots \otimes \operatorname{Hom}_{\mathcal{Q}}(\sigma_{n-1}, \sigma_{n}), \mathcal{G}(\sigma_{n}) \Big) [-n] = \prod_{n \geq 0} \prod_{\sigma_{0} < \dots < \sigma_{n}} \operatorname{Hom}^{\bullet} \Big( \mathcal{F}(\sigma_{0}), \mathcal{G}(\sigma_{n}) \Big) [-n].$$

$$(160)$$

One equips it with a natural differential, getting a complex  $\operatorname{Hom}^{\bullet}(\mathcal{F},\mathcal{G})$ .

2.  $\mathcal{H}$ -supported complexes of constructible sheaves on a manifold. Let X be an oriented n-dimensional manifold. A *coorientation* of a hypersurface H in X is a choice of a connected component of the conormal bundle to H minus the zero section. This component is called the conormal bundle to the cooriented hypersurface H.

Recall that the microlocal support of a complex of constructible sheaves  $\mathcal{F}$  on X [KS]. It is a closed conical Lagrangian subvariety of  $T^*X$ , defined as follows. Take a non-zero covector  $\eta \in T_x^*X$ , and a little ball passing through the point x and tangent to the hyperplane  $\eta = 0$  in  $T_xX$ . Move it slightly, getting a ball  $B_{\eta}$  containing x; move it the other way, getting a ball  $B'_{\eta}$  which does not contain x. Let  $B''_{\eta} := B'_{\eta} \cap B_{\eta}$ . Consider the cone of the restriction map from  $B_{\eta}$  to  $B''_{\eta}$ :

$$\operatorname{Cone}\left(\mathcal{F}(B_{\eta}) \xrightarrow{\operatorname{Res}} \mathcal{F}(B_{\eta}^{"})\right). \tag{161}$$

Then  $\eta$  does not enter the microlocal support of  $\mathcal{F}$  if and only if the complex (161) is acyclic. Finally, if an open neighborhood U of x is contained in the support of  $\mathcal{F}$ , then the zero section of  $T^*U$  belongs to the microlocal support of  $\mathcal{F}$ .

**Definition 7.2.** Let  $\mathcal{H}$  be a collection of cooriented hypersurfaces in a manifold X. A complex of constructible sheaves on X is  $\mathcal{H}$ -supported if its microlocal support is contained in the union of the zero section of  $T^*X$  and the conormal bundles to the cooriented hypersurfaces in  $\mathcal{H}$ .

The triangulated categories of complexes of constructible sheaves with microlocal support on a given collection of hypersurfaces has been studied before, see [STZ14]. Our goal is to describe a simple dg-model of its certain subcategory, that is a dg-category canonically equivalent to this subcategory, which can be studied by elementary means, which also work in the non-commutative set up.

3. Generic cooriented stratification  $\mathcal{H}$  of a manifold. Take a collection of cooriented hypersurfaces in generic position, that is locally isomorphic to a collection of coordinate hyperplanes. It provides a stratification  $\mathcal{H}$  of X. The 0-cells are the intersection points of n hypersurfaces. The 1-cells are components of the intersections of n-1 hypersurfaces minus 0-cells, and so on. Let S be a codimesion k stratum of the stratification  $\mathcal{H}$ . We can identify an open neighbourhood of S with  $S \times \mathbb{R}^k$ , where  $\mathbb{R}^k$  is the vector space with coordinates  $\{x_i\}$ , so that the codimension 1 strata containing S are given by equations  $x_i = 0$ , cooriented by  $dx_i > 0$ . The conormal bundle  $T_S^*X$  contains  $2^k$  octants. Using an isomorphism  $T_S^*X = \mathbb{R}^k \times S$ , they are given by inequalities  $\pm x_1 \geq 0, \ldots, \pm x_k \geq 0$ . The octant  $x_1 \geq 0, \ldots, x_k \geq 0$  is called the *positive octant*, and denoted by  $T_S^+X$ . The dual stratification is described by an oriented cube  $\mathcal{K}_S$ . Its vertices match the octants in  $\mathbb{R}^k$ . The oriented edges match the cooriented codinension 1 strata, etc. The cubes  $\mathcal{K}_S$  for different strata S are assembled into a cubical complex  $\mathcal{K}$  dual to the stratification  $\mathcal{H}$ , see Figure 42.

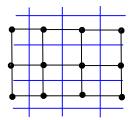

Figure 42: A cubical complex dual to a generic stratification.

In particular, for each face K of K there is a vertex  $v_{-}(K)$  assigned to the negative octant, and the opposite vertex  $v_{+}(K)$  assigned to the positive octant. They coincide if  $\dim(K) = 0$ .

**Lemma 7.3.** The microlocal support of an  $\mathcal{H}$ -supported constructible complex of sheaves  $\mathcal{F}$  on X is contained in the union of the positive octants  $T_S^+X$ , where S are the strata of  $\mathcal{H}$ .

Proof. The microlocal support of  $\mathcal{F}$  is a union of certain octants in  $T_S^*X$ . Indeed, varying the convector  $\eta$  inside of one octant we do not change the cohomology groups of complex (161). If the microlocal support intersects one of the non-positive open octants, the closure of this octant intersects a negative component of the conormal bundle to one of the codimension 1 strata, which contradicts to the condition that  $\mathcal{F}$  is  $\mathcal{H}$ -supported.

4.  $\mathcal{H}$ -supported dg-sheaves on a manifold. A dg-enhancement of the derived category of  $\mathcal{H}$ -supported complexes of constructible sheaves is given by the  $\mathcal{H}$ -supported dg-sheaves. Let us define a more economic model for it for stratifications by generic cooriented hypersurfaces.

**Proposition 7.4.** Let  $\mathcal{H}$  be a stratification of a manifold X by generic cooriented hypersurfaces, such that the closures of all strata are balls. Then  $\mathcal{H}$ -supported dg-sheaves can be described as follows, using the dual cubical complex  $\mathcal{K}$ :

### Data:

- A graded vector space  $C_v^{\bullet}$  assigned to each vertex v of K.
- A map  $\delta_K: C^{\bullet}_{v_{-}(K)} \longrightarrow C^{\bullet}_{v_{+}(K)}[1-k]$  for each k-dimensional face K of K, where  $k \geq 0$ .

**Condition:** For each face K of K, take the direct sum of the graded spaces  $C_v^{\bullet}$  at the vertices v of K, shifted by the distance  $d_v$  from v to the vertex  $v_-(K)$ .<sup>19</sup>

$$C_K^{\bullet} := \bigoplus_{v \in K} C_v^{\bullet}[-d_v].$$

<sup>&</sup>lt;sup>19</sup>If one parametrizes the vertices of a cube K by  $(\varepsilon_1, \ldots, \varepsilon_k)$ , where  $\varepsilon_i \in \{0, 1\}$ , then the distance is  $\varepsilon_1 + \ldots + \varepsilon_k$ .

• Then the signed sum  $d_K$  of the maps  $\delta_F$  assigned to the faces F of K in K satisfies  $d_K^2 = 0$ .

**Example.** Let us elaborate the cubical description of an  $\mathcal{H}$ -supported dg-sheaf in the dimension 3: For each vertex v we get a complex  $(C_v^{\bullet}, \delta_v)$ .

For each oriented edge E = (0,1) we get a morphism of complexes  $\delta_E : C_0^{\bullet} \longrightarrow C_1^{\bullet}$ .

For each square K with the vertices (00, 01, 10, 11) we get a homotopy

$$h_K: C_{00}^{\bullet} \longrightarrow C_{11}^{\bullet}[-1], \quad \delta_{11}h_K + h_K\delta_{00} = \delta_{01\to 11} \circ \delta_{00\to 01} - \delta_{10\to 11} \circ \delta_{00\to 10}.$$

For each cube C with vertices  $\{\varepsilon_1, \varepsilon_2, \varepsilon_3\}$  we get a higher homotopy  $H_{\rm C}: C_{000}^{\bullet} \longrightarrow C_{111}^{\bullet}[-2]$ :

$$\delta H_{\rm C} - H_{\rm C}\delta = \delta_{110 \to 111} \circ h_{000 \to 110} + \delta_{101 \to 111} \circ h_{000 \to 101} + \delta_{011 \to 111} \circ h_{000 \to 011} - h_{100 \to 111} \circ \delta_{000 \to 100} - h_{010 \to 111} \circ \delta_{000 \to 010} - h_{001 \to 111} \circ \delta_{000 \to 001}.$$

$$(162)$$

*Proof.* Let us show how a data  $(C_v^{\bullet}, \delta_K)$  determines a dg-sheaf on X. We start with a simple observation. Let H be a component of a cooriented hypersurface strata. Denote by  $\mathcal{D}^+$  and  $\mathcal{D}^-$  the connected domains of  $X - \mathcal{H}$  sharing H, so that H is cooriented towards  $\mathcal{D}^+$ . Let  $\mathcal{F}$  be an  $\mathcal{H}$ -supported dg-sheaf on X. Then the natural map

$$\mathcal{F}_{|H} \longrightarrow \mathcal{F}_{|\mathcal{D}^-}$$
 (163)

is a quasi-isomorphism. Indeed, its cone detects the microlocal support of  $\mathcal{F}$  in the direction opposite to the coorientation of H, and hence is acyclic. We can alter the dg-sheaf data on the component H so that the map (163) is an isomorphism, getting a quasi-isomorphic dg-sheaf.

Generalising this, let us construct an  $A_{\infty}$ -functor  $\mathcal{F}$ . Given a stratum  $\sigma$  of  $\mathcal{H}$ , let us define  $\mathcal{F}(\sigma)$ . Let us move a bit the point  $p \in \sigma$  inside of the unique n-dimensional stratum  $S_p$  in the negative direction from p, whose closure contains p. The stratum  $S_p$  is encoded by a vertex v of  $\mathcal{K}$ . We set  $\mathcal{F}(\sigma) := C_v^{\bullet}$ . The maps  $f_{\sigma_1, \dots, \sigma_n}$  are defined naturally.

Let us describe a dg-sheaf  $\mathcal{C}^{\bullet}$  near the intersection point v of two cooriented lines in  $\mathbb{R}^2$  on Figure 43. The cubical description of the dg-sheaf  $\mathcal{C}^{\bullet}$  near v is given by the following data, where  $h: C_{00}^{\bullet} \longrightarrow C_{11}^{\bullet}[-1]$ , see also Figure 43:

$$C_{01}^{\bullet} \xrightarrow{g_{1}} C_{11}^{\bullet}$$

$$f_{0} \uparrow \qquad \uparrow f_{1}$$

$$C_{00}^{\bullet} \xrightarrow{g_{0}} C_{10}^{\bullet}$$

$$(164)$$

The restriction of  $\mathcal{C}^{\bullet}$  to a ball  $\mathcal{B}$  around v is given, by the definition, by the complex  $C_{00}^{\bullet}$ . The restriction of  $\mathcal{C}^{\bullet}$  to the domain  $\mathcal{D}$  on Figure 43 is given by the following complex, where  $C_{ij}^{0}$  is in the degree i+j-1:

$$C_{01}^{\bullet} \xrightarrow{g_1} C_{11}^{\bullet}$$

$$\uparrow_{f_1}$$

$$C_{10}^{\bullet}$$

$$(165)$$

Indeed, to calculate  $C_{|\mathcal{D}}^{\bullet}$  we cover  $\mathcal{D}$  by open subsets  $\mathcal{U}$  and  $\mathcal{V}$ , where  $\mathcal{U}$  is disjoint with the horizontal line, and  $\mathcal{V}$  with the vertical. Then  $C_{|\mathcal{U}}^{\bullet} = C_{01}^{\bullet}$ ,  $C_{|\mathcal{V}}^{\bullet} = C_{10}^{\bullet}$ . Their restrictions to  $\mathcal{V} \cap \mathcal{U}$  are given by the maps  $g_1, f_1$ .

Assume that  $\mathcal{D} \subset \mathcal{B}$ . Then, using (165), the restriction of  $\mathcal{C}_{|\mathcal{B}}^{\bullet}$  to  $\mathcal{D}$  is given by the map of complexes:

$$(f_0, g_0, h): C_{00}^{\bullet} \longrightarrow \operatorname{Cone}\left(C_{01}^{\bullet} \oplus C_{10}^{\bullet} \xrightarrow{(g_1, f_1)} C_{11}^{\bullet}\right)[-1].$$
 (166)

The shifted cone of this map is the total complex associated with (164).

Figure 43: The domain  $\mathcal{D}$  intersects the two lines, but does not contain their intersection v.

**Lemma 7.5.** Given an  $\mathcal{H}$ -supported complex of sheaves  $\mathcal{F}$  on X, the complex (161) for any convector  $\eta$  inside the positive octant  $T_S^+X$  is quasiisomorphic to the complex  $(C_K^{\bullet}, d_K)$ , where K is the face of K dual to the strata S.

*Proof.* Let us elaborate the microlocal support at the vertex v on Figure 43. Then the map (161) is given by the map (166). So the claim boils down to the last sentence of the proof of Proposition 7.4.

5.  $\mathcal{H}$ -admissible dg-sheaves. Among all  $\mathcal{H}$ -supported dg-sheaves we distinguish a crucial for us subcategory of  $\mathcal{H}$ -admissible dg-sheaves.

**Definition 7.6.** Given a stratification  $\mathcal{H}$  provided by a collection of cooriented hypersurfaces in a manifold X whose Legendrians are disjoint, an  $\mathcal{H}$ -supported dg-sheaf as in Proposition 7.4 is  $\mathcal{H}$ -admissible if

ullet The complexes  $(C_K^ullet, d_K)$  satisfy the following conditions:

i) dim K = 0: 
$$H^p(C_K^{\bullet}) = 0$$
 if  $p \notin \{0, 1\}$ ,  
ii) dim K = 1:  $H^p(C_K^{\bullet}) = 0$  if  $p \notin \{0\}$ ,  
iii) dim K > 1:  $H^p(C_K^{\bullet}) = 0$  for all  $p$ .

**Lemma 7.7.** The restriction of an  $\mathcal{H}$ -admissible dq-sheaf to each hypersurface of  $\mathcal{H}$  is a local system.

*Proof.* Follows the same idea as the proof of Lemma 7.10.

Remark. Below we need subcategories of  $\mathcal{H}$ -admissible dg-sheaves with microlocal support on the (conormal bundles to) hypersurfaces of an a priori given collection of hypersurfaces  $\mathcal{H}$ . However we do not want to assume that the induced stratification is topologically trivial. A typical example is a punctured surface S with a collection of small loops near each puncture. So we consider in addition to  $\mathcal{H}$  a collection of dummy hypersurfaces, and require that the microlocal support of dg-sheaves on them is trivial, i.e. the dg-sheaves are non-singular along them. We denote by  $\widetilde{\mathcal{H}}$  the bigger collection of hypersurfaces, and choose it so that the induced stratification is topologically trivial. There is a functor from the category of  $\widetilde{\mathcal{H}}$ -admissible dg-sheaves to the triangulated category of complexes of constructible sheaves with the microlocal support in  $\mathcal{H}$ , where the latter was defined in [KS], which is is an equivalence. Using these functors one sees that the categories of  $\widetilde{\mathcal{H}}$ -admissible dg-sheaves are equivalent, and they all equivalent to the original category of  $\mathcal{H}$ -admissible dg-sheaves. See also [STZ14, Section 3] where, as the referee pointed out, the related issues are discussed.

### 7.2 The bigon and triangle moves

We consider moves of the hypersurfaces supporting the microlocal support of an admissible dg-sheaf such that the corresponding Legendrians remain disjoint. We call them admissible moves. Focusing on the dimension 2, we prove that admissible moves preserve the category of  $\mathcal{H}$ -admissible dg-sheaves.

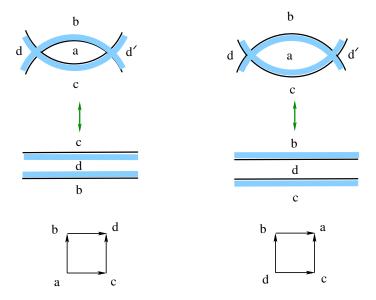

Figure 44: There are two different admissible bigon moves.

The bigon moves. There are two different admissible moves of a pair of cooriented lines in the plane, called bigon moves and shown on Figure 44. Complexes assigned to the faces and arrows between them corresponding to the cooriented lines separating them are described by the vertices and oriented edges of a square, shown at the bottom of each move.

Recall that any object of the triangulated category of representations of a Dynkin quiver is a direct sum of the shifts  $R_i[n_i]$ ,  $n_i \in \mathbb{Z}$  of indecomposable representations  $R_i$ . The isomorphism classes of the latter are parametrized by positive roots of the root system.

The two arrows from the bottom left vertex of the square form an  $A_3$ -quiver. It has six indecomposable representations. Taking into account a  $\mathbb{Z}/2\mathbb{Z}$ -symmetry of the  $A_3$ -quiver, there are just four of them to consider, depicted on Figure 45. Each of them determines uniquely an acyclic homotopy square, as shown on Figure 45.<sup>20</sup>

The quiver representation obtained by forgetting the vertex a of the square and the arrows from this vertex describe a dg-sheaf obtained by the elementary move of the original dg-sheaf.

**Theorem 7.8.** The bigon moves transform admissible dq-sheaf to admissible ones.

*Proof.* We use the remark in the end of Section 7.1 to extend to a bigger collection  $\mathcal{H}$  with topologically trivial strata of the induced stratification, to be able to restrict considerations to a small ball where we will perform the isotopy. Then the claim is clear from Figure 45.

 $<sup>^{20}</sup>$ Below we use the fact that the classification of the indecomposable reprsentations of quivers of type  $A_m$ ,  $m \leq 3$  and  $D_4$  over a skew field is exactly the same as over a field. Following the request of the referee, we present the proof in the  $D_4$  case when all arrows to a vertex v. In the paper we also need the case when they go out of v. Over a field one reduces to the other by the dualisation. Over a skew field dualisation does not work, but one proceeds by the analogy. So take a  $D_4$ -quiver with vertices a,b,c,v, and all arrows going to v. The only fact we use is that a proper linear subspace of an R-vector space has a complement. So we reduce to the case when all maps are injective: otherwise we split off a representation with  $V_v = 0$ . So from now on  $V_a, V_b, V_c \subset V_v$ . Similarly we can assume  $V_a + V_b + V_c = V_d$ . If  $W_{abc} := V_a \cap V_b \cap V_c \neq 0$ , we get a non-decomposable if  $V_a = V_b = V_c$  is of rank 1, which we can split off off an indecomposable with the dimension vector (1,0,0,1). Otherwise we get an indecomposable only of  $V_a = V_b$  is one dimensional. So we can assume  $V_a, V_b, V_c \neq 0$ . Next, we can assume that any two of  $V_a, V_b, V_c$  intersect by 0: otherwise we split off a representation of an  $A_3$  quiver with the dimension vector (1,1,1). If  $\dim(V_a) > 1$ , we can split off a subspace from  $V_a$ . So we can assume  $V_a, V_b, V_c$  are one-dimensional. We get the last indecomposable with the dimension vector (1,1,1,2).

