Abstract

The emotions we experience involve complex processes; besides physiological aspects, research in psychology has studied *cognitive appraisals* where people assess their situations subjectively, according to their own values (Scherer, 2005). Thus, the same situation can often result in different emotional experiences. While the *detection* of emotion is a well-established task, there is very limited work so far on the automatic prediction of cognitive appraisals. This work fills the gap by presenting COVIDET-APPRAISALS, the most comprehensive dataset to-date that assesses 24 appraisal dimensions, each with a natural language rationale, across 241 Reddit posts. COVIDET-APPRAISALS presents an ideal testbed to evaluate the ability of large language models — excelling at a wide range of NLP tasks — to automatically assess and explain cognitive appraisals. We found that while the best models are performant, open-sourced LLMs fall short at this task, presenting a new challenge in the future development of emotionally intelligent models. We release our dataset at <https://github.com/honglizhan/CovidET-Appraisals-Public>.

1 Introduction

Emotions constitute a crucial aspect of people's lives, and understanding them has a profound impact on improving public mental health problems as well as policy-making (Choudhury and De, 2014; Gjurković and Šnajder, 2018; Arora et al., 2021; Uban et al., 2021). The emotions we experience involve complex processes: the same situation can often result in different emotional experiences, based on an individual's subjective evaluations. These are called *cognitive appraisals*, and have been extensively studied in psychology through theoretical, behavioral, and hand-coded studies (Arnold, 1960; Lazarus, 1966; Lazarus et al., 1980; Roseman, 1984; Scherer et al., 1984; Smith and

Figure 1: An example from COVIDET-APPRAISALS. The fact that the narrator is blaming nobody but circumstances beyond anyone's control for causing long-COVID contributes to their feeling of *sadness*. We showcase an annotation together with LLMs' responses in Appendix §A.

Ellsworth, 1985; Weiner, 1985; Clore and Ortony, 2000; Roseman and Smith, 2001; Scherer et al., 2001; Ellsworth and Scherer, 2003; Sander et al., 2005; Ong et al., 2015, 2019; Ortony et al., 2022; Yeo and Ong, 2023). For instance, being fired from a job, if judged to be due to one's own controllable mistakes, could result in regret; if evaluated to be unfair and due to someone else's intentional actions, would make one feel angry; and if appraised to be leaving a toxic work environment, could instead result in relief and even happiness. **The different dimensions along which people subjectively inter-**

pret or appraise the situation characterizes the specific emotions they feel (Moors et al., 2013).

Although emotion *detection* is a well-established NLP task (Strapparava and Mihalcea, 2007; Mihalcea and Strapparava, 2012; Wang et al., 2012; Lei et al., 2014; Abdul-Mageed and Ungar, 2017; Khanpour and Caragea, 2018; Liu et al., 2019; Sosea and Caragea, 2020; Demszky et al., 2020; Desai et al., 2020; Sosea et al., 2022), it mostly involves classification from text to emotion labels directly, skipping the appraisal step that is necessary to interpret why the emotion is experienced by an individual in a particular event. Hence, we do not yet have a data-driven understanding of these cognitive appraisals in textual data. Yet recent work has started to show its necessity: Hofmann et al. (2020) showed that appraisals are informative for an emotion detection model; Zhan et al. (2022) further recognized appraisals to be an integral part of emotion triggers, though appraisals were not explicit in their work.

This work aims at construing an empirical, explicit understanding of *perceived* cognitive appraisals in human readers and large language models (LLMs) alike, via a comprehensive 24 dimensions, along with their corresponding natural language rationales. A language model’s capability of assessing cognitive appraisals reflects a more nuanced understanding of emotions, where it could contextualize individual subjectivity in responses to the same situation, while offering explanations (“they are feeling [*emotion*] because of [*appraisal*]”). This could be groundwork for emotional support agents, e.g., one capable of positive reframing (Ziems et al., 2022) or producing empathetic responses.

We first introduce COVIDET-APPRAISALS, a dataset of 24 appraisal dimensions annotated across 241 Reddit posts sourced from Zhan et al. (2022) about COVID-19. Each post was manually annotated with 24 appraisal dimensions from a recent meta-analysis covering all appraisal dimensions proposed and studied in the literature (Yeo and Ong, 2023). For each appraisal dimension, annotators not only rated the extent to which they perceived the narrator is experiencing the said dimension, but also provided a *rationale* in their own language to justify their rating selection. An example from COVIDET-APPRAISALS is shown in Figure 1.

COVIDET-APPRAISALS serves as an ideal testbed to evaluate the capability of a model to un-

cover implicit information for emotion understanding. Benchmarking on COVIDET-APPRAISALS, we evaluate the performance of LLMs to (1) provide Likert-scale ratings for the appraisal dimensions; and (2) generate natural language rationales for their ratings. The elicitation of the rationales can be seen as a way of probing (Le Scao and Rush, 2021; Gu et al., 2022), where we prefix a question with an elaborated situation. We evaluate a range of LLMs, including ChatGPT, Flan-T5 (Chung et al., 2022), Alpaca (Taori et al., 2023), Dolly (Conover et al., 2023). With an extensive human evaluation of the natural language rationales from LLMs as well as our annotators, we find that ChatGPT performs on par with (and in some cases better than) human-annotated data; this opens a new avenue of investigation to improve its performance on emotion-related tasks (Kocoń et al., 2023). In comparison, other open-sourced LLMs fall short on this task, presenting a new challenge in the future development of emotionally intelligent open models.

We publicly release our annotated dataset COVIDET-APPRAISALS, model outputs, and our human evaluation data at <https://github.com/honglizhan/CovidET-Appraisals-Public>.

2 Background and Related Work

Cognitive Appraisal Theories. The cognitive appraisal theories of emotion state that emotions arise from an individual’s subjective understanding and interpretation of situations that hold personal importance for their overall well-being (Arnold, 1960; Lazarus, 1966; Lazarus et al., 1980; Roseman, 1984; Scherer et al., 1984; Smith and Ellsworth, 1985; Weiner, 1985; Clore and Ortony, 2000; Roseman and Smith, 2001; Scherer et al., 2001; Sander et al., 2005; Ortony et al., 2022). In practical terms, people interpret and appraise situations along a range of different dimensions, and it is the specific manner in which they appraise their situations that give rise to the distinct emotions they experience. The primary focus of cognitive appraisal theories of emotions revolves around the identification of these appraisal dimensions that are associated with specific emotional experiences and how these dimensions contribute to distinguishing between different emotional states (Lazarus, 1993; Roseman, 1996; Scherer et al., 2001; Moors, 2010; Scherer and Moors, 2019).

While appraisal theorists agree on the impor-

tance of motivationally-relevant appraisals in triggering emotions, they have not reached a consensus on the specific appraisal dimensions that play a significant role in this process (Yeo and Ong, 2023). Various theories have put forth distinct sets of appraisal dimensions that are considered crucial in triggering and distinguishing emotions. From prior literature, Yeo and Ong (2023) identified and assembled a taxonomy of all appraisal dimensions that have been studied, and produced a condensed list of 24 cognitive appraisal dimensions which we focus on in this paper.

Cognitive Appraisals in NLP. Appraisals provide the necessary computational structure allowing for the distillation of real-life situations that depend on a multitude of factors into a (large but) finite set of appraisal dimensions (Ong et al., 2015). Despite its importance, however, few works have explored the implications of cognitive appraisals on emotions in NLP. Hofmann et al. (2020) experimented with a small set of cognitive appraisal dimensions (including *attention*, *certainty*, *effort*, *pleasantness*, *responsibility*, *control*, and *circumstance*) to assist the automatic detection of emotions in text, and found that accurate predictions of appraisal dimensions boost emotion classification performance. They introduced a dataset of 1,001 sentences following the template “I feel [emotion], when ...” (average sentence length: 27 tokens). In comparison, our work covers a much wider range of 24 appraisal dimensions found in prior literature, over lengthy (176 tokens on average) Reddit posts that were natural and emotionally charged. We also collect natural language rationales as a key contribution to reveal human’s in-depth understanding of such cognitive appraisals in context.

