Abstract. We construct a 2-representation categorifying the symmetric Howe representation of $\mathfrak{gl}_m$ using a deformation of an algebra introduced by Webster. As a consequence, we obtain a categorical braid group action taking values in a homotopy category.

1. Introduction

1.1. Howe pairs and link homology

Beginning with the algebro-geometric constructions of link homology theories by Cautis and Kamnitzer [CK08] and further developed in [CKL10], categorical skew Howe duality has proven to be a powerful tool in higher representation theory and link homology theory. The key idea originates in the decategorified context where Toledano Laredo [Lar02] used Howe duality to show that the braid group action on an m -fold tensor product of $\mathfrak{sl}_n$ -representations can be realized via the deformed Weyl group action associated with an auxiliary quantum group for $\mathfrak{sl}_m$. This perspective was fundamental in the resolution of several important conjectures in link homology theory that have resisted proof by other techniques. These include:

- the first complete definition of $\mathfrak{sl}_n$ -foams with a combinatorial evaluation for closed foams not requiring the use of the Kapustin–Li formula; see [LQR15], [QR16],
- a completely integral formulation of $\mathfrak{sl}_n$ -link homology; see [QR16],
- the study of $\mathfrak{sl}_n$ deformations analogous to Lee homology in the $\mathfrak{sl}_2$ -case; see [RW16],
- the discovery of direct connections between quantum groups and Chern–Simon’s gauge theory; see [CGR17],
- the definition of $\mathfrak{sl}_n$ -web algebras generalizing Khovanov’s arc algebra; see [MPT14], [MY19],
- a proof of the exponential growth of coloured HOMFLYPT homology; see [Wed16], and
- a unification of $\mathfrak{sl}_n$ link homologies constructed using wildly different techniques (e.g., category $\mathcal{O}$, matrix factorizations, Webster’s categorification of tensor products, and coherent sheaves on orbits in the affine Grassmannian); see [Cau15], [MW18].

Starting with the work of Cautis, Kamnitzer, and Morrison [CKM14], these methods have proven to be incredibly powerful even in the decategorified setting. They give a complete diagrammatic description of the category generated by tensor products of fundamental quantum $\mathfrak{sl}_n$ -representations using $\mathfrak{sl}$ -webs. The Karoubi envelope of this category is the full category of quantum $\mathfrak{sl}_n$ -representations, since every irreducible arises as a summand of a tensor product of fundamental representations. In this framework, relations on $\mathfrak{sl}_n$ webs arise from relations in quantum $\mathfrak{gl}_m$ under a natural action on so-called ladder webs. The proof that these relations suffice uses Howe duality and the commuting actions of quantum $\mathfrak{gl}_m$ and $\mathfrak{sl}_n$ on the space $\bigwedge^N (C_q^n \otimes C_q^m)$. This idea has been generalized in several directions [CW12], [ES18], [Gra16], [Que15], [TVW17]. This approach was also instrumental in the second author’s work with Garoufalidis and Lê resolving the q -holonomicity conjecture for the HOMFLYPT polynomial [GLL18].

In the classical theory of Howe duality, one considers the commuting actions of $\mathfrak{gl}_m$ and $\mathfrak{sl}_n$ on the space $\mathrm{Sym}^N (C^n \otimes C^m)$. This duality was extended to the quantum setting in [RT16], extending the work of [BZ08]. Quantum symmetric Howe duality for $(\mathfrak{gl}_m, \mathfrak{sl}_2)$ was used in [RT16] to provide a generators and relations description for the ‘symmetric web category’; that is, a generators and relations

description of the full space of intertwiners between tensor powers of symmetric powers of fundamental $\mathfrak{sl}_2$ -representations, not requiring a passage to the Karoubi envelope. This was later extended to symmetric powers of quantum $\mathfrak{sl}_h$ -representations in [TVW17].

In this paper, we utilize the commuting actions of quantum $\mathfrak{gl}_m$ and $\mathfrak{sl}_2$ on the symmetric representation $\mathrm{Sym}^N(\mathbb{C}_q^2 \otimes \mathbb{C}_q^m)$ in the categorical setting. Our framework introduces deformations of Webster's tensor product algebras associated to symmetric powers of $\mathfrak{sl}_2$. Closely related deformations were studied for fundamental representations by Mackaay and Webster [MW18]. Our framework allows us to define a categorical coloured braid invariant where strands are coloured by arbitrary irreducibles of $\mathfrak{sl}_2$ (viewed as symmetric powers of the defining representation). Our approach also suggests a natural generalization to deformations of Webster's algebras for tensor products of fundamental $\mathfrak{sl}_h$ representations.

1.2. Motivation for symmetric Howe duality from link homology theory

The first author's original categorification of the Jones polynomial [Kho00, Kho02] can be defined entirely within the homotopy category of complexes over an additive category. In this approach, the homologies associated with knots and links are finite dimensional. An approach to coloured $\mathfrak{sl}_2$ link invariants using cabling was proposed in [Kho05]. An alternative approach was proposed by Cooper and Krushkal [CK12b] using categorified Jones–Wenzl projectors where the homologies are infinitely dimensional for coloured unknots. Hogancamp gave a refinement of this invariant where the homology of the unknot is finite dimensional over a larger ground ring [Hog19]. An alternative approach to categorification of Jones–Wenzl projectors was given by Rozansky [Roz14]. A Lie theoretic approach was outlined in [FSS12].

Utilizing the higher representation theory framework arising from the theory of categorified quantum groups [KL09], [KL11], [KL10], [Rou08], Webster gave a general combinatorial categorification of Reshetikhin–Turaev invariants [Web17] for links coloured by arbitrary irreducible representations of the quantum group associated to a semisimple Lie algebra $\mathfrak{g}$. The invariants are constructed using algebras that are defined in an elementary way. However, the associated tangle invariants are difficult to compute. For example, in order to associate a functor to a braid, one must work in the derived category rather than the homotopy category as in [Kho02]. Furthermore, invariants for the unknot coloured by non-miniscale representations are infinite dimensional in this approach.

Our interest in the symmetric Howe 2-representation $\mathrm{Sym}^N(\mathbb{C}_q^2 \otimes \mathbb{C}_q^m)$ stems from the goal of modifying Webster's approach to obtain coloured $\mathfrak{sl}_2$ -link invariants using finite complexes in the homotopy category, rather than the derived category. This work can be viewed as providing a potential algebraic categorification of the symmetric web category from [RT16]. We expect that this work should be closely related to the geometric categorification of symmetric Howe duality given by Cautis and Kamnitzer using the derived category of coherent sheaves on the Beilinson–Drinfeld Grassmannian [CK18]. A foam setting for symmetric Howe duality was recently studied in [RW18], [HQS18].

Cautis defines a link homology theory (which could be rephrased in the language of Soergel bimodules) where each component of the link is coloured by an arbitrary

partition [Cau17]. The resulting homology categorifies the coloured HOMFLYPT polynomial. Cautis also defines differentials d_N leading to a categorified $\mathfrak{sl}_N$ coloured link homology theory. When the components are coloured by symmetric powers of the defining representation, the homology of the link is finite dimensional. Both of our constructions have ingredients coming from the theory of Soergel bimodules and it is enticing to understand how our braid group actions (and optimistically coloured link homologies built from them) are related.

1.3. The redotted Webster algebra and categorical braid group action

Webster defined a family of algebras categorifying an arbitrary tensor product $V_{\lambda_1} \otimes V_{\lambda_2} \otimes \cdots \otimes V_{\lambda_k}$ of irreducible representations of the quantum group associated with a semisimple Lie algebra $\mathfrak{g}$. These algebras admit a diagrammatic interpretation extending the diagrammatic categorifications of quantum groups and their irreducibles from [Lau08], [KL09], [KL11], [KL10]. In this presentation, generators of the algebra correspond to planar diagrams consisting of gray strands labelled by the dominant weights λ_i of irreducibles and black strands labelled by the simple roots of the Lie algebra $\mathfrak{g}$ that are governed by the KLR-algebra of type $\mathfrak{g}$. Here we will be primarily interested in the case when $\mathfrak{g} = \mathfrak{sl}_2$, so that the black strands are governed by the nilHecke algebra.

Webster's tensor product algebras admit deformations, not only for $\mathfrak{sl}_2$, but in vast generality (e.g., [Web13] and [MW18]). The first and third authors independently studied these deformations in the context of $\mathfrak{sl}_2$ where all the gray strands are labelled by the fundamental $\mathfrak{sl}_2$ representation. In this context, the deformation led to additional generators where gray strands are also allowed to carry dots and additional diagrammatic relations are required. The resulting algebras were called the *redotted Webster algebra* $W(\mathfrak{g}, n)$ in [KS18], where there are n black strands and 1^m indicates m gray strands labelled by the fundamental $\mathfrak{sl}_2$ -representation. These algebras were studied with the aim of simplifying Webster's braid invariants.

The algebras $W(\mathfrak{g}, 0)$, corresponding to non-black strands, are directly related to Soergel bimodules. In this language, early work by Rouquier [Rou04] defines a braid group action on the homotopy category of modules for $W(1^m, 0)$. This categorical braid group action was shown to be a strong action by Elias and Krasner [EK10b], meaning that it extends to braid cobordisms. This categorical braid group action was extended to a link invariant in [Kho07] based on earlier work with Rozansky [KR08].

More recently, the case of a single black strand was studied, where a strong braid group action was constructed [KS18] on the homotopy category of modules for $W(1^m, 1)$, and it was conjectured that a categorical braid group action can be defined on the homotopy category of $W(\mathfrak{g}, n)$ -modules for all n . In this article, we prove this conjecture in much greater generality. We extend the algebra $W(\mathfrak{g}, n)$ to $W(\mathbf{s}, n)$ where $\mathbf{s} = (s_1, \dots, s_m)$ is a tuple of natural numbers corresponding to gray strands coloured by symmetric powers of the fundamental representation of $\mathfrak{sl}_2$. We then extend the braid group action to $W(\mathbf{s}, n)$. In [MW18] the authors use formal arguments and connections with category $\mathcal{O}$ to place deformations of Webster algebras into the skew Howe framework. The authors work in the derived

category. Here we work in the context of *symmetric* Howe duality and our explicit constructions allow us to use elementary techniques and to stay in the homotopy category.

The technical work involved is to show that a version of the $\mathfrak{gl}_n$ 2-category $U = U(\mathfrak{gl}_n)$ [KL10], [MSV13] acts on direct sums of categories of bimodules for $W(\mathbf{s}, n)$, so that the categorical quantum Weyl group action of $\mathfrak{gl}_n$ can be used to induce the braiding. The arXiv version of this article contains additional details for lengthy computational proofs (where all gray strands appear red). The computationally most difficult relations to verify are the EF and FE decompositions. A key observation provided to us by Cautis allowed us to avoid these calculations. The braid group action for $W(1^m, 1)$ constructed in [KS18] avoided the use of categorified $\mathfrak{gl}_m$ but fits into the framework of this paper.

The categories of modules over Webster's $\mathfrak{sl}$ algebras were shown to admit the structure of a 2-representation of the categorified quantum group for $\mathfrak{sl}_2$ [Web17]. It would be interesting to extend that action to our redotted context, as our framework is well suited to understanding the full categorified Reshetikhin–Turaev invariant set up, including the commuting quantum group action. A related action of categorified $\mathfrak{sl}_2$ (and its generalizations) on cyclotomic nilHecke algebras (and its generalizations) was studied in [KK12].

1.4. Connections with Soergel bimodules

A diagrammatic category $SC_1(m)$ describing Soergel bimodules in type A was introduced in [EK10a]. In [MSV13], the authors construct a functor from the diagrammatic Soergel category $SC_1(m)$ into endomorphisms of the (1^m) weight space of a *Schur quotient* of $U(\mathfrak{gl}_n)$

$$\Sigma_{m,m} : SC_1(m) \rightarrow U(1^m, 1^m)/h\lambda \in \Lambda(m, m)i,$$

where

$$\Lambda(m, m) = \{\lambda = (\lambda_1, \dots, \lambda_n) \mid \lambda_i \in \mathbb{Z}_{\geq 0}, \lambda_1 + \dots + \lambda_m = m\}.$$

Under the 2-functor $\Sigma_{m,m}$, Rouquier's braiding on Soergel bimodules is sent to the braid group action on the homotopy category of the Schur quotient coming from two term Rickard complexes (see (9.1) for more details). Elias and Krasner's proof that Rouquier complexes give a strong braid group action [EK10b] can then be used to show that two term Rickard complexes also give rise to a strong braid group action (functorial under braid cobordisms) in the context of the Schur quotient $U(1^m, 1^m)/h\lambda \in \Lambda(m, m)i$. Thus the homotopy category of a category that is the image of $U(\mathcal{Q}, 1^m)/h\lambda \in \Lambda(m, m)i$ under a categorical action also has the structure of a *strong* braid group action.

The categorical $U(\mathfrak{gl}_n)$ action we define on the redotted Webster algebras factors through the Schur quotient $U(1^m, 1^m)/h\lambda \in \Lambda(m, m)i$ when the sequence $\mathbf{s} = (1, 1, \dots, 1)$. This allows us to deduce that the braid group action we construct is a strong action in this case. Note that the Rickard complexes for more general of weights $\mathbf{s} = (s_1, \dots, s_n)$ in $U(\mathfrak{gl}_m)$ (with s_i not all equal to 1) will not usually be two term complexes, so the results of Elias and Krasner do not apply.

1.5. Connections with singular Soergel bimodules

In [KS18], it was shown that a *cyclotomic quotient* of the algebra $W(1^m, 1)$ is isomorphic to the endomorphism algebra of a direct sum of all the unique indecom-

posable objects of the category of singular Soergel bimodules ${}^{(1^m)}R^{(1,m-1)}$ for the polynomial ring $k[Y_1, \dots, Y_m]$. We conjecture that the cyclotomic quotient of the algebra $W(\mathbf{s}, n)$ is Morita equivalent to the endomorphism algebra of a direct sum of all the indecomposable objects for the category of singular Soergel bimodules ${}^{(\mathbf{s})}R^{(n, |\mathbf{s}|-n)}$ where $|\mathbf{s}| = s_1 + \dots + s_m$.

1.6. Roots of unity

Part of the motivation in reformulating Webster's link invariants in the context of the redotted Webster algebra is that we anticipate this framework will be useful in the program of categorification at a root of unity. If one hopes to obtain a categorification of the Witten–Reshetikhin–Turaev 3-manifold invariant, it is expected that we must be able to define categorifications of coloured $\mathfrak{sl}_2$ link invariants specialized at a root of unity.

Categorification at an N th root of unity requires categorifying the base ring of Laurent polynomials in q modulo the ideal generated by the N th cyclotomic polynomial $\Phi_N(q)$. A framework for such a theory, known as hopfological algebra, was proposed in [Kho16] when N is a power of a prime p , via the stable category of p -complexes: generalized complexes over a field of characteristic p with the p th power of the differential rather than the second power being 0. Recently, p -complexes were successfully used as the ground category to categorify small and big quantum $\mathfrak{sl}_2$ at a p th root of unity [KQ15], [Qi14], [EQ16a], [EQ16b]. A categorification of the Burau representation was given in [QS16]. There, a braid group action was constructed on the compact derived category of a special case of a p -DG Webster algebra. It would be interesting to reformulate that work in the context of the redotted Webster algebra. The paper [KQ15] contains an explicit proposal about extending this categorification from $\mathfrak{sl}_2$ to other simply-laced Lie algebras, as well as extending it to Webster's categorification [Web17] of tensor products of integrable representations of quantum groups. We anticipate that redotted Webster algebras will provide a framework for defining p -DG analogs of coloured Khovanov homology.

1.7. Towards link homology

How to extend the braid invariant we construct here to a link invariant is a natural question. When $m = 0$, it is shown by Khovanov that taking Hochschild cohomology yields a link invariant categorifying the HOMFLYPT polynomial. It is not clear that this procedure will work for $m > 0$. Even when $m = 0$, taking Hochschild cohomology seems conceptually wrong here since we expect to categorify the Jones polynomial. The Reshetikhin–Turaev procedure for recovering the Jones polynomial requires one to work in the middle weight space of $V_1^{\otimes m}$ (m should be even). So again, it is not clear that the braid invariant existing for arbitrary m and n should give rise to a non-trivial link invariant.

2. The nilHecke algebra

In subsequent sections, the nilHecke algebra will play two roles. It is an ingredient in the definition of the categorified quantum group for $\mathfrak{gl}_n$. It is also part of the definition of the algebra $W(\mathbf{s}, n)$.

2.1. Definition

Let NH_n be the nilHecke algebra of rank n over k . It is generated by commuting degree 2 elements $x_1, \dots, x_n$ and elements $\partial_1, \dots, \partial_{n-1}$ of degree -2 . The generators satisfy the following relations:

- (1) $\partial_i^2 = 0$,
- (2) $\partial_i \partial_j \partial_i = \partial_j \partial_i \partial_j$ if $|i - j| = 1$,
- (3) $\partial_i \partial_j = \partial_j \partial_i$ if $|i - j| > 1$,
- (4) $x_i \partial_i - \partial_i x_{i+1} = 1 = \partial_i x_i - x_{i+1} \partial_i$.

In general, for a $\mathbb{Z}$ -graded algebra A and a graded module M over A , let M_i be the subset of M contained in degree i . Let $M[r]$ be the shift of M up by r . That is, $(M[r])_i = M_{i-r}$. We will use the following notation for a direct sum of shifts of M :

$$[r]M = M[r-1] \oplus M[r-3] \oplus \dots \oplus M[r-1] \oplus M[r-1].$$

We now present this algebra in a diagrammatic fashion. Consider collections of smooth arcs in the plane connecting n points on one horizontal line with n points on another horizontal line. Arcs are assumed to have no critical points (in other words no cups or caps). Arcs are allowed to intersect, but no triple intersections are allowed. Arcs can carry dots. Two diagrams that are related by an isotopy that does not change the combinatorial types of the diagrams or the relative position of crossings are taken to be equal. The elements of the vector space NH are formal linear combinations of these diagrams modulo the local relations given below. We give NH_n the structure of an algebra by concatenating diagrams vertically.

Dots on strands correspond to generators x_i given earlier. Strands which cross correspond to generators ∂_i . The generating elements of NH_n and their degrees are given below:

$$\deg \begin{array}{c} | \\ \bullet \end{array} = 2, \quad \deg \begin{array}{c} \diagup \diagdown \\ \diagdown \diagup \end{array} = -2.$$

The diagrams satisfy the relations given below:

$$\begin{array}{c} \diagup \diagdown \\ \diagdown \diagup \end{array} = \begin{array}{c} \diagdown \diagup \\ \diagup \diagdown \end{array}, \quad \begin{array}{c} \diagup \diagdown \\ \diagup \diagdown \end{array} = 0,$$

$$\begin{array}{c} \diagup \diagdown \\ \bullet \end{array} - \begin{array}{c} \diagdown \diagup \\ \bullet \end{array} = \begin{array}{c} | \\ | \end{array} = \begin{array}{c} \diagup \diagdown \\ \bullet \end{array} - \begin{array}{c} \diagdown \diagup \\ \bullet \end{array}.$$

It is not hard to show that these relations imply the following:

Lemma 2.1. *The following equalities hold in the nilHecke algebra:*

$$\begin{array}{c} \text{Diagram: a crossing with a dot on the left strand labeled } d \\ = \sum_{A+B=d-1} X \text{ Diagram: a crossing with dots on both strands labeled } A \text{ and } B \end{array}, \quad \begin{array}{c} \text{Diagram: a crossing with a dot on the right strand labeled } d \\ = - \sum_{A+B=d-1} X \text{ Diagram: a crossing with dots on both strands labeled } A \text{ and } B \end{array}.$$

2.2. Thick calculus

It is convenient to introduce an enhanced diagrammatic calculus for the nilHecke algebra – the so-called ‘thick calculus’. This notation is helpful for providing a graphical calculus for the category of finitely generated projective NH_n -modules. We are primarily interested in the category of $\mathbb{Z}$ -graded projective modules over the nilHecke algebra. We can access this category diagrammatically by viewing NH_n as a one object k -linear category where the morphisms are the elements of NH_n . We then pass to the Karoubi envelope allowing us to split idempotents in the diagrammatic language. We review some of the relevant details here, but the reader is referred to [KLMS12] for more details.

Box diagrams. For any composition $\mu = (\mu_1, \dots, \mu_n)$ write $x_\mu := x_1^{\mu_1} x_2^{\mu_2} \dots x_n^{\mu_n}$. We depict these diagrammatically as

$$\underline{x^\mu} = \begin{array}{c} \mu_1 \quad \mu_2 \quad \dots \quad \mu_n \\ \text{Diagram: } n \text{ vertical lines with dots at heights } \mu_1, \mu_2, \dots, \mu_n \end{array} = \begin{array}{c} \text{Diagram: a box labeled } \underline{x^\mu} \text{ with } n \text{ vertical lines passing through it} \end{array} \quad (2.1)$$

Since the center of the nilHecke algebra $Z(\text{NH}_n)$ is isomorphic to the ring of symmetric polynomials $Z[x_1, \dots, x_n]^{S_n}$, it is convenient to set notation for certain bases of symmetric polynomials. The box labelled h_d and e_d represents the d th complete and elementary symmetric function in n variables, respectively:

$$\begin{array}{c} \text{Diagram: a box labeled } h_d \text{ with } n \text{ vertical lines passing through it} \\ = \sum_{d_1 + \dots + d_n = d} X \text{ Diagram: } n \text{ vertical lines with dots at heights } d_1, d_2, \dots, d_n \end{array},$$

$$\begin{array}{c} \text{Diagram: a box labeled } e_d \text{ with } n \text{ vertical lines passing through it} \\ = \sum_{\substack{d_1 + \dots + d_n = d \\ 0 \leq d_i \leq 1}} X \text{ Diagram: } n \text{ vertical lines with dots at heights } d_1, d_2, \dots, d_n \end{array}.$$

More generally, we denote the Schur polynomial associated to a partition $\mu = (\mu_1, \dots, \mu_n)$ by a box labelled s_μ .

