Phys. 9:785801. doi: 10.3389/fphy.2021.785801 We have performed combined elastic neutron diffuse, electrical transport, specific heat, and thermal conductivity measurements on the quasi-one-dimensional $Ba_3Co_2O_6(CO_3)_{0.7}$ single crystal to characterize its transport properties. A modulated superstructure of polyatomic $CO_3^{2^-}$ is formed, which not only interferes the electronic properties of this compound, but also reduces the thermal conductivity along the c-axis. Furthermore, a large magnetic entropy is observed to be contributed to the heat conduction. Our investigations reveal the influence of both structural and magnetic effects on its transport properties and suggest a theoretical improvement on the thermoelectric materials by building up superlattice with conducting ionic group.

Keywords: cobalt oxide, neutron diffuse, spin entropy, carrier mobility, thermal conductivity, scattering mechanism

INTRODUCTION

Thermoelectric (TE) materials can recycle waste heat into usable electricity based on the Seebeck effect and are believed to play a significant role in efficient use of energy [1]. As the energy conversion performance of TE materials is evaluated by the dimensionless figure of merit zT, $zT = S^2 \sigma T / (\kappa_{ele} + \kappa_{latt})$, where T is operating temperature, σ is electrical conductivity, S is Seebeck coefficient, κ_{ele} is electronic thermal conductivity, and κ_{latt} is lattice thermal conductivity, the research on the TE material is usually focused on two main approaches: (1) increasing the power factor $S^2 \sigma$ through electronic structure or energy band engineering [2–4] and (2) reducing the lattice thermal conductivity κ_{latt} by introducing additional phonon scattering and manipulating phonon structure [5-9]. Actually, those approaches are very complex. For example, the electrical transport ($\sigma = n\mu e$) could be regulated by the carrier concentration *n*, the carrier mobility μ , and the electron charge e, whereas the acoustic phonon scattering introduces a $\mu \propto T^{-1.5}$ dependence, and the ionized impurity scattering gives a $\mu \propto T^{1.5}$ relationship [10]. Furthermore, the lattice thermal conductivity, κ_{latt} , could be decreased by the grain boundary scattering, point defect scattering, disorder scattering, and Umklapp scattering [11, 12]. Therefore, if the scattering mechanisms of both the electrical and thermal transport could be well understood, the energy conversion performance of TE materials can be better optimized.

1

dependence of the peak intensity of the (1/3 1/3 2.85).

At present, alloy TE materials have been widely applied as a TE compound. Although the performance has been continuously improved, there are some unavoidable limitations on the environment, expenses, oxidization stability, and so on [13–15]. Therefore, the investigation of oxide TE materials has been proposed. Because of its special crystal structure and magnetic effect, the cobalt oxide has good electronic properties and low lattice thermal conductivity [16–21]. For example, the power factor ($S^2\sigma$) of NaCo₂O₄ is 5×10^{-3} W · m⁻¹ · K⁻², even higher than that of Bi₂Te₃ [22]. Among them, NaCo₂O₄, Ca₃Co₄O₉, and Bi₂Sr₂Co₂O_x have received much attention, and their TE performance is also continuously improved and even higher than some alloys [17, 23–26].

Recently, a quasi-one-dimensional cobaltate $Ba_3Co_2O_6(CO_3)_{0.7}$ has been reported as a new excellent potential TE material [27]. This compound comprised face-sharing CoO₆ octahedra and carbonate CO₃²⁻ molecular chains along its c-axis with the space group of P-6, a = 9.683 Å and c = 9.518 Å [28], **Figures 1A, B**. The average occupancy of the polyatomic CO₃²⁻ molecule is 0.7. Although *z* of

 $Ba_3Co_2O_6(CO_3)_{0.7}$ was reported as 5.1×10^{-5} K⁻¹, which is comparable to NaxCoO₂-y at 300 K, and it was considered as a promising cobalt oxide TE material [24], the thermal conductivity, transport properties, and the physics remain unknown.

In this article, we report neutron diffuse scattering, electrical conductivity, Hall effect, specific heat, and thermal conductivity of $Ba_3Co_2O_6(CO_3)_{0.7}$ single crystal. Moreover, the magnetic effect of the Co ions is discussed.

EXPERIMENTAL DETAILS

Single crystal of $Ba_3Co_2O_6(CO_3)_{0.7}$ was grown by a flux method using a mixture of Co_3O_4 , $BaCO_3$, K_2CO_3 , and $BaCl_2$ [27]. These single crystals have the shape of short hexagonal rods. The c-axis was determined using the X-ray Laue method to be along the rod direction.

