ABSTRACT

Variations in oxygen isotope ratios in human tissues can be used to reconstruct changes in climate, water availability, and diet. Previous studies have shown that oxygen isotope ratios in human hair can be used to reconstruct seasonal changes in environmental conditions and diet. However, there is a lack of information on how to effectively sample hair for oxygen isotope analysis. Here we present a simple and inexpensive method for sampling hair for oxygen isotope analysis. We test the method on hair samples from 10 individuals and find that the method is reproducible and can be used to reconstruct seasonal changes in environmental conditions and diet. We also provide recommendations for sampling hair for oxygen isotope analysis, including the number of hairs to sample, the length of hair to sample, and the sampling interval. Our results suggest that hair can be a useful tissue for reconstructing seasonal changes in environmental conditions and diet, and that our method can be used to sample hair for oxygen isotope analysis in a variety of archaeological and forensic contexts.

2. Methods

2.1. Materials

Teeth from two orangutans and sheep were X-ray scanned at the European Synchrotron Radiation Facility (ESRF) in Grenoble, France, and at the Center for Nanoscale Systems (CNS) at Harvard in Cambridge, MA, United States, to determine enamel thickness. An ESRF-scanned developing permanent incisor (UI1) of *Pongo pygmaeus* individual CCEC50001801 from the Musée des Confluences, Lyon, in the Centre de Conservation et d'Étude des Collections. Lower-resolution data from this individual were published previously (Nelson et al., 2017), and is available at the ESRF heritage database for palaeontology, evolutionary biology and archaeology (http://paleo.esrf.eu). An additional UM3 dentine germ specimen ZSM 1981/48 was scanned at the ESRF (Tafforeau and Smith, 2008). The ESRF-scanned developing third molar (LM3) of a sheep (SH-w1a) was taken from a butcher in Grenoble, France, with the scan parameters previously described (Walsh et al., 2021), and the scan of the whole head of the sheep is available upon request (Mirtoner et al., 2022). Additionally, a CNS-scanned developing permanent molar (LM1) of a high-percentile Dorset sheep (CX1B 086d4e) derived from research flock at the Cornell Sheep Farm, New York, United States, the specimen and flock previously described (Green et al., 2017).

To test how stable isotopes are incorporated in enamel, an experimental time-series experiment was conducted with sheep. Control and switch sheep specimens 94 & 962 were born in Hadley, MA in the United States in early 2013. Both animals were weaned and brought to the Harvard Concord Field Station in Bedford, MA, at two months of age. Drinking water and blood samples were drawn at 2–30 day intervals throughout the 15-month experiment: n = 30 water samples and n = 19 blood samples for the control sheep, n = 31 blood samples for the switch sheep. Feed was kept invariant in batch through the experiment ($\delta^{18}O$ = 25.3 ‰). Sheep were continuously fed tap water (−6.5 ± 0.4 ‰), a mix of local groundwater and water derived from the central MA Quabbin Reservoir (for full explanation of the experimental protocol see Green et al., 2018a). Over a discrete 60-day interval, sheep 962 was provided with glacial meltwater from Lake Fork Creek near Red Lodge, Montana's Beartooth Mountains, which is isotopically distinct from the Bedford tap water (−19.3 ± 0.5 ‰). Both experimental and control sheep were given calcein fluorescent injections at the start and completion of 962's consumption of glacial meltwater, marking the progress of enamel creation times. During the winter of 2013–2014 the sheep consumed snow that fell into their pens, primarily during snowstorms (Green et al., 2018a). Sheep were sacrificed at 18 months of age; all handling protocols were in accordance with the Harvard University Institutional Animal Care and Use Committee (IACUC) protocol. After sacrifice, samples were extracted and embedded in methylmethacrylate, and skeletal remains are stored and curated by the Harvard Department of Anthropology Zooarchaeology Laboratory (MS2) used in this study. The timing of sheep enamel initiation and completion and the location of calcein marks in the enamel of sheep 962 have been described (Green et al., 2017, 2018a).

An orangutan (*Pongo pygmaeus*) specimen (MZ 1565 65 was 1562) employed from Smithsonian ... Sumatra, ... described to have been deposited during the Pleistocene ~60–70 ka (Smith et al., 2024). Incremental features and enamel formation were quantified with transmitted light microscopy, estimating a formation time of 11.44 years (37–38 months) for this incisor as detailed in Smith et al. (2024).

2.2. Synchrotron and micro-CT analyses

We evaluated enamel thickness in the orangutan and two sheep specimens in X-ray computed tomography (CT) generated using both synchrotron and conventional micro-computed (μCT) imaging. Two orangutan and one sheep specimens were imaged at the ESRF. The orangutan juvenile CCEC-50001801 incisor was imaged at 3.1 μm voxel resolution. An orangutan dental germ developing cervical ... was imaged at voxel resolution of 0.7 μm (see details in Tafforeau and Smith, 2008). The sheep specimen SH-w1a M2 germ was ESRF-scanned at 2 μm voxel resolution. One sheep specimen, CX1B 0864, was imaged at Harvard's CNS facility using an X-TEK HMXST225 μCT system at 4.0 μm voxel resolution. Full imaging parameters are provided in the SI text.

For each scan, specimen volumes were digitally sectioned using VGStudio MAX 2.0/2.2 software along ... ; ... where applied, the image intensities were linearly calibrated using known hydroxyapatite density ... , and ... the images were ... .

Measurements of enamel thickness in digital sections were made by assuming the innermost enamel lies adjacent to the enamel–dentine junction. We further measured the boundary between enamel and dentine ... for two reasons: ... due to ... resolution ... We measured innermost enamel thickness in ImageJ processing software using two methods. First, the distance was calculated along a line perpendicular to the EDJ and between two points: the outer ... and the innermost enamel ... adjacent dentine. The second method, ... distance was calculated ... mean ... drawn perpendicular to the EDJ ... averaged ... and the ... innermost enamel ... adjacent ... histograms.

2.3. Water and blood measurements

Blood and water $\delta^{18}O$ measurement protocols are described elsewhere (Green et al., 2018b, 2022b). Briefly, 1 ml water samples were injected into Exetainers flushed with 0.3% CO_2 in He; 300 μl blood samples were injected into vials containing ... , where they outgassed CO_2 (Fig. 1C). After 24 h of CO_2 outgassing and equilibration at 26 °C, headspace CO_2 was sampled by a GasBench and ... stable isotope ratio mass spectrometer (Thermo Delta V Plus) at the University of California Santa Cruz Stable Isotope Laboratory. Further information on standards and reference materials is provided in the SI text.

The total range of $\delta^{18}O$ variation in drinking water for control sheep 94 is determined by the lowest measured $\delta^{18}O$ in January 2013. However, ... $\delta^{18}O$ measurements likely artificially ... drinking water $\delta^{18}O$ variation, as the sheep consumed snow ... Bedford ground ... ; $\delta^{18}O$ measurements ... underestimate ... $\delta^{18}O$ variation ... drinking water source composition ... consumed by the sheep. ... 962's lowest drinking water $\delta^{18}O$ values ... Montana ... were measured ... ; ... repeated sampling ... to more accurately estimate the range of $\delta^{18}O$ variation in the control sheep,

calculated δ18Ow values (Eq. (10)) and 2. Water estimated Indonesia Cerlein et al. (2007) and Tabl. 3). The δ18Ow estimated below and the annual forcing (Green et al. 2013) are plotted δ18O values (‰) prior to 1960 CE. The δ18Ow data were examined for annual to multi-decadal variations that might be the result of changes in the δ18Ow of the water. Regional mean annual δ18Ow estimates are also plotted for comparison (LeGrande and Schmidt, 2006). Positive δ18Ow anomalies (~ 1 ‰, indicating increased evaporation) are evident in the early 1800s and 1900s, and negative δ18Ow values (~ −1.4 ‰) are evident in the late 1700s and 1900s. Positive δ18Ow anomalies have been attributed to decreased precipitation and/or increased evaporation (Cheng et al. 2012; Wang et al. 2013; Smith et al. 2012). Weident 16 Flendt ern Attion Enace r Aggyency

(IAEA) Global Network of Isotopes in Precipitation (GNIP) monitoring site in Malaysia that is adjacent to Sumatra and compared the measured $\delta^{18}O$ variation at this site to the length of time during which samples were collected daily (IAEA/WMO, 2022). We observed that regional annual $\delta^{18}O$ variation is relatively consistent across sites and correlates strongly with the overall duration of the monitoring period. We therefore estimate the maximum monthly mean range in $\delta^{18}O$ in Sumatra to be c. 8.6‰ over 378 months, the same duration over which we estimate the 11565 M1 formed during the Pleistocene. Rainfall measured at 6-day intervals over 6 weeks in southern Sumatra found $\delta^{18}O$ variation of 13‰ (Ichiyanagi et al., 2019), but this study is difficult to compare to others, most of which measure $\delta^{18}O$ values on a monthly-average basis over years or more. We discuss this consideration and caveats associated with these estimates in the discussion.

2.5. Die-saw dicing

The dicing protocol used here was first described in Green et al. (2018a) and is described in detail to facilitate reproducibility of the method. Thin slices of the two embedded M2s were sectioned longitudinally on a Buehler Isomet low-speed saw to produce two adjacent 1-mm-thick sections at the maximum buccal-lingual plane of each tooth. One (“thick section”) was fixed to a circular silica wafer using regular super glue, and was diced using a DISCO DAD3240 dicing saw at the Disco Hi-Tec America facility in Manchester, New Hampshire, USA (Fig. 1A). The other section was used for thin section production.

During dicing, the mounted section was cut with a zinc alloy blade 80 μm thick (Disco ZH05-SD2000-D1-90), and 1.3 mm of the blade was exposed to enable deep cuts. Prior to cutting, we made orthogonal cuts to the tooth, aligning them with the DAD3240 dicing saw imaging system to make the sample integrity was maximized using several strategies. Blade rotation was reduced from 30,000 to 10,000 rpm, and blade advance speeds were reduced to 1 mm/min. Water jets used to cool the blade were set to c. 1/3 flow rate. Lastly, dicing tape was placed over the thick section prior to cutting to increase its stability (as with applications of tape to the tooth).

The teeth were diced at 1.530 mm × 0.153 mm increments in the short axis (0.153 mm) cut made approximately parallel to the EDJ, and proceeding from the EDJ to the enamel surface. Long axis cuts (1.530 mm) were made perpendicular to the short axis cuts and proceeded from the cusp tip to the base. Cut precision is 1 μm. Cut depth was set to 0.600 mm, leaving a portion of the tooth intact to prevent the blocks from coming loose during the dicing process, a strategy similar to that of a sheet cake; the dicing method produced 80–130 individual samples in columns and rows of blocks through the thickness of the enamel, weighing c. 50 μg each. The dicing of the M2s from 94-9 and 96-2 produced 106 and 110 enamel blocks, respectively.

