#### Abstract

Steric properties of crystallographically and computationally determined structures of linear palladium(0) and square planar palladium(II) complexes of di(tert-butyl) neopentylphosphine ( $\mathrm{P}(t-$ $\left.\mathrm{Bu})_{2} \mathrm{~Np}\right)$, tert-butyldineopentylphosphine $\left(\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}\right)$, and trineopentylphosphine $\left(\mathrm{PNp}_{3}\right)$ have been determined. Structures of linear palladium( 0 ) complexes show that steric demand increases as tertbutyl groups are replaced with neopentyl groups ( $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}<\mathrm{P}(t-$ $\mathrm{Bu}) \mathrm{Np}_{2}<\mathrm{PNp}_{3}$ ). In square planar palladium(II) complexes, $\mathrm{PNp} \mathrm{p}_{3}$ gives the smallest steric parameters, whereas $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$ has the largest steric demand. The change in the steric demand of $\mathrm{PN} \mathrm{p}_{3}$ compared to $\mathrm{P}(t-$ $\mathrm{Bu})_{2} \mathrm{~Np}$ and $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$ results from a significant conformational change in $\mathrm{PNp}_{3}$ depending on the coordination number of the metal.  The steric properties of these ligands were also probed by measuring the equilibrium constant for coordination of free phosphine to dimeric $\left[\left(\mathrm{R}_{3} \mathrm{P}\right) \mathrm{Pd}(\mu-\mathrm{Cl}) \mathrm{Cl}\right]_{2}$ complexes. Binding equilibria follow the same trend as the steric parameters for square planar complexes with $\mathrm{PNp}_{3}$ having the highest binding constant. In contrast to the normal trend, the neopentylphosphines show increased pyramidalization at phosphorus with increasing steric demand. We hypothesize that this unusual dependence reflects the low back side strain of the neopentyl group, which allows the ligand to be more pyramidalized while still exerting a significant front side steric demand.

## INTRODUCTION

Phosphorus-based ligands represent the predominant class of supporting ligands for homogeneous catalytic processes involving late transition metals. Because phosphorus-based ligands can be synthesized with a nearly infinite variety of substituents, the properties of these ligands can be widely varied to promote desired catalytic reactions. Electronic properties can be varied from strongly $\sigma$-donating trialkylphosphines to $\pi$-accepting phosphites. Steric properties can similarly be varied over a wide range of cone angles from $\mathrm{PMe}_{3}$ $\left(118^{\circ}\right)$ to $\mathrm{P}(\text { mesityl })_{3}\left(212^{\circ}\right)$. This wide range of steric and electronic variability makes it important to be able to quantify steric and electronic properties to allow ligand properties to be compared. Quantifying steric properties becomes particularly challenging with conformationally flexible ligands that may have different low energy conformations as a function of the structure of the coordinated metal complex.

A number of steric and electronic descriptors have been developed in an effort to quantify the effects of ligands on metal centers in catalyst systems. ${ }^{1}$ The Tolman cone angle $(\theta)$ was the first quantified description of the steric impact of ligands and remains a widely used steric descriptor (Figure 1). ${ }^{2}$ The Tolman cone angle is based on the least sterically
demanding conformation of a ligand, which is not always the lowest energy conformation. Allen's exact cone angle parameter uses Tolman's definition but is based on the low energy conformation of the metal-ligand complex. ${ }^{3}$ To address ligands with nonsymmetric steric profiles, the solid cone angle ( $\Omega$ ) was developed. ${ }^{4}$ The solid cone angle is derived from the area of the shadow projected by the ligand atoms on a sphere surrounding the metal, which can be converted to a vertex angle analogous to the Tolman cone angle.

The percent buried volume ( $\% V_{\text {bur }}$ ) parameter developed by Nolan et al. measures the percentage of a sphere occupied by the ligand. ${ }^{5}$ The $\% V_{\text {bur }}$ has gained popularity as it can be calculated with a simple web interface and handles nonsymmetric ligands, such as NHCs and chelating ligands, more

[^0]

Figure 1. Steric descriptors of phosphine ligands.
easily than the cone angle description. Orpen et al. described the angular symmetric deformation parameter ( $\mathrm{S} 4^{\prime}$ ) as an easily measured steric descriptor. $\mathrm{S}^{\prime}{ }^{\prime}$ is defined as the difference between the sum of the $\mathrm{M}-\mathrm{P}-\mathrm{C}$ angles $(\alpha)$ and $\mathrm{P}-\mathrm{C}-\mathrm{C}$ angles $(\beta) .{ }^{6}$ This parameter provides a measure of the pyramidalization of the phosphorus center and is found to inversely correlate with the Tolman cone angle. ${ }^{7}$

The Tolman electronic parameter ( $\chi$ ) based on the symmetric CO stretch of $\mathrm{LNi}(\mathrm{CO})_{3}$ complexes is the basis for the majority of reported ligand electronic properties. ${ }^{2 \mathrm{~b}, 8}$ Because of the toxicity of $\mathrm{Ni}(\mathrm{CO})_{4}$; molybdenum, iridium, and rhodium carbonyl complexes have been correlated with the original Tolman scale. ${ }^{9}$ Other electronic parameters that have been applied to analyzing phosphine ligands include the $\mathrm{p} K_{\mathrm{a}}$ of phosphonium ions, proton affinity, calculated charge on phosphorus, and the HOMO energy level of the phosphine. ${ }^{1 \mathrm{~b}, 10}$

Our group has been interested in phosphines containing conformationally flexible neopentyl substituents, such as di-tert-butylneopentylphosphine $\left(\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}\right.$; Figure 2), tert-

Figure 2. Structures of $\mathrm{P}(t-\mathrm{Bu})_{3}$ and neopentyl phosphines
butyldineopentylphosphine $\left(\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}\right)$, and trineopentylphosphine $\left(\mathrm{PNp}_{3}\right) . \mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ provides active catalysts for a variety of traditional palladium-catalyzed cross-coupling reactions of aryl bromides and chlorides. ${ }^{11}$ Interesting differences between catalysts derived from $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ and $\mathrm{PNp}_{3}$ have been observed in these reactions. In the Heck coupling of cyclic alkenes, $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ and $\mathrm{PNp}_{3}$ afford catalysts with orthogonal olefin product selectivity. ${ }^{12}$ The $\mathrm{P}(t-$ $\mathrm{Bu})_{2} \mathrm{~Np} / \mathrm{Pd}$ catalyst system is not effective for cross-coupling of sterically demanding substrates. In contrast, the catalyst derived from palladium and $\mathrm{PNp}_{3}$ is effective at coupling sterically demanding aryl halides. ${ }^{11 d, 13}$ The ability of $\mathrm{PNp}_{3}{ }^{-}$ derived catalysts to couple sterically demanding substrates has
been ascribed to its conformational flexibility compared to more rigid ligands like $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ and $\mathrm{P}(t-\mathrm{Bu})_{3}{ }^{13 \mathrm{~b}, 14}$

The replacement of tert-butyl substituents with neopentyl groups introduces a degree of conformational flexibility into the ligand. The steric demand of the neopentyl substituent is expected to vary depending on the $\mathrm{M}-\mathrm{P}-\mathrm{C}-\mathrm{C}$ dihedral angle (Figure 3). When the neopentyl group is syn coplanar with the

Figure 3. Potential effect of the change in the $\mathrm{Pd}-\mathrm{P}-\mathrm{C}-\mathrm{C}$ dihedral angle of neopentylphosphines on the ligand steric demand.
$\mathrm{P}-\mathrm{Pd}$ bond (A), it has maximum steric impact. As the $\mathrm{Pd}-\mathrm{P}-$ $\mathrm{C}-\mathrm{C}$ dihedral angle increases, the steric demand is expected to decrease with a minimal value in the anti conformation (C). This flexibility is analogous to that observed in phosphite ligands. ${ }^{15}$ Analysis of crystal structures shows that $\mathrm{P}(\mathrm{OMe})_{3}$ can have cone angles ranging from 103 to $139^{\circ}$, with the majority of experimental structures having much larger values than the Tolman cone angle of $107^{\circ} .^{16}$

The steric and electronic properties of the neopentylphosphine ligands have been previously analyzed using experimental and computational data. ${ }^{11 a, b}$ Solid cone angles based on calculated $\operatorname{LPd}(0)$ complexes showed that replacing tertbutyl groups with neopentyl substituents increased the ligand steric demand. The low energy conformations for these complexes have small $\mathrm{Pd}-\mathrm{P}-\mathrm{C}-\mathrm{C}$ dihedral angles for the neopentyl substituents (conformation A, Figure 3). We have since reported crystal structures of square planar palladium(II) complexes with these ligands, that have conformations of type $B$ and C. ${ }^{11 \mathrm{c}, \mathrm{f}, 13 \mathrm{~b}, 14}$ On the basis of these observations, we hypothesized that the steric parameters determined for $\operatorname{LPd}(0)$ may not be relevant to the square planar palladium(II) complexes that are key catalytic intermediates in crosscoupling reactions. In particular, $\mathrm{PNp}_{3}$ undergoes a large conformational change depending on the metal coordination number, which might be expected to significantly affect the steric properties of this ligand.

In this work, a detailed analysis of the structure of the $\mathrm{P}(t-$ $\mathrm{Bu})_{n} \mathrm{~Np}_{3-n}(n=0-3)$ has been performed for the ligands coordinated in linear palladium(0) and square planar palladium(II) complexes to determine how coordination number affects the conformation and steric properties of neopentylphosphines. Both types of complexes are relevant to the palladium-catalyzed cross-coupling reaction catalytic cycle involving a $\mathrm{Pd}(0 / \mathrm{II})$ redox cycle. We report that the steric demand of $\mathrm{PNp}_{3}$ varies significantly depending on the coordination number of the metal complex, whereas the more rigid $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ has a smaller range of steric effects. The effective steric demand of these ligands was probed by measuring the binding equilibrium for these ligands with $[\operatorname{LPd}(\mu-\mathrm{Cl}) \mathrm{Cl}]_{2}$ complexes to afford trans- $\mathrm{L}_{2} \mathrm{PdCl}_{2}$.