A single crystal with dimension of $2 \times 2 \times 6 \text{ mm}^3$ was aligned in the (H, K, 0) horizontal scattering plane for the diffuse

scattering studies using the elastic single crystal diffuse scattering spectrometer CORELLI at the Spallation Neutron Source (SNS), Oak Ridge Nation Laboratory [29]. Based on the Hall effect, the carrier concentration of Ba₃Co₂O₆(CO₃)_{0.7} in the temperature range of 80 to 300 K was measured by the van der Pauw technique at a reversible magnetic field of 2 T. And the conductivity along the c-direction was obtained by Physical Property Measurement System (PPMS, Quantum Design) with resistivity option, using the four-probe method. The specific heat measurement was applied on PPMS's heat capacity option in two steps. First, the background specific heat was measured by an empty puck with a small amount of N-grease in the temperature range from 2 to 250 K at zero field. Then, a Ba₃Co₂O₆ (CO₃)_{0.7} sample (approximately 4.71 mg) was placed in the measured N-grease, and the total specific heat was measured at same conditions. Finally, we gained the specific heat of the sample by subtracting the background specific heat from the total specific heat. The thermal conductivity along the c-axis was characterized using PPMS with thermal transport options, and the four-probe lead configuration method was used. During the measurement, the matching gold-plated copper bar in PPMS was used as leads. More detail for the measurement of carrier concentration, specific heat and thermal conductivity can be find in Supplementary Material. The diffuse scattering studies, carrier concentration, electrical conductivity, and thermal conductivity, were carried out on the same crystal, and the sample for the measurement of the specific heat was cut from this crystal too.

RESULTS AND DISCUSSION

Elastic Diffuse Scattering

To further understand the structural details of Ba₃Co₂O₆(CO₃)_{0.7}, we study the elastic diffuse scattering behavior of it. **Figures 1C**, **D** show the contour plot of neutron intensity at 50 K in the (H, K, 0) plane of Ba₃Co₂O₆(CO₃)_{0.7} with L = 0 and L = -2.85. The sharp spots in **Figure 1C** demonstrate the good crystallinity of the single crystal. The signals of strong diffuse scattering are clearly observed at L = -2.85. **Figure 1F**, corresponding to the red solid line in **Figure 1E**, shows the elastic intensity along the [H, H, 0]

direction and the relative diffuse intensity of each diffuse spot. Morgan et al. [30] have analyzed the short-range diffuse scattering using reverse Monte Carlo method and concluded that the diffuse scattering has short-range correlation between the disorder vibrations of polyatomic $\rm CO_3^{2-}$.

Figure 1G shows the temperature dependence of the superlattice (1/3, 1/3, 2.85) reflection. Upon warming, the intensity starts to decrease at 150 K and approaches a T-independent constant greater than 250 K. Thus, the vibrations of polyatomic $\rm CO_3^{2-}$ should be affected by the thermal effect, and the localization of the $\rm CO_3^{2-}$ cluster should be relaxed.

Electrical Transport Properties

To obtain the electrical transport properties of Ba₃Co₂O₆(CO₃)_{0.7} single crystal, Hall carrier concentration $n_{\rm H}$ was collected at a reversible magnetic field of 2 T, and Hall mobility $\mu_{\rm H}$ was determined with zero-field resistivity, as shown in **Figure 2**. The exponential increase of carrier concentration with rising temperature indicates the thermal excitation of carriers. The charge polarity is dominated by holes in the measured temperature range, which is consistent with the positive Seebeck coefficients reported by Igarashi et al. [31]. The low carrier concentrations suggest that the further acceptor doping is required for TE applications. As marked in **Figure 2A**, there are two anomalies at 150 and 250 K, which agrees very well with the diffuse data and confirmed that CO₃²⁻ ion is a conductor in the system.

