(Received 23 January 2020; accepted 18 February 2020; published 9 April 2020)

While exploring potential superconductors in the C-S-H ternary system using first-principles crystal structure prediction methods, we uncovered a class of hydride perovskites based on the intercalation of methane into an H<sub>3</sub>S framework. These intriguing H<sub>3</sub>S-CH<sub>4</sub> structures emerge as metastable at  $\sim 100$  GPa. Electron-phonon coupling calculations indicate that phases with CSH<sub>7</sub> stoichiometry are potential superconductors with  $T_c$  values ranging from 100 K to 190 K at megabar pressures. The results are expected to guide the experimental search for new high- $T_c$  superconductors, including those stable at lower pressures than previously documented superconducting hydrides such as H<sub>3</sub>S and LaH<sub>10</sub>.

## I. INTRODUCTION

The pursuit of high- $T_c$  and even room-temperature superconductivity has been a grand challenge in physics since the 1911 discovery of superconductivity [1]. The Bardeen-Cooper-Schrieffer (BCS) theory [2] can describe well the mechanism for conventional superconductors, opening the door for the discovery and design of high- $T_c$  materials. Ashcroft [3] proposed that compressed hydrides are good candidates for high- $T_c$  superconductors due to chemical “pre-compression” effects. Subsequent theoretical studies provided explicit predictions of these phenomena, and they have led to the discovery of very high temperature superconductivity, first in H<sub>3</sub>S ( $T_c$  of 203 K) [4] and more recently in LaH<sub>10</sub> ( $T_c$  up to 260 K) [5–7]. These experimental results confirmed theoretical predictions for both the structures and basic mechanism of superconductivity [8–11], thereby marking a new era for both superconductivity and “materials by design” [5,12–14].

Compared to binary hydrides, exploration of high- $T_c$  superconductors in ternary hydrides greatly enlarges the configurational space and opens up new chemistry and physics that could in principle enhance both  $T_c$  and stability, including at modest pressures. This additional elemental degree of freedom in compressed ternary hydride systems has led to new predicted high- $T_c$  superconductors such as CaYH<sub>12</sub> ( $T_c = 258$  K at 200 GPa) [15], LiPH<sub>6</sub> ( $T_c = 150$ –167 K at 200 GPa) [16], and most remarkably Li<sub>2</sub>MgH<sub>16</sub> ( $T_c = 473$  K at 250 GPa) [17]. On the other hand, existing experimental studies have uncovered only relatively low- $T_c$  materials

such as in BaReH<sub>9</sub> ( $T_c = 7$  K) [18] and Li<sub>5</sub>MoH<sub>11</sub> ( $T_c = 6.5$  K) [19]. Returning to sulfur-containing systems, carbon disulfide (CS<sub>2</sub>) has been shown to transform to a metal at 50 GPa, and a superconductor with a  $T_c$  of  $\sim 6$  K at 60–170 GPa [20]. Several ternary hydrides based on the H<sub>3</sub>S structure are predicted to exhibit high- $T_c$  behavior, including H<sub>6</sub>SSe (i.e., SH<sub>3</sub>-SeH<sub>3</sub>, with an estimated  $T_c$  of 195 K at 200 GPa) [21], Y(La)SH<sub>6</sub> [SH<sub>3</sub>-Y(La)H<sub>3</sub>,  $T_c = 95$  and 35 K at 210 and 300 GPa, respectively] [22], and even the noble gas Xe with H<sub>3</sub>S (H<sub>3</sub>SXe,  $T_c = 89$  K at 240 GPa) [23]. Moreover, several superconductors have also been reported in ternary F-S-H, Y-S-H, and B-S-H compounds [24–26].