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

We will make use of the following crossing diagrams:

$$\begin{aligned} C_1 &= \text{[diagram of } C_1 \text{]} = \text{[diagram of } C_1 \text{]}, & C_k &= \text{[diagram of } C_k \text{]}, \\ \mathfrak{C}_k &= \text{[diagram of } \mathfrak{C}_k \text{]} \quad \text{for } k > 1, \end{aligned} \quad (2.2)$$

$$\begin{aligned} D_1 &= \text{[diagram of } D_1 \text{]}, & D_k &= \text{[diagram of } D_k \text{]} \quad \text{for } k > 1, \end{aligned} \quad (2.3)$$

which are used to define a minimal idempotent e_k in NH_k via

$$e_k = \text{[diagram of } e_k \text{]} \quad (2.4)$$

Note that for any reduced expression $w = s_{i_1} s_{i_2} \dots s_{i_\ell} \in S_k$ we write

$$\partial_w := \partial_{i_1} \partial_{i_2} \dots \partial_{i_\ell}.$$

The relations in the nilHecke algebra imply that ∂_w is independent of the reduced expression for w . In the language, the element D_k corresponds to ∂_{w_0} where w_0 denotes the longest word in S_k . Hence, $D_k e_k = \partial_{w_0} (x_1^{k-1} x_2^{k-2} \dots x_k^0) D_k = D_k$, which implies the idempotence of e_k .

Thick calculus definitions. We introduce a thick line carrying a label corresponding to the idempotent e_k . Then, for a map between thick labelled strands to be well-defined it must be invariant under pre- and post-composing with the relevant idempotents. In particular, the endomorphisms of a thick strand are given by multiplication by symmetric functions $x \in \text{Sym}_k$, since these commute with the idempotent e_k :

$$\begin{aligned} \text{[diagram of thick strand]} &:= \text{[diagram of } e_k \text{]}, & \text{[diagram of thick strand with dot]} & \text{for } x \in \text{Sym}_k, \\ \text{[diagram of thick strand with dots]} &= \text{[diagram of thick strand with dots]} \end{aligned}$$

where the product xy is well-defined since $x e_k y e_k = x y e_k$. We have splitter maps:

$$\begin{aligned} \text{[diagram of splitter map]} &:= \text{[diagram of } e_a \text{ and } e_b \text{]}, & \text{[diagram of splitter map]} &:= \text{[diagram of } e_{a+b} \text{]}. \end{aligned}$$

These maps satisfy (co)associativity relations making it possible to define

unambiguously. For any Schur polynomial S_μ corresponding to the partition $\mu = (\mu_1, \dots, \mu_k)$, one can show that

where $\mu + \delta$ is the partition $(\mu_1 + k - 1, \mu_2 + k - 2, \dots, \mu_k + 0)$. Symmetric functions can be slid through splitters via the relations

and more generally for any $x \in \text{Sym}_k$,

Primitive idempotents. The set of sequences

$$\text{Sq}(n) := \{ \underline{v} = (v_1, \dots, v_{n-1}) \mid 0 \leq v_i \leq i, \quad v_i = 1, 2, \dots, n-1 \} \quad (2.7)$$

has size $|\text{Sq}(n)| = n!$. Let $|\underline{v}| = \sum_{i=1}^{n-1} v_i$, and set $\mathbf{b} = j - \underline{v}$. Define a composition with n -parts by

$$\underline{b} = (b_1, \dots, b_{n-1}) = (0, 1 - v_1, 2 - v_2, \dots, n-1 - v_{n-1}). \quad (2.8)$$

Let $e_r^{(a)}$ denote the r th elementary symmetric polynomial in a variables. The standard elementary monomials are given by

$$\mathbf{e}_{\underline{a}} := e_1^{(1)} e_2^{(2)} \dots e_{a-1}^{(a-1)}. \quad (2.9)$$

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

We depict these diagrammatically as:

$$e_{-} = \begin{array}{c} \begin{array}{c} \vdots \\ \vdots \\ \vdots \end{array} \begin{array}{c} \boxed{e_2} \\ \vdots \\ \boxed{e_{n-1}} \end{array} \end{array} =: \boxed{e_{-}} \quad (2.10)$$

These polynomials can be used to provide a complete set of primitive orthogonal idempotents decomposing the identity of NH_n .

Lemma 2.2 ([KLMS12, Prop. 2.5.3]).

$$\begin{array}{c} \vdots \\ \vdots \\ \vdots \end{array} = \sum_{\underline{b} \in \text{Sq}(n)} (-1)^{|\underline{b}|} \begin{array}{c} \boxed{e_{-}} \\ \vdots \\ \boxed{x_{-}^{\underline{b}}} \end{array} = \delta_{\underline{0}, \underline{0}} \quad (2.11)$$

Remark 2.3. The polynomial ring $Z[x_1, \dots, x]$ is a free module of rank $n!$ over the ring $\Lambda_n = Z[x_1, \dots, x]^{S_n}$ of symmetric functions [Man01, Prop. 2.5.5]. There is a Λ_n bilinear form on $Z[x_1, \dots, x]$ defined by $(x, y) = \partial_{w_0}(xy)$, for w_0 the longest element in the symmetric group. The significance of the sets $\{e_{-} \mid \underline{b} \in \text{Sq}(n)\}$ and $\{x_{-}^{\underline{b}} \mid \underline{b} \in \text{Sq}(n)\}$ are that they are dual bases for the polynomial ring $Z[x_1, \dots, x]$ as a Λ_n -module with respect to this form. Another dual set of bases are given by Schubert polynomials and dual Schubert polynomials [Man01, Prop. 2.5.7].

Helpful thick calculus lemmas. We collect here several lemmas that will be useful in establishing our main results in later sections.

Lemma 2.4 ([KLMS12, Lem. 2.2.3]).

$$\begin{array}{c} \begin{array}{c} \vdots \\ \vdots \\ \vdots \end{array} \begin{array}{c} \boxed{D_k} \end{array} = \begin{cases} (-1)^{k-1} \begin{array}{c} \boxed{h_{d-k+1}} \\ \boxed{D_k} \end{array} & \text{if } d \geq k-1, \\ 0 & \text{otherwise.} \end{cases}$$

Lemma 2.5. We have the following equalities involving the diagrams defined in (2.2), (2.3), and (2.4):

$$\begin{array}{c} \begin{array}{c} \vdots \\ \vdots \\ \vdots \end{array} \begin{array}{c} \boxed{C_k} \end{array} - \begin{array}{c} \begin{array}{c} \vdots \\ \vdots \\ \vdots \end{array} \begin{array}{c} \boxed{C_k} \end{array} = \sum_{\underline{b} \in \text{Sq}(n)} \begin{array}{c} \boxed{C_{\underline{b}}} \end{array} \quad (2.12)$$

$$\begin{array}{c} \cdots \times \cdots \\ \boxed{D_k} \end{array} = 0, \quad \begin{array}{c} \boxed{C} \cdots \\ \boxed{D_k} \end{array} = 0 \quad \text{for } 2 \leq \ell \leq k. \quad (2.13)$$

Proof. The equations in (2.12) and (2.13) follow easily from the defining relations of the nilHecke algebra.

Lemma 2.6.

$$\begin{array}{c} \cdots \\ \boxed{D_{k-1}} \end{array} = \sum_{d=0}^{k-1} (-1)^d \begin{array}{c} \bullet \\ \vdots \\ \boxed{D_k} \\ \boxed{e_d} \end{array}.$$

Proof. By a variant of [KLMS12, Lem. 2.4.5], we have that

$$\begin{array}{c} \vdots \\ \boxed{D_{k-1}} \end{array} = \sum_{d=0}^{k-1} (-1)^d \begin{array}{c} \bullet \\ \vdots \\ \boxed{D_k} \\ \boxed{e_d} \end{array} = \sum_{d=0}^{k-1} (-1)^d \begin{array}{c} \bullet \\ \vdots \\ \boxed{e_{k-1}} \\ \boxed{C_k} \\ \boxed{e_k} \\ \boxed{e_d} \end{array}.$$

Applying the diagram D_{k-1} to the top of the diagrams on both sides the result follows.

The following lemma holds in a context more general than the nilHecke algebra NH_k . We use it to establish results for the redotted Webster algebras defined in Section 4. We denote a region with appropriate inputs and outputs that we make absolutely no assumption about whatsoever by a box labelled X . The identity holds completely externally to any assumption about the content of X .

Lemma 2.7. *For an arbitrary diagram X , the following identity holds:*

$$\begin{array}{c} X \\ \sum_{\ell \in \text{Sq}(k)} (-1)^{\ell} \end{array} \begin{array}{c} \boxed{e_-} \\ \boxed{X} \\ \boxed{x_-^b} \end{array} = \begin{array}{c} X \\ \sum_{\ell \in \text{Sq}(k-1)} (-1)^{\ell} \end{array} \sum_{d=0}^{k-1} (-1)^d \begin{array}{c} \bullet \\ \vdots \\ \boxed{e_-} \\ \boxed{X} \\ \boxed{e_d} \\ \boxed{x_-^b} \end{array}.$$

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

Proof. For $\underline{\lambda} = (\lambda_1, \dots, \lambda_{k-1}) \in \text{Sq}(k)$, we have

$$\begin{aligned} e_{\underline{\lambda}}(x_1, x_2, \dots, x_k) &= \sum_{i=1}^k e_i(x_1, x_2, \dots, x_k) \\ &= \sum_{\substack{j=(j_1, \dots, j_{k-2}) \\ \in \{0,1\}^{k-2}}} \sum_{\substack{\lambda^0 \in \text{Sq}(k-1), \\ \underline{\lambda}^0 + j = (\lambda_2, \dots, \lambda_{k-1})}} x_1^{\lambda_1 + |j|} e_{\underline{\lambda}^0}(x_2, \dots, x_k), \end{aligned}$$

where we used the standard relation of elementary symmetric functions

$$e_i(x_1, x_2, \dots, x_k) = e_{-i}(x_2, \dots, x_k) + x_1 e_{i-1}(x_2, \dots, x_k).$$

Letting $j = (j_1, \dots, j_{k-2}) \in \{0, 1\}^{k-2}$ and $\lambda^0 \in \text{Sq}(k-1)$ such that $\lambda^0 + j = (\lambda_2, \dots, \lambda_{k-1})$, we have

$$\begin{aligned} x_{\underline{\lambda}}^b &= \sum_{i=1}^k x_{i+1}^{i-\lambda_i} = x_2^{1-\lambda_1} \sum_{i=2}^k x_{i+1}^{i-\lambda_{i-1}-j_{i-1}} \\ &= x_2^{1-\lambda_1} x_3^{1-j_1} x_4^{1-j_2} \dots x_k^{1-j_{k-2}} \sum_{i=2}^k x_{i+1}^{i-1-\lambda_{i-1}^0}. \end{aligned}$$

Therefore, we have

$$\begin{aligned} & \sum_{\underline{\lambda} \in \text{Sq}(k)} (-1)^{|j|} \begin{array}{c} \text{---} \\ \boxed{e_{\underline{\lambda}}} \\ \text{---} \\ \boxed{X} \\ \text{---} \\ \boxed{x_{\underline{\lambda}}^b} \\ \text{---} \end{array} \\ &= \sum_{\substack{\lambda^0 \in \text{Sq}(k-1) \\ j=(j_1, \dots, j_{k-2}) \\ \in \{0,1\}^{k-2}}} \sum_{\substack{\lambda \in \text{Sq}(k), \\ \underline{\lambda}^0 + j = (\lambda_2, \dots, \lambda_{k-1})}} (-1)^{|j|} \begin{array}{c} \lambda_1 + |j| \\ \bullet \\ \text{---} \\ \boxed{e_{\lambda^0}} \\ \text{---} \\ \boxed{X} \\ \text{---} \\ \bullet \quad \bullet \quad \bullet \quad \bullet \\ 1-\lambda_1 \quad 1-j_1 \quad 1-j_2 \quad \dots \quad 1-j_{k-2} \\ \text{---} \\ \boxed{x_{\lambda^0}^b} \\ \text{---} \end{array}. \end{aligned}$$

Collecting the $(\lambda_1, |j|) = (0, 0)$ term, the $(\lambda_1, |j|) = (0, d)$, $(1, d-1)$ for $1 \leq d \leq k-2$, and the $(\lambda_1, |j|) = (1, k-2)$ piece gives the desired result.

3. Quantum $\mathfrak{gl}_m$ 2-category

We recall here the $\mathfrak{gl}_m$ version of the categorified quantum group from [MSV13]. The 2-category $\mathcal{U} = \mathcal{U}(\mathfrak{gl}_m)$ is obtained from the corresponding $\mathfrak{sl}_m$ category defined in [KL10], [CL14] by switching from $\mathfrak{sl}_m$ weights to $\mathfrak{gl}_m$ weights [MSV13]. However, the coefficients in the defining relations for the 2-category take on subtle changes. This is further studied in [BKLW16], [Lau18]. A minimal presentation of this category can be determined from [Bru16].

Here we identify the weight lattice X of $\mathfrak{gl}_m$ with Z^m and write

$$\varepsilon_i = (0, \dots, 0, 1, 0, \dots, 0) \in X,$$

with a single 1 on the i th coordinate. Let $I = \{1, 2, \dots, m-1\}$ and define $\alpha_i = \varepsilon_i - \varepsilon_{i+1} \in X$ for $i \in I$. There is a bilinear form on $Z[I]$ defined by

$$i \cdot j = \begin{cases} 2, & \text{if } i = j; \\ -1, & \text{if } j = i \pm 1; \\ 0, & \text{otherwise.} \end{cases}$$

For $\lambda \in Z^m$, let λ_i denote the i th component of λ . Define the associated $\mathfrak{sl}$ weight $\bar{\lambda} \in Z^{m-1}$ by setting the i th component $\bar{\lambda}_i = \lambda_i - \lambda_{i+1}$.

Definition 3.1. The 2-category U is the graded additive k -linear 2-category consisting of:

- *Objects* λ for $\lambda \in X$.
- *1-morphisms* are formal direct sums of (shifts of) compositions of

$$1_\lambda, \quad 1_{\lambda+\alpha_i} E_i = 1_{\lambda+\alpha_i} E_i 1_\lambda, \quad \text{and} \quad 1_{\lambda-\alpha_i} F_i = 1_{\lambda-\alpha_i} F_i 1_\lambda$$

for $i \in I$ and $\lambda \in X$. We denote the grading shift by $h1_i$, so that for each 1-morphism x in U and $t \in Z$ we have a 1-morphism xht_i .

- *2-morphisms* are k -vector spaces spanned by compositions of decorated tangle-like diagrams coloured by $i \in I$ illustrated below:

$$\begin{array}{ll} \begin{array}{c} \lambda + \alpha_i \\ \uparrow \\ \bullet \\ i \\ \downarrow \end{array} : E_i 1_\lambda \rightarrow E_i 1_\lambda h1_i \cdot ii, & \begin{array}{c} \lambda \\ \nearrow \\ i \\ \searrow \\ j \end{array} : E_i E_j 1_\lambda \rightarrow E_j E_i 1_\lambda h^{-i} \cdot ji, \\ \begin{array}{c} i \\ \cup \\ \lambda \end{array} : 1_\lambda \rightarrow F_i E_i 1_\lambda h1_i + \bar{\lambda}_i i, & \begin{array}{c} i \\ \cup \\ \lambda \end{array} : 1_\lambda \rightarrow E_i F_i 1_\lambda h1_i - \bar{\lambda}_i i, \\ \begin{array}{c} \lambda \\ \downarrow \\ i \end{array} : F_i E_i 1_\lambda \rightarrow 1_\lambda h1_i + \bar{\lambda}_i i, & \begin{array}{c} \lambda \\ \downarrow \\ i \end{array} : E_i F_i 1_\lambda \rightarrow 1_\lambda h1_i - \bar{\lambda}_i i. \end{array}$$

In this 2-category (and those throughout the paper), we read diagrams from right to left and bottom to top. The identity 2-morphism of the 1-morphism $E_i 1_\lambda$ is represented by an upward-oriented line labelled by i and the identity 2-morphism of $F_i 1_\lambda$ is represented by a downward-oriented line.

The 2-morphisms satisfy the following relations:

- (1) The 1-morphisms $E_i 1_\lambda$ and $F_i 1_\lambda$ are biadjoint (up to a specified degree shift).
- (2) The 2-morphisms are cyclic with respect to this biadjoint structure.

$$\begin{array}{c} \lambda \\ \downarrow \\ i \end{array} \begin{array}{c} \lambda \\ \downarrow \\ i \end{array} = \begin{array}{c} i \\ \downarrow \\ \lambda + \alpha_i \end{array} \begin{array}{c} i \\ \downarrow \\ \lambda + \alpha_i \end{array} =: \begin{array}{c} i \\ \downarrow \\ \lambda \\ \downarrow \\ \lambda + \alpha_i \end{array}. \quad (3.1)$$

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

The cyclic relations for crossings are given by:

$$\begin{array}{c} \text{crossing} \end{array}^{\lambda} = \begin{array}{c} \text{braid} \end{array}^{\lambda} = \begin{array}{c} \text{braid} \end{array}^{\lambda}. \quad (3.2)$$

Sideways crossings are equivalently defined by the following identities:

$$\begin{array}{c} \text{sideways crossing} \end{array}^{\lambda} := \begin{array}{c} \text{braid} \end{array}^{\lambda} = \begin{array}{c} \text{braid} \end{array}^{\lambda}, \quad (3.3)$$

$$\begin{array}{c} \text{sideways crossing} \end{array}^{\lambda} = \begin{array}{c} \text{braid} \end{array}^{\lambda} = \begin{array}{c} \text{braid} \end{array}^{\lambda}. \quad (3.4)$$

(3) The E 's (respectively F 's) carry an action of the KLR algebra for a fixed choice of parameters Q . We find it convenient to take a particular choice of parameters in this paper. Set

$$t_{ij} = \begin{cases} 0, & \text{if } i = j; \\ -1, & \text{if } j = i + 1; \\ 1, & \text{otherwise.} \end{cases}$$

The KLR algebra R associated to a fixed set of parameters Q is defined by finite k -linear combinations of braid-like diagrams in the plane, where each strand is labelled by a vertex $i \in I$. Strands can intersect and carry dots, but triple intersections are not allowed. Diagrams are considered up to planar isotopy that do not change the combinatorial type of the diagram. We recall the local relations:

i) The quadratic KLR relations are

$$\begin{array}{c} \text{crossing} \end{array}^{\lambda} = \begin{cases} t_{ij} \begin{array}{c} \text{strand } i \text{ with dot} \end{array} \begin{array}{c} \text{strand } j \end{array}^{\lambda} + t_{ji} \begin{array}{c} \text{strand } i \end{array} \begin{array}{c} \text{strand } j \text{ with dot} \end{array}^{\lambda} & \text{if } i \cdot j < 0, \\ t_{ij} \begin{array}{c} \text{strand } i \end{array} \begin{array}{c} \text{strand } j \end{array}^{\lambda} & \text{otherwise.} \end{cases} \quad (3.5)$$

ii) The dot sliding relations are

$$\begin{array}{c} \text{crossing} \end{array}^{\lambda} - \begin{array}{c} \text{crossing} \end{array}^{\lambda} = \begin{array}{c} \text{crossing} \end{array}^{\lambda} - \begin{array}{c} \text{crossing} \end{array}^{\lambda} = \delta_{ij} \begin{array}{c} \text{strand } i \end{array} \begin{array}{c} \text{strand } j \end{array}. \quad (3.6)$$

iii) The cubic KLR relations are

$$\begin{array}{c} \begin{array}{c} \nearrow \searrow \\ \nwarrow \nearrow \end{array} \begin{array}{c} \nearrow \searrow \\ \nwarrow \nearrow \end{array} \begin{array}{c} \nearrow \searrow \\ \nwarrow \nearrow \end{array} - \begin{array}{c} \nearrow \searrow \\ \nwarrow \nearrow \end{array} \begin{array}{c} \nearrow \searrow \\ \nwarrow \nearrow \end{array} \begin{array}{c} \nearrow \searrow \\ \nwarrow \nearrow \end{array} = -(\alpha_i, \alpha_j) \delta_{i,k} t_{ij} \begin{array}{c} \uparrow \\ \uparrow \\ \uparrow \end{array} \begin{array}{c} \uparrow \\ \uparrow \\ \uparrow \end{array} \begin{array}{c} \uparrow \\ \uparrow \\ \uparrow \end{array} . \quad (3.7)$$

(4) When $i \neq j$, one has the mixed relations relating $E_i F_j$ and $F_j E_i$:

$$\begin{array}{c} \begin{array}{c} \nearrow \searrow \\ \nwarrow \nearrow \end{array} \begin{array}{c} \nearrow \searrow \\ \nwarrow \nearrow \end{array} = \begin{array}{c} \uparrow \\ \uparrow \end{array} \begin{array}{c} \uparrow \\ \uparrow \end{array} , \quad \begin{array}{c} \begin{array}{c} \nearrow \searrow \\ \nwarrow \nearrow \end{array} \begin{array}{c} \nearrow \searrow \\ \nwarrow \nearrow \end{array} = \begin{array}{c} \uparrow \\ \uparrow \end{array} \begin{array}{c} \uparrow \\ \uparrow \end{array} . \quad (3.8)$$

(5) Negative degree bubbles are zero. That is, for all $m \in \mathbb{Z}_{>0}$, one has

$$\begin{array}{c} \begin{array}{c} \lambda \\ \circlearrowleft \end{array} \begin{array}{c} i \\ m \end{array} = 0 \quad \text{if } m < \bar{\lambda}_i - 1, \quad \begin{array}{c} \lambda \\ \circlearrowright \end{array} \begin{array}{c} i \\ m \end{array} = 0 \quad \text{if } m < -\bar{\lambda}_i - 1. \quad (3.9)$$

Furthermore, dotted bubbles of degree zero are a scalar multiple of the identity 2-morphism

$$\begin{array}{c} \begin{array}{c} \lambda \\ \circlearrowleft \end{array} \begin{array}{c} i \\ \bar{\lambda}_i - 1 \end{array} = (-1)^{\lambda_{i+1}} \quad \text{for } \bar{\lambda}_i \geq 1, \\ \begin{array}{c} \lambda \\ \circlearrowright \end{array} \begin{array}{c} i \\ \bar{\lambda}_i - 1 \end{array} = (-1)^{\lambda_{i+1} - 1} \quad \text{if } \bar{\lambda}_i \leq -1. \end{array} \quad (3.10)$$

For the final relations, it is convenient to add additional generating diagrams called *fake bubbles*. These fake bubbles are represented by dotted bubbles of positive total degree, but with a negative label for the dots. These symbols make it possible to express the relations independent of the weight λ .