## RESULTS

Synthesis of $\left[\left(\mathrm{R}_{3} \mathrm{P}\right) \mathrm{Pd}(\mu-\mathrm{Cl}) \mathrm{Cl}\right]_{2}$ and trans- $\left(\mathrm{R}_{3} \mathrm{P}\right)_{2} \mathrm{PdCl}_{2}$ Complexes. The neopentylphosphine palladium complexes were prepared using known procedures to give $\left[\left(\mathrm{R}_{3} \mathrm{P}\right) \mathrm{Pd}(\mu\right.$ $\mathrm{Cl}) \mathrm{Cl}]_{2}(\mathbf{1 a}-\mathbf{1 c})$ and $\left(\mathrm{R}_{3} \mathrm{P}\right)_{2} \mathrm{PdCl}_{2}(\mathbf{2 a - 2 c})$ complexes (Scheme 1). ${ }^{11 \mathrm{f}}$ The complexes are air stable and show no

Scheme 1. Synthesis of $\left[\left(\mathrm{R}_{3} \mathrm{P}\right) \mathrm{Pd}(\mu-\mathrm{Cl}) \mathrm{Cl}\right]_{2}(1 \mathrm{a}-1 \mathrm{c})$ and trans- $\left(\mathrm{R}_{3} \mathrm{P}\right)_{2} \mathrm{PdCl}_{2}(2 \mathrm{a}-2 \mathrm{c})$ Complexes

signs of decomposition upon storage in air at ambient temperature for extended periods. In contrast, $\left[\left((t-\mathrm{Bu})_{3} \mathrm{P}\right) \mathrm{Pd}-\right.$ $(\mu-\mathrm{Cl}) \mathrm{Cl}]_{2}$ undergoes decomposition by ligand metalation over the course of several days. ${ }^{17}\left((t-\mathrm{Bu})_{3} \mathrm{P}\right)_{2} \mathrm{PdCl}_{2}$ has been reported, ${ }^{18}$ but no structural or spectroscopic data have been published for this complex. Our attempts to prepare this complex indicated that it undergoes cyclometalation over the course of several hours in solution.

The ${ }^{31} \mathrm{P}$ NMR chemical shifts for the $\left[\left(\mathrm{PR}_{3}\right) \mathrm{Pd}(\mu-\mathrm{Cl}) \mathrm{Cl}\right]_{2}$ complexes ( $\mathbf{1 a}, \mathbf{1 c}$ ) are $20-30 \mathrm{ppm}$ downfield compared to the $\left(\mathrm{PR}_{3}\right)_{2} \mathrm{PdCl}_{2}$ complexes ( $\mathbf{2 a - 2 c}$, Table S4, Supporting Information) as observed in similar systems. ${ }^{19}$ Ligand dissociation occurs upon dissolving the bisphosphine complexes (2a, 2b) in $\mathrm{CDCl}_{3}$ to give an equilibrium mixture of complex 2, the $\left[\left(\mathrm{PR}_{3}\right) \mathrm{Pd}(\mu-\mathrm{Cl}) \mathrm{Cl}\right]_{2}$ complex (1), and free phosphine. In $\mathrm{C}_{6} \mathrm{D}_{6}$, less than $5 \%$ of ligand dissociation from 2a to give free $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ and $\mathbf{1 a}$ was observed. A larger extent $(10 \%)$ of dissociation of $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$ from $\mathbf{2 b}$ was observed in $\mathrm{C}_{6} \mathrm{D}_{6}$. Ligand dissociation was not observed in the ${ }^{31} \mathrm{P}$ NMR spectrum of complex 2 c in either solvent. ${ }^{31} \mathrm{P}$ NMR chemical shifts were calculated for complexes 1a-1c and 2a2c. The calculated chemical shifts were higher than the experimental values by $39.7-42.5 \mathrm{ppm}$ for $\mathbf{1 a}-1 \mathrm{c}$ and $16.6-$ 22.4 ppm for $\mathbf{2 a} \mathbf{- 2 c}$, similar to previously reported calculated ${ }^{31} \mathrm{P}$ NMR shifts. ${ }^{20}$ Although the absolute shifts were too high, the calculated values accurately predicted the difference in chemical shift between the complexes within each series of compounds.

Structural analysis of $\left[\left(\mathrm{R}_{3} \mathrm{P}\right) \mathrm{Pd}(\mu-\mathrm{Cl}) \mathrm{Cl}\right]_{2}$, trans$\left(\mathrm{R}_{3} \mathrm{P}\right)_{2} \mathrm{PdCl}_{2}$, and $\left(\mathrm{R}_{3} \mathrm{P}\right)_{2} \mathrm{Pd}$ complexes. X-ray quality crystals of $\mathbf{1 a} \cdot 2 \mathrm{CHCl}_{3}$ were obtained by slow evaporation from chloroform (Figure 4). Diffusion of hexane into an acetonitrile solution of 1c gave X-ray quality crystals of the solvent-free complex. Both structures were chloride-bridged dimers with coplanar palladium square planes. Alternate nonplanar polymorphic structures of $\mathbf{1 a}$ and $\mathbf{1 c}$ were obtained by diffusion of pentane into methylene chloride. The alternate structures had similar structural parameters apart from the angle between the palladium square planes (Figures S21 and

Figure 4. Thermal ellipsoid plots ( $50 \%$ probability) of $\left[\left(\mathrm{PR}_{3}\right) \operatorname{Pd}(\mu\right.$ $\mathrm{Cl}) \mathrm{Cl}]_{2}$ complexes $\left(\mathbf{1 a}, \mathrm{PR}_{3}=\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np} ; \mathbf{1 c}, \mathrm{PR}_{3}=\mathrm{PNp}_{3}\right)$. Hydrogen atoms and cocrystallized solvent (1a) are omitted for clarity. (a) 1a, (b) 1c. Structural data are provided in Table 1.

S23, Tables S5 and S6, Supporting Information). Several single crystals of $\mathbf{1 b}$ were obtained from various conditions, but all the crystals were disordered and gave low resolution structures.

The crystal structure of $\mathbf{2 a}$ has been previously reported by our group. ${ }^{11 c}$ Crystals of $2 b$ and $2 c$ were obtained by pentane diffusion into methylene chloride solutions. Like 2a, complexes $\mathbf{2 b}$ and 2c crystallized with two molecules in the asymmetric unit with similar structural parameters (Figure 5 and Figures

Figure 5. Thermal ellipsoid plots ( $50 \%$ probability) of $\left(\mathrm{R}_{3} \mathrm{P}\right)_{2} \mathrm{PdCl}_{2}$ complexes (2a, $\left.\mathrm{PR}_{3}=\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np} ; \mathbf{2 c}, \mathrm{PR}_{3}=\mathrm{PNp}_{3}\right)$. Plots show one of two molecules in the asymmetric unit with hydrogen atoms omitted for clarity. (a) 2b, (b) 2c. Structural data are provided in Table 2.

S24 and S25, Supporting Information). Both molecules in the asymmetric unit have a point of inversion at the palladium center. Data for the one molecules (Pd1) is discussed here, and values for both structures are reported in the Supporting Information (Tables S7-S9).

Because complex $\mathbf{1 b}$ did not give X-ray quality crystals, an alternative monophosphine complex of $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$ was prepared to approximate the structure of $\mathbf{1 b}$. Structural characterization of $\left(\mathrm{PNp}_{3}\right) \mathrm{Pd}(\mathrm{Ar})$ (pyridine) Br complexes shows that pyridine ligands have little effect on the phosphine structure compared to halide-bridged analogs $\left(\left[\left(\mathrm{PNp}_{3}\right) \mathrm{Pd}\right.\right.$ $\left.(\mathrm{Ar}) \mathrm{Br}]_{2}\right){ }^{14}$ The reaction between $\mathbf{1 b}$ and 4-picoline provided complete conversion to $\left[\left(\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}\right) \mathrm{PdCl}_{2}(4\right.$-picoline $\left.)\right](3 \mathbf{b}$; eq 1). X-ray quality crystals of complex $\mathbf{3 b}$ were obtained by cooling a concentrated solution of $\mathbf{1 b}$ in methylene chloride with excess 4-picoline (Figure 6).

A comparison of selected experimental and calculated bond lengths and angles for complexes $\mathbf{1 a}, \mathbf{3 b}, \mathbf{1 c}$, and $\mathbf{2 a - 2} \mathbf{c}$ are shown in Tables 1 and 2 (Figure 7). Crystal structures of $\mathrm{Pd}(0)$ complexes $\left(\mathrm{R}_{3} \mathrm{P}\right)_{2} \mathrm{Pd} \quad\left(\mathrm{PR}_{3}=\mathrm{P} t \mathrm{Bu}_{2}(\mathrm{~Np})(4 \mathbf{a}),{ }^{11 \mathrm{c}}\right.$ $\mathrm{PtBu}(\mathrm{Np})_{2}(\mathbf{4 b}),{ }^{21}$ and $\mathrm{P}(\mathrm{Np})_{3}(4 \mathrm{c})^{13 \mathrm{a}}$ ) have been previously reported by our group (Figures S28-S30). Experimental and computational structural parameters are reported in Table S10

Figure 6. Thermal ellipsoid plot of $\left(\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}\right) \mathrm{PdCl}_{2}$ (4-picoline) (3b). Thermal ellipsoids drawn at the $50 \%$ probability level. Hydrogens are omitted for clarity.
(Supporting Information). The calculated structures were obtained at the DFT level using the BP86 ${ }^{22}$ and SVWNS ${ }^{23}$ functionals. The DFT optimized structures with the BP86 and SVWN5 functionals bracket the experimental bond distances. The calculated bond angles are within $3^{\circ}$ of experimental values. For $\mathbf{1 a}$ and $\mathbf{3 b}$, the calculated and experimental torsion angles agree to experimental values within $5^{\circ}$. There is more variation between the computed and experimental torsion angles for 1 c with differences up to $20^{\circ}$.