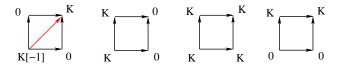

Figure 45: The squares for bigon moves. The non-trivial homotopy is shown by a red arrow. Each arrow  $K \to K$  is an isomorphism.

The triangle moves. There are two moves of a triple of cooriented lines in the plane, called IIa and IIb moves, or just triangle moves, shown on Figure 46. The complexes assigned to the faces and the arrows between them are described by the quivers shown on the bottom.

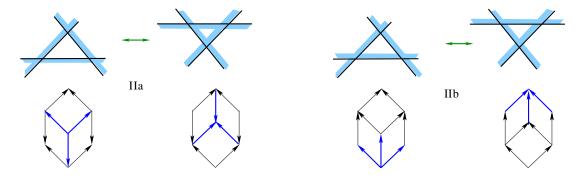

Figure 46: The triangle moves. The  $D_4$ -quivers are shown by blue arrows.

The three arrows from the central vertex form an  $D_4$ -quiver. A  $D_4$ -quiver has 12 indecomposable representations. Pick an orientation of the edges of the  $D_4$ -quiver such that the three arrows go out of the central vertex. The symmetry group of this quiver is the group  $S_3$ . Modulo the  $S_3$ -symmetry, there are 6 indecomposable representations. They are depicted on Figure 47 for the  $D_4$ -quiver whose central vertex is the bottom left vertex of the cube.

A triangle move of three cooriented lines in a 2d space is described in the 3d space-time by the three cooriented coordinate planes. The  $\mathcal{H}$ -supported dg-sheaves for the union of cooriented coordinate planes are described by data on a cube shown on Figure 47, and their shifts.

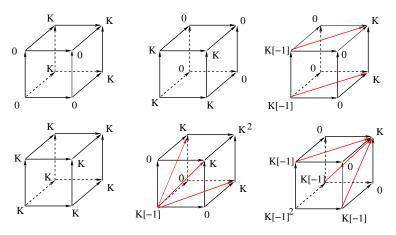

Figure 47: The cubes for elementary moves IIa and IIb. Homotopies are shown by red arrows.

Forgetting the top right vertex of the cube diagram we describe the original admissible dg-sheaf.

Forgetting the bottom left vertex we describe the resulting one. This shows how indecomposable dg-sheaves transforms under type IIa moves. Type IIb moves are treated similarly, with the comment that this time we remove bottom right vertex instead of the top right.

**Theorem 7.9.** Triangle moves transform admissible dg-sheafs to admissible ones.

*Proof.* This is clear from Figure 47. Indeed, the dg-sheaf in  $\mathbb{R}^3$  assigned to the cube is admissible, so forgetting any vertex we still get an admissible dg-sheaf.

Triangle moves provide a bijection between the isomorphism classes of indecomposable objects for two differently oriented  $A_3$ -quivers: the one oriented out of the central vertex to the one oriented towards the central vertex for the IIa move, and to the one with two edges oriented towards the central vertex for the IIb move.

### 7.3 Local systems on ideal bipartite graphs and decorated surfaces

1. Bipartite ribbon graphs and zig-zag paths. A bipartite graph  $\Gamma$  gives rise to a collection of zig-zag paths on the decorated surface  $\mathbb S$  associated with  $\Gamma$ . Denote by  $\mathcal Z$  their union. The complement  $\mathbb S-\mathcal Z$  is a disjoint union of connected domains of three types:  $\bullet$ ,  $\circ$ , and mixed domains, see Figure 48. The  $\bullet$ -domains are the ones containing a single  $\bullet$ -vertex of  $\Gamma$ . The  $\circ$ -domains contain a single  $\circ$ -vertex of  $\Gamma$ . The rest are mixed domains. The  $\bullet$  and  $\circ$ -domains are contractible.

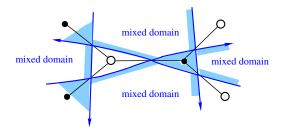

Figure 48: Zig-zag paths for a bipartite graph  $\Gamma$  on a surface  $\mathbb{S}$  cut the surface into  $\bullet$ ,  $\circ$ , and mixed domains. Each zig-zag path is coorientated by a shaded area to the right of the path.

Each zig-zag path is orientated so that the •-vertices are on the right. This plus the surface orientation provide coorientation of zig-zag paths: moving along a zig-zag path the coorientation points to the right. All sides of a •-domain are cooriented inside, all sides of a o-domain are cooriented outside, and coorintations of the sides of a mixed domain alternate.

So the union of zig-zag paths give rise to a cooriented stratification  $\mathcal{Z}$  of  $\mathbb{S}$ . Its zero stratum is the set  $\mathcal{Z}^0$  of crossing points. So there is a category of  $\mathcal{Z}$ -admissible dg-sheaves on  $\mathbb{S}$ .

- 2.  $\mathbb{Z}$ -admissible dg-sheaves. A  $\mathbb{Z}$ -admissible dg-sheaf on  $\mathbb{S}$  is given by the following data:
  - A complex of local systems  $\mathcal{F}_{\mathcal{D}}^{\bullet}$  on each domain  $\mathcal{D}$  of  $\mathbb{S} \mathcal{Z}$ , concentrated in degrees [0,1]:
  - A map of complexes  $\varphi_{\gamma}: \mathcal{F}_{\mathcal{D}^{-}}^{\bullet} \to \mathcal{F}_{\mathcal{D}^{+}}^{\bullet}$  for each component  $\gamma$  of  $\mathcal{Z} \mathcal{Z}^{0}$ , such that

$$H^i \text{Cone}(\varphi_{\gamma}) = 0 \text{ unless } i = 0.$$
 (168)

• For each crossing point of zig-zags  $\gamma$  and  $\mu$ , a homotopy - see Figure 49:

$$h: \mathcal{F}_{\mathcal{D}_{00}}^{\bullet} \longrightarrow \mathcal{F}_{\mathcal{D}_{11}}^{\bullet}[-1], \quad dh + hd = \varphi_{\mu^{+}} \circ \varphi_{\gamma^{-}} - \varphi_{\gamma^{+}} \circ \varphi_{\mu^{-}}.$$

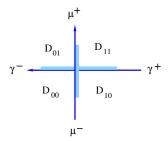

Figure 49: The stratification near a crossing point of zig-zag paths  $\gamma$  and  $\mu$  has one 0-dimensional stratum, four 1-dimensional strata  $\gamma^{\pm}$ ,  $\mu^{\pm}$  and four 2-dimensional strata  $\mathcal{D}_{**}$ .

• Let D be the signed sum of the differentials on  $\mathcal{F}_{\mathcal{D}_{ij}}^{\bullet}$ , the maps  $\varphi_{\mu^{\pm}}$ ,  $\varphi_{\gamma^{\pm}}$ , and h. The data above satisfies the condition that the following complex with the differential D is acyclic:

$$\mathcal{F}_{\mathcal{D}_{00}}^{\bullet} \oplus \mathcal{F}_{\mathcal{D}_{01}}^{\bullet}[-1] \oplus \mathcal{F}_{\mathcal{D}_{10}}^{\bullet}[-1] \oplus \mathcal{F}_{\mathcal{D}_{11}}^{\bullet}[-2]. \tag{170}$$

The last condition is equivalent to either of the following conditions:

- 1. The natural map of complexes  $\operatorname{Cone}(\varphi_{\gamma^-}) \longrightarrow \operatorname{Cone}(\varphi_{\gamma^+})$  is a quasi-isomorphism
- 2. The natural map of complexes  $\operatorname{Cone}(\varphi_{\mu^-}) \longrightarrow \operatorname{Cone}(\varphi_{\mu^+})$  is a quasi-isomorphism.
- a)  $\mathbb{Z}$ -admissible dg-sheaves on  $\mathbb{S} \longrightarrow \text{local systems on zig-zag paths.}$  Condition (168) just means that on each component  $\gamma$  of  $\mathbb{Z} \mathbb{Z}^0$  there is a local system  $\text{Cone}(\varphi_{\gamma})$ .

**Lemma 7.10.** Given a zig-zag path  $\gamma$ , local systems  $\operatorname{Cone}(\varphi_{\gamma})$  on  $\gamma$  – {crossing points} extend to a local system on  $\gamma$ , denoted by  $\operatorname{Cone}(\varphi_{\gamma})$ .

*Proof.* Condition (170) implies that for each crossing point on  $\gamma$  separating two germs of zig-zags  $\gamma^-$  and  $\gamma^+$ , there is an isomorphism  $\operatorname{Cone}(\varphi_{\gamma^-}) \xrightarrow{\sim} \operatorname{Cone}(\varphi_{\gamma^+})$ . It allows to extend local systems on components of  $\gamma$  – {crossing points} to a local system on  $\gamma$ .

b) Local systems on  $\Gamma \longrightarrow \mathcal{Z}$ -admissible dg-sheaves on  $\mathbb{S}$ , acyclic on mixed strata. A local system of vector spaces on a graph  $\Gamma$  is given by a collection of vector spaces  $V_v$  at the vertices v of  $\Gamma$  and linear maps  $\varphi_{(v,w)}: V_v \to V_w$  for each edge (v,w) of  $\Gamma$ , so that  $\varphi_{(w,v)} = \varphi_{(v,w)}^{-1}$ .

Given a local system  $\mathcal{V}$  on a bipartite graph  $\Gamma$  on  $\mathbb{S}$ , let us define a  $\mathcal{Z}$ -admissible dg-sheaf  $\mathcal{F}_{\mathcal{V}}$  on  $\mathbb{S}$ . Since the  $\bullet$  and  $\circ$  domains of  $\mathbb{S} - \mathcal{Z}$  are contractible, we can talk about the fibers of a complex of  $\mathcal{Z}$ -constructible sheaves over them. Then we define

- The fiber of  $\mathcal{F}_{\mathcal{V}}$  at the  $\circ$ -domain with a vertex  $\circ$  of  $\Gamma$  is the shifted fiber  $\mathcal{V}_{\circ}[-1]$  of  $\mathcal{V}$  at  $\circ$ .
- The fiber of  $\mathcal{F}_{\mathcal{V}}$  at the •-domain containing a vertex of  $\Gamma$  is the fiber  $\mathcal{V}_{\bullet}$  of  $\mathcal{V}$ .
- The fibers of  $\mathcal{F}_{\mathcal{V}}$  over mixed domains are zero. So the maps  $\varphi_{\gamma}$  for zig-zags  $\gamma$  are zero.

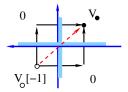

Figure 50: The admissible dg-sheaf  $\mathcal{F}_{\mathcal{V}}$  on  $\mathbb{S}$  assigned to a local system  $\mathcal{V}$  on  $\Gamma$ .

• The homotopy map for each edge  $\circ - \bullet$  of  $\Gamma$ , as illustrated on Figure 50:

$$h: \mathcal{V}_{\circ}[-1] \longrightarrow \mathcal{V}_{\bullet}[-1].$$
 (171)

This map is the shift of the parallel transport map along the edge  $\circ - \bullet$ .

So we get the following diagram near each crossing of two zig-zag paths:

$$\begin{array}{ccc}
0 & \longrightarrow \mathcal{V}_{\bullet} \\
\uparrow & & \uparrow \\
\mathcal{V}_{\circ}[-1] & \longrightarrow 0
\end{array} (172)$$

c)  $\mathcal{Z}$ -admissible dg-sheaves on  $\mathbb{S}$ , acyclic on mixed strata  $\longrightarrow$  local systems on  $\Gamma$ . Construction b) can be inverted. Namely, let  $\mathcal{F}$  be a  $\mathcal{Z}$ -admissible dg-sheaf  $\mathcal{F}$  on  $\mathbb{S}$ , acyclic on mixed strata. Then  $\mathcal{Z}$ -admissibility implies that

$$H^{i}(\mathcal{F}_{\mathcal{D}_{\circ}}) = 0 \quad \text{if } i \neq 1, \qquad H^{i}(\mathcal{F}_{\mathcal{D}_{\bullet}}) = 0 \quad \text{if } i \neq 0.$$
 (173)

Furthermore, the homotopy h provides an isomorphism

$$h: H^1(\mathcal{F}_{\mathcal{D}_{\circ}}) \xrightarrow{=} H^0(\mathcal{F}_{\mathcal{D}_{\bullet}})[-1].$$

So we get a local system  $\mathcal{L}_{\mathcal{F}}$  on the bipartite graph  $\Gamma$  by assigning the spaces  $H^1(\mathcal{F}_{\mathcal{D}_{\circ}})[1]$  to the  $\circ$ -vertices  $\circ$  of  $\Gamma$ , the ones  $H^0(\mathcal{F}_{\mathcal{D}_{\bullet}})$  to the  $\bullet$ -vertices  $\bullet$  of  $\Gamma$ , and using the isomorphism h as the parallel transport along the edge  $\circ \to \bullet$ .

d) Framed local systems on  $\mathbb{S}$  as  $\mathcal{Z}_m$ -admissible dg-sheaves. Given a decorated surface  $\mathbb{S}$ , consider a collection of m nested simple clockwise loops around each puncture, and a collection of m simple clockwise arcs around each special point, which do not intersect and do not self-intersect. They are cooriented "inside the surface", see Figure 51. Denote by  $\mathcal{Z}_m$  their union.

**Lemma 7.11.** A  $\mathcal{Z}_m$ -admissible dg-sheaf on a decorated surface  $\mathbb{S}$ , acyclic near the punctures and special points, is equivalent to an m-dimensional local system on  $\mathbb{S}$  with a framing.

*Proof.* Take a punctured disc  $\mathcal{D}^*$  with m concentric circles going clockwise around the puncture, see Figure 51. Take a radius of the disc and restrict to it a  $\mathcal{Z}_m$ -admissible complex of sheaves on  $\mathcal{D}^*$ . The restriction is described by complexes  $V_0^{\bullet}, \ldots V_m^{\bullet}$  and maps  $\varphi_{i,i+1}: V_i^{\bullet} \longrightarrow V_{i+1}^{\bullet}$  between them. To proceed further we need the following simple observation.

Let  $f: W_1^{\bullet} \longrightarrow W_2^{\bullet}$  be a map of complexes of vector spaces with the following properties:

- 1. Cone(f) is quasi isomorphic to a one dimensional vector space in the degree 0.
- 2.  $H^{i}(W_{1}^{\bullet}) = 0$  if  $i \neq 0$ .

Then  $H^i(W_2^{\bullet}) = 0$  if  $i \neq 0$ , and the induced map  $H^0(W_1^{\bullet}) \longrightarrow H^0(W_2^{\bullet})$  is injective.

Figure 51: An admssible dg-sheaf on a punctured disc stratified by m concentric outward cooriented circles, which is zero near the puncture, is a filtered vector space.

We apply this to the maps  $\varphi_{i,i+1}$ . Since  $H^{\bullet}(V_0^{\bullet}) = 0$ , we get a flag of vector spaces:

$$V_0 \hookrightarrow V_1 \hookrightarrow V_2 \hookrightarrow \ldots \hookrightarrow V_m$$
,  $\dim V_i = i$ ,  $V_i := H^0(V_i^{\bullet})$ .

The monodromy around the puncture provides an operator in the vector space  $V_m$  preserving the flag. This just means that we get a framed m-dimensional local system of vector spaces over the punctured disc  $\mathcal{D}^*$ . Applying this argument at all punctures and special points we get an m-dimensional local system on the surface  $\mathbb{S}$  equipped with an invariant flag near each puncture and each special point, that is a framed local system on the decorated surface  $\mathbb{S}$ .

Framed local systems on  $\mathbb{S} \longleftrightarrow$  flat line bundles on an ideal bipartite graph  $\Gamma$ . Let  $\mathcal{L}$  be a one dimensional local system on a  $\mathrm{GL}_m$ -bipartite graph  $\Gamma$  on  $\mathbb{S}$ . It determines a  $\mathcal{Z}$ -admissible dg-sheaf  $\mathcal{F}_{\mathcal{L}}$  on  $\mathbb{S}$  via Construction b). By the very definition, the zig-zag paths of  $\Gamma$  can be deformed using the elementary moves to a collection  $\mathcal{Z}_m$ , formed by m nested loops/arcs near each marked points. By Lemma 7.11, the resulting  $\mathcal{Z}_m$ -admissible dg-sheaf is just a framed m-dimensional local system on  $\mathbb{S}$ . The elementary moves provide birational equivalences between the corresponding categories of  $\mathcal{Z}$ -admissible dg-sheaves.

Conversely, let  $\mathcal{L}$  be a framed m-dimensional local system on  $\mathbb{S}$ . Construction d) assigns to it a  $\mathcal{Z}_m$ -admissible dg-sheaf on  $\mathbb{S}$ . Deforming back using the elementary moves the collection  $\mathcal{Z}_m$  of loops/arcs around the marked points to the collection  $\mathcal{Z}_{\Gamma}$  of zig-zag paths of the ideal bipartite graph  $\Gamma$ , we get a  $\mathcal{Z}_{\Gamma}$ -admissible dg-sheaf  $\mathcal{E}_{\mathcal{L}}$  on  $\mathbb{S}$ , which is zero near the marked points. As Figure 52 shows, this admissible

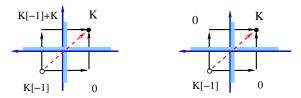

Figure 52: Two admissible dg-sheaves near a crossing point. Each provides a rank one local system on the microlocal support.

dg-sheaf may not be acyclic on all mixed domain. However for a generic  $\mathcal{Z}_m$ -admissible dg-sheaf on  $\mathbb{S}$  we get an admissible dg-sheaf acyclic on the mixed domain. The microlocal support of the obtained  $\mathcal{Z}_{\Gamma}$ -admissible dg-sheaf is described by flat line bundles on zig-zag paths  $\gamma$  of  $\Gamma$ . They are the same line bundles we had on  $\gamma$  before the deformation. Construction c) gives us a flat line bundle on the graph  $\Gamma$ .

