Abstract

In this paper, we prove one divisibility of the Iwasawa–Greenberg main conjecture for the Rankin–Selberg product of a weight two cusp form and an ordinary complex multiplication form of higher weight, using congruences between Klingen Eisenstein series and cusp forms on $\mathrm{GU}(3,1)$, generalizing an earlier result of the third-named author to allow nonordinary cusp forms. The main result is a key input in the third-named author’s proof of Kobayashi’s $\pm$ -main conjecture for supersingular elliptic curves. The new ingredient here is developing a semiordinary Hida theory along an appropriate smaller weight space and a study of the semiordinary Eisenstein family.

1. Introduction

Let p be an odd prime number. In this paper, under some assumptions, we prove one divisibility of a two-variable Greenberg-type main conjecture for a weight 2 newform unramified at p . The result is a key ingredient in the third author’s proof [Wan21] of the Iwasawa main conjecture, formulated by Kobayashi [Kob03], for elliptic curves with supersingular reduction at p and $a_p = 0$, as well as in the proof of its extension to the case $a_p \neq 0$ by Sprung [Spr16]. Another application of our main result is in the proof by the first and third authors [CW16] of a p -converse to the theorem of Gross–Zagier and Kolyvagin for supersingular primes.

Let π be an irreducible cuspidal automorphic representation of $\mathrm{GL}_2(\mathbb{A}_{\mathbb{Q}})$ generated by a newform of weight 2. Associated to π is a continuous two-dimensional p -adic Galois representation ρ_{π} of $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ over L , a finite extension of $\mathbb{Q}_p$. (We use the geometric convention for Galois representations. The determinant of ρ_{π} is $\epsilon_{\mathrm{cyc}}^{-1}$.) For the representation ρ_{π} over L , we can fix a $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ -stable $\mathcal{O}_L$ -lattice T_{π} .

Take $\mathcal{K}$ to be an imaginary quadratic field in which p splits as $\mathfrak{p}\bar{\mathfrak{p}}$. Denote by $\mathcal{K}_\infty$ the maximal abelian pro- p extension of $\mathcal{K}$ unramified outside p . Then the Galois group $\text{Gal}(\mathcal{K}_\infty/\mathcal{K})$ is isomorphic to $\mathbb{Z}_p^2$ and we denote it by $\Gamma_{\mathcal{K}}$. We have the tautological character

$$\Psi_{\mathcal{K}} : \text{Gal}(\bar{\mathbb{Q}}/\mathcal{K}) \rightarrow \Gamma_{\mathcal{K}} \hookrightarrow \mathbb{Z}_p[[\Gamma_{\mathcal{K}}]]^\times.$$

Let $\xi : \mathcal{K}^\times \backslash \mathbb{A}_{\mathcal{K}}^\times \rightarrow \mathbb{C}^\times$ be an algebraic Hecke character. We can associate to it a p -adic character $\text{Gal}(\bar{\mathbb{Q}}/\mathcal{K}) \rightarrow \mathcal{O}_L^\times$, which we denote also by ξ .

We consider the $\text{Gal}(\bar{\mathbb{Q}}/\mathcal{K})$ -module

$$T_{\pi, \mathcal{K}, \xi} := T_{\pi}(\epsilon_{\text{cyc}}^2)|_{\text{Gal}(\bar{\mathbb{Q}}/\mathcal{K})}(\xi^{-1}) \otimes \mathbb{Z}_p[[\Gamma_{\mathcal{K}}]](\Psi_{\mathcal{K}}^{-1}).$$

Define the Selmer group

$$\text{Sel}_{\pi, \mathcal{K}, \xi} = \ker \left\{ \begin{array}{l} H^1(\mathcal{K}, T_{\pi, \mathcal{K}, \xi} \otimes_{\mathcal{O}_L[[\Gamma_{\mathcal{K}}]]} \mathcal{O}_L[[\Gamma_{\mathcal{K}}]]^*) \\ \rightarrow \prod_{\mathfrak{v} \neq \mathfrak{p}} H^1(I_{\mathfrak{v}}, T_{\pi, \mathcal{K}, \xi} \otimes_{\mathcal{O}_L[[\Gamma_{\mathcal{K}}]]} \mathcal{O}_L[[\Gamma_{\mathcal{K}}]]^*) \end{array} \right\}, \quad (1.0.1)$$

with $\mathcal{O}_L[[\Gamma_{\mathcal{K}}]]^* = \text{Hom}_{\mathbb{Z}_p}(\mathcal{O}_L[[\Gamma_{\mathcal{K}}]], \mathbb{Q}_p/\mathbb{Z}_p)$, the Pontryagin dual of $\mathcal{O}_L[[\Gamma_{\mathcal{K}}]]$. (This Selmer group has relaxed condition at $\mathfrak{p}$ and unramified condition at $\bar{\mathfrak{p}}$.) Let

$$X_{\pi, \mathcal{K}, \xi} := \text{Hom}_{\mathbb{Z}_p}(\text{Sel}_{\pi, \mathcal{K}, \xi}, \mathbb{Q}_p/\mathbb{Z}_p), \quad (1.0.2)$$

which is well known to be a finitely generated $\mathcal{O}_L[[\Gamma_{\mathcal{K}}]]$ -module. We recall the following definition of characteristic ideals.

Definition 1.0.1. For a Noetherian normal domain A and a finitely generated A -module M , we define the characteristic ideal of M as

$$\text{char}_A(M) = \left\{ x \in A \mid \begin{array}{l} \text{ord}_P(x) \geq \text{length}_{A_P}(M_P) \text{ for all } \\ \text{height one prime ideals } P \subset A \end{array} \right\}.$$

The Iwasawa–Greenberg main conjecture [Gre94] predicts that the characteristic ideal of $X_{\pi, \mathcal{K}, \xi}$ is generated by the following p -adic L -function.

Denote by $\hat{\mathcal{O}}_L^{\text{ur}}$ the completion of the maximal unramified extension of $\mathcal{O}_L$. By using the construction in [Hid91], it is proved in Proposition 8.2.2 that there is a p -adic L -function

$$\mathcal{L}_{\pi, \mathcal{K}, \xi} \in \text{Meas}(\Gamma_{\mathcal{K}}, \hat{\mathcal{O}}_L^{\text{ur}}) \cong \hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_{\mathcal{K}}]]$$

satisfying the interpolation property: For all algebraic Hecke characters $\tau : \mathcal{K}^\times \backslash \mathbb{A}_{\mathcal{K}}^\times \rightarrow \mathbb{C}^\times$ with p -adic avatars $\tau_{p\text{-adic}}$ factoring through $\Gamma_{\mathcal{K}}$ and $\xi\tau$ of ∞ -type (k_1, k_2) with $k_1, k_2 \in \mathbb{Z}$, $k_1 \leq 0$, $k_2 \geq 2 - k_1$,

$$\begin{aligned} \mathcal{L}_{\pi, \mathcal{K}, \xi}(\tau_{p\text{-adic}}) &= \left(\frac{\Omega_p}{\Omega_\infty} \right)^{2(k_2 - k_1)} \frac{\Gamma(k_2)\Gamma(k_2 - 1)}{(2\pi i)^{2k_2 - 1}} \cdot \gamma_p \left(\frac{3 - (k_1 + k_2)}{2}, \pi_p^\vee \times (\xi_0 \tau_0)^{-1}_{\bar{\mathfrak{p}}} \right) \\ &\quad \times L^{\{\infty, p\}} \left(\frac{k_1 + k_2 - 1}{2}, \text{BC}(\pi) \times \xi_0 \tau_0 \right), \end{aligned} \quad (1.0.3)$$

where $\xi_0 \tau_0 = \xi\tau| \cdot |_{\mathbb{A}_{\mathcal{K}}}^{-\frac{k_1 + k_2}{2}}$ and $\text{BC}(\pi)$ denotes the unitary automorphic representation of $\text{GL}_2(\mathbb{A}_{\mathcal{K}})$ obtained as the base change of π .

We are interested in the following (two-variable) Greenberg-type main conjecture.

Conjecture 1.0.2.

$$\mathrm{char}_{\hat{\mathcal{O}}_L^{\mathrm{ur}}[[\Gamma_K]]}(X_{\pi, K, \xi}) = (\mathcal{L}_{\pi, K, \xi}).$$

The main result of this paper is Theorem 8.2.3, which is a partial result towards this conjecture. Like the previous works [Urb01, Urb06, SU14, Wan20] on proving Greenberg-type main conjectures for modular forms, the proof uses the congruences between Klingen Eisenstein series and cuspidal automorphic forms. The L -values in our case here are of the same type as those in [Wan20], and we also use Klingen Eisenstein series on $\mathrm{GU}(3, 1)$ as in *loc.cit.* The main difference is that the modular form here is not assumed to be ordinary at p , so the standard Hida theory is not applicable.

The key idea is to introduce the notion of *semiordinary* automorphic forms on $\mathrm{GU}(3, 1)$. In §§2–4, we develop a Hida theory for p -adic families of (cuspidal and noncuspidal) semiordinary forms on $\mathrm{GU}(3, 1)$ along an appropriate two-dimensional subspace of the usual three-dimensional weight space for $\mathrm{GU}(3, 1)$. The main results are stated in Theorem 2.9.1. In §5, by using the doubling method, we construct a Klingen Eisenstein family $E_{\varphi}^{\mathrm{Kling}}$ and prove its semiordinarity. In §6, we study the degenerate Fourier–Jacobi coefficients of $E_{\varphi}^{\mathrm{Kling}}$. The analogous computations in [Wan20] assume a sufficient ramification condition (see Definition 6.30 in *op.cit.*) which is not available in our case here, so we need a better way to do the computation at p by using the functional equations for local doubling zeta integrals. In §7, we study the nondegenerate Fourier–Jacobi coefficients of $E_{\varphi}^{\mathrm{Kling}}$. This part is very similar to [Wan20], and we cite many results there, but the presentation is slightly rearranged. For example, the auxiliary data for constructing the Klingen Eisenstein family are chosen at the beginning of the construction (§5.6) instead of at the end of the analysis of the nondegenerate Fourier–Jacobi coefficients, and an explanation of the strategy for analyzing the nondegenerate Fourier–Jacobi coefficients is included in §7.5. In §8, combining the results in §6 and §7, we deduce a result on the Klingen Eisenstein congruence ideal and use it as an input for the lattice construction to deduce the results on Selmer groups.

Notation. We fix a prime $p \geq 3$ and an imaginary quadratic field K in which p splits in K as $\mathfrak{p}\bar{\mathfrak{p}}$. Denote by $D_{K/\mathbb{Q}}$ the discriminant of $K/\mathbb{Q}$ and by $\mathfrak{d}_{K/\mathbb{Q}}$ the different ideal of $K/\mathbb{Q}$. Denote by $\eta_{K/\mathbb{Q}}$ the quadratic character of $\mathbb{Q}^{\times} \backslash \mathbb{A}_{\mathbb{Q}}^{\times}$ associated to $K/\mathbb{Q}$. Denote by c the nontrivial element in $\mathrm{Gal}(K/\mathbb{Q})$. For $x \in K$, denote by $\bar{x}$ its image under c . For a finite place v of $\mathbb{Q}$, we put $K_v = K \otimes_{\mathbb{Q}} \mathbb{Q}_v$ and $\mathcal{O}_{K,v} = \mathcal{O}_K \otimes_{\mathbb{Z}} \mathbb{Z}_v$.

Fix embeddings

$$\iota_{\infty} : K \hookrightarrow \mathbb{C}, \quad \iota_p : K \hookrightarrow \mathbb{Q}_p \quad (1.0.4)$$

such that the valuation of $\mathbb{Q}_p$ and ι_p induce the valuation of K given by $\mathfrak{p}$. The embedding $\iota_p : K \hookrightarrow \mathbb{Q}_p$ induces a homomorphism $\varrho_{\mathfrak{p}} : K_p = K \otimes_{\mathbb{Q}} \mathbb{Q}_p \rightarrow \mathbb{Q}_p$. We denote by $\varrho_{\bar{\mathfrak{p}}} : K \otimes_{\mathbb{Q}} \mathbb{Q}_p \rightarrow \mathbb{Q}_p$ the composition of ϱ_p and the nontrivial element $c \in \mathrm{Gal}(K/\mathbb{Q})$. We have the isomorphism

$$(\varrho_{\mathfrak{p}}, \varrho_{\bar{\mathfrak{p}}}) : K \otimes_{\mathbb{Q}} \mathbb{Q}_p \longrightarrow \mathbb{Q}_p \times \mathbb{Q}_p, \quad a \longmapsto (\varrho_{\mathfrak{p}}(a), \varrho_{\bar{\mathfrak{p}}}(a))$$

We also fix a totally imaginary element $\delta \in K$ such that $\mathrm{Nm}(\delta) = \delta\bar{\delta}$ is a p -adic unit.

Fix the standard additive character $\mathbf{e}_{\mathbb{A}_{\mathbb{Q}}} = \bigotimes_v \mathbf{e}_v : \mathbb{Q} \backslash \mathbb{A} \rightarrow \mathbb{C}^{\times}$ with

$$\mathbf{e}_v(x) = \begin{cases} e^{-2\pi i \{x\}_v}, & v \neq \infty, \\ e^{2\pi i x}, & v = \infty, \end{cases} \quad (1.0.5)$$

where $\{x\}_v$ is the fractional part of x .

2. Hida theory for semiordinary forms on $\mathrm{GU}(3, 1)$

In this section, we define semiordinary forms on $\mathrm{GU}(3, 1)$ and state the control theorem for semiordinary families (Theorem 2.9.1). The proof of Theorem 2.9.1 is given in the following sections: 3 and 4.

2.1. Some notation

Let L_0 be a free $\mathcal{O}_K$ -module of rank 2 with basis w_1, w_2 , and we equip $L_0 \otimes_{\mathbb{Z}} \mathbb{Q}$ with a skew-Hermitian form $\langle, \rangle_{L_0}$ whose matrix with respect to the basis w_1, w_2 is given by a matrix $\zeta_0 \in \text{skew-Her}_2(\mathcal{O}_K)$ with $\delta\zeta_0$ positive definite. Let X, Y be free $\mathcal{O}_K$ -modules of rank 1 with bases x_1, y_1 . Let $X^\vee = \mathfrak{d}_{K/\mathbb{Q}}^{-1} \cdot x_1$ and $L = X^\vee \oplus L_0 \oplus Y$. Equip $L \otimes_{\mathbb{Z}} \mathbb{Q}$ with the skew-Hermitian form $\langle, \rangle_L$ whose matrix with respect to the basis x_1, w_1, w_2, y_1 is given by $\zeta = \begin{pmatrix} & & & 1 \\ & & \zeta_0 & \\ & -1 & & \\ & & & \end{pmatrix}$.

Define the similitude unitary groups $G' = \text{GU}(2)$ and $G = \text{GU}(3, 1)$ (over $\mathbb{Z}$) as: for all $\mathbb{Z}$ -algebra R

$$\begin{aligned} \text{GU}(2)(R) &= \{(g, \nu) \in \text{GL}_{\mathcal{O}_K \otimes_{\mathbb{Z}} R}(L_0 \otimes_{\mathbb{Z}} R) \times R^\times : \langle gv_1, gv_2 \rangle_{L_0} = \nu \langle v_1, v_2 \rangle_{L_0}\}, \\ \text{GU}(3, 1)(R) &= \{(g, \nu) \in \text{GL}_{\mathcal{O}_K \otimes_{\mathbb{Z}} R}(L \otimes_{\mathbb{Z}} R) \times R^\times : \langle gv_1, gv_2 \rangle_L = \nu \langle v_1, v_2 \rangle_L\}, \end{aligned} \quad (2.1.1)$$

and the unitary groups $\text{U}(2)$ (resp. $\text{U}(3, 1)$) as the subgroup of $\text{GU}(2)$ (resp. $\text{GU}(3, 1)$) consisting of elements with $\nu = 1$.

2.2. Shimura variety

We fix an open compact subgroup $K_f^P \subset G(\mathbb{A}_{\mathbb{Q}, f}^P)$, assumed throughout to be neat. Let $2\pi i \langle, \rangle : L \times L \rightarrow \mathbb{Z}(1)$ be the alternating pairing $2\pi i \cdot \text{Tr}_{K/\mathbb{Q}} \circ \langle, \rangle_L$ and $h : \mathbb{C} \rightarrow \text{End}_{\mathcal{O}_K \otimes_{\mathbb{Z}} \mathbb{R}}(L \otimes_{\mathbb{Z}} \mathbb{R})$ be the homomorphism given by

$$h(u + iv) : (x_1, w_1, w_2, y_1) \mapsto (x_1, w_1, w_2, y_1) \begin{pmatrix} 1 \otimes u & & & -1 \otimes v \\ & 1 \otimes u + \delta \otimes \frac{v}{\sqrt{\delta\delta}} & & \\ & & 1 \otimes u + \delta \otimes \frac{v}{\sqrt{\delta\delta}} & \\ 1 \otimes v & & & 1 \otimes u \end{pmatrix}.$$

Then the tuple $(\mathcal{O}_K, c, L, 2\pi i \langle, \rangle, h)$ defines a Shimura datum of polarization, endomorphism and level structure (PEL) type with reflex field K .

Consider the moduli problem sending every locally Noetherian connected $\mathcal{O}_{K, (p)}$ -scheme S to the set of isomorphism classes of tuples $(A, \lambda, i, \alpha^P)$ with:

- A an abelian scheme of relative dimension 4 over S ;
- $\lambda : A \rightarrow A^\vee$ a $\mathbb{Z}_{(p)}^\times$ -polarization;
- $i : \mathcal{O}_K \hookrightarrow \text{End}_S A$ an embedding such that the induced $\mathcal{O}_K$ -action on $\text{Lie } A/S$ satisfies the *determinant condition*, that is,

$$\det(X - i(b)| \text{Lie } A/S) = (X - b)^3(X - \bar{b})$$

for all $b \in \mathcal{O}_K$;

- α^P an (integral) K_f^P -level structure on (A, λ, i) of type $(L \otimes \widehat{\mathbb{Z}}^{(p)}, \text{Tr}_{K/\mathbb{Q}} \circ \langle, \rangle_L)$; that is, a $\pi_1(S, \bar{s})$ -invariant K_f^P -orbit of $\mathcal{O}_K$ -module isomorphisms $L \otimes \widehat{\mathbb{Z}}^{(p)} \rightarrow T^{(p)} A_{\bar{s}}$, where $\bar{s}$ is a geometric point of S and $T^{(p)} A_{\bar{s}}$ is the prime-to- p Tate module of $A_{\bar{s}}$, together with an isomorphism $\widehat{\mathbb{Z}}^{(p)}(1) \xrightarrow{\sim} \mathbb{G}_{m, \bar{s}}$ making the following diagram commute:

$$\begin{array}{ccc} (L \otimes \widehat{\mathbb{Z}}^{(p)}) \times (L \otimes \widehat{\mathbb{Z}}^{(p)}) & \xrightarrow{\text{Tr}_{K/\mathbb{Q}} \circ \langle, \rangle_L} & \widehat{\mathbb{Z}}^{(p)}(1) \\ \downarrow & & \downarrow \\ T^{(p)} A_{\bar{s}} \times T^{(p)} A_{\bar{s}} & \xrightarrow{\lambda\text{-Weil}} & \mathbb{G}_{m, \bar{s}}. \end{array}$$

(See [Lan13, Def. 1.4.1.4].)

Since K_f^P is neat, the above moduli problem is represented by a smooth quasi-projective scheme $\mathcal{S}$ over $\mathcal{O}_{\mathcal{K},(p)}$ (see [Lan13, Thm. 1.4.1.2, Cor. 7.2.3.10]).

Denote by $\mathcal{S}^{\text{tor}}$ the toroidal compactification of $\mathcal{S}$, which is a proper smooth scheme over $\mathcal{O}_{\mathcal{K},(p)}$ containing $\mathcal{S}$ as an open dense subscheme with complement being a relative Cartier divisor with normal crossings. (In our special case $\text{GU}(3, 1)$ here, there is a unique choice of the polyhedral cone decomposition for the toroidal compactification.) We denote by $\mathcal{I}_{\mathcal{S}^{\text{tor}}}$ the ideal sheaf of the boundary of $\mathcal{S}^{\text{tor}}$. By [Lan13, Thm. 6.4.1.1], the universal family $(\mathcal{A}, \lambda, i, \alpha^P)$ over $\mathcal{S}$ extends to a degenerating family $(\mathcal{G}, \lambda, i, \alpha^P)$ over $\mathcal{S}^{\text{tor}}$. Moreover, the base change of $\mathcal{S}$ (resp. $\mathcal{S}^{\text{tor}}$) to $\mathcal{K}$ agrees with the Shimura variety over $\mathcal{K}$ (resp. its toroidal compactification) representing the moduli problem with full level structure at p (see [Lan15, (A.4.17), (A.4.18)]).

2.3. Hasse invariant

Set $\underline{\omega} := e^* \Omega_{\mathcal{G}/\mathcal{S}^{\text{tor}}}^1$, where $e : \mathcal{S}^{\text{tor}} \rightarrow \mathcal{G}$ is the zero section of the semiabelian scheme $\mathcal{G}$ over $\mathcal{S}^{\text{tor}}$. Let ω be the line bundle $\det \underline{\omega} = \wedge^{\text{top}} \underline{\omega}$. The minimal compactification of $\mathcal{S}$ is defined as

$$\mathcal{S}^{\min} = \text{Proj} \left(\bigoplus_{k \geq 0} H^0(\mathcal{S}^{\text{tor}}, \omega^k) \right).$$

Let $\pi : \mathcal{S}^{\text{tor}} \rightarrow \mathcal{S}^{\min}$ be the canonical projection. The push-forward $\pi_* \omega$ is an ample line bundle, and $\pi^* \pi_* \omega \cong \omega$ (see [Lan13, Thm. 7.2.4.1]).

In the following, with a slight abuse of notation, we also denote by $\mathcal{S}^{\text{tor}}$ and $\mathcal{S}^{\min}$ their base change to $\mathbb{Z}_p$ via the map $\mathcal{O}_{\mathcal{K},(p)} \rightarrow \mathbb{Z}_p$ induced by our fixed embedding ι_p , and let $\mathcal{S}_{/\mathbb{F}_p}^{\text{tor}}$ and $\mathcal{S}_{/\mathbb{F}_p}^{\min}$ be their corresponding special fibers.

Let $\text{Ha} \in H^0(\mathcal{S}_{/\mathbb{F}_p}^{\text{tor}}, \omega^{p-1})$ be the Hasse invariant defined as in [Lan18, §6.3.1]. In particular, for each geometric point $\bar{s}$ of $\mathcal{S}_{/\mathbb{F}_p}^{\text{tor}}$, the Hasse invariant of the corresponding semiabelian scheme $\mathcal{G}_{\bar{s}}$ is nonzero if and only if the abelian part of $\mathcal{G}_{\bar{s}}$ is ordinary. Because $\pi_* \omega$ is ample, for some $t_E > 0$, there exists an element in $H^0(\mathcal{S}^{\min}, (\pi_* \omega)^{t_E(p-1)})$ lifting the t_E -th power of the push-forward of Ha ; we denote by E the pullback under π of any such lift, which (because $\pi^* \pi_* \omega \cong \omega$) defines an element $E \in H^0(\mathcal{S}^{\text{tor}}, \omega^{t_E(p-1)})$.

2.4. Some groups

Before moving on, we need to introduce some more group-theoretic notations. Given a matrix $a \in \text{GL}_4(\mathcal{K} \otimes_{\mathbb{Q}} \mathbb{Q}_p)$, we define $a^+, a^- \in \text{GL}_4(\mathbb{Q}_p)$ as

$$a^+ = \varrho_p(a), \quad a^- = \varrho_{\bar{p}}(a),$$

where $(\varrho_p, \varrho_{\bar{p}}) : \mathcal{K} \otimes_{\mathbb{Q}} \mathbb{Q}_p \rightarrow \mathbb{Q}_p \times \mathbb{Q}_p$ are defined as in **Notation**, and we view an element $g \in G(\mathbb{Q}_p)$ as a matrix inside $\text{GL}_4(\mathcal{K} \otimes_{\mathbb{Q}} \mathbb{Q}_p)$ via the basis $(\mathbf{x}_1, \mathbf{w}_1, \mathbf{w}_2, \mathbf{y}_1)$. Then the corresponding matrices $g^+, g^- \in \text{GL}_4(\mathbb{Q}_p)$ satisfy

$${}^t g^- \varrho_{\bar{p}}(\zeta) g^+ = \nu(g) \cdot \varrho_p(\zeta).$$

In the following, we will often write $g \in G(\mathbb{Q}_p)$ as (g^+, g^-) . Note that the map

$$\begin{aligned} G(\mathbb{Q}_p) &\rightarrow \text{GL}_4(\mathbb{Q}_p) \times \mathbb{Q}_p^\times \\ g &\mapsto (g^+, \nu(g)) \end{aligned} \tag{2.4.1}$$

is an isomorphism.

There is a filtration $D = \{D^i\}_i$ of $L \otimes_{\mathbb{Z}} \mathbb{Z}_p$ given by

$$D^1 = 0 \subset D^0 = X_p^+ \oplus L_{0,p}^+ \oplus X_p^- \subset D^{-1} = L \otimes_{\mathbb{Z}} \mathbb{Z}_p, \quad (2.4.2)$$

where $X_p^+ \subset X^\vee \otimes_{\mathbb{Z}} \mathbb{Z}_p = X \otimes_{\mathbb{Z}} \mathbb{Z}_p$ (resp. $X_p^- \subset X^\vee \otimes_{\mathbb{Z}} \mathbb{Z}_p$, $L_{0,p}^+ \subset L_0 \otimes_{\mathbb{Z}} \mathbb{Z}_p$) is the subspace on which $b \in \mathcal{O}_{\mathcal{K}}$ acts by $\iota_p(b)$ (resp. $\iota_p(\bar{b})$, $\iota_p(b)$). Note that D^0 is isotropic with respect to $\text{Tr}_{\mathcal{K}/\mathbb{Q}} \circ \langle, \rangle_L$. For $R = \mathbb{Z}_p$ or $\mathbb{Q}_p$, we put

$$P_D(R) = \{g \in G(R) : g(D^0) = D^0\};$$

that is, $P_D(R)$ is the subgroup of $G(R)$ stabilizing the filtration D in (2.4.2). We see that $P_D^\pm(R) := \{g^\pm : g \in P_D(R)\}$ are the subgroups of $\text{GL}_4(R)$ given by

$$P_D^+ = \left\{ \begin{pmatrix} * & * & * & * \\ * & * & * & * \\ * & * & * & * \\ * & * & * & * \end{pmatrix} \right\}, \quad P_D^- = \left\{ \begin{pmatrix} * & * & * & * \\ * & * & * & * \\ * & * & * & * \\ * & * & * & * \end{pmatrix} \right\}.$$

Because P_D preserves both $X_p^+ \oplus L_{0,p}^+$ and X_p^- , there is a natural projection $P_D(R) \rightarrow \text{GL}_3(R) \times \text{GL}_1(R)$ which in terms of matrices is given by

$$g = (g^+, g^-) = \left(\begin{pmatrix} a_{11} & a_{12} & a_{13} & a_{14} \\ a_{21} & a_{22} & a_{23} & a_{24} \\ a_{31} & a_{32} & a_{33} & a_{34} \\ & & & a_{44} \end{pmatrix}, \begin{pmatrix} b_{11} & b_{12} & b_{13} & b_{14} \\ b_{22} & b_{23} & b_{24} \\ b_{32} & b_{33} & b_{34} \\ b_{42} & a_{43} & b_{44} \end{pmatrix} \right) \mapsto \left(\begin{pmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{pmatrix}, b_{11} \right).$$

We will consider the p -level subgroups given by

$$K_{p,n}^1 := \left\{ g \in G(\mathbb{Z}_p) : g^+ \equiv \begin{pmatrix} * & * & * & * \\ p & * & * & * \\ * & * & * & * \\ * & * & * & * \end{pmatrix} \pmod{p^n} \right\},$$

$$K_{p,n}^0 := \left\{ g \in G(\mathbb{Z}_p) : g^+ \equiv \begin{pmatrix} * & * & * & * \\ p & * & * & * \\ * & * & * & * \\ * & * & * & * \end{pmatrix} \pmod{p^n} \right\},$$

where n is a positive integer.

2.5. Igusa towers

Let $\mathcal{T}_n$ be the ordinary locus of level $K_{p,n}^1$ attached to the PEL-type Shimura data introduced in §2.2 and the filtration D in (2.4.2), as constructed in [Lan18, Theorem 3.4.2.5]. By [Lan18, Prop. 3.4.6.3], $\mathcal{T}_n$ is a smooth quasi-projective scheme over $\mathbb{Z}_p$ representing a moduli problem for tuples $(A, \lambda, i, \alpha^p, \alpha_p)$, where $(A, \lambda, i, \alpha^p)$ is as in §2.2, and α_p is an ordinary $K_{p,n}^1$ -level structure of A , that is, a $K_{p,n}^1$ -orbit of group scheme embeddings $\mu_{p^n} \otimes D^0 \hookrightarrow A[p^n]$ with image isotropic for the λ -Weil pairing, compatible with the $\mathcal{O}_{\mathcal{K}}$ -actions on D^0 and $A[p^n]$ through i , as described in [HLTT16, §3.1.1].

Remark 2.5.1. In [Lan18, Chapter 3], the ordinary locus is defined as a normalization of the naive moduli problem introduced in [loc.cit., Def. 3.4.1.1]. In our case, because p is a good prime in the sense of [Lan18, Def. 1.1.1.6] and $\nu(K_{p,n}^1) = \mathbb{Z}_p^\times$, this construction of the ordinary locus agrees with the moduli problem. (See [HLTT16, B.10] for more details.)

Let $\mathcal{T}_n^{\text{tor}}$ be the partial toroidal compactification of the ordinary locus $\mathcal{T}_n$ ([Lan18, Thm. 5.2.1.1]); it is obtained by gluing to $\mathcal{T}_n$ the toroidal boundary charts parameterizing degenerating families defined in [Lan18, Def. 3.4.2.0] (including an extensibility condition on the ordinary level structure). We note that, even though the generic fiber of $\mathcal{T}_n$ agrees with the Shimura variety of level $K_f^p K_{p,n}^1$ over $\mathbb{Q}_p$, the generic fiber of $\mathcal{T}_n^{\text{tor}}$ is in general just an open subscheme of a toroidal compactification of the Shimura variety of level $K_f^p K_{p,n}^1$ over $\mathbb{Q}_p$.

Let $\mathcal{T}_{n,m}^{\text{tor}}$ (resp. $\mathcal{S}_m^{\text{tor}}$) be the base change of $\mathcal{T}_n^{\text{tor}}$ (resp. $\mathcal{S}^{\text{tor}}$) to $\mathbb{Z}/p^m\mathbb{Z}$. By [Lan18, Lem. 6.3.2.7], $\mathcal{S}_m^{\text{tor}}[1/E]$ agrees with the ordinary locus in [Lan18, Thm. 5.2.1.1] for full level at p , and by [Lan18, Cor. 5.2.2.3] the map $\mathcal{T}_{n,m}^{\text{tor}} \rightarrow \mathcal{S}_m^{\text{tor}}[1/E]$ that forgets the ordinary $K_{p,n}^1$ -level structure is finite étale. Concretely, we can describe $\mathcal{T}_{n,m}^{\text{tor}}$ as

$$\underline{\text{Isom}}_{\mathcal{S}_m^{\text{tor}}[1/E]}(\mu_{p^n} \otimes \mathbb{D}^0, \mathcal{G}[p^n]^{\text{mult}}) / K_{p,n}^1 \cap P_{\mathbb{D}}(\mathbb{Z}_p), \quad (2.5.1)$$

where $P_{\mathbb{D}}(\mathbb{Z}_p)$ acts on an element $\alpha_p \in \underline{\text{Isom}}_{\mathcal{S}_m^{\text{tor}}[1/E]}(\mu_{p^n} \otimes \mathbb{D}^0, \mathcal{G}[p^n]^{\text{mult}})$ by $(g \cdot \alpha_p)(v) = \alpha_p(g^{-1}v)$ for $v \in \mathbb{D}^0$. The fiber at a geometric point $\bar{s} \in \mathcal{S}_{n,m}^{\text{tor}}$ parameterizes tuples $(\mathbf{F}^{\pm}, \delta_3^+, \delta_1^-, \mathbf{F}_1^+[p])$, where $\mathbf{F}^{\pm}$ are filtrations

$$\begin{aligned} \mathbf{F}^+ : 0 &= \mathbf{F}_0^+ \subset \mathbf{F}_2^+ \subset \mathbf{F}_3^+ = \mathcal{G}_{\bar{s}}[p^n]^{\text{mult}+} \\ \mathbf{F}^- : 0 &= \mathbf{F}_0^- \subset \mathbf{F}_1^- = \mathcal{G}_{\bar{s}}[p^n]^{\text{mult}-} \end{aligned} \quad (2.5.2)$$

compatible with the Weil pairing; δ_3^+ and δ_1^- are isomorphisms

$$\delta_3^+ : \mu_{p^n} \cong \text{Gr}_3^{\mathbf{F}^+}, \quad \delta_1^- : \mu_{p^n} \cong \text{Gr}_1^{\mathbf{F}^-};$$

and $0 \subset \mathbf{F}_1^+[p] \subset \mathbf{F}_2^+[p]$ is a two-step filtration of $\mathbf{F}_2^+[p]$.

2.6. *p*-adic forms

Define the space of mod p^m automorphic forms on G of level n by

$$V_{n,m} := H^0(\mathcal{T}_{n,m}^{\text{tor}}, \mathcal{O}_{\mathcal{T}_{n,m}^{\text{tor}}}).$$

Letting $\mathcal{I}_{\mathcal{T}_{n,m}^{\text{tor}}} := (\mathcal{T}_{n,m}^{\text{tor}} \rightarrow \mathcal{S}_m^{\text{tor}}[1/E])^* \mathcal{I}_{\mathcal{S}^{\text{tor}}}$, we similarly define the space of mod p^m cuspidal automorphic forms on G of level n by

$$V_{n,m}^0 := H^0(\mathcal{T}_{n,m}^{\text{tor}}, \mathcal{I}_{\mathcal{T}_{n,m}^{\text{tor}}}).$$

Passing to the limit, we obtain corresponding spaces of p -adic automorphic forms (with p -power torsion coefficients) by

$$\mathcal{V} := \varinjlim_m \varprojlim_n V_{n,m}, \quad \mathcal{V}^0 := \varinjlim_m \varprojlim_n V_{n,m}^0.$$

Let $T_{\text{so}}(\mathbb{Z}_p) = \mathbb{Z}_p^{\times} \times \mathbb{Z}_p^{\times}$. The map sending (a_1, a_2) to $g \in G(\mathbb{Z}_p)$ with $g^+ = \begin{pmatrix} 1 & & \\ & 1 & \\ & & a_1 \\ & & & a_2^{-1} \end{pmatrix}$ and $v(g) = 1$ identifies $T_{\text{so}}(\mathbb{Z}/p^n) = (\mathbb{Z}/p^n\mathbb{Z})^{\times} \times (\mathbb{Z}/p^n\mathbb{Z})^{\times}$ with $K_{p,n}^0/K_{p,n}^1$. Hence, the group $T_{\text{so}}(\mathbb{Z}_p)$ naturally acts on $V_{n,m}, V_{n,m}^0, \mathcal{V}, \mathcal{V}^0$ making these spaces into $\mathbb{Z}_p[[T_{\text{so}}(\mathbb{Z}_p)]]$ -modules.

By a *p*-adic weight (for a semiordinary form) we mean a $\overline{\mathbb{Q}}_p$ -valued character of $T_{\text{so}}(\mathbb{Z}_p)$, that is, a pair (τ^+, τ^-) , where $\tau^{\pm} : \mathbb{Z}_p^{\times} \rightarrow \overline{\mathbb{Q}}_p^{\times}$ are continuous characters, and we say that a p -adic weight is *arithmetic* if it is of the form $(x, y) \mapsto \epsilon^+(x)x^{t^+} \cdot \epsilon^-(y)y^{t^-}$, where $\epsilon^{\pm}$ is of finite order and $t^{\pm} \in \mathbb{Z}$. If (τ^+, τ^-) is arithmetic, we put $\tau_{\text{f}}^{\pm} := \epsilon^{\pm}$ and $\tau_{\text{alg}}^{\pm} = t^{\pm}$. Given a p -adic weight (τ^+, τ^-) , we denote by $V_{n,m}[\tau^+, \tau^-]$ the subspace of $V_{n,m} \otimes_{\mathbb{Z}_p} \mathcal{O}_{\mathbb{Q}_p(\tau^+, \tau^-)}$ on which $T_{\text{so}}(\mathbb{Z}_p)$ acts by the inverse of the character (τ^+, τ^-) . Similarly, we define the spaces $V_{n,m}^0[\tau^+, \tau^-], \mathcal{V}[\tau^+, \tau^-], \mathcal{V}^0[\tau^+, \tau^-]$.

2.7. Classical automorphic forms

The weights of classical holomorphic automorphic forms on G are indexed by tuples of integers $\underline{t} = (t_1^+, t_2^+, t_3^+, t_1^-)$ with $t_1^+ \geq t_2^+ \geq t_3^+$. (When $t_3^+ \geq -t_1^- + 4$, the Archimedean component of the corresponding automorphic representation is isomorphic to a holomorphic discrete series.)

Let $W_{\underline{t}}$ be the algebraic representation of $\mathrm{GL}_3 \times \mathrm{GL}_1$ given by

$$W_{\underline{t}} := W_{(t_1^+, t_2^+, t_3^+)} \boxtimes W_{t_1^-}.$$

Here, for any algebra R , letting $R[\underline{x}, \det \underline{x}^{-1}]$ be the polynomial ring in the variables x_{ij} ($1 \leq i, j \leq 3$) and $(\det(x_{ij})_{1 \leq i, j \leq 3})^{-1}$, $W_{(t_1^+, t_2^+, t_3^+)}(R)$ is the R -submodule of $R[\underline{x}, (\det \underline{x})^{-1}]$ spanned by

$$x_{11}^{a_1} x_{12}^{a_2} x_{13}^{a_3} \det \begin{pmatrix} x_{11} & x_{12} \\ x_{21} & x_{22} \end{pmatrix}^{b_1} \det \begin{pmatrix} x_{11} & x_{13} \\ x_{21} & x_{23} \end{pmatrix}^{b_2} \det \begin{pmatrix} x_{12} & x_{13} \\ x_{22} & x_{23} \end{pmatrix}^{b_3} \det \begin{pmatrix} x_{11} & x_{12} & x_{13} \\ x_{21} & x_{22} & x_{23} \\ x_{31} & x_{32} & x_{33} \end{pmatrix}^{t_3^+},$$

where $a_i, b_i \geq 0$, $a_1 + a_2 + a_3 = t_1^+ - t_2^+$, $b_1 + b_2 + b_3 = t_2^+ - t_3^+$, and $W_{t_1^-}(R)$ is the R -submodule of $R[\underline{x}, \det \underline{x}^{-1}]$ spanned by $x^{t_1^-}$.

The groups GL_3 and GL_1 act on $W_{\underline{t}}$ by right translation. One can check that the left translation of $\begin{pmatrix} a_1 & a_2 \\ * & * \end{pmatrix}$ on $W_{(t_1^+, t_2^+, t_3^+)}$ is by the scalar $a_1^{t_1^+} a_2^{t_2^+} a_3^{t_3^+}$; when $R = \mathbb{C}$, it is the irreducible algebraic representation of $\mathrm{GL}_3(\mathbb{C})$ of highest weight (t_1^+, t_2^+, t_3^+) . Let $\mathbf{e}_{\mathrm{can}} : W_{\underline{t}} \rightarrow \mathbb{A}^1$ be the linear functional defined by the evaluation at $(\mathbf{1}_3, \mathbf{1}_1)$.

Let $\underline{\omega}^+$ (resp. $\underline{\omega}^-$) be the subsheaf of $\underline{\omega}$ on which $i(b)$ acts by b (resp. $\bar{b}$) for all $b \in \mathcal{O}_{\mathcal{K}}$. Because p is unramified in $\mathcal{K}$, $\underline{\omega}^+$ (resp. $\underline{\omega}^-$) is locally free of rank 3 (resp. rank 1) and $\underline{\omega} = \underline{\omega}^+ \oplus \underline{\omega}^-$.

Set

$$\begin{aligned} \omega_{(t_1^+, t_2^+, t_3^+)}^+ &= \underline{\mathrm{Isom}}_{\mathcal{S}^{\mathrm{tor}}}(\mathcal{O}_{\mathcal{S}^{\mathrm{tor}}}^{\oplus 3}, \underline{\omega}^+) \times^{\mathrm{GL}_3} W_{(t_1^+, t_2^+, t_3^+)}, \\ \omega_{t_1^-}^+ &= \underline{\mathrm{Isom}}_{\mathcal{S}^{\mathrm{tor}}}(\mathcal{O}_{\mathcal{S}^{\mathrm{tor}}}, \underline{\omega}^+) \times^{\mathrm{GL}_1} W_{t_1^-} \cong (\underline{\omega}^-)^{\otimes t_1^-}, \end{aligned}$$

and put $\omega_{\underline{t}} = \omega_{(t_1^+, t_2^+, t_3^+)}^+ \otimes \omega_{t_1^-}^-$.

Letting $F/\mathbb{Q}_p$ be a finite extension containing the values of the finite-order character $\epsilon^\pm$ of $\mathbb{Z}_p^\times$, and $S_{K_f^p K_{p,n}^1}^{\mathrm{tor}}$ be the toroidal compactification of the Shimura variety of level $K_f^p K_{p,n}^1$ defined over $\mathcal{K}$, we have

$$M_{(0,0,t^+;t^-)}(K_f^p K_{p,n}^1, \epsilon^+, \epsilon^-; F) = \left(H^0(S_{K_f^p K_{p,n}^1}^{\mathrm{tor}}, \underline{\omega}_{(0,0,t^+;t^-)}) \otimes_{\mathcal{K}} F \right) [\epsilon^+, \epsilon^-],$$

the space of classical automorphic forms on G of weight $(0, 0, t^+; t^-)$, level $K_f^p K_{p,n}^1$, and nebentypus (ϵ^+, ϵ^-) for the action of $K_{p,n}^0/K_{p,n}^1$. Here, F is viewed as a $\mathcal{K}$ -algebra via $\mathcal{K} \xrightarrow{\iota_p} \mathbb{Q}_p \rightarrow F$. Similarly, we have the space of classical cuspidal automorphic forms

$$M_{(0,0,t^+;t^-)}^0(K_f^p K_{p,n}^1, \epsilon^+, \epsilon^-; F) = \left(H^0(S_{K_f^p K_{p,n}^1}^{\mathrm{tor}}, \underline{\omega}_{(0,0,t^+;t^-)} \otimes \mathcal{I}_{\mathcal{S}^{\mathrm{tor}}}) \otimes_{\mathcal{K}} F \right) [\epsilon^+, \epsilon^-].$$

There are classical embeddings

$$\begin{aligned} H^0(\mathcal{S}^{\mathrm{tor}}, \underline{\omega}_{(0,0,t^+;t^-)}) &\hookrightarrow \varprojlim_m \varinjlim_n V_{n,m}[t^+, t^-], \\ H^0(\mathcal{S}^{\mathrm{tor}}, \underline{\omega}_{(0,0,t^+;t^-)} \otimes \mathcal{I}_{\mathcal{S}^{\mathrm{tor}}}) &\hookrightarrow \varprojlim_m \varinjlim_n V_{n,m}^0[t^+, t^-], \end{aligned} \tag{2.7.1}$$

induced by the trivialization of $\underline{\omega}$ over the Igusa tower and the canonical functional $\mathbf{e}_{\text{can}}$. More precisely, the trivialization of $\underline{\omega}$ arises from the Hodge–Tate map $(\mathcal{G}/S[p^n]^{\text{mult}})^D \otimes_{\mathbb{Z}} \mathcal{O}_S \xrightarrow{\sim} e^* \Omega_{\mathcal{G}/S}^1 \otimes_{\mathbb{Z}} \mathbb{Z}/p^n \mathbb{Z}$, where $\mathcal{G}/S$ is an ordinary semiabelian variety over S , the superscript D denotes the Cartier dual, and $e : S \rightarrow \mathcal{G}$ is the zero section.

Similarly, we have embeddings

$$\begin{aligned} M_{(0,0,t^+;t^-)}(K_f^p K_{p,n}^1, \epsilon^+, \epsilon^-; F) &\hookrightarrow \left(\varprojlim_m \varinjlim_n V_{n,m} \otimes_{\mathbb{Z}_p} F \right) [(t^+, \epsilon^+), (t^-, \epsilon^-)], \\ M_{(0,0,t^+;t^-)}^0(K_f^p K_{p,n}^1, \epsilon^+, \epsilon^-; F) &\hookrightarrow \left(\varprojlim_m \varinjlim_n V_{n,m}^0 \otimes_{\mathbb{Z}_p} F \right) [(t^+, \epsilon^+), (t^-, \epsilon^-)]. \end{aligned} \quad (2.7.2)$$

2.8. The $\mathbb{U}_p$ -operator

Given a tuple $(A, \lambda, i, \alpha^p, \alpha_p)$ parameterized by $\mathcal{T}_{n,m}$, where $\alpha_p : \mu_{p^n} \otimes \mathbb{D}^0 \rightarrow A[p^n]^{\text{mult}}$ is an isomorphism up to $K_{p,n}^1 \cap P_{\mathbb{D}}(\mathbb{Z}_p)$, the corresponding filtration $F^\pm$ of $A[p^n]^{\text{mult}\pm}$ is

$$\begin{aligned} F^+ : 0 &= F_0^+ \subset F_2^+ = \{e_1^+, e_2^+\} \subset F_3^+ = \{e_1^+, e_2^+, e_3^+\} = A[p^n]^{\text{mult}+}, \\ F^- : 0 &= F_0^- \subset F_1^- = \{e_1^-\} = A[p^n]^{\text{mult}-}, \end{aligned}$$

where $(e_1^+, e_2^+, e_3^+; e_1^-) = \alpha_p(\mathbf{x}_1^+, \mathbf{w}_1^+, \mathbf{w}_2^+; \mathbf{x}_1^-)$.

Now, we define three $\mathbb{U}_p$ -operators $U_{p,2}^+, U_{p,3}^+, U_{p,1}^-$.

2.8.1. $\mathbb{U}_p$ -operators on $V_{n,m}$

For $j = 2, 3$, let $\mathcal{C}_{j,n,m}^+$ denote the solution to the moduli problem classifying tuples $(A, \lambda, i, \alpha^p, \alpha_p, C)$ with $C \subset A[p^2]$ a Lagrangian subgroup, (that is, maximal isotropic for the λ -Weil pairing) stable under the $\mathcal{O}_{\mathcal{K}}$ -action through i such that $A[p] = C[p] \oplus F_j^+[p]$. With $e_1^\pm, e_2^\pm, e_3^\pm, e_4^\pm$ a basis of $A[p^n]$ corresponding to α_p , such a C is spanned by $(e_1^\pm, e_2^\pm, e_3^\pm, e_4^\pm) \cdot p^n \gamma_{C,p}^\pm$, where for $j = 2$

$$\begin{aligned} \gamma_{C,p}^+ &= \begin{pmatrix} 1 & u_1 & * \\ & 1 & u_2 & * \\ & & 1 & \\ & & & 1 \end{pmatrix} \begin{pmatrix} 1 & & & \\ & 1 & & \\ & & \frac{1}{p} & \\ & & & \frac{1}{p} \end{pmatrix}, \\ \gamma_{C,p}^- &= \begin{pmatrix} 1 & & & \\ & \iota_p(\bar{\zeta}_0)^{-1} & & \\ & & 1 & \\ & & & 1 \end{pmatrix} \begin{pmatrix} 1 & * & * \\ & 1 & \\ -u_2 & 1 & u_1 \\ & & 1 \end{pmatrix} \begin{pmatrix} \frac{1}{p} & & & \\ & \frac{1}{p^2} & & \\ & & \frac{1}{p} & \\ & & & \frac{1}{p^2} \end{pmatrix} \begin{pmatrix} 1 & & & \\ & \iota_p(\bar{\zeta}_0) & & \\ & & 1 & \\ & & & 1 \end{pmatrix} \end{aligned} \quad (2.8.1)$$

with $u_1, u_2, * \in \mathbb{Z}_p$, and for $j = 3$,

$$\gamma_{C,p}^+ = \begin{pmatrix} 1 & & * \\ & 1 & * \\ & & 1 & * \\ & & & 1 \end{pmatrix} \begin{pmatrix} 1 & & & \\ & 1 & & \\ & & 1 & \\ & & & \frac{1}{p} \end{pmatrix}, \quad \gamma_{C,p}^- = \begin{pmatrix} 1 & & * \\ & 1 & * \\ & & 1 & * \\ & & & 1 \end{pmatrix} \begin{pmatrix} \frac{1}{p} & & & \\ & \frac{1}{p^2} & & \\ & & \frac{1}{p} & \\ & & & \frac{1}{p^2} \end{pmatrix} \quad (2.8.2)$$

with $* \in \mathbb{Z}_p$.

Similarly, let $\mathcal{C}_{1,n,m}^-$ be the moduli space classifying tuples $(A, \lambda, i, \alpha^p, \alpha_p, C)$ with $C \subset A[p^2]$ a Lagrange subgroup stable under the $\mathcal{O}_K$ -action through i such that $A[p] = C[p] \oplus F_1^-[p]$. Then such a C is spanned by $(e_1^\pm, e_2^\pm, e_3^\pm, e_4^\pm) \cdot p^n \gamma_{C,p}^\pm$ with

$$\gamma_{C,p}^+ = \begin{pmatrix} 1 & & * \\ & 1 & * \\ & & 1 \end{pmatrix} \begin{pmatrix} \frac{1}{p} \\ \frac{1}{p} \\ \frac{1}{p^2} \end{pmatrix}, \quad \gamma_{C,p}^- = \begin{pmatrix} 1 & & * \\ & 1 & * \\ & & 1 \end{pmatrix} \begin{pmatrix} \frac{1}{p} \\ \frac{1}{p} \\ \frac{1}{p} \end{pmatrix}. \quad (2.8.3)$$

For $(\bullet, j) = (+, 2), (+, 3), (-, 1)$, we consider the diagram

$$\begin{array}{ccc} & \mathcal{C}_{j,n,m}^\bullet & \\ p_1 \swarrow & & \searrow p_2 \\ \mathcal{T}_{n,m} & & \mathcal{T}_{n,m} \end{array} \quad (2.8.4)$$

with p_1, p_2 the projections given by

$$\begin{aligned} p_1 : (A, \lambda, i, \alpha^p, \alpha_p, C) &\mapsto (A, \lambda, i, \alpha^p, \alpha_p), \\ p_2 : (A, \lambda, i, \alpha^p, \alpha_p, C) &\mapsto (A', \lambda', i', (\alpha^p)', \alpha_p'), \end{aligned}$$

where $A' = A/C$, λ' is such that $\pi^\vee \circ \lambda \circ \pi = p^2 \lambda'$ with $\pi : A \rightarrow A'$ the natural projection, i' is the $\mathcal{O}_K$ -action i on A descended to A' , $(\alpha^p)' = \pi \circ \alpha^p$, and α_p' given by $(e_1^{+'}, e_2^{+'}, e_3^{+'}; e_1^{-'})$ defined as

$$(e_1^{+'}, e_2^{+'}, e_3^{+'}; e_1^{-'}) = \begin{cases} \pi \left((e_1^+, e_2^+, e_3^+, e_1^-) \begin{pmatrix} 1 & u_1 \\ & 1 & u_2 \\ & & 1 \end{pmatrix} \begin{pmatrix} 1 & & \\ & 1 & \\ & & p^{-1} \end{pmatrix} \right), & \bullet = +, j = 2, \\ \pi \left((e_1^+, e_2^+, e_3^+, e_1^-) \begin{pmatrix} 1 & & \\ & 1 & \\ & & p^{-1} \end{pmatrix} \right), & \bullet = +, j = 3, \\ \pi \left((e_1^+, e_2^+, e_3^+, e_1^-) \begin{pmatrix} p^{-1} & & \\ & p^{-1} & \\ & & 1 \end{pmatrix} \right), & \bullet = -, j = 1. \end{cases}$$

One can check that if $(e_1^+, e_2^+, e_3^+, e_1^-)$ is up to $K_{p,n}^1 \cap P_D(\mathbb{Z}_p)$, then $(e_1^{+'}, e_2^{+'}, e_3^{+'}; e_1^{-'})$ is well-defined up to $K_{p,n}^1 \cap P_D(\mathbb{Z}_p)$.

Define

$$U_{p,j}^+ : H^0(\mathcal{T}_{n,m}, \mathcal{O}_{\mathcal{T}_{n,m}}) \xrightarrow{p_2^*} H^0(\mathcal{C}_{j,n,m}^+, \mathcal{O}_{\mathcal{T}_{n,m}}) \xrightarrow{p^{-j} \text{Tr } p_1} H^0(\mathcal{T}_{n,m}, \mathcal{O}_{\mathcal{T}_{n,m}}), \quad (j = 2, 3) \quad (2.8.5)$$

$$U_{p,1}^- : H^0(\mathcal{T}_{n,m}, \mathcal{O}_{\mathcal{T}_{n,m}}) \xrightarrow{p_2^*} H^0(\mathcal{C}_{1,n,m}^-, \mathcal{O}_{\mathcal{T}_{n,m}}) \xrightarrow{p^{-3} \text{Tr } p_1} H^0(\mathcal{T}_{n,m}, \mathcal{O}_{\mathcal{T}_{n,m}}). \quad (2.8.6)$$

The normalization factors p^{-j} and p^{-3} are the inverse of the pure inseparability degree of the corresponding projection p_1 ; they are the optimal normalization to preserve integrality [Hid02, p.71]. By computing the effect of equations (2.8.5) and (2.8.6) on Fourier–Jacobi expansions, one can check that the operators preserve $V_{n,m}$ and $V_{n,m}^0$.

2.8.2. $\mathbb{U}_p$ -operators on $H^0(\mathcal{T}_{n,m}^{0,\text{tor}}, \omega_L)$

Let $\mathcal{T}_{n,m}^{0,\text{tor}}$ be the quotient of $\mathcal{T}_{n,m}^{\text{tor}}$ by $K_{p,n}^0$, which can be described as

$$\underline{\text{Isom}}_{\mathcal{S}_m^{\text{tor}}[1/E]}(\mu_{p^n} \otimes \mathbb{D}^0, \mathcal{G}[p^n]^{\text{mult}}) / K_{p,n}^0.$$

Compared to $\mathcal{T}_{n,m}^{\text{tor}}$, the level structure at p for $\mathcal{T}_{n,m}^{0,\text{tor}}$ forgets δ_3^+, δ_1^- and parameterizes $(F^\pm, F_1^+[p])$. We can define $\mathbb{U}_p$ -operators on $H^0(\mathcal{T}_{n,m}^{0,\text{tor}}, \omega_L)$. In order to see that they increase the level, we need to introduce Igusa towers of more general level structure at p .

Given $1 \leq n_1, n_2 \leq n_3 \leq n_1 + n_2$, define the level group

$$K_{p,n_1,n_2,n_3}^0 = \left\{ g \in G(\mathbb{Z}_p) : g^+ = \begin{pmatrix} * & * & * & * \\ p^{n_1*} & p^{n_1*} & * & * \\ p^{n_3*} & p^{n_3*} & p^{n_2*} & * \end{pmatrix} \right\}.$$

Define $\mathcal{T}_{n_1,n_2,n_3,m}^0$ as the quotient of $\mathcal{T}_{n,m}$, $n \geq n_1, n_2, n_3$, by $K_{p,n_1,n_2,n_3}^0 \cap P_{\mathbb{D}}(\mathbb{Z}_p)$, that is, the corresponding level structure at p parameterizes isomorphism $\alpha_p : \mu_{p^n} \otimes \mathbb{D}^0 \rightarrow A[p^n]^{\text{mult}}$ up to $K_{p,n_1,n_2,n_3}^0 \cap P_{\mathbb{D}}(\mathbb{Z}_p)$.

Like above, for $(\bullet, j) = (+, 2), (+, 3), (-, 1)$, let $\mathcal{E}_{j,n_1,n_2,n_3,m}^{0,\bullet}$ be the moduli space parameterizing tuples $(A, \lambda, i, \alpha^p, \alpha_p, C)$ with $C \subset A[p^2]$ a Lagrangian subgroup stable under the $\mathcal{O}_{\mathcal{K}}$ -action through i such that $A[p] = C[p] \oplus \mathbb{F}_j^\bullet$.

Consider the diagrams

where p_1, p_2 are defined in the same way as in the diagram (2.8.4). This time, for $(e_1^+, e_2^+, e_3^+, e_1^-)$ up to $K_{p,n_1,n_2,n_3}^0 \cap P_{\mathbb{D}}(\mathbb{Z}_p)$, the $(e_1^{\prime+}, e_2^{\prime+}, e_3^{\prime+}, e_1^{\prime-})$ is well defined up to $K_{p,n_1+1,n_2,n_3+1}^0 \cap P_{\mathbb{D}}(\mathbb{Z}_p)$ in case $\mathcal{E}_{2,n,m}^{0,+}$, and well defined up to $K_{p,n_1,n_2+1,n_3+1}^0 \cap P_{\mathbb{D}}(\mathbb{Z}_p)$ in case $\mathcal{E}_{3,n,m}^{0,+}$ and case $\mathcal{E}_{1,n_1,n_2,n_3,m}^{0,-}$.

In order to define the $\mathbb{U}_p$ -operators on the global sections of vector bundles, we also need maps

$$\begin{aligned} \pi^* : H^0(\mathcal{E}_{1,n_1+1,n_2,n_3+1,m}^{0,-}, p_2^* \omega_L) &\longrightarrow H^0(\mathcal{E}_{1,n_1,n_2,n_3,m}^{0,-}, p_1^* \omega_L) \\ \pi^* : H^0(\mathcal{E}_{1,n_1,n_2+1,n_3+1,m}^{0,-}, p_2^* \omega_L) &\longrightarrow H^0(\mathcal{E}_{1,n_1,n_2,n_3,m}^{0,-}, p_1^* \omega_L). \end{aligned}$$

Suppose that $\underline{\varepsilon}_A$ (resp. $\underline{\varepsilon}_{A/C}$) is a basis of $\underline{\omega}_A$ (resp. $\underline{\omega}_{A/C}$) compatible with α_p (resp. α'_p). We have $\underline{\varepsilon}_A = (\pi^* \underline{\omega}_{A/C})g$ with

$$g = \begin{cases} h \begin{pmatrix} 1 & & \\ & p^{-1} & \\ & & p^{-1} \end{pmatrix} h', & \bullet = +, j = 2, \\ h \begin{pmatrix} 1 & & \\ & 1 & \\ & & p^{-1} \end{pmatrix} h', & \bullet = +, j = 3, \\ h \begin{pmatrix} p^{-1} & & \\ & p^{-1} & \\ & & 1 \end{pmatrix} h', & \bullet = -, j = 1, \end{cases}$$

for some $h, h' = \begin{pmatrix} * & p^{n*} & p^{n*} \\ * & * & p^{n*} \\ * & * & * \end{pmatrix} \in \mathrm{GL}_4(\mathbb{Z}_p)$. In all the cases, g^{-1} belongs to the semigroup

$$\Delta_+ = \left\{ \left(h \begin{pmatrix} a_1 & & \\ & a_2 & \\ & & a_3 \end{pmatrix} h', a_4 \right) : h, h' = \begin{pmatrix} * & p^{n*} & p^{n*} \\ * & * & p^{n*} \\ * & * & * \end{pmatrix} \in \mathrm{GL}_3(\mathbb{Z}_p), a_1^{-1} a_2, a_2^{-1} a_3 \in \mathbb{Z}_p \right\}.$$

We make Δ_+ act on $W_{\underline{t}}$ by

$$\begin{aligned} & \left(h \begin{pmatrix} a_1 & & \\ & a_2 & \\ & & a_3 \end{pmatrix} h', a_4 \right) \cdot q(\underline{x}, y) \\ &= q \left(\begin{pmatrix} p^{-v_p(a_1)} & & \\ & p^{-v_p(a_2)} & \\ & & p^{-v_p(a_3)} \end{pmatrix} \underline{x} h \begin{pmatrix} a_1 & & \\ & a_2 & \\ & & a_3 \end{pmatrix} h', p^{-v_p(a_4)y} a_4 \right), \end{aligned} \quad (2.8.7)$$

and define π^* as

$$\begin{aligned} \pi^* \vec{f}(A, \lambda, i, \alpha^p, \alpha_p, C, \underline{\varepsilon}_A) &= \vec{f}(A, \lambda, i, \alpha^p, \alpha_p, C, \underline{\varepsilon}_A, (\pi^* \underline{\varepsilon}_{A/C})g) \\ &= g^{-1} \cdot \vec{f}(A, \lambda, i, \alpha^p, \alpha_p, C, \underline{\varepsilon}_{A/C}). \end{aligned}$$

The $\mathbb{U}_p$ -operators are defined as

$$\begin{aligned} U_{p,2}^+ : H^0(\mathcal{T}_{n_1+1,n_2,n_3+1,m}^0, \omega_{\underline{t}}) &\xrightarrow{p_2^*} H^0(\mathcal{C}_{2,n_1,n_2,n_3,m}^{0,+}, p_2^* \omega_{\underline{t}}) \\ &\xrightarrow{\pi^*} H^0(\mathcal{C}_{2,n_1,n_2,n_3,m}^{0,+}, p_1^* \omega_{\underline{t}}) \xrightarrow{p^{-2} \mathrm{Tr} p_1} H^0(\mathcal{T}_{n_1,n_2,n_3,m}^0, \omega_{\underline{t}}), \\ U_{p,3}^+ : H^0(\mathcal{T}_{n_1,n_2+1,n_3+1,m}^0, \omega_{\underline{t}}) &\xrightarrow{p_3^*} H^0(\mathcal{C}_{3,n_1,n_2,n_3,m}^{0,+}, p_3^* \omega_{\underline{t}}) \\ &\xrightarrow{\pi^*} H^0(\mathcal{C}_{3,n_1,n_2,n_3,m}^{0,+}, p_1^* \omega_{\underline{t}}) \xrightarrow{p^{-3} \mathrm{Tr} p_1} H^0(\mathcal{T}_{n_1,n_2,n_3,m}^0, \omega_{\underline{t}}), \\ U_{p,1}^- : H^0(\mathcal{T}_{n_1,n_2+1,n_3+1,m}^0, \omega_{\underline{t}}) &\xrightarrow{p_1^*} H^0(\mathcal{C}_{1,n_1,n_2,n_3,m}^{0,-}, p_1^* \omega_{\underline{t}}) \\ &\xrightarrow{\pi^*} H^0(\mathcal{C}_{1,n_1,n_2,n_3,m}^{0,-}, p_1^* \omega_{\underline{t}}) \xrightarrow{p^{-2} \mathrm{Tr} p_1} H^0(\mathcal{T}_{n_1,n_2,n_3,m}^0, \omega_{\underline{t}}). \end{aligned}$$

Similarly as $V_{n,m}$, one can check that these $\mathbb{U}_p$ -operators preserve the spaces $H^0(\mathcal{T}_{n,m}^{0,\mathrm{tor}}, \omega_{\underline{t}})$ and $H^0(\mathcal{T}_{n,m}^{0,\mathrm{tor}}, \omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{T}_{n,m}^{0,\mathrm{tor}}})$. It is also easy to see that $U_{p,2}^+ U_{p,3}^+ U_{p,1}^-$ maps $H^0(\mathcal{T}_{n,m}^{0,\mathrm{tor}}, \omega_{\underline{t}})$ (resp.