The $\mathrm{Pd}-\mathrm{P}$ bond lengths for the $\left(\mathrm{PR}_{3}\right) \mathrm{PdCl}_{2}(\mathrm{~L})$ complexes ( $\mathbf{1 a}$ and $\mathbf{1 c}, \mathrm{L}=\mu-\mathrm{Cl} ; 3 \mathbf{b}, \mathrm{~L}=4$-picoline) are shorter than
those in the $\left(\mathrm{PR}_{3}\right)_{2} \mathrm{PdCl}_{2}$ complexes $\mathbf{2 a - 2 c}$. The $\mathrm{Pd}-\mathrm{P}$ bond distances also decrease as the number of neopentyl substituents increases ( $\mathbf{1 a}>\mathbf{3 b}>\mathbf{1 c} ; \mathbf{2 a}>\mathbf{2 b}>\mathbf{2 c}$ ), a trend consistent with decreasing front steric strain between the ligand and $\mathrm{PdCl}_{2}$ unit. ${ }^{6,7}$ The $\mathrm{Pd}-\mathrm{P}$ distances in $\mathbf{2 a}$ and $\mathbf{2 b}$ are longer than that seen for $\left(\left(\mathrm{P}(t-\mathrm{Bu})_{3}\right) \mathrm{P}\right)_{2} \mathrm{Pd}(\mathrm{H}) \mathrm{Cl}(2.361 \AA),{ }^{24}$ whereas 2c has a similar $\mathrm{Pd}-\mathrm{P}$ bond length to the $\mathrm{P}(t-\mathrm{Bu})_{3}$ complex. The $\mathrm{L}_{2} \mathrm{Pd}(0)$ complexes $(4 \mathbf{a}-4 \mathrm{c})$ have shorter $\mathrm{Pd}-\mathrm{P}$ bond lengths than 2a-2c. The Pd-P bond lengths of $\mathbf{4 a}$ and $4 b$ are similar to those of $\mathbf{1 a}$ and $\mathbf{3 b}$, whereas $\mathrm{PNp}_{3}$ complex $\mathbf{1 c}$ has a shorter $\mathrm{Pd}-\mathrm{P}$ bond length than $\mathbf{4 c}$. The $\mathrm{Pd}-\mathrm{P}$ bonds of $\mathbf{4 a}-\mathbf{4 c}$ are the same within error.

Monophosphine complexes 1a, 3b, and 1c have slight seesaw distortions to the square plane with angles between trans ligands ranging from $168.25-179.20^{\circ}\left(1 \mathrm{a}: \tau_{4}=0.10, \tau_{4}{ }^{\prime}\right.$ $=0.07$; 3b: $\tau_{4}=0.09, \tau_{4}{ }^{\prime}=0.09$; 1c: $\left.\tau_{4}=0.03, \tau_{4}{ }^{\prime}=0.02\right) .{ }^{25}$ The angle between the phosphine and the cis $\mu$-chloride is expanded ( $\mathbf{1 a}=98.8^{\circ}$; $\mathbf{1 c}=95.6^{\circ}$ ) and the $\mathrm{Cl}-\mathrm{Pd}-\mathrm{Cl}$ angle for the bridging chlorides is compressed ( $\mathbf{1 a}=83.2^{\circ}$; $\mathbf{1 c}=$ $84.3^{\circ}$ ). In complex $3 \mathbf{b}$, the large $\mathrm{P}-\mathrm{Pd}-\mathrm{Cl}$ angle is for the chlorine that is nearly eclipsed with the tert-butyl substituent, and the chlorine that roughly bisects the $\mathrm{Np}-\mathrm{P}-\mathrm{Np}$ has a $90^{\circ}$ $\mathrm{P}-\mathrm{Pd}-\mathrm{Cl}$ bond angle. The bis(phosphine) complexes ( $2 \mathrm{a}-$ 2c) have nearly ideal square planar geometries with $\tau$ and $\tau^{\prime}=$ 0 and cis $\mathrm{L}-\mathrm{Pd}-\mathrm{L}$ bond angles close to $90^{\circ}$.

The methylene unit of the neopentyl substituent provides a degree of flexibility through bond rotation ( $\mathrm{Pd}-\mathrm{P}-\mathrm{C}-\mathrm{C}$ dihedral angle), expansion of the $\mathrm{P}-\mathrm{C}-\mathrm{C}$ angle, and compression of the $\mathrm{C}-\mathrm{P}-\mathrm{C}$ angles. The response of the

3b, 2b

1c,2c

Figure 7. Key to structure descriptors used in Tables 2 and 3.
$\mathrm{Pd}-\mathrm{P}-\mathrm{C}-\mathrm{C}$ dihedral angle can be seen most dramatically when comparing linear $\mathrm{L}_{2} \mathrm{Pd}(0)$ complexes ( $\mathbf{4 a} \mathbf{- 4} \mathbf{c}$, Table S10) and square planar palladium(II) complexes (1a, 3b, 1c, and 2a-2c, Tables 1 and 2). The neopentyl group in the $\mathrm{Pd}\left(\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}\right)_{2}$ complex is eclipsed with the $\mathrm{Pd}-\mathrm{P}$ bond ( $\left.\mathrm{Pd} 1-\mathrm{P} 1-\mathrm{C} 1-\mathrm{C} 2=0.3(1)^{\circ}\right)$. In the four coordinate complexes, the neopentyl substituent rotates away from the chloride ligand and adopts a gauche conformation to the $\mathrm{Pd}-\mathrm{P}$ bond in the monophosphine complex (Pd1-P1-C1-C2 (1a) $\left.=62.7(9)^{\circ}\right)$ and the bisphosphine complex (Pd1-P1-C28$\mathrm{C} 30(2 \mathbf{a})=64.5^{\circ}$ ).

A similar trend is seen with $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$ and $\mathrm{PNp}_{3}$ complexes. One of the neopentyl groups of $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$ is eclipsed with the $\mathrm{Pd}-\mathrm{P}$ bond in $\mathrm{Pd}\left(\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}\right)_{2}(\mathrm{Pd}-\mathrm{P}-\mathrm{C}-$ $\left.\mathrm{C}=2.2(6)^{\circ}\right)$ with the other neopentyl group also having a relatively small dihedral angle $\left(29.6(6)^{\circ}\right)$, whereas the dihedral angles are larger in $\mathbf{3 b}$ and $\mathbf{2 b}$. $\operatorname{The} \operatorname{Pd}\left(\mathrm{PNp}_{3}\right)_{2}$ complex has $C_{3}$ symmetry along the $\mathrm{P}-\mathrm{Pd}-\mathrm{P}$ axis with all the neopentyl
substituents oriented toward the palladium with a $\mathrm{Pd}-\mathrm{C}-\mathrm{C}-$ C dihedral angle of $34.6^{\circ}$. The $\mathrm{Pd}(\mathrm{II})$ complexes of $\mathrm{PNp}_{3}$ (1c, 2c) adopt a conformation in which one neopentyl group is approximately anti to the $\mathrm{Pd}-\mathrm{P}$ bond and the other two neopentyl groups are gauche $\left(\mathrm{Pd}-\mathrm{P}-\mathrm{C}-\mathrm{C}: \mathbf{1 c}=170.9(1)^{\circ}\right.$, $56.3(2)^{\circ}, 41.9(2)^{\circ} ; 2 \mathrm{c}=145.1^{\circ}, 72.3^{\circ}$, and $\left.56.2^{\circ}\right)$. This pattern is consistent with other structurally characterized 4 coordinate complexes of trineopentylphosphine, ${ }^{13 \mathrm{a}, 14}$ as well as complexes of other primary alkylphosphines, such as $\mathrm{PEt}_{3}$ and $\mathrm{P}(n-\mathrm{Bu})_{3}{ }^{26}$

Changing from linear to square planar structures results in an increase in the $\mathrm{P}-\mathrm{C}-\mathrm{C}$ angle of the neopentyl substituents. In $\operatorname{Pd}\left(\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}\right)_{2}(4 \mathbf{a})$, the $\mathrm{P}-\mathrm{C}-\mathrm{C}$ angle of the neopentyl substituent is $119.62^{\circ}$. In the four-coordinate complexes ( 1 a , 2a), the neopentyl $\mathrm{P}-\mathrm{C}-\mathrm{C}$ angles increases to $126.7^{\circ}$ (1a) and $126.2^{\circ}(\mathbf{1 b})$, respectively. A similar trend is seen with $\mathrm{P}(t$ $\mathrm{Bu}) \mathrm{Np}_{2}$ and $\mathrm{PNp}_{3}$. The two-coordinate $\mathrm{L}_{2} \mathrm{Pd}$ complexes have neopentyl $\mathrm{P}-\mathrm{C}-\mathrm{C}$ angles similar to that of $\operatorname{Pd}\left(\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}\right)_{2}$. Palladium (II) $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$ complexes $\mathbf{3 b}$ and $\mathbf{2 b}$ have neopentyl $\mathrm{P}-\mathrm{C}-\mathrm{C}$ angles ranging from 125.5 to $127.4^{\circ}$ compared to $121^{\circ}$ in $\mathbf{4 b}$. In the trineopentylphosphine system ( $\mathbf{1 c}, \mathbf{2 c}$, and 4 c ), the $\mathrm{P}-\mathrm{C}-\mathrm{C}$ angles of the neopentyl groups increase from $120.4^{\circ}$ for the linear 4 c to $121.9-125.5^{\circ}$ in $\left[\left(\mathrm{PNp}_{3}\right) \mathrm{Pd}\right.$ -$(\mu-\mathrm{Cl}) \mathrm{Cl}]_{2}(1 \mathrm{c})$ and $123.4-127.9^{\circ}$ for $\left(\mathrm{PNp}_{3}\right)_{2} \mathrm{PdCl}_{2}(2 \mathrm{c})$. The largest angle in each case is the neopentyl group anti to the $P d-P$ bond.

For each of the ligands, the $\sum_{\mathrm{C}-\mathrm{P}-\mathrm{C}}$ value increases on going from the $\mathrm{L}_{2} \mathrm{Pd}(4)$ to $\mathrm{L}_{2} \mathrm{PdCl}_{2}(2)$ to $[\operatorname{LPd}(\mu-\mathrm{Cl}) \mathrm{Cl}]_{2}(\mathbf{1})$ complexes. Increased $\pi$-backbonding in the $\operatorname{Pd}(0)$ complexes compared to $\mathrm{Pd}(\mathrm{II})$ would be expected to result in smaller $\sum_{\mathrm{C}-\mathrm{P}-\mathrm{C}}$ values. ${ }^{27}$ Increased $\pi$-backbonding should also increase the $\mathrm{P}-\mathrm{C}$ bond lengths. This trend is seen for the $\mathrm{PNp}_{3}$ complexes ( 4 c vs 1 c ), but the $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ complexes
only show a statistically significant difference for the $\mathrm{P}-\mathrm{Np}$ bond. The $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2} \mathrm{P}-\mathrm{C}$ bond lengths do not have differences greater than $3 \sigma$.

