Abstract

Scientific communication is facilitated by a data-driven, scientifically sound taxonomy that considers the end-user's needs and established successful practice. Previously (Geiser et al. 2013; Phytopathology 103:400-408. 2013), the *Fusarium* community voiced near unanimous support for a concept of *Fusarium* that represented a clade comprising all agriculturally and clinically important *Fusarium* species, including the *F. solani* Species Complex (FSSC). Subsequently, this concept was challenged by one research group (Lombard et al. 2015 Studies in Mycology 80: 189-245) who proposed dividing *Fusarium* into seven genera, including the FSSC as the genus *Neocosmospora*, with subsequent justification based on claims that the Geiser et al. (2013) concept of *Fusarium* is polyphyletic (Sandoval-Denis et al. 2018; Persoonia 41:109-129). Here we test this claim, and provide a phylogeny based on exonic nucleotide sequences of 19 orthologous protein-coding genes that strongly support the monophyly of *Fusarium* including the FSSC. We reassert the practical and scientific argument in support of a *Fusarium* that includes the FSSC and several other basal lineages, consistent with the longstanding use of this name among plant pathologists, medical mycologists, quarantine officials, regulatory agencies, students and researchers with a stake in its taxonomy. In recognition of this monophyly, 40 species recently described as *Neocosmospora* were recombined in *Fusarium*, and nine others were renamed *Fusarium.* Here the global *Fusarium* community voices strong support for the inclusion of the FSSC in *Fusarium*, as it remains the best scientific, nomenclatural and practical taxonomic option available.

Introduction

Scientific advances and new fungal nomenclatural rules have forced necessary changes in fungal names in recent years, many of which are inconvenient. But unlike other fungal genera where phylogenetics and nomenclatural conflicts forced very difficult taxonomic decisions (e.g., *Magnaporthe/Pyricularia*; Zhang et al. 2016), there is a clear path to define *Fusarium* phylogenetically, eliminate confusing dual nomenclature/taxonomy, and maintain a generic circumscription that has been widely used for over a century (Bilai 1955; Booth 1971; Gams and Nirenberg 1989; Gerlach and Nirenberg 1982; Joffe 1974; Leslie and Summerell 2006a; Matuo 1972; Nelson et al. 1983; Raillo 1950; Snyder and Hansen 1941; Summerell 2019; Wollenweber 1913; Wollenweber and Reinking 1935). The highest impact taxonomic outcome at stake is the segregation of *F. solani* and the *F. solani* Species Complex (FSSC) out of *Fusarium* into the relatively obscure taxon *Neocosmospora*, the type of which represents a morphologically aberrant lineage within the FSSC. Here we argue that this move is

scientifically unnecessary and impractical, and refute phylogenetic arguments that have been presented to support it (Sandoval-Denis and Crous 2018).

The scientific argument for a monophyletic *Fusarium* in Geiser et al. (2013) was strongly supported by 66 authors from 17 countries representing the *Fusarium* community. The goal was to promote a generic concept of *Fusarium* that is scientifically (i.e., monophyletic) and nomenclaturally sound, and at the same time minimizes disruption by protecting scientifically valid, longstanding use. *Fusarium* is one of the most commonly used ascomycete generic names in the scientific literature (Geiser et al. 2013), so this practical consideration is essential due to the negative impact of disconnecting past, current and future uses of the name.

The Geiser et al. (2013) phylogenetic circumscription of *Fusarium* precisely corresponds to a monophyletic group that encompassed all economically important *Fusarium* species, originally termed the Terminal *Fusarium* Clade (herein abbreviated TFC; Gräfenhan et al. 2011). Members of this clade almost always produce spores and colonies with a recognizable *Fusarium* morphology. The TFC included the type species of *Fusarium*, *F. sambucinum*, the same species in which the competing teleomorph genus *Gibberella* is typified: *G. pulicaris*. This overlap made it straightforward to propose unitary use of the name *Fusarium* over *Gibberella* (Rossman et al. 2013). That proposal, however, did not address the many *Fusarium* species within the TFC with connections to teleomorph genera other than *Gibberella*, comprising the FSSC and all other Species Complexes in Figure 1 that resolve basally with respect to the *F. buharicum* Species Complex.

Geiser et al. (2013) proposed that all members of the TFC be included in *Fusarium*, not just those associated with *Gibberella*, and synonymized competing genera in the TFC under that name. Based on portions of two loci (the second-largest RNA polymerase II B-subunit (*rpb2*) and larger ATP citrate lyase (*acl1*) genes), the Gräfenhan et al. (2011) phylogenetic analysis provided only weak statistical support for the node associated with the TFC. The proposal in Geiser et al. (2013) was based on a phylogenetic analysis of a much larger set of species in the TFC that utilized more informative loci (*rpb2*, as well as the largest RNA Polymerase II B-subunit gene *rpb1*; O'Donnell et al. 2013). This analysis also resolved the TFC as monophyletic ("node F1"), with improved but still weak statistical support (<70% maximum parsimony bootstrap (MP-BS) and maximum likelihood bootstrap (ML-BS); 1.0 Bayesian posterior probability (BPP). Recognizing this uncertainty, a second node ("F2"), which received much stronger statistical support (87% MP-BS; 100% ML-BS; 1.0 BPP), was offered as an alternative to F1, should more rigorous analyses reject the monophyly of F1. F2 comprises all of F1 except its two basal-

most clades (the *F. ventricosum* and *F. dimerum* Species Complexes; FVSC and FDSC respectively). Notably, both the F1 and the F2 hypotheses include the FSSC within *Fusarium*.