Degree zero fake bubbles are equal to

$$\begin{array}{c} \begin{array}{c} \lambda \\ \circlearrowleft \end{array} \begin{array}{c} i \\ \bar{\lambda}_i - 1 \end{array} = (-1)^{\lambda_{i+1}} \quad \text{for } \bar{\lambda}_i < 1, \\ \begin{array}{c} \lambda \\ \circlearrowright \end{array} \begin{array}{c} i \\ \bar{\lambda}_i - 1 \end{array} = (-1)^{\lambda_{i+1} - 1} \quad \text{if } \bar{\lambda}_i > -1. \end{array} \quad (3.11)$$

(compare to (3.10)).

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

Higher degree fake bubbles for $\bar{\lambda}_i < 0$ are defined inductively as

$$\begin{array}{c} \lambda \\ \text{bubble with } i \text{ and } \bar{\lambda}_i - 1 + j \end{array} = \begin{cases} -(-1)^{\lambda_{i+1}} \sum_{\substack{x+y=j, \\ y \geq 1}} \text{bubble with } i \text{ and } \bar{\lambda}_i - 1 + x \otimes \text{bubble with } i \text{ and } \bar{\lambda}_i - 1 + y & \text{if } 0 < j < -\bar{\lambda}_i + 1; \\ 0 & \text{if } j < 0. \end{cases}$$

Higher degree fake bubbles for $\bar{\lambda}_i > 0$ are defined inductively as

$$\begin{array}{c} \lambda \\ \text{bubble with } i \text{ and } \bar{\lambda}_i - 1 + j \end{array} = \begin{cases} -(-1)^{\lambda_{i+1}} \sum_{\substack{x+y=j, \\ x \geq 1}} \text{bubble with } i \text{ and } \bar{\lambda}_i - 1 + x \otimes \text{bubble with } i \text{ and } \bar{\lambda}_i - 1 + y & \text{if } 0 < j < \bar{\lambda}_i + 1; \\ 0 & \text{if } j < 0. \end{cases}$$

The above relations are sometimes referred to as the *infinite Grassmannian relations*.

(6) The $\mathfrak{sl}_2$ relations (which we also refer to as the *EF* and *FE* decompositions) are:

$$\begin{array}{c} \text{crossing with } i \text{ and } i \\ \text{downward arrow with } i \end{array} - \begin{array}{c} \text{upward arrow with } i \\ \text{downward arrow with } i \end{array} = \sum_{\substack{f_1 + f_2 + f_3 = \bar{\lambda}_i - 1}} \text{bubble with } i \text{ and } -\bar{\lambda}_i - 1 + f_2 \otimes \text{bubble with } i \text{ and } f_1 \otimes \text{bubble with } i \text{ and } f_3, \quad (3.12)$$

$$\begin{array}{c} \text{crossing with } i \text{ and } i \\ \text{upward arrow with } i \end{array} - \begin{array}{c} \text{downward arrow with } i \\ \text{upward arrow with } i \end{array} = \sum_{\substack{f_1 + f_2 + f_3 = -\bar{\lambda}_i - 1}} \text{bubble with } i \text{ and } \bar{\lambda}_i - 1 + f_2 \otimes \text{bubble with } i \text{ and } f_1 \otimes \text{bubble with } i \text{ and } f_3. \quad (3.13)$$

4. Redotted Webster algebra for $\mathfrak{sl}$

In this section, we generalize a deformation of Webster's algebra considered in [KS18] to allow for the possibility of certain objects to be labelled by all natural numbers rather than just 1. Related deformations were also introduced by Webster (see, e.g., [Web13]). An algebraic and graphical description of this algebra are provided. We construct a faithful representation of this algebra allowing us to write a basis. The section is concluded with certain symmetries of the algebra.

4.1. The definition of $W(\mathbf{s}, n)$

Let $m \geq 0$ be an integer. For a sequence of non-negative integers $\mathbf{s} = (s_1, \dots, s_m)$, let $\text{Seq}(\mathbf{s}, n)$ be the set of all sequences $\mathbf{i} = (i_1, \dots, i_{m+n})$ in which n of the entries are b and s appears exactly once and in the order in which it appears in $\mathbf{s}$. Denote by i_j the j th entry of $\mathbf{i}$ and denote by $I_{\mathbf{s}}$ the set $\{s_i | 1 \leq i \leq m\}$.

Let S_{n+m} be the symmetric group on $n + m$ letters generated by simple transpositions $\sigma_1, \dots, \sigma_{n+m-1}$. Each transposition σ_j naturally acts on a sequence $\mathbf{i}$. Note that if $\mathbf{i} \in \text{Seq}(\mathbf{s}, n)$ it is not always the case that $\sigma_j \cdot \mathbf{i} \in \text{Seq}(\mathbf{s}, n)$.

Let $W(\mathbf{s}, n)$ be the algebra over k generated by $e(\mathbf{i})$, where $\mathbf{i} \in \text{Seq}(\mathbf{s}, n)$, X_j , $E(d)_j$, where $1 \leq j \leq m + n$, $d \geq 1$, and ψ_j , where $1 \leq j \leq m + n - 1$, satisfying the relations below. For convenience, we use the notation $E(0) = 1$.

$$e(\mathbf{i})e(\mathbf{j}) = \delta_{\mathbf{i}, \mathbf{j}} e(\mathbf{i}), \quad (4.1)$$

$$E(d)_j e(\mathbf{i}) = e(\mathbf{i}) E(d)_j, \quad (4.2)$$

$$E(d)_j e(\mathbf{i}) = 0 \quad \text{if } i_j = b, \quad (4.3)$$

$$E(d)_j e(\mathbf{i}) = 0 \quad \text{if } d > i_j \in I_{\mathbf{s}}, \quad (4.4)$$

$$X_j e(\mathbf{i}) = e(\mathbf{i}) X_j, \quad (4.5)$$

$$X_j e(\mathbf{i}) = 0 \quad \text{if } i_j \in I_{\mathbf{s}}, \quad (4.6)$$

$$\psi_j e(\mathbf{i}) = e(\sigma_j(\mathbf{i})) \psi_j, \quad (4.7)$$

$$\psi_j e(\mathbf{i}) = 0 \quad \text{if } i_j, i_{j+1} \in I_{\mathbf{s}}, \quad (4.8)$$

$$X_j X_{j+1} = X_{j+1} X_j, \quad (4.9)$$

$$E(d)_j X_{j+1} = X_{j+1} E(d)_j, \quad (4.10)$$

$$E(d)_j E(d')_{j+1} = E(d')_{j+1} E(d)_j, \quad (4.11)$$

$$\psi_j X_{j+1} = X_{j+1} \psi_j \quad \text{if } i_j = i_{j+1} = b, \quad (4.12)$$

$$\psi_j E(d)_{j+1} = E(d)_j \psi_j \quad \text{if } i_j = i_{j+1} = b, \quad (4.13)$$

$$\psi_j E(d)_j = E(d)_{j+1} \psi_j, \quad (4.14)$$

$$E(d)_j \psi_j = \psi_j E(d)_{j+1}, \quad (4.15)$$

$$\psi_j \psi_{j+1} = \psi_{j+1} \psi_j \quad \text{if } |j - j+1| > 1, \quad (4.16)$$

$$X_j \psi_j e(\mathbf{i}) - \psi_j X_{j+1} e(\mathbf{i}) = \delta_{i_j, i_{j+1}} e(\mathbf{i}) \quad \text{unless } i_j \in I_{\mathbf{s}} \text{ and } i_{j+1} \in I_{\mathbf{s}}, \quad (4.17)$$

$$\psi_j X_j e(\mathbf{i}) - X_{j+1} \psi_j e(\mathbf{i}) = \delta_{i_j, i_{j+1}} e(\mathbf{i}) \quad \text{unless } i_j \in I_{\mathbf{s}} \text{ and } i_{j+1} \in I_{\mathbf{s}}, \quad (4.18)$$

$$\psi_j^2 e(\mathbf{i}) = \begin{cases} 0 & \text{if } i_j = i_{j+1} = b, \\ X_j^{i_j} (-1)^{d_j} E(d)_j X_{j+1}^{i_{j+1}-d_j} e(\mathbf{i}) & \text{if } i_j \in I_{\mathbf{s}}, i_{j+1} = b, \\ X_j^{i_j} (-1)^{d_j} X_{j+1}^{i_{j+1}-d_j} E(d)_{j+1} e(\mathbf{i}) & \text{if } i_j = b, i_{j+1} \in I_{\mathbf{s}}, \end{cases} \quad (4.19)$$

$$\begin{aligned} & (\psi_j \psi_{j+1} \psi_{j+2} - \psi_{j+1} \psi_j \psi_{j+2}) e(\mathbf{i}) \\ &= \begin{cases} (-1)^{d_1+d_2+d_3} X_j^{d_1} E(d_1)_{j+1} X_{j+2}^{d_2} e(\mathbf{i}) & \text{if } i_{j+1} \in I_{\mathbf{s}}, \\ 0 & \text{if } i_j = i_{j+2} = b, \\ 0 & \text{otherwise.} \end{cases} \end{aligned} \quad (4.20)$$

Remark 4.1. Denote by $\overline{W}(\mathbf{s}, n)$ the quotient of $W(\mathbf{s}, n)$ by the extra *cyclotomic relation* $e(\mathbf{i}) = 0$ if $\mathbf{i}_{-1} = \mathbf{b}$. This cyclotomic quotient (when $\mathbf{s} = (1^m)$ and $n = 1$) was the main object of study in [KS18]. As mentioned there, the braid group action works whether or not we work in the cyclotomic quotient. It is more difficult to find a basis for the cyclotomic quotient (except in the special case in [KS18]), which is why we prefer to work with the larger algebra here. We expect that this cyclotomic quotient categorifies a weight space of a tensor product of finite dimensional irreducible representations of quantum $\mathfrak{sl}_2$.

$W(\mathbf{s}, n)$ is a graded algebra with the degrees of generators:

$$\begin{aligned} \deg(e(\mathbf{i})) &= 0, & \deg(x_j) &= 2, & \deg(E(d)_j) &= 2d, \\ \deg(\psi e(\mathbf{i})) &= \begin{cases} -2 & \text{if } \mathbf{i}_j = \mathbf{i}_{j+1} = \mathbf{b}, \\ \mathbf{i}_j & \text{if } \mathbf{i}_j \in I_{\mathbf{s}}, \mathbf{i}_{j+1} = \mathbf{b}, \\ \mathbf{i}_{j+1} & \text{if } \mathbf{i}_j = \mathbf{b}, \mathbf{i}_{j+1} \in I_{\mathbf{s}}. \end{cases} \end{aligned} \quad (4.21)$$

Remark 4.2. Relation 4.4, together with the grading convention above, allow us to identify $E(d)_j e(\mathbf{i})$ (where $\mathbf{i}_j \in I_{\mathbf{s}}$) with the elementary symmetric function e_d in the ring of symmetric functions. This identification is further justified by the basis result below in Proposition 4.9 and the relations on bimodules studied in Section 5.1.

We describe a diagrammatic presentation of $W(\mathbf{s}, n)$ in next subsection.

Remark 4.3. $W((0^m), n)$ is just the nilHecke algebra NH_n .

4.2. Diagrammatic presentation of $W(\mathbf{s}, n)$

There is a graphical presentation of $W(\mathbf{s}, n)$ similar to the algebra introduced in [KS18]. We consider collections of smooth arcs composed of n black arcs corresponding to $\mathbf{b}$ and m gray arcs with $I_{\mathbf{s}}$ -labelling. Arcs are assumed to have no critical points (in other words no cups or caps). Arcs are allowed to intersect (as long as they are both not red), but no triple intersections are allowed. Arcs can carry dots. Two diagrams that are related by an isotopy that does not change the combinatorial types of the diagrams or the relative position of crossings and or dots are taken to be equal. The elements of the vector space $W(\mathbf{s}, n)$ are formal linear combinations of these diagrams modulo the local relations given below. We give $W(\mathbf{s}, n)$ the structure of an algebra by concatenating diagrams vertically as long as the colors of the endpoints match. If they do not, the product of two diagrams is taken to be zero.

The generators $e(\mathbf{i})$ for $\mathbf{i} \in \text{Seq}(\mathbf{s}, n)$ represent the diagram consisting entirely of vertical strands whose j th strand (counting from left for each j) is black if $\mathbf{i}_j$ is $\mathbf{b}$ or thick gray with $\mathbf{i}_j$ -labelling if $\mathbf{i}_j$ is in $I_{\mathbf{s}}$. The gray strand with 1-labelling will often be represented by a thin gray strand without 1-labelling. Dots on black strands correspond to generators x given earlier. Dots on gray strands correspond to generators $E(d)_j$ defined in the previous subsection. A crossing of two strands corresponds to a generator ψ .

Example 4.4. In the case of $\mathbf{s} = (2, 1)$ and $n = 2$, the set $\text{Seq}((2, 1), 2)$ is

$$\{(2, 1, \mathbf{b}, \mathbf{b}), (2, \mathbf{b}, 1, \mathbf{b}), (\mathbf{b}, 2, 1, \mathbf{b}), (2, \mathbf{b}, \mathbf{b}, 1), (\mathbf{b}, 2, \mathbf{b}, 1), (\mathbf{b}, \mathbf{b}, 2, 1)\}.$$

The diagrammatic presentation of $e(\mathbf{i})$ corresponding to sequences of $\text{Seq}((2, 1), 2)$ are

$$\begin{array}{cccccc} \begin{array}{c} \parallel \\ 2 \end{array} \begin{array}{c} \parallel \\ 1 \end{array} \begin{array}{c} | \\ 1 \end{array}, & \begin{array}{c} \parallel \\ 2 \end{array} \begin{array}{c} \parallel \\ 1 \end{array} \begin{array}{c} | \\ 1 \end{array}, & \begin{array}{c} \parallel \\ 2 \end{array} \begin{array}{c} \parallel \\ 1 \end{array} \begin{array}{c} | \\ 1 \end{array}, & \begin{array}{c} \parallel \\ 2 \end{array} \begin{array}{c} \parallel \\ 1 \end{array} \begin{array}{c} | \\ 1 \end{array}, & \begin{array}{c} \parallel \\ 2 \end{array} \begin{array}{c} \parallel \\ 1 \end{array} \begin{array}{c} | \\ 1 \end{array}, & \begin{array}{c} \parallel \\ 2 \end{array} \begin{array}{c} \parallel \\ 1 \end{array} \begin{array}{c} | \\ 1 \end{array}. \end{array}$$

The generators $x_j e(\mathbf{i})$ and $E(d)_j e(\mathbf{i})$ represent the dot on the j th strand counting from left of the $(m + n)$ strand diagram:

$$\begin{aligned} x_j e(\mathbf{i}) &= \begin{array}{c} | \\ \bullet \end{array} \text{ if } \mathbf{i}_j = b, \\ E(d)_j e(\mathbf{i}) &= \begin{array}{c} \parallel \\ e_d \\ | \\ \mathbf{i}_j \end{array} \text{ if } \mathbf{i}_j \in I_{\mathbf{s}} \text{ and } 1 \leq d \leq \mathbf{i}_j \end{aligned}$$

where we make use of the identification from Remark 4.2 to identify gray dots with elementary symmetric functions. In particular, we have that $E_d = e_d$ on the gray arc with i -labelling is zero if d is bigger than i . Note that on thin gray strands, we only have dots labelled by e_1 . For simplicity in this case, we will abuse notation and label a dot d when we really mean e_1^d .

The generator $\psi_j e(\mathbf{i})$ represents the crossing diagram as follows.

$$\psi_j e(\mathbf{i}) = \begin{cases} \begin{array}{c} \text{crossing} \\ \mathbf{i}_j, \mathbf{i}_{j+1} \end{array}, & \text{if } \mathbf{i}_j = b, \mathbf{i}_{j+1} = b; \\ \begin{array}{c} \text{crossing} \\ \mathbf{i}_j, \mathbf{i}_{j+1} \end{array}, & \text{if } \mathbf{i}_j = b, \mathbf{i}_{j+1} \in I_{\mathbf{s}}; \\ \begin{array}{c} \text{crossing} \\ \mathbf{i}_j, \mathbf{i}_{j+1} \end{array}, & \text{if } \mathbf{i}_j \in I_{\mathbf{s}}, \mathbf{i}_{j+1} = b. \end{cases}$$

The degrees of the generating diagrams are

$$\begin{aligned} \deg \begin{array}{c} | \\ \bullet \end{array} &= 2, \quad \deg \begin{array}{c} \parallel \\ e_d \\ | \\ \mathbf{i}_j \end{array} = 2d, \\ \deg \begin{array}{c} \text{crossing} \\ \mathbf{i}_j \end{array} &= -2, \quad \deg \begin{array}{c} \text{crossing} \\ \mathbf{i}_j \end{array} = \deg \begin{array}{c} \text{crossing} \\ \mathbf{i}_j \end{array} = i. \end{aligned}$$

The elements of the vector space $W(\mathbf{s}, n)$ are formal linear combinations of these diagrams modulo isotopy, nilHecke relations on the black strands, and the following local relations. We give the algebra structure of $W(\mathbf{s}, n)$ by concatenating diagrams vertically when the colors on the endpoints of two diagrams match:

$$\begin{array}{c} \text{crossing} \\ \mathbf{i} \end{array} = \sum_{d_1 + d_2 = i} (-1)^{d_2} \begin{array}{c} | \\ \bullet \end{array} \begin{array}{c} | \\ \bullet \end{array} \begin{array}{c} \parallel \\ e_{d_2} \\ | \\ \mathbf{i} \end{array}, \quad \begin{array}{c} \text{crossing} \\ \mathbf{i} \end{array} = \sum_{d_1 + d_2 = i} (-1)^{d_1} \begin{array}{c} \parallel \\ e_{d_1} \\ | \\ \mathbf{i} \end{array} \begin{array}{c} | \\ \bullet \end{array} \begin{array}{c} | \\ \bullet \end{array}, \quad (4.22)$$

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

$$\begin{array}{c} \text{Diagram 1} = \text{Diagram 2}, \quad \text{Diagram 3} = \text{Diagram 4}, \end{array} \quad (4.23)$$

$$\begin{array}{c} \text{Diagram 5} = \text{Diagram 6}, \quad \text{Diagram 7} = \text{Diagram 8}, \end{array} \quad (4.24)$$

$$\begin{array}{c} \text{Diagram 9} = \text{Diagram 10}, \quad \text{Diagram 11} = \text{Diagram 12}, \end{array} \quad (4.25)$$

$$\text{Diagram 13} - \text{Diagram 14} = \sum_{a+b+c=i-1} (-1)^c \text{Diagram 15} \quad (4.26)$$

Lemma 4.5.

$$\begin{array}{c} \text{Diagram 16} \\ k \end{array} = \sum_{d_1+d_2=k} (-1)^{d_2} \text{Diagram 17} \quad \text{Diagram 18} = \sum_{d_1+d_2=k} (-1)^{d_1} \text{Diagram 19} \quad (4.27)$$

Proof. This follows easily from the defining relations along with the definition of the thick black strand.

Lemma 4.6. Recall the diagrams defined in (2.2). We have the following equality:

$$\text{Diagram 20} = \text{Diagram 21} + \sum_{i=1}^{k-1} \text{Diagram 22} \quad (4.28)$$

Proof. The lemma follows from repeated use of (4.26).

4.3. A faithful representation and basis

We will construct a faithful (left) action of $W(\mathbf{s}, n)$ on a direct sum of polynomial algebras.

For $1 \leq j \leq m+n$, let

$$\#_{B, \mathbf{i}}(j) = |\{r | 1 \leq r \leq j-1, \mathbf{i}_r = b\}| \quad \#_{R, \mathbf{i}}(j) = j-1 - \#_{B, \mathbf{i}}(j).$$

In other words, $\#_{B, \mathbf{i}}(j)$ is the number of the first $j-1$ entries of $\mathbf{i}$ that are b and $\#_{R, \mathbf{i}}(j)$ is the number of the first $j-1$ entries that belong to $I_{\mathbf{s}}$. When the sequence $\mathbf{i}$ is fixed, we simply write $\#_B(j)$ and $\#_R(j)$.

Let Y_{s_j} be an alphabet in s_j variables and define

$$R = \text{Sym}(Y_{s_1}) \otimes \cdots \otimes \text{Sym}(Y_{s_m})$$

where $\text{Sym}(Y_{s_j})$ is the algebra over k of symmetric functions in the alphabet Y_{s_j} . Note that R is determined by the sequence $\mathbf{s}$.