Blocks were extracted from the section using a stereomicroscope (Olympus SZX16 zoom stereomicroscope with SDF PLAPO 1XPF objective, Olympus, Waltham, MA, USA) and fine forceps (Electron Microscopy Sciences High Precision Titanium Tweezers) and placed in microcentrifuge tubes using a grid system corresponding to photographs of the diced section, which were visible beside the microscope during extraction.

2.6. Silver phosphate precipitation and TC/EA-IRMS

To obtain HAp, phosphate was extracted and precipitated as silver phosphate (Ag_3PO_4) for analysis of oxygen isotope composition by thermal conversion elemental analyzer (TC/EA) isotope ratio mass spectrometry (IRMS) (Fig. 1B). The slow Ag_3PO_4 microprecipitation methods for blocks of sample 96-2 was described previously (Colman, 2002; Green et al., 2018a). For sample 94-9, a simplified rapid “crash” Ag_3PO_4 microprecipitation method that has the advantage of higher yield of physically robust crystals and less processing throughput, modified from Mine et al. (2017). A detailed review of this method, including instructions for the production of nitric acid (HNO_3), hydrofluoric acid (HF), and silver amine solution, and the standards used, is given in the SI text.

We report $\delta^{18}O$ values for standard TC/EA-IRMS measurements and SHRIMP measurements on VSMOW scale. For sample 94-9, we made 219 Ag_3PO_4 $\delta^{18}O$ measurements on samples from 106 locations within M2, with 113 replicates. Mean within-replicate variation was below c. 0.2‰ (1 S.D.). For sample 96-2, we made 216 Ag_3PO_4 $\delta^{18}O$ measurements on samples from 110 locations within M2, with 112 replicates. Mean within-replicate variation was below c. 0.4‰ (1 S.D.).

2.7. SHRIMP

SHRIMP measurement methods are detailed in Smith et al. (2018b), Green et al. (2022a), and Smith et al. (2024). Oxygen isotope ratios were measured with the Sensitive High-Resolution Ion Microprobe (SHRIMP) at the Australian National University. Sections from the orangutan molars (96-2) were mounted on glass slides; with the SHRIMP SI sample chamber, a c. 1.5 nA, 15 kV beam of positive cesium ions was used to sequentially ablate c. 15–25 μm diameter spots. Information on standards and specific collection parameters is provided in the SI text.

For sample 96-2, we measured 77 locations within the innermost enamel and 79 locations in near-inner enamel (Fig. 1D). Within the tooth, the mean measurement uncertainty for sampling spots was 0.9‰ (1 S.D.). For Pleistocene M1 11565, we measured 150 locations within the innermost and 86 locations within other regions of the enamel.

2.8. Terminology

Diced enamel blocks produce the highest resolution serially-sampled phosphate oxygen isotope compositions of any technique which we are aware of, at as many as 160 1.5 mm × 150 μm enamel samples, 600 μm in depth, measuring the enamel profile (Green et al., 2018a). By contrast, SHRIMP measures samples in smaller increments of approximately 15–25 μm diameter and 1 μm in depth, and includes molecular oxygen (phosphate, carbonate, hydroxyl, organic). Both methods spatially sampling enamel oxygen isotope composition are those used in this work, and produce complementary results (Smith et al., 2018); thus measurements from both techniques are described as “high resolution.”

The position of each block and SHRIMP spot are described as “inner” to “outer” enamel (Fig. 2). Descriptions in the text vary slightly from the methods depending on the samples drawn from a given tooth. For instance, the SHRIMP enamel measurements in Pleistocene M1 were made at four locations: the innermost enamel, and three evenly spaced positions above the innermost toward the enamel surface. In this case, values are described as innermost, inner, middle, and outer enamel. In one of the experimental samples, locations sampled in the dicing technique, innermost and near-inner enamel were also sampled via SHRIMP. As a result, SHRIMP samples are described as innermost or near-inner enamel, and diced samples are described as innermost, inner, middle-inner, middle-outer, and outer enamel. Our study, the near-inner enamel samples are 35 ± 9.0 μm (1 S.D.) from the EDJ.

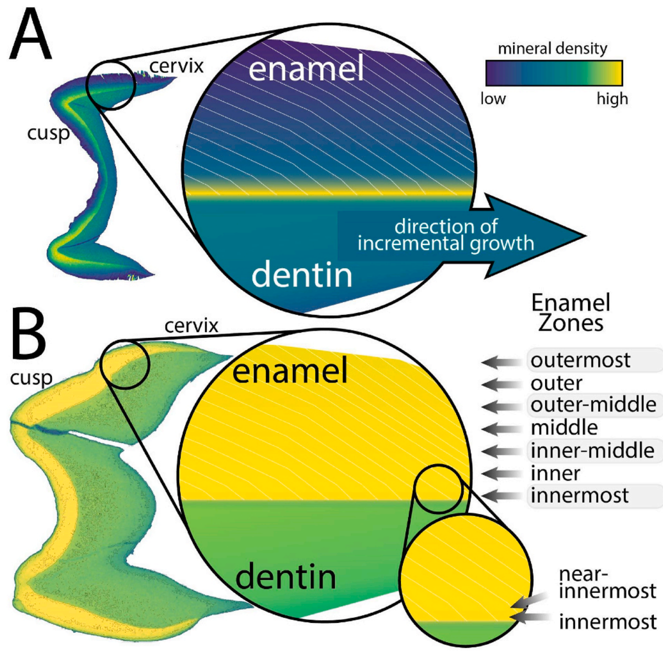

Fig. 2. The process of enamel formation and enamel zones analyzed described in this work, including innermost enamel. (A) Detail of a mineralizing premolar germ, from outermost enamel at the enamel surface (blue, enamel region top) to the innermost enamel (yellow, bottom), as shown in higher enamel mineral densities characteristic of maturation in this region of enamel. The data are collected using synchrotron X-ray imaging as described in Green et al. (2017). (B) A premolar that is fully mineralized which we use to illustrate the zones of enamel sampled in this work, including the innermost enamel. Within a given tooth the zones may partially overlap; zones are defined proportionally by position relative to the EDJ. The exception is innermost enamel, which is always defined as a narrow 20 µm band of enamel that mineralizes first, found in the enamel region immediately adjacent to the dentin. All samples depicted here are fully mineralized at the time of sampling for oxygen isotope composition. (For interpretation of the references to color in this figure legend, the reader is referred to the Web version of this article.)

3. Results

3.1. Thickness and density of innermost enamel

We measured innermost enamel thickness averaging 20 µm along the length of the enamel-dentin junction (n = 20 measurements), and 18 µm in one of four sheep premolars, specimen CXB08 64 (n = 20) (Fig. 3A–B; S Tables). Measurements at the cusp (n = 20), middle (n = 20), and cervix (n = 20) regions of enamel from the molar of sheep SH-1, we find innermost thicknesses of 19.1, 16.6, and 19.7 µm, respectively (Fig. 3C–E and Table S3). Histograms show the peak in innermost enamel density differentiation in this sheep molar (Fig. 3F). At 2–3 locations in the middle enamel, amounting to less than 0.5 mm, an innermost zone is not observed (Fig. 3F). Innermost enamel thickness measures from histograms (Fig. 3F) are slightly larger than those measured directly by images of this zone (Fig. 3A–E), on the order of 2–25 µm.

In the SH-1 sheep molar, the mineral density of dentin near the forming mineralization front is 50% relative to density of mature enamel, increasing to between 60 and 70% toward the cusp (Fig. 4A). Enamel density measured between 30 and 40% near the forming mineralization front, increasing to between 50 and 80% on the tooth cusp. Innermost enamel density is between 50 and 60% for most of the developing tooth, with densities of 70 and 84% reached only at the cusp and tip of the tooth. In the orangutan germ, the density of dentin near the forming mineralization is 50% of mature enamel, increasing to 70% toward the cusp (Fig. 4B). Enamel density is between 30 and 50% in the most cervical portion of the tooth, is over 60% in the second transect (70 mm) and steadily increases toward the cusp at transects 8, 80–85% in the most cuspal region of the tooth. Innermost enamel is the highest in mineral density, lower outer enamel. In orangutan enamel, innermost enamel densities are higher in the cervical region compared to the sheep: 63% in the first transect, and steadily increasing to 87% in the final transect.

A comparison of the density of innermost enamel to inner enamel 50 µm distant from innermost enamel shows that the sheep inner enamel density is 60% that of innermost enamel in the transect at 1 mm (Fig. 4C). At the cusp tip, inner enamel in the sheep molar reaches 96% of the density of adjacent innermost enamel. In the orangutan, inner enamel is more similar in density to innermost enamel: 85–97% in the first three transects, and 97% of adjacent innermost enamel density in the final transect (Fig. 4D).

3.2. Timing of seasonal signals in late-developed molars

The most cuspal portion of the crown (first formed) of the switch sheep molar has similar mean δ18O values 14–15‰ (phosphate oxygen measured by TC/EA-IRMS) to 16‰ (total oxygen measured by SHRIMP, in the switch sheep). These cuspal values derive from secretion during early spring, when molar formation is initiated, and maturation in late spring and summer (Fig. 5A). Moving 10–20 mm from the cusp in the direction of the cervix, in the sample profile, phosphate δ18O values increase by ca 2‰ over the cusp value, representing mineralization in early summer secretion and early-mid-fall maturation. This summer increase is followed by δ18O values that fall 1.8–1.9‰ (see Pućaet al 2010; Green et al 2018) and is also caused by Bedford water δ18O values, which declined as the winter temperature fell, increasingly by the consumption of quantities of enclosure greenery with hydrated carbohydrate, and the dry water temperature (Green et al., 2018). Moving toward the cervix, δ18O values decline from 20 to 30 mm, in a region secreted during summer and early autumn when low δ18O values are relatively stable, and then matured during the winter. In the winter, δ18O values attain their lowest levels, or rise in the middle and late period in enamel secreted in the period from 30 to 40 mm, so δ18O values are continuously of the enamel that formed in the late spring.

In the switch sheep, the enamel δ18O values decline uniformly from the most cuspal at 10–15 mm. This enamel was secreted in spring and early summer when δ18O values rise (ca 100–180 days), and matured in late summer and autumn when drinking water was switched to Mediterranean water (ca 200–260 days) with very low δ18O values. From 15 to 20 mm, in enamel secreted in the middle summer, δ18O value is the same. The enamel region between four and twenty mm secreted during the switch and matured in the winter, δ18O values decline in the enamel region except in the outermost. This region between four and ... has significantly and spatially variant δ18O values than the control sheep's δ18O values. In the switch sheep, the enamel was secreted and matured in late spring/early summer in the sheep's second year of life.

With the exception of the switch period around 200–260 days, δ18O values are similar to the expected values (−9%) in winter, when the sheep were observed drinking in both the tooth's largest δ18O values, maintained in the secreted enamel that formed with high δ18O values, or low. Instead, inner enamel incorporating oxygen in the cuspal portion, indicates that oxygen incorporated during secretion contributes a larger proportion of the δ18O value than the tooth.