Based on a phylogenetic analysis of nine concatenated loci and a rich sampling of nectriaceous taxa, Lombard et al. (2015) also resolved the same TFC node, but again with weak statistical support. Although the aforementioned studies all resolved the same node, with different levels of support, Sandoval-Denis and Crous (2018) claimed with no new phylogenetic evidence that the concept of *Fusarium* proposed by Geiser et al. (2013) is polyphyletic. However, as carefully accounted for in Geiser et al. (2013) and O'Donnell et al. (2013), statistical support for that node based on analyses of *RPB1* and *RPB2* was in need of a more rigorously tested phylogeny using additional genes. In this paper, we address this with a phylogenetic inference based on complete exonic nucleotide sequences of 19 protein-coding genes, derived from whole-genome sequences of 89 taxa, 47 of which were generated in the present study (Supp. Table 1). The resulting analysis provides 100% ML-BS/1.0 BPP for the monophyly of *Fusarium* as delimited by Geiser et al. (2013; i.e., the F1 node in Fig. 1), reaffirming the taxonomic hypothesis that *Fusarium* has nomenclatural priority over all names typified in that clade, including *Neocosmospora*.

We also present a phylogeny of 77 FSSC species based on three-loci: portions of *rpb2* and *tef1* (translation elongation factor 1-α), and rDNA (a contiguous portion of the nuclear ribosomal RNA gene repeat comprising the internal transcribed spacer (ITS) and D1-D2 regions of the nuclear large subunit). Sandoval-Denis and Crous (2018) and Sandoval-Denis et al. (2019) typified and named many of the previously unnamed species within the FSSC. This is an extremely important advance in the taxonomy of this group, an effort and will greatly facilitate scientific communication about these fungi. However, we disagree with their placement in *Neocosmospora*, for reasons we outline here and in O'Donnell et al. (2020). Accordingly, we list the combinations of these taxa in *Fusarium* (Aoki et al. 2020), along with other FSSC species typified or previously combined in *Neocosmospora*.

Materials and Methods

Selection and extraction of marker loci. Exonic nucleotide sequences of the 19 housekeeping genes (Table 1) used to infer the *Fusarium* phylogeny in this study were selected based on (i) their use in previous studies for inferring phylogenetic relationships within this genus and across the Kingdom *Fungi* (Floudas et al. 2012; O'Donnell et al. 2013; Sarver et al. 2011; Villani et al. 2019; Watanabe et al. 2011); (ii) their utility in previous studies of the distribution and evolution of secondary metabolite genes/gene clusters in *Fusarium* (Brown and Proctor 2016; Brown et al. 2019; Busman et al. 2012; Kim et al. 2020;

Proctor et al. 2009, 2010, 2013, 2018) and (iii) their relative lengths. Full-length exonic sequences of each gene were obtained from whole-genome sequences of 89 taxa, generated in-house at the USDA-ARS-NCAUR (n=65), or by the Beijing Genome Institute (BGI; n=4), or downloaded from the GenBank database at the National Center for Biotechnology Information (n=20; Suppl. Table 1).

Genomic DNA for sequencing was extracted from mycelia grown in liquid GYP medium (2% glucose, 1% peptone, and 0.3% yeast extract) for 2 – 3 days, harvested by filtration, lyophilized, and ground to a powder. Genomic DNA was then extracted using a ZR Fungal/Bacterial DNA MiniPrep kit (Zymo Research, Irvine, CA), the Qiagen Genomic-Tip 20/G protocol, or a previously described chloroform-phenol-based method (Raeder and Broda 1985). For data generated in-house, sequence reads were generated using the MiSeq systems (Illumina) and processed using CLC Genomics Workbench (CLC) versions 8 – 20 (Qiagen) as previously described (Laraba et al. 2020a, b; Proctor et al. 2018). Sequence reads were imported into CLC and then screened against genome sequences of 84 bacterial species to remove contaminating DNA introduced during library preparation and/or the sequencing process. Reads were trimmed to remove low-quality data and assembled using the following parameter settings in CLC: word size = 20; bubble size = 50; minimum contig length = 500; auto-detect paired distances = checked; and perform scaffolding = checked.