$H^0(\mathcal{T}_{n,m}^{0,\text{tor}}, \omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{T}_{n,m}^{0,\text{tor}}})$ into $H^0(\mathcal{T}_{n-1,m}^{0,\text{tor}}, \omega_{\underline{t}})$ (resp. $H^0(\mathcal{T}_{n-1,m}^{0,\text{tor}}, \omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{T}_{n-1,m}^{0,\text{tor}}})$), that is, the operator $U_{p,2}^+ U_{p,3}^+ U_{p,1}^-$ increases the level.

2.8.3. Adelic $\mathbb{U}_p$ -operators

If we identify $G(\mathbb{Q}_p)$ with $\text{GL}_4(\mathbb{Q}_p) \times \text{GL}_1(\mathbb{Q}_p)$ via equation (2.4.1), the $\mathbb{U}_p$ -operators defined above acting on classical automorphic forms on G of weight $(t_1^+, t_2^+, t_3^+; t_1^-)$ correspond to the following adelic operators (up to the action of the center of $G(\mathbb{Q}_p)$):

$$\begin{aligned} U_{p,2}^+ : & \quad p^{\langle (t_1^+, t_2^+, t_3^+; -t_1^-) + 2\rho_c, (1,1,0;0) \rangle} \int_{N(\mathbb{Z}_p)} R\left(u \begin{pmatrix} p & & & \\ & p & & \\ & & p & \\ & & & 1 \end{pmatrix}, 1\right) du; \\ U_{p,3}^+ : & \quad p^{\langle (t_1^+, t_2^+, t_3^+; -t_1^-) + 2\rho_c, (1,1,1;0) \rangle} \int_{N(\mathbb{Z}_p)} R\left(u \begin{pmatrix} p & & & \\ & p & & \\ & & p & \\ & & & 1 \end{pmatrix}, 1\right) du; \\ U_{p,1}^- : & \quad p^{\langle (t_1^+, t_2^+, t_3^+; -t_1^-) + 2\rho_c, (0,0,0;-1) \rangle} \int_{N(\mathbb{Z}_p)} R\left(u \begin{pmatrix} 1 & & & \\ & 1 & & \\ & & 1 & \\ & & & p^{-1} \end{pmatrix}, 1\right) du, \end{aligned} \quad (2.8.8)$$

where $N(\mathbb{Z}_p) = \left\{ \begin{pmatrix} 1 & * & * & * \\ & 1 & * & * \\ & & 1 & * \\ & & & 1 \end{pmatrix} \in \text{GL}_4(\mathbb{Z}_p) \right\}$, $R(-)$ denotes the right translation, and $2\rho_c = (2, 0, -2; 0)$ is the sum of the compact positive roots of G .

2.9. Statement of main theorem

Let $T_{\text{so}}(\mathbb{Z}_p)^\circ$ be the connected component of $T_{\text{so}}(\mathbb{Z}_p)$ containing $\mathbf{1}_2$, that is, $T_{\text{so}}(1 + p\mathbb{Z}_p)$, and put $\Lambda_{\text{so}} = \mathbb{Z}_p[[T_{\text{so}}(\mathbb{Z}_p)^\circ]]$.

Theorem 2.9.1. *The following hold:*

- (1) Let $U_p = U_{p,2}^+ U_{p,3}^+ U_{p,1}^-$. Then for each $f \in \mathcal{V}$, $\lim_{r \rightarrow \infty} (U_p)^{r!} f$ converges, and we can define the semiordinary projector as $e_{\text{so}} = \lim_{r \rightarrow \infty} (U_p)^{r!}$. The $\mathbb{Z}_p[[T_{\text{so}}(\mathbb{Z}_p)]]$ -modules

$$\mathcal{V}_{\text{so}}^{0,*} = \text{Hom}_{\mathbb{Z}_p}(e_{\text{so}} \mathcal{V}^0, \mathbb{Q}_p/\mathbb{Z}_p), \quad \mathcal{V}_{\text{so}}^* = \text{Hom}_{\mathbb{Z}_p}(e_{\text{so}} \mathcal{V}, \mathbb{Q}_p/\mathbb{Z}_p)$$

are both free of finite rank over Λ_{so} .

- (2) The spaces of Λ_{so} -families of tame level K_f^P are defined as

$$\mathcal{M}_{\text{so}}^0 = \text{Hom}_{\Lambda_{\text{so}}}(\mathcal{V}_{\text{so}}^{0,*}, \Lambda_{\text{so}}), \quad \mathcal{M}_{\text{so}} = \text{Hom}_{\Lambda_{\text{so}}}(\mathcal{V}_{\text{so}}^*, \Lambda_{\text{so}}).$$

For a given weight $(\tau^+, \tau^-) \in \text{Hom}_{\text{cont}}(T_{\text{so}}(\mathbb{Z}_p), F^\times)$, let $\mathcal{P}_{\tau^+, \tau^-}$ be the ideal in $\mathcal{O}_F[[T_{\text{so}}(\mathbb{Z}_p)]]$ generated by $\{(x, y) - \tau^+(x)\tau^-(y) : (x, y) \in T_{\text{so}}(\mathbb{Z}_p)\}$. We have

$$\begin{aligned} \mathcal{M}_{\text{so}}^0 \otimes_{\mathbb{Z}_p[[T_{\text{so}}(\mathbb{Z}_p)]]} \mathcal{O}_F[[T_{\text{so}}(\mathbb{Z}_p)]]/\mathcal{P}_{\tau^+, \tau^-} & \xrightarrow{\sim} \left(\varprojlim_m \varinjlim_n e_{\text{so}} V_{n,m}^0 \otimes_{\mathbb{Z}_p} \mathcal{O}_F \right) [\tau^+, \tau^-], \\ \mathcal{M}_{\text{so}} \otimes_{\mathbb{Z}_p[[T_{\text{so}}(\mathbb{Z}_p)]]} \mathcal{O}_F[[T_{\text{so}}(\mathbb{Z}_p)]]/\mathcal{P}_{\tau^+, \tau^-} & \xrightarrow{\sim} \left(\varprojlim_m \varinjlim_n e_{\text{so}} V_{n,m} \otimes_{\mathbb{Z}_p} \mathcal{O}_F \right) [\tau^+, \tau^-]. \end{aligned} \quad (2.9.1)$$

The semiordinary projector preserves the spaces of classical forms, and by combining equation (2.9.1) with equation (2.7.2), we have the embeddings

$$e_{\text{so}} M_{(0,0,t^+;t^-)}^0 \left(K_f^P K_{p,n}^1, \epsilon^+, \epsilon^-; F \right) \hookrightarrow \left(\mathcal{M}_{\text{so}}^0 \otimes_{\mathbb{Z}_p} [[T_{\text{so}}(\mathbb{Z}_p)]] \mathcal{O}_F [[T_{\text{so}}(\mathbb{Z}_p)]] / \mathcal{P}_{\tau^+, \tau^-} \right) [1/p],$$

$$e_{\text{so}} M_{(0,0,t^+;t^-)} \left(K_f^P K_{p,n}^1, \epsilon^+, \epsilon^-; F \right) \hookrightarrow \left(\mathcal{M}_{\text{so}} \otimes_{\mathbb{Z}_p} [[T_{\text{so}}(\mathbb{Z}_p)]] \mathcal{O}_F [[T_{\text{so}}(\mathbb{Z}_p)]] / \mathcal{P}_{\tau^+, \tau^-} \right) [1/p],$$

where $t^\pm = \tau_{\text{alg}}^\pm$ with $(0, 0, t^+; t^-)$ dominant and $\epsilon^\pm = \tau_f^\pm$.

- (3) Given $0 \geq t^+$, there exists $A \geq -t^+ + 4$ such that the above embedding for the cuspidal forms is surjective if $t^- \geq A$.
- (4) There is the following so-called fundamental exact sequence (in the study of Klingen Eisenstein congruences),

$$0 \longrightarrow \mathcal{M}_{\text{so}}^0 \longrightarrow \mathcal{M}_{\text{so}} \xrightarrow{\oplus \Phi_g} \bigoplus_g M_{(0,0)}(K'_{f,g}; \mathbb{Z}_p) \otimes_{\mathbb{Z}_p} \mathbb{Z}_p [[T_{\text{so}}(\mathbb{Z}_p)]] \longrightarrow 0,$$

with g runs over $(G'_1(\mathbb{Q}) \times P'_1(\mathbb{A}_{\mathbb{Q},f}^P)) \backslash G(\mathbb{A}_{\mathbb{Q},f}^P) / K_f^P$ and Φ_g the Siegel operator obtained by restriction to the boundary stratum indexed by g . The level group $K'_{f,g} = K'_{f,g} K'_{p,g} \subset G'(\mathbb{A}_{\mathbb{Q},f}^P)$ is defined in equation (4.4.1), and $M_{(0,0)}(K'_{f,g}; \mathbb{Z}_p)$ denotes the space of classical automorphic forms on G' of weight $(0, 0)$ and level $K'_{f,g}$.

Remark 2.9.2. In general, one can consider semiordinary families whose members have weight $\underline{t} = (t_1^+, t_2^+, t_3^+, t_1^-)$ with t_1^+, t_2^+ fixed and t_3^+, t_1^- varying in the family. We only consider the case $t_1^+ = t_2^+ = 0$ because it suffices for proving Theorem 8.2.3, and we want to avoid having the main idea obscured by the extra complications of working with vector bundles. For the general case, instead of considering the global sections of the structure sheaf over the Igusa tower, one considers the global sections of a vector bundle $\omega_{\underline{t}}$. For defining $\mathcal{V}^b$ (cf. §4.3) such that the quotient $\mathcal{V} / \mathcal{V}^b$ has a nice structure, besides the requirement of vanishing outside the strata labeled by cusp labels in $C(K_f^P K_{p,n}^1)_{\text{ord}}^b$, one also requires that the elements are global sections of $\omega_{\underline{t}}^b \subset \omega_{\underline{t}}$ with $\omega_{\underline{t}}^b$ a subsheaf defined as in [Hsi14a, Section 4.1].

3. The proof of Theorem 2.9.1 for the cuspidal part

In this section, we prove Theorem 2.9.1 for cuspidal families. The results for cuspidal families will be used to deduce the results for noncuspidal families in §4.

Proposition 3.0.1 (Base change property). *Let $\mathcal{T}_n^{0,\text{tor}}[1/E]$ be the open subscheme of $\mathcal{T}_n^{0,\text{tor}}$ where E , our fixed lift of Hasse invariant viewed as a section over $\mathcal{T}_n^{0,\text{tor}}$, is nonvanishing. For any classical dominant weight $\underline{t}$, the natural map*

$$H^0 \left(\mathcal{T}_n^{0,\text{tor}}[1/E], \omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{T}_n^{0,\text{tor}}} \right) \otimes \mathbb{Z}/p^m \mathbb{Z} \hookrightarrow H^0 \left(\mathcal{T}_{n,m}^{0,\text{tor}}, \omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{T}_{n,m}^{0,\text{tor}}} \right)$$

is an isomorphism.

Proof. Over $\mathcal{T}_n^{\text{tor}}$, we have the exact sequence of sheaves

$$0 \longrightarrow \omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{T}_n^{\text{tor}}} \xrightarrow{p^m} \omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{T}_n^{\text{tor}}} \longrightarrow \omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{T}_{n,m}^{\text{tor}}} \longrightarrow 0.$$

By [Lan18, Thm. 8.2.1.1], $R^1_{\pi_n,*}(\omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{T}_n^{\text{tor}}}) = 0$ (where π_n is the projection $\pi_n : \mathcal{T}_n^{\text{tor}} \rightarrow \mathcal{T}_n^{\text{min}}$), so we have the exact sequence of sheaves

$$0 \rightarrow \pi_{n,*}(\omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{T}_n^{\text{tor}}}) \xrightarrow{p^m} \pi_{n,*}(\omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{T}_n^{\text{tor}}}) \rightarrow \pi_{n,*}(\omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{T}_{n,m}^{\text{tor}}}) \rightarrow 0$$

over $\mathcal{T}_n^{\text{min}}$. Since $\mathcal{T}_n^{\text{min}}[1/E]$ is affine by definition, taking global sections gives the result. $\square$

Proposition 3.0.2. *Let $U_p = U_{p,2}^+ U_{p,3}^+ U_{p,1}^-$. Let $f \in \mathcal{V}^0$ and $\vec{f} \in H^0(\mathcal{T}_{n,m}^{0,\text{tor}}, \omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{T}_{n,m}^{0,\text{tor}}})$. Then both limits $\lim_{r \rightarrow \infty} (U_p)^{r!} f$ and $\lim_{r \rightarrow \infty} (U_p)^{r!} \vec{f}$ converge.*

Proof. Consider $\tilde{\mathcal{T}}_n$, the ordinary locus of level

$$\tilde{K}_{p,1}^n = \left\{ g \in G(\mathbb{Z}_p) \mid g^+ \equiv \begin{pmatrix} 1 & * & * & * \\ & 1 & * & * \\ & & 1 & * \\ & & & 1 \end{pmatrix} \pmod{p^n} \right\}.$$

Let $\tilde{\mathcal{T}}_n^{\text{tor}}$ be the partial toroidal compactification of $\tilde{\mathcal{T}}_n$, and put $\tilde{V}_{n,m}^0 = H^0(\tilde{\mathcal{T}}_n^{\text{tor}}, \omega_{\underline{t}} \otimes \mathcal{I}_{\tilde{\mathcal{T}}_n^{\text{tor}}})$, which contains $V_{n,m}^0$ as a subspace. The definition of the U_p -operators in §2.8 can be naturally extended to $\tilde{V}_{n,m}^0$, so it suffices to show that $\lim_{r \rightarrow \infty} (U_p)^{r!} f$ converges for every $f \in \tilde{V}_{n,m}^0$. As explained in [Hid02], $\varprojlim_m \varinjlim_n \tilde{V}_{n,m}^0$ is p -torsion free and there is an embedding

$$\bigoplus_{\underline{t} \text{ dominant}} H^0(\mathcal{S}^{\text{tor}}, \omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{S}^{\text{tor}}}) \otimes \mathbb{Q} \hookrightarrow \left(\varprojlim_m \varinjlim_n \tilde{V}_{n,m}^0 \right) [1/p].$$

The $\mathbb{Z}_p$ -modules $H^0(\mathcal{S}^{\text{tor}}, \omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{S}^{\text{tor}}})$ are free of finite rank and stable under the action of U_p , so the limit $\lim_{r \rightarrow \infty} (U_p)^{r!}$ exists on them. Since

$$\left(\bigoplus_{\underline{t} \text{ dominant}} H^0(\mathcal{S}^{\text{tor}}, \omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{S}^{\text{tor}}}) \otimes \mathbb{Q} \right) \cap \varprojlim_m \varinjlim_n \tilde{V}_{n,m}^0 \quad (3.0.1)$$

is dense in $\varprojlim_m \varinjlim_n \tilde{V}_{n,m}^0$ by [Hid02], the convergence of $\lim_{r \rightarrow \infty} (U_p)^{r!} f$ for every $f \in \tilde{V}_{n,m}^0$ follows.

On the other hand, let $\vec{f} \in H^0(\mathcal{T}_{n,m}^{0,\text{tor}}, \omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{T}_{n,m}^{0,\text{tor}}})$. By Proposition 3.0.1, $\vec{f}$ lifts to

$$\vec{\tilde{f}} \in H^0(\mathcal{T}_n^{0,\text{tor}}[1/E], \omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{T}_n^{0,\text{tor}}}).$$

For $l \gg 0$, we have $\vec{\tilde{f}} E^l \in H^0(\mathcal{T}_n^{0,\text{tor}}, \omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{T}_n^{0,\text{tor}}})$, which by the Koecher principle can be viewed as an element in the finite-dimensional space $M_{t+lE(p-1)}^0(K_f^p K_{p,n}^0; \mathbb{Q}_p)$. Thus, the limit $\lim_{r \rightarrow \infty} (U_p)^{r!} (\vec{\tilde{f}} E^l)$ converges. Since $E \equiv 1 \pmod{p}$, we have $\vec{\tilde{f}} E^l \equiv \vec{f} \pmod{p^m}$, and the convergence of $\lim_{r \rightarrow \infty} (U_p)^{r!} \vec{f}$ follows. $\square$

Thanks to the convergence of $\lim_{r \rightarrow \infty} (U_p)^{r!}$ on $\mathcal{V}^0$ and $H^0(\mathcal{T}_{n,m}^{0,\text{tor}}, \omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{T}_{n,m}^{0,\text{tor}}})$, we can define the semiordinary projector on them as $e_{\text{so}} = \lim_{r \rightarrow \infty} (U_p)^{r!}$.

Proposition 3.0.3. *For $n \geq m$ and a dominant weight $(0, 0, t^+, t^-)$, the map*

$$e_{\text{so}} H^0(\mathcal{T}_{n,m}^{0,\text{tor}}, \omega_{(0,0,t^+,t^-)} \otimes \mathcal{I}_{\mathcal{T}_{n,m}^{0,\text{tor}}}) \rightarrow e_{\text{so}} V_{n,m}^0[t^+, t^-]$$

induced by equation (2.7.1) is an isomorphism.

Proof. Given $\vec{f}$, we have

$$\begin{aligned} & (U_p^n \vec{f})(A, \lambda, i, \alpha^P, \alpha_p, \underline{\varepsilon}_{\alpha_p}) \\ &= p^{-(2+3+3)n} \sum_C \left({}^t u_C^{-1} \begin{pmatrix} p^n & & \\ & p^n & \\ & & p^{2n} \end{pmatrix}, p^{2n} \right) \cdot \vec{f}(A/C, \lambda', i', (\alpha^P)', \alpha'_p, \underline{\varepsilon}_{\alpha'_p}). \end{aligned} \quad (3.0.2)$$

Here, C runs over the subgroups of $A[p^{4n}]$ which can be spanned as

$$\begin{aligned} & (e_1^+, e_2^+, e_3^+, e_4^+) \cdot p^n \begin{pmatrix} 1 & u_1 & * \\ & 1 & u_2 \\ & & 1 \end{pmatrix} \begin{pmatrix} p^{-n} & & \\ & p^{-2n} & \\ & & p^{-4n} \end{pmatrix}, \\ & (e_1^-, e_2^-, e_3^-, e_4^-) \cdot p^n \begin{pmatrix} 1 & * & * & * \\ & 1 & & \\ -u_2 & 1 & -u_1 & \\ & & 1 & \end{pmatrix} \begin{pmatrix} p^{-2n} & & & \\ & p^{-5n} & & \\ & & p^{-4n} & \\ & & & p^{-5n} \end{pmatrix}, \end{aligned}$$

with $e_1^\pm, e_2^\pm, e_3^\pm, e_4^\pm$ a basis of $A[p^n]$ compatible with α_p . For such a C , $u_C = \begin{pmatrix} 1 & u_1 \\ & 1 & u_2 \\ & & 1 \end{pmatrix}$. By our definition of the Δ_+ -action on W_t (in equation (2.8.7)), we know that if $w \in W_{(0,0,t^+,t^-)}$ is a vector of nonhighest weight, then

$$\left(\begin{pmatrix} p^n & & \\ & p^n & \\ & & p^{2n} \end{pmatrix}, p^{2n} \right) \cdot w \equiv 0 \pmod{p^n}.$$

Therefore, from equation (3.0.2) we see that $U_p^n \vec{f}$ is actually determined by the projection of its values to the highest weight space.

On one hand, this shows that the map in the statement is injective. On the other hand, given $f \in e_{\text{so}} V_{n,m}^0[t^+, t^-]$, we can define $\vec{f}$ by the rule

$$\vec{f}(A, \lambda, i, \alpha^P, \alpha_p, \underline{\varepsilon}_{\alpha_p}) = p^{-(2+3+3)n} \sum_C \left({}^t u_C^{-1}, 1 \right) \cdot w_{(0,0,t^+,t^-)} f(A/C, \lambda', i', (\alpha^P)', \alpha'_p), \quad (3.0.3)$$

where C runs over the same range as above. One can check that $\vec{f}$ satisfies

$$\vec{f}(A, \lambda, i, \alpha^P, \alpha_p \circ g, \underline{\varepsilon}_{\alpha_p \circ g}) = \left(\begin{pmatrix} * & p^* & \\ * & * & \\ u_1 & u_2 & a_1 \end{pmatrix}, a_2 \right)^{-1} \cdot \vec{f}(A, \lambda, i, \alpha^P, \alpha_p, \underline{\varepsilon}_{\alpha_p})$$

for $g^+ \equiv \begin{pmatrix} * & * & u_1 & * \\ p^* & * & u_2 & * \\ & & a_1 & \\ & & & a_2^{-1} \end{pmatrix} \pmod{p^n}$, so equation (3.0.3) defines an element in $H^0(\mathcal{T}_{n,m}^{0,\text{tor}}, \omega_{(0,0,t^+,t^-)} \otimes \mathcal{I}_{\mathcal{T}_{n,m}^{\text{tor}}})$, and it is easy to check its semiordinarity from the semiordinarity of f . The composition of equation (3.0.3) and the map in the statement is U_p^n . Hence, the map is a bijection. $\square$

Proposition 3.0.4. $e_{\text{so}} H^0(\mathcal{T}_{n,m}^{0,\text{tor}}, \omega_t \otimes \mathcal{I}_{\mathcal{T}_{n,m}^{\text{tor}}}) = e_{\text{so}} H^0(\mathcal{T}_{1,m}^{0,\text{tor}}, \omega_t \otimes \mathcal{I}_{\mathcal{T}_{1,m}^{\text{tor}}})$.

Proof. This follows immediately from the fact that U_p maps the space $H^0(\mathcal{T}_{n,m}^{0,\text{tor}}, \omega_t \otimes \mathcal{I}_{\mathcal{T}_{n,m}^{\text{tor}}})$ into $H^0(\mathcal{T}_{n-1,m}^{0,\text{tor}}, \omega_t \otimes \mathcal{I}_{\mathcal{T}_{n,m}^{\text{tor}}})$. (See §2.8.2.) $\square$

Proposition 3.0.5. For a fixed tame level K_f^P and a fixed integer $B \geq 0$, the dimension of $e_{\text{so}} M_t^0(K_f^P K_{p,1}^0; \mathbb{Q}_p)$ is uniformly bounded for all $t_1^+ \geq t_2^+ \geq t_3^+ \geq -t_1^- + 4$ with $t_1^+ - t_2^+ \leq B$.

Proof. Suppose that Π is an irreducible cuspidal automorphic representation of $G(\mathbb{A}_{\mathbb{Q}})$ generated by a semiordinary form $\varphi \in e_{\text{so}} M_L^0(K_f^P K_{p,n}^0; \mathbb{Q}_p)$ whose (generalized) eigenvalue of $U_{p,2}^+$ (resp. $U_{p,3}^+$, $U_{p,1}^-$) is λ_2^+ (resp. λ_3^+ , λ_1^-). The semiordinarity condition implies that λ_2^+ , λ_3^+ , λ_1^- are all p -adic units. We view Π_p as an irreducible representation of $\text{GL}_4(\mathbb{Q}_p)$ via equation (2.4.1). Let Q be the parabolic subgroup $\left\{ \begin{pmatrix} * & * & * & * \\ * & * & * & * \\ * & * & * & * \\ * & * & * & * \end{pmatrix} \right\} \subset \text{GL}_4$ with Levi factorization $Q = M_Q N_Q$. Let

$$\Pi_{p,N_Q} = \Pi_p / \{ \Pi_p(u)v - v : v \in \Pi_p, u \in N_Q(\mathbb{Q}_p) \},$$

the Jacquet module of Π_p with respect to the parabolic Q acted on by $M_Q(\mathbb{Q}_p) \cong \text{GL}_2(\mathbb{Q}_p) \times \text{GL}_1(\mathbb{Q}_p) \times \text{GL}_1(\mathbb{Q}_p)$. It follows from Jacquet's lemma (see [Cas95, Theorem 4.1.2, Proposition 4.1.4]) that $\Pi_{p,N_Q}^{M_Q(\mathbb{Q}_p) \cap K_{p,n}^0}$ equals the image under the natural projection of

$$\bigcap_{r \geq 1} (U_{p,\text{loc}})^r \Pi_p^{K_{p,n}^0}, \quad U_{p,\text{loc}} = \int_{N_Q(\mathbb{Z}_p)} \Pi_p \left(u \begin{pmatrix} p^2 & & & \\ & p^2 & & \\ & & p & \\ & & & p^{-1} \end{pmatrix} \right) du.$$

The semiordinary form $\varphi \in \Pi$ is fixed by $K_{p,n}^0$ and belongs to a generalized eigenspace of $U_{p,\text{loc}}$ with a nonzero eigenvalue. Thus, we deduce that $\Pi_{p,N_Q}^{M_Q(\mathbb{Q}_p) \cap K_{p,n}^0} \neq 0$ and Π_p is isomorphic to a subquotient of

$$\text{Ind}_{Q(\mathbb{Q}_p)}^{\text{GL}_4(\mathbb{Q}_p)} \sigma \boxtimes \chi \boxtimes \chi',$$

where σ is an irreducible smooth admissible representation of $\text{GL}_2(\mathbb{Q}_p)$, and χ, χ' are smooth characters of $\mathbb{Q}_p^\times$. We have $M_Q(\mathbb{Q}_p) \cap K_{p,1}^0 \cong K'_p \times (1 + p^n \mathbb{Z}_p) \times (1 + p^n \mathbb{Z}_p)$ with $K'_p = \left\{ \begin{pmatrix} * & * \\ p & * \end{pmatrix} \right\} \subset \text{GL}_2(\mathbb{Z}_p)$.

From $\Pi_{p,N_Q}^{M_Q(\mathbb{Q}_p) \cap K_{p,n}^0} \neq 0$, we know that $\sigma^{K'_p} \neq 0$ ([Cas95, Theorem 6.3.5]). This implies that σ is not supercuspidal, and Π_p is isomorphic to a subquotient of a principal series. Denote by $\alpha_1, \alpha_2, \alpha_3, \alpha_4$ the evaluations at p of the corresponding characters of $\mathbb{Q}_p^\times$. Then, up to reordering, we have

$$\lambda_2^+ = p^{t_1^+ + \frac{1}{2}} \alpha_1 \cdot p^{t_2^+ - \frac{1}{2}} \alpha_2, \quad (3.0.4)$$

$$\lambda_3^+ = p^{t_1^+ + \frac{1}{2}} \alpha_1 \cdot p^{t_2^+ - \frac{1}{2}} \alpha_2 \cdot p^{t_3^+ - \frac{3}{2}} \alpha_3, \quad (3.0.5)$$

$$\lambda_1^- = p^{t_1^- - \frac{3}{2}} \alpha_4^{-1}. \quad (3.0.6)$$

Now, in addition to $U_{p,2}^+, U_{p,3}^+, U_{p,1}^-$, we also consider the action of the operator

$$U_{p,1}^+ = p^{\langle t_1^+, t_2^+, t_3^+; -t_1^- \rangle + 2\rho_c, (1,0,0;0)} \int_{N(\mathbb{Z}_p)} R \left(u \begin{pmatrix} p & & & \\ & 1 & & \\ & & 1 & \\ & & & 1 \end{pmatrix}, 1 \right) du \quad (3.0.7)$$

on $M_L^0(K_f^P K_{p,n}^0; \mathbb{Q}_p)$. The operator $U_{p,1}^+$ has a geometric interpretation analogous to equation (2.8.5), and the above normalization makes all its eigenvalues p -integral. If $\alpha_1^{-1} \alpha_2 \neq p^{\pm 1}$, then $p^{t_1^+ + \frac{1}{2}} \alpha_1$ and $p^{t_1^+ + \frac{1}{2}} \alpha_2$ are both eigenvalues for the action of $U_{p,1}^+$ on the holomorphic forms in Π of level $K_f^P K_{p,n}^0$, so

$$v_p(\alpha_1) + t_1^+ + \frac{1}{2} \geq 0, \quad v_p(\alpha_2) + t_1^+ + \frac{1}{2} \geq 0. \quad (3.0.8)$$

By using that equation (3.0.4) is a p -adic unit and our condition $0 \leq t_1^+ - t_2^+ \leq B$, we get

$$(v_p(\alpha_1) + t_1^+ + \frac{1}{2}) + (v_p(\alpha_2) + t_1^+ + \frac{1}{2}) = t_1^+ - t_2^+ + 1 \leq B + 1. \quad (3.0.9)$$

Combining equation (3.0.8) and equation (3.0.9), we get

$$0 \leq v_p(\alpha_j) + t_1^+ + \frac{1}{2} \leq B + 1, \quad j = 1, 2. \quad (3.0.10)$$

If $\alpha_1^{-1}\alpha_2 = p^{\pm 1}$, then equation (3.0.4) being a p -adic unit implies that

$$\frac{t_1^+ - t_2^+}{2} \leq v_p(\alpha_j) \leq \frac{t_1^+ - t_2^+}{2} + 1, \quad j = 1, 2.$$

Combining it with our condition $0 \leq t_1^+ - t_2^+ \leq B$, we get

$$0 \leq v_p(\alpha_j) \leq \frac{B}{2} + 1, \quad j = 1, 2. \quad (3.0.11)$$

Therefore, for $t_1^+ \geq t_2^+ \geq t_3^+ \geq -t_1^- + 4$, $t_1^+ - t_2^+ \leq B$, all the semiordinary forms in $e_{\text{so}}M_{\underline{t}}^0(K_f^P K_{p,1}^0; \mathbb{Q}_p)$ have slopes $\leq B$ for the $\mathbb{U}_p$ -operator $U_{p,1}^+ U_{p,2}^+ U_{p,3}^+ U_{p,1}^-$.

Recall that the theory of Coleman families for unitary groups (developed in [Bra16] as a generalization of [AIP15]) shows that, for every point in the weight space $\text{Hom}_{\text{cont}}((\mathbb{Z}_p^\times)^4, \mathbb{C}_p^\times)$, there exists a neighborhood $\mathcal{U}$ of that point and a projective $\mathcal{A}_{\mathcal{U}}$ -module of finite rank interpolating all the cuspidal overconvergent forms of weights in $\mathcal{U}$ and $U_{p,1}^+ U_{p,2}^+ U_{p,3}^+ U_{p,1}^-$ -slope $\leq B$ and a fixed tame level. Since all the algebraic weights $\underline{t}$ are contained in a compact subset of $\text{Hom}_{\text{cont}}((\mathbb{Z}_p^\times)^4, \mathbb{C}_p)$, when $\underline{t}$ varies among all the algebraic weights, there is a uniform bound on the dimension of the space of cuspidal overconvergent forms of weight $\underline{t}$ and slopes $\leq B$ and tame level K_f^P . The proposition follows. $\square$

Proposition 3.0.6.

- (1) $\dim_{\mathbb{F}_p} e_{\text{so}}H^0(\mathcal{T}_{1,1}^{0,\text{tor}}, \omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{T}_{1,1}^{0,\text{tor}}}) < \infty$.
- (2) (Classicity) There is a canonical embedding

$$e_{\text{so}}M_{(0,0,t^+;t^-)}^0(K_f^P K_{p,0}^1; \mathbb{Q}_p) \hookrightarrow \left(\varprojlim_m \varinjlim_n e_{\text{so}}V_{n,m}^0[t^+, t^-] \right) \otimes \mathbb{Q}_p,$$

and for a given $t^+ \leq 0$, there exists $A(t^+) \geq -t^+ + 4$ such that if $t^- \geq A(t^+)$, then the embedding is an isomorphism.

Proof. (1) Suppose that $\overline{f}_1, \dots, \overline{f}_d \in e_{\text{so}}H^0(\mathcal{T}_{1,1}^{0,\text{tor}}, \omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{T}_{1,1}^{0,\text{tor}}})$ are linearly independent. By Proposition 3.0.1, they lift to $f_1, \dots, f_d \in H^0(\mathcal{T}_1^{0,\text{tor}}[1/E], \omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{T}_1^{0,\text{tor}}})$. Recall that E has scalar weight $t_E(p-1)$ and let $\underline{t} + lk_E(p-1) = (t_1^+ + lt_E(p-1), t_2^+ + lt_E(p-1), t_3^+ + lt_E(p-1); t_1^- + lt_E(p-1))$. For $l \gg 0$, we have

$$f_1 E^l, \dots, f_d E^l \in H^0(\mathcal{T}_n^{0,\text{tor}}, \omega_{\underline{t} + lt_E(p-1)} \otimes \mathcal{I}_{\mathcal{T}_n^{0,\text{tor}}}).$$

Because $E \equiv 1 \pmod{p}$, we have $\overline{e_{\text{so}}(f_j E^l)} = \overline{f_j}$, and therefore $e_{\text{so}}(f_1 E^l), \dots, e_{\text{so}}(f_d E^l)$ are linearly independent. Thus, d can be at most the bound in Proposition 3.0.5.

(2) We have $M_{(0,0,t^+,t^-)}^0(K_f^p K_{p,1}^0; \mathbb{Q}_p) = H^0(\mathcal{T}_1^{0,\text{tor}}, \omega_{(0,0,t^+,t^-)} \otimes \mathcal{I}_{\mathcal{T}_1^{0,\text{tor}}} \otimes_{i_p} \mathbb{Q}_p)$. (As mentioned above, the base change of $\mathcal{T}_1^{0,\text{tor}}$ to $\mathcal{K}$ is an open subscheme of $S_{K_f^p K_{p,1}^0}^{\text{tor}}$; here, we use the Koecher principle to get the equality of global sections.) The map (2.7.1) induces

$$H^0(\mathcal{T}_1^{0,\text{tor}}, \omega_{(0,0,t^+,t^-)} \otimes \mathcal{I}_{\mathcal{T}_1^{0,\text{tor}}}) \rightarrow \left(\lim_{\leftarrow m} \lim_{\rightarrow n} e_{\text{so}} V_{n,m}^0[t^+, t^-] \right),$$

and this gives the canonical embedding in the statement.

Put $V_{\text{so}}^0[t^+, t^-] = \lim_{\leftarrow m} \lim_{\rightarrow n} e_{\text{so}} V_{n,m}^0[t^+, t^-]$. Note that from Propositions 3.0.3 and 3.0.4, for $n \geq m$, we have

$$e_{\text{so}} V_{n,m}^0[t^+, t^-] \simeq e_{\text{so}} H^0(\mathcal{T}_{1,m}^{0,\text{tor}}, \omega_{(0,0,t^+,t^-)} \otimes \mathcal{I}_{\mathcal{T}_{1,m}^{0,\text{tor}}}).$$

It follows that $V_{\text{so}}^0[t^+, t^-]$ is p -torsion free, and together with Proposition 3.0.1 we get

$$\begin{aligned} \dim_{\mathbb{F}_p} V_{\text{so}}^0[t^+, t^-] / p V_{\text{so}}^0[t^+, t^-] &= \dim_{\mathbb{F}_p} e_{\text{so}} H^0(\mathcal{T}_{1,1}^{0,\text{tor}}, \omega_{(0,0,t^+,t^-)} \otimes \mathcal{I}_{\mathcal{T}_{1,1}^{0,\text{tor}}}) \\ &= \dim_{\mathbb{Q}_p} e_{\text{so}} H^0(\mathcal{T}_1^{0,\text{tor}}[1/E], \omega_{(0,0,t^+,t^-)} \otimes \mathcal{I}_{\mathcal{T}_1^{0,\text{tor}}}) \otimes \mathbb{Q}_p. \end{aligned}$$

Denote this dimension by d . The above shows that $V_{\text{so}}^0[t^+, t^-]$ is a free $\mathbb{Z}_p$ -module of rank d . Thus, it suffices to show that there exists $A(t^+) \geq -t^+$ such that $\dim_{\mathbb{Q}_p} e_{\text{so}} M_{(0,0,t^+,t^-)}^0(K_f^p K_{p,1}^0; \mathbb{Q}_p) \geq d$ for $t^- \geq A(t^+)$. Pick an unramified Hecke character χ of $\mathcal{K}^\times \backslash \mathbb{A}_{\mathcal{K}}^\times$ of ∞ -type $(-t_E(p-1), 0)$. Twisting E by the character obtained by composing χ with $\det : G(\mathbb{Q}) \backslash G(\mathbb{A}_{\mathbb{Q}}) \rightarrow \mathcal{K}^\times \backslash \mathbb{A}_{\mathcal{K}}^\times$, we get a holomorphic form E' of weight $(0, 0, 0; 2t_E(p-1))$ with the same vanishing locus as E . Multiplying by $(E')^l$ and applying e_{so} gives an injection

$$e_{\text{so}} M_{(0,0,t^+,t^-)}^0(K_f^p K_{p,1}^0; \mathbb{Q}_p) \hookrightarrow e_{\text{so}} M_{(0,0,t^+,t^-+2t_E(p-1))}^0(K_f^p K_{p,1}^0; \mathbb{Q}_p),$$

so

$$\dim_{\mathbb{Q}_p} e_{\text{so}} M_{(0,0,t^+,t^-)}^0(K_f^p K_{p,1}^0; \mathbb{Q}_p) \leq \dim_{\mathbb{Q}_p} e_{\text{so}} M_{(0,0,t^+,t^-+2t_E(p-1))}^0(K_f^p K_{p,1}^0; \mathbb{Q}_p).$$

By the definition of d , we thus see that for each $0 \leq j \leq 2t_E(p-1) - 1$ there exists $l_j(t^+) \geq 0$ such that

$$\dim_{\mathbb{Q}_p} e_{\text{so}} M_{(0,0,t^+,-t^++4+j+2t_E(p-1)l_j(t^+))}^0(K_f^p K_{p,1}^0; \mathbb{Q}_p) \geq d.$$

Therefore, $A(t^+) = -t^+ + 4 + 2t_E(p-1)(\max_j \{l_j(t^+)\} + 1)$ has the required property. $\square$

Theorem 3.0.7 (Vertical control theorem). $\mathcal{V}_{\text{so}}^{0,*}$ is a free Λ_{so} -module of finite rank.

Proof. Let $\mathfrak{m}$ be a maximal ideal of $\mathbb{Z}_p[[T_{\text{so}}(\mathbb{Z}_p)]]$. (We know that $\mathfrak{m} \cap \Lambda_{\text{so}} = (p, T^+, T^-)$, where we identify Λ_{so} with $\mathbb{Z}_p[[T^+, T^-]]$ by identifying $(1+p, 1) \in T_{\text{so}}(\mathbb{Z}_p)$ (resp. $(1, 1+p) \in T_{\text{so}}(\mathbb{Z}_p)$) with T^+ (resp. T^-).) We show that $\mathcal{V}_{\text{so},\mathfrak{m}}^{0,*}$, the localization of $\mathcal{V}_{\text{so}}^{0,*}$ at $\mathfrak{m}$, is a free Λ_{so} -module of finite rank.

First, we consider the quotient $\mathcal{V}_{\text{so}, \mathfrak{m}}^{0,*} \otimes_{\Lambda_{\text{so}}} \Lambda_{\text{so}} / (p, T^+, T^-)$, which by definition, equals $(e_{\text{so}} \mathcal{V}[\mathfrak{m}])^*$. Take $0 \geq t^+ \geq -t^- + 4$ with $\mathcal{P}_{t^+, t^-} \subset \mathfrak{m}$. Then

$$\begin{aligned} e_{\text{so}} \mathcal{V}[\mathfrak{m}] &= p\text{-torsion of } \lim_{\substack{\longrightarrow \\ m}} \lim_{\substack{\longrightarrow \\ n}} e_{\text{so}} V_{n,m}^0[t^+, t^-] \\ &\stackrel{(\text{Prop } 3.0.3)}{=} p\text{-torsion of } \lim_{\substack{\longrightarrow \\ m}} \lim_{\substack{\longrightarrow \\ n}} e_{\text{so}} H^0\left(\mathcal{T}_{n,m}^{0,\text{tor}}, \omega_{(0,0,t^+;t^-)} \otimes \mathcal{I}_{\mathcal{T}_{n,m}^{0,\text{tor}}}\right) \\ &\stackrel{(\text{Prop } 3.0.4)}{=} p\text{-torsion of } \lim_{\substack{\longrightarrow \\ m}} e_{\text{so}} H^0\left(\mathcal{T}_{1,m}^{0,\text{tor}}, \omega_{(0,0,t^+;t^-)} \otimes \mathcal{I}_{\mathcal{T}_{1,m}^{0,\text{tor}}}\right) \\ &= e_{\text{so}} \left[p\text{-torsion of } \lim_{\substack{\longrightarrow \\ m}} H^0\left(\mathcal{T}_{1,m}^{0,\text{tor}}, \omega_{(0,0,t^+;t^-)} \otimes \mathcal{I}_{\mathcal{T}_{1,m}^{0,\text{tor}}}\right) \right]. \end{aligned}$$

Also, Proposition 3.0.1 implies

$$\lim_{\substack{\longrightarrow \\ m}} H^0\left(\mathcal{T}_{1,m}^{0,\text{tor}}, \omega_{(0,0,t^+;t^-)} \otimes \mathcal{I}_{\mathcal{T}_{1,m}^{0,\text{tor}}}\right) = \lim_{\substack{\longrightarrow \\ m}} H^0\left(\mathcal{T}_1^{0,\text{tor}}[1/E], \omega_{(0,0,t^+;t^-)} \otimes \mathcal{I}_{\mathcal{T}_1^{0,\text{tor}}}\right) \otimes \mathbb{Z}/p^m\mathbb{Z}.$$

It follows that

$$\begin{aligned} &p\text{-torsion of } \lim_{\substack{\longrightarrow \\ m}} H^0\left(\mathcal{T}_{1,m}^{0,\text{tor}}, \omega_{(0,0,t^+;t^-)} \otimes \mathcal{I}_{\mathcal{T}_{1,m}^{0,\text{tor}}}\right) \\ &= H^0\left(\mathcal{T}_1^{0,\text{tor}}[1/E], \omega_{(0,0,t^+;t^-)} \otimes \mathcal{I}_{\mathcal{T}_1^{0,\text{tor}}}\right) \otimes \mathbb{Z}/p\mathbb{Z} \\ &= H^0\left(\mathcal{T}_{1,1}^{0,\text{tor}}, \omega_{(0,0,t^+;t^-)} \otimes \mathcal{I}_{\mathcal{T}_{1,1}^{0,\text{tor}}}\right), \end{aligned}$$

where Proposition 3.0.1 is used again for the second equality. Thus,

$$e_{\text{so}} \mathcal{V}[\mathfrak{m}] = e_{\text{so}} H^0\left(\mathcal{T}_{1,1}^{0,\text{tor}}, \omega_{(0,0,t^+;t^-)} \otimes \mathcal{I}_{\mathcal{T}_{1,1}^{0,\text{tor}}}\right).$$

By Proposition 3.0.6, we know this is finite dimensional over $\mathbb{F}_p$. Hence, $\mathcal{V}_{\text{so}, \mathfrak{m}}^{0,*} \otimes_{\Lambda_{\text{so}}} \Lambda_{\text{so}} / (p, T^+, T^-) = (e_{\text{so}} \mathcal{V}[\mathfrak{m}])^*$ is finite dimensional over $\mathbb{F}_p$. Let

$$d = \dim_{\mathbb{F}_p} \mathcal{V}_{\text{so}, \mathfrak{m}}^{0,*} \otimes_{\Lambda_{\text{so}}} \Lambda_{\text{so}} / (p, T^+, T^-).$$

By Nakayama's lemma, there exist $F_1, \dots, F_d \in \mathcal{V}_{\text{so}, \mathfrak{m}}^{0,*}$ such that

$$\mathcal{V}_{\text{so}, \mathfrak{m}}^{0,*} = \Lambda_{\text{so}} F_1 + \dots + \Lambda_{\text{so}} F_d.$$

Next, we show that $F_1, \dots, F_d$ are Λ_{so} -linearly independent. Suppose that $a_1, \dots, a_d \in \Lambda_{\text{so}}$ are such that $a_1 F_1 + \dots + a_d F_d = 0$. Given any $0 \geq t^+ \geq -t^- + 4$ with $\mathcal{P}_{t^+, t^-} \subset \mathfrak{m}$, we put

$$\mathcal{P}_{t^+, t^-}^\circ = \Lambda_{\text{so}} \cap \mathcal{P}_{t^+, t^-}.$$

In view of Proposition 3.0.1, the $\mathbb{Z}_p$ -module $\lim_{\substack{\longrightarrow \\ m}} \lim_{\substack{\longrightarrow \\ n}} H^0\left(\mathcal{T}_{n,m}^{0,\text{tor}}, \omega_{\underline{t}} \otimes \mathcal{I}_{\mathcal{T}_{n,m}^{0,\text{tor}}}\right)$ is p -divisible, and by Proposition 3.0.3 so is $e_{\text{so}} \mathcal{V}^0[t^+, t^-]$. Therefore,

$$\mathcal{V}_{\text{so}, \mathfrak{m}}^{0,*} \otimes_{\Lambda_{\text{so}}} \Lambda_{\text{so}} / \mathcal{P}_{t^+, t^-}^\circ = \left(e_{\text{so}} \mathcal{V}^0[t^+, t^-] \right)^*$$

is p -torsion free. On the other hand,

$$\dim_{\mathbb{F}_p} \left(\mathcal{V}_{\text{so}, \mathfrak{m}}^{0,*} \otimes_{\Lambda_{\text{so}}} \Lambda_{\text{so}} / \mathcal{P}_{t^+, t^-}^\circ \right) \otimes_{\mathbb{Z}} \mathbb{Z} / p\mathbb{Z} = \dim_{\mathbb{F}_p} \mathcal{V}_{\text{so}, \mathfrak{m}}^{0,*} \otimes_{\Lambda_{\text{so}}} \Lambda_{\text{so}} / (p, T^+, T^-) = d.$$

It follows that the $\mathbb{Z}_p$ -module $\mathcal{V}_{\text{so}, \mathfrak{m}}^{0,*} \otimes_{\Lambda_{\text{so}}} \Lambda_{\text{so}} / \mathcal{P}_{t^+, t^-}^\circ$ is free of rank d , and therefore $a_1, \dots, a_d \in \mathcal{P}_{t^+, t^-}^\circ$. Then from $\bigcap_{0 \geq t^+ \geq -t^-+4} \mathcal{P}_{t^+, t^-}^\circ = 0$, we conclude that $a_1 = \dots = a_d = 0$, and hence $\mathcal{V}_{\text{so}, \mathfrak{m}}^{0,*}$ is a free Λ_{so} -module of rank d . $\square$

This completes the proof of part (1) of Theorem 2.9.1 for cuspidal forms. For part (2), because $\mathcal{V}_{\text{so}}^{0,*}$ is free over Λ_{so} , letting $V_{m, \text{so}}^0[\tau^+, \tau^-] = e_{\text{so}} \varinjlim_n V_{n, m}^0 \otimes_{\mathbb{Z}_p} \mathcal{O}_F[\tau^+, \tau^-]$ we have

$$\begin{aligned} \mathcal{M}_{\text{so}}^0 \otimes_{\mathbb{Z}_p} [[T_{\text{so}}(\mathbb{Z}_p)]] \mathcal{O}_F[[T_{\text{so}}(\mathbb{Z}_p)]] / \mathcal{P}_{\tau^+, \tau^-} &\cong \text{Hom}_{\mathbb{Z}_p} \left(\mathcal{V}_{\text{so}}^{0,*} \otimes_{\mathbb{Z}_p} \mathcal{O}_F / \mathcal{P}_{\tau^+, \tau^-}, \mathbb{Z}_p \right) \\ &= \text{Hom}_{\mathbb{Z}_p} \left((e_{\text{so}} \mathcal{V}^0[\tau^+, \tau^-])^*, \mathbb{Z}_p \right) \\ &= \text{Hom}_{\mathbb{Z}_p} \left(\left(\varinjlim_m V_{m, \text{so}}^0[\tau^+, \tau^-] \right)^*, \mathbb{Z}_p \right). \end{aligned} \quad (3.0.12)$$

Since the left-hand side is a free $\mathbb{Z}_p$ -module (because $\mathcal{M}_{\text{so}}^0$ is a free Λ_{so} -module), we see that $\varinjlim_m V_{m, \text{so}}^0[\tau^+, \tau^-]$ is p -divisible, and $V_{m+1, \text{so}}^0[\tau^+, \tau^-] \rightarrow V_{m, \text{so}}^0[\tau^+, \tau^-]$ is surjective, so

$$\text{Hom}_{\mathbb{Z}_p} \left(\varinjlim_m V_{m, \text{so}}^0[\tau^+, \tau^-], \mathbb{Q}_p / \mathbb{Z}_p \right) \cong \text{Hom}_{\mathbb{Z}_p} \left(\varprojlim_m V_{m, \text{so}}^0[\tau^+, \tau^-], \mathbb{Z}_p \right)$$

and hence

$$\begin{aligned} (3.0.12) &= \text{Hom}_{\mathbb{Z}_p} \left(\text{Hom}_{\mathbb{Z}_p} \left(\varprojlim_m V_{m, \text{so}}^0[\tau^+, \tau^-], \mathbb{Z}_p \right), \mathbb{Z}_p \right) = \varprojlim_m V_{m, \text{so}}^0[\tau^+, \tau^-] \\ &= \left(\varprojlim_m \varinjlim_n e_{\text{so}} V_{n, m}^0 \otimes_{\mathbb{Z}_p} \mathcal{O}_F \right) [\tau^+, \tau^-], \end{aligned}$$

concluding the proof of part (2) of Theorem 2.9.1 for cuspidal forms. Part (3) follows from Proposition 3.0.6.

4. The proof of Theorem 2.9.1 for the noncuspidal part

We apply the approach in [LR20] to prove the vertical control theorem for semiordinary forms on $\text{GU}(3, 1)$ by analyzing the quotient $\mathcal{V} / \mathcal{V}^0$ and using the vertical control theorem for cuspidal semiordinary forms on $\text{GU}(3, 1)$. When studying $\mathcal{V} / \mathcal{V}^0$, we introduce an auxiliary space $\mathcal{V}^b$. One difference from *loc.cit* is that q -expansions are used there to reduce proving some properties for the $\mathbb{U}_p$ -action on $\mathcal{V}$, $\mathcal{V}^b$ to matrix computations, but q -expansions are not available in the case of $\text{GU}(3, 1)$. The analogue of those properties in our case are proved in §4.5 by working with semiabelian schemes over the boundary of the partial toroidal compactification.

4.1. Cusp labels

Following [Lan13], a *cusp label* is a K_f -orbit of triples (Z, Φ, δ) , with:

- $Z : 0 \subset Z_{-2} \subset Z_{-1} = Z_{-2}^\perp \subset L \otimes \hat{\mathbb{Z}}$ a fully symplectic admissible filtration.
- $\Phi = (X, Y, \phi, \varphi_{-2}, \varphi_0)$ a torus argument, where $\phi : Y \rightarrow X$ is an $\mathcal{O}_K$ -linear embedding of locally free $\mathcal{O}_K$ -modules with finite cokernel, and $\varphi_{-2} : \text{Gr}_{-2}^Z \xrightarrow{\sim} \text{Hom}(X \otimes \hat{\mathbb{Z}}, \hat{\mathbb{Z}}(1))$ and $\varphi_0 : \text{Gr}_0^Z \xrightarrow{\sim} Y \otimes \hat{\mathbb{Z}}$, with $\text{Gr}_{-i}^Z = Z_{-i}/Z_{-i-1}$, are isomorphisms such that $\langle v, w \rangle = \varphi_0(v)(\phi(\varphi_{-2}(w)))$,
- $\delta : \text{Gr}^Z = \text{Gr}_{-2}^Z \oplus \text{Gr}_{-1}^Z \oplus \text{Gr}_0^Z \xrightarrow{\sim} L \otimes \hat{\mathbb{Z}}$ is an $\mathcal{O}_K \otimes \hat{\mathbb{Z}}$ -equivariant splitting.

Following [Lan18, Def. 3.2.3.1], an *ordinary cusp label* of tame level K_f^P is a $K_f^P P_D(\mathbb{Z}_p)$ -orbit of triples (Z, Φ, δ) as above compatible with D , in the sense that

$$Z_{-2} \otimes_{\hat{\mathbb{Z}}} \mathbb{Z}_p \subset D \subset Z_{-1} \otimes_{\hat{\mathbb{Z}}} \mathbb{Z}_p.$$

There is a unique cusp label for which $Z_{-2} = 0$, and in our case, all other cusp labels have Z_{-2} with rank 1. As explained in [HLTT16, B.2, B.3, B.11], the latter are parametrized by a certain double coset space. To recall this, we have the filtration

$$X^\vee \subset X^\vee \oplus L_0 \subset L = X^\vee \oplus L_0 \oplus Y. \quad (4.1.1)$$

Let $P \subset G$ be the parabolic subgroup preserving this filtration, and $P' \subset P$ be the kernel of the natural projection $P \rightarrow \text{GL}(Y)$. Define the triple $(Z^{(1)}, \Phi^{(1)}, \delta^{(1)})$ as

- $Z^{(1)} : Z_{-2} = X^\vee \otimes \hat{\mathbb{Z}}, Z_{-1} = (X^\vee \oplus L_0) \otimes \hat{\mathbb{Z}}$.
- $\Phi^{(1)} = (X^{(1)}, Y^{(1)}, \phi^{(1)}, \varphi_{-2}^{(1)}, \varphi_0^{(1)})$ with $X^{(1)} = \text{Hom}_{\mathcal{O}_K}(X^\vee, \mathcal{O}_K(1))$, $Y^{(1)} = Y$, $\phi^{(1)} : Y \rightarrow \text{Hom}_{\mathcal{O}_K}(\mathfrak{d}_{K/\mathbb{Q}}^{-1} \cdot \mathfrak{x}_1, \mathcal{O}_K(1))$ induced by our fixed basis of $\mathfrak{x}_1$ and y_1 of X and Y and the pairing $2\pi i \cdot \text{Tr}_{K/\mathbb{Q}} \circ \langle \cdot, \cdot \rangle_L$, $\varphi_{-2}^{(1)} = 2\pi\sqrt{-1} \cdot \text{id}$ and $\varphi_0^{(1)} = \text{id}$.
- $\delta^{(1)} = \text{id}$.

Denote by $V : 0 \subset V_{-2} \subset V_{-1} \subset L \otimes \mathbb{Q}$ the filtration obtained as equation (4.1.1) tensored with $\mathbb{Q}$. For every $g \in G(\mathbb{A}_{\mathbb{Q},f})$, define $(Z^{(g)}, \Phi^{(g)}, \delta^{(g)})$ by

- $Z_j^{(g)} = (g^{-1}(V_j \otimes \mathbb{A}_{\mathbb{Q},f})) \cap (L \otimes \hat{\mathbb{Z}})$.
- $\Phi^{(g)} = (X^{(g)}, Y^{(g)}, \phi^{(g)}, \varphi_{-2}^{(g)}, \varphi_0^{(g)})$ with $(X^{(g)}, Y^{(g)}, \phi^{(g)}) = (X^{(1)}, Y^{(1)}, \phi^{(1)})$, $\varphi_{-2}^{(g)}$ (resp. $\varphi_0^{(g)}$) is the composition of $\varphi_{-2}^{(1)}$ (resp. $\varphi_0^{(1)}$) with $g : \text{Gr}_{-2}^{Z^{(g)}} \rightarrow \text{Gr}_{-2}^Z$ (resp. $g : \text{Gr}_0^{Z^{(g)}} \rightarrow \text{Gr}_0^Z$).
- $\delta^{(g)}$ is $\text{Gr}^{Z^{(g)}} \xrightarrow{\text{Gr}^{(g)}} \text{Gr}^{Z^{(1)}} \xrightarrow{\delta^{(1)}} L \otimes \hat{\mathbb{Z}} \xrightarrow{g^{-1}} L \otimes \hat{\mathbb{Z}}$.

Then the map that sends g to (the cusp label represented by) $(Z^{(g)}, \Phi^{(g)}, \delta^{(g)})$ sets up a bijection between the set of cusp labels with Z_{-2} rank 1 and the double coset space

$$C(K_f^P) = \text{GL}(X \otimes \mathbb{Q}) \ltimes P'(\mathbb{A}_{\mathbb{Q},f}^P) \backslash G(\mathbb{A}_{\mathbb{Q},f}^P) / K_f^P.$$

(See [Lan15, Prop. A.5.9].)

Similarly, the ordinary cusp labels with Z_{-2} of rank 1 are parameterized by

$$C(K_f^P K_{p,n}^1)_{\text{ord}} = \text{Im} \left(G(\mathbb{A}_{\mathbb{Q},f}^P) P_D(\mathbb{Q}_p) \longrightarrow \text{GL}(X \otimes \mathbb{Q}) \ltimes P'(\mathbb{A}_{\mathbb{Q},f}) \backslash G(\mathbb{A}_{\mathbb{Q},f}) / K_f^P K_{p,n}^1 \right), \quad (4.1.2)$$

which is in a natural bijection with

$$\begin{aligned} & \left(\text{GL}(X_{(p)}) \ltimes (P'(\mathbb{A}_{\mathbb{Q},f}^P) \times P'(\mathbb{Z}_p)) \right) \backslash G(\mathbb{A}_{\mathbb{Q},f}^P) \times P_D(\mathbb{Z}_p) / K_f^P (K_{p,n}^1 \cap P_D(\mathbb{Z}_p)) \\ & \cong C(K_f^P) \times \left(U_{K,K_f^P} \ltimes P'(\mathbb{Z}_p) \backslash P_D(\mathbb{Z}_p) / K_{p,n}^1 \cap P_D(\mathbb{Z}_p) \right), \end{aligned} \quad (4.1.3)$$

where $U_{\mathcal{K}, K_f^P} = \left\{ a \in \mathcal{O}_{\mathcal{K}}^{\times} : \begin{pmatrix} a & \\ & 1_{\bar{a}^{-1}} \end{pmatrix} \in K_f^P \right\}$. By abuse of notation, we shall denote by g both elements in $G(\mathbb{A}_{\mathbb{Q}, f}^P)P_{\mathbb{D}}(\mathbb{Q}_p)$ and in its quotient $C(K_f^P K_{p,n}^1)_{\text{ord}}$. The context should eliminate any possible confusions.

4.2. The formal completion along boundary strata

Let $\mathcal{X}_{g,n}$ be the stratum associated to $g \in C(K_f^P K_{p,n}^1)_{\text{ord}}$ in the partial toroidal compactification $\mathcal{T}_n^{\text{tor}}$. Then we have

$$\mathcal{T}_n^{\text{tor}} = \mathcal{T}_n \sqcup \bigsqcup_{g \in C(K_f^P K_{p,n}^1)_{\text{ord}}} \mathcal{X}_{g,n}.$$

(The choice of a polyhedral cone decomposition is unique in our special case $\text{GU}(3, 1)$ because with $\left(\mathbf{S}_{\Phi_{K_f^P K_{p,n}^1}^{(g)}} \right)$ defined as below and $\mathbf{P}_{\Phi_{K_f^P K_{p,n}^1}^{(g)}}$ the subset of $\text{Hom}_{\mathbb{Z}} \left(\mathbf{S}_{\Phi_{K_f^P K_{p,n}^1}^{(g)}}, \mathbb{Z} \right) \otimes \mathbb{R}$ consisting of positive semidefinite Hermitian forms, we have $\mathbf{P}_{\Phi_{K_f^P K_{p,n}^1}^{(g)}} = \mathbb{R}_{\geq 0}$.) Let $\mathcal{T}_n^{\text{min}}$ be the partial minimal compactification of $\mathcal{T}_n$ (constructed in [Lan18, Theorem 6.2.1.1]). Denoting by $\mathcal{Y}_{g,n}$ the stratum associated to $g \in C(K_f^P K_{p,n}^1)_{\text{ord}}$ in $\mathcal{T}_n^{\text{min}}$, we similarly have

$$\mathcal{T}_n^{\text{min}} = \mathcal{T}_n \sqcup \bigsqcup_{g \in C(K_f^P K_{p,n}^1)_{\text{ord}}} \mathcal{Y}_{g,n}.$$

The stratum $\mathcal{Y}_{g,n}$ can be identified with the 0-dimensional Shimura variety $\mathcal{S}_{G', K'_{f,g,n}}$, where

$$K'_{f,g,n} = \text{Im} \left(P(\mathbb{A}_{\mathbb{Q}, f}) \cap g K_f^P K_{p,n}^1 g^{-1} \rightarrow G'(\mathbb{A}_{\mathbb{Q}, f}) \right). \quad (4.2.1)$$

We have the following diagram:

$$\begin{array}{ccc} \Xi_{g,n}^{\text{ord}} & \hookrightarrow & \overline{\Xi}_{g,n}^{\text{ord}} \\ \downarrow & \swarrow & \\ \mathcal{C}_{g,n}^{\text{ord}} & & \\ \downarrow h & & \\ \mathcal{S}_{G', K'_{f,g,n}} & & \end{array} \quad (4.2.2)$$

where $\mathcal{C}_{g,n}^{\text{ord}} \rightarrow \mathcal{S}_{G', K'_{f,g,n}}$ is a torsor of an abelian scheme quasi-isogenous to $\text{Hom}_{\mathcal{O}_{\mathcal{K}}}(\mathbf{X}^{(g)}, \mathcal{A})$ with $\mathcal{A}$ the universal abelian scheme over $\mathcal{S}_{G', K'_{f,g,n}}$, and $\Xi_{g,n}^{\text{ord}} \rightarrow \mathcal{C}_{g,n}^{\text{ord}}$ is a torsor of the torus with character group $\mathbf{S}_{\Phi_{K_f^P K_{p,n}^1}^{(g)}}$, which is a finite index subgroup of the free quotient of

$$\left(\frac{1}{N} \mathbf{Y}^{(g)} \otimes_{\mathbb{Z}} \mathbf{X}^{(g)} \right) \bigg/ \left(y \otimes \phi^{(g)}(y') - y' \otimes \phi^{(g)}(y) \right)_{y, y' \in \mathbf{Y}^{(g)}, x \in \mathbf{X}^{(g)}, b \in \mathcal{O}_{\mathcal{K}}}$$

with N sufficiently large with respect to the level $K_f^P K_{p,n}^1$; and $\Xi_{g,n}^{\text{ord}} \hookrightarrow \overline{\Xi}_{g,n}^{\text{ord}}$ is the torus embedding with respect to the unique cone decomposition.

