The crystal structure of methyl 2-acetamido-2-deoxy- $\beta$-D-glycopyranosyl$(1 \rightarrow 4)$ - $\beta$-D-mannopyranoside monohydrate, $\mathrm{C}_{15} \mathrm{H}_{27} \mathrm{NO}_{11} \cdot \mathrm{H}_{2} \mathrm{O}$, was determined and its structural properties compared to those in a set of mono- and disaccharides bearing $N$-acetyl side-chains in $\beta$ GlcNAc aldohexopyranosyl rings. Valence bond angles and torsion angles in these side chains are relatively uniform, but $\mathrm{C}-\mathrm{N}$ (amide) and $\mathrm{C}-\mathrm{O}$ (carbonyl) bond lengths depend on the state of hydrogen bonding to the carbonyl O atom and $\mathrm{N}-\mathrm{H}$ hydrogen. Relative to N -acetyl side chains devoid of hydrogen bonding, those in which the carbonyl O atom serves as a hydrogen-bond acceptor display elongated $\mathrm{C}-\mathrm{O}$ and shortened $\mathrm{C}-\mathrm{N}$ bonds. This behavior is reproduced by density functional theory (DFT) calculations, indicating that the relative contributions of amide resonance forms to experimental $\mathrm{C}-\mathrm{N}$ and $\mathrm{C}-\mathrm{O}$ bond lengths depend on the solvation state, leading to expectations that activation barriers to amide cis-trans isomerization will depend on the polarity of the environment. DFT calculations also revealed useful predictive information on the dependencies of inter-residue hydrogen bonding and some bond angles in or proximal to $\beta$-( $1 \rightarrow 4$ ) $O$-glycosidic linkages on linkage torsion angles $\phi$ and $\psi$. Hypersurfaces correlating $\phi$ and $\psi$ with the linkage $\mathrm{C}-\mathrm{O}-\mathrm{C}$ bond angle and total energy are sufficiently similar to render the former a proxy of the latter.

## 1. Introduction

$N$-Acetyl-d-glucosamine (GlcNAc) is a key constituent of many biologically important N - and O -glycans in eukaryotic cells (Rudd \& Dwek, 1997). This 2-aminosugar contributes to the pentasaccharide core structure of $N$-glycans and to its elaboration to give complex and hybrid N -glycans (Fig. 1a) (Johansen et al., 1961). Proteins that are $O$-glycosylated often contain GlcNAc in glycosidic linkage to other residues, such as found in the $\beta$ GlcUA- $(1 \rightarrow 3)$ - $\beta$ GlcNAc disaccharide repeating unit of hyaluronic acid (Kaye \& Stacey, 1951). Posttranslational mono-GlcNAcylation affects protein biological function, often occurring in crosstalk with $O$-phosphorylation (Yang et al., 2006). The interplay between $O$-GlcNAcylation and $O$-phosphorylation is a key mechanism in the biological control of protein function (Hart et al., 2011).

The co-translational introduction of N -glycans into proteins involves the initial insertion of a common precursor, $\mathrm{Glc}_{3} \mathrm{Man}_{9^{-}}$ $\mathrm{GlcNAc}_{2}$, via a dolichol bisphosphate donor. Subsequent restructuring of this 14 -mer occurs partly in the endoplasmic reticulum (ER), but mostly in the Golgi apparatus. A series of glycosyltransferases and glycosidases, presumably distributed asymmetrically in the cis, medial, and trans Golgi network,
remodel the parent $N$-glycan into high-mannose, complex-type, and hybrid $N$-glycans. Of interest to the present work are the $N$-acetylglucosaminyltransferases (GNTs) required to assemble complex-type and hybrid chains, the most common of which are GNT-I, GNT-II, and GNT-III. The former two enzymes attach GlcNAc residues in a $\beta-(1 \rightarrow 2)$ linkage to $\alpha$ Man residues 4 and $4^{\prime}$ of the core pentasaccharide (Fig. $1 a$ ), respectively, thereby allowing further elongation of both arms with $\beta$ Gal and $N$-acetyl- $\alpha$-neuraminic acid (Neu5Ac) to give mature complex-type $N$-glycans (Geisler \& Jarvis, 2012). GNT-III catalyzes the addition of GlcNAc in a $\beta-(1 \rightarrow 4)$ linkage to $\beta$ Man residue 3 [see (I) and (II) in Fig. 1] (Takahashi et al., 2009; Nagae et al., 2013). The introduction of $\beta$-( $1 \rightarrow 4$ )-linked GlcNAc apparently prevents further elongation of the $N$-glycan at GlcNAc 5 and $5^{\prime}$, resulting in truncated chains. GNT-III-mediated chain modification appears to confer new properties to the proteins that bears it, including effects on tumor metastasis and human longevity (Takahashi et al., 2009; Ruhaak et al., 2010; Andre et al., 2007; Sultan et al., 1997).

(III)

(V)

(VII)

(VIII)
Scheme 1

The introduction of $\beta \mathrm{GlcNAc}$ at O 4 of $\beta$ Man 3 produces a $3,4,5$-trisubstituted $\beta$ Man residue, leading to increased steric interactions and the possibility of conformational distortion of one or more of the four $O$-glycosidic linkages involving $\beta$ Man 3. These conformational effects have recently been investigated by Yamaguchi and co-workers (Hanashima et al., 2018). The effects of structural context on linkage conformation are best evaluated using reference disaccharides in which
context effects are presumed to be small or zero (Zhang et al., 2017). Knowledge of the conformational properties of reference disaccharides permits a quantitative determination of whether context effects are significant, achieved by comparing the behavior of a reference disaccharide to that of the same disaccharide embedded in a larger oligosaccharide. While the natural inclination is to anticipate changes in linkage conformation as a function of context, other saccharide conformational elements may also be affected, such as the preferred geometries of hydroxy groups and other exocyclic appendages. An impediment to quantifying these effects has been the lack of a method that provides continuous models of conformational elements based exclusively on experimental data. This obstacle has been recently overcome with the development of $M A A^{\prime} A T$ analysis, which uses circular statistics and redundant NMR $J$-couplings to derive single- and multi-state models of conformational behaviors in solution (Zhang et al., 2017, 2019).

To characterize saccharide structures from a conformational standpoint, knowledge of their X-ray structures can be beneficial, if only to compare crystal conformations with those observed in solution to determine whether solvation (e.g. by explicit solvent water or by the crystalline lattice itself) affects conformational preference. In prior work, a group of biologically relevant disaccharides has been studied by crystallography, and the present work extends this effort to the $\beta$ GlcNAc-( $1 \rightarrow 4$ )- $\beta$ Man linkage shown in (II) (Fig. 1b). Methyl 2-acetamido-2-deoxy- $\beta$-D-glucopyranosyl-( $1 \rightarrow 4$ )- $\beta$-Dmannopyranoside, (III) [Scheme 1; the scheme shows the conventional atom numbering and identifies the $\mathbf{a}$ and $\mathbf{b}$ residues of (III), (V), (VII), and (VIII)], was prepared by chemical synthesis and crystallized, and its low-temperature crystal structure determined. The structural parameters observed in crystalline (III) are compared to those in methyl 2-acetamido-2-deoxy- $\beta$-D-glucopyranoside, (IV) (Hu et al., 2011), 2-acetamido-2-deoxy- $\beta$-D-glucopyranosyl-( $1 \rightarrow 4$ )-2-acet-amido-2-deoxy- $\beta$-D-glucopyranose, (V) (Mo, 1979), 2-acet-amido-2-deoxy- $\beta$-D-glucopyranosyl-( $1 \rightarrow 4$ )-2-acetamido-2-deoxy-$\alpha$-D-glucopyranose, (VI) (Mo \& Jensen, 1978), 2-acetamido-2-deoxy- $\beta$-D-glucopyranose, (VII) (Mo \& Jensen, 1975), and methyl $\beta$-D-xylopyranosyl-(1 $\rightarrow 4$ )- $\beta$-D-mannopyranoside, (VIII) (Zhang et al., 2013).