Recent studies (Zhan et al., 2022; Sosea et al., 2023) acknowledged both *what happened* and *how one appraised the situation* as inherent components of emotion triggers, although the appraisal of events was not explicit in their work. Instead we provide datasets and perform evaluation on appraisals explicitly, such that language models can build on this work to achieve a comprehensive and explicit understanding of cognitive appraisals from written text.

LLMs on Emotion-Related Tasks. Autoregressive LLMs have been explored extensively in emotion-related tasks such as sentiment analysis (Zhong et al., 2023; Qin et al., 2023; Susnjak,

2023), emotion recognition (Kocoń et al., 2023), disclosing the representation of human emotions encapsulated in LLMs (Li et al., 2023), and interpreting mental health analysis (Yang et al., 2023). However, few have tapped into the understanding of cognitive appraisals of emotions innate in LLMs. In this work, we dive into the extent to which LLMs comprehend the profound cognitive appraisals underlying emotions in situations, and further elicit natural language rationales from the language models to disclose the reason behind such predictions from the otherwise baffling black-box LLMs (Gilpin et al., 2018). Aligning with Marasović et al. (2020) who performed human evaluation on rationales generated by GPT, we additionally perform an in-depth human evaluation of the rationales from human annotators and LLMs alike on the novel task of providing natural language explanations for cognitive appraisals of situations that underlie narrators’ emotional experiences.

3 The COVIDET-APPRAISALS Dataset

COVIDET-APPRAISALS contains 241 Reddit posts sampled from the COVIDET dataset (Zhan et al., 2022), where the Reddit posts are sourced from r/COVID19_support. Each post is manually annotated with one or more of the 7 emotions: *anger*, *anticipation*, *joy*, *trust*, *fear*, *sadness*, and *disgust*. The 241 posts in COVIDET-APPRAISALS have an average of 175.82 tokens and 2.67 emotions per post. From Yeo and Ong (2023)’s work, we identify 24 cognitive emotion appraisal dimensions (Table 1). We provide the instructions given to the annotators (including the full questions for each of these 24 dimensions) in Appendix §B.

Annotators. We recruited 2 linguistics students at a university to work on our annotation task; both of them are native speakers of English. Both annotators underwent training using a set of posts already annotated by our group. Throughout the annotation, we monitored the inter-annotator agreement and provided feedback on their work.

Instructions. Given a Reddit post from COVIDET, annotators are asked to judge 24 emotion appraisal dimensions pertaining to how the narrator feels about and views the situation that they are going through (e.g., whether the narrator feels the situation they are in is something they could control). For each appraisal dimension, annotators need to select a Likert rating on the

Table 1: The 24 appraisal dimensions and their abbreviations we used throughout this paper. See Appendix §B for full questions for each dimension, and Figure 1 for an example of how the items for 1: *self-responsibility*, 2: *other-responsibility*, 3: *circumstances-responsibility*, and 24: *expectedness* were framed.

Figure 2: Percentage of “not mentioned” labels in each dimension in COVIDET-APPRAISALS.

scales of 1 to 9. A “not mentioned” (NA) option is provided in case the dimension being asked is absent in the given post. In addition, we also ask the annotators to provide rationales for their ratings in the form of *natural language explanations*.

On average, our trained annotators spent around 30 minutes to complete the annotation of one post. Owing to the immense effort involved, we doubly annotate 40 posts to measure inter-annotator agreement while leaving the rest annotated by one annotator.

Post-Processing and Aggregation. Given a fixed topic (COVID-19 in our case), it is highly likely that certain dimensions frequently don’t ap-

ply (Yeo and Ong, 2023). This can be seen in Figure 2 which plots the percentage of NA labels: dimensions such as *civ* (consistency with internal values), *fair* (fairness), and *csn* (consistency with social norms) contain mostly NA labels (around 80%). Therefore, we remove these dimensions from subsequent analyses and evaluations of the dataset. **This results in a total of 21 applicable appraisal dimensions in COVIDET-APPRAISALS.**

We collected 241 posts in total. For the subset of 40 posts that are doubly annotated, we aggregate the Likert-scale ratings by taking the mean of each post’s ratings for each appraisal dimension (if an annotator labels a dimension as NA, we then exclude the particular dimension of that post that they annotate). In terms of the rationales, we consider both rationales as ground truth references and use multi-reference metrics in our experiments.

Inter-Annotator Agreement. We report inter-annotator agreement on the Likert-scale ratings. Since there is no reliable, automatic way to evaluate natural language rationales (as discussed in §4), we evaluate them with human validation in §7.2.

To measure the agreement for selecting the NA label, we average the Fleiss’ Kappa values (Fleiss, 1971; Randolph, 2005) across *all* 24 appraisal dimensions, yielding a value of 0.769 indicating substantial agreement (Artstein and Poesio, 2008).

For the 1-9 Likert-scale ratings, we report on the 21 applicable dimensions: (1) Spearman’s ρ between our two annotators, calculated per dimension then averaged across all dimensions; (2) Krippendorff’s alpha (using interval distance) (Krippendorff, 1980); and (3) mean absolute difference (*abs. delta*). Here the agreement is calculated if neither annotator gave a NA judgment. Krippendorff’s alpha yields a value of 0.647 indicating substantial agreement (Artstein and Poesio, 2008). The average Spearman’s correlation is 0.497 with significance, and the absolute delta values also have a small mean of 1.734. These measures indicate that while the task is subjective, annotators do align with each other with only a small difference compared to the scale of ratings (1-9). Agreement values differ by dimension, which we showcase in Appendix C.

4 Dataset Analysis

How do the scales distribute across dimensions and emotions? The distribution of the Likert-scale ratings is shown in Figure 3. The rat-

Figure 3: Distribution of the ratings for each dimension.

Figure 4: Mean Likert-scale ratings for each dimension in each emotion.

ings for some dimensions are consistent (e.g., dimensions *crsp* (circumstances-responsibility), *ccrl* (circumstances-controllable), and *chl* (challenge)), whereas for some other dimensions, the ratings have higher variance (e.g., dimensions *ocrl* (other-controllable) and *loss*).

We analyze the connections between our Likert-scale annotations and COVIDET’s emotion annotations. Figure 4 shows the mean Likert-scale rating for each dimension within each post with respect to the perceived emotion. While it is evident that most dimensions show consistency (the posts are all related to COVID-19), some emotions stand out distinctly in particular dimensions. For example, *trust* and *joy* have higher Likert-scale ratings on dimensions *pfc* (problem-focused coping) and *gnd* (goal conduciveness) compared to other emotions, suggesting the inter-correlation between these appraisal dimensions with positive emotions. We further explore whether appraisal dimensions alone are indicative of perceived emotions already annotated in COVIDET in Appendix §D.1.

What are the characteristics of the natural language rationales? On average, each rationale is 1.2 sentences (std.dev = 0.4) and 28.9 tokens (std.dev = 10.0) long. Following Marfurt and Henderson (2021), we also measure the abstractiveness of the rationales from our human annotators by calculating the percentage of novel bigrams in the rationales with respect to the Reddit posts and in-

	RATIONALE		
	BLEU-4	ROUGE-L	BERTSc
ANNOTATORS	0.042	0.253	0.357
BASELINE-P	0.060	0.261	0.336
BASELINE-D	0.059	0.247	0.332

Table 2: Automatic measures of similarity on the natural language rationales of COVIDET-APPRAISALS. BASELINE-P denotes “baseline (same dimension, *different posts*)”, and BASELINE-D denotes “baseline (same post, *different dimensions*)”.

structions (i.e., evaluating a specific appraisal dimension) that the annotators were given. As shown in Table 4, our human annotators attain a % of novel bigrams of 86.7%, indicating a high abstractiveness. We showcase the most prominent topics extracted from the annotated rationales using Latent Dirichlet Allocation (LDA) (Blei et al., 2003) in Appendix §D.2.