So we get a regular injective map from the moduli space  $Loc_1(\Gamma)$  of flat line bundles on the graph  $\Gamma$  to the moduli space  $\mathcal{X}_{GL_m,\mathbb{S}}$  of framed m-dimensional local systems on  $\mathbb{S}$ , called the reconstruction map:

$$R_{\Gamma}: \operatorname{Loc}_{1}(\Gamma) \hookrightarrow \mathcal{X}_{\operatorname{GL}_{m},\mathbb{S}}.$$
 (174)

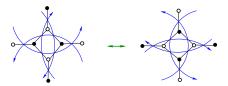

Figure 53: A two by two move of bipartite graphs.

It provides an open domain in the moduli space space  $\mathcal{X}_{\mathrm{GL}_m,\mathbb{S}}$ , which is a cluster Poisson torus. This is achieved by the following chain of constructions:

Flat line bundles on a rank m ideal bipartite graph  $\Gamma$  on  $\mathbb{S} \stackrel{b)+c)}{\longleftrightarrow}$   $\mathcal{Z}_{\Gamma}\text{-admissible dg-sheaves on } \mathbb{S}, \text{ acyclic on mixed domains } \stackrel{\text{Sec. 7.2}}{\subset}$   $\mathcal{Z}_{m}\text{-admissible dg-sheaves, vanishing near the marked points } \stackrel{d)}{\longleftrightarrow}$ Framed m-dimensional local systems on  $\mathbb{S}$ .

The middle map in (175) is an open embedding. The others are isomorphisms of moduli spaces.

A Lagrangian surface in  $\mathcal{L}_{\Gamma} \subset T^*\mathbb{S}$ . Given a bipartite graph  $\Gamma$ , note the following:

- 1. Each  $\bullet$  or  $\circ$ -domain  $\mathcal{D} \subset \mathbb{S}$  gives rise to a domain  $\mathcal{D} \subset T^*\mathbb{S}$  the zero section on  $\mathcal{D}$ .
- 2. Each cooriented zig-zag path  $\gamma$  gives rise to the conormal bundle  $T_{\gamma}^*\mathbb{S} \subset T^*\mathbb{S}$ .

**Definition 7.12.** The surface  $\mathcal{L}_{\Gamma} \subset T^*\mathbb{S}$  is the union of all these domains in  $T^*\mathbb{S}$ :

$$\mathcal{L}_{\Gamma} := \cup_{\bullet} \mathcal{D}_{\bullet} \cup_{\circ} \mathcal{D}_{\circ} \cup_{\gamma} T_{\gamma}^{*} \tag{176}$$

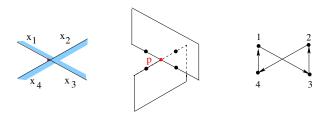

Figure 54: The link of the surface  $\mathcal{L}_{\Gamma}$  near a crossing point p is a circle  $1 \to 3 \to 2 \to 4 \to 1$ .

**Lemma 7.13.** The surface  $\mathcal{L}_{\Gamma}$  is homeomorphic to a smooth oriented surface, identified with the oriented spectral surface  $\Sigma_{\Gamma}$ .

Proof. The surface  $\mathcal{L}_{\Gamma}$  is evidently homeomorphic to a smooth surface everywhere except the crossing point of the conormal bundles  $p:=T_{\gamma_1}^*\mathbb{S}\cap T_{\gamma_2}^*\mathbb{S}$  given by the zero cotangent vector at the crossing point  $\gamma_1\cap\gamma_2$  of two zig-zag paths. To prove that it is homeomorphic to a smooth surface at p, we calculate the intersection of a small sphere at p with  $T_{\gamma_1}^*\mathbb{S}\cup T_{\gamma_2}^*\mathbb{S}$ . We claim that it is homeomorphic to a circle. This is proved on Figure 54, where we showed the link of a crossing point, observing at the same time that the projection  $\mathcal{L}_{\Gamma}\longrightarrow\mathbb{S}$  reversing the orientation on one of the triangles. (Indeed, both arrows  $3\to 2$  and  $4\to 1$  look up on Figure 54).

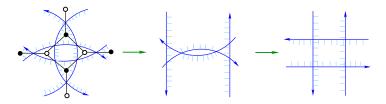

Figure 55: From the left to the right: two type II triangle moves, followed by a bigon move.

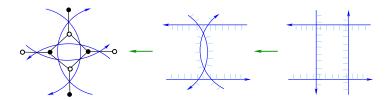

Figure 56: From the right to the left: a bigon move, followed by two triangle moves.

Two by two moves of bipartite graphs. Recall the two by two move  $\Gamma_1 \to \Gamma_2$  of bipartite graphs on Figure 53. It is decomposed into a sequence of bigon and triangle moves on Figures 55 - 56. Note that the collections of cooriented lines which we get in the process are no longer associated with bipartite graphs.

Starting from a local system  $\mathcal{L}_1$  on the graph  $\Gamma_1$ , we interpret it as an admissible dg-sheaf, and transform accordantly along the sequence of admissible moves above. In the process we get admissible dg-sheaf not associated with any bipartite graphs. However, assuming that we started from a generic local system  $\mathcal{L}_1$  on the graph  $\Gamma_1$ , the resulting admissible dg-sheaf in the end does correspond to a local system  $\mathcal{L}_1$  on the graph  $\Gamma_2$ . So we get a birational isomorphism of stacks of local systems on the graphs  $\Gamma_1$  and  $\Gamma_2$ . In particular, we get a birational isomorphism between the stacks of flat line bundles:

$$Loc_1(\Gamma_1) \longrightarrow Loc_1(\Gamma_2).$$

Our next goal is to get an explicit expression for this map for any skew field R.

Let  $B_1, B_2, B_3, B_4$  be the fibers of the local system over the  $\bullet$ -domains and  $W_1, W_3$  the fibers over the  $\circ$ -domains on the left on Figure 55. Then in the domain on the Figure the local system and hence the corresponding dg-sheaf are described by the following diagram of isomorphisms:

$$B_{1} \stackrel{\sim}{\longleftarrow} W_{1} \qquad W_{3} \stackrel{\sim}{\longrightarrow} B_{3}$$

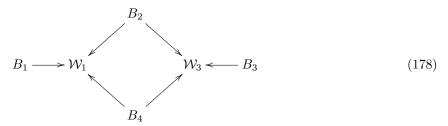

$$(177)$$

Let us set

$$\mathcal{W}_1 := \frac{B_1 \oplus B_2 \oplus B_4}{W_1}, \quad \mathcal{W}_3 := \frac{B_2 \oplus B_3 \oplus B_4}{W_3}.$$

Here we identify  $W_1$  with its image under the map  $W_1 \hookrightarrow B_1 \oplus B_2 \oplus B_4$ , and similarly for  $W_3$ . Then after the triangle moves at the two  $\circ$ -vertices we get a dg-sheaf with the microlocal support shown in the middle picture on Figure 55. Since an admissible dg-sheaf related to a bipartite graph has zero fibers over the mixed domains, the only relevant picture describing a single type IIa triangle move is the fifth

picture on Figure 47. It follows that the resulting dg-sheaf is described by the following diagram:

These maps are no longer isomorphisms since  $\operatorname{rk}(W_1) = \operatorname{rk}(W_3) = 2\operatorname{rk}(B_i)$ , and the diagram is no longer assigned to a bipartite graph. There are canonical isomorphisms

$$\mathcal{W}_1 \stackrel{\sim}{\longleftarrow} B_2 \oplus B_4 \stackrel{\sim}{\longrightarrow} \mathcal{W}_3.$$

The left one is the embedding  $B_2 \oplus B_4 \hookrightarrow B_1 \oplus B_2 \oplus B_4$ , followed by the projection to  $\mathcal{W}_1$ . The right one is similar. Combining them we get an isomorphism  $f: \mathcal{W}_1 \xrightarrow{\sim} \mathcal{W}_3$ . Setting  $X:=\mathcal{W}_1 \stackrel{f}{=} \mathcal{W}_3$ , we get a diagram

$$B_{1} \xrightarrow{B_{2}} \downarrow$$

$$\downarrow$$

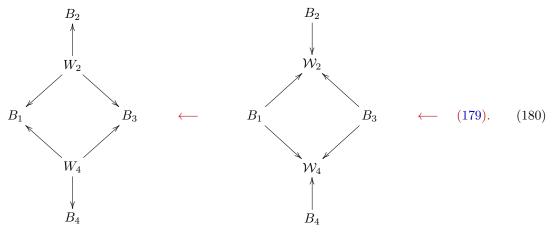

$$A \leftarrow B_{3}$$

$$\downarrow$$

$$B_{4}$$

$$(179)$$

It describes the dg-sheaf on the right of Figure 55. The transition  $(177) \rightarrow (179)$  describes the composition of the three moves on Figure 55. Then we apply the three moves on Figure 56. The corresponding transformations of quiver representations are recorded on diagram (180).

As the result we altered the dg-sheaf in the domain  $\mathcal{D}$  inside of the four  $\bullet$ -vertices, but did not alter it outside. Let us calculate how the corresponding local system inside of the domain  $\mathcal{D}$  changes. Consider the following diagram on the left, where all maps are isomorphisms:

$$\begin{array}{cccc}
L_{2} & & L_{2} \\
\downarrow & & \downarrow \\
L_{1} & \downarrow & & \downarrow \\
L_{1} & \stackrel{i_{1}}{\longleftarrow} L & \stackrel{i_{3}}{\longrightarrow} L_{3} & L_{1} & \longrightarrow \mathcal{L} & \longleftarrow L_{3}
\end{array} \tag{181}$$

Setting  $\mathcal{L} := (L_1 \oplus L_2 \oplus L_3)/L$ , it determines the diagram on the right. So there are three subspaces in  $\mathcal{L}$ . Then the third subspace  $L_3$  provides a linear isomorphism

$$\varphi_{L_1}: L_2 \longrightarrow L_3.$$

We claim that  $\varphi_{L_1} = -i_3 \circ i_2^{-1}$ . Indeed, for any  $l \in L$ , let  $l_k := i_k(l)$ . Then there are three vectors in  $\mathcal{L}$  which sum to zero:

$$(l_1, 0, 0) + (0, l_2, 0) + (0, 0, l_3) = 0$$
 in  $\mathcal{L}$ .

Now return to diagram (179), providing four subspaces in X. Then there are two isomorphisms:

$$\varphi_{B_3}: B_1 \longrightarrow B_2, \quad \varphi_{B_4}: B_1 \longrightarrow B_2.$$

Let  $M_{\rm B_2}: {\rm B_2} \longrightarrow {\rm B_2}$  be the <u>minus</u> counterclockwise monodromy in diagram (177), given by

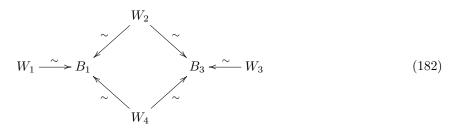

$$B_2 \longrightarrow W_1 \longrightarrow B_4 \longrightarrow W_3 \longrightarrow B_2$$
.

#### Lemma 7.14. One has

$$\varphi_{\rm B_4} = (1 + M_{\rm B_2})\varphi_{\rm B_3}.$$

*Proof.* If our local system is a rank one flat R-line bundle, it is proved by the calculation done in proof of Proposition 2.5.

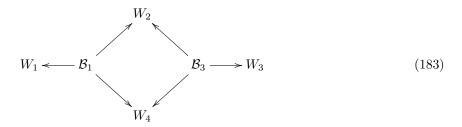

Changing  $\{\bullet\text{-vertices}\} \longleftrightarrow \{\circ\text{-vertices}\}\$  and reversing the arrows amounts to dualisation of the diagrams. Precisely, let  $W_1, W_2, W_3, W_4$  be the fibers of the local system over the black domains, and  $B_1, B_3$  the fibers over the white domains. Then the local system is described by the following diagram where all maps are isomorphisms:

Let us set

$$\mathcal{B}_1 := \operatorname{Ker} \Big( W_1 \oplus W_2 \oplus W_4 \longrightarrow B_1 \Big), \quad \mathcal{B}_3 := \operatorname{Ker} \Big( W_2 \oplus W_3 \oplus W_4 \longrightarrow B_3 \Big).$$

After the triangle moves at the two •-vertices we get a dg-sheaf described by the diagram

The composition of canonical isomorphisms  $\mathcal{B}_1 \xrightarrow{\sim} W_2 \oplus W_4 \xleftarrow{\sim} \mathcal{B}_3$  provides an isomorphism  $g: \mathcal{B}_1 \xrightarrow{\sim} \mathcal{B}_3$ . Setting  $Y:=\mathcal{B}_1=\mathcal{B}_3$ , we get a diagram

$$W_{1} \longleftarrow Y \longrightarrow W_{3}$$

$$\downarrow \qquad \qquad \downarrow$$

$$W_{4}$$

$$(184)$$

**Conclusion.** Section 7.3 gives an alternative approach to main definitions & results of Section 2.1.

**Twisted and untwisted dg-sheaves.** Given a sheaf of categories  $\mathcal{C}$  on a space X, and a cocycle  $c_2$  representing a class in  $H^2(X, \operatorname{Cent}(\mathcal{C})^*)$ , where  $\operatorname{Cent}(\mathcal{C})^*$  is given by the invertible elements of  $\mathcal{C}$ , one can make a new sheaf of categories  $\widetilde{\mathcal{C}}$ , by twisting  $\mathcal{C}$  by the 2-cocycle  $c_2$ . Precisely, take an open cover  $\{U_i\}$  of X. Then an object of  $\widetilde{\mathcal{C}}$  over X is given by objects  $A_i$  of categories  $\mathcal{C}(U_i)$ , related by isomorphisms  $f_{ij}: A_i \longrightarrow A_j$  on  $U_i \cap U_j$  which satisfy the following relations on the triple intersections:

$$f_{ik} \circ f_{ij} = c_2(U_i, U_j, U_k) f_{ik}$$

Below we use twisting by the second Stiefel-Whitney class  $\mathrm{sw}_2(\mathbb{S}) \in H^2(\mathbb{S}, \mathbb{Z}/2\mathbb{Z})$ . We can twist both the Fukaya category and the category of constructible or dg-sheafs. The Fukaya category of objects with the microlocal support on  $T_Z^*\mathbb{S}$  is naturally equivalent to the twisted constructible category on  $\mathbb{S}$ , and vice versa, see [GPS, Remark 5.2]. Note that  $\mathrm{sw}_2(\mathbb{S}) = 0$  unless  $\mathbb{S}$  is a compact non-oriented surface. So in our case the twisted category is equivalent to the original one. Yet the twisted version is somewhat better. It is the one providing positivity phenomenon in all formulas.

# 8 Non commutative stacks of framed Stokes data

At Section 8 we adopt a faster pace of the exposition than in the rest of the paper.

#### 8.1 Stokes data: local and global pictures

1. Admissible sheaves and local Stokes data. We start with two topological definitions.

**Definition 8.1.** A collection  $\mathcal{L}$  of smooth oriented loops  $L_1, \ldots, L_n$  in the punctured disc  $D^* \subset \mathbb{C}^*$  is called ideal if it enjoys the following properties:

- 1. The (self)intersection  $L_i \cap L_j$  of any two loops is transversal.
- 2. Each loop  $L_i$  rotates to the right, that is the argument function  $\varphi$  on  $D^*$  strictly decreases as we go along the loop following its orientation. We coorient the loops out of the puncture.

Cooriented loops  $L_i$  are the connected components of the Legendrian link in  $ST(D^*)$  provided by  $\mathcal{L}$ . We refer to  $\mathcal{L}$  as an *ideal Legendrian link*, although it is only a projection of a Legendrian.

**Lemma 8.2.** An ideal Legendrian link on the punctured disc  $D^*$  is the same thing as an element of the cyclic envelope  $[Br_n^+]$  of the braid semigroup,  $n \ge 0$ .

*Proof.* Cut the collection of curves  $\mathcal{L}$  by a generic ray r from the origin. Scanning the  $\mathcal{L}$  by rotating the ray to the right we get a sequence of permutations, and hence an element of the braid semigroup  $\operatorname{Br}_n^+$ , given by their product. The n=0 case is the empty link. This construction can evidently be inverted. Scanning stating from a different ray produces the same element of the cyclic braid semigroup.

Consider the subcategory  $C_0(D^*, \mathcal{L})$  of the category  $C(D^*, \mathcal{L})$  of admissible dg-sheaves on  $D^*$  for an ideal Legendrian  $\mathcal{L}$  consisting of admissible dg-sheaves which are acyclic near the puncture. By Proposition 8.5, they are automatically concentrated in the degree zero, so we refer to them just as admissible sheaves. We denote by  $[\mathcal{L}]$  the homotopy class of an ideal Legendrian  $\mathcal{L}$  on  $D^*$  under Legendrian isotopies keeping Legendrians ideal and disjunct, called admissible isotopies. Categories assigned to admissibly isotopic Legendrians  $\mathcal{L}$  are equivalent by Theorems 7.8-7.9. So the category  $C_0(D^*, \mathcal{L})$  is determined by the admissible isotopy class  $[\mathcal{L}]$ .

**Definition 8.3.** An ideal Legendrian  $\mathcal{L}$  in the punctured disc  $D^* \subset \mathbb{C}^*$  is of Stokes type if it

• The intersection  $L_i \cap L_j$  of any two different components of  $\mathcal{L}$  is non-empty.

**Definition 8.4.** A local Stokes data is a local system V of vector spaces on the circle of rays in the tangent space at zero, with an increasing filtration  $\mathcal{F}_{\bullet}$  everywhere except the fibers over a finite number of rays, called Stokes rays, related near them as follows.

