ABSTRACT: A series of arene-bridged dithorium complexes was synthesized via the reduction by potassium graphite of a Th(IV) precursor in the presence of arenes. All these compounds adopt an inverse-sandwich structure, with the arene bridging two thorium centers in a μ - η^6 , η^6 -mode. Structural and spectroscopic data support the assignment of two Th(IV) ions and an arene tetraanion, which is an aromatic structure according to Hückel's rule. Arene exchange reactions revealed that the stability of the corresponding com-

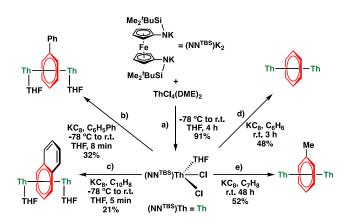

pounds follows the series naphthalene \ll toluene < benzene \approx biphenyl. Reactivity studies showed that they function as four-electron reductants capable to reduce anthracene, cyclooctatetraene, alkynes, and azobenzene, while a mononuclear thorium anthracene complex could reduce benzene. Density functional theory calculations unveiled that the bonding interactions consist of δ bonds between thorium 6d and 5f orbitals and π^* orbitals of the arenes, showing a significant covalent character, able to stabilize highly reduced arene ligands.

f Element arene interactions¹⁻³ proved critical in f-element catalysis⁴⁻⁷ and stabilizing novel oxidation states.⁸⁻¹² Among f element arene complexes, arene-bridged dinuclear compounds with an inverse-sandwich structure are arguably the most studied.²⁻³ Examples include benzene-bridged dinuclear lanthanide complexes,¹³⁻¹⁷ tetraanionic biphenyl-bridged dinuclear rare earth metal complexes,¹⁸⁻¹⁹ and, most notably, a large number of arene-bridged diuranium complexes.^{3, 20-33} The remarkable robustness of the inverse-sandwich diuranium arene motif was emphasized by a ready exchange of the ancillary ligand,²³ a facile change of metal oxidation states,28,30 and C-H borylation of the arene.²⁷ In-depth experimental and computational studies elucidated that the unusual stability of the U-arene interaction should be attributed to the formation of two δ bonds between uranium 5f_{δ} orbitals and arene π^* orbitals, which lie lower in energy than the nonbonding 5f orbitals.^{22, 31-32} Inverse-sandwich diuranium arene complexes were employed as low valent uranium synthons to obtain novel compounds,25-26, 33-34 which would otherwise be difficult to synthesize, as well as inspired the incorporation of arene in a supporting ligand framework,³⁵ ³⁶ resulting in an unprecedented redox reactivity.^{4-5, 37-39}

However, despite the many precedents of inverse-sandwich diuranium arenes,³ and the close analogy between thorium and uranium,⁴⁰⁻⁴² there is no example of an inverse-sandwich dithorium arene complex. Even thorium complexes of reduced arenes are rare: only three structurally characterized thorium reduced naphthalene complexes, in which Th(IV) was bound to a distorted naphthalene dianion in an η^4 -mode, were reported by Gambarotta et al.⁴³⁻⁴⁵

We previously reported a series of inverse-sandwich rareearth metal biphenyl complexes $[(NN^{TBS})M]_2(\mu-\eta^6,\eta^6-C_6H_5Ph)[K(solvent)]_2$ (**M2-biph-K2**, NN^{TBS} = fc(NSi'BuMe2)_2, fc = 1,1'-ferrocenediyl, M = Sc, Y, La, Lu, Gd, Dy, Er)^{18-19} and the inverse-sandwich diuranium toluene complex $[(NN^{TBS})U]_2(\mu-\eta^6,\eta^6-C_6H_5Me)$ (**U2-tol**).²⁵ Encouraged by these results, we sought to pursue the analogous inverse-sandwich dithorium arene complexes. Herein, we report their synthesis and characterization together with reactivity studies and a computational analysis of their electronic structure and bonding interaction.

The Th(IV) precursor (NN^{TBS})ThCl₂(THF) (**ThCl**₂) was prepared from ThCl₄(DME)₂ and (NN^{TBS})K₂(OEt₂)⁴⁶ (**Scheme 1a**). Following the protocol for **Y**₂-**biph-K**₂,¹⁸ the addition of 2.5 equivalents of KC₈ into a pre-cooled THF solution of an equivalent of **ThCl**₂ and 0.5 equivalents of biphenyl at -78 °C resulted in an immediate color change to black (**Scheme 1b**). The ¹H NMR spectrum of the crude reaction mixture showed diamagnetic peaks similar to those of **Y**₂-**biph-K**₂.¹⁸ X-ray crystallography confirmed the product to be $[(NN^{TBS})Th(THF)]_2(\mu \eta^6, \eta^6-C_6H_5Ph)$ (**Th**₂-**biph**). The other **Th**₂-**arene** complexes were prepared analogously (**Th**₂-**naph**, **Th**₂-**benzene**, **Th**₂-**to**], **Scheme 1c-e**).