Calculated $\sum_{\text {C-P-C }}$ values for the free ligands are similar to the values in the $\mathrm{L}_{2} \mathrm{Pd}$ complexes (Table 3). The $\sum_{\mathrm{C}-\mathrm{P}-\mathrm{C}}$ value

Table 3. Calculated $\sum_{\text {c-p-c }}$ Values for the Free Ligands

|  | $\sum_{\mathrm{C}-\mathrm{P}-\mathrm{C}}(\mathrm{deg})$ |  |  |
| :--- | :---: | :---: | :---: |
| functional | $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ | $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$ | $\mathrm{PNp}_{3}$ |
| BP86 | 313.4 | 304.7 | $297.3^{a} / 311.0^{b}$ |
| SVWN5 | 311.5 | 305.9 | $297.9^{a} / 309.2^{b}$ |

${ }^{a}$ Low energy $C_{3}$ symmetry configuration ${ }^{b}$ Ligand in the optimized conformation found in complexes 1c and 2c
for $\mathrm{PNp}_{3}$ is similar to those of $\mathrm{PEt}_{3}\left(299.4^{\circ}\right)$ and $\mathrm{PMe}_{3}$ $\left(297.4^{\circ}\right) .{ }^{28}$ The pyramidalization of the neopentylphosphines does not change significantly upon complexing to palladium(0) (4). The free ligands all have smaller $\sum_{\mathrm{C}-\mathrm{P}-\mathrm{C}}$ values than the palladium(II) complexes ( $\mathbf{1 a}, \mathbf{1 c}, \mathbf{3 b}$, and $\mathbf{2 a} \mathbf{- 2 c}$ ), which is expected with a less $\pi$-basic metal center. ${ }^{6}$ The $\sum_{\text {C-P-C }}$ value for the low symmetry conformation of $\mathrm{PNp}_{3}$ found in 1 c and 2 c was also calculated. This value is smaller than that of $\mathrm{PNp}_{3}$ in 1c and 2c. The lower symmetry conformation of $\mathrm{PNp}_{3}$ is higher in energy in the gas phase by 4.7 (SVWN5) and 5.7 (BP86) kcal/mol.

For the free ligands and the $\mathrm{L}_{2} \operatorname{Pd}(0)$ complexes, the phosphorus becomes increasingly pyramidalized as tert-butyl groups are replaced with neopentyl groups $\left(\mathrm{PNp}_{3}<\mathrm{P}(t-\right.$
$\left.\mathrm{Bu}) \mathrm{Np}_{2}<\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}\right)$. In contrast, the trend with square planar palladium(II) centers is $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}<\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np} \approx$ $\mathrm{PNp}_{3}$. The $\sum_{\mathrm{C}-\mathrm{P}-\mathrm{C}}$ value increases by approximately $7^{\circ}$ for $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ and $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$ going from complex 4 to complex $\mathbf{1 a}$ or $\mathbf{3 b}$. The increase is significantly larger for $\mathrm{PNp}_{3}$ complexes 4 c and 1c $\left(25^{\circ}\right)$, which accounts for the change in the trend. The larger change in $\sum_{\mathrm{C}-\mathrm{P}-\mathrm{C}}$ value likely reflects the more significant conformational change that $\mathrm{PNp}_{3}$ undergoes from the $L_{2} \mathrm{Pd}(4 \mathrm{c})$ to the palladium(II) structures ( 1 c and 2 c ).

Ligand Steric Parameters. The steric properties of the neopentylphosphine ligands in different coordination environments were determined using the experimental and calculated structural data for the $\left(\mathrm{R}_{3} \mathrm{P}\right)_{2} \mathrm{Pd},\left[\left(\mathrm{R}_{3} \mathrm{P}\right) \mathrm{Pd}(\mu-\mathrm{Cl}) \mathrm{Cl}\right]_{2}$, and $\left(\mathrm{R}_{3} \mathrm{P}\right)_{2} \mathrm{PdCl}_{2}$ complexes, as well as $\mathrm{LPd}^{0}$ and $\mathrm{LPdCl}_{2}$ (Table 4). In the case of the $L_{2} \mathrm{Pd}(0)$ complexes (4), the solid cone angle increases as tert-butyl groups are replaced with neopentyl substituents $\left(\mathrm{P}(t-\mathrm{Bu})_{3}<\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}<\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}<\mathrm{PNp}_{3}\right)$. The same trend is seen for calculated structures of $\mathrm{LPd}^{0}$ complexes. The solid cone angles increase for $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ and $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$ in the palladium(II) complexes $\mathbf{1}$ and 2 . In contrast, the solid cone angle for $\mathrm{PNp}_{3}$ decreases going from palladium(0) to palladium(II). As a result, the trend for the $\left(\mathrm{PR}_{3}\right) \mathrm{PdCl}_{2} \mathrm{~L}^{\prime}\left(\mathbf{1 a}, \mathbf{1} \mathbf{c}, \mathbf{3 b} ; \mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np} \approx \mathrm{PNp}_{3}<\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}\right)$ and $\left(\mathrm{PR}_{3}\right)_{2} \mathrm{PdCl}_{2}\left(\mathbf{2 a - 2 c} ; \mathrm{PNp}_{3}<\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}<\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}\right)$ indicate that $\mathrm{PNp}_{3}$ is smaller than $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$ and similar in size to $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ in the square planar palladium(II) complexes. Cone angles for the calculated $\mathrm{LPdCl}_{2}$ and $\mathrm{L}_{2} \mathrm{PdCl}_{2}$ follow the same trend of $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}<\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$

Table 4. Steric Parameters for $\mathrm{P}(t-\mathrm{Bu})_{3}, \mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}, \mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$, and $\mathrm{PNp}_{3}$ Complexes

${ }^{a}$ Solid cone angle determined using the STERIC program. ${ }^{4 b}{ }^{b}$ BP86/DZVP2 optimized geometries. ${ }^{c}$ Exact cone angle determined by the Allen method ${ }^{3}{ }^{d}$ Percent buried volume calculated with SambVca $2.0^{5 \mathrm{c}}{ }^{e} \mathrm{~S} 4^{\prime}=\sum_{\text {Pd-P-C }}-\sum_{\text {P-C-C. }}{ }^{f}$ The first value is for the optimal $C_{3}$ symmetry configuration found in the free ligand, and the second value is for the ligand in the optimized conformation found in the palladium complex.

$<\mathrm{PNp}_{3}$. Exact cone angles $(\theta)$ were calculated using Allen's method. ${ }^{3}$ The exact cone angles were smaller than the solid cone angles by $0-20^{\circ}$ but followed similar trends.

The $\% V_{\text {bur }}$ for the ligands depends on the coordination environment at palladium (Table 4). In the two-coordinate $\mathrm{L}_{2} \mathrm{Pd}^{0}$ complexes, the $\% V_{\text {bur }}$ values increase as additional neopentyl groups are added $\left(\mathrm{P}(t-\mathrm{Bu})_{3}<\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}<\mathrm{P}(t-\right.$ $\mathrm{Bu}) \mathrm{Np}_{2}<\mathrm{PNp}_{3}$ ). The LPd complexes follow the same trend with larger values. The 4 -coordinate $[\operatorname{LPd}(\mu-\mathrm{Cl}) \mathrm{Cl}]_{2}$ complexes have smaller $\% V_{\text {bur }}$ values than the $\mathrm{L}_{2} \mathrm{Pd}^{0}$ complexes. The decrease in $\% V_{\text {bur }}$ is largest for $\mathrm{PNp}_{3}$ and smallest for $\mathrm{P}(t-$ $\mathrm{Bu}) \mathrm{Np}_{2}$. As a result, the $\% V_{\text {bur }}$ increases in the order $\mathrm{P}(t-$ $\mathrm{Bu})_{2} \mathrm{~Np}<\mathrm{PNp}_{3}<\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$. Adding a second phosphine to the coordination sphere further decreases the $\% V_{\text {bur }}$ for all three ligands, with $\mathrm{PNp}_{3}$ having the largest decrease. The ordering for the $\mathrm{L}_{2} \mathrm{PdCl}_{2}$ complexes is $\mathrm{PNp}_{3}<\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}<$ $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$.

Experimental and calculated structures for the neopentylphosphine series give similar S4' values (Table 4). For the LPd and $\mathrm{L}_{2} \mathrm{Pd}$ complexes, the $\mathrm{S4}^{\prime}$ parameter increases in the order $\mathrm{P}(t-\mathrm{Bu})_{3}<\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}<\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}<\mathrm{PNp}_{3}$. Previously reported values of $\mathrm{S}^{\prime}$ for $\mathrm{P}(t-\mathrm{Bu})_{3}(7.4), \mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}\left(23.3^{\circ}\right)$, $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}\left(43.4^{\circ}\right)$, and $\mathrm{PNp}_{3}\left(48.6^{\circ}\right)$ based on calculated LAuCl structures are similar to those calculated for LPd complexes. ${ }^{10 \mathrm{~b}}$ Significantly, the $\mathrm{S} 4^{\prime}$ parameter for these ligands correlates positively with cone angle and $\% V_{\text {bur }}$ values, which is opposite of the expected trend. ${ }^{7}$

The palladium(II) complexes have smaller S $^{\prime}$ values than the palladium( 0 ) complexes due in part to decreased $\pi$ backbonding from palladium. The $\mathrm{L}_{2} \mathrm{PdCl}_{2}$ complexes have larger $\mathrm{S}^{\prime}$ values for each ligand than the $[\operatorname{LPd}(\mu-\mathrm{Cl}) \mathrm{Cl}]_{2}$ complexes. For all of the palladium(II) complexes analyzed, $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ and $\mathrm{PNp}_{3}$ have similar $\mathrm{S}^{\prime}$ values, whereas $\mathrm{P}(t-$ $\mathrm{Bu}) \mathrm{Np}_{2}$ has a significantly larger value. For example, in the $\mathrm{L}_{2} \mathrm{PdCl}_{2}$ complexes, the values are $\mathrm{PNp}_{3}=19.72^{\circ}, \mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ $=21.42^{\circ}$, and $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}=37.04^{\circ}$. These values correlate positively with cone angle and $\% V_{\text {bur }}$ values, rather than the expected inverse correlation.
Analysis of Ligand Electronic Properties. The proton affinity (PA) is a measure of the Lewis basicity of the phosphines. The proton affinities of the phosphines were calculated at the BP86 and SVWN5 levels (Table 5). The PA

