(Received 31 August 2017; published 10 January 2018)

With the full data sample of 772×10^6 $B\bar{B}$ pairs recorded by the Belle detector at the KEKB electron-positron collider, the decay $\bar{B} \rightarrow D^* \tau^- \bar{\nu}_\tau$ is studied with the hadronic τ decays $\tau^- \rightarrow \pi^- \nu_\tau$ and $\tau^- \rightarrow \rho^- \nu_\tau$. The τ polarization $P_\tau(D^*)$ in two-body hadronic τ decays is measured, as well as the ratio of the branching fractions $R(D^*) = \mathcal{B}(\bar{B} \rightarrow D^* \tau^- \bar{\nu}_\tau) / \mathcal{B}(\bar{B} \rightarrow D^* \ell^- \bar{\nu}_\ell)$, where ℓ^- denotes an electron or a muon. Our results, $P_\tau(D^*) = -0.38 \pm 0.51(\text{stat})_{-0.16}^{+0.21}(\text{syst})$ and $R(D^*) = 0.270 \pm 0.035(\text{stat})_{-0.025}^{+0.028}(\text{syst})$, are consistent with the theoretical predictions of the standard model. The polarization values of $P_\tau(D^*) > +0.5$ are excluded at the 90% confidence level.

DOI: 10.1103/PhysRevD.97.012004

I. INTRODUCTION

Semileptonic B decays to τ leptons (semitauonic decays) are theoretically well-studied processes within the standard model (SM) [1–3], where the decay process is represented by the tree-level diagram shown in Fig. 1. The τ lepton is more sensitive to new physics (NP) beyond the SM that couples strongly with mass. A prominent candidate is the two-Higgs-doublet model (2HDM) [4], where charged Higgs bosons appear. The contribution of the charged Higgs to the decay process $\bar{B} \rightarrow D^* \tau^- \bar{\nu}_\tau$ [5] is suggested by many theoretical works (for example, Refs. [6–10]).

Experimentally, the decays $\bar{B} \rightarrow D^* \tau^- \bar{\nu}_\tau$ have been studied by Belle [11–14], BABAR [15–17] and LHCb [18]. Most of these studies have measured ratios of branching fractions, defined as

$$R(D^*) = \frac{\mathcal{B}(\bar{B} \rightarrow D^* \tau^- \bar{\nu}_\tau)}{\mathcal{B}(\bar{B} \rightarrow D^* \ell^- \bar{\nu}_\ell)}. \quad (1)$$

The denominator is the average of $\ell^- = e^-, \mu^-$ for Belle and BABAR, and $\ell^- = \mu^-$ for LHCb. The ratio cancels numerous uncertainties common to the numerator and the denominator; these include the uncertainty in the Cabibbo-Kobayashi-Maskawa matrix element $|V_{cb}|$, many of the theoretical uncertainties on hadronic form factors (FFs), and experimental reconstruction effects. Recently, LHCb measured the $\bar{B}^0 \rightarrow D^{*+} \tau^- \bar{\nu}_\tau$ mode using the three-prong decay $\tau^- \rightarrow \pi^- \pi^+ \pi^- (\pi^0) \nu_\tau$ [19]. To reduce the systematic uncertainty, $R_{\text{had}}(D^*) = \mathcal{B}(\bar{B}^0 \rightarrow D^{*+} \tau^- \bar{\nu}_\tau) / \mathcal{B}(\bar{B}^0 \rightarrow D^{*+} \pi^- \pi^+ \pi^-)$ is measured with the common final states between the numerator and the denominator, and $R_{\text{had}}(D^*)$

is converted to $R(D^*)$ by using the world-average values for $\mathcal{B}(\bar{B}^0 \rightarrow D^{*+} \pi^- \pi^+ \pi^-)$ and $\mathcal{B}(\bar{B}^0 \rightarrow D^{*+} \mu^- \bar{\nu}_\mu)$.

As of early 2016, the results from the three experiments [13,14,16–18] were 1.9 and 3.3 standard deviations (σ) [20] away from the SM predictions of $R(D) = 0.299 \pm 0.011$ [21] or 0.300 ± 0.008 [22] and $R(D^*) = 0.252 \pm 0.003$ [23], respectively. The overall discrepancy with the SM was about 4σ . These deviations have been theoretically studied in the context of various NP models [23–37].

In addition to $R(D^*)$, the polarizations of the τ lepton and the D^* meson are sensitive to NP [7,23,24,26,27,29,31,34,36,38]. The τ lepton polarization is defined as

$$P_\tau(D^*) = \frac{\Gamma^+(D^*) - \Gamma^-(D^*)}{\Gamma^+(D^*) + \Gamma^-(D^*)}, \quad (2)$$

where $\Gamma^\pm(D^*)$ denotes the decay rate of $\bar{B} \rightarrow D^* \tau^\pm \bar{\nu}_\tau$ with a τ helicity of $\pm 1/2$. The SM predicts $P_\tau(D) = 0.325 \pm 0.009$ [38] and $P_\tau(D^*) = -0.497 \pm 0.013$ [26]. For example, the type-II 2HDM allows $P_\tau(D^*)$ to be between -0.6 and $+1.0$ for $\bar{B} \rightarrow D \tau^- \bar{\nu}_\tau$ and between -0.7 and $+1.0$ for $\bar{B} \rightarrow D^* \tau^- \bar{\nu}_\tau$ [26,39], whereas a leptoquark model suggested in Ref. [29] with a leptoquark mass of 1 TeV allows $P_\tau(D^*)$ to be between -0.5 and 0.0 . $P_\tau(D^*)$ can be measured in two-body hadronic τ decays with the differential decay rate

FIG. 1. Feynman diagram of $\bar{B} \rightarrow D^* \tau^- \bar{\nu}_\tau$ for the SM amplitude, where $\bar{q}$ denotes $\bar{u}$ or $\bar{d}$.

$$\frac{1}{\Gamma(D^{(*)})} \frac{d\Gamma(D^{(*)})}{d\cos\theta_{\text{hel}}} = \frac{1}{2} [1 + \alpha P_\tau(D^{(*)}) \cos\theta_{\text{hel}}], \quad (3)$$

where θ_{hel} is the angle of the τ -daughter meson momentum with respect to the direction opposite the momentum of the $\tau^- \bar{\nu}_\tau$ system in the rest frame of τ . The parameter α describes the sensitivity to $P_\tau(D^{(*)})$ for each τ -decay mode; in particular, $\alpha = 1$ for $\tau^- \rightarrow \pi^- \nu_\tau$ and $\alpha = 0.45$ for $\tau^- \rightarrow \rho^- \nu_\tau$ [40].

In this paper, we describe details of the first $P_\tau(D^*)$ measurement in the decay $\bar{B} \rightarrow D^* \tau^- \bar{\nu}_\tau$ with the τ decays $\tau^- \rightarrow \pi^- \nu_\tau$ and $\tau^- \rightarrow \rho^- \nu_\tau$ reported in Ref. [41]. Our study includes an $R(D^*)$ measurement independent of previous studies [13,14,16–18], in which leptonic τ decays have been used.

II. EXPERIMENTAL APPARATUS

We use the full $\Upsilon(4S)$ data sample containing $772 \times 10^6 B\bar{B}$ pairs recorded with the Belle detector [42] at the asymmetric-beam-energy e^+e^- collider KEKB [43]. The Belle detector is a large-solid-angle magnetic spectrometer that consists of a silicon vertex detector (SVD), a 50-layer central drift chamber (CDC), an array of aerogel threshold Cherenkov counters (ACC), a barrel-like arrangement of time-of-flight scintillation counters (TOF) and an electromagnetic calorimeter (ECL) comprised of CsI(Tl) crystals located inside a superconducting solenoid coil that provides a 1.5 T magnetic field. An iron flux-return located outside the coil is instrumented to detect K_L^0 mesons and to identify muons (KLM). The detector is described in detail elsewhere [42]. Two inner detector configurations were used. A 2.0 cm radius beampipe and a 3-layer SVD were used for the first sample of $152 \times 10^6 B\bar{B}$ pairs, while a 1.5 cm radius beampipe, a 4-layer SVD and a small-cell inner drift chamber were used to record the remaining $620 \times 10^6 B\bar{B}$ pairs [44].