Denote by $\mathfrak{X}_{g,n}$ the formal completion of $\mathcal{T}_n^{\text{tor}}$ along the stratum $\mathcal{Z}_{g,n}$. Then $\mathfrak{X}_{g,n}$ is canonically isomorphic to the quotient by Γ_g of the formal completion of $\overline{\Xi}_{g,n}^{\text{ord}}$ along the boundary $\overline{\Xi}_{g,n}^{\text{ord}} - \Xi_{g,n}^{\text{ord}}$. Here, Γ_g is the (finite, in our case) subgroup of $\text{GL}(X^{(g)}) \times \text{GL}(Y^{(g)})$ preserving $\varphi_{-2}^{(g)}$ and $\varphi_0^{(g)}$ (as orbits).

4.3. The subset $C(K_f^P K_{p,n}^1)_{\text{ord}}^b$ of $C(K_f^P K_{p,n}^1)_{\text{ord}}$ and the subspace $\mathcal{V}^b$ of $\mathcal{V}$

By a generic point, denoted by η , of the formal completion $\mathfrak{X}_{g,n}$, we mean a generic point of $\text{Spec}(\Gamma(U, \mathcal{O}_U))$ with U an affine open subscheme of $\mathfrak{X}_{g,n}$. Let $(\mathcal{G}, \lambda, i, \alpha^P, \alpha_p)$ be the pullback to $\text{Spec}(\Gamma(U, \mathcal{O}_U))$ of the family of semiabelian varieties over $\mathcal{T}_n^{\text{tor}}$, which is a degenerating family obtained by Mumford's construction. Let

$$0 \longrightarrow \mathcal{T} \longrightarrow \mathcal{G}^{\natural} \longrightarrow \mathcal{A} \longrightarrow 0$$

be the Raynaud extension of $\mathcal{G}$. Then, for any positive integer N , the group $\mathcal{T}[N]$ (resp. $\mathcal{G}^{\natural}[N]$) is canonically isomorphic to a subgroup of $\mathcal{G}[N]$, which we denote by $(\mathcal{G}[N])^{\mu}$ (resp. $(\mathcal{G}[N])^{\natural}$). We have $(\mathcal{G}[N])^{\mu} \subset (\mathcal{G}[N])^{\natural}$ and the quotient $(\mathcal{G}[N])^{\text{ab}} = (\mathcal{G}[N])^{\natural} / (\mathcal{G}[N])^{\mu}$ is canonically isomorphic to $\mathcal{A}[N]$. (See also [Lan18, §3.4.2].)

Let $\bar{\eta}$ be a geometric point over η . The ordinary level structure $\alpha_{p,\bar{\eta}}$ of $\mathcal{G}_{\bar{\eta}}$ gives rise to a filtration

$$\mathbf{F}_{\bar{\eta}}^+ : 0 \subset \mathbf{F}_{2,\bar{\eta}}^+ \subset \mathbf{F}_{3,\bar{\eta}}^+ \subset \mathcal{G}_{\bar{\eta}}[p^n]^{\text{mult+}}$$

(refer to text around equation (2.5.2)). We define a subset $C(K_f^P K_{p,n}^1)_{\text{ord}}^b \subset C(K_f^P K_{p,n}^1)_{\text{ord}}$ in terms of the relative positions of $\mathbf{F}_{2,\bar{\eta}}^+$ and $(\mathcal{G}_{\bar{\eta}}[p])^{\mu}$.

Definition 4.3.1. Define $C(K_f^P K_{p,n}^1)_{\text{ord}}^b$ as the subset of $C(K_f^P K_{p,n}^1)_{\text{ord}}$ consisting of g such that

$$\mathbf{F}_{2,\bar{\eta}}^+ \cap (\mathcal{G}_{\bar{\eta}}[p])^{\mu} = 0$$

for a geometric point $\bar{\eta}$ over a generic point η of $\mathfrak{X}_{g,n}$.

One can check that the preceding definition does not depend on the choice of $\bar{\eta}$. Let

$$P_{\mathbf{D}}^b(\mathbb{Q}_p) = \left\{ g \in P_{\mathbf{D}}(\mathbb{Q}_p) \left| g^+ = \begin{pmatrix} a_{11} & a_{12} & a_{13} & a_{14} \\ a_{21} & a_{22} & a_{23} & a_{24} \\ a_{31} & a_{32} & a_{33} & a_{34} \\ & & & a_{44} \end{pmatrix} \text{ with } \begin{pmatrix} a_{21} & a_{22} \\ a_{31} & a_{32} \end{pmatrix}^{-1} \begin{pmatrix} a_{23} \\ a_{33} \end{pmatrix} \in \mathbb{Z}_p^2 \right\}$$

and

$$\begin{aligned} P_{\mathbf{D}}^b(\mathbb{Z}_p) &= \left\{ g_p \in P_{\mathbf{D}}(\mathbb{Z}_p) \left| g_p^+ = \begin{pmatrix} a_{11} & a_{12} & a_{13} & a_{14} \\ a_{21} & a_{22} & a_{23} & a_{24} \\ a_{31} & a_{32} & a_{33} & a_{34} \\ & & & a_{44} \end{pmatrix} \text{ with } \begin{pmatrix} a_{21} & a_{22} \\ a_{31} & a_{32} \end{pmatrix} \in \text{GL}_2(\mathbb{Z}_p) \right\} \\ &= P'(\mathbb{Z}_p) \begin{pmatrix} 1 & & & \\ & 1 & & \\ & & 1 & \\ & & & 1 \end{pmatrix} (K_{p,n}^0 \cap P_{\mathbf{D}}(\mathbb{Z}_p)). \end{aligned}$$

Proposition 4.3.2. We have

$$C(K_f^P K_{p,n}^1)_{\text{ord}}^b = \text{Im} \left(G(\mathbb{A}_{\mathbb{Q},f}^P) P_{\mathbf{D}}^b(\mathbb{Q}_p) \longrightarrow \text{GL}(X \otimes \mathbb{Q}) \ltimes P'(\mathbb{A}_{\mathbb{Q},f}) \backslash G(\mathbb{A}_{\mathbb{Q},f}) / K_f^P K_{p,n}^1 \right), \quad (4.3.1)$$

which is in a natural bijection with

$$C(K_f^P) \times \left(U_{\mathcal{K},K_f^P} \ltimes P'(\mathbb{Z}_p) \backslash P_{\mathbf{D}}^b(\mathbb{Z}_p) / K_{p,n}^1 \cap P_{\mathbf{D}}(\mathbb{Z}_p) \right). \quad (4.3.2)$$

Proof. Given $g_p \in P_D(\mathbb{Z}_p)$ with

$$g_p^+ = \begin{pmatrix} a_{11} & a_{12} & a_{13} & * \\ a_{21} & a_{22} & a_{23} & * \\ a_{31} & a_{32} & a_{33} & * \end{pmatrix}, \quad (g_p^{-1})^+ = \begin{pmatrix} c_{11} & c_{12} & c_{13} & * \\ c_{21} & c_{22} & c_{23} & * \\ c_{31} & c_{32} & c_{33} & * \end{pmatrix}, \quad (g_p^{-1})^- = \begin{pmatrix} d_{11} & * & * & * \\ * & * & * & * \\ * & * & * & * \\ * & * & * & * \end{pmatrix},$$

the corresponding $F_{2,\bar{\eta}}$ is spanned by the image of x_1^+, w_1^+ under $\alpha_{p,\bar{\eta}}$, and $\mathcal{T}_{\bar{\eta}}[p]$ is spanned by the image under $\alpha_{p,\bar{\eta}}$ of

$$(\mathbf{x}_1^+, \mathbf{w}_1^+, \mathbf{w}_2^+, \mathbf{x}_1^-) \begin{pmatrix} c_{11} & c_{12} & c_{13} \\ c_{21} & c_{22} & c_{23} \\ c_{31} & c_{32} & c_{33} \\ d_{11} \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & 1 \end{pmatrix}. \quad (4.3.3)$$

Therefore, the condition $F_{2,\bar{\eta}}^+ \cap (\mathcal{G}_{\bar{\eta}}[p])^\mu = 0$ is equivalent to the condition that $c_{11}\mathbf{x}_1^+ + c_{21}\mathbf{w}_1^+ + c_{31}\mathbf{w}_2^+$ does not belong to $\text{Span}_{\mathbb{F}_p}\{\mathbf{x}_1^+, \mathbf{w}_1^+\}$, which is equivalent to $c_{31} \in \mathbb{Z}_p^\times$. The condition $c_{31} \in \mathbb{Z}_p^\times$ for $(g_p^{-1})^+$ is equivalent to the condition $\begin{pmatrix} a_{21} & a_{22} \\ a_{31} & a_{32} \end{pmatrix} \in \text{GL}_2(\mathbb{Z}_p)$ for g_p^+ . This shows that $C(K_f^P K_{p,n}^1)_{\text{ord}}^b$ equals equation (4.3.2). It is also easy to see that there is a natural bijection between equations (4.3.1) and (4.3.2). $\square$

Definition 4.3.3. Define

$$V_{n,m}^b = \left\{ f \in V_{n,m} : f|_{\mathcal{X}_{g,n}} = 0 \text{ for all } g \in C(K_f^P K_{p,n}^1)_{\text{ord}} - C(K_f^P K_{p,n}^1)_{\text{ord}}^b \right\},$$

that is, the subspace of $V_{n,m}$ consisting of forms vanishing along all the boundary strata of $\mathcal{T}_n^{\text{tor}}$ indexed by ordinary cusp labels outside $C(K_f^P K_{p,n}^1)_{\text{ord}}^b$, and define

$$\mathcal{V}^b = \varinjlim_m \varinjlim_n V_{n,m}^b.$$

4.4. The exact sequence for $V_{n,m}^b$

When $g \in C(K_f^P K_{p,n}^1)_{\text{ord}}^b$, the level $K'_{f,g,n}$ is independent of n , and we denote it by $K'_{f,g}$. We have

$$\begin{aligned} K'_{f,g}{}^P &= \text{Im} \left(P(\mathbb{A}_{\mathbb{Q},f}^P) \cap g K_f^P g^{-1} \longrightarrow G'(\mathbb{A}_{\mathbb{Q},f}^P) \right), \\ K'_{p,g} &= \left\{ h \in G'(\mathbb{Z}_p) : h^+ \equiv \begin{pmatrix} * & * \\ * & * \end{pmatrix} \pmod{p} \right\}. \end{aligned} \quad (4.4.1)$$

Let $M_{(0,0)}(K'_{f,g}; \mathbb{Z}/p^m\mathbb{Z})$ be the space of classical automorphic forms on G' valued in $\mathbb{Z}/p^m\mathbb{Z}$ of weight $(0,0)$ and level $K'_{f,g}$ (which are functions valued in $\mathbb{Z}/p^m\mathbb{Z}$ on the finite set $G'(\mathbb{Q}) \backslash G'(\mathbb{A}_{\mathbb{Q},f})/K'_{f,g}$), and $M_{(0,0)}(K'_{f,g}; \mathbb{Q}_p/\mathbb{Z}_p) = \varinjlim_m M_{(0,0)}(K'_{f,g}; \mathbb{Z}/p^m\mathbb{Z})$.

Proposition 4.4.1. *We have the exact sequences*

$$0 \longrightarrow V_{n,m}^0 \longrightarrow V_{n,m}^b \xrightarrow{\oplus \Phi_g} \bigoplus_{g \in C(K_f^P)} M_{(0,0)}(K'_{f,g}; \mathbb{Z}/p^m\mathbb{Z}) \otimes \mathbb{Z}_p[[T_{\text{so}}(\mathbb{Z}_p)/U_{\mathcal{K},K_f^P}]] \longrightarrow 0 \quad (4.4.2)$$

and

$$0 \longrightarrow \mathcal{V}^0 \longrightarrow \mathcal{V}^b \xrightarrow{\oplus \Phi_g} \bigoplus_{g \in C(K_f^P)} M_{(0,0)}(K'_{f,g}; \mathbb{Q}_p/\mathbb{Z}_p) \otimes \mathbb{Z}_p[[T_{\text{so}}(\mathbb{Z}_p)/U_{\mathcal{K},K_f^P}]] \longrightarrow 0, \quad (4.4.3)$$

where the map Φ_g is obtained by restriction to the stratum $\mathcal{X}_{g,n}$ (whose global sections are the same as the global sections of $\mathcal{Y}_{g,n}$, which can be identified with the 0-dimensional Shimura variety $\mathcal{S}_{G',K'_{f,g}}$), and is sometimes called a Siegel operator.

Proof. Let $\pi_n : \mathcal{T}_n^{\text{tor}} \rightarrow \mathcal{T}_n^{\text{min}}$ be the natural map. By [Lan18, Lem. 8.2.2.10], we have

$$\left(\pi_{n,*} \mathcal{O}_{\mathcal{T}_{n,m}^{\text{tor}}} / \pi_{n,*} \mathcal{I}_{\mathcal{T}_{n,m}^{\text{tor}}} \right)_{\mathcal{Y}_{g,n}}^{\wedge} \simeq h_* \mathcal{O}_{\mathcal{C}_{g,n}^{\text{ord}}} \otimes \mathbb{Z}/p^m \mathbb{Z} = \mathcal{O}_{\mathcal{S}_{G',K'_{f,g}}} \otimes \mathbb{Z}/p^m \mathbb{Z}.$$

(Here, h is the map in the diagram (4.2.2).) Taking global sections over the affine scheme $\mathcal{T}_{n,m}^{\text{min}}$, we get

$$V_{n,m}/V_{n,m}^0 = \bigoplus_{g \in C(K_f^P K_{p,n}^1)_{\text{ord}}} M_{(0,0)}(K'_{f,g}; \mathbb{Z}/p^m \mathbb{Z}). \quad (4.4.4)$$

By definition, an element in $V_{n,m}$ belongs to $V_{n,m}^b$ if and only if it vanishes along the strata associated to the cusp labels outside $C(K_f^P K_{p,n}^1)_{\text{ord}}^b$, so

$$V_{n,m}^b/V_{n,m}^0 = \bigoplus_{g \in C(K_f^P K_{p,n}^1)_{\text{ord}}^b} M_{(0,0)}(K'_{f,g}; \mathbb{Z}/p^m \mathbb{Z}). \quad (4.4.5)$$

The action of $T_{\text{so}}(\mathbb{Z}_p)$ on $V_{n,m}$ preserves $V_{n,m}^0$, so it descends to $V_{n,m}/V_{n,m}^0$. This action permutes the direct summands of the right-hand side of equation (4.4.4). More precisely, the corresponding action of $(a_1, a_2) \in T_{\text{so}}(\mathbb{Z}_p)$ on the index set

$$C(K_f^P K_{p,n}^1)_{\text{ord}} = C(K_f^P) \times \left(U_{\mathcal{K}, K_f^P} \ltimes P'(\mathbb{Z}_p) \backslash P_D(\mathbb{Z}_p) / K_{p,n}^1 \cap P_D(\mathbb{Z}_p) \right)$$

sends $g = g^P g_p$ to $g^P g_p t_{a_1, a_2}$, where $t_{a_1, a_2} \in G(\mathbb{Z}_p)$ with $t_{a_1, a_2}^+ = \begin{pmatrix} 1 & & \\ & 1 & a_1 \\ & & a_2^{-1} \end{pmatrix}$. It is easy to see that

$T_{\text{so}}(\mathbb{Z}_p)$ -action on $C(K_f^P K_{p,n}^1)_{\text{ord}}$ preserves $C(K_f^P K_{p,n}^1)_{\text{ord}}^b$, so the $T_{\text{so}}(\mathbb{Z}_p)$ on $V_{n,m}$ preserves $V_{n,m}^b$ and induces an action on $V_{n,m}^b/V_{n,m}^0$.

For given $g \in C(K_f^P)$, set

$$\begin{aligned} C(K_f^P K_{p,n}^1)_{\text{ord}, g} &= \{\text{elements in } C(K_f^P K_{p,n}^1)_{\text{ord}} \text{ whose projection to } C(K_f^P) \text{ is } g\}, \\ C(K_f^P K_{p,n}^1)_{\text{ord}, g}^b &= \{\text{elements in } C(K_f^P K_{p,n}^1)_{\text{ord}}^b \text{ whose projection to } C(K_f^P) \text{ is } g\}. \end{aligned} \quad (4.4.6)$$

The $\mathbb{Z}_p[[T_{\text{so}}(\mathbb{Z}_p)]]$ -module structures of $V_{n,m}/V_{n,m}^0$ (resp. $V_{n,m}^b/V_{n,m}^0$) are determined by the $\mathbb{Z}_p[[T_{\text{so}}(\mathbb{Z}_p)]]$ -actions on $C(K_f^P K_{p,n}^1)_{\text{ord}, g}$ (resp. $C(K_f^P K_{p,n}^1)_{\text{ord}, g}^b$). The $T_{\text{so}}(\mathbb{Z}_p)$ -action on $C(K_f^P K_{p,n}^1)_{\text{ord}, g}$ has too many orbits, and the number of orbits grows with n , so $V_{n,m}/V_{n,m}^0$ is not very nice as a $\mathbb{Z}_p[[T_{\text{so}}(\mathbb{Z}_p)]]$ -module. In contrast, the $T_{\text{so}}(\mathbb{Z}_p)$ -action on $C(K_f^P K_{p,n}^1)_{\text{ord}, g}^b$ is transitive, factoring through $\mathbb{Z}_p[[T_{\text{so}}(\mathbb{Z}_p/p^n \mathbb{Z})/U_{\mathcal{K}, K_f^P}]]$, and the action of this quotient is free. Therefore, by fixing an element in $P_D^b(\mathbb{Z}_p)$, which we will always choose to be $\begin{pmatrix} 1 & & \\ & 1 & \\ & & 1 \end{pmatrix}$, we get the isomorphism

$$\text{Right hand side of (4.4.5)} \cong M_{(0,0)}(K'_{f,g}; \mathbb{Z}/p^m \mathbb{Z}) \otimes \mathbb{Z}_p[[T_{\text{so}}(\mathbb{Z}_p)/U_{\mathcal{K}, K_f^P}]], \quad (4.4.7)$$

from which the exact sequence (4.4.2) follows. The exact sequence (4.4.3) follows from equation (4.4.2) by taking the direct limit. $\square$

4.5. Three propositions on the $\mathbb{U}_p$ -action on $\mathcal{V}$ and $\mathcal{V}^b$.

We introduce some setting for the proof of the following propositions. Given $g \in C(K_f^p K_{p,n}^1)_{\text{ord}}$, recall that η denotes a generic point of $\mathfrak{X}_{g,n,m}$, and $\bar{\eta}$ denotes a geometric point over η . Let $(\mathcal{G}_{\bar{\eta}}, i_{\bar{\eta}}, \lambda_{\bar{\eta}}, \alpha_{\bar{\eta}}^p, \alpha_{p,\bar{\eta}})$ be the pullback to $\bar{\eta}$ of the family of semiabelian schemes over $\mathcal{T}_{n,m}^{\text{tor}}$. Recall that certain Lagrangian subgroups $C \subset \mathcal{G}_{\bar{\eta}}[p^2]$ are used in the construction of $\mathcal{C}_{j,n,m}^\bullet$ for defining $U_{p,j}^\bullet$ in §2.8. (Here, $(\bullet, j) = (+, 2)$, $(+, 3)$ or $(-, 1)$.) Let

$$(\mathcal{G}'_{\bar{\eta}} = \mathcal{G}_{\bar{\eta}}/C, i'_{\bar{\eta}}, \lambda'_{\bar{\eta}}, (\alpha_{\bar{\eta}}^p)', \alpha'_{p,\bar{\eta}}) \quad (4.5.1)$$

be the tuple defined as in the construction of $\mathcal{C}_{j,n,m}^\bullet$. If $(e_1^\pm, e_2^\pm, e_3^\pm, e_4^\pm)$ is a basis of $\mathcal{G}_{\bar{\eta}}[p^n]$ compatible with $\alpha_{p,\bar{\eta}}$, then C is spanned by $(e_1^\pm, e_2^\pm, e_3^\pm, e_4^\pm) \cdot p^n \gamma_{C,p}^\pm$ with $\gamma_{C,p}$ given as in equations (2.8.1), (2.8.2) and (2.8.3). From Mumford's construction of the degenerating family over $\mathfrak{X}_{g,n,m}$, we see that the tuple (4.5.1), corresponds to a geometric point $\bar{\eta}'$ over a generic point η' of $\mathfrak{X}_{g',n,m}$ with $g' = g \cdot \gamma_{C,p}$.

Proposition 4.5.1. *The space $\mathcal{V}^b$ is preserved by the $\mathbb{U}_p$ -operators.*

Proof. We shall show that $g' = g \cdot \gamma_{C,p} \in C(K_f^p K_{p,n}^1)_{\text{ord}}^b$ only if $g \in C(K_f^p K_{p,n}^1)_{\text{ord}}^b$. By the definition of the $\mathbb{U}_p$ -operators, this will imply that if $f \in \mathcal{V}$ vanishes along the strata outside $C(K_f^p K_{p,n}^1)_{\text{ord}}^b$, then so does $U_{p,j}^\bullet(f)$. We use the description (4.3.1) for $C(K_f^p K_{p,n}^1)_{\text{ord}}^b$. Consider the case $(\bullet, j) = (+, 2)$. Write

$$g_p^+ = \begin{pmatrix} a_{11} & a_{12} & a_{13} & a_{14} \\ a_{21} & a_{22} & a_{23} & a_{24} \\ a_{31} & a_{32} & a_{33} & a_{34} \\ & & & a_{44} \end{pmatrix} \text{ and } g_p^{+*} = g_p^+ \cdot \gamma_{C,p}^+ = \begin{pmatrix} a'_{11} & a'_{12} & a'_{13} & a'_{14} \\ a'_{21} & a'_{22} & a'_{23} & a'_{24} \\ a'_{31} & a'_{32} & a'_{33} & a'_{34} \\ & & & a'_{44} \end{pmatrix} \text{ with } \gamma_{C,p}^+ \text{ as in equation (2.8.1). We have}$$

$$\begin{pmatrix} a'_{11} & a'_{12} & a'_{13} & a'_{14} \\ a'_{21} & a'_{22} & a'_{23} & a'_{24} \\ a'_{31} & a'_{32} & a'_{33} & a'_{34} \\ & & & a'_{44} \end{pmatrix} = \begin{pmatrix} a_{11} & a_{12} & \frac{a_{13}+u_1 a_{11}+u_2 a_{12}}{p} & * \\ a_{21} & a_{22} & \frac{a_{23}+u_1 a_{21}+u_2 a_{22}}{p} & * \\ a_{31} & a_{32} & \frac{a_{33}+u_1 a_{31}+u_2 a_{32}}{p} & * \\ & & & \frac{a_{44}}{p} \end{pmatrix} \quad (4.5.2)$$

and

$$\begin{pmatrix} a'_{21} & a'_{22} \\ a'_{31} & a'_{32} \end{pmatrix}^{-1} \begin{pmatrix} a'_{23} \\ a'_{33} \end{pmatrix} = p^{-1} \left[\begin{pmatrix} a_{21} & a_{22} \\ a_{31} & a_{32} \end{pmatrix}^{-1} \begin{pmatrix} a_{23} \\ a_{33} \end{pmatrix} + \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} \right]. \quad (4.5.3)$$

Since $u_1, u_2 \in \mathbb{Z}_p$, the right-hand side can be integral only if $\begin{pmatrix} a_{21} & a_{22} \\ a_{31} & a_{32} \end{pmatrix}^{-1} \begin{pmatrix} a_{23} \\ a_{33} \end{pmatrix} \in \mathbb{Z}_p^2$. Therefore, $g' = g \cdot \gamma_{C,p} \in C(K_f^p K_{p,n}^1)_{\text{ord}}^b$ only if $g \in C(K_f^p K_{p,n}^1)_{\text{ord}}^b$. The argument for the other two cases is similar. $\square$

Proposition 4.5.2. *There exists a positive integer N such that the exact sequences in Proposition 4.4.1 are $(U_{p,j}^\bullet)^N$ -equivariant for $(\bullet, j) = (+, 2), (+, 3), (-, 1)$ in the sense that for all $g \in C(K_f^p K_{p,n}^1)_{\text{ord}}^b$ and $f \in \mathcal{V}^b$, we have*

$$\Phi_g \left((U_{p,j}^\bullet)^N f \right) = \Phi_g(f).$$

Proof. Take $g \in C(K_f^p K_{p,n}^1)_{\text{ord}}^b$, and we use the setting described at the beginning of this subsection. In order to look at the image of $U_{p,j}^\bullet f$ under the Siegel operator Φ_g , we consider the abelian quotients $\mathcal{A}_{\bar{\eta}}$ and $\mathcal{A}_{\bar{\eta}'}$ of the Raynaud extensions

$$0 \longrightarrow \mathcal{T}_{\bar{\eta}} \longrightarrow \mathcal{G}_{\bar{\eta}}^b \longrightarrow \mathcal{A}_{\bar{\eta}} \longrightarrow 0, \quad 0 \longrightarrow \mathcal{T}_{\bar{\eta}'} \longrightarrow \mathcal{G}_{\bar{\eta}'}^b \longrightarrow \mathcal{A}_{\bar{\eta}'} \longrightarrow 0.$$

Let

$$C^f = (C + (\mathcal{G}_{\bar{\eta}}[p^n])^\mu) \cap (\mathcal{G}_{\bar{\eta}}[p^n])^f, \quad C^{\text{ab}} = C^f / (\mathcal{G}_{\bar{\eta}}[p^n])^\mu. \quad (4.5.4)$$

(See the beginning of §4.3 for the definition of $(\mathcal{G}_{\bar{\eta}}[p^n])^\mu$ and $(\mathcal{G}_{\bar{\eta}}[p^n])^f$.) Then we have

$$\mathcal{A}_{\bar{\eta}'} = \mathcal{A}_{\bar{\eta}} / C^{\text{ab}}.$$

We use the description (4.1.3) and equation (4.3.2) for $C(K_f^p K_{p,n}^1)_{\text{ord}}$ and $C(K_f^p K_{p,n}^1)_{\text{ord}}^b$. Write $g = g^p g_p$ with $g_p \in P_D(\mathbb{Z}_p)$ and

$$(g_p^{-1})^+ = \begin{pmatrix} c_{11} & c_{12} & c_{13} & * \\ c_{21} & c_{22} & c_{23} & * \\ c_{31} & c_{32} & c_{33} & * \\ & & & * \end{pmatrix}, \quad (g_p^{-1})^- = \begin{pmatrix} d_{11} & * & * & * \\ * & * & * & * \\ * & * & * & * \\ * & * & * & * \end{pmatrix}. \quad (4.5.5)$$

The condition $g \in C(K_f^p K_{p,n}^1)_{\text{ord}}^b$ implies that $c_{31}^{-1} c_{11}, c_{31}^{-1} c_{21} \in \mathbb{Z}_p$. Thus, we see that $(\mathcal{G}_{\bar{\eta}}[p^n])^\mu$ is spanned by

$$c_{31}^{-1} c_{11} e_1^+ + c_{31}^{-1} c_{21} e_2^+ + e_3^+, \quad e_1^- \quad (4.5.6)$$

(cf. equation (4.3.3)), and $(\mathcal{G}_{\bar{\eta}}[p^n])^f$ is spanned by

$$e_1^+, \quad e_2^+, \quad e_3^+, \quad e_1^-, \quad (e_2^-, e_3^-, e_4^-) \begin{pmatrix} -\iota_p(\bar{\zeta}_0) & & & \\ & 1 & & \\ & & 1 & \\ & & & 1 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ c_{31}^{-1} c_{11} & c_{31}^{-1} c_{21} \\ 1 & 0 \end{pmatrix}. \quad (4.5.7)$$

We first consider the operator $U_{p,3}^+$. By a direct computation, we see that for $g \in C(K_f^p K_{p,n}^1)_{\text{ord}}^b$, the p -part of $g' \in C(K_f^p K_{p,n}^1)_{\text{ord}}$ is

$$g_p^{+} = g_p^+ \cdot \gamma_{C,p}^+ = \begin{pmatrix} 1 & * & & \\ & 1 & * & \\ & & 1 & * \\ & & & p^{-1} \end{pmatrix} g_p^+, \quad (4.5.8)$$

where $*$ $\in \mathbb{Q}_p$. This shows that the cusp label g' is independent of C and belongs to $C(K_f^p K_{p,n}^1)_{\text{ord}}^b$. For given C spanned by $(e_1^\pm, e_2^\pm, e_3^\pm, e_4^\pm) \cdot p^{n-2} \gamma_{C,p}^\pm$ with $\gamma_{C,p}^\pm$ as in (2.8.2), from the definition (4.5.4) and the basis (4.5.7) of $(\mathcal{G}_{\bar{\eta}}[p^n])^f$, we see that C^f is spanned by

$$c_{31}^{-1} c_{11} e_1^+ + c_{31}^{-1} c_{21} e_2^+ + e_3^+, \quad e_1^-, \quad (e_2^-, e_3^-, e_4^-) \cdot p^{n-2} \begin{pmatrix} -\iota_p(\bar{\zeta}_0) & & & \\ & 1 & & \\ & & 1 & \\ & & & 1 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ c_{31}^{-1} c_{11} & c_{31}^{-1} c_{21} \\ 1 & 0 \end{pmatrix}.$$

Its quotient C^{ab} is independent of the choice of C and is spanned by $(\epsilon_1^-, \epsilon_2^-) \cdot p^{n-2}$, with $(\epsilon_1^-, \epsilon_2^-)$ the image of $(e_2^-, e_3^-, e_4^-) \begin{pmatrix} -\iota_p(\bar{\zeta}_0) & & & \\ & 1 & & \\ & & 1 & \\ & & & 1 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ c_{31}^{-1} c_{11} & c_{31}^{-1} c_{21} \\ 1 & 0 \end{pmatrix}$ under the quotient map $\mathcal{G}_{\bar{\eta}}^h \rightarrow \mathcal{A}_{\bar{\eta}}$ which is a basis of $\mathcal{A}_{\bar{\eta}}[p^n]^-$. (Here, we identify $(\mathcal{G}_{\bar{\eta}}[p^n])^f$ with $\mathcal{G}_{\bar{\eta}}^h[p^n]$ by the canonical isomorphism between them.) Thus, we get

$$\mathcal{A}_{\bar{\eta}'} = \mathcal{A}_{\bar{\eta}} / \mathcal{A}_{\bar{\eta}}[p^2]^-. \quad (4.5.9)$$

Denote by $\langle p \rangle^-$ the operator on $M_{(0,0)}(K'_{f,g}; \mathbb{Z}/p^m \mathbb{Z})$ induced by taking the quotient by $\mathcal{A}[p^2]^-$. Combining equations (4.5.8) and (4.5.9), we see that the trace cancels the normalizer in equation (2.8.5) due to the independence of the choice of C , and

$$\Phi_g(U_{p,3}^+ f) = (\langle p \rangle^-)^2 \Phi_{g'}(f).$$

With K_f^p fixed, there exists $N_1 \geq 1$, such that $\begin{pmatrix} 1 & & * \\ & 1 & * \\ & & p^{-N_1} \end{pmatrix}_p g$ and g represent the same element in the double coset $C(K_f^p K_{p,n}^1)_{\text{ord}}^b$, and $(\langle p \rangle^-)^{2N_1} = 1$ on $M_{(0,0)}(K'_{f,g}; \mathbb{Z}/p^m \mathbb{Z})$. For such N_1 , we deduce that

$$\Phi_g((U_{p,3}^+)^{N_1} f) = \Phi_g(f)$$

for all $f \in \mathcal{V}^b$ and $g \in C(K_f^p K_{p,n}^1)_{\text{ord}}^b$. A similar calculation shows that there exists $N_2 \geq 1$ such that

$$\Phi_g((U_{p,1}^-)^{N_2} f) = \Phi_g(f)$$

for all $f \in \mathcal{V}^b$ and $g \in C(K_f^p K_{p,n}^1)_{\text{ord}}^b$.

It remains to consider $U_{p,2}^+$. Write $g_p^+ = \begin{pmatrix} a_{11} & a_{12} & a_{13} & * \\ a_{21} & a_{22} & a_{23} & * \\ a_{31} & a_{32} & a_{33} & * \end{pmatrix}$ and $g_p'^+ = g_p^+ \cdot \gamma_{C,p}^+ = \begin{pmatrix} a'_{11} & a'_{12} & a'_{13} & a'_{14} \\ a'_{21} & a'_{22} & a'_{23} & a'_{24} \\ a'_{31} & a'_{32} & a'_{33} & a'_{34} \\ & & & a'_{44} \end{pmatrix}$ with $\gamma_{C,p}^+$ as in (2.8.1). Then we have equations (4.5.2) and (4.5.3), and $g' \in C(K_f^p K_{p,n}^1)_{\text{ord}}^b$ if and only if

$$\begin{pmatrix} u_1 \\ u_2 \end{pmatrix} \equiv - \begin{pmatrix} a_{21} & a_{22} \\ a_{31} & a_{32} \end{pmatrix}^{-1} \begin{pmatrix} a_{23} \\ a_{33} \end{pmatrix} \pmod{p}. \quad (4.5.10)$$

Now, suppose $g' \in C(K_f^p K_{p,n}^1)_{\text{ord}}^b$, that is, the entries u_1, u_2 in $\gamma_{C,p}^\pm$ (see (2.8.1)) satisfy the congruence (4.5.10). Then we have $g_p'^+ \in \begin{pmatrix} p^{-1} & * & * \\ & 1 & * \\ & & p^{-1} \end{pmatrix} g_p^+ K_{p,n}^1$, and as an element in the double coset $C(K_f^p K_{p,n}^1)_{\text{ord}}^b$, g' represents the same element as $\begin{pmatrix} p^{-1} & & \\ & 1 & \\ & & p^{-1} \end{pmatrix} g$ in $C(K_f^p K_{p,n}^1)_{\text{ord}}^b$. The congruence (4.5.10) implies that the c_{ij} 's in equation (4.5.5) satisfies

$$u_1 \equiv -c_{31}^{-1} c_{11} \pmod{p}, \quad u_2 \equiv -c_{31}^{-1} c_{21} \pmod{p}. \quad (4.5.11)$$

From the definition (4.5.4) and the relation (4.5.11), by using the basis (4.5.7) of $(\mathcal{G}_{\bar{\eta}}[p^n])^f$ and the basis of C in equation (2.8.1), we see that C^f is spanned by

$$c_{31}^{-1} c_{11} e_1^+ + c_{31}^{-1} c_{21} e_2^+ + e_3^+, \quad e_1^-, \quad (e_2^-, e_3^-, e_4^-) \cdot p^{n-2} \begin{pmatrix} -\iota_p(\bar{\xi}_0)^{-1} \\ 1 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ c_{31}^{-1} c_{11} & c_{31}^{-1} c_{21} \\ 1 & 0 \end{pmatrix}.$$

Like in the case of $U_{p,3}^+$, we can deduce that $C^{\text{ab}} = \mathcal{A}_{\bar{\eta}}[p^n]^-$, and

$$\mathcal{A}_{\bar{\eta}'} = \mathcal{A}_{\bar{\eta}} / \mathcal{A}_{\bar{\eta}}[p^2]^-.$$

The independence of C^{ab} on the $*$'s in $\gamma_{C,p}^+$ cancels the normalizer in equation (2.8.5), and we get

$$\Phi_g(U_{p,2}^+ f) = (\langle p \rangle^-)^2 \Phi_{g'}(f).$$

For fixed K_f^p , take N_3 such that $\begin{pmatrix} p^{-1} & & \\ & 1 & \\ & & 1 \end{pmatrix}_{p^{-1}}^{N_3} g$ and g represent the same element in the double coset $C(K_f^p K_{p,n}^1)_{\text{ord}}^b$ and $(\langle p \rangle^-)^{2N_3} = 1$ on $M_{(0,0)}(K'_{f,g}; \mathbb{Z}/p^m \mathbb{Z})$. Then

$$\Phi_g \left((U_{p,3}^+)^{N_3} f \right) = \Phi_g(f)$$

for all $f \in \mathcal{V}^b$ and $g \in C(K_f^p K_{p,n}^1)_{\text{ord}}^b$. By taking $N = N_1 N_2 N_3$, we conclude the proof. $\square$

Proposition 4.5.3. $(U_{p,2}^+)^m f \in V_{n,m}^b$ for all $f \in V_{n,m}$.

Proof. We shall show that for all $g \in C(K_f^p K_{p,n}^1)_{\text{ord}} - C(K_f^p K_{p,n}^1)_{\text{ord}}^b$ and $f \in V_{n,m}$,

$$\Phi_g \left(U_{p,2}^+ f \right) \in pM_{(0,0)}(K'_{f,g}; \mathbb{Z}/p^m \mathbb{Z}), \quad (4.5.12)$$

from which the proposition follows. For a given $g \in C(K_f^p K_{p,n}^1)_{\text{ord}} - C(K_f^p K_{p,n}^1)_{\text{ord}}^b$, we use the setting described at the beginning of this subsection. As in the proof of Proposition 4.5.2, we consider $\mathcal{A}_{\bar{\eta}'}$, the abelian quotient of the Raynaud extension associated to $\mathcal{G}_{\bar{\eta}'} = \mathcal{G}_{\bar{\eta}}/C$. We have

$$\mathcal{A}_{\bar{\eta}'} = \mathcal{A}_{\bar{\eta}}/C^{\text{ab}},$$

where $\mathcal{A}_{\bar{\eta}}$ is the abelian quotient of the Raynaud extension associated to $\mathcal{G}_{\bar{\eta}}$, and C^{ab} is defined in equation (4.5.4). Since the $\mathbb{U}_p$ -operator considered here is $U_{p,2}^+$, the Lagrangian subgroup $C \subset \mathcal{G}_{\bar{\eta}}[p^2]$ is spanned by $(e_1^\pm, e_2^\pm, e_3^\pm, e_4^\pm) \cdot p^n \gamma_{C,p}^\pm$ with $\gamma_{C,p}^\pm$ as in equation (2.8.1). We use the description (4.1.3) and equation (4.3.2) for $C(K_f^p K_{p,n}^1)_{\text{ord}}$ and $C(K_f^p K_{p,n}^1)_{\text{ord}}^b$. Write $(g_p^{-1})^+ = \begin{pmatrix} c_{11} & c_{12} & c_{13} & * \\ c_{21} & c_{22} & c_{23} & * \\ c_{31} & c_{32} & c_{33} & * \end{pmatrix}$, $(g_p^{-1})^- = \begin{pmatrix} d_{11} & * & * & * \\ * & * & * & * \\ * & * & * & * \end{pmatrix}$ (which are elements in $\text{GL}_4(\mathbb{Z}_p)$). The condition $g \notin C(K_f^p K_{p,n}^1)_{\text{ord}}^b$ implies that $c_{31} \in p\mathbb{Z}_p$ and c_{11} or c_{21} belongs to $\mathbb{Z}_p^\times$.

Suppose $c_{11} \in \mathbb{Z}_p^\times$. The group $(\mathcal{G}_{\bar{\eta}}[p^n])^\mu$ is spanned by

$$c_{11}e_1^+ + c_{21}e_2^+ + c_{31}e_3^+, \quad e_1^-, \quad (4.5.13)$$

and $(\mathcal{G}_{\bar{\eta}}[p^n])^f$ is spanned by

$$e_1^+, \quad e_2^+, \quad e_3^+, \quad e_1^-, \quad (e_2^-, e_3^-, e_4^-) \begin{pmatrix} -t_p^c(\zeta_0)^{-1} & \\ & 1 \end{pmatrix} \begin{pmatrix} c_{11} & 0 \\ 0 & c_{11} \\ -c_{21} & c_{31} \end{pmatrix}. \quad (4.5.14)$$

By the definition of C^f in equation (4.5.4), a direct computation shows that C^f is spanned by $(\mathcal{G}_{\bar{\eta}}[p^n])^\mu$ plus

$$((c_{11}u_2 - c_{21}u_1)e_2^+ + c_{11}e_3^+) \cdot p^{n-1}, \quad (e_2^-, e_3^-, e_4^-) \begin{pmatrix} -t_p^c(\zeta_0)^{-1} & \\ & 1 \end{pmatrix} \begin{pmatrix} c_{11} & 0 \\ 0 & c_{11} \\ -c_{21} & c_{31} \end{pmatrix} \begin{pmatrix} c_{11} & 0 \\ c_{11}u_2 - c_{21}u_1 & p \end{pmatrix}. \quad (4.5.15)$$

Hence, C^{ab} is spanned by the image of equation (4.5.15) modulo $(\mathcal{G}_{\bar{\eta}}[p^n])^\mu$. Let $u'_2 = c_{11}u_2 - c_{21}u_1$. The trace in equation (2.8.5) corresponds to a sum with u_1, u'_2 and the two $*$'s in $\gamma_{C,p}$ varying in $\mathbb{Z}/p\mathbb{Z}$. Since equation (4.5.15) depends only on u'_2 , we see that C^{ab} , and hence $\mathcal{A}_{\bar{\eta}'}$ depends only on u'_2 . Its independence of the two $*$'s implies that the sum over the two $*$'s cancels the normalization factor in equation (2.8.5). Its independence of u_1 implies that the sum over u_1 contributes a factor p . Therefore,

the evaluation of $\Phi_g(U_{p,2}^+ f)$ at $\bar{\eta}'$ is divisible by p . This shows the inclusion (4.5.12), hence the result in this case. The case $c_{21} \in \mathbb{Z}_p^\times$ can be similarly treated. $\square$

4.6. The ordinary projection on $\mathcal{V}$ and the fundamental exact sequence

In this section, we use the exact sequence in Proposition 4.4.1 and the three propositions proved in §4.5 to show that $\lim_{r \rightarrow \infty} (U_p)^{r!} f$ converges for all $f \in \mathcal{V}$ and that $\mathcal{V}_{\text{so}}^* = \text{Hom}_{\mathbb{Z}_p}(e_{\text{so}} \mathcal{V}, \mathbb{Q}_p/\mathbb{Z}_p)$ is a free Λ_{so} -module of finite rank and deduce the fundamental exact sequence in part (4) of Theorem 2.9.1.

Theorem 4.6.1 (Vertical control theorem). *Let $U_p = U_{p,2}^+ U_{p,3}^+ U_{p,1}^-$. Then for each $f \in \mathcal{V}$, $\lim_{r \rightarrow \infty} (U_p)^{r!} f$ converges, and we can define the semiordinary projector as $e_{\text{so}} = \lim_{r \rightarrow \infty} (U_p)^{r!}$. The $\mathbb{Z}_p[[T_{\text{so}}(\mathbb{Z}_p)]]$ -module $\mathcal{V}_{\text{so}}^* = \text{Hom}_{\mathbb{Z}_p}(e_{\text{so}} \mathcal{V}, \mathbb{Q}_p/\mathbb{Z}_p)$ is free of finite rank over Λ_{so} .*

Proof. Given $f \in V_{n,m}$, we define the following finiteness property for f :

$$\text{The submodule generated by } (U_p)^r f, r \geq 0, \text{ is finitely generated over } \mathbb{Z}/p^m. \quad (\text{F})$$

It is easy to see that the convergence of $\lim_{r \rightarrow \infty} (U_p)^{r!} f$ follows from the property (F) for f . By Proposition 4.5.3, in order to show that all $f \in V_{n,m}$ satisfy (F), it suffices to show that all $f \in V_{n,m}^b$ satisfy (F). Given $f \in V_{n,m}^b$, it follows from Proposition 4.5.2 that $f' = U_p^N f - f$ belongs to $V_{n,m}^0$. Proposition 3.0.2 implies that there exists $M \geq 0$ such that

$$U_p^{M+1} f' \in \text{Span}_{\mathbb{Z}}\{f', U_p f', U_p^2 f', \dots, U_p^M f'\}.$$

Then

$$U_p^{M+N+1} f \in \text{Span}_{\mathbb{Z}}\{f, U_p f, U_p^2 f, \dots, U_p^{M+N} f\},$$

from which it follows that for all $r \geq 0$,

$$U_p^r f \in \text{Span}_{\mathbb{Z}}\{f, U_p f, U_p^2 f, \dots, U_p^{M+N} f\}.$$

Hence, (F) holds for f . Therefore, we have proved that $\lim_{r \rightarrow \infty} (U_p)^{r!} f$ converges for all $f \in \mathcal{V}$, and we can define the semiordinary projector e_{so} on $\mathcal{V}$ as

$$e_{\text{so}} = \lim_{r \rightarrow \infty} (U_p)^{r!}. \quad (4.6.1)$$

By Proposition 4.5.3, we have

$$e_{\text{so}} \mathcal{V} = e_{\text{so}} \mathcal{V}^b. \quad (4.6.2)$$

Applying e_{so} to the Pontryagin dual of the exact sequence in Proposition 4.4.1 and using equation (4.6.2), we obtain the exact sequence

$$0 \longrightarrow M_{(0,0)}(K'_{f,g}; \mathbb{Z}_p) \otimes \mathbb{Z}_p[[T_{\text{so}}(\mathbb{Z}_p)/U_{K,K_f^p}]] \longrightarrow \mathcal{V}_{\text{so}}^* \longrightarrow \mathcal{V}_{\text{so}}^{0,*} \longrightarrow 0. \quad (4.6.3)$$

We know that $M_{(0,0)}(K'_{f,g}; \mathbb{Z}_p)$ is a free $\mathbb{Z}_p$ -module of finite rank, so the leftmost term in equation (4.6.3) is a free Λ_{so} -module of finite rank. The rightmost term $\mathcal{V}_{\text{so}}^{0,*}$ is also a free Λ_{so} -module of finite rank by Theorem 3.0.7. Since $\text{Ext}_{\Lambda_{\text{so}}}^1(M, N)$ vanishes for free Λ_{so} -modules M , we deduce that $\mathcal{V}_{\text{so}}^*$, as a Λ_{so} -module, is isomorphic to the direct sum of the terms on the two ends of equation (4.6.3) and therefore is a free Λ_{so} -module of finite rank. $\square$

Part (2) of Theorem 2.9.1 for noncuspidal semiordinary families can be proved in the same way as the cuspidal semiordinary families. The freeness of $\mathcal{V}_{\text{so}}^{0,*}$ implies that applying $\text{Hom}_{\Lambda_{\text{so}}}(\cdot, \Lambda_{\text{so}})$ preserves the exactness of equation (4.6.3), and part (4) of Theorem 2.9.1 follows.

4.7. The Fourier–Jacobi expansion

We introduce the Fourier–Jacobi expansions of p -adic forms on $\text{GU}(3, 1)$, which will be used in §7 for analyzing the Klingen Eisenstein family on $\text{GU}(3, 1)$ constructed in §5.

In §4.2, for an ordinary cusp label $g \in C(K_f^p K_{p,n}^1)_{\text{ord}}$, we described $\mathfrak{X}_{g,n}$, the formal completion of $\mathcal{T}_n^{\text{tor}}$ along the boundary stratum $\mathcal{X}_{g,n}$. From the description there, we see that

$$H^0(\mathfrak{X}_{g,n}, \mathcal{O}_{\mathfrak{X}_{g,n}}) = \left(\prod_{\beta} H^0(\mathcal{C}_{g,n}^{\text{ord}}, \mathcal{L}(\beta)) \right)^{\Gamma_g},$$

where β runs over $\mathbf{S}_{\Phi_f^{(g)} K_f^p K_{p,n}^1}^{\vee} \cap \mathbf{P}_{\Phi_f^{(g)} K_f^p K_{p,n}^1}$, which can be identified with a subset of $\text{Her}_1(\mathcal{K})_{\geq 0}$, and $\mathcal{L}(\beta)$ is

the invertible sheaf over $\mathcal{C}_{g,n}^{\text{ord}}$ of β -homogeneous functions on $\Xi_{g,n}^{\text{ord}}$. Therefore, given $g \in C(K_f^p K_{p,n}^1)_{\text{ord}}$ and $\beta \in \text{Her}_1(\mathcal{K})_{\geq 0}$, the restriction to $\mathfrak{X}_{g,n}$ induces a map

$$V_{n,m} \longrightarrow H^0(\mathcal{C}_{g,n}^{\text{ord}}, \mathcal{L}(\beta) \otimes \mathbb{Z}/p^m \mathbb{Z}). \quad (4.7.1)$$

We consider $g = \mathbf{1}_4$ and $\beta \in \text{Her}_1(\mathcal{K})_{\geq 0}$. In this case, the p -component of level group for the Shimura variety $\mathcal{S}_{G', K'_f, \mathbf{1}_4, n}$ in the diagram (4.2.2) is

$$K'_{p, \mathbf{1}_4, n} = \left\{ g \in \text{GU}(2)(\mathbb{Z}_p) : g^+ \equiv \begin{pmatrix} * & * \\ 0 & 1 \end{pmatrix} \pmod{p^n} \right\},$$

(depending on n). Let

$$V_{\text{GU}(2)}^{J, \beta} = \varprojlim_m \varinjlim_n H^0(\mathcal{C}_{\mathbf{1}_4, n}^{\text{ord}}, \mathcal{L}(\beta) \otimes \mathbb{Z}/p^m \mathbb{Z}). \quad (4.7.2)$$

The map gives the map of taking the β -th Fourier–Jacobi coefficient of p -adic forms on $\text{GU}(3, 1)$ along the boundary stratum labeled by $\mathbf{1}_4$:

$$\text{FJ}_{\beta} : V_{\text{GU}(3, 1)} \longrightarrow V_{\text{GU}(2)}^{J, \beta}. \quad (4.7.3)$$

5. The construction of the Klingen family

5.1. Some notation

Let $\mathcal{K}_{\infty}$ be the maximal abelian pro- p extension of $\mathcal{K}$ unramified outside p and $\Gamma_{\mathcal{K}} = \text{Gal}(\mathcal{K}_{\infty}/\mathcal{K})$. Then $\Gamma_{\mathcal{K}} \cong \mathbb{Z}_p^2$. Denote by $\Omega_{\infty} \in \mathbb{C}^{\times}$ (resp. $\Omega_p \in \hat{\mathbb{Z}}_p^{\text{ur}, \times}$) the complex complex multiplication (CM) period (p -adic CM period) with respect to the embeddings in equation (1.0.4) (cf. [Hsi14a, Section 2.8]). We also fix an isomorphism $\overline{\mathbb{Q}}_p \cong \mathbb{C}$ compatible with the embeddings in equation (1.0.4). Let $L \subset \overline{\mathbb{Q}}_p$ be a sufficiently large finite extension of $\mathbb{Q}_p$, and denote by $\hat{\mathcal{O}}_L^{\text{ur}}$ the ring of integers of the completion of the maximal unramified extension of L .

For our later use of theta correspondence for unitary groups, we also fix a Hecke character

$$\lambda : \mathcal{K}^{\times} \backslash \mathbb{A}_{\mathcal{K}}^{\times} \longrightarrow \mathbb{C}^{\times},$$

such that

$$\lambda|_{\mathbb{A}_{\mathbb{Q}}^{\times}} = \eta_{\mathcal{K}/\mathbb{Q}}, \quad \lambda_{\infty}(z) = \frac{|z\bar{z}|^{1/2}}{z}.$$

5.2. Our setup

Let π be an irreducible cuspidal automorphic representation of $\mathrm{GL}_2(\mathbb{A}_{\mathbb{Q}})$ generated by a newform f of weight 2. Take a finite extension L of $\mathbb{Q}_p$ containing all the Hecke eigenvalues of f . We assume the following conditions on π :

- for all finite places v of $\mathbb{Q}$, π_v is either unramified or Steinberg or Steinberg twisted by an unramified quadratic character of $\mathbb{Q}_v^{\times}$,
- π_p is unramified,
- there exists a prime q not split in $\mathcal{K}$ such that π is ramified at q , and if 2 does not split in $\mathcal{K}$, then π is ramified at 2,
- $\bar{\rho}\pi|_{\mathrm{Gal}(\bar{\mathbb{Q}}/\mathcal{K})}$ is irreducible, (which is automatically true if π is not ordinary at p because in this case $\bar{\rho}\pi|_{G_{\mathcal{K},p}} \cong \bar{\rho}\pi|_{G_{\mathbb{Q},p}}$ is irreducible by [Edi92]), where $\bar{\rho}\pi$ denotes the residual representation of the p -adic Galois representation $\rho_{\pi} : \mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q}) \rightarrow \mathrm{GL}_2(L)$.

We also fix

- an algebraic Hecke character $\xi : \mathcal{K}^{\times} \backslash \mathbb{A}_{\mathcal{K}}^{\times} \rightarrow \mathbb{C}^{\times}$ of ∞ -type $(0, k_0)$ with k_0 an even integer.

5.3. The weight space

The weight space we will use for constructing the semiordinary Klingen Eisenstein family on $\mathrm{GU}(3, 1)$ is $\mathrm{Hom}_{\mathrm{cont}}(\Gamma_{\mathcal{K}}, \bar{\mathbb{Q}}_p^{\times})$. By identifying $\Gamma_{\mathcal{K}}$ with a quotient of $\mathcal{K}^{\times} \backslash \mathbb{A}_{\mathcal{K},f}^{\times}$, the arithmetic points in the weight space are p -adic avatars of the algebraic Hecke characters of $\mathcal{K}^{\times} \backslash \mathbb{A}_{\mathcal{K}}^{\times}$ whose p -adic avatars factor through $\Gamma_{\mathcal{K}}$. (Given an algebraic Hecke character $\chi : \mathcal{K}^{\times} \backslash \mathbb{A}_{\mathcal{K}}^{\times} \rightarrow \mathbb{C}^{\times}$ of ∞ -type (k_1, k_2) , its p -adic avatar is the continuous character $\mathcal{K}^{\times} \backslash \mathbb{A}_{\mathcal{K},f}^{\times} \rightarrow \bar{\mathbb{Q}}_p^{\times}$ sending x to $\chi(x)x_p^{k_1}x_{\bar{p}}^{k_2}$.) We will use τ to denote such Hecke characters.

Given an algebraic Hecke character χ , we denote by χ_0 its associated unitary Hecke character, that is,

$$\chi_0 = \chi| \cdot |_{\mathbb{A}_{\mathcal{K}}}^{-\frac{k_1+k_2}{2}},$$

and denote by $\chi_{p\text{-adic}}$ its p -adic avatar. Applying this convention to ξ, τ , we get $\xi_0, \xi_{p\text{-adic}}, \tau_0, \tau_{p\text{-adic}}$.

The interpolation points we will use are the τ 's satisfying that $\xi\tau$ has ∞ -type $(0, k)$ with k an even integer ≥ 6 . (One can consider more general ∞ -types by using Masss–Shimura differential operators. For our purpose here, only considering the case of ∞ -type $(0, k)$ suffices.)

5.4. The groups

By the assumption on π in §5.2, we can fix a prime q such that

$$\begin{cases} q \text{ does not split in } \mathcal{K} \text{ and } \pi_q \text{ is ramified,} & \text{if 2 splits in } \mathcal{K}, \\ q = 2, & \text{if 2 does not split in } \mathcal{K}. \end{cases}$$

Let D be the quaternion algebra over $\mathbb{Q}$ ramified exactly at q and ∞ , and let π^D be the Jacquet–Langlands transfer of π to $D^{\times}(\mathbb{A}_{\mathbb{Q}})$.

We can take a square free positive integer $\mathfrak{s}$, coprime to $pD_{\mathcal{K}/\mathbb{Q}}$ and all the primes inert in $\mathcal{K}$ where D splits such that $\text{inv}_v(D) = (-\mathfrak{s}, D_{\mathcal{K}/\mathbb{Q}})_v$, where $(\cdot, \cdot)_v$ is the Hilbert symbol. Define $\zeta_0 = \delta \begin{pmatrix} \mathfrak{s} & \\ & 1 \end{pmatrix}$ with δ the totally imaginary element in $\mathcal{K}$ with δ^2 a p -adic unit as fixed in **Notation**. This ζ_0 is a skew-Hermitian matrix. Define the unitary group $\text{U}(2)$ (resp. similitude unitary group $\text{GU}(2)$) over $\mathbb{Z}$ as: for all $\mathbb{Z}$ -algebra R ,

$$\text{U}(2)(R) = \{g \in \text{GL}_2(R \otimes_{\mathbb{Z}} \mathcal{O}_{\mathcal{K}}) : g\zeta_0 {}^t\bar{g} = \zeta_0\} \quad (5.4.1)$$

$$\text{GU}(2)(R) = \{g \in \text{GL}_2(R \otimes_{\mathbb{Z}} \mathcal{O}_{\mathcal{K}}) : g\zeta_0 {}^t\bar{g} = \nu(g)\zeta_0, \nu(g) \in R^\times\}. \quad (5.4.2)$$

We have

$$D = \{g \in M_2(\mathcal{K}) : g\zeta_0 {}^t\bar{g} = \det(g)\zeta_0\} = \left\{ \begin{pmatrix} a & -\mathfrak{s}\bar{b} \\ b & \bar{a} \end{pmatrix} : a, b \in \mathcal{K} \right\},$$

and we view both $D^\times$ and $\text{GU}(2)$ as subgroups of $\text{Res}_{\mathcal{K}/\mathbb{Q}} \text{GL}_2(\mathcal{K})$. Then the homomorphism

$$\mathcal{K}^\times \times D^\times \longrightarrow \text{GU}(2)(\mathbb{Q}), \quad (a, g) \longmapsto ag$$

induces an isomorphism

$$\text{GU}(2) \simeq (\text{Res}_{\mathcal{K}/\mathbb{Q}} \mathbb{G}_m \times D^\times) / \{(a, a^{-1}\mathbf{1}_2) : a \in \mathbb{G}_m\}. \quad (5.4.3)$$

Given an automorphic form on ϕ on $D^\times$ with central character χ_1 , by picking an extension χ of χ_1 to $\mathcal{K}^\times \backslash \mathbb{A}_{\mathcal{K}}^\times$, one obtains an automorphic form $\phi^{\text{GU}(2)}$ on $\text{GU}(2)$ by equation (5.4.3).

We denote by π^D the Jacquet–Langlands transfer of π to $D^\times$, and by f^D the unique automorphic form on $D^\times$ which is a newform for the action of $D^\times(\mathbb{Q}_v) \simeq \text{GL}_2(\mathbb{Q}_v)$ for all $v \neq q, \infty$ and takes value 1 at $\mathbf{1}_2$. By our assumption, π^D has trivial central character. We can extend f^D to a form $f^{\text{GU}(2)}$ via equation (5.4.3) and the trivial character and denote by $\pi^{\text{GU}(2)}$ the automorphic representation of $\text{GU}(2)(\mathbb{A}_{\mathbb{Q}})$ generated by $f^{\text{GU}(2)}$.

Define the unitary group $\text{U}(3, 1)$ (resp. similitude unitary group $\text{GU}(3, 1)$) over $\mathbb{Z}$ as

$$\begin{aligned} \text{U}(3, 1)(R) &= \left\{ g \in \text{GL}_4(R \otimes_{\mathbb{Z}} \mathcal{O}_{\mathcal{K}}) : g \begin{pmatrix} & & & 1 \\ & & \zeta_0 & \\ & -1 & & \\ & & & \end{pmatrix} {}^t\bar{g} = \begin{pmatrix} & & & 1 \\ & & \zeta_0 & \\ & -1 & & \\ & & & \end{pmatrix} \right\}, \\ \text{GU}(3, 1)(R) &= \left\{ g \in \text{GL}_4(R \otimes_{\mathbb{Z}} \mathcal{O}_{\mathcal{K}}) : g \begin{pmatrix} & & & 1 \\ & & \zeta_0 & \\ & -1 & & \\ & & & \end{pmatrix} {}^t\bar{g} = \nu(g) \begin{pmatrix} & & & 1 \\ & & \zeta_0 & \\ & -1 & & \\ & & & \end{pmatrix}, \nu(g) \in R^\times \right\}. \end{aligned}$$

Let

$$P_{\text{GU}(3,1)} = \left\{ \begin{pmatrix} x & * & * \\ & g & * \\ & & \nu(g)\bar{x}^{-1} \end{pmatrix} \in \text{GU}(3, 1) : g \in \text{GU}(2), x \in \text{Res}_{\mathcal{K}/\mathbb{Q}} \mathbb{G}_m \right\}, \quad (5.4.4)$$

the (standard) Klingen parabolic subgroup of $\text{GU}(3, 1)$. Its Levi subgroup is

$$M_{P_{\text{GU}(3,1)}} \simeq \text{Res}_{\mathcal{K}/\mathbb{Q}} \mathbb{G}_m \times \text{GU}(2).$$

(Over $\mathbb{Q}$, the groups $\text{GU}(2)$ and $\text{GU}(3, 1)$ are the same as the groups defined in equation (2.1.1) written with respect to the basis w_1, w_2 and x_1, w_1, w_2, y_1 .)