Denote by  $\mathcal{F}_{\bullet}^{\pm}(\mathcal{V})$  filtrations to the right and to the left of a Stokes ray r. Then  $\mathcal{F}_{i}^{+}(\mathcal{V}) = \mathcal{F}_{i}^{-}(\mathcal{V})$  if  $i \neq a$ , and the subquotient  $\operatorname{gr}_{[a+1,a]}\mathcal{F}(\mathcal{V})$  is the direct sum of its subspaces  $\operatorname{gr}_{a}\mathcal{F}^{\pm}(\mathcal{V})$ :

$$\operatorname{gr}_{[a+1,a]}\mathcal{F}(\mathcal{V}) := \mathcal{F}_{a+1}(\mathcal{V})/\mathcal{F}_{a-1}(\mathcal{V}) = \operatorname{gr}_{a}\mathcal{F}^{+}(\mathcal{V}) \oplus \operatorname{gr}_{a}\mathcal{F}^{-}(\mathcal{V}). \tag{185}$$

**Proposition 8.5.** The following categories are canonically equivalent:

- 1. The category of local Stokes data from Definition 8.4.
- 2. The direct sum of categories  $\bigoplus_{[\mathcal{L}]} \mathcal{C}_0(D^*, \mathcal{L})$  over all homotopy types  $[\mathcal{L}]$  of Stokes Legendrians.

*Proof.* Before we proceed to the proof, let us state the following simple Lemma.

**Lemma 8.6.** An admissible sheaf near a simple crossing point is determined by a commutative diagram

Figure 57: An admissible sheaf near a crossing point.

of four vector spaces  $V_i$  on the right of Figure 57, where all arrows are injective, and the map

$$V_2/V_1 \oplus V_3/V_1 \xrightarrow{\sim} V_4$$
 (186)

is an isomorphism.

Now let us prove the Proposition.

2)  $\longrightarrow$  1). The circle  $S^1$  of rays minus the Stokes rays is a union of a finite number of intervals:

$$S^1 - \{\text{Stokes rays}\} = I_1 \cup \ldots \cup I_m.$$

Since the sheaf is zero near the puncture, the admissibility just means that on each of the intervals  $I_k$  we get a local system of filtered vector spaces. It follows from Lemma 8.6 that the admissibility implies that

this local system extends across the Stokes rays, while the filtration is altered: the filtration in  $gr_{[a+1,a]}$  flips, and the rest of the filtration data is preserved.

1)  $\longrightarrow$  2). We start from a local Stokes data on  $S^1$ . For each ray  $r \in I_k$ , we assign the associate graded quotients  $\operatorname{gr}_i \mathcal{F}^+(\mathcal{V})$  to some points of the ray so that the index i grows when we go along the ray, and when the ray moves in the interval  $I_k$ , we get a collection of curves together with local systems of vector spaces on them for each sector between the Stokes rays. We erase the curves with the zero local systems on them.

Let us glue these curves with local systems, which we have so far in the sectors of the punctured disc determined by the Stokes rays. For each  $i \neq a, a+1$ , at a Stokes ray r, we glue the curves which carry the local systems  $\operatorname{gr}_i$ , and then glue the local systems on them using the local system structure on  $\mathcal V$  near the ray. Finally, we glue the curve which carries  $\operatorname{gr}_a$  on the one side of r with the one with  $\operatorname{gr}_{a+1}$  on the other side, and glue local systems on them via the isomorphisms provided by condition (185):

$$\operatorname{gr}_a \mathcal{F}^-(\mathcal{V}) \xrightarrow{\sim} \operatorname{gr}_{a+1} \mathcal{F}^+(\mathcal{V}), \qquad \operatorname{gr}_{a+1} \mathcal{F}^-(\mathcal{V}) \xrightarrow{\sim} \operatorname{gr}_a \mathcal{F}^+(\mathcal{V}).$$
 (187)

We get a collection  $\mathcal{L}$  of loops on the disc, which never turn back, with simple crossings at the Stokes rays. Each of the loops carries a local system of vector spaces.

The claim that we get an admissible sheaf follows from Lemma 8.6. Proposition 8.5 is proved.  $\Box$ 

**Remark.** One can relax condition 1) in Definition 8.3 allowing m > 2 curves intersect at a point, with different tangents. Let us describe the corresponding analog of condition (185) in Definition 8.4. Recall that a pair of length m flags  $\mathcal{F}_{\bullet}$  and  $\mathcal{G}_{\bullet}$  in a vector space V is complimentary if  $V = \mathcal{F}_a \oplus \mathcal{G}_b$  if a + b = m.

**Lemma 8.7.** An admissible sheaf near an m-fold crossing point with different tangents, see Figure 58, is determined by a pair of vector spaces  $V_0 \subset V$  and two length m complimentary flags in  $V/V_0$ .

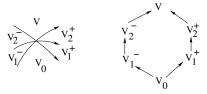

Figure 58: An admissible sheaf near a triple crossing point: the following two flags in  $V/V_0$  are complimentary to each other:  $V_1^-/V_0 \subset V_2^-/V_0$  and  $V_1^+/V_0 \subset V_2^+/V_0$ .

*Proof.* Given such an admissible sheaf, going from the bottom to the top on the left of the crossing points gives one flag, and going from the right gives the other flag.  $\Box$ 

Then there is an analog of Proposition 8.5 if instead of (185) we have the following condition: The left and right flags in the subquotient associated with the crossing point are opposite to each other.

Our next goal is to explain how Stokes Legendrian links  $\mathcal{L}$  and the categories  $\mathcal{C}_0(D^*, \mathcal{L})$  arise in complex geometry, as topological invariants of holomorphic vector bundles with connections on a punctured disc with any, possibly irregular, singularity at zero. For this we need to recall classification of connections on a formal punctured disc Spec  $\mathbb{C}((z))$ , due to Hukuhara, Turrittin, Levelt [M2].

2. Formal classification of irregular singularities. A Puiseux series is a Laurent series in  $z^{1/d}$ ,  $d \in \mathbb{Z}_{\geq 1}$ . The field of all Puiseux series is the algebraic closure  $\overline{\mathbb{C}((z))}$  of the field  $\mathbb{C}((z))$  of Laurent series in z, with the Galois group  $\widehat{\mathbb{Z}}$ . The integral closure of the ring of Taylor series  $\mathbb{C}[[z]]$  is the local ring  $\mathcal{O}_{\overline{\mathbb{C}((z))}}$  of this field. It is given by Taylor series in  $z^{1/d}$ ,  $d \geq 1$ .

Consider the quotient of the field of Puiseux series by its local ring:

$$\overline{\mathbb{C}((z))} / \mathcal{O}_{\overline{\mathbb{C}((z))}} = \lim_{d > 1} \mathbb{C}((z^{1/d})) / \mathbb{C}[[z^{1/d}]]. \tag{188}$$

**Definition 8.8.** The space  $\mathcal{G}$  is the space of orbits of the Galois action on the elements f(z) in (188).

So an element  $f(z) \in \mathcal{G}$  is presented as a Puiseux polynomial in  $z^{-1/d}$  for some positive integer d:

$$f(z) = \sum_{k>1} \lambda_k z^{-k/d}, \quad \lambda_k \in \mathbb{C},$$
(189)

where we identify  $\{f(z)\} \sim \{f(e^{2\pi i/d}z)\}\$ , and assume d is the smallest such integer.

Consider the d:1 cover of the formal punctured disc:

$$\pi_d : \operatorname{Spec} \mathbb{C}((w)) \longrightarrow \operatorname{Spec} \mathbb{C}((z)), \quad z = w^d, \quad d \ge 1.$$

Take a holonomic  $\mathcal{D}$ -module on this cover, given by the tensor product of the  $\mathcal{D}$ -module generated by  $e^{f(z)}$ , and a local system  $\mathcal{V}_w$  on Spec  $\mathbb{C}((w))$ :

$$e^{f(z)} \otimes \mathcal{V}_{w}$$
.

The  $\mathcal{V}_w$  is determined by a local system on the circle of the rays in the tangent space to 0 in the w-plane. We consider the push-forward of this  $\mathcal{D}$ -module under the map  $\pi_d$ :

$$\pi_{d*}(e^{f(z)}\otimes \mathcal{V}_w).$$

**Theorem 8.9.** The category of holonomic  $\mathcal{D}-$ modules on the formal punctured disc is decomposed into blocks, parametrised by the elements of  $\mathcal{G}$ . So any holonomic  $\mathcal{D}-$ modules on Spec  $\mathbb{C}((z))$  is isomorphic to a direct sum of the standard  $\mathcal{D}-$ modules

$$\bigoplus_{j=1}^{m} \pi_{d_j *}(e^{f_j(z)} \otimes \mathcal{V}_{w_j}), \quad f_j(z) \in \mathcal{G}.$$

$$\tag{190}$$

3. Legendrian links  $\mathcal{L}$  of Stokes type, and local Stokes data. Take a flat connection on a disc with a single singular point. By Theorem 8.9, its restriction to the formal punctured disc is a direct sum (190). So it determines a collection of different Puiseux polynomials with negative exponents:<sup>21</sup>

$$f_j(z) = \sum_{k \in \mathbb{Z}_{\geq 1}} \lambda_{j,k} z^{-k/d_j}, \quad \lambda_{j,k} \in \mathbb{C}, \quad d_j \in \mathbb{Z}_{\geq 1}, \quad j = 1, ..., m.$$

$$(191)$$

They define multivalued functions  $f_j(z)$ . Restricting them to a certain concrete but sufficiently small radius  $\varepsilon$  circle  $\{\varepsilon e^{i\theta}\}$  centered at 0, we get a collection of curves  $\{L_j\}$  given parametrically by

$$Z_j(\theta) := R_j(\theta) \cdot e^{i\theta}, \qquad R_j(\theta) := e^{\operatorname{Re} f_j(\varepsilon e^{i\theta})} \qquad j = 1, ..., m.$$
 (192)

Taking the 1-jet of the radial part  $R_j(\theta)$  of the function  $Z_j(\theta)$ , we get a Legendrian knot  $L_j$  in the space  $\mathcal{J}^1(S^1)$  of 1-jets of real functions on the circle. Explicitly,

$$\theta \longmapsto (\theta, R_i(\theta), dR_i(\theta)).$$

Their union is a Legendrian link  $\mathcal{L}$  in  $\mathcal{J}^1(S^1)$ . We call it a Legendrian link of *Stokes stype*. For a generic small  $\varepsilon$  it fits Definition 8.3.

 $<sup>^{21}</sup>$ An irreducible analytic flat connection on a punctured disc, restricted to the formal punctured disc, can be a sum of several  $\mathcal{D}$ -modules from different blocks.

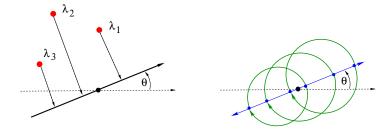

Figure 59: On the left: projecting red complex points  $\lambda_1, \lambda_2, \lambda_3$  onto a line. On the right: rotating their exponentials - blue points on the axis. The curve  $\mathcal{L}$  is the union of three green loops obtained this way.

The push-forward of the local systems  $\mathcal{V}_{w_j}$  provides a local system  $\mathcal{V}_j$  of vector spaces on the loop  $L_j$ . The pairs  $(L_j, \mathcal{V}_j)$  describe the microlocal support of an admissible sheaf.

The filtration by the order of growth provides the filtration at all but Stokes rays.

Therefore we get a local Stokes data from Definition 8.4.

Legendrian links  $\mathcal{L}$  assigned to different sufficiently small  $\varepsilon$  are isotopic, although considered as collections of curves they may look differently. Therefore the corresponding categories are canonically equivalent by Theorem 7.9.

One can consider, as Deligne and Malgrange do [M1], [M2], the limiting case when  $\varepsilon \to 0$ . Then the corresponding Legendrian link may have non-transversal crossings, with different tangents. Note that Deligne-Malgrange Stokes rays are determined by the singularity, while our Stokes rays depend also on the choice of a small radius  $\varepsilon$ .

**4. Example.** Given an  $n \times n$  matrix A with distinct eigenvalues  $\{\lambda_j\}$ , consider a differential equation

$$df = \frac{A}{z^2} f(z) dz. (193)$$

Its solutions in the eigenbasis of A are linear combinations of functions  $f_j(z) = e^{-\lambda_j/z}$ . To draw the curve  $\mathcal{L}$ , we project orthogonally points  $\{\lambda_j\}$  onto the oriented line obtained by rotating the real axis by an angle  $\theta$ , exponentiate their coordinates on the line, and put them onto the positive ray in the direction  $\theta$ . Rotating  $\theta$  from 0 to  $2\pi$ , these points move along the curve  $\mathcal{L}$ . Rotating  $\theta \to \theta + \pi$ , we change the order of the points on the ray to the opposite one, see Figure 59. So any two of these loops intersect. Therefore we get a collection of loops as in Definition 8.3.

The Stokes rays are the rays  $\text{Re}(\lambda_i - \lambda_j) = 0$  in  $\mathbb{C}$ . The local Stokes data from Definition 8.4 is given by filtration of the space of solutions in a sector around a non-Stokes ray r by the growth of a solution. It satisfies the transversality assumption (185) if no three  $\lambda_i$ 's are on the same line.

In a more general situation, solutions of type  $f_j(z) = z^{\alpha} e^{-\lambda_j/z}$  describe one dimensional local systems on these circles with the monodromies  $e^{2\pi i\alpha}$ .

**5. Legendrian links of analytic Stokes type.** Only some Stokes Legendrians describe the singular type of a connection on a disc. We call them Legendrian links of *analytic Stokes* type.

One can describe Legendrian links of analytic Stokes type as follows. Take a radius  $\varepsilon$  sphere  $S^3 \subset \mathbb{C}^2$ , and delete from it the circle in the x=0 plane. The obtained contact threefold  $S^3_{(0)}$  is identified with  $\mathcal{J}^1(S^1)$ . Let us consider a germ of an algebraic curve C in  $\mathbb{C}^2$ , reduced, but possibly reducible, with a singularity at (0,0). So it is the set of zeros of a product of different irreducible polynomials in two variables. Intersecting the curve C with  $S^3_{(0)} \subset \mathbb{C}^2$  we get a Legendrian link. All Legendrian links of analytic Stokes type are obtained this way.

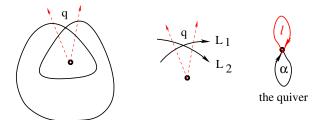

Figure 60: At the crossing point q, the local arc  $L_1$  is above the one  $L_2$ , producing a loop  $\alpha$  of the quiver. The loop l on the diagram, shown red, corresponds to the loop itself

We are now return back to arbitrary Stokes Legendrinans, and describe the corresponding category of admissible sheaves in terms of representations of a certain quiver.

- **6. Quiver description.** Consider an oriented quiver  $Q_{\mathcal{L}}$  with the vertices  $v_i$  assigned to the oriented loops  $L_i$  of  $\mathcal{L}$ , and the following arrows assigned to the loops and crossing points of  $\mathcal{L}$ , see Figure 60:
  - 1. For each vertex v, there is a simple loop  $l_v: v \longrightarrow v$  at this vertex.
  - 2. For each crossing  $q \in L_i \cap L_j$ , we have an arrow  $\alpha_q : v_i \to v_j$  if  $L_i$  is above  $L_j$  to the right of q.

**Theorem 8.10.** 1. The category  $C(D^*, \mathcal{L})$  is abelian. It is equivalent to the category  $\mathcal{R}(Q_{\mathcal{L}}^*)$  of representations of the quiver  $Q_{\mathcal{L}}$ , with invertible arrows  $l_v$ .

2. If a Legendrian link  $\mathcal{L}$  is of analytic Stokes type, that is arises from a singular point of a holomorphic vector bundle with connection on  $D^*$ , possibly irregular, then the stack  $\mathcal{M}_{D^*}(\mathcal{L})$  is equivalent to the Betti stack of given irregular type, also known as the stack of Stokes data.

Remark. Since the category of representations of the quiver  $Q_{\mathcal{L}}$  is abelian, the category  $\mathcal{C}_{D^*}(\mathcal{L})$  is abelian. The category  $\mathcal{C}(D^*, \mathcal{L})$  assigned to a general ideal Legendrian is not abelian. Indeed, if  $\mathcal{L}$  is isotopic to a collection of concentric circles, we get the category of filtered vector spaces.

*Proof.* i) Pick a reference point  $p_i$  at each loop  $L_i$  of  $\mathcal{L}$ .

For each intersection/selfintersection point  $q \in L_i \cap L_j$ , let  $\kappa_1, \kappa_2$  be little intervals on the loops  $L_i$ ,  $L_j$  containing q. They are ordered so that the interval  $\kappa_1$  goes above  $\kappa_2$  to the right of q, see Figure 60. Pick paths in the positive direction connecting the point q with reference points  $p_i$  and  $p_j$ .

Let us assign to a representation  $\mathcal{R}$  of the quiver  $Q_{\mathcal{L}}$  a sheaf  $\mathcal{S}_{\mathcal{R}}$  on the punctured disc D\*.

First, we define a local system  $\mathcal{V}_i$  on each loop  $L_i$ . Recall the vertex v of the quiver assigned to the loop  $L_i$ . Put the vector space  $\mathcal{R}(v)$  to the reference point  $p_i$  on  $L_i$ . Then the operator  $\mathcal{R}(l_v) : \mathcal{R}(v) \longrightarrow \mathcal{R}(v)$  for the loop  $l_v$  describes the monodromy of the local system on the loop  $L_i$  in the positive direction.

Next, we define the fiber of the sheaf  $\mathcal{S}_{\mathcal{R}}$  at a point  $d \in D^* - \{\text{Stokes rays}\}$ . Denote by  $\gamma_1, \ldots, \gamma_k$  the little intervals on the curve  $\mathcal{L}$  containing the intersection points of the segment connecting 0 and d with  $\mathcal{L}$ . Then fiber of the sheaf  $\mathcal{S}_{\mathcal{R}}$  at d is the direct sum of the fibers of the local systems  $\mathcal{V}_i$  at the intervals:

$$\mathcal{S}_{\mathcal{R}}(d) := \bigoplus_{i=1}^k \mathcal{V}_i(\gamma_i).$$

We order the intervals away from 0, and filter the fiber by subspaces  $\bigoplus_{i=1}^{p} \mathcal{V}_i(\gamma_i)$ .

We extend the sheaf to  $D^* - \{\text{crossing points}\}\$  in the obvious way. Note that the filtration above is defined only away from the Stokes rays. Let us use the maps  $\mathcal{R}(\alpha_q)$  assigned to the arrows  $\alpha_q$  of the quiver to extend the sheaf to the crossing points.