## 2. Experimental

### 2.1. Chemical synthesis and crystallization of (III) (Fig. 2)

2.1.1. Methyl 3,6-di-O-benzyl- $\beta$-D-mannopyranoside (2). Methyl $\beta$-d-mannopyranoside (1) ( $5.90 \mathrm{~g}, 30.4 \mathrm{mmol}$ ) and di-$n$-butyltin oxide ( $17.0 \mathrm{~g}, 68.3 \mathrm{mmol}$ ) were added to anhydrous toluene ( 60 ml ). After stirring at 373 K for 3 h , the reaction mixture was concentrated to 30 ml , and benzyl bromide $(20 \mathrm{ml}, 168 \mathrm{mmol})$ and tetrabutylammonium bromide $(5.00 \mathrm{~g}$, 15.5 mmol ) were added. The resulting mixture was stirred at 373 K for an additional 20 h , and then concentrated in vacuo. The residue was dissolved in ethyl acetate, washed with distilled water, dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and concen-

(b)

Figure 1
(a) The structure of a complex-type $N$-glycan, (I), containing a bisecting $\beta$-( $1 \rightarrow 4$ )-linked GlcNAc to $\beta$ Man (disaccharide fragment highlighted in blue) of $\mathrm{Man}_{3} \mathrm{GlcNAc}_{2}$. (b) Tetrasaccharide subfragment of (I) containing residues $3,3^{\prime}, 3$ and $4^{\prime}$, showing the molecular structure in the vicinity of the bisecting $\beta$ GlcNAc.
trated to a syrup, which was purified by flash chromatography on silica gel to afford glycoside 2 (yield: $7.50 \mathrm{~g}, 20.1 \mathrm{mmol}$, $66 \%$ ) (Qin \& Grindley, 1994). In this and all of the following steps, flash column chromatography on silica gel (preparative scale) was performed on a Reveleris X2 flash chromatography system. A mixture of hexanes and ethyl acetate was used as the eluent.
2.1.2. Methyl 2-O-benzoyl-3,6-di-O-benzyl- $\beta$-d-mannopyranoside (3). Compound 2 ( $7.50 \mathrm{~g}, 20.1 \mathrm{mmol}$ ) was dissolved in anhydrous toluene ( 60 ml ) and anhydrous pyridine $(8 \mathrm{ml})$ was added. Benzoyl chloride ( $2.50 \mathrm{ml}, 21.5 \mathrm{mmol}$ ) was then added dropwise at 273 K and the reaction mixture was stirred at 273 K for 2 h . The mixture was then evaporated to
dryness and purified by flash chromatography on silica gel, affording product 3 (yield: $8.40 \mathrm{~g}, 17.6 \mathrm{mmol}, 87 \%$ ).
2.1.3. 2-Deoxy-2-phthalimido-3,4,6-tri-O-acetyl- $\alpha$-D-glucopyranosyl trichloroacetimidate (7). D-Glucosamine hydrochloride (4) ( $6.33 \mathrm{~g}, 29.2 \mathrm{mmol}$ ), $\mathrm{Na}_{2} \mathrm{CO}_{3}(3.10 \mathrm{~g}, 29.2 \mathrm{mmol})$, and phthalic anhydride ( $4.32 \mathrm{~g}, 29.2 \mathrm{mmol}$ ) were added to water ( 38 ml ). The mixture was stirred at room temperature overnight and concentrated to dryness. The residue was dissolved in pyridine ( 100 ml ), and $\mathrm{Ac}_{2} \mathrm{O}(40 \mathrm{ml}, 423 \mathrm{mmol})$ was added. After stirring at room temperature for 12 h , the mixture was concentrated at 313 K in vacuo. The residue was dissolved in ethyl acetate, washed with distilled water, dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and concentrated to give compound

Notes: (a) in silico models of (IV) differ in the number of explicit 'solvent' water and/or methanol molecules included during geometry optimization. (b) Model was protonated at the carbonyl O atom. (c) After geometry optimization. (d) Calculations were conducted using self-consistent reaction field (SCRF) with implicit methanol solvent. (e) Calculations included effects of solvent water, which were treated using the SCRF and Integral Equation Formalism (polarizable continuum) model (IEFPCM); see Calculation methods ( $(\$ 2.2$ ). ( $f$ ) Includes hydrogen bond to acceptor water from the $\mathrm{N}-\mathrm{H}$ hydrogen. (g) Geometry optimization conducted with $\mathrm{C} 1-\mathrm{C} 2-\mathrm{N} 2-\mathrm{CO}$ torsion angle in (IV) (see Scheme 1 ) constrained at $112^{\circ}$.
5. Compound 5 was dissolved in tetrahydrofuran (THF, 150 ml ), the resulting solution was cooled in an ice bath, and benzylamine ( $3.82 \mathrm{ml}, 35.0 \mathrm{mmol}$ ) was added. After stirring for 4 h at room temperature, the THF was removed in vacuo. The residue was dissolved in ethyl acetate, washed with 1 N aqueous HCl solution, saturated aqueous $\mathrm{NaHCO}_{3}$ solution, and distilled water sequentially, and then dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$. After concentration, crystallization from an ethyl acetate/hexane ( $\sim 3: 1 \mathrm{v} / \mathrm{v}$ ) mixed solvent afforded pure compound 6 (yield: $8.00 \mathrm{~g}, 18.4 \mathrm{mmol}, 63 \%$ ). Compound 6 ( $3.00 \mathrm{~g}, 6.89 \mathrm{mmol}$ ) was dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(30 \mathrm{ml})$, and trichloroacetonitrile ( $2.00 \mathrm{ml}, 19.9 \mathrm{mmol}$ ) and several drops of 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) were added. The reaction solution was stirred for 3 h at room temperature and concentrated in vacuo. Flash chromatography on silica gel gave trichloroacetimidate 7 (yield: $3.10 \mathrm{~g}, 5.35 \mathrm{mmol}, 78 \%$ ) (Liu \& Wei, 2012; Schmidt \& Michel, 1985).
2.1.4. Methyl 2-deoxy-2-phthalimido-3,4,6-tri-O-acetyl- $\beta$ -D-glucopyranosyl-(1 $\rightarrow 4$ )-2-O-benzoyl-3,6-di-O-benzyl- $\beta$-Dmannopyranoside (8). A mixture of trichloroacetimidate 7 ( $750 \mathrm{mg}, 1.30 \mathrm{mmol}$ ), methyl glycoside 3 ( $480 \mathrm{mg}, 1.00 \mathrm{mmol}$ ), and molecular sieves ( $4 \AA, 2.0 \mathrm{~g}$ ) was dried under high vacuum, and then anhydrous $\mathrm{CH}_{2} \mathrm{Cl}_{2}(20 \mathrm{ml})$ was added. The solution was cooled to 273 K and treated with TMSOTf ( $20 \mathrm{ml}, 0.11 \mathrm{mmol}$ ) under $\mathrm{N}_{2}$. After 2 h , the reaction was quenched with the addition of a few drops of triethylamine and the molecular sieves were removed by filtration. The solution was concentrated to a syrup in vacuo, and the residue was purified by flash chromatography on silica gel to afford disaccharide 8 (yield: $790 \mathrm{mg}, 0.88 \mathrm{mmol}, 88 \%$ ).
2.1.5. Methyl 2-acetamido-2-deoxy- $\beta$-d-glucopyranosyl( $1 \rightarrow 4$ )- $\beta$-d-mannopyranoside, (III). Compound 8 ( 300 mg , 335 mmol ) was dissolved in methanol ( 15 ml ) and treated with $\mathrm{Pd} / \mathrm{C}(10 \%, 100 \mathrm{mg})$ and $\mathrm{H}_{2}$ overnight. The $\mathrm{Pd} / \mathrm{C}$ catalyst was removed by filtration and the filtrate was concentrated to dryness in vacuo. The residue was dissolved in ethanol ( 20 ml ) and hydrazine hydrate $(3.00 \mathrm{ml})$ was added. After refluxing for 20 h , the reaction mixture was concentrated in vacuo to a syrup, which was dried under high vacuum. The dried residue was dissolved in pyridine $(20 \mathrm{ml})$ and $\mathrm{Ac}_{2} \mathrm{O}(4.00 \mathrm{ml}$, 42.3 mmol ) was added. The mixture was stirred at room
temperature overnight and concentrated in vacuo. After concentrating in vacuo, the residue was purified by flash chromatography on silica gel to give an acetylated disaccharide, which was treated with sodium methoxide in methanol ( $20 \mathrm{ml}, \mathrm{pH}>10$ ) overnight. Final product (III) was purified by crystallization from a mixture of water and methanol (yield: $90 \mathrm{mg}, 230 \mathrm{mmol}, 69 \%$ ). Disaccharide (III) was recrystallized from water, characterized by ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectroscopy (see Table S1 in the supporting information for ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ chemical shifts, and Figs. S 1 and S 2 for ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra), and used in the X-ray structure analysis.