Define the unitary group $U(1)$ over $\mathbb{Z}$ by

$$U(1)(R) = \{a \in (R \times_{\mathbb{Z}} \mathcal{O}_{\mathcal{K}})^{\times} : a\bar{a} = 1\}.$$

The projection $\varrho_{\mathfrak{p}} : \mathcal{K}_p = \mathcal{K} \otimes \mathbb{Q}_p \rightarrow \mathbb{Q}_p$ induces maps

$$U(2)(\mathbb{Q}_p) \longrightarrow GL_2(\mathbb{Q}_p), \quad U(3,1)(\mathbb{Q}_p) \longrightarrow GL_4(\mathbb{Q}_p), \quad U(1)(\mathbb{Q}_p) \longrightarrow \mathbb{Q}_p^{\times},$$

and they are all isomorphisms. We denote the inverse maps by $\varrho_{\mathfrak{p}}^{-1}$:

$$\varrho_{\mathfrak{p}}^{-1} : GL_2(\mathbb{Q}_p) \xrightarrow{\cong} U(2)(\mathbb{Q}_p), \quad \varrho_{\mathfrak{p}}^{-1} : GL_4(\mathbb{Q}_p) \xrightarrow{\cong} U(3,1)(\mathbb{Q}_p), \quad \varrho_{\mathfrak{p}}^{-1} : \mathbb{Q}_p^{\times} \xrightarrow{\cong} U(1)(\mathbb{Q}_p). \quad (5.4.5)$$

5.5. The Klingen Eisenstein series and the doubling method

We briefly recall the definition of Klingen Eisenstein series and Garrett's (generalized) doubling method formula which expresses a Klingen Eisenstein series on $GU(3,1)$ as an integral involving a Siegel Eisenstein series on $GU(3,3)$.

5.5.1. The Klingen Eisenstein series on $GU(3,1)$

Let $U_{P_{GU(3,1)}}$ be the unipotent subgroup of the Klingen parabolic subgroup $P_{GU(3,1)}$ in equation (5.4.4). For a unitary character $\xi_0\tau_0 : \mathcal{K}^{\times} \backslash \mathbb{A}_{\mathcal{K}}^{\times} \rightarrow \mathbb{C}^{\times}$ and a complex number s , define $I_{P_{GU(3,1)}}(s, \xi_0\tau_0)$ as the space of smooth K -finite functions (where K is a maximal compact subgroup of $GU(3,1)(\mathbb{A}_{\mathbb{Q}})$)

$$F(s, \xi_0\tau_0) : U_{P_{GU(3,1)}}(\mathbb{A}_{\mathbb{Q}})M_{P_{GU(3,1)}}(\mathbb{Q}) \backslash GU(3,1)(\mathbb{A}_{\mathbb{Q}}) \longrightarrow \mathbb{C}$$

satisfying

- (i) $F(s, \xi_0\tau_0) \left(\begin{pmatrix} x & & \\ & 1_2 & \\ & & \bar{x}^{-1} \end{pmatrix} g \right) = \xi_0\tau_0(x) |x\bar{x}|_{\mathbb{A}_{\mathbb{Q}}}^{s+\frac{3}{2}}$ for all $x \in \mathbb{A}_{\mathcal{K}}^{\times}$, $g \in GU(3,1)(\mathbb{A}_{\mathbb{Q}})$,
- (ii) for all $g \in GU(3,1)(\mathbb{A}_{\mathbb{Q}})$, the function $g_1 \mapsto F(s, \xi_0\tau_0) \left(\begin{pmatrix} 1 & & \\ & g_1 & \\ & & \nu(g_1) \end{pmatrix} g \right)$ is an automorphic form on $GU(2)(\mathbb{A}_{\mathbb{Q}})$.

The Klingen Eisenstein series on $GU(3,1)$ attached to $F(s, \xi_0\tau_0) \in I_{P_{GU(3,1)}}(s, \xi_0\tau_0)$ is defined as

$$E^{\text{Kling}}(g; F(s, \xi_0\tau_0)) = \sum_{\gamma \in P_{GU(3,1)}(\mathbb{Q}) \backslash GU(3,1)(\mathbb{Q})} F(s, \xi_0\tau_0)(\gamma g).$$

If the cuspidal automorphic form in (ii) belongs to $\pi^{GU(2)}$, the Galois representation attached to $E^{\text{Kling}}(\cdot; F(s, \xi_0\tau_0))|_{s=\frac{k-3}{2}}$ (where we assume that $\xi\tau$ has ∞ -type $(0, k)$) is

$$\xi\tau \cdot \epsilon_{\text{cyc}}^{-2} \circ \text{Nm} \oplus (\xi\tau)^{-c} \cdot \epsilon_{\text{cyc}} \circ \text{Nm} \oplus \rho\pi|_{\text{Gal}(\overline{\mathbb{Q}}/\mathcal{K})},$$

where the Hecke characters of $\mathcal{K}^{\times} \backslash \mathbb{A}_{\mathcal{K}}^{\times}$ are viewed as characters of $\text{Gal}(\overline{\mathbb{Q}}/\mathcal{K})$. The congruences between this Klingen Eisenstein series and cuspidal forms on $GU(3,1)$ can be used to construct elements in the Selmer group for $\rho\pi(\epsilon_{\text{cyc}}^2)|_{\text{Gal}(\overline{\mathbb{Q}}/\mathcal{K})} \otimes \xi^{-1}\tau^{-1}$.

5.5.2. The Siegel Eisenstein series on $\mathrm{GU}(3, 3)$

Let $\mathrm{GU}(3, 3)$ be the similitude unitary group over $\mathbb{Z}$ defined by

$$\mathrm{GU}(3, 3)(R) = \left\{ g \in \mathrm{GL}_6(R \otimes_{\mathbb{Z}} \mathcal{O}_{\mathcal{K}}) : g \begin{pmatrix} & \mathbf{1}_3 \\ -\mathbf{1}_3 & \end{pmatrix} \bar{g} = \nu(g) \begin{pmatrix} & \mathbf{1}_3 \\ -\mathbf{1}_3 & \end{pmatrix}, \nu(g) \in R^{\times} \right\}.$$

The group $\mathrm{GU}(3, 1) \times_{\mathbb{G}_m} \mathrm{GU}(2) = \{(g_1, g_2) \in \mathrm{GU}(3, 1) \times \mathrm{GU}(2) : \nu(g_1) = \nu(g_2)\}$ embeds into H by

$$\begin{aligned} \iota : \mathrm{GU}(3, 1) \times_{\mathbb{G}_m} \mathrm{GU}(2) &\longrightarrow \mathrm{GU}(3, 3) \\ (g_1, g_2) &\longrightarrow \mathcal{S}^{-1} \begin{pmatrix} g_1 & \\ & g_2 \end{pmatrix} \mathcal{S}, \end{aligned} \quad (5.5.1)$$

$$\text{where } \mathcal{S} = \begin{pmatrix} 1 & & & \\ & \mathbf{1}_2 & & -\frac{\xi_0}{2} \\ & & 1 & \\ & -\mathbf{1}_2 & & -\frac{\xi_0}{2} \end{pmatrix}.$$

Let $\mathcal{Q}_{\mathrm{GU}(3,3)}$ be the (standard) Siegel parabolic subgroup of $\mathrm{GU}(3, 3)$. For a $\mathbb{Z}$ -algebra R ,

$$\mathcal{Q}_{\mathrm{GU}(3,3)}(R) = \left\{ \begin{pmatrix} A & B \\ 0 & D \end{pmatrix} \in \mathrm{GL}_6(R \otimes_{\mathbb{Z}} \mathcal{O}_{\mathcal{K}}) : D = \nu^t \bar{A}^{-1}, \nu \in R^{\times}, A^{-1}B \in \mathrm{Her}_3(R \otimes_{\mathbb{Z}} \mathcal{O}_{\mathcal{K}}) \right\}.$$

For a place v of $\mathbb{Q}$, a unitary character $\xi_{0,v} \tau_{0,v}$ of $\mathcal{K}_v^{\times}$ and a complex number s , the degenerate principal series $I_{\mathcal{Q}_{\mathrm{GU}(3,3),v}}(s, \xi_{0,v} \tau_{0,v})$ is defined as the space consisting of smooth $\mathrm{GU}(3, 3)(\mathbb{Z}_v)$ -finite functions $f_v(s, \xi_{0,v} \tau_{0,v}) : \mathrm{GU}(3, 3)(\mathbb{Q}_v) \rightarrow \mathbb{C}$ satisfying

$$f_v(s, \xi_{0,v} \tau_{0,v}) \left(\begin{pmatrix} A & B \\ 0 & D \end{pmatrix} g \right) = \xi_{0,v} \tau_{0,v}(\det A) |\det AD^{-1}|_v^{s+\frac{3}{2}} f_v(g)$$

for all $g \in \mathrm{GU}(3, 3)(\mathbb{Q}_v)$, $\begin{pmatrix} A & B \\ 0 & D \end{pmatrix} \in \mathcal{Q}_{\mathrm{GU}(3,3)}(\mathbb{Q}_v)$.

Given a unitary character $\xi_0 \tau_0 : \mathcal{K}^{\times} \backslash \mathbb{A}_{\mathcal{K}}^{\times} \rightarrow \mathbb{C}^{\times}$ and a section $f(s, \xi_0 \tau_0) = \bigotimes'_v f_v(s, \xi_{0,v} \tau_{0,v})$ inside $\bigotimes'_v I_{\mathcal{Q}_{\mathrm{GU}(3,3),v}}(s, \xi_{0,v} \tau_{0,v})$, the Siegel Eisenstein series on $\mathrm{GU}(3, 3)$ attached to $f(s, \xi_0 \tau_0)$ is defined as

$$E^{\mathrm{Sieg}}(g; f(s, \xi_0 \tau_0)) = \sum_{\gamma \in \mathcal{Q}_{\mathrm{GU}(3,3)}(\mathbb{Q}) \backslash \mathrm{GU}(3,3)(\mathbb{Q})} f(s, \xi_0 \tau_0)(\gamma g).$$

5.5.3. The (generalized) doubling method formula

Theorem 5.5.1 [Gar89]. Let $\xi_0 \tau_0 : \mathcal{K}^{\times} \backslash \mathbb{A}_{\mathcal{K}}^{\times} \rightarrow \mathbb{C}^{\times}$ be a unitary character. For a section $f(s, \xi_0 \tau_0) \in I_{\mathcal{Q}_{\mathrm{GU}(3,3)}}(s, \xi_0 \tau_0)$ and a cuspidal automorphic form φ on $\mathrm{GU}(2)(\mathbb{A}_{\mathbb{Q}})$,

$$\int_{\mathrm{U}(2)(\mathbb{Q}) \backslash \mathrm{U}(2)(\mathbb{A}_{\mathbb{Q}})} E^{\mathrm{Sieg}}(\iota(g, g_1 t); f(s, \xi_0 \tau_0)) \varphi(g_1 t) (\xi_0 \tau_0)^{-1} (\det g_1 t) dg_1 = E^{\mathrm{Kling}}(g; F(f(s, \xi_0 \tau_0), \varphi)),$$

where t is an element of $\mathrm{GU}(3, 1)(\mathbb{A}_{\mathbb{Q}})$ with $\nu(t) = \nu(g)$ (and it is easy to see that the left-hand side does not depend on the choice of t), and $F(f(s, \xi_0 \tau_0), \varphi)$ is the section in $I_{P_{\mathrm{GU}(3,1)}}(s, \xi_0 \tau_0)$ defined by

$$F(f(s, \xi_0 \tau_0), \varphi)(g) = \int_{\mathrm{U}(2)(\mathbb{A}_{\mathbb{Q}})} f(s, \tau_0)(\iota(g, g_1 t)) \varphi(g_1 t) (\xi_0 \tau_0)^{-1} (\det g_1 t) dg_1.$$

5.6. The auxiliary data for the Klingen family

Let Σ be the set of finite places of $\mathbb{Q}$ containing the prime 2, the prime q , the finite places $v \neq p$ where π or ξ or $\mathcal{K}/\mathbb{Q}$ is ramified and the primes dividing $\mathfrak{s}$. We denote by Σ_s the set of primes in Σ split in $\mathcal{K}$ and Σ_{ns} the set of primes in Σ nonsplit in $\mathcal{K}$.

The Klingen Eisenstein family we will construct is not of the optimal level. It depends on some auxiliary data which are chosen such that we can prove the desired properties of its nondegenerate Fourier–Jacobi coefficients. In this subsection, we fix these auxiliary data.

The Siegel Eisenstein family on $\mathrm{GU}(3, 3)$ we will use for constructing the Klingen Eisenstein family depends on the choice of $\ell, \ell', c_v, v \in \Sigma \cup \{\ell, \ell'\}$. We will define a space (5.6.11) depending on $\chi_{h,v}, v \in \Sigma_s \cup \{\ell\}$, from which we will choose an automorphic form on $\mathrm{GU}(2)$ to pair with the restriction of the Siegel Eisenstein family to $\mathrm{GU}(3, 1) \times_{\mathbb{G}_m} \mathrm{GU}(2)$. The characters χ_θ, χ_h will show up in our analysis of nondegenerate Fourier coefficients.

Before choosing the auxiliary data, we first introduce a proposition on certain Schwartz functions in the Schrödinger model of Weil representations of $\mathrm{U}(2, 1)$. Let V, V^- (resp. W_β) be the two-dimensional skew-Hermitian spaces (resp. one-dimensional Hermitian space) over $\mathcal{K}$, and $e_1, e_2 \in V \otimes W_\beta, e_1^-, e_2^- \in V^- \otimes W_\beta$ as in §7.1. We have $\mathrm{U}(V \oplus V^-) \cong \mathrm{U}(2, 2)$ and $\mathrm{U}(W_\beta) \cong \mathrm{U}(1)$.

Proposition 5.6.1. *Let v be a finite place of $\mathbb{Q}$ nonsplit in $\mathcal{K}/\mathbb{Q}$. Denote by $\omega_{\beta,v}(\cdot, \cdot)$ the Weil representation of $\mathrm{U}(2, 2)(\mathbb{Q}_v) \times \mathrm{U}(1)(\mathbb{Q}_v)$ on the Schrödinger model $S(\mathcal{K}_v(e_1 + e_1^-) \oplus \mathcal{K}_v(e_2 + e_2^-))$ (with respect to $\lambda_{W_\beta} = \lambda$). Let*

$$\mathcal{T} : S(\mathbb{Q}_v e_1 \oplus \mathbb{Q}_v e_2 \oplus \mathbb{Q}_v e_1^- \oplus \mathbb{Q}_v e_2^-) \longrightarrow S(\mathcal{K}_v(e_1 + e_1^-) \oplus \mathcal{K}_v(e_2 + e_2^-))$$

be the intertwining map between Schrödinger models.

For $\beta = 1$ and $m > \max\{\mathrm{ord}_v(\mathrm{cond}(\lambda_v)), 3\}$, there exists a character $\chi_v : \mathrm{U}(1)(\mathbb{Q}_v^\times) \rightarrow \mathbb{C}^\times$ of conductor at least $\varpi_v^{\max\{\mathrm{ord}_v(\mathrm{cond}(\lambda_v)), 3\}+1}$, a Schwartz function $\phi_{1,v}$ on $\mathbb{Q}_v e_1 \oplus \mathbb{Q}_v e_2$, and $u_1, \dots, u_t \in \mathrm{U}(1)(\mathbb{Q}_v), b_1, \dots, b_t \in \mathbb{C}$ such that the function

$$y \longmapsto \sum_{j=1}^t b_j \int_{\mathbb{Q}_v e_1 \oplus \mathbb{Q}_v e_2} \mathcal{T}^{-1} \left(\omega_{\beta,v} \left(\begin{pmatrix} \mathbf{1}_2 & q^{-m} \cdot \mathbf{1}_2 \\ 0 & \mathbf{1}_2 \end{pmatrix}, u_j \right) \Phi_{0,v} \right) (x, y) \cdot \phi_{1,v}(x) \, dx$$

is nonzero and belongs to the $\chi_v \lambda_v^2|_{\mathrm{U}(1)(\mathbb{Q}_v)}$ -eigenspace for the action of $\mathrm{U}(1)(\mathbb{Q}_v)$, where $\Phi_{0,v}$ is the characteristic function of $\mathcal{O}_{K,v} \frac{e_1 + e_1^-}{2} \oplus \mathcal{O}_{K,v} \frac{e_2 + e_2^-}{2}$.

Proof. [Wan20, Lemma 6.26]. □

We fix:

- primes $\ell, \ell' \neq 2, p$ such that ℓ splits in $\mathcal{K}/\mathbb{Q}$, ℓ' is inert in $\mathcal{K}/\mathbb{Q}$, and $\pi_\ell, \pi_{\ell'}$ are unramified,
- a positive integer c_v for each place $v \in \Sigma \cup \{\ell, \ell'\}$,
- auxiliary Hecke characters $\chi_\theta, \chi_h : \mathcal{K}^\times \backslash \mathbb{A}_{\mathcal{K}}^\times \rightarrow \mathbb{C}^\times$ of ∞ -type $(0, 0)$ with $\chi_h \chi_\theta^c|_{\mathbb{A}_{\mathcal{K}}^\times} = \mathrm{triv}$

satisfying the following properties:

- (1) χ_θ, χ_h are unramified away from $\Sigma \cup \{p, \ell, \ell'\}$ and $\chi_h \chi_\theta^c$ is unramified at q ;
- (2) $\chi_{\theta,p}, \chi_{h,\bar{p}}$ are unramified, and $\chi_{h,\bar{p}}|_{\mathbb{Z}_p^\times} = \chi_{\theta,\bar{p}}^{-1}|_{\mathbb{Z}_p^\times} = \xi_{0,\bar{p}}|_{\mathbb{Z}_p^\times}$;
- (3) For $v \in \Sigma_{ns} \cup \{\ell'\}$,

$$c_v > \max\{\mathrm{ord}_v(\mathrm{cond}(\pi_v)), \mathrm{ord}_v(\mathrm{cond}(\lambda_v)), 3\}$$

$$\chi_{\theta,v}|_{\mathrm{U}(1)(\mathbb{Q}_v)} = \chi_v \text{ as in Proposition 5.6.1 with } m = c_v,$$

$$\mathrm{ord}_v \left(\mathrm{cond}(\chi_{h,v} \chi_{\theta,v}^c) \right), \mathrm{ord}_v \left(\mathrm{cond}((\lambda_v^2 \chi_{h,v} \chi_{\theta,v}^c)) \right) > \mathrm{ord}_v(\mathrm{cond}(\pi_v)), \text{ if } v \neq q,$$

$$\mathrm{ord}_v(\mathrm{cond}(\chi_{\theta,v})|_{\mathrm{U}(1)(\mathbb{Q}_v)}) \geq \max\{\mathrm{ord}_v(\mathrm{cond}(\chi_{h,v})|_{\mathrm{U}(1)(\mathbb{Q}_v)}), \mathrm{ord}_v(\mathrm{cond}(\lambda_v) + 1)\};$$

(4) For $v = \mathfrak{v}\bar{v} \in \Sigma_s \cup \{\ell\}$, $\chi_{\theta, \mathfrak{v}}$ is unramified, and

$$\begin{aligned} \text{ord}_{\bar{v}}(\text{cond}(\chi_{\theta, \bar{v}})) &\geq 2\text{ord}_v(\text{cond}(\pi_v)) + 2, \\ \text{ord}_v(\text{cond}((\chi_h \chi_{\theta}^c)_v)) &= \begin{cases} \text{ord}_v(\text{cond}(\chi_{\theta, \bar{v}})) - \text{ord}_v(\text{cond}(\pi_v)), & \pi_v \text{ ramified,} \\ \text{ord}_v(\text{cond}(\chi_{\theta, \bar{v}})) - 1, & \pi_v \text{ unramified;} \end{cases} \\ c_v &> \max \left\{ \text{ord}_{\bar{v}}(\text{cond}(\chi_{\theta, \bar{v}})), \text{ord}_v(\text{cond}(\xi_{0, v})), \text{ord}_{\bar{v}}(\text{cond}(\xi_{0, \bar{v}})), \text{ord}_{\bar{v}}(\text{cond}(\lambda_{\bar{v}})) \right\} \end{aligned}$$

(5) If $q = \mathfrak{q}^2$ is ramified in $\mathcal{K}/\mathbb{Q}$,

$$(\chi_h \chi_{\theta}^c)_q(\varpi_q) = \chi_q(q),$$

where ϖ_q is a uniformizer of $\mathcal{K}_q$ and χ_q is the unramified quadratic character of $\mathcal{K}_q^\times$ such that $\pi_q \cong \text{Steinberg} \otimes \chi_q$;

(6) Furthermore, the value

$$\left(\frac{\Omega_p}{\Omega_\infty} \right)^4 \pi^{-3} \cdot \gamma_p \left(\frac{1}{2}, \pi_p \times \left(\lambda^2 \chi_h \chi_{\theta} \right)_{\bar{p}} \right)^{-1} L \left(\frac{1}{2}, \text{BC}(\pi) \times \lambda^2 \chi_h \chi_{\theta} \right) \quad (5.6.1)$$

is a p -adic unit, and

$$L^q \left(\frac{1}{2}, \text{BC}(\pi) \times \chi_h \chi_{\theta}^c \right) \neq 0. \quad (5.6.2)$$

For some algebraic Hecke character $\tau : \mathcal{K}^\times \backslash \mathbb{A}_{\mathcal{K}}^\times \rightarrow \mathbb{C}^\times$ such that $\tau_{p\text{-adic}}$ factors through $\Gamma_{\mathcal{K}}$ and $\xi\tau$ has ∞ -type $(0, k)$, $k \geq 2$, the values

$$\left(\frac{\Omega_p}{\Omega_\infty} \right)^k (2\pi i)^{1-k} \Gamma(k-1) \cdot \gamma_p \left(\frac{k-2}{2}, \chi_h \chi_{\theta}^c \xi_0 \tau_0 \right)^{-1} L^{p\infty} \left(\frac{k-2}{2}, \chi_h \chi_{\theta}^c \xi_0 \tau_0 \right), \quad (5.6.3)$$

$$\left(\frac{\Omega_p}{\Omega_\infty} \right)^{k-2} (2\pi i)^{2-k} \Gamma(k-2) \cdot L_p \left(\frac{k-2}{2}, \lambda^2 \chi_h \chi_{\theta}^c \xi_0^c \tau_0^c \right) L^{p\infty} \left(\frac{k-2}{2}, \lambda^2 \chi_h \chi_{\theta}^c \xi_0^c \tau_0^c \right), \quad (5.6.4)$$

$$1 - (\chi_h \chi_{\theta}^c \xi_0 \tau_0)_q(q) q^{-\frac{k-2}{2}}, \quad (5.6.5)$$

are all p -adic units.

We can first fix places ℓ, ℓ' and positive integers c_v for $v \in \Sigma_{\text{ns}} \cup \{\ell'\}$. Next, we can choose $\chi_{\theta, 1}, \chi_{h, 1}$ satisfying the conditions (1)–(5) except the last one in (4). (The inert prime ℓ' is introduced to ensure the existence.) Then we apply the mod p nonvanishing results—[Hsi14b] for the L -values in equation (5.6.1), [Hsi12] for the L -values in equations (5.6.3)(5.6.4) and in [Hun17] for the L -value in equation (5.6.2)—to choose a character ν of ℓ -power conductor such that $\chi_{\theta} = \chi_{\theta, 1}\nu$, $\chi_h = \chi_{h, 1}\nu$ satisfy (1)–(6) except the last one in (4). (The conditions in (3) on the conductors at nonsplit primes and the condition (5) implies that the local root numbers are +1 as required for applying [Hsi14b, Hun17]. Our assumption that ξ has ∞ -type $(0, k_0)$ with k_0 even implies that the L -values in equations (5.6.3)(5.6.4) fall into the nonresidually self-dual case for which [Hsi12, Theorem B] can be applied. Since we only need the L -value in equation (5.6.2) to be nonvanishing rather than mod p nonvanishing, we can choose a prime $p' \neq \ell$, different from p , such that the results in [Hun17] apply.) Then we fix positive integers c_v for $v \in \Sigma_s \cup \{\ell\}$. (The strategy outlined in §7.5 explains why we need to make such a choice of the auxiliary χ_{θ}, χ_h .)

With our fixed c_v 's for all $v \in \Sigma \cup \{\ell, \ell'\}$, define

$$K'_v = \left\{ g \in \text{GU}(2)(\mathbb{Z}_v) : g \equiv \mathbf{1}_2 \pmod{q_v^{2c_v + \text{ord}_v(\mathfrak{s}\delta)}} \right\}, \quad (5.6.6)$$

and the tame level group $K_f'^P \subset \mathrm{GU}(2)(\widehat{\mathbb{Z}}^{(p)})$ as

$$K_f'^P = \bigotimes_{v \notin \Sigma \cup \{\infty, \ell, \ell', p\}} \mathrm{GU}(2)(\mathbb{Z}_v) \bigotimes_{v \in \Sigma \cup \{\ell, \ell'\}} K'_v. \quad (5.6.7)$$

Given an open subgroup $K_p' \subset \mathrm{GU}(2)(\mathbb{Z}_p)$ and a ring R , let

$$M_{\mathrm{GU}(2)}(K_f'^P K_p'; R) = \left\{ \text{functions on } \mathrm{GU}(2)(\mathbb{Q}) \backslash \mathrm{GU}(2)(\mathbb{A}_{\mathbb{Q}}) / K_f'^P K_p' \mathrm{U}(2)(\mathbb{R}) \text{ valued } R \right\}, \quad (5.6.8)$$

the space of R -valued automorphic forms on $\mathrm{GU}(2)$ of weight $(0, 0)$ and level $K_f'^P K_p'$.

We also define the following twist of the form $f^{\mathrm{GU}(2)}$:

$$f_{\chi_h}^{\mathrm{GU}(2)} = \prod_{v=\infty \bar{v} \in \Sigma_{\infty} \cup \{\ell'\}} \sum_{n \in (\mathbb{Z}_v / q_v^{t_v} \mathbb{Z}_v)^{\times}} \chi_{h, \bar{v}}(-n) R \left(\begin{pmatrix} 1 & \\ n & 1 \end{pmatrix}_v \begin{pmatrix} q_v^{-t_v} & \\ & 1 \end{pmatrix}_v \right) f^{\mathrm{GU}(2)}, \quad (5.6.9)$$

where $t_v = \mathrm{ord}_{\bar{v}}(\mathrm{cond}(\chi_{h, \bar{v}}))$. We have $f_{\chi_h}^{\mathrm{GU}(2)} \in M_{\mathrm{GU}(2)}(K_f'^P \mathrm{GU}(2)(\mathbb{Z}_p); \mathcal{O}_L)$. Let

$$L[\mathrm{GU}(2)(\mathbb{Q}_{\Sigma_{\mathrm{ns}} \cup \{\ell'\}})] \cdot f_{\chi_h}^{\mathrm{GU}(2)} \quad (5.6.10)$$

denote the space generated by $f_{\chi_h}^{\mathrm{GU}(2)}$ and the action of $\mathrm{GU}(\mathbb{Q}_v)$, $v \in \Sigma_{\mathrm{ns}} \cup \{\ell'\}$.

Remark 5.6.2. In the sentence beginning ‘the twist at the split’, please define CM. We will choose a φ inside the space

$$M_{\mathrm{GU}(2)}(K_f'^P \mathrm{GU}(2)(\mathbb{Z}_p); \mathcal{O}_L) \cap L[\mathrm{GU}(2)(\mathbb{Q}_{\Sigma_{\mathrm{ns}} \cup \{\ell'\}})] \cdot f_{\chi_h}^{\mathrm{GU}(2)} \quad (5.6.11)$$

to pair with the Siegel Eisenstein family on $\mathrm{GU}(3, 3)$ to get the Klingen Eisenstein family on $\mathrm{GU}(3, 1)$. The twist at the split primes is to make the nebentypus match those of the auxiliary CM families θ and h constructed from our chosen auxiliary characters χ_{θ} and χ_h . The flexibility at the nonsplit primes is to ensure the nonvanishing of the local triple product integrals at the nonsplit primes.

5.7. The choice of the local sections for the Siegel Eisenstein series on $\mathrm{GU}(3, 3)$

With c_v ’s chosen in §5.6, given an algebraic Hecke character τ such that $\xi\tau$ has ∞ -type $(0, k)$ with k an even integer ≥ 6 , we make the following choices of $f(s, \xi_0\tau_0) \in I_{Q_{\mathrm{GU}(3,3)}}(s, \xi_0\tau_0)$ so that after a suitable normalization, $E^{\mathrm{Siegl}}(\cdot; f(s, \xi_0\tau_0))|_{s=\frac{k-3}{2}}$ can be interpolated by a two-variable p -adic family when τ varies.

5.7.1. The Archimedean place

We choose $f_{\infty}(s, \xi_0\tau_0) \in I_{Q_{\mathrm{GU}(3,3)}, \infty}(s, \tau_0)$ as

$$f_{\infty}(s, \xi_0\tau_0) \left(g = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \right) = (\det g)^k |\det(g)|_{\mathbb{C}}^{\frac{s}{2} + \frac{3}{4} - \frac{k}{4}} \\ \times \det \left(C \begin{pmatrix} i & \frac{\xi_0}{2} \end{pmatrix} + D \right)^{-k} \left\| \det \left(C \begin{pmatrix} i & \frac{\xi_0}{2} \end{pmatrix} + D \right) \right\|_{\mathbb{C}}^{-s - \frac{3}{2} + \frac{k}{2}}.$$

5.7.2. Unramified places

For $v \notin \Sigma \cup \{p, \ell, \ell'\}$, we choose $f_v(s, \xi_0\tau_0) \in I_{Q_{\mathrm{GU}(3,3)}, v}(s, \tau_0)$ to be the standard spherical section, that is, the section that is invariant under the right translation of $\mathrm{GU}(3, 3)(\mathbb{Z}_v)$ and takes value 1 at $\mathbf{1}_6$.

5.7.3. Places $v \in \Sigma \cup \{\ell, \ell'\}$

We choose $f_v(s, \xi_0 \tau_0) \in I_{Q_{\text{GU}(3,3),v}}(s, \tau_0)$ as

$$f_v(s, \xi_0 \tau_0) \left(g = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \right) = |\nu(g)|_v^{s+\frac{3}{2}} |\det C^t \bar{C}|_v^{-s-\frac{3}{2}} (\xi_0 \tau_0)_v \left(\nu(g) (\det \bar{C})^{-1} \right) \\ \times \mathbb{1}_{\text{Her}(3, \mathcal{O}_{K,v})} \left(C^{-1} D + \begin{pmatrix} 0 & 0 \\ 0 & q_v^{-c_v} \cdot \mathbf{1}_2 \end{pmatrix} \right), \quad (5.7.1)$$

where c_v is the fixed positive integer in §5.6.

5.7.4. The place p

We have the isomorphisms

$$\begin{aligned} \text{U}(3, 3)(\mathbb{Q}_p) &\longrightarrow \text{GL}_6(\mathbb{Q}_p), & g = (a_{ij}) &\longmapsto (\varrho_p(a_{ij})), \\ \text{Her}_3(\mathcal{K}_p) &\longrightarrow M_{3,3}(\mathbb{Q}_p), & x = (x_{ij}) &\longmapsto \varrho_p(x) = (\varrho_p(x_{ij})), \end{aligned}$$

and we will often use them to identify $\text{U}(3, 3)(\mathbb{Q}_p)$ with $\text{GL}_6(\mathbb{Q}_p)$ and $\text{Her}_3(\mathcal{K}_p)$ with $M_{3,3}(\mathbb{Q}_p)$.

For $x \in \text{Her}_3(\mathcal{K}_p)$, we write $\varrho_p(x)$ as $\begin{pmatrix} x_{11} & x_{12} & x_{13} \\ x_{21} & x_{22} & x_{23} \\ x_{31} & x_{32} & x_{33} \end{pmatrix}$. Define the Schwartz function $\alpha_{\xi\tau,p}$ on $\text{Her}_3(\mathcal{K}_p)$ as

$$\alpha_{\xi\tau,p}(x) = \mathbb{1}_{\text{Her}_3(\mathcal{O}_{K,p})}(x) \cdot \mathbb{1}_{\mathbb{Z}_p^\times}(x_{21}) \mathbb{1}_{\text{GL}_2(\mathbb{Z}_p)} \begin{pmatrix} x_{21} & x_{22} \\ x_{31} & x_{32} \end{pmatrix} (\xi_0 \tau_0)_p^{-1} \left(\det \begin{pmatrix} x_{21} & x_{22} \\ x_{31} & x_{32} \end{pmatrix} \right),$$

and let $\mathcal{F}^{-1} \alpha_{\xi\tau,p}$ be the inverse Fourier transform of $\alpha_{\xi\tau,p}$, that is,

$$\mathcal{F}^{-1} \alpha_{\xi\tau,p}(x) = \int_{\text{Her}_3(\mathcal{K}_p)} \alpha_{\xi\tau,p}(y) \mathbf{e}_p(\text{Tr } xy) dy,$$

where $\mathbf{e}_p$ is the additive character in equation (1.0.5). (A simple computation shows that

$$\mathcal{F}^{-1} \alpha_{\xi\tau,p}(x) = p^{-3t} \mathbf{g} \left((\xi_0 \tau_0)_p^{-1} \right)^2 \cdot \mathbb{1}_{\mathbb{Z}_p^\times}(x_{11}, x_{21}, x_{31}, x_{32}, x_{33}) \cdot \mathbb{1}_{\mathbb{Z}_p^\times}(x_{23}^{-1} x_{13}, x_{23}^{-1} x_{22}) \\ \times \mathbb{1}_{p^{-t} \mathbb{Z}_p^\times}(x_{23}) \mathbb{1}_{p^{-t} \mathbb{Z}_p^\times}(x_{12} - x_{13} x_{23}^{-1} x_{22}) (\xi_0 \tau_0)_p \left(p^{2t} \det \begin{pmatrix} x_{12} & x_{13} \\ x_{22} & x_{23} \end{pmatrix} \right), \quad (5.7.2)$$

if $(\xi_0 \tau_0)_p$ has conductor p^t , $t \geq 1$.) In order to define the $f_p(s, \xi_0 \tau_0)$ for our purpose, we first define the section

$$f_p^{\text{big-cell}}(-s, (\xi_0 \tau_0)^{-c}) \left(g = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \right) = |\nu(g)|_p^{-s+\frac{3}{2}} |\det C^t \bar{C}|_p^{s-\frac{3}{2}} (\xi_0 \tau_0)_p (\nu(g) (\det C)) \\ \times \mathcal{F}^{-1} \alpha_{\xi\tau,p}(C^{-1} D),$$

which belongs to $I_{Q_{\text{GU}(3,3),p}}(-s, (\xi_0 \tau_0)^{-c})$ and is supported on the big cell

$$Q_{\text{GU}(3,3)(\mathbb{Q}_p)} \begin{pmatrix} 0 & -\mathbf{1}_3 \\ \mathbf{1}_3 & 0 \end{pmatrix} Q_{\text{GU}(3,3)(\mathbb{Q}_p)}.$$

We choose $f_p(s, \xi_0 \tau_0) \in I_{Q_{GU(3,3),p}}(s, \xi_0 \tau_0)$ as

$$\begin{aligned} f_p(s, \xi_0 \tau_0)(g) &= \gamma_p\left(-2s, (\xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})^{-1}\right) \gamma_p\left(-2s-1, (\xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})^{-1} \eta_{K/\mathbb{Q}}\right) \gamma_p\left(-2s-2, (\xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})^{-1}\right) \\ &\quad \times M_p(-s, (\xi_0 \tau_0)^{-c}) f_p^{\text{big-cell}}(-s, (\xi_0 \tau_0)^{-c})(g \Upsilon_p), \end{aligned} \quad (5.7.3)$$

where $\xi_0^{\mathbb{Q}}$ (resp. $\tau_0^{\mathbb{Q}}$) denotes the restriction of ξ_0 (resp. τ_0) to $\mathbb{Q}^\times \backslash \mathbb{A}_{\mathbb{Q}}^\times$, and $M_p(-s, (\xi_0 \tau_0)^{-c})$ is the intertwining operator, that is,

$$\begin{aligned} &M_p(-s, (\xi_0 \tau_0)^{-c}) f_p^{\text{big-cell}}(-s, (\xi_0 \tau_0)^{-c})(g \Upsilon_p) \\ &= \int_{\text{Her}_3(K_p)} f_p^{\text{big-cell}}(-s, (\xi \tau_0)^{-c}) \left(\begin{pmatrix} & & \\ & \mathbf{1}_3 & \\ \mathbf{1}_3 & & \end{pmatrix} \begin{pmatrix} \mathbf{1}_3 & y \\ & \mathbf{1}_3 \end{pmatrix} g \Upsilon_p \right) dy, \end{aligned} \quad (5.7.4)$$

and Υ_p is the element in $U(3, 3)(\mathbb{Q}_p)$ such that

$$\varrho_p(\Upsilon_p) = \begin{pmatrix} 1 & & \\ & \mathbf{1}_2 & -\frac{\xi_0}{2} \\ & & 1 \\ & -\mathbf{1}_2 & -\frac{\xi_0}{2} \end{pmatrix}^{-1}.$$

Remark 5.7.1. When $(\xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})_p$ is ramified with conductor p^t ,

$$\begin{aligned} &\gamma_p\left(-2s, (\xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})^{-1}\right) \gamma_p\left(-2s-1, (\xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})^{-1} \eta_{K/\mathbb{Q}}\right) \gamma_p\left(-2s-2, (\xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})^{-1}\right) \\ &= \mathfrak{g}\left((\xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})_p^{-1}\right)^{-3} (\xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})_p(p)^{-3t} p^{(6s+6)t}. \end{aligned}$$

Combining this with equation (5.7.2), one can see that the formula for the section $f_p(s, \xi_0 \tau_0)$ in equation (5.7.3) agrees with the formula in [Wan20, (6-5)].

Remark 5.7.2. For the unitary group attached to $\begin{pmatrix} & \mathbf{1}_n \\ -\mathbf{1}_n & \end{pmatrix}$ and $\beta \in \text{Her}_n(K)$, the factor for the functional equation of the β -th local Fourier coefficients of the degenerate principal series inducing $(\xi_0 \tau_0)_p^{-c} | \cdot |_{K_p}^{-s}$ is

$$\begin{aligned} &c_{n,p}(-s, (\xi_0 \tau_0)^{-c}, \beta) \\ &= c_{\beta,p} \cdot (\xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})_p(\det \beta) |\det \beta|_{\mathbb{Q}_p}^{2s} \cdot \prod_{j=1}^n \gamma_p\left(-2s+1-j, (\xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})^{-1} \eta_{K/\mathbb{Q}}^{n+j}\right)^{-1}, \end{aligned} \quad (5.7.5)$$

where $c_{\beta,p}$ is a constant independent of s and $\xi_0 \tau_0$. This factor also shows up in the functional equation of the doubling zeta integrals. Note that in our choice of $f_p(s, \xi_0 \tau_0)$ in equation (5.7.3), the product of gamma factors is exactly the product of gamma factors in $c_{3,p}(-s, (\xi_0 \tau_0)^{-c}, \beta)$.

Next, we construct a p -adic family interpolating these $E^{\text{Sieg}}(-; f(s, \xi_0 \tau_0))|_{s=\frac{k-3}{2}}$ with $f(s, \xi_0 \tau_0)$ chosen as above. We will construct p -adic families of automorphic forms as measures on Γ_K valued in the space of p -adic forms. The next subsection introduces some notions about p -adic measures.

5.8. *p*-adic measures and *p*-adic families of automorphic forms

For a *p*-adically complete $\mathcal{O}_L$ -module M and a compact abelian group Y with totally disconnected topology, denote by $\mathcal{M}eas(Y, M)$ the space of M -valued *p*-adic measures on Y . Given $\mu \in \mathcal{M}eas(Y, M)$ and a continuous function $\eta : Y \rightarrow R$ with R a *p*-adically complete $\mathcal{O}_L$ -algebra, we write

$$\mu(\eta) = \int_Y \eta(y) d\mu(y)$$

to denote the value of μ at η , which is an element in $R \widehat{\otimes}_{\mathcal{O}_L} M$.

For each $y \in Y$, we have the delta measure $\delta_y \in \mathcal{M}eas(Y, M)$ defined by

$$\delta_y(\eta) = \eta(y). \quad (5.8.1)$$

Given M_1, M_2 and $\mu_i \in \mathcal{M}eas(Y, M_i)$, $i = 1, 2$, the convolution $\mu_1 * \mu_2 \in \mathcal{M}eas(Y, M_1 \widehat{\otimes} M_2)$ is defined by

$$(\mu_1 * \mu_2)(\eta) = \int_Y \int_Y \eta(yz) d\mu_1(y) d\mu_2(z). \quad (5.8.2)$$

If χ is a continuous character of Y valued in $\mathcal{O}_L^\times$, then

$$(\mu_1 * \mu_2)(\chi) = \mu_1(\chi) \otimes \mu_2(\chi). \quad (5.8.3)$$

Let A be a group with a homomorphism $A \rightarrow Y$ and an action on M . Then the group A acts on $\mathcal{M}eas(Y, M)$ in two ways:

- A acts on $\mathcal{M}eas(Y, M)$ via its action on M ,
- A acts on $\mathcal{M}eas(Y, M)$ via the homomorphism $A \rightarrow Y$ and the translation of Y on itself.

Define

$$\mathcal{M}eas(Y, M)^\natural = \left\{ \begin{array}{l} p\text{-adic measures in } \mathcal{M}eas(Y, M) \text{ on which} \\ \text{the two actions of } A \text{ are compatible} \end{array} \right\}. \quad (5.8.4)$$

In our applications, Y will be taken to be $\Gamma_{\mathcal{K}}$ or $U_{\mathcal{K}, p} = 1 + p\mathcal{O}_{\mathcal{K}, p}$, A will be taken to be $\mathbb{Z}_p^\times \times \mathbb{Z}_p^\times$, which we identify with $\mathcal{O}_{\mathcal{K}, p}^\times$ via $(\varrho_p, \varrho_{\bar{p}})$, and M will be taken to be either $\hat{\mathcal{O}}_L^{\text{ur}}$ or spaces of *p*-adic forms on unitary groups. Next, we introduce the spaces of *p*-adic families of automorphic forms we will use.

5.8.1. *p*-adic families on $\text{GU}(3, 1)$

Define the tame level group

$$K_v = \left\{ g \in \text{GU}(3, 1)(\mathbb{Z}_v) : g \equiv \mathbf{1}_4 \pmod{q_v^{2c_v + \text{ord}_v(\mathfrak{s}\delta)}} \right\},$$

$$K_f^p = \bigotimes_{v \notin \Sigma \cup \{\infty, \ell, \ell', p\}} \text{GU}(3, 1)(\mathbb{Z}_v) \bigotimes_{v \in \Sigma \cup \{\ell, \ell'\}} K_v.$$

Let $V_{\text{GU}(3, 1)} = \varprojlim_m \varinjlim_n V_{n, m}$ (with $V_{n, m}$ defined in §2.6) of tame level K_f^p . In equation (5.8.4), put $Y = \Gamma_{\mathcal{K}}$, $A = \mathbb{Z}_p^\times \times \mathbb{Z}_p^\times$ with the homomorphism

$$A \simeq \mathcal{O}_{\mathcal{K}, p}^\times \xrightarrow{\text{natural embedding}} \mathcal{K}^\times \backslash \mathbb{A}_{\mathcal{K}}^\times \xrightarrow{\text{natural projection}} \Gamma_{\mathcal{K}} = Y, \quad (5.8.5)$$

and $M = V_{\mathrm{GU}(3,1), \xi}$, the component of $V_{\mathrm{GU}(3,1)}$ on which the kernel of equation (5.8.5) acts through the character $\xi_{p\text{-adic}}$. We make $(a_1, a_2) \in \mathbb{Z}_p^\times \times \mathbb{Z}_p^\times$ act on $V_{\mathrm{GU}(3,1), \xi}$ by the usual action of $\varrho_p^{-1} \begin{pmatrix} 1 & & & \\ & 1 & & \\ & & a_1 & \\ & & & a_2 \end{pmatrix} \in T_{\mathrm{so}}(\mathbb{Z}_p) \subset \mathrm{U}(3,1)(\mathbb{Z}_p)$ on $V_{\mathrm{GU}(3,1), \xi}$ multiplied by the scalar $\xi_{p\text{-adic}, p}^{-1}(a_1, a_2)$. (Here, ϱ_p^{-1} is the isomorphism in equation (5.4.5), and this action factors through the quotient of $\mathbb{Z}_p^\times \times \mathbb{Z}_p^\times$ by the kernel of equation (5.8.5).) Then we get

$$\mathrm{Meas}(\Gamma_{\mathcal{K}}, V_{\mathrm{GU}(3,1), \xi})^{\natural}, \quad (5.8.6)$$

the $\xi_{p\text{-adic}}$ -component of the space of p -adic families on $\mathrm{GU}(3,1)$. The compatibility of the two actions of $\mathbb{Z}_p^\times \times \mathbb{Z}_p^\times$ implies that the value at $\tau_{p\text{-adic}}$ of an element in equation (5.8.6) is a p -adic form with p -adic nebentypus

$$(\mathrm{triv}, \mathrm{triv}, (\xi\tau)_{p\text{-adic}, \mathfrak{p}}, (\xi\tau)_{p\text{-adic}, \mathfrak{p}}^{-1}).$$

(By saying p -adic nebentypus, we refer to the usual action of $\varrho_p^{-1} \begin{pmatrix} a_1 & * & * & * \\ & a_2 & * & * \\ & & a_3 & * \\ & & & a_4 \end{pmatrix} \in \mathrm{U}(3,1)(\mathbb{Z}_p)$ on $V_{\mathrm{GU}(3,1)}(\cdot)$.)

The base change to $\hat{\mathcal{O}}_L^{\mathrm{ur}}$ of the space (5.8.6) contains the subspace of semiordinary families:

$$\mathrm{Meas}(\Gamma_{\mathcal{K}}, e_{\mathrm{so}} V_{\mathrm{GU}(3,1), \xi} \hat{\otimes} \hat{\mathcal{O}}_L^{\mathrm{ur}})^{\natural}, \quad (5.8.7)$$

which is naturally equipped with an $\hat{\mathcal{O}}_L^{\mathrm{ur}}[[\Gamma_{\mathcal{K}}]]$ -module structure. The Klingen Eisenstein family we will construct belongs to this space. (It is tautological that an element in equation (5.8.7) gives rise to an element in $\xi_{p\text{-adic}}$ -component of $\mathcal{M}_{\mathrm{so}} \hat{\otimes}_{\mathbb{Z}_p} [[T_{\mathrm{so}}(\mathbb{Z}_p)]] \hat{\mathcal{O}}_L^{\mathrm{ur}}[[\Gamma_{\mathcal{K}}]] = \mathrm{Hom}_{\hat{\mathcal{O}}_L^{\mathrm{ur}}[[\Gamma_{\mathcal{K}}]]}(\mathcal{V}_{\mathrm{so}}^*, \hat{\mathcal{O}}_L^{\mathrm{ur}}[[\Gamma_{\mathcal{K}}]])$; see §8.1.)

5.8.2. p -adic families on $\mathrm{GU}(3,3)$

Let $V_{\mathrm{GU}(3,3)}$ be the space of p -adic forms on $\mathrm{GU}(3,3)$ defined by considering global sections of the structure sheaf on the Igusa towers for the Shimura variety of $\mathrm{GU}(3,3)$. We will construct a Siegel Eisenstein family in

$$\mathrm{Meas}(\Gamma_{\mathcal{K}}, V_{\mathrm{GU}(3,3)}).$$

5.8.3. p -adic families on $\mathrm{U}(2)$

For constructing the Klingen Eisenstein family, we use an automorphic form φ in the space (5.6.11), which is spherical at p and does not vary over the weight space. It is when analyzing the nondegenerate Fourier–Jacobi coefficients of our Klingen Eisenstein family that we need auxiliary p -adic families on $\mathrm{U}(2)$.

Let

$$N_p(\mathbb{Z}_p) = \left\{ g \in \mathrm{U}(2)(\mathbb{Z}_p) : \varrho_p(g) = \begin{pmatrix} * & * \\ 0 & 1 \end{pmatrix} \right\},$$

$$N'_p(\mathbb{Z}_p) = \left\{ g \in \mathrm{U}(2)(\mathbb{Z}_p) : \varrho_p(g) = \begin{pmatrix} 1 & * \\ 0 & * \end{pmatrix} \right\}.$$

We define the following two spaces of p -adic forms on $\mathrm{U}(2)$ of tame level $K_f'^p \cap \mathrm{U}(2)(\widehat{\mathbb{Z}}^{(p)})$:

$$V_{\mathrm{U}(2)} = \left\{ \text{continuous functions } \mathrm{U}(2)(\mathbb{Q}) \backslash \mathrm{U}(2)(\mathbb{A}_{\mathbb{Q},f}) / (K_f'^p \cap \mathrm{U}(2)(\widehat{\mathbb{Z}}^{(p)})) N_p(\mathbb{Z}_p) \rightarrow \mathcal{O}_L \right\},$$

$$V'_{\mathrm{U}(2)} = \left\{ \text{continuous functions } \mathrm{U}(2)(\mathbb{Q}) \backslash \mathrm{U}(2)(\mathbb{A}_{\mathbb{Q},f}) / (K_f'^p \cap \mathrm{U}(2)(\widehat{\mathbb{Z}}^{(p)})) N'_p(\mathbb{Z}_p) \rightarrow \mathcal{O}_L \right\},$$

and let $V_{U(2), \xi}$ (resp. $V'_{U(2), \xi^{-1}}$) denote the subspace of $V_{U(2)}$ (resp. $V'_{U(2)}$) on which the kernel of equation (5.8.5) acts through the character $(\text{triv}, \xi_{p\text{-adic}, p})$ (resp. $(\xi_{p\text{-adic}, p}^{-1}, \text{triv})$). We have the operator U_p acting on $F \in V_{U(2), \xi}$ (resp. $F \in V'_{U(2), \xi^{-1}}$) as

$$(U_p F)(g) = \sum_{x \in \mathbb{Z}/p\mathbb{Z}} F\left(g \varrho_p^{-1} \begin{pmatrix} p & x \\ & 1 \end{pmatrix}\right)$$

with ϱ_p^{-1} the isomorphism in equation (5.4.5). The ordinary projection is defined as $e_{\text{ord}} = \lim_{n \rightarrow \infty} U_p^{n!}$.

In equation (5.8.4), put $Y = \Gamma_K$, $A = \mathbb{Z}_p^\times \times \mathbb{Z}_p^\times$ with the homomorphism $A \rightarrow Y$ as in equation (5.8.5), and $M = V_{U(2), \xi}$ on which we make $(a_1, a_2) \in \mathbb{Z}_p^\times \times \mathbb{Z}_p^\times$ act by the right translation of $\varrho_p^{-1} \begin{pmatrix} 1 & \\ & a_1 \end{pmatrix}$ multiplied by the scalar $\xi_{p\text{-adic}, p}^{-1}(a_1)$. (This action factors through the quotient of $\mathbb{Z}_p^\times \times \mathbb{Z}_p^\times$ by the kernel of equation (5.8.5).) Then we get

$$\text{Meas}(\Gamma_K, V_{U(2), \xi})^{\natural}. \quad (5.8.8)$$

The evaluation at $\tau_{p\text{-adic}}$ of an element in equation (5.8.8) is a p -adic form on $U(2)$ with p -adic nebentypus

$$(\text{triv}, (\xi\tau)_{p\text{-adic}, p}).$$

The nondegenerate Fourier–Jacobi coefficients of our Klingen Eisenstein family are p -adic measures on Γ_K valued in p -adic Jacobi forms on $U(2)$. Pairing them with a fixed Jacobi form on $U(2)$ gives an element in equation (5.8.8). (See §7.6.)

We will also need to consider some auxiliary p -adic families which are p -adic measures on $U_{K,p} = 1 + p\mathcal{O}_{K,p}$ valued in $V_{U(2), \xi}$ and $V'_{U(2), \xi^{-1}}$. We will fix N , a power of p , such that raising to the N -th power maps Γ_K into $U_{K,p}$. (See §7.7.1 for an explanation why we need to consider $U_{K,p}$ and fix such an N .)

Put $Y = U_{K,p} = 1 + p\mathcal{O}_{K,p}$, $A = \mathbb{Z}_p^\times \times \mathbb{Z}_p^\times$ with the homomorphism

$$A = \mathbb{Z}_p^\times \times \mathbb{Z}_p^\times \xrightarrow{(5.8.5)} \Gamma_K \xrightarrow{N\text{-th power}} U_{K,p} = Y,$$

and $M = e_{\text{ord}} V_{U(2), \xi}$ (resp. $e_{\text{ord}} V'_{U(2), \xi^{-1}}$) in equation (5.8.4), on which we make $(a_1, a_2) \in A$ act through the right translation by $\varrho_p^{-1} \begin{pmatrix} 1 & \\ & a_1 \end{pmatrix}$ (resp. $\varrho_p^{-1} \begin{pmatrix} a_1^{-1} & \\ & 1 \end{pmatrix}$) multiplied by the scalar $\xi_{p\text{-adic}, p}^{-1}(a_1)$ (resp. $\xi_{p\text{-adic}, p}(a_1)$). Then we get

$$\text{Meas}(U_{K,p}, e_{\text{ord}} V_{U(2), \xi})^{\natural} \quad \left(\text{resp. } \text{Meas}(U_{K,p}, e_{\text{ord}} V'_{U(2), \xi^{-1}})^{\natural} \right). \quad (5.8.9)$$

For $\tau_{p\text{-adic}} \in \text{Hom}_{\text{cont}}(\Gamma_K, \overline{\mathbb{Q}_p^\times})$, the evaluation at $\tau_{p\text{-adic}}|_{U_{K,p}}$ of an element in equation (5.8.8) is a p -adic form on $U(2)$ with nebentypus

$$(\text{triv}, (\xi\tau^N)_{p\text{-adic}, p}) \quad \left(\text{resp. } (\xi\tau^N)_{p\text{-adic}, p}^{-1}, \text{triv} \right).$$

We will construct auxiliary CM families

$$\theta, \tilde{h}_3 \in \text{Meas}(U_{K,p}, e_{\text{ord}} V_{U(2), \xi})^{\natural}, \quad \tilde{\theta}_3, h \in \text{Meas}(U_{K,p}, e_{\text{ord}} V'_{U(2), \xi^{-1}})^{\natural},$$

in §7.7 and use them to study the nondegenerate Fourier–Jacobi coefficients of the Klingen Eisenstein family (which are elements in equation (5.8.8) and gives rise to measures on $U_{K,p}$ by the map (7.7.1).)

5.9. The p -adic family of Siegel Eisenstein series on $\mathrm{GU}(3, 3)$

We normalize the Siegel Eisenstein series $E^{\mathrm{Sieg}}(\cdot; f(s, \xi_0 \tau_0))|_{s=\frac{k-3}{2}}$ (with $f(s, \xi_0 \tau_0)$ chosen as in §5.7) as

$$E_{\xi\tau}^{\mathrm{Sieg}} = \left(\frac{2^{-6}(-2\pi i)^{3k}}{\pi^3 \prod_{j=0}^2 \Gamma(k-j)} \right)^{-1} d_3^{\Sigma \cup \{\infty, p, \ell, \ell'\}}(s, \xi_0 \tau_0) \cdot E^{\mathrm{Sieg}}(\cdot; f(s, \xi_0 \tau_0))|_{s=\frac{k-3}{2}}, \quad (5.9.1)$$

where

$$\begin{aligned} d_3^{\Sigma \cup \{\infty, p, \ell, \ell'\}}(s, \xi_0 \tau_0) &= \prod_{v \notin \Sigma \cup \{p, \ell, \ell'\}} d_{3,v}(s, \xi_0 \tau_0), \\ d_{3,v}(s, \xi_0 \tau_0) &= \prod_{j=1}^3 L_v \left(2s + j, \xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}} \eta_{\mathcal{K}/\mathbb{Q}}^{3-j} \right). \end{aligned} \quad (5.9.2)$$

Theorem 5.9.1. *There exists a p -adic measure $E^{\mathrm{Sieg}} \in \mathrm{Meas}(\Gamma_{\mathcal{K}}, V_{\mathrm{GU}(3,3)})$ such that*

$$E^{\mathrm{Sieg}}(\tau_{p\text{-adic}}) = E_{\xi\tau}^{\mathrm{Sieg}}$$

for all algebraic Hecke character $\tau : \mathcal{K}^\times \backslash \mathbb{A}_{\mathcal{K}}^\times \rightarrow \mathbb{C}^\times$ such that its p -adic avatar $\tau_{p\text{-adic}}$ factors through $\Gamma_{\mathcal{K}}$ and $\xi\tau$ has ∞ -type $(0, k)$ with $k \geq 6$ even.

Proof. The measure is constructed by interpolating the q -expansions of the $E_{\xi\tau}^{\mathrm{Sieg}}$'s. First, we record the formulas for the Fourier coefficients in [Wan20, §§6E-6H]. Given $\beta \in \mathrm{Her}_3(\mathcal{K})$ and $g \in \mathrm{GU}(3, 3)(\mathbb{A}_{\mathbb{Q}})$, let

$$W_{\beta,v}(g_v, f_v(s, \xi_0 \tau_0)) = \int_{\mathrm{Her}_3(\mathcal{K}_v)} f_v(s, \xi_0 \tau_0) \left(\begin{pmatrix} & -\mathbf{1}_3 \\ \mathbf{1}_3 & \end{pmatrix} \begin{pmatrix} \mathbf{1}_3 & \varsigma \\ 0 & \mathbf{1}_3 \end{pmatrix} g_v \right) \mathbf{e}_v(-\mathrm{Tr} \beta \varsigma) d\varsigma$$

(where $\mathbf{e}_v$ is the additive character in equation (1.0.5)), and

$$E_{\beta}^{\mathrm{Sieg}}(g; f(s, \xi_0 \tau_0)) = \int_{\mathrm{Her}_3(\mathcal{K} \backslash \mathbb{A}_{\mathcal{K}})} E^{\mathrm{Sieg}} \left(\begin{pmatrix} \mathbf{1}_3 & \varsigma \\ 0 & \mathbf{1}_3 \end{pmatrix} g; f(s, \xi_0 \tau_0) \right) \mathbf{e}_{\mathbb{A}_{\mathbb{Q}}}(-\mathrm{Tr} \beta \varsigma) d\varsigma.$$

Because the sections at $v \in \Sigma \cup \{\ell, \ell'\}$ are chosen to be supported on the big cell, for $g \in Q_{\mathrm{GU}(3,3)}(\mathbb{A}_{\mathbb{Q}})$, we have

$$E_{\beta}^{\mathrm{Sieg}}(g; f(s, \xi_0 \tau_0)) = \prod_v W_{\beta,v}(g_v, f_v(s, \xi_0 \tau_0)).$$

For our choice of $f_v(s, \xi_0 \tau_0)$ in §5.7, the formulas for $W_{\beta,v}(g_v, f_v(s, \xi_0 \tau_0))$ are as follows.

– *The Archimedean place.*

$$\begin{aligned} W_{\beta,\infty} \left(\begin{pmatrix} y & x^t \bar{y}^{-1} \\ 0 & {}^t \bar{y}^{-1} \end{pmatrix}; f_{\infty}(s, \xi_0 \tau_0) \right) \Big|_{s=\frac{k-3}{2}} \\ = \begin{cases} \frac{2^{-6}(-2\pi i)^{3k}}{\pi^3 \prod_{j=0}^2 \Gamma(k-j)} (\det \bar{y})^k \mathbf{e}_{\mathbb{R}}(\mathrm{Tr} \beta(x + i y^t \bar{y})) \cdot (\det \beta)^{k-3}, & \beta \in \mathrm{Her}_3(\mathcal{K})_{>0} \\ 0, & \text{otherwise.} \end{cases} \end{aligned}$$

– $v \notin \Sigma \cup \{p, \ell, \ell'\}$. For $\det \beta \neq 0$,

$$W_{\beta,v}(\text{diag}(A, D); f_v(s, \xi_0 \tau_0)) \Big|_{s=\frac{k-3}{2}} = \xi_{0,v} \tau_{0,v} (\det D) |\det AD^{-1}|_{\mathbb{Q}_v}^{-\frac{k}{2}+3} \cdot d_{3,v}(s, \xi_0 \tau_0)^{-1} \\ \times \mathbb{1}_{\text{Her}_3(\mathcal{O}_{\mathcal{K},v})^*}(D^{-1}\beta A) \cdot h_{v,D^{-1}\beta A}(\xi_{0,v}^{\mathbb{Q}} \tau_{0,v}^{\mathbb{Q}} (q_v)^{-k}),$$

where $h_{v,D^{-1}\beta A} \in \mathbb{Z}[X]$ is a monic polynomial depending only on v and $D^{-1}\beta A$, and is the constant polynomial when $D^{-1}\beta A$ belongs to $\text{GL}_3(\mathcal{O}_{\mathcal{K},v})$.