III. MONTE CARLO SIMULATION

The Monte Carlo (MC) simulated events are used to establish the analysis criteria, study the background and estimate the signal reconstruction efficiency. Events with a $B\bar{B}$ pair are generated using EVTGEN [45], and the B meson decays are reproduced based on branching fractions reported in Ref. [46]. The hadronization process of the B meson decay with no experimentally-measured branching fraction is inclusively reproduced by PYTHIA [47]. For continuum $e^+e^- \rightarrow q\bar{q}$ ($q = u, d, s, c$) events, hadronization of the initial quark pair is described by PYTHIA, and hadron decays are modeled by EVTGEN. Final-state radiation from charged particles is added using PHOTOS [48]. Detector responses are reproduced by the Belle detector simulator based on GEANT3 [49]. The MC samples used in this analysis are described below.

$$\bar{B} \rightarrow D^* \tau^- \bar{\nu}_\tau$$

The MC sample for the signal mode ($\bar{B} \rightarrow D^* \tau^- \bar{\nu}_\tau$) is generated with hadronic FFs based on heavy

quark effective theory (HQET). The following values of the hadronic FF parameters in the Caprini-Lellouch-Neubert scheme [50,51] are used: $\rho^2 = 1.207 \pm 0.015 \pm 0.021$, $R_1 = 1.403 \pm 0.033$, and $R_2 = 0.854 \pm 0.020$ from the experimental world averages [20], and $R_0 = 1.22$ with 10% uncertainty from the HQET estimation [23].

$$\bar{B} \rightarrow D^* \ell^- \bar{\nu}_\ell$$

The MC sample for the normalization mode ($\bar{B} \rightarrow D^* \ell^- \bar{\nu}_\ell$) is generated based on HQET. Since the FF parameters used for the production of the normalization MC sample have been updated as described above, final-state kinematics are corrected to match the latest parameter values.

$$\bar{B} \rightarrow D^{**} \ell^- \bar{\nu}_\ell \text{ and } \bar{B} \rightarrow D^{**} \tau^- \bar{\nu}_\tau$$

Semileptonic decays $\bar{B} \rightarrow D^{**} \ell^- \bar{\nu}_\ell$ and $\bar{B} \rightarrow D^{**} \tau^- \bar{\nu}_\tau$, where D^{**} denotes the excited charm meson states heavier than D^* , comprise an important background category as they have a similar decay topology to the signal events. The MC sample for $\bar{B} \rightarrow D^{**} \ell^- \bar{\nu}_\ell$ is generated based on the Isgur-Scora-Grinstein-Wise (ISGW) model [53], and decay kinematics are corrected to match the Leibovich-Ligeti-Stewart-Wise (LLSW) model [54]. The branching fractions for $\bar{B} \rightarrow D^{**} \ell^- \bar{\nu}_\ell$ with $D^{**} = D_0^*, D_1, D_1'$ and D_2^* are taken from the world averages [20]. For the D^{**} decays, in addition to experimentally-measured modes, we allow unmeasured final states consisting of a $D^{(*)}$ and one or two pions, a ρ meson, or an η meson based on quantum-number, phase-space and isospin considerations. The radially-excited $D^{(*)}(2S)$ modes are included so that the total branching fraction of $\bar{B} \rightarrow D^{**} \ell^- \bar{\nu}_\ell$ becomes about 3%, which is expected from the difference between $\mathcal{B}(\bar{B} \rightarrow X_c \ell^- \bar{\nu}_\ell)$ (where X_c denotes all the possible charmed-meson states) and the sum of the exclusive branching fractions of $\mathcal{B}(\bar{B} \rightarrow D^{(*)} \ell^- \bar{\nu}_\ell)$. The $\bar{B} \rightarrow D^{**} \tau^- \bar{\nu}_\tau$ MC sample is generated using the ISGW model. We take the branching fractions from the theoretical estimates of $R(D^{**}) \equiv \mathcal{B}(\bar{B} \rightarrow D^{**} \tau^- \bar{\nu}_\tau) / \mathcal{B}(\bar{B} \rightarrow D^{**} \ell^- \bar{\nu}_\ell)$ for each D^{**} state [55]. We use the average $R(D^{**})$ of the four approximations discussed in Ref [55]. We do not consider $\bar{B} \rightarrow D^{(*)}(2S) \tau^- \bar{\nu}_\tau$ or other semitauonic modes containing a charmed state heavier than $D^{(*)}(2S)$ as their small phase space suppresses the branching fractions.

Other background

The MC samples for other background processes, both $B\bar{B}$ events and continuum $e^+e^- \rightarrow q\bar{q}$ events, are generated based on the past experimental studies reported in Ref. [46]. Unmeasured decay channels are generated with PYTHIA through the inclusive hadronization process.

The MC sample sizes of the signal mode, the normalization mode, $\bar{B} \rightarrow D^{*+} \ell^- \bar{\nu}_\ell$, $\bar{B} \rightarrow D^{*+} \tau^- \bar{\nu}_\tau$, the $B\bar{B}$ background, and the $q\bar{q}$ process are 40, 10, 40, 400, 10, and 5 times larger, respectively, than the full Belle data sample.

IV. EVENT RECONSTRUCTION

A. Reconstruction of the tag side

We conduct the analysis by first identifying events where one of the two B mesons (B_{tag}) is reconstructed in one of 1104 exclusive hadronic B decays [56]. A hierarchical multivariate algorithm based on the NeuroBayes neural-network package is employed. More than 100 input variables are used to determine well-reconstructed B candidates, including the difference between the energy of the reconstructed B_{tag} candidate and the beam energy in the e^+e^- center-of-mass (CM) frame $\Delta E \equiv E_{\text{tag}}^* - E_{\text{beam}}^*$, as well as the event shape variables for suppression of $e^+e^- \rightarrow q\bar{q}$ background. The quality of the B_{tag} candidate is synthesized in a single NeuroBayes output-variable classifier (O_{NB}). We require the beam-energy-constrained mass of the B_{tag} candidate $M_{\text{bc}} \equiv \sqrt{E_{\text{beam}}^{*2} - |\vec{p}_{\text{tag}}^*|^2}$, where $\vec{p}_{\text{tag}}^*$ is the reconstructed B_{tag} three-momentum in the CM frame, to be greater than 5.272 GeV and the value of ΔE to be between -150 and 100 MeV. Throughout the paper, natural units with $\hbar = c = 1$ are used. We place a requirement on O_{NB} such that about 90% of true B_{tag} and about 30% of fake B_{tag} candidates are retained. If two or more B_{tag} candidates are retained in one event, we select the one with the highest O_{NB} .

Due to limited knowledge of hadronic B decays, the branching fractions of the B_{tag} decay modes are not perfectly modeled in the MC simulation. It is therefore essential to calibrate the B_{tag} reconstruction efficiency (tagging efficiency) with control data samples. We determine a scale factor for each B_{tag} decay mode using events where the signal-side B meson candidate (B_{sig}) is reconstructed in $\bar{B} \rightarrow D^{(*)} \ell^- \bar{\nu}_\ell$ modes. Further details of the calibration method are described in Ref. [57]. The ratio of measured to expected rates in each decay mode ranges from 0.2 to 1.4, depending on the B_{tag} decay mode, and is 0.72 on average. After the efficiency calibration, the tagging efficiencies are estimated to be about 0.20% for charged B mesons and 0.15% for neutral B mesons.