For each $\mathbf{i} = (i_1, \dots, i_{m+n}) \in \text{Seq}(\mathbf{s}, n)$ in which the letters are b , we associate a vector space

$$V_{\mathbf{i}} = R[X_{1,\mathbf{i}}, \dots, X_{n,\mathbf{i}}], \quad V = \bigoplus_{\mathbf{i} \in \text{Seq}(\mathbf{s}, n)} V_{\mathbf{i}}.$$

Sometimes we write $f \in V_{\mathbf{i}}$ as $f(X_{\mathbf{i}})$ to emphasize the alphabet for which the variables of f are taken.

For $1 \leq r \leq n-1$, let

$$\partial_r : V_{\mathbf{i}} \rightarrow V_{\mathbf{i}}, \quad f(X_{1,\mathbf{i}}, \dots, X_{n,\mathbf{i}}) \mapsto \frac{f(X_{1,\mathbf{i}}, \dots, X_{n,\mathbf{i}}) - f(X_{\sigma_r(1),\mathbf{i}}, \dots, X_{\sigma_r(n),\mathbf{i}})}{X_{r,\mathbf{i}} - X_{r+1,\mathbf{i}}}$$

be the r th divided difference operator where each $\sigma \in S_n$ is the simple transposition fixing all elements except r and $r+1$.

Each generator of $W(\mathbf{s}, n)$ is declared to act trivially (by zero) on V except in the following cases:

- $e(\mathbf{i}) : f \in V_{\mathbf{i}} \mapsto f \in V_{\mathbf{i}}$,
- $X_j e(\mathbf{i}) : f \in V_{\mathbf{i}} \mapsto X_{\#_{B(j)+1}, \mathbf{i}} f \in V_{\mathbf{i}}$, if $\mathbf{i}_j = b$,
- $E(d)_j e(\mathbf{i}) : f \in V_{\mathbf{i}} \mapsto e_{\beta}(Y_{s_{\#_{B(j)+1}}}) f \in V_{\mathbf{i}}$, if $\mathbf{i}_j \neq b$,
- $\psi_j e(\mathbf{i}) : f \in V_{\mathbf{i}} \mapsto \partial_{\#_{B(j)+1}} f \in V_{\mathbf{i}}$, if $\mathbf{i}_j = \mathbf{i}_{j+1} = b$,
- $\psi_j e(\mathbf{i}) : f(X_{\mathbf{i}}) \in V_{\mathbf{i}} \mapsto f(X_{\sigma_j(\mathbf{i})}) \in V_{\sigma_j(\mathbf{i})}$, if $\mathbf{i}_j \neq b$ and $\mathbf{i}_{j+1} = b$,
- $\psi_j e(\mathbf{i}) : f(X_{\mathbf{i}}) \in V_{\mathbf{i}} \mapsto \sum_{\substack{\alpha+\beta=\mathbf{i}_{j+1} \\ \text{if } \mathbf{i}_j = b \text{ and } \mathbf{i}_{j+1} \neq b}} (-1)^{\beta} X_{\#_{B(j)+1}, \sigma_j(\mathbf{i})} e_{\beta}(Y_{s_{\#_{B(j)+1}}}) f(X_{\sigma_j(\mathbf{i})}) \in V_{\sigma_j(\mathbf{i})}$,

Proposition 4.7. *The action of the generators of $W(\mathbf{s}, n)$ above extends to a representation of $W(\mathbf{s}, n)$ on V .*

Proof. The fact that the generators of $W(\mathbf{s}, n)$ prescribed above extend to a representation of the algebra on V is a routine exercise.

Let $\mathbf{i}, \mathbf{i}' \in \text{Seq}(\mathbf{s}, n)$. There is a partial order on $\text{Seq}(\mathbf{s}, n)$ declaring $\mathbf{i} < \mathbf{i}'$ if

$$\#_{B,\mathbf{i}}(j) > \#_{B,\mathbf{i}'}(j) \quad \text{for } j = 1, \dots, m+n. \quad (4.29)$$

Informally, the more to the left the black strands of $\mathbf{i}$ are, the smaller $\mathbf{i}$ is.

Example 4.8. Let $\mathbf{s} = (1, 1)$ and $n = 1$. Then order the elements of $\text{Seq}(\mathbf{s}, n)$ as follows:

$$(b, 1, 1) < (1, b, 1) < (1, 1, b).$$

Consider a diagram D whose bottom boundary is determined by the sequence $\mathbf{i}$ and whose top boundary is determined by $\mathbf{i}'$. Using the relations of the algebra we

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

may assume that any pair of strands of D intersect at most once and that all of the dots are at the bottom of the diagram. Such a D is determined by a minimal presentation $w = \sigma_{i_1} \cdots \sigma_{i_r}$ for an element $w \in S_{n+m}$ (along with the dots at the bottom).

Let ${}_{\mathbf{i}^0}S_{\mathbf{i}}$ be the subset of S_{n+m} consisting of permutations each of which takes $\mathbf{i}$ to $\mathbf{i}^0$ by the standard action of S_{n+m} on sequences. For each $w \in {}_{\mathbf{i}^0}S_{\mathbf{i}}$ we convert a minimal presentation w into an element $\mathcal{W}$ of $e(\mathbf{i}^0)W(\mathbf{s}, n)e(\mathbf{i})$. Let

$${}_{\mathbf{i}^0}\mathcal{B}_{\mathbf{i}} = \{ \mathcal{W} \mid w \in {}_{\mathbf{i}^0}S_{\mathbf{i}} \}.$$

Let

$${}_{\mathbf{i}^0}B_{\mathbf{i}} = \left\{ \mathcal{W} \prod_{j \in I_{\mathbf{s}}} x_j^{r_j} \prod_{j \in I_{\mathbf{s}^0}} y_j^{r_{y_j}} E(y)_j^{r_{y_j}} e(\mathbf{i}) \mid w \in {}_{\mathbf{i}^0}S_{\mathbf{i}}, r_j, r_{y_j} \in \mathbb{Z}_{\geq 0} \right\}.$$

The diagram for each element in this set consists of crossings matching $\mathbf{i}^0$ and $\mathbf{i}$ on the top and dots on the bottom. The gray dots are labelled by elementary symmetric functions.

The proof of the following proposition is similar to the proof of [KL09, Thm. 2.5].

Proposition 4.9. $e(\mathbf{i}^0)W(\mathbf{s}, n)e(\mathbf{i})$ is a free graded abelian group with a homogeneous basis ${}_{\mathbf{i}^0}B_{\mathbf{i}}$.

Proof. It is straightforward to check that ${}_{\mathbf{i}^0}B_{\mathbf{i}}$ is a spanning set.

Let ${}_{\mathbf{i}^0}M_{\mathbf{i}}$ be the dotless diagram with the fewest number of crossings such that the bottom boundary points correspond to $\mathbf{i}$ and the top boundary points correspond to $\mathbf{i}^0$. Note that strands with the same color do not intersect in ${}_{\mathbf{i}^0}M_{\mathbf{i}}$ and that ${}_{\mathbf{i}^0}M_{\mathbf{i}} = e(\mathbf{i})$. We have

$$({}_{\mathbf{i}^0}M_{\mathbf{i}^0})({}_{\mathbf{i}^0}M_{\mathbf{i}}) = \sum_{\alpha+\beta=\mathbf{i}} \prod_{a \in \beta} (-1)^{\beta} x_a^{\alpha} E(\beta)_b + \sum_{\alpha+\beta=\mathbf{i}} \prod_{a \in \alpha} (-1)^{\alpha} E(\alpha)_a x_b^{\beta} \quad (4.30)$$

where the first product in (4.30) is over pairs (a, b) such that $1 \leq a < b \leq m+n$ and the arcs in ${}_{\mathbf{i}^0}M_{\mathbf{i}}$ ending at the a th and b th bottom points counting from the left intersect and $\mathbf{i}_a = b$. The second product in (4.30) is over pairs (a, b) such that $1 \leq a < b \leq m+n$ and the arcs in ${}_{\mathbf{i}^0}M_{\mathbf{i}}$ ending at the a th and b th bottom points counting from the left intersect and $\mathbf{i}_a \neq b$. Thus elements of the form ${}_{\mathbf{i}^0}M_{\mathbf{i}}$ are non-zero.

We prove that the elements of ${}_{\mathbf{i}^0}B_{\mathbf{i}}$ are linearly independent by induction on $|\mathbf{i}^0|$ using the partial order defined in (4.29). The minimal possible $|\mathbf{i}^0|$ is of the form

$$(b, \dots, b, \mathfrak{s}, \dots, \mathfrak{s}).$$

Each $w \in {}_{\mathbf{i}^0}S_{\mathbf{i}}$ could be written as $w = w_{-1}w_0$ where w_0 is an element in ${}_{\mathbf{i}^0}S_{\mathbf{i}}$ with no black strands crossing and $w_{-1} \in S_n$. Each minimal length representative $\mathcal{W}_{-1}$ of w_{-1} determines the same element $\mathcal{W}_{-1}$ of ${}_{\mathbf{i}^0}\mathcal{B}_{\mathbf{i}}$. Similarly, each minimal length representative $\mathcal{W}_0$ of w_0 determines the same element $\mathcal{W}_0$ of ${}_{\mathbf{i}^0}\mathcal{B}_{\mathbf{i}^0}$.

The elements of ${}_{\mathbf{i}^0}B_{\mathbf{i}}$ are of the form $b\mathcal{W}_{-1}\mathcal{W}_0x^u e(\mathbf{i})$ where x^u is a product of dots. Let f be a monomial in $V_{\mathbf{i}}$. By the action defined in Proposition 4.7, the

element $\psi_0 x^u$ takes f to $x^{-u} f \in V_{\mathbf{i}^0}$ (suitably re-labelled). The element ψ_1 acts on monomials as products of divided difference operators. Since the action of the nilHecke algebra on the ring of polynomials is faithful, the elements $\psi_1 \psi_0 x^u e(\mathbf{i})$ are linearly independent.

Assume inductively that the elements of $\mathbf{i}^0 B_{\mathbf{i}}$ are linearly independent. Assume $\mathbf{i}_k^0 = \mathbf{b}$, $\mathbf{i}_{k+1}^0 \neq \mathbf{b}$ and that $\mathbf{i}^{00} = \sigma_k(\mathbf{i}^0)$. In order to show that $\mathbf{i}^{00} B_{\mathbf{i}}$ is a linearly independent set, we consider its image under the map:

$$\psi_k : e(\mathbf{i}^{00}) W(\mathbf{s}, n) e(\mathbf{i}) \rightarrow e(\mathbf{i}) W(\mathbf{s}, n) e(\mathbf{i}).$$

Define a partial order on $\mathbf{i}^0 B_{\mathbf{i}}$ by $w_1 f_1 < w_2 f_2$ if $l(w_1) < l(w_2)$ or if $w_1 = w_2$ and the dots on the first $j-1$ gray strands counting from left to right are the same but the degree of $E(s_j)$ in f_1 is less than the degree of $E(s_j)$ in f_2 where the j th gray strand is labelled s_j . Extend this partial order to a total order.

Let $\delta : \mathbf{i}^{00} B_{\mathbf{i}} \rightarrow \mathbf{i}^0 B_{\mathbf{i}}$ be defined by $\delta(y) = \psi_k y$ if the strands with top boundary points at positions k and $k+1$ are disjoint.

If the strands do intersect, set $\delta(y) = y^0 E(d)$ where y^0 is obtained from y by removing the crossing between the two strands and the gray strand ending at position $k+1$ on the top is labelled by d and the bottom boundary of that strand is at position $\cdot$ from the left.

The map δ is clearly injective. Note that $\psi_k y = \delta(y)$ plus lower terms. Now the linear independence of $\mathbf{i}^{00} B_{\mathbf{i}}$ follows from the inductive hypothesis.

Corollary 4.10. *The action of $W(\mathbf{s}, n)$ on V is faithful.*

Example 4.11. Let $\mathbf{s} = (1, 1)$ and $n = 1$. There are three elements in $\text{Seq}(\mathbf{s}, n)$:

$$\mathbf{i} = (1, \mathbf{b}, 1), \quad \mathbf{j} = (\mathbf{b}, 1, 1), \quad \mathbf{k} = (1, 1, \mathbf{b}).$$

Elements of $\mathbf{j} B_{\mathbf{i}}$, $\mathbf{i} B_{\mathbf{i}}$, and $\mathbf{k} B_{\mathbf{i}}$ respectively are of the form:

where $r_1, r_2, r_3 \in \mathbb{Z}_{\geq 0}$.

4.4. Connection to Webster's algebra

Let $\mathcal{P}$ be the algebra introduced by Webster in [Web17, Sect. 4] for $\mathfrak{sl}_2$ for $\underline{\lambda} = (s_1, \dots, s_m)$ and $(i_1, \dots, i_l) = (1, \dots, 1)$.

Let $I(\mathbf{s}, n)$ be the two-sided ideal that is generated by $E(d)_j$, where $1 \leq j \leq m+n$ and $1 \leq d$. Then $\mathcal{P} \cong W(\mathbf{s}, n)/I(\mathbf{s}, n)$.

4.5. Symmetries of the algebra

There is an algebra automorphism τ of the nilHecke algebra defined diagrammatically by the symmetry of rescaling each crossing $\times \xrightarrow{\mathbb{Z}} \times$ and reflecting

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

diagrams across the vertical axis. Algebraically, this corresponds to the algebra homomorphism defined on generators by

$$\tau : X_i \mapsto X_{n+1-i}, \quad \partial_i \mapsto -\partial_{n+1-i}. \quad (4.31)$$

This symmetry immediately extends to the algebras $W(\mathbf{s}, n)$ since the relations involving gray strands remain invariant under this symmetry.

In [Lau08], this symmetry (denoted by σ there) is extended to define a 2-functor $\tau : U(\mathfrak{sl}_2) \rightarrow U(\mathfrak{sl}_2)$ define diagrammatically by rescaling each crossing, reflecting across the vertical axis, and sending weights λ to $-\lambda$. In [KLMS12], the symmetry τ is used to deduce new thick calculus relations from others by applying τ . Working with the symmetry τ in the Karoubi envelope $\dot{U} = \text{Kar}(U)$ is somewhat subtle, as the idempotents e_a used to define divided powers $E^{(a)}$ are not stable under the symmetry τ . One can see that

$$\tau \left(\begin{array}{c} \uparrow \uparrow \uparrow \uparrow \\ \text{---} e_a \text{---} \\ \downarrow \downarrow \downarrow \downarrow \end{array} \lambda \right) := (-1)^{\frac{a(a-1)}{2}} -\lambda \begin{array}{c} \uparrow \uparrow \uparrow \uparrow \\ \text{---} D_a \text{---} \\ \downarrow \downarrow \downarrow \downarrow \end{array} \quad (4.32)$$

and that the idempotent $1_{-\lambda} e_a$ is equivalent to the idempotent $\tau(e_a 1_\lambda)$ since

$$\tau(e_a 1_\lambda)(1_{-\lambda} e_a) = \tau(e_a 1_\lambda), \quad \text{and} \quad (1_{-\lambda} e_a)\tau(e_a 1_\lambda) = (1_{-\lambda} e_a).$$

Since these idempotents are equivalent, they give rise to isomorphic 1-morphisms in $\dot{U}$.

In what follows, we would like to apply the symmetry τ to thick calculus identities in $W(\mathbf{s}, n)$ in order to obtain new thick calculus identities. However, doing so is complicated by the above observation that $\tau(E^{(a)} 1_\lambda) := (1_{-\lambda} E^a, \tau(e_a 1_\lambda))$, so to obtain new thick calculus identities we must use the isomorphisms relating $\tau(e_a 1_\lambda)$ to $1_{-\lambda} e_a$.

Signed sequences Let $\underline{\varepsilon} = \varepsilon_1^{a_1} \dots \varepsilon_m^{a_m}$ denote a *divided power signed sequence* with each $\varepsilon \in \{+, -\}$ and each $a_i \in \mathbb{Z}_{\geq 0}$. To each such sequence we define a 1-morphism

$$E_{\underline{\varepsilon}} 1_\lambda = E_{\varepsilon_1}^{(a_1)} \dots E_{\varepsilon_m}^{(a_m)} 1_\lambda$$

in $\dot{U}$, where $E_+ := E$ and $E_- := F$. Write $e_{\underline{\varepsilon}} 1_\lambda$ for the idempotent $e_{a_1} \otimes e_{a_2} \otimes \dots \otimes e_{a_m} 1_\lambda$ built from the horizontal composition of idempotents defining each $E_{\varepsilon_i}^{(a_i)}$, so that in $\dot{U}$ we have

$$E_{\underline{\varepsilon}} 1_\lambda := (E_{\varepsilon_1}^{a_1} \dots E_{\varepsilon_m}^{a_m} 1_\lambda, e_{\underline{\varepsilon}} 1_\lambda).$$

Given a divided power signed sequence $\underline{\varepsilon}$ let

$$\tau(\underline{\varepsilon}) := \varepsilon_m^{a_m} \varepsilon_{m-1}^{a_{m-1}} \dots \varepsilon_1^{a_1}.$$

This should not be confused with the result of applying the 2-isomorphism τ to the idempotent $e_{\underline{\varepsilon}}$. These two possibilities are related by the following lemma.

Lemma 4.12. *There is an isomorphism*

$$z_{\underline{\varepsilon}} : \tau \left(E_{\underline{\varepsilon}} 1_{\lambda}, e_{\underline{\varepsilon}} \right) = 1_{-\lambda} E_{\underline{\varepsilon}_m}^{a_m} E_{\underline{\varepsilon}_{m-1}}^{a_{m-1}} \dots E_{\underline{\varepsilon}_1}^{a_1}, \tau(e_{\underline{\varepsilon}}) \rightarrow 1_{-\lambda} E_{\tau(\underline{\varepsilon})}$$

between 1-morphisms in $\dot{U}$.

Proof. Let $z_{\underline{\varepsilon}} = e_{\tau(\underline{\varepsilon})}$ and $z_{\underline{\varepsilon}}^{-1} = \tau(e_{\underline{\varepsilon}})$.

Proposition 4.13. *Given an equality of 2-morphisms*

$$X 1_{\lambda} = Y 1_{\lambda} : E_{\underline{\varepsilon}} 1_{\lambda} \rightarrow E_{\underline{\varepsilon}^0} 1_{\lambda}$$

in $\dot{U}$ we have an equality

$$z_{\underline{\varepsilon}^0} \tau(X 1_{\lambda}) z_{\underline{\varepsilon}}^{-1} = z_{\underline{\varepsilon}^0} \tau(Y 1_{\lambda}) z_{\underline{\varepsilon}}^{-1} : 1_{-\lambda} E_{\tau(\underline{\varepsilon})} \rightarrow 1_{-\lambda} E_{\tau(\underline{\varepsilon}^0)}.$$

The above proposition gives rise to a simple effective rule for obtaining new thick calculus identities by reflecting thick diagrams across the vertical axis and rescaling all splitters:

$$\tau \left(\begin{array}{c} a \quad b \\ \diagup \quad \diagdown \\ \text{---} \\ a+b \end{array} \right) = (-1)^{ab} \begin{array}{c} b \quad a \\ \diagdown \quad \diagup \\ \text{---} \\ a+b \end{array}. \quad (4.33)$$

Note that this definition is consistent with the factorization of a thin crossing through a thickness two strand:

$$\begin{array}{c} \diagup \quad \diagdown \\ \diagdown \quad \diagup \end{array} = \begin{array}{c} \diagdown \quad \diagup \\ \diagup \quad \diagdown \end{array}.$$

4.6. Inclusion map

Let $\mathbf{s} = (s_1, s_2, \dots, s_m)$ be a sequence of m non-negative integers. For $j = 1, \dots, m-1$, denote by $\mathbf{s}^j$ the sequence of $m-1$ integers obtained from $\mathbf{s}$ by replacing the pair (s_j, s_{j+1}) with the singleton $s_j + s_{j+1}$. Denote by $\varphi_{j,a}(\mathbf{s})$, where $j = 1, \dots, m$ and $0 \leq a \leq s_j$, the sequence of $m+1$ integers obtained from $\mathbf{s}$ by replacing the integer s_j with the pair $(s_j - a, a)$:

$$\begin{aligned} \mathbf{s}^j &= (s_1, \dots, s_j, s_j + s_{j+1}, s_{j+2}, \dots, s_m), \\ \varphi_{j,a}(\mathbf{s}) &= (s_1, \dots, s_j, s_j - a, a, s_{j+1}, \dots, s_m). \end{aligned}$$

Note that we have $\varphi_{j,s_j}(\mathbf{s}^j) = \mathbf{s}$.