– $v \in \Sigma \cup \{\ell, \ell'\}$.

$$W_{\beta,v}(\text{diag}(A, D); f_v(s, \xi_0 \tau_0)) \Big|_{s=\frac{k-3}{2}} = |D_{\mathcal{K}/\mathbb{Q}}|_v^{3/2} \cdot \xi_{0,v} \tau_{0,v} (\det D) |\det AD^{-1}|_{\mathbb{Q}_v}^{-\frac{k}{2}+3} \\ \times \mathbb{1}_{\text{Her}_3(\mathcal{O}_{\mathcal{K},v})^*}(D^{-1}\beta A) \mathbf{e}_v \left(\frac{(D^{-1}\beta A)_{22} + (D^{-1}\beta A)_{33}}{q_v^{c_v}} \right).$$

– *The place p .* An easy computation shows that

$$W_{\beta,p}(\mathbf{1}_6; f_p^{\text{big-cell}}(-s, \xi_0^{-c} \tau_0^{-c})) \Big|_{s=\frac{k-3}{2}} = \mathcal{F}(\mathcal{F}^{-1} \alpha_{\xi\tau,p})(\beta) = \alpha_{\xi\tau,p}(\beta).$$

The functional equation for $W_{\beta,p}$ in [LR05, (14)] implies that

$$W_{\beta,p}(g; M_p(-s, \xi_0^{-c} \tau_0^{-c}) f_p^{\text{big-cell}}(-s, \xi_0^{-1} \tau_0^{-1})) \\ = c_{3,p}(-s, \xi_0^{-c} \tau_0^{-c}, \beta) \cdot W_{\beta,p}(g; f_p^{\text{big-cell}}(-s, \xi_0^{-c} \tau_0^{-c}))$$

with $c_{3,p}(-s, \xi_0^{-c} \tau_0^{-c}, \beta)$ defined as in equation (5.7.5). It follows that

$$W_{\beta,p}(\mathbf{1}; f_p(s, \xi_0 \tau_0)) \Big|_{s=\frac{k-3}{2}} = c_{\beta,p} \cdot (\xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})_p (\det \beta) |\det \beta|_{\mathbb{Q}_p}^{2s} \cdot \alpha_{\xi\tau,p}(\beta).$$

Denote by $E_{\xi\tau,\beta}^{\text{Sieg}}(\text{diag}(A, D))$ the β -th coefficient in the (p -adic) q -expansion of $E_{\xi\tau}^{\text{Sieg}}$ at the (0-dimensional) cusp indexed by $\text{diag}(A, D) \in \text{GU}(3, 3)(\mathbb{A}_{\mathcal{K},f}^p)$. From the above formulas for the local Fourier coefficients at the p and ∞ , we see that $E_{\xi\tau,\beta}^{\text{Sieg}}(\text{diag}(A, D))$ is nonzero only for β inside

$$\mathfrak{S}_3 = \left\{ \beta \in \text{Her}_3(\mathcal{O}_{\mathcal{K}})_{>0} : \varrho_p(\beta_{21}) \in \mathbb{Z}_p^\times, \begin{pmatrix} \varrho_p(\beta_{21}) & \varrho_p(\beta_{22}) \\ \varrho_p(\beta_{31}) & \varrho_p(\beta_{32}) \end{pmatrix} \in \text{GL}_2(\mathbb{Z}_p) \right\},$$

and for $\beta \in \mathfrak{S}_3$, combining the above formulas gives

$$E_{\xi\tau,\beta}^{\text{Sieg}}(\text{diag}(A, D)) = \text{a constant independent of } \tau \\ \times (\xi\tau)_{p\text{-adic}}(\det D) \prod_{v \notin \Sigma \cup \{p, \ell, \ell'\}} h_{v, \mathfrak{t} \tilde{A} \beta A}((\xi\tau)_{p\text{-adic},v}^{\mathbb{Q}}(q_v)), \quad (5.9.3) \\ \times (\xi\tau)_{p\text{-adic},p} \left(\det \begin{pmatrix} \beta_{21} & \beta_{22} \\ \beta_{31} & \beta_{32} \end{pmatrix}^{-1} \right) (\xi\tau)_{p\text{-adic},p}^{\mathbb{Q}}(\det \beta).$$

(Note that thanks to the condition that $\xi\tau$ has ∞ -type $(0, k)$, we have $(\xi\tau)_{p\text{-adic},p} = (\xi\tau)_p$ and $(\xi\tau)_{p\text{-adic}}|_{\mathcal{O}_{\mathcal{K},p}^\times} = \xi_0 \tau_0|_{\mathcal{O}_{\mathcal{K},p}^\times}$.)

The factors on the right-hand side of equation (5.9.3) are interpolated by δ -measures in $\text{Meas}(\Gamma_{\mathcal{K}}, \mathcal{O}_L)$. The convolution of those δ -measures gives an element in $\text{Meas}(\Gamma_{\mathcal{K}}, \mathcal{O}_L)$ which

interpolates the Fourier coefficient $E_{\xi\tau,\beta}^{\text{Sieg}}(\text{diag}(A, D))$. (See equations (5.8.1)(5.8.2)(5.8.3) for the definitions of δ -measures and the convolution of p -adic measures.) We see that there exists a p -adic measure

$$E^{\text{Sieg}} \in \text{Meas}\left(\Gamma_{\mathcal{K}}, \bigoplus_{p\text{-adic cusps}} \mathcal{O}_L[[\mathfrak{S}_3]]\right)$$

that interpolates the p -adic q -expansions of $E_{\xi\tau}^{\text{Sieg}}$. By the q -expansion principle and the fact that the $E_{\xi\tau}^{\text{Sieg}}$'s are automorphic forms on $\text{GU}(3, 3)$, we deduce that E^{Sieg} belongs to $\text{Meas}(\Gamma_{\mathcal{K}}, V_{\text{GU}(3,3)})$. (Here, we view the space of p -adic measures valued in $V_{\text{GU}(3,3)}$ as a subspace of the space of p -adic measures valued in copies of $\mathcal{O}_L[[\mathfrak{S}]]$ via the embedding of $V_{\text{GU}(3,3)}$ into the $\mathcal{O}_L$ -module of q -expansions.) $\square$

5.10. The semiordinary family of Klingen Eisenstein series

Let $E_{\xi\tau}^{\text{Sieg}}|_{\text{GU}(3,1) \times \text{GU}(2)}$ be the automorphic form obtained by the composition of the restriction from $\text{GU}(3, 3)$ to $\text{GU}(3, 1) \times_{\mathbb{G}_m} \text{GU}(2)$ via the embedding (5.5.1) and the extension by zero from $\text{GU}(3, 1) \times_{\mathbb{G}_m} \text{GU}(2)$ to $\text{GU}(3, 1) \times \text{GU}(2)$. Define the twist $E_{\xi\tau}^{\text{Sieg}}|_{\text{GU}(3,1) \times \text{GU}(2)}^{\star}$ as

$$E_{\xi\tau}^{\text{Sieg}}|_{\text{GU}(3,1) \times \text{GU}(2)}^{\star}(g_1, g_2) = E_{\xi\tau}^{\text{Sieg}}|_{\text{GU}(3,1) \times \text{GU}(2)}(g_1, g_2) \cdot \xi_{p\text{-adic}}^{-1} \tau_{p\text{-adic}}^{-1}(\det g_2).$$

Then by our choice of the section $f_p(s, \xi_0 \tau_0)$, we see that

$$E_{\xi\tau}^{\text{Sieg}}|_{\text{GU}(3,1) \times \text{GU}(2)}^{\star} \in V_{\text{GU}(3,1), \xi} \otimes M_{\text{GU}(2)}\left(K_f'^p K'_{p,0}; \hat{\mathcal{O}}_L^{\text{ur}}\right)$$

with $K'_{p,0} = \left\{g \in \text{GU}(2)(\mathbb{Z}_p) : \varrho_{\mathfrak{p}}(g) = \begin{pmatrix} * & * \\ p* & * \end{pmatrix}\right\}$. (Note that $K'_{p,0}$ equals the $K'_{p,g}$ in equation (4.4.1).

See equation (5.6.8) for the definition of $M_{\text{GU}(2)}\left(K_f'^p K'_{p,0}; \hat{\mathcal{O}}_L^{\text{ur}}\right)$.

Therefore, by applying a twist of $(\xi\tau)_{p\text{-adic}}^{-1} \circ \det$ to the family $E^{\text{Sieg}}|_{\text{GU}(3,1) \times \text{GU}(2)}$ on the second factor, we obtain the p -adic family

$$E_{\xi\tau}^{\text{Sieg}}|_{\text{GU}(3,1) \times \text{GU}(2)}^{\star} \in \text{Meas}\left(\Gamma_{\mathcal{K}}, V_{\text{GU}(3,1), \xi}^{\mathfrak{h}} \widehat{\otimes} M_{\text{GU}(2)}\left(K_f'^p K'_{p,0}; \hat{\mathcal{O}}_L^{\text{ur}}\right)\right) \quad (5.10.1)$$

interpolating $E_{\xi\tau}^{\text{Sieg}}|_{\text{GU}(3,1) \times \text{GU}(2)}^{\star}$ when τ varies. (To see that it belongs to the $\mathfrak{h}$ -subspace, one just needs to check the nebentypus.)

Attached to a φ in the space (5.6.11) is a linear functional

$$\begin{aligned} \langle \cdot, \varphi \rangle : M_{\text{GU}(2)}\left(K_f'^p K'_{p,0}; \hat{\mathcal{O}}_L^{\text{ur}}\right) &\longrightarrow \hat{\mathcal{O}}_L^{\text{ur}} \\ \varphi' &\longmapsto \langle \varphi', \varphi \rangle = \int_{\text{GU}(2)(\mathbb{Q}) \backslash \text{GU}(2)(\mathbb{A}_{\mathbb{Q},f})} \varphi'(g) \varphi(g) dg, \end{aligned}$$

where the integral is understood as a sum over the finite set $\text{GU}(2)(\mathbb{Q}) \backslash \text{GU}(2)(\mathbb{A}_{\mathbb{Q},f}) / K_f'^p K'_{p,0}$. Applying the linear functional $\langle \cdot, \varphi \rangle$ to equation (5.10.1) gives a family

$$E_{\varphi}^{\text{Kling}} = \left\langle E_{\xi\tau}^{\text{Sieg}}|_{\text{GU}(3,1) \times \text{GU}(2)}^{\star}, \varphi \right\rangle \in \text{Meas}\left(\Gamma_{\mathcal{K}}, V_{\text{GU}(3,1), \xi}^{\mathfrak{h}} \widehat{\otimes} \hat{\mathcal{O}}_L^{\text{ur}}\right)^{\mathfrak{h}} \otimes_{\mathbb{Z}} \mathbb{Q}. \quad (5.10.2)$$

Proposition 5.10.1. For $\tau_{p\text{-adic}}$ satisfying the conditions in Theorem 5.9.1, the evaluation of the family E_φ^{Kling} at $\tau_{p\text{-adic}}$ is a Klingen Eisenstein series on $\text{GU}(3, 1)$ inducing $\xi_0\tau_0|\cdot|^{\frac{k-3}{2}}\boxtimes\pi^{\text{GU}(2)}$, more precisely, the automorphic form

$$g \mapsto \int_{\text{U}(2)(\mathbb{Q}) \backslash \text{U}(2)(\mathbb{A}_{\mathbb{Q}})/\text{U}(2)(\mathbb{R})} E^{\text{Sieg}}(\iota(g, g_2); f(s, \xi_0\tau_0))\varphi(g_2)(\xi_0\tau_0)^{-1}(\det g_2) dg_2 \Big|_{s=\frac{k-3}{2}} \quad (5.10.3)$$

normalized by the factor in equation (5.9.1).

Moreover, $E_\varphi^{\text{Kling}} \in \text{Meas}\left(\Gamma_{\mathcal{K}}, e_{\text{so}}V_{\text{GU}(3,1)}, \xi \widehat{\otimes} \hat{\mathcal{O}}_L^{\text{ur}}\right)^{\natural} \otimes_{\mathbb{Z}} \mathbb{Q}$, that is, is a semiordinary family.

Proof. From the construction of the family E_φ^{Kling} , it is easy to see that its evaluation $\tau_{p\text{-adic}}$ satisfying the conditions in Theorem 5.9.1 equals the form given in equation (5.10.3) normalized by the factor in equation (5.9.1). By the doubling method formula (Theorem 5.5.1), we know that equation (5.10.3) is a Klingen Eisenstein series inducing $\xi_0\tau_0|\cdot|^{\frac{k-3}{2}}\boxtimes\pi^{\text{GU}(2)}$.

In order to show that E_φ^{Kling} is a semiordinary family, for all τ satisfying the conditions in Theorem 5.9.1 and $(\xi\tau)_p$ ramified, we look at the action of $\mathbb{U}_p$ -operators on the form (5.10.3), which has weight $(0, 0, 0; k)$. Given integers $m, m', m'' \geq 0$, by the formula for adelic $\mathbb{U}_p$ -operators in equation (2.8.8) and our choice of the local section at p in §5.7, the action of $(U_{p,2}^+)^m(U_{p,3}^+)^{m'}(U_{p,1}^-)^{m''}$ on the form (5.10.3) can be computed by considering

$$p^{2m+km''} \int_{N(\mathbb{Z}_p)} f_p^{\text{big-cell}}\left(\frac{3-k}{2}, (\xi_0\tau_0)^{-c}\right) \left(gu \begin{pmatrix} p^{m+m'} & & & \\ & p^{m+m'} & & \\ & & p^{m'} & \\ & & & p^{-m''} \\ & & & & 1 \\ & & & & & 1 \end{pmatrix} \right) du, \quad (5.10.4)$$

where we identify $\text{U}(3, 3)(\mathbb{Q}_p)$ with $\text{GL}_6(\mathbb{Q}_p)$ via $\varrho_p: \mathcal{K} \otimes_{\mathbb{Q}} \mathbb{Q}_p \rightarrow \mathbb{Q}_p$. Writing $g = \begin{pmatrix} A & B \\ C & D \end{pmatrix}$ in 3×3 blocks, we have

$$\begin{aligned} (5.10.4) &= p^{2m+km''} \cdot \left((\xi\tau)_p(p)p^3 \right)^{2m+3m'} \left((\xi\tau)_{\bar{p}}(p)p^3 \right)^{m''} \\ &\quad \times p^{-4m-3m'-3m''} \sum_{u_1, u_2 \in \mathbb{Z}/p^{m'}\mathbb{Z}} \sum_{\substack{v_1, v_2 \in \mathbb{Z}/p^{m+m'+m''}\mathbb{Z} \\ v_3 \in \mathbb{Z}/p^{m'+m''}\mathbb{Z}}} \\ &\quad \left(\mathcal{F}^{-1} \alpha_{\xi\tau, p} \right) \left(\begin{pmatrix} p^{-m-m'} & & \\ & p^{-m-m'} & \\ & & p^{-m'} \end{pmatrix} \begin{pmatrix} 1 & -u_1 & \\ & 1 & -u_2 \\ & & 1 \end{pmatrix} \left(C^{-1}D + \begin{pmatrix} v_1 & 0 & 0 \\ v_2 & 0 & 0 \\ v_3 & 0 & 0 \end{pmatrix} \right) \begin{pmatrix} p^{-m''} & & \\ & 1 & \\ & & 1 \end{pmatrix} \right). \end{aligned} \quad (5.10.5)$$

A direct computation by using the formula (5.7.2) shows that when $(\xi\tau)_p$ is ramified

$$\begin{aligned} &\sum_{u_1, u_2} \sum_{v_1, v_2, v_3} \left(\mathcal{F}^{-1} \alpha_{\xi\tau, p} \right) \left(\begin{pmatrix} p^{-m-m'} & & \\ & p^{-m-m'} & \\ & & p^{-m'} \end{pmatrix} \begin{pmatrix} 1 & -u_1 & \\ & 1 & -u_2 \\ & & 1 \end{pmatrix} \left(C^{-1}D + \begin{pmatrix} v_1 & 0 & 0 \\ v_2 & 0 & 0 \\ v_3 & 0 & 0 \end{pmatrix} \right) \begin{pmatrix} p^{-m''} & & \\ & 1 & \\ & & 1 \end{pmatrix} \right) \\ &= p^{2m} \left(\mathcal{F}^{-1} \alpha_{\xi\tau, p} \right) \left(C^{-1}D \begin{pmatrix} 1 & & \\ & p^{-m-m'} & \\ & & p^{-m-m'} \end{pmatrix} \right). \end{aligned} \quad (5.10.6)$$

Combining equations (5.10.5) and (5.10.6), we obtain

$$\begin{aligned}
 (5.10.4) &= p^{6m+6m'} (\xi\tau)_p(p)^{2m+3m'} \left((\xi\tau)_{\bar{p}}(p)p^k \right)^{m''} \cdot \left((\xi\tau)_{\bar{p}}(p)p^3 \right)^{-2m-2m'} \\
 &\quad \times f_p^{\text{big-cell}} \left(\frac{3-k}{2}, (\xi_0\tau_0)^{-c} \right) \left(g \begin{pmatrix} 1_4 & \\ & p^{-m-m'} \cdot 1_2 \end{pmatrix} \right), \\
 &= (\xi\tau)_p(p)^{m'} \left((\xi\tau)_{\bar{p}}(p)p^k \right)^{m''} \cdot (\xi\tau)_{\bar{p}}(\xi\tau)_p^{-1}(p)^{-2m-2m'} \\
 &\quad \times f_p^{\text{big-cell}} \left(\frac{3-k}{2}, (\xi_0\tau_0)^{-c} \right) \left(g \begin{pmatrix} 1_4 & \\ & p^{-m-m'} \cdot 1_2 \end{pmatrix} \right),
 \end{aligned}$$

and the corresponding Siegel Eisenstein series paired with $\varphi \cdot (\xi_0\tau_0)^{-1} \circ \det$ over $U(2)$ gives

$$(\xi\tau)_p(p)^{m'} \left((\xi\tau)_{\bar{p}}(p)p^k \right)^{m''} \cdot \text{the automorphic form given in equation (5.10.3)}.$$

Here, we use the condition that φ has trivial central character. Both $(\xi\tau)_p(p)$ and $(\xi\tau)_{\bar{p}}(p)p^k$ are p -adic units, so the form (5.10.3) is an eigenvector for the action of $(U_{p,2}^+)^m (U_{p,3}^+)^{m'} (U_{p,1}^-)^{m''}$ with eigenvalue a p -adic unit. This shows that the evaluations of the Klingen Eisenstein family E_φ^{Kling} at all τ satisfying the conditions in Theorem 5.9.1 with $(\xi\tau)_p$ ramified are semiordinary. Hence, E_φ^{Kling} is semiordinary. $\square$

6. The degenerate Fourier–Jacobi coefficients of the Klingen family

This section is devoted to proving Theorem 6.1.1, which states that the degenerate Fourier–Jacobi coefficients of E_φ^{Kling} are divisible by the p -adic L -function attached to $\text{BC}(\pi)$.

6.1. The divisibility of the degenerate Fourier–Jacobi coefficients by p -adic L -functions

Given a cusp label $g \in C(K_f^P)$, we have the map

$$\Phi_g : \text{Meas} \left(\Gamma_{\mathcal{K}}, e_{\text{so}} V_{\text{GU}(3,1)}, \xi \widehat{\otimes} \hat{\mathcal{O}}_L^{\text{ur}} \right)^{\natural} \longrightarrow \text{Meas} \left(\Gamma_{\mathcal{K}}, M_{\text{GU}(2)} \left(K_{f,g}'^P K_{p,0}' ; \hat{\mathcal{O}}_L^{\text{ur}} \right) \right),$$

(which corresponds to the map Φ_g in the fundamental exact sequence in part (4) of Theorem 2.9.1). Here, $K_{f,g}'^P$ is an open subgroup of $\text{GU}(2)(\widehat{\mathbb{Z}}^{(P)})$ depending on the cusp label $g \in C(K_f^P)$. Applying it to our Klingen Eisenstein family E_φ^{Kling} , we get

$$\Phi_g \left(E_\varphi^{\text{Kling}} \right) \in \text{Meas} \left(\Gamma_{\mathcal{K}}, M_{\text{GU}(2)} \left(K_{f,g}'^P K_{p,0}' ; \hat{\mathcal{O}}_L^{\text{ur}} \right) \right) \otimes_{\mathbb{Z}} \mathbb{Q}.$$

Evaluating it at $g' \in \text{GU}(2)(\mathbb{A}_{\mathbb{Q},f})$ gives

$$\Phi_g \left(E_\varphi^{\text{Kling}} \right) (g') \in \text{Meas} \left(\Gamma_{\mathcal{K}}, \hat{\mathcal{O}}_L^{\text{ur}} \right) \otimes_{\mathbb{Z}} \mathbb{Q} \simeq \hat{\mathcal{O}}_L^{\text{ur}} [[\Gamma_{\mathcal{K}}]] \otimes_{\mathbb{Z}} \mathbb{Q}.$$

By the work of Kubota–Leopoldt on p -adic L -functions for Dirichlet characters, there exists a (unique) p -adic L -function $\mathcal{L}_{\xi,\mathbb{Q}}^{\Sigma \cup \{\ell, \ell'\}} \in \hat{\mathcal{O}}_L^{\text{ur}} [[\Gamma_{\mathcal{K}}]]$ satisfying the interpolation property:

$$\mathcal{L}_{\xi,\mathbb{Q}}^{\Sigma \cup \{\ell, \ell'\}}(\tau_{p\text{-adic}}) = \frac{\Gamma(k-2)}{(2\pi i)^{k-2}} \cdot \gamma_p \left(3-k, (\xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})^{-1} \right) \cdot L^{\Sigma \cup \{\infty, p, \ell, \ell'\}} \left(k-2, \xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}} \right) \quad (6.1.1)$$

for all algebraic Hecke character $\tau : \mathcal{K}^\times \backslash \mathbb{A}_{\mathcal{K}}^\times \rightarrow \mathbb{C}^\times$ such that $\tau_{p\text{-adic}}$ factors through $\Gamma_{\mathcal{K}}$ and $\tau_\infty^{\mathbb{Q}} = \text{sgn}^k | \cdot |_R^k$.

By [EW16] (and the Archimedean computation in [EL]), there exists a (unique) p -adic L -function $\mathcal{L}_{\pi, \mathcal{K}, \xi}^{\Sigma \cup \{\ell, \ell'\}} \in \hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_{\mathcal{K}}]] \otimes_{\mathbb{Z}} \mathbb{Q}$ satisfying the interpolation property: for all algebraic Hecke character $\tau : \mathcal{K}^\times \backslash \mathbb{A}_{\mathcal{K}}^\times \rightarrow \mathbb{C}^\times$ such that $\tau_{p\text{-adic}}$ factors through $\Gamma_{\mathcal{K}}$ and $\xi\tau$ has ∞ -type (k_1, k_2) with $k_1, k_2 \in \mathbb{Z}$, $k_1 \leq 0, k_2 \geq 2 - k_1$,

$$\begin{aligned} & \mathcal{L}_{\pi, \mathcal{K}, \xi}^{\Sigma \cup \{\ell, \ell'\}}(\tau_{p\text{-adic}}) \\ &= \left(\frac{\Omega_p}{\Omega_\infty} \right)^{2(k_2 - k_1)} \frac{\Gamma(k_2)\Gamma(k_2 - 1)}{(2\pi i)^{2k_2 - 1}} \cdot \gamma_p \left(\frac{3 - (k_1 + k_2)}{2}, \pi_p^\vee \times (\xi_0 \tau_0)^{-1} \right) \\ & \quad \times L^{\Sigma \cup \{\infty, p, \ell, \ell'\}} \left(\frac{k_1 + k_2 - 1}{2}, \text{BC}(\pi) \times \xi_0 \tau_0 \right). \end{aligned} \quad (6.1.2)$$

Theorem 6.1.1. Suppose that φ belongs to the space (5.6.11). Then for all cusp labels $g \in C(K_f^p)$ and $g' \in \text{GU}(2)(\mathbb{A}_{\mathbb{Q}, f})$, we have

$$\left(\Phi_g \left(E_\varphi^{\text{Kling}} \right) (g') \right) \subset \left(\mathcal{L}_{\xi, \mathbb{Q}}^{\Sigma \cup \{\ell, \ell'\}} \mathcal{L}_{\pi, \mathcal{K}, \xi}^{\Sigma \cup \{\ell, \ell'\}} \right)$$

in $\hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_{\mathcal{K}}]] \otimes_{\mathbb{Z}} \mathbb{Q}$.

Proof. For τ as in Theorem 5.9.1, that is, $\tau_{p\text{-adic}}$ factoring through $\Gamma_{\mathcal{K}}$ and $\xi\tau$ has ∞ -type $(0, k)$ with $k \geq 6$ (even), let $E_{\varphi, \xi\tau}^{\text{Kling}}$ be the classical Klingen Eisenstein series whose corresponding p -adic form is $E_\varphi^{\text{Kling}}(\tau_{p\text{-adic}})$. The theorem is proved by computing $\Phi_g \left(E_\varphi^{\text{Kling}} \right) (\tau_{p\text{-adic}})$ with

$$g = k_{\Sigma, \ell, \ell'} = \bigotimes_{v \in \Sigma \cup \{\ell, \ell'\}} k_v, \quad k_v \in \text{U}(3, 1)(\mathbb{Z}_v).$$

The value of $\Phi_g \left(E_\varphi^{\text{Kling}} \right) (\tau_{p\text{-adic}})$ at $g' \in \text{GU}(2)(\mathbb{A}_{\mathbb{Q}})$ is the 0-th Fourier–Jacobi coefficient of the $E_{\varphi, \xi\tau}^{\text{Kling}}$ at

$$x = \begin{pmatrix} 1 & & \\ & g' & \\ & & \nu(g') \end{pmatrix} k_{\Sigma_f, \ell, \ell'} w_{3, p}$$

multiplied by $\left(\frac{\Omega_p}{\Omega_\infty} \right)^{2k}$, where $w_{3, p} \in \text{U}(3, 1)(\mathbb{Q}_p)$ is defined by

$$\mathcal{Q}_p(w_{3, p}) = \begin{pmatrix} & & 1 \\ & 1 & \\ 1 & & \\ & & 1 \end{pmatrix}.$$

Note that $w_{3, p} \in \text{U}(3, 1)(\mathbb{Q}_p)$ is also our fixed element in $P_{\mathbb{D}}^b(\mathbb{Z}_p)$ for obtaining the isomorphism (4.4.7).

By the description of $E_\varphi^{\text{Kling}}(\tau_{p\text{-adic}})$ in equation (5.10.3) and the doubling method formula (Theorem 5.5.1), we have

$$E_{\varphi, \xi\tau}^{\text{Kling}}(x) = \frac{\text{normalization factor}}{\text{on the RHS of equation (5.9.1)}} \cdot E^{\text{Kling}}(x; F(f(s, \xi_0 \tau_0), \varphi)) \Big|_{s=\frac{k-3}{2}}$$

with $F(f(s, \xi_0 \tau_0), \varphi)$ the section in $I_{P_{\mathrm{GU}(3,1)}}(s, \xi_0 \tau_0)$ given by

$$\begin{aligned} F(f(s, \tau_0), \varphi)(x) &= \int_{\mathrm{U}(2)(\mathbb{A}_{\mathbb{Q}})} f(s, \xi_0 \tau_0)(\iota(x, g_1 t)) \varphi(g_1 t)(\xi_0 \tau_0)^{-1} (\det g_1 t) dg_1 \\ &= \int_{\mathrm{U}(2)(\mathbb{A}_{\mathbb{Q}})} f(s, \xi_0 \tau_0) \left(\iota \left(k_{\Sigma_f, \ell, \ell'} w_{3,p}, g_1 \right) \right) \varphi(g' g_1)(\xi_0 \tau_0)^{-1} (\det g_1) dg_1, \end{aligned}$$

where t is an element in $\mathrm{GU}(2)(\mathbb{A}_{\mathbb{Q}})$ with $\nu(t) = \nu(x)$. What we need to compute is

$$\int_{U_{P_{\mathrm{GU}(3,1)}}(\mathbb{Q}) \backslash U_{P_{\mathrm{GU}(3,1)}}(\mathbb{A}_{\mathbb{Q}})} E^{\mathrm{Kling}}(ux; F(f(s, \xi_0 \tau_0), \varphi)) du. \quad (6.1.3)$$

It follows from [MW94, II.1.7] that

$$(6.1.3) = F(f(s, \xi_0 \tau_0), \varphi)(x) + M_{P_{\mathrm{GU}(3,1)}}(s, \xi_0 \tau_0) F(f(s, \xi_0 \tau_0), \varphi)(x).$$

The Archimedean computation in [Wan15, Corollary 5.11] shows that for our choice of $f_{\infty}(s, \xi_0 \tau_0)$ in §5.7 and $k \geq 6$,

$$M_{P_{\mathrm{GU}(3,1)}}(s, \xi_0 \tau_0) F(f(s, \xi_0 \tau_0), \varphi) \Big|_{s=\frac{k-3}{2}} = 0. \quad (6.1.4)$$

We reduce to compute $F(f(s, \xi_0 \tau_0), \varphi)(x)$. Take arbitrary $\varphi' \in \bar{\pi}^{\mathrm{GU}(2)}$ spherical away from $\Sigma \cup \{\ell, \ell'\}$ and factorizable with respect to an isomorphism $\bar{\pi}^{\mathrm{GU}(2)} \simeq \bigotimes_v \bar{\pi}_v^{\mathrm{GU}(2)}$. Put

$$\begin{aligned} &\langle F(f(s, \xi_0 \tau_0), \varphi)(\cdot k_{\Sigma_f, \ell, \ell'} w_{3,p}), \varphi' \rangle \\ &= \int_{\mathrm{GU}(2)(\mathbb{Q}) Z_{\mathrm{GU}(2)}(\mathbb{A}_{\mathbb{Q}}) \backslash \mathrm{GU}(2)(\mathbb{A}_{\mathbb{Q}})} F(f(s, \xi_0 \tau_0), \varphi)(g' k_{\Sigma, \ell, \ell'} w_{3,p}) \varphi'(g') dg'. \end{aligned}$$

Then we have

$$\begin{aligned} &\langle F(f(s, \xi_0 \tau_0), \varphi)(\cdot k_{\Sigma, \ell, \ell'} w_{3,p}), \varphi' \rangle \\ &= \prod_{v \notin \Sigma \cup \{p, \ell, \ell'\}} Z_v(f_v(s, \xi_0 \tau_0), \mathbf{1}_4, \varphi_v, \varphi'_v) \\ &\quad \times \prod_{v \in \Sigma \cup \{\ell, \ell'\}} Z_v(f_v(s, \xi_0 \tau_0), k_v, \varphi_v, \varphi'_v) \cdot Z_p(f_p(s, \xi_0 \tau_0), w_{3,p}, \varphi_p, \varphi'_p), \end{aligned}$$

where for $g_v \in \mathrm{GU}(3, 1)(\mathbb{Q}_v)$,

$$\begin{aligned} &Z_v(f_v(s, \xi_0 \tau_0), g_v, \varphi_v, \varphi'_v) \\ &= \int_{\mathrm{U}(2)(\mathbb{Q}_v)} f_v(s, \xi_0 \tau_0)(\iota(g_v, g_1))(\xi_0 \tau_0)_v^{-1} (\det g_1) \left\langle \pi_v^{\mathrm{GU}(2)}(g_1) \varphi_v, \varphi'_v \right\rangle dg_1. \end{aligned} \quad (6.1.5)$$

The restriction of $f_v(s, \xi_0 \tau_0)(\cdot \iota(g_v, \mathbf{1}_2))$ to $\mathrm{U}(2, 2)(\mathbb{Q}_v)$ is a section in the degenerate principal series of $\mathrm{U}(2, 2)(\mathbb{Q}_v)$ inducing $\xi_0 \tau_0| \cdot |_{\mathbb{A}_{\mathcal{K}}}^{s+\frac{1}{2}}$. Hence, the integral (6.1.5) is essentially a doubling zeta integral. We have the following formulas.

– *The Archimedean place.*

$$Z_{\infty}(f_{\infty}(s, \xi_0 \tau_0), \mathbf{1}_4, \varphi_{\infty}, \varphi'_{\infty}) = \langle \varphi_{\infty}, \varphi'_{\infty} \rangle$$

because $f_{\infty}(s, \xi_0 \tau_0)(\iota(\mathbf{1}_4, \cdot), \varphi_{\infty}, \varphi'_{\infty})$ are all invariant under $\mathrm{U}(2)(\mathbb{R})$.

– $v \notin \Sigma \cup \{\ell, \ell', p\}$.

$$Z_v(f_v(s, \xi_0 \tau_0), \mathbf{1}_4, \varphi_v, \varphi'_v) = d_{2,v} \left(s + \frac{1}{2}, \xi_0 \tau_0 \right)^{-1} \cdot L_v(s+1, \text{BC}(\pi) \times \xi_0 \tau_0)$$

with

$$d_{2,v}(s, \xi_0 \tau_0) = \prod_{j=1}^2 L_v(2s+1+j, \xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}} \eta_{\mathcal{K}/\mathbb{Q}}^{2-j}).$$

This follows from the standard formula for unramified local doubling zeta integrals [LR05, Proposition 3, Remark 3].

– $v \in \Sigma \cup \{\ell, \ell'\}$. By [Wan20, Lemma 6.20] or an easy direct computation, one can see that for φ in the space (5.6.11),

$$Z_v(f_v(s, \xi_0 \tau_0), k_v, \varphi_v, \varphi'_v) = 0, \quad \text{if } k_v \notin P_{\text{U}(3,1)}(\mathbb{Z}_v) \begin{pmatrix} & 1 \\ \mathbf{1}_2 & \\ & -1 \end{pmatrix} P_{\text{U}(3,1)}(\mathbb{Z}_v),$$

and for k_v such that $Z_v(f_v(s, \xi_0 \tau_0), k_v, \varphi_v, \varphi'_v) \neq 0$,

$$Z_v(f_v(s, \xi_0 \tau_0), k_v, \varphi_v, \varphi'_v) = \text{vol}(\mathfrak{Y}_{c_v}) \cdot \left((\xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})_v(q_v) |q_v|_v^{s+\frac{3}{2}} \right)^{-c_v} \langle \varphi_v, \varphi'_v \rangle,$$

where $\mathfrak{Y}_{c_v}$ is an open subgroup of $\{k'_v \in \text{U}(2)(\mathbb{Z}_v) : k'_v \equiv \mathbf{1}_2 \pmod{q_v^{c_v}}\}$, and c_v is the positive integer in the definition of $f_v(s, \xi_0 \tau_0)$ in equation (5.7.1).

– The place p .

$$Z_p(f_p(s, \xi_0 \tau_0), w_{3,p}, \varphi_p, \varphi'_p) = \gamma_p(-2s, (\xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})^{-1}) \gamma_p(-s, \pi_p \times (\xi_0 \tau_0)^{-1}_{\mathfrak{p}}) \langle \varphi_p, \varphi'_p \rangle. \quad (6.1.6)$$

See §6.2 for the computation. Note that we only need the value at $w_{3,p} \in \text{GU}(3,1)(\mathbb{Q}_p)$ rather than a general $k_p \in \text{GU}(3,1)(\mathbb{Z}_p)$. This significantly simplifies the computation. The value at a general $k_p \in \text{GU}(3,1)(\mathbb{Z}_p)$ can be difficult to compute since intertwining operators are not easy to compute completely.

Combining the local formulas, since φ' is arbitrary, we see that for τ as in Theorem 5.9.1, $F(f(s, \xi_0 \tau_0), \varphi)(x)|_{s=\frac{k-3}{2}}$ is either 0 or equals

$$d_3^{\Sigma \cup \{\infty, p, \ell, \ell'\}}(s, \xi_0 \tau_0)^{-1} \cdot C_{\Sigma \cup \{\ell, \ell'\}} \cdot \gamma_p(-2s, (\xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})^{-1}) L^{\Sigma \cup \{\infty, p, \ell, \ell'\}}(2s+1, \xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}}) \\ \times \gamma_p(-s, \pi_p \times (\xi_0 \tau_0)^{-1}_{\mathfrak{p}}) L^{\Sigma \cup \{\infty, \ell, \ell', p\}}(s+1, \text{BC}(\pi) \times \xi_0 \tau_0) \Big|_{s=\frac{k-3}{2}} \cdot \varphi(g')$$

for some $C_{\Sigma \cup \{\ell, \ell'\}} \in L$ independent of τ . Combining this formula with the normalization (5.9.1), we see that at all $\tau_{a\text{-adic}}$ as in Theorem 5.9.1, if $\Phi_g(E_{\varphi}^{\text{Kling}})(g')$ is nonzero, then its value agree with the value of $C_{\Sigma \cup \{\ell, \ell'\}} \cdot \mathcal{L}_{\xi, \mathbb{Q}}^{\Sigma \cup \{\ell, \ell'\}} \mathcal{L}_{\pi, \mathcal{K}, \xi}^{\Sigma \cup \{\ell, \ell'\}}$. Evaluations at these $\tau_{p\text{-adic}}$'s uniquely determine elements in $\hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_{\mathcal{K}}]] \otimes_{\mathbb{Z}} \mathbb{Q}$. Therefore, $\Phi_g(E_{\varphi}^{\text{Kling}})(g')$ is either 0 or equals $C_{\Sigma \cup \{\ell, \ell'\}} \cdot \mathcal{L}_{\xi, \mathbb{Q}}^{\Sigma \cup \{\ell, \ell'\}} \mathcal{L}_{\pi, \mathcal{K}, \xi}^{\Sigma \cup \{\ell, \ell'\}}$, and in particular the desired divisibility holds in $\hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_{\mathcal{K}}]] \otimes_{\mathbb{Z}} \mathbb{Q}$. $\square$

6.2. The computation of local zeta integrals at p

The ramification conditions in [Wan20, Definition 6.30] on $\xi_{0,p}\tau_{0,p}$ and the characters from which π_p is induced are not satisfied in our case here because our π_p is unramified. Those conditions are used in *loc.cit* to simplify the computation involving the intertwining operators. Here, we use the functional equation for doubling zeta integrals to handle the intertwining operator and compute $Z_p\left(f_p(s, \xi_0\tau_0), w_{3,p}, \varphi_p, \varphi'_p\right)$.

Proof of equation (6.1.6). Inside the degenerate principal series on $\mathrm{GU}(2, 2)(\mathbb{Q}_p)$ inducing the character $(\xi_0\tau_0)_p^{-c}|\cdot|^{-s}$, we define the section $f_p^{\mathrm{U}(2,2)}(-s, (\xi_0\tau_0)^{-c})$ as

$$\begin{aligned} f_p^{\mathrm{U}(2,2)}(-s, (\xi_0\tau_0)^{-c})\left(g_2 = \begin{pmatrix} A & B \\ C & D \end{pmatrix}\right) \\ = |\det C^t \bar{C}|_p^{s-1} (\xi_0\tau_0)_p (\det C) \cdot \mathcal{F}^{-1} \alpha_{\xi\tau,p} \begin{pmatrix} 0 & C^{-1}D \\ 0 & 0 \end{pmatrix}, \end{aligned}$$

where the Schwartz function $\alpha_{\xi\tau,p}$ is defined in equation (5.7.2). Then we have

$$\begin{aligned} \int_{y_1 \in \mathbb{Q}_p, y_2 \in \mathcal{K}_p^2} f_p^{\mathrm{big-cell}}(-s, (\xi_0\tau_0)^{-c}) \left(\begin{pmatrix} 1 & & & \\ & \mathbf{1}_2 & & \\ & & & \\ & & & 1 \end{pmatrix} \begin{pmatrix} 1 & -y_2 & y_1 & \\ & \mathbf{1}_2 & & \\ & & & \\ & & & {}^t\bar{y}_2 & 1 \end{pmatrix} J(g_2) \Upsilon_p^{-1} \iota(w_{3,p}, \mathbf{1}_2) \Upsilon_p \right) dy_1 dy_2 \\ = f_p^{\mathrm{U}(2,2)}\left(-s - \frac{1}{2}, (\xi_0\tau_0)^{-c}\right)(g_2), \end{aligned} \tag{6.2.1}$$

where $J : \mathrm{U}(2, 2) \rightarrow \mathrm{U}(3, 3)$ is defined as

$$J\begin{pmatrix} A & B \\ C & D \end{pmatrix} = \begin{pmatrix} 1 & & & \\ & A & B & \\ & & 1 & \\ & C & & D \end{pmatrix}.$$

To see equation (6.2.1), writing $g_2 = \begin{pmatrix} A & B \\ C & D \end{pmatrix}$, we have

$$\begin{aligned} \mathcal{Q}_p \left(\begin{pmatrix} 1 & & & \\ & \mathbf{1}_2 & & \\ & & & \\ & & & 1 \end{pmatrix} \begin{pmatrix} 1 & -y_2 & y_1 & \\ & \mathbf{1}_2 & & \\ & & & \\ & & & {}^t\bar{y}_2 & 1 \end{pmatrix} J(g_2) \Upsilon_p^{-1} \iota(w_{3,p}, \mathbf{1}_2) \Upsilon_p \right) \\ = \mathcal{Q}_p \begin{pmatrix} 0 & 0 & -1 & 0 \\ 0 & A & 0 & B \\ 1 & -y_2 A & y_1 & -y_2 B \\ 0 & C & {}^t\bar{y}_2 & D \end{pmatrix} \begin{pmatrix} 1 & & & \\ & \mathbf{1}_2 & & \\ & & 1 & \\ & & & \mathbf{1}_2 \end{pmatrix} = \mathcal{Q}_p \begin{pmatrix} 0 & 0 & -1 & 0 \\ A & 0 & 0 & B \\ -y_2 A & 1 & y_1 & -y_2 B \\ C & 0 & {}^t\bar{y}_2 & D \end{pmatrix} \end{aligned}$$

and

$$\mathcal{Q}_p \left(\begin{pmatrix} -y_2 A & 1 \\ C & 0 \end{pmatrix}^{-1} \begin{pmatrix} y_1 & -y_2 B \\ {}^t\bar{y}_2 & D \end{pmatrix} \right) = \mathcal{Q}_p \begin{pmatrix} C^{-1} {}^t\bar{y}_2 & C^{-1} D \\ y_1 + y_2 A C^{-1} {}^t\bar{y}_2 & y_2 {}^t\bar{C}^{-1} \end{pmatrix}.$$

It follows that the integrand of the left-hand side of equation (6.2.1) equals

$$f_p^{\mathrm{U}(2,2)}\left(-s + \frac{1}{2}, (\xi_0\tau_0)^{-c}\right)(g_2) \cdot \mathbb{1}_{\mathbb{Z}_p}(y_1) \cdot \mathbb{1}_{\mathcal{O}_{\mathcal{K},p}^2}(y_2 {}^t\bar{C}^{-1}),$$

so

$$\begin{aligned}\text{Left hand side of equation (6.2.1)} &= f_p^{U(2,2)}\left(-s + \frac{1}{2}, (\xi_0\tau_0)^{-c}\right)(g_2) \cdot \det |C^t \bar{C}|_p \\ &= f_p^{U(2,2)}\left(-s - \frac{1}{2}, (\xi_0\tau_0)^{-c}\right)(g_2).\end{aligned}$$

Put $S_0 = \begin{pmatrix} 1 & -\frac{\xi_0}{2} \\ -1 & -\frac{\xi_0}{2} \end{pmatrix}$ and $Y_{0,p}$ to be the element in $U(2, 2)(\mathbb{Q}_p)$ such that $\varrho_p(Y_{0,p}) = S_0^{-1}$. Set

$$\iota_0 : U(2) \times U(2) \longrightarrow U(2, 2), \quad \iota_0(g_1, g'_1) = S_0^{-1} \begin{pmatrix} g_1 & \\ & g'_1 \end{pmatrix}. \quad (6.2.2)$$

By the definition of the intertwining operator $M_p(-s, \xi\tau_0^{-1}(\xi_0\tau_0)^{-c})$ (in equations (5.7.4)) and (6.2.1),

$$\begin{aligned}& M_p(-s, (\xi_0\tau_0)^{-c}) f_p^{\text{big-cell}}(-s, (\xi_0\tau_0)^{-c})(\iota(w_{3,p}, g_1)) \\ &= \int_{\begin{pmatrix} y_1 & y_2 \\ \imath y_2 & y_4 \end{pmatrix} \in \text{Her}_3(\mathcal{K}_p)} f_p^{\text{big-cell}}(-s, (\xi_0\tau_0)^{-c}) \left(\begin{pmatrix} 1 & \mathbf{1}_2 & -1 \\ & 1 & \\ & & 1 \end{pmatrix} \begin{pmatrix} 1 & -y_2 & y_1 \\ & \mathbf{1}_2 & \\ & & \imath y_2 & 1 \end{pmatrix} \right. \\ &\quad \left. \begin{pmatrix} 1 & & \\ & \mathbf{1}_2 & 1 & -\mathbf{1}_2 \end{pmatrix} \begin{pmatrix} 1 & \mathbf{1}_2 & y_4 \\ & 1 & \mathbf{1}_2 \end{pmatrix} \iota(w_{3,p}, g_1) Y_p \right) dudy_4 \\ &= M_p^{U(2,2)}\left(-s - \frac{1}{2}, (\xi_0\tau_0)^{-c}\right) f_p^{U(2,2)}\left(-s - \frac{1}{2}, (\xi_0\tau_0)^{-c}\right)(\iota_0(1, g_1) Y_{0,p}),\end{aligned}$$

and

$$\begin{aligned}& f_p(s, \xi_0\tau_0)(\iota(w_{3,p}, g_1)) \\ &= \gamma_p\left(-2s, (\xi_0^{\mathbb{Q}}\tau_0^{\mathbb{Q}})^{-1}\right) \gamma_p\left(-2s - 1, (\xi_0^{\mathbb{Q}}\tau_0^{\mathbb{Q}})^{-1}\eta_{\mathcal{K}/\mathbb{Q}}\right) \gamma_p\left(-2s - 2, (\xi_0^{\mathbb{Q}}\tau_0^{\mathbb{Q}})^{-1}\right) \\ &\quad \times M_p^{U(2,2)}\left(-s - \frac{1}{2}, (\xi_0\tau_0)^{-c}\right) f_p^{U(2,2)}\left(-s - \frac{1}{2}, (\xi_0\tau_0)^{-c}\right)(\iota_0(1, g_1) Y_{0,p}).\end{aligned}$$

By the functional equation of the local doubling zeta integral [LR05, (19)(25)],

$$\begin{aligned}& \int_{U(2)(\mathbb{Q}_p)} M_p^{U(2,2)}\left(-s - \frac{1}{2}, (\xi_0\tau_0)^{-c}\right) f_p^{U(2,2)}\left(-s - \frac{1}{2}, (\xi_0\tau_0)^{-c}\right)(\iota_0(1, g_1) Y_{0,p}) \\ &\quad \times (\xi_0\tau_0)_p^c (\det g_1) \left\langle \pi_p^{\text{GU}(2)}(g_1) \varphi_p, \varphi'_p \right\rangle dg_1 \\ &= c_{2,p} \left(-s - \frac{1}{2}, (\xi_0\tau_0)^{-c}, \begin{pmatrix} & \mathbf{1}_2 \\ \mathbf{1}_2 & \end{pmatrix}\right) \gamma_p(-s, \text{BC}(\pi) \times (\xi_0\tau_0)^{-c}) \\ &\quad \times \int_{U(2)(\mathbb{Q}_p)} f_p^{U(2,2)}\left(-s - \frac{1}{2}, (\xi_0\tau_0)^{-c}\right)(\iota_0(1, g_1) Y_{0,p}) (\xi_0\tau_0)_p^c (\det g_1) \left\langle \pi_p^{\text{GU}(2)}(g_1) \varphi_p, \varphi'_p \right\rangle dg_1,\end{aligned}$$

with the factor

$$c_{2,p} \left(-s - \frac{1}{2}, (\xi_0\tau_0)^{-c}, \begin{pmatrix} & \mathbf{1}_2 \\ \mathbf{1}_2 & \end{pmatrix}\right) = \gamma_p\left(-2s - 1, (\xi_0^{\mathbb{Q}}\tau_0^{\mathbb{Q}})^{-1}\eta_{\mathcal{K}/\mathbb{Q}}\right)^{-1} \gamma_p\left(-2s - 2, (\xi_0^{\mathbb{Q}}\tau_0^{\mathbb{Q}})^{-1}\right)^{-1}$$

as defined in equation (5.7.5). Therefore,

$$\begin{aligned} & Z_p \left(f_p(s, \xi_0 \tau_0), w_{3,p}, \varphi_p, \varphi'_p \right) \\ &= \gamma_p \left(-2s, (\xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})^{-1} \right) \gamma_p \left(-s, \text{BC}(\pi) \times (\xi_0 \tau_0)^{-c} \right) \\ & \quad \times \int_{\text{U}(2)(\mathbb{Q}_p)} f_p^{\text{U}(2,2)} \left(-s - \frac{1}{2}, (\xi_0 \tau_0)^{-c} \right) \left(\iota_0(1, g_1) Y_{0,p} \right) (\xi_0 \tau_0)_p^c (\det g_1) \left\langle \pi_p^{\text{GU}(2)}(g_1) \varphi_p, \varphi'_p \right\rangle dg_1. \end{aligned} \quad (6.2.3)$$

By noting that

$$f_p^{\text{U}(2,2)} \left(-s - \frac{1}{2}, (\xi_0 \tau_0)^{-c} \right) \left(\iota_0(1, g_1) Y_{0,p} \right) = \mathcal{F}^{-1} \alpha_{\xi \tau, p} \begin{pmatrix} 0 & g_1 \\ 0 & 0 \end{pmatrix}$$

and using the formula (5.7.2) for $\mathcal{F}^{-1} \alpha_{\xi \tau, p}$ and that φ_p is spherical, an easy computation shows that

$$\text{the integral on the RHS of equation (6.2.3)} = p^{-2ts-2t} \mathfrak{g} \left((\xi_0 \tau_0)_p^{-1} \right)^2 (\xi_0 \tau_0)_p(p)^{2t} \cdot \langle \varphi_p, \varphi'_p \rangle, \quad (6.2.4)$$

where p^t , $t \geq 1$, is the conductor of $(\xi_0 \tau_0)_p$. Since π_p is unramified with trivial central character, we have

$$p^{-2ts-2t} \mathfrak{g} \left((\xi_0 \tau_0)_p^{-1} \right)^2 (\xi_0 \tau_0)_p(p)^{2t} = \gamma_p(s+1, \pi_p \times (\xi_0 \tau_0)_p). \quad (6.2.5)$$

Combining equations (6.2.3), (6.2.4) and (6.2.5), we get

$$\begin{aligned} (6.2.3) &= \gamma_p \left(-2s, (\xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})^{-1} \right) \gamma_p \left(-s, \text{BC}(\pi) \times (\xi_0 \tau_0)^{-c} \right) \gamma_p(s+1, \pi_p \times (\xi_0 \tau_0)_p) \cdot \langle \varphi_p, \varphi'_p \rangle \\ &= \gamma_p \left(-2s, (\xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})^{-1} \right) \gamma_p \left(-s, \pi_p \times (\xi_0 \tau_0)_p^{-1} \right) \cdot \langle \varphi_p, \varphi'_p \rangle. \end{aligned} \quad \square$$

7. The nondegenerate Fourier–Jacobi coefficients of the Klingen family

The map (4.7.3) of taking the β -th Fourier–Jacobi coefficient along the boundary stratum indexed by the cusp label $\mathbf{1}_4 \in C(K_f^p K_{p,n}^1)_{\text{ord}}$ induces

$$\text{FJ}_{\beta} : \text{Meas}(\Gamma_{\mathcal{K}}, V_{\text{GU}(3,1)}) \longrightarrow \text{Meas}(\Gamma_{\mathcal{K}}, V_{\text{GU}(2)}^{J,\beta}).$$

For $u \in \bigotimes_{v \in \Sigma_{\text{ns}}} \text{U}(1)(\mathbb{Q}_v)$, let

$$\mathbf{E}_{\varphi, \beta, u}^{\text{Kling}} = \text{FJ}_{\beta} \left(\begin{pmatrix} u & \\ & \mathbf{1}_2 \end{pmatrix}_u \mathbf{E}_{\varphi}^{\text{Kling}} \right) \in \text{Meas}(\Gamma_{\mathcal{K}}, V_{\text{GU}(2)}^{J,\beta} \widehat{\otimes} \hat{\mathcal{O}}_L^{\text{ur}}). \quad (7.0.1)$$

(The group $\text{GU}(3, 1)(\mathbb{A}_f^p)$ acts on the Igusa tower and acts on $V_{\text{GU}(3,1)}$, and $\begin{pmatrix} u & \\ & \mathbf{1}_2 \end{pmatrix}_u \mathbf{E}_{\varphi}^{\text{Kling}}$ denotes the action of $\begin{pmatrix} u & \\ & \mathbf{1}_2 \end{pmatrix}_u$ on $\mathbf{E}_{\varphi}^{\text{Kling}}$.) The goal of this section is to prove Proposition 7.11.3 on the nonvanishing properties of the $\mathbf{E}_{\varphi, \beta, u}^{\text{Kling}}$'s.

In §7.1–§7.2, we briefly recall some basics we will use about Weil representations, theta series, Jacobi forms and p -adic Petersson inner products. In §7.4 and §7.5, we unfold the Siegel Eisenstein series on $\text{GU}(3, 3)$ to compute the nondegenerate Fourier–Jacobi coefficients of the Klingen Eisenstein series on $\text{GU}(3, 1)$, and sketch our strategy for relating them to certain L -values, for which we can apply mod p nonvanishing results. Following that strategy, we need to choose an auxiliary Jacobi form on $\text{U}(2)$ and

two CM families on $U(2)$. §7.6-§7.10 are about constructing the auxiliary Jacobi form and CM families and some other technical preparations. The desired nonvanishing property is proved in §7.11.

7.1. The Schrödinger model of Weil representation and the intertwining maps for different polarizations

The nondegenerate terms in the Fourier–Jacobi expansion of an automorphic form on $GU(3, 1)(\mathbb{A})$ are Jacobi forms on the Jacobi group associated $GU(2)$.

Let V (resp. V^-) be the two-dimensional skew-Hermitian space $(\mathcal{K}^2, \zeta_0)$ (resp. $(\mathcal{K}^2, -\zeta_0)$). We write elements in V, V^- as row vectors and fix the basis $v_1 = (1, 0), v_2 = (0, 1)$ for V (resp. $v_1^- = (1, 0), v_2^- = (0, 1)$ for V^-). With respect to the fixed basis, the unitary groups $U(V)$ and $U(V^-)$ are naturally identified with our $U(2)$ (defined in equation (5.4.1)).

We fix the basis v_1, v_2, v_1^-, v_2^- for $V \oplus V^-$ and identify $U(V \oplus V^-)$ with the unitary group whose R -points are

$$\left\{ g \in GL_4(R \otimes_{\mathbb{Z}} \mathcal{O}_{\mathcal{K}}) : {}^t \bar{g} \begin{pmatrix} \zeta_0 & \\ & -\zeta_0 \end{pmatrix} g = \begin{pmatrix} \zeta_0 & \\ & -\zeta_0 \end{pmatrix} \right\}.$$

Define the unitary group $U(2, 2)$ as

$$U(2, 2)(R) = \left\{ g \in GL_4(R \otimes_{\mathbb{Z}} \mathcal{O}_{\mathcal{K}}) : {}^t \bar{g} \begin{pmatrix} & \mathbf{1}_2 \\ -\mathbf{1}_2 & \end{pmatrix} g = \begin{pmatrix} & \mathbf{1}_2 \\ -\mathbf{1}_2 & \end{pmatrix} \right\}.$$

We fix the isomorphism

$$U(V \oplus V^-) \longrightarrow U(2, 2), \quad g \longmapsto \begin{pmatrix} \mathbf{1}_2 & -\frac{\zeta_0}{2} \\ -\mathbf{1}_2 & -\frac{\zeta_0}{2} \end{pmatrix}^{-1} g \begin{pmatrix} \mathbf{1}_2 & -\frac{\zeta_0}{2} \\ -\mathbf{1}_2 & -\frac{\zeta_0}{2} \end{pmatrix},$$

which induces the embedding

$$U(2) \times U(2) \longrightarrow U(2, 2), \quad (g_1, g_2) \longmapsto \begin{pmatrix} \mathbf{1}_2 & -\frac{\zeta_0}{2} \\ -\mathbf{1}_2 & -\frac{\zeta_0}{2} \end{pmatrix}^{-1} \begin{pmatrix} g_1 & \\ & g_2 \end{pmatrix} \begin{pmatrix} \mathbf{1}_2 & -\frac{\zeta_0}{2} \\ -\mathbf{1}_2 & -\frac{\zeta_0}{2} \end{pmatrix}.$$

For a nonzero $\beta \in \text{Her}_1(\mathcal{K})$, denote by W_β the one-dimensional Hermitian space $(\mathcal{K}, \beta)$. Fix a basis $w_\beta = 1$ for W_β , and we can identify $U(W_\beta)$ with the group $U(1)$ defined by

$$U(1)(R) = \{ g \in GL_1(R \otimes_{\mathbb{Z}} \mathcal{O}_{\mathcal{K}}) : \bar{g} g = 1 \}.$$

We consider the Weil representations for the dual pairs $U(2) \times U(1)$ and $U(2, 2) \times U(1)$. The space $V \otimes_{\mathcal{K}} W_\beta$ is a four-dimensional $\mathbb{Q}$ -vector space equipped with a nondegenerate symplectic pairing induced from the skew-Hermitian form on V and the Hermitian form on W_β . The group $U(V) \times U(W_\beta)$ embeds into $\text{Sp}(V \otimes_{\mathcal{K}} W_\beta)$ and forms a reductive dual pair. Let $\widetilde{\text{Sp}}(V \otimes_{\mathcal{K}} W_\beta)$ denote the metaplectic group. Given a pair of Hecke characters $\lambda_V, \lambda_{W_\beta} : \mathcal{K}^\times \backslash \mathbb{A}_{\mathcal{K}}^\times \rightarrow \mathbb{C}^\times$ such that $\lambda_V|_{\mathbb{A}_{\mathbb{Q}}^\times} = \eta_{\mathcal{K}/\mathbb{Q}}^{\dim_{\mathcal{K}} V}$ and $\lambda_{W_\beta}|_{\mathbb{A}_{\mathbb{Q}}^\times} = \eta_{\mathcal{K}/\mathbb{Q}}^{\dim_{\mathcal{K}} W_\beta}$, there is a splitting

$$U(V_v) \times U(W_{\beta, v}) \hookrightarrow \widetilde{\text{Sp}}(V_v \otimes_{\mathcal{K}} W_{\beta, v}) \quad (7.1.1)$$

for all places v of $\mathbb{Q}$. The Weil representation of $\widetilde{\text{Sp}}(V_v \otimes_{\mathcal{K}} W_{\beta, v})$ (with respect to our fixed additive character $\mathbf{e}_{\mathbb{A}_{\mathbb{Q}}} : \mathbb{Q} \backslash \mathbb{A}_{\mathbb{Q}} \rightarrow \mathbb{C}^\times$ in equation (1.0.5)) induces the Weil representation of $U(V_v) \times U(W_{\beta, v})$.

Similarly, with respect to $\lambda_{V^-}, \lambda_{V \oplus V^-} : \mathcal{K}^\times \backslash \mathbb{A}_{\mathcal{K}}^\times \rightarrow \mathbb{C}^\times$ satisfying $\lambda_{V^-}|_{\mathbb{A}_{\mathcal{K}}^\times} = \eta_{\mathcal{K}/\mathbb{Q}}^{\dim_{\mathcal{K}} V^-}$, $\lambda_{V \oplus V^-}|_{\mathbb{A}_{\mathcal{K}}^\times} = \eta_{\mathcal{K}/\mathbb{Q}}^{\dim_{\mathcal{K}} V + \dim_{\mathcal{K}} V^-}$, we have the Weil representations of $U(V_v^-) \times U(W_{\beta,v})$ and $U(V \oplus V_v^-) \times U(W_{\beta,v})$.

We choose our $\lambda_V, \lambda_{V^-}, \lambda_{W_\beta}$ as

$$\lambda_V = \lambda_{V^-} = \lambda^2, \quad \lambda_{W_\beta} = \lambda, \quad (7.1.2)$$

where λ is the Hecke character fixed in §5.1.

Remark 7.1.1. In some literature, instead of $\lambda_V = \lambda_{V^-} = \lambda^2$, $\lambda_V = \lambda_{V^-} = \text{triv}$ is used.

Put

$$e_1 = v_1 \otimes w_\beta, \quad e_2 = v_2 \otimes w_\beta, \quad e_1^- = v_1^- \otimes w_\beta, \quad e_2^- = v_2^- \otimes w_\beta.$$

Then $\mathbb{Q}e_1 \oplus \mathbb{Q}e_2$ is a maximal isotropic subspace of the symplectic space $V \otimes_{\mathcal{K}} W_\beta$. We have the polarizations

$$V \otimes_{\mathcal{K}} W_\beta = (\mathbb{Q}e_1 \oplus \mathbb{Q}e_2) \oplus (\mathbb{Q}\delta e_1 \oplus \mathbb{Q}\delta e_2), \quad (7.1.3)$$

(where δ is our fixed totally imaginary element in $\mathcal{K}$.) The Schrödinger model of the Weil representation of $U(V_v) \times U(W_{\beta,v})$ is an action of $U(V_v) \times U(W_{\beta,v})$ on $S(\mathbb{Q}_v e_1 \oplus \mathbb{Q}_v e_2)$, the space of Schwartz functions on $\mathbb{Q}_v e_1 \oplus \mathbb{Q}_v e_2$. We write this action as

$$\omega_{\beta,v}(g, u) : S(\mathbb{Q}_v e_1 \oplus \mathbb{Q}_v e_2) \longrightarrow S(\mathbb{Q}_v e_1 \oplus \mathbb{Q}_v e_2), \quad g \in U(V_v), u \in U(W_{\beta,v}).$$

Similarly, we have the polarization

$$V^- \otimes W_\beta = (\mathbb{Q}e_1^- \oplus \mathbb{Q}e_2^-) \oplus (\mathbb{Q}\delta e_1^- \oplus \mathbb{Q}\delta e_2^-) \quad (7.1.4)$$

and the Schrödinger model

$$\omega_{\beta,v}(g, u) : S(\mathbb{Q}_v e_1^- \oplus \mathbb{Q}_v e_2^-) \longrightarrow S(\mathbb{Q}_v e_1^- \oplus \mathbb{Q}_v e_2^-), \quad g \in U(V_v^-), u \in U(W_{\beta,v}).$$

For a place $v = \mathfrak{v}\bar{\mathfrak{v}}$ split in $\mathcal{K}$, we have $\mathcal{K}_v \simeq \mathcal{K}_{\mathfrak{v}} \times \mathcal{K}_{\bar{\mathfrak{v}}}$ with $\mathcal{K}_{\mathfrak{v}} \simeq \mathcal{K}_{\bar{\mathfrak{v}}} \simeq \mathbb{Q}_v$. In addition to the above polarizations, we also consider the polarizations

$$\begin{aligned} V_v \otimes W_{\beta,v} &= (\mathcal{K}_{\mathfrak{v}} e_1 \oplus \mathcal{K}_{\bar{\mathfrak{v}}} e_2) \oplus (\mathcal{K}_{\bar{\mathfrak{v}}} e_1 \oplus \mathcal{K}_{\mathfrak{v}} e_2), \\ V_v^- \otimes W_{\beta,v} &= (\mathcal{K}_{\mathfrak{v}} e_1^- \oplus \mathcal{K}_{\bar{\mathfrak{v}}} e_2^-) \oplus (\mathcal{K}_{\bar{\mathfrak{v}}} e_1^- \oplus \mathcal{K}_{\mathfrak{v}} e_2^-), \end{aligned}$$

and the intertwining maps

$$S(\mathcal{K}_{\mathfrak{v}} e_1 \oplus \mathcal{K}_{\bar{\mathfrak{v}}} e_2) \longrightarrow S(\mathbb{Q}_v e_1 \oplus \mathbb{Q}_v e_2), \quad (7.1.5)$$

$$S(\mathcal{K}_{\mathfrak{v}} e_1^- \oplus \mathcal{K}_{\bar{\mathfrak{v}}} e_2^-) \longrightarrow S(\mathbb{Q}_v e_1^- \oplus \mathbb{Q}_v e_2^-). \quad (7.1.6)$$

For $V \oplus V^-$, we have the polarization:

$$(V \oplus V^-) \otimes W_\beta = (\mathcal{K}(e_1 + e_1^-) \oplus \mathcal{K}(e_2 + e_2^-)) \oplus (\mathcal{K}(e_1 - e_1^-) \oplus \mathcal{K}(e_2 - e_2^-)).$$

Writing an element in $\mathcal{K}_v(e_1 + e_1^-) \oplus \mathcal{K}_v(e_2 + e_2^-)$ as $X \in M_{1,2}(\mathcal{K}_v)$, for the Schrödinger model, $(g, u) \in U(2, 2) \times U(W_{\beta,v})$,

$$\omega_{\beta,v}(g, u) : S(\mathcal{K}(e_1 + e_1^-) \oplus \mathcal{K}(e_2 + e_2^-)) \longrightarrow S(\mathcal{K}(e_1 + e_1^-) \oplus \mathcal{K}(e_2 + e_2^-)),$$

we have the following formulas:

$$\begin{aligned}\omega_{\beta,v}(\mathbf{1}_4, u) \Phi(X) &= \Phi(u^{-1}X), \\ \omega_{\beta,v}\left(\begin{pmatrix} A & \\ & {}^t\bar{A} \end{pmatrix}, 1\right) \Phi(X) &= \lambda_v(\det A) |\det A|_{\mathcal{K}_v}^{1/2} \cdot \Phi(XA), \\ \omega_{\beta,v}\left(\begin{pmatrix} \mathbf{1}_2 & B \\ & \mathbf{1}_2 \end{pmatrix}, 1\right) \Phi(X) &= \mathbf{e}_v(\beta \cdot XB^t\bar{X}) \cdot \Phi(X), \\ \omega_{\beta,v}\left(\begin{pmatrix} & -\mathbf{1}_2 \\ \mathbf{1}_2 & \end{pmatrix}, 1\right) \Phi(X) &= |\beta|_{\mathbb{Q}_v} \int \Phi(Y) \cdot \mathbf{e}_v(\mathrm{Tr}_{\mathcal{K}_v/\mathbb{Q}_v}(\beta \cdot Y^t\bar{X})) dY.\end{aligned}\tag{7.1.7}$$

7.2. The Heisenberg group and Jacobi forms

Jacobi forms on $\mathrm{U}(2)$ and $\mathrm{U}(2, 2)$ show up in our computation of the nondegenerate Fourier–Jacobi coefficients of the evaluations at classical points of the Klingen family $\mathbf{E}^{\mathrm{Kling}}$.