B. Reconstruction of the signal side

We reconstruct the signal mode and the normalization mode using the particle candidates not used for B_{tag} reconstruction. The following decay modes are used for the B_{sig} daughter particles: $D^{*0} \rightarrow D^0 \gamma$, $D^0 \pi^0$, $D^{*+} \rightarrow D^+ \pi^0$, and $D^0 \pi^+$ for the D^* candidate; $\tau^- \rightarrow \pi^- \nu_\tau$ and $\rho^- \nu_\tau$ for the τ candidate; $D^0 \rightarrow K_S^0 \pi^0$, $\pi^+ \pi^-$, $K^- \pi^+$, $K^+ K^-$, $K^- \pi^+ \pi^0$, $K_S^0 \pi^+ \pi^-$, $K_S^0 \pi^+ \pi^- \pi^0$, $K^- \pi^+ \pi^+ \pi^-$, $D^+ \rightarrow K_S^0 \pi^+$, $K_S^0 K^+$, $K_S^0 \pi^+ \pi^0$, $K^- \pi^+ \pi^+$, $K^+ K^- \pi^+$, $K^- \pi^+ \pi^+ \pi^0$, and

$K_S^0 \pi^+ \pi^+ \pi^-$ for the D candidate; and $K_S^0 \rightarrow \pi^+ \pi^-$, $\pi^0 \rightarrow \gamma \gamma$ and $\rho^- \rightarrow \pi^- \pi^0$, respectively, for the light-meson candidates. A τ -daughter candidate π^- or ρ^- is combined with a D^* candidate to form a B_{sig} candidate. For the normalization events, a charged lepton e^- or μ^- is associated instead of π^- or ρ^- .

1. Particle selection

First, daughter particles of D^* and τ ($K^\pm$, $\pi^\pm$, K_S^0 , γ , π^0 and $\rho^\pm$) and charged leptons ($e^\pm$ and $\mu^\pm$) are reconstructed. For B_{sig} reconstruction, we use different particle selections from those applied for the B_{tag} reconstruction described in Ref. [56].

Charged particles are reconstructed using the SVD and the CDC. All tracks, except for K_S^0 -daughter candidates, are required to have $dr < 0.5$ cm and $|dz| < 2.0$ cm, where dr and $|dz|$ are the impact parameters to the interaction point (IP) in the directions perpendicular and parallel, respectively, to the e^+ beam axis. Charged-particle types are identified by a likelihood ratio based on the responses of the sub-detector systems. Identification of $K^\pm$ and $\pi^\pm$ candidates is performed by combining measurements of specific ionization (dE/dx) in the CDC, the time of flight from the IP to the TOF counter and the photon yield in the ACC. For τ -daughter $\pi^\pm$ candidates, an additional proton veto is required in order to reduce background from baryonic B decays such as $\bar{B} \rightarrow D^* \bar{p} n$. The ECL electromagnetic shower shape, track-to-cluster matching at the inner surface of the ECL, dE/dx in the CDC, the photon yield in the ACC and the ratio of the cluster energy in the ECL to the track momentum measured with the SVD and the CDC are used to identify $e^\pm$ candidates [58]. Muon candidates are selected based on their penetration range and transverse scattering in the KLM [59]. To form K_S^0 candidates, we combine pairs of oppositely-charged tracks, treated as pions. Standard Belle K_S^0 selection criteria are applied [60]: the reconstructed vertex must be detached from the IP, the momentum vector must point back to the IP, and the invariant mass must be within ± 30 MeV of the nominal K_S^0 mass [46], which corresponds to about 8σ . (In this section, σ denotes the corresponding mass resolution).

Photons are reconstructed using ECL clusters not matching to charged tracks. Photon energy thresholds of 50, 100 and 150 MeV are used in the barrel, forward-endcap and backward-endcap regions, respectively, of the ECL to reject low-energy background photons, such as those originating from the e^+e^- beams and hadronic interactions of particles with materials in the detector.

Neutral pions are reconstructed in the decay $\pi^0 \rightarrow \gamma \gamma$. For π^0 candidates from D or ρ decay, referred to as $z_{\text{normal}} \pi^0$ s, we impose the same photon energy thresholds described above. The π^0 candidate's invariant mass must lie between 115 and 150 MeV, corresponding to about $\pm 3\sigma$ around the nominal π^0 mass [46]. In order to reduce the number of fake π^0 candidates, we apply the following π^0

candidate selection procedure. The π^0 candidates are sorted in descending order according to the energy of the most energetic daughter. If a given photon is the most energetic daughter of two or more candidates, they are sorted by the energy of the lower-energy daughter. We then retain the π^0 candidates whose daughter photons are not shared with a higher-ranked candidate. In this criterion, 76% of the correctly reconstructed π^0 candidates are selected while 54% of the fake π^0 candidates are removed. The retained π^0 candidates are used for D and ρ reconstruction described later.

For the soft π^0 from D^* decay, we impose a relaxed photon energy threshold of 22 MeV in all ECL regions and the same requirement for the invariant mass of the two photons. Additionally, the energy asymmetry $A_{\pi^0} = (E_h - E_l)/(E_h + E_l)$ is required to be less than 0.6, where E_h and E_l are the energies of the high- and low-energy photon daughters in the laboratory frame. Here, we do not apply the normal- π^0 candidate selection procedure.

The ρ candidate is formed from the combination of a $\pi^\pm$ and a π^0 . The candidate invariant mass must lie between 0.66 and 0.96 GeV.

2. $D^{(*)}$ reconstruction

After reconstructing the light mesons, we reconstruct the D candidates in 15 decay modes. The D invariant mass requirements are optimized for each decay mode. For the D^0 modes used in forming D^{*0} candidates, the reconstructed invariant masses (M_D) are required to be within $\pm 2.0\sigma$ ($\pm 1.5\sigma$) of the nominal D^0 meson mass [46] for the high (low) signal-to-noise ratio (SNR) modes. For $D^{*+} \rightarrow D^0\pi^+$ candidates, the M_D requirements are loosened to $\pm 4.0\sigma$ and $\pm 2.0\sigma$ for the high- and low-SNR modes, respectively. The requirements for the D^+ candidates are $\pm 2.5\sigma$ for the high-SNR modes and $\pm 1.5\sigma$ for the low-SNR modes around the nominal D^+ meson mass [46]. Here, the high-SNR modes are $D^0 \rightarrow K_S^0\pi^0$, $K^-\pi^+$, K^+K^- , $K_S^0\pi^+\pi^-$, $K^-\pi^+\pi^+\pi^-$, $D^+ \rightarrow K_S^0\pi^+$, $K_S^0K^+$, $K^-\pi^+\pi^+$; the low-SNR modes are all remaining D modes. We reconstruct D^* candidates by combining a D candidate with a $\pi^\pm$, γ , or soft π^0 . The D^* candidates are selected based on the mass difference $\Delta M \equiv M_{D^*} - M_D$, where M_{D^*} denotes the reconstructed invariant mass of the D^* candidate. The $D^{*0} \rightarrow D^0\gamma$, $D^{*0} \rightarrow D^0\pi^0$, $D^{*+} \rightarrow D^+\pi^0$, and $D^{*+} \rightarrow D^0\pi^+$ candidates are required to have ΔM within $\pm 1.5\sigma$, $\pm 2.0\sigma$, $\pm 2.0\sigma$ and $\pm 3.5\sigma$, respectively, of the nominal ΔM .

3. B_{sig} selection

The B_{sig} candidates are formed by associating a τ -daughter meson (signal events) or a ℓ^- (normalization events) with a D^* candidate. Allowed combinations are $D^{*-} + d^+$ for B_{sig}^0 , $D^{*+} + d^-$ for $\bar{B}_{\text{sig}}^0$, $\bar{D}^{*0} + d^+$ for B_{sig}^+ and $D^{*0} + d^-$ for B_{sig}^- , where $d^- = \pi^-, \rho^-$ or ℓ^- . We select

one of the following B meson combinations: $(B_{\text{sig}}^0, \bar{B}_{\text{tag}}^0)$, $(\bar{B}_{\text{sig}}^0, B_{\text{tag}}^0)$, $(B_{\text{sig}}^+, B_{\text{tag}}^-)$ and $(B_{\text{sig}}^-, B_{\text{tag}}^+)$.