There is also general interest in carbon-containing high- $T_c$  superconductors. Dense carbides that are isostructural with hydrides have been predicted to exhibit high- $T_c$  behavior and to be stable on decompression due to their rigid carbon  $sp^3$  frameworks [27]. Various hydrocarbons (e.g., CH<sub>4</sub>, C<sub>2</sub>H<sub>4</sub>, and C<sub>2</sub>H<sub>6</sub>) are stable in different molecular phases to megabar pressures [28–30]. CH<sub>4</sub> and Mg are predicted to form CH<sub>4</sub>Mg, a potential superconductor with a  $T_c$  of 84–121 K at 75–120 GPa [31]. The related compound CH<sub>4</sub>K has a predicted  $T_c$  of about 12 K at 80 GPa [32]. These results encouraged us to theoretically search for high- $T_c$  superconductors in the C-S-H ternary system. As shown in detail below,  $Cm$ ,  $R3m$ , and  $Pnma$  symmetry phases were found, for which electron-phonon coupling calculations reveal superconductivity with  $T_c$ 's as high as 194 K at 150 GPa, as estimated by solving the Eliashberg equations numerically using the typical choice of the Coulomb potential,  $\mu^* = 0.10$ –0.13.

## II. RESULTS AND DISCUSSION

We began by identifying stable structures in the C-S-H system, focusing on C<sub>x</sub>S<sub>y</sub>H<sub>z</sub> ( $x = 1 - 2$ ;  $y = 1 - 2$ ;  $z = 1 - 8$ ) compositions at megabar pressures (100–200 GPa),

FIG. 1. (a)  $\text{H}_3\text{S}$  ( $Im\bar{3}m$  structure) and (b)  $R3m$  symmetry methane intercalated  $\text{H}_3\text{S}$  perovskite,  $\text{CSH}_7$ . The brown, blue, and yellow-green spheres denote C, S, and H atoms, respectively (see the supplemental material [37] for more detailed structural information).

using heuristic algorithms based on particle swarm optimization [33–35] and evolutionary algorithms [36] in combination with first-principles theory [computational details are provided in the supporting information (SI) [37]]. The  $\text{CSH}_7$  stoichiometry emerged as being particularly stable relative to the elements in the pressure range considered. The enthalpies of formation from the elemental phases for  $\text{CSH}_7$  were  $-70$ ,  $-62$ ,  $-53$ , and  $-30$  meV/at at 100, 130, 150, and 200 GPa, respectively. Interestingly, the structures of  $\text{CSH}_7$ , shown in Fig. S1 of the SI, are composed of  $\text{CH}_4$  molecules intercalated within different, but related,  $\text{H}_3\text{S}$  networks. At 100 GPa, the  $\text{H}_3\text{S}$  sublattice is characterized by  $\text{SH}_5$  layers. Upon compression perovskite structures derived from the phase shown in Fig. 1 become enthalpically favored, with  $\text{CH}_4$  molecules intercalated into the cubic  $\text{H}_3\text{S}$  framework formed by two neighboring  $\text{SH}_5$  layers that are linked via shared H atoms.

Although the enthalpies of formation of the  $\text{CSH}_7$  phases are negative with respect to the elemental phases, these species do not lie on the 3D convex hull. In fact, they are metastable with respect to  $\text{CH}_4 + \text{H}_3\text{S}$  (and  $\text{CH}_4 + \text{H}_2\text{S} + 1/2\text{H}_2$ ), but stable relative to  $\text{H}_2\text{S} + \text{C} + 5/2\text{H}_2$  below 188 GPa. The zero-point energy (ZPE) uncorrected enthalpy of  $R3m$  is 33 meV/at above the convex hull at 130 GPa. As shown in Table S1 of the SI, inclusion of the ZPE or finite-temperature effects does not stabilize the ternary phase. It should, however, be noted that a number of compressed hydrides found to be metastable via first-principles calculations have been synthesized in the laboratory. Examples include a  $\text{Ca}_2\text{H}_5$  phase, which was calculated to be 20 meV/at above the convex hull [38], and hydrides of phosphorus, which are at least 30 meV/at above the convex hull [39–41]. Moreover, these phases could potentially be stabilized by anharmonic or nuclear quantum effects as found for  $\text{LaH}_{10}$  [42]. Therefore, it is expected that the  $\text{CSH}_7$  phases could be realized experimentally, especially if they are calculated to be dynamically stable.

The relative enthalpies of the  $\text{CSH}_7$  phases between 100 and 300 GPa are shown in Fig. S2. The small differences in the static lattice enthalpies calculated for these hydride perovskites suggests there may be many other phases, differing in the number of atoms in the formula unit and rotations of the methane molecules, that could be realized. Phonon calculations reveal that  $Cm$  is dynamically stable from 100

to 110 GPa, whereas  $R3m$  is dynamically stable from 130 to 300 GPa, and  $Pnma$  is dynamically stable at the current level of approximation from at least 150 to 300 GPa (Fig. S3). Molecular-dynamics simulations (Fig. S4), suggest that at finite temperature the methane molecules may become rotationally disordered.