First, we introduce Jacobi forms on $\mathrm{U}(2)$. Recall that V is the skew-Hermitian space $(\mathcal{K}^2, \zeta_0)$. Denote by $H(V)$ the Heisenberg group associated to V . For a $\mathbb{Q}$ -algebra R

$$H(V)(R) = (V \otimes_{\mathbb{Q}} R) \ltimes R,$$

and the multiplication is

$$(x_1, \sigma_1)(x_2, \sigma_2) = \left(x_1 + x_2, \sigma_1 + \sigma_2 + \frac{x_1\zeta_0^t\bar{x}_2 + \overline{x_1\zeta_0^t\bar{x}_2}}{2}\right).$$

It is easy to see that $H(V)$ is isomorphic to $U_{P_{\mathrm{GU}(3,1)}}$ via

$$(x, \sigma) \mapsto u(x, \sigma) = \begin{pmatrix} 1 & x & \sigma + \frac{1}{2}x\zeta_0^t\bar{x} \\ & \mathbf{1}_2 & \zeta_0^t\bar{x} \\ & & 1 \end{pmatrix}.\tag{7.2.1}$$

The Jacobi group associated to V is the semidirect product $H(V) \ltimes \mathrm{U}(V)$, which we identify with a subgroup of $P_{\mathrm{GU}(3,1)}$ by

$$((x, \sigma), g_1) \mapsto u(x, \sigma) m(g_1), \quad (x, \sigma) \in H(W_0), \quad g_1 \in \mathrm{U}(V),\tag{7.2.2}$$

where for $g_1 \in \mathrm{U}(V)$,

$$m(g_1) = \begin{pmatrix} 1 & & \\ & g_1 & \\ & & 1 \end{pmatrix}.$$

A Jacobi form on $H(V) \ltimes \mathrm{U}(V)$ or a Jacobi form on $\mathrm{U}(V)$ of index β is a smooth function on $H(V)(\mathbb{Q}) \ltimes \mathrm{U}(V)(\mathbb{Q}) \backslash H(V)(\mathbb{A}_{\mathbb{Q}}) \ltimes \mathrm{U}(V)(\mathbb{A}_{\mathbb{Q}})$ such that

- for all $\sigma \in \mathbb{A}_{\mathbb{Q}}$, the left translation by $((0, \sigma), \mathbf{1}_2)$ equals the multiplication by $\mathbf{e}_{\mathbb{A}_{\mathbb{Q}}}(\beta\sigma)$,
- the right translation of a maximal compact subgroup and the action of the center of the universal enveloping Lie algebra at ∞ satisfy finiteness conditions.

It is easy to see that a Jacobi form of index β holomorphic at ∞ of weight $(0, 0)$ corresponds a section in $H^0(\mathcal{C}, \mathcal{L}(\beta))$ with $\mathcal{C}$ a torsor over the Shimura variety of $\mathrm{GU}(2)$ of an abelian scheme isogeneous to the universal abelian scheme, and $\mathcal{L}(\beta)$ the invertible sheaf over $\mathcal{C}$ of β -homogeneous functions.

We will also need Jacobi forms on $U(2, 2)$. Denote by $\mathbb{V}$ the skew-Hermitian space $\mathcal{K}^4$ equipped with the skew-Hermitian form $\begin{pmatrix} & \mathbf{1}_2 \\ -\mathbf{1}_2 & \end{pmatrix}$, and by $H(\mathbb{V})$ its associated Heisenberg group whose R -points for a $\mathbb{Q}$ -algebra R are

$$H(\mathbb{V})(R) = (\mathbb{V} \otimes_{\mathbb{Q}} R) \ltimes R.$$

We write an element in $H(\mathbb{V})(R)$ as (x, y, σ) , $x, y \in R \otimes_{\mathbb{Q}} \mathcal{K}^2$, $\sigma \in R$. The multiplication is given by

$$(x_1, y_1, \sigma_1)(x_2, y_2, \sigma_2) = \left(x_1 + x_2, y_1 + y_2, \sigma_1 + \sigma_2 + \frac{x_1^t \bar{y}_2 + \bar{x}_1^t y_2 - {}^t y_1 \bar{x}_2 - \bar{y}_1^t x_2}{2} \right).$$

The Jacobi group associated to $\mathbb{V}$ is the semidirect product $H(\mathbb{V}) \rtimes U(\mathbb{V})$.

Denote by $P_{GU(3,3)}$ the parabolic subgroup of $GU(3, 3)$ consisting of elements whose entries in the first column are all 0 except the $(1, 1)$ entry, and denote by $U_{P_{GU(3,3)}}$ its unipotent subgroup. We identify $H(\mathbb{V})$ with $U_{P_{GU(3,3)}}$ by

$$(x, y, \sigma) \mapsto u(x, y, \sigma) = \begin{pmatrix} 1 & x & \sigma + \frac{x^t \bar{y} - y^t \bar{x}}{2} & y \\ & \mathbf{1}_2 & {}^t \bar{y} & \\ & & 1 & \\ & & -{}^t \bar{x} & \mathbf{1}_2 \end{pmatrix},$$

and identify $H(\mathbb{V}) \rtimes U(2, 2)$ with a subgroup of $P_{GU(3,3)}$ by

$$((x, y, \sigma), g) \mapsto u(x, y, \sigma) m(g), \quad (x, y, \sigma) \in H(\mathbb{W}_0), g \in U(2, 2), \quad (7.2.3)$$

where for $g = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \in U(2, 2)$,

$$m(g) = \begin{pmatrix} 1 & & & \\ & A & B & \\ & & 1 & \\ & C & D & \end{pmatrix}. \quad (7.2.4)$$

Similarly as above, we define Jacobi forms on $U(\mathbb{V})$ of index β to be smooth functions on $H(\mathbb{V})(\mathbb{Q}) \rtimes U(\mathbb{V})(\mathbb{Q}) \backslash H(\mathbb{V})(\mathbb{A}_{\mathbb{Q}}) \rtimes U(\mathbb{V})(\mathbb{A}_{\mathbb{Q}})$ on which the left translation of $((0, 0, \sigma), \mathbf{1}_4)$ equal the multiplication of $\mathbf{e}_{\mathbb{A}_{\mathbb{Q}}}(\beta\sigma)$ plus finiteness conditions for the right translation of a maximal compact subgroup and the center of the universal enveloping Lie algebra at ∞ .

We have the following embedding of skew-Hermitian spaces

$$V \longrightarrow \mathbb{V}, \quad x \longmapsto \left(x, -\frac{x\zeta_0}{2} \right).$$

It induces the embedding of unitary groups

$$U(V) \longrightarrow U(\mathbb{V}) = U(2, 2), \quad g_1 \longrightarrow \begin{pmatrix} \mathbf{1}_2 & -\frac{\zeta_0}{2} \\ -\mathbf{1}_2 & -\frac{\zeta_0}{2} \end{pmatrix}^{-1} \begin{pmatrix} g_1 & \\ & \mathbf{1}_2 \end{pmatrix} \begin{pmatrix} \mathbf{1}_2 & -\frac{\zeta_0}{2} \\ -\mathbf{1}_2 & -\frac{\zeta_0}{2} \end{pmatrix}$$

and induces an embedding of the Jacobi groups

$$H(V) \rtimes U(V) \longrightarrow H(\mathbb{V}) \rtimes U(\mathbb{V}), \quad \left((x, \sigma), \begin{pmatrix} a & b \\ c & d \end{pmatrix} \right) \mapsto \left(\left(x, -\frac{x\zeta_0}{2}, \sigma \right), \begin{pmatrix} \mathbf{1}_2 & -\frac{\zeta_0}{2} \\ -\mathbf{1}_2 & -\frac{\zeta_0}{2} \end{pmatrix}^{-1} \begin{pmatrix} g_1 & \\ & \mathbf{1}_2 \end{pmatrix} \begin{pmatrix} \mathbf{1}_2 & -\frac{\zeta_0}{2} \\ -\mathbf{1}_2 & -\frac{\zeta_0}{2} \end{pmatrix} \right). \quad (7.2.5)$$

From this embedding, we also get the embedding

$$(H(V) \rtimes U(V)) \times U(V^-) \longrightarrow H(\mathbb{V}) \rtimes U(\mathbb{V}),$$

$$((x, \sigma), g_1, g_2) \longmapsto \left(\left(x, -\frac{x\zeta_0}{2}, \sigma \right), \begin{pmatrix} \mathbf{1}_2 & -\frac{\zeta_0}{2} \\ -\mathbf{1}_2 & -\frac{\zeta_0}{2} \end{pmatrix}^{-1} \begin{pmatrix} g_1 & \\ & g_2 \end{pmatrix} \begin{pmatrix} \mathbf{1}_2 & -\frac{\zeta_0}{2} \\ -\mathbf{1}_2 & -\frac{\zeta_0}{2} \end{pmatrix} \right). \quad (7.2.6)$$

The embeddings (7.2.2)(7.2.3)(7.2.6) are compatible with the embedding ι in equation (5.5.1) in the sense that the following diagram commutes:

$$\begin{array}{ccc} (H(V) \rtimes U(V)) \times U(V^-) & \xrightarrow{(7.2.2) \times \text{id}} & \text{GU}(3, 1) \times_{\mathbb{G}_m} \text{GU}(2) \\ \downarrow (7.2.6) & & \downarrow \iota \\ H(\mathbb{V}) \rtimes U(\mathbb{V}) & \xrightarrow{(7.2.3)} & \text{GU}(3, 3). \end{array}$$

7.3. Theta series

Given a Schwartz function $\phi \in \bigotimes'_v \mathcal{S}(\mathbb{Q}_v e_1 \oplus \mathbb{Q}_v e_2)$ (with $\phi_v = \mathbf{1}_{\mathbb{Z}_v e_1 + \mathbb{Z}_v e_2}$ for all most all finite places v), we define the theta series $\theta(\phi, \cdot)$, which is an automorphic form on $U(V)(\mathbb{A}_{\mathbb{Q}})$, as

$$\theta(\phi, g) = \sum_{x \in \mathbb{Q}e_1 \oplus \mathbb{Q}e_2} \omega_{\beta}(g) \Phi(x).$$

We can also define the Jacobi theta series $\theta^J(\phi, \cdot, \cdot)$, which is a Jacobi form on $H(V) \rtimes U(2)$, as

$$\theta^J(\phi, (y, \sigma), g) = \sum_{x \in \mathbb{Q}e_1 \oplus \mathbb{Q}e_2} \mathbf{e}_{\mathbb{A}_{\mathbb{Q}}} \left(\beta \left(\sigma + \frac{1}{2} y \zeta_0^t \bar{x} \right) \right) \cdot \omega_{\beta}(g) \Phi(x + y). \quad (7.3.1)$$

Similarly, given $\phi \in \bigotimes'_v \mathcal{S}(\mathbb{Q}_v e_1^- \oplus \mathbb{Q}_v e_2^-)$, we can define the theta series $\theta_{\beta}(\phi, \cdot)$ on $U(V^-)(\mathbb{A}_{\mathbb{Q}})$.

7.4. The unfolding

Given a holomorphic automorphic form $\mathcal{F}$ on $\text{GU}(3, 1)(\mathbb{A})$ and $g \in \text{GU}(3, 1)(\mathbb{A}_{\mathbb{Q}})$ and $\beta \in \text{Her}_1(\mathcal{K})_{>0} = \mathbb{Q}_{>0}$, the β -th Fourier–Jacobi coefficient of $\mathcal{F}$ at g is defined as

$$a_{\beta}(g; \mathcal{F}) = \int_{\sigma \in \text{Her}_1(\mathcal{K}) \setminus \text{Her}_1(\mathbb{A}_{\mathcal{K}})} \mathcal{F} \left(\begin{pmatrix} 1 & \sigma \\ & \mathbf{1}_2 \\ & & 1 \end{pmatrix} g \right) \mathbf{e}_{\mathbb{A}}(-\beta \sigma) d\sigma.$$

With $g \in \text{GU}(3, 1)(\mathbb{A}_{\mathbb{Q}})$ fixed, the function

$$\begin{aligned} H(V)(\mathbb{A}_{\mathbb{Q}}) \rtimes U(V)(\mathbb{A}_{\mathbb{Q}}) &\longrightarrow \mathbb{C} \\ ((x, \sigma), g_1) &\longmapsto a_{\beta}(u(x, \sigma)m(g_1); \mathcal{F}) \end{aligned}$$

is a Jacobi form on $H(V) \rtimes U(V)$ of index β .

The Klingen Eisenstein family E_φ^{Kling} interpolates a normalization of the Klingen Eisenstein series $E^{\text{Kling}}(\cdot; F(f(s, \xi_0 \tau_0), \varphi))$, which can be expressed as the integral in equation (5.10.3). We can compute its β -th Fourier–Jacobi coefficients by first computing

$$E_\beta^{\text{Sieg}}(g; f(s, \xi_0 \tau_0)) = \int_{\text{Her}_1(\mathcal{K}) \setminus \text{Her}_1(\mathbb{A}_{\mathcal{K}})} E^{\text{Sieg}} \left(\begin{pmatrix} 1 & & & \\ & \mathbf{1}_2 & & \\ & & 1 & \\ & & & \mathbf{1}_2 \end{pmatrix} g; f(s, \xi_0 \tau_0) \right) \mathbf{e}_{\mathbb{A}_{\mathbb{Q}}}(-\beta \sigma) d\sigma, \quad (7.4.1)$$

and then pairing its restriction to $\text{GU}(3, 1) \times_{\mathbb{G}_m} \text{GU}(2)$ with φ on $\text{GU}(2)$. By unfolding the Siegel Eisenstein series in the integrand on the right-hand side of equation (7.4.1), it's not difficult to show that

$$E_\beta^{\text{Sieg}}(h; f(s, \xi_0 \tau_0)) = \sum_{\gamma \in Q_{\text{U}(2,2)}(\mathbb{Q}) \setminus \text{U}(2,2)(\mathbb{Q})} \sum_{x \in \mathcal{K}^2} \int_{\text{Her}_1(\mathbb{A}_{\mathcal{K}})} f(s, \xi_0 \tau_0) \left(\begin{pmatrix} & & & \\ & \mathbf{1}_3 & & \\ & & -\mathbf{1}_3 & \end{pmatrix} \begin{pmatrix} 1 & \varsigma & x \\ & \mathbf{1}_2 & {}^t \bar{x} \\ & & 1 \\ & & & \mathbf{1}_2 \end{pmatrix} m \left(\begin{pmatrix} & & & \\ & \mathbf{1}_2 & & \\ & & -\mathbf{1}_2 & \end{pmatrix} \gamma \right) h \right) \mathbf{e}_{\mathbb{A}_{\mathbb{Q}}}(-\beta \sigma) d\varsigma, \quad (7.4.2)$$

where $m(\cdot)$ is the embedding of $\text{U}(2, 2)$ into $\text{U}(3, 3)$ as defined in equation (7.2.4). (cf [Wan15, Section 3C1])

Definition 7.4.1. For $g_v \in \text{GU}(3, 3)(\mathbb{Q}_v)$, $x_v \in \mathcal{K}_v^2$ and $f_v(s, \xi_0 \tau_0) \in I_{Q_{\text{GU}(3,3)}, v}(s, \xi_0 \tau_0)$, define

$$\begin{aligned} & \text{FJ}_{\beta, v}(g_v, x_v; f_v(s, \xi_0 \tau_0)) \\ &= \int_{\text{Her}_1(\mathcal{K}_v)} f_v(s, \xi_0 \tau_0) \left(\begin{pmatrix} & & & \\ & \mathbf{1}_3 & & \\ & & -\mathbf{1}_3 & \end{pmatrix} \begin{pmatrix} 1 & \varsigma & x_v \\ & \mathbf{1}_2 & {}^t \bar{x}_v \\ & & 1 \\ & & & \mathbf{1}_2 \end{pmatrix} m \left(\begin{pmatrix} & & & \\ & \mathbf{1}_2 & & \\ & & -\mathbf{1}_2 & \end{pmatrix} g_v \right) \right) \mathbf{e}_{\mathbb{A}}(-\beta \sigma) d\sigma. \end{aligned}$$

For $g \in \text{GU}(3, 3)(\mathbb{A}_{\mathbb{Q}})$, $x \in \mathbb{A}_{\mathcal{K}}^2$ and $f(s, \xi_0 \tau_0) = \otimes_v f_v(s, \xi_0 \tau_0)$, let

$$\text{FJ}_\beta(g, x; f(s, \xi_0 \tau_0)) = \otimes_v \text{FJ}_{\beta, v}(g_v, x_v; f_v(s, \xi_0 \tau_0)).$$

The unfolding result (7.4.2) gives the following proposition.

Proposition 7.4.2. Let $\beta \in \text{Her}_1(\mathcal{K})_{>0}$ and $f(s, \xi_0 \tau_0) \in I_{Q_{\text{GU}(3,3)}}(s, \xi_0 \tau_0)$. The β -th Fourier–Jacobi coefficient of the Siegel Eisenstein series $E^{\text{Sieg}}(\cdot; f(s, \xi_0 \tau_0))$ at $g \in \text{U}(3, 3)(\mathbb{A}_{\mathbb{Q}})$ equals

$$E_\beta^{\text{Sieg}}(g; f(s, \xi_0 \tau_0)) = \sum_{\gamma \in Q_{\text{U}(2,2)}(\mathbb{Q}) \setminus \text{U}(2,2)(\mathbb{Q})} \sum_{x \in \mathcal{K}^2} \text{FJ}_\beta(m(\gamma)g, x; f(s, \xi_0 \tau_0)),$$

with FJ_β defined as in Definition 7.4.1 and $m(\cdot)$ the embedding (7.2.4).

One can easily check that $\text{FJ}_{\beta, v}$ satisfies

$$\begin{aligned} & \text{FJ}_{\beta, v}(u(x, y, \sigma)g, x_0; f_v(s, \xi_0 \tau_0)) = \mathbf{e}_v \left(\beta \left(\sigma + \frac{x^t \bar{y} - y^t \bar{x}}{2} \right) \right) \text{FJ}_{\beta, v}(g, x_0 + x; f_v(s, \xi_0 \tau_0)), \\ & \text{FJ}_{\beta, v} \left(m \left(\begin{pmatrix} A & B \\ 0 & {}^t \bar{A}^{-1} \end{pmatrix} \right) g, x_0; f_v(s, \xi_0 \tau_0) \right) = |\det A^t \bar{A}|_v^{s+1} \xi_0 \tau_0 (\det A) \cdot |\det A^t \bar{A}|_v^{\frac{1}{2}} \mathbf{e}_v(\beta x B^t \bar{A}^t \bar{x}) \\ & \quad \times \text{FJ}_{\beta, v}(g, x_0 A; f_v(s, \xi_0 \tau_0)). \end{aligned}$$

Comparing them with the formulas in equation (7.1.7) for the Schrödinger model of Weil representations, we see that for a fixed $g_v \in \mathrm{U}(3, 3)(\mathbb{Q}_v)$, $\mathrm{FJ}_{\beta, v}(u(x_v, y_v, \sigma_v) m(g_{1, v}) g_v, x_0; f_v(s, \xi_0 \tau_0))$ is essentially (a finite sum of) the product

$$f_{2, v}(s, \xi_0 \tau_0 \lambda^{-1})(g_{1, v}) \cdot \omega_{\beta, v}(u(x_v, y_v, \sigma_v) m(g_{1, v})) \Phi_v(x_0),$$

with $f_{2, v}(s, \xi_0 \tau_0 \lambda^{-1})$ a section in the degenerate principal series $I_{Q_{\mathrm{U}(2, 2), v}}(s, \xi_0 \tau_0 \lambda^{-1})$, Φ_v a Schwartz function on $\mathcal{K}_v^2$ and $\omega_{\beta, v}$ the Weil representation of $\mathrm{U}(2, 2)$ briefly recalled in §7.1. Both $f_{2, v}(s, \xi_0 \tau_0 \lambda^{-1})$ and Φ_v are determined by $f_v(s, \xi_0 \tau_0) \in I_{Q_{\mathrm{GU}(3, 3), v}}(s, \xi_0 \tau_0)$ and $g_v \in \mathrm{GU}(3, 3)(\mathbb{Q}_v)$. The computation at an unramified place v gives

$$\begin{aligned} & \mathrm{FJ}_{\beta, v}(u(x, y, \sigma) m(g_{1, v}), x_0; f_v^{\mathrm{sph}}(s, \xi_0 \tau_0)) \\ &= L_v(2s + 3, \xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})^{-1} \cdot f_{2, v}^{\mathrm{sph}}(s, \xi_0 \tau_0 \lambda^{-1})(g_{1, v}) \cdot \omega_{\beta, v}(u(x, y, \sigma) m(g_{1, v})) \mathbb{1}_{\mathcal{O}_{\mathcal{K}, v}^2}(x_0). \end{aligned}$$

Therefore, the Jacobi form on $H(\mathbb{V}) \rtimes \mathrm{U}(2, 2)$ given by

$$((x, y, \sigma), g) \mapsto E_{\beta}^{\mathrm{Sieg}}(u(x, y, \sigma) m(g); f(s, \xi_0 \tau_0))$$

is essentially (a finite sum of) the product

$$L(2s + 3, \xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})^{-1} \cdot E_2^{\mathrm{Sieg}}(s, \xi_0 \tau_0 \lambda^{-1}) \cdot \Theta^J,$$

with $E_2^{\mathrm{Sieg}}(s, \xi_0 \tau_0 \lambda^{-1})$ a Siegel Eisenstein series on $\mathrm{U}(2, 2)$ and Θ^J a Jacobi theta function on the $H(\mathbb{V}) \rtimes \mathrm{U}(2, 2)$. The restriction of Θ^J from $H(\mathbb{V}) \rtimes \mathrm{U}(2, 2)$ to $(H(V) \rtimes \mathrm{U}(2)) \times \mathrm{U}(2)$ via equation (7.2.3) is essentially (a finite sum of) $\theta_3^J \boxtimes \theta_2$, with θ_3^J (resp. θ_2) a Jacobi theta function (resp. theta function) on $H(V) \rtimes \mathrm{U}(2)$ (resp. $\mathrm{U}(2)$) attached to a Schwartz function ϕ_3 (resp. ϕ_2) on $\mathbb{A}_{\mathcal{K}}$. Therefore,

$$\begin{aligned} & E_{\beta}^{\mathrm{Sieg}}(\cdot; f(s, \xi_0 \tau_0)) \Big|_{(H(V) \rtimes \mathrm{U}(2)) \times \mathrm{U}(2)} \\ & \approx L(2s + 3, \xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})^{-1} \cdot \theta_3^J \boxtimes \theta_2 \cdot E_2^{\mathrm{Sieg}}(s, \xi_0 \tau_0 \lambda^{-1}) \Big|_{\mathrm{U}(2) \times \mathrm{U}(2)}. \end{aligned} \tag{7.4.3}$$

Here, $\approx$ means equal up to normalizations and more precise formulas for local sections are needed to be an actual identity. We will also use the notation $\approx$ several times in the next section. All the identities with $\approx$ are only for the purpose of illustrating the ideas of relating the nondegenerate Fourier–Jacobi coefficients with L -values and will not be used for our rigorous analysis of $E_{\varphi, \beta, u}^{\mathrm{Kling}}$ starting from §7.6.

7.5. Our strategy of analyzing the nondegenerate Fourier–Jacobi coefficients of the Klingen Eisenstein family

Before we move on to the involved computations, we give a brief explanation of how we choose the auxiliary data to study the pairing of equation (7.4.3) with φ . The discussion in this section should also explain why the choices of the auxiliary data in §5.6 are made for constructing $E_{\varphi}^{\mathrm{Kling}}$ and guaranteeing that its nondegenerate Fourier–Jacobi coefficients satisfy the nonvanishing properties needed for applications.

7.5.1. Choosing the auxiliary θ_1^J

The first step to analyze equation (7.4.3) is to pick a suitable Schwartz function ϕ_1 on $\mathbb{A}_{\mathcal{K}}$, to which we can associate a Jacobi theta function θ_1^J on $H(V) \rtimes \mathrm{U}(2)$ (defined as in equation (7.3.1)), and define the linear functional

$$l_{\theta_1^J} : \{\text{Jacobi forms on } H(V) \rtimes \mathrm{U}(2)\} \longrightarrow \{\text{automorphic forms on } \mathrm{U}(2)\}$$

by

$$l_{\theta_1^J}(\varphi^J)(g_1) = \int_{H(V)(\mathbb{Q}) \backslash H(V)(\mathbb{A})} \theta_1^J((x, \sigma), g_1) \varphi^J((x, \sigma), g_1) dx d\sigma. \quad (7.5.1)$$

Applying $l_{\theta_1^J}$ to equation (7.4.3), we obtain an automorphic form on $U(2) \times U(2)$ whose value at (g_1, g_2) equals

$$\int_{H(V)(\mathbb{Q}) \backslash H(V)(\mathbb{A})} \theta_1^J((w, \sigma), g_1) \cdot E_{\beta}^{\text{Sieg}}(\iota(u(x, \sigma)m(g_1), g_2); f(s, \xi_0 \tau_0)) dx d\sigma. \quad (7.5.2)$$

It is a standard fact that for two Schwartz functions ϕ, ϕ' on $\mathbb{A}_{\mathcal{K}}$,

$$\int_{H(V)(\mathbb{Q}) \backslash H(V)(\mathbb{A})} \theta_{\phi}^J((x, \sigma), g_1) \overline{\theta_{\phi'}^J((x, \sigma), g_1)} dx d\sigma = \langle \phi, \overline{\phi'} \rangle = \int_{\mathcal{K} \backslash \mathbb{A}_{\mathcal{K}}} \phi(x) \overline{\phi'(x)} dx,$$

independent of $g_1 \in U(2)$. Thanks to this fact, from equations (7.4.3) and (7.5.2) we obtain

$$\begin{aligned} & l_{\theta_1^J} \left(E_{\beta}^{\text{Sieg}}(\cdot; f(s, \xi_0 \tau_0 \lambda^{-1})) \Big|_{(H(V) \rtimes U(2)) \times U(2)} \right) \\ & \approx \frac{\langle \phi_1, \phi_3 \rangle}{L(2s+3, \xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})} \cdot (1 \boxtimes \theta_2) \cdot E_2^{\text{Sieg}}(s, \xi_0 \tau_0) \Big|_{U(2) \times U(2)}. \end{aligned} \quad (7.5.3)$$

Here, $1 \boxtimes \theta_2$ denotes the automorphic form on $U(2) \times U(2)$ which is the constant function 1 on the first factor and θ_2 on the second factor.

For an automorphic form on F on $U(2)$ and a Hecke character $\chi: \mathcal{K}^{\times} \backslash \mathbb{A}_{\mathcal{K}}^{\times} \rightarrow \mathbb{C}^{\times}$, we use the notation F^{χ} to denote the form

$$F^{\chi}(g) = F(g) \cdot \chi(\det g), \quad g \in U(2)(\mathbb{A}_{\mathbb{Q}}). \quad (7.5.4)$$

Our Klingen Eisenstein series $E^{\text{Kling}}(\cdot; F(f(s, \xi_0 \tau_0), \varphi))$ is obtained by pairing the restriction of the Siegel Eisenstein series with $\varphi^{\overline{\xi_0 \tau_0}}$, so we have

$$\begin{aligned} & l_{\theta_1^J} \left(E_{\beta}^{\text{Kling}}(\cdot; F(f(s, \xi_0 \tau_0), \varphi)) \right) \\ & \approx \frac{\langle \phi_1, \phi_3 \rangle}{L(2s+3, \xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})} \cdot \left\langle \theta_2 \varphi^{\overline{\xi_0 \tau_0}}, E_2^{\text{Sieg}}(s, \xi_0 \tau_0 \lambda^{-1}) \Big|_{U(2) \times U(2)} \right\rangle_{1 \times U(2)}, \end{aligned} \quad (7.5.5)$$

where $\langle \cdot, \cdot \rangle_{1 \times U(2)}$ means integration over the second copy of $U(2)$.

The standard doubling method formula [LR05] implies

$$E_2^{\text{Sieg}}(s, \xi_0 \tau_0 \lambda^{-1}) \Big|_{U(2) \times U(2)} \approx \sum_h \frac{L\left(s + \frac{1}{2}, \text{BC}(\pi_h) \times \xi_0 \tau_0 \lambda^{-1}\right)}{L\left(2s+1, \xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}}\right) L\left(2s+2, \xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}} \eta_{\mathcal{K}/\mathbb{Q}}\right)} \frac{\overline{h} \boxtimes h^{\xi_0 \tau_0 \bar{\lambda}}}{\langle \bar{h}, h \rangle},$$

where h runs over a certain orthonormal basis of automorphic forms on $U(2)$ of certain level. By picking an h , we have

$$\begin{aligned} & \left\langle l_{\theta^1} \left(E_{\beta}^{\text{Kling}}(-; F(f(s, \xi_0 \tau_0), \varphi)) \right), h \right\rangle \\ & \approx \langle \phi_1, \phi_3 \rangle \frac{L\left(s + \frac{1}{2}, \text{BC}(\pi_h) \times \xi_0 \tau_0 \lambda^{-1}\right)}{d_3(s, \xi_0 \tau_0)} \left\langle \theta_2 \varphi^{\overline{\xi_0 \tau_0}}, h^{\xi_0 \tau_0 \bar{\lambda}} \right\rangle \\ & = \langle \phi_1, \phi_3 \rangle \frac{L\left(s + \frac{1}{2}, \text{BC}(\pi_h) \times \xi_0 \tau_0 \lambda^{-1}\right)}{d_3(s, \xi_0 \tau_0)} \left\langle \theta_2^{\bar{\lambda}} \varphi, h \right\rangle, \end{aligned} \quad (7.5.6)$$

where $d_3(s, \xi_0 \tau_0)$ is as in equation (5.9.2). The Petersson inner product $\left\langle \theta_2^{\bar{\lambda}} \varphi, h \right\rangle$ is related to the central value of a triple product L -function by Ichino's formula.

7.5.2. Choosing auxiliary h and θ and relating to L -values

We will choose suitable CM forms h and θ on $U(2)$ such that we can apply the available mod p nonvanishing results to study $L\left(s + \frac{1}{2}, \text{BC}(\pi_h) \times \xi_0 \tau_0 \lambda^{-1}\right)$ and $\left\langle \theta_2^{\bar{\lambda}} \varphi, h \right\rangle$ in equation (7.5.6).

Let χ_h and χ_{θ} be two unitary Hecke characters of $\mathcal{K}^{\times} \backslash \mathbb{A}_{\mathcal{K}}^{\times}$ such that $\chi_h \chi_{\theta}^c|_{\mathbb{A}_{\mathbb{Q}}^{\times}} = \text{triv}$ (as chosen in §5.6). Let h_0 be the theta lift of $\chi_h^{-1}|_{U(1)}$ to $U(2)$, and h be the automorphic form on $U(2)$ obtained from h_0 by

$$h(g) = \chi_h \chi_{\theta}^c(a) \cdot h_0(g), \quad g \in U(2), a \in \mathbb{A}_{\mathcal{K}}^{\times}, \det g = a \bar{a}^{-1}. \quad (7.5.7)$$

Thanks to the condition $\chi_h \chi_{\theta}^c|_{\mathbb{A}_{\mathbb{Q}}^{\times}} = \text{triv}$, the definition of $h(g)$ does not depend on the choice of $a \in \mathbb{A}_{\mathcal{K}}^{\times}$.

The form θ_2 does not generate an irreducible representation of $U(2)$. Let θ be the projection of θ_2 to its $\chi_{\theta} \lambda^2|_{U(1)}$ -eigenspace for the action of the center of $U(2)$. Then θ is a theta lift of $\chi_{\theta} \lambda^2|_{U(1)}$. Since our φ is assumed to have the trivial central character and h has the central character $\chi_{\theta}^{-1}|_{U(1)}$, we have

$$\left\langle \theta_2^{\bar{\lambda}} \varphi, h \right\rangle = \left\langle \theta^{\bar{\lambda}} \varphi, h \right\rangle. \quad (7.5.8)$$

By [GI14, Theorem C.5], with the choice of the splitting characters for the theta correspondence between $U(2)$ and $U(1)$ as in equation (7.1.2), we have

$$\begin{aligned} \text{BC}(\pi_h) &= \text{BC}(\pi_{h_0}) \otimes \chi_h \chi_{\theta}^c = \left(\text{BC}\left(\chi_h^{-1}|_{U(1)}\right) \lambda^{-1} \oplus \lambda \right) \otimes \chi_h \chi_{\theta}^c \\ &= \left(\chi_h^{-1} \chi_h^c \lambda^{-1} \oplus \lambda \right) \otimes \chi_h \chi_{\theta}^c = \chi_h^c \chi_{\theta}^c \lambda^{-1} \oplus \chi_h \chi_{\theta}^c \lambda, \end{aligned} \quad (7.5.9)$$

and

$$\text{BC}(\pi_{\theta^{\bar{\lambda}}}) = \left(\text{BC}\left(\chi_{\theta} \lambda^2|_{U(1)}\right) \lambda^{-1} \oplus \lambda \right) \bar{\lambda} \bar{\lambda}^{-c} = \left(\chi_{\theta} \chi_{\theta}^{-c} \lambda^3 \oplus \lambda \right) \lambda^{-2} = \chi_{\theta} \chi_{\theta}^{-c} \lambda \oplus \lambda^{-1}. \quad (7.5.10)$$

Thus, we have

$$\begin{aligned} & L\left(s + \frac{1}{2}, \text{BC}(\pi_h) \times \lambda^{-1} \xi_0 \tau_0\right) \\ &= L\left(s + \frac{1}{2}, \lambda^{-2} \chi_h^c \chi_{\theta}^c \xi_0 \tau_0\right) L\left(s + \frac{1}{2}, \chi_h \chi_{\theta}^c \xi_0 \tau_0\right) \\ &= L\left(s + \frac{1}{2}, \lambda^2 \chi_h \chi_{\theta} \xi_0^c \tau_0^c\right) L\left(s + \frac{1}{2}, \chi_h \chi_{\theta}^c \xi_0 \tau_0\right). \end{aligned} \quad (7.5.11)$$

By the triple product formula,

$$\begin{aligned} \langle \theta^{\bar{1}} \varphi, h \rangle \langle \tilde{\theta}_3^{\lambda} \tilde{\varphi}, \tilde{h}_3 \rangle &\approx \frac{\langle \varphi, \tilde{\varphi} \rangle}{L(1, \pi, \text{Ad})} \frac{\langle h, \tilde{h}_3 \rangle}{\zeta_{\mathcal{K}}(1) L(1, \chi_h \chi_h^{-1} \lambda^2)} \frac{\langle \theta, \tilde{\theta}_3 \rangle}{\zeta_{\mathcal{K}}(1) L(1, \chi_{\theta} \chi_{\theta}^{-c} \lambda^2)} \\ &\times L\left(\frac{1}{2}, \text{BC}(\pi) \times \chi_h \chi_{\theta} \lambda^2\right) L\left(\frac{1}{2}, \text{BC}(\pi) \times \chi_h \chi_{\theta}^c\right), \end{aligned} \quad (7.5.12)$$

where $\tilde{\varphi}$ (resp. $\tilde{h}_3, \tilde{\theta}_3$) are suitable forms taken from the dual representation of $\pi^{\text{U}(2)} = \pi_{\varphi}$ (resp. π_h, π_{θ}). (In our case here, the triple product L -function for $\pi^D \times \pi_{\theta}^D \times \pi_h^D$ factorizes as the product of the two L -functions in equation (7.5.12). Also, note that Ichino's triple product formula is for automorphic forms on $D^{\times}$, we actually need to relate the integral on $\text{U}(2)$ for $\langle \theta^{\bar{1}} \varphi, h \rangle \langle \tilde{\theta}_3^{\lambda} \tilde{\varphi}, \tilde{h}_3 \rangle$ to an integral on $D^{\times}$. In §7.10, we discuss extending automorphic forms on $\text{U}(2)$ to $\text{GU}(2)$. Thanks to equation (5.4.3), the integral over $\text{GU}(2)$ is the same as the integral over $D^{\times}$.)

Combining equations (7.5.6)(7.5.8)(7.5.11)(7.5.12), we get

$$\begin{aligned} &d_3(s, \xi_0 \tau_0) \cdot \left\langle l_{\theta^J} \left(E_{\beta}^{\text{Kling}}(\cdot; F(f(s, \xi_0 \tau_0), \varphi)) \right), h \right\rangle \langle \tilde{\theta}_3^{\lambda} \tilde{\varphi}, \tilde{h}_3 \rangle \\ &\approx \langle \phi_1, \phi_3 \rangle \frac{\langle \varphi, \tilde{\varphi} \rangle}{L(1, \pi, \text{Ad})} \cdot \frac{\langle h, \tilde{h}_3 \rangle}{\zeta_{\mathcal{K}}(1) L(1, \chi_h \chi_h^{-1} \lambda^2)} \frac{\langle \theta, \tilde{\theta}_3 \rangle}{\zeta_{\mathcal{K}}(1) L(1, \chi_{\theta} \chi_{\theta}^{-c} \lambda^2)} \\ &\times L\left(s + \frac{1}{2}, \lambda^2 \chi_h \chi_{\theta} \xi_0^c \tau_0^c\right) L\left(s + \frac{1}{2}, \chi_h \chi_{\theta}^c \xi_0 \tau_0\right) \\ &\times L\left(\frac{1}{2}, \text{BC}(\pi) \times \chi_h \chi_{\theta} \lambda^2\right) L\left(\frac{1}{2}, \text{BC}(\pi) \times \chi_h \chi_{\theta}^c\right). \end{aligned} \quad (7.5.13)$$

The relation between $E_{\beta}^{\text{Kling}}(-; F(f(s, \xi_0 \tau_0), \varphi))$ and L -values illustrated in equation (7.5.13) explains the nonvanishing conditions on the L -values in equations (5.6.1)(5.6.2)(5.6.3)(5.6.4) in our choice of the auxiliary Hecke characters χ_{θ} and χ_h in §5.6.

In the following, guided by the strategy described in this section, we carry out the necessary local computations and the construction of the auxiliary objects to prove the desired property of $E_{\varphi, \beta, u}^{\text{Kling}}$ with $\beta = 1$. The computation is place by place, and we have the following cases:

- For the Archimedean place, we only need to consider the cases for which there are standard choices of local sections and computations are easy.
- For unramified places, we have the standard formulas for spherical sections.
- For the place p and the places in $\Sigma_s \cup \{\ell\}$, we compute precise formulas.
- For the places in $\Sigma_{\text{ns}} \cup \{\ell'\}$, we do not attempt to compute precise formulas. At these places, the local data actually do not change when τ varies in a p -adic family, and we only make sure that local integrals contribute a nonzero scalar.

7.6. The auxiliary Jacobi form θ_1^J

Given a Schwartz function ϕ on $\mathbb{A}_{\mathbb{Q}}^2$ such that ϕ_{∞} is the standard Gaussian function, let θ^J be its associated Jacobi form on $\text{U}(2)$ (as defined in equation (7.3.1)). The map attached to this θ^J defined in equation (7.5.1) extends to $V_{\text{GU}(2)}^{J, \beta}$ and induces

$$l_{\theta^J} : \text{Meas}\left(\Gamma_{\mathcal{K}}, V_{\text{GU}(2)}^{J, \beta}\right) \longrightarrow \text{Meas}(\Gamma_{\mathcal{K}}, V_{\text{U}(2)}). \quad (7.6.1)$$

Apply it to $E_{\varphi, \beta, u}^{\text{Kling}}$ (defined in equation (7.0.1)), we get

$$l_{\theta^J} \left(E_{\varphi, \beta, u}^{\text{Kling}} \right) \in \text{Meas} \left(\Gamma_{\mathcal{K}}, V_{U(2)}, \xi \widehat{\otimes} \hat{\mathcal{O}}_L^{\text{ur}} \right)^{\natural}.$$

Proposition 7.6.1. *Let $\beta = 1 \in \text{Her}_1(\mathcal{K})$. There exists a Schwartz function ϕ_1 on $\mathbb{A}_{\mathbb{Q}}^2$ with $\phi_{1, \infty}$ the standard Gaussian function, elements $u_1, \dots, u_r \in \bigotimes_{v \in \Sigma_{\text{ns}} \cup \{\ell'\}} \text{U}(1)(\mathbb{Q}_v)$, and constants $b_1, \dots, b_r \in \mathcal{O}_L$, (all independent of τ), such that, denoting l_{θ^J} the map (7.6.1) attached to the Jacobi form θ_1^J corresponding to ϕ_1 ,*

$$l_{\theta_1^J} \left(\sum_i b_i E_{\varphi, \beta, u_i}^{\text{Kling}} \right) \in \text{Meas}(\Gamma_{\mathcal{K}}, V_{U(2)}, \xi)^{\natural}$$

satisfies the following interpolation properties: For all τ such that $\xi\tau$ is ramified at $\mathfrak{p}$ and satisfies the conditions in Theorem 5.9.1,

$$l_{\theta_1^J} \left(\sum_i b_i E_{\varphi, \beta, u_i}^{\text{Kling}} \right) (\tau_{p\text{-adic}}) = d_2^{\Sigma \cup \{p, \ell', \ell'\}} \left(s, \xi_0 \tau_0 \lambda^{-1} \right) \times \left\langle \theta(\phi_{2, \tau}) \left(\cdot \begin{pmatrix} & \\ & 1 \end{pmatrix} \right) \varphi^{\xi_0 \tau_0}, E_2^{\text{Sieg}} \left(-; f_2(s, \xi_0 \tau_0 \lambda^{-1}) \right) \right|_{U(2) \times U(2)} \Big|_{1 \times U(2)}, \quad (7.6.2)$$

with $\phi_{2, \xi\tau} \in S(\mathbb{A}_{\mathbb{Q}}^2)$ (independent of τ except $v = p$) and $f_2(s, \xi_0 \tau_0 \lambda^{-1}) \in \bigotimes_v I_{Q_{U(2,2)}, v}(s, \xi_0 \tau_0 \lambda^{-1})$ described as follows:

– $v = \infty$,

$$\phi_{2, \xi\tau, \infty}(y_1, y_2) = \frac{s^{1/4} \text{Nm}(\delta)^{1/4}}{2} e^{-2\pi \sqrt{\text{Nm}(\delta)} (y_1 \ y_2) \xi_0 \begin{pmatrix} y_1 \\ y_2 \end{pmatrix}},$$

$$f_{2, \infty}(s, \xi_0 \tau_0 \lambda^{-1}) \left(g' = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \right) = \frac{(-2\pi i)^k}{\Gamma(k)} \cdot \det \left(C \frac{\xi_0}{2} + D \right)^{-k} \left| C \frac{\xi_0}{2} + D \right|_{\mathbb{C}}^{-s+1+\frac{k}{2}}$$

– $v \notin \Sigma \cup \{\ell', p\}$.

$$\phi_{2, \xi\tau, v} = \mathbb{1}_{\mathbb{Z}_v} \times \mathbb{1}_{\mathbb{Z}_v},$$

$$f_{2, v}(s, \xi_0 \tau_0 \lambda^{-1}) = L_v \left(2s + 3, \xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}} \right)^{-1} \cdot f_{2, v}^{\text{sph}}(s, \xi_0 \tau_0 \lambda^{-1})$$

– $v = \mathfrak{v}\bar{\mathfrak{v}} \in \Sigma_{\text{s}} \cup \{\ell'\}$.

$$\phi_{2, \xi\tau, v} = \text{Image of equation (7.1.6) of } \left((y_1, y_2) \mapsto \mathbb{1}_{\mathcal{O}_{\mathcal{K}, \mathfrak{v}}}(y_1) \cdot \mathbb{1}_{\mathcal{O}_{\mathcal{K}, \bar{\mathfrak{v}}}^{\times}}(y_2) \chi_{\theta, \bar{\mathfrak{v}}} \lambda_{\bar{\mathfrak{v}}}(y_2) \right)$$

$$f_{2, v}(s, \xi_0 \tau_0 \lambda^{-1}) \left(g' = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \right) = |\det C^t \bar{C}|^{-s-1} (\xi_0 \tau_0 \lambda^{-1})_v \left(\det \bar{C}^{-1} \right) \times \mathbb{1}_{\text{Her}_2(\mathcal{O}_{\mathcal{K}, v})} \left(C^{-1} D + q_v^{-c_v} \cdot \mathbf{1}_2 \right) \quad (7.6.3)$$

– $v \in \Sigma_{\text{ns}} \cup \{\ell'\}$.

$\phi_{2, \xi\tau, v}$ = a nonzero Schwartz function on $\mathbb{Q}_v^2$ inside the $\chi_{\theta} \lambda^2|_{U(1)(\mathbb{Q}_v)}$ -eigenspace for the action of $U(1)(\mathbb{Q}_v)$, invariant under K_v , independent of τ ,

$f_{2, v}(s, \xi_0 \tau_0 \lambda^{-1})$ = same as equation (7.6.3).

– The place p .

$$\phi_{2,\xi\tau,p} = \text{Image of equation (7.1.6) of} \\ \left((y_1, y_2) \mapsto p^{-2t} \mathbf{g} \left((\xi_0 \tau_0)_p^{-1} \right) \cdot \mathbb{1}_{\mathbb{Z}_p^\times} (p^t y_1) (\xi_0 \tau_0)_p (-p^t y_1) \cdot \mathbb{1}_{\mathbb{Z}_p} (p^t y_2) \right), \quad (7.6.4)$$

$$f_{2,p}(s, \xi_0 \tau_0 \lambda^{-1}) = \gamma_p \left(-2s, (\xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})^{-1} \eta_{\mathcal{K}/\mathbb{Q}} \right) \gamma_p \left(-2s - 1, (\xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})^{-1} \right) \\ \times M'_p \left(-s, (\xi_0 \tau_0 \lambda^{-1})^{-c} \right) f_{2,p}^{\text{big-cell}} \left(-s, (\xi_0 \tau_0 \lambda)^{-c} \right) (\cdot Y'_p),$$

where

- $M'_p(-s, (\xi_0 \tau_0 \lambda)^{-c}) : I_{\mathcal{Q}_{\mathbb{U}(2,2),p}}(-s, (\xi_0 \tau_0 \lambda)^{-c}) \rightarrow I_{\mathcal{Q}_{\mathbb{U}(2,2),p}}(s, \xi_0 \tau_0 \lambda^{-1})$ is the intertwining operator,
- Y'_p is the element in $\mathbb{U}(2, 2)(\mathbb{Q}_p)$ with $\varrho_p(Y'_p) = \begin{pmatrix} \mathbf{1}_1 & -\frac{\xi_0}{2} \\ -\mathbf{1}_2 & -\frac{\xi_0}{2} \end{pmatrix}^{-1}$,
- writing $t = \text{ord}_p(\text{cond}(\xi_p \tau_p))$, $\varrho_p(x) = \begin{pmatrix} x_{11} & x_{12} \\ x_{21} & x_{22} \end{pmatrix}$,

$$f_{2,p}^{\text{big-cell}}(-s, (\xi_0 \tau_0 \lambda)^{-c}) \begin{pmatrix} A & B \\ C & D \end{pmatrix} \\ = |\det C^t \bar{C}|_p^{s-1} (\xi_0 \tau_0 \lambda^{-1})_p (\det C) \cdot \alpha'_{\xi\tau,p}(C^{-1}D),$$

with $\alpha'_{\xi\tau,p}$ the Schwartz function on $\text{Her}_2(\mathcal{K}_p)$ defined as

$$\alpha'_{\xi\tau,p}(x) = \mathbf{g} \left((\xi_0 \tau_0)_p^{-1} \right) \cdot \mathbb{1}_{\mathbb{Z}_p^3}(x_{11}, x_{21}, x_{22}) \cdot \mathbb{1}_{\mathbb{Z}_p^\times}(p^t x_{12}) (\xi_0 \tau_0)_p (p^t x_{12}).$$

Proof. This proposition is proved in [Wan20, sections 6.E-6.H] by computing $\text{FJ}_{\beta,v}(g, x; f_v(s, \xi_0 \tau_0))$ place by place. The place ∞ is done in Lemmas 6.9 and 6.11 and the unramified places are done in Lemma 6.18. (Note that, at the unramified places, we have $d_{2,v}(s, \xi_0 \tau_0 \lambda^{-1}) = \frac{d_{3,v}(s, \xi_0 \tau_0)}{L_v(2s+3, \xi_0^{\mathbb{Q}} \tau_0^{\mathbb{Q}})}$.) The places in $\Sigma_s \cup \{\ell\}$ are done in Lemmas 6.22 and 6.24, and the places in $\Sigma_{\text{ns}} \cup \{\ell'\}$ are done in Lemmas 6.22 and 6.26. Note that Lemma 6.26 *loc.cit* is already recalled in Proposition 5.6.1 and in §5.6 we choose χ_θ such that at $v \in \Sigma_{\text{ns}} \cup \{\ell'\}$ we have nonzero $\phi_{2,\xi\tau,v}$ described in this proposition. The place p is done from Lemma 6.35 to the end of the Section 6.H. The Schwartz function $\phi_{2,\tau_0,p}$ is the $\phi'_{2,p}$ given below Definition 6.38. Note that our $\text{FJ}_{\beta,v}(g, x; f_v(s, \xi_0 \tau_0))$ defined in Definition 7.4.1 equals $\text{FJ}_{\beta}(f_{\text{siege},v}; z, x, g\eta^{-1}, 1)$ in [Wan20] with $z = s$ and $\eta = \begin{pmatrix} & \mathbf{1}_2 \\ -\mathbf{1}_2 & \end{pmatrix}$, so the results in *loc.cit* all contain the extra η but the formulas in this proposition do not.

At the place p , in fact the pairing of $\phi_{1,p}(x)$ and $\text{FJ}_{\beta,p}(g, (x, y)_p; f_p(s, \xi_0 \tau_0))$ along x does not directly equal $\phi_{2,\tau,p}(y) \cdot f_{2,p}(s, \xi_0 \tau_0 \lambda^{-1})(g)$ but equals the average

$$\int_{\mathbb{Z}_p} \omega_{\beta,p} \left(\varrho_p^{-1} \begin{pmatrix} 1 & 0 \\ n & 1 \end{pmatrix}, 1 \right) \phi_{2,\tau,p}(y) \cdot f_{2,p}(s, \tau_0 \lambda^{-1}) \left(g Y'_p \begin{pmatrix} 1 & & \\ & 1 & \\ & & n & 1 \end{pmatrix} \right) dn. \quad (7.6.5)$$

Meanwhile, φ is spherical at p , in particular invariant under the right translation by $\begin{pmatrix} 1 & \\ \mathbb{Z}_p & 1 \end{pmatrix}$, so replacing equation (7.6.5) by $\phi_{2,\tau,p}(y) \cdot f_{2,p}(s, \xi_0 \tau_0 \lambda^{-1})(g)$ does not change the resulting Petersson inner product with φ over $\mathbb{U}(V^-) = \mathbb{U}(2)$.

The Schwartz function (7.6.4) is the (v_3, v_4) -part of $\Phi_{\mathcal{D}, p}$, the Schwartz function on $\mathbb{Q}_p^4$ defined and appearing in [Wan20, Lemma 6.37, Definition 6.36]. As mentioned above, our formula in the proposition corresponds to replacing g by $g\eta^{-1}$ in the formula in *loc.cit.*, so there is a translation by $\begin{pmatrix} & -1 \\ 1 & \end{pmatrix}$ in the theta series in equation (7.6.2). $\square$

7.7. The construction of the auxiliary CM families $h, \tilde{h}_3, \theta, \tilde{\theta}_3$

Besides θ_1^J , our strategy described in §7.5 also includes auxiliary CM forms. We want to construct a CM family $\mathbf{h}$ on $U(V) = U(2)$ and pair it with $l_{\theta_1^J} \left(\sum_i b_i E_{\varphi, \beta, u_i}^{\text{Kling}} \right)$. The splitting characters for the theta correspondence between $U(2)$ and $U(1)$ are chosen as in equation (7.1.2).

7.7.1. The auxiliary group $U_{\mathcal{K}, p}$

First, we note that for $\tau_{p\text{-adic}}$ as in Theorem 5.9.1, the nebentypus of $l_{\theta_1^J} \left(\sum_i b_i E_{\varphi, \beta, u_i}^{\text{Kling}} \right)$ at p is $\left(\text{triv}, (\xi_0 \tau_0)_p |_{\mathbb{Z}_p^\times} \right)$, that is, $\varrho_p^{-1} \begin{pmatrix} * & * \\ 0 & a_2 \end{pmatrix} \in U(2)(\mathbb{Z}_p)$ acts by $(\xi_0 \tau_0)_p(a_2)$. In order to get a CM family $\mathbf{h}$ with the correct nebentypus to pair with $l_{\theta_1^J} \left(\sum_i b_i E_{\varphi, \beta, u_i}^{\text{Kling}} \right)$, we want Hecke characters of $\mathcal{K}^\times \backslash \mathbb{A}_{\mathcal{K}}^\times$ unramified away from $p\infty$ with restriction $\left(\tau_{0, p} |_{\mathbb{Z}_p^\times}, \text{triv} \right)$ on $\mathcal{O}_{\mathcal{K}, p}^\times$. However, in general there is no canonical way to extend local characters $\left(\tau_{0, p} |_{\mathbb{Z}_p^\times}, \text{triv} \right)$ of $\mathcal{O}_{\mathcal{K}, p}^\times$ to global Hecke characters. Hence, we need to consider an auxiliary group $U_{\mathcal{K}, p}$ and the nonstandard type of p -adic measures defined in equation (5.8.9).

Let $U_{\mathcal{K}, p} = 1 + p\mathcal{O}_{\mathcal{K}, p}$ and $U_{\mathcal{K}, \mathfrak{p}} = 1 + p\mathcal{O}_{\mathcal{K}, \mathfrak{p}}$, $U_{\mathcal{K}, \bar{\mathfrak{p}}} = 1 + p\mathcal{O}_{\mathcal{K}, \bar{\mathfrak{p}}}$. Then the natural map

$$U_{\mathcal{K}, p} \longrightarrow \mathcal{K}^\times \backslash \mathbb{A}_{\mathcal{K}, f}^\times \longrightarrow \Gamma_{\mathcal{K}}$$

is an injection. We can pick N , a nonnegative power of p , such that raising to the N -th power maps $\Gamma_{\mathcal{K}}$ into $U_{\mathcal{K}, p}$. Define

$$\mathcal{P}_N : \Gamma_{\mathcal{K}} \xrightarrow{\text{N-th power}} U_{\mathcal{K}, p} \xrightarrow{\text{natural proj.}} U_{\mathcal{K}, p} \simeq 1 + p\mathbb{Z}_p.$$

Then given a (local) p -adic character $\epsilon : U_{\mathcal{K}, p} \rightarrow \overline{\mathbb{Q}_p}^\times$, the composition $\epsilon \circ \mathcal{P}_N$ is a (global) p -adic character of $\Gamma_{\mathcal{K}}$ whose restriction back to $U_{\mathcal{K}, p} = U_{\mathcal{K}, \mathfrak{p}} \times U_{\mathcal{K}, \bar{\mathfrak{p}}}$ is $(\epsilon^N, \text{triv})$.

In particular, for an algebraic Hecke character $\tau : \mathcal{K}^\times \backslash \mathbb{A}_{\mathcal{K}}^\times \rightarrow \mathbb{C}^\times$ of ∞ -type $(0, k)$ whose p -adic avatar $\tau_{p\text{-adic}}$ factors through $\Gamma_{\mathcal{K}}$, we can define

$$\tau_{\mathfrak{p}, \mathcal{P}_N} = \tau_{p\text{-adic}}|_{U_{\mathcal{K}, p}} \circ \mathcal{P}_N.$$

Then $\tau_{\mathfrak{p}, \mathcal{P}_N}$ is a p -adic Hecke character of $\Gamma_{\mathcal{K}}$ with

$$\tau_{\mathfrak{p}, \mathcal{P}_N}|_{\mathcal{O}_{\mathcal{K}, p}^\times} = \left(\tau_p^N |_{\mathbb{Z}_p^\times}, \text{triv} \right) = \left(\tau_{0, p}^N |_{\mathbb{Z}_p^\times}, \text{triv} \right).$$

Because τ has ∞ -type $(0, k)$, the local character $\tau_{p\text{-adic}}|_{U_{\mathcal{K}, p}}$ is of finite order, and it follows that the (global) character $\tau_{\mathfrak{p}, \mathcal{P}_N} : \Gamma_{\mathcal{K}} \rightarrow \overline{\mathbb{Q}_p}^\times$ is also of finite order. Hence, it takes values in $\overline{\mathbb{Q}^\times}$ and is also an algebraic Hecke character of $\mathcal{K}^\times \backslash \mathbb{A}_{\mathcal{K}}^\times$ of ∞ -type $(0, 0)$. (From the definition of p -adic avatars recalled in §5.3, we can see that the p -adic avatar of a Hecke character of ∞ -type $(0, 0)$ is itself.)

The map $\mathcal{P}_{\mathbb{N}}$ induces a map

$$\mathcal{P}_{\mathbb{N},*} : \mathcal{M}eas(\Gamma_{\mathcal{K}}, V_{\mathrm{U}(2)})^{\natural} \longrightarrow \mathcal{M}eas(U_{\mathcal{K},p}, V_{\mathrm{U}(2)})^{\natural}. \quad (7.7.1)$$

(See §5.8.3 for the definition of these spaces of p -adic measures.) We have

$$\mathcal{P}_{\mathbb{N},*} \left(l_{\theta'_1} \left(\sum_i b_i \mathbf{E}_{\varphi,\beta,u_i}^{\mathrm{Kling}} \right) \right) (\tau_{p\text{-adic}}|_{U_{\mathcal{K},p}}) = l_{\theta'_1} \left(\sum_i b_i \mathbf{E}_{\varphi,\beta,u_i}^{\mathrm{Kling}} \right) (\tau_{p\text{-adic}}^{\mathbb{N}})$$

for every $\tau_{p\text{-adic}} \in \mathrm{Hom}_{\mathrm{cont}}(\Gamma_{\mathcal{K}}, \overline{\mathbb{Q}}_p^{\times})$. In order to show the nonvanishing property of $l_{\theta'_1} \left(\sum_i b_i \mathbf{E}_{\varphi,\beta,u_i}^{\mathrm{Kling}} \right)$ in Proposition 7.11.3, it suffices to show the nonvanishing property for $\mathcal{P}_{\mathbb{N},*} \left(l_{\theta'_1} \left(\sum_i b_i \mathbf{E}_{\varphi,\beta,u_i}^{\mathrm{Kling}} \right) \right)$.

Next, we construct auxiliary CM families $\mathbf{h}$, $\tilde{\mathbf{h}}_3$, $\boldsymbol{\theta}$, $\tilde{\boldsymbol{\theta}}_3$ on $\mathrm{U}(2)$ as p -adic measures on $U_{\mathcal{K},p}$.