Scheme 1. Synthesis of a) ThCl₂; b) Th₂-biph; c) Th₂-naph; d) Th₂-benzene; e) Th₂-tol.

All Th2-arene compounds feature an inverse-sandwich structure with both thorium ions bound to the same phenyl ring in a symmetric μ - η^6 , η^6 -fashion (Th₂-benzene, Figure S34; Th₂-tol, Figure S35; Th₂-biph, Figure S36; Th₂-naph, Figure S37). The structures of Th2-tol and Th2-naph are shown as representatives (Figure 1) and will be discussed for comparison. For Th₂-tol, the average Th– C_{ring} distance of 2.62 Å and the average Th-C_{centroid} distance of 2.18 Å are comparable to the corresponding values in U₂-tol²⁵ when taking account of the difference between their ionic radii.47 The C-C distances of the bound ring range from 1.441(7) to 1.459(7) Å with an average of 1.45 Å. These values are close to those of U_2 -tol (1.44(1) to 1.47(1)) Å with an average of 1.45 Å).²⁵ The average Th–N distance of 2.37 Å is 0.10 Å longer than that of 2.27 Å in ThCl₂, but comparable to the average U-N distance of 2.31 Å in U₂-tol.²⁵ This elongation was also observed in Y2-biph-K2, when it was attributed to the weakening of the Y-N bond rather than a change in the metal's oxidation state.¹⁸ In addition, a close contact between the ferrocene backbone and thorium was present in Th₂tol, indicating a donor-acceptor type interaction between these fragments.48

Despite crystallizing with a coordinating THF molecule per thorium, the structural parameters for Th₂-naph resemble those of Th₂-tol. An intriguing feature is the alternating C-C distances of the unbound ring (1.454(1), 1.351(1), 1.429(1), 1.357(1) and 1.437(1) Å), implying a diene-like character, in accord with the distinct ¹³C NMR chemical shifts of the unbound ring carbon atoms at 125.6 and 98.9 ppm. A similar dearomatization was observed in inverse-sandwich diuranium naphthalene complexes.²¹The Th-C_{centroid} distances for Th₂arene, ranging from 2.177 to 2.241 Å, are much shorter than those for Th(IV) neutral arene complexes (2.655 to 2.95 Å), and also shorter than those of 2.463(7) and 2.497(7) Å in the thorium complexes with partially reduced arene backbones. In addition, the average Th–C distances of 2.62-2.65 Å in Th₂-arene are significantly shorter than the average Th-C distances of 2.72-2.73 Å in mononuclear Th(IV) reduced naphthalene complexes.⁴³⁻⁴⁴ In addition, the Th-arene interaction in Th₂-arene should be stronger than that in previously reported thorium arene complexes⁴³⁻⁴⁵ but comparable to that in the inverse-sandwich diuranium³ and rare-earth metal arene complexes.¹⁸

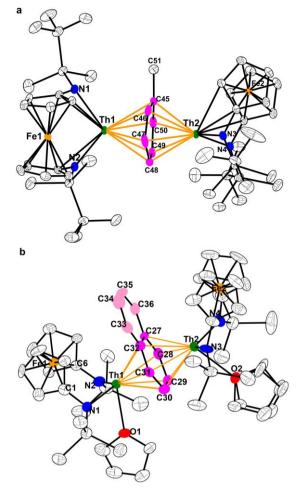

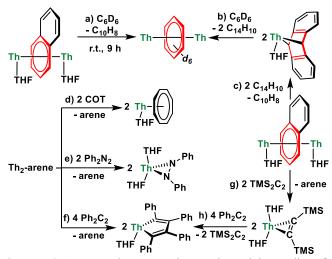

Figure 1. Thermal-ellipsoid (50% probability) representations of Th_2 -tol (a) and Th_2 -naph (b). Hydrogen atoms were omitted for clarity.