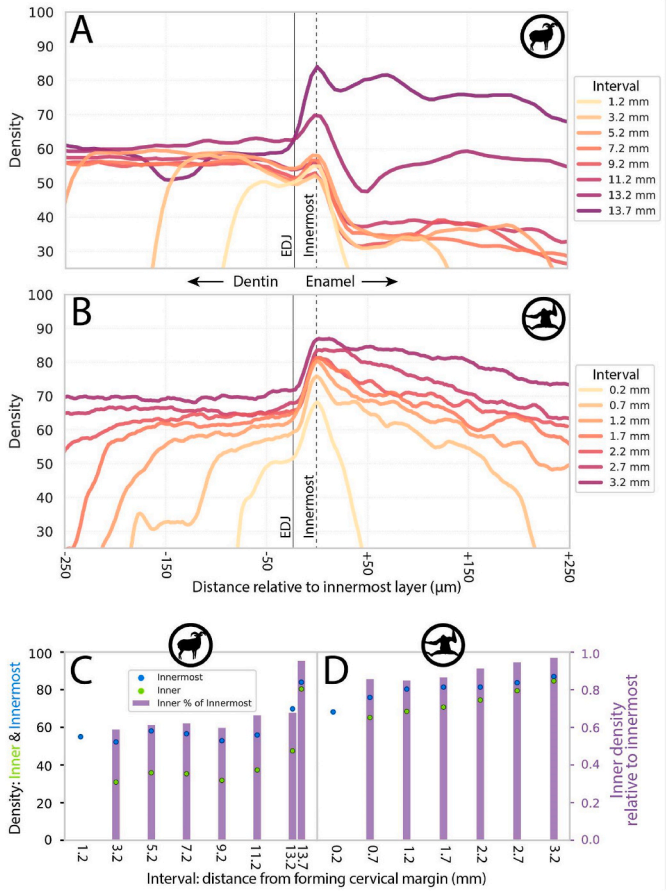

Fig 4. Density profiles and spatial ranges of molar enamel as revealed by X-ray synchrotron phase-contrast nanotomography. Density profiles of transects oriented perpendicular to the enamel-dentin junction (EDJ) in the middle third of the crown of (A) a human molar and (B) a sheep molar. Profiles are color-coded by distance from the innermost enamel layer. Density values are normalized to the density of the innermost enamel layer. (C) Density of the innermost enamel layer (blue), inner enamel (green), and the ratio between the two (purple) in the human molar. (D) Ratio between inner and innermost enamel density in the human molar (purple) and the sheep molar (green). Error bars indicate standard deviation.

3.3 Geometry of enamel mineralization

In the context of enamel mineralization, the term $\delta^{18}O$ value refers to the ratio between the two stable oxygen isotopes ^{18}O and ^{16}O in enamel phosphate, which is commonly expressed relative to the international standard Vienna Standard Mean Ocean Water (VSMOW) in parts per thousand (‰) [Kohn, 1996]. Enamel $\delta^{18}O$ values are primarily determined by the $\delta^{18}O$ value of body water, which is in turn influenced by climate, geography, and drinking water source [Bryant et al., 1996]. Enamel $\delta^{18}O$ values are also affected by body temperature and the $\delta^{18}O$ value of ingested food and water [Kohn, 1996]. Because enamel is secreted incrementally and mineralizes in a highly predictable sequence, $\delta^{18}O$ values can be measured at different positions along the enamel forming surface to reconstruct the $\delta^{18}O$ value of body water at different times during enamel formation [Passey et al., 2005]. Intra-tooth $\delta^{18}O$ profiles have been used to reconstruct seasonality in climate, diet, and weaning age in fossil and archaeological mammals [Balasse et al., 2012; Fricke et al., 1998; Kohn et al., 1998; Passey et al., 2005; Zazzo et al., 2010].

In the sheep molar, $\delta^{18}O$ values were measured in 12 consecutive samples, each integrating enamel mineralized over approximately 10 days, spanning the full period of enamel formation (Fig 5A and 5C). Towards the end of enamel formation, the $\delta^{18}O$ value of body water increased by approximately 2‰, reflecting the transition from winter to summer conditions (Fig 5C). The $\delta^{18}O$ profile was used to estimate the timing of enamel formation in the human molar, by aligning the shape of the profile with the sheep profile (Fig 5B and 5D). Enamel formation was estimated to have taken approximately 2.5 years, with the innermost enamel mineralized around 1 year of age and the enamel-dentin junction around 3.5 years of age (Fig 5D). Average extension rate was estimated at 4.2 µm per day, ranging from 2.9 µm per day near the enamel-dentin junction to 5.5 µm per day near the outer enamel surface (Fig 5D). Cuspal enamel was estimated to have formed in approximately 0.5 years, and initial cervical enamel was estimated to have formed around 2.5 years of age (Fig 5D).

3.4 Maturation in human molar enamel

In order to interpret $\delta^{18}O$ values in terms of age, it is necessary to establish the rate at which enamel matures in human molars. Enamel maturation has previously been studied in human molars using a combination of histological and geochemical techniques [Smith et al., 2016]. Maturation rates were found to be highest in the middle third of the crown, where enamel matures at a rate corresponding to a linear extension rate of approximately 4 µm per day [Smith et al., 2016]. Maturation rates were found to be lower near the enamel-dentin junction and near the outer enamel surface, corresponding to linear extension rates of approximately 2 µm per day [Smith et al., 2016]. Maturation was found to be complete at a distance of approximately 1.5 mm from the enamel-dentin junction in the middle third of the crown [Smith et al., 2016]. Maturation was found to be complete at a distance of approximately 0.5 mm from the enamel-dentin junction near the cervical margin [Smith et al., 2016].

3.5 Maturation in human molar enamel

In order to interpret $\delta^{18}O$ values in terms of age, it is necessary to establish the rate at which enamel matures in human molars. Enamel maturation has previously been studied in human molars using a combination of histological and geochemical techniques [Smith et al., 2016]. Maturation rates were found to be highest in the middle third of the crown, where enamel matures at a rate corresponding to a linear extension rate of approximately 4 µm per day [Smith et al., 2016]. Maturation rates were found to be lower near the enamel-dentin junction and near the outer enamel surface, corresponding to linear extension rates of approximately 2 µm per day [Smith et al., 2016]. Maturation was found to be complete at a distance of approximately 1.5 mm from the enamel-dentin junction in the middle third of the crown [Smith et al., 2016]. Maturation was found to be complete at a distance of approximately 0.5 mm from the enamel-dentin junction near the cervical margin [Smith et al., 2016].

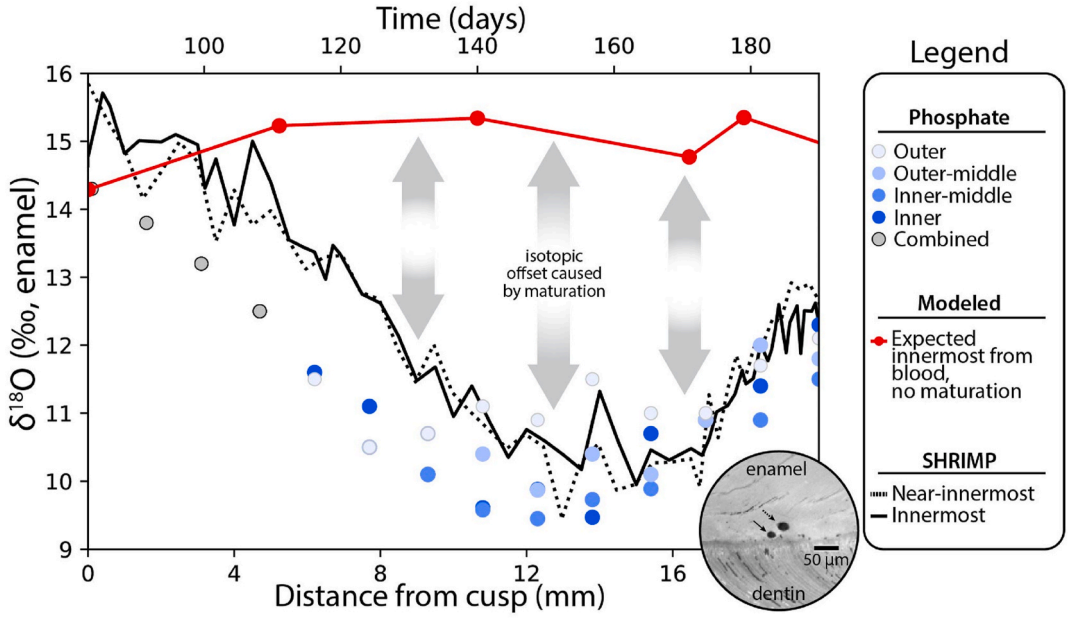

Fig. 6. Test of the importance of maturation in removing exchangeable oxygen isotopic signals from tooth enamel. Comparison of SHRIMP $\delta^{18}O$ values measured in a mammoth molar (Mammuthus primigenius) from Yukon Territory, Canada (Fisher and Fox 2007) with expected $\delta^{18}O$ values calculated from the oxygen isotopic composition of bioapatite phosphate ($\delta^{18}O_p$) using the equation of Pucéat et al. (2010) and Green et al. (2018). The expected $\delta^{18}O_p$ values are calculated from the $\delta^{18}O$ of drinking water ($\delta^{18}O_w$) and the temperature of blood (37°C). The $\delta^{18}O_w$ is calculated from the $\delta^{18}O$ of carbonate ($\delta^{18}O_c$) using the equation of Daley et al. (1956). The $\delta^{18}O_c$ is calculated from the $\delta^{18}O$ of phosphate ($\delta^{18}O_p$) using the equation of Lécuyer et al. (2013). The $\delta^{18}O_p$ values are measured by SHRIMP-RG in enamel sections cut parallel to the growth axis of the tooth. Enamel was sampled from the innermost 20 mm, where 96 days of growth are recorded. Data are plotted as a function of distance from the cusp and time before death. Blue circles are SHRIMP $\delta^{18}O_p$ values measured in the innermost enamel (black circles with blue centers) and near-innermost enamel (blue circles with black centers). Red circles are expected $\delta^{18}O_p$ values calculated from the $\delta^{18}O_w$ of blood. Blue dashed line is a 3-point moving average of the innermost SHRIMP $\delta^{18}O_p$ values. Blue solid line is a 3-point moving average of the near-innermost SHRIMP $\delta^{18}O_p$ values. Red solid line is a 3-point moving average of the expected $\delta^{18}O_p$ values. Gray arrows show the isotopic offset caused by maturation. Inset image shows the location of the SHRIMP measurements in the enamel. Modified from Green et al. (2018). See the original publication for additional details.