Table 5. Phosphines Proton Affinities at 298 K in $\mathrm{kcal} / \mathrm{mol}$ for Different DFT Starting Geometries

| phosphine | BP86 | SVWN5 | G3MP2 | exp |
| :--- | :--- | :--- | :--- | :--- |
| $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ | 240.9 | 233.3 |  |  |
| $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$ | 237.6 | 230.4 |  |  |
| $\mathrm{PNp}_{3}$ | $236.4 / 240.2^{a}$ | $230.0 / 232.4^{a}$ |  |  |
| $\mathrm{PH}_{3}$ | 185.7 | 178.9 | 187.3 | $187.3^{31}$ |

| ${ }^{a}$ Using the experimental conformation in 2c |  |  |  |  |

was benchmarked by calculating the values for $\mathrm{PH}_{3}$ and $\mathrm{PMe}_{3}$ at the DFT levels as well as at the G3MP2 level. ${ }^{30}$ There is good agreement between the G3MP2 values and experimental values, ${ }^{51}$ and the BP86 values are also in agreement with the experimental and the G3MP2 calculated values within $2 \mathrm{kcal} /$ mol. The PA for the low symmetry $\mathrm{PNp}_{3}$ conformation found in complexes 1c and 2 c is higher than in the optimal $C_{3}$ structure. The PA values have little variation between the ligands but increase in the order $\mathrm{PNp}_{3} \lesssim \mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}<\mathrm{P}(t-$
$\mathrm{Bu})_{2} \mathrm{~Np}$. The trend is similar to that previously reported by us with other electronic descriptors, including CO stretching frequencies of trans- $\left(\mathrm{R}_{3} \mathrm{P}\right)_{2} \mathrm{Rh}(\mathrm{CO}) \mathrm{Cl}$ complexes, calculated charge on phosphorus of the free ligands, and HOMO energy levels for the free ligand. ${ }^{11 \mathrm{~b}}$

Ligand Binding Equilibria. Complexes 2a and 2b undergo ligand dissociation in solution to establish an equilibrium between the corresponding monophosphine dimer ( $\mathbf{1 a - 1 c}$ ), free phosphine, and the diphosphine complex (2a-2c). Quantification of the equilibrium constants for these reactions would provide a way to assess the effective steric demand of these ligands as it affects ligand binding equilibria. Reaction equilibria were measured by analyzing the bridge cleavage reaction of complexes $\mathbf{1 a - 1 c}$ with neopentylphosphines (eq 2, Table 6). Solutions with varied concentrations of

the palladium dimer complex (1) and free ligand were analyzed by ${ }^{31} \mathrm{P}$ NMR spectroscopy in both $\mathrm{C}_{6} \mathrm{D}_{6}$ and $\mathrm{CDCl}_{3}$. The reactions reached equilibrium within minutes and showed no further change over time.

Phosphine binding to $\mathbf{1 a} \mathbf{- 1} \mathbf{c}$ was exothermic for all three ligands, resulting in equilibrium constants ranging from $10^{2}$ to $10^{6}$. For all three complexes, the equilibrium constants obtained in $\mathrm{C}_{6} \mathrm{D}_{6}$ were larger than those measured in $\mathrm{CDCl}_{3}$. For $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ and $\mathrm{P} t-\mathrm{Bu}(\mathrm{Np})_{2}$, the equilibrium constant was an order of magnitude larger in benzene compared to chloroform, whereas the difference was only a factor of 2 for $\mathrm{PNp}_{3}$. For each solvent system, the equilibrium constants increased in the order Pt - $\mathrm{Bu}(\mathrm{Np})_{2}<\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}<\mathrm{PNp}_{3}$, with the difference between each ligand being $1-2$ orders of magnitude. The binding equilibria correlate positively with the cone angle, $\% V_{\text {bur }}$, and $\mathrm{S}^{\prime}$ trends for complexes 1 and 2.

The binding equilibria were also analyzed computationally. The binding of phosphine to $\left[\left(\mathrm{PR}_{3}\right) \mathrm{Pd}(\mu-\mathrm{Cl}) \mathrm{Cl}\right]_{2}$ complexes 1a-1c (eq 2) can be considered to occur in two different steps: (1) dissociation of $\left[\left(\mathrm{PR}_{3}\right) \mathrm{Pd}(\mu-\mathrm{Cl}) \mathrm{Cl}\right]_{2}$ into two molecules of $\left(\mathrm{PR}_{3}\right) \mathrm{PdCl}_{2}$ (Reaction 3) and (2) addition of the phosphine to $\left(\mathrm{PR}_{3}\right) \mathrm{PdCl}_{2}$ (Reaction 4). The energy of reaction 2 is then $3+2(4)$.

$$
\begin{align*}
& {\left[\left(\mathrm{PR}_{3}\right) \mathrm{Pd}(\mu-\mathrm{Cl}) \mathrm{Cl}\right]_{2} \rightarrow 2\left(\mathrm{PR}_{3}\right) \mathrm{PdCl}_{2}}  \tag{3}\\
& \left(\mathrm{PR}_{3}\right) \mathrm{PdCl}_{2}+\mathrm{PR}_{3} \rightarrow\left(\mathrm{PR}_{3}\right)_{2} \mathrm{PdCl}_{2} \tag{4}
\end{align*}
$$

To benchmark the DFT functionals, the energy of reaction 3 with $\mathrm{PR}_{3}=\mathrm{PH}_{3}$ was calculated at the Feller-Peterson-Dixon (FPD) level ${ }^{32}$ using coupled cluster $\operatorname{CCSD}(\mathrm{T})$ theory calculations extrapolated to the complete basis set limit plus additional corrections (Tables S11). The energy for reaction 4 at the FPD level was previously reported. ${ }^{33}$ The correction factors determined from the FPD calculations on $\left[\left(\mathrm{PH}_{3}\right) \operatorname{Pd}(\mu\right.$ $\mathrm{Cl}) \mathrm{Cl}]_{2}$ were used for the larger phosphines, an approximation that does not consider additional corrections for steric effects. Single point energies were calculated with a variety of gradient corrected functionals which treat long-range steric interactions in different ways: BP86, ${ }^{22}$ B3LYP, ${ }^{34} \omega$ B97x-D, ${ }^{35}$ CAMB3LYP, ${ }^{36}$ M06, ${ }^{33}$ TPSS, ${ }^{38}$ and HSEh1PBE. ${ }^{39}$

${ }^{a}$ Value determined experimentally by ${ }^{31} \mathrm{P}$ NMR analysis of the cleavage of dimer 1 with phosphine. ${ }^{b}$ Calculated from experimentally determined $K_{\text {eq }}$ value

All the functionals predict reaction 3 to be endothermic with the B3LYP and BP86 functionals predicting the least endothermicity (Table S12, SI). The endothermicities for all the functionals fall in the range of 8.5 to $14.0 \mathrm{kcal} / \mathrm{mol}$ for the neopentylphosphines. The reactions are predicted to be less endothermic in $\mathrm{CHCl}_{3}$ than in $\mathrm{C}_{6} \mathrm{H}_{6}$. The smallest endothermicities are predicted for $\mathrm{P}(t-\mathrm{Bu})_{3}$, suggesting that it has the largest steric effect. The dimer dissociation energy is predicted to be within $1 \mathrm{kcal} / \mathrm{mol}$ for each neopentylphosphine using all the functionals, except M06 and $\omega$ B97x-D.

For reaction 4, there is a wider range of ligand bond energies depending on the functional (Table S13, Supporting Information). This value has a factor of 2 impact on the energy of reaction 2 , so it contributes significantly to the overall energy. The BP86, B3LYP, CAMB3LYP, HSEh1PBE, and TPSS functionals all show binding energies between 0 and $-10 \mathrm{kcal} / \mathrm{mol}$ in $\mathrm{C}_{6} \mathrm{H}_{6}$ indicating exothermic binding. In $\mathrm{CHCl}_{3}$, these five functionals show that $\mathrm{PNp}_{3}$ binds exothermically but that $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ and $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$ have endothermic or slightly exothermic binding ( +2.1 to -2.3 $\mathrm{kcal} / \mathrm{mol}$ ). The $\omega \mathrm{B} 97 \mathrm{x}-\mathrm{D}$ and M06 functionals lead to significantly larger binding energies of -14 to $-22 \mathrm{kcal} / \mathrm{mol}$. Thus, the latter two functionals predict smaller steric interactions between the two ligands on $\left(\mathrm{PR}_{3}\right)_{2} \mathrm{PdCl}_{2}$ than the first five functionals. In all cases, the binding energy of the second ligand is in the order of $\mathrm{PNp}_{3}>\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}>\mathrm{P}(t-$ $\mathrm{Bu}) \mathrm{Np}_{2} \gg \mathrm{P}(t-\mathrm{Bu})_{3} . \mathrm{P}(t-\mathrm{Bu})_{3}$ is not predicted to bind to $(\mathrm{P}(t-$ $\left.B u)_{3}\right) \mathrm{PdCl}_{2}$ except for very weak binding in $\mathrm{C}_{6} \mathrm{H}_{6}$ with the $\omega \mathrm{B} 97 \mathrm{x}-\mathrm{D}$ and M06 functionals.

The calculated values for reaction 2 in Table 6 show that each functional predicts the correct order for the reactivity for the ligands in comparison to the experiment $\left(\mathrm{PNp}_{3}>\mathrm{P}(t-\right.$ $\left.\mathrm{Bu})_{2} \mathrm{~Np}>\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}>\mathrm{PNp}_{3}\right)$. All the functionals predict that the energies for reaction 2 are less exothermic or more endothermic in $\mathrm{CHCl}_{3}$ than in $\mathrm{C}_{6} \mathrm{H}_{6}$. For reaction 2 energies, the HSEh1PBE functional gave excellent agreement for $\mathrm{PNp}_{3}$, but the energies for $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ and $\mathrm{P} t-\mathrm{Bu}(\mathrm{Np})_{2}$ were too endothermic.

Modest errors of a few kilocalories per mole in each reaction step can significantly affect the calculated energies for reaction 2. The calculations with the BP86, B3LYP, CAMB3LYP, HSEh1PBE, and TPSS functionals likely overestimate the binding energy of $\left[\left(\mathrm{PR}_{3}\right) \mathrm{Pd}(\mu-\mathrm{Cl}) \mathrm{Cl}\right]_{2}(\mathbf{1})$ and underestimate the binding energy of the second phosphine in $\left(\mathrm{PR}_{3}\right)_{2} \mathrm{PdCl}_{2}$ (2). In contrast, the $\omega \mathrm{B} 97 \mathrm{x}-\mathrm{D}$ and M06 functionals predict that the dimer is strongly bound and the binding energy of the
second phosphine in $\left(\mathrm{PR}_{3}\right)_{2} \mathrm{PdCl}_{2}$ is too large. The large binding energy in reaction 4 dominates and makes the energy of reaction 2 too negative.