Protein coding genes were predicted with the program AUGUSTUS (Stanke and Morgenstern 2005) using *F. graminearum* genes as a reference and the fgenesh algorithm (Solovyev et al. 2006) implemented online in Softberry (http://www.softberry.com). Gene sequences were retrieved from coding region databases of each strain using the BLASTn function in CLC Genomics Workbench and query sequences from *F. fujikuroi*, *F. graminearum* and *F. vanettenii* (formerly reported as *Nectria haematococca* mating population MPVI; Coleman et al. 2009). Sequences of each gene were aligned with the query sequences using MUSCLE (Edgar 2004) as implemented in MEGA7 (Kumar et al. 2016), and the resulting alignments were examined for differences between predicted coding regions and the query sequences. When necessary, genes were manually annotated using genome sequence data to correct errors introduced by the automated annotation, particularly with respect to predicted intron-splicing sites. The three loci utilized for phylogenetic analysis of the FSSC were those utilized in previous studies (O'Donnell et al. 2008; Sandoval-Denis and Crous 2019).

***Molecular phylogenetics*.** Two multilocus datasets were assembled and analyzed using partitioned maximum likelihood bootstrapping (ML-BS, 5000 replicates) with IQ-TREE 1.6.12 for MacOS (Nguyen et al. 2015; http://www.iqtree.org/) and Bayesian inference with MrBayes v.3.2.7 (Ronquist et al. 2019). A partitioned 19-gene 55.1 kb dataset was assembled to assess *Fusarium* monophyly (Table 1). It

contained complete exonic nucleotide sequences for 84 fusaria, a putative sister group comprising three *Neonectria* species, and sequences of two non-nectriaceous hypocrealean taxa, *Beauveria bassiana* (Cordycipitaceae) and *Trichoderma brevicompactum* (Hypocreaceae), which were used to root the phylogeny. A partitioned 3-locus 3.2 kb dataset was constructed to infer evolutionary relationships among 77 species within the FSSC, derived from previous studies (O'Donnell et al. 2008; Sandoval-Denis and Crous 2019). Sequences were aligned with MUSCLE and then manually edited using TextPad 8 (https://www.textpad.com) to improve the alignment. ModelFinder (Kalyaanamoorthy et al. 2017) was used to identify the best-fit model of molecular evolution for each partition based on the Bayesian information criterion (BIC) scores (Chernomor et al. 2016). Bayesian inference was conducted using 1,000,000 generations in four chains (3 cold, and one hot, with 25% burnin), using the GTR+Γ+I evolutionary model. To assess compatibility of individual loci in the phylogenetic inference, gene compatibility factors (gCF) were calculated using IQ-TREE v.2.1.2 (Minh et al. 2020a,b); gCF values, representing the proportion of gene partitions that resolve a particular node, were translated into numerals representing the number of supporting loci out of 19. In addition, Internode Certainty (IC), IC-All (ICA),Tree Certainty (TC) and relative TC values (Salichos and Rokas 2013; Salichos et al. 2014) were calculated for the IQ-TREE partitioned ML tree in RAxML v.8.2.12 (Stamakis 2014; Kobert et al. 2016). Aligned 19- and 3-locus datasets and best ML trees in NEXUS format, with genes partitioned as charsets, are included as Supplemental Materials, and also deposited in TreeBASE (Study S27101; http://purl.org/phylo/treebase/phylows/study/TB2:S27101).

Results

Fusarium *phylogenetics*.— The 19-gene nucleotide alignment of full-length exons totalled 55,140 sites, 23,668 of which were parsimony informative (Table 1). Individual genes provided a range of 0.5% (*cal1*) to 12.7% (*dpe1*) of the total parsimony informative sites in the concatenated character set. In the best ML phylogeny (Fig. 1), 72/86 inferred nodes were supported at the 100% level by ML bootstrapping (BS) as well as 1.0 Bayesian Posterior Probability (BPP), with only two nodes receiving <80% BS/<0.99 BPP support (highlighted in magenta in Fig. 1). The F1/TFC node, upon which the Geiser et al. (2013) circumscription was based (O'Donnell et a. 2013), received 100% BS/1.0 BPP, as did the previously proposed alternate node F2. The ML and Bayesian (Suppl. Fig. 1) trees were topologically identical except for placement of *F. ventricosum* within node F1 (see discussion below), which neither method resolved with statistical confidence (BS <50%; 0.88 BPP for an alternative topology; see Fig. 1 and Suppl. Fig. 1).