Spectroscopic data also agreed with the electronic structures of tetraanionic arenes and thorium(IV). The ¹H and ¹³C NMR spectra of Th₂-arene displayed signals in the diamagnetic region, implying a closed-shell ground state. Chemical shifts of ¹³C NMR spectra assigned to the coordinating phenyl ring in Th₂-arene complexes (Th₂-benzene: 78.6 ppm; Th₂-tol: 88.4, 85.1, 80.8, 80.6 ppm; **Th₂-biph**: 82.0, 77.5, 69.5, 66.1 ppm; Th₂-naph: 76.2, 73.8, 69.4 ppm) are at higher fields compared to those of neutral arenes (for example, 128.6 ppm for benzene and 137.9, 129.3, 128.56, 125.7 ppm for toluene), indicating a highly reduced nature of the arene ligands in Th₂-arene. Moreover, the ¹³C NMR chemical shifts of the bound phenyl ring in Th₂-arene were similar to those of Y₂-biph-K₂,¹⁸ implying the arenes were quadruply reduced (Table S1). The UV-Vis-NIR absorption spectra of Th₂-arene showed broad and intense band between 400-600 nm (Figure S46-51); however, no characteristic peaks of Th(III) around 700 and 800 nm were observed.⁴⁹ Furthermore, X-ray photoelectron spectroscopy (Table S2) and the absence of an electron paramagnetic resonance signal also support a formal oxidation state of +4 for thorium in **Th**₂-arene.

It is worth mentioning that **Th**₂-**benzene** is the first metal complex that contains the parent tetranionic benzene, which is the prototypical 6C, 10π -electron aromatic system.⁵⁰ In addition, the fact that the arene rather than thorium was reduced during the formation of **Th**₂-arene is also in line with the formation of **M**₂-biph-K₂ (M = Sc, Y, La, Lu, Gd, Dy, Er, Sm).⁵¹⁻⁵²

Scheme 2. Arene exchange reactions and reactivity studies of Th₂-arene.

Arene exchange reactions were previously observed in inverse-sandwich diuranium arene complexes.^{20, 22, 32} Arene exchange is also accessible with **Th₂-arene** and we observed a slow exchange when heating **Th₂-benzene** or **Th₂-tol** in C₆D₆, while no exchange was observed for **Th₂-benzene** in C₇D₈ or **Th₂-biph** in C₆D₆. A competitive reaction to synthesize **Th₂-benzene** and **Th₂-tol** starting with an equal molar mixture of benzene and toluene resulted in a product ratio of 10:1 for **Th₂-benzene** and **Th₂-tol**.

For **Th₂-naph**, a rapid exchange with C_6D_6 was observed (**Scheme 2a**). This result seems counterintuitive since benzene is considered more difficult to reduce than naphthalene based on their reduction potentials. However, the dearomatization of the unbound ring in **Th₂-naph** may account for this abnormal reactivity. Moreover, an arene exchange was observed between **Th₂-naph** and biphenyl and between **Th₂-tol** and biphenyl. Therefore, the arene exchange study established the stability of

$Th_2\text{-}arene \text{ as }Th_2\text{-}naph \ll Th_2\text{-}tol < Th_2\text{-}benzene \approx Th_2\text{-}biph.$

The low stability of **Th₂-naph** prompted us to investigate the reduction of **ThCl₂** in the presence of anthracene, which is known to form a stable dianion upon reduction.¹ This reaction led to the formation of a mononuclear thorium complex of dianionic anthracene, $[(NN^{TBS})Th(THF)](9,10-\eta^2-C_{14}H_{10})$ (**Th-anth**). Intriguingly, when heating in C₆D₆, **Th-anth** reduced benzene to form **Th₂-benzene** (Scheme 2b). To the best of our knowledge, this is the first confirmed benzene reduction by a well-defined metal anthracene complex, although such compounds were proposed as intermediates.²⁷ While the reverse reaction of **Th₂-benzene** and anthracene did not take place, **Th₂-naph** could reduce anthracene to yield **Th-anth** (Scheme 2c). The arene exchange reactivity highlights the higher stability for non-fused arenes over more readily reducible fused arenes in the inverse-sandwich dithorium arene complexes.

We also explored the reactivity of **Th**₂-**arene** toward unsaturated substrates. **Th**₂-**arene** functioned as four-electron reductants to reduce cyclooctatetraene (**Scheme 2d**) or azobenzene (**Scheme 2e**) to form (NN^{TBS})Th(THF)(η^{8} -COT) (**Th**-COT) or (NN^{TBS})Th(THF)₂(η^{2} -N₂Ph₂) (**Th**-N₂Ph₂), respectively, in a similar fashion as the inverse-sandwich diuranium arene complexes.^{20-21, 23} The outcome of the alkyne reduction reactions were dependent on the nature of the alkyne. While all **Th**₂-

arene could reduce diphenylacetylene (Scheme 2f) to form a five-membered metallocycle (NN^{TBS})Th(THF)(η^2 -C₄Ph₄) (Th-C₄Ph₄), the reduction of bis(trimethylsilyl)acetylene took place only with the most reactive Th₂-naph (Scheme 2g) and resulted in the formation of a rare actinide metallacyclopropene,⁵³⁻⁵⁵ (NN^{TBS})Th(THF)₂(η^2 -C₂(SiMe₃)₂), which could further react with diphenylacetylene to generate Th-C₄Ph₄ (Scheme 2h).