## DISCUSSION

Our group has previously hypothesized about the impact of the conformational flexibility of neopentylphosphines, particularly trineopentylphosphine, on catalytic performance. ${ }^{11, f, f, 12-14}$ The structural analysis of these ligands reported here provides quantitative data on the impact of these structural changes on the steric properties of these ligands in different coordination environments. Due to the more significant conformational change for $\mathrm{PNp}_{3}$ compared to $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ and $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$, the relative ordering in steric demand changes depending on the coordination number of the metal complex. For the linear palladium ( 0 ) complexes, solid cone angle, exact cone angle, and $\% V_{\text {bur }}$ all show that the steric trend is $\mathrm{P}(t-\mathrm{Bu})_{3}<\mathrm{P}(t-$ $\mathrm{Bu})_{2} \mathrm{~Np}<\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}<\mathrm{PNp}_{3}$. This trend is consistent with calculated steric trends based on the $\mathrm{He}_{8}$ steric parameter for these ligands. ${ }^{10}$ In square planar palladium(II) complexes, the ordering for these steric descriptors is $\mathrm{P}(t-\mathrm{Bu})_{3}<\mathrm{PNp}_{3} \lesssim \mathrm{P}(t-$ $\mathrm{Bu})_{2} \mathrm{~Np}<\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$. Thus, $\mathrm{PNp}_{3}$ is predicted to have the largest steric demand in linear palladium(0) complexes and the smallest in square planar palladium(II) complexes for the neopentylphosphine series.

Both the solid cone angle and exact cone angle give increasing values going from linear $\mathrm{L}_{2} \mathrm{Pd}(\mathbf{1})$ to square planar $\mathrm{L}_{2} \mathrm{PdCl}_{2}$ (2) to $[\operatorname{LPd}(\mu-\mathrm{Cl}) \mathrm{Cl}]_{2}$ (1) complexes with the exception of $\mathrm{PNp}_{3}$ as noted previously. This trend is unexpected as cone angles have been shown to decrease as the coordination number increases. ${ }^{40}$ Although the neopentyl group does rotate away from the metal center, the ligand retains a significant steric impact and results in increased steric interaction between the palladium and the tert-butyl group(s). For example, in $\operatorname{Pd}\left(\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}\right)_{2}$ (4a), the closest $\mathrm{Pd}-\mathrm{C}$ distance for the neopentyl group is $3.604 \AA$ and the closest tertbutyl $\mathrm{Pd}-\mathrm{C}$ distance is $3.727 \AA \begin{aligned} & \text {. In } 2 \mathrm{a} \\ & \text {, the neopentyl distance }\end{aligned}$ increases to $3.701 \AA$ as the $\mathrm{Pd}-\mathrm{P}-\mathrm{C}-\mathrm{C}$ dihedral increases, but the $\mathrm{Pd}-\mathrm{P}-\mathrm{C}$ angle to one of the tert-butyl groups decreases, resulting in the nearest tert-butyl carbon being closer to palladium ( $3.545 \AA$ ). Overall, these changes result in an increase in cone angle. In the case of $\mathbf{1 a}$, the neopentyl ( 3.599 $\AA$ ) and tert-butyl groups have closer contacts ( $3.360 \AA$ ) than in either $\mathbf{2 a}$ or $\mathbf{4 a}$, likely due to the shorter $\mathrm{Pd}-\mathrm{P}$ bond in 1a.

Although the neopentylphosphines have larger cone angle and buried volume values than $\mathrm{P}(t-\mathrm{Bu})_{3}$ based on our
structural analysis (Table 4), it is not clear that they are in fact more sterically demanding. Within the neopentyl series, the binding equilibria (Table 6) follow the trend in steric demand for the palladium(II) complexes. The low stability of the $[(\mathrm{P}(t-$ $\left.\left.\mathrm{Bu})_{3}\right) \mathrm{Pd}(\mu-\mathrm{Cl}) \mathrm{Cl}\right]_{2}$ and $\left(\mathrm{P}(t-\mathrm{Bu})_{3}\right)_{2} \mathrm{PdCl}_{2}$ complexes did not allow us to compare the binding equilibria of $\mathrm{P}(t-\mathrm{Bu})_{3}$ with the neopentylphosphines. Calculated $\Delta G$ values for this system show that $\mathrm{P}(t-\mathrm{Bu})_{3}$ binding is much more endothermic than the neopentylphosphines, suggesting that it is effectively larger. $\mathrm{P}(t-\mathrm{Bu})_{3}$ is also able to enforce a three-coordinate T -shaped structure in $\left(\mathrm{P}(t-\mathrm{Bu})_{3} \mathrm{Pd}(\mathrm{Ar}) \mathrm{X}\right.$ complexes, ${ }^{41}$ whereas $\mathrm{P}(t-$ $\mathrm{Bu})_{2} \mathrm{~Np}$ and $\mathrm{PNp}_{3}$ give halide-bridged dimers. ${ }^{11,13,14}$ In contrast, $\mathrm{Pd}-\mathrm{P}$ bond lengths for $\left(\mathrm{PR}_{3}\right)_{2} \mathrm{PdCl}_{2}$ complexes $\mathbf{2 a} \mathbf{- 2 c}$ are the same as (2c) or longer than for ( $\mathrm{P}(t-$ $\mathrm{Bu})_{2} \mathrm{Pd}(\mathrm{H}) \mathrm{Cl}$, suggesting a similar or larger steric effect for the neopentylphosphines. The steric bulk of $\mathrm{P}(t-\mathrm{Bu})_{3}$ is closer to the phosphorus and more rigid than in the case of $\mathrm{PNp}_{3}$. Although $\mathrm{PNp}_{3}$ may have a larger cone angle and buried volume, this steric demand is more distant from the metal and appears to have a less significant steric impact on the metal, at least in some cases, than does $\mathrm{P}(t-\mathrm{Bu})_{3}$.

The degree of pyramidalization at a phosphorus center is sensitive to both steric and electronic effects. Pyramidalization at phosphorus lowers the energy of the HOMO orbital, which is primarily the phosphorus lone pair. ${ }^{27 a}$ In the absence of steric strain, highly pyramidalized structures are favored, such as $\mathrm{PH}_{3}\left(\sum_{\mathrm{H}-\mathrm{P}-\mathrm{H}}=279^{\circ}\right)$. As the substituents on phosphorus become larger, steric repulsion requires that the $\mathrm{Z}-\mathrm{P}-\mathrm{Z}$ angles increase, resulting in a more planar structure. Upon complexation to a metal, $\sigma$ donation from phosphorus depopulates the phosphorus HOMO, resulting in a decreased pyramidalization. ${ }^{6}$ This effect is offset by $\pi$-backbonding from the metal, which increases pyramidalization.

Across a wide range of phosphines and metal complexes, $\mathrm{S4}^{\prime}$, which is a measure of pyramidalization, has been found to correlate negatively with cone angle and $\% V_{\text {bur }}$, since larger substituents typically result in a more planar phosphorus. ${ }^{6,7,40}$ In the neopentylphosphine series, $\mathrm{S} 4^{\prime}$ has a strong positive correlation with increasing cone angle and $\% V_{\text {bur }}$. The key to this behavior appears to be the that the sterically demanding substituent is separated from the phosphorus by a methylene spacer. The neopentyl group can exert a large steric demand, while accommodating a more pyramidalized phosphorus. As a result, pyramidalization as measured by $\mathrm{S}^{\prime}$ and steric parameters have a direct, rather than inverse, relationship.

In free trineopentylphosphine, the phosphorus is highly pyramidalized because of the relatively small back-side strain of the methylene units (Figure 8). The bulky $\mathrm{CMe}_{3}$ unit is projected toward the front side of the phosphorus center, where they can exert a large steric demand. When the neopentyl groups are replaced with tert-butyl substituents ( $\mathrm{P}(t-$ $\mathrm{Bu}) \mathrm{Np}_{2}$ and $\left.\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{NP}\right)$, the larger back strain of the $t-\mathrm{Bu}$ group forces the phosphorus to become more planar. Complexation to palladium (0) to give $\mathrm{L}_{2} \mathrm{Pd}$ complexes (4) results in little change in the phosphine conformation or the degree of pyramidalization. The effects of the $\sigma$ donation from phosphorus and $\pi$ backbonding from the metal appear to largely cancel out.

Coordination of $\mathrm{PNp}_{3}$ to a square planar palladium(II) center results in a significant conformation change that rotates one neopentyl group anti to the $\mathrm{P}-\mathrm{Pd}$ bond. This results in a significant decrease in the pyramidalization of phosphorus as the back-side strain is increased (Figure 8). The steric demand

$\Sigma_{\mathrm{C}-\mathrm{P}-\mathrm{C}}=321^{\circ}$
 $\sqrt{\text { Small increase }}$ in $\Sigma_{\text {C-P-C }}$

$\Sigma_{\mathrm{C}-\mathrm{P}-\mathrm{C}}=321^{\circ}$

Figure 8. Changes in degree of pyramidalization in neopentylphosphines.
of $\mathrm{PNp}_{3}$ is also decreased as a result. $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ and $\mathrm{P}(t-$ $\mathrm{Bu}) \mathrm{Np}_{2}$ undergo less significant conformational changes upon coordination to a palladium(II) center, resulting in smaller decreases in the degree of pyramidalization and changes in steric demand. As a result, $\mathrm{PNp}_{3}$ has larger steric parameters and is more pyramidal than $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ and $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$ as a free ligand and when complexed to palladium( 0 ). When complexed to a palladium(II) center, $\mathrm{PNp}_{3}$ has similar steric demand and pyramidalization to $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ and is smaller and less pyramidal than $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$. The two neopentyl substituents of $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$ are in gauche relationships to the $\mathrm{Pd}-\mathrm{P}$ bond. As a result there is less back strain than in $\mathrm{P}(t-$ $\mathrm{Bu})_{2} \mathrm{~Np}$ or $\mathrm{PNp}_{3}$, allowing the phosphorus to be more pyramidal. The neopentyl groups of $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}$ still exert significant steric demand on the coordinated metal.

Palladium-catalyzed cross-coupling reactions involve both linear palladium $(0)$ species $\left(\mathrm{L}_{2} \mathrm{Pd}\right.$ and LPd$)$ and square planar or T-shaped palladium(II) complexes. In the oxidative addition step, more sterically demanding ligands, that favor the LPd species, provide more active catalysts. On the basis of this trend, $\mathrm{PNp}_{3}$, which is more sterically demanding than $\mathrm{P}(t-$ $\mathrm{Bu})_{2} \mathrm{~Np}$ when complexed to $\mathrm{Pd}(0)$, might be expected to give a more active catalyst than $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$. In fact, the opposite is true in a variety of cross-coupling reactions. ${ }^{11 \mathrm{a}, \mathrm{b}}$ One interpretation of this result would be that ligand dissociation from $\left(\mathrm{PNp}_{3}\right)_{2} \mathrm{Pd}$ is less favorable than the analogous $\mathrm{P}(t-\mathrm{Bu})_{3}$ or $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$ as is seen for the palladium(II) complexes. The more distant steric bulk of the neopentyl group may be less effective at promoting the low coordination LPd species, compared to $t$-Bu-substituted phosphines. The $\mathrm{Pd}-\mathrm{P}$ bond lengths of the $\left(\mathrm{PR}_{3}\right)_{2} \mathrm{Pd}$ complexes $(\mathbf{4 a}-\mathbf{4 c})$ suggest that there is little difference in the front side strain in these complexes. Alternatively, this trend may indicate that ligand steric effects on the palladium(II) species on the catalytic cycle are more important for the catalyst performance.