Are rationales repetitive? We also look into automatic measures of similarity to assess how much rationales from different annotators, or from different dimensions/posts, differ from one another. Specifically, we calculate BLEU-4 (Papineni et al., 2002), ROUGE-L (Lin, 2004), and re-scaled BERTScore (Zhang et al., 2019) between our two annotators’ rationales. We establish 2 random baselines for comparison: (1) rationales of the same dimension from different posts; (2) rationales from different dimensions/posts within the same post. In each case we report similarity between 3 randomly sampled rationales and the annotated ones.

Table 2 shows that the textual similarity in all conditions are somewhat low; the BLEU and ROUGE scores show that there is very little lexical overlap, although BERTScore shows higher semantic similarity between two annotators for the same dimension within the same post. Upon closer inspection, we observe that these commonly used automatic measures do not adequately capture semantic similarity in our dataset (see Appendix §D.3 for an example). This adds to the challenge of evaluating rationales; as a result, we resort to the human evaluation in §7.2.

5 Can LLMs understand emotional appraisals?

COVIDET-APPRAISALS provides an ideal testbed that evaluates models’ performance on predicting both the Likert ratings, as well as their nat-

ural language explanations. Using COVIDET-APPRAISALS, we evaluate the zero-shot performance of LLMs in an attempt to evaluate their innate ability to comprehend emotional appraisals from social media text without in-context learning.

Models. We evaluate the following instruction-tuned LLMs¹: **1) ChatGPT**, i.e., GPT-3.5-Turbo; **2) FLAN-T5-XXL (11B)** (Chung et al., 2022), which is the instruction fine-tuned version of T5 (Raffel et al., 2020); **3) Alpaca (7B, 13B)** (Taori et al., 2023) is fine-tuned from LLaMA (7B and 13B) (Touvron et al., 2023) on 52K instruction-following examples created with GPT text-davinci-003 in the manner of self-instruct (Wang et al., 2022); **4) Dolly-V2 (7B, 12B)** (Conover et al., 2023) is an instruction-tuned LLM trained on ~15k demonstrations consisting of both instructions and responses.

Prompts and Setup. The templates for prompting the LLMs are shown in Appendix Figure 17. After extensive experimentation, we found that only ChatGPT is able to generate both a rating and a rationale with a single prompt; this type of “1-step” prompting leads to ill-formed responses for other models. Thus, for models other than ChatGPT, we instead use a pipeline or “2-step” prompting similar to the strategy used in Press et al. (2022): we first elicit the rating for the appraisal dimension, then conditioned on the response for the rating we further elicit the rationale for the selection.

We carry out all our experiments on 4 Nvidia A40 GPUs. We use the HuggingFace Transformers (Wolf et al., 2020) library for model inference. We set the temperature value of all models to 0.1.² To enable a fair comparison of models, we sample from the LLMs five times with different model initializations and report average values for both scales and rationales.

6 Evaluation: Likert-Scale Ratings

We report model performance for Likert-scale ratings on the 21 *applicable* dimensions using two

¹While we have also experimented with non-instruction-tuned LLMs (including GPT-3 davinci and LLaMA (7B and 13B)), they largely fail to generate sensible outputs for this task. We showcase examples of responses from non-instruction-tuned models in Appendix §A. For these reasons, we do not include their results in this paper.

²We experimented with higher temperatures on a validation set consisting of 10 Reddit posts annotated by our group which are not included in COVIDET-APPRAISALS, and the models yielded worse and more unstable performance.

	MAE	SCALE SPEARMAN’S ρ	NA F1
CHATGPT	1.694	0.388^{††}	0.918
FLAN-T5	3.266	0.225 [†]	0.852
ALPACA-7B	2.353	0.081	0.918
ALPACA-13B	3.872	−0.035	0.602
DOLLY-7B	2.812	−0.013	0.645
DOLLY-12B	2.747	0.022	0.711

Table 3: Experiment results from LLMs. [†] indicates $p < 0.1$ for Spearman correlation, and ^{††} indicates $p < 0.05$. In addition, we also provide the results of the F1 score on measuring the agreement between the models’ ratings and the gold ratings for selecting the “not mentioned” label across *all* 24 dimensions.

standard regression metrics: Mean Absolute Error (MAE) and Spearman’s correlation. We treat the selection of the NA labels as a binary classification task and report F1 measures across *all* 24 dimensions. For the 40 gold examples that were doubly annotated by human annotators, we consider a dimension as NA when both annotators select the label.

Results. To evaluate the performance, we clean the responses elicited from the LLMs. Specifically, we use regular expressions to extract the first numeric value ranging from 1-9 from the scale responses³. The results of the models’ performance are shown in Table 3. We showcase examples of the models’ responses in Appendix §A. Additional analyses of the LLMs’ responses are shown in Appendix §G.

For the NA labels (Table 3, right), ChatGPT and Alpaca-7B score the highest with an F1 of 0.918. In general, the average performance across the language models we evaluate is 0.774 for F1, indicating these models are performant at predicting whether a dimension applies.

For the Likert-rating predictions, results show that ChatGPT-3.5 consistently yields the highest performance compared to the other language models, with a significant Spearman’s correlation of 0.388 and an MAE of 1.694. We note that FLAN-T5-XXL is the second best-performing model. Alpaca and Dolly perform poorly on our task, with negative correlations with the gold labels⁴. Inter-

³For example, one of Alpaca-7B’s scale responses is “*The narrator thought that Circumstances Beyond Anyone’s Control were responsible for causing the situation to a moderate extent (4 on a scale of 1-9).*”. After cleaning, the response is formatted to “4”.

⁴As shown in Appendix Figure 9, the ratings generated by

	LENGTH	ABSTRACTIVENESS	AUTO EVAL			HUMAN EVAL			
	# TOKENS	%NOVEL BIGRAMS	BLEU-4	ROUGE-L	BERTSc	FAC	REL	JUS	USE
ANNOTATORS	28.9	86.7%	—			0.73	0.88	0.95	0.72
CHATGPT	58.0	81.8%	0.044	0.224	0.347	0.84	0.88	0.93	0.85
FLAN-T5	45.3	16.0%	0.008	0.066	0.053	0.40	0.29	0.24	0.13
ALPACA-7B	48.6	71.9%	0.040	0.230	0.297	0.55	0.82	0.82	0.51

Table 4: Experiment results from LLMs. Additional evaluations of *all* language models (including Alpaca-13B, Dolly-7B, and Dolly-12B) are provided in Table 11. A more comprehensive report of the automatic metrics BLEU-4, ROUGE-L, and BERTSCORE is provided in Table 9, Appendix §F.

estingly, we notice a drop in performance when the size of the model parameters increases for Alpaca. The results highlight the challenging nature of our task, and the gap between open-sourced LLMs vs. ChatGPT (Gudibande et al., 2023).

Additionally, we also measure the systems’ performance on all 24 appraisal dimensions, including the 3 appraisal dimensions where the NA rates are around 80%. Results revealed marginal change in performance across all LLMs. For most LLMs the performance dropped as expected: measured with Spearman’s ρ , ChatGPT-3.5 ($\downarrow$ 0.018), Alpaca-7B ($\downarrow$ 0.008), and Dolly-12B ($\downarrow$ 0.007). On the other hand, the performance of FLAN-T5 ($\uparrow$ 0.005), Alpaca-13B ($\uparrow$ 0.027), and Dolly-7B ($\uparrow$ 0.020) increased.

