#### ABSTRACT

We present the discovery of a low-mass comoving system found by means of the NOIRLab Source Catalog (NSC) DR2. The system consists of the high proper-motion star LEHPM 5005 and an ultracool companion 2MASS J22410186-4500298 with an estimated spectral type of L2. The primary (LEHPM 5005) is likely a mid-M dwarf but over-luminous for its color, indicating a possible close equal mass binary. According to the Gaia EDR3 parallax of the primary, the system is located at a distance of  $58 \pm 2$  pc. We calculated an angular separation of 7".2 between both components, resulting in a projected physical separation of 418 AU.

Keywords: Low mass stars(2050) — Binary stars(154)

# INTRODUCTION

The NSC (Nidever et al. 2021) is a catalog of most of the public image data in NOIRLab's Astro Data Archive. These images come from telescopes in both hemispheres (CTIO-4m+DECam, KPNO-4m+Mosaic3 and Bok-2.3+90Prime) and cover  $\sim 35,000$  square degrees of the sky. The second NSC public data release includes more than 3.9 billion single objects with over 68 billion individual source measurements. It has depths of  $\sim 23$ rd magnitude in most broadband filters, accurate proper motions and an astrometric accuracy of  $\sim 2$  mas. The NSC can measure motions to several magnitudes beyond the *Gaia* limit for sources of all colors, which makes it an excellent resource for discovering rare moving late-type objects and their possible companions.

## DISCOVERY METHOD

The system has been discovered by cross-matching a list of previously identified brown dwarf candidates with the NSC DR2 catalog, and by comparing their respective proper motions. The list of brown dwarf candidates was obtained by employing NSC DR2 proper motions and photometry. Using the z, i and Y filter bandpasses along with the relations described in Carnero Rosell et al. (2019), we were able to determine an appropriate color cut for the brown dwarf selection. Candidates having proper motions below 100 mas yr<sup>-1</sup> have been discarded from the selection to reduce the number of false positives and to provide proper motions significant enough to be visually confirmed by blinking images of different epochs.

By following this method, we identified the high-proper motion star known as LEHPM 5005 and its ultracool companion 2MASS J2241-4500.

### SYSTEM CHARACTERISTICS

Both components of the system have NSC DR2 detections with high significance proper motions. We determined a difference in proper motion between the primary and the secondary of less than 0.5 mas yr<sup>-1</sup> in RA and less than 3.8 mas yr<sup>-1</sup> in DEC. Furthermore, we find that the primary's proper motions from *Gaia* EDR3 (*Gaia* Collaboration et al. 2021) seem to confirm the NSC DR2 measurements (Table 1 Astrometry).

We calculated a distance of  $58 \pm 2$  pc for the primary using its Gaia EDR3 parallax. Although the secondary has Gaia DR2 and EDR3 detections, neither data release includes a parallax measurements for this source. Since the secondary is listed in 2MASS and VISTA VHS DR6 (McMahon et al. 2021), we can use the J –  $K_s$  color to perform a spectral type estimate and calculate its photometric distance. We determined a spectral type of L3 for the 2MASS J –  $K_s$  color and a spectral type of L2 for the VHS DR6 J –  $K_s$  color, resulting in photometric distances between 47.8 and 51.3 pc using the 2MASS photometry and between 59.8 and 60.2 pc using the VHS DR6 photometry. The spectral type estimates and corresponding absolute magnitudes, necessary to calculate the photometric distances, were derived from the relations reported in Best et al. (2018).

We used the NSC DR2 positions of both components to compute their angular separation of 7.2, corresponding to a projected physical separation of 418 AU. The position of the primary was corrected for proper motion to the epoch of the secondary. Using the *Gaia* EDR3 parallax and proper motions of the primary, we calculated a tangential velocity of  $87 \pm 3$  km s<sup>-1</sup> for this system.

We estimated spectral types between M4 and M6 for the primary and between L0 and L4 for the secondary, resulting in a mean spectral type of M5.5 for the primary and L2 for the secondary (Table 1 Spectral types). These spectral type estimates were obtained by employing *Gaia* EDR3, NSC DR2, 2MASS, VISTA VHS DR6 and AllWISE photometry (Table 1 Photometry) and by applying the relations described in Kiman et al. (2019), Carnero Rosell et al. (2019) and Best et al. (2018).

Physical properties of the primary were determined in Stassun et al. (2019) and given in Table 1 Fundamentals.

## CHANCE ALIGNMENT PROBABILITY

We calculated two chance alignment probabilities, one without a distance constraint and one with the previously calculated photometric distances of the secondary.

If we use no distance constraint and a proper motion matching tolerance of  $\pm 10$  mas yr<sup>-1</sup>, we find that the secondary has 52 Gaia EDR3 proper motion matches over the entire sky, corresponding to a chance alignment probability of  $3.61 \times 10^{-5}$  that one of these 52 would randomly happen to fall within a radius corresponding to the distance at which a mid-M dwarf could retain, with  $\sim 50\%$  probability, a companion over the age of the system. For this purpose, we assume an age of  $\sim 5$  Gyr, which for a solar-type star corresponds to a separation of about 0.1 pc ( $\sim 20,000$  AU).

If we additionally put in a distance constraint of 47.8 pc < d < 60.2 pc, this decreases the number of *Gaia* EDR3 matches to 9 over the entire sky and the chance alignment probability accordingly goes down to  $6.25 \times 10^{-6}$ .

Alternatively, we used the CoMover code from Gagné et al. (2021), which is based on models instead of catalog data, and obtained a chance alignment probability of  $6.65 \times 10^{-6}$ . This result appears to be consistent with the chance alignment probability previously calculated using a distance constraint.

## DISCUSSION

We found that the primary has a substantially high Gaia RUWE <sup>1</sup> of 7.9 in DR2 and 14.0 in EDR3. According to the Gaia DR2 documentation, the RUWE is expected to be around 1.0 for sources where the single-star model provides a good fit to the astrometric observations. A value significantly greater than 1.0 could indicate that either the source is non-single, or problematic for the astrometric solution. Given the system's angular separation of 7".2 and the Gaia effective angular resolution of 0".4 (DR2), we can exclude that the high RUWE is caused by the actual secondary.

The primary is over-luminous for its color, indicating that it is very likely a close binary. Its position on the *Gaia* color magnitude diagram and its high RUWE (Belokurov et al. 2020) (Penoyre et al. 2020), increasing between data releases, seem to confirm that hypothesis.

Furthermore, the primary finds mention in Gunther et al. (2020), a catalog of 8695 flares from 1228 stars in TESS sectors 1 & 2, which may be a further hint of binarity, since close binaries can cause flaring and a more rapid rotation.