Predicted 0 K structures of  $\text{CSH}_7$  and cubic  $Im\bar{3}m$   $\text{H}_3\text{S}$  are shown in Fig. 1 and Fig. S1. In pure  $\text{H}_3\text{S}$ , the S atoms form a bcc lattice with each S atom octahedrally coordinated by H atoms [Fig. 1(a)]. The  $\text{CSH}_7$  phases are based on the  $\text{H}_3\text{S}$  structure with the central  $\text{SH}_6$  unit replaced by a  $\text{CH}_4$  molecule, and a distortion of the cubic framework. In the  $Cm$  phase [Fig. S1(a)], the cubic  $\text{H}_3\text{S}$  lattice is replaced by two layers of  $\text{SH}_5$ . The H-S distance between neighboring  $\text{SH}_5$  layers is too long (1.906 Å) to form an H-S covalent bond. In the  $R3m$  structure, for example, the  $\text{H}_3\text{S}$  framework is retained but with a slight rhombohedral distortion such that the  $\vec{a}$ ,  $\vec{b}$ , and  $\vec{c}$  unit-cell vectors are equal in length, but the  $\alpha$ ,  $\beta$ , and  $\gamma$  angles measure  $89.4^\circ$  (instead of  $90^\circ$ ). The rotation barrier of the  $\text{CH}_4$  unit in  $R3m$ - $\text{CSH}_7$  was estimated to be  $<1$  meV/at at 150 GPa (Fig. S5), suggesting the molecule may exhibit rotational disorder, and that this may occur in other structures, consistent with the molecular dynamics simulations (Fig. S4).

To explore the bonding in the  $\text{CSH}_7$  phases, their electronic localization functions (ELFs) were plotted (Fig. S6). The ELF is useful for visualizing covalent bonds and lone pairs; it maps values in the range from 0 to 1, where 1 corresponds to perfect localization of the valence electrons indicative of a strong covalent bond. The ELF values for the S-H and C-H bonds are close to 0.9, indicating their strong covalent character. The  $Cm$  structure is characterized by five S-H bonds (bond lengths of 1.38–1.55 Å) and one lone electron pair [Figs. S6(a) and S6(b)]. Similar to free methane, the  $\text{CH}_4$  units contain four strong covalent C-H bonds, as shown in the three-dimensional ELF plots. In the  $R3m$  and  $Pnma$  structure, the cubic  $\text{H}_3\text{S}$  framework (i.e.,  $Pm\bar{3}m$ ) is clearly evident.

The calculated pressure-volume equation of states (EOS) of  $\text{CSH}_7$  and assemblages consisting of  $\text{CH}_4$  and  $\text{H}_3\text{S}$ , as well as  $\text{C} + \text{S} + 7/2\text{H}_2$ , are shown in Fig. 2. The sum of the volume of the predicted  $\text{CH}_4$  ( $Cmca$ ) [43] and  $\text{H}_3\text{S}$  ( $R3m$  and  $Im\bar{3}m$ ) [9] phases is also plotted for comparison. The evolution of the volume under pressure of  $\text{CSH}_7$  falls between the experimental and theoretical data obtained for  $\text{CH}_4 + \text{H}_3\text{S}$ . As shown in Fig. S7, the  $PV$  contribution to the enthalpy favors the assemblages over  $\text{CSH}_7$  within this pressure range. The pressure dependence of select S-H distances is plotted in Fig. S8. Under pressure the S1-H and S2-H bonds in the  $Cm$  phase approach each other, and the S3-H distance decreases, as the phase undergoes pressure-induced bond equalization. Because the  $\text{CH}_4$  molecule breaks the symmetry, the S-H1 and S-H2 bonds in the  $R3m$  phase differ slightly. Both S-H bonds in  $R3m$ - $\text{CSH}_7$  are slightly shorter than those calculated for  $Im\bar{3}m$   $\text{H}_3\text{S}$ , whose highest  $T_c$ , 203 K, was measured at 155 GPa [4]. If the S-H distance, which can be modulated by the identity of the intercalant molecule as well as the pressure, is an important factor in determining the  $T_c$ , it is expected that the maximum value for  $\text{CSH}_7$  would be at lower pressures, consistent with the explicit calculations of  $T_c$  discussed below.