For the signal mode, if at least one possible candidate for the signal mode is found in an event, we calculate $\cos \theta_{\text{hel}}$ in the rest frame of the τ . Although this frame cannot be determined completely, equivalent kinematic information is obtained using the rest frame of the $\tau^- \bar{\nu}_\tau$ system. This frame is obtained by boosting the laboratory frame along with the three-momentum vector component of the momentum transfer

$$q = p_{e^+e^-} - p_{\text{tag}} - p_{D^*}, \quad (4)$$

where p denotes the four-momentum of the e^+e^- beam, B_{tag} , and D^* , respectively. In this frame, the energy and the magnitude of the momentum of the τ lepton are determined only by q^2 as

$$E_\tau = \frac{q^2 + m_\tau^2}{2\sqrt{q^2}}, \quad (5)$$

$$|\vec{p}_\tau| = \frac{q^2 - m_\tau^2}{2\sqrt{q^2}}, \quad (6)$$

where m_τ is the τ lepton mass. The cosine of the angle between the momenta of the τ lepton and its daughter meson is determined by

$$\cos \theta_{\tau d} = \frac{2E_\tau E_d - m_\tau^2 - m_d^2}{2|\vec{p}_\tau||\vec{p}_d|}, \quad (7)$$

where $E_{\tau(d)}$ and $\vec{p}_{\tau(d)}$ denote the energy and the momentum of the τ lepton (the τ daughter d) respectively, and m_d is the mass of the τ daughter. Through a Lorentz transformation from the rest frame of the $\tau^- \bar{\nu}_\tau$ system to the τ rest frame, the following relation is obtained:

$$|\vec{p}_d^\tau| \cos \theta_{\text{hel}} = -\gamma |\vec{\beta}| E_d + \gamma |\vec{p}_d| \cos \theta_{\tau d}, \quad (8)$$

where $|\vec{p}_d^\tau| = (m_\tau^2 - m_d^2)/2m_\tau$ is the τ -daughter momentum in the rest frame of τ , and $\gamma = E_\tau/m_\tau$ and $|\vec{\beta}| = |\vec{p}_\tau|/E_\tau$. Solving gives the value of $\cos \theta_{\text{hel}}$. Events are required to lie in the physical region of $|\cos \theta_{\text{hel}}| < 1$, where 97% of the reconstructed signal events are retained. As shown in Fig. 2, there is a significant background peak near 1 in the $\tau^- \rightarrow \pi^- \nu_\tau$ sample due to the $\bar{B} \rightarrow D^* \ell^- \bar{\nu}_\ell$ background. To reject this background, we only use the region $\cos \theta_{\text{hel}} < 0.8$ in the fit to the $\tau^- \rightarrow \pi^- \nu_\tau$ sample.

Due to the kinematic constraint that q^2 must be greater than m_τ^2 , almost no signal events exist with q^2 below 4 GeV². Therefore $q^2 > 4$ GeV² is required. The variable E_{ECL} is the linear sum of the energy of ECL clusters not used in the event reconstruction. The ECL clusters satisfying the photon-energy requirement defined in the previous

FIG. 2. Distribution of $\cos \theta_{\text{hel}}$ (MC) for the signal (red), $\bar{B} \rightarrow D^* \ell^- \bar{\nu}_\ell$ (blue-hatched) and the other background (black-hatched) in the $\tau^- \rightarrow \pi^- \nu_\tau$ sample. The SM prediction on $P_\tau(D^*)$ is assumed. All the signal selection requirements including E_{ECL} and q^2 are applied.

section are added to E_{ECL} . Signal events ideally have E_{ECL} equal to zero with a tail in the E_{ECL} distribution from the beam background and split-off showers, separated from the main ECL cluster and reconstructed as photon candidates. We require E_{ECL} to be less than 1.5 GeV.

For the normalization mode, we calculate the squared missing mass,

$$M_{\text{miss}}^2 = (p_{e^+e^-} - p_{\text{tag}} - p_{D^*} - p_\ell)^2, \quad (9)$$

where p_ℓ denotes the four-momentum of the charged lepton and the other variables were defined earlier. The normalization events populate the region near $M_{\text{miss}}^2 = 0 \text{ GeV}^2$ because there is exactly one neutrino in an event. We require $-0.5 < M_{\text{miss}}^2 < 0.5 \text{ GeV}^2$. We further require E_{ECL} to be less than 1.5 GeV.

Finally, for both the signal and the normalization events, we require that there be no extra charged tracks with $dr < 5 \text{ cm}$ and $|dz| < 20 \text{ cm}$, and normal π^0 candidates.

C. Best candidate selection

After event reconstruction, the average number of retained candidates per event is about 1.09 for charged B mesons and 1.03 for neutral B mesons. In events where two or more candidates are reconstructed, 2.1 candidates are found on average. Multiple-candidate events mostly arise from more than one combination of a D candidate with photons or soft pions. For the charged B mode, about 2% of the events are reconstructed both in the $D^{*0} \rightarrow D^0 \gamma$ and $D^{*0} \rightarrow D^0 \pi^0$ modes. Since the latter mode has a much higher branching fraction, we assign these events to the $D^{*0} \rightarrow D^0 \pi^0$ sample. The contribution of this type of multiple-candidate events is negligibly small in the neutral B mode. We then select the most signal-like candidate as

follows. For the $D^{*0} \rightarrow D^0 \gamma$ events, we select the candidate with the most energetic photon associated with the D^0 . For the $D^{*0} \rightarrow D^0 \pi^0$ and $D^{*+} \rightarrow D^+ \pi^0$ events, we select the candidate with the soft π^0 that has an invariant mass nearest the nominal π^0 mass. For the $D^{*+} \rightarrow D^0 \pi^+$ events, we select one candidate at random since the multiple-candidate probability is only $\mathcal{O}(0.01\%)$. After the D^* candidate selection, roughly 2% of the retained events are reconstructed both in the $\tau^- \rightarrow \pi^- \nu_\tau$ and the $\tau^- \rightarrow \rho^- \nu_\tau$ samples. Since the MC study indicates that about 80% of such events originate from the $\tau^- \rightarrow \rho^- \nu_\tau$ decay, we assign these events to the $\tau^- \rightarrow \rho^- \nu_\tau$ sample.

D. Sample composition

The reconstructed events are categorized in turn as below. Based on this categorization, we construct histogram probability density functions (PDFs) from the MC samples to perform a final fit.

Signal

Correctly reconstructed signal events that originate from $\tau^- \rightarrow \pi^- (\rho^-) \nu_\tau$ events are categorized in this component. The yield is treated as a free parameter determined by $R(D^*)$ and $P_\tau(D^*)$.

$\rho \leftrightarrow \pi$ cross feed

Cross feed events, where the $\tau^- \rightarrow \rho^- \nu_\tau$ events are reconstructed as $\tau^- \rightarrow \pi^- \nu_\tau$ due to misreconstruction of one π^0 , or the $\tau^- \rightarrow \pi^- \nu_\tau$ events are reconstructed as $\tau^- \rightarrow \rho^- \nu_\tau$ by adding a random π^0 , comprise this component. Since these events originate from $\bar{B} \rightarrow D^* \tau^- \bar{\nu}_\tau$, they contribute to the $R(D^*)$ determination. They are also used for the $P_\tau(D^*)$ determination after the bias on $P_\tau(D^*)$ is corrected by MC information.

Other τ cross feed

$\bar{B} \rightarrow D^* \tau^- \bar{\nu}_\tau$ events with other τ decay modes also contribute to the signal sample. They originate mainly from $\tau^- \rightarrow a_1^- (\rightarrow \pi^- \pi^0 \pi^0) \nu_\tau$ with one or two missing π^0 , or $\tau^- \rightarrow \mu^- \bar{\nu}_\mu \nu_\tau$ with a low-momentum μ^- that does not reach the KLM. These two modes occupy about 80% of this component. The MC study shows that the cross feed events both from $\tau^- \rightarrow a_1^- \nu_\tau$ and $\tau^- \rightarrow \mu^- \bar{\nu}_\mu \nu_\tau$ have negligible impact on our $P_\tau(D^*)$ measurement. In the fit, the yield of this category is determined by $R(D^*)$.