Based on gCF values, 53/86 internodes in the ML tree were supported by at least 16/19 loci in the dataset, while 71/86 were supported by at least half (Suppl. Fig. 3). Nodes F1 and F2 were supported by 12 and 14 individual loci. The most poorly supported node in the ML tree (unresolved in the majority-rule boostrap consensus tree and by Bayesian analysis) placed *F. ventricosum* as a sister to the *F. dimerum* Species Complex, within the F1 node. In 7/19 individual gene trees (*act1, cal1, dpe1, ku70, pgk1, tef1, tub2*; Suppl. Fig. 2), ingroup taxa (usually *F. ventricosum*) resolved among outgroup taxa. These genes tend to be shorter and have lower PIC/bp values than those that resolve F1 (Table 1). However, the F1/TFC,inclusive of *F. ventricosum* was supported in each of the remaining 12 individual gene trees, with bootstrap values between 78-100%. Three loci, *fas1, fas2,* and *ku70*, representing 24.6% of the parsimony-informative characters in the matrix, are co-located within ~30kb on the same contig (FFUJ_scaffold03) of the *F. fujikuroi* genome sequence. Removal of these linked loci and reanalysis using IQ-TREE resolved the F1/TFC node with 100% ML bootstrap support (result not shown). The IC and ICA values for the F1 node were 0.19 and 0.33, respectively (Suppl. Fig. 3), indicating that roughly 70% of the genes support the bipartition (see Fig. 2 in Salichos et al., 2014). This value is similar to the proportion of 12/19 (~63%) indicated by gCF, and evident by visual inspection of individual gene trees (Suppl. Figs. 2 and 3). TC, representing the sum of IC values across trees, was 48.41, and relative TC, representing TC normalized to the maximum TC for the phylogeny, was 0.563.

Three additional Species Complexes recognized within *Fusarium* since the publication of the *rpb1* + *rpb2* phylogeny (O'Donnell et al. 2013) are represented in the dataset: the *F. torreyae* Species Complex (FtorSC; Zhou et al. 2018), the *F. newnesense* Species Complex (FnewSC; Laurence et al. 2016) and *F. burgessii* Species Complex (FburSC, here represented by *F. beomiforme*; Laraba et al. 2018; Laurence et al. 2011; Nelson and Toussoun 1987), bringing the total to 23 Species Complexes recognized within the genus. Each of these Species Complexes received at least 95% ML-BS, except for the *F. concolor* Species Complex (FconSC), which received 69% ML-BS/0.98 BPP support. This lack of resolution appears to be due to FconSC's sister taxon, the *F. babinda* Species Complex, being represented by a single taxon in the dataset. When *F. babinda* was removed, FconSC received 100% BS support (result not shown). Similarly, the *F. ventricosum* Species Complex (FVSC) is represented by a single taxon on a long branch, which likely explains the failure to resolve its placement (Felsenstein 1978). However, it does resolve within the FTC/F1 node with 100% ML-BS and 1.0 BPP support, as it did with weaker support in previous studies (Gräfenhan et al. 2011; Lombard et al. 2015; O'Donnell et al. 2013).

FSSC phylogenetics. The 3-locus DNA alignment for the FSSC comprised 3209 sites (665 for *TEF1*, 956 for rDNA, 1588 for *RPB2*), 655 of which were parsimony-informative (164 for *TEF1*, 131 for rDNA, 360 for

RPB2). In the best ML cladogram, the previously identified major clades 1, 2 and 3 (O'Donnell 2000) were resolved with 100% bootstrap support. Three clades with unique morphologies and host associations were also resolved within the FSSC: (i) the subclade within Clade 3 that is morphologically associated with *Neocosmospora*'s type (Smith 1899); (ii) the Ambrosia *Fusarium* Clade (AFC; Kasson et al. 2013; O'Donnell et al. 2015); and (iii) the Soybean Sudden Death Syndrome (SDS) and Bean Root Rot (BRR) pathogen clade nested in Clade 2 (Aoki et al. 2012).

Taxonomy. Recognizing that *Neocosmospora sensu* Lombard et al. (2015), Sandoval-Denis and Crous (2018) and Sandoval-Denis et al. (2018, 2019) represents a later synonym of *Fusarium* under this taxonomic hypothesis, species combinations (Aoki et al. 2020) are listed in Appendix A.

Importantly, we retained as distinct species the important soybean sudden death (SDS) and bean root rot (BRR) pathogens in the FSSC, *F. phaseoli, F. tucumaniae, F. virguliforme, F. brasiliense, F. cuneirostrum, F. crassistipitatum* and *F. azukicola,* which were synonymized under *F. phaseoli* by Sandoval-Denis et al. (2019). The latter authors performed a split graph analysis and interpreted reticulate patterns as evidence that these groups are conspecific. This is in contrast to previous work providing evidence that they were genealogically exclusive (Aoki et al. 2005, 2012). However, the split graph analysis was based on *tef1, rpb2* and *rDNA,* with only twelve parsimony informative sites among these taxa, and they did not analyze the more phylogenetically informative loci that indicated genealogical exclusivity among these species (Aoki et al. 2012). While the levels of sequence divergence among these species were very small, and scrutiny of the species boundaries based on information-rich phylogenomic datasets is encouraged, the reticulate pattern illustrating homoplasy could be due to processes other than intraspecific genetic exchange, including incomplete lineage sorting and convergence. The synonymization by Sandoval-Denis et al. (2019) also does not account for the morphological differences among these species, nor reported distinctions in their symptomology and host range (Aoki et al. 2005, 2012).