The band structures and partial densities of states (DOSs) for  $\text{CSH}_7$  perovskite structures were calculated to further

FIG. 2. Calculated  $\text{CSH}_7$  EOS ( $Rm3$  structure; the volumes of  $R3m$  and  $Pnma$  are within 0.5%) compared with the molecular assemblage  $\text{CH}_4 + \text{H}_3\text{S}$ , and the assemblage  $\text{C} + \text{S} + 7/2\text{H}_2$ . The green and violet lines represent theoretical values for  $\text{CSH}_7$ , and the sum of the volume of  $\text{CH}_4$  ( $Cmca$ ) [43] +  $\text{H}_3\text{S}$  ( $R3m$  and  $Im\bar{3}m$ ) [9]. The inset shows the experimental EOS for  $\text{H}_2$  [44],  $\text{C}$  [45],  $\text{S}$  [46],  $\text{CH}_4$  [47], and  $\text{H}_3\text{S}$  [48]; the points are the measured data.

explore their electronic properties [Fig. 3(a), Fig. S9(a) and Fig. S10(a)]. They exhibit metallic features, wherein the states near the Fermi level are mainly from the contribution of the  $\text{H}_3\text{S}$  framework, with negligible character from the  $\text{CH}_4$  molecules. The significant overlap of states with H and S character indicates strong H-S hybridization under pressure, which has been demonstrated to play a key role in driving the high- $T_c$  superconductivity of cubic  $\text{H}_3\text{S}$  [12].

Figure 3(b), Fig. S9(b) and Fig. S10(b) show the phonon dispersions, projected phonon density of states (PHDOS), Eliashberg spectral function,  $\alpha^2F(\omega)$ , and electron-phonon coupling integral,  $\lambda(\omega)$ , for perovskite  $\text{CSH}_7$ . A notable feature of the  $\text{CH}_4$  intercalation in the structures is the separation of the vibrational modes into three well distinct regions: The lower frequencies (below 20 THz) are associated with the heavier S and C atoms, and modes including some of the  $\text{CH}_4$  hydrogens; the intermediate frequencies (between 30 and 63 THz) are derived from combinations of H-wagging, bending, and stretching modes; and the higher frequencies ( $\sim 100$  THz,  $3300\text{ cm}^{-1}$ ) are derived primarily from the C-H stretching modes of the molecular  $\text{CH}_4$  units, close to the asymmetric stretching modes of free  $\text{CH}_4$  ( $\sim 97$  THz,  $3200\text{ cm}^{-1}$ ).

The superconducting properties of the  $\text{CSH}_7$  phases were estimated by the Allen-Dynes modified McMillan equation [49], using typical values of the Coulomb pseudopotential,  $\mu^* = 0.13\text{--}0.1$ . As shown in Table I, below 250 GPa,  $\lambda$  was calculated to be appreciable for all three phases. At 100 GPa,  $\lambda$  was 1.2 and  $\omega_{\log}$  was 1091 K for the  $Cm$  phase, yielding a  $T_c$  of 86–98 K. For  $R3m$  at 150 GPa,  $\lambda$  was 2.47,

FIG. 3. Calculated (a) band structure, total DOS, and site-projected DOS near the Fermi level, and (b) phonon-dispersion curves, PHDOS, projected on the C, S, and H atoms, Eliashberg spectral function,  $\alpha^2F(\omega)$ , and  $\lambda(\omega) = \int_0^\omega d\omega' 2\alpha^2F(\omega')/(\omega')$  for  $\text{CSH}_7$  ( $R3m$  structure) at 150 GPa. Red solid circles represent the phonon linewidth with the radius proportional to the respective coupling strength.