Denote by  $\mathcal{V}_{\kappa_i}$  the fiber of the local system on  $\mathcal{L}$  over the interval  $\kappa_i$ , i = 1, 2. The stalk  $\mathcal{S}_{\mathcal{R}}(q)$  of the sheaf at a crossing point q is mapped by the restriction map to the stalks  $\mathcal{S}_{\mathcal{R}}(q_{\pm})$  on the right/left of q. These maps are isomorphisms, since the sheaf does not have microlocal support in those directions. So an extension of the sheaf to the point q provides isomorphisms

$$\mathcal{V}_{\leq q} \oplus \mathcal{V}_{\kappa_1} \oplus \mathcal{V}_{\kappa_2} =: \mathcal{S}_{\mathcal{R}}(q_-) \stackrel{\sim}{\longleftarrow} \mathcal{S}_{\mathcal{R}}(q) \stackrel{\sim}{\longrightarrow} \mathcal{S}_{\mathcal{R}}(q_+) := \mathcal{V}_{\leq q} \oplus \mathcal{V}_{\kappa_1} \oplus \mathcal{V}_{\kappa_2}.$$

So to extend the sheaf to the point q one just needs to define a linear automorphism of  $\mathcal{V}_{\leq q} \oplus \mathcal{V}_{\kappa_1} \oplus \mathcal{V}_{\kappa_2}$ , which is the identitity on  $\mathcal{V}_{\leq q}$ , and preserves  $\mathcal{V}_{\kappa_1} \oplus \mathcal{V}_{\kappa_2}$ . We define the latter by setting

$$(v_1, v_2) \longrightarrow (v_1, \mathcal{R}(\alpha_q)(v_1) + v_2). \qquad \mathcal{R}(\alpha_q) : V_{\kappa_1} \longrightarrow V_{\kappa_2}.$$
 (194)

Then it also preserving the filtration  $V_{\kappa_1} \subset V_{\kappa_1} \oplus V_{\kappa_2}$ , as required in our situation.

This functor is an equivalence. This is a non-trivial result, and we do not present here a proof.

- ii) This is a reformulation of the known description [DMR], [M2] of the analytic Stokes data in terms of the filtration of the space of solutions given by the order of growth, and the way it changes when we cross Stokes rays.
- 7. Global Stokes data. Below S is an oriented topological surface, possibly with punctures.

**Definition 8.11.** A Legendrian  $\mathcal{L}$  on S is ideal / Stokes type, if it admissibly isotopic to a disjoint union of Legendrians  $\mathcal{L}_p$  from Definition 8.1 / 8.3 near punctures p on S:

$$\mathcal{L} = \cup_p \mathcal{L}_p, \quad \mathcal{L}_p \cap \mathcal{L}_q = \emptyset.$$

**Definition 8.12.** A Stokes data on S is a local system V of vector spaces on S, plus a local Stokes data at the specialization of V to each puncture.

The following Proposition is an immediate consequence of Proposition 8.5.

**Proposition 8.13.** Given an ideal Legendrian  $\mathcal{L}$  on S, the category of Stokes data on S of the topological type  $\mathcal{L}$  is equivalent to the category  $\mathcal{C}_0(S;\mathcal{L})$  of admissible sheaves on S with the microlocal support on  $\mathcal{L}$  and the zero section of  $T^*S$ , which vanish near the marked points.

8. Non-commutative stacks of Stokes data. Denote by  $\mathcal{S}(\mathcal{L}, d)$  the stack of Stokes data of a given topological type  $(\mathcal{L}, d)$  on S. The topological types are described by the pairs  $(\mathcal{L}, d)$ , where  $\mathcal{L}$  is an ideal Legendrian links on ST(S) from Definition 8.11, modulo admissible Legendrian isotopies, equipped with local systems of vector spaces on the connected components  $\mathcal{L}_{\alpha}$  of the Legendrian  $\mathcal{L}$ . Dimensions of local systems are encoded by the dimension vector  $d = \{d_{\alpha}\}$ . When  $\mathcal{L}$  is empty, we recover the stack  $Loc_m(S)$ .

**Definition 8.14.** The non-commutative stack of Stokes data  $\mathcal{S}^{nc}(\mathcal{L}, d)$  of the topological type  $(\mathcal{L}, d)$  is the stack  $\mathcal{M}_0(\mathcal{L}, d)$  of  $\mathcal{L}$ -admissible dg-sheaves of R-vector spaces on S vanishing near the punctures of S, whose microlocal support on  $\mathcal{L}_{\alpha}$  is a local system on the loop  $\mathcal{L}_{\alpha}$  of dimension  $d_{\alpha}$ :

$$\mathcal{S}^{\mathrm{nc}}(\mathcal{L}, d) := \mathcal{M}_0(\mathcal{L}, d).$$

## 8.2 The Riemann-Hilbert correspondence and the wild mapping class group

In Section 8.2 we work in the commutative set-up.

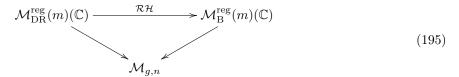

1. The classical Riemann-Hilbert correspondence. Given a Riemann surface  $\Sigma$ , recall the de Rham stack  $\mathcal{M}_{\mathrm{DR}}^{\mathrm{reg}}(m,\Sigma)$  of rank m vector bundles with meromorphic connections with regular singularities on  $\Sigma$ . Its Betti variant is the stack  $\mathrm{Loc}_m(S)$  of local systems of m-dimensional vector spaces on the topological surface S underlying  $\Sigma$ .

The classical Riemann-Hilbert correspondence [D] identifies the associated complex analytic stacks:

$$\mathcal{RH}^{\mathrm{reg}}_{\Sigma}: \mathcal{M}^{\mathrm{reg}}_{\mathrm{DR}}(m,\Sigma)(\mathbb{C}) \xrightarrow{\sim} \mathrm{Loc}_m(S)(\mathbb{C}).$$

However the algebraic structures of these stacks are different. The algebraic structure of  $\mathcal{M}_{\mathrm{DR}}^{\mathrm{reg}}(m,\Sigma)$  depends on the complex structure on  $\Sigma$ . When  $\Sigma$  varies, we get the algebraic de Rham stack  $\mathcal{M}_{\mathrm{DR}}^{\mathrm{reg}}(m)$  over the moduli space  $\mathcal{M}_{g,n}$ . Contrary to this, the algebraic structure of the Betti stack depends only on the topology of  $\Sigma$ . When  $\Sigma$  varies, we get a local system of the Betti stacks over  $\mathcal{M}_{g,n}$ . Equivalently, the mapping class group  $\Gamma_S = \pi_1(\mathcal{M}_{g,n})$  of S acts by automorphisms of the stack  $\mathrm{Loc}_m(S)$ .

Summarising, we get the canonical universal Riemann-Hilbert equivalence:

To generalize it to irregular singularities, we need the Betti side, given by moduli spaces of Stokes data.

**2.** The Riemann-Hilbert correspondence. We start with a pair  $(S, \mathcal{L})$ , where  $\mathcal{L} = \cup \mathcal{L}_p$  is a Legendrian link of analytic Stokes type on a surface S, considered up to admissible isotopies.

**Definition 8.15.** The moduli space  $\mathcal{P}_{S,\mathcal{L}}$  parametrises data  $(\Sigma, \{f_j\})$ , where  $\Sigma$  is a Riemann surface of the topological type S, and  $\{f_j \in \mathcal{G}_p\}$  is a collection of distinct Puiseux polynomials<sup>22</sup> from Definition 8.8 near the punctures p on  $\Sigma$ , with a given admissible isotopy class of the corresponding Legendrian  $\mathcal{L}$ .

Forgetting Puiseux polynomilas, we get a projection, where S is a genus g surface with n punctures:

$$\mathcal{P}_{S,\mathcal{L}} \longrightarrow \mathcal{M}_{q,n}.$$
 (196)

Given a Legendrian link  $\mathcal{L}$  of Stokes type on S, there are the following categories and stacks:

- 1. The category of admissible sheaves  $\mathcal{C}(S,\mathcal{L})$ , and the stack of its objects  $\mathcal{M}(S,\mathcal{L})$ .
- 2. The DeRham stack  $\mathcal{M}_{DR}(S,\mathcal{L})$  of holomorphic vector bundles with connection over a Riemann surface  $\Sigma$  of topological type S, with the given homotopy class of the Legendrian link  $\mathcal{L}$  assigned to its formal equivalence class. It is fibered over the stack  $\mathcal{P}_{S,\mathcal{L}}$ :

$$\mathcal{M}_{\mathrm{DR}}(S,\mathcal{L}) \longrightarrow \mathcal{P}_{S,\mathcal{L}}.$$
 (197)

3. The Betti stack  $\mathcal{M}_{B}(S,\mathcal{L})$ , which is a local system of stacks  $\mathcal{M}_{B}(S,\mathcal{L})$  over  $\mathcal{P}_{S,\mathcal{L}}$ .

Its fiber over a point  $(\Sigma, \{f_j\}) \in \mathcal{P}_{S,\mathcal{L}}$  is the stack  $\mathcal{M}(S,\mathcal{L})$  for the Legendrian link  $\mathcal{L}$  of  $\{f_j\}$ .

The fact that it is indeed a well defined local system of stacks, e.g. does not depend on the choice of radius  $\varepsilon$  in the assignment  $\{f_j\} \longmapsto \mathcal{L}$ , and locally constant over the base, is guaranteed by Theorem 7.9.

The wild Riemann-Hilbert correspondence [M2] is a complex analytic equivalence of stacks over  $\mathcal{P}_{\mathcal{S},\mathcal{L}}$ :

$$\mathcal{M}_{\mathrm{DR}}(S,\mathcal{L}) \xrightarrow{\mathcal{RH}} \mathcal{M}_{\mathrm{B}}(S,\mathcal{L})$$

$$\mathcal{P}_{S,\mathcal{L}} \tag{198}$$

<sup>&</sup>lt;sup>22</sup>The space  $\mathcal{G}_p$  is defined via the local ring  $\mathcal{O}_p$  of functions at a point  $p \in \Sigma$ . It does not depend on a local parameter z.

The algebraic structure of the fibers of the De Rham stack over  $\mathcal{P}_{S,\mathcal{L}}$  varies, while for the Betti stack it does not. The Betti stack form a local system of stacks over  $\mathcal{P}_{S,\mathcal{L}}$ . In particular, we can define the analog of isomonodromic deformation for irregular holomorphic connections.

3. The wild mapping class group. Comparing the classical Riemann-Hilbert correspondence (195) with the one (198), we see that the right analog of  $\mathcal{M}_{q,n}$  is the moduli space  $\mathcal{P}_{S,\mathcal{L}}$ , and arrive at

**Definition 8.16.** The wild mapping class group is the fundamental group  $\Gamma_{S,\mathcal{L}} := \pi_1(\mathcal{P}_{S,\mathcal{L}})$ .

The wild mapping class group  $\Gamma_{S,\mathcal{L}}$  acts by automorphisms of the stack  $\mathcal{M}(S,\mathcal{L})$ .

The map (196) provides a surjection  $\Gamma_{S,\mathcal{L}} \longrightarrow \Gamma_S$ . The group  $\Gamma_{S,\mathcal{L}}$  is an extension of the mapping class group  $\Gamma_S$  by the product over the punctures p of S of the local wild mapping class groups  $\Gamma_{D^*,\mathcal{L}_p}$ :

$$1 \longrightarrow \prod_{p} \Gamma_{D^*, \mathcal{L}_p} \longrightarrow \Gamma_{S, \mathcal{L}} \longrightarrow \Gamma_S \longrightarrow 1.$$
 (199)

**Example.** In example (193) in Section 8.1, the space  $\mathcal{P}_{D^*,\mathcal{L}}$  for the punctured disc is given by collections of distinct complex numbers  $\{\lambda_j\}$ . The wild mapping class group  $\Gamma_{S,\mathcal{L}}$  is the braid group  $\operatorname{Br}_n$ .

Below we will discuss topological ramifications of this definition.

- 4. Three flavors of Legendrian mapping class groups. There are three flavors of the space of Legendrian links  $\mathcal{L} \subset \mathrm{ST}^*(S)$  and Hamiltonian isotopies betwen them. Therefore there are three flavors of Legendrian mapping class group, defined as the fundamental group of the connected component of  $\mathcal{L}$ .
- 1. The space of <u>all</u> Legendrians  $\mathcal{L} \subset ST^*(S)$  and Hamiltonian isotopies. The Legendrian mapping class group  $\Gamma_{leg,S,\mathcal{L}}$  is the fundamental group of the connected component containing  $\mathcal{L}$ . By [GKS], it acts by autoequivelences of the triangulated/dg category of constructible sheaves on S.
- 2. Legendrians given by <u>smooth</u> loops in S, and <u>admissible</u> Hamiltonian isotopies between them. The admissible Legendrian mapping class group  $\Gamma_{\text{adm},S,\mathcal{L}}$  is the fundamental group of the component of  $\mathcal{L}$ . By Theorems 7.8 7.9, it acts by autoequivelences of the category  $\mathcal{C}(S,\mathcal{L})$  of admissible dg-sheaves.
- 3. The <u>ideal</u> Legendrians  $\mathcal{L}$  which are, by the definition, admissibly isotopic to a union of local ideal Legendrians  $\mathcal{L}_p$  near the punctures p of S, modulo admissible Hamiltonian isotopies. The *wild mapping class group*  $\Gamma_{S,\mathcal{L}}$  is the fundamental group of the connected component of  $\mathcal{L}$ . It acts by preserving cluster structures of the moduli spaces of Stokes data, see Section 8.3.

These spaces are nested:  $(3) \subset (2) \subset (1)$ . Therefore there are maps of the corresponding groups:

$$\Gamma_{S,\mathcal{L}} \longrightarrow \Gamma_{\text{adm},S,\mathcal{L}} \longrightarrow \Gamma_{\text{leg},S,\mathcal{L}}.$$
 (200)

5. A combinatorial description of the wild mapping class group. Given a Weyl group W, consider the following stratified space  $\mathcal{C}_W$ . Its strata  $\mathcal{S}_{\beta}$  are given by collections  $\beta = \{w_1, ..., w_n\}$  of the cyclically ordered elements of W assigned to distinct points on a circle, so that the cyclic order of the points on the circle coincides with the one of  $\beta$ . So  $\mathcal{S}_{\beta}$  is homeomorphic to  $S^1 \times \mathbb{R}^{n-1}$ .

If  $l(w_i w_{i+1}) = l(w_i) + l(w_{i+1})$ , the stratum  $S_{w_1, \dots, w_i w_{i+1}, \dots, w_n}$  lies on the boundary of  $S_{w_1, \dots, w_i, w_{i+1}, \dots, w_n}$ . Denote by  $C_{\beta}$  the connected component of the cell complex  $C_W$  containing the strata  $S_W$ . The space  $C_{\beta}$  is determined by the image  $[\beta]$  of the element  $\beta$  in the cyclic envelope of the braid semigroup  $Br_W^+$  assigned to W, discussed in Section 8.4.

Let  $W = S_N$ . Then  $[\beta]$  determines a cyclic braid. Denote the corresponding Legendrian by  $\mathcal{L}_{[\beta]}$ .

**Proposition 8.17.** The local wild mapping class group  $\Gamma_{\mathcal{L}_{[\beta]}}$  is the fundamental group of  $\mathcal{C}_{\beta}$ :

$$\Gamma_{\mathcal{L}_{[\beta]}} := \pi_1(\mathcal{C}_\beta).$$

## 8.3 Non-commutative cluster structure of spaces of Stokes data

By a non-commutative space  $\mathcal{X}$  we mean a functor from a category of skew fields to the category of sets which assigns to a skew field R a set  $\mathcal{X}(R)$ . We say that  $\mathcal{X}$  is defined over  $\operatorname{Spec}(\mathbb{Q})$  if we consider all skew fields R of characteristic zero.

By a non-commutative stack  $\mathcal{X}$  we just mean the quotient of a non-commutative space  $\mathcal{Y}$ , equipped with an action of the group  $\mathrm{GL}_N(R)$ , by the action of this group. So for any skew field R we have a set  $\mathcal{X}(R) := \mathcal{Y}(R)/\mathrm{GL}_N(R)$ .

We say, e.g. in Theorem 8.19, that a non-commutative space  $\mathcal{X}$  admits a structure of a non-commutative cluster Poisson variety if it is birationally isomorphic to a cluster Poisson variety associated to a bipartite ribbon graph  $\Gamma$ , as discussed in paragraph 3 of Section 1.2 and in Section 2.2.

This means that there exists a non-empty collection of bipartite ribbon graphs  $\{\Gamma\}$  such that any two of the graphs are related by a sequence of two by two moves, for each  $\Gamma$  from the collection there is a birational isomorphism

$$\alpha: \operatorname{Loc}_1(\Gamma) \longrightarrow \mathcal{X},$$

and for any pair of the graphs related by a two by two move  $\mu:\Gamma\longrightarrow\Gamma'$  there is a commutative diagram

$$\operatorname{Loc}_{1}(\Gamma) \xrightarrow{\alpha} \mathcal{X} \\
\downarrow^{\mu_{*}} \qquad \qquad \downarrow = \\
\operatorname{Loc}_{1}(\Gamma') \xrightarrow{\alpha'} \mathcal{X}$$
(201)

where the birational isomorphism  $\mu_*$  was described in Section 2.1.

Next, let  $\operatorname{Mod}_{\mathcal{X}}$  be a discrete group acting by birational automorphisms of  $\mathcal{X}$ . We say that  $\mathcal{X}$  admits a structure of a non-commutative  $\operatorname{Mod}_{\mathcal{X}}$ -equivariant cluster Poisson variety if for any  $g \in \operatorname{Mod}_{\mathcal{X}}$  there is a bipartite ribbon graph  $\Gamma'$  together with a birational isomorphism

$$\alpha' : \operatorname{Loc}_1(\Gamma') \longrightarrow \mathcal{X},$$

and a composition of two by two moves  $\mu_g: \Gamma' \longrightarrow \Gamma'$ , which induces a birational non-commutative cluster Poisson transformation  $\mu_{g*}: \operatorname{Loc}_1(\Gamma) \longrightarrow \operatorname{Loc}_1(\Gamma')$  providing a commutative diagram

$$\operatorname{Loc}_{1}(\Gamma)(R) \xrightarrow{\alpha} \mathcal{X}$$

$$\downarrow^{\mu_{g*}} \qquad \qquad \downarrow^{g}$$

$$\operatorname{Loc}_{1}(\Gamma')(R) \xrightarrow{\alpha'} \mathcal{X}$$
(202)

1. Non-commutative stacks of framed Stokes data. Just like in the regular case, to quantize the stack of Stokes data  $\mathcal{S}(\mathcal{L}, d)$ , we introduce a larger stack  $\mathcal{X}(\mathcal{L}, d)$  of framed Stokes data. Namely, we add a framing, defined as a complete filtration of the local system  $\mathcal{L}_{\alpha}$  on each loop  $\alpha$  of the Legendrian  $\mathcal{L}$ , invariant under the monodromy around the loop.