7 Evaluation: Rationales

As rationalizing emotional appraisals with natural language is a novel task, we perform both automatic (§7.1) and human evaluation (§7.2).

7.1 Automatic Evaluation

We use commonly used automatic reference-based metrics including BLEU (Papineni et al., 2002), ROUGE (Lin, 2004) and BERTScore (Zhang et al., 2019), comparing generated rationales vs. annotated ones (in a multi-reference fashion).

Results. Similar to the performance in selecting Likert-scale ratings, ChatGPT remains the best-performing language model in providing natural language rationales (Table 4). The values ChatGPT achieves are lower than, though comparable to, those between different rationales from our two annotators. Alpaca-7B also achieves comparable performance in these automatic measures,

the language models (specifically, Alpaca-7B and Dolly-12B) for some of the dimensions lack variance (i.e., they gave a constant rating for certain appraisal dimensions). Therefore, the Spearman correlation is set to zero in these dimensions, indicating no correlation.

despite its relatively poor capability in terms of selecting Likert-scale ratings. We note that FLAN-T5 lags behind considerably compared to ChatGPT and Alpaca-7B. We provide the additional auto-evaluation statistics for other LLMs including Dolly-7B, Dolly-12B, and Alpaca-13B in Appendix Table 11.

How long and how abstractive are the rationales generated by LLMs?

In addition, we also measure the length and abstractiveness of the rationales generated by LLMs. Following the setup in §4, we evaluate abstractiveness using % of novel bigrams, comparing LLMs’ generated rationales against the Reddit posts as well as the prompts (i.e., evaluating a specific appraisal dimension) they were given. As shown in Table 4, rationales generated by LLMs are at least 1.5x longer than those provided by our annotators, with ChatGPT being the most verbose. The LLMs also provide rationales that are more extractive compared to our annotators, with FLAN-T5 being the most extractive.

7.2 Human Evaluation

Data. Because the natural language rationales are explanations for a particular rating, we only evaluate and analyze LLM-generated rationales when the model made a near-correct prediction of the Likert-scale rating for that particular dimension compared against the gold human ratings. Specifically, we sample the *intersection* of (post, dimension) tuples where the 3 *best-performing* LLMs’ (i.e., ChatGPT, FLAN-T5, and Alpaca-7B) ratings fall in the range of an absolute difference of 1 to one of the annotated scale-ratings. In cases where there are 2 gold annotations for a particular dimension, both are evaluated. In Appendix §F we also show the human evaluation of rationales for such intersection of *all* LLMs. We additionally evaluate **human-written rationales** as well, and we mix those (in random order) with LLMs’ responses.

The above desiderata results in an evaluation

of 108 rationales annotated by human annotators and 65 natural language rationales from each LLM. The evaluation covers 19 out of the 21 applicable dimensions (no such overlap is found for dimensions *crsp* (*circumstances-responsibility*) and *pls* (*pleasantness*)). Moreover, we make sure that there are no ground truth labels annotated by the human annotators in which the rating is NA.

Instructions. Given a Reddit post and the scale provided by the human annotators or the LLM (blinded to the annotators), annotators are asked to judge the rationales pertaining to the emotion appraisal dimension regarding the post as well as the stated scale. The rationales are distributed to annotators at random. We evaluate the natural language rationales based on the following criteria. In Appendix §H, We provide the detailed instructions and examples given to the annotators, together with the layout of the human evaluation task.

1) Factuality: For the rationale, the model may not generate something that is factual: sometimes it generates rationales for the sole purpose of justifying its answer (Ye and Durrett, 2022). Therefore, we include the aspect of *hallucination and factuality* as one of our evaluation criteria, and ask evaluators whether the rationale faithfully reflects what’s stated in the post. Options of “Yes”, “Minor Error”, and “No” are provided.

2) Relevance: We evaluate whether the rationale directly addresses the specific appraisal dimension question that is being asked about the post. We ask evaluators on a Likert-scale of 1 to 5, with 1 being “least relevant” and 5 being “most relevant”, whether the rationale focuses on the specific aspect of the post that is being appraised, and whether it strays off-topic or provides irrelevant information.

3) Justification: We ask human evaluators whether the rationale justifies the selected scale by adequately explaining why the selected rating scale is the most appropriate or relevant one to use for the aspect being evaluated. Annotators need to select either “Yes” or “No”.

4) Usefulness: Finally, we evaluate whether the rationale provides useful or informative insights or explanations of useful information pertaining to the appraisal dimension being judged. Options of “Yes”, “Maybe”, and “No” can be selected.

Annotators. We recruit annotators from the Amazon Mechanical Turk (MTurk) to work on our human evaluation task. The crowd workers were

involved in a pre-annotation *qualification as well as training* process before commencing the evaluation of the natural language rationales. We assign 2 crowd workers per natural language rationale evaluation. We ensure that the crowd workers earn a minimum salary of \$10 per hour.

We report the inter-evaluator agreement using Krippendorff’s Alpha with interval distance in Table 5, showing substantial agreement (Artstein and Poesio, 2008) across all criteria.

Label Transformation. For the convenience of measuring inter-annotator agreement as well as interpreting the results, we convert the labels of each criterion to numeric values within the range of 0 to 1. Specifically, for criteria *Factuality*, *Justification*, and *Usefulness*, “Yes” is converted to 1, “Minor Error/Maybe” to 0.5, and “No” to 0. As for the criterion *Relevance* which is judged on a 5-scale Likert rating, we map the Likert scale of 1 into 0, 2 into 0.25, 3 into 0.5, 4 into 0.75, and 5 into 1.

Results. The result of the mean ratings for each criterion from the human evaluation task is provided in Table 4. We provide box plots of the ratings as well as the human evaluation results for the rationales from all 6 LLMs in Appendix §F.

From Table 4 we observe that our human annotators and ChatGPT provide natural language rationales of the highest quality among all models, according to human evaluators. Surprisingly, we find ChatGPT performs on par with our human annotators, with (slightly) better performance in terms of *factuality* and *usefulness*. This can be attributed to the verbosity and extractiveness of ChatGPT (as shown in Table 4), especially in dimensions where the scale rating is low. We showcase an example in Appendix §I.

Alpaca-7B attains lower results compared to the other LLMs, especially in terms of the criteria *factuality* and *usefulness*. FLAN-T5, on the other hand, ranks the worst on all criteria among the LLMs. Further analysis reveals that FLAN-T5 occasionally generates responses for natural language rationales that are the same as its scale answers, resulting in irrelevant and useless rationales.

8 Conclusion

To achieve a more accurate and holistic understanding of emotions from written text, NLP models need to work towards understanding the subjective cognitive appraisals of emotions underlying

	FAC	REL	JUS	USE
EVALUATORS	0.590	0.718	0.576	0.668

Table 5: Inter-annotator agreement statistics for the human evaluation task, measured using Krippendorff’s Alpha with interval distance.

situations. In this work, we construe an empirical and explicit understanding of *perceived* cognitive appraisals in human readers and LLMs alike. We present COVIDET-APPRAISALS, a dataset of 241 Reddit posts annotated with a comprehensive range of 24 subjective cognitive appraisals that follow a situation, along with their corresponding natural language rationales. Experiments reveal that COVIDET-APPRAISALS is a vital resource to evaluate the capability of a language model to uncover implicit information for emotional understanding. Our thorough evaluation of LLMs’ performance on assessing emotion appraisal dimensions emphasizes that COVIDET-APPRAISALS is a challenging benchmark, and our in-depth human evaluation of the natural language rationales indicates potential areas of improvement (e.g., improving the *factuality* and *usefulness* of the rationales) for open-source LLMs.