which is twice the value found for  $Cm$  and comparable to that calculated for cubic  $\text{H}_3\text{S}$  at 200 GPa ( $\lambda = 2.19$ ) [9], resulting in a  $T_c$  of 143–152 K. The logarithmic average phonon frequency of  $R3m$   $\text{CSH}_7$  at 150 GPa is somewhat lower than that of  $Im\bar{3}m$   $\text{H}_3\text{S}$  at 200 GPa [9], 925 K versus 1335 K, which is the reason for the slightly lower  $T_c$  of the ternary. The increase in  $\lambda$  for  $R3m$  as compared to  $Cm$  is not unreasonable in view of the differences in their phonon band structures. In  $R3m$ ,

TABLE I. The calculated electron-phonon coupling parameter ( $\lambda$ ), logarithmic average phonon frequency ( $\omega_{\log}$ ), and the estimated  $T_c$  for selected  $\text{CSH}_7$  structures using the Allen-Dynes modified McMillan (ADM) equation [49], and numerically solving the Eliashberg equations [50] with  $\mu^* = 0.10$  (0.13).

| Phase  | Pressure (GPa) | $\lambda$ | $\omega_{\log}$ (K) | $T_c$ (K) |            |
|--------|----------------|-----------|---------------------|-----------|------------|
|        |                |           |                     | ADM       | Eliashberg |
| $Cm$   | 100            | 1.20      | 1091                | 98 (86)   | 108 (97)   |
| $R3m$  | 150            | 2.47      | 925                 | 152 (143) | 194 (181)  |
|        | 200            | 1.35      | 1379                | 137 (128) | 158 (144)  |
| $Pnma$ | 150            | 3.06      | 672                 | 122 (116) | 170 (157)  |
|        | 200            | 1.06      | 1622                | 123 (107) | 138 (120)  |

FIG. 4. Calculated anisotropic superconducting gap of CSH<sub>7</sub> in the (a) *R3m* and (b) *Pnma* structures at 150 GPa.

there are two obvious Kohn anomalies and softened modes at 18–32 THz located along the  $F$ - $\Gamma$  and  $\Gamma$ - $Z$  high-symmetry lines, which contribute a significant amount ( $\sim 36\%$ ) to  $\lambda$ . In addition,  $\lambda$  of *R3m* and *Pnma* was found to decrease with increasing pressure, which was not offset by the increase in  $\omega_{\log}$  so that  $T_c$  decreased from 150 to 300 GPa. The maximum  $T_c$  for CSH<sub>7</sub>, therefore, occurs at a slightly lower pressure than for H<sub>3</sub>S. Notably, it is larger than the highest value computed for H<sub>3</sub>SXe, 89 K at 240 GPa [23], because of the smaller mass of CH<sub>4</sub> relative to Xe. For strongly coupled superconductors ( $\lambda > 1.5$ ), Eliashberg theory [50] gives a better estimate of  $T_c$ , and therefore we also numerically solved the Eliashberg equations for select pressures, as shown in Table I, Table SII and Fig. 4. As expected, the estimated  $T_c$  values were higher, 181–194 and 157–170 K for *R3m* and *Pnma*, respectively.

### III. CONCLUSIONS

In summary, we have explored the stability and electronic properties of C<sub>x</sub>S<sub>y</sub>H<sub>z</sub> ternary compounds at high pressure.

Stoichiometric CSH<sub>7</sub> was found to be dynamically stable above 100 GPa, adopting phases with space-group symmetries based on distortions of the high-symmetry *Pm3m* structure. These perovskite-type structures are characterized by CH<sub>4</sub> intercalated to form distorted H<sub>3</sub>S perovskite frameworks, which could represent a new class of high-temperature superconductors. Electron-phonon coupling calculations indicate that CSH<sub>7</sub> phases are promising conventional superconductors with  $T_c$ 's estimated to be as high as  $\sim 200$  K. The results are expected to stimulate the search for other high- $T_c$  H<sub>3</sub>S intercalation compounds and more chemically complex hydride superconductors, especially in carbon-bearing systems. Just like pressure, the size of the intercalant molecule can be used to modulate the H-S framework, and thereby to tune its properties, such as  $T_c$ . Additional theoretical studies would be useful to examine the effects of quantum and anharmonic dynamics on the calculated critical temperatures and stability of this class of materials, as well as mechanisms for enhancing their phase stabilities at lower pressures.