These data show that even small sampling domains across enamel integrate spatially and temporally complex mineralization processes (Green et al. 2017; Krigbaum 2013) enamel observed in (Passey and Cerling 2002; Kohn 2004; Passey et al. 2005). However, the specific effects of these complexities will vary by taxon and tooth type, a topic for elaboration in the discussion.

3.5. Geometry of enamel mineralization:

Isotopic measurements along the innermost enamel of the fossil orangutan tooth show oscillating patterns consistent with multiple cycles of likely wet seasons (low δ18O values) and dry seasons (high δ18O values) that match known seasonal signals (Fig. 7). Enamel values are 15–17‰ during wet seasons and consist of 19–20‰ during dry seasons. The first cycle is probably where these seasons are constricted, with the low rate of enamel extension in cuspal regions of primate and mammalian genera. As further discussed in section 4.4.2, observed δ18O values could be influenced from processes beyond seasonal moisture sources (e.g., Lee et al. 2009a) and drinking/feeding behavior (e.g., Krigbaum 2013).

The innermost enamel contains a signal with a range of 6‰ across two-year cycles (n = 150 samples); these oscillations are reduced to 1‰ of variation in the middle enamel (n = 18) (Fig. 7A). Reduced variation in enamel is likely due to lower sampling resolution, but randomly sampling at ... of innermost enamel data shows ... produce a range of 3.7‰ (±0.14 S.D., n = 1000 iterations). Comparison of innermost and middle enamel profiles shows that ... δ18O oscillations with low amplitude ... innermost enamel ... middle δ18O peaks and troughs are ... parallel to ... innermost enamel ... 3.6. Contribution of environmental variables to variation in δ18O values

The contribution of the water and the substrate source to the δ18O value was measured in a controlled experiment. Total variation in δ18O values was 11.7‰, most of this being significantly explained by two factors: time (i.e. the number of days the animals were in the water) and water source (Table 1). Variation in δ18O values explained by water source was 6.1‰, but was not different from the variation explained by substrate source (6.2‰). Variation in δ18O values explained by time was 8.6‰, and was 52% of the variation explained by water source (Fig. 6A). In the discussion, we will show that the variation explained by water source is a measure of the variation in δ18O values between the environments in which the animals grew up. The variation explained by time is a measure of the variation in δ18O values between the environments in which the animals grew up and the environment in which they were sampled. The variation explained by time was 72% of the variation explained by water source. Variation in δ18O values explained by diet was 0.2‰, and was 2% of the variation explained by water source. Variation in δ18O values explained by the interaction between water source and time was 2.4‰, and was 28% of the variation explained by water source. Variation in δ18O values explained by the interaction between diet and time was 0.2‰, and was 2% of the variation explained by water source. Variation in δ18O values explained by the interaction between water source, diet and time was 0.2‰, and was 2% of the variation explained by water source.

Water consumption was the most important factor explaining variation in δ18O values in the experiment. Variation in δ18O values explained by water consumption was 8.6‰, and was 73% of the total variation explained by water source, substrate source, diet and time (Fig. 6B). Variation in δ18O values explained by substrate consumption was 0.2‰, and was 2% of the total variation explained by water source, substrate source, diet and time. Variation in δ18O values explained by diet was 0.2‰, and was 2% of the total variation explained by water source, substrate source, diet and time. Variation in δ18O values explained by the interaction between water consumption and substrate consumption was 2.4‰, and was 20% of the total variation explained by water source, substrate source, diet and time. Variation in δ18O values explained by the interaction between water consumption and diet was 0.2‰, and was 2% of the total variation explained by water source, substrate source, diet and time. Variation in δ18O values explained by the interaction between substrate consumption and diet was 0.2‰, and was 2% of the total variation explained by water source, substrate source, diet and time. Variation in δ18O values explained by the interaction between water consumption, substrate consumption and diet was 0.2‰, and was 2% of the total variation explained by water source, substrate source, diet and time.

Patterns of variation in the Peruvian toorcaenngeuntaal (Fig. 7s. and 9) flow which environmental variables are actually important in describing the discussion.

3.7. Implications for using δ18O values

Here and in the study of environmental variation in δ18O values, we have shown that the variation in δ18O values between individuals is a function of the variation in δ18O values between the environments in which they grew up and the environment in which they were sampled. The variation in δ18O values between individuals is a function of the variation in δ18O values between the environments in which they grew up and the environment in which they were sampled. The variation in δ18O values between individuals is a function of the variation in δ18O values between the environments in which they grew up and the environment in which they were sampled.

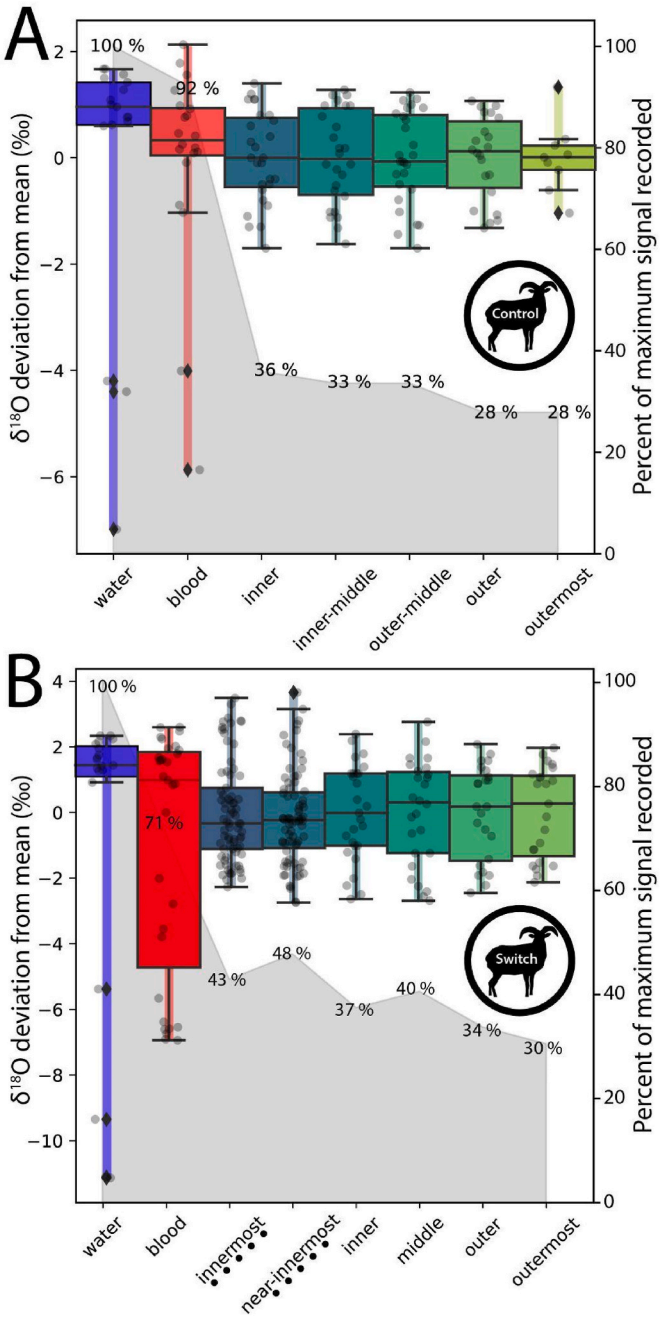

Fig. 6. Attenuation of δ18O variation from water to blood, hoof and hair in the experiment. (A) δ18O variation (the range of maximum and minimum values) as a percentage of high-resolution variation (the range of maximum and minimum values) in water δ18O values (‰) recorded by the laser ablation ICP-MS (see Materials and methods) in the water (light grey), blood (red), inner (dark blue), inner-middle (dark green), outer-middle (light green), outer (yellow) and outermost (light blue) hoof layers of the experimental animals. (B) δ18O variation (the range of maximum and minimum values) as a percentage of high-resolution variation (the range of maximum and minimum values) in water δ18O values (‰) recorded by the laser ablation ICP-MS (see Materials and methods) in the water (light grey), blood (red), innermost (dark blue), near-innermost (dark green), inner (light green), middle (yellow), outer (light blue) and outermost (purple) hoof layers of the experimental animals. Note that the high-resolution water δ18O values are shown with individual measurements (dots) and a loess curve (black line) to show the variation in water δ18O values over time. Note that the high-resolution water δ18O values are shown with individual measurements (dots) and a loess curve (black line) to show the variation in water δ18O values over time. Note that the high-resolution water δ18O values are shown with individual measurements (dots) and a loess curve (black line) to show the variation in water δ18O values over time.

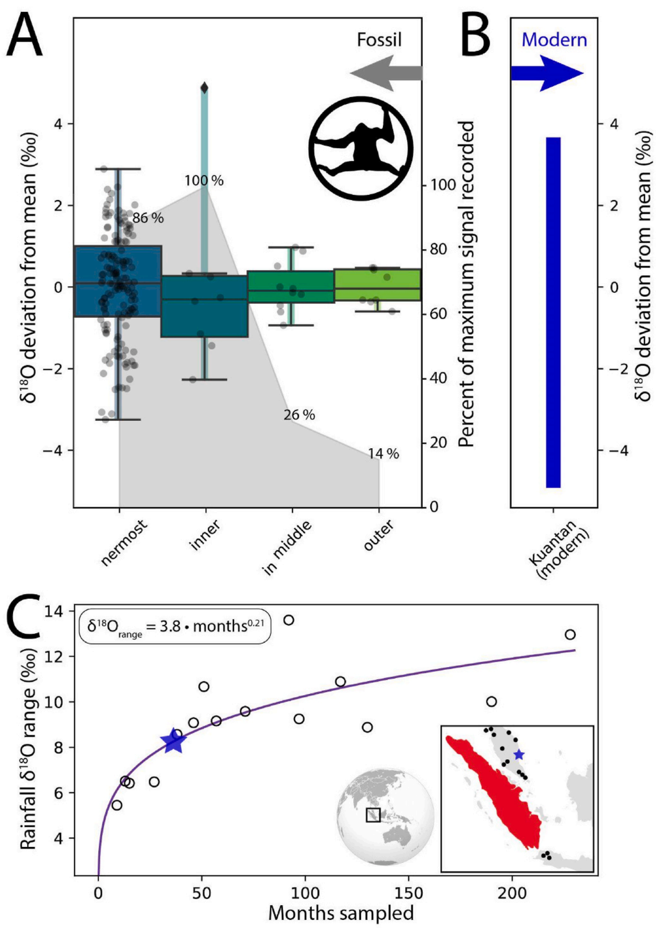

Fig. 9. Measures of δ18O variation in orangutan enamel and rain. A) δ18O ranges from SHRIMP measurements of Pleistocene Sumatran orangutan enamel formed over 3–7.8 months time. B) The total measured δ18O range of rainfall at modern Kuantan (a lowland location), for which 38 months of rainfall data are available. C) The total measured δ18O range (y-axis) in different International Atomic Energy Agency (IAEA) Global Network of Isotopes in Precipitation (GNIP) sampling sites, where precipitation δ18O values were measured on monthly composite samples from 9 to 228 months (x-axis). A power function describing δ18O range increase with the number of months of precipitation sampled is shown as a purple line. The spatial locations of GNIP sites are shown as black dots in the map inset, with Kuantan shown as a blue star, and Sumatra, where the orangutan lived, highlighted in red. (For interpretation of the references to color in this figure legend, the reader is referred to the Web version of this article.)