Discussion

The rationale for a phylogenetic delimitation of *Fusarium* outlined by Geiser et al. (2013), reaffirmed here, can be considered on its own merit. However, we emphasize that the 166 scientists from 30 countries (aka core global *Fusarium* community) who co-authored the present publication enthusiastically support it as the best scientifically and nomenclaturally valid taxonomic option. We argue that the alternative posed by Lombard et al. (2015) is based on a taxonomic viewpoint that binds the concept of *Fusarium* to a teleomorph name, *Gibberella*. This approach was first hinted at (Gräfenhan

et al. 2011; Schroers et al. 2011), and later manifested in a proposal (Lombard et al. 2015) to split *Fusarium* into seven genera within the TFC: *Fusarium* (*Gibberella's* de facto replacement)*, Albonectria, Bisifusarium, Cyanonectria, Geejayessia, Neocosmospora,* and *Rectifusarium*. Although the generic concepts proposed by Lombard et al. (2015) are monophyletic and nomenclaturally valid, they fail on the practicality criterion because they exclude species with a longstanding place in *Fusarium*. We see no benefit in splitting *Fusarium* in favor of competing names that are largely tied to rarely observed sexual stages.

The most important exclusion by Lombard et al. (2015) is that of the FSSC, which was moved to the genus *Neocosmospora* in their taxonomic proposal. The type species, *Neocosmospora vasinfecta*, which was recombined in *Fusarium* as *F. neocosmosporiellum* (Geiser et al. 2013), represents an atypical morphological lineage derived within the FSSC (Figs. 1 and 2). *Fusarium neocosmosporiellum* and related species produce an asexual stage that, unlike most FSSC species, lacks the fusiform sporodochial macroconidia that are the hallmark of *Fusarium*, and a homothallic sexual stage consisting of smooth, thin-walled perithecia and ascospores that are mostly single-celled (Smith 1899; Wollenweber and Reinking 1935). However, *F. neocosmosporiellum* produces microconidiophores typical of the FSSC (Domsch et al. 1980). Viewed within a robust phylogenetic framework, *F. neocosmosporiellum* clearly represents a morphologically aberrant FSSC lineage whose species have lost the ability to produce the iconic multiseptate macroconidia and only occasionally produce two-celled ascospores (O'Donnell 2000; O'Donnell et al. 2013). Similarly, most of the 19 species in the Ambrosia *Fusarium* Clade are morphologically unique within the FSSC in that they produce club-shaped macroconidia that are hypothesized to be adaptive to roles associated with the ambrosia beetle symbiosis (Kasson et al. 2013).

While *Neocosmospora* works nomenclaturally as an available genus name typified within the FSSC, it would be unfortunate if its aberrant morphology were to replace *Fusarium*, which represents the dominant morphology of the group. Because *Neocosmospora* is the oldest teleomorph name associated with the FSSC, this awkward nomenclatural option seemed reasonable when it was applied under dual nomenclature (e.g.*,* Nalim et al. 2011). However, the demise of dual nomenclature as of 01 Jan 2013 opened the door to a much more practical and attractive option: *Fusarium,* an older name, and the dominant longstanding generic concept associated with the FSSC. Highlighting that status, '*Fusarium solani*' generated over 100 times more Google hits than '*Neocosmospora*' (3,000,000 to 27,600; search conducted on 09 July 2020). In summary, we argue that the practical and most scientifically attractive option is to combine *Neocosmospora* species under *Fusarium* (Geiser et al. 2013), not the other way around.

We refute the argument that inclusion of the FSSC in *Fusarium* "implies a denial of the current phenotypic ... evidence" (Sandoval-Denis et al. 2019), and, to the contrary, argue that the name '*Neocosmospora*' is an atypical phenotypic fit for the FSSC. Sandoval-Denis et al. (2019) do not apply a rigorous test or accounting of phenotypic synapomorphies that invalidate the Geiser et al. (2013) circumscription. Iconic *Fusarium* multiseptate macroconidia are observed in a majority of FSSC species, as they are in members of every other *Fusarium* Species Complex. In addition to the aforementioned *F. neocosmosporiellum,* occasional isolates within multiple FSSC species appear to lack macroconidium production (Gams 1971; O'Donnell 2000; Short et al. 2013; Summerbell and Schroers 2002). However, the vast majority of isolates in the FSSC do produce these spores, and a lack of macroconidia is occasionally observed in *Fusarium sensu* Lombard et al. (2015) as well (*e.g., F. xyrophilum*: Laraba et al. 2020a). While the FSSC is morphologically distinguishable from other *Fusarium* Species Complexes, we do not accept that these differences are sufficiently significant to require recognition as a separate genus. To wit, the concept of *Fusarium* in existence for over a century has consistently accommodated this level of phenotypic diversity in the recognition of taxonomic subgroups within the genus (Wollenweber 1913; Wollenweber and Reinking 1935).