We interpret a filtration on a  $d_j$ -dimensional local system on the loop  $\alpha_j$  of the Legendrian  $\mathcal{L}$  as follows. We replace the loop  $\alpha_j$  by a collection of  $d_j$  loops  $\alpha_j^{(1)}, \ldots, \alpha_j^{(d_j)}$  obtained by expanding the loop  $\alpha_j$  out of the puncture by  $\varepsilon, 2\varepsilon, \ldots, d_j\varepsilon$ , see Figure 61. We equip each loop  $\alpha_j^{(p)}$  with the local system given by  $\operatorname{gr}^p$  of the filtration on the loop  $\alpha_j$ . So get a new link  $\mathcal{L}_d$  supporting one dimensional local systems.

Set  $\mathbf{1} := (1, ..., 1)$ . Consider the stack  $\mathcal{M}_0(\mathcal{L}_d, \mathbf{1})$  of  $\mathcal{L}_d$ -admissible dg-sheaves on S, vanishing near the punctures, whose microlocal support is described by the union of the zero section and arbitrary 1-dimensional local systems on the Legendrian  $\mathcal{L}_d$ . The next observation generalizes Lemma 1.15.

Figure 61: Inflating a Legendrian link.

**Lemma 8.18.** The non-commutative stack  $\mathcal{M}_0(\mathcal{L}_d, \mathbf{1})$  is canonically equivalent to the one of framed Stokes data of type  $(\mathcal{L}, d)$ :

$$\mathcal{M}_0(\mathcal{L}_d, \mathbf{1}) = \mathcal{X}(\mathcal{L}, d). \tag{203}$$

There is a projection given by assigning the microlocal support local system on the Legendrian  $\mathcal{L}_d$ :

$$\mu: \mathcal{M}_0(\mathcal{L}_d, \mathbf{1}) \longrightarrow \operatorname{Loc}_1(S^1)^{|d|}, \qquad |d| := \sum_{\alpha} d_{\alpha}.$$
 (204)

The product of the symmetric groups  $\prod_{\alpha} S_{d_{\alpha}}$  acts by birational automorphisms of  $\mathcal{X}(\mathcal{L},d)$ . To define it, note that given a generic p-dimensional R-local system on a circle, there are p! complete filtrations of the local system. Indeed, a generic linear automorphism L of an p-dimensional vector space  $V_p$  is decomposed uniquely into a direct sum of L-invariant one-dimensional subspaces. The filtrations are parametrised by orderings of these subspaces. Therefore the symmetric group  $S_p$  acts on the filtrations.

This just means that the canonical projection, obtained by forgetting the filtrations

$$p: \mathcal{X}(\mathcal{L}, d) \longrightarrow \text{Loc}(\mathcal{L}, d)$$
 (205)

is a Galois cover at the generic point with the Galois group  $\prod_{\alpha} S_{d_{\alpha}}$ .

**Theorem 8.19.** For any decorated surface  $\mathbb{S}$ , and any topological data  $(\mathcal{L}, d)$  where  $\mathcal{L}$  is an ideal Legendrian on  $\mathbb{S}$ , the stack  $\mathcal{X}(\mathcal{L}, d)$  of framed non-commutative Stokes data has a non-commutative cluster Poisson structure equivariant under the wild cluster mapping class group  $\Gamma_{\mathcal{L}, d}$ .

In the commutative case, the subalgebra  $\mu^*\mathcal{O}(\mathbb{G}_m^{|d|})$ , see (204), is the Poisson center of  $\mathcal{O}(\mathcal{X}(\mathcal{L},d))$ .

We prove Theorem 8.19 assuming that in the case when  $\mathbb{S} = S^2 - \{\infty\}$  the Legendrian  $\mathcal{L}$  is not very degenerate, see Theorem 8.21 for the precise statement.

- 2. Idea of the proof of Theorem 8.19. Lemma 8.18 tells that any stack of framed Stokes data has a canonical realization as a stack of admissible sheaves with the following two features:
  - i) The admissible sheaves vanish near the punctures.
  - ii) The microlocal support local systems on the Legendrian  $\mathcal{L}_d$  are one-dimensional.

We show that the Legendrian link  $\mathcal{L}_d$  has an admissible deformation to (a slight modification of) the web  $\mathcal{Z}_{\Gamma}$  of zig-zag strands for a certain bipartite graph  $\Gamma$  on S. By the invariance of the stack of admissible dg-shaves under admissible deformations,  $\mathcal{M}(\mathcal{L}_d, \mathbf{1}) = \mathcal{M}(\mathcal{Z}_{\Gamma}, \mathbf{1})$ . By Lemma 1.14, the stack  $\operatorname{Loc}_1(\Gamma)$  of 1-dimensional local systems on  $\Gamma$  is realised as the open substack defined by the condition of vanishing on mixed domains:  $\operatorname{Loc}_1(\Gamma) \subset \mathcal{M}(\mathcal{Z}_{\Gamma}, \mathbf{1})$ . Since vanishing on mixed domains implies vanishing near the punctures, we get an open embedding

$$Loc_1(\Gamma) \subset \mathcal{M}_0(\mathcal{L}_d, \mathbf{1}) = \mathcal{X}(\mathcal{L}, d).$$

The last equivalence is given by Lemma 1.14. This way we get an open cluster Poisson torus assigned to the graph  $\Gamma$ . The tori assigned to different graphs  $\Gamma$  provide the cluster atlas. The elements of the cluster wild mapping class group transform such a graph  $\Gamma$  to another one  $\Gamma'$ , related to  $\Gamma$  by two by two moves. Therefore we get a cluster Poisson atlas equivariant under the wild mapping class group.

Before we start the proof, let us recall the following.

3. Bipartite graphs and triple crossing diagrams. Let us recall triple crossing diagrams [Th].

Figure 62: A triple crossing diagram.

**Definition 8.20.** A triple crossing diagram is a collection  $\mathcal{I}$  of smooth oriented strands on an oriented decorated surface  $\mathbb{S}$  such that:

- 1. Each intersection point of  $\mathcal{I}$  is a triple point.
- 2. Strand orientations are consistent with an orientation of each component of  $\mathbb{S} \mathcal{I}$ .
- 3. Each strand is either a loop, or ends on the boundary of S. Endpoinds of strands are disjunct.

See counterexamples to condition 2) on Figure 63). Note that condition 2) implies the following:

- For each intersection point, passing strands are oriented as on Figure 62.
- $\bullet$  Going along a strand of  $\mathcal{I}$ , the orientations of the intersecting it strands alternate, as on Figure 62.

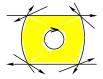

Figure 63: Strand orientations are not consistent with any orientations of internal (yellow) components.

Any bipartite graph can be transformed to a bipartite graph with 3-valent  $\bullet$ -vertices obtained by splitting the  $\bullet$ -vertices of valency > 3 by adding edges, and introducing 2-valent  $\circ$ -vertices in the middle of these edges. A bipartite ribbon graph  $\Gamma$  with 3-valent  $\bullet$ -vertices gives rise to a triple crossing diagram on the associated surface  $S_{\Gamma}$ , provided by its zig-zag strands, [GK, Section 2.6]. Namely, we first push zig-zag strands out of the graph, and then shrink the triangles near the  $\bullet$ -vertices to points, see Figure 48. Then all original double crossings collide into triple crossings corresponding to the  $\bullet$ -vertices.

This construction can be inverted. Any triple crossing diagram  $\mathcal{I}$  on  $\mathbb{S}$  has a canonical up to isotopy resolution defined as follows [GK, Section 2.3]. For each crossing, move slightly one of the strands, inflating the crossing into a little triangle, whose strands are oriented consistently with the orientation of  $\mathbb{S}$  - counterclockwise - getting a web  $\mathcal{I}'$ . There are three types of components of  $\mathbb{S} - \mathcal{I}'$ , see Figure 48:

- i) Black components, whose boundary strands are oriented clockwise.
- ii) White components, whose boundary strands are oriented counterclockwise.
- iii) Mixed components, whose boundary strands orientations alternate.

We shrink all black (respectively white) components to black (respectively white) vertices, and connect two vertices by an edge if they are separated by a crossing of the web  $\mathcal{I}'$ . We get a bipartite graph  $\Gamma_{\mathcal{I}}$ .

4. Ideal Legendrians  $\rightarrow$  triple crossing diagrams  $\rightarrow$  non-commutative cluster Poisson varieties. Take an ideal Legendrian  $\mathcal{L}$  on a punctured surface S, whose local components  $\mathcal{L}_p$  are ideal Legendrians near punctures p. So each  $\mathcal{L}_p$  satisfies conditions of Definition 8.1, different  $\mathcal{L}_p$  are disjunct, and  $\mathcal{L} = \cup_p \mathcal{L}_p$ . The number of crossings of a generic ray r from p with  $\mathcal{L}_p$  is the local rank of  $\mathcal{L}_p$  at p. An ideal Legendrian  $\mathcal{L}$  is of rank m if for each local Legendrian  $\mathcal{L}_p$  its local rank at p is equal to m.

**Theorem 8.21.** Any rank m ideal Legendrian  $\mathcal{L}$  on a punctured surface S different from  $S^2 - \{\infty\}$ , or a rank m ideal Legendrian on  $S^2 - \{\infty\}$  corresponding to a cyclic closure of the braid,  $w_0xw_0y$ , for any  $x, y \in \operatorname{Br}_m$ , can be admissibly isotoped to a triple crossing diagram with the following property:

The black and white components are either contractible, or homeomorphic to an annulus. The union of all annuli is a disjoint union of punctured discs around (some of the) punctures.

Before we proceed to the proof of Theorem 8.21, let us discuss its main implications.

The triple crossing diagrams  $\mathcal{L}$  which appear in our story have black and white components which are either contractible, or annuli. Furthermore, let us assume that the union of all annuli is given by a union of discs around the punctures. Assuming these conditions, consider the category  $\mathcal{C}(S; \mathcal{L}, \mathbf{1})$  of  $\mathcal{L}$ -admissible dg-sheaves such that the local systems of the microlocal support supported on the components of  $\mathcal{L}$  are 1-dimensional. Denote by  $\mathcal{M}_0(S; \mathcal{L}, \mathbf{1})$  the substack of the stack of objects  $\mathcal{M}(S; \mathcal{L}, \mathbf{1})$  of the category  $\mathcal{C}(S; \mathcal{L}, \mathbf{1})$  given by  $\mathcal{L}$ -admissible dg-sheaves which are zero on the mixed components.

**Lemma 8.22.** The stack  $\mathcal{M}_0(S; \mathcal{L}, \mathbf{1})$  is a torus.

*Proof.* According to our assumption, the annuli surrounding a given puncture

Corollary 8.23. Any rank m ideal Legendrian  $\mathcal{L}$  on S gives rise to a Zariski open torus  $\mathcal{M}_0(S; \mathcal{L}, \mathbf{1})$  in the non-commutative moduli stack  $\mathcal{M}(S; \mathcal{L}, \mathbf{1})$  of  $\mathcal{L}$ -admissible dg-sheaves with one-dimensional local systems on the components of  $\mathcal{L}$ .

We will proceed to the proof of Theorem 8.21, after discussing two examples.

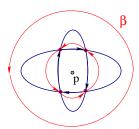

5. The simplest example. The stack of m-dimensional local systems on  $S^2 - \{0, \infty\}$  with complete filtrations near the punctures is just the stack of admissible sheaves vanishing near the punctures for the oriented web  $\mathcal{L}_m$ , illustrated for m=3 on the left of Figure 64. An admissible deformation of  $\mathcal{L}_m$  shown on the right describes the following constructible sheaves. Denote by  $\mathcal{A}_1, \mathcal{A}_2, ..., \mathcal{A}_{2m+1}$  the open components of  $S^2 - \mathcal{L}_m$ , counted from 0. Then the sheaves are zero on  $\mathcal{A}_{2k+1}$ , and are 1-dimensional local systems on  $\overline{\mathcal{A}}_{2k}$ . Their moduli space is  $(\mathbb{G}_m)^m$ , parametrising the monodromies.

Figure 64: Left: the link  $\mathcal{L}_3$  describing the stack of rank 3 local systems on  $\mathbb{C}^*$  with complete filtrations near the punctures. Right: admissible deformed link providing an open locus identified with  $\mathbb{G}_m^3$ .

**6. Another simple example.** Let  $S^2 - \{0, \infty\}$  be a sphere a regular puncture at  $\infty$ , and an irregular one at 0. The Legendrian  $\mathcal{L}_0$  goes clockwise around 0. It bounds a domain  $\mathcal{D}_{\mathcal{L}_0}$ . Precisely, take a point  $x \in \mathbb{D}^*$ . Let  $r_x$  be the ray from p to x. Then  $x \in \mathcal{D}_{\mathcal{L}_0}$  if and only if it is in the convex hull of  $\{r_x \cap \mathcal{L}_0\}$ .

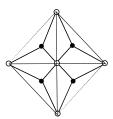

Figure 65: Left: a triple crossing diagram from two intersecting clockwise oriented loops around the puncture. Right: the corresponding bipartite graph.

Now we follow [FG3]. Call the selfintersection points of  $\mathcal{L}_0$  vertices. Take a component  $\mathcal{V}$  of  $\mathcal{D}_{\mathcal{L}_0} - \mathcal{L}_0$ . Connect the rightmost vertex on the boundary of  $\mathcal{V}$  with the leftmost one by a counterclockwise path  $\gamma_{\mathcal{V}} \subset \mathcal{V}$ , transversal to  $\mathcal{L}_0$ . Take the union of these paths, a counterclockwise arc  $\beta$  near  $\infty$ , and  $\mathcal{L}_0$ , see Figure 65:

$$\mathcal{I} := \cup_{\mathcal{V}} \gamma_{\mathcal{V}} \cup \beta \cup \mathcal{L}_0. \tag{206}$$

It is a triple point diagram. Its number of counterclockwise arcs is the same as the local rank of  $\mathcal{L}_0$  at 0.

- 7. Proof of Theorem 8.21. Take a triangulation  $\mathcal{T}$  of S with vertices at the punctures. Inflate each side of  $\mathcal{T}$  to a pair of thin *bigons*, see Figure 66. Then S {the bigons} = a union of *internal triangles*. Performing admissible isotopies, we can assume that  $\mathcal{L}$  crosses internal triangles t and bigons t as follows.
  - 1. For each vertex v of t: the  $\mathcal{L}$  induces m non-intersecting, clockwise (red) arcs around v.
- 2. For each bigon b: near one of its angles, called the *red angle*,  $\mathcal{L}$  induces m non-intersecting clockwise arcs near its vertex. We put no conditions on the restriction of  $\mathcal{L}$  to the other one, called the *blue angle*.
  - 3. For each vertex v of each edge of  $\mathcal{T}$ : just one of the bigons at this edge has a red angle at v.

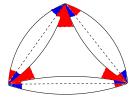

Figure 66: Inflating an edge to a pair of bigons. Inflating edges of a triangle to pairs of colored bigons.

Let b be a bigon. Denote by  $\mathcal{L}_b$  the Legendrian in the bigon.

**Lemma 8.24.** One can admissibly isotope the Legendrian  $\mathcal{L}_b$  to a Legendrian  $\mathcal{L}_b'$  so that

- 1. On each side of the bigon b, the endpoints of the red and blue strands of  $\mathcal{L}_b'$  alternate.
- 2. The strands of  $\mathcal{L}'_h$  form a triple crossing diagram.

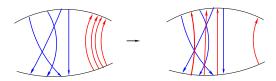

Figure 67: From concentric red and blue arcs near the vertices of a bigon, to a triple crossing diagram.

*Proof.* Move the red arcs towards the blue angle of b so that condition 1) holds. Then there is a unique up to isotopy way to deform them to a triple crossing diagram, with the minimal number of crossings.

Namely, forget the red arcs. Then for each component of the complement to the blue arcs pick the leftmost vertex/boundary point, and the similar rightmost one, and connect them by the unique up to isotopy red arc inside the component, see Figure 67. We get a triple crossing diagram.

Lemma 8.24 provides triple crossing diagrams in the bigons. For each internal triangle t, see Figure 66, there is a standard triple crossing diagram provided by the m-trianulation of the triangle, which induces on the boundary the given alternating sequence of intersection points of  $\mathcal{L}'_b$  provided by Lemma 8.24. Indeed, take the m-trianulation of a triangle, see Figure 68, and move each of its strands towards the parallel to it side of the triangle, so that the centers of looking down small triangles become the triple

crossing points. Then the endpoints alternate, and we can match them with the ones on the bigons  $\mathcal{L}'_b$ . We denote this triple crossing diagram by  $\mathcal{L}'_t$ . Take the union of these triple point diagrams:

$$\mathcal{L}_{\mathcal{T}} := \cup_t \mathcal{L}_t' \bigcup \cup_b \mathcal{L}_b'. \tag{207}$$

Theorem 8.21 is proved.

Figure 68: A triple crossing diagram assigned to an m-triangulation of the triangle t, for m = 1, 2.

#### 8.4 Cluster structure of stacks of G-Stokes data on surfaces

1. The cyclic envelope  $\operatorname{Br}_{\mathfrak{g}}^+$  of the braid semigroup. Let G be a split semi-simple algebraic group over  $\mathbb{Q}$ . Denote by I the set of positive simple roots, and by  $C_{ij}$  the Cartan matrix of the root system of the Lie algebra  $\mathfrak{g}$  of G. Let  $\operatorname{Br}_{\mathfrak{g}}$  (respectively  $\operatorname{Br}_{\mathfrak{g}}^+$ ) be the braid group (respectively semigroup) of the root system of  $\mathfrak{g}$ . It is generated by the elements  $s_i, i \in I$ , subject to the relations

$$\begin{aligned}
 s_{i}s_{j} &= s_{j}s_{i} & \text{if} \quad C_{ij} &= C_{ji} &= 0, \\
 s_{i}s_{j}s_{i} &= s_{j}s_{i}s_{j} & \text{if} \quad C_{ij} &= C_{ji} &= -1, \\
 s_{i}s_{j}s_{i}s_{j} &= s_{j}s_{i}s_{j}s_{i} & \text{if} \quad C_{ij} &= 2C_{ji} &= -2, \\
 s_{i}s_{j}s_{i}s_{j}s_{i}s_{j} &= s_{j}s_{i}s_{j}s_{i}s_{j}s_{i} & \text{if} \quad C_{ij} &= 3C_{ji} &= -3.
 \end{aligned}$$
(208)

The Weyl group W is the quotient of the group  $\operatorname{Br}_{\mathfrak{g}}$  by the relations  $s_i^2 = 1$ . Denote by l(\*) the length function on W. There is a set theoretic section  $\mu: W \to \operatorname{Br}_{\mathfrak{g}}^+$ , such that  $\mu(s_i) = s_i$  and  $\mu(ss') = \mu(s)\mu(s')$  if l(ss') = l(s) + l(s'). Abusing notation, we denote by  $s_i$  the elements  $\mu(s_i) \in \operatorname{Br}_{\mathfrak{g}}^+$ .