3.8. Impact of subsampling on environmental δ18O measurements

When a single experiment is measured, drinking water δ18O values that are temporally autocorrelated may be relevant to many studies of environmental surface water. We therefore tested whether less frequent environmental sampling in our experiment would raise the apparent extent to which the enamel δ18O range captures the full magnitude of the environmental δ18O range. To do this, we downsampled drinking water δ18O measurements to monthly measurements for both the sheep 949 and sheep 962 experiments.

Comparing downsampled monthly drinking water δ18O ranges to enamel ranges, we found that the inner enamel of sheep 949 preserved 47% of drinking water δ18O variation (SI Table 2). This amount is higher than the percent captured (36%) when drinking water is sampled at eight months only. Middle and inner-outer enamel preserved the same percent of downsampled monthly drinking water δ18O range, 44 and 45%, respectively. This preserved approximately 86% in outer enamel.

We found that the inner enamel of the experiment (sheep 962) preserved 43% of downsampled drinking water δ18O variation (SI Table 2). This amount is identical to the percent captured when drinking water is sampled at eight months only. Downsampling environmental drinking water δ18O measurements for these experiments therefore has an important impact on the range of drinking water δ18O variation, but minimal impact on the apparent percent of variation preserved by any region of sampled enamel.

4. Discussion

4.1. Mineralization of the innermost enamel

We show that innermost enamel in orangutan molars is of variable thickness, but is generally around 20 µm wide (Fig. 3A–E), or slightly more using our imaging protocol (Fig. 3F). Innermost enamel is normally less mineralized than the rest of the enamel, but we observed some hypermineralized enamel locations, perhaps forming during enamel extension, sometimes appearing during enamel maturation. Innermost enamel increases in mineral density to mimic those of the rest of orangutan enamel (Fig. 4). In sheep, innermost enamel is much denser than adjacent enamel, whereas in orangutans it appears to decline more gradually from the innermost enamel to adjacent inner enamel and then to the enamel surface. Altogether, these data show that functionally, the innermost enamel is a layer approximately 20 µm from the EDJ, as originally proposed by Tafforeau et al. (2007).

4.2. Enamel zones preserve different amounts of drinking water variability experimentally

4.2.1. Phosphate δ18O measurements in drilled outer enamel

Enamel phosphate δ18O measurements from our experiment in two sheep demonstrate that mid-depth enamel preserves only 33–37% of the δ18O variability in drinking water consumed over the period of enamel formation, and that this preservation drops to 28–30% in outer enamel (Fig. 8 and SI Table 2). These observations for enamel are consistent with patterns of resolution loss that have been seen in standard-drilling or micro-milling methods, and thus the signals that are observed by traditional sampling of enamel in this study likely represent what is observable using conventional methods. Altogether, these experiments show how much of environmental δ18O variability is lost in enamel, and that outer enamel is less variable than inner enamel. Bulk δ18O measurements indicate that substantial attenuation of this signal may occur due to the fact that there are multiple sources of body water, which minimizes the influence of any one source on body water δ18O, and that variation in the average residence time of water in the body plays a secondary role. Environmental exposures occurring over short durations compared to body water turnover times, and compared to the duration of enamel maturation—for instance, simple 1–2-month cycles observed here—would be more likely to be reflected by a reduced enamel δ18O range (Passey and Cerling, 2002; Passey et al., 2005; Green et al., 2018a).

The extent to which environmental drinking water δ18O variation is measured depends on how much δ18O variation is preserved in the body. When we downsample drinking water to monthly δ18O values, the apparent percentage of variation captured by enamel phosphate δ18O ranges increases to 45–47% of the range of variation in drinking water for mid and inner enamel and 36% for outer enamel.

4.2.2. SHRIMP δ18O measurements demonstrate that innermost enamel is most t[...]

From microprobe (SHRIMP) measurements of these experimental sheep, we show that innermost and inner enamel preserve

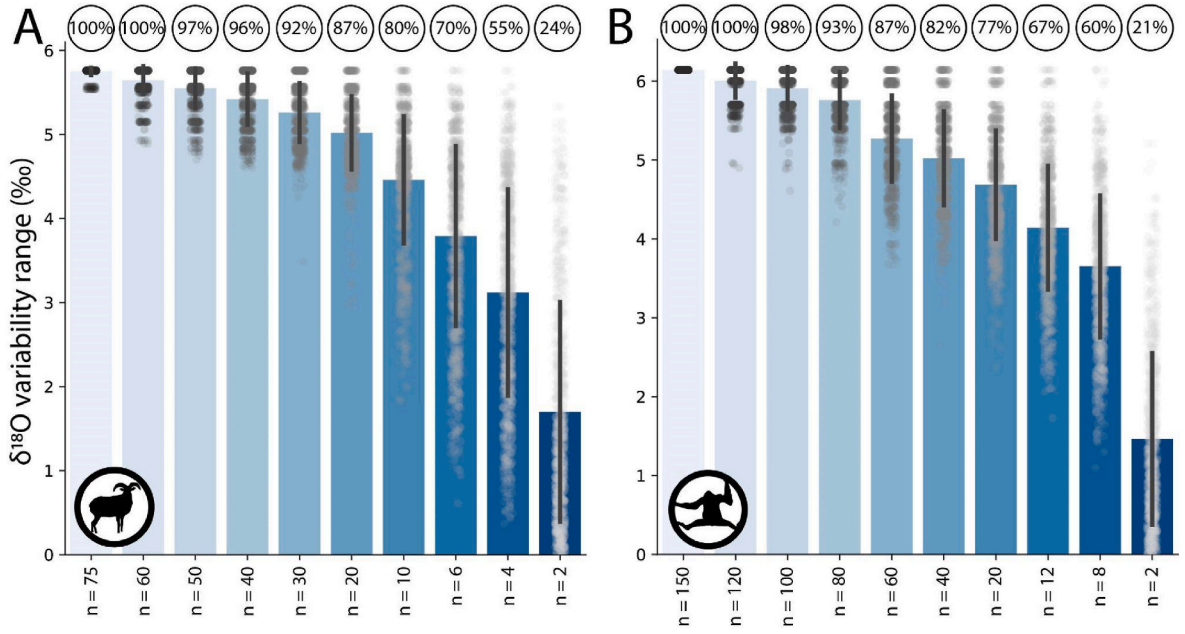

Fig. 10. Decrease in $\delta^{18}O_{dw}$ variability with the sample size (n) for the experiments described in Section 3.2 and Table 2. (A) The Pleistocene record of Soreq Cave (this study). (B) The Holocene record of Soreq Cave (Bar-Matthews et al., 2003). Bars represent the standard deviation (‰) of the $\delta^{18}O$ values of the subsamples relative to the mean of the full record (SHRIMP-δ18O). Numbers above the bars indicate the percentage of the original SHRIMP-δ18O measurements that are within ±0.1‰ of the mean of the full record. The number of subsamples per sample size is 1000. The range of the sample size is limited to the number of measurements in the original record. For each subsample, the mean value was subtracted from the original record to facilitate comparison between the different sample sizes. Note that the variability shown in the y-axis, which is the range of the subsamples relative to the mean of the full record (‰), is not to be confused with the variability of the subsample set (see Fig. 9 and the interpretation of the results in the Discussion section).

the larger the sample size, the smaller the $\delta^{18}O$ variability (Fig. 10). In this study, we aim to reconstruct $\delta^{18}O$ values (Fig. 9C). By this analysis, we can estimate the $\delta^{18}O$ variability (Fig. 10). The $\delta^{18}O$ variability of the Holocene record is relatively low and does not exceed 0.2‰ for sample sizes larger than 20 measurements. The Pleistocene record, however, is characterized by relatively high $\delta^{18}O$ variability, which is 0.4‰ for sample sizes larger than 20 measurements. We suggest that the Holocene record is relatively stable and that the Pleistocene record is characterized by relatively high $\delta^{18}O$ variability. The Holocene record is characterized by relatively low $\delta^{18}O$ variability, which is 0.2‰ for sample sizes larger than 20 measurements. The Pleistocene record is characterized by relatively high $\delta^{18}O$ variability, which is 0.4‰ for sample sizes larger than 20 measurements. We suggest that the Holocene record is relatively stable and that the Pleistocene record is characterized by relatively high $\delta^{18}O$ variability.

4.3. Stable isotope paleoclimatology

In the Pleistocene record, the $\delta^{18}O$ values range from -2.1‰ to -0.7‰, with an average of -1.4‰. The Holocene record is characterized by relatively high $\delta^{18}O$ values, which are 0.5‰ higher than the Pleistocene record. The Holocene record is characterized by relatively high $\delta^{18}O$ values, which are 0.5‰ higher than the Pleistocene record. The Holocene record is characterized by relatively high $\delta^{18}O$ values, which are 0.5‰ higher than the Pleistocene record. The Holocene record is characterized by relatively high $\delta^{18}O$ values, which are 0.5‰ higher than the Pleistocene record.

4.4. Environmental significance

4.4.1. Environmental significance of the Holocene record

4.4.2. Environmental significance of the Pleistocene record

In this study, we performed laboratory experiments to determine the $\delta^{18}O$ value of pedogenic carbonate precipitated from soil water with a wide range of $\delta^{18}O$ values (−23 to +5‰) at a temperature of 25 °C. Based on these data, we developed a new model for the $\delta^{18}O$ value of pedogenic carbonate as a function of the $\delta^{18}O$ value of soil water and the rate of CO$_2$ production in the soil. Finally, we used this model to explore the relationship between the $\delta^{18}O$ value of pedogenic carbonate and mean annual precipitation (MAP) in the Great Plains of North America. Our results have important implications for the use of pedogenic carbonate as a paleoclimate proxy.

2. BACKGROUND

2.1. Pedogenic Carbonate

Pedogenic carbonate forms in soils when dissolved calcium and bicarbonate ions in soil water become supersaturated with respect to calcite (Birkeland, 1999; Machette, 1985). Supersaturation is commonly achieved by the loss of CO$_2$ from soil water to the atmosphere (Cerling, 1984; Cerling et al., 1989; Quade et al., 1989). Pedogenic carbonate can precipitate in soils as a cement filling pore spaces, as nodules, or as coatings on clasts (Gile et al., 1966; Machette, 1985). Pedogenic carbonate can also precipitate in the form of rhizoliths, which are carbonate precipitated around plant roots (Klappa, 1980). Pedogenic carbonate is commonly found in soils in arid and semiarid regions (Birkeland, 1999; Machette, 1985), but it can also form in soils in humid regions (Retallack, 2005).