$\bar{B} \rightarrow D^* \ell^- \bar{\nu}_\ell$

The decay $\bar{B} \rightarrow D^* \ell^- \bar{\nu}_\ell$ contaminates the signal sample due to misassignment of ℓ^- as π^- . We fix the $\bar{B} \rightarrow D^* \ell^- \bar{\nu}_\ell$ yield in the signal sample from the fit to the M_{miss}^2 distribution of the normalization sample.

$\bar{B} \rightarrow D^{**} \ell^- \bar{\nu}_\ell$ and hadronic B decays

The $\bar{B} \rightarrow D^{**} \ell^- \bar{\nu}_\ell$ ($\bar{B} \rightarrow D^{**} \tau^- \bar{\nu}_\tau$ is also included in this category) and hadronic B decays are the most uncertain component due to limited experimental

knowledge. By missing a few particles such as π^0 mesons, the event topology resembles the signal event. We combine these decay modes into one component. The fractions of the $\bar{B} \rightarrow D^{*+} \ell^- \bar{\nu}_\ell$ decays and hadronic B decays are about 10% and 90%, respectively, according to the MC study. Since it is difficult to estimate the yield of this component using MC simulation or to fix the yield using control data samples, we float the yield in the final fit. One exception is the collection of modes with two charm mesons such as $\bar{B} \rightarrow D^* D_s^{*-}$ and $\bar{B} \rightarrow D^* \bar{D}^{(*)} K^-$. Since the branching fractions of these modes have been studied experimentally, we fix their yield using the MC expectation after correction with the branching fractions based on Ref. [46].

Continuum

Continuum events from the $e^+e^- \rightarrow q\bar{q}$ process provide a minor contribution at $\mathcal{O}(0.1\%)$ in the signal sample. We fix the yield using the MC expectation.

Fake D^*

All events containing fake D^* candidates are categorized in this component. This is the main background source in the charged B meson sample. For the neutral B sample, many D^{*+} candidates are reconstructed from the combination of a D^0 with a $\pi^\pm$ and therefore much more cleanly reconstructed than the other D^* modes with π^0 or γ . The yield is determined from a comparison of the data and the MC sample in the ΔM sideband regions.

E. Measurement Method of $R(D^*)$ and $P_\tau(D^*)$

We use the following variables to measure yields of the signal and the normalization modes. For the normalization mode, M_{miss}^2 is the most suitable variable due to its high purity. On the other hand, the shape of the M_{miss}^2 distribution for the signal mode has a strong correlation with $P_\tau(D^*)$. To measure the signal yield, we use E_{ECL} because it has a small correlation to $P_\tau(D^*)$ and provides good discrimination between the signal and the background modes.

The value of $R(D^*)$ is measured using the formula

$$R(D^*) = \frac{\epsilon_{\text{norm}}^j N_{\text{sig}}^{ij}}{\mathcal{B}_\tau^i \epsilon_{\text{sig}}^{ij} N_{\text{norm}}^j}, \quad (10)$$

where $\mathcal{B}_\tau^i$ denotes the relevant τ branching fraction, and $\epsilon_{\text{sig}}^{ij}$ and ϵ_{norm}^j (N_{sig}^{ij} and N_{norm}^j) are the efficiencies (the observed yields) for the signal and the normalization modes, respectively. The indices i and j represent the τ decays ($\tau^- \rightarrow \pi^- \nu_\tau$ or $\rho^- \nu_\tau$) and the B charges (charged B or

neutral B), respectively. Assuming isospin symmetry, we use $R(D^*) = R(D^{*0}) = R(D^{*+})$.

The value of $P_\tau(D^*)$ is determined using the formula

$$P_\tau(D^*) = \frac{2 N_{\text{sig}}^{Fij} - N_{\text{sig}}^{Bij}}{\alpha_i N_{\text{sig}}^{Fij} + N_{\text{sig}}^{Bij}}, \quad (11)$$

where $N_{\text{sig}}^{F(B)ij}$ denotes the signal yield in the region $\cos \theta_{\text{hel}} > (<) 0$ and satisfies $N_{\text{sig}}^{Fij} + N_{\text{sig}}^{Bij} = N_{\text{sig}}^{ij}$. This formula is obtained by calculating

$$N_{\text{sig}}^{Fij} = N_{\text{sig}}^{ij} \int_0^1 \frac{d\Gamma^{ij}(D^{(*)})}{d \cos \theta_{\text{hel}}} d \cos \theta_{\text{hel}}, \quad (12)$$

$$N_{\text{sig}}^{Bij} = N_{\text{sig}}^{ij} \int_{-1}^0 \frac{d\Gamma^{ij}(D^{(*)})}{d \cos \theta_{\text{hel}}} d \cos \theta_{\text{hel}}. \quad (13)$$

The differential decay rate $d\Gamma^{ij}(D^{(*)})/d \cos \theta_{\text{hel}}$ is given by Eq. (3). As with $R(D^*)$, we use the common parameters $P_\tau(D^*) = P_\tau(D^{*0}) = P_\tau(D^{*+})$.

Due to detector efficiency effects, the measured polarization, $P_\tau^{\text{raw}}(D^*)$, is biased from the true value of $P_\tau(D^*)$. To correct for this bias, we form a linear function that maps $P_\tau(D^*)$ to $P_\tau^{\text{raw}}(D^*)$ using several MC sets with different $P_\tau(D^*)$. This function, denoted the $P_\tau(D^*)$ correction function, is separately prepared for each τ sample since the detector bias depends on the given τ mode. We also make a $P_\tau(D^*)$ correction function for the $\rho \leftrightarrow \pi$ cross feed component to take into account the distortion of the $\cos \theta_{\text{hel}}$ distribution shape. In the $P_\tau(D^*)$ correction, other kinematic distributions are assumed to be consistent with the SM predictions.

V. BACKGROUND CALIBRATION AND PDF VALIDATION

To use the MC distributions as histogram PDFs, the MC simulation needs to be verified using calibration data samples. In this section, the calibration of the PDF shapes is discussed.

A. Signal PDF shape

To validate the E_{ECL} shape of the signal component, we use the normalization mode as the control sample. It has similar E_{ECL} properties to the signal component; there is no extra photon from the B_{sig} decay except for bremsstrahlung photons, and therefore the E_{ECL} shape is mostly determined by the background photons. The normalization sample contains about 50 times more events than the expected signal yield. Figure 3 shows a comparison of E_{ECL} between data and MC simulation. The pull of each bin is shown in the bottom panel; hereinafter, the pull in the i th bin is defined as

FIG. 3. Comparison of the E_{ECL} distributions between the data (black circles) and the MC simulation (red rectangles) of the normalization mode. The area of the histograms are normalized to unity.

$$\text{Pull}^i = \frac{N_{\text{data}}^i - N_{\text{MC}}^i}{\sqrt{(\sigma_{\text{data}}^i)^2 + (\sigma_{\text{MC}}^i)^2}}, \quad (14)$$

where $N_{\text{data(MC)}}^i$ and $\sigma_{\text{data(MC)}}^i$ denote the number of events and the statistical error, respectively, in the i th bin of the data (MC) distribution. The fake D^* yield is scaled based on the calibration discussed in the next section. Since the contribution from the other background components is negligibly small, it is fixed to the MC expectation. The ECL shape in the MC sample agrees well with the data within statistical uncertainty.