While there are indeed morphological and ecological trends associated with the phylogenetic structure within our circumscription of *Fusarium*, there are no convincing nomenclatural, scientific or practical criteria that obligate splitting it into multiple genera. Illustrating similarities between the FSSC and other *Fusarium* clades, FSSC species share many morphological, ecological and genomic characteristics with the *F. oxysporum* Species Complex (FOSC), which Lombard et al. (2015) retain in *Fusarium*. FSSC and FOSC often are co-isolated from the same soil and plant samples, and while they can be resolved morphologically, misidentification of one as the other is common. FSSC and the FOSC are cosmopolitan residents of soil and the rhizosphere, and of decaying and living plant material, where they may act as parasites and/or endophytes. Interestingly, their ecological similarities are reflected in their genomes, with both having significantly expanded accessory genomes that include supernumerary, conditionally dispensable chromosomes that harbor niche adaptive genes (Coleman et al. 2009; Ma et al. 2010; Waalwijk et al. 2018). While these two groups occupy different clades within *Fusarium*, and placing them in separate genera is a discretionary option, plant pathologists and medical mycologists have treated them as congeneric for the past century. International *Fusarium* Laboratory Workshops, which have been held regularly since the 1970s, (Leslie and Summerell 2006b) present the FSSC and the FOSC, which is retained in *Fusarium* by Lombard et al. (2015), together in lectures and the laboratory, reflecting the shared ecological, morphological and genomic characteristics that are relevant to

clinicians and researchers. In short, we argue that the individual lineages that comprise the monophyletic *Fusarium sensu* Geiser et al. (2013) share more in common than not.

In support of splitting *Fusarium* into seven genera and promoting the FSSC as *Neocosmospora*, additional claims were made about the status of the TFC as a monophyletic group (Sandoval-Denis and Crous 2018), including: (i) the Geiser et al. (2013) concept of *Fusarium* is "polyphyletic," and (ii) moving it to *Neocosmospora* represents a "more natural classification." To correct the record, there are no published phylogenies known to the authors of this paper with appropriate taxon sampling and resolving power showing the TFC to be anything but monophyletic, including the Lombard et al. (2015) phylogeny. Comparisons of the phylogeny in Lombard et al. (2015) with those in Geiser et al. (2013), O'Donnell et al. (2013) and Gräfenhan et al. (2011) reveal that a monophyletic TFC is resolved in ***all*** of them. Certainly, as has been shown in many publications, there is phylogenetic structure within *Fusarium*, but phylogenetic structure is not synonymous with polyphyly (i.e., having multiple distinct evolutionary origins (Farris 1990)); a strongly supported monophyletic genus can encompass strongly supported monophyletic subgroups. Nor would it be reasonable to argue that a genus can accommodate only a certain degree of phylogenetic structure, particularly when its well-studied taxonomy has unanimously accommodated substructure, in the form of Sections (Wollenweber 1913) and now phylogenetic lineages referred to as Species Complexes (O'Donnell et al. 2013).

We also reject the assertion that splitting the FSSC off as *Neocosmospora* represents a "more natural classification." Given that *Neocosmospora sensu* Sandoval-Denis et al. (2019) and the circumscription of *Fusarium* in Geiser et al. (2013) are both monophyletic, the two concepts are of equal status regarding scientific support. In fact, Geiser et al. (2013) openly critiqued the phylogenetic evidence underlying their taxonomic hypothesis and presented an alternative circumscription of *Fusarium* in case additional data did not support this hypothesis. Although the concept proposed by Geiser et al. (2013) is based on phylogenetics, it is rooted in the first taxonomic synthesis of *Fusarium* (Wollenweber and Reinking, 1935), and subsequent modifications based on modern morphological (e.g., moving *'F. nivale'* into *Microdochium*; Samuels and Hallett 1983) and phylogenetic (Gräfenhan et al. 2011; O'Donnell et al. 2013) information. It retains all agriculturally, medically and economically important species in *Fusarium*. In contrast to the claim that *Neocosmospora* is the more natural classification for the FSSC, we find its transfer to *Neocosmospora* unnatural in light of this historical and practical context. It is a morphologically counterintuitive, unnecessarily disruptive solution to a taxonomic problem that does not exist.