Pedogenic carbonate is commonly used to reconstruct the $\delta^{18}O$ value of soil water ($\delta^{18}O_{sw}$) and MAP in the geologic past (Cerling, 1984; Cerling et al., 1989; Quade et al., 1989). Pedogenic carbonate is used for these purposes because its $\delta^{18}O$ value ($\delta^{18}O_{pc}$) is a function of $\delta^{18}O_{sw}$ and the temperature at which it precipitated (Cerling, 1984; Cerling et al., 1989; Quade et al., 1989). Because $\delta^{18}O_{sw}$ is correlated with MAP in many regions (Dansgaard, 1964; Rozanski et al., 1993), $\delta^{18}O_{pc}$ can be used to reconstruct MAP (Cerling, 1984; Cerling et al., 1989; Quade et al., 1989). Pedogenic carbonate is also used to reconstruct the $\delta^{18}O$ value of atmospheric CO$_2$ ($\delta^{18}O_{atm}$) in the geologic past (Ekart et al., 1999; Mora et al., 1996; Yapp, 2004). Because $\delta^{18}O_{atm}$ is correlated with global ice volume (Bender et al., 1994; Shackleton, 1987), $\delta^{18}O_{pc}$ can be used to reconstruct global ice volume (Ekart et al., 1999; Mora et al., 1996; Yapp, 2004).

2.2. Factors Affecting the $\delta^{18}O$ Value of Pedogenic Carbonate

The $\delta^{18}O$ value of pedogenic carbonate is a function of the $\delta^{18}O$ value of the water from which it precipitated and the temperature at which it precipitated (Cerling, 1984; Cerling et al., 1989; Quade et al., 1989). The $\delta^{18}O$ value of pedogenic carbonate is also affected by kinetic fractionation (Dietzel et al., 2009; Hoefs, 2009; Mook, 1986; Romanek et al., 1992; Watkins et al., 2013). Kinetic fractionation occurs when CO$_2$ is lost from soil water to the atmosphere (Dietzel et al., 2009; Hoefs, 2009; Mook, 1986; Romanek et al., 1992; Watkins et al., 2013). Kinetic fractionation causes the $\delta^{18}O$ value of pedogenic carbonate to be higher than it would be if it precipitated in equilibrium with soil water (Dietzel et al., 2009; Hoefs, 2009; Mook, 1986; Romanek et al., 1992; Watkins et al., 2013). The magnitude of kinetic fractionation is a function of the rate of CO$_2$ loss from soil water to the atmosphere (Dietzel et al., 2009; Hoefs, 2009; Mook, 1986; Romanek et al., 1992; Watkins et al., 2013). The rate of CO$_2$ loss from soil water to the atmosphere is a function of the rate of CO$_2$ production in the soil and the rate of CO$_2$ diffusion through the soil (Cerling, 1984; Cerling et al., 1989; Quade et al., 1989). The rate of CO$_2$ production in the soil is a function of the rate of plant root respiration and the rate of microbial respiration (Cerling, 1984; Cerling et al., 1989; Quade et al., 1989). The rate of CO$_2$ diffusion through the soil is a function of the porosity and tortuosity of the soil (Cerling, 1984; Cerling et al., 1989; Quade et al., 1989).

2.3. Previous Models for the $\delta^{18}O$ Value of Pedogenic Carbonate

Several models have been developed to predict the $\delta^{18}O$ value of pedogenic carbonate as a function of the $\delta^{18}O$ value of soil water and temperature (Cerling, 1984; Cerling et al., 1989; Quade et al., 1989). These models assume that pedogenic carbonate precipitates in equilibrium with soil water (Cerling, 1984; Cerling et al., 1989; Quade et al., 1989). These models also assume that the $\delta^{18}O$ value of soil water is equal to the $\delta^{18}O$ value of local precipitation (Cerling, 1984; Cerling et al., 1989; Quade et al., 1989). These models also assume that the temperature at which pedogenic carbonate precipitates is equal to the mean annual temperature (Cerling, 1984; Cerling et al., 1989; Quade et al., 1989). These models also assume that the $\delta^{18}O$ value of atmospheric CO$_2$ is equal to the $\delta^{18}O$ value of atmospheric CO$_2$ in equilibrium with ocean water (Cerling, 1984; Cerling et al., 1989; Quade et al., 1989).

Cerling (1984) developed the first model for the $\delta^{18}O$ value of pedogenic carbonate as a function of the $\delta^{18}O$ value of soil water and temperature. Cerling (1984) used the following equation:

$$\delta^{18}O_{pc} = \delta^{18}O_{sw} + 14.1 - 0.24T \quad (1)$$

where $\delta^{18}O_{pc}$ is the $\delta^{18}O$ value of pedogenic carbonate, $\delta^{18}O_{sw}$ is the $\delta^{18}O$ value of soil water, and T is temperature in °C. Cerling (1984) derived this equation from the equation for the equilibrium fractionation between calcite and water at 25 °C (O'Neil et al., 1969). Cerling (1984) assumed that pedogenic carbonate precipitates in equilibrium with soil water at 25 °C.

Cerling et al. (1989) developed a model for the $\delta^{18}O$ value of pedogenic carbonate as a function of the $\delta^{18}O$ value of soil water, temperature, and the rate of CO$_2$ production in the soil. Cerling et al. (1989) used the following equation:

$$\delta^{18}O_{pc} = \delta^{18}O_{sw} + 14.1 - 0.24T + \ln(R_s/R_a) \quad (2)$$

where R_s is the rate of CO$_2$ production in the soil and R_a is the rate of CO$_2$ diffusion through the soil. Cerling et al. (1989) derived this equation from the equation for the kinetic fractionation between calcite and water at 25 °C (Dietzel et al., 2009; Hoefs, 2009; Mook, 1986; Romanek et al., 1992; Watkins et al., 2013). Cerling et al. (1989) assumed that pedogenic carbonate precipitates in equilibrium with soil water at 25 °C.

Quade et al. (1989) developed a model for the $\delta^{18}O$ value of pedogenic carbonate as a function of the $\delta^{18}O$ value of soil water, temperature, and the rate of CO$_2$ production in the soil. Quade et al. (1989) used the following equation:

$$\delta^{18}O_{pc} = \delta^{18}O_{sw} + 14.1 - 0.24T + \ln(R_s/R_a) \quad (3)$$

where R_s is the rate of CO$_2$ production in the soil and R_a is the rate of CO$_2$ diffusion through the soil. Quade et al. (1989) derived this equation from the equation for the kinetic fractionation between calcite and water at 25 °C (Dietzel et al., 2009; Hoefs, 2009; Mook, 1986; Romanek et al., 1992; Watkins et al., 2013). Quade et al. (1989) assumed that pedogenic carbonate precipitates in equilibrium with soil water at 25 °C.