The $\mathrm{PNpP}_{3}$ ligand provides more effective catalysts for cross-coupling of sterically demanding aryl bromides. ${ }^{11 e, 13}$ The effectiveness of these catalyst systems appears to correlate with the steric demand in the palladium(II) complexes on the catalytic cycle. This result may suggest that the stability of the resulting oxidative addition products is a more important factor in catalyst productivity than the rate of oxidative addition. We have observed that $\left[\left(\mathrm{PNp}_{3}\right) \mathrm{Pd}(\mathrm{Ar}) \mathrm{X}\right]_{2}$ complexes are more stable than $\left[\left(\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}\right) \operatorname{Pd}(\mathrm{Ar}) \mathrm{X}\right]_{2}$ complexes, which are more prone to arene elimination to afford catalytically inactive
palladacyclic species. ${ }^{11 f, 13 \mathrm{~b}}$ Alternatively, the $\left(\mathrm{PNp}_{3}\right) \mathrm{Pd}$ complex may be more reactive with sterically hindered aryl halides than $\left(\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}\right) \mathrm{Pd}$, despite its larger cone angle, because the steric bulk is further from the metal and more flexible.

## - CONCLUSIONS

Analysis of the series of $\mathrm{P}(t-\mathrm{Bu})_{n} \mathrm{~Np}_{3-n}(n=0-3)$ has provided a detailed picture of the structure and steric demand of these ligands. The structures of the free ligands and their linear palladium(0) complexes show a consistent trend of increasing steric demand and increasing pyramidalization as the number of neopentyl groups is increased $\left(\mathrm{P}(t-\mathrm{Bu})_{3}<\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}<\right.$ $\left.\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}<\mathrm{PNp}_{3}\right)$. In square planar palladium(II) complexes, the trend is $\mathrm{P}(t-\mathrm{Bu})_{3}<\mathrm{PNp}_{3}<\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}<$ $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}$. This change in order is due to the dramatic conformational change that $\mathrm{PNp}_{3}$ undergoes upon coordination to a square planar metal center, which results in a smaller cone angle and decreased pyramidalization of the phosphorus. The other neopentyl ligands do not undergo a similar conformational change.

This study shows that care must be taken when using steric parameters, particularly for ligands with a high degree of conformational flexibility and those in which the steric demand is more remote from the metal center. Steric parameters determined for low-coordinate metal complexes, such as the commonly used LAuCl, may overestimate steric demand for higher coordination number complexes that may be relevant to catalytic systems. More importantly, the relative ordering of ligands may be inaccurate. Last, care must be taken when considering steric parameters of ligands in which the steric bulk has different radial distributions relative to the metal. Although larger steric parameter values are obtained for neopentylphosphines than $\mathrm{P}(t-\mathrm{Bu})_{3}$, there is evidence to suggest that $\mathrm{P}(t-\mathrm{Bu})_{3}$ has a larger effective steric demand on a metal center. This may be due to the fact that the steric demand of a tert-butyl group is located closer to the metal center and is more rigid than the neopentyl groups of $\mathrm{PNp}_{3}$.

## - EXPERIMENTAL SECTION

General Methods. $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np},{ }^{42} \mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2},{ }^{42} \mathrm{PNp}_{3},{ }^{42}$ and $\left[\left(\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}\right) \mathrm{Pd}(\mu-\mathrm{Cl}) \mathrm{Cl}\right]_{2}^{11 f}$ were prepared according to literature procedures. $\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{2} \mathrm{PdCl}_{2}$ was prepared by refluxing palladium dichloride in acetonitrile and was freshly prepared as needed. Toluene was dried and deoxygenated by refluxing over sodium and distilling under nitrogen. Methylene chloride was distilled over $\mathrm{CaH}_{2}$ and deoxygenated under a vacuum. $\mathrm{C}_{6} \mathrm{D}_{6}$ and $\mathrm{CDCl}_{3}$ were deoxygenated under a vacuum. All other solvents and reagents were used as received.

General Method for the Synthesis of $\left[\left(\mathrm{R}_{3} \mathrm{P}\right) \mathrm{Pd}(\mu-\mathrm{Cl}) \mathrm{Cl}\right]_{2}$. In a glovebox, $\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{2} \mathrm{PdCl}_{2}$ ( 1 equiv) and $\mathrm{R}_{3} \mathrm{P}$ ( 0.8 equiv) were added to an oven-dried flask. The flask was sealed and removed from the drybox. Anhydrous toluene ( 2 mL ) and anhydrous methylene chloride ( 1 mL ) were added to the reaction flask via syringe under $\mathrm{N}_{2}$ flow. The reaction was stirred under $\mathrm{N}_{2}(\mathrm{~g})$ at ambient temperature overnight. The crude reaction mixture was exposed to air and filtered over a plug of Celite to remove any undissolved solids. The solvent was removed under reduced pressure to yield the product as a solid. In some cases, the product was further purified via recrystallization from hot hexanes.
$\left[\left(P(t-\mathrm{Bu}) \mathrm{Np}_{2}\right) \mathrm{Pd}(\boldsymbol{\mu}-\mathrm{Cl}) \mathrm{Cl}\right]_{2}(1 \mathrm{~b}) .\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{2} \mathrm{PdCl}_{2}(50 \mathrm{mg}, 0.2$ $\mathrm{mmol})$ and $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}(37 \mathrm{mg}, 0.16 \mathrm{mmol})$ were reacted following the general method. Product was purified via recrystallization from hexanes to yield 40 mg (61\%) of the product as a red-orange crystalline solid. ${ }^{1} \mathrm{H}$ NMR $\left(500 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta 2.22$ (dd, $J=13.0$, $15.0 \mathrm{~Hz}, 4 \mathrm{H}$ ), $1.84(\mathrm{dd}, J=13.0,15.0 \mathrm{~Hz}, 4 \mathrm{H}) 1.44\left(\mathrm{~d}, J_{P-H}=15.6\right.$
$\mathrm{Hz}, 18 \mathrm{H}), 1.44(\mathrm{~s}, 36 \mathrm{H}) .{ }^{13} \mathrm{C} \operatorname{NMR}\left(125 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta 40.5$ (d, $\left.J_{P-C}=21.2 \mathrm{~Hz}\right), 35.6\left(\mathrm{~d}, J_{P-C}=23.4 \mathrm{~Hz}\right), 33.5\left(\mathrm{~d}, J_{P-C}=6.7 \mathrm{~Hz}\right)$, $31.7\left(\mathrm{~d}, J_{P-C}=4.2 \mathrm{~Hz}\right), 29.0\left(\mathrm{~d}, J_{P-C}=2.7 \mathrm{~Hz}\right) .{ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}(\mathrm{MHz}$, $\mathrm{CDCl}_{3}$ ): $\delta 49.59$ (s). Anal. Calcd for $\mathrm{C}_{30} \mathrm{H}_{66} \mathrm{Cl}_{4} \mathrm{P}_{2} \mathrm{Pd}_{2}: \mathrm{C}, 42.72 ; \mathrm{H}$, $7.89 ; \mathrm{Cl}, 16.81$. Found: C, 43.00; H, 8.04; Cl, 17.09.