The temperature versus $\mu_{\rm H}$ of Ba₃Co₂O₆(CO₃)_{0.7} single crystal is nonmonotonic, as shown in **Figure 2B**. The calculated mobility involving both the ionized impurity scattering and acoustic phonon scattering can well match the experimental values over a wide temperature range. $\mu_{\rm H}$ follows a temperature dependence closing to $T^{1.5}$ at low temperature range, implying that ionized impurity scattering dominates at low temperature in Ba₃Co₂O₆(CO₃)_{0.7} single crystal. We believe that the ionized impurity scattering relates to polyatomic CO₃²⁻. As the temperature increases, the localized ordering of CO₃²⁻ weakens, and the scattering of ionized impurity also diminishes. On the other hand, the lattice vibrations become

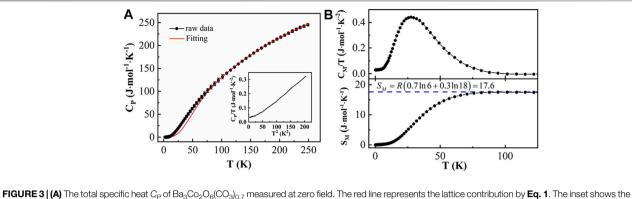

FIGURE 3 (A) The total specific heat C_P of Ba₃Co₂O₆(CO₃)_{0.7} measured at zero field. The red line represents the lattice contribution by Eq. 1. The inset shows the C_P/T vs T^2 (B) The magnetic specific heat is obtained by subtracting the lattice contribution C_P from the raw data. (C) Magnetic entropy obtained by integrating C_M/T over the entire measured temperature range.

stronger with increasing temperature. These two factors together lead to the acoustic phonon scattering, gradually overshadowing the ionized impurity scattering and becoming the dominant scattering mechanism in the material, which causes a negative temperature-dependence slope of $\mu_{\rm H}$ greater than 250 K. The ${\rm CO_3}^{2-}$ is delocalized when T > 250 K, which might introduce other scattering mechanisms affecting the carriers transports and make the carrier mobility lower than the theoretical value.

Results of $C_P(T)$

To investigate the thermal effect in Ba₃Co₂O₆(CO₃)_{0.7}, the specific heat C_P was measured in the temperature range from 2 to 250 K at zero field. As shown in **Figure 3A**, the profile of data is very smooth, and no obvious peak is detected, indicating the absence of structure and magnetic transitions. The inset of **Figure 3A** displays the data as a C_P/T versus T^2 . According to the Debye model, the lattice term of the total specific heat C_P/T is linear with T^2 at low T, but the data demonstrate a deviation from the linear relationship at low temperature and a nonzero intercept (approximately 0.29 J \cdot mol⁻¹ \cdot K⁻²) at 0 K. The nonzero intercept is an order of magnitude larger than that for NaCo₂O₄, which is a strongly correlated electronic cobalt system [32], and suggests Ba₃Co₂O₆(CO₃)_{0,7} as also a strongly correlated electronic system.

In order to further study the specific heat of $Ba_3Co_2O_6(CO_3)_{0.7}$, a fitting was gained by using the Debye–Einstein model, which can fit the lattice specific heat data well at both low and high temperature. The model is written as follows [33]:

$$C_{p}(T) = C_{D} \left[9R \left(\frac{T}{\theta_{D}} \right)^{3} \int_{0}^{x_{D}} \frac{x^{4} e^{x}}{\left(e^{x} - 1 \right)^{2}} dx \right]$$

+
$$\sum_{i} C_{E_{i}} \left[3R \left(\frac{\theta_{E_{i}}}{T} \right)^{2} \frac{\exp\left(\frac{\theta_{E_{i}}}{T} \right)}{\left[\exp\left(\frac{\theta_{E_{i}}}{T} \right) - 1 \right]^{2}} \right], \qquad (1)$$

where the first term is the contribution from the acoustic branch (Debye term), and the remaining terms are related to the contribution of the optical branch (Einstein terms). C_D and C_{Ei} are the relative weights of the Debye and Einstein terms,

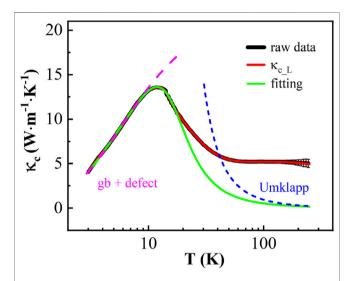

FIGURE 4 The temperature dependence of the thermal conductivity κ_c and the lattice thermal conductivity ($\kappa_{c,L}$) along the c-axis of Ba₃Co₂O₆(CO₃)_{0.7} at zero field. The black line is experimental data of the thermal conductivity; the red line is $\kappa_{c,L}$, and the green one represents the result of fitting by **Eq. 2**. The magenta dashed line is the contribution of the grain boundary and the point defect scattering, and the blue one is Umklapp process scattering.

respectively. *R* is the universal gas constant. θ_D and θ_{Ei} represent Debye and Einstein temperatures. There are 13.8 atoms per formula in our system. The best fitting for our data results is one Debye term and three E terms with a ratio 1:6:2.8:4 for C_D: C_{E1}:C_{E2}:C_{E3} and $\theta_D = 163$ K, $\theta_{E1} = 816$ K, $\theta_{E2} = 179$ K, and $\theta_{E3} = 290$ K, respectively.