### 2.2. Calculation methods

Density functional theory (DFT) calculations were performed to investigate the effect of hydrogen bonding on the $\mathrm{C}-\mathrm{N}$ and $\mathrm{C}-\mathrm{O}$ bond lengths in the $N$-acetyl side chain of methyl 2-acetamido-2-deoxy- $\beta$-d-glucopyranoside, (IV). The calculations were performed in two steps to ensure accurate positions of explicit solvent water molecules with respect to (IV). The first step utilized molecular dynamics (MD) simulations to minimize the energy of the solvated molecule. The second step employed density functional theory (DFT) to fully optimize the monosaccharide with explicit solvent water molecules.
2.2.1. Solvation and initial energy minimization. The initial structure of (IV) was built using the Carbohydrate Builder module available at the GLYCAM web site (http://www.glycam.org) (Woods Group, 2019). The structure was solvated with TIP3P (Jorgensen et al., 1983) water using a $10 \AA$ buffer in a cubic box and the LEaP module in the AMBER18 software package (Case et al., 2018). The solvated structure then underwent energy minimization under constant volume (500 steps steepest descent, followed by 24500 steps of conjugategradient minimization). The GLYCAM06 (Version j) force field (Kirschner et al., 2008) was employed for energy minimization. The Cartesian coordinates of the minimized structure and solvent were extracted and examined using the molecular viewing software Chem3D (PerkinElmer Informatics). Only the three solvent water molecules that were
hydrogen bonded to the carbonyl O atom or amide H atom were retained in subsequent calculations.
2.2.2. Geometry optimizations. DFT calculations were conducted within GAUSSIAN16 (Frisch et al., 2016) using the B3LYP functional (Becke, 1993) and 6-311++G(d,p) basis set (McLean \& Chandler, 1980; Frisch et al., 1984) for geometry optimizations. Two sets of calculations were conducted, i.e. in vacuo and with the inclusion of implicit solvent modeling. Two implicit solvent models were employed, water and methanol, both using the self-consistent reaction field (SCRF) (Cances et al., 1997) and the integral equation formalism (polarizable continuum) model (IEFPCM) (Cammi et al., 2000). In all calculations, the $\mathrm{C} 1-\mathrm{C} 2-\mathrm{N} 2-\mathrm{CO}$ torsion angle in the $N$-acetyl side chain was initially set to $113^{\circ}$ and allowed to optimize freely unless otherwise indicated. Geometry optimizations were conducted on nine models of (IV) that differed in the number of explicit solvent water molecules (Table 1) that were hydrogen bonded to the side chain. The $\mathrm{C}-\mathrm{N}$ and $\mathrm{C}-\mathrm{O}$ bond lengths were extracted from the optimized geometries using Python (Jones et al., 2014).

### 2.3. Refinement

Crystal data, data collection, and structure refinement details are summarized in Table 2. The structure of (III) was solved using dual-space methods (Sheldrick, 2015a) and refined routinely. H atoms bonded to C atoms were included in idealized positions riding on the C atom to which they are bonded, with $\mathrm{C}-\mathrm{H}=1.00$ (methine), 0.99 (methyl), or $0.98 \AA$ (methylene), and $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{C})$ (methine and methylene) or $1.5 U_{\text {eq }}(\mathrm{C})$ (methyl). Methyl H atoms were treated as a rotating model to minimize the electron-density contribution from these atoms. Hydroxy, water, and amide H atoms were initially located from a difference Fourier map. In the final model, hydroxy and water H atoms were refined as a rotating model to minimize their electron-density contribution, with $U_{\text {iso }}(\mathrm{H})=1.5 U_{\text {eq }}(\mathrm{O})$ and $\mathrm{O}-\mathrm{H}=0.84$ (hydroxy) or $0.85 \AA$ (water). The amide H atom was refined freely. This model was adopted after some of the hydroxy H atoms refined unreasonably when treated as freely refined atoms.

## 3. Results and discussion

3.1. General structural features and crystal packing description of (III)

The crystal structure of (III) (Fig. 3) reveals the $\beta$ GlcNAc and $\beta$ Man aldohexopyranosyl rings in ${ }^{4} C_{1}$ conformations, and an internal $O$-glycosidic linkage characterized by $p h i\left(\phi ; \mathrm{H1}^{\prime}-\right.$ $\left.\mathrm{C}^{\prime}-\mathrm{O} 1^{\prime}-\mathrm{C} 4\right)$ and $p s i\left(\psi ; \mathrm{C}^{\prime}-\mathrm{O}^{\prime}-\mathrm{C} 4-\mathrm{H} 4\right)$ torsion angles of 42.9 and $-15.5^{\circ}$, respectively. The exocyclic hydroxymethyl $\left(\mathrm{CH}_{2} \mathrm{OH}\right)$ groups appended to the $\beta \mathrm{GlcNAc}$ and $\beta$ Man rings adopt $g g$ conformations characterized by $\mathrm{O}^{\prime} / \mathrm{O} 5-\mathrm{C}^{\prime} / \mathrm{C} 5-$ $\mathrm{C}^{\prime} / \mathrm{C} 6-6^{\prime} / \mathrm{O} 6$ torsion angles of -56.3 and $-70.1^{\circ}$, respectively. An inter-residue hydrogen bond between O3H (donor) and $\mathrm{O}^{\prime}$ is observed, characterized by an $\mathrm{O} 3 \cdots 5^{\prime}$ internuclear distance of $2.71 \AA$. The $N$-acetyl side chain in the $\beta \mathrm{GlcNAc}$ residue adopts a trans configuration ( $\mathrm{C} 2^{\prime}-\mathrm{N} 2^{\prime}-$