7.7.2. The auxiliary CM families $\mathbf{h}$ and $\tilde{\mathbf{h}}_3$

Proposition 7.7.1. *There exist a CM family $\mathbf{h}_0 \in \mathcal{M}eas(U_{\mathcal{K},p}, e_{\mathrm{ord}} V'_{\mathrm{U}(2)}, \xi^{-1} \hat{\otimes} \hat{\mathcal{O}}_L^{\mathrm{ur}})^{\natural} \otimes_{\mathbb{Z}} \mathbb{Q}$ and a CM family $\mathbf{h}'_0 \in \mathcal{M}eas(U_{\mathcal{K},p}, e_{\mathrm{ord}} V_{\mathrm{U}(2)}, \xi \hat{\otimes} \hat{\mathcal{O}}_L^{\mathrm{ur}})^{\natural} \otimes_{\mathbb{Z}} \mathbb{Q}$ such that for every $\tau_{p\text{-adic}}$ as in Theorem 5.9.1 sufficiently ramified at p ,*

$$\begin{aligned} \mathbf{h}_0 \left(\tau_{p\text{-adic}}|_{U_{\mathcal{K},p}} \right) (g) &= \int_{\mathrm{U}(1)(\mathbb{Q}) \backslash \mathrm{U}(1)(\mathbb{A}_{\mathbb{Q}})} \theta(\phi_{h,\tau})(g, u) (\chi_h \tau_{\mathbf{p}, \mathbf{p}_{\mathbb{N}}})(u) du, \\ \mathbf{h}'_0 \left(\tau_{p\text{-adic}}|_{U_{\mathcal{K},p}} \right) (g) &= \int_{\mathrm{U}(1)(\mathbb{Q}) \backslash \mathrm{U}(1)(\mathbb{A}_{\mathbb{Q}})} \theta(\phi'_{h,\tau})(g, u) (\chi_h^{-1} \tau_{\mathbf{p}, \mathbf{p}_{\mathbb{N}}}^{-1})(u) du, \end{aligned}$$

the theta lift of $\chi_h^{-1} \tau_{\mathbf{p}, \mathbf{p}_{\mathbb{N}}}^{-1}|_{\mathrm{U}(1)}$ (resp. $\chi_h \tau_{\mathbf{p}, \mathbf{p}_{\mathbb{N}}}|_{\mathrm{U}(1)}$) to $\mathrm{U}(2)$) with respect to the Schwartz function $\phi_{h,\tau}$ (resp. $\phi'_{h,\tau}$) on $\mathbb{A}_{\mathbb{Q}}^2$ described as follows:

– $v \notin \Sigma \cup \{\ell, \ell', p\}$.

$$\phi_{h,\tau,v} = \phi'_{h,\tau,v} = \phi_{2,\xi \tau^{\mathbb{N}},v} \text{ in Proposition 7.6.1.}$$

– $v = \mathbf{v}\bar{\mathbf{v}} \in \Sigma_s \cup \{\ell\}$. We have $\chi_h \tau_{\mathbf{p}, \mathbf{p}_{\mathbb{N}}}|_{\mathcal{O}_{\mathcal{K},v}^{\times}} = \chi_h|_{\mathcal{O}_{\mathcal{K},v}^{\times}}$.

$$\begin{aligned} \phi_{h,\tau,v} &= \text{Image of equation (7.1.6) of } \left((y_1, y_2) \longmapsto \mathbb{1}_{\mathbb{Z}_v}(y_1) \cdot \mathbb{1}_{\mathbb{Z}_v^{\times}}(y_2) \chi_{h,\mathbf{v}}^{-1} \lambda_{\bar{\mathbf{v}}}^{-1}(y_2) \right), \\ \phi'_{h,\tau,v} &= \text{Image of equation (7.1.6) of } \left((y_1, y_2) \longmapsto \mathbb{1}_{\mathbb{Z}_v}(y_1) \cdot \mathbb{1}_{\mathbb{Z}_v^{\times}}(y_2) \chi_{h,\mathbf{v}}^{-1} \lambda_{\bar{\mathbf{v}}}(y_2) \right). \end{aligned}$$

– $v \in \Sigma_{\mathrm{ns}} \cup \{\ell'\}$. We have $\chi_h \tau_{\mathbf{p}, \mathbf{p}_{\mathbb{N}}}|_{\mathrm{U}(1)(\mathbb{Q}_v)} = \chi_h|_{\mathrm{U}(1)(\mathbb{Q}_v)}$.

$$\begin{aligned} \phi_{h,\tau,v} &= \text{a Schwartz function on } \mathbb{Q}_v^2 \text{ invariant under } K_v, \text{ independent of } \tau, \\ &\quad \text{belonging to the } \chi_{h,\mathbf{v}}^{-1}|_{\mathrm{U}(1)(\mathbb{Q}_v)}\text{-eigenspace for the action of } \mathrm{U}(1)(\mathbb{Q}_v), \\ \phi'_{h,\tau,v} &= \text{a Schwartz function on } \mathbb{Q}_v^2 \text{ invariant under } K_v, \text{ independent of } \tau, \\ &\quad \text{belonging to the } \chi_{h,\mathbf{v}}|_{\mathrm{U}(1)(\mathbb{Q}_v)}\text{-eigenspace for the action of } \mathrm{U}(1)(\mathbb{Q}_v), \\ &\quad \text{and } \int_{\mathbb{Q}_v^2} \phi_{h,\tau,v}(y) \phi'_{h,\tau,v}(y) dy \neq 0. \end{aligned}$$

– $v = p$. We have $(\chi_h \tau_{p, \mathbb{P}_h})_p = (\xi_0 \tau_0^N)_p$. Let $t = \text{ord}_p(\text{cond}((\xi_0 \tau_0^N)_p))$.

$\phi_{h, \tau, p} = \text{Image of equation (7.1.6) of}$

$$\left((y_1, y_2) \mapsto p^{-t} g \left((\xi_0 \tau_0^N)_p^{-1} \right) \cdot \mathbb{1}_{p^{-t} \mathbb{Z}_p^\times}(y_2) (\xi_0 \tau_0^N)_p(-p^t y_2) \cdot \mathbb{1}_{\mathbb{Z}_p}(y_1) \right),$$

$\phi'_{h, \tau, p} = \text{Image of equation (7.1.6) of} \left((y_1, y_2) \mapsto \mathbb{1}_{\mathbb{Z}_p^\times}(y_1) (\xi_0 \tau_0^N)_p(y_1) \cdot \mathbb{1}_{\mathbb{Z}_p}(y_2) \right).$

Proof. See [Wan20, §8B]. The idea of constructing $\mathbf{h}_0$ (resp. $\mathbf{h}'_0$) is to first use suitably chosen Schwartz functions to construct a family of theta series on $\text{U}(2, 2)$ by interpolating the q -expansions and then restrict the family to $\text{U}(V) \times \text{U}(V^-)$ and evaluate at a suitable point $u_{aux} \in \text{U}(V)(\mathbb{A}_{\mathbb{Q}})$ (resp. $u'_{aux} \in \text{U}(V^-)(\mathbb{A}_{\mathbb{Q}})$) to get the desired family on $\text{U}(V^-)$ (resp. $\text{U}(V)$). $\square$

Definition 7.7.2. The map (7.5.7) between automorphic forms on $\text{U}(2)$ defined in terms of the tame character $\chi_h \chi_\theta^c$ extends to a map from $V_{\text{U}(2)}$ to $V_{\text{U}(2)}$. Applying this twisting map to $\mathbf{h}_0$ in Proposition 7.7.1 defines the CM family $\mathbf{h} \in \text{Meas} \left(U_{\mathcal{K}, p}, e_{\text{ord}} V'_{\text{U}(2), \xi^{-1}} \right)^{\natural} \otimes_{\mathbb{Z}} \mathbb{Q}$.

Replacing $\chi_h \chi_\theta^c$ by $\chi_h^{-1} \chi_\theta^{-c}$ and applying the corresponding twisting map to $\mathbf{h}'_0$ in Proposition 7.7.1 defines the CM family $\tilde{\mathbf{h}}_3 \in \text{Meas} \left(U_{\mathcal{K}, p}, e_{\text{ord}} V_{\text{U}(2), \xi} \right)^{\natural} \otimes_{\mathbb{Z}} \mathbb{Q}$.

7.7.3. The auxiliary CM families θ and $\tilde{\theta}_3$

We construct a CM family θ whose specializations are closely related to the theta series $\theta(\phi_{2, \tau})$ in Proposition 7.6.1. (The theta series $\theta(\phi_{2, \tau})$ is not an eigenform and does not belong to the theta lift of one character of $\text{U}(1)$. The specialization of θ at $\tau_{p\text{-adic}}|_{U_{\mathcal{K}, p}}$ is essentially the projection of $\theta(\phi_{2, \tau^N})$ to the theta lift of $\lambda^2 \chi_\theta \tau_{p, \mathbb{P}_h}^{-c}|_{\text{U}(1)}$.) We also construct a CM family $\tilde{\theta}_3$ dual to θ .

Proposition 7.7.3. (1) There exists a CM family $\theta \in \text{Meas} \left(U_{\mathcal{K}, p}, e_{\text{ord}} V_{\text{U}(2), \xi} \hat{\otimes} \hat{\mathcal{O}}_L^{\text{ur}} \right)^{\natural} \otimes_{\mathbb{Z}} \mathbb{Q}$ and also a CM family $\tilde{\theta}_3 \in \text{Meas} \left(U_{\mathcal{K}, p}, e_{\text{ord}} V'_{\text{U}(2), \xi^{-1}} \hat{\otimes} \hat{\mathcal{O}}_L^{\text{ur}} \right)^{\natural} \otimes_{\mathbb{Z}} \mathbb{Q}$ such that for every $\tau_{p\text{-adic}}$ as in Theorem 5.9.1 ramified at p ,

$$\begin{aligned} \theta \left(\tau_{p\text{-adic}}|_{U_{\mathcal{K}, p}} \right) (g) &= \int_{\text{U}(1)(\mathbb{Q}) \backslash \text{U}(1)(\mathbb{A}_{\mathbb{Q}})} \theta(\phi_{\theta, \tau})(g, u) \left(\lambda^2 \chi_\theta \tau_{p, \mathbb{P}_h}^{-c} \right)^{-1}(u) du, \\ \tilde{\theta}_3 \left(\tau_{p\text{-adic}}|_{U_{\mathcal{K}, p}} \right) (g) &= \int_{\text{U}(1)(\mathbb{Q}) \backslash \text{U}(1)(\mathbb{A}_{\mathbb{Q}})} \theta(\phi'_{\theta, \tau})(g, u) (\lambda^2 \chi_\theta \tau_{p, \mathbb{P}_h}^{-c})(u) du, \end{aligned} \quad (7.7.2)$$

the theta lift of $\lambda^2 \chi_\theta \tau_{p, \mathbb{P}_h}^{-c}|_{\text{U}(1)}$ (resp. $\lambda^{-2} \chi_\theta^{-1} \tau_{p, \mathbb{P}_h}^c|_{\text{U}(1)}$) to $\text{U}(2)$ with respect to the Schwartz function $\phi_{\theta, \tau}$ (resp. $\phi'_{\theta, \tau}$) on $\mathbb{A}_{\mathbb{Q}}^2$ described as follows:

– $v \notin \Sigma \cup \{\ell, \ell', p\}$.

$$\phi_{\theta, \tau, v} = \phi'_{\theta, \tau, v} = \phi_{2, \xi \tau^N, v} \text{ in Proposition 7.6.1.}$$

– $v = v\bar{v} \in \Sigma_s \cup \{\ell'\}$. We have $\chi_\theta \tau_{p, \mathbb{P}_h}^{-c}|_{\mathcal{O}_{\mathcal{K}, v}^\times} = \chi_\theta|_{\mathcal{O}_{\mathcal{K}, v}^\times}$ and $\chi_{\theta, v}$ unramified.

$$\begin{aligned} \phi_{\theta, \tau, v} &= \text{Image of equation (7.1.6) of} \left((y_1, y_2) \mapsto \mathbb{1}_{\mathcal{O}_{\mathcal{K}, v}}(y_1) \cdot \mathbb{1}_{\mathcal{O}_{\mathcal{K}, \bar{v}}^\times}(y_2) \chi_{\theta, \bar{v}} \lambda_{\bar{v}}(y_2) \right) \\ &= \phi_{2, \tau^N, v} \text{ in Proposition 7.6.1,} \end{aligned}$$

$$\phi'_{\theta, \tau, v} = \text{Image of equation (7.1.6) of} \left((y_1, y_2) \mapsto \mathbb{1}_{\mathcal{O}_{\mathcal{K}, v}}(y_1) \cdot \mathbb{1}_{\mathcal{O}_{\mathcal{K}, \bar{v}}^\times}(y_2) (\chi_{\theta, \bar{v}} \lambda_{\bar{v}})^{-1}(y_2) \right).$$

– $v \in \Sigma_{\text{ns}} \cup \{\ell'\}$. We have $\chi_{\theta} \tau_{\mathfrak{p}, \mathfrak{p}_{\mathbb{N}}}^{-c}|_{\text{U}(1)(\mathbb{Q}_v)} = \chi_{\theta}|_{\text{U}(1)(\mathbb{Q}_v)}$.

$\phi_{\theta, \tau, v} = \phi_{2, \xi \tau^{\mathbb{N}}, v}$ in Proposition 7.6.1,

$\phi'_{\theta, \tau, v}$ is a Schwartz function on $\mathbb{Q}_v^2$ invariant under K_v , independent of τ ,
belonging to the $\chi_{\theta}^{-1} \lambda^{-2}|_{\text{U}(1)(\mathbb{Q}_v)}$ -eigenspace for the action of $\text{U}(1)(\mathbb{Q}_v)$,

and $\int_{\mathbb{Q}_v^2} \phi_{\theta, \tau, v}(y) \phi'_{\theta, \tau, v}(y) dy \neq 0$.

– $v = p$. We have $(\chi_{\theta} \tau_{\mathfrak{p}, \mathfrak{p}_{\mathbb{N}}}^{-c})_{\bar{\mathfrak{p}}} = (\xi_0 \tau_0^{\mathbb{N}})^{-1}_{\bar{\mathfrak{p}}}$. Let $t = \text{ord}_p(\text{cond}((\xi_0 \tau_0^{\mathbb{N}})_{\bar{\mathfrak{p}}}))$.

$\phi_{\theta, \tau, p}$ is Image of equation (7.1.6) of

$$\begin{aligned} & \left((y_1, y_2) \mapsto p^{-t} \mathfrak{g}((\xi_0 \tau_0^{\mathbb{N}})^{-1}_{\bar{\mathfrak{p}}}) \cdot \mathbb{1}_{p^{-t} \mathbb{Z}_p^{\times}}(y_1) (\xi_0 \tau_0^{\mathbb{N}})_{\bar{\mathfrak{p}}}(-p^t y_1) \cdot \mathbb{1}_{\mathbb{Z}_p}(y_2) \right), \\ &= \sum_{\mathbb{Z}/p^t \mathbb{Z}} \omega_{\beta, p} \left(\begin{pmatrix} 1 & 0 \\ n & 1 \end{pmatrix}, 1 \right) \phi_{2, \tau^{\mathbb{N}}, p}, \end{aligned}$$

$\phi'_{\theta, \tau, p}$ is Image of equation (7.1.6) of $\left((y_1, y_2) \mapsto \mathbb{1}_{\mathbb{Z}_p}(y_1) \cdot \mathbb{1}_{\mathbb{Z}_p^{\times}}(y_2) (\xi_0 \tau_0^{\mathbb{N}})_{\bar{\mathfrak{p}}}(y_2) \cdot \right)$,

where $\phi_{2, \tau^{\mathbb{N}}, p}$ is as in Proposition 7.6.1.

(2) The specialization $\theta(\tau_{p\text{-adic}}|_{U_{K, p}})$ equals the projection of $\sum_{n \in \mathbb{Z}/p^t \mathbb{Z}} \theta(\phi_{2, \tau^{\mathbb{N}}}) \left(g \begin{pmatrix} 1 & 0 \\ n & 1 \end{pmatrix} \right)$ to the $\lambda^2 \chi_{\theta} \tau_{\mathfrak{p}, \mathfrak{p}_{\mathbb{N}}}^{-c}|_{\text{U}(1)}$ -eigenspace for the action of the center of $\text{U}(2)$. (Note that the projection of a theta series to the $\lambda^2 \chi_{\theta} \tau_{\mathfrak{p}, \mathfrak{p}_{\mathbb{N}}}^{-c}|_{\text{U}(1)}$ -eigenspace for the action of the center is a theta lift of $\lambda^2 \chi_{\theta} \tau_{\mathfrak{p}, \mathfrak{p}_{\mathbb{N}}}^{-c}|_{\text{U}(1)}$.)

Proof. See [Wan20, §8B]. The idea is the same as the construction of $\mathbf{h}_0$ and $\mathbf{h}'_0$, and (2) follows immediately from (1). $\square$

7.8. p -adic Petersson inner product on $\text{U}(2)$

We need p -adic Petersson inner product for families on $\text{U}(2)$. Let $V_{\text{U}(2)}$, $e_{\text{ord}} V'_{\text{U}(2)}$ be as defined in §5.8.3, an $K'_{p,0}(p^n) \subset \text{U}(2)(\mathbb{Z}_p)$ be the subgroup consisting of g with $\mathfrak{p}(g) \equiv \begin{pmatrix} * & * \\ 0 & * \end{pmatrix} \pmod{p^n}$. Following [Hsi21, p.33], we can define a p -adic Petersson inner product

$$\langle \cdot, \cdot \rangle_{p\text{-adic}} : e_{\text{ord}} V'_{\text{U}(2)} \times V_{\text{U}(2)} \longrightarrow \mathcal{O}_L \quad (7.8.1)$$

such that for all $\phi \in V_{\text{U}(2)}$ with $K'_{p,0}(p^n)$ -nebentypus (triv, χ) and $\phi' \in e_{\text{ord}} V'_{\text{U}(2)}$ with $K'_{p,0}(p^n)$ -nebentypus (χ', triv) ,

$$\langle \phi', \phi \rangle_{p\text{-adic}} = \begin{cases} \sum_g (U_p^{-n} \phi') \left(g \varrho_p^{-1} \begin{pmatrix} & 1 \\ -p^n & \end{pmatrix} \right) \phi(g), & \chi \chi' = \text{triv}, \\ 0, & \chi \chi' \neq \text{triv}, \end{cases}$$

where in the summation, g runs over the finite set $\text{U}(2)(\mathbb{Q}) \backslash \text{U}(2)(\mathbb{A}_{\mathbb{Q}, f}) / K_f'^p K'_{p,0}(p^n)$. A useful property of this p -adic Petersson inner product is that

$$\langle \phi', U_p \phi \rangle_{p\text{-adic}} = \omega_{\phi', p}(\varrho_p^{-1}(p))^{-1} \langle U_p \phi, \phi' \rangle_{p\text{-adic}}$$

if ϕ' has central character $\omega_{\phi'}$. Here, ϱ_p^{-1} is the isomorphism from $\mathbb{Q}_p^{\times}$ to $\text{U}(1)(\mathbb{Q}_p)$.

The p -adic Petersson inner product in equation (7.8.1) induces the p -adic Petersson inner product for p -adic families on $U(2)$:

$$\begin{aligned} \langle \cdot, \cdot \rangle_{p\text{-adic}} : \text{Meas}(U_{\mathcal{K},p}, e_{\text{ord}} V'_{U(2)}, \xi^{-1})^{\natural} \times \text{Meas}(U_{\mathcal{K},p}, V_{U(2)}, \xi)^{\natural} \\ \longrightarrow \text{Meas}(U_{\mathcal{K},p}, \mathcal{O}_L) \simeq \mathcal{O}_L[[U_{\mathcal{K},p}]]. \end{aligned} \quad (7.8.2)$$

7.9. The Rallis inner product formulas for $\langle \theta, \tilde{\theta}_3 \rangle_{p\text{-adic}}$ and $\langle h, \tilde{h}_3 \rangle_{p\text{-adic}}$.

From the description of our strategy in §7.5, in particular equation (7.5.13), we see that we need a formula relating $\langle \theta, \tilde{\theta}_2 \rangle_{p\text{-adic}}$ and $\langle h, \tilde{h}_3 \rangle_{p\text{-adic}}$ to certain p -adic L -functions.

Let $\mathcal{L}_3, \mathcal{L}_4 \in \text{Meas}(U_{\mathcal{K},p}, \hat{\mathcal{O}}_L^{\text{ur}}) \otimes_{\mathbb{Z}} \mathbb{Q} \simeq \hat{\mathcal{O}}_L^{\text{ur}}[[U_{\mathcal{K},p}]] \otimes_{\mathbb{Z}} \mathbb{Q}$ be the L -function interpolating the special value at $s = 1$ of $L(s, \pi_{\theta}^{\text{GL}_2}, \text{Ad})$, $L(s, \pi_h^{\text{GL}_2}, \text{Ad})$, which factorize as

$$\begin{aligned} L(s, \pi_{\theta}^{\text{GL}_2}, \text{Ad}) &= L(s, \eta_{\mathcal{K}/\mathbb{Q}}) L(s, \lambda^2 \chi_{\theta} \chi_{\theta}^{-c} \tau_{\mathfrak{p}, \mathfrak{p}_N} \tau_{\mathfrak{p}, \mathfrak{p}_N}^{-c}), \\ L(s, \pi_h^{\text{GL}_2}, \text{Ad}) &= L(s, \eta_{\mathcal{K}/\mathbb{Q}}) L(s, \lambda^{-2} \chi_h^{-1} \chi_h^c \tau_{\mathfrak{p}, \mathfrak{p}_N}^{-1} \tau_{\mathfrak{p}, \mathfrak{p}_N}^c) \\ &= L(s, \eta_{\mathcal{K}/\mathbb{Q}}) L(s, \lambda^2 \chi_h \chi_h^{-c} \tau_{\mathfrak{p}, \mathfrak{p}_N} \tau_{\mathfrak{p}, \mathfrak{p}_N}^{-c}). \end{aligned}$$

More precisely, for $\tau_{p\text{-adic}}$ as in Theorem 5.9.1,

$$\begin{aligned} \mathcal{L}_3(\tau_{p\text{-adic}}|_{U_{\mathcal{K},p}}) &= \pi^{-1} \cdot L^{\infty}(1, \eta_{\mathcal{K}/\mathbb{Q}}) \\ &\quad \times \left(\frac{\Omega_p}{\Omega_{\infty}} \right)^2 \pi^{-2} \cdot \gamma_{\mathfrak{p}} \left(0, \lambda^2 \chi_{\theta} \chi_{\theta}^{-c} \tau_{\mathfrak{p}, \mathfrak{p}_N} \tau_{\mathfrak{p}, \mathfrak{p}_N}^{-c} \right)^{-1} \cdot L^{p\infty} \left(1, \lambda^2 \chi_{\theta} \chi_{\theta}^{-c} \tau_{\mathfrak{p}, \mathfrak{p}_N} \tau_{\mathfrak{p}, \mathfrak{p}_N}^{-c} \right), \\ \mathcal{L}_4(\tau_{p\text{-adic}}|_{U_{\mathcal{K},p}}) &= \pi^{-1} \cdot L^{\infty}(1, \eta_{\mathcal{K}/\mathbb{Q}}) \\ &\quad \times \left(\frac{\Omega_p}{\Omega_{\infty}} \right)^2 \pi^{-2} \cdot \gamma_{\mathfrak{p}} \left(0, \lambda^2 \chi_h \chi_h^{-c} \tau_{\mathfrak{p}, \mathfrak{p}_N} \tau_{\mathfrak{p}, \mathfrak{p}_N}^{-c} \right)^{-1} \cdot L^{p\infty} \left(1, \lambda^2 \chi_h \chi_h^{-c} \tau_{\mathfrak{p}, \mathfrak{p}_N} \tau_{\mathfrak{p}, \mathfrak{p}_N}^{-c} \right). \end{aligned}$$

The existence of $\mathcal{L}_3, \mathcal{L}_4$ follows from Katz p -adic L -functions [Kat78, HT93].

Proposition 7.9.1. *There exists $C_{\theta}, C_h \in L^{\times}$ such that*

$$\langle \tilde{\theta}_3, \theta \rangle_{p\text{-adic}} = C_{\theta} \cdot \mathcal{L}_3, \quad \langle h, \tilde{h}_3 \rangle_{p\text{-adic}} = C_h \cdot \mathcal{L}_4.$$

(See equation (7.8.2) for the definition of the p -adic Petersson inner product for families.)

Proof. The proof is the same as [Wan20, Proposition 8.9], which computes the specializations of the left-hand side by using the Rallis inner product formula. $\square$

7.10. Extending CM forms on $U(2)$ to $GU(2)$

Let $H = GU(2)(\mathbb{Q}) Z_{GU(2)}(\mathbb{A}_{\mathbb{Q}}) U(2)(\mathbb{A}_{\mathbb{Q}})$. Then H is a subgroup of $GU(\mathbb{A}_{\mathbb{Q}})$ of index 2 consisting of $g \in GU(2)(\mathbb{A})$ with $\nu(g) \in \mathbb{Q}^{\times} \text{Nm}(\mathbb{A}_{\mathcal{K}}^{\times})$. Suppose that ϕ is an automorphic form on $U(2)$ and generates an irreducible automorphic representation π_{ϕ} of $U(2)(\mathbb{A}_{\mathbb{Q}})$. Let $\omega : \mathcal{K}^{\times} \backslash \mathbb{A}_{\mathcal{K}}^{\times} \rightarrow \mathbb{C}^{\times}$ be a Hecke character extending the central character of π_{ϕ} . We can first extend ϕ to a function on H by

$$\gamma a g_1 \longmapsto \omega(a) \phi(g_1), \quad \gamma \in GU(2)(\mathbb{Q}), a \in Z_{GU(2)}(\mathbb{A}_{\mathbb{Q}}), g_1 \in U(2)(\mathbb{A}_{\mathbb{Q}})$$

and then extend this function by zero from H to $GU(2)(\mathbb{A}_{\mathbb{Q}})$. We denote this extension of ϕ to $GU(2)(\mathbb{A}_{\mathbb{Q}})$ by $\check{\phi}$. This $\check{\phi}$ is an automorphic form on $GU(2)(\mathbb{A}_{\mathbb{Q}})$.

Proposition 7.10.1. *Suppose that π_ϕ is a theta lift from $\mathrm{U}(1)$. Then $\check{\phi}$ generates an irreducible automorphic representation $\pi_{\check{\phi}}$ of $\mathrm{GU}(2)(\mathbb{A})$. Moreover, if $\phi \in \pi_\phi$ is a pure tensor in $\pi_\phi \simeq \bigotimes_v \pi_{\phi,v}$, then $\check{\phi}$ is also a pure tensor in $\pi_{\check{\phi}} \simeq \bigotimes_v \pi_{\check{\phi},v}$.*

Proof. Let $\pi_{\check{\phi}}$ be the automorphic representation of $\mathrm{GU}(2)(\mathbb{A}_{\mathbb{Q}})$ generated by $\check{\phi}$, and $\pi_{\check{\phi}}^D$ be the corresponding automorphic representation of $D^\times(\mathbb{A}_{\mathbb{Q}})$ (via equation (5.4.3)). Let σ be an irreducible direct summand of $\pi_{\check{\phi}}^D$ and $\mathrm{BC}(\sigma)$ be the base change to $\mathrm{GL}(2)/\mathcal{K}$. Then for each prime $\mathfrak{v}$ of $\mathcal{K}$ over a split prime v in $\mathbb{Q}$, we have $\mathrm{BC}(\sigma)_{\mathfrak{v}} \cong \omega_{\mathfrak{v}} \lambda_{\mathfrak{v}}^{-1} \oplus \omega_{\mathfrak{v}}^c \lambda_{\mathfrak{v}}^{-c}$. Therefore, $\mathrm{BC}(\sigma) \cong \mathrm{BC}(\pi_{\omega}^D)$ with π_{ω}^D the automorphic representation of $D^\times(\mathbb{A}_{\mathbb{Q}})$ corresponding to the theta lift of ω from $\mathrm{GU}(1)$ to $\mathrm{GU}(2)$ ([Ram15, Corollary B]). It follows that $\sigma = \pi_{\omega}^D$, and we see that all the irreducible direct summands of $\pi_{\check{\phi}}^D$ are isomorphic. Hence, $\pi_{\check{\phi}}^D$ is irreducible and so is $\pi_{\check{\phi}}$. (See also [Wan20, Lemma 8.1].)

Since $\check{\phi}$ is obtained by extension by zero, it belongs to the direct summand π_ϕ in $\pi_{\check{\phi}|_{\mathrm{U}(2)}}$. Hence, ϕ being a pure tensor in π_ϕ implies that $\check{\phi}$ is a pure tensor in $\pi_{\check{\phi}}$. $\square$

The above extension from $\mathrm{U}(2)$ to $\mathrm{GU}(2)$ also works for p -adic automorphic forms. We denote by $\check{\mathbf{h}}$ the extension of $\mathbf{h}$ whose specialization at $\tau_{p\text{-adic}}$ is the extension by zero of $\mathbf{h}(\tau_{p\text{-adic}})$ to $\mathrm{GU}(2)$ with respect to the character $\chi_\theta^{-1} \tau_{\mathfrak{p}, \mathfrak{p}_h}^{-1}$. Similarly, we denote by $\check{\mathbf{h}}_3$ (resp. $\check{\theta}, \check{\theta}_3$) the extension of $\mathbf{h}_3$ whose specialization at $\tau_{p\text{-adic}}$ is the extension by zero of $\mathbf{h}_3(\tau_{p\text{-adic}})$ to $\mathrm{GU}(2)$ with respect to the character $\chi_\theta \tau_{\mathfrak{p}, \mathfrak{p}_h}$ (resp. $\chi_\theta \tau_{\mathfrak{p}, \mathfrak{p}_h}, \chi_\theta^{-1} \tau_{\mathfrak{p}, \mathfrak{p}_h}^{-1}$).

7.11. The nonvanishing property of the degenerate Fourier–Jacobi coefficients of the Klingen Eisenstein family

Let $\mathcal{L}_5, \mathcal{L}_6 \in \mathrm{Meas}\left(\mathrm{U}_{\mathcal{K}, p}, \hat{\mathcal{O}}_L^{\mathrm{ur}}\right) \otimes_{\mathbb{Z}} \mathbb{Q} \simeq \hat{\mathcal{O}}_L^{\mathrm{ur}}[[\mathrm{U}_{\mathcal{K}, p}]] \otimes_{\mathbb{Z}} \mathbb{Q}$ be the Katz p -adic L -functions interpolating special values of $L(s, \chi_h \chi_\theta^c \xi_0 \tau_0^N)$, $L\left(s, \lambda^2 \chi_h \chi_\theta \tau_{\mathfrak{p}, \mathfrak{p}_h}^{-1} \tau_{\mathfrak{p}, \mathfrak{p}_h}^c (\xi_0 \tau_0^N)^c\right)$. In particular, for a Hecke character $\tau : \mathcal{K}^\times \backslash \mathbb{A}_{\mathcal{K}}^\times \rightarrow \mathbb{C}^\times$ as in Theorem 5.9.1,

$$\begin{aligned} \mathcal{L}_5\left(\tau_{p\text{-adic}}|_{\mathrm{U}_{\mathcal{K}, p}}\right) &= \left(\frac{\Omega_p}{\Omega_\infty}\right)^{Nk} 2\pi i \Gamma(Nk-1) \cdot \gamma_{\bar{\mathfrak{p}}}\left(\frac{4-Nk}{2}, (\chi_h \chi_\theta^c \xi_0 \tau_0^N)^{-1}\right) \\ &\quad \times L^{p^\infty}\left(\frac{Nk-2}{2}, \chi_h \chi_\theta^c \xi_0 \tau_0^N\right), \\ \mathcal{L}_6\left(\tau_{p\text{-adic}}|_{\mathrm{U}_{\mathcal{K}, p}}\right) &= \left(\frac{\Omega_p}{\Omega_\infty}\right)^{Nk-2} \Gamma(Nk-2) \cdot L_{\mathfrak{p}}\left(\frac{Nk-2}{2}, \lambda^2 \chi_h \chi_\theta \tau_{\mathfrak{p}, \mathfrak{p}_h}^{-c} \tau_{\mathfrak{p}, \mathfrak{p}_h}^c (\xi_0 \tau_0^N)^c\right), \\ &\quad \times L^{p^\infty}\left(\frac{Nk-2}{2}, \lambda^2 \chi_h \chi_\theta \tau_{\mathfrak{p}, \mathfrak{p}_h}^{-c} \tau_{\mathfrak{p}, \mathfrak{p}_h}^c (\xi_0 \tau_0^N)^c\right). \end{aligned}$$

The product of $\mathcal{L}_5 \mathcal{L}_6$ interpolates the special values of $L(s, \mathrm{BC}(\pi_h) \times \xi_0 \tau_0 \lambda^{-1})$, where π_h is the automorphic representation associated to specializations of the CM family $\mathbf{h}$. Note that the restriction of $\lambda^2 \chi_h \chi_\theta \tau_{\mathfrak{p}, \mathfrak{p}_h}^{-c} \tau_{\mathfrak{p}, \mathfrak{p}_h}^c (\xi_0 \tau_0^N)^c$ to $\mathcal{O}_{\mathcal{K}, p}^\times$ is $(\xi_{0, \mathfrak{p}} \xi_{0, \bar{\mathfrak{p}}} \tau_{0, \mathfrak{p}}^N \tau_{0, \bar{\mathfrak{p}}}^N, \mathrm{triv})$, so $\mathcal{L}_6$ is essentially of one variable. In fact, $\mathcal{L}_6$ is the so-called ‘improved’ p -adic L -function, for which the local factor at p in the interpolation formula is a partial local L -factor instead of a partial local γ -factor.

Proposition 7.11.1. *For φ inside the space (5.6.11), an operator $\mathcal{T}_{\mathrm{ns}} \in \bigotimes_{v \in \Sigma_{\mathrm{ns}} \cup \{\ell'\}} \mathcal{O}_L[\mathrm{GU}(2)(\mathbb{Q}_v)]$ such that $\mathcal{T}_{\mathrm{ns}} \mathbf{h}$ is still invariant under the tame level group K_f^p (defined equation (5.6.7)), and $u_1, \dots, u_r \in \bigotimes_{v \in \Sigma_{\mathrm{ns}} \cup \{\ell'\}} \mathrm{U}(1)(\mathbb{Q}_v)$, $b_1, \dots, b_r \in \mathcal{O}_L$ as in Proposition 7.6.1,*

$$\begin{aligned} & \left\langle \left(\mathcal{T}_{\text{ns}} \check{\mathbf{h}} \right) |_{\text{U}(2)}, \mathcal{P}_{N,*} \left(l_{\theta^J} \left(\sum_i b_i \mathbf{E}_{\varphi, \beta, u_i}^{\text{Kling}} \right) \right) \right\rangle_{p\text{-adic}} \\ &= \mathcal{C}_1 \cdot \mathcal{L}_5 \mathcal{L}_6 \cdot \left\langle \left(\mathcal{T}_{\text{ns}} \check{\mathbf{h}} \right) |_{\text{U}(2)}, \theta^{\bar{\lambda}} \varphi \right\rangle_{p\text{-adic}}, \end{aligned} \quad (7.11.1)$$

where $\theta^{\bar{\lambda}} = \theta \cdot (\bar{\lambda} \circ \det)$ and $\mathcal{C}_1 \in \left(\hat{\mathcal{O}}_L^{\text{ur}}[[U_{\mathcal{K},p}]] \otimes_{\mathbb{Z}} \mathbb{Q} \right)^{\times}$.

Proof. The identity is proved by comparing the evaluations of both sides at $\tau_{p\text{-adic}}$ as in Theorem 5.9.1. For such a $\tau_{p\text{-adic}}$, put $\theta_{\tau} = \theta(\tau_{p\text{-adic}}|_{U_{\mathcal{K},p}})$ and $h_{\tau} = \mathbf{h}(\tau_{p\text{-adic}}|_{U_{\mathcal{K},p}})$, which are classical ordinary CM forms. The description of $l_{\theta^J} \left(\sum_i b_i \mathbf{E}_{\varphi, \beta, u_i}^{\text{Kling}} \right)$ in Proposition 7.6.1 and the definition of the p -adic Petersson inner product in §7.8 imply that

$$\begin{aligned} & \left(\frac{\Omega_p}{\Omega_{\infty}} \right)^{-2Nk+2} \cdot \text{LHS of equation (7.11.1) evaluated at } \tau_{p\text{-adic}} \\ &= d_2^{\Sigma \cup \{p, \ell, \ell'\}} \left(s, \xi_0 \tau_0^N \lambda^{-1} \right) \int_{\text{U}(2)(\mathbb{Q}) \setminus \text{U}(2)(\mathbb{A}_{\mathbb{Q}})} \theta_{\tau} \left(g_2 \varrho_p^{-1} \begin{pmatrix} & 1 \\ -1 & \end{pmatrix} \right) \varphi^{\tilde{\xi}_0 \tilde{\tau}_0^N}(g_2) \\ & \quad \int_{\text{U}(2)(\mathbb{Q}) \setminus \text{U}(2)(\mathbb{A}_{\mathbb{Q}})} E_2^{\text{Siege}} \left(\iota_0(g_1, g_2); f_2(s, \xi_0 \tau_0^N \lambda^{-1}) \xi_0^{-1} \tau_0^{-N} \lambda(\det g_1) \right. \\ & \quad \left. \times (U_p^{-m} \mathcal{T}_{\text{ns}} \check{h}_{\tau}) \left(g_1 \begin{pmatrix} & 1 \\ -p^m & \end{pmatrix}_p \right) dg_1 dg_2 \right|_{s=\frac{Nk-3}{2}} \\ &= \int_{\text{U}(2)(\mathbb{Q}) \setminus \text{U}(2)(\mathbb{A}_{\mathbb{Q}})} \theta_{\tau}^{\bar{\lambda}}(g_2) \varphi(g_2) h'_{\tau}(g_2) dg_2 \end{aligned} \quad (7.11.2)$$

with ι_0 defined in equation (6.2.2) and

$$\begin{aligned} h'_{\tau}(g_2) &= d_2^{\Sigma \cup \{p, \ell, \ell'\}} \left(s, \xi_0 \tau_0^N \lambda^{-1} \right)^{-1} \cdot \int_{\text{U}(2)(\mathbb{A}_{\mathbb{Q}})} f_{2,v} \left(s, \xi_0 \tau_0^N \lambda^{-1} \right) \left(\iota_0 \left(\begin{pmatrix} & 1 \\ -1 & \end{pmatrix}_p g, 1 \right) \right) \\ & \quad \times (U_p^{-m} \mathcal{T}_{\text{ns}} \check{h}_{\tau}) \left(g_2 g \begin{pmatrix} & 1 \\ -p^m & \end{pmatrix}_p \right) dg \Big|_{s=\frac{Nk-3}{2}}, \end{aligned}$$

where m is any sufficiently large integer. The integral over g is essentially doubling local zeta integral.

By using the same computation results in the proof of Theorem 6.1.1 for all $v \neq p$, we obtain

$$\begin{aligned} h'_{\tau}(g_2) &= \mathcal{C}_1(\tau_{p\text{-adic}}) \cdot \frac{\Gamma(Nk-1)\Gamma(Nk-2)}{(2\pi i)^{2Nk-3}} \cdot L^{p\infty} \left(\frac{Nk-2}{2}, \text{BC}(\pi_{h_{\tau}}) \times \xi_0 \tau_0^N \lambda^{-1} \right) \\ & \quad \times \int_{\text{U}(2)(\mathbb{Q}_p)} f_{2,p} \left(s, \xi_0 \tau_0^N \lambda^{-1} \right) \left(\iota_0 \left(\begin{pmatrix} & 1 \\ -1 & \end{pmatrix}_p g, 1 \right) \right) \\ & \quad \times (U_p^{-m} \mathcal{T}_{\text{ns}} \check{h}_{\tau}) \left(g_2 g \begin{pmatrix} & 1 \\ -p^m & \end{pmatrix}_p \right) dg \Big|_{s=\frac{Nk-3}{2}}, \end{aligned} \quad (7.11.3)$$

where $\mathcal{C}_1$ is the product of

- the local doubling zeta integrals at $v \in \Sigma \cup \{\ell, \ell'\}$, which is a nonzero constant in L by our choice, and
- the element in $\hat{\mathcal{O}}_L^{\text{ur}}[[U_{\mathcal{K},p}]]$ interpolating $L_q \left(\frac{Nk-2}{2}, \chi_h \chi_{\theta}^c \xi_0 \tau_0^N \right)^{-1}$, which is a unit by our assumption on equation (5.6.5).

Our choice of χ_h, χ_{θ} implies that $L_v(s, \text{BC}(\pi_{h_{\tau}}) \times \xi_0 \tau_0^N \lambda^{-1}) = 1$ for $v \in \Sigma \cup \{\ell, \ell'\}$. The computation at p is slightly different from that in the construction of p -adic L -functions because the section

$f_{2,p}(s, \xi_0 \tau_0 \lambda^{-1})$ is slightly different from the one for p -adic L -functions. The Schwartz function $\alpha'_{\xi\tau,p}$ in the description of $f_{2,p}(s, \xi_0 \tau_0 \lambda^{-1})$ in Proposition 7.6.1 only requires x_{12} to be supported on $p^{-t} \mathbb{Z}_p^\times$.

Unlike the section for constructing p -adic L -functions, $\alpha'_{\xi\tau,p}$ does not require the whole $\begin{pmatrix} x_{11} & x_{12} \\ x_{21} & x_{22} \end{pmatrix}$ to be supported on $p^{-t} \mathrm{GL}_2(\mathbb{Z}_p)$. (In fact, $f_{2,p}(s, \tau_0 \lambda^{-1})$ is essentially of the same type as the section in [LR20, Table 2 on p.210] for constructing the ‘improved’ p -adic L -function.) The computation at p is done in [Wan20, 6I], and plugging it into equation (7.11.3), we get

$$\begin{aligned} h'_\tau(g_2) &= \mathcal{C}_1(\tau_{p\text{-adic}}) \cdot \frac{\Gamma(Nk-1)\Gamma(Nk-2)}{(2\pi i)^{2Nk-3}} \cdot L^{p\infty}\left(\frac{Nk-2}{2}, \mathrm{BC}(\pi_{h_\tau}) \times \xi_0 \tau_0 \lambda^{-1}\right) \\ &\quad \times \gamma_{\bar{p}}\left(\frac{4-Nk}{2}, (\chi_h \chi_\theta^c \xi_0 \tau_0^N)^{-1}\right) L_{\bar{p}}\left(\frac{Nk-2}{2}, \lambda^2 \chi_h \chi_\theta \tau_{\bar{p}, \mathbb{A}_h} \tau_{\bar{p}, \mathbb{A}_h}^{-c} (\xi_0 \tau_0^N)^c\right) \\ &\quad \times (U_p^{-m} \mathcal{T}_{\mathrm{ns}} \check{h}_\tau) \left(g_2 \begin{pmatrix} & 1 \\ -p^m & \end{pmatrix}_p \right). \end{aligned}$$

Plugging this into equation (7.11.2), we see that the evaluations at $\tau_{p\text{-adic}}$ of the two sides of equation (7.11.1) are equal. $\square$

We introduce some more p -adic L -functions. Let $\mathcal{L}_1 \in \mathrm{Meas}(U_{\mathcal{K},p}, \hat{\mathcal{O}}_L^{\mathrm{ur}}) \otimes_{\mathbb{Z}} \mathbb{Q} \simeq \hat{\mathcal{O}}_L^{\mathrm{ur}}[[U_{\mathcal{K},p}]] \otimes_{\mathbb{Z}} \mathbb{Q}$ be the p -adic L -function interpolating the central values of $L\left(s, \mathrm{BC}(\pi) \times \lambda^2 \chi_h \chi_\theta \tau_{\bar{p}, \mathbb{A}_h}^{-1} \tau_{\bar{p}, \mathbb{A}_h}^c\right)$, that is, for $\tau_{p\text{-adic}}$ as in Theorem 5.9.1,

$$\begin{aligned} \mathcal{L}_1(\tau_{p\text{-adic}}|_{U_{\mathcal{K},p}}) &= \left(\frac{\Omega_p}{\Omega_\infty}\right)^4 \pi^{-3} \cdot \gamma_p\left(\frac{1}{2}, \pi_{f,p} \times \left(\lambda^2 \chi_h \chi_\theta \tau_{\bar{p}, \mathbb{A}_h} \tau_{\bar{p}, \mathbb{A}_h}^{-c}\right)_{\bar{p}}\right)^{-1} \\ &\quad \times L^{p\infty}\left(\frac{1}{2}, \mathrm{BC}(\pi) \times \lambda^2 \chi_h \chi_\theta \tau_{\bar{p}, \mathbb{A}_h} \tau_{\bar{p}, \mathbb{A}_h}^{-c}\right). \end{aligned}$$

The existence of such a p -adic L -function follows from [Hsi14b]. Let

$$\mathcal{L}_2 = \pi^{-2} \langle f, \bar{f} \rangle^{-1} \cdot L^\infty\left(\frac{1}{2}, \mathrm{BC}(\pi) \times \chi_h \chi_\theta^c\right) \in L^{\mathrm{ur}}.$$

The product of $\mathcal{L}_1 \mathcal{L}_2$ interpolates the central values of $L\left(s, \pi \times \pi_h^{\mathrm{GL}_2} \times \pi_{\theta^\lambda}^{\mathrm{GL}_2}\right)$ with h, θ specializations of the CM families $\mathbf{h}, \boldsymbol{\theta}$.

Note that because π has trivial central character and $\chi_h \chi_\theta^c|_{\mathbb{A}_Q^\times} = \mathrm{triv}$, when $\mathrm{cond}(\xi_{0,p} \tau_{0,p}^N) = p^t$,

$$\begin{aligned} &\gamma_p\left(\frac{1}{2}, \pi_p \times \left(\lambda^2 \chi_h \chi_\theta \tau_{\bar{p}, \mathbb{A}_h} \tau_{\bar{p}, \mathbb{A}_h}^{-c}\right)_{\bar{p}}\right)^{-1} \\ &= \mathfrak{g}\left((\xi_0 \tau_0^N)_p^{-1}\right)^2 \cdot \left(\lambda_{\bar{p}}^2 \chi_{h,\bar{p}} \chi_{\theta,\bar{p}} \tau_{0,p}^{-N}(p) p^{1/2}\right)^{-2t} \\ &= p^{-t} \cdot \mathfrak{g}\left((\xi_0 \tau_0^N)_p^{-1}\right) \left(\lambda_{\bar{p}}^2 \chi_{\theta,\bar{p}} \chi_{\theta,\bar{p}}^{-1} \tau_{0,p}^{-N}(p)\right)^{-t} \cdot \mathfrak{g}\left((\xi_0 \tau_0^N)_p^{-1}\right) \left(\lambda_{\bar{p}}^2 \chi_{h,\bar{p}} \chi_{h,\bar{p}}^{-1} \tau_{0,p}^{-N}(p)\right)^{-t} \\ &= p^{-t} \cdot \gamma_{\bar{p}}\left(0, \lambda^2 \chi_\theta \chi_\theta^{-c} \tau_{\bar{p}, \mathbb{A}_h} \tau_{\bar{p}, \mathbb{A}_h}^{-c}\right)^{-1} \cdot \gamma_{\bar{p}}\left(0, \lambda^2 \chi_h \chi_h^{-c} \tau_{\bar{p}, \mathbb{A}_h} \tau_{\bar{p}, \mathbb{A}_h}^{-c}\right)^{-1}. \end{aligned} \tag{7.11.4}$$

Combining equation (7.11.4), the above interpolation formulas for $\mathcal{L}_1, \mathcal{L}_2$, and the interpolation formulas for $\mathcal{L}_3, \mathcal{L}_4$ in §7.9, we see that when $\mathrm{cond}(\xi_{0,p} \tau_{0,p}^N) = p^t$,

$$\begin{aligned}
 & \left(\frac{\mathcal{L}_1 \mathcal{L}_2}{\mathcal{L}_3 \mathcal{L}_4} \right) \left(\tau_{p\text{-adic}}|_{U_{\mathcal{K},p}} \right) \\
 &= \pi \cdot p^{-t} L_p \left(\frac{1}{2}, \text{BC}(\pi) \times \chi_h \chi_\theta^c \right) \\
 & \quad \times \frac{L^{p\infty} \left(\frac{1}{2}, \text{BC}(\pi) \times \lambda^2 \chi_h \chi_\theta \tau_{\mathfrak{p}, \mathfrak{p}_\mathbb{N}} \tau_{\mathfrak{p}, \mathfrak{p}_\mathbb{N}}^{-c} \right) \cdot L^{p\infty} \left(\frac{1}{2}, \text{BC}(\pi) \times \chi_h \chi_\theta^c \right)}{L^\infty(1, \eta_{\mathcal{K}, \mathbb{Q}})^2 \cdot L^{p\infty} \left(1, \lambda^2 \chi_\theta \chi_\theta^{-c} \tau_{\mathfrak{p}, \mathfrak{p}_\mathbb{N}} \tau_{\mathfrak{p}, \mathfrak{p}_\mathbb{N}}^{-c} \right) \cdot L^{p\infty} \left(1, \lambda^2 \chi_h \chi_h^{-c} \tau_{\mathfrak{p}, \mathfrak{p}_\mathbb{N}} \tau_{\mathfrak{p}, \mathfrak{p}_\mathbb{N}}^{-c} \right)} \\
 &= \pi \frac{L^\infty(1, \pi, \text{Ad})}{\langle f, \bar{f} \rangle} \cdot p^{-t} \frac{L_p \left(\frac{1}{2}, \text{BC}(\pi) \times \chi_h \chi_\theta^c \right)}{L_p(1, \eta_{\mathcal{K}/\mathbb{Q}})^2 \cdot L_p(1, \pi, \text{Ad})} \\
 & \quad \times \frac{L^{p\infty} \left(\frac{1}{2}, \pi \times \pi_h^{\text{GL}_2} \times \pi_{\theta^\lambda}^{\text{GL}_2} \right)}{L^{p\infty}(1, \pi, \text{Ad}) \cdot L^{p\infty} \left(1, \pi_{\theta^\lambda}^{\text{GL}_2}, \text{Ad} \right) \cdot L^{p\infty} \left(1, \pi_h^{\text{GL}_2}, \text{Ad} \right)}.
 \end{aligned} \tag{7.11.5}$$

Proposition 7.11.2. *There exist operators $\mathcal{T}_{\text{ns}}, \mathcal{T}'_{\text{ns}} \in \bigotimes_{v \in \Sigma_{\text{ns}} \cup \{\ell'\}} \mathcal{O}_L[\text{GU}(2)(\mathbb{Q}_v)]$, and φ inside the space (5.6.11), φ' inside the space (5.6.10) such that $\mathcal{T}_{\text{ns}} \mathbf{h}$ is invariant under the tame level group $K_f'^p$ (defined in equation (5.6.7)) and*

$$\begin{aligned}
 & \left\langle \left(\mathcal{T}_{\text{ns}} \check{\mathbf{h}} \right) |_{U(2)}, \theta^\lambda \varphi \right\rangle_{p\text{-adic}} \left\langle \left(\mathcal{T}'_{\text{ns}} \check{\mathbf{h}}_3 \right) |_{U(2)}, \check{\theta}_3^\lambda \varphi' \right\rangle_{p\text{-adic}} \\
 &= C_2 \cdot \langle \theta, \check{\theta}_3 \rangle_{p\text{-adic}} \langle \mathbf{h}, \check{\mathbf{h}}_3 \rangle_{p\text{-adic}} \cdot \frac{\mathcal{L}_1 \mathcal{L}_2}{\mathcal{L}_3 \mathcal{L}_4}
 \end{aligned} \tag{7.11.6}$$

with $C_2 \in L^\times$.

Proof. For $\mathcal{T}_{\text{ns}}, \mathcal{T}'_{\text{ns}} \in \bigotimes_{v \in \Sigma_{\text{ns}} \cup \{\ell'\}} \mathcal{O}_L[\text{GU}(2)(\mathbb{Q}_v)]$ and φ, φ' in equation (5.6.11) corresponding to pure tensors in $\bigotimes_v \pi_v^{\text{GU}(2)}$, we consider evaluations at $\tau_{p\text{-adic}}$ as in Theorem 5.9.1 with $\text{cond}(\tau_{\mathfrak{p}}) = p^t$. Put $\theta_\tau = \theta(\tau_{p\text{-adic}})$ and $\mathbf{h}_\tau = \mathbf{h}(\tau_{p\text{-adic}})$.

$$\begin{aligned}
 \text{LHS of equation (7.11.6)} \\
 \text{valued at } \tau_{p\text{-adic}} &= \int_{U(2)(\mathbb{Q}) \backslash U(2)(\mathbb{A}_{\mathbb{Q}})} \theta_\tau^\lambda(g) \varphi(g) \left(\mathcal{T}_{\text{ns}} \check{\mathbf{h}}_\tau \right) \left(g \begin{pmatrix} & 1 \\ -p^t & \end{pmatrix}_p \right) dg \\
 & \quad \times \int_{U(2)(\mathbb{Q}) \backslash U(2)(\mathbb{A}_{\mathbb{Q}})} \check{\theta}_\tau^\lambda(g) \varphi'(g) \left(\mathcal{T}'_{\text{ns}} \check{\mathbf{h}}_\tau \right) \left(g \begin{pmatrix} & 1 \\ -p^t & \end{pmatrix}_p \right) dg.
 \end{aligned} \tag{7.11.7}$$

We can replace θ_τ^λ (resp. $\check{\theta}_\tau^\lambda$) in the integrand by $\check{\theta}_\tau^\lambda$ (resp. $\check{\check{\theta}}_\tau^\lambda$), its extension by zero to $\text{GU}(2)$ with respect the character $\chi_\theta \tau_{\mathfrak{p}, \mathfrak{p}_\mathbb{N}}$ (resp. $\chi_\theta^{-1} \tau_{\mathfrak{p}, \mathfrak{p}_\mathbb{N}}^{-1}$) (as described at the beginning of §7.10) and replace the domain of integration by $\text{GU}(2)(\mathbb{Q}) Z_{\text{GU}(2)}(\mathbb{A}_{\mathbb{Q}}) \backslash \text{GU}(2)(\mathbb{A}_{\mathbb{Q}})$. Thanks to equation (5.4.3), we can further replace $\text{GU}(2)(\mathbb{Q}) Z_{\text{GU}(2)}(\mathbb{A}_{\mathbb{Q}}) \backslash \text{GU}(2)(\mathbb{A}_{\mathbb{Q}})$ by $D^\times(\mathbb{Q}) Z_D(\mathbb{A}_{\mathbb{Q}}) \backslash D^\times(\mathbb{A}_{\mathbb{Q}})$. Then for $\mathcal{T}_{\text{ns}}, \mathcal{T}'_{\text{ns}} \in \bigotimes_{v \in \Sigma_{\text{ns}} \cup \{\ell'\}} \mathcal{O}_L[D^\times(\mathbb{Q}_v)] \subset \bigotimes_{v \in \Sigma_{\text{ns}} \cup \{\ell'\}} \mathcal{O}_L[\text{GU}(2)(\mathbb{Q}_v)]$, we can rewrite equation (7.11.7) as

$$\begin{aligned}
 \text{LHS of equation (7.11.6)} \\
 \text{valued at } \tau_{p\text{-adic}} &= \int_{\mathbb{A}_{\mathbb{Q}}^\times \backslash D^\times(\mathbb{A}_{\mathbb{Q}})} \check{\theta}_\tau^\lambda(g) \varphi(g) \left(\mathcal{T}_{\text{ns}} \check{\mathbf{h}}_\tau \right) \left(g \begin{pmatrix} & 1 \\ -p^t & \end{pmatrix}_p \right) dg \\
 & \quad \times \int_{\mathbb{A}_{\mathbb{Q}}^\times \backslash D^\times(\mathbb{A}_{\mathbb{Q}})} \check{\check{\theta}}_\tau^\lambda(g) \varphi'(g) \left(\mathcal{T}'_{\text{ns}} \check{\mathbf{h}}_\tau \right) \left(g \begin{pmatrix} & 1 \\ -p^t & \end{pmatrix}_p \right) dg.
 \end{aligned} \tag{7.11.8}$$

This is the triple product integral.

Let

$$F_\tau = \left(\check{\theta}_\tau^\lambda \otimes \varphi \otimes \mathcal{T}_{\text{ns}} \check{h}_\tau \right) |_{D^\times(\mathbb{A})}, \quad F'_\tau = \left(\check{\theta}_{3,\tau}^\lambda \otimes \varphi' \otimes \mathcal{T}'_{\text{ns}} \check{h}_{3,\tau} \right) |_{D^\times(\mathbb{A})}.$$

Then F_τ generates $\Pi_\tau = \pi_{\check{\theta}_\tau^\lambda}^D \otimes \pi_{\check{h}_\tau}^D \otimes \pi^D$, where $\pi_{\check{\theta}_\tau^\lambda}^D$ (resp. $\pi_{\check{h}_\tau}^D, \pi^D$) is the automorphic representation of $D^\times(\mathbb{A}_\mathbb{Q})$ generated by the restriction of $\check{\theta}_\tau^\lambda$ (resp. $\check{h}_\tau, \varphi$) to $D^\times$, and F'_τ generates $\tilde{\Pi}_\tau$, the contragredient representation of Π_τ . By the isomorphism (5.4.3) and Proposition 7.10.1, we know that $\pi_{\check{\theta}_\tau^\lambda}^D, \pi_{\check{h}_\tau}^D$ are irreducible and $\check{\theta}_\tau^\lambda, \check{h}_\tau$ are pure tensors. By the definition of φ , we know that $\pi_\varphi^D = \pi^D$. Hence, Π_τ (resp. $\tilde{\Pi}_\tau$) is irreducible, and the image of F_τ (resp. F'_τ) under $\Pi_\tau \simeq \bigotimes_v \Pi_{\tau,v}$ ($\tilde{\Pi}_\tau \simeq \bigotimes_v \tilde{\Pi}_{\tau,v}$) is a pure tensor $\bigotimes_v F_{\tau,v}$ (resp. $\bigotimes_v F'_{\tau,v}$). By Ichino's triple product formula [Ich08], equation (7.11.8) becomes

$$\begin{aligned} & \text{LHS of equation (7.11.6) valued at } \tau_{p\text{-adic}} \\ &= \prod_v \int_{\mathbb{A}_\mathbb{Q}^\times \backslash D^\times(\mathbb{A}_\mathbb{Q})} \langle \Pi_v(g_v) F_{\tau,v}, F'_{\tau,v} \rangle_v dg_v \\ &= \langle f^D, \bar{f}^D \rangle \langle \theta_\tau, \tilde{\theta}_{3,\tau} \rangle_{p\text{-adic}} \langle h_\tau, \tilde{h}_{3,\tau} \rangle_{p\text{-adic}} \cdot \frac{\zeta^{\Sigma \cup \{\infty, p, \ell, \ell'\}}(2)^2 \cdot L^{\Sigma \cup \{\infty, p, \ell, \ell'\}}\left(\frac{1}{2}, \Pi\right)}{L^{\Sigma \cup \{\infty, p, \ell, \ell'\}}(1, \Pi, \text{Ad})} \\ & \quad \times \prod_{v \in \Sigma \cup \{\infty, \ell, \ell'\}} \frac{\int_{\mathbb{Q}_v^\times \backslash D^\times(\mathbb{Q}_v)} \langle \Pi_v(g) F_{\tau,v}, F'_{\tau,v} \rangle_v dg}{\langle f_v^D, \bar{f}_v^D \rangle_v \langle \theta_{\tau,v}, \tilde{\theta}_{3,\tau,v} \rangle_v \langle h_{\tau,v}, \tilde{h}_{3,\tau,v} \rangle_v} \\ & \quad \times \frac{\int_{\mathbb{Q}_p^\times \backslash D^\times(\mathbb{Q}_p)} \langle \Pi_p(g) F_{\tau,p}, F'_{\tau,p} \rangle_p dg}{\langle f_p^D, \bar{f}_p^D \rangle_p \langle \theta_{\tau,p}, \begin{pmatrix} -p' & 1 \end{pmatrix} \tilde{\theta}_{3,\tau,p} \rangle_p \langle h_{\tau,p}, \begin{pmatrix} -p' & 1 \end{pmatrix} \tilde{h}_{3,\tau,p} \rangle_p}. \end{aligned} \quad (7.11.9)$$

We have the following results for the local integrals at $v \in \Sigma \cup \{\infty, p, \ell, \ell'\}$:

– $v \in \Sigma_s \cup \{\infty, \ell\}$.

$$\frac{\int_{\mathbb{Q}_v^\times \backslash D^\times(\mathbb{Q}_v)} \langle \Pi_v(g) \phi_v, \phi'_v \rangle_v dg}{\langle f_v^D, \bar{f}_v^D \rangle_v \langle \theta_{\tau,v}, \tilde{\theta}_{3,\tau,v} \rangle_v \langle h_{\tau,v}, \tilde{h}_{3,\tau,v} \rangle_v} = \text{a nonzero constant independent of } \tau.$$

For $v = \infty$, the integral is 1 because Π_∞ is the trivial representation. For $v = \Sigma_s \cup \{\ell\}$, this is [Wan20, Lemmas 8.13–8.17]. Note that the twist at $v \in \Sigma_s \cup \{\ell\}$ in equation (5.6.9) guarantees that the local integrals are nonzero constants.

– $v \in \Sigma_{\text{ns}} \cup \{\ell'\}$. There exist $\mathcal{T}_v, \mathcal{T}'_v \in \mathcal{O}_L[D^\times(\mathbb{Q}_v)] \subset \mathcal{O}_L[\text{GU}(2)(\mathbb{Q}_v)]$ and $\varphi_v, \varphi'_v \in \pi_v^{\text{GU}(2)}$ such that φ_v and $\mathcal{T}_v h$ are invariant under the level group K_v (defined in equation (5.6.6)) and

$$\frac{\int_{\mathbb{Q}_v^\times \backslash D^\times(\mathbb{Q}_v)} \langle \Pi_v(g) F_{\tau,v}, F'_{\tau,v} \rangle_v dg}{\langle f_v^D, \bar{f}_v^D \rangle_v \langle \theta_{\tau,v}, \tilde{\theta}_{3,\tau,v} \rangle_v \langle h_{\tau,v}, \tilde{h}_{3,\tau,v} \rangle_v} = \text{a nonzero constant independent of } \tau$$

This is proved in the following §7.12.