As there is no distinct phase transition in the specific heat data, and the magnetic long-range order was not observed down to 2 K [34], the deviation of the experimental data from the fitted values indicates the presence of short-range magnetic fluctuations. **Figures 3B, C** display the magnetic specific heat, C_{M} , by subtracting the fitted lattice contribution from raw data, and the related magnetic entropy S_{M} , respectively. The S_{M} enhances with increasing temperature, and almost 100% recovered the theoretical value $17.6 \text{ J} \cdot \text{mol}^{-1} \cdot \text{K}^{-1}$ at approximately 100 K. Both contributions of spin and orbital degrees of freedom are suggested to be considered [35]: Co^{4+} has high-spin state with S = 1/2 ($3d^5$), and Co^{3+} has intermediate-spin state with S = 1 ($3d^6$), leading to $S_M = R(0.7 \ln 6 + 0.3 \ln 18) = 17.6 \text{ J} \cdot \text{mol}^{-1} \cdot \text{K}^{-1}$, as shown by the blue dotted line in **Figure 3C**. There may be spin-phonon scattering in the huge magnetic entropy regimen that interferes with the thermal conductivity.

Thermal Transport Properties

Figure 4 shows the temperature dependence of the total thermal conductivity κ_c and the lattice thermal conductivity $\kappa_{c L}$ of Ba₃Co₂O₆(CO₃)_{0.7} parallel to the c-axis from 3 to 250 K κ_c consists of $\kappa_{c L}$ and the electronic thermal conductivity $\kappa_{c e}$ where the electronic thermal conductivity can be determined by the Wiedemann–Franz law ($\kappa_e = \sigma L_n T$, where the Lorenz number $L_{\rm p} = 2.45 \times 10^{-8} \,\mathrm{W} \cdot \Omega \cdot \mathrm{K}^{-2}$) and subtracted. At low temperatures, $\kappa_{\rm c}$ and $\kappa_{\rm c}$ L almost completely overlap due to the very small electronic thermal conductivity. As the temperature increases, κ_c and $\kappa_{c L}$ begin to separate because of the exponential increase in conductivity. Although $\kappa_{c,e}$ is maximum at 250 K, it is only a few percent of $\kappa_{\rm c \ L}$. The contribution of phonon to $\kappa_{\rm c}$ is domain. $\kappa_{\rm c \ L}$ increases rapidly at low temperature with the dominant boundary scattering, which displays a $\kappa_{c \ L} \propto T^3$ dependence. A maximum with a value of $13.5 \text{ W} \cdot \text{m}^{-1} \cdot \text{K}^{-1}$ appears at approximately 12 K, where the Umklapp processes with exp (θ_D/bT) dependence become frequent and enough to compare with boundary scattering. One notes that the peak of $\kappa_{c,L}$ is an order of magnitude smaller than that of other cobalt oxides, such as Ca₃Co₂O₆ [36]. This difference may be caused by the superlattice in $Ba_3Co_2O_6(CO_3)_{0.7}$, which can enhance the scatting of $\kappa_{\rm c \ L}$. As temperature increases further, $\kappa_{\rm c \ L}$ drops very quickly and reflects that the Umklapp process scattering gradually becomes the main scattering mechanism. When the temperature is higher than 60 K, the trend of the curve gets flat. At approximately 250 K, the lattice thermal conductivity of Ba₃Co₂O₆(CO₃)_{0.7} along the c-axis is $5.02 \text{ W} \cdot \text{m}^{-1} \cdot \text{K}^{-1}$.