$\mathrm{C}_{\mathrm{car}}-\mathrm{CH}_{3}$ torsion angle of $177.1^{\circ}$ ), and the conformation about the $\mathrm{C}^{\prime}-\mathrm{N}^{\prime}$ bond positions the $\mathrm{C}_{\mathrm{car}}=\mathrm{O}_{\text {car }}$ and $\mathrm{C}^{\prime}-$ $\mathrm{H} 2^{\prime}$ bonds (pseudo-torsion $\mathrm{O}^{\prime}-\mathrm{C}^{\prime} \cdots \mathrm{C}^{\prime}-\mathrm{H} 2^{\prime}$; see Fig. 3) in a near-eclipsed orientation (see Table 2 for refinement details).

Figure 3
The labeling scheme for (III). Displacement ellipsoids are depicted at the $50 \%$ probability level. H atoms are shown as spheres of arbitrary radii.

All of the hydroxy groups in (III) are involved in hydrogen bonding, as are both water H atoms. Surprisingly, the second water H atom that was located from a difference Fourier map is not oriented towards nearby acceptor atoms, but rather into a void space within the lattice. As described above, O3 forms an intramolecular hydrogen bond to $\mathrm{O5}^{\prime}$; all other hydrogenbond interactions are intermolecular. Glycosidic linkage atom O1' and the methoxy atom O1 do not participate in hydrogen bonding. Atom O1 is spatially close to a neighboring hydroxy O6 atom, however, the contact is long and would be bifurcated with the O6‥O2 hydrogen bond (see Table 3 for details). Ring atom O 5 serves as an acceptor in a hydrogen bond from $\mathrm{N}^{\prime}{ }^{\prime}\left(\mathrm{N} 2^{\prime} \cdots \mathrm{O} 5^{\text {i }}\right.$; for symmetry codes, see Table 3; the relationship is by a screw axis along $b$ ). This hydrogen bond is bifurcated with $\mathrm{O} 2{ }^{\mathrm{i}}$. Hydroxy atom O 4 only donates a hydrogen bond to $\mathrm{O} 3^{\text {ii }}$ (a second screw axis parallel to the $b$ axis) and $\mathrm{O}^{\prime}$ only donates to $\mathrm{O3}^{\prime \text { 'iii }}$ (a third, unique, screw axis along $b$ ). All other hydroxy groups are both donors and acceptors. Amide atom $\mathrm{O}^{\prime}$ is an acceptor in a hydrogen bond from the water of crystallization ( $\mathrm{O} 1 W \cdots \mathrm{O}^{\text {iv }}$; related by a screw axis along the crystallographic $c$ axis). The water molecule is also a donor in a hydrogen bond to $\mathrm{O}^{\mathbf{\prime v}}$. In turn, the water molecule serves as an acceptor in a hydrogen bond from O2. Hydroxy atom O6 has a strong hydrogen bond to $\mathrm{O} 2^{\mathrm{i}}$, that is also slightly bifurcated and much weaker to $\mathrm{O} 1^{\mathrm{i}}$. Atom O6 is the acceptor in a hydrogen bond from $\mathrm{O}^{\prime}$ ( $\mathrm{O}^{\prime} \cdots{ }^{\prime} \cdots 6^{\mathrm{i}}$ ). The overall motif is a three-dimensional hydrogen-bonded network (Fig. 4). Graph-set analysis of the strutcure reveals that the hydrogen bonds involving the water molecule are both $D$ (discrete) contacts, the O3 $\cdots \mathrm{O}^{\prime}$ interaction is an $S$ (self-interacting) contact and all other local contacts are $C$ (chain) hydrogen bonds (Etter et al., 1990).

The following discussion treats structurally related $\beta$ GlcNAc residues at the nonreducing ends of (III), (V), and $(\mathrm{VI})$, and the $\beta \mathrm{GlcNAc}$ rings $\left(\mathrm{IV}_{\mathrm{A}}\right)$ and $\left(\mathrm{IV}_{\mathrm{B}}\right)$. GlcNAc residues at the reducing ends of (V) and (VII), and the $\alpha \mathrm{GlcNAc}$ ring in (VII) are treated when anomeric configuration and

Figure 5
Phi $(\phi)$ and psi $(\psi)$ glycosidic torsion angles in (III), (V), (VI), and (VIII) in their crystal structures, defined as $\mathrm{C}^{\prime}-\mathrm{C1}^{\prime}-\mathrm{O}^{\prime}-\mathrm{C} 4$ and $\mathrm{Cl}^{\prime}-\mathrm{O}^{\prime}-$ $\mathrm{C} 4-\mathrm{C} 3$, respectively. Torsion angles for the conventional definitions of $\phi$ $\left(\mathrm{H}^{\prime}-\mathrm{Cl}^{\prime}-\mathrm{O}^{\prime}-\mathrm{C} 4\right)$ and $\psi\left(\mathrm{Cl}^{\prime}-\mathrm{O}^{\prime}-\mathrm{C} 4-\mathrm{H} 4\right)$ are shown in brackets. Values shown in red are the $\mathrm{O} 3 \cdots 5^{\prime}$ and $\mathrm{O} 3 \cdots 6^{\prime}$ internuclear distances (in $\AA$; atoms $\mathrm{O} 3, \mathrm{O}^{\prime}$ and $\mathrm{O}^{\prime}$ are shown in bold red) observed in the crystal structures. The atom numbering in these disaccharides is identical to the numbering shown in Scheme 1.
related structural factors assist the discussion. Structural properties of the $\beta$ Man ring of (III) (residue a) (see Scheme 1 for the identification of residues $\mathbf{a}$ and $\mathbf{b}$ ) are compared to those of the $\beta$ Man ring of (VIII) (residue a). Structural parameters in (III)-(VIII), which are summarized in Table S2 in the supporting information, informed the following discussion.
3.2. O-Glycosidic linkage conformations in (III), (V), (VI), and (VIII), and inter-residue hydrogen bonding

The conformation of the internal $O$-glycosidic linkage in (III) resembles that in (VIII), as reflected by the virtually

Figure 4
Packing diagram of (III), viewed along the $a$ axis. $\mathrm{C}-\mathrm{H}$ hydrogens have been omitted for clarity. Hydrogen bonds are depicted as blue dashed lines.