Limitations

This work presents a new dataset entitled COVIDET-APPRAISALS to evaluate LLMs’ capability in cognitive emotion appraisals. Due to the highly demanding nature of our task (e.g., the same situation can result in different subjective evaluations), COVIDET-APPRAISALS is annotated by 2 annotators. Future work can explore a larger pool of annotators. Furthermore, it should be acknowledged that COVIDET-APPRAISALS is restricted to social media posts during the COVID-19 pandemic, and they are written in English solely. This makes it challenging to evaluate LLMs’ ability in other domains as well as languages. Also, we note the appraisals we collect are from the *perceived* end, which are not subjective appraisals from the narrators and authors themselves.

We note that the size of COVIDET-APPRAISALS is relatively small. We have not intended this dataset to be one for supervised model training but rather a very high-quality dataset for evaluation (since this is the first dataset of its kind). A key reason is that the collection of appraisal annotations is both challenging and time-consuming: we have 24

dimensions to analyze per post, and the annotation for one post for one trained annotator takes half an hour. Future work may establish the validity of training data obtained from LLMs, and explore approaches such as distillation.

In addition, we experiment with LLMs under a zero-shot setup only, while we highlight that this is the first work towards the assessment of cognitive appraisals of emotions in language models, and it lays the foundation for future research on deciphering the intrinsic emotional dynamics that remain unexplored in current state-of-the-art models. We believe that this warrants a careful construction of the dataset with thorough analysis; and we leave these interesting engineering questions to future work.

Acknowledgements

This research was partially supported by National Science Foundation (NSF) grant IIS-2107524. We thank Kathryn Kazanas and Keziah Kaylyn Reina for their dedication and hard work on the annotation of COVIDET-APPRAISALS. We also thank our reviewers for their insightful feedback and comments.

A Dataset Example and LLM Responses

In Figure 10, Figure 11, and Figure 12, we show case an annotation from COVIDET-APPRAISALS together with LLMs’ responses regarding dimension 3 *crsp* (circumstances-responsibility). In addition to LLMs evaluated in this paper (including ChatGPT, FLAN-T5-XXL, Alpaca (7B, 13B), and Dolly-V2 (7B, 12B)), we also present responses elicited from other non-instruction-tuned models such as GPT-3-davinci (a vanilla base model of GPT-3) and LLaMA (7B, 13B) (Touvron et al., 2023) using the “2-step” prompting template given in Figure 17. As the example shows, these non-instruction-tuned LLMs perform poorly on our task of cognitive emotion appraisal, generating nonsensical responses for both selecting Likert-scale ratings as well as providing natural language rationales.

B Dataset Annotation Framework

We provide the instructions given to the annotators in Figure 13. In addition, we also provide the layout for the annotation task (which includes the full questions for each of the 24 cognitive emotion appraisal dimensions abbreviated in Table 1) in Figures 14, 15, 16.

C Inter-Annotator Agreement by Dimension in COVIDET-APPRAISALS

To better understand the inter-annotator agreement pertaining to each emotion appraisal dimension in COVIDET-APPRAISALS, we measure Spearman’s ρ and Krippendorff’s alpha on each of the 21 applicable dimensions. We provide the inter-annotator agreement statistics per dimension in Figure 5. As the plot shows, the human annotators have strong agreement on dimensions such as *efc* (emotion-focused coping) and *pfc* (problem-focused coping), whilst disagreeing with each other most often on dimensions *grlv* (goal relevance), *exp* (expectedness), and *loss*. This can be attributed to the nature of our domain: in these Reddit posts, the narrator is mainly sharing their experiences in life around COVID-19, while preserving doubts about the future.

Figure 5: Inter-annotator agreement of the Likert-scale ratings within each dimension. The dimensions are ranked by the order of Spearman’s ρ , and the colors indicate the inter-annotator agreement measured by Krippendorff’s alpha using interval distance.

	AGR	DSG	FER	JOY	SDN	TRS	ANC	AVG

D Additional Dataset Analyses

D.1 Are the Dimensions Informative for Emotions?

The cognitive appraisal theories provide insights into the nature of the appraisal dimensions in distinguishing various emotions (Hofmann et al., 2020; Yeo and Ong, 2023): while different individuals may appraise the same situation distinctively, they are more likely to experience the same emotion when a consistent appraisal pattern emerges. For example, the cognitive dimension *pls* (pleasantness) is often linked to joy, but unlikely to be associated with disgust (Smith and Ellsworth, 1985). Therefore, specific emotions are hypothesized to stem from corresponding appraisal patterns (Yeo and Ong, 2023). By understanding how individuals appraise the situations they experience, we can subsequently make predictions regarding their emotional state. As a result, appraisal dimensions are valuable in differentiating emotional states, especially in cases where the emotions are highly interchangeable (e.g., *disgust* and *anger*).

Here, using the cognitive appraisal dimensions annotated in COVIDET-APPRAISALS, we further explore and validate whether these appraisal dimensions alone are indicative of perceived emotions already annotated in COVIDET. While in the ideal scenario, both the appraisal and the objective event need to be present for emotion prediction, this small experiment will allow us to gauge which dimensions are more likely discriminative for a particular emotion. For each of the 7 emo-

Table 7: Cognitive emotion appraisal dimensions that are predictive of emotions (including *anger*, *fear*, *joy*, *sadness*, and *disgust*), identified by a recent meta-analysis conducted by Yeo and Ong (2023). + indicates appraisal dimensions that are significantly positively predictive of emotions, and - indicates appraisal dimensions that are significantly negatively predictive of emotions. We highlight in red the indicative appraisal dimensions captured by our logistic regression models that are in line with Yeo and Ong (2023)’s findings. [†] signifies weights in our logistic regression models with $p < 0.1$, and ^{††} signifies significant weights with $p < 0.05$.

tion classes labeled in COVIDET, we train a logistic regression model using the scales of the annotated 21 applicable appraisal dimensions as features. We split COVIDET-APPRAISALS using a random 80:20 train-test partitioning, and aggregate the Likert-scale ratings for the 40 posts that are doubly annotated by our human annotators following the aggregation setup discussed in §3. We down-sample the training data for each logistic regression model to handle class imbalance issues. In addition, we encode the “not mentioned” (NA) labels as an independent real-valued feature, and substitute their values with 0. To prevent features of different scales or magnitudes from having a disproportionate influence on the models, we Z -normalize the scale ratings within each dimension for each annotator.

The F1 scores for each emotion using the trained logistic regression models on the test set are reported in Table 6. We observe that the models are most capable at predicting emotions such as *fear* and *sadness*, whilst performing poorly on emotions *disgust* and *trust*. This is possibly due to the domain of our dataset: in COVIDET, *fear* and *sadness* are the most commonly found emotions whereas *disgust* and *trust* are scarcely present. On average, the classifiers achieve an average F1 of 0.22 on the

test set across all emotions.