The data of $\kappa_{c_{L}}$ were fitted to the formula given by the Debye model of phonon thermal conductivity[37].

$$\kappa_{c_{-L}} = \frac{k_B}{2\pi^2 \nu_p} \left(\frac{k_B}{\hbar}\right)^3 T^3 \int_0^{\theta_D/T} \frac{x^4 e^x}{\left(e^x - 1\right)^2} \tau(\omega, T) dx, \qquad (2)$$

where $k_{\rm B}$ is the Boltzmann's constant, $v_{\rm p}$ is the average sound velocity, \hbar is the Planck constant, $x = \hbar \omega / k_{\rm B}T$, ω is frequency, and τ is the mean lifetime of phonon. The phonon relaxation is usually defined as follows:

$$\tau^{-1} = \nu_p / L + A\omega^4 + BT\omega^3 \exp\left(-\frac{\theta_D}{bT}\right). \tag{3}$$

These three items correspond with phonon boundary scattering, phonon point defect scattering, and the phonon–phonon Umklapp processes, respectively. *L*, *A*, *B*, and *b* are the fitting parameters. v_p can be calculated by the Debye temperature $\theta_D = 163$ K obtained by the fitting above and Eq. 4:

$$\theta_D = \frac{\hbar \nu_p}{k_B} \left(\frac{6\pi^2 N}{V} \right)^{\frac{1}{2}} \tag{4}$$

where *N* is the number of atoms in crystal, and *V* is the volume of crystal, and then we obtain the average sound velocity of the sample $v_{\rm p} \approx 1,343 \text{ m} \cdot \text{s}^{-1}$.

The best fitting is shown in **Figure 4** as green solid line with $L = 1.6 \times 10^{-5}$ m, $A = 1.7 \times 10^{-41}$ s³, $B = 7.4 \times 10^{-29}$ K⁻¹ s², and b = 2.7. The lattice thermal conductivity is mainly the contribution of phonons below approximately 18 K. As the temperature increases, the fitted values gradually deviate from the raw data. An extra contribution of the thermal conductivity has also been observed in Ca₃Co₂O₆ [38]. In combination with the heat capacity, the deviation of thermal conductivity might be due to the overestimation of the lattice thermal conductivity, because of the magnetic contribution to the total thermal conductivity: (1) The magnetic entropy increases rapidly after 18 K; in the meantime, $\kappa_{c L}$ starts to be higher than the theoretical value. (2) After the magnetic entropy reaches saturation at approximately 100 K, the $\kappa_{c L}$ also decreases slowly with growing temperature at the same rate as the theoretical one. As the electron concentration is very low, the electron-phonon scattering is not dominant in the system, and the CO_3^{2-} affects grain boundary and defect.

CONCLUSION

In summary, we have studied the structural, electrical, and thermal transport properties of quasi-one-dimensional Ba₃Co₂O₆(CO₃)_{0.7} single crystal and the connection between the lattice structure, magnetism, and its transport properties. Neutron diffuse reveals that a modulated superstructure of CO_3^{2-} is formed in $Ba_3Co_2O_6(CO_3)_{0.7}$. The main hole carriers in the systems are continuously excited with increasing temperature and scattered not only by short-range ordered polyatomic CO₃²⁻ at low temperature, but also by acoustic phonon and nonlocalized CO32- at high temperature. No lattice and magnetic phase transition are observed by the specific heat measurement, and the magnetic entropy is consistent with mixed Co³⁺ and Co⁴⁺ valence. The thermal conductivity of Ba₃Co₂O₆(CO₃)_{0.7} shows an enhancement at higher temperatures over classic phonon heat transfer due to the contribution of the itinerant magnetism. The unique lattice and transport properties in $Ba_3Co_2O_6(CO_3)_{0.7}$ suggest a potential superlattice designs for regulating the TE properties.

DATA AVAILABILITY STATEMENT

The original contributions presented in the study are included in the article/**Supplementary Material**, further inquiries can be directed to the corresponding author.

AUTHOR CONTRIBUTIONS

MC and JM conceived the project. QH and HZ provided single crystals used in this study. FY and ZD performed neutron scattering experiments and analyzed the data with the help

from JM JW and VR. ZC, CL and YP performed carrier concentration measurement. MC performed specific heat and conductivity measurements and analyzed the data with the help with GW, GL and JJ. GW carried out the thermal property measurements. All authors discussed the results and contributed to the writing of the manuscript.

FUNDING

MC, JW, JJ, GW, GL, and JM thank the financial support from the National Science Foundation of China (Nos. 11774223, and U2032213), the interdisciplinary program Wuhan National High Magnetic Field Center (Grant No. WHMFC 202122), Huazhong University of Science and Technology, and the National Key Research and Development Program of China (Grant Nos. 2016YFA0300501 and 2018YFA0704300).