Figure 6
Internuclear distances for (a) $\mathrm{O} 3 \cdots \mathrm{O}^{\prime}$ and (b) $\mathrm{O} 3 \cdots \mathrm{O}^{\prime}$ as a function of $\phi$ and $\psi$ determined by DFT calculations using (IX) as a model. For O3 $\cdots 5^{\prime}, \phi$ and $\psi$ values of $\sim 45-180$ and $240-340^{\circ}$, respectively, yield distances compatible with inter-residue hydrogen bonding. For O3 . . O $6^{\prime}$, $\phi$ and $\psi$ values that permit hydrogen bonding are more limited (40-120 and $260-320^{\circ}$, respectively) in structures having $\mathrm{O}^{\prime}-\mathrm{C}^{\prime}-\mathrm{C}^{\prime}-\mathrm{O}^{\prime}$ torsion angles in residue $\mathbf{b}$ near $+60^{\circ}$ (gt rotamer). Phi/psi values observed in the crystal structures of (III) (star), (V) (circle), (VI) (triangle), and (VIII) (square) are superimposed on each map.
identical $\mathrm{C}^{\prime}-\mathrm{C1}^{\prime}-\mathrm{O} 1^{\prime}-\mathrm{C} 4$ torsion angles that report on $p h i$ $(\phi)$, and the similar $\mathrm{C}^{\prime}-\mathrm{O} 1^{\prime}-\mathrm{C} 4-\mathrm{C} 3$ torsion angles $\left(\Delta=3^{\circ}\right)$ that report on psi ( $\psi$ ) (Fig. 5). The internuclear distances between O3 and O5 ${ }^{\prime}$ in (III) and (VIII) are also similar $(\sim 2.70 \AA ; \Delta=0.024 \AA)$ and consistent with inter-residue hydrogen bonding. Rotameric properties of the C3-O3 bonds in residues a of (III) and (VIII) are also similar. For example, the $\mathrm{C} 2-\mathrm{C} 3-\mathrm{O} 3-\mathrm{H}$ torsion angles are 156 and $168^{\circ}$, respectively, which places O 3 H in close proximity to $\mathrm{O}^{\prime}$. The $\mathrm{O} 3-\mathrm{H} \cdots \mathrm{O}^{\prime}$ pseudo-bond angles in residues a of (III) and (VIII) are 164 and $157^{\circ}$, respectively, which approach the $\sim 180^{\circ}$ value considered optimal for hydrogen bonding (Kroon \& Kanters, 1974).

The $O$-glycosidic linkage conformations in (V) and (VI) differ significantly from one another and from the internal linkages in (III) and (VIII) (Fig. 5). In (VI), $\phi$ is similar to values observed in (III) and (VIII) $\left(\Delta=\sim 3^{\circ}\right)$, but $\psi$ increases by $\sim 29^{\circ}$. Consequently, the internuclear distance between O3 and $\mathrm{O}^{\prime}$ in (VI) increases to $3.311 \AA$, a value too large to support inter-residue hydrogen bonding. The $\mathrm{C} 2-\mathrm{C} 3-\mathrm{O} 3-$ H torsion angle in residue a of (VI) $\left(143^{\circ}\right)$, and the $\mathrm{O}^{\prime}-$
$\mathrm{H} \cdots \mathrm{O} 5$ pseudo-bond angle ( $143^{\circ}$ ) are both smaller than the corresponding values in (III) and (VIII), suggesting a weaker interaction, if any, between O 3 H and $\mathrm{O}^{\prime}$.
$O$-Glycosidic linkage conformation in (V) deviates significantly from those found in (III), (VI), and (VIII) (Fig. 5). Both $\phi$ and $\psi$ are affected, the latter more than the former [ $\Delta=$ $\sim 12^{\circ}$ for $\phi$ and $\Delta=\sim 27^{\circ}$ for $\psi$, relative to (III) and (VIII)]. While the absolute difference for $\psi$ is similar for (V) and (VI) relative to (III)/(VIII), these angles change in opposite directions. Interestingly, the $\phi$ and $\psi$ torsion angles in (V) yield an O3..O $5^{\prime}$ internuclear distance of $2.796 \AA$, which would allow inter-residue hydrogen bonding. The $\mathrm{C} 2-\mathrm{C} 3-$ $\mathrm{O} 3-\mathrm{H}$ torsion angle $\left(-149^{\circ}\right)$ and $\mathrm{O} 3-\mathrm{H} \cdots \mathrm{O} 5^{\prime}$ pseudo-bond angle $\left(133^{\circ}\right)$ in (V) differ considerably from those in (III), (VI), and (VIII), however, which may weaken the interaction. In addition, the exocyclic hydroxymethyl conformation in residue $\mathbf{b}$ of $(\mathrm{V})$ ( $g t$ rotamer; gt $=$ gauche-trans) orients O 3 relatively close to $\mathrm{O}^{\prime}(2.875 \AA)$, resulting in additional interresidue hydrogen bonding. However, the $\mathrm{O} 3-\mathrm{H} \cdots \mathrm{O}^{\prime}$ pseudo-bond angle in (VI) is small $\left(139^{\circ}\right)$, which may render the interaction weak.

Theoretical calculations of the dependence of the O3...O5' and O3 $\cdots 6^{\prime}$ internuclear distances on $\phi$ and $\psi$ in $\beta-(1 \rightarrow 4)$ linked disaccharides were conducted using density functional theory (DFT) and methyl $\beta$-lactoside (methyl $\beta$-D-galacto-

Figure 7
(a) Internuclear $\mathrm{O} 3 \cdots 1^{\prime}$ distances and (b) $\mathrm{O}^{\prime}-\mathrm{C} 4-\mathrm{C} 3$ bond angles in (IX) as a function of $\phi$ and $\psi$ determined by DFT. The $\mathrm{C1}^{\prime}-\mathrm{O}^{\prime}-\mathrm{C} 4$ and $\mathrm{C} 4-\mathrm{C} 3-\mathrm{O} 3$ bond angles showed no correlation with the O3...O1' internuclear distance (data not shown; see text).

pyranosyl-( $1 \rightarrow 4$ )- $\beta$-D-glucopyranoside), (IX), as a model (Fig. 6). These calculations were originally conducted for studies of the linkage torsion angles in (IX) (Zhang et al., 2017). The phi $(\phi)$ and $p s i(\psi)$ torsion angles in (IX) were rotated in $15^{\circ}$ increments, yielding 576 geometry-optimized conformers. Internuclear distances and bond angles were extracted from these conformers to generate the contour plots in Figs. 4 and 6 using Python. A small region of $\phi / \psi$ space correlates with internuclear distances compatible with hydrogen bonding, especially for $\mathrm{O} 3 \cdots \mathrm{O}^{\prime}$. In the latter case, the exocyclic hydroxymethyl group must adopt the $g t$ conformation in residue $\mathbf{b}$ to allow hydrogen bonding. Superimposition of crystallographic distances in (III), (V), (VI), and (VIII) on these theoretical maps explains why (V) accommodates hydrogen bonding between O 3 and $\mathrm{O}^{\prime} / \mathrm{O}^{\prime}$, and (VI) does not. The DFT calculations also reveal that, while the O3-O1' internuclear distance in $\beta$ - $(1 \rightarrow 4)$-linked disaccharides is expected to be relatively constant and independent of linkage conformation, a discernable dependence is nevertheless observed (Fig. 7). This behavior appears to correlate with the $\mathrm{O}^{\prime}-\mathrm{C} 4-\mathrm{C} 3$ bond angle. In contrast, the $\mathrm{C} 4-\mathrm{C} 3-\mathrm{O} 3$ bond angle is essentially unaffected by $\phi$ and $\psi$, whereas the $\mathrm{C1}^{\prime}-\mathrm{O} 1^{\prime}-\mathrm{C} 4$ bond angle is affected but does not correlate with the O1'...O3 internuclear distance (data not shown). However, the $\mathrm{C1}^{\prime}-\mathrm{O}^{\prime}-\mathrm{C} 4$ bond angle appears to be a proxy for the total energy of the molecule, with smaller angles associated with lower-energy structures (see Fig. S3 in the supporting information).