General Method for the Synthesis of $\left(\mathrm{R}_{3} \mathrm{P}\right)_{2} \mathrm{PdCl}_{2}$. In a glovebox, $\left(\mathrm{CH}_{3} \mathrm{CN}\right){ }_{2} \mathrm{PdCl}_{2}$ (1 equiv) and $\mathrm{R}_{3} \mathrm{P}$ ( 2 equiv) were added to an oven-dried flask. The flask was sealed and removed from the drybox. Anhydrous toluene $(2-3 \mathrm{~mL})$ was added to the reaction flask via syringe under $\mathrm{N}_{2}$ flow. The reaction was stirred under $\mathrm{N}_{2}$ at ambient temperature overnight. The crude reaction mixture was exposed to air and filtered over Celite to remove any undissolved solids. The solvent was removed under reduced pressure to yield the product as a solid. In some cases, the product was further purified via recrystallization from hot hexanes.
$\left(\mathbf{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}\right)_{2} \mathrm{PdCl}_{2}(\mathbf{2 a}) .{ }^{11 \mathrm{c}}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{2} \mathrm{PdCl}_{2}(50 \mathrm{mg}, 0.2 \mathrm{mmol})$ and $\mathrm{P}(t-\mathrm{Bu})_{2} \mathrm{~Np}(103 \mu \mathrm{~L}, 0.4 \mathrm{mmol})$ were reacted following the general method to yield $100.1 \mathrm{mg}(82 \%)$ of the product as a yellow solid. ${ }^{1} \mathrm{H}$ NMR $\left(500 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}\right): \delta 1.96(\mathrm{~m}, 4 \mathrm{H}), 1.29\left(\mathrm{vt}, J_{P-H}=\right.$ $6.4 \mathrm{~Hz}, 36 \mathrm{H}), 1.17(\mathrm{~s}, 18 \mathrm{H}) .{ }^{13} \mathrm{C}$ NMR ( $125 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 37.1(\mathrm{t}$, $\left.J_{P-C}=6.7 \mathrm{~Hz}\right), 33.5(\mathrm{br}), 31.3,31.1,30.4\left(\mathrm{t}, J_{P-C}=4.5 \mathrm{~Hz}\right) .{ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR (MHz, $\left.\mathrm{C}_{6} \mathrm{D}_{6}\right): \delta$ 43.6. Anal. Calcd for $\mathrm{C}_{26} \mathrm{H}_{58} \mathrm{Cl}_{2} \mathrm{P}_{2} \mathrm{Pd}$ : C, 51.19; H, 9.58; Cl, 11.62. Found: C, 50.73; H, 9.50; Cl, 11.89.
$\left(\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}\right)_{2} \mathrm{PdCl}_{2}(2 \mathrm{~b}) .\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{2} \mathrm{PdCl}_{2}(50 \mathrm{mg}, 0.2 \mathrm{mmol})$ and $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}(92 \mathrm{mg}, 0.4 \mathrm{mmol})$ were reacted following the general method. The crude mixture was purified via recrystallization from hexanes to yield $73 \mathrm{mg}(57 \%)$ of the product as a yellow crystalline solid. ${ }^{1} \mathrm{H}$ NMR $\left(500 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}\right): \delta 2.35(\mathrm{~m}, 4 \mathrm{H}), 1.88$ $(\mathrm{m}, 4 \mathrm{H}), 1.43(\mathrm{~m}, 54 \mathrm{H}) .{ }^{13} \mathrm{C} \operatorname{NMR}\left(125 \mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}\right): \delta 38.8\left(\mathrm{t}, J_{P-C}\right.$ $=7.0 \mathrm{~Hz}), 34.3\left(\mathrm{t}, J_{P-C}=9.8 \mathrm{~Hz}\right), 33.6,31.8,29.6 .{ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}$ $\left(\mathrm{MHz}, \mathrm{C}_{6} \mathrm{D}_{6}\right): \delta 24.6$. Anal. Calcd for $\mathrm{C}_{28} \mathrm{H}_{62} \mathrm{Cl}_{2} \mathrm{P}_{2} \mathrm{Pd}: \mathrm{C}, 52.71 ; \mathrm{H}$, 9.79; Cl, 11.11. Found: C, 52.98; H, 9.81; Cl, 10.79.
$\left(\mathrm{PNp}_{3}\right)_{2} \mathrm{PdCl}_{2}(2 \mathrm{c}) .{ }^{43}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{2} \mathrm{PdCl}_{2}(50 \mathrm{mg}, 0.2 \mathrm{mmol})$ and $\mathrm{PNp}_{3}(98 \mathrm{mg}, 0.4 \mathrm{mmol})$ were reacted following the general method to yield $97.9 \mathrm{mg}(73 \%)$ of the product as a yellow solid. ${ }^{1} \mathrm{H}$ NMR $\left(500 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta 2.20\left(\mathrm{t}, J_{P-H}=3.6 \mathrm{~Hz}, 12 \mathrm{H}\right), 1.26(\mathrm{~s}, 54 \mathrm{H})$. ${ }^{13} \mathrm{C}$ NMR $\left(125 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta 37.3\left(\mathrm{t}, J_{P-C}=9.4 \mathrm{~Hz}\right), 33.1\left(\mathrm{t}, J_{P-C}\right.$ $=2.8 \mathrm{~Hz})$, 32.5. ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR (202.5 MHz, $\left.\mathrm{CDCl}_{3}\right): \delta$ 3.2. Anal. Calcd for $\mathrm{C}_{30} \mathrm{H}_{66} \mathrm{Cl}_{2} \mathrm{P}_{2} \mathrm{Pd}$ : C, $54.09 ; \mathrm{H}, 9.99 ; \mathrm{Cl}, 10.64$. Found: C, 54.52; H, 10.20; Cl, 10.29.

Synthesis of ( $\left.\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}\right) \mathrm{PdCl}_{2}$ (4-picoline) (3b). Compound $\mathbf{1 b}(70 \mathrm{mg}, 0.09 \mathrm{mmol})$ was added to a vial and dissolved in 1 mL of DCM to give an orange solution. 4-Picoline ( $17 \mu \mathrm{~L}, 0.18 \mathrm{mmol}$ ) was added to the solution, and an immediate color change to yellow was observed. Conversion to product was determined by ${ }^{31} \mathrm{P}$ NMR spectroscopy. X-ray quality crystals were obtained by cooling a concentrated solution of product in DCM with an excess of 4-picoline (10 equiv). Proton and phosphorus NMR spectra were obtained by dissolving a crystal in $\mathrm{CDCl}_{3}{ }^{1} \mathrm{H} \operatorname{NMR}\left(500 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta 8.92$ $(\mathrm{m}, 2 \mathrm{H}), 6.34(\mathrm{~d}, J=5.8 \mathrm{~Hz}, 2 \mathrm{H}), 2.55(\mathrm{dd}, J=15.0 \mathrm{~Hz}, 12.2 \mathrm{~Hz}$, $2 \mathrm{H}), 1.79(\mathrm{dd}, J=14.8 \mathrm{~Hz}, 12.8 \mathrm{~Hz}, 2 \mathrm{H}), 1.67(\mathrm{~s}, 18 \mathrm{H}), 1.57(\mathrm{~d}, J=$ $14 \mathrm{~Hz}, 9 \mathrm{H}), 1.57(\mathrm{~s}, 3 \mathrm{H}) .{ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR (202.5 MHz, $\left.\mathrm{CDCl}_{3}\right): \delta$ 36.1.

General Method for ${ }^{31} \mathrm{P}$ NMR Spectroscopy Equilibrium Experiments. All solutions were prepared in the drybox in ovendried volumetric glassware. For all experiments, standard solutions of known concentration were first prepared for each component of the mixture. Trimethyl phosphate was used as an internal standard. For all experiments, a 0.13 M solution of trimethyl phosphate was freshly prepared by adding $15 \mu \mathrm{~L}$ of trimethyl phosphate to a 1 mL volumetric flask and was diluted to the mark with corresponding solvent $\left(\mathrm{CDCl}_{3}\right.$ or $\left.\mathrm{C}_{6} \mathrm{D}_{6}\right)$. In all experiments, a 0.026 M solution of
$\left[\left(\mathrm{R}_{3} \mathrm{P}\right) \mathrm{Pd}(\mu-\mathrm{Cl}) \mathrm{Cl}\right]_{2}$ was prepared. For experiments using $\mathrm{P}(t-$ $\mathrm{Bu})_{2} \mathrm{~Np}$ and $\mathrm{PNp}_{3} 1 \mathrm{M}$ solutions of free ligand were prepared. And for experiments using $\mathrm{P}(t-\mathrm{Bu}) \mathrm{Np}_{2}, 0.1 \mathrm{M}$ solutions were prepared. For all experiments, $100 \mu \mathrm{~L}$ of 0.13 M trimethyl phosphate and $500 \mu \mathrm{~L}$ of $0.026 \mathrm{M}\left[\left(\mathrm{R}_{3} \mathrm{P}\right) \mathrm{Pd}(\mu-\mathrm{Cl}) \mathrm{Cl}\right]_{2}$ were first added to an empty 1 mL volumetric flask. For each set of experiments, four solutions were prepared with constant initial concentrations of trimethyl phosphate and $\left[\left(\mathrm{R}_{3} \mathrm{P}\right) \operatorname{Pd}(\mu-\mathrm{Cl}) \mathrm{Cl}\right]_{2}$ and varied initial concentrations of free ligand (Table S2, Supporting Information). The resulting solutions analyzed by ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR using an inverse-gated, proton-phosphorus decoupled pulse program setting the delay time to $3 \times \mathrm{T} 1$ for each ligand. Inversion recovery experiments were used for each ligand to determine the ${ }^{31} \mathrm{P} \mathrm{T} 1$ value as described in the Supporting Information (Table S1).

Computational Methods. The geometries were optimized at the density functional level ${ }^{44}$ with two different functionals, BP86 ${ }^{22}$ and SVWN5. ${ }^{23}$ The calculations used the DZVP2 ${ }^{45}$ basis set for the first and second row atoms ( $\mathrm{H}, \mathrm{C}, \mathrm{N}, \mathrm{P}$ ) and the pseudopotential (PP) based aug-cc-pVDZ-PP correlation-consistent basis set for Pd. ${ }^{46}$ Vibrational frequencies were calculated to ensure that the optimized structures were minima. Additional single point calculation using the same basis sets and BP86 optimized geometries were done using the B3LYP exchange-correlation functional, ${ }^{34} \mathrm{M} 06,{ }^{37} \omega \mathrm{~B} 97 \mathrm{xD},{ }^{35}$ CAMB3LYP, ${ }^{36}$ and HSEh1PBE. ${ }^{39}$ The gas phase calculations were performed using the Gaussian 09 program system. ${ }^{47}$ Calculations in $\mathrm{CHCl}_{3}(\varepsilon=4.71), \mathrm{C}_{6} \mathrm{H}_{6}(\varepsilon=2.27)$, THF $(\varepsilon=7.43)$, and DMSO $(\varepsilon=$ 46.83) solutions were performed using a self-consistent reaction field approach (SCRF) ${ }^{48}$ with the COSMO parameters ${ }^{49}$ using Gaussian $03 .{ }^{50}$ The Gibbs free energy in solution $\left(\Delta G_{\text {sol }}\right)$ at 298 K was calculated from eq 5 :

$$
\begin{equation*}
\Delta G_{\text {sol }}=\Delta G_{\text {gas }}+\Delta G_{\text {solv }} \tag{5}
\end{equation*}
$$

where $\Delta G_{\text {gas }}$ is the gas phase free energy at 298 K and $\Delta G_{\text {solv }}$ is the solvation free energy at 298 K . The solvation energy is the electrostatic term (polarized solute - solvent). The SVWN5 geometries were used to predict the ${ }^{31} \mathrm{P}$ NMR chemical shifts in the gas phase and in $\mathrm{CHCl}_{3}$ solvent using the ADF program system ${ }^{51}$ with the BP86 as a functional and the TZ2P basis sets implemented in ADF using the GIAO approach. ${ }^{52}$ Scalar relativistic effects were included at the two-component zero-order regular approximation (ZORA) level for the NMR calculations. ${ }^{53}$ The ${ }^{31} \mathrm{P}$ NMR chemical shifts are reported relative to $\mathrm{H}_{3} \mathrm{PO}_{4}$ as standard calculated at the same level.

## Notes

The authors declare no competing financial interest.

## ACKNOWLEDGMENTS

Acknowledgment is made to the National Science Foundation (CHE-1058984) for partial financial support of the experimental work. The structures of both polymorphs of 1a were obtained on an X-ray diffractometer purchased with support from the NSF MRI program (CHE MRI 1828078). JohnsonMatthey is acknowledged for donation of palladium salts. The computational work was supported by the Chemical Sciences, Geosciences and Biosciences Division, Office of Basic Energy Sciences, U.S. Department of Energy (DOE) under the Catalysis Center Program by a subcontract from the Pacific Northwest National Laboratory (KC0301050-47319). D.A.D. also thanks the Robert Ramsay Chair Fund of The University of Alabama for support. K.L.B. acknowledges support from a GAANN fellowship (DoEd, P200A150329).