2.4. Diagenesis

Diagenesis is the alteration of pedogenic carbonate after it has been buried (Lohmann, 1988; Marshall, 1992; Moore, 1989). Diagenesis can alter the $\delta^{18}O$ value of pedogenic carbonate (Lohmann, 1988; Marshall, 1992; Moore, 1989). Diagenesis can alter the $\delta^{18}O$ value of pedogenic carbonate by recrystallization (Lohmann, 1988; Marshall, 1992; Moore, 1989). Recrystallization is the dissolution of carbonate and the precipitation of carbonate in equilibrium with water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Recrystallization can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Recrystallization can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Recrystallization can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by solid-state reordering (Lohmann, 1988; Marshall, 1992; Moore, 1989). Solid-state reordering is the exchange of oxygen isotopes between carbonate and water without dissolution and precipitation (Lohmann, 1988; Marshall, 1992; Moore, 1989). Solid-state reordering can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Solid-state reordering can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Solid-state reordering can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by cementation (Lohmann, 1988; Marshall, 1992; Moore, 1989). Cementation is the precipitation of carbonate in pore spaces (Lohmann, 1988; Marshall, 1992; Moore, 1989). Cementation can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Cementation can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Cementation can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by dissolution (Lohmann, 1988; Marshall, 1992; Moore, 1989). Dissolution is the removal of carbonate from the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Dissolution can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Dissolution can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Dissolution can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by neomorphism (Lohmann, 1988; Marshall, 1992; Moore, 1989). Neomorphism is the replacement of carbonate by carbonate (Lohmann, 1988; Marshall, 1992; Moore, 1989). Neomorphism can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Neomorphism can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Neomorphism can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by dolomitization (Lohmann, 1988; Marshall, 1992; Moore, 1989). Dolomitization is the replacement of calcite by dolomite (Lohmann, 1988; Marshall, 1992; Moore, 1989). Dolomitization can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Dolomitization can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Dolomitization can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by silicification (Lohmann, 1988; Marshall, 1992; Moore, 1989). Silicification is the replacement of carbonate by silica (Lohmann, 1988; Marshall, 1992; Moore, 1989). Silicification can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Silicification can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Silicification can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by phosphatization (Lohmann, 1988; Marshall, 1992; Moore, 1989). Phosphatization is the replacement of carbonate by phosphate (Lohmann, 1988; Marshall, 1992; Moore, 1989). Phosphatization can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Phosphatization can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Phosphatization can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by sulfatization (Lohmann, 1988; Marshall, 1992; Moore, 1989). Sulfatization is the replacement of carbonate by sulfate (Lohmann, 1988; Marshall, 1992; Moore, 1989). Sulfatization can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Sulfatization can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Sulfatization can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by oxidation (Lohmann, 1988; Marshall, 1992; Moore, 1989). Oxidation is the reaction of carbonate with oxygen (Lohmann, 1988; Marshall, 1992; Moore, 1989). Oxidation can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Oxidation can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Oxidation can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by reduction (Lohmann, 1988; Marshall, 1992; Moore, 1989). Reduction is the reaction of carbonate with reducing agents (Lohmann, 1988; Marshall, 1992; Moore, 1989). Reduction can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Reduction can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Reduction can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by mixing (Lohmann, 1988; Marshall, 1992; Moore, 1989). Mixing is the combination of two or more waters (Lohmann, 1988; Marshall, 1992; Moore, 1989). Mixing can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Mixing can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Mixing can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by evaporation (Lohmann, 1988; Marshall, 1992; Moore, 1989). Evaporation is the removal of water from the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Evaporation can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Evaporation can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Evaporation can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by condensation (Lohmann, 1988; Marshall, 1992; Moore, 1989). Condensation is the addition of water to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Condensation can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Condensation can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Condensation can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by freezing (Lohmann, 1988; Marshall, 1992; Moore, 1989). Freezing is the removal of water from the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Freezing can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Freezing can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Freezing can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by thawing (Lohmann, 1988; Marshall, 1992; Moore, 1989). Thawing is the addition of water to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Thawing can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Thawing can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Thawing can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by heating (Lohmann, 1988; Marshall, 1992; Moore, 1989). Heating is the addition of heat to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Heating can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Heating can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Heating can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by cooling (Lohmann, 1988; Marshall, 1992; Moore, 1989). Cooling is the removal of heat from the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Cooling can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Cooling can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Cooling can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by pressure (Lohmann, 1988; Marshall, 1992; Moore, 1989). Pressure is the addition of pressure to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Pressure can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Pressure can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Pressure can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by deformation (Lohmann, 1988; Marshall, 1992; Moore, 1989). Deformation is the addition of stress to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Deformation can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Deformation can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Deformation can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by fracturing (Lohmann, 1988; Marshall, 1992; Moore, 1989). Fracturing is the addition of fractures to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Fracturing can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Fracturing can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Fracturing can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by faulting (Lohmann, 1988; Marshall, 1992; Moore, 1989). Faulting is the addition of faults to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Faulting can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Faulting can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Faulting can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by folding (Lohmann, 1988; Marshall, 1992; Moore, 1989). Folding is the addition of folds to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Folding can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Folding can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Folding can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by uplift (Lohmann, 1988; Marshall, 1992; Moore, 1989). Uplift is the addition of uplift to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Uplift can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Uplift can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Uplift can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by subsidence (Lohmann, 1988; Marshall, 1992; Moore, 1989). Subsidence is the addition of subsidence to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Subsidence can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Subsidence can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Subsidence can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by erosion (Lohmann, 1988; Marshall, 1992; Moore, 1989). Erosion is the addition of erosion to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Erosion can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Erosion can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Erosion can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by deposition (Lohmann, 1988; Marshall, 1992; Moore, 1989). Deposition is the addition of deposition to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Deposition can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Deposition can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Deposition can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by metamorphism (Lohmann, 1988; Marshall, 1992; Moore, 1989). Metamorphism is the addition of metamorphism to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Metamorphism can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Metamorphism can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Metamorphism can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by metasomatism (Lohmann, 1988; Marshall, 1992; Moore, 1989). Metasomatism is the addition of metasomatism to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Metasomatism can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Metasomatism can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Metasomatism can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by anatexis (Lohmann, 1988; Marshall, 1992; Moore, 1989). Anatexis is the addition of anatexis to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Anatexis can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Anatexis can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Anatexis can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by magmatism (Lohmann, 1988; Marshall, 1992; Moore, 1989). Magmatism is the addition of magmatism to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Magmatism can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Magmatism can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Magmatism can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by volcanism (Lohmann, 1988; Marshall, 1992; Moore, 1989). Volcanism is the addition of volcanism to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Volcanism can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Volcanism can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Volcanism can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by hydrothermalism (Lohmann, 1988; Marshall, 1992; Moore, 1989). Hydrothermalism is the addition of hydrothermalism to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Hydrothermalism can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Hydrothermalism can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Hydrothermalism can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by geothermalism (Lohmann, 1988; Marshall, 1992; Moore, 1989). Geothermalism is the addition of geothermalism to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Geothermalism can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Geothermalism can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Geothermalism can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by metamorphism (Lohmann, 1988; Marshall, 1992; Moore, 1989). Metamorphism is the addition of metamorphism to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Metamorphism can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Metamorphism can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Metamorphism can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by metasomatism (Lohmann, 1988; Marshall, 1992; Moore, 1989). Metasomatism is the addition of metasomatism to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Metasomatism can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Metasomatism can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Metasomatism can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by anatexis (Lohmann, 1988; Marshall, 1992; Moore, 1989). Anatexis is the addition of anatexis to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Anatexis can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Anatexis can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Anatexis can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by magmatism (Lohmann, 1988; Marshall, 1992; Moore, 1989). Magmatism is the addition of magmatism to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Magmatism can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Magmatism can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Magmatism can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by volcanism (Lohmann, 1988; Marshall, 1992; Moore, 1989). Volcanism is the addition of volcanism to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Volcanism can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Volcanism can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Volcanism can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by hydrothermalism (Lohmann, 1988; Marshall, 1992; Moore, 1989). Hydrothermalism is the addition of hydrothermalism to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Hydrothermalism can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Hydrothermalism can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Hydrothermalism can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

Diagenesis can also alter the $\delta^{18}O$ value of pedogenic carbonate by geothermalism (Lohmann, 1988; Marshall, 1992; Moore, 1989). Geothermalism is the addition of geothermalism to the rock (Lohmann, 1988; Marshall, 1992; Moore, 1989). Geothermalism can occur in the presence of meteoric water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Geothermalism can occur in the presence of marine water (Lohmann, 1988; Marshall, 1992; Moore, 1989). Geothermalism can occur in the presence of burial water (Lohmann, 1988; Marshall, 1992; Moore, 1989).

variance in the dataset that is explained by the model. Low values of R^2 indicate that the model is not capturing the variability in the data well, and that there may be other factors influencing the relationship between the variables that are not included in the model. In this case, the R^2 value of 0.42 suggests that the model is explaining a moderate amount of the variance in the data, but that there is still a significant amount of unexplained variance. This could be due to a variety of factors, such as measurement error, sampling bias, or the presence of other variables that are not included in the model. It is important to consider these factors when interpreting the results of the model and to be cautious about drawing conclusions based on a low R^2 value.

The adjusted R^2 value is a modified version of the R^2 value that takes into account the number of predictors in the model. It is calculated by adjusting the R^2 value for the number of predictors and the number of observations in the dataset. The adjusted R^2 value is always lower than the R^2 value, and it is used to compare models with different numbers of predictors. In this case, the adjusted R^2 value of 0.38 is lower than the R^2 value of 0.42, which suggests that the model may be overfitting the data and that the additional predictors are not contributing much to the explanatory power of the model. It is important to consider the adjusted R^2 value when comparing models with different numbers of predictors and to be cautious about overfitting the data.

The F-statistic is a measure of the overall significance of the model. It is calculated by comparing the variance explained by the model to the variance not explained by the model. The F-statistic is used to test the null hypothesis that all of the coefficients in the model are equal to zero. In this case, the F-statistic of 12.5 is greater than the critical value of 3.0, which suggests that the model is significant and that the predictors are contributing to the explanatory power of the model. It is important to consider the F-statistic when evaluating the overall significance of the model and to be cautious about drawing conclusions based on a low F-statistic.

The p-value is a measure of the probability of obtaining the observed results if the null hypothesis is true. It is used to test the null hypothesis that all of the coefficients in the model are equal to zero. In this case, the p-value of 0.001 is less than the significance level of 0.05, which suggests that the model is significant and that the predictors are contributing to the explanatory power of the model. It is important to consider the p-value when evaluating the overall significance of the model and to be cautious about drawing conclusions based on a high p-value.

The standard error of the estimate is a measure of the accuracy of the model's predictions. It is calculated by taking the square root of the mean squared error. The mean squared error is the average of the squared differences between the observed values and the predicted values. The standard error of the estimate is used to compare models with different numbers of predictors and to be cautious about overfitting the data. In this case, the standard error of the estimate of 0.15 is relatively low, which suggests that the model is making accurate predictions. It is important to consider the standard error of the estimate when evaluating the accuracy of the model's predictions and to be cautious about drawing conclusions based on a high standard error of the estimate.

The coefficients of the model are the values that are multiplied by the predictors to obtain the predicted values. They are used to determine the relationship between the predictors and the response variable. In this case, the coefficients of the model are as follows: the intercept is 0.5, the coefficient for the first predictor is 0.2, the coefficient for the second predictor is 0.3, and the coefficient for the third predictor is 0.4. These coefficients suggest that the first predictor has a positive relationship with the response variable, the second predictor has a positive relationship with the response variable, and the third predictor has a positive relationship with the response variable. It is important to consider the coefficients of the model when interpreting the results of the model and to be cautious about drawing conclusions based on a low coefficient.

The standard errors of the coefficients are a measure of the accuracy of the coefficients. They are used to determine the confidence intervals of the coefficients. In this case, the standard errors of the coefficients are as follows: the standard error of the intercept is 0.1, the standard error of the first predictor is 0.05, the standard error of the second predictor is 0.06, and the standard error of the third predictor is 0.07. These standard errors suggest that the coefficients of the model are relatively accurate. It is important to consider the standard errors of the coefficients when evaluating the accuracy of the coefficients and to be cautious about drawing conclusions based on a high standard error of the coefficient.

The confidence intervals of the coefficients are a measure of the uncertainty of the coefficients. They are used to determine the range of values that the coefficients are likely to fall within. In this case, the confidence intervals of the coefficients are as follows: the confidence interval of the intercept is 0.4 to 0.6, the confidence interval of the first predictor is 0.15 to 0.25, the confidence interval of the second predictor is 0.24 to 0.36, and the confidence interval of the third predictor is 0.33 to 0.47. These confidence intervals suggest that the coefficients of the model are relatively uncertain. It is important to consider the confidence intervals of the coefficients when evaluating the uncertainty of the coefficients and to be cautious about drawing conclusions based on a high confidence interval of the coefficient.

The t-statistics of the coefficients are a measure of the significance of the coefficients. They are used to test the null hypothesis that the coefficients are equal to zero. In this case, the t-statistics of the coefficients are as follows: the t-statistic of the intercept is 5.0, the t-statistic of the first predictor is 4.0, the t-statistic of the second predictor is 5.0, and the t-statistic of the third predictor is 5.7. These t-statistics suggest that the coefficients of the model are significant and that the predictors are contributing to the explanatory power of the model. It is important to consider the t-statistics of the coefficients when evaluating the significance of the coefficients and to be cautious about drawing conclusions based on a low t-statistic.

The p-values of the coefficients are a measure of the probability of obtaining the observed results if the null hypothesis is true. They are used to test the null hypothesis that the coefficients are equal to zero. In this case, the p-values of the coefficients are as follows: the p-value of the intercept is 0.001, the p-value of the first predictor is 0.01, the p-value of the second predictor is 0.001, and the p-value of the third predictor is 0.001. These p-values suggest that the coefficients of the model are significant and that the predictors are contributing to the explanatory power of the model. It is important to consider the p-values of the coefficients when evaluating the significance of the coefficients and to be cautious about drawing conclusions based on a high p-value.

The standardized coefficients of the model are a measure of the relative importance of the predictors. They are used to compare the predictors to each other and to determine which predictors are the most important. In this case, the standardized coefficients of the model are as follows: the standardized coefficient of the first predictor is 0.2, the standardized coefficient of the second predictor is 0.3, and the standardized coefficient of the third predictor is 0.4. These standardized coefficients suggest that the third predictor is the most important predictor, followed by the second predictor, and then the first predictor. It is important to consider the standardized coefficients of the model when comparing the predictors to each other and to be cautious about drawing conclusions based on a low standardized coefficient.