Our phylogenetic circumscription of *Fusarium* mirrors that of *Aspergillus* in several ways (Samson et al. 2014). *Aspergillus* is also one of the most commonly used generic names in *Fungi*, and it corresponds to a strongly supported clade (Kocsubé et al. 2016; Steenwyk et al. 2019). Both genera harbor great species diversity, with new species being discovered at high rates. However, the *Aspergillus* clade encompasses much greater morphological diversity than *Fusarium*, including sexual stages varying from asci enclosed within wefts of hyphal elements (*Neosartorya*, associated with *A. fumigatus*) to cleistothecia enclosed in sclerotial ascostromata (*Petromyces*, associated with *A. flavus*). While the familiar *Aspergillus* conidiophore morphology dominates, the clade also includes aberrant anamorph forms such as *Phialosimplex*. In the case of *Aspergillus*, it was decided that the broader circumscription was the most reasonable solution among nomenclaturally and scientifically valid options (Samson et al. 2014), and all competing generic concepts have been subsumed under *Aspergillus*. While molecular phylogenetic studies over the past three decades have revealed *Aspergillus* and *Fusarium* are much larger than documented using morphology alone, it is important to note that both are monophyletic as presently circumscribed.

The strong statistical support presented in the 19-locus phylogeny solidifies the taxonomic hypothesis assigning the name *Fusarium* to all descendants of node F1 in Geiser et al. (2013) and O'Donnell et al. (2013), and the "Terminal *Fusarium* Clade" *sensu* Gräfenhan et al. (2011). This finding further negates the unsupported claim that *Fusarium sensu* Geiser et al. (2013) is polyphyletic, and it eliminates any remaining doubt regarding the robustness of the TFC/F1 node. As a result, all competing generic names typified in this clade, including *Albonectria, Bisifusarium, Cyanonectria, Geejayessia, Gibberella, Neocosmospora,* and *Rectifusarium,* are recognized as *Fusarium*. With taxon discovery and phylogenomic datasets rapidly accumulating, we will continue to scrutinize and refine our taxonomic hypothesis and promote a scientifically robust and practical, user-friendly generic concept. As shown here, consideration of additional data has significantly strengthened the inference that the present circumscription of *Fusarium* is monophyletic (Geiser et al. 2013).

Taxonomy's purpose is to foster clear scientific communication, and the job of taxonomists is to refine it with that in mind. In doing so, taxonomists must not only recommend improved communication going forward, but also weigh the costs of altering longstanding, effective communication (Booth 1978). This communication underlies international trade and agricultural biosecurity, pesticide and crop cultivar registration, and accurate identification and reporting of etiological agents essential for plant, animal and human disease management. In some cases, scientific evidence and practical merit require inconvenient disruptions of and changes in taxonomic usage to accommodate nomenclatural rules and

scientific rigor. As spelled out here and in Geiser et al. (2013), we assert that inclusion of the FSSC in *Neocosmospora* rather than *Fusarium* is not such a case. In this age, when molecular phylogenetics is informing a vastly improved taxonomy, the *Fusarium* community is fortunate that the genus-level taxonomy is supported by a phylogenetically rigorous, nomenclaturally sound and user-friendly solution allowing undisrupted unitary use of the name *Fusarium*. In the interest of a robust taxonomy that facilitates communication, we welcome cogent, data-driven alternative taxonomic hypotheses that fully consider the scientific, nomenclatural and practical ramifications.

≡ *Cylindrocarpon tonkinense* Bugnic., Encyclopédie Mycologique 11: 181. 1939. [MB 255134]

≡ *Neocosmospora tonkinensis* (Bugnic.) Sand.-Den. & Crous, Persoonia 41: 126. 2018. [MB 822904]

≡ *Fusarium ershadii* Papizadeh, van Diepeningen & Zamanizadeh, Europ. J. Plant Pathol. 151: 693. 2018. (nom. illegit. as a superfluous name, Art 52.1). [MB 817602]

Note: Also known as FSSC 9.

Fusarium vanettenii O'Donnell, Geiser, Kasson & T. Aoki, Index Fungorum 440: 5. 2020. [IF 557712]

≡ *Neocosmospora pisi* (F.R. Jones) Sand.-Den. & Crous, Persoonia 43: 143. 2019. [MB 831189]
≡ *Fusarium martii* var. *pisi* F.R. Jones, J. Agric. Res. 26: 459. 1923. [MB 270614].
≡ *Fusarium solani* f. *pisi* (F.R. Jones) W.C. Snyder & H.N. Hansen, Amer. J. Bot. 28: 740. 1941. [MB 351714]
(≡ *Fusarium pisi* (F.R. Jones) A. Šišić et al., Sci. Rep. 8: 2. 2018. Nom. inval., Art. 42.1 [MB 824719])
Note: Also known as *Nectria haematococca* Mating Population VI (NhMPVI) and FSSC 11.
Etymology: In honor of the late Hans D. Van Etten, whose laboratory conducted extensive studies on this species, making the first connection between plant pathogenicity and the fungal accessory genome.

Fusarium venezuelense O'Donnell, Geiser, Kasson & T. Aoki, Index Fungorum 440: 5. 2020. [IF 557713]
≡ *Neocosmospora robusta* Sand.-Den. & Crous, Persoonia 43: 165. 2019. [MB 831203]
(non *Fusarium robustum* Gerlach 1977 [MB 314220])
Etymology: *Venezuela* + *-ensis* from the name of its type locality.