The map $\varphi_{j,a}$ extends to a map from $\text{Seq}(\mathbf{s}, n)$ to $\text{Seq}(\varphi_{j,a}(\mathbf{s}), n)$ by replacing the integer s_j in $\mathbf{i}$ with the pair $(s_j - a, a)$. When $\mathbf{i} = s_j$,

$$\varphi_{j,a}(\mathbf{i}) = (\dots, \mathbf{i}_{j-1}, s_j - a, a, \mathbf{i}_{j+1}, \dots) \in \text{Seq}(\varphi_a(\mathbf{s}), n).$$

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

Define an inclusion map of algebras which is non-unital

$$\Phi_{j,a} : W(\mathbf{s}, n) \rightarrow W(\varphi_a(\mathbf{s}), n) \quad (4.34)$$

determined by sending idempotents $e(\mathbf{i})$ for $\text{Seq}(\mathbf{s}, n)$ by

$$\Phi_{j,a} (e(\mathbf{i})) = e(\varphi_{j,a} (\mathbf{i})).$$

Assume the j th gray entry occur in position $\cdot^0$ of $\mathbf{i}$. The “dot” generators $E(d) \cdot$ are mapped via

$$\Phi_{j,a}(E(d) \cdot e(\mathbf{i})) = \begin{cases} E(d) \cdot e(\varphi_{j,a}(\mathbf{i})) & \text{if } \cdot^0 < \cdot^0, \\ E(d) \cdot_{+1} e(\varphi_{j,a}(\mathbf{i})) & \text{if } \cdot^0 < \cdot^0, \\ \prod_{d_1+d_2=d} E(d_1) \cdot_{+1} E(d_2) \cdot_{+1} e(\varphi_{j,a}(\mathbf{i})) & \text{if } \cdot^0 = \cdot^0, 1 \leq d \leq s_j. \end{cases}$$

On “dot” generators $x \cdot$ define it by

$$\Phi_{j,a}(x \cdot e(\mathbf{i})) = \begin{cases} x \cdot e(\varphi_{j,a}(\mathbf{i})) & \text{if } \cdot < \cdot^0, \\ x_{+1} \cdot e(\varphi_{j,a}(\mathbf{i})) & \text{if } \cdot^0 < \cdot. \end{cases}$$

On “crossing” generators ψ define it by

$$\Phi_{j,a}(\psi \cdot e(\mathbf{i})) = \begin{cases} \psi \cdot e(\varphi_{j,a}(\mathbf{i})) & \text{if } \cdot < \cdot^0 - 1, \\ \psi_{+1} \psi \cdot e(\varphi_{j,a}(\mathbf{i})) & \text{if } \mathbf{i}^{\cdot^0 - 1} = \mathbf{b}, \cdot = \cdot^0 - 1, \\ \psi \cdot \psi_{+1} \cdot e(\varphi_{j,a}(\mathbf{i})) & \text{if } \mathbf{i}^{\cdot^0 + 1} = \mathbf{b}, \cdot = \cdot^0, \\ \psi_{+1} \cdot e(\varphi_{j,a}(\mathbf{i})) & \text{if } \cdot > \cdot^0. \end{cases}$$

In particular, $\Phi_{j,a}$ is diagrammatically represented by

$$\Phi_{j,a} \left(\begin{array}{c} | \\ e_d \\ s_j \end{array} \right) \xrightarrow{\quad} X \quad \begin{array}{cc} e_{d_1} & e_{d_2} \\ | & | \\ s_j - a & a \end{array}, \quad (4.35)$$

$$\Phi_{j,a} \left(\begin{array}{c} \text{Diagram 1} \\ s_j \end{array} \right) \xrightarrow{\mathbb{Z}} \begin{array}{c} \text{Diagram 2} \\ s_j - a \quad a \end{array}, \quad \Phi_{j,a} \left(\begin{array}{c} \text{Diagram 3} \\ s_j \end{array} \right) \xrightarrow{\mathbb{Z}} \begin{array}{c} \text{Diagram 4} \\ s_j - a \quad a \end{array}. \quad (4.36)$$

Proposition 4.14. *The following map is injective:*

$$\Phi_{j, s_{j+1}} : W(\mathbf{s}^j, n) \rightarrow W(\mathbf{s}, n). \quad (4.37)$$

Proof. Injectivity of $\Phi_{j,s_{j+1}}$ is an immediate consequence of its definition on basis elements.

5. Reddotted bimodules

In this section, we will introduce certain bimodules $E_i^{(a)}$ and $F_i^{(a)}$ over $W(\mathbf{s}, n)$ for various sequences $\mathbf{s}$. The Lie theoretic notation of these bimodules is chosen so that these bimodules will be the targets of the 1-morphisms of a categorical quantum group action.

In order to describe these bimodules, we will first introduce "halves" of these bimodules which we call *splitter* bimodules. Then we will introduce *ladder* bimodules.

5.1. Splitter bimodules

The bimodules that we will first define algebraically are called splitter bimodules because of their graphical descriptions.

First note that the inclusion $\Phi_{j, s_{j+1}}$ determines the left action of $W(\mathbf{s}^j, n)$ on $W(\mathbf{s}, n)$. Define the $(W(\mathbf{s}^j, n), W(\mathbf{s}, n))$ -bimodule $4^j(\mathbf{s})$ as the bimodule

$$4^j(\mathbf{s}) := W(\mathbf{s}^j, n) \otimes_{W(\mathbf{s}^j, n)} W(\mathbf{s}, n) \{ -s_j \cdot s_{j+1} \} \quad (5.1)$$

and the $(W(\mathbf{s}, n), W(\mathbf{s}^j, n))$ -bimodule $5^j(\mathbf{s})$ as the bimodule

$$5^j(\mathbf{s}) := W(\mathbf{s}, n) \otimes_{W(\mathbf{s}^j, n)} W(\mathbf{s}^j, n). \quad (5.2)$$

We diagrammatically represent elements of these bimodules as follows

with n black strands intersecting the pictures in a manner similar to that described in Section 4.2 along with gray and black dots.

Proposition 5.1. *There are relations*

Proof. Use the definition of the inclusion (4.37) along with relations in the algebra.

The first two equalities of Proposition 5.1 imply the following.

Corollary 5.2.

$$\begin{aligned}
 & \begin{array}{c} S_j + S_{j+1} \\ | \\ \bullet \\ / \quad \backslash \\ S_j \quad S_{j+1} \end{array} = \sum_{d_1+d_2=d} (-1)^{d_2} \begin{array}{c} S_j + S_{j+1} \\ | \\ \bullet \\ / \quad \backslash \\ S_j \quad S_{j+1} \end{array}, \\
 & \begin{array}{c} S_j + S_{j+1} \\ | \\ \bullet \\ / \quad \backslash \\ S_j \quad S_{j+1} \end{array} = \sum_{d_1+d_2=d} (-1)^{d_2} \begin{array}{c} S_j + S_{j+1} \\ | \\ \bullet \\ / \quad \backslash \\ S_j \quad S_{j+1} \end{array}, \\
 & \begin{array}{c} S_j \quad S_{j+1} \\ / \quad \backslash \\ \bullet \\ | \\ S_j + S_{j+1} \end{array} = \sum_{d_1+d_2=d} (-1)^{d_2} \begin{array}{c} S_j \quad S_{j+1} \\ / \quad \backslash \\ \bullet \\ | \\ S_j + S_{j+1} \end{array}, \\
 & \begin{array}{c} S_j \quad S_{j+1} \\ / \quad \backslash \\ \bullet \\ | \\ S_j + S_{j+1} \end{array} = \sum_{d_1+d_2=d} (-1)^{d_2} \begin{array}{c} S_j \quad S_{j+1} \\ / \quad \backslash \\ \bullet \\ | \\ S_j + S_{j+1} \end{array}.
 \end{aligned}$$

5.2. Ladder bimodules

The main bimodules introduced in this section are called ladder bimodules because of their graphical depiction.

For a sequence $\mathbf{s} = (s_1, s_2, \dots, s_n)$, we have maps

$$\begin{aligned}
 \varphi_{j,a}(\mathbf{s})^{j+1} &= (\dots, s_{j-1}, s_j - a, s_{j+1} + a, s_{j+2}, \dots), \\
 \varphi_{j+1,s_{j+1}-a}(\mathbf{s})^j &= (\dots, s_{j-1}, s_j + a, s_{j+1} - a, s_{j+2}, \dots).
 \end{aligned}$$

We denote by $\alpha^{+j,a}(\mathbf{s})$ the sequence $\varphi_{j+1,s_{j+1}-a}(\mathbf{s})^j$ and denote by $\alpha^{-j,a}(\mathbf{s})$ the sequence $\varphi_{j,a}(\mathbf{s})^{j+1}$. These maps $\alpha^{\pm j,a}$ extend into the set $\text{Seq}(\mathbf{s}, n)$ by

$$\begin{aligned}
 \alpha^{+j,a}(\mathbf{i}) &= (\dots, s_j + a, b, \dots, b, s_{j+1} - a, \dots), \\
 \alpha^{-j,a}(\mathbf{i}) &= (\dots, s_j - a, b, \dots, b, s_{j+1} + a, \dots);
 \end{aligned}$$

$\alpha^{+j,a}$ maps the elements s_j and s_{j+1} in $\mathbf{i}$ into $s_j + a$ and $s_{j+1} - a$ and $\alpha^{-j,a}$ maps s_j and s_{j+1} into $s_j - a$ and $s_{j+1} + a$.

We define the $(W(\alpha^{+i,a}(\mathbf{s}), n), W(\mathbf{s}, n))$ -bimodule $E_i^{(a)} 1_{\mathbf{s}}$ as the bimodule

$$\begin{aligned} E_i^{(a)} 1_{\mathbf{s}} &= 4^{-i} (\varphi_{i+1, S_{i+1}-a}(\mathbf{s})) \otimes_{W(\varphi_{i+1, S_{i+1}-a}(\mathbf{s}), n)} 5^{i+1} (\varphi_{i+1, S_{i+1}-a}(\mathbf{s})) \\ &\cong W(\varphi_{i+1, S_{i+1}-a}(\mathbf{s})^i, n) \otimes_{W(\varphi_{i+1, S_{i+1}-a}(\mathbf{s}), n)} W(\varphi_{i+1, S_{i+1}-a}(\mathbf{s}), n) \\ &\quad \otimes_{W(\mathbf{s}, n)} W(\mathbf{s}, n) \{-s_i \cdot a\} \end{aligned}$$

and the $(W(\alpha^{-i,a}(\mathbf{s}), n), W(\mathbf{s}, n))$ -bimodule $F_i^{(a)} 1_{\mathbf{s}}$ as the bimodule

$$\begin{aligned} F_i^{(a)} 1_{\mathbf{s}} &= 4^{-i+1} (\varphi_{i,a}(\mathbf{s})) \otimes_{W(\varphi_{i,a}(\mathbf{s}), n)} 5^i (\varphi_{i,a}(\mathbf{s})) \\ &\cong W(\varphi_{i,a}(\mathbf{s})^{i+1}, n) \otimes_{W(\varphi_{i,a}(\mathbf{s})^{i+1}, n)} W(\varphi_{i,a}(\mathbf{s}), n) \\ &\quad \otimes_{W(\mathbf{s}, n)} W(\mathbf{s}, n) \{-s_{i+1} \cdot a\}. \end{aligned}$$

By definition, these bimodules have elements diagrammatically depicted by

with n black strands intersecting the pictures in a manner similar to that described in Section 4.2 along with gray and black dots. We will refer to the gray strand connecting vertical strands as a step. When a step is not labelled, following earlier conventions we will assume that it has a label of 1.

Proposition 5.3. *The bimodules $E_i E_{i+1} 1_{\mathbf{s}}$ and $E_{i+1} E_i 1_{\mathbf{s}}$ are generated by diagrams of the form*

respectively with $k_1, k_2, k_3 \geq 0$.

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

Proof. Using the first two equalities of Proposition 5.1 and Corollary 5.2, any gray dot on the above diagram could be replaced by a sum of terms with gray dots at the top and bottom of strands of the diagram. For instance, a term with a gray dot in the middle of the vertical strand labelled s_{i+1} of the left diagram could be replaced by a sum of terms with gray dots at the top of that middle vertical strand and dots on the upper step of the diagram. A term with a dot on the upper step could be expressed as a sum of terms with dots on the top and bottom of the left-most vertical gray strand using a complete-elementary symmetric function relation.

Proposition 5.4. *The bimodules $E_i E_{i+1} E_i 1_{\mathbf{s}}$ and $E_{i+1} E_i E_{i+1} 1_{\mathbf{s}}$ are generated by elements of the form*

$$\begin{array}{c}
 \begin{array}{c}
 s_i + 2 \quad s_{i+1} - 1 \quad s_{i+2} - 1 \\
 \begin{array}{c}
 \text{Diagram 1: A vertical strand labeled } s_i \text{ with a gray dot at the bottom, connected to a strand labeled } s_{i+1} \text{ with a gray dot at the top, which is then connected to a strand labeled } s_{i+2} \text{ with a gray dot at the top.} \\
 s_i \quad k_1 \quad s_{i+1} \quad k_2 \quad k_3 \quad s_{i+2}
 \end{array}
 \end{array}
 ,
 \begin{array}{c}
 s_i + 1 \quad s_{i+1} + 1 \quad s_{i+2} - 2 \\
 \begin{array}{c}
 \text{Diagram 2: A vertical strand labeled } s_i \text{ with a gray dot at the bottom, connected to a strand labeled } s_{i+1} \text{ with a gray dot at the top, which is then connected to a strand labeled } s_{i+2} \text{ with a gray dot at the top.} \\
 s_i \quad k_1 \quad s_{i+1} \quad k_2 \quad k_3 \quad s_{i+2}
 \end{array}
 \end{array}
 \end{array} \quad (5.3)$$

respectively with $f, k_1, k_2, k_3 \geq 0$.

Proof. The proof of this is similar to the proof of Proposition 5.3. Note that in this case we can always write a term with a gray dot on a step as a linear combination of terms with gray dots at the top and bottom of the diagram and at the step of the ladder as indicated.

6. Bimodule homomorphisms

6.1. Morphisms $\partial_{(s_j - 1, 1)}^j$ and $\partial_{(1, s_j - 1)}^j$

We define the *derivation* maps $\partial_{(s_j - 1, 1)}^j$ and $\partial_{(1, s_j - 1)}^j$.

These are $(W(\mathbf{s}, n), W(\mathbf{s}, n))$ -bimodule maps

$$\partial_{(s_j - 1, 1)}^j : 4^j (\varphi_{j,1}(\mathbf{s})) \otimes_{W(\varphi_{j,1}(\mathbf{s}), n)} 5^j (\varphi_{j,1}(\mathbf{s})) \rightarrow W(\mathbf{s}, n),$$

$$\partial_{(1, s_j - 1)}^j : 4^j (\varphi_{j, s_j - 1}(\mathbf{s})) \otimes_{W(\varphi_{j, s_j - 1}(\mathbf{s}), n)} 5^j (\varphi_{j, s_j - 1}(\mathbf{s})) \rightarrow W(\mathbf{s}, n)$$

determined by

$$\begin{array}{c}
 \partial_{(s_j - 1, 1)}^j : \begin{array}{c} s_j \\ \text{Diagram: A vertical strand labeled } s_j \text{ with a gray dot at the bottom, connected to a strand labeled } s_j \text{ with a gray dot at the top, which is then connected to a strand labeled } s_j \text{ with a gray dot at the top.} \\ s_j - 1 \quad 1 \end{array} \xrightarrow{7} \begin{array}{c} s_j \\ \text{Diagram: A vertical strand labeled } s_j \text{ with a gray dot at the bottom, connected to a strand labeled } s_j \text{ with a gray dot at the top, which is then connected to a strand labeled } s_j \text{ with a gray dot at the top.} \\ s_j \end{array} , \\
 \partial_{(1, s_j - 1)}^j : \begin{array}{c} s_j \\ \text{Diagram: A vertical strand labeled } s_j \text{ with a gray dot at the bottom, connected to a strand labeled } s_j \text{ with a gray dot at the top, which is then connected to a strand labeled } s_j \text{ with a gray dot at the top.} \\ 1 \quad m \end{array} \xrightarrow{(-1)^{s_j - 1}} \begin{array}{c} s_j \\ \text{Diagram: A vertical strand labeled } s_j \text{ with a gray dot at the bottom, connected to a strand labeled } s_j \text{ with a gray dot at the top, which is then connected to a strand labeled } s_j \text{ with a gray dot at the top.} \\ s_j - 1 \end{array} ,
 \end{array} \quad (6.1)$$

where h_j is the j th complete symmetric function in terms of the elementary symmetric functions $e_1, \dots, e_j$.

The degrees of the morphisms $\partial_{(s_j-1,1)}^j$ and $\partial_{(1,s_j-1)}^j$ are both $1 - s_j$.

6.2. Morphisms $\partial_{(s_j-1,1)}^j$ and $\partial_{(1,s_j-1)}^j$

We define the *creation maps* $\partial_{(s_j-1,1)}^j$ and $\partial_{(1,s_j-1)}^j$.

There are $(W(\mathbf{s}, n), W(\mathbf{s}, n))$ -bimodule maps $\partial_{(s_j-1,1)}^j : W(\mathbf{s}, n) \rightarrow 4^j(\varphi_{j,1}(\mathbf{s})) \otimes_{W(\varphi_{j,1}(\mathbf{s}), n)} 5^j(\varphi_{j,1}(\mathbf{s}))$ and $\partial_{(1,s_j-1)}^j : W(\mathbf{s}, n) \rightarrow 4^j(\varphi_{j,s_j-1}(\mathbf{s})) \otimes_{W(\varphi_{j,s_j-1}(\mathbf{s}), n)} 5^j(\varphi_{j,s_j-1}(\mathbf{s}))$ determined by

$$\partial_{(s_j-1,1)}^j : \begin{array}{c} \text{Diagram: A vertical line with } s_j \text{ strands entering from the bottom and } s_j-1 \text{ strands exiting from the top, with a loop on the right strand.} \end{array} \xrightarrow{\mathbb{Z}} \begin{array}{c} \text{Diagram: A vertical line with } s_j \text{ strands entering from the bottom and } s_j-1 \text{ strands exiting from the top, with a loop on the right strand.} \end{array}, \quad \partial_{(1,s_j-1)}^j : \begin{array}{c} \text{Diagram: A vertical line with } s_j \text{ strands entering from the bottom and } s_j-1 \text{ strands exiting from the top, with a loop on the left strand.} \end{array} \xrightarrow{\mathbb{Z}} \begin{array}{c} \text{Diagram: A vertical line with } s_j \text{ strands entering from the bottom and } s_j-1 \text{ strands exiting from the top, with a loop on the left strand.} \end{array}. \quad (6.2)$$

The degrees of the morphisms $\partial_{(s_j-1,1)}^j$ and $\partial_{(1,s_j-1)}^j$ are $1 - s_j$.

6.3. Morphisms $\partial_{(s_j,1)}^j$ and $\partial_{(1,s_{j+1})}^j$

Let $\mathbf{s}_{(j)}$ be a sequence $(s_2, \dots, s_m)$ of m non-negative integers such that the j th integer s_j is one.

For a sequence $\mathbf{i}_1 \in \text{Seq}(\mathbf{s}_{(j)}, n)$ such that s_j and s_{j+1} are neighbors, and a sequence $\mathbf{i}_2 \in \text{Seq}(\mathbf{s}_{(j)}, n)$ such that s_j and s_{j+1} are neighbors (i.e., $\mathbf{i}_1 = (\dots, s_j, 1, \dots)$ and $\mathbf{i}_2 = (\dots, 1, s_{j+1}, \dots)$), there is a map

$$e(\mathbf{i}_1)(5^j(\mathbf{s}_{(j+1)}) \otimes_{W(\mathbf{s}_{(j+1)}, n)} 4^j(\mathbf{s}_{(j+1)}))e(\mathbf{i}_1) \rightarrow e(\mathbf{i}_1)W(\mathbf{s}_{(j+1)}, n)e(\mathbf{i}_1)$$

and a map

$$e(\mathbf{i}_2)(5^j(\mathbf{s}_{(j)}) \otimes_{W(\mathbf{s}_{(j)}, n)} 4^j(\mathbf{s}_{(j)}))e(\mathbf{i}_2) \rightarrow e(\mathbf{i}_2)W(\mathbf{s}_{(j)}, n)e(\mathbf{i}_2)$$

determined by

$$\begin{array}{c} \text{Diagram: A vertical line with } s_j \text{ strands entering from the bottom and } s_j+1 \text{ strands exiting from the top, with a loop on the right strand.} \end{array} \xrightarrow{\mathbb{Z}} \begin{array}{c} \text{Diagram: A vertical line with } s_j \text{ strands entering from the bottom and } s_j+1 \text{ strands exiting from the top, with a loop on the right strand.} \end{array}, \quad \begin{array}{c} \text{Diagram: A vertical line with } s_{j+1} \text{ strands entering from the bottom and } s_{j+1}+1 \text{ strands exiting from the top, with a loop on the left strand.} \end{array} \xrightarrow{\mathbb{Z}} \begin{array}{c} \text{Diagram: A vertical line with } s_{j+1} \text{ strands entering from the bottom and } s_{j+1}+1 \text{ strands exiting from the top, with a loop on the left strand.} \end{array}. \quad (6.3)$$

The degree of the first morphism is s_j and the degree of the second morphism is s_{j+1} .

This implies the morphisms

$$e(\mathbf{i}_1)(5^j(\mathbf{s}_{(j+1)}) \otimes_{W(\mathbf{s}_{(j+1)}, n)} 4^j(\mathbf{s}_{(j+1)}))e(\mathbf{i}_1) \rightarrow e(\mathbf{i}_1)W(\mathbf{s}_{(j+1)}, n)e(\mathbf{i}_1),$$

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

$$e(\mathbf{i}_2)(5^j(\mathbf{s}_{(j)}) \otimes_{W(\mathbf{s}_{(j)}, n)} 4^j(\mathbf{s}_{(j)}))e(\mathbf{i}_2) \rightarrow e(\mathbf{i}_2)W(\mathbf{s}_{(j)}, n)e(\mathbf{i}_2)$$

where $\mathbf{i} = (\dots, 1, \underset{k}{\underbrace{b, \dots, b}_{k}}, s_{j+1}, \dots)$ and $\mathbf{j} = (\dots, s, \underset{k}{\underbrace{b, \dots, b}_{k}}, b_1, \dots)$ for $0 \leq k \leq n$ are of degrees s and s_{j+1} , respectively.

As a diagrammatic presentation, the first map is determined by the following mapping:

$$(6.4)$$

where $k_1 + k_2 = k$. The second map is determined by

$$(6.5)$$

where $k_1 + k_2 = k$. Note that the diagram in the image of this map can be simplified using Relation (4.27).