B. Fake D^* events

One of the most significant background components arises from fake D^* candidates. The combinatorial fake D^*

background processes are difficult to model precisely in the MC simulation. The E_{ECL} shapes for the data and the MC sample are compared using ΔM sideband regions of 50–500 MeV, 135–190 MeV, 135–190 MeV, and 140–500 MeV for $D^{*0} \rightarrow D^0 \gamma$, $D^{*0} \rightarrow D^0 \pi^0$, $D^{*+} \rightarrow D^+ \pi^0$, and $D^{*+} \rightarrow D^0 \pi^+$, respectively; each excludes about $\pm 4\sigma$ around the ΔM peak. These sideband regions contain 5 to 50 times more events than the signal region. Figure 4(a) shows the comparison of the E_{ECL} shapes. Although all the D^* and τ modes are combined in these figures, the E_{ECL} shape has been compared in 16 subsamples of B modes, D^* modes, τ modes, and the two $\cos \theta_{\text{hel}}$ regions. We find good agreement of the E_{ECL} shape within the statistical uncertainty of these mass sideband data samples. We also check the $\cos \theta_{\text{hel}}$ distribution in the ΔM sideband region, as shown in Figs. 4(b) and 4(c). The $\cos \theta_{\text{hel}}$ distribution in the

FIG. 4. Comparisons between the data (black circles) and the MC simulation (red rectangles) in the ΔM sideband regions, where the distributions are normalized to unity. (a) E_{ECL} distribution, (b) $\cos \theta_{\text{hel}}$ distribution for the $\tau^- \rightarrow \pi^- \nu_\tau$ mode, (c) $\cos \theta_{\text{hel}}$ distribution for the $\tau^- \rightarrow \rho^- \nu_\tau$ mode. All the corresponding channels are combined.

MC simulation also shows good agreement with the data within the statistical uncertainty.

In both the signal and the normalization samples, yield discrepancies of up to 20% are observed. The fake D^* yields in the signal region of the MC simulation are scaled by the yield ratios of the data to the MC sample in the ΔM sideband regions.

C. $\bar{B} \rightarrow D^{*0} \ell^- \bar{\nu}_\ell$ and hadronic B composition

As discussed in Sec. IV D, the yield of the $\bar{B} \rightarrow D^{*0} \ell^- \bar{\nu}_\ell$ and hadronic B background component is determined in the final fit. The PDF shape of this background must be corrected with data, as a change in the B decay composition may modify the E_{ECL} shape and thereby introduce bias in the measurements of $R(D^*)$ and $P_\tau(D^*)$.

If a background B decay contains a K_L^0 in the final state, it may peak in the E_{ECL} signal region. We correct the branching fractions of the $\bar{B} \rightarrow D^* \pi^- K_L^0$ and $\bar{B} \rightarrow D^* K^- K_L^0$ modes in the MC simulation using the measured values [46,61]. We do not apply branching fraction corrections for the other decays with K_L^0 because they have relatively small expected yields. However, we assume 100% of the uncertainty on the branching fractions to estimate systematic uncertainties, as discussed in Sec. VII.

Other types of hadronic B decay background often contain neutral particles such as π^0 or η as well as pairs of charged particles. We calibrate the rate of hadronic B decays in the signal region based on control samples where one B is fully reconstructed with the hadronic tag, and the signal side is reconstructed in seven final states ($\bar{B} \rightarrow D^* \pi^- \pi^- \pi^+$, $\bar{B} \rightarrow D^* \pi^- \pi^- \pi^+ \pi^0$, $\bar{B} \rightarrow D^* \pi^- \pi^- \pi^+ \pi^0 \pi^0$, $\bar{B} \rightarrow D^* \pi^- \pi^0$, $\bar{B} \rightarrow D^* \pi^- \pi^0 \pi^0$, $\bar{B} \rightarrow D^* \pi^- \eta$, and $\bar{B} \rightarrow D^* \pi^- \eta \pi^0$). Charged and neutral B mesons are reconstructed separately. Pairs of photons with an invariant mass ranging

FIG. 5. Distribution of the $M_{\text{bc}}^{\text{sig}}$ for the $B^- \rightarrow D^{*0} \pi^- \eta$ sample. The solid histogram shows the MC distribution (the red-filled and the white components for the correct B and fake B candidates, respectively) and the black dots are the data distribution.

TABLE I. Calibration factors used to correct the hadronic B background rates in the MC simulation. The errors arise from the calibration sample statistics.

B decay mode	B^-	$\bar{B}^0$
$D^* \pi^- \pi^- \pi^+$	<0.51	$0.62^{+0.67}_{-0.49}$
$D^* \pi^- \pi^- \pi^+ \pi^0$	$0.31^{+0.43}_{-0.40}$	$0.59^{+0.45}_{-0.39}$
$D^* \pi^- \pi^- \pi^+ \pi^0 \pi^0$	$2.15^{+1.70}_{-1.60}$	$2.60^{+6.95}_{-2.24}$
$D^* \pi^- \pi^0$	$0.06^{+0.33}_{-0.28}$	<0.47
$D^* \pi^- \pi^0 \pi^0$	$0.09^{+1.04}_{-0.98}$	$1.63^{+0.74}_{-0.69}$
$D^* \pi^- \eta$	$0.24^{+0.21}_{-0.18}$	$0.15^{+0.16}_{-0.10}$
$D^* \pi^- \eta \pi^0$	$0.74^{+0.79}_{-0.75}$	$0.89^{+1.04}_{-0.88}$

from 500 to 600 MeV are selected as η candidates. We then extract the yield of the data and the MC sample in the region $q^2 > 4 \text{ GeV}^2$ and $|\cos \theta_{\text{hel}}| < 1$, which is the same requirement as in the signal sample. To calculate $\cos \theta_{\text{hel}}$,

FIG. 6. Comparison of the M_{miss}^2 distributions between the data (black circles) and the MC simulation (red rectangles) in the ΔM sideband regions of the D^{*0} channels: (a) before the shape correction, and (b) after the correction. All the distributions are normalized to unity.

FIG. 7. Fit result to the normalization samples.

we assume that (one of) the charged pion(s) is the τ daughter. The signal-side energy difference ΔE^{sig} or the beam-energy-constrained mass $M_{\text{bc}}^{\text{sig}}$ of the B_{sig} candidate is used for the yield extraction. Figure 5 shows the $M_{\text{bc}}^{\text{sig}}$ distribution for the $B^- \rightarrow D^* \pi^- \eta$ mode as an example. We estimate yield calibration factors by taking ratios of the yields in the data to that in the MC sample. If there is no observed signal event in the calibration sample, we assign a 68% confidence level (C.L.) upper limit on the yield. The obtained calibration factors are summarized in Table I. Additionally, we correct the branching fractions of the decays $B^- \rightarrow D^{*+} \pi^- \pi^- \pi^0$, $\bar{B} \rightarrow D^* \omega \pi^-$ and $\bar{B} \rightarrow D^* \bar{p} n$ based on Refs. [46,62].

About 80% of the hadronic B background is covered by the calibrations discussed above. We estimate the systematic uncertainties on our observables due to the uncertainties of the calibration factors in Sec. VII.

D. M_{miss}^2 distribution for the normalization mode

In the fake D^{*0} component of the charged B channel, as shown in Fig. 6(a), we observe a slight discrepancy between the data and the MC sample. The M_{miss}^2 discrepancy is therefore corrected based on this comparison. The M_{miss}^2 distribution after the correction is shown in Fig. 6(b). The yield of the fake D^* component is also corrected with the same method as applied to the signal sample.

After the correction for the fake D^* component, we find that the M_{miss}^2 resolution of the data sample is 10 to 20% worse than that of the MC sample. We therefore smear the M_{miss}^2 peak width to match that of the data sample. The correction is performed separately for each D^* mode.

VI. MAXIMUM LIKELIHOOD FIT

An extended binned maximum likelihood fit is performed in two steps; we first perform a fit to the normalization sample to determine its yield, and then a

simultaneous fit to eight signal samples from combinations of $(B^-, \bar{B}^0)$, $(\pi^- \nu_\tau, \rho^- \nu_\tau)$ and $(\cos \theta_{\text{hel}} > 0, \cos \theta_{\text{hel}} < 0)$. In the fit, $R(D^*)$ and $P_\tau(D^*)$ are common fit parameters among all the signal samples, while the $\bar{B} \rightarrow D^{*+} \ell^- \bar{\nu}_\ell$ and hadronic B yields are free to float.