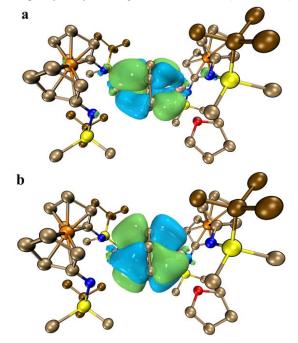

Figure 2. HOMO and HOMO-1 Kohn-Sham orbitals (isovalue 0.03) of Th₂-benzene. Hydrogen atoms are omitted for clarity.

Density functional theory (DFT) calculations of Th₂-arene show that the highest occupied molecular orbital (HOMO) and HOMO-1 of Th₂-benzene (Figure 2, see Figures S60-62 for other Th₂-arene) are close in energy (-4.04 and -4.07 eV, Table **S3**). They feature δ -type bonding orbitals composed of the π_4 and π_5 orbitals of benzene and the $6d_{\delta}$ and $5f_{\delta}$ orbitals of thorium. A composition analysis showed that the contributions from benzene-based orbitals are 66.5% and 67.4%, while from thorium orbitals are 28.2% (6d: 15.8%; 5f: 12.4%) and 28.7% (6d: 16.9%; 5f: 11.8%) for HOMO and HOMO-1, respectively. The HOMO and HOMO-1 of Th₂-tol and Th₂-biph share similar energy levels and orbital compositions as Th2-benzene (Tables **S9-10**). However, the HOMO of Th₂-naph (-3.44 eV) is 0.36 eV higher in energy than HOMO-1 and also significantly higher than the HOMOs of other **Th₂-arene**, which may explain the low stability of Th₂-naph (Table S11). In addition, the Mulliken population analysis showed that the charge of the bound ring in Th₂-naph (-0.66) differs from those in other Th₂-arene (-1.30 to -1.61) (Table S12).Furthermore, the Wiberg Th-C bond orders in Th₂-arene (Table S13) are 0.53-0.58; the average C-C bond orders for the bound rings are 1.17-1.23. The latter values are much weaker than the bond orders of the corresponding free arenes (1.49-1.58) (Table S14). These values indicate a strong interaction between thorium and arenes and a significant weakening of the C-C bonds of the bound ring, consistent with the presence of δ bonding interactions. Notably, the bond orders of the unbound ring in Th₂-naph have different values of 1.27, 1.69, 1.42, 1.69, and 1.27, consistent with the structural parameters for a diene-like character.

We also compared the δ bonding interactions in **Th**₂-**arene** with those in the inverse-sandwich diuranium and rare-earth metal arene complexes. The contributions from thorium orbitals in δ bonds are slightly under 30%, in between the values for **Y**₂-**biph-K**₂ (ca. 20% Y orbitals)¹⁸ and those of inverse-sandwich diuranium arene complexes (ca. 50% U orbitals).^{22, 32} These values indicate that the thorium–arene interaction is more covalent than the rare-earth metal–arene interaction but less covalent than the U–arene interaction, in line with the general trend of covalency for f elements. Moreover, the contribution of Th 6d orbitals is higher than that of 5f orbitals, in contrast to the case of the inverse-sandwich diuranium arene complexes, in which the contribution of U 5f orbitals is more than double than that of 6d orbitals.²² This trend is in accordance with the relative energies for actinide 6d and 5f orbitals.⁵⁶

In summary, we synthesized and characterized the first inverse-sandwich dithorium arene-bridged complexes with benzene, toluene, biphenyl, and naphthalene. The structural and spectroscopic parameters are consistent with a bridged tetraanionic arene and thorium(IV) centers, analogous to our findings for the corresponding bridged tetranionic arene rare-earth metal complexes. The arene exchange reaction established the relative stability of Th₂-arene, and reactivity studies showed their use as low valent thorium synthons. DFT calculations unveiled the presence of a δ bonding interaction in these compounds, in analogy to relevant uranium and rare-earth metal complexes. These compounds possess high synthetic utility, in particular, enabling multi-electron redox chemistry for thorium. Moreover, they provide insight into the electronic structures of thorium complexes in comparison to those of uranium and rare earth metals. Further reactivity studies and an in-depth analysis of the electronic structure and bonding interactions of Th₂-arene are currently ongoing.