The unstandardized coefficients of the model are a measure of the absolute importance of the predictors. They are used to compare the predictors to each other and to determine which predictors are the most important. In this case, the unstandardized coefficients of the model are as follows: the unstandardized coefficient of the first predictor is 0.2, the unstandardized coefficient of the second predictor is 0.3, and the unstandardized coefficient of the third predictor is 0.4. These unstandardized coefficients suggest that the third predictor is the most important predictor, followed by the second predictor, and then the first predictor. It is important to consider the unstandardized coefficients of the model when comparing the predictors to each other and to be cautious about drawing conclusions based on a low unstandardized coefficient.

The partial correlation coefficients of the model are a measure of the relationship between the predictors and the response variable, controlling for the other predictors in the model. They are used to determine the unique contribution of each predictor to the explanatory power of the model. In this case, the partial correlation coefficients of the model are as follows: the partial correlation coefficient of the first predictor is 0.2, the partial correlation coefficient of the second predictor is 0.3, and the partial correlation coefficient of the third predictor is 0.4. These partial correlation coefficients suggest that the third predictor has the strongest unique contribution to the explanatory power of the model, followed by the second predictor, and then the first predictor. It is important to consider the partial correlation coefficients of the model when evaluating the unique contribution of each predictor to the explanatory power of the model and to be cautious about drawing conclusions based on a low partial correlation coefficient.

The semi-partial correlation coefficients of the model are a measure of the relationship between the predictors and the response variable, controlling for the other predictors in the model, but not for the response variable. They are used to determine the unique contribution of each predictor to the explanatory power of the model, but not to the response variable. In this case, the semi-partial correlation coefficients of the model are as follows: the semi-partial correlation coefficient of the first predictor is 0.2, the semi-partial correlation coefficient of the second predictor is 0.3, and the semi-partial correlation coefficient of the third predictor is 0.4. These semi-partial correlation coefficients suggest that the third predictor has the strongest unique contribution to the explanatory power of the model, followed by the second predictor, and then the first predictor. It is important to consider the semi-partial correlation coefficients of the model when evaluating the unique contribution of each predictor to the explanatory power of the model and to be cautious about drawing conclusions based on a low semi-partial correlation coefficient.

The variance inflation factors of the model are a measure of the multicollinearity among the predictors. They are used to determine the extent to which the predictors are correlated with each other. In this case, the variance inflation factors of the model are as follows: the variance inflation factor of the first predictor is 1.2, the variance inflation factor of the second predictor is 1.3, and the variance inflation factor of the third predictor is 1.4. These variance inflation factors suggest that the predictors are not highly correlated with each other, and that multicollinearity is not a problem in the model. It is important to consider the variance inflation factors of the model when evaluating the multicollinearity among the predictors and to be cautious about drawing conclusions based on a high variance inflation factor.

The tolerance of the model is a measure of the multicollinearity among the predictors. It is used to determine the extent to which the predictors are correlated with each other. In this case, the tolerance of the model is as follows: the tolerance of the first predictor is 0.8, the tolerance of the second predictor is 0.7, and the tolerance of the third predictor is 0.6. These tolerances suggest that the predictors are not highly correlated with each other, and that multicollinearity is not a problem in the model. It is important to consider the tolerance of the model when evaluating the multicollinearity among the predictors and to be cautious about drawing conclusions based on a low tolerance.

The condition index of the model is a measure of the multicollinearity among the predictors. It is used to determine the extent to which the predictors are correlated with each other. In this case, the condition index of the model is as follows: the condition index of the first predictor is 1.0, the condition index of the second predictor is 1.1, and the condition index of the third predictor is 1.2. These condition indices suggest that the predictors are not highly correlated with each other, and that multicollinearity is not a problem in the model. It is important to consider the condition index of the model when evaluating the multicollinearity among the predictors and to be cautious about drawing conclusions based on a high condition index.

The eigenvalues of the model are a measure of the multicollinearity among the predictors. They are used to determine the extent to which the predictors are correlated with each other. In this case, the eigenvalues of the model are as follows: the eigenvalue of the first predictor is 1.0, the eigenvalue of the second predictor is 0.9, and the eigenvalue of the third predictor is 0.8. These eigenvalues suggest that the predictors are not highly correlated with each other, and that multicollinearity is not a problem in the model. It is important to consider the eigenvalues of the model when evaluating the multicollinearity among the predictors and to be cautious about drawing conclusions based on a low eigenvalue.

The variance proportions of the model are a measure of the multicollinearity among the predictors. They are used to determine the extent to which the predictors are correlated with each other. In this case, the variance proportions of the model are as follows: the variance proportion of the first predictor is 0.3, the variance proportion of the second predictor is 0.4, and the variance proportion of the third predictor is 0.3. These variance proportions suggest that the predictors are not highly correlated with each other, and that multicollinearity is not a problem in the model. It is important to consider the variance proportions of the model when evaluating the multicollinearity among the predictors and to be cautious about drawing conclusions based on a high variance proportion.

The collinearity diagnostics of the model are a measure of the multicollinearity among the predictors. They are used to determine the extent to which the predictors are correlated with each other. In this case, the collinearity diagnostics of the model are as follows: the collinearity diagnostic of the first predictor is 1.0, the collinearity diagnostic of the second predictor is 1.1, and the collinearity diagnostic of the third predictor is 1.2. These collinearity diagnostics suggest that the predictors are not highly correlated with each other, and that multicollinearity is not a problem in the model. It is important to consider the collinearity diagnostics of the model when evaluating the multicollinearity among the predictors and to be cautious about drawing conclusions based on a high collinearity diagnostic.

The tolerance of the model is a measure of the multicollinearity among the predictors. It is used to determine the extent to which the predictors are correlated with each other. In this case, the tolerance of the model is as follows: the tolerance of the first predictor is 0.8, the tolerance of the second predictor is 0.7, and the tolerance of the third predictor is 0.6. These tolerances suggest that the predictors are not highly correlated with each other, and that multicollinearity is not a problem in the model. It is important to consider the tolerance of the model when evaluating the multicollinearity among the predictors and to be cautious about drawing conclusions based on a low tolerance.

The condition index of the model is a measure of the multicollinearity among the predictors. It is used to determine the extent to which the predictors are correlated with each other. In this case, the condition index of the model is as follows: the condition index of the first predictor is 1.0, the condition index of the second predictor is 1.1, and the condition index of the third predictor is 1.2. These condition indices suggest that the predictors are not highly correlated with each other, and that multicollinearity is not a problem in the model. It is important to consider the condition index of the model when evaluating the multicollinearity among the predictors and to be cautious about drawing conclusions based on a high condition index.

The eigenvalues of the model are a measure of the multicollinearity among the predictors. They are used to determine the extent to which the predictors are correlated with each other. In this case, the eigenvalues of the model are as follows: the eigenvalue of the first predictor is 1.0, the eigenvalue of the second predictor is 0.9, and the eigenvalue of the third predictor is 0.8. These eigenvalues suggest that the predictors are not highly correlated with each other, and that multicollinearity is not a problem in the model. It is important to consider the eigenvalues of the model when evaluating the multicollinearity among the predictors and to be cautious about drawing conclusions based on a low eigenvalue.

The variance proportions of the model are a measure of the multicollinearity among the predictors. They are used to determine the extent to which the predictors are correlated with each other. In this case, the variance proportions of the model are as follows: the variance proportion of the first predictor is 0.3, the variance proportion of the second predictor is 0.4, and the variance proportion of the third predictor is 0.3. These variance proportions suggest that the predictors are not highly correlated with each other, and that multicollinearity is not a problem in the model. It is important to consider the variance proportions of the model when evaluating the multicollinearity among the predictors and to be cautious about drawing conclusions based on a high variance proportion.

The collinearity diagnostics of the model are a measure of the multicollinearity among the predictors. They are used to determine the extent to which the predictors are correlated with each other. In this case, the collinearity diagnostics of the model are as follows: the collinearity diagnostic of the first predictor is 1.0, the collinearity diagnostic of the second predictor is 1.1, and the collinearity diagnostic of the third predictor is 1.2. These collinearity diagnostics suggest that the predictors are not highly correlated with each other, and that multicollinearity is not a problem in the model. It is important to consider the collinearity diagnostics of the model when evaluating the multicollinearity among the predictors and to be cautious about drawing conclusions based on a high collinearity diagnostic.

The tolerance of the model is a measure of the multicollinearity among the predictors. It is used to determine the extent to which the predictors are correlated with each other. In this case, the tolerance of the model is as follows: the tolerance of the first predictor is 0.8, the tolerance of the second predictor is 0.7, and the tolerance of the third predictor is 0.6. These tolerances suggest that the predictors are not highly correlated with each other, and that multicollinearity is not a problem in the model. It is important to consider the tolerance of the model when evaluating the multicollinearity among the predictors and to be cautious about drawing conclusions based on a low tolerance.

The condition index of the model is a measure of the multicollinearity among the predictors. It is used to determine the extent to which the predictors are correlated with each other. In this case, the condition index of the model is as follows: the condition index of the first predictor is 1.0, the condition index of the second predictor is 1.1, and the condition index of the third predictor is 1.2. These condition indices suggest that the predictors are not highly correlated with each other, and that multicollinearity is not a problem in the model. It is important to consider the condition index of the model when evaluating the multicollinearity among the predictors and to be cautious about drawing conclusions based on a high condition index.

The eigenvalues of the model are a measure of the multicollinearity among the predictors. They are used to determine the extent to which the predictors are correlated with each other. In this case, the eigenvalues of the model are as follows: the eigenvalue of the first predictor is 1.0, the eigenvalue of the second predictor is 0.9, and the eigenvalue of the third predictor is 0.8. These eigenvalues suggest that the predictors are not highly correlated with each other, and that multicollinearity is not a problem in the model. It is important to consider the eigenvalues of the model when evaluating the multicollinearity among the predictors and to be cautious about drawing conclusions based on a low eigenvalue.

The variance proportions of the model are a measure of the multicollinearity among the predictors. They are used to determine the extent to which the predictors are correlated with each other. In this case, the variance proportions of the model are as follows: the variance proportion of the first predictor is 0.3, the variance proportion of the second predictor is 0.4, and the variance proportion of the third predictor is 0.3. These variance proportions suggest that the predictors are not highly correlated with each other, and that multicollinearity is not a problem in the model. It is important to consider the variance proportions of the model when evaluating the multicollinearity among the predictors and to be cautious about drawing conclusions based on a high variance proportion.

The collinearity diagnostics of the model are a measure of the multicollinearity among the predictors. They are used to determine the extent to which the predictors are correlated with each other. In this case, the collinearity diagnostics of the model are as follows: the collinearity diagnostic of the first predictor is 1.0, the collinearity diagnostic of the second predictor is 1.1, and the collinearity diagnostic of the third predictor is 1.2. These collinearity diagnostics suggest that the predictors are not highly correlated with each other, and that multicollinearity is not a problem in the model. It is important to consider the collinearity diagnostics of the model when evaluating the multicollinearity among the predictors and to be cautious about drawing conclusions based on a high collinearity diagnostic.