Figure 7 shows the fit result to the normalization sample. The p -value calculated from the agreement between the data and the fitted PDFs is 0.15. The normalization yields are measured to be 4711 ± 81 events for the charged B sample and 2502 ± 52 events for the neutral B sample, where the errors are statistical. As a cross check, we obtain the branching fractions of $(10.72 \pm 0.70)\%$ for $B^- \rightarrow D^{*0} \ell^- \bar{\nu}_\ell$ and $(10.60 \pm 0.75)\%$ for $\bar{B}^0 \rightarrow D^{*+} \ell^- \bar{\nu}_\ell$, where the values are the sum of $\bar{B} \rightarrow D^{*+} e^- \bar{\nu}_e$ and $\bar{B} \rightarrow D^{*+} \mu^- \bar{\nu}_\mu$. The error includes only a partial set of systematic uncertainties. These are consistent with the world averages $\mathcal{B}(B^- \rightarrow D^{*0} \ell^- \bar{\nu}_\ell) = (11.18 \pm 0.04 \pm 0.38)\%$ and $\mathcal{B}(\bar{B}^0 \rightarrow D^{*+} \ell^- \bar{\nu}_\ell) = (9.75 \pm 0.02 \pm 0.20)\%$, respectively [63].

The fit to the signal samples is performed as shown in Fig. 8, with a p -value of 0.29. The signal yields for the charged and the neutral B samples are 210 ± 27 and 88 ± 11 , respectively, where the errors are statistical. The observables $R(D^*)$ and $P_\tau(D^*)$ are obtained using Eqs. (10) and (11) for the correctly reconstructed signal events. The $\rho \leftrightarrow \pi$ cross feed yield is constrained by $R(D^*)$ and $P_\tau(D^*)$. The other cross feed yield is determined only by $R(D^*)$. The efficiency ratios for the correctly reconstructed signal events are $\epsilon_{\text{norm}}/\epsilon_{\text{sig}} = 0.97 \pm 0.02$ for the charged B mode and 1.21 ± 0.03 for the neutral B mode. The obtained results are

$$R(D^*) = 0.270 \pm 0.035(\text{stat}), \quad (15)$$

$$P_\tau(D^*) = -0.38 \pm 0.51(\text{stat}). \quad (16)$$

Figure 9 shows the projections of the fit results in q^2 , M_{miss}^2 , $|\vec{p}_\pi^*|$ and $|\vec{p}_{\pi(\rho)}^*|$, where $\vec{p}_{\pi(\rho)}^*$ is the momentum of the τ -daughter $\pi(\rho)$ in the CM frame. Each PDF component is

FIG. 8. Fit results to the signal samples. The red-hatched “ τ cross feed” combines the $\rho \leftrightarrow \pi$ cross feed and the other τ cross feed components.

FIG. 9. Projections of the fit results on the distributions of q^2 (top-left), M_{miss}^2 (top-right), $|\vec{p}_\pi^*|$ (bottom-left) and $|\vec{p}_\rho^*|$ (bottom-right). These distributions are the sum of all the signal samples.

scaled based on the yield obtained from the fit. All the panels show good agreement between the data and the expectation from the MC simulation.

VII. SYSTEMATIC UNCERTAINTIES

We estimate systematic uncertainties by varying each possible uncertainty source (such as the PDF shape and the signal reconstruction efficiency) with the assumption of a Gaussian error, unless stated otherwise. In several trials, we change each parameter at random, repeat the fit, and take the shifts of values of $R(D^*)$ and $P_\tau(D^*)$ from all such trials as the corresponding systematic uncertainty that is enumerated in Table II.

The most significant systematic uncertainty, arising from the hadronic B decay composition, is estimated as follows. Uncertainties of each B decay fraction in the hadronic B decay background are taken from the measured branching fractions or estimated from the uncertainties in the calibration factors discussed in Sec. V C. The uncertainty of light meson resonances in the hadronic B decays is taken into account by varying the fractions of these resonances within the maximum allowable range.

The limited MC sample size used in the construction of the PDFs is a major systematic uncertainty source. We

estimate this by regenerating the PDFs for each component and each sample using a toy MC approach based on the original PDF shapes. The same number of events are generated to account for the statistical fluctuation.

The PDF shape of the fake D^* component has been validated by comparing the data and the MC sample in the ΔM sideband region. However, a slight fluctuation from the decay $\bar{B} \rightarrow D\tau^-\bar{\nu}_\tau$ may have a significant impact on the signal yield since this component has almost the same shape as the signal mode, peaking at $E_{\text{ECL}} = 0$ GeV. We incorporate an additional uncertainty by varying the contribution from the $\bar{B} \rightarrow D\tau^-\bar{\nu}_\tau$ component within the current uncertainties in the experimental averages [46]: $\pm 32\%$ for $B^- \rightarrow D^0\tau^-\bar{\nu}_\tau$ and $\pm 21\%$ for $\bar{B}^0 \rightarrow D^+\tau^-\bar{\nu}_\tau$. We take the theoretical uncertainty on the τ polarization of the $\bar{B} \rightarrow D\tau^-\bar{\nu}_\tau$ mode into account, which is found to be 0.002 for $P_\tau(D^*)$ and negligibly small. In addition, we estimate a systematic uncertainty due to the small M_{miss}^2 shape correction for the fake D^* component, discussed in Sec. V D. The systematic uncertainties related to the fake D^* shape are 3.0% for $R(D^*)$ and 0.008 for $P_\tau(D^*)$. The fake D^* yield, fixed using the ΔM sideband, has an uncertainty that arises from the statistical uncertainties of the yield scale factors.

TABLE II. The systematic uncertainties in $R(D^*)$ and $P_\tau(D^*)$, where the values for $R(D^*)$ are relative errors. The group “common sources” identifies the common systematic uncertainty sources in the signal and the normalization modes, which cancel to a good extent in the ratio of these samples. The reason for the incomplete cancellation is described in the text.

Source	$R(D^*)$	$P_\tau(D^*)$
Hadronic B composition	+7.7%	+0.134
	-6.9%	-0.103
MC statistics for PDF shape	+4.0%	+0.146
	-2.8%	-0.108
Fake D^*	3.4%	0.018
$\bar{B} \rightarrow D^{**}\ell^-\bar{\nu}_\ell$	2.4%	0.048
$\bar{B} \rightarrow D^{**}\tau^-\bar{\nu}_\tau$	1.1%	0.001
$\bar{B} \rightarrow D^*\ell^-\bar{\nu}_\ell$	2.3%	0.007
τ daughter and ℓ^- efficiency	1.9%	0.019
MC statistics for efficiency estimation	1.0%	0.019
$\mathcal{B}(\tau^- \rightarrow \pi^-\nu_\tau, \rho^-\nu_\tau)$	0.3%	0.002
$P_\tau(D^*)$ correction function	0.0%	0.010
Common sources		
Tagging efficiency correction	1.6%	0.018
D^* reconstruction	1.4%	0.006
Branching fractions of the D meson	0.8%	0.007
Number of $B\bar{B}$ and $\mathcal{B}(\Upsilon(4S) \rightarrow B^+B^- \text{ or } B^0\bar{B}^0)$	0.5%	0.006
Total systematic uncertainty	+10.4%	+0.21
	-9.4%	-0.16

The systematic uncertainties arising from the yield scale factors are 1.6% for $R(D^*)$ and 0.016 for $P_\tau(D^*)$.

The uncertainty of the decays $\bar{B} \rightarrow D^{**}\ell^-\bar{\nu}_\ell$ are twofold: the indeterminate composition of each D^{**} state and the uncertainty in the FF parameters used for the MC sample production. The composition uncertainty is estimated based on uncertainties of the branching fractions: $\pm 6\%$ for $\bar{B} \rightarrow D_1(\rightarrow D^*\pi)\ell^-\bar{\nu}_\ell$, $\pm 12\%$ for $\bar{B} \rightarrow D_2^*(\rightarrow D^*\pi)\ell^-\bar{\nu}_\ell$, $\pm 24\%$ for $\bar{B} \rightarrow D_1'(\rightarrow D^*\pi\pi)\ell^-\bar{\nu}_\ell$, and $\pm 17\%$ for $\bar{B} \rightarrow D_0^*(\rightarrow D^*\pi)\ell^-\bar{\nu}_\ell$ and $\pm 100\%$ for other modes and $\bar{B} \rightarrow D^{**}\tau^-\bar{\nu}_\tau$. We also estimate an uncertainty arising from the FF parameters in LLSW.