### 3.3. N-Acetyl side-chain structural properties in (III)-(VII)

Average structural parameters in the $N$-acetyl side chains of (III)-(VII) are shown in Fig. 8 (throughout the following discussion and as shown in Fig. 8, N -acetyl side-chain atoms are denoted $\mathrm{N} 2, \mathrm{C}_{\mathrm{car}}, \mathrm{O}_{\text {car }}$, and $\mathrm{CH}_{3}$ to allow comparisons between different structures). The $\mathrm{C} 2-\mathrm{N} 2$ and $\mathrm{C}_{\mathrm{car}}-\mathrm{O}_{\text {car }}$ bond lengths are relatively constant, giving standard deviations of $\pm 0.005 \AA$. The amide bond, $\mathrm{N} 2-\mathrm{C}_{\mathrm{car}}$, exhibits the largest variability, giving a standard deviation of $0.012 \AA$. Residue b in (VI) contains the shortest $\mathrm{N} 2-\mathrm{C}_{\mathrm{car}}$ bond ( $1.317 \AA$ ), whereas residue $\mathbf{b}$ in (III) contains the longest bond $(1.348 \AA)$, for an overall difference of $0.031 \AA$. Shorter amide
bonds suggest greater double-bond character and larger activation barriers for cis-trans isomerization (Hu et al., 2010). Prior studies of noncarbohydrate systems have shown that activation barriers to amide bond rotation depend on solvation state, with nonpolar solvents lowering the activation barriers relative to polar and/or hydrogen-bonding solvents (Wiberg et al., 1995; Pluth et al., 2008). Nonpolar solvents are believed to stabilize the relatively nonpolar transition state for amide bond rotation while destabilizing the more polar ground state (Wiberg et al., 1995; Pluth et al., 2008). An inspection of the crystal structures of (III) and (VI) reveals different hydrogen-bonding interactions involving $\mathrm{O}_{\text {car }}$ and the $\mathrm{N}-\mathrm{H}$ hydrogen (only internuclear distances $<3.0 \AA$ between the heavy atoms involved in hydrogen bonds were considered in this treatment, since those with greater distances are comparatively weak and are not likely to be significant contributors to the observed $\mathrm{N} 2-\mathrm{C}_{\mathrm{car}}$ and $\mathrm{C}_{\mathrm{car}}-\mathrm{O}_{\mathrm{car}}$ bondlength effects). For (III), the $\mathrm{N}-\mathrm{H}$ hydrogen is involved in weak bifurcated hydrogen bonds to $\mathrm{O} 2^{\mathrm{i}}$ and $\mathrm{O} 5^{\mathrm{i}}$, and the carbonyl O atom serves as a monoacceptor from a water molecule $(2.840 \AA)$, although not in an optimal hydrogenbonding geometry $\left[\mathrm{C}_{\mathrm{car}}-\mathrm{O}_{\mathrm{car}} \cdots \mathrm{H}\right.$ bond angle of $122 / 107^{\circ}$ (bifurcated); $\mathrm{N} 2-\mathrm{C}_{\mathrm{car}}-\mathrm{O}_{\mathrm{car}} \cdots \mathrm{H}$ pseudo-torsion angle of 142/ $115^{\circ}$ (bifurcated)] (Wiberg et al., 1995; Pluth et al., 2008). In (VI), the $\mathrm{N}-\mathrm{H}$ hydrogen serves as a donor to a water molecule, and the carbonyl O atom serves as a monoacceptor in a near-optimal hydrogen-bonding geometry $\left(\mathrm{C}_{\mathrm{car}}-\mathrm{O}_{\mathrm{car}} \cdots \mathrm{H}\right.$ bond angle of $119^{\circ}$; $\mathrm{N} 2-\mathrm{C}_{\mathrm{car}}-\mathrm{O}_{\mathrm{car}} \cdots \mathrm{H}$ pseudo-torsion angle of $-176^{\circ}$ ), assuming that the two lone-pair orbitals on the carbonyl O atom are directional and lie in the $-\mathrm{NH}-(\mathrm{CO})-$ $\mathrm{CH}_{3}$ plane (Wiberg et al., 1995; Pluth et al., 2008). If the hydrogen-bonding interactions in (VI) are, on average,

Figure 8
Averaged structural parameters for the $N$-acetyl side chains in (III)-(VII) obtained from the data in Table S1 (see supporting information), showing ( $a$ ) bond lengths, ( $b$ ) valence bond angles, and (c) torsion angles. Mean values are shown, with s.u. values in parentheses.
assumed to be stronger than those in (III), the effect enhances the double-bond character of the amide bond. This finding may be explained by postulating that the relative contributions of resonance forms of the amide bond (Fig. 9) differ in nonpolar and polar solvents, with the former favoring forms containing an amide $\mathrm{C}-\mathrm{N}$ single bond, and the latter favoring forms containing an amide $\mathrm{C}=\mathrm{N}$ double bond. When $\mathrm{O}_{\text {car }}$ is involved as a hydrogen-bond acceptor, resonance forms containing the amide $\mathrm{C}=\mathrm{N}$ double bond are more favored, leading to a shorter bond and higher activation barrier to rotation.

DFT calculations on nine in silico models of methyl 2-acet-amido-2-deoxy- $\beta$-D-glucopyranoside, (IV), reveal the sensitivities of the $\mathrm{N} 2-\mathrm{C}_{\mathrm{car}}$ and $\mathrm{C}_{\mathrm{car}}-\mathrm{O}_{\mathrm{car}}$ bond lengths to the hydrogen-bonding state of the amide side chain (Table 1, and Figs. S4 and S5 in the supporting information). The results support the contention that carbonyl hydrogen bonding reduces the $\mathrm{N} 2-\mathrm{C}_{\mathrm{car}}$ bond lengths and may slightly elongate the $\mathrm{C}_{\mathrm{car}}-\mathrm{O}_{\text {car }}$ bond lengths (models 2-6), whereas $\mathrm{N}-\mathrm{H}$ hydrogen bonding exerts smaller effects on these bond lengths (model 6 relative to model 4). This conclusion is consistent with the experimental data (Fig. 8) that indicate a greater change in the $\mathrm{N} 2-\mathrm{C}_{\mathrm{car}}$ bond length than in the $\mathrm{C}_{\mathrm{car}}-\mathrm{O}_{\mathrm{car}}$ bond length in response to different hydrogen-bonding patterns. When hydrogen bonding to $\mathrm{O}_{\text {car }}$ is replaced by formal protonation (model 9), the bond-length effects are amplified, with the $\mathrm{N} 2-\mathrm{C}_{\text {car }}$ bond shortened by $\sim 0.06 \AA$ and the $\mathrm{C}_{\mathrm{car}}-\mathrm{O}_{\text {car }}$ bond lengthened by an equivalent amount relative to bond lengths in the vacuum model (model 1). These results may have implications for N -acetyl side-chain behavior in more complex oligosaccharides, where states of solvation and/or hydration could affect the activation barriers to cistrans isomerization and indirectly influence the binding of oligosaccharides to biological receptors and/or $O$-glycosidic linkage conformation when the side chain is in close proximity to the linkage (Wiberg et al., 1994; Kirby, 1983a). Since N -glycosidic linkages in the N -glycans of glycopeptides and

Figure 9
Resonance models of an $N$-acetyl side chain (a) in vacuo and in nonpolar solvents, and (b) in polar and/or hydrogen-bonding solvents. In part (b), the hydrogen bond to the carbonyl O atom shifts the relative contributions of the resonance forms towards those bearing a $\mathrm{C}=\mathrm{N}$ double bond. Participation of the $\mathrm{N}-\mathrm{H}$ hydrogen as a hydrogen-bond donor appears to exert weaker but reinforcing effects on the $\mathrm{C}-\mathrm{N}$ and $\mathrm{C}-\mathrm{O}$ bond lengths (see Table 1).
glycoproteins are structurally related to N -acetyl side chains (Fig. 10), the effects of solvent on their behaviors should mimic those for $N$-acetyl side chains.