To reveal the appraisal dimensions that are indicative of each emotion, we examine the weights from the trained logistic regression models. Specifically, we aim to validate the emotion appraisal dimensions that Yeo and Ong (2023) identified to be predictive of emotions (including *anger*, *fear*, *joy*, *sadness*, and *disgust*) from prior studies in psychology. In Table 7, we show the appraisal dimensions found to be either positively predictive (+) or negatively predictive (-) of emotions. Please note that these indications are extracted from a recent meta-analysis from Yeo and Ong (2023) with significance ($p < 0.05$). In Table 7, we highlight the indicative appraisal dimensions captured by our logistic regression models that are in line with Yeo and Ong (2023)’s findings. We observe a certain degree of overlap between Yeo and Ong (2023)’s identified emotion appraisal dimensions that are predictive of emotions and those captured by our logistic regression models. It should be noted that some appraisal dimensions may not be useful for all emotions included in Table 7, since in COVIDET there are no Reddit posts annotated with neutral emotions: for example, as shown in Table 7, *crsp* (circumstances-responsibility) is found to be positively indicative for *fear* and *sadness*, while neutral

Table 8: LDA results on the annotated rationales for each appraisal dimension.

for all other emotions. However, when compared to neutral emotions (i.e., in texts where no emotions are present), *crsp* (circumstances-responsibility) may be a negative indicator for *disgust*. Therefore, experimenting with COVIDET-APPRAISALS may not reveal the extensive range of appraisal dimensions indicative of each emotion. Further investigations are needed to explore the predictability of these appraisal dimensions for emotions compared against neutral emotions.

D.2 Topic Variations in Rationales

We use Latent Dirichlet Allocation (LDA) (Blei et al., 2003) to extract topics from the natural language rationales annotated in COVIDET-APPRAISALS. Stop-words such as common English function words and words that occur frequently in our instructions (e.g., *narrator*, *situation*) are removed prior to the topic modeling. The most prominent topic extracted by the LDA model for each dimension is shown in Table 8. We notice clear patterns of topics related to the ap-

praisal dimension being assessed. For example, in dimension *crsp* (circumstances-responsibility) we observe narrators of Reddit posts worrying about and blaming Delta, a COVID-19 variant, for causing the status quo, whereas in dimension *fml* (familiarity) we note people are generally unfamiliar with the situation, as they are prone to seek advice and probe for information on the forum.

D.3 An Example of Semantic Similarity

As discussed in §4, commonly used automatic measures such as BLEU (Papineni et al., 2002), ROUGE (Lin, 2004), and BERTScore (Zhang et al., 2019) do not adequately capture semantic similarity in COVIDET-APPRAISALS. Taking the post in Figure 1 for example. Both rationales for dimension 24, namely “*The narrator mentions how people who are vaccinated and mildly sick are still experiencing long COVID symptoms. They seem surprised by the continued COVID symptoms people are experiencing and how the situation seems to evolve.*” and “*The narrator really didn’t expect*

	BLEU			ROUGE			BERTScore	
	BLEU-2	BLEU-3	BLEU-4	ROUGE-1	ROUGE-2	ROUGE-L	BERTScore	Re-scaled

ALPACA-7B	0.136	0.069	0.040	0.292	0.101	0.230	0.881	0.297
ALPACA-13B	0.007	0.004	0.003	0.019	0.005	0.017	0.842	0.066
DOLLY-7B	0.067	0.034	0.020	0.185	0.047	0.142	0.858	0.157
DOLLY-12B	0.086	0.043	0.024	0.223	0.066	0.165	0.865	0.199
FLAN-T5-XXL	0.026	0.014	0.008	0.091	0.018	0.066	0.840	0.053

Table 9: The full rationale statistics measured for LLMs’ responses against the gold annotations, measured across 5 independent runs.

	FAC	REL	JUS	USE
EVALUATORS	0.721	0.711	0.632	0.672

Table 10: Inter-annotator agreement statistics for the human evaluation task, measured using Krippendorff’s Alpha with interval distance.

this situation since they mention being able to taste freedom, believing the pandemic is ending, when suddenly they heard news that vaccinated people are still getting long covid and now they think the pandemic will never end.” convey the reasons for why the narrator fails to expect the situation to occur. However, the automatic metrics reveal low agreement between these two rationales, with a BLEU-4 score of 0.018, ROUGE-L of 0.231, and a re-scaled BERTScore of 0.237. This finding is in line with work showing the challenges of *evaluating* generation (Gehrmann et al., 2021; Celikyilmaz et al., 2020); we similarly conclude that automatic evaluation metrics may poorly reflect the correctness of a rationale for a subjective emotion appraisal dimension.

E Prompt Templates

The templates for prompting the LLMs are shown in Figure 17. We use “1-step” prompting to elicit both a rating and a rationale with a single prompt from ChatGPT. For all other language models, we apply “2-step” prompting, which first elicits the rating for the appraisal dimension, then conditioned on the response for the rating we further elicit the rationale for the selection.

F Full LLM Rationale Measures

Rationale Automatic Evaluation. We provide the full statistics of the automatic rationale agreement measured using BLEU (Papineni et al., 2002), ROUGE (Lin, 2004), and BERTScore (Zhang et al., 2019) for the *all 6 LLMs’ responses* against the

gold annotations in Table 9.

As discussed in §7.1, ChatGPT is the most performant language model in providing natural language rationales, with values from these metrics comparable to those between different rationales from our two annotators. Alpaca-7B also achieves comparable performance in these automatic measures, despite its relatively poor capability in terms of selecting Likert-scale ratings.

In addition, we observe that other language models such as FLAN-T5 and Dolly lag behind considerably compared to ChatGPT and Alpaca-7B. Enchantingly, the automatic metrics suggest that Alpaca-13B is the worst language model among our LLMs under assessment, with a markable degradation from Alpaca-7B. Further investigation reveals that Alpaca-13B tends to respond with “*Tell us why.* </s>” when prompted to generate the natural language rationale for the Likert-scale rating it selects, which takes up more than 84% of its rationale responses. The debasement of the Alpaca model in spite of the increase in the model’s scale raises questions regarding the scaling law in our current task of appraising cognitive emotion dimensions in context.

Rationale Human Evaluation. We provide the box plots of the results from the human evaluation for *the most-performant* 3 language models (i.e., ChatGPT, Alpaca-7B, and FLAN-T5) in Figure 6.

Furthermore, we also provide the results for the human evaluation regarding *all 6 LLMs* assessed in this paper. Following the setup in §7.2, we evaluate and analyze LLM-generated rationales when the model made a near-correct prediction of the Likert-scale rating for that particular dimension compared against the gold human ratings. Specifically, we sample the *intersection* of dimensions (post, dimension) tuples where *all 6 LLMs’* (i.e., ChatGPT, FLAN-T5, Alpaca-7B, Alpaca-13B, Dolly-7B, and Dolly-12B) ratings fall in the range of an abso-

	LENGTH	ABSTRACTIVENESS	AUTO EVAL			HUMAN EVAL

DOLLY-12B	73.3	55.1%	0.024	0.165	0.199	0.38	2.79	0.56	0.38

Table 11: Experiment results from LLMs. We report the average performance across five independent runs. A more comprehensive report of the automatic metrics BLEU-4, ROUGE-L, and BERTSCORE is provided in Table 9, Appendix §F.

Figure 6: Box plots of the results from the human evaluation task for *the most-performant* 3 LLMs (i.e., ChatGPT, Alpaca-7B, and FLAN-T5).

lute difference of 1 to *one* of the annotated scale-ratings. This results in 30 rationales annotated by human annotators and 26 natural language rationales from each LLM. We report the inter-evaluator agreement using Krippendorff’s Alpha with interval distance in Table 10, which shows substantial agreement (Artstein and Poesio, 2008) across all criteria.

Results from the human evaluation for *all* 6 LLMs are reported in Table 11. We observe that apart from ChatGPT and Alpaca-7B, all other LLMs including FLAN-T5, Alpaca-13B, Dolly-7B, and Dolly-12B achieve similarly low performance on providing natural language rationales for cognitive emotion appraisals. We provide the box plots of the results from the human evaluation for *all* 6 language models in Figure 7.

G Model Responses Analyses

The LLMs’ performance in terms of Likert-scale rating selections measured using Spearman correlation and Krippendorff’s alpha against the gold annotations are shown in Figure 8. Additionally,

Figure 7: Box plots of the results from the human evaluation task for *all* 6 LLMs.

the box plots for each LLM’s Likert-scale ratings are shown in Figure 9.