We define the bimodule morphisms $U_{(s_j, 1)}^j$ and $U_{(1, s_{j+1})}^j$, called *lollipop* (unzip) maps,

$$U_{(s_j, 1)}^j : 5^j(\mathbf{s}_{(j+1)}) \otimes_{W(\mathbf{s}_{(j+1)}, n)} 4^j(\mathbf{s}_{(j+1)}) \rightarrow W(\mathbf{s}_{(j+1)}, n)$$

and

$$U_{(1, s_{j+1})}^j : 5^j(\mathbf{s}_{(j)}) \otimes_{W(\mathbf{s}_{(j)}, n)} 4^j(\mathbf{s}_{(j)}) \rightarrow W(\mathbf{s}_{(j)}, n)$$

determined by the morphisms in (6.3).

Moreover, composing the morphism $U_{(s_j, 1)}^j$ and $\partial_{(1, s_{j+1}-1)}^{j+1}$ (resp. $U_{(1, s_j)}^j$ and $\partial_{(s_j-1, 1)}^j$) using (4.27) we define the following morphism $U_{\mathbf{s}, l}^j$ (resp. $U_{\mathbf{s}, r}^j$)

$$U_{\mathbf{s}, l}^j : F_j E_j 1_{\mathbf{s}} \rightarrow W(\mathbf{s}, n),$$

$$U_{\mathbf{s}, r}^j : E_j F_j 1_{\mathbf{s}} \rightarrow W(\mathbf{s}, n).$$

By definition, the degree of the morphism $U_{\mathbf{s}, l}^j$ is $s_j - s_{j+1} + 1$ and the degree of the morphism $U_{\mathbf{s}, r}^j$ is $-s_j + s_{j+1} + 1$.

As a diagrammatic presentation, the morphism $U_{\mathbf{s}, l}^j$ is determined by the following mappings:

$$\begin{array}{c}
 \begin{array}{ccc}
 \begin{array}{c} S_j \\ \parallel \\ S_j \end{array} & \begin{array}{c} S_{j+1} \\ \parallel \\ S_{j+1} \end{array} \\
 \begin{array}{c} 1 \\ \parallel \\ 1 \end{array} & \begin{array}{c} \delta \\ \bullet \end{array} \\
 \begin{array}{c} S_j \\ \parallel \\ S_j \end{array} & \begin{array}{c} S_{j+1} \\ \parallel \\ S_{j+1} \end{array}
 \end{array} \xrightarrow{U^j_{(S_j, 1)}} \begin{array}{ccc}
 \begin{array}{c} S_j \\ \parallel \\ S_j \end{array} & \begin{array}{c} S_{j+1} \\ \parallel \\ S_{j+1} \end{array} \\
 \begin{array}{c} \delta \\ \bullet \end{array} & \begin{array}{c} -1 \end{array} \\
 \begin{array}{c} S_j \\ \parallel \\ S_j \end{array} & \begin{array}{c} S_{j+1} \\ \parallel \\ S_{j+1} \end{array}
 \end{array}
 \end{array}
 \end{array}
 \xrightarrow{(4.27)} \sum_{d=0}^k (-1)^{k-d} \begin{array}{ccc}
 \begin{array}{c} S_j \\ \parallel \\ S_j \end{array} & \begin{array}{c} S_{j+1} \\ \parallel \\ S_{j+1} \end{array} \\
 \begin{array}{c} e_d \\ \bullet \end{array} & \begin{array}{c} k-d+\delta \\ \bullet \end{array} \\
 \begin{array}{c} S_j \\ \parallel \\ S_j \end{array} & \begin{array}{c} S_{j+1} \\ \parallel \\ S_{j+1} \end{array}
 \end{array}
 \end{array}
 \xrightarrow{\partial^{j+1}_{(1,S)} \xrightarrow{-1}} \sum_{d=0}^k (-1)^{S_{j+1}-1+k-d} \begin{array}{ccc}
 \begin{array}{c} S_j \\ \parallel \\ S_j \end{array} & \begin{array}{c} S_{j+1} \\ \parallel \\ S_{j+1} \end{array} \\
 \begin{array}{c} e_d \\ \bullet \end{array} & \begin{array}{c} h_{k-d-S_{j+1}+\delta+1} \\ \bullet \end{array} \\
 \begin{array}{c} S_j \\ \parallel \\ S_j \end{array} & \begin{array}{c} S_{j+1} \\ \parallel \\ S_{j+1} \end{array}
 \end{array}
 \end{array}
 .$$

The morphism $U^j_{\mathbf{s},r}$ is determined by the following mappings:

$$\begin{array}{c}
 \begin{array}{ccc}
 \begin{array}{c} S_j \\ \parallel \\ S_j \end{array} & \begin{array}{c} S_{j+1} \\ \parallel \\ S_{j+1} \end{array} \\
 \begin{array}{c} S_j - 1 \\ \parallel \\ S_j - 1 \end{array} & \begin{array}{c} \delta \\ \bullet \end{array} \\

 \end{array}
 .$$

6.4. Morphisms $\zeta_{\mathbf{s},r}^j$ and $\zeta_{\mathbf{s},l}^j$

First we define the zip maps $\zeta_{(S_j, 1)}^j$ and $\zeta_{(1, S_{j+1})}^j$. Recall the sequence $\mathbf{s}_j$ defined in Section 6.3.

For $\mathbf{i}_1 = (\dots, s, b, \dots, b_1, \dots) \in \text{Seq}(\mathbf{s}_j, n)$ and $\mathbf{i}_2 = (\dots, 1, b, \dots, b_1, \dots, s_{j+1}, \dots) \in \text{Seq}(\mathbf{s}_{j+1}, n)$, there is a map

$$\zeta_{(S_j, 1)}^j : W(\mathbf{s}_{j+1}, n) \rightarrow 5^j(\mathbf{s}_{j+1}) \otimes_{W(\mathbf{s}_{j+1}, n)} 4^j(\mathbf{s}_{j+1})$$

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

of degree $\mathfrak{s}_j$ determined by

$$\zeta_{(\mathfrak{s}_j, 1)}^j : \begin{array}{c} \text{Diagram with } s_j \text{ strands, } k \text{ strands, and } 1 \text{ strand} \end{array} \xrightarrow{\gamma \rightarrow (-1)^{k-1}} \begin{array}{c} \text{Diagram with } s_j \text{ strands, } k \text{ strands, and } 1 \text{ strand} \end{array} + \sum_{\substack{d_1+d_2+d_3 \\ =s_j-k}} (-1)^{s_j+d_1+d_2} \begin{array}{c} \text{Diagram with } s_j \text{ strands, } k \text{ strands, and } 1 \text{ strand} \end{array}, \quad (6.6)$$

and a map

$$\zeta_{(1, s_{j+1})}^j : W(\mathfrak{s}_{(j)}, n) \rightarrow 5^j(\mathfrak{s}_{(j)}) \otimes_{W(\mathfrak{s}_{(j)}, n)} 4^j(\mathfrak{s}_{(j)})$$

of degree $\mathfrak{s}_{j+1}$ determined by

$$\zeta_{(1, s_{j+1})}^j : \begin{array}{c} \text{Diagram with } 1 \text{ strand, } k \text{ strands, and } s_{j+1} \text{ strands} \end{array} \xrightarrow{\gamma \rightarrow (-1)^{\mathfrak{s}_{j+1}}} \begin{array}{c} \text{Diagram with } 1 \text{ strand, } k \text{ strands, and } s_{j+1} \text{ strands} \end{array} + \sum_{\substack{d_1+d_2+d_3 \\ =s_{j+1}-k}} (-1)^{s_{j+1}+d_3+k} \begin{array}{c} \text{Diagram with } 1 \text{ strand, } k \text{ strands, and } s_{j+1} \text{ strands} \end{array}. \quad (6.7)$$

Note that these maps are determined by the image of a thick black strand because by Lemma 2.2 the identity on k strands factors through the thickness k thick strand. For example,

$$\begin{array}{c} \text{Diagram with } 1 \text{ strand, } 1 \text{ strand, } 1 \text{ strand, } 1 \text{ strand, } 1 \text{ strand} \end{array} = \sum_{\underline{b} \in \text{Sq}(k)} (-1)^{|\underline{b}|} \begin{array}{c} \text{Diagram with } e_- \text{ and } x_-^b \end{array} \xrightarrow{\gamma \rightarrow -} \sum_{\underline{b} \in \text{Sq}(k)} (-1)^{|\underline{b}|} \begin{array}{c} \text{Diagram with } e_- \text{ and } x_-^b \end{array}$$

which can be generalized to thicker gray strands in the obvious way. Furthermore, this determines the image of any element $x \in \text{NH}_k$ by placing x at the top or

bottom of the diagram on the right. This is well-defined by the following Lemmas 6.1 and 6.2. Note that the proofs of each of the following two lemmas do not use maneuvers using the gray strands. However, the presence of the gray strands complicates the proof (since both diagrams would be zero without them).

Lemma 6.1. *For arbitrary thickness of gray strands a and b , the following identity holds:*

$$\sum_{\underline{\iota} \in \text{Sq}(k)} X_{\underline{\iota}} (-1)^{|\underline{\iota}|} \left(\text{Diagram 1} \right) = \sum_{\underline{\iota} \in \text{Sq}(k)} X_{\underline{\iota}} (-1)^{|\underline{\iota}|} \left(\text{Diagram 2} \right). \quad (6.8)$$

Proof. Recall from Remark 2.3 that the sets $\{e_{\underline{\iota}} \mid \underline{\iota} \in \text{Sq}(k)\}$ and $\{x_{\underline{\iota}}^b \mid \underline{\iota} \in \text{Sq}(k)\}$ both form bases for the polynomial ring as a free module over the ring of symmetric functions Λ_k . In particular, if we multiply any element in either of these bases by x_i , it is possible to rewrite the resulting polynomial as some Λ_k -combination of basis elements. The first part of Lemma 2.2 shows that multiplying by a black dot on the i th strand on top of the sum

$$\sum_{\underline{\iota} \in \text{Sq}(k)} X_{\underline{\iota}} (-1)^{|\underline{\iota}|} \left(\text{Diagram 3} \right)$$

gives the same result as multiplying by a black dot on the bottom of the sum. Using (2.5), all of the symmetric functions produced in rewriting either basis can be put on the thick k labelled strand. Hence, if we rewrite each diagram on the left-hand side of (6.8) in the basis $\{e_{\underline{\iota}} \mid \underline{\iota} \in \text{Sq}(k)\}$ and push the symmetric functions onto the thick k -labelled strand, these symmetric functions can be pushed to the bottom of the diagram using (2.5). By Lemma 2.2, this gives the same result as rewriting each diagram on the right hand side of (6.8) using the basis $\{x_{\underline{\iota}}^b \mid \underline{\iota} \in \text{Sq}(k)\}$ establishing the lemma.

Lemma 6.2. *For arbitrary thickness of gray strands a and b , the following identity holds:*

$$\sum_{\vec{b} \in \text{Sq}(k)} (-1)^{|\vec{b}|} \left(\text{Diagram 1} \right) = \sum_{\vec{b} \in \text{Sq}(k)} (-1)^{|\vec{b}|} \left(\text{Diagram 2} \right). \quad (6.9)$$

Proof. Suppose we act by a black crossing on the i th and $(i+1)$ -st black strands. It is helpful to note that the elementary symmetric function $e_i^{(j)}$ on the first i black strands in the standard elementary monomial e_- can be written as

$$e_i^{(j)} = e_i^{(j-1)} + x_i e_{i-1}^{(j-1)}. \quad (6.10)$$

Since the $(i, i+1)$ black crossing commutes with $e_a^{(a)}$ for $a \neq i$, the left-hand side of (6.9) can be simplified using (6.10), where the first term involving $e_i^{(j-1)}$ vanishes as a result of the definition of the splitter and (1) in the definition of the nilHecke algebra ($\partial_i^2 = 0$). The remaining term can be further simplified using (4) in the definition of the nilHecke algebra ($\partial_i x_i = x_{i+1} \partial_i + 1$) and again noting that the term where the black crossing does not resolve, again vanishes by the definition of the splitter and (1) in the definition of the nilHecke algebra. Hence, the left-hand side reduces to

$$\sum_{\vec{b} \in \text{Sq}(k)} (-1)^{|\vec{b}|} \left(\text{Diagram 3} \right) \quad (6.11)$$

where

$$e_-^o = e_1^{(1)} \cdots e_{i-1}^{(i-1)} e_{i-1}^{(i-1)} e_{i+1}^{(i+1)} \cdots e_k^{(k)},$$

so that there are no elementary symmetric functions in the first i variables.

For the right-hand side of (6.9), it is helpful to break the summation into two pieces depending on if $b_{i+1} < b_i + 1$ (so that $b_i < b_{i+1}$) or $b_i + 1 < b_{i+1}$ (so that

$b_i > b_{i+1}$.) The case when $b_i = b_{i+1}$ vanishes. Then using Lemma 2.1 we can simplify

$$\begin{array}{c} \text{Diagram: Crossing with dots at } b_i \text{ and } b_{i+1} \end{array} = \begin{cases} \begin{array}{c} \text{Diagram: Crossing with dots at } b_i + A \text{ and } b_i + B \\ \text{if } b_i < b_{i+1}; \end{array} \\ \begin{array}{c} \text{Diagram: Crossing with dots at } b_{i+1} + A \text{ and } b_{i+1} + B \\ \text{if } b_i > b_{i+1}. \end{array} \end{cases}$$

where $b_i := i - \cdot_i$ and $b_{i+1} := i + 1 - \cdot_{i+1}$. Combining this fact with (6.10), one can show that the right-hand side of (6.9) is equal to the sum (6.11), completing the proof.

Proposition 6.3. The assignments $\zeta_{(a,1)}^j$ and $\zeta_{(1,a)}^j$ define bimodule homomorphisms.

Proof. Here we show that $\zeta_{(1,a)}^j$ is a bimodule morphism. The proof for $\zeta_{(a,1)}^j$ is similar.

• Red dot action: First, we check the equation

$$\begin{array}{c} \text{Diagram: Crossing with red dot at } b_i \end{array} + \begin{array}{c} \text{Diagram: Crossing with red dot at } b_{i+1} \end{array} = \begin{array}{c} \text{Diagram: Crossing with red dot at } b_i \end{array} + \begin{array}{c} \text{Diagram: Crossing with red dot at } b_{i+1} \end{array} \quad (6.12)$$

This follows using Relations (4.22), (4.23), and (4.24) and then by [KLMS12, Prop. 2.4.1].

Next, we check the gray dot action on the thick gray strand. For $1 \leq i \leq a$, we check the equation

$$\begin{array}{c} \text{Diagram: Crossing with gray dot at } b_i \end{array} + \begin{array}{c} \text{Diagram: Crossing with gray dot at } b_{i+1} \end{array} = \begin{array}{c} \text{Diagram: Crossing with gray dot at } b_i \end{array} + \begin{array}{c} \text{Diagram: Crossing with gray dot at } b_{i+1} \end{array} \quad (6.13)$$

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

This relation follows by sliding the elementary symmetric function e_i on the left-hand side of this equation and using (6.12).

- Thin red-black crossing: We check the equation

$$\begin{aligned}
 & \sum_{\underline{i} \in \text{Sq}(k)} (-1)^{|\underline{i}|} \text{Diagram 1} + \sum_{\substack{d_1+d_2+d_3=a-k}} (-1)^{d_3+k} \text{Diagram 2} \\
 &= \sum_{\underline{i} \in \text{Sq}(k-1)} (-1)^{|\underline{i}|} \text{Diagram 3} + \sum_{\substack{d_1+d_2+d_3=a-k+1}} (-1)^{d_3+k-1} \text{Diagram 4}
 \end{aligned} \tag{6.14}$$

The diagrams are as follows:

- Diagram 1:** A braid with a strands. The top $k-1$ strands are grouped by a box labeled e_- . The bottom 1 strand is grouped by a box labeled x_-^b . The strands are labeled 1 and a at the bottom.
- Diagram 2:** A braid with a strands. The top 1 strand is grouped by a box labeled h_{d_1} . The bottom a strands are grouped by a box labeled e_{d_3} . The strands are labeled 1 and a at the bottom.
- Diagram 3:** A braid with a strands. The top $k-2$ strands are grouped by a box labeled e_- . The bottom 1 strand is grouped by a box labeled x_-^b . The strands are labeled 1 and a at the bottom.
- Diagram 4:** A braid with a strands. The top 1 strand is grouped by a box labeled h_{d_1} . The bottom a strands are grouped by a box labeled e_{d_3} . The strands are labeled 1 and a at the bottom.

Using (4.28), (2.13), and (4.22), and Lemmas 2.4 and 2.2, the first summation on the left-hand side of (6.14) simplifies

$$\sum_{\underline{i} \in \text{Sq}(k)} (-1)^{|\underline{i}|} \text{Diagram 1}$$

The diagram is as follows:

- Diagram 1:** A braid with a strands. The top $k-1$ strands are grouped by a box labeled e_- . The bottom 1 strand is grouped by a box labeled x_-^b . The strands are labeled 1 and a at the bottom.

$$= \sum_{d=0}^{a-k+1} (-1)^{d+k-1} \text{ (diagram with box } h_{a-k+1-d} \text{)} + \sum_{\underline{b} \in \text{Sq}(k)} (-1)^{|\underline{b}|} \text{ (diagram with boxes } e_-, C_{k-1}, D_k, \underline{x}^b \text{)}.$$

By Lemmas 2.6 and 2.7 and standard properties of complete symmetric functions, this is equal to

$$\sum_{\substack{d_1+d_3 \\ =a-k+1}} \sum_{d=0}^{d_1+d_3} (-1)^{d_3+k-1} \text{ (diagram with box } h_{d_1-d} \text{)} + \sum_{\underline{b} \in \text{Sq}(k-1)} (-1)^{|\underline{b}|} \text{ (diagram with boxes } e_-, C_{k-1}, D_{k-1}, \underline{x}^b \text{)} \cdot (6.15)$$

On the other hand, we have

$$\begin{aligned} & \sum_{\substack{d_1+d_2+d_3 \\ =a-k}} (-1)^{d_3+k} \text{ (diagram with box } h_{d_1} \text{)} \\ &= \sum_{d_3=0}^{a-k} (-1)^{d_3+k} \sum_{d_1=1}^{a-k-d_3+1} \sum_{d=1}^{d_1} \text{ (diagram with box } h_{d_1-d} \text{)} \\ &\quad - \sum_{\substack{d_1+d_2+d_3 \\ =a-k}} (-1)^{d_3+k} \text{ (diagram with box } h_{d_1} \text{)} \end{aligned}$$

Therefore, we find that the left-hand side of (6.14) (the above summation and the summation (6.15)) is equal to the right-hand side.

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

- Thick red-black crossing: the invariance under the thick gray line with a thin black strand can be established by a similar direct computation for which it is helpful to note the thick calculus identity

$$\begin{array}{c} | \\ 1 \end{array} \quad \begin{array}{c} || \\ k-1 \end{array} = \sum_{d=0}^{k-1} (-1)^d \begin{array}{c} \text{diagram with } k-1-d \text{ and } \Theta_d \end{array}$$

together with (4.26).

Composing the morphisms $l_{(1, S_{j+1}-1)}^{j+1}$ and $\zeta_{(S_j, 1)}^j$ (resp. $l_{(S_j-1, 1)}^j$ and $\zeta_{(1, S_{j+1})}^j$), we define the following bimodule homomorphisms

$$\begin{aligned} \zeta_{\mathbf{s}, r}^j &: W(\mathbf{s}, n) \rightarrow \overline{F} E_j 1_{\mathbf{s}}, \\ \zeta_{\mathbf{s}, l}^j &: W(\mathbf{s}, n) \rightarrow \overline{E}_j F_j 1_{\mathbf{s}}. \end{aligned}$$

By definition, the degree of the morphism $\zeta_{\mathbf{s}, r}^j$ is $s_j - s_{j+1} + 1$ and the degree of the morphism $\zeta_{\mathbf{s}, l}^j$ is $-s_j + s_{j+1} + 1$.

As a diagrammatic presentation, the morphism $\zeta_{\mathbf{s}, r}^j$ is determined by the following mapping:

$$\begin{aligned} \zeta_{\mathbf{s}, r}^j : & \begin{array}{c} || \\ s_j \end{array} \quad \begin{array}{c} || \\ k \end{array} \quad \begin{array}{c} || \\ s_{j+1} \end{array} \xrightarrow{l_{(1, S_{j+1}-1)}^{j+1}} \begin{array}{c} || \\ s_j \end{array} \quad \begin{array}{c} || \\ k \end{array} \quad \begin{array}{c} \text{diagram with } s_{j+1}-1 \end{array} \\ & \xrightarrow{\zeta_{(S_j, 1)}^j} \begin{array}{c} \text{diagram with } s_j, k, s_{j+1} \end{array} \\ & + \sum_{\substack{d_1+d_2+d_3 \\ = s_j - k}} (-1)^{s_j + d_1 + d_2} \begin{array}{c} \text{diagram with } s_j, k, s_{j+1} \end{array} \end{aligned} \quad (6.16)$$

The morphism $\zeta_{\mathbf{s},l}^j$ is determined by the following mappings:

$$\begin{aligned}
 \zeta_{\mathbf{s},l}^j : & \quad \begin{array}{c} \text{Diagram 1} \\ \text{Diagram 2} \end{array} \xrightarrow{l_{(s_j \rightarrow 1,1)}^j} \begin{array}{c} \text{Diagram 3} \\ \text{Diagram 4} \end{array} \\
 & \quad \zeta_{(1, \mathbf{s}_{j+1})}^{j+1} (-1)^{s_{j+1}} \begin{array}{c} \text{Diagram 5} \end{array} \\
 & \quad + \sum_{\substack{d_1+d_2+d_3 \\ = s_{j+1}-k}} (-1)^{s_{j+1}+d_3+k} \begin{array}{c} \text{Diagram 6} \end{array} .
 \end{aligned} \tag{6.17}$$

6.5. Morphisms κ_j

In this subsection, we will prove that for $|i - j| = 1$ there are bimodule homomorphisms

$$\kappa_{i,j} : E_i E_j 1_{\mathbf{s}} \rightarrow E_j E_i 1_{\mathbf{s}}.$$

When i and j satisfy other conditions, we will also have maps $E E_j 1_{\mathbf{s}} \rightarrow E_j E_i 1_{\mathbf{s}}$. When $|i - j| \neq 1$, it is easier to prove these are bimodule homomorphisms, so we consider only the difficult cases in this subsection.