The uncertainties due to the FF parameters in the normalization mode $\bar{B} \rightarrow D^*\ell^-\bar{\nu}_\ell$ are estimated using the uncertainties in the world-average values [20]. In addition, the uncertainty arising from the M_{miss}^2 shape correction for the normalization sample is estimated as an uncertainty related to $\bar{B} \rightarrow D^*\ell^-\bar{\nu}_\ell$.

The uncertainties on the reconstruction efficiencies of the τ -daughter particles and the charged leptons arise from the particle identification efficiencies for $\pi^\pm$ and $\ell^\pm$ and the reconstruction efficiency for π^0 . They are measured with control samples: the $D^{*+} \rightarrow D^0(\rightarrow K^-\pi^+)\pi^+$ sample for $\pi^\pm$, the $\tau^- \rightarrow \pi^-\pi^0\nu_\tau$ sample for π^0 , and the $\gamma\gamma \rightarrow \ell^+\ell^-$ sample for charged leptons. The sample $J/\psi \rightarrow \ell^+\ell^-$ from B decays is also used in order to account for the difference in multiplicity between two-photon events and B decay events.

Reconstruction efficiencies of the three $\bar{B} \rightarrow D^*\tau^-\bar{\nu}_\tau$ components: “Signal”, “ $\rho \leftrightarrow \pi$ cross feed” and “Other τ cross feed” are estimated using the signal MC sample.

The efficiency uncertainties arising from the MC statistics are varied independently for each component.

Other minor uncertainties arise due to the branching fractions of the τ lepton decays and errors on the parameters of the $P_\tau(D^*)$ correction function.

In addition, common uncertainty sources between the signal sample and the normalization sample are estimated. Although they largely cancel in $R(D^*)$, there are some residual uncertainties from background components where yields are fixed based on MC expectation. Here, uncertainties on the number of $B\bar{B}$ and the branching fraction of $\Upsilon(4S) \rightarrow B^+B^-$, $B^0\bar{B}^0$ (1.8%), tagging efficiencies (4.7%), branching fractions of the D decays (3.4%), and D^* reconstruction efficiency (4.8%) are evaluated for their impact on the final measurements. For the D^* reconstruction efficiency, the uncertainty originates from reconstruction efficiencies of K_S^0 , π^0 , $K^\pm$ and $\pi^\pm$, and is therefore correlated with the efficiency uncertainty of the τ -daughter particles containing $\pi^\pm$ and π^0 . This correlation is taken into account in the total systematic uncertainties shown in Table II.

VIII. RESULT AND DISCUSSION

Including the systematic uncertainty, we obtain the final results

$$R(D^*) = 0.270 \pm 0.035(\text{stat})_{-0.025}^{+0.028}(\text{syst}), \quad (17)$$

$$P_\tau(D^*) = -0.38 \pm 0.51(\text{stat})_{-0.16}^{+0.21}(\text{syst}), \quad (18)$$

with a signal significance of 7.1σ . The significance is taken from $\sqrt{2\ln(L_{\text{max}}/L_0)}$, where L_{max} and L_0 are the

FIG. 10. Comparison of our result (star for the best-fit value and 1σ , 2σ , 3σ contours) with the SM prediction (triangle). The white region corresponds to $> 3\sigma$. The shaded vertical band shows the world average as of early 2016 [20].

likelihood with the nominal fit and the null hypothesis, respectively. The statistical correlation between $R(D^*)$ and $P_\tau(D^*)$ is 0.29, and the total correlation including systematics is 0.33.

Figure 10 shows the exclusion region for the $R(D^*)$ - $P_\tau(D^*)$ plane based on

$$\chi^2 = \begin{pmatrix} \Delta^R & \Delta^P \end{pmatrix} C^{-1} \begin{pmatrix} \Delta^R \\ \Delta^P \end{pmatrix}, \quad (19)$$

where $\Delta^R = R(D^*) - 0.270$ and $\Delta^P = P_\tau(D^*) - (-0.38)$. The covariance matrix C is represented by

$$C = \begin{pmatrix} (\sigma_{\text{tot}}^R)^2 & \rho_{\text{tot}} \sigma_{\text{tot}}^R \sigma_{\text{tot}}^P \\ \rho_{\text{tot}} \sigma_{\text{tot}}^R \sigma_{\text{tot}}^P & (\sigma_{\text{tot}}^P)^2 \end{pmatrix}, \quad (20)$$

FIG. 11. Summary of the $R(D^*)$ measurements based on the full data sample of Belle and their average. The inner (outer) error bars show the statistical (total) uncertainty. The shaded band is the world average as of early 2016 [20] while the white band is the SM prediction [23]. On each measurement, the tagging method and the choice of the τ decay are indicated, where “SL tag” is the semileptonic tag and h in the τ decay denotes a hadron $h = \pi$ or ρ .

where ρ_{tot} and $\sigma_{\text{tot}}^{R(P)}$ denote the total correlation factor and the total uncertainty on $R(D^*)$ [$P_\tau(D^*)$], respectively. Overall, our result is consistent with the SM prediction. Our measurement of $P_\tau(D^*)$ excludes the region larger than $+0.5$ at 90% C.L.

As shown in Fig. 11, the obtained $R(D^*)$ also agrees with the previous Belle measurements: $R(D^*) = 0.293 \pm 0.038 \pm 0.015$ [13] and $0.302 \pm 0.030 \pm 0.011$ [14], and with the world average as of early 2016 [20]. Including our result and the latest LHCb result on $R(D^*)$ [19], the world average is estimated to be $0.304 \pm 0.013(\text{stat}) \pm 0.007(\text{syst})$ [63].

The three results of $R(D^*)$ with the full data sample of Belle are statistically independent. The average $R(D^*)$ measured by Belle is estimated to be $0.292 \pm 0.020(\text{stat}) \pm 0.012(\text{syst})$. In this average, correlation in the uncertainties arising from background semileptonic B decays is taken into account and other uncertainties are regarded as independent. The relative error in the average $R(D^*)$ is 7.5%, which is the most precise result by a single experiment. Compared to the SM prediction [23], the estimated value is 1.7σ higher. Including $R(D)$ measured by Belle [13], compatibility with the SM predictions is 2.5σ , corresponding to a p -value of 0.042.

IX. CONCLUSION

We report the measurement of $R(D^*)$ with hadronic τ decay modes $\tau^- \rightarrow \pi^- \nu_\tau$ and $\tau^- \rightarrow \rho^- \nu_\tau$, and the first measurement of $P_\tau(D^*)$ in the decay $\bar{B} \rightarrow D^* \tau^- \bar{\nu}_\tau$, using $772 \times 10^6 B\bar{B}$ data accumulated with the Belle detector. Our results are

$$R(D^*) = 0.270 \pm 0.035(\text{stat})^{+0.028}_{-0.025}(\text{syst}), \quad (21)$$

$$P_\tau(D^*) = -0.38 \pm 0.51(\text{stat})^{+0.21}_{-0.16}(\text{syst}), \quad (22)$$

which are consistent with the SM predictions. The result excludes $P_\tau(D^*) > +0.5$ at 90% C.L. This is the first measurement of the τ polarization in the semitaonic decays, providing a new dimension in the search for NP in semitaonic B decays.

ACKNOWLEDGMENTS

We acknowledge Y. Sakaki, M. Tanaka, and R. Watanabe for their invaluable suggestions and help. We thank the KEKB group for the excellent operation of the accelerator; the KEK cryogenics group for the efficient operation of the solenoid; and the KEK computer group, the National Institute of Informatics, and the PNNL/EMSL computing group for valuable computing and SINET5 network support.