H Human Evaluation Framework

We provide the instructions given to the human evaluators of the rationales (described in §7.2) in Figure 18 and Figure 19. Additionally, we showcase the human evaluation task layout in Figure 20.

I Why Does ChatGPT Perform (Slightly) Better Than Human Annotators in Providing Rationales?

As discussed in §7.2, ChatGPT was scored slightly higher in terms of *factuality* and *usefulness* on providing natural language rationales than our human annotators, according to human evaluators. This can be attributed to ChatGPT’s wordiness and extractiveness (as shown in Table 4), especially in cognitive emotion appraisal dimensions where the scale rating is low. As an example, we showcase in Table 12 where both ChatGPT and our human annotator give the same rating for a dimension, but ChatGPT scores higher than our human experts on

Figure 8: LLMs’ performance in terms of Spearman correlation and Krippendorff’s alpha (using interval distance) against the gold annotations within each group of dimensions (averaged performance across 5 independent runs).

metrics *factuality* and *usefulness*.

As shown in the example, given the same Reddit post as well as the instruction to evaluate the cognitive emotion appraisal dimension *orcl* (other-controllable), both our human annotator and ChatGPT give a Likert rating of 1 indicating a small extent to which the narrator believes other people were controlling what was happening in the situation. Similarly, in their natural language rationales, both our annotator and ChatGPT express that there is no mention of other people controlling the situation in the Reddit post. However, in the post, although to a small degree, the narrator is hinting that other people are in control of the situation since their school is deciding on the mask policy for the school year. This lowers the human annotation to a mean *factuality* rating of 0.25 and a mean *usefulness* rating of 0.50. On the other hand, ChatGPT iterates and summarizes the information provided in the post, mentioning that the narrator is “seeking advice on where to find masks that are more suitable for their needs”. The provision of such information thus leads to a higher score than our annotator, resulting in a mean rating of 0.75 for both *factuality* and *usefulness*.

REDDIT POST	
I want to clarify that I am in no way shape an anti masker, I believe we do need them during the pandemic and any future outbreaks. However, the masks are a nightmare for me personally. They trigger off my migraines, I could hardly concentrate at school because of it. I also have a sensory disability, which makes wearing masks 10 times harder. Everything is brighter, louder, and everything feels more crowded when I wear them. Its horrible. And it looks like we have to wear them for the next school year, and its my final year. I cant risk it. So I want to know if any you know where I can get masks that are migraine/sensory friendly? While still doing the job a normal medical mask does. Thanks.	
APPRAISAL DIMENSION <i>orcl</i>	
To what extent did the narrator think that OTHER PEOPLE were controlling what was happening in the situation?

Reddit Post

I've recently heard of stories that people who are getting mildly sick after being vaccinated are still coming down with long covid. People on the covid long hauler subreddit are saying that we're going to have a huge problem on our hands because no vaccine protects against long covid....This isn't going to end, isn't it? Right as I think I've tasted freedom, I find out information that makes me want to stay inside forever like a hermit...

Cognitive Emotion Appraisal Dimension

Dimension 3: To what extent did the narrator think that CIRCUMSTANCES BEYOND ANYONE'S CONTROL were responsible for causing the situation? (For example, if the narrator thought that the situation was caused by luck, or by weather, or by some other things outside anyone's control.)

Example Annotations and Models' Responses

[An example from CovidET-Appraisals]

Human Annotators

- [Scale]: 8
- [Rationale]: The narrator mentions long COVID and the inability to currently protect against long COVID. This is a factor that is still outside of anyone's control, including doctors and nurses, and the situation continues to evolve in uncontrollable ways.

[Responses from LLMs evaluated in the paper]

ChatGPT

- [Scale]: 7
- [Rationale]: The narrator seems to be acknowledging that the situation is beyond anyone's control, as they mention "stories" and information that they have heard. They also express a sense of helplessness and resignation, stating that "This isn't going to end, isn't it?" and feeling like they want to "stay inside forever like a hermit." However, they do not explicitly state that circumstances are completely responsible, as they may still believe that there are some actions that can be taken to mitigate the situation.

FLAN-T5-XXL (11B)

- [Scale]: 1
- [Rationale]: 1

Alpaca (7B)

- [Scale]: 5
- [Rationale]: The narrator believes that circumstances beyond anyone's control were responsible for causing the situation to a moderate extent. They believe that luck, weather, and other external factors played a role in creating the current situation, but that it was not completely due to luck or external factors.

Alpaca (13B)

- [Scale]: 0
- [Rationale]: Tell us why.

Dolly-V2 (7B)

- [Scale]: 0
- [Rationale]: I don't know what you're talking about, but I'm going to go outside and play with my new remote-controlled helicopter.

Dolly-V2 (12B)

- [Scale]: 7
- [Rationale]: I think circumstances were completely responsible for causing the situation. The narrator believes that getting vaccinated gives you the same immunity to the long covid as a natural infection would. However, there is research to suggest that this is not the case. The narrator is also assuming that everyone who has gotten vaccinated has gotten the same ineffective vaccination as him, which is not the case. Additionally, the text suggests that the long

1

Figure 10: A comprehensive example from COVIDET-APPRAISALS for Dimension 3 (*circumstances-responsibility*) (Page 1/3).

covid is not going to end, which is also not the case. The long covid is a pandemic that is going to last for many years, not just a few months. The pandemic is going to cause a huge problem on the US population, because there is no vaccine that protects against long covid, and the long covid can cause serious health issues.

[Responses from other LLMs]

LLaMA (7B)

- **[Scale]:** I think the narrator thinks that circumstances beyond anyone's control are responsible for causing the situation. The narrator says that people who are getting mildly sick after being vaccinated are still coming down with long covid. The narrator also says that people on the covid long hauler subreddit are saying that we're going to have a huge problem on our hands because no vaccine protects against long covid. The narrator also says that this isn't going to end, isn't it? Right as I think I've tasted freedom, I find out information that makes me want to stay inside forever like a hermit.

Help Us Understand Emotion Appraisals!

- You'll read a Reddit post about someone's experiences during COVID-19.
- We ask you to judge **24 aspects** about how they feel about and view the situation. (For example, whether they felt the situation they were in was something they could control.)
- For each of these aspects, please select **a rating using the scales we provide (from 1 to 9)**. You can also select the **[NOT MENTIONED]** option in case the aspect is not mentioned in the given post.
- **In addition**, please tell us why you picked that rating!
- **Examples** are provided below.

Please read the following examples:

Reddit Post: "Just recently went grocery shopping. I also forgot to bring my receipt to the tailor, so I had to go back home after grocery shopping just to pick it up and deliver it to her to pick my trimmed down pants. And now I feel like I'm spreading COVID-19 to my parents, despite myself getting vaccinated against it. Like, I know the best I'm going to experience is mild symptoms anytime I *do* get it, plus my parents are vaccinated as well, so either they'll experience mild symptoms or no symptoms at all any time I spread it to them. But COVID-19 has the potential to mutate and thus evade our immune systems much more easily. And with that many unvaccinated people spreading it among each other for the sake of their otherwise nonexistent "freedoms", it's going to mutate and infect all of us vaccinated people and kill us all. So is there anyone who will help me with this? Thanks!"

Question: To what extent did the narrator think that THEY were responsible for causing the situation?

--> **Rating:** 6 (out of 9)

--> **Reason :** The narrator expresses concern about potentially spreading COVID-19 to their parents, even though they have been vaccinated and their parents have also been vaccinated. They seem to recognize that there is a potential for the virus to mutate and evade immunity, but also seem to feel some level of personal responsibility for this outcome. The text suggests that the narrator feels some level of guilt or responsibility for causing the situation.