Valence bond angles in N -acetyl side chains are relatively constant, with standard deviations of $0.4-1.3^{\circ}$ (Fig. 8). Bond angles involving $\mathrm{C}_{\mathrm{car}}$ are asymmetric, with the $\mathrm{N} 2-\mathrm{C}_{\mathrm{car}}-\mathrm{O}_{\mathrm{car}}$ and $\mathrm{O}_{\mathrm{car}}-\mathrm{C}_{\mathrm{car}}-\mathrm{CH}_{3}$ angles very similar and $\sim 6^{\circ}$ larger than the $\mathrm{N} 2-\mathrm{C}_{\mathrm{car}}-\mathrm{CH}_{3}$ angle. This behavior is similar to that observed in $O$-acetyl side chains (Wiberg et al., 1994; Kirby, 1983b).

Torsion angles that report on the rotameric properties of the $\mathrm{C} 2-\mathrm{N} 2$ bond show significant variability, with standard deviations of $\sim 17^{\circ}$. In general, geometries about the $\mathrm{C} 2-\mathrm{N} 2$ bond that orient H 2 and $\mathrm{O}_{\text {car }}$ in eclipsed arrangements, or nearly so, are favored, similar to the behavior of $O$-acetyl side chains (Turney et al., 2017, 2019). By comparison, the rotameric behavior of the amide bond, $\mathrm{N} 2-\mathrm{C}_{\mathrm{car}}$, is highly constrained, favoring a geometry that orients C 2 anti to $\mathrm{CH}_{3}$, although some mobility is observed, as reflected in the standard deviation of $\sim 5^{\circ}$.

### 3.4. Aldohexopyranosyl ring and exocyclic hydroxymethyl conformations in (III)-(VIII)

The aldohexopyranosyl rings in (III)-(VIII) adopt ${ }^{4} C_{1}$ conformations in the crystals, although small deviations from idealized chairs are indicated by the Cremer-Pople puckering parameters (Table 4). Values of $\theta$ vary over the range $0-11^{\circ}$, with the ideal ${ }^{4} C_{1}$ conformer observed only in the $\beta$ GlcNAc residue in (III) $\left(\theta=0^{\circ}\right)$ and the greatest distortion from ${ }^{4} C_{1}$ observed in $\left(\mathrm{IV}_{\mathrm{B}}\right)\left(\theta=11^{\circ}\right)$. Within (III), (V), (VI), and (VIII), the most distorted ring geometries occur in (V), with both $\beta \mathrm{GlcNAc}$ residues giving $\theta$ values of 4.8 and $8.7^{\circ}$. The direction of chair distortion favors $\theta$ values ranging from approximately 270 to $90^{\circ}$ (i.e. one continuous half of the pseudorotational itinerary at $\theta=90^{\circ}$ ), which encompasses the ${ }^{\mathrm{C1}} S_{\mathrm{C} 5}$, $B_{\mathrm{C} 2, \mathrm{C} 5},{ }^{\mathrm{O} 5} S_{\mathrm{C} 2},{ }^{\mathrm{C} 3, \mathrm{O} 5} B,{ }^{\mathrm{C} 3} S_{\mathrm{C} 1}, B_{\mathrm{C} 1, \mathrm{C} 4}$, and ${ }^{\mathrm{C} 5} S_{\mathrm{C} 1}$ forms (Table 4).

Other indicators of conformational variability of the aldohexopyranosyl rings in (III)-(VII) are the endocyclic $\mathrm{C} 1-\mathrm{C} 2-\mathrm{C} 3-\mathrm{C} 4$ and $\mathrm{C} 1-\mathrm{O} 5-\mathrm{C} 5-\mathrm{C} 4$ torsion angles, with average values of $-52.69 \pm 3.31$ and $63.26 \pm 3.54^{\circ}$, respectively, indicating roughly equivalent deviations along both pathways.

Exocyclic hydroxymethyl groups in (III)-(VIII) assume either $g g$ (H5 anti to O6; $g g=$ gauche - gauche $)$ or $g t(\mathrm{C} 4$ anti to O6) conformations. Average values of the $\mathrm{O} 5-\mathrm{C} 5-\mathrm{C} 6-\mathrm{O} 6$ torsion angles for residues adopting $g g$ and $g t$ conformations are $-64.64 \pm 6.80$ and $66.08 \pm 7.4^{\circ}$, respectively. For disaccharides (III), (V), (VI), and (VIII), the hydroxymethyl confor-

Notes: (a) see Scheme 1 for the definitions of residues $\mathbf{a}$ and $\mathbf{b}$ in (III), (V), (VI), and (VIII). (b) $B=$ boat and $S=$ twist-boat or skew. Parameters shown for (IV)-(VIII) were extracted from crystal structures reported in Hu et al. (2011), Mo (1979), Mo \& Jensen (1978), Mo \& Jensen (1975), and Zhang et al. (2013), respectively.
bility in the $\mathrm{C} 3-\mathrm{C} 4-\mathrm{O} 4-\mathrm{H}$ torsion angles is observed ( 57 to $133^{\circ}$ ), although these changes may not be sufficient to explain the observed behavior. Other factors may pertain, such as different hydrogen bonding to O4/O5 and/or differences in the conformation of the exocyclic hydroxymethyl group, although the latter is not expected to be significant based on DFT calculations (data not shown).

## 4. Conclusions

Structural parameters in the $N$-acetyl side chains in saccharides are relatively uniform with respect to bond and torsion angles, but bond
mation in residue $\mathbf{b}$ influences the inter-residue hydrogen bonding involving O 3 H as a donor. In (V), residue $\mathbf{b}$ adopts a $g t$ conformation, which allows $\mathrm{O}^{\prime}$ (in addition to $\mathrm{O5}^{\prime}$ ) to participate as a hydrogen-bond acceptor with O3H. This interaction is not possible when the hydroxymethyl group adopts a $g g$ (or $t g$ ) conformation.

### 3.5. Other structural considerations

Exocyclic $\mathrm{O} 5-\mathrm{C} 1-\mathrm{O} 1$ bond angles in all of residues (III)(VIII) fall into two groups, those associated with rings having the $\alpha$-anomeric configuration [112.18 $\pm 0.40^{\circ}$; residue $\mathbf{a}$ in (VI) and (VII)] and those associated with rings having the $\beta$-anomeric configuration ( $107.41 \pm 0.61^{\circ}$; remaining eight residues). This dependence has been described previously; $\alpha$-anomers are subject to the endo-anomeric effect and $\beta$-anomers are not (Juaristi \& Cuevas, 1995; Kirby, 1983b), rendering $s p^{2}$-like character to C 1 in the former, resulting in an increased $\mathrm{O} 5-$ $\mathrm{C} 1-\mathrm{O} 1$ bond angle. Similar arguments pertain to the endocyclic $\mathrm{C} 1-\mathrm{O} 5-\mathrm{C} 5$ bond angles, which also fall into two groups. Rings having the $\alpha$-anomeric configuration give larger values [114.72 $\pm 0.33^{\circ}$; residue $\mathbf{a}$ in (VI) and (VII)] than rings having the $\beta$-anomeric configuration $\left[112.09 \pm 0.55^{\circ}\right.$; remaining residues except residue $\mathbf{b}$ in (III)]. The exception is residue $\mathbf{b}$ of (III), which contains a $\mathrm{C} 1-\mathrm{O} 5-\mathrm{C} 5$ bond angle of $115.47^{\circ}$, significantly larger than expected.