Denote by  $[\mathrm{Br}_{\mathfrak{g}}^+]$  the set of coinvariants of the cyclic shift  $s_{j_1} \dots s_{j_{n-1}} s_{j_n} \longmapsto s_{j_n} s_{j_1} \dots s_{j_{n-1}}$  on  $\mathrm{Br}_{\mathfrak{g}}^+$ , called the *cyclic envelope* of the braid semigroup.

We denote by  $[s_{j_1} \dots s_{j_n}] \in [\mathrm{Br}_{\mathfrak{g}}^+]$  the cyclic element corresponding to  $s_{j_1} \dots s_{j_n} \in \mathrm{Br}_{\mathfrak{g}}^+$ .

Given a pair of flags B, B', we define  $w(B, B') \in W$  via the isomorphism  $G \setminus (\mathcal{B} \times \mathcal{B}) = W$ .

Take a defining relation  $s_{l_1}s_{l_2}...s_{l_m} = s_{r_1}s_{r_2}...s_{r_m}$  in (208). For any flags  $(B_0, ..., B_m)$  with  $w(B_{a-1}, B_a) = s_{j_a}$ , where a = 1, ..., m, there is a unique collection of flags  $(B'_0, ..., B'_m)$  with  $w(B'_{a-1}, B'_a) = s_{r_a}$ .

Given a reduced decomposition  $s_{j_1}s_{j_2}...s_{j_k}$  of a cyclic element  $\beta \in [\mathrm{Br}_{\mathfrak{g}}^+]$  there is the moduli space of G-orbits of flags  $(\mathrm{B}_1,...,\mathrm{B}_k)$  such that  $w(\mathrm{B}_{i-1},\mathrm{B}_i)=s_{j_i}$ , where  $i\in\mathbb{Z}/k\mathbb{Z}$ . The moduli spaces assigned to different reduced decompositions of  $\beta$  are canonically isomorphic.

The moduli space  $\mathcal{X}(G, \beta; S)$ . Let  $\mathcal{B}$  be the flag variety of G. A G-local system  $\mathcal{L}$  on S gives rise to the associated local system of flags  $\mathcal{L}_{\mathcal{B}} := \mathcal{L} \times_G \mathcal{B}$ . Denote by  $S_p^1$  the circle of rays at  $T_pS$ . Given a reduced decomposition  $s_{j_1} \dots s_{j_k}$  of the cyclic word  $\beta_p \in [\mathrm{Br}_{\mathfrak{g}}^+]$ , take distinct points  $x_1, \dots, x_k \in S_p^1$  going cyclically around the circle, and put the elements  $s_{j_i}$  at the points  $x_i$ .

**Definition 8.25.** Let  $\beta := \{\beta_p\}$  be a collection of elements of  $[Br_{\mathfrak{g}}^+]$  assigned to the punctures  $\{p\}$  of a surface S. A  $\beta_p$ -framing at a puncture p on a G-local system  $\mathcal{L}$  on S is given by flat sections  $\varphi = (\varphi_1, \ldots, \varphi_k)$  of the local system of flags  $\mathcal{L}_{\mathcal{B}}$  over intervals  $x_1x_2, \ldots, x_kx_1$  on  $S_p^1$  so that  $w(\varphi_i, \varphi_{i+1}) = s_{\alpha_i}$ :

$$\varphi_1 \xrightarrow{s_{j_1}} \varphi_2 \xrightarrow{s_{j_2}} \dots \varphi_k \xrightarrow{s_{j_k}} \varphi_1.$$

A  $\beta$ -framing on  $\mathcal{L}$  is a collection of local framings  $\{\beta_p\}$  at the punctures of S. The moduli space  $\mathcal{X}(G, \beta; S)$  parametrises  $\beta$ -framed G-local systems  $\mathcal{L}$  on S.

The stack  $\mathcal{X}(G, \beta; S)$  depends on the elements  $\beta_p \in [Br_{\mathfrak{q}}^+]$ , rather than their reduced decompositions.

Figure 69: Cyclic framing of type  $[s_1s_2s_3]$ .

#### Examples of stacks $\mathcal{X}(G, \beta; S)$ .

- 1. If  $G = GL_m$ , a local <u>framed</u> Stokes data is just a  $\beta$ -framing at the puncture on an m-dimensional local system of vector spaces on the punctured disc for an element  $\beta \in [Br_{\mathfrak{gl}}^+]$ .
- 2. If  $\beta_p = e$  is the unit, then a local  $\beta_p$ -framing at the puncture p is just a monodromy invariant flag near the puncture.
- 3. If all  $\beta_p = e$  are the unit elements, then  $\mathcal{X}(G, \beta; S)$  is the stack  $\mathcal{X}(G, S)$  [FG1] parametrising G-local system  $\mathcal{L}$  on S with a flat section of the local system of flags  $\mathcal{L}_{\mathcal{B}}$  near each puncture of S.
- 4. Let S be a decorated surface with k boundary components, with  $b_1, ..., b_k$  special points on them. If  $\beta_p = [\mu(w_0) \cdot ... \cdot \mu(w_0)] \in [\operatorname{Br}_{\mathfrak{g}}^+]$  is the cyclic product of  $b_p$  elements  $\mu(w_0)$  assigned to the longest element  $w_0 \in W$ , then  $\mathcal{X}(G, \beta; S)$  is the stack  $\mathcal{X}_{G,\mathbb{S}}$  for from [FG1], as we show in Section 8.5. The cluster Poisson structure on moduli spaces 1) and 2) was defined for  $G = \operatorname{PGL}_m$  in [FG1], for classical groups and  $G_2$  by case-by case study in [Le1]-[Le2], and in the general case in [GS19].
- 5. If  $S = S^2 \{0, \infty\}$  is a punctured disc, and  $\beta_0 = e$ ,  $\beta_\infty = \beta$ , then the stack  $\mathcal{X}(G, \{e, \beta\}; D^*)$  carries a cluster Poisson variety structure assigned to the cyclic braid semigroup element  $\beta$  in [FG4].
- 6. If  $S = S^2 \{0, \infty\}$ , then the stack  $\mathcal{X}(G, \beta_0, \beta_p; D^*)$  contains as a Zariski open part the double Bott-Samelson variety [SW] assigned to a pair cyclic braid semigroup elements  $\beta_0, \beta_\infty \in [Br_{\mathfrak{q}}^+]$ .

**Theorem 8.26.** Any stack of framed G-Stokes data on a surface S is the stack  $\mathcal{X}(G, \beta; S)$  for some  $\beta$ .

*Proof.* This can be deduced from the formal classification in the G-case just as in Section 8.1.  $\Box$ 

**Theorem 8.27.** Let S be a punctured surface, and  $S \neq S^2 - \{\infty\}$ . Then the stack  $\mathcal{X}(G, \beta; S)$  has a cluster Poisson structure, equivariant under the wild mapping class group. Therefore the stack  $\mathcal{X}(G, \beta; S)$  admits a cluster quantization, equivariant under the wild mapping class group.

For each puncture p, the braid group  $\operatorname{Br}_{\mathfrak{g}}$  acts by automorphisms of the stack  $\mathcal{X}(G,\beta;S)$ , preserving the cluster Poisson structure.

*Proof.* Assume first that  $S \neq S^2 - \{0, \infty\}$ . Then there is an ideal triangulation  $\mathcal{T}$  of S.

Take an ideal triangulation  $\mathcal{T}$  of S, and inflate each of its edges E to a pair of thin bigons  $b_E$ , as we did in Section 8.3. For each puncture p, put all the points  $x_1, ..., x_{b_p}$  inside of the arc on the circle  $S_p^1$  located inside of the left bigon at one of the edges sharing p. Then the moduli space  $\mathcal{X}(G, \beta; S)$  is birationally equivalent to the result of amalgamation of the moduli spaces  $\mathcal{P}_{G,t}$  from [GS19] assigned to the triangulation, and the moduli spaces  $\mathcal{P}_{G,r_E}$  assigned to the rectangles corresponding to the bigons, that is the edges of  $\mathcal{T}$ . The independence of the choice of  $\mathcal{T}$  follows from [FG4] & [GS19].

Now let  $S = S^2 - \{0, \infty\}$  be a cylinder. Recall the decorated flag variety  $\mathcal{A} := G/U$ . Recall the elementary moduli space  $\mathcal{P}_{G,s}$  paramterising triples  $(B_1, A_2, A_3) \in G \setminus (\mathcal{B} \times \mathcal{A} \times \mathcal{A})$ , such that the pairs  $(B_1, A_2)$  and  $(B_1, A_2)$  are generic, and  $w(B_2, B_3) = s$  for the pair of flags  $(B_2, B_3)$  underlying the decorated flags  $(A_2, A_3)$ . We picture such a triple by a wedge with the flag  $B_1$  at the vertex, and two arrows pointing

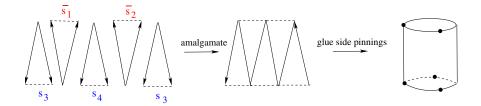

Figure 70: Getting a cluster chart with  $\beta_0 = s_1 s_2$ ,  $\beta_\infty = s_3 s_4 s_3$  on a cylinder by the amalgamation.

out to the decorated flags at the vertices on the short edge. The space  $\mathcal{P}_{G,s}$  carries a cluster Poisson structure [GS19, Section 6]. The same space with the opposite Poisson structure is denoted by  $\mathcal{P}_{G,\bar{s}}$ .

Take reduced decompositions for the braid semigroup elements  $\beta_0 = s_{i_1}...s_{i_a}$  and  $\beta_\infty = \overline{s}_{j_1}...\overline{s}_{j_b}$ . Amalgamate the corresponding moduli spaces  $\mathcal{P}_{G,s_i}$  and  $\mathcal{P}_{G,\overline{s}_j}$  so that the order of the spaces  $\mathcal{P}_{G,s_i}$  (respectively  $\mathcal{P}_{G,\overline{s}_j}$ ) follows a reduced decomposition  $\beta_0$  (respectively  $\beta_\infty$ ), see Figure 70. Then glue the left and the right pairs (A,B) for the resulting moduli spaces if they oriented the same way. Otherwise alter one of them by  $(B_1,A_2) \longrightarrow \overline{w}_0(B_1,A_2)$  where  $\overline{w}_0$  is the canonical lift of  $w_0$  to G, and then glue.

This way we get a Zariski open part of  $\mathcal{X}(G,\beta;S)$ . Therefore the result follows from [GS19].

The second claim follows from this by applying the cluster Poisson quantization machine [FG4].

Let us define the action  $a_p$  of the braid group  $\operatorname{Br}_{\mathfrak{g}}$  on the stack  $\mathcal{X}(G,\beta;S)$ . Pick a generator  $s_i$  of the the braid group  $\operatorname{Br}_{\mathfrak{g}}$ . Take a cyclic word  $\mathbf{b} = [s_{j_1} \cdot \ldots \cdot s_{j_n}]$  assigned to the cyclic collection of points  $x_1, \ldots, x_n$  on the circle  $S_p^1 = T_p S - \{0\}/\mathbb{R}_{>0}$ . We write this schematically as  $[s_{j_1}|x_1, \ldots, s_{j_n}|x_n]$ . Then we find its representative of  $[\mathbf{b}]$  starting from  $s_1$ , and shift the cyclic word by one step to the right:

$$[s_1|x_1, s_{i_2}|x_2, \dots, s_{i_n}|x_n] \longmapsto [s_1|x_2, s_{i_2}|x_3, \dots, s_{i_n}|x_1].$$

which starts from  $s_i$ .

7. Cluster quantization of  $\mathcal{M}_{DR}(G, \beta; S)$ . To quantize the De Rham stack  $\mathcal{M}_{DR}(G, \beta; S)(\mathbb{C})$ , we apply the G-analog of the universal Riemann-Hilbert equivalence (198), and then develope the  $\Gamma_{G,\beta;S}$ -equivariant quantization of the Betti stack  $\mathcal{M}_{B}(G, \beta; S)$ .

To do this, we quantize first the bigger stack  $\mathcal{X}(G, \beta; S)$  of framed Stokes data. There is a finite group  $W_{G,S,\beta}$  which acts birationally on  $\mathcal{X}(G,\beta;S)$  by altering filtrations. Forgetting the filtrations we get a map, which is a finite Galois cover at the generic point:

$$p: \mathcal{X}(G, \beta; S) \longrightarrow \mathcal{M}_{B}([S, \mathcal{L}]).$$

The space  $\mathcal{X}(G, \beta; S)$  has a  $\Gamma_{G,\beta;S} \times W_{G,\beta;S}$ -equivariant Poisson structure. Therefore [FG4] gives its  $\Gamma_{G,\beta;S} \times W_{G,\beta;S}$ -equivariant cluster Poisson quantization, given by:

- 1. A q-deformed algebra of functions  $\mathcal{O}_q(\mathcal{X}(G,\beta;S))$ .
- 2. A unitary projective representation of the group  $\Gamma_{G,\beta;S} \times W_{G,\beta;S}$  in a Hilbert space  $\mathcal{H}$ .
- 3. A representation of the \*-algebra given by the modular double

$$\mathcal{O}_q(\mathcal{X}(G,\beta;S)) \otimes \mathcal{O}_{q^{\vee}}(\mathcal{X}(G,\beta;S)), \quad q = e^{i\pi\hbar}, \quad q^{\vee} = e^{i\pi/\hbar}.$$
 (209)

by unbounded operators in the Hilbert space  $\mathcal{H}$ , intertwining the action of the group  $\Gamma_{G,\beta;S} \times W_{G,\beta;S}$  on the \*-algebra (209) with its projective unitary action in  $\mathcal{H}$  from 2). Here  $\hbar \in \mathbb{R}_{>0}$  or  $|\hbar| = 1$ .

The group  $W_{G,\beta;S}$  acts by cluster Poisson transformations (the regular case is done in [GS19]). Set

$$\mathcal{O}_q(\mathcal{M}_{\mathrm{B}}(G,\beta;S)) := \mathcal{O}_q(\mathcal{X}(G,\beta;S))^{W_{G,\beta;S}}$$

We consider the representation of the modular double of this subalgebra in the Hilbert space  $\mathcal{H}$ . It commutes with the unitary action of the group  $W_{G,\beta;S}$  in  $\mathcal{H}$ .

## 8.5 More examples

1. Non-commutative stacks  $\mathcal{X}_m(\mathbb{S})$  and  $\mathcal{A}_m(\mathbb{S})$  as stacks of Stokes data Below  $\mathbb{S}$  is a decorated surface with boundary. We assume that the local systems on the strands of the webs, provided by the microlocal supports of admissible sheaves, are one dimensional.

We assign to each boundary component  $\pi$  of  $\mathbb{S}$ , with  $b_{\pi}$  special points, an ideal Legendrian link  $\mathcal{L}_{\pi,m}$  in a little cylinder  $C_{\pi} \subset \mathbb{S}$  containing  $\pi$ , obtained by concatenating  $b_{\pi}$  copies of the Legendrian with m strands on a rectangle realising the longest permutation  $w_0: (1, 2, ..., m) \longmapsto (m, ..., 2, 1)$ , see Figure 71.

Let us assign to each puncture p on  $\mathbb{S}$  a collection  $\mathcal{L}_{p,m}$  of m small disjoint loops around the puncture. Denote by  $\mathcal{L}_{\mathbb{S},m}$  the union of these Legendrians:

$$\mathcal{L}_{\mathbb{S},m} := \bigcup_{\pi \in \pi_0(\partial \mathbb{S})} \mathcal{L}_{\pi,m} \cup \bigcup_{\text{punctures } p} \mathcal{L}_{p,m}. \tag{210}$$

**Definition 8.28.** The non-commutative stack  $\mathcal{M}_{\mathcal{X}}^{(1)}(\mathbb{S}, \mathcal{L}_{\mathbb{S},m})$  parametrises admissible sheaves on  $\mathbb{S}$  from  $\mathcal{C}(\mathbb{S}, \mathcal{L}_{\mathbb{S},m})$ , vanishing near marked points, whose microlocal support restricted to the Legendrian  $\mathcal{L}_{\mathbb{S},m}$  is given by one dimensional non-commutative local systems.

The stack  $\mathcal{M}^{(1)}_{\mathcal{A}}(\mathbb{S}, \mathcal{L}_{\mathbb{S},m})$  parametrises similar data with trivialized local systems on the Legendrian.

**Theorem 8.29.** The stack  $\mathcal{M}_{\mathcal{X}}^{(1)}(\mathbb{S}, \mathcal{L}_{\mathbb{S},m})$  is birationally isomorphic to the stack  $\mathcal{X}_m(\mathbb{S})$ . It has a non-commutative  $\Gamma_{\mathbb{S},\mathcal{L}_{\mathbb{S},m}}$ -equivariant cluster Poisson structure. The stack  $\mathcal{M}_{\mathcal{A}}^{(1)}(\mathbb{S},\mathcal{L}_{\mathbb{S},m})$  is birationally isomorphic to the stack  $\mathcal{A}_m(\mathbb{S})$ . It has a  $\Gamma_{\mathbb{S},\mathcal{L}_{\mathbb{S},m}}$ -equivariant non-commutative cluster  $\mathcal{A}$ -structure.

*Proof.* The complement  $\mathbb{S} - \mathcal{L}_{\mathbb{S},m}$  contains the unique internal component. It is homotopic to  $\mathbb{S}$ . Its boundary is a union of circles  $\{S_p^1\}$  and  $\{S_{\pi}^1\}$  parametrised by punctures p and boundary components  $\pi$ .