It is easier to define $\kappa_{i,j}$ when $j = i + 1$:

$$\kappa_{i,i+1} : \left(\begin{array}{c} \text{Diagram 1} \\ \text{Diagram 2} \end{array} \xrightarrow{7 \rightarrow} \begin{array}{c} \text{Diagram 3} \\ \text{Diagram 4} \end{array} \right) . \tag{6.18}$$

The other case is more involved since there is an extra set of generators given by a thick black strand going through the middle vertical gray line. The definition of $\kappa_{i+1,i}$ breaks down into three cases depending upon the thickness of this black strand:

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

$$\left(\begin{array}{c} \begin{array}{c} S_i + 1 \quad S_{i+1} \quad S_{i+2} - 1 \\ \text{Diagram 1} \\ S_i \quad k_1 \quad S_{i+1} \quad k_2 S_{i+2} \end{array} \\ \mathbb{Z} \rightarrow \begin{array}{c} \begin{array}{c} S_i + 1 \quad S_{i+1} \quad S_{i+2} - 1 \\ \text{Diagram 2} \\ S_i \quad k_1 \quad S_{i+1} \quad k_2 S_{i+2} \end{array} - \begin{array}{c} S_i + 1 \quad S_{i+1} \quad S_{i+2} - 1 \\ \text{Diagram 3} \\ S_i \quad k_1 \quad S_{i+1} \quad k_2 S_{i+2} \end{array} \end{array} \right), \quad (6.19)$$

$$\left(\begin{array}{c} \begin{array}{c} S_i + 1 \quad S_{i+1} \quad S_{i+2} - 1 \\ \text{Diagram 4} \\ S_i \quad k_1 \quad S_{i+1} \quad k_2 S_{i+2} \end{array} \\ \mathbb{Z} \rightarrow \begin{array}{c} \begin{array}{c} S_i + 1 \quad S_{i+1} \quad S_{i+2} - 1 \\ \text{Diagram 5} \\ S_i \quad k_1 \quad S_{i+1} \quad k_2 S_{i+2} \end{array} - \begin{array}{c} S_i + 1 \quad S_{i+1} \quad S_{i+2} - 1 \\ \text{Diagram 6} \\ S_i \quad k_1 \quad S_{i+1} \quad k_2 S_{i+2} \end{array} \end{array} \right), \quad (6.20)$$

$$\left(\begin{array}{c} \begin{array}{c} S_i + 1 \quad S_{i+1} \quad S_{i+2} - 1 \\ \text{Diagram 7} \\ S_i \quad k_1 \quad S_{i+1} \quad k_2 \quad k_3 S_{i+2} \end{array} \\ \mathbb{Z} \rightarrow \begin{array}{c} \begin{array}{c} S_i + 1 \quad S_{i+1} \quad S_{i+2} - 1 \\ \text{Diagram 8} \\ S_i \quad k_1 \quad S_{i+1} \quad k_2 \quad k_3 S_{i+2} \end{array} \end{array} \right). \quad (6.21)$$

When $k = 0$, (6.19) is a bimodule homomorphism by Soergel calculus. In order to check that all of the $\mathfrak{N}_{i,j}$ are in fact bimodule homomorphisms, we must compare how $W(\mathbf{s}, n)$ acts on the top and bottom of the diagrams for these generators.

- Black dot action: The compatibility of the actions of black dots with respect to these maps follows from the black dot sliding relation (4.23).
- Red dot action: The compatibility of the actions of gray dots with respect to these maps follows from standard manipulations of elementary symmetric functions.
- The action of red-black crossings: This proof follows by induction on k . A detailed proof appears in the arXiv version of this paper.

7. Categorical symmetric Howe duality

In this section, we define a 2-representation of the 2-category U using ladder bimodules of $W(\mathbf{s}, n)$. The proof that the assignments defined here give rise to a 2-representation is checked in the next section where it is shown that all relations of the 2-morphisms hold.

7.1. The 2-category $\mathbf{Bim}(n)$

Here we define the target 2-category for our 2-representation of the 2-category U .

Definition 7.1. Define a graded additive 2-category $\mathbf{Bim}(n)$ as the idempotent completion inside the 2-category of graded bimodules with:

- Objects consisting of sequences $\mathbf{s} = (s_1, \dots, s_n)$ such that each $s_i \in \mathbb{Z}_{\geq 0}$ and a symbol $*$.
- The 1-morphisms are generated under tensor product of bimodules by identity bimodules $1_{\mathbf{s}} = W(\mathbf{s}, n)$ and

$$E_i^{(a)} 1_{\mathbf{s}} = \cdots \begin{array}{c} \text{Diagram showing a crossing between strands } s_i \text{ and } s_{i+1} \text{ with grading shifts } s_i + a \text{ and } s_{i+1} - a. \end{array} \cdots$$

$$F_i^{(a)} 1_{\mathbf{s}} = \cdots \begin{array}{c} \text{Diagram showing a crossing between strands } s_i \text{ and } s_{i+1} \text{ with grading shifts } s_i - a \text{ and } s_{i+1} + a. \end{array} \cdots$$

together with their grading shifts. For the symbol $*$, the set of 1-morphisms is the empty set:

$$\text{Hom}(*, *) = \text{Hom}(*, \mathbf{s}) = \text{Hom}(\mathbf{s}, *) = \emptyset.$$

Hence, an arbitrary 1-morphism is a summand of a direct sum of tensor products of these bimodules and their shifts.

- The 2-morphisms of $\mathbf{Bim}(n)$ are the degree-preserving bimodule homomorphisms between these bimodules.

7.2. The 2-representation

There is a 2-representation

$$\Psi: U \rightarrow \mathbf{Bim}(n), \quad (7.1)$$

$$\mathbf{s} \mapsto \begin{cases} \mathbf{s} & \text{if } \mathbf{s} \in \mathbb{Z}_{\geq 0}^m, \\ * & \text{if } \mathbf{s} \notin \mathbb{Z}_{\geq 0}^m. \end{cases} \quad (7.2)$$

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

By definition we have $\text{Hom}(*, *) = \text{Hom}(*, \mathbf{s}) = \text{Hom}(\mathbf{s}, *) = 0$. Therefore, when $\mathbf{s} \notin \mathbb{Z}_{\geq 0}^m$, the 1-morphisms and 2-morphisms get mapped to zero. When $\mathbf{s} \in \mathbb{Z}_{\geq 0}^m$, we define

$$\begin{aligned} E_i 1_{\mathbf{s}} &\mapsto E_i 1_{\mathbf{s}}, \\ F_i 1_{\mathbf{s}} &\mapsto F_i 1_{\mathbf{s}}. \end{aligned}$$

with 2-morphisms defined by the following assignments

$$\begin{aligned} \Psi \left(\begin{array}{c} \uparrow \\ \bullet \\ \mathbf{s} \\ \downarrow \\ i \end{array} \right) &: E_i 1_{\mathbf{s}} \rightarrow E_i 1_{\mathbf{s}} \\ &\left(\begin{array}{c} s_i + 1 \quad s_{i+1} - 1 \\ \text{[Diagram 1]} \quad \mathbb{Z} \quad \text{[Diagram 2]} \\ s_i \quad k \quad s_{i+1} \end{array} \right), \\ \Psi \left(\begin{array}{c} \downarrow \\ \bullet \\ \mathbf{s} \\ \uparrow \\ i \end{array} \right) &: F_i 1_{\mathbf{s}} \rightarrow F_i 1_{\mathbf{s}} \\ &\left(\begin{array}{c} s_i - 1 \quad s_{i+1} + 1 \\ \text{[Diagram 3]} \quad \mathbb{Z} \quad \text{[Diagram 4]} \\ s_i \quad k \quad s_{i+1} \end{array} \right), \\ \Psi \left(\begin{array}{c} \curvearrowright \\ \mathbf{s} \\ \downarrow \\ i \end{array} \right) &: E_i F_i 1_{\mathbf{s}} \xrightarrow{\psi_{\mathbf{s},r}^i} 1_{\mathbf{s}} \\ &\left(\begin{array}{c} s_i \quad s_{i+1} \quad s_i \quad s_{i+1} \\ \text{[Diagram 5]} \quad \mathbb{Z} \quad \text{[Diagram 6]} \\ s_i \quad k \quad s_{i+1} \end{array} \right) \\ &\quad \mathbb{Z} \sum_{d=0}^k (-1)^{k-d} \text{[Diagram 7]}, \end{aligned}$$

$$\Psi \left(\begin{array}{c} \text{Diagram 6} \\ i \quad ji \end{array} \right) : E_i E_j 1_{\mathbf{s}} \rightarrow E_j E_i 1_{\mathbf{s}}$$

$$\left(\begin{array}{c} \begin{array}{c} s_j + 1 \\ \parallel \\ s_j \end{array} \quad \begin{array}{c} s_{j+1} - 1 \\ \parallel \\ k_1 \end{array} \quad \begin{array}{c} s_{j+1} \\ \parallel \\ s_{j+1} \end{array} \quad \dots \quad \begin{array}{c} s_i + 1 \\ \parallel \\ s_i \end{array} \quad \begin{array}{c} s_{i+1} - 1 \\ \parallel \\ k_2 \end{array} \quad \begin{array}{c} s_{i+1} \\ \parallel \\ s_{i+1} \end{array} \\ \text{Diagram 7} \end{array} \right) \xrightarrow{\mathbb{Z}} \left(\begin{array}{c} \begin{array}{c} s_j + 1 \\ \parallel \\ s_j \end{array} \quad \begin{array}{c} s_{j+1} - 1 \\ \parallel \\ k_1 \end{array} \quad \begin{array}{c} s_{j+1} \\ \parallel \\ s_{j+1} \end{array} \quad \dots \quad \begin{array}{c} s_i + 1 \\ \parallel \\ s_i \end{array} \quad \begin{array}{c} s_{i+1} - 1 \\ \parallel \\ k_2 \end{array} \quad \begin{array}{c} s_{i+1} \\ \parallel \\ s_{i+1} \end{array} \\ \text{Diagram 8} \end{array} \right),$$

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

$$\Psi \left(\begin{array}{c} \text{crossing} \\ \text{with arrows} \\ \text{bottom labels } i, i \end{array} \right) : E_i E_i 1_{\mathbf{s}} \rightarrow E_i E_i 1_{\mathbf{s}}$$

$$\left(\begin{array}{c} \text{diagram with strands } S_i, k, S_{i+1} \text{ and labels } S_i+2, S_{i+1}-2, y, x \\ \xrightarrow{7} \\ \text{diagram with strands } S_i, k, S_{i+1} \text{ and labels } S_i+2, S_{i+1}-2, \partial_1(x_1^x x_2^y) \end{array} \right).$$

The formula for $\partial(x_1^x x_2^y)$ above is given by $\partial(x_1^x x_2^y) = (x_1^x x_2^y - x_2^x x_1^y)/(x_2 - x_1)$.

The following fact could sometimes be used to simplify a calculation.

Remark 7.2. While the map associated to the crossing with the bottom boundary points labelled $i+1$ and i seems arbitrary, note that for $s_i \geq 1$ and $k > 1$ there is an equality

$$\begin{array}{c} \text{diagram 1} \\ \text{diagram 2} \end{array} = (-1)^{k-2} \begin{array}{c} \text{diagram 3} \\ \text{diagram 4} \end{array}.$$

7.3. Formulas implied by definition of Ψ

In this section, we compute the bimodule homomorphisms associated to non-generating 2-morphisms in U . These formulas will be useful for verifying the defining relations of U in Section 8.

Sideways crossings (same labelling). The crossing formulas above, along with cup and cap maps, imply the following formulas.

Lemma 7.3. *The ii-sideways crossings are given by the following formulas:*

$$\Psi \left(\begin{array}{c} \text{crossing} \\ \text{with arrows} \\ \text{bottom labels } i, i \end{array} \right) : \begin{array}{c} \text{diagram with strands } S_i, k, S_{i+1} \\ \text{and labels } S_i, k, S_{i+1} \end{array}$$

$$7 \rightarrow \sum_{f=0}^k \sum_{\substack{d_1+d_2+d_3=j \\ d_3 \geq 1}} (-1)^f \text{ (diagram) } \quad (7.3)$$

$$+ \sum_{\substack{d_1+d_2+d_3=j \\ d_3 \geq 1}} \sum_{f=0}^k \sum_{g=k-\delta}^k (-1)^{j+d_1+d_2+s_i+g} \text{ (diagram) } ,$$

$$\Psi \left(\begin{array}{c} \text{diagram} \\ \text{diagram} \end{array} \right) : \sum_{g=0}^k \sum_{\substack{d_1+d_2+d_3=j \\ d_2 \geq 1}} (-1)^g \text{ (diagram) } \quad (7.4)$$

$$+ \sum_{\substack{d_1+d_2+d_3=j \\ d_2 \geq 1}} \sum_{f=0}^k \sum_{g=k+f-\delta}^k (-1)^{d_3+g+k} \text{ (diagram) } .$$

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

Proof. These follow by direct computations using the definitions from the previous subsection.

Sideways crossings (different labelling).

Lemma 7.4. For $|i - j| > 1$ we have the following assignments by Ψ for sideways crossings:

$$\begin{aligned}
 & \Psi \left(\begin{array}{c} \text{sideways crossing with } s \text{ on the right} \\ \text{strand } i \text{ from bottom-left to top-right} \\ \text{strand } ji \text{ from top-left to bottom-right} \end{array} \right) \\
 & \quad \xrightarrow{7} \left(\begin{array}{c} s_j + 1 \quad s_{j+1} - 1 \quad \dots \quad s_j - 1 \quad s_{j+1} + 1 \quad s_i + 1 \quad s_{i+1} - 1 \quad s_j - 1 \quad s_{j+1} + 1 \\ \text{diagram} \end{array} \right) \xrightarrow{\mathbb{Z}} \left(\begin{array}{c} s_i + 1 \quad s_{i+1} - 1 \quad \dots \quad s_j - 1 \quad s_{j+1} + 1 \\ \text{diagram} \end{array} \right), \\
 & \Psi \left(\begin{array}{c} \text{sideways crossing with } s \text{ on the left} \\ \text{strand } i \text{ from bottom-left to top-right} \\ \text{strand } ji \text{ from top-left to bottom-right} \end{array} \right) \\
 & \quad \xrightarrow{7} \left(\begin{array}{c} s_j - 1 \quad s_{j+1} + 1 \quad \dots \quad s_j + 1 \quad s_{j+1} - 1 \quad s_i - 1 \quad s_{i+1} + 1 \quad s_j + 1 \quad s_{j+1} - 1 \\ \text{diagram} \end{array} \right) \xrightarrow{\mathbb{Z}} \left(\begin{array}{c} s_i - 1 \quad s_{i+1} + 1 \quad \dots \quad s_j + 1 \quad s_{j+1} - 1 \\ \text{diagram} \end{array} \right), \\
 & \Psi \left(\begin{array}{c} \text{sideways crossing with } s \text{ on the right} \\ \text{strand } i \text{ from top-left to bottom-right} \\ \text{strand } ji \text{ from bottom-left to top-right} \end{array} \right) \\
 & \quad \xrightarrow{7} \left(\begin{array}{c} s_j - 1 \quad s_{j+1} + 1 \quad \dots \quad s_i + 1 \quad s_{i+1} - 1 \quad s_j - 1 \quad s_{j+1} + 1 \quad s_i + 1 \quad s_{i+1} - 1 \\ \text{diagram} \end{array} \right) \xrightarrow{\mathbb{Z}} \left(\begin{array}{c} s_j - 1 \quad s_{j+1} + 1 \quad \dots \quad s_i + 1 \quad s_{i+1} - 1 \\ \text{diagram} \end{array} \right), \\
 & \Psi \left(\begin{array}{c} \text{sideways crossing with } s \text{ on the left} \\ \text{strand } i \text{ from top-left to bottom-right} \\ \text{strand } ji \text{ from bottom-left to top-right} \end{array} \right) \\
 & \quad \xrightarrow{7} \left(\begin{array}{c} s_j + 1 \quad s_{j+1} - 1 \quad \dots \quad s_i - 1 \quad s_{i+1} + 1 \quad s_j + 1 \quad s_{j+1} - 1 \quad s_i - 1 \quad s_{i+1} + 1 \\ \text{diagram} \end{array} \right) \xrightarrow{\mathbb{Z}} \left(\begin{array}{c} s_j + 1 \quad s_{j+1} - 1 \quad \dots \quad s_i - 1 \quad s_{i+1} + 1 \\ \text{diagram} \end{array} \right).
 \end{aligned}$$

Proof. These follow from the definitions. The proof of Proposition 8.1 is used in this calculation.

Lemma 7.5. For $|i - j| = 1$ we have the following assignments for sideways crossings:

$$\begin{array}{c}
 \begin{array}{c} \text{sideways crossing} \\ \text{with } i+1 \text{ on the left and } i \text{ on the right} \end{array} \xrightarrow{\mathbf{s} \mathbb{Z}} \left(\begin{array}{c} S_i - 1 \quad S_{i+1} + 2 \quad S_{i+2} - 1 \\ \text{diagram} \\ S_i \quad k_1 \quad S_{i+1} \quad k_2 \quad S_{i+2} \end{array} \right) \xrightarrow{\mathbb{Z}} \left(\begin{array}{c} S_i - 1 \quad S_{i+1} + 2 \quad S_{i+2} - 1 \\ \text{diagram} \\ S_i \quad k_1 \quad S_{i+1} \quad k_2 \quad S_{i+2} \end{array} \right), \\
 \\
 \begin{array}{c} \text{sideways crossing} \\ \text{with } i+1 \text{ on the left and } i \text{ on the right} \end{array} \xrightarrow{\mathbf{s} \mathbb{Z}} \left(\begin{array}{c} S_i + 1 \quad S_{i+1} - 2 \quad S_{i+2} + 1 \\ \text{diagram} \\ S_i \quad k_1 \quad S_{i+1} \quad k_2 \quad S_{i+2} \end{array} \right) \xrightarrow{\mathbb{Z}} \left(\begin{array}{c} S_i + 1 \quad S_{i+1} - 2 \quad S_{i+2} + 1 \\ \text{diagram} \\ S_i \quad k_1 \quad S_{i+1} \quad k_2 \quad S_{i+2} \end{array} \right), \\
 \\
 \begin{array}{c} \text{sideways crossing} \\ \text{with } i \text{ on the left and } i+1 \text{ on the right} \end{array} \xrightarrow{\mathbf{s} \mathbb{Z}} \left(\begin{array}{c} S_i - 1 \quad S_{i+1} + 2 \quad S_{i+2} - 1 \\ \text{diagram} \\ S_i \quad k_1 \quad S_{i+1} \quad k_2 \quad S_{i+2} \end{array} \right) \xrightarrow{\mathbb{Z}} \left(\begin{array}{c} S_i - 1 \quad S_{i+1} + 2 \quad S_{i+2} - 1 \\ \text{diagram} \\ S_i \quad k_1 \quad S_{i+1} \quad k_2 \quad S_{i+2} \end{array} \right), \\
 \\
 \begin{array}{c} \text{sideways crossing} \\ \text{with } i \text{ on the left and } i+1 \text{ on the right} \end{array} \xrightarrow{\mathbf{s} \mathbb{Z}} \left(\begin{array}{c} S_i + 1 \quad S_{i+1} - 2 \quad S_{i+2} + 1 \\ \text{diagram} \\ S_i \quad k_1 \quad S_{i+1} \quad k_2 \quad S_{i+2} \end{array} \right) \xrightarrow{\mathbb{Z}} \left(\begin{array}{c} S_i + 1 \quad S_{i+1} - 2 \quad S_{i+2} + 1 \\ \text{diagram} \\ S_i \quad k_1 \quad S_{i+1} \quad k_2 \quad S_{i+2} \end{array} \right).
 \end{array}$$

Proof. These are lengthy yet straightforward calculations using the definitions of cup, cap, and crossing bimodule homomorphisms.