– $v = p$.

$$\begin{aligned} & \frac{\int_{\mathbb{Q}_p^\times \backslash D^\times(\mathbb{Q}_p)} \langle \Pi_p(g) F_{\tau,p}, F'_{\tau,p} \rangle_p dg}{\langle f_p^D, \bar{f}_p^D \rangle_p \langle \theta_{\tau,p}, \begin{pmatrix} -p' & 1 \end{pmatrix} \tilde{\theta}_{3,\tau,p} \rangle_p \langle h_{\tau,p}, \begin{pmatrix} -p' & 1 \end{pmatrix} \tilde{h}_{3,\tau,p} \rangle_p} \\ &= p^{-t} \frac{\zeta_p(2)^2 \cdot L_p\left(\frac{1}{2}, \text{BC}(\pi) \times \chi_h \chi_\theta^c\right)}{L_p(1, \eta_{\mathcal{K}/\mathbb{Q}})^2 \cdot L_p(1, \pi, \text{Ad})}. \end{aligned}$$

This is a direct consequence of [Hsi21, Proposition 6.3]. We also use the formulas for local norms of the chosen vectors in the proof of Lemma 6.4 of *loc.cit.*

Plug these results on local integrals into equation (7.11.9) and compare with equation (7.11.5), we see that

$$\begin{aligned} & \text{LHS of equation (7.11.6) valued at } \tau_{p\text{-adic}} \\ &= C_2 \cdot \langle \theta_\tau, \tilde{\theta}_3, \tau \rangle_{p\text{-adic}} \langle h_\tau, \tilde{h}_3, \tau \rangle_{p\text{-adic}} \cdot \left(\frac{\mathcal{L}_1 \mathcal{L}_2}{\mathcal{L}_3 \mathcal{L}_4} \right) \left(\tau_{p\text{-adic}}|_{U_{\mathcal{K},p}} \right) \end{aligned}$$

with $C_2 \in L^\times$ the product of

- the local triple product integrals divided by the norms at $v \in \Sigma \cup \{\ell, \ell'\}$, which are nonzero constants,
- $\prod_{v \in \Sigma \cup \{\ell, \ell'\}} \left(\frac{\zeta_v(2)^2 L_v(\frac{1}{2}, \Pi)}{L_v(1, \Pi, \text{Ad})} \right)^{-1}$, which, by our choice of the Hecke characters χ_θ, χ_h , equals $L_q\left(\frac{1}{2}, \text{BC}(\pi) \times \chi_h \chi_\theta^c\right)^{-1} \prod_{v \in \Sigma \cup \{\ell, \ell'\}} \zeta_v(2)^{-2} L_v(1, \eta_{\mathcal{K}/\mathbb{Q}})^2 L_v(1, \pi, \text{Ad})$, a nonzero constant,
- $\left(\pi \frac{L^\infty(1, \pi, \text{Ad})}{\langle f, \bar{f} \rangle} \cdot \langle f^D, \bar{f}^D \rangle \right)^{-1} \in \mathbb{Q}^\times$. □

Given $g \in \text{U}(2)(\mathbb{A}_{\mathbb{Q},f})$, evaluating a p -adic form at g induces a map

$$\text{Meas}\left(\Gamma_{\mathcal{K}}, V_{\text{U}(2)} \widehat{\otimes} \hat{\mathcal{O}}_L^{\text{ur}}\right)^{\natural} \longrightarrow \text{Meas}\left(\Gamma_{\mathcal{K}}, \hat{\mathcal{O}}_L^{\text{ur}}\right) \simeq \hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_{\mathcal{K}}]].$$

Denote by $l_{\theta_1^J}\left(E_{\varphi, \beta, u}^{\text{Kling}}\right)(g) \in \hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_{\mathcal{K}}]]$ the image of $l_{\theta_1^J}\left(E_{\varphi, \beta, u}^{\text{Kling}}\right)$ under this map.

Proposition 7.11.3. *Let $\beta = 1 \in \text{Her}_1(\mathcal{K})$, θ_1^J be the Fourier–Jacobi form on $\text{U}(2)$ as in Proposition 7.6.1 and φ be an automorphic form on $\text{U}(2)$ as in Proposition 7.11.2. Let $J \subseteq \hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_{\mathcal{K}}]] \otimes_{\mathbb{Z}} \mathbb{Q}$ be the ideal generated by*

$$l_{\theta_1^J}\left(E_{\varphi, \beta, u}^{\text{Kling}}\right)(g), \quad g \in \text{U}(2)(\mathbb{A}_{\mathbb{Q},f}), \quad u \in \bigotimes_{v \in \Sigma_{\text{ns}} \cup \{\ell'\}} \text{U}(1)(\mathbb{Q}_v).$$

Then $J = \hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_{\mathcal{K}}]] \otimes_{\mathbb{Z}} \mathbb{Q}$.

Proof. Suppose that $J \neq \hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_{\mathcal{K}}]] \otimes_{\mathbb{Z}} \mathbb{Q}$. Then J is contained in a maximal ideal of $\hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_{\mathcal{K}}]] \otimes_{\mathbb{Z}} \mathbb{Q}$ so is contained in the maximal ideal associated to a p -adic character $\kappa : \Gamma_{\mathcal{K}} \rightarrow \overline{\mathbb{Q}}_p^\times$. Let $\kappa' : \Gamma_{\mathcal{K}} \rightarrow \overline{\mathbb{Q}}_p^\times$ be a p -adic character whose N -th power is κ . Then

$$\mathcal{P}_{N,*}\left(l_{\theta_1^J}\left(E_{\varphi, \beta, u}^{\text{Kling}}\right)\right)(\kappa'|_{U_{\mathcal{K},p}}) = l_{\theta_1^J}\left(E_{\varphi, \beta, u}^{\text{Kling}}\right)(\kappa) = 0$$

for all $u \in \bigotimes_{v \in \Sigma_{\text{ns}} \cup \{\ell'\}} \text{U}(1)(\mathbb{Q}_v)$. Then it follows from Propositions 7.11.1 and 7.11.2 that

$$\left(\langle \theta, \tilde{\theta}_3 \rangle_{p\text{-adic}} \langle h, \tilde{h}_3 \rangle_{p\text{-adic}} \cdot \frac{\mathcal{L}_1 \mathcal{L}_2 \mathcal{L}_5 \mathcal{L}_6}{\mathcal{L}_3 \mathcal{L}_4} \right) (\kappa'|_{U_{\mathcal{K},p}}) = 0,$$

which, combining with Proposition 7.9.1, implies that

$$(\mathcal{L}_1 \mathcal{L}_2 \mathcal{L}_5 \mathcal{L}_6)(\kappa'|_{U_{\mathcal{K},p}}) = 0.$$

However, the condition (3) in our choice of χ_h, χ_θ in §5.6 implies that $\mathcal{L}_1 \mathcal{L}_2 \mathcal{L}_5 \mathcal{L}_6$ is a unit in $\hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_K]] \otimes_{\mathbb{Z}} \mathbb{Q}$ so is nonzero at all characters in $\text{Hom}_{\text{cont}}(U_{K,p}, \overline{\mathbb{Q}}_p^\times)$. We get a contradiction. Therefore, $J = \hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_K]] \otimes_{\mathbb{Z}} \mathbb{Q}$. $\square$

7.12. The local triple product integrals at nonsplit places

Lemma 7.12.1. *Let v be a place of $\mathbb{Q}$ nonsplit in K and $\sigma : K_v^\times \rightarrow \mathbb{C}^\times$ be a character nontrivial on the kernel of $\text{Nm}_{K_v/\mathbb{Q}_v}$. Let π_σ be the dihedral supercuspidal representation of $\text{GL}_2(\mathbb{Q}_v)$ obtained by the theta lift of σ . (See [Sch02, §1.2] for the precise definition.) Then by [Sch02, Theorem in §2.3.2], we have the formula for the conductor of π_σ :*

$$c(\pi_\sigma) = \begin{cases} 2\text{cond}(\sigma), & v \text{ inert}, \\ \text{cond}(\sigma) + 1, & v \text{ ramified}. \end{cases} \quad (7.12.1)$$

Let W be the Kirillov model of π_σ with respect to the additive character $\mathbf{e}_v^{\pm 1}$ of $\mathbb{Q}_v$. (W consists of Schwartz functions on $\mathbb{Q}_v^\times$ since π_σ is supercuspidal.) For $w \in W$, define

$$n(w) = \min \left\{ n \in \mathbb{Z} : w \text{ is fixed by } \begin{pmatrix} 1 & 0 \\ \varpi_v^n \mathbb{Z}_v & 1 \end{pmatrix} \right\}. \quad (7.12.2)$$

Let ϑ be a character of $\mathbb{Z}_v^\times$ and ϑ^* be its extension to $\mathbb{Q}_v^\times$ taking value 1 at ϖ_v . For each integer m , define $w_\vartheta^m \in W$ as

$$w_\vartheta^m(x) = \mathbb{1}_{\varpi_v^m \mathbb{Z}_v^\times}(x) \vartheta^*(x).$$

Then the following hold:

- (1) Let $w = \sum_{m=l_1}^{l_2} c_m w_\vartheta^m$ with $c_{l_2} \neq 0$. Then $n(w) = n(w_\vartheta^{l_2}) = n(w_\vartheta^0) + l_2$.
- (2) We have

$$n(w_\vartheta^m) = m + c(\pi_\sigma \otimes \vartheta^{*-1}) = \begin{cases} m + 2\text{cond}(\sigma \cdot \vartheta^{*-1} \circ \text{Nm}_{K_v/\mathbb{Q}_v}), & v \text{ inert}, \\ m + \text{cond}(\sigma \cdot \vartheta^{*-1} \circ \text{Nm}_{K_v/\mathbb{Q}_v}) + 1, & v \text{ ramified}. \end{cases}$$

Proof. The action $B(\mathbb{Q}_v) \subset \text{GL}_2(\mathbb{Q}_v)$ on W has the formula:

$$\begin{pmatrix} a & b \\ 0 & d \end{pmatrix} \cdot w(x) = \omega_\sigma(d) \mathbf{e}_v^{\pm 1}(bd^{-1}x) w(ad^{-1}x), \quad w \in W, \quad (7.12.3)$$

where ω_σ is the central character of σ .

(1) It is easy to see that $\begin{pmatrix} \varpi_v^l & \\ & 1 \end{pmatrix} \cdot w_\vartheta^m = w_\vartheta^{m-l}$. Thus, $n(w_\vartheta^m) = n(w_\vartheta^0) + m$. It follows that $n(w_\vartheta^m) \leq n(w_\vartheta^{l_2})$ for all $m \leq l_2$, so $n(w) \leq n(w_\vartheta^{l_2})$. On the other hand, if $n(w) \leq n(w_\vartheta^{l_2}) - 1$, then $n(w_\vartheta^{l_2}) = n\left(c_l^{-1}\left(w - \sum_{l_1}^{l_2-1} c_m w_\vartheta^m\right)\right) \leq n(w_\vartheta^{l_2}) - 1$. This is a contradiction. Hence, $n(w) = n(w_\vartheta^{l_2})$.

(2) Let W' the representation of $\text{GL}_2(\mathbb{Q}_v)$ whose underlying $\mathbb{C}$ -vector space equals that of W with the action of $\text{GL}_2(\mathbb{Q}_v)$ defined as the action of $\text{GL}_2(\mathbb{Q}_v)$ on W twisted by $\vartheta^{*-1} \circ \det$, that is, for $g \in \text{GL}_2(\mathbb{Q}_v)$ and $w \in W'$, the action of g on w gives $\vartheta^{*-1}(\det g)(g \cdot w)$, where $g \cdot w$ denotes the action of g on w viewed as an element in W . Then $W' \cong \pi_\sigma \otimes \vartheta^{*-1}$. Suppose that $w' \in W'$ is the new vector, then $\begin{pmatrix} \mathbb{Z}_v^\times & \mathbb{Z}_v \\ 0 & d \end{pmatrix}$, $d \in \mathbb{Z}_v^\times$, acts on it by the scalar $\sigma \vartheta^{-2}(d)$, and we have $w' = \sum_{m=l_1}^{l_2} c_m w_\vartheta^m$ with $c_{l_1} \neq 0$ for some

$l_1 \geq 0$. (In this equality, we view $w_{\mathfrak{g}}^m$ as a vector in W' . From the formula (7.12.3) and the definition of $w_{\mathfrak{g}}^m$, we know that the invariance of w' under the action of $\begin{pmatrix} 1 & \mathbb{Z}_v \\ 0 & 1 \end{pmatrix}$ implies that $l_1 \geq 0$.) Then

$$n(w_{\mathfrak{g}}^0) \geq c(\pi_{\sigma} \otimes \vartheta^{*-1}) = n(w') = n(w_{\mathfrak{g}}^0) + l_2, \quad (7.12.4)$$

where the first inequality follows from the definition of new vectors with $w_{\mathfrak{g}}^0$ viewed as a vector in W' , the middle equality is because w' is the new vector, and the right equality follows from (1). Equation (7.12.4) implies that $l_1 = l_2 = 0$, $w_{\mathfrak{g}}^0$ is the new vector in W' , and $n(w_{\mathfrak{g}}^0) = c(\pi_{\sigma} \otimes \vartheta^{*-1})$. Since $n(w_{\mathfrak{g}}^m) = n(w_{\mathfrak{g}}^0) + m$, we see that $n(w_{\mathfrak{g}}^m) = m + c(\pi_{\sigma} \otimes \vartheta^{*-1})$. $\square$

Proposition 7.12.2. *For $v \in \Sigma_{\text{ns}} \cup \{\ell'\}$, there exist $\mathcal{T}_v, \mathcal{T}'_v \in \mathcal{O}_L[D^{\times}(\mathbb{Q}_v)] \subset \mathcal{O}_L[\text{GU}(2)(\mathbb{Q}_v)]$ and $\varphi_v, \varphi'_v \in \pi_v^D$ such that φ_v and $\mathcal{T}_v \mathbf{h}$ are invariant under the level group K_v (defined in equation (5.6.6)), and*

$$\int_{\mathbb{Q}_v^{\times} \backslash D^{\times}(\mathbb{Q}_v)} \langle \Pi_v(g) F_{\tau,v}, F'_{\tau,v} \rangle_v dg = a \text{ nonzero constant independent of } \tau, \quad (7.12.5)$$

where

$$F_{\tau,v} = \left(\check{\theta}_{\tau,v}^{\bar{\lambda}} \otimes \varphi_v \otimes \mathcal{T}_v \check{h}_{\tau,v} \right) |_{D^{\times}(\mathbb{Q}_v)}, \quad F'_{\tau,v} = \left(\check{\theta}_{3,\tau,v}^{\lambda} \otimes \varphi'_v \otimes \mathcal{T}'_v \check{h}_{3,\tau,v} \right) |_{D^{\times}(\mathbb{Q}_v)}.$$

Proof. Let v be a place in $\Sigma_{\text{ns}} \cup \{\ell'\}$. Then $\text{U}(1)(\mathbb{Q}_v) \subset \mathcal{O}_{\mathcal{K},v}^{\times}$ and $\tau_{\mathfrak{p},\mathfrak{p}_h}|_{\text{U}(1)(\mathbb{Q}_v)}$ is trivial. From the construction of $\mathbf{h}, \check{h}_3$ in §7.7.2 and $\theta, \check{\theta}_3$ in §7.7.3, we see that $\pi_{h_{\tau,v}}, \pi_{\theta_{\tau,v}}$ and $h_{\tau,v}, \check{h}_{3,\tau,v}, \theta_{\tau,v}, \check{\theta}_{3,\tau,v}$ do not change when τ varies. It follows that the left-hand side of equation (7.12.5) is independent of τ .

Next, we show the nonvanishing. By our choice of χ_h, χ_{θ} , we have $\text{Hom}_{D^{\times}(\mathbb{Q}_v)}(\Pi_v, \mathbb{C}) \neq 0$. By [Pra90, Theorem 1.4], we can pick $\mathcal{T}'_v \in \mathcal{O}_L[D^{\times}(\mathbb{Q}_v)]$ and $\varphi'_v \in \pi_v^D$ such that the linear functional

$$\mathcal{L}_{F'_{\tau,v}} : \Pi_v \longrightarrow \mathbb{C}, \quad \mathcal{L}_{F'_{\tau,v}}(F_v) = \int_{\mathbb{Q}_v^{\times} \backslash D^{\times}(\mathbb{Q}_v)} \langle \Pi_v(g) F_v, F'_{\tau,v} \rangle_v dg \quad (7.12.6)$$

is nonzero and spans the one-dimensional space $\text{Hom}_{D^{\times}(\mathbb{Q}_v)}(\Pi_v, \mathbb{C})$. What we need to show is that there exists $\mathcal{T}_v \check{h}_{\tau,v} \in \pi_{h_{\tau,v}}^D$ and $\varphi_v \in \pi_v^D$ invariant under the level group K_v defined in equation (5.6.6) such that $\mathcal{L}_{F'_{\tau,v}}(\check{\theta}_{\tau,v}^{\bar{\lambda}} \otimes \varphi_v \otimes \mathcal{T}_v \check{h}_{\tau,v}) \neq 0$. Since $\check{\theta}_{\tau,v}^{\bar{\lambda}}$ is invariant under K_v , it suffices to show that there exists $\mathcal{T}_v \check{h}_{\tau,v} \in \pi_{h_{\tau,v}}^D$ invariant under K_v such that the linear functional

$$\mathcal{L}_{F'_{\tau,v}}(\check{\theta}_{\tau,v}^{\bar{\lambda}} \otimes \cdot \otimes \mathcal{T}_v \check{h}_{\tau,v}) : \pi_v \longrightarrow \mathbb{C} \quad (7.12.7)$$

is nonzero. There are two cases.

Case 1: $v \neq q$, $D^{\times}(\mathbb{Q}_v) \cong \text{GL}_2(\mathbb{Q}_v)$. Recall that at the beginning of §5.4, we have fixed the positive integer $\mathfrak{s}$ and the totally imaginary element δ in $\mathcal{K}$, and $\text{U}(2)$ is the unitary group for the skew-Hermitian form $\zeta_0 = \delta \begin{pmatrix} \mathfrak{s} & \\ & 1 \end{pmatrix}$. By our assumption on $\mathfrak{s}$, there exists $\mathfrak{r} \in \mathcal{O}_{\mathcal{K},v}^{\times}$ such that $\text{Nm}_{\mathcal{K}_v/\mathbb{Q}_v}(\mathfrak{r}) = -\mathfrak{s}$. We fix the following isomorphism

$$\mathfrak{i} : \text{GU}(2)(\mathbb{Q}_v) \xrightarrow{\cong} \text{GU}(1,1)(\mathbb{Q}_v), \quad g \longmapsto \begin{pmatrix} \frac{\delta}{2} & \frac{\delta \mathfrak{r}}{2} \\ 1 & -\mathfrak{r} \end{pmatrix} g \begin{pmatrix} \frac{\delta}{2} & \frac{\delta \mathfrak{r}}{2} \\ 1 & -\mathfrak{r} \end{pmatrix}^{-1},$$

where $\mathrm{GU}(1, 1)$ denotes the unitary group attached to the skew-Hermitian form $\begin{pmatrix} & 1 \\ -1 & \end{pmatrix}$. Let $K_v^{\mathrm{GL}_2} = \mathfrak{i}(K_v) \cap \mathrm{GL}_2(\mathbb{Z}_v)$. By our assumptions in §5.2, $v \neq 2$. One can check that

$$K_v^{\mathrm{GL}_2} = \begin{pmatrix} 1 + \varpi_v^{c_v} \mathbb{Z}_v & \varpi_v^{c_v + \epsilon_v} \mathbb{Z}_v \\ \varpi_v^{c_v} \mathbb{Z}_v & 1 + \varpi_v^{c_v} \mathbb{Z}_v \end{pmatrix} \subset \mathrm{GL}_2(\mathbb{Z}_v),$$

where $\epsilon_v = \begin{cases} 0, & v \text{ inert} \\ 1, & v \text{ ramified} \end{cases}$.

Given a character $\chi_v : \mathbb{Q}_v^\times \rightarrow \mathbb{C}^\times$, we denote also by χ_v the character $B(\mathbb{Q}_v) \rightarrow \mathbb{C}^\times$, $\begin{pmatrix} a & b \\ 0 & d \end{pmatrix} \mapsto \chi_v(ad^{-1})$, and $\mathrm{Ind}_B^{\mathrm{GL}_2}(\chi_v)$ the (normalized) induction of χ_v . By our assumption on π , π_v is either isomorphic to $\mathrm{Ind}_B^{\mathrm{GL}(2)}(\chi_v)$ for an unramified character $\chi_v \neq |\cdot|_{\mathbb{Q}_v}^{\pm 1/2}$ or is isomorphic to the irreducible quotient of $\mathrm{Ind}_B^{\mathrm{GL}(2)}(\chi_v)$ with $\chi_v = |\cdot|_{\mathbb{Q}_v}^{-1/2}$. Let $\psi_1 = \mathbf{e}_v$, the additive character of $\mathbb{Q}_v$ defined in equation (1.0.5), $\psi_2 = \bar{\mathbf{e}}_v$, and W_1 (resp. W_2) be the Kirillov model of $\pi_1 = \pi_{\theta_{\tau,v}^D}$ (resp. $\pi_2 = \pi_{h_{\tau,v}^D}$) with respect to ψ_1 (resp. ψ_2). We have

$$\begin{aligned} \mathrm{Hom}_{\mathrm{GL}_2(\mathbb{Q}_v)}(W_1 \otimes W_2, \tilde{\pi}) &\cong \mathrm{Hom}_{\mathrm{GL}_2(\mathbb{Q}_v)}(W_1 \otimes W_2, \mathrm{Ind}_B^{\mathrm{GL}_2}(\chi_v^{-1})) \\ &\cong \mathrm{Hom}_{B(\mathbb{Q}_v)}(W_1 \otimes W_2, \chi_v^{-1} |\cdot|_{\mathbb{Q}_v}^{1/2}), \end{aligned} \quad (7.12.8)$$

where the second isomorphism is deduced from the Frobenius reciprocity, and when $\chi_v = |\cdot|_{\mathbb{Q}_v}^{-1/2}$, the first isomorphism is because by our choice of $\chi_\theta, \chi_h, W_1 \not\cong \tilde{W}_2$. It is easy to see that the map

$$\mathcal{L}(w_1, w_2) = \int_{\mathbb{Q}_v^\times} w_1(x) w_2(x) \cdot \chi_v(x) |x|_{\mathbb{Q}_v}^{-1/2} d^\times x, \quad w_1 \in W_1, w_2 \in W_2 \quad (7.12.9)$$

is a nonzero element in the second line of equation (7.12.8), which is one dimensional, so it equals the image of $\mathcal{L}_{F'_{\tau,v}}(\check{\theta}_{\tau,v}^{\bar{1}} \otimes \cdot \otimes \cdot)$ in the second line of equation (7.12.8) up to a nonzero scalar. Hence, showing the existence of $\mathcal{T}_v \check{h}_{\tau,v} \in \pi_{h_{\tau,v}^D}^D$ invariant under K_v such that equation (7.12.7) is nonzero reduces to showing the existence of $y_2 \in W_2$ invariant under $K_v^{\mathrm{GL}_2}$ such that $\mathcal{L}(y_1, y_2) \neq 0$, where $y_1 \in W_1$ is the vector invariant under $K_v^{\mathrm{GL}_2}$ corresponding to $\check{\theta}_{\tau,v}^{\bar{1}} \in \pi_{\theta_{\tau,v}^D}^D$.

For a character $\vartheta : \mathbb{Z}_v^\times \rightarrow \mathbb{C}^\times$, put

$$y_{1,\vartheta}(x) = \int_{\mathbb{Z}_v^\times} \vartheta^{-1}(a) y_1(ax) dx,$$

the projection of y_1 to the ϑ -eigenspace for the action of $\mathrm{diag}(\mathbb{Z}_v^\times, 1)$. Let ϑ^* be the extension of ϑ to $\mathbb{Q}_v^\times$ taking value 1 at ϖ_v . For each integer m , put define $w_{j,\vartheta}^m \in W_j$, $j = 1, 2$, as

$$w_{j,\vartheta}^m(x) = \mathbb{1}_{\varpi_v^m \mathbb{Z}_v^\times}(x) \vartheta^*(x).$$

Then we have $y_{1,\vartheta} = \sum_m c_m w_{1,\vartheta}^m$ with $c_m \in \mathbb{C}$ finitely many nonzero m , and $\mathcal{L}(y_1, w_{2,\vartheta^{-1}}^m) = \mathcal{L}(y_{1,\vartheta}, w_{2,\vartheta^{-1}}^m)$. We can take a ϑ of conductor $\leq \varpi_v^{c_v}$ such that $y_{1,\vartheta} \neq 0$. This $y_{1,\vartheta}$ is still invariant under $K_v^{\mathrm{GL}_2}$. By the formula (7.12.3) and (1) of Lemma 7.12.1, we deduce that

$$y_{1,\vartheta} = \sum_{m=-(c_v+\epsilon_v)}^{c_v-n(w_{1,\vartheta}^0)} c_m w_{1,\vartheta}^m, \quad c_m \in \mathbb{C},$$

with $n(w_{1,\vartheta}^0)$ defined as in equation (7.12.2). Take $-(c_v + \epsilon_v) \leq m_0 \leq c_v - n(w_{1,\vartheta}^0)$ such that $c_{m_0} \neq 0$. Then

$$\mathcal{L}(y_1, w_{2,\vartheta^{-1}}^{m_0}) = c_{m_0} \mathcal{L}(w_{1,\vartheta}^{m_0}, w_{2,\vartheta^{-1}}^{m_0}) \neq 0,$$

and by the formula (7.12.3), we know that $w_{2,\vartheta^{-1}}^{m_0}$ is invariant under $\begin{pmatrix} 1 + \varpi_v^{c_v} \mathbb{Z}_v & \varpi_v^{c_v + \epsilon_v} \mathbb{Z}_v \\ 0 & 1 + \varpi_v^{c_v} \end{pmatrix}$, and by (2) of Lemma 7.12.1, we know that

$$n(w_{2,\vartheta^{-1}}^{m_0}) = m_0 + c(\pi_2 \otimes \vartheta) \leq c_v - n(w_{1,\vartheta}^0) + c(\pi_2 \otimes \vartheta^*) = c_v - c(\pi_1 \otimes \vartheta^{*-1}) + c(\pi_2 \otimes \vartheta^*).$$

By our choice of χ_ϑ, χ_h and the formula (7.12.1), we have $c(\pi_1 \otimes \vartheta^{*-1}) \geq c(\pi_2 \otimes \vartheta^*)$. Hence, $n(w_{2,\vartheta^{-1}}^{m_0}) \geq c_v$, and $w_{2,\vartheta^{-1}}^{m_0}$ is invariant under $\begin{pmatrix} 1 & 0 \\ \varpi_v^{c_v} \mathbb{Z}_v & 1 \end{pmatrix}$. Therefore, $y_2 = w_{2,\vartheta^{-1}}^{m_0}$ is the desired vector in W_2 invariant under $K_v^{\text{GL}_2}$ such that $\mathcal{L}(y_1, y_2) \neq 0$.

Case 2: $v = q$, $D^\times(\mathbb{Q}_q)$ modulo its center is compact and π_v^D is one-dimensional isomorphic to $\chi_q \circ \text{Nm}_D$, where χ_q is the unramified quadratic character in condition (5) in the choice of χ_ϑ, χ_h at the beginning of §5.6, and Nm_D denotes the norm of D . By our choice of χ_ϑ, χ_h , we have

$$\pi_{\vartheta_\tau, q}^D \otimes \chi_q \circ \text{Nm}_D \cong \tilde{\pi}_{h_\tau, q}^D.$$

It follows that there exists $\mathcal{T}_q \in \mathcal{O}_L[D^\times(\mathbb{Q}_v)]$ such that equation (7.12.7) is nonzero. Since K_v is a normal subgroup of $D^\times(\mathbb{Q}_q)$, $\mathcal{T}_q \check{h}_{\tau, q}$ is still invariant under K_v . $\square$

8. Proof of Greenberg–Iwasawa main conjecture

8.1. The Klingen Eisenstein ideal

Let $\mathcal{M}_{\text{so}} = \text{Hom}_{\Lambda_{\text{so}}}(\mathcal{V}_{\text{so}}^*, \Lambda_{\text{so}})$ be the $\mathcal{O}_L[[T_{\text{so}}(\mathbb{Z}_p)]]$ -module of semiordinary families on $\text{GU}(3, 1)$ of tame level K_f^p as in Theorem 2.9.1. Identifying $T_{\text{so}}(\mathbb{Z}_p)$ with $\mathbb{Z}_p^\times \times \mathbb{Z}_p^\times \simeq \mathcal{O}_{\mathcal{K}, p}^\times$, we have the map

$$T_{\text{so}}(\mathbb{Z}_p) \longrightarrow \mathcal{O}_{\mathcal{K}, p}^\times \longrightarrow \Gamma_{\mathcal{K}}, \quad (8.1.1)$$

with kernel $\mu_p \times \mu_p$. Denote by $\mathcal{V}_{\text{so}, \xi}$ (resp. $\mathcal{M}_{\text{so}, \xi}$) the sub- $\mathcal{O}_L[[T_{\text{so}}(\mathbb{Z}_p)]]$ -module of $e_{\text{so}} \mathcal{V}$ (resp. $\mathcal{M}_{\text{so}}$) on which $\mu_p \times \mu_p$ acts through $\xi_{p\text{-adic}}$. We make $T_{\text{so}}(\mathbb{Z}_p)$ act on $\mathcal{V}_{\text{so}, \xi}$ and $\mathcal{M}_{\text{so}, \xi}$ through its usual action multiplied by the character $\xi_{p\text{-adic}}^{-1}$. Then this action factors through the image of $T_{\text{so}}(\mathbb{Z}_p)$ in $\Gamma_{\mathcal{K}}$ under the map (8.1.1). Let $\mathcal{V}_{\text{so}, \xi}^0 \subset \mathcal{V}_{\text{so}, \xi}$, $\mathcal{M}_{\text{so}, \xi}^0 \subset \mathcal{M}_{\text{so}, \xi}$ be the cuspidal part. We consider the $\mathcal{O}_L[[\Gamma_{\mathcal{K}}]]$ -modules

$$\begin{aligned} \mathcal{M}_{\text{so}, \xi, \Gamma_{\mathcal{K}}} &= \mathcal{M}_{\text{so}, \xi} \otimes_{\mathcal{O}_L[[T_{\text{so}}(\mathbb{Z}_p)]]} \hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_{\mathcal{K}}]], \\ \mathcal{M}_{\text{so}, \xi, \Gamma_{\mathcal{K}}}^0 &= \mathcal{M}_{\text{so}, \xi}^0 \otimes_{\mathcal{O}_L[[T_{\text{so}}(\mathbb{Z}_p)]]} \hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_{\mathcal{K}}]]. \end{aligned}$$

The semiordinary Klingen Eisenstein family E_φ^{Kling} constructed in §5.10 belongs to the space $\text{Meas}(\Gamma_{\mathcal{K}}, e_{\text{so}} V_{\text{GU}(3,1), \xi} \hat{\otimes} \hat{\mathcal{O}}_L^{\text{ur}}) \otimes_{\mathbb{Z}} \mathbb{Q}$. By the natural pairing between $V_{\text{GU}(3,1), \text{so}}$ and the space $\mathcal{V}_{\text{so}}^*$ in Theorem 2.9.1, we see that there is a natural map

$$\text{Meas}(\Gamma_{\mathcal{K}}, e_{\text{so}} V_{\text{GU}(3,1), \xi} \hat{\otimes} \hat{\mathcal{O}}_L^{\text{ur}}) \times (\mathcal{V}_{\text{so}, \xi})^* \longrightarrow \text{Meas}(\Gamma_{\mathcal{K}}, \hat{\mathcal{O}}_L^{\text{ur}}) \simeq \hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_{\mathcal{K}}]],$$

and it induces a $\hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_{\mathcal{K}}]]$ -linear Hecke-equivariant map

$$\text{Meas}(\Gamma_{\mathcal{K}}, e_{\text{so}} V_{\text{GU}(3,1), \xi} \hat{\otimes} \hat{\mathcal{O}}_L^{\text{ur}}) \longrightarrow \text{Hom}_{\mathcal{O}_L[[T_{\text{so}}(\mathbb{Z}_p)]]}((\mathcal{V}_{\text{so}, \xi}^*, \hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_{\mathcal{K}}]])) = \mathcal{M}_{\text{so}, \xi, \Gamma_{\mathcal{K}}}.$$

Therefore, we can view $\mathbf{E}_\varphi^{\text{Kling}}$ as an element in $\mathcal{M}_{\text{so}, \xi, \Gamma_K} \otimes_{\mathbb{Z}} \mathbb{Q}$. Let $\mathbb{T}$ be the abstract algebra generated by the unramified Hecke algebras away from $\Sigma \cup \{p, \ell, \ell'\}$ and $\mathbb{U}_p$ -operators at p . Then $\mathbf{E}_\varphi^{\text{Kling}}$ is an eigen-family for the action of $\mathbb{T}$, and we denote by $\lambda_{\text{Eis}, \pi, \xi} : \mathbb{T} \rightarrow \hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_K]]$ the corresponding eigen-system.

Let $\mathbb{T}_{\text{so}, \xi, \Gamma_K}^0$ be the reduced Hecke algebra generated by $\mathbb{T}$ acting on $\mathcal{M}_{\text{so}, \xi, \Gamma_K}^0$. Let $\mathcal{I}_{\text{Eis}, \pi, \xi} \subset \mathbb{T}_{\text{so}, \xi, \Gamma_K}^0$ be the ideal generated by the images of $T - \lambda_{\text{Eis}, \pi, \xi}(T)$ in $\mathbb{T}_{\text{so}, \xi, \Gamma_K}^0$, $T \in \mathbb{T}$. We define the Klingen Eisenstein ideal as

$$\mathcal{E}_{\pi, \xi} = \ker \left(\hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_K]] \xrightarrow[\text{map}]{\text{structure}} \mathbb{T}_{\text{so}, \xi, \Gamma_K}^0 / \mathcal{I}_{\text{Eis}, \pi, \xi} \right).$$

It measures the congruences between the Hecke eigen-systems in $\mathbb{T}_{\text{so}, \xi, \Gamma_K}^0$ and the Hecke eigen-system $\lambda_{\text{Eis}, \pi, \xi}$ attached to $\mathbf{E}_\varphi^{\text{Kling}}$.

Theorem 8.1.1. *Let φ be as in Proposition 7.11.2. Let P be a height one prime ideal of $\hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_K]]$ such that $P \cap \hat{\mathcal{O}}_L^{\text{ur}} = (0)$. Then*

$$\text{ord}_P \left(\mathcal{L}_{\pi, K, \xi}^{\Sigma \cup \{\ell, \ell'\}} \mathcal{L}_{\xi, \mathbb{Q}}^{\Sigma \cup \{\ell, \ell'\}} \right) \leq \text{ord}_P(\mathcal{E}_{\pi, \xi}),$$

(where $\mathcal{L}_{\xi, \mathbb{Q}}^{\Sigma \cup \{\ell, \ell'\}}, \mathcal{L}_{\pi, K, \xi}^{\Sigma \cup \{\ell, \ell'\}} \in \hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_K]] \otimes_{\mathbb{Z}} \mathbb{Q}$ are the p -adic L -function satisfying the interpolation property in equation (6.1.1)(6.1.2)).

Proof. By Theorem 2.9.1, we have the fundamental exact sequence

$$0 \rightarrow \mathcal{M}_{\text{so}, \xi, \Gamma_K}^0 \rightarrow \mathcal{M}_{\text{so}, \xi, \Gamma_K} \rightarrow \bigoplus_{g \in C(K_f^p)} M_{\text{GU}(2)} \left(K_{f, g}'^p K_{p, 0}', \hat{\mathcal{O}}_L^{\text{ur}} \right) \otimes_{\mathbb{Z}_p} \mathbb{Z}_p[[\Gamma_K]] \rightarrow 0.$$

Combining it with Theorem 6.1.1 on the degenerate Fourier-Jacobi coefficients of $\mathbf{E}_\varphi^{\text{Kling}}$, we deduce that there exists $\mathbf{E}' \in \mathcal{M}_{\text{so}, \xi, \Gamma_K}$ such that

$$\mathbf{F} = \mathbf{E}_\varphi^{\text{Kling}} - \mathcal{L}_{\xi, \mathbb{Q}}^{\Sigma \cup \{\ell, \ell'\}} \mathcal{L}_{\pi, K, \xi}^{\Sigma \cup \{\ell, \ell'\}} \cdot \mathbf{E}' \in \mathcal{M}_{\text{so}, \xi, \Gamma_K}^0 \otimes_{\mathbb{Z}} \mathbb{Q}.$$

Let P be a height one prime ideal of $\hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_K]]$ such that

$$P \cap \hat{\mathcal{O}}_L^{\text{ur}} = (0), \quad \text{ord}_P \left(\mathcal{L}_{\xi, \mathbb{Q}}^{\Sigma \cup \{\ell, \ell'\}} \mathcal{L}_{\pi, K, \xi}^{\Sigma \cup \{\ell, \ell'\}} \right) = m \geq 1.$$

By Proposition 7.11.3, for $\beta = 1$, there exists $g \in \text{U}(2)(\mathbb{A}_{\mathbb{Q}})$ and $u \in \bigotimes_{v \in \Sigma_{\text{ns}} \cup \{\ell'\}} \text{U}(1)(\mathbb{Q}_v)$ such that $l_{\theta_1^J}(\mathbf{E}_{\varphi, \beta, u}^{\text{Kling}})(g) \notin P$. Then $l_{\theta_1^J}(\mathbf{F}_{\beta, u})(g) \notin P$, and we have the $\hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_K]]_P$ -linear map

$$\left(\mathbb{T}_{\text{so}, \xi, \Gamma_K}^0 \right)_P \longrightarrow \hat{\mathcal{O}}_K^{\text{ur}}[[\Gamma_K]]_P / P^m \hat{\mathcal{O}}_K^{\text{ur}}[[\Gamma_K]]_P, \quad (8.1.2)$$

which sends the image of $T \in \mathbb{T}$ in $\left(\mathbb{T}_{\text{so}, \xi, \Gamma_K}^0 \right)_P$ to

$$\frac{l_{\theta_1^J}((T \cdot \mathbf{F})_{\beta, u})(g)}{l_{\theta_1^J}(\mathbf{F}_{\beta, u})(g)} \equiv \frac{l_{\theta_1^J}((T \cdot \mathbf{E}_{\varphi}^{\text{Kling}})_{\beta, u})(g)}{l_{\theta_1^J}(\mathbf{E}_{\varphi, \beta, u}^{\text{Kling}})(g)} \equiv \lambda_{\text{Eis}, \pi, \xi}(T) \pmod{P^m}.$$

We see that equation (8.1.2) factors through $\left(\mathbb{T}_{\text{so}, \xi, \Gamma_K}^0\right)_P / \mathcal{I}_{\text{Eis}, \pi, \xi} \left(\mathbb{T}_{\text{so}, \xi, \Gamma_K}^0\right)_P$. It follows that the composition

$$\hat{\mathcal{O}}_K^{\text{ur}}[[\Gamma_K]]_P \xrightarrow{\text{structure map}} \left(\mathbb{T}_{\text{so}, \xi, \Gamma_K}^0\right)_P \xrightarrow{(8.1.2)} \hat{\mathcal{O}}_K^{\text{ur}}[[\Gamma_K]]_P / P^m \hat{\mathcal{O}}_K^{\text{ur}}[[\Gamma_K]]_P \quad (8.1.3)$$

factors through $\hat{\mathcal{O}}_K^{\text{ur}}[[\Gamma_K]]_P / \mathcal{E}_{\pi, \xi} \hat{\mathcal{O}}_K^{\text{ur}}[[\Gamma_K]]_P$. By the definition of equation (8.1.2), we also know that the composition (8.1.3) is the natural projection. Hence, we deduce that $\mathcal{E}_{\pi, \xi} \hat{\mathcal{O}}_K^{\text{ur}}[[\Gamma_K]]_P \subset P^m \hat{\mathcal{O}}_K^{\text{ur}}[[\Gamma_K]]_P$, and

$$\text{ord}_P(\mathcal{E}_{\pi, \xi}) \geq m = \text{ord}_P\left(\mathcal{L}_{\pi, K, \xi}^{\Sigma \cup \{\ell, \ell'\}} \mathcal{L}_{\pi, K, \xi}^{\Sigma \cup \{\ell, \ell'\}}\right). \quad \square$$

8.2. The main theorem

By relaxing the conditions at $v \in \Sigma \cup \{\ell, \ell'\}$ in the definition of $\text{Sel}_{\pi, K, \xi}$ in equation (1.0.1) and $X_{\pi, K, \xi}$ in equation (1.0.2), we define the $\Sigma \cup \{\ell, \ell'\}$ -primitive Selmer group:

$$\text{Sel}_{\pi, K, \xi}^{\Sigma \cup \{\ell, \ell'\}} = \ker \left\{ \begin{array}{c} H^1(K, T_{\pi, K, \xi} \otimes_{\mathcal{O}_L} \mathcal{O}_L[[\Gamma_K]]^*) \\ \longrightarrow \prod_{\substack{v \neq p \\ v \nmid \text{places in } \Sigma \cup \{\ell, \ell'\}}} H^1(I_v, T_{\pi, K, \xi} \otimes_{\mathcal{O}_L} \mathcal{O}_L[[\Gamma_K]]^*) \end{array} \right\}.$$

and

$$X_{\pi, K, \xi}^{\Sigma \cup \{\ell, \ell'\}} := \text{Hom}_{\mathbb{Z}_p} \left(\text{Sel}_{\pi, K, \xi}^{\Sigma \cup \{\ell, \ell'\}}, \mathbb{Q}_p / \mathbb{Z}_p \right).$$

Denote by Γ_K^+ the rank one $\mathbb{Z}_p$ -module of Γ_K on which the complex conjugation acts by +1, and put

$$\mathcal{R} = \mathcal{O}_L^{\text{ur}}[[\Gamma_K]] \otimes_{\mathcal{O}_L[[\Gamma_K^+]]} \text{Frac}(\mathcal{O}_L[[\Gamma_K^+]]). \quad (8.2.1)$$

Theorem 8.2.1. *For an imaginary quadratic field K , a prime $p \geq 3$ split in K and π, ξ as in §5.2,*

$$\left(\mathcal{L}_{\pi, K, \xi}^{\Sigma \cup \{\ell, \ell'\}}\right) \supset \text{char}_{\mathcal{R}} \left(X_{\pi, K, \xi}^{\Sigma \cup \{\ell, \ell'\}} \otimes_{\mathcal{O}_L[[\Gamma_K]]} \mathcal{R} \right), \quad (8.2.2)$$

as ideals of $\mathcal{R}$. (Here $\mathcal{L}_{\pi, K, \xi}^{\Sigma \cup \{\ell, \ell'\}} \in \hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_K]] \otimes_{\mathbb{Z}} \mathbb{Q}$ is the p -adic L -function constructed in [EW16] with the interpolation properties described in equation (6.1.2).)

Proof. We can assume that the module $X_{\pi, K, \xi}^{\Sigma \cup \{\ell, \ell'\}}$ is $\mathcal{R}$ -torsion (since otherwise its characteristic ideal is defined to be (0) and the inclusion (8.2.2) automatically holds). We need to show that given a height one prime ideal $P \subset \hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_K]]$ such that $P \cap \hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_K^+]] = (0)$, we have the inequality

$$\text{ord}_P \left(\mathcal{L}_{\pi, K, \xi}^{\Sigma \cup \{\ell, \ell'\}} \right) \leq \text{length}_{\mathcal{O}_L^{\text{ur}}[[\Gamma_K]]_P} \left(\left(X_{\pi, K, \xi}^{\Sigma \cup \{\ell, \ell'\}} \right)_P \right). \quad (8.2.3)$$

By Theorem 8.1.1, we reduce to showing that

$$\text{ord}_P(\mathcal{E}_{\pi, \xi}) \leq \text{length}_{\mathcal{O}_L^{\text{ur}}[[\Gamma_K]]_P} \left(\left(X_{\pi, K, \xi}^{\Sigma \cup \{\ell, \ell'\}} \right)_P \right). \quad (8.2.4)$$

We have the following setup.

- $A_0 = \hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_K]]$ and $A = \hat{A}_{0, P}$.
- $R_0 = \mathbb{T}_{\text{so}, \xi, \Gamma_K}^0$, a prime ideal $Q \subset R$ such that $Q \cap A_0 = P$, and $R = \hat{R}_{0, Q}$.
- $H = G_{\mathbb{Q}} = \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ and $G = G_K = \text{Gal}(\overline{\mathbb{Q}}/K)$.

The following data give us the setup (1)–(5) on [Wan20, page 478].

- (1) Let $\nu : H \rightarrow A_0^\times$ be the trivial character.
- (2) $\chi = \xi\Psi_K : G \rightarrow A_0^\times$, with $\chi \not\equiv \chi^{-c}$ modulo the maximal ideal of A_0 by the choice of ξ .
- (3) $\rho : G \rightarrow \text{Aut}_A(V)$, a Galois representation obtained from the two-dimensional Galois representation $\rho_\pi : H \rightarrow \text{GL}(V_\pi)$ with $V = T_\pi \otimes_{\mathcal{O}_L} A$ and $T_\pi \subset V_\pi$ a G -stable lattice.
- (4) $\sigma : G \rightarrow \text{Aut}_{R \otimes_A F}(M)$, a Galois representation on $M = (R \otimes_A \text{Frac}(A))^4$ obtained as the pseudo-representation associated to R_0 as in [SU14, Proposition 7.2.1]
- (5) $I = \mathcal{E}_{\pi, \xi} A_P$ and $J = \ker(R \rightarrow A/I)$, where the map $R \rightarrow A$ is defined as the map (8.1.2) and is surjective, and $A/I = R/J$.

Moreover, the data satisfy the properties (6)–(9) on [Wan20, page 478]. Properties (6)–(8) are checked in the same way as *loc.cit.*

Property (9) is about the irreducibility of σ . It requires that, for each $\text{Frac}(A)$ -algebra homomorphism $\lambda : R \otimes_A \text{Frac}(A) \rightarrow K$, K a finite extension of $\text{Frac}(A)$, the representation $\sigma_\lambda : G \rightarrow \text{GL}_4(K)$ obtained from σ via λ is either absolutely irreducible or contains an absolutely irreducible two-dimensional subrepresentation whose trace is congruent to $\chi + \chi^{-c} \pmod{I}$. It can be checked as follows. Let $\mathcal{T} : G \rightarrow A$ be the pseudo representation giving rise to σ . Suppose that σ does not satisfy (9). Then $\mathcal{T} = \delta_1 + \delta_2 + \delta_3$ with δ_1, δ_2 characters and δ_3 a two-dimensional pseudo-representation with irreducible residual representation is $\text{Tr} \bar{\rho}_\pi$. Take an arithmetic point $x : \mathbb{T}_{\text{so}, \xi, \Gamma_K}^0 \rightarrow \overline{\mathbb{Q}}_p$ corresponding to an automorphic representation Π of $\text{U}(3, 1)(\mathbb{A}_{\mathbb{Q}})$ generated by a classical semiordinary cuspidal automorphic form fixed by $K_{p,1}^0$ of weight $(0, 0, t^+; t^-)$, $0 \gg t^+ \gg -t^-$. We can associate a two-dimensional (irreducible) Galois representation $\rho_{3,x} : G \rightarrow \text{GL}_2(\overline{\mathbb{Q}}_p)$ to the specialization of δ_3 at x . As in [SU14, Theorem 7.5], a twist of $\rho_{3,x}$ descends to $\text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$, which we denote by $\rho'_{3,x} : \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \rightarrow \text{GL}_2(\overline{\mathbb{Q}}_p)$.

If π is ordinary at p , then Π is ordinary at p . By the argument in [SU14, Theorem 7.5], we know that $\rho'_{3,x}$ is modular and Π is cuspidal associated to parabolic subgroup (CAP), but the condition on the weights $(0, 0, t^+; t^-)$ excludes this possibility ([Har84, Theorem 2.5.6]).

If π is not ordinary at p , then $\bar{\rho}_\pi|_{G_{K,p}} \cong \bar{\rho}_\pi|_{G_{\mathbb{Q},p}}$ is irreducible by [Edi92]. Since $\bar{\rho}_\Pi \cong \bar{\rho}_\pi|_G \oplus$ two characters, we deduce that the semisimplification of $\rho_\Pi|_{G_{K,p}}$ is not a direct sum of four characters. Identify $\text{U}(3, 1)(\mathbb{Q}_p)$ with $\text{GL}_4(\mathbb{Q}_p)$, and let $Q \subset \text{GL}_4$ be a parabolic subgroup with its Levi subgroup isomorphic to $\text{GL}_2 \times \text{GL}_1 \times \text{GL}_1$. As in the proof of Proposition 3.0.5, it follows from the theory of Jacquet modules that Π_p is isomorphic to a subquotient of $\text{Ind}_{Q(\mathbb{Q}_p)}^{\text{GL}_4(\mathbb{Q}_p)} \sigma \boxtimes \chi \boxtimes \chi'$ with χ, χ' characters of $\mathbb{Q}_p^\times$ and σ an irreducible admissible representation of $\text{GL}_2(\mathbb{Q}_p)$ containing a nonzero vector fixed by the Iwahori subgroup. Since the semisimplification of $\rho_\Pi|_{G_{K,p}}$ is not a direct sum of four characters, σ is not Steinberg or a twist of Steinberg, and must be unramified. Hence, Π_p is isomorphic to a subquotient of $\text{Ind}_{B(\mathbb{Q}_p)}^{\text{GL}_4(\mathbb{Q}_p)} \chi_1 \boxtimes \chi_2 \boxtimes \chi_3 \boxtimes \chi_4$ with $\chi_1, \chi_2, \chi_3, \chi_4$ unramified characters of $\mathbb{Q}_p^\times$. Let $\alpha_j = \chi_j(p)$, $1 \leq j \leq 4$. We can assume that $\text{val}_p(\alpha_1) \leq \text{val}_p(\alpha_2) \leq \text{val}_p(\alpha_3) \leq \text{val}_p(\alpha_4)$. The semiordinarity of Π at p implies that

$$\text{val}_p(\alpha_1) + \text{val}_p(\alpha_2) = 0, \quad \text{val}_p(\alpha_3) = -t^+ + \frac{3}{2}, \quad \text{val}_p(\alpha_4) = t^- - \frac{3}{2}, \quad (8.2.5)$$

and the integrality of the operator $U_{p,1}^+$ (defined in equation (3.0.7)) implies that

$$\text{val}_p(\alpha_1), \text{val}_p(\alpha_2) \geq -\frac{1}{2}. \quad (8.2.6)$$

Thanks to the condition $0 \gg t^+ \gg -t^-$, equations (8.2.5) and (8.2.6) imply that $\alpha_i \alpha_j^{-1} \neq p^{\pm 1}$ unless $\{i, j\} = \{1, 2\}$ and $\text{val}_p(\alpha_1) = -\frac{1}{2}$, $\text{val}_p(\alpha_2) = \frac{1}{2}$. However, $\text{val}_p(\alpha_1) = -\frac{1}{2}$, $\text{val}_p(\alpha_2) = \frac{1}{2}$ imply that Π is ordinary at p and this contradicts that $\rho_\Pi|_{G_{K,p}}$ is not a direct sum of four characters. Therefore, we

have $\alpha_i \alpha_j^{-1} \neq p^{\pm 1}$ for all i, j , so $\text{Ind}_{Q(\mathbb{Q}_p)}^{\text{GL}_4(\mathbb{Q}_p)} \sigma \boxtimes \chi \boxtimes \chi'$ is irreducible and Π_p is unramified. It follows that $\rho_\Pi|_{G_{K,p}}$ is crystalline, so $\rho'_{3,x}|_{G_{Q,p}}$ is crystalline. Also, $\bar{\rho}'_{3,x} \equiv \bar{\rho}\pi$ is not induced from a Galois character for $\mathbb{Q}(\sqrt{(-1)^{(p-1)/2}p})$, because its restriction to I_p has semisimplification $\omega_2^i \oplus \omega_2^{pi}$ with ω_2 the fundamental character of level 2 and $i \equiv 1 \pmod{p-1}$ (since $\rho_\pi|_{G_{Q,p}}$ is crystalline of weight $(0, 1)$), and if $\bar{\rho}$ was induced from a Galois character for $\mathbb{Q}(\sqrt{(-1)^{(p-1)/2}p})$, i must be a multiple of $\frac{p+1}{2}$, which is impossible when p is odd. Thus, we can apply [Kis09], we deduce that $\rho'_{3,x}$ is modular. Then Π is CAP, that is, it has the same system of Hecke eigenvalues as a Klingen-type Eisenstein series. This is impossible thanks to the condition on the weights $(0, 0, t^+, t^-)$ by [Har84, Theorem 2.5.6]. Property (9) is verified.

Let

$$X_{\xi \circ \text{Nm}}^{\Sigma \cup \{\ell, \ell'\}} = \text{Hom}_{\mathbb{Z}_p} \left(\ker \left\{ H^1 \left(\mathbb{Q}, \xi \Psi_K \circ \text{Nm} \right) \rightarrow \prod_{v \notin \Sigma \cup \{\ell, \ell'\}} H^1 \left(I_v, \xi \Psi_K \circ \text{Nm} \right) \right\}, \mathbb{Q}_p / \mathbb{Z}_p \right),$$

where $\xi \Psi_K \circ \text{Nm}$ is understood as a character of $\text{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$ valued in $\hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_K]]^*$. With the input (1)–(5) satisfying the properties (6)–(9), applying the lattice construction [Wan20, Proposition 9.2], one proves that if $P \subset \mathcal{O}_L^{\text{ur}}[[\Gamma_K]]$ is a height one prime such that $\text{ord}_P(\mathcal{E}_{\pi, \xi}) > 0$ and $(X_{\xi \circ \text{Nm}} \otimes_{\mathbb{Z}} \mathbb{Q})_P = 0$, then the inequality (8.2.4) holds. It follows that for all height one prime ideals $P \subset \mathcal{O}_L^{\text{ur}}[[\Gamma_K]]$ with $P \cap \mathcal{O}_L^{\text{ur}}[[\Gamma_K^+]] = (0)$, the desired inequality (8.2.3) holds.

(The congruence ideal $\mathcal{E}_{\pi, \xi}$ is bounded by the product $\mathcal{L}_{\xi, \mathbb{Q}}^{\Sigma \cup \{\ell, \ell'\}} \mathcal{L}_{\pi, K, \xi}^{\Sigma \cup \{\ell, \ell'\}}$ and is expected to give a bound for the product of the characteristic ideals of $X_{\xi \circ \text{Nm}}^{\Sigma \cup \{\ell, \ell'\}}$ and $X_{\pi, K, \xi}^{\Sigma \cup \{\ell, \ell'\}}$. Although, the characteristic ideals of $X_{\xi \circ \text{Nm}}^{\Sigma \cup \{\ell, \ell'\}}$ is known to be generated by $\mathcal{L}_{\xi, \mathbb{Q}}^{\Sigma \cup \{\ell, \ell'\}}$ by the Iwasawa main conjecture proved in [MW84], the lattice construction argument in [SU14, Wan20] only proves the desired bound for $\text{ord}_P(\text{char}_{\mathcal{O}_L^{\text{ur}}[[\Gamma_K]]}(X_{\pi, K, \xi}^{\Sigma \cup \{\ell, \ell'\}}))$ when $(X_{\xi \circ \text{Nm}} \otimes_{\mathbb{Z}} \mathbb{Q})_P = 0$. In [Wan20], height one primes in $\mathcal{O}_L^{\text{ur}}[[\Gamma_K^+]] \otimes_{\mathbb{Z}} \mathbb{Q}$ do not need to be excluded thanks to Lemma 9.3 in *loc.cit* and the fact that $\mathcal{L}_{\pi, K, \xi}$ is not contained in any height one prime ideal in $\mathcal{O}_L^{\text{ur}}[[\Gamma_K]]$ by [Hsi14b]. However, in our case with π fixed instead of moving in a family, we cannot prove an analogue of Lemma 9.3 in [Wan20].) $\square$

Next, we deduce partial results towards Conjecture 1.0.2 from Theorem 8.2.1. We first introduce the following integral primitive p -adic L -function.

Proposition 8.2.2. *Suppose that ξ (fixed in §5.2) further satisfies the following conditions:*

- $\xi_p \not\equiv \xi_{\bar{p}}$ modulo the maximal ideal of $\mathcal{O}_L$ (so that $\text{Ind}_K^{\mathbb{Q}} \rho_{\xi}$, the p -adic Galois representation corresponding to a CM eigenform associated to ξ , is residually absolutely irreducible and the two characters of $(\text{Ind}_K^{\mathbb{Q}} \xi)|_{G_{Q,p}}$ on the diagonal are distinct),
- the conductor of ξ is only divisible by primes split in $K/\mathbb{Q}$.

Then there exists a p -adic L -function $\mathcal{L}_{\pi, K, \xi} \in \hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_K]]$ such that for all algebraic Hecke characters $\tau : K^\times \backslash \mathbb{A}_K^\times \rightarrow \mathbb{C}^\times$ with $\tau_{p\text{-adic}}$ factoring through Γ_K and $\xi\tau$ of ∞ -type (k_1, k_2) with $k_1, k_2 \in \mathbb{Z}$, $k_1 \leq 0$, $k_2 \geq 2 - k_1$,

$$\begin{aligned} \mathcal{L}_{\pi, K, \xi}(\tau_{p\text{-adic}}) &= \left(\frac{\Omega_p}{\Omega_\infty} \right)^{2(k_2 - k_1)} \frac{\Gamma(k_2) \Gamma(k_2 - 1)}{(2\pi i)^{2k_2 - 1}} \cdot \gamma_p \left(\frac{3 - (k_1 + k_2)}{2}, \pi_p^\vee \times (\xi_0 \tau_0)^{-1} \right) \\ &\quad \times L^{\{\infty, p\}} \left(\frac{k_1 + k_2 - 1}{2}, \text{BC}(\pi) \times \xi_0 \tau_0 \right). \end{aligned}$$

Proof. When both modular forms are ordinary and move in Hida families, the three-variable (nonintegral) p -adic Rankin–Selberg p -adic L -function is constructed in [Hid91], and the integral p -adic L -function obtained by multiplying a generator of a congruence ideal is constructed in

[Wan20, Definition 7.8] when the dominant-weight family is CM, and in [CH20] for the general case under the assumption that the Galois representation associated to the weight-dominant form is residually absolutely irreducible and residually p -distinguished, which guarantees that its associated congruence ideals is principal. In fact, when the form of nondominant weight, that is, our f here) is fixed, the ordinarity assumption on it is not necessary for constructing the two-variable p -adic Rankin–Selberg p -adic L -function.

Like in [Wan20, Definition 7.8], we let $\xi' = \xi \cdot (\chi_{g\xi}^{\text{tw}} \circ \text{Nm}_{\mathcal{K}/\mathbb{Q}})$ with $\chi_{g\xi}^{\text{tw}}$ a finite-order Dirichlet character unramified outside $\Sigma \cup \{p\}$ such that the automorphic representation of $\text{GL}(2, \mathbb{A}_{\mathbb{Q}})$ corresponding to ξ' is minimal in the sense of [HT93, Section 7] at all finite places. Denote by $\mathbf{g}_{\xi'}$ the ordinary CM family associated to $\xi'\Psi_{\mathcal{K}}$.

In [Hid91], a three-variable Eisenstein measure valued in p -adic modular forms is constructed. Denote by E the restriction of the three-variable Eisenstein measure to the two-variable weight space corresponding to f being fixed. Let f' be the twist of f by $\chi_{g\xi}^{\text{tw}, -1}$. Then the product $f'E$ gives a two-variable p -adic measure valued in p -adic modular forms. We can apply to it the ordinary projector and get an ordinary family $e_{\text{ord}}(fE)$. Applying the Hecke projector $\mathbb{1}_{\mathbf{g}_{\xi'}}$ to $e_{\text{ord}}(fE)$ and taking the first Fourier coefficient gives an element in $\mathcal{L}_{\pi, \mathcal{K}, \xi}^{\text{frac}} \in \text{Frac}(\hat{\mathcal{O}}_L^{\text{ur}}[[\Gamma_{\mathcal{K}}]])$. Under the assumptions on ξ , the same argument in [Wan20, Definition 7.8] shows that the desired p -adic L -function (up to a p -adic unit) can be obtained by multiplying $\text{Cl}_{\mathcal{K}} \cdot \mathcal{L}_{\mathcal{K}, \xi}^{\text{Katz}}$ to $\mathcal{L}_{\pi, \mathcal{K}, \xi}^{\text{frac}}$. $\square$

Theorem 8.2.3. *Let $\mathcal{K}$ be an imaginary quadratic field, $p \geq 3$ be a prime split in $\mathcal{K}$, and π, ξ as in §5.2 with ξ also satisfying the conditions in Proposition 8.2.2.*

(1) *As ideals of $\mathcal{R}$,*

$$(\mathcal{L}_{\pi, \mathcal{K}, \xi}) \supset \text{char}_{\mathcal{R}}(X_{\pi, \mathcal{K}, \xi} \otimes_{\mathcal{O}_L[[\Gamma_{\mathcal{K}}]]} \mathcal{R})$$

(where the ring $\mathcal{R}$ is defined in equation (8.2.1), the $\mathcal{O}_L[[\Gamma_{\mathcal{K}}]]$ -module $X_{\pi, \mathcal{K}, \xi}$ and its characteristic ideal are defined in §1, and the p -adic L -function $\mathcal{L}_{\pi, \mathcal{K}, \xi}$ is given in Proposition 8.2.2).

(2) *If ξ further satisfies:*

$$- \xi|_{\mathbb{A}_{\mathbb{Q}}^{\times}} = \omega^2 \text{ with } \omega : \mathbb{Q}^{\times} \backslash \mathbb{A}_{\mathbb{Q}}^{\times} \rightarrow \mathbb{C}^{\times} \text{ the Teichmüller character, and } k_0 \equiv 0 \pmod{2(p-1)},$$

$$- \text{for every finite place of } \mathbb{Q} \text{ nonsplit in } \mathcal{K}, \epsilon_v\left(\frac{1}{2}, \text{BC}(\pi) \times \xi_0\right) = 1,$$

then

$$(\mathcal{L}_{\pi, \mathcal{K}, \xi}) \supset \text{char}_{\mathcal{O}_L^{\text{ur}}[[\Gamma_{\mathcal{K}}]]}(X_{\pi, \mathcal{K}, \xi}).$$

Proof.

(1) By the same argument as in the proof of [JSW17, Theorem 6.1.6], which uses the fact that the sizes of the unramified cohomology groups at primes outside p are controlled by the local Euler factors of the p -adic L -functions, the inclusion in (1) follows from Theorem 8.2.1.

(2) With those further conditions on ξ , one can use the vanishing of the anticyclotomic μ -invariant proved in [Hsi14b] to deduce that the $\mathcal{L}_{\pi, \mathcal{K}, \xi}$ is not divisible by any height one prime ideal in $\mathcal{O}_L^{\text{ur}}[[\Gamma_{\mathcal{K}}^+]]$. Thus, the inclusion in (1) implies the inclusion in (2). $\square$

Acknowledgments. We would like to thank Eric Urban for pointing out to us the possibility of developing the semiordinary Hida theory needed in this paper. We also thank Ming-Lun Hsieh, Kai-Wen Lan and Christopher Skinner for useful communications. We also thank the referees for their careful reading of the paper and many useful suggestions.

Conflict of Interest. The authors have no conflict of interest to declare.