Restricting an admissible sheaf  $S \in \mathcal{M}^{(1)}(\mathbb{S}, \mathcal{L}_{\mathbb{S},m})$  to the internal component of  $\mathbb{S} - \mathcal{L}_{\mathbb{S},m}$  we get an m-dimensional local system  $\mathcal{V}$ . For each puncture p, its restriction to the circle  $S_p^1$  has a complete filtration, provided by the Legendrian  $\mathcal{L}_p$ .

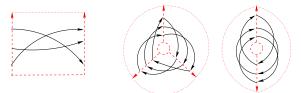

Figure 71: A Legendrian realising permutation  $(1,2,3) \rightarrow (3,2,1)$ , and examples of concatenation.

Given a boundary component  $\pi$ , consider  $b_{\pi}$  generic normal rays cutting the cylinder  $C_{\pi}$  into  $b_{\pi}$  rectangles, see Figure 71, so that the link  $\mathcal{L}_{\pi,m}$  is a concatenation of Legendrians in these rectangles realizing the longest permutation  $w_0$ . For each of the rays r, the admissible sheaf  $\mathcal{S}$  provides a flag  $\mathcal{F}_{\pi,r}$  in the fiber of  $\mathcal{V}$  over  $S_{\pi}^1 \cap r$ . The local system  $\mathcal{V}$  with the flags on the circles  $\{S_{\pi}^1\}$  and filtrations on the circles  $\{S_{\pi}^1\}$  is exactly the data which determines a framed local system on  $\mathbb{S}$  of dimension m.

Evidently, this construction can be inverted starting with a framed local systems with the flags  $\mathcal{F}_{\pi,r}$  in generic position. So we get a birational isomorphism. The  $\mathcal{A}$ -case is completely similar.

The rest follows from the already established results about the spaces  $\mathcal{X}_m(\mathbb{S})$  and  $\mathcal{A}_m(\mathbb{S})$ .

Alternatively, we can deform a Legendrian  $\mathcal{L}_{\mathbb{S},m}$  to a web of zig-zags of a bipartite graph of type  $\mathbb{S}$ , say by using an ideal triangulation of  $\mathbb{S}$  for a start. So we get a cluster torus of each of the two flavors.  $\square$ 

2. Non-commutative Grassmannians as stacks of Stokes data Consider a web  $W_{k,n}$  given by a collection of oriented arcs on a disc, cooriented away from the boundary, as shown on Figure 72. We

can describe it as follows. Take n special points on the boundary, and consider arcs which encircle k-1 subsequent points, so that for each point there is just one arc starting a bit to the right of a special points, and ending a bit to the left of another special point.

Consider the stack  $C_{\mathcal{X}}^{\circ}(\mathcal{W}_{k,n})$  of admissible dg-sheaves with the following two properties:

- i) They vanish in the middle of each interval between the special points.
- ii) The local system on each arc describing the microlocal support is one dimensional.

In fact these dg-sheaves are sheaves: they are concentrated in the degree zero.

The  $\mathcal{A}$ -flavor of this space is the stack  $C^{\circ}_{\mathcal{A}}(\mathcal{W}_{k,n})$  of admissible sheaves as above such that the one dimensional local systems on each curve are trivialized.

**Lemma 8.30.** i) The stack  $C_{\mathcal{X}}^{\circ}(\mathcal{W}_{k,n})$  describes cyclically ordered collections of n one dimensional subspaces in a k-dimensional R-vector space such that any subsequent k of them generate the space. It has a non-commutative cluster Poisson variety structure.

ii) The stack  $C^{\circ}_{\mathcal{A}}(W_{k,n})$  describes cyclic collections of n vectors in a k-dimensional R-vector space such that any subsequent k of them generate the space. It has a cluster  $\mathcal{A}$ -variety structure.

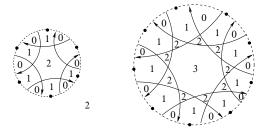

Figure 72: The webs  $W_{2,5}$  and  $W_{3,9}$  on a disc describe configurations of 5 and 9 lines/vectors in non-commutative vector spaces of dimension 2 and 3 repectively, as stacks of admissible sheaves. The numbers tell dimensions of the fibers of admissible sheaves in each component of the complement to the web.

*Proof.* The ambient vector space is reconstructed as the fiber of an admissible sheaf in the center of the disc. The one-dimensional subspaces are the fibers of the admissible sheaf near special boundary points. The non-zero vectors generating these one dimensional subspaces are given by trivializations of the local systems sitting on the arcs of the web. The admissibility at a crossing point is given by Lemma 8.6. This implies that the admissibility at the crossing points is equivalent to the condition that each k subsequent subspaces generate the space.

To get a cluster description, it is sufficient to find a bipartite graph whose zig-zag web is admissibly isotopic to a web  $W_{k,n}$ . Then our general result implies that the torus  $Loc_1(\Gamma)$  sits inside of the stack we consider. This kind of zig-zag webs are the ones considered by Postnikov [P].

# 9 Theorem 4.12 and the Steinberg relation for non-commutative 2-forms

In Section 9 we prove Theorem 4.12, and then observe that one of the key steps of the calculation can be viewed as an identity between non-commutative 2-forms generalizing the Steinberg relation. It would be very interesting to find similar identities for the non-commutative n-forms generalizing the Steinberg identity  $d \log(z_1) \wedge \ldots \wedge d \log(1+x) \wedge \ldots \wedge d \log(x) \wedge \ldots \wedge d \log(z_{n-2}) = 0$ .

## 9.1 The proof of Theorem 4.12

Recall the transformation formulas, where  $A_1 = a_1 a_2 a_3 a_4$  etc.:

$$b_{1} = (1 + A_{3}^{-1})a_{3} = a_{3}(1 + A_{4}^{-1}),$$

$$b_{2} = (1 + A_{4})^{-1}a_{4} = a_{4}(1 + A_{1})^{-1},$$

$$b_{3} = (1 + A_{1}^{-1})a_{1} = a_{1}(1 + A_{2}^{-1}),$$

$$b_{4} = (1 + A_{2})^{-1}a_{2} = a_{2}(1 + A_{3})^{-1}.$$
(211)

Recall the identities

$$\{a,b\} = -\{b^{-1}, a^{-1}\}, 
 \{b,c\} - \{ab,c\} + \{a,bc\} - \{a,b\} = 0, 
 \{xy,y^{-1}\} = -\{x,y\}, 
 \{x^{-1},xy\} = -\{x,y\}.$$
(212)

#### Lemma 9.1.

$$\{b_2, b_3\} = \{a_2 a_3 a_4, (1 + A_1)^{-1}\} + \{a_2 a_3, a_4\} + \{1 + A_1, a_4^{-1}\}.$$
(213)

*Proof.* By the definition (146), we have

$${b_2, b_3} = {a_4(1+A_1)^{-1}, (1+A_1^{-1})a_1}.$$
 (214)

By the cocycle identity in (212) for the triple  $(a_4, (1+A_1)^{-1}, (1+A_1^{-1})a_1)$ ,

$${b_2, b_3} = {(1 + A_1)^{-1}, (1 + A_1^{-1})a_1} + {a_4, A_1^{-1}a_1} - {a_4, (1 + A_1)^{-1}}.$$
 (215)

By the cocycle identity for the triple  $((1+A_1)^{-1}, 1+A_1^{-1}, a_1)$  we can rewrite the first term, and get

$$\{b_2, b_3\} = \{A_1^{-1}, a_1\} - \{1 + A_1^{-1}, a_1\} + \{(1 + A_1)^{-1}, 1 + A_1^{-1}\} + \{a_4, A_1^{-1}a_1\} - \{a_4, (1 + A_1)^{-1}\}.$$
 (216)

Writing the middle term as  $-\{1+A_1,A_1^{-1}\}$  by using the last identity in (212), applying the cocycle identity for the triple  $(1+A_1,A_1^{-1},a_1)$ , and observing that  $\{a_4,A_1^{-1}a_1\}=\{a_2a_3,a_4\}$  and  $\{a_3,A_4^{-1}\}=\{a_4a_1a_2,a_3\}$  using the last line in (212), we get the claim.

#### Lemma 9.2.

$$-\{b_1, b_2\} = \{a_3 A_4^{-1}, (1 + A_4)\} - \{a_4, a_1 a_2\} - \{a_4^{-1}, 1 + A_4\}.$$
(217)

*Proof.* By the definition (146), we have

$$\{b_2^{-1}, b_1^{-1}\} = \{a_4^{-1}(1 + A_4), (1 + A_4^{-1})^{-1}a_3^{-1}\}.$$
(218)

Using the cocycle identity for the triple  $(a_4^{-1}(1+A_4),(1+A_4^{-1})^{-1},a_3^{-1})$  we write this as

$$-\{b_1, b_2\} = -\{(1 + A_4^{-1})^{-1}, a_3^{-1}\} + \{a_4^{-1}A_4, a_3^{-1}\} + \{a_4^{-1}(1 + A_4), (1 + A_4^{-1})^{-1}\}$$

$$= \{a_3, 1 + A_4^{-1}\} - \{a_1a_2, a_3\} - \{1 + A_4^{-1}, (1 + A_4)^{-1}a_4\}.$$
(219)

The cocycle identity in (212) allows to write the last term as

$$\{1 + A_4, (1 + A_4^{-1})^{-1}\} - \{a_4^{-1}, A_4\} - \{a_4^{-1}, 1 + A_4\}.$$
 (220)

Since the first term here is equal to  $\{A_4^{-1}, 1 + A_4\}$  and  $\{a_3, A_4^{-1}a_4\} = \{a_1a_2, a_3\}$ , we get

$$-\{b_1,b_2\} = \{a_3,A_4^{-1}(1+A_4)\} - \{a_1a_2,a_3\} + \{A_4^{-1},(1+A_4)\} - \{a_4,a_1a_2a_3\} - \{a_4^{-1},1+A_4\}.$$
 (221)

Using the cocycle relation for the triple  $(a_3, A_4^{-1}, 1 + A_4)$ , and then the cocycle relation for  $(a_4, a_1a_2, a_3)$  we get the claim.

Denote by  $\operatorname{Cycl}_2$  the operator on functions in  $a_1, ..., a_4$  given by the identity + the cyclic shift by two:

$$Cycl_2F(a_1, a_2, a_3, a_4) = F(a_1, a_2, a_3, a_4) + F(a_3, a_4, a_1, a_2).$$

We split the sum to calculate as A + B, where:

A) It is the total contribution of the middle terms in the Lemmas is:

$$\operatorname{Cycle}_{2}\left(-\{a_{4}, a_{1}a_{2}\} + \{a_{2}a_{3}, a_{4}\}\right)$$

$$= -\{a_{4}, a_{1}a_{2}\} + \{a_{2}a_{3}, a_{4}\} - \{a_{2}, a_{3}a_{4}\} + \{a_{4}a_{1}, a_{2}\}$$

$$= \{a_{1}, a_{2}\} - \{a_{2}, a_{3}\} + \{a_{3}, a_{4}\} - \{a_{4}, a_{1}\}.$$

$$(222)$$

The last equality uses cocycle identities for  $(a_4, a_1, a_2)$  and  $(a_2, a_3, a_4)$ . We get exactly what we wanted.

B) It is the rest:

$$Cycle_{2}(\{1+A_{1}, a_{4}^{-1}\} + \{a_{2}a_{3}a_{4}, (1+A_{1})^{-1}\} - \{a_{4}^{-1}, 1+A_{4}\} - \{(1+A_{4})^{-1}, a_{4}a_{1}a_{2}\}.$$
(223)

This can be rewritten as

$$\operatorname{Cycle}_{2}\left(\left(-dA_{1}a_{4}^{-1}da_{4}+dA_{1}(a_{2}a_{3}a_{4})^{-1}d(a_{2}a_{3}a_{4})\right)(1+A_{1})^{-1}+\right.$$

$$\left(da_{4}a_{4}^{-1}dA_{4}-d(a_{4}a_{1}a_{2})(a_{4}a_{1}a_{2})^{-1}dA_{4}\right)(1+A_{4})^{-1}\right).$$
(224)

Expanding this, we get

$$d(a_{1}a_{2}a_{3}a_{4})(a_{2}a_{3}a_{4})^{-1}d(a_{2}a_{3})a_{4}(1+A_{1})^{-1} +d(a_{3}a_{4}a_{1}a_{2})(a_{4}a_{1}a_{2})^{-1}d(a_{4}a_{1})a_{2}(1+A_{3})^{-1} -a_{4}d(a_{1}a_{2})(a_{4}a_{1}a_{2})^{-1}dA_{4}(1+A_{4})^{-1} -a_{2}d(a_{3}a_{4})(a_{2}a_{3}a_{4})^{-1}dA_{2}(1+A_{2})^{-1}.$$

$$(225)$$

Interchanging lines 2 and 3, writing  $1 + A_4 = a_4(1 + A_1)a_4^{-1}$ , and similarly for  $1 + A_3$  and  $1 + A_2$ , we get:

$$d(a_{1}a_{2}a_{3}a_{4})(a_{2}a_{3}a_{4})^{-1}d(a_{2}a_{3})a_{4}(1+A_{1})^{-1}$$

$$-d(a_{1}a_{2})(a_{4}a_{1}a_{2})^{-1}d(a_{4}a_{1}a_{2}a_{3})a_{4}(1+A_{1})^{-1}$$

$$+(a_{3}a_{4})^{-1}d(a_{3}a_{4}a_{1}a_{2})(a_{4}a_{1}a_{2})^{-1}d(a_{4}a_{1})a_{2}a_{3}a_{4}(1+A_{1})^{-1}$$

$$-(a_{3}a_{4})^{-1}d(a_{3}a_{4})(a_{2}a_{3}a_{4})^{-1}d(a_{2}a_{3}a_{4}a_{1})a_{2}a_{3}a_{4}(1+A_{1})^{-1}.$$
(226)

**Lemma 9.3.** The expression (226) is equal to zero.

*Proof.* Let us write the first two lines as

$$\left(d(a_1a_2)a_2^{-1}d(a_2a_3)a_4 + a_1a_2d(a_3a_4)(a_2a_3a_4)^{-1}d(a_2a_3)a_4 - d(a_1a_2)(a_4a_1a_2)^{-1}d(a_4a_1)a_2a_3a_4 - d(a_1a_2)a_2^{-1}d(a_2a_3)a_4\right)(1+A_1).$$
(227)

The terms 1 and 4 cancel, so we get

$$(227) = \left(a_1 a_2 d(a_3 a_4)(a_2 a_3 a_4)^{-1} d(a_2 a_3) a_4 - d(a_1 a_2)(a_4 a_1 a_2)^{-1} d(a_4 a_1) a_2 a_3 a_4\right) (1 + A_1). \tag{228}$$

A similar calculation with the lines 3 and 4 in (226) gives

$$\left( (a_3 a_4)^{-1} d(a_3 a_4) a_4^{-1} d(a_4 a_1) + d(a_1 a_2) (a_4 a_1 a_2)^{-1} d(a_4 a_1) - (a_3 a_4)^{-1} d(a_3 a_4) (a_2 a_3 a_4)^{-1} d(a_2 a_3) a_4 a_1 - (a_3 a_4)^{-1} d(a_3 a_4) a_4^{-1} d(a_4 a_1) \right) a_2 a_3 a_4 (1 + A_1).$$
(229)

The terms 1 and 4 cancel, so we get

$$(229) = \left(d(a_1a_2)(a_4a_1a_2)^{-1}d(a_4a_1) - (a_3a_4)^{-1}d(a_3a_4)(a_2a_3a_4)^{-1}d(a_2a_3)a_4a_1\right)a_2a_3a_4(1+A_1). \quad (230)$$

Therefore (227) + (229) is equal to

$$\left(a_{1}a_{2}d(a_{3}a_{4})(a_{2}a_{3}a_{4})^{-1}d(a_{2}a_{3})a_{4} - d(a_{1}a_{2})(a_{4}a_{1}a_{2})^{-1}d(a_{4}a_{1})a_{2}a_{3}a_{4} + d(a_{1}a_{2})(a_{4}a_{1}a_{2})^{-1}d(a_{4}a_{1})a_{2}a_{3}a_{4} - (a_{3}a_{4})^{-1}d(a_{3}a_{4})(a_{2}a_{3}a_{4})^{-1}d(a_{2}a_{3})a_{4}A_{1}\right)(1 + A_{1}).$$
(231)

Terms 2 and 3 evidently cancel. Terms 1 and 4 cancel if we permute  $A_1$  and  $1 + A_1$  in the term 4.  $\Box$  Therefore the sum B) is equal to zero. Theorem 4.12 is proved.

## 9.2 An analog of the Steinberg relation for non-commutative 2-forms.

Note that

$$\{x,y^{-1}\} = -x^{-1}dxy^{-1}dy, \quad \{x^{-1},y\} = -dxx^{-1}dyy^{-1}.$$

Theorem 9.4. Let us introduce the notation

$$\langle a|b\rangle := \{1 + ab, b^{-1}\} - (b^{-1}, 1 + ba\}.$$
 (232)

Then one has

$$\operatorname{Cycle}_{2}\left(\langle a_{1}a_{2}a_{3}|a_{4}\rangle - \langle a_{1}|a_{2}a_{3}a_{4}\rangle\right) = 0. \tag{233}$$

*Proof.* We can write (223) as

$$Cycle_{2}(\{1+A_{1}, a_{4}^{-1}\} - \{1+A_{1}, (a_{2}a_{3}a_{4})^{-1}\} - \{a_{4}^{-1}, 1+A_{4}\} + \{(a_{4}a_{1}a_{2})^{-1}, 1+A_{4}\}).$$
(234)

This coincides with (233). But we already proved that the sum (223) is equal to zero.

**Remark.** If variables  $a_i$  commute, then  $\langle a|b\rangle = -2 \cdot d\log(1+ab) \wedge d\log b$ , and identity (233) reads as

$$d\log(1 + a_1a_2a_3a_4) \wedge d\log(a_1a_2a_3a_4) = 0.$$

However for a general matrix X we have  $d\log(1+X) \wedge d\log X \neq 0$ . The identity (233) is the analog of the Steinberg relation  $d\log(1+z) \wedge d\log(z) = 0$  for the non-commutative 2-forms. It is interesting that it involves four non-commutative variables  $a_1, a_2, a_3, a_4$  rather than one.

It would be interesting to find a similar non-commutative generalization of the de Rham realization of the defining relation in the Milnor K-group:  $d \log(1+z) \wedge d \log(z) \wedge d \log(z_1) \wedge \ldots \wedge d \log(z_n) = 0$ .