ChatGPT: 1-Step Prompting	Other LLMs: 2-Step Prompting
{Reddit Post} Given the above text, to what extent did the narrator think that THEY were responsible for causing the situation? Rate on a scale from 1 to 9, with 1 being “Narrator thought they were: Not at all responsible” and 9 being “Narrator thought they were: Completely responsible”. If the text doesn't address this question, please mark it as “NA”. Additionally, tell us why. The format of the answer should be as follows: <likert>[]</likert><rationale>[]</rationale>	1st-Step: Below is an instruction that describes a task, paired with an input that provides further context. Write a response that appropriately completes the request. ### input: {Reddit Post} ### Instruction: To what extent did the narrator think that THEY were responsible for causing the situation? Rate on a scale from 1 to 9, with 1 being “Narrator thought they were: Not at all responsible” and 9 being “Narrator thought they were: Completely responsible”. If the text doesn't address this question, please mark it as “NA”. ### Response: 2nd-Step: Below is an instruction that describes a task, paired with an input that provides further context. Write a response that appropriately completes the request. ### input: {Reddit Post} ### Instruction: To what extent did the narrator think that THEY were responsible for causing the situation? Rate on a scale from 1 to 9, with 1 being “Narrator thought they were: Not at all responsible” and 9 being “Narrator thought they were: Completely responsible”. If the text doesn't address this question, please mark it as “NA”. The selected scale is {scale answer from the 1st-step}. Tell us why. ### Response:

Instructions and Examples for Evaluating Rationales for Emotion Dimensions

[Instructions]

This is an annotation task for evaluating the *rationales* for selected ratings. During the evaluation, you will first read a Reddit post. Then, you will see a pair of (question, answer) relating to the emotional state of the author of the post. The answer will first give a rating (that is verified to be correct) on a scale of 1 to 9 (including a “Not Mentioned” label is provided in case the aspect is not mentioned in the post), followed by a rationale explaining why the rating is selected. The rationale is the portion we ask you to evaluate.

The evaluation will be conducted based on 4 criteria, namely “factual consistency”, “relevance”, “justifiability”, and “usefulness”. The detailed instructions for each question are shown below.

1) Is the rationale **factually consistent** with the post?

- ★ Whether the *rationale* faithfully reflects what’s stated in the post. In other words, does the rationale accurately describe what the post is saying, or does it misrepresent or hallucinate the content in some way?
 - **“Yes”**: if the rationale is accurate with no errors
 - **“Minor Error”**: if the rationale contains some minor errors or omissions
 - **“No”**: if the rationale contains significant errors, misrepresentations, or significant hallucinations to the question

2) Is the rationale **relevant** to the aspect question being asked?

- ★ Whether the *rationale* directly addresses the specific question that is being asked about the post. This means that the rationale should be focused on the specific aspect of the post that is being evaluated, and should not stray off-topic or provide irrelevant information.

(Most Relevant) (Least Relevant)
5 4 3 2 1
○ ——— ○ ——— ○ ——— ○ ——— ○

3) Does the rationale **justify** the selected scale?

- ★ Does the *rationale* adequately explain why the selected rating scale is the most appropriate or relevant one to use for the aspect being evaluated?

Yes No
○ ——— ○

4) Is the rationale **useful (informative)**?

- ★ Whether the *rationale* provides useful or informative insights or explanations related to the aspect being evaluated. In other words, does the rationale provide helpful information or insights that can aid in evaluating the aspect question being asked?
 - **“Yes”**: if the rationale provides clear and informative explanations or insights for the reasons why the Likert-scale rating is selected
 - **“Maybe”**: if the rationale provides some information that may be useful, but is not entirely clear or may not fully address the reasons why the Likert-scale rating is selected
 - **“No”**: if the rationale does not provide any useful or informative insights or explanations for the reasons why the Likert-scale rating is selected

Figure 18: Instructions for the human evaluation described in §7.2 (Page 1/2).

[Examples]

Reddit Post:

I'm being vague as to not give away my employer but I'm frustrated and wondering how you're coping with being one of the only fields in CA that will be stuck in the past with no end date in sight. I have a lot of various traumas from this, as I'm sure many do, and being left out as the rest of my (all vaccinated, myself included) family gets to finally unmask at work is definitely not helping my mental state.

Example Rationales to Evaluate:

Dimension 20: To what extent did the narrator think that the situation was **FAMILIAR? (For example, if the narrator thought that they had experienced this situation before in the past.)**

→ [Scale]: Situation was
(Not at all familiar) (Completely familiar)
1 2 3 4 5 6 7 8 9 Not mentioned
○ — ○ — ○ — ○ — ○ — ● — ○ — ○ — ○ — ○ —

→ [Rationale]: The narrator seems to be familiar with the situation of being frustrated and traumatized due to their personal health conditions, as indicated by a rating of 6. This indicates that the narrator believes that the situation cannot be reversed and that something of value has been permanently lost.

Human Evaluation Example:

1) Is the rationale **factually consistent** with the post?

Yes Minor Error No
○ ———— ● ———— ○

2) Is the rationale **relevant** to the question being asked?

Most Relevant Least Relevant
5 4 3 2 1
○ ——— ○ ——— ● ——— ○ ——— ○

3) Does the rationale **justify** the selected scale?

Yes No
● ———— ○

4) Is the rationale **useful (informative)**?

Yes Maybe No
○ ———— ● ———— ○

Figure 19: Instructions for the human evaluation described in §7.2 (Page 2/2).

InstructionsShortcuts

Evaluate the Appraisal Rationales

See [here](#) for instructions and examples. Please read them carefully prior to evaluating!

"My mental health was never great before the pandemic but I felt more grounded. Even though pandemic-wise things are objectively much better than they were, I'm still feeling the after-effects of a year of isolation and high stress at work. I can feel a noticeable notch down in my mood just compared to last summer. I feel dead inside and doing anything requires a huge amount of energy. I feel sad all the time, I cry more. I feel sad when I see people having fun with friends and family; I don't have that. My family isn't great and I have no contact with them. I had no close friends but I lost all my distant friends during the pandemic. I have a therapist I see infrequently since I can't afford more, but I'm starting to feel like he can't help me. I've known him for quite some time so that's a sad thought, but I feel like everything he says is a repeat of something he's said before rather than tailored advice to my actual situation in the present. We all repeat ourselves to some extent. I probably need a fresh perspective, I don't know. He's told me I can call him if I get in a very bad way, so at least I have his support on that level. I don't expect any advice or solution to this. At the end of the day we're alone in our struggles, I can't expect anybody else but me to get myself out of it. But I feel like sharing it to somebody."

To what extent did the narrator think they needed to exert **EFFORT** to deal with the situation? (For example, if the narrator thought that the situation required expending a large amount of mental or physical effort to deal with the situation.) Rate on a scale from 1 to 9, with 1 being "Narrator thought that: No effort was needed" and 9 being "Narrator thought that: Very much effort was needed". If the text doesn't address this question, please mark it as 0.

→ **Selected Scale: 8**

→ **Rationale for the Scale Selected:** "The narrator mentions that doing anything requires a huge amount of energy and that they feel dead inside. They also mention feeling sad all the time and crying more. These are all indicators that the narrator feels that a significant amount of effort is needed to deal with their situation."

1) Is the rationale **factually consistent** with the post?

☐ Yes ☐ Minor Error ☐ No

2) Is the rationale **relevant** to the question being asked?

☐ 5 ☐ 4 ☐ 3 ☐ 2 ☐ 1

(Most Relevant) (Least Relevant)

3) Does the rationale **justify** the selected scale?

☐ Yes ☐ No

4) Is the rationale **useful (informative)**?

☐ Yes ☐ Maybe ☐ No