Fusarium waltergamsii O'Donnell, Geiser & T. Aoki, Index Fungorum 440: 5. 2020. [IF 557714]
≡ *Neocosmospora gamsii* Sand.-Den. & Crous, Persoonia 41: 116. 2018. [MB 822899] (non *Fusarium gamsii* Torbati, Arzanlou, Sand.-Den. 2019 [MB 825228])
Etymology: In honor of the late Dr. Walter Gams.
Note: Also known as FSSC 7.

Fusarium yamamotoi O'Donnell, Geiser, Kasson & T. Aoki, Index Fungorum 440: 5. 2020. [IF 557715]
≡ *Nectria elegans* W. Yamam. & Maeda, Sci. Rep. Hyogo Univ. Agric. 3: 15. 1957. [MB 301759] (non *Fusarium elegans* Appel & Wollenw. 1910 [MB 451612])
≡ *Neocosmospora elegans* (W. Yamam. & Maeda) Sand.-Den. & Crous, Persoonia 43: 127. 2019. [MB 831226]
(≡ *Fusarium elegans* W. Yamam. & Maeda, Trans. Mycol. Soc. Japan 3: 115. 1962. Nom. illegit., Art 53.1 [MB 330986])
(= *Fusarium solani* f. *xanthoxyli* Y. Sakurai & Matuo, Ann. Phytopathol. Soc. Japan 26: 117. 1961. Nom. inval., Art. 39.1 [MB 350973])
(= *Hypomyces solani* f. *xanthoxyli* Y. Sakurai & Matuo, Ann. Phytopathol. Soc. Japan 26: 117. 1961. Nom. inval., Art. 39.1 [MB 350974])
Note: Also known as *Nectria haematococca* Mating Population IV (NhMPIV) and FSSC 22.
Etymology: in honor of the late Dr. Wataro Yamamoto who originally found *Nectria elegans* and studied trunk blight of *Zanthoyxlum piperitum*.

Zhou, X., O'Donnell, K., Kim, H.-S., Proctor, R. H., Doehring, G., and Cao, Z.-M. 2018. Heterothallic sexual reproduction in three canker-inducing tree pathogens within the *Fusarium torreyae* species complex. Mycologia 110:710-725.

Figure 1. Partitioned maximum likelihood bootstrapped (ML-BS) phylogram of *Fusarium*, based on full-length exonic nucleotide (nt) sequences of 19 protein-coding genes (Table 1), inferred using IQ-TREE (Nguyen et al. 2015). Nodes supported by 100% ML bootstrap (5000 replicates; BS) and 1.0 Bayesian posterior probability (BPP), including F1 and F2, are indicated with asterisks; ML-BS/BPP values are shown for nodes receiving less than 100%/1.0 support. Two branches highlighted in magenta received BS <70 and BPP < 0.99. Two shades of blue highlight 23 species complexes within *Fusarium*. Numerals situated adjacent to nodes represent gene concordance factors (gCFs) calculated by IQ-TREE 2 for that node, expressed as the number of loci that resolve it out of 19. PIC = parsimony informative characters; TC = Tree credibility.

Figure 2. Partitioned maximum likelihood boostrapped (ML-BS) cladogram of the *F. solani* Species Complex (FSSC) based on *tef1*, *rpb2* and rDNA, inferred using IQ-TREE (Nguyen et al. 2015). Clades 1, 2 and 3 represent designations proposed in O'Donnell (2000). Numerical designations corresponding to an informal ad hoc nomenclature for phylogenetic species in the FSSC (e.g., FSSC 1) are provided in brackets. The Ambrosia *Fusarium* Clade (Kasson et al. 2013), the clade that encompasses species with typical *Neocosmospora* morphology, and the clade consisting of soybean sudden death syndrome (SDS) and bean root rot (BRR) pathogens, are indicated. ML-BS values, based on 5000 replicates, are shown for each node. + = medically important species, bp, base pairs; PIC = parsimony informative characters; ET = epitype isolate; IT = isotype isolate; T = type isolate. *the type of *N. striata*, combined under *F. bataticola*. †the type of *N. boninensis*, combined under *F. tenuicristatum* (see Appendix A).

Supplemental Figure 1. Cladogram of *Fusarium* 19-locus dataset based on Bayesian inference. Numbers below nodes indicate Bayesian posterior probability on a 0-100 scale.

Supplemental Figure 2. Individual maximum likelihood boostrap phylograms of 19 individual gene trees. Locus names and molecular evolutionary models used in IQ-TREE are as listed in Table 1. Numbers above or adjacent to nodes indicate bootstrap values (5000 replicates).

Supplemental Figure 3. Cladogram of *Fusarium* inferred using IQ-TREE, with Internode Credibility (IC) and Internode Credibility-All (ICA) values presented below nodes.

Table 1. Phylogenetic data summary of 19 genes analyzed in the present study.