For the $\beta$ GlcNAc rings of residue $\mathbf{b}$ in disaccharides (III), $(\mathrm{V})$, and (VI), and in monosaccharides ( $\mathrm{IV}_{\mathrm{A}}$ ) and ( $\left.\mathrm{IV}_{\mathrm{B}}\right)$, the following average endocyclic bond lengths were calculated with their corresponding s.u. values [indicated atoms would be primed in (III), (V), and (V), but not in ( $\mathrm{IV}_{\mathrm{A}}$ ) and ( $\mathrm{IV}_{\mathrm{B}}$ ); for clarity, unprimed atoms are used here]: $\mathrm{C} 1-\mathrm{C} 2=$ $1.525 \pm 0.007 \AA, \quad \mathrm{C} 2-\mathrm{C} 3=1.529 \pm 0.007 \AA, \quad \mathrm{C} 3-\mathrm{C} 4=$ $1.520 \pm 0.006 \AA, \quad \mathrm{C} 4-\mathrm{C} 5=1.525 \pm 0.011 \AA, \quad \mathrm{C} 5-\mathrm{O} 5=$ $1.436 \pm 0.006 \AA$, and $\mathrm{O} 5-\mathrm{C} 1=1.423 \pm 0.007 \AA$. A larger s.u. value is observed for the $\mathrm{C} 4-\mathrm{C} 5$ bond, whose length is likely affected, among other factors, by the rotameric states of the $\mathrm{C} 4-\mathrm{C} 5, \mathrm{C} 5-\mathrm{O} 5$, and $\mathrm{C} 4-\mathrm{O} 4$ bonds (Carmichael et al., 1993). The former two are dictated by ring conformation and do not vary appreciably (by $\sim 10^{\circ}$; the $\mathrm{C} 3-\mathrm{C} 4-\mathrm{C} 5-\mathrm{O} 5$ torsion angle ranges from -55 to $-64^{\circ}$ and the $\mathrm{C} 4-\mathrm{C} 5-$ $\mathrm{O} 5-\mathrm{C} 1$ torsion angle ranges from 59 to $69^{\circ}$ ). Greater varia-
lengths, especially for the amide $\mathrm{N} 2-\mathrm{C}_{\mathrm{car}}$ and carbonyl $\mathrm{C}_{\mathrm{car}}-$ $\mathrm{O}_{\mathrm{car}}$ bonds, are sensitive to the state of hydrogen bonding. DFT calculations support the empirical observations and generally show $\mathrm{O}_{\text {car }}$ serving as a hydrogen-bond acceptor in which both lone-pair orbitals are directional, although this behavior is not uniformly observed in both the crystal structures and the DFT calculations (the donor H atom may orient between the lone pairs, implying a kidney-shaped electron distribution around the O atom). As discussed previously (Wiberg et al., 1995; Pluth et al., 2008), amide solvation can influence the activation barriers to cis-trans isomerization, with increasingly higher barriers correlating with increasing solvent polarity and/or increased formal hydrogen bonding to $\mathrm{O}_{\text {car }}$. The $N$-acetyl side chains in complex saccharides could exhibit different kinetics properties depending on their states of solvation, a prediction that can be tested experimentally using saturation-transfer and related NMR methods (Hu et al., 2010). The biological implications of this behavior could be significant in terms of ligand binding to receptors.

Given the important role that the $\beta$ GlcNAc-( $1 \rightarrow 4$ )$\beta \mathrm{GlcNAc}$ linkage plays in glycobiology (Fig. 1), modern lowtemperature crystal structures of methyl 2-acetamido-2-de-oxy- $\beta$-D-glucopyranosyl-(1 $\rightarrow 4$ )-2-acetamido-2-deoxy- $\alpha$ - and $\beta$-D-glucopyranoside should be determined, since current databases contain crystal structures of only reducing disaccharides (VI) and (V), and their reported structures contain disorder caused by the presence of minor anomers and/or other factors.

DFT calculations on model disaccharide (IX) confirm that a relatively limited region of $\phi / \psi$ space yields O3.. O5' internuclear distances compatible with inter-residue hydrogen bonding in $\beta$ - $(1 \rightarrow 4) O$-glycosidic linkages, and an even more restricted space is compatible with $\mathrm{O} 3 \cdots \mathrm{O}^{\prime}$ hydrogen bonding. The calculated hypersurface shows that relatively large but correlated changes in $\phi$ and $\psi$ are capable of supporting hydrogen bonding between O 3 H and $\mathrm{O}^{\prime}$. Calculated hypersurfaces correlating $\phi$ and $\psi$ with the $\mathrm{O}_{3} \cdots \mathrm{O}^{\prime}$ internuclear distance and the $\mathrm{O}^{\prime}-\mathrm{C} 4-\mathrm{C} 3$ bond angle are similar and indicate that the former distance is not fixed but responds to changes in the latter bond angle brought about by altered linkage conformation. In $\beta$ - $(1 \rightarrow 4)$ linkages, transglycoside $\mathrm{Cl}^{\prime}-\mathrm{O} 1^{\prime}-\mathrm{C} 4$ bond angles appear to serve as
proxies of total energy; hypersurfaces correlating $\phi$ and $\psi$ and either total energy or $\mathrm{C}^{\prime}-\mathrm{O}^{\prime}-\mathrm{C} 4$ bond angle contain virtually identical local and global minima. Whether a similar behavior is associated with two-bond $O$-glycosidic linkages in general remains to be determined.

## Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Notes: (a) to simplify structural comparisons between like residues in (III)-(VII), atom representations in this table differ, in some cases, from those found in their X-ray structures. These changes involve primed atoms that normally distinguish atoms in the two residues of (III), (V) and (VI), atom numberings, and/or the use of 'car' subscripts to denote carbonyl C and O atoms in the $N$-acetyl side chains of (III)-(VII). (b) $O$-Glycosidic torsion angles $\varphi, \varphi^{\prime}$ and $\psi$ ', which specify the rotational properties of the $\mathrm{C} 1-\mathrm{O} 1, \mathrm{C} 1^{\prime}-\mathrm{O} 1^{\prime}$ and $\mathrm{O} 1^{\prime}-\mathrm{C} 4$ bonds, respectively, in (III), (V) and (VI), can be defined by three different vicinal pathways, which are distinguished by the a-c subscripts. (b) See Scheme 1 for the definitions of residues a and bin (III), (V) and (VI). (c) (IVA) and (IVB) refer to the two molecules of (IV) observed in the reported crystal structure (Hu et al., 2011). (d) Data for (IV)-(VII) were taken from Hu et al. (2011), Mo (1979), Mo \& Jensen (1978) and Mo \& Jensen (1975), respectively. [Two notes (b)?]