Counter-clockwise bubble. It is convenient to compute the bimodule homomorphism for dotted bubbles. For notational convenience in this section, we assume

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

that $s_i = a$ and $s_{i+1} = b$, so that $\bar{s}_i = a - b$.

$$\begin{aligned}
 \Psi \left(\begin{array}{c} \text{bubble with } i \text{ and } m \text{ dots} \end{array} \right) : & \begin{array}{c} a \quad k \quad b \\ \parallel \quad \parallel \quad \parallel \\ a \quad k \quad b \end{array} \\
 \xrightarrow{\sum_{\alpha=0}^{\infty} \sum_{\beta=0}^{\infty} \sum_{\gamma=0}^{\infty} X^{\alpha} X^{\beta} X^{\gamma}} & (-1)^{a+b+\beta+\gamma+1} \begin{array}{c} a \quad k \quad b \\ \text{dots} \quad \text{dots} \quad \text{dots} \\ a \quad k \quad b \end{array} \\
 + \sum_{\substack{d_1+d_2+d_3=a-k}} X^{d_1} X^{d_2} X^{d_3} & (-1)^{d_3+\alpha+b+1} \begin{array}{c} a \quad k \quad b \\ \text{dots} \quad \text{dots} \quad \text{dots} \\ a \quad k \quad b \end{array} .
 \end{aligned} \tag{7.5}$$

This simplifies to

$$\begin{aligned}
 \Psi \left(\begin{array}{c} \text{bubble with } i \text{ and } m \text{ dots} \end{array} \right) : & \begin{array}{c} s_i \quad k \quad s_{i+1} \\ \parallel \quad \parallel \quad \parallel \\ s_i \quad k \quad s_{i+1} \end{array} \\
 \xrightarrow{\sum_{\beta=0}^{\infty} X^{\beta}} & (-1)^{s_i+s_{i+1}+\beta+1} \begin{array}{c} s_i \quad k \quad s_{i+1} \\ \text{dots} \quad \text{dots} \quad \text{dots} \\ s_i \quad k \quad s_{i+1} \end{array} .
 \end{aligned} \tag{7.6}$$

Clockwise bubble. Just as in Section 7.3 we calculate that

$$\begin{aligned}
 \Psi \left(\begin{array}{c} \text{clockwise bubble with } i \text{ and } m \text{ dots} \end{array} \right) : & \begin{array}{c} s_i \quad k \quad s_{i+1} \\ \parallel \quad \parallel \quad \parallel \\ s_i \quad k \quad s_{i+1} \end{array} \\
 \xrightarrow{\sum_{\beta=0}^{\infty} X^{\beta}} & (-1)^{\beta} \begin{array}{c} s_i \quad k \quad s_{i+1} \\ \text{dots} \quad \text{dots} \quad \text{dots} \\ s_i \quad k \quad s_{i+1} \end{array} .
 \end{aligned} \tag{7.7}$$

8. Proof of categorical action

We now verify the defining relations of the 2-morphisms in U .

8.1. Isotopic relations and cyclicity

Proposition 8.1. *We have the following equalities of bimodule homomorphisms:*

$$\Psi \left(\begin{array}{c} \text{isotopic relation diagram} \end{array} \right) = \Psi \left(\begin{array}{c} \text{isotopic relation diagram} \end{array} \right) = \Psi \left(\begin{array}{c} \text{isotopic relation diagram} \end{array} \right), \tag{8.1}$$

$$\Psi \left(\begin{array}{c} i \\ \downarrow \\ \text{strand with a loop} \\ \downarrow \\ \mathbf{s} \end{array} \right) = \Psi \left(\begin{array}{c} i \\ \downarrow \\ \mathbf{s} \end{array} \right) = \Psi \left(\begin{array}{c} \mathbf{s} \\ \downarrow \\ \text{strand with a loop} \\ \downarrow \\ i \end{array} \right). \quad (8.2)$$

Proof. This is a direct calculation.

Proposition 8.2. *The assignment Ψ preserves the dot cyclicity relation:*

$$\Psi \left(\begin{array}{c} \mathbf{s} \\ \downarrow \\ \text{strand with a dot} \\ \downarrow \\ i \end{array} \right) = \Psi \left(\begin{array}{c} i \\ \downarrow \\ \mathbf{s} \end{array} \right) = \Psi \left(\begin{array}{c} \mathbf{s} \\ \downarrow \\ \text{strand with a dot} \\ \downarrow \\ i \end{array} \right).$$

Proof. This follows from the gray dot action invariance in the proof of Proposition 6.3.

Proposition 8.3. *There is the following equality of bimodule homomorphisms:*

$$\Psi \left(\begin{array}{c} i \\ \downarrow \\ \text{crossing} \\ \downarrow \\ j \end{array} \right) \mathbf{s} := \Psi \left(\begin{array}{c} j \\ \downarrow \\ \text{strand with a loop} \\ \downarrow \\ i \end{array} \right) = \Psi \left(\begin{array}{c} \mathbf{s} \\ \downarrow \\ \text{strand with a loop} \\ \downarrow \\ j \end{array} \right).$$

Proof. This is a lengthy calculation that depends on different cases for i and j .

8.2. KLR relations

Proposition 8.4. *When the strands are labelled by adjacent nodes $|i - j| = 1$, we have*

$$\begin{aligned} \Psi \left(\begin{array}{c} i \\ \downarrow \\ \text{crossing} \\ \downarrow \\ i+1 \end{array} \right) \mathbf{s} &= \Psi \left(\begin{array}{c} i \\ \downarrow \\ \text{strand with a dot} \\ \downarrow \\ i+1 \end{array} \right) - \Psi \left(\begin{array}{c} i+1 \\ \downarrow \\ \text{strand with a dot} \\ \downarrow \\ i \end{array} \right), \\ \Psi \left(\begin{array}{c} i+1 \\ \downarrow \\ \text{crossing} \\ \downarrow \\ i \end{array} \right) \mathbf{s} &= \Psi \left(\begin{array}{c} i+1 \\ \downarrow \\ \text{strand with a dot} \\ \downarrow \\ i \end{array} \right) - \Psi \left(\begin{array}{c} i \\ \downarrow \\ \text{strand with a dot} \\ \downarrow \\ i+1 \end{array} \right). \end{aligned}$$

Proof. The two parts of the proposition are similar so we only sketch the second identity. The generators for the bimodule $E_{i+1} E_i 1_{\mathbf{s}}$ are given in (8.3):

$$\begin{array}{c} S_i + 1 \quad S_{i+1} \quad S_{i+2} - 1 \\ \downarrow \quad \downarrow \quad \downarrow \\ \text{diagram of strands and crossings} \\ \downarrow \quad \downarrow \quad \downarrow \\ S_i \quad k_1 \quad S_{i+1} \quad k_2 \quad k_3 \quad S_{i+2} \end{array}. \quad (8.3)$$

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

There are three cases to consider: $k_2 = 0$, $k_2 = 1$, and $k_2 > 1$.

For $k_2 = 0$, the image of one of the crossing maps produces a sum of dots on the gray step strands labelled by 1, along with a change in the relative heights of those gray strands. The other crossing map simply changes the relative heights of the gray strands labelled by 1.

The cases $k_2 > 0$ are verified in a straightforward manner from the definitions using Lemma 4.5. For $k_2 > 1$, one must use [KLMS12, Prop. 2.5.3] to simplify the diagrams.

Proposition 8.5. *If $|i - j| > 1$, then*

$$\Psi \left(\begin{array}{c} \text{crossing of strands } i \text{ and } j \\ \text{with strand } s \text{ crossing over} \end{array} \right) = \Psi \left(\begin{array}{c} \text{parallel strands } i \text{ and } j \\ \text{with strand } s \text{ crossing over} \end{array} \right).$$

Proof. This follows immediately from the definitions of the bimodule homomorphisms since each one just corresponds to an isotopy of diagrams of elements in the bimodule.

Proposition 8.6. *There is an action of the nilHecke algebra $\mathcal{NH}$ on the bimodule $E_i^a 1_s$. That is, we have equalities of the following bimodule homomorphisms:*

$$\begin{aligned} \Psi \left(\begin{array}{c} \text{crossing of strands } i \text{ and } i \\ \text{with strand } s \text{ crossing over} \end{array} \right) &= 0, \\ \Psi \left(\begin{array}{c} \text{crossing of strands } i \text{ and } i \text{ with a dot on the left strand} \\ \text{with strand } s \text{ crossing over} \end{array} \right) - \Psi \left(\begin{array}{c} \text{crossing of strands } i \text{ and } i \text{ with a dot on the right strand} \\ \text{with strand } s \text{ crossing over} \end{array} \right) &= \Psi \left(\begin{array}{c} \text{parallel strands } i \text{ and } i \text{ with a dot on the left strand} \\ \text{with strand } s \text{ crossing over} \end{array} \right) - \Psi \left(\begin{array}{c} \text{parallel strands } i \text{ and } i \text{ with a dot on the right strand} \\ \text{with strand } s \text{ crossing over} \end{array} \right) = \Psi \left(\begin{array}{c} \text{parallel strands } i \text{ and } i \\ \text{with strand } s \text{ crossing over} \end{array} \right), \\ \Psi \left(\begin{array}{c} \text{crossing of strands } i \text{ and } i \\ \text{with strand } s \text{ crossing over} \end{array} \right) &= \Psi \left(\begin{array}{c} \text{crossing of strands } i \text{ and } i \\ \text{with strand } s \text{ crossing over} \end{array} \right) \end{aligned}$$

along with identities arising from Ψ for faraway strands.

Proof. Recall that the bimodule $E_i^a 1_s$ is spanned by diagrams as in (8.4) with black strands in the background, and all strands may carry dots:

$$\begin{array}{c} s_i + a \quad s_{i+1} - a \\ \vdots \\ s_i \quad s_{i+1} \end{array} \quad (8.4)$$

A nilHecke dot on the i th strand starting from the right corresponds to a dot on the i th gray strand labelled by 1 starting from the bottom. A nilHecke crossing

on the i th and $(i + 1)$ -st strands starting from the right corresponds to the divided difference operator applied to dots on the i th and $(i + 1)$ -st gray strands starting from the bottom. It is then immediate that the nilHecke relations are satisfied.

Proposition 8.7. *For $i \neq j$ the following dot sliding relations hold:*

$$\Psi \begin{array}{c} \nearrow \\ \searrow \\ i \quad j \end{array} \begin{array}{c} \nearrow \\ \searrow \\ \bullet \end{array} \mathbf{s} = \Psi \begin{array}{c} \nearrow \\ \searrow \\ i \quad j \end{array} \mathbf{s}, \quad \Psi \begin{array}{c} \nearrow \\ \searrow \\ i \quad j \end{array} \begin{array}{c} \nearrow \\ \searrow \\ \bullet \end{array} \mathbf{s} = \Psi \begin{array}{c} \nearrow \\ \searrow \\ i \quad j \end{array} \mathbf{s}.$$

Proof. This follows easily from the definition of Ψ .

Proposition 8.8. *Unless $i = i^0$ and $|i - j| = 1$, the relation*

$$\Psi \left(\begin{array}{c} \text{Diagram 1} \\ i \quad j \quad i^0 \end{array} \right) \mathbf{s} = \Psi \left(\begin{array}{c} \text{Diagram 2} \\ i \quad j \quad i^0 \end{array} \right) \mathbf{s}$$

holds. Otherwise, $|i - j| = 1$ and

$$\Psi \left(\begin{array}{c} \text{Diagram 1} \\ i \quad j \pm 1 \quad i \end{array} \right) \mathbf{s}_- - \Psi \left(\begin{array}{c} \text{Diagram 2} \\ i \quad j \pm 1 \quad i \end{array} \right) \mathbf{s}_+ = \mp \Psi \left(\begin{array}{c} \text{Diagram 3} \\ i \quad j \pm 1 \quad i \end{array} \right) \mathbf{s}_+.$$

Proof. This is a lengthy calculation depending on various case considerations.

8.3. Infinite Grassmannian relations

For notational convenience in this section, we assume that $s = a$ and $s_{i+1} = b$, so that $\bar{s}_i = a - b$. We show that the 2-functor Ψ preserves the infinite Grassmannian relations

$$\Psi \left(\begin{array}{c} X \\ x+y=\alpha \end{array} \right) \left(\begin{array}{c} \text{Diagram with two circles and arrows, labeled } i, \bar{s}_j-1+x, s_j-1+y, \text{ and } \mathbf{s} \end{array} \right) : \quad (8.5)$$

For a term in this triple sum to be nonzero, we must have $x - g \geq 0$ and $y - f = \alpha - x - f \geq 0$ (or $g \leq x$ and $x \leq \alpha - f$). By further simplifying summations using that indices for h_s must be positive, the result follows using symmetric function identities for elementary and complete symmetric functions.

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

Proof. Both items are proved in the same way. In fact, the second part follows from the first part by symmetry so we only sketch the proof of the first equation.

By definition, the term on the left side of the equation vanishes. It is a routine calculation to check that the second term on the right side is negative of the identity morphism. Note that in the course of the computation one sees that $f_1 = f_2 = 0$ and $f_3 = a - 1$.

The next crucial result is due to Cautis. Let $\mathbf{s}$ be a sequence of non-negative integers $(s_1, \dots, s_m)$ and then set $\mathbf{s}^0 = (s_1, \dots, s_i, 0, s_{i+1}, \dots, s_m)$ to be a sequence of $m + 1$ integers.

Proposition 8.13 *For any sequence $\mathbf{s}$, there are isomorphisms:*

- (1) *If $s_i \geq s_{i+1}$, then $E_i F_i 1_{\mathbf{s}} \cong F_i E_i 1_{\mathbf{s}} \oplus [s_i - s_{i+1}] 1_{\mathbf{s}}$.*
- (2) *If $s_i \leq s_{i+1}$, then $F_i E_i 1_{\mathbf{s}} \cong E_i F_i 1_{\mathbf{s}} \oplus [s_{i+1} - s_i] 1_{\mathbf{s}}$.*

Proof. We will only establish the first isomorphism as the second one is proved in a similar way. We proceed by induction on $s_i + s_{i+1}$. The isomorphism exists for the special case that $s_{i+1} = 0$ by Proposition 8.12.

Decomposing $E_i F_i 1_{\mathbf{s}}$ is the same as decomposing $E_i E_{i+1} F_{i+1} F_i 1_{\mathbf{s}^0}$ under the canonical identification of $W(\mathbf{s}, n)$ with $W(\mathbf{s}^0, n)$:

We begin by considering $E_i F_{i+1} E_{i+1} F_i 1_{\mathbf{s}^0}$. Note that

$$\begin{aligned} E_i F_{i+1} E_{i+1} F_i 1_{\mathbf{s}^0} &\cong F_{i+1} E_i F_i E_{i+1} 1_{\mathbf{s}^0} \\ &\cong F_{i+1} F_i E_i E_{i+1} 1_{\mathbf{s}^0} \oplus [s_i - 1] F_{i+1} E_{i+1} 1_{\mathbf{s}^0} \\ &\cong F_{i+1} F_i E_i E_{i+1} 1_{\mathbf{s}^0} \oplus [s_{i+1}] [s_i - 1] 1_{\mathbf{s}^0} \end{aligned}$$

where the first isomorphism is a consequence of Proposition 8.9, the second isomorphism follows from induction, and the third isomorphism follows from 8.12. On the other hand,

$$\begin{aligned} E_i F_{i+1} E_{i+1} F_i 1_{\mathbf{s}^0} &\cong E_i E_{i+1} F_{i+1} F_i 1_{\mathbf{s}^0} \oplus [s_{i+1} - 1] E_i F_i 1_{\mathbf{s}^0} \\ &\cong E_i E_{i+1} F_{i+1} F_i 1_{\mathbf{s}^0} \oplus [s_i] [s_{i+1} - 1] 1_{\mathbf{s}^0} \end{aligned}$$

where the first isomorphism follows from induction and the second isomorphism is a consequence of Proposition 8.12. Thus,

$$E_i E_{i+1} F_{i+1} F_i 1_{\mathbf{s}^0} \oplus [s_i] [s_{i+1} - 1] 1_{\mathbf{s}^0} \cong F_{i+1} F_i E_i E_{i+1} 1_{\mathbf{s}^0} \oplus [s_{i+1}] [s_i - 1] 1_{\mathbf{s}^0}. \quad (8.6)$$

Since the graded homomorphism spaces between these bimodules are finite-dimensional, we may apply the Krull–Schmidt theorem to (8.6) and obtain

$$E_i E_{i+1} F_{i+1} F_i 1_{\mathbf{s}^0} \cong F_{i+1} F_i E_i E_{i+1} 1_{\mathbf{s}^0} \oplus [s_i - s_{i+1}] 1_{\mathbf{s}^0}$$

which proves the proposition.

Proposition 8.14 Let $\mathbf{s} = (s_1, \dots, s_m)$. We then have the following equalities of bimodule homomorphisms:

$$(1) \Psi \left(\begin{array}{c} \text{crossing} \\ i \downarrow \quad i \uparrow \end{array} \mathbf{s} \right) = \Psi \left(\begin{array}{c} \uparrow \\ i \downarrow \end{array} \mathbf{s} \right) + \Psi \left(\begin{array}{c} \text{P} \\ f_1+f_2+f_3 \\ =a-b-1 \end{array} \begin{array}{c} \text{diagram} \\ i \downarrow \quad i \uparrow \end{array} \mathbf{s} \right).$$

$$(2) \Psi \left(\begin{array}{c} \text{crossing} \\ i \uparrow \quad i \downarrow \end{array} \mathbf{s} \right) = \Psi \left(\begin{array}{c} \downarrow \\ i \uparrow \end{array} \mathbf{s} \right) + \Psi \left(\begin{array}{c} \text{P} \\ f_1+f_2+f_3 \\ =b-a-1 \end{array} \begin{array}{c} \text{diagram} \\ i \uparrow \quad i \downarrow \end{array} \mathbf{s} \right).$$

Proof. In [CL14, Thm. 1.1] (see also [Bru16]), it is proved that if one has all 2-categorical relations along with abstract isomorphisms (from Proposition 8.13)

$$\begin{aligned} E_i F_i 1_{\mathbf{s}} &\cong F_i E_i 1_{\mathbf{s}} \oplus [s_i - s_{i+1}] 1_{\mathbf{s}}, \\ F_i E_i 1_{\mathbf{s}} &\cong E_i F_i 1_{\mathbf{s}} \oplus [s_{i+1} - s_i] 1_{\mathbf{s}} \end{aligned}$$

for $s_i \geq s_{i+1}$ and $s_{i+1} \geq s_i$ respectively, that these isomorphisms could be written in terms of generators for the 2-category and they satisfy the relations of the proposition.

9. Main Theorems

In this section, we state the main results of this paper.

Theorem 9.1. The assignment Ψ extends to a 2-functor $\Psi : U \rightarrow \text{Bim}(n)$.

Proof. This follows from the check of the relations in Section 8.

Definition 9.2. Let Br_m be the braid group of type A_m . That is, it is generated by elements T_i, T_i^0 for $i = 1, \dots, m-1$ subject to relations

- $T_i T_i^0 = 1 = T_i^0 T_i$,
- $T_i T_j = T_j T_i$ if $|i - j| > 1$,
- $T_i T_j T_i = T_j T_i T_j$ if $|i - j| = 1$.

It was shown in [CK12a] that a categorical U action gives rise to a categorical Br_m action. Cautis and Kamnitzer's work extended the foundational work of Chuang and Rouquier [CR08] where $\mathfrak{sl}_2$ categorification was developed.

We will now recall the main result of [CK12a] in the context of a particular weight space of a representation of $\mathfrak{gl}_n$.

Let $\mathbf{s} = (s_1, \dots, s_m)$. There are complexes

$$\begin{aligned} T_i 1_{\mathbf{s}} &= E_i^{(s_{i+1} - s_i)} 1_{\mathbf{s}} \rightarrow E_i^{(s_{i+1} - s_i + 1)} F_i^{(1)} 1_{\mathbf{s}} h 1_i \rightarrow \dots \rightarrow E_i^{(s_{i+1} - s_i + j)} F_i^{(j)} 1_{\mathbf{s}} h j_i \rightarrow \dots \\ &= F_i^{(s_i - s_{i+1})} 1_{\mathbf{s}} \rightarrow F_i^{(s_i - s_{i+1} + 1)} E_i^{(1)} 1_{\mathbf{s}} h 1_i \rightarrow \dots \rightarrow F_i^{(s_i - s_{i+1} + j)} E_i^{(j)} 1_{\mathbf{s}} h j_i \rightarrow \dots \end{aligned}$$

for $s_{i+1} \geq s_i$ and $s_i \geq s_{i+1}$ respectively, and

BRAID GROUP ACTIONS FROM DEFORMED WEBSTER ALGEBRAS

$$\begin{aligned} 1_s T_i^0 &= \dots \rightarrow 1_s E_i^{(j)} F_i^{(S_{i+1} - S_i + j)} h^{-ji} \rightarrow \dots \rightarrow 1_s F_i^{(S_{i+1} - S_i)} \\ &= \dots \rightarrow 1_s F_i^{(j)} E_i^{(S_i - S_{i+1} + j)} h^{-ji} \rightarrow \dots \rightarrow 1_s E_i^{(S_i - S_{i+1})} \end{aligned}$$

for $S_{i+1} \geq S_i$ and $S_i \geq S_{i+1}$ respectively, where the differentials are given by explicit bimodule homomorphisms. For example, see [LQR15, Sect. 2.2].

Note that when $\mathbf{s} = (1, \dots, 1)$, these complexes simplify to

$$T_i^0 = E_i F_i 1_{\mathbf{s}h-1i} \xrightarrow{d} \text{Id}, \quad T_i = \text{Id} \xrightarrow{d^0} E_i F_i 1_{\mathbf{s}h1i} \quad (9.1)$$

with the differentials given by

$$d = \begin{array}{c} \text{---} s \text{---} \\ \curvearrowright \\ i \end{array}, \quad d^0 = \begin{array}{c} i \\ \curvearrowleft \\ \text{---} s \text{---} \end{array}. \quad (9.2)$$

Theorem 9.3. *As functors on the homotopy category of $W(\mathbf{s}, n)$ -modules, the complexes $\mathbb{T}, \mathbb{T}^0$ satisfy braid group relations. That is, there are isomorphisms*

- $T_i^0 T_j \cong \text{Id}$,
- $T_i T_i^0 \cong \text{Id}$,
- $T_i T_j \cong T_j T_i$ if $|i - j| > 1$,
- $T_i T_j T_i \cong T_j T_i T_j$ if $|i - j| = 1$.

Furthermore, as endofunctors on $K^b(W(1^m, n)\text{-mod})$, the complexes T_i and T_i^0 satisfy strong braid group relations.

Proof. These complexes satisfy braid group relations by Theorem 9.1 and [CK12a, Thm. 6.3].

Restricting to the weight space $(\mathfrak{f}^m)$ of $\text{Bim}(n)$, the complexes simplify to (9.1) with the maps given in (9.2). The work of Elias and Krasner [EK10b] combined with the connection between Soergel calculus and the 2-category $\mathcal{U}$ from [MSV13, Lem. 6.5] shows that this is a strong braid group action.
