10 Key words: ACTH, elasmobranch, melanocyte-stimulating hormone, Mrap1, Mrap2

11

12 **ABSTRACT**

13 The hypothalamus-pituitary-adrenal/interrenal (HPA/I) axis is a conserved vertebrate
14 neuroendocrine mechanism regulating the stress response. The penultimate step of the HPA/I
15 axis is the exclusive activation of the melanocortin-2 receptor (Mc2r) by adrenocorticotropic
16 hormone (ACTH), requiring an accessory protein, Mrap1 or Mrap2. Limited data for only three
17 cartilaginous fishes support the hypothesis that Mc2r/Mrap1 function in bony vertebrates is a
18 derived trait. Further, Mc2r/Mrap1 functional properties appear to contrast among cartilaginous
19 fishes, (i.e., the holocephalans and elasmobranchs). This study sought to determine whether
20 functional properties of Mc2r/Mrap1 are conserved across elasmobranchs and in contrast to
21 holocephalans. The deduced amino acids of Pacific spiny dogfish (*Squalus suckleyi*; pd) pdMc2r,
22 pdMrap1, and pdMrap2 were obtained from a *de novo* transcriptome of the interrenal gland.
23 pdMc2r showed high primary sequence similarity with elasmobranch and holocephalan Mc2r
24 except at extracellular domains 1 and 2, and transmembrane domain 5. pdMraps showed
25 similarly high sequence similarity with holocephalan and other elasmobranch Mraps, with all
26 cartilaginous fish Mrap1 orthologs lacking an activation motif. cAMP reporter gene assays
27 demonstrated that pdMc2r requires an Mrap for activation, and can be activated by stingray (sr)
28 ACTH(1-24), srACTH(1-13)NH₂, and γ -melanocyte-stimulating hormone at physiological
29 concentrations. However, pdMc2r was three orders of magnitude more sensitive to srACTH(1-
30 24) than srACTH(1-13)NH₂. Further, pdMc2r was two orders of magnitude more sensitive to
31 srACTH(1-24) when expressed with pdMrap1 than with pdMrap2. These data suggest that
32 functional properties of pdMc2r/pdMrap1 reflect other elasmobranchs and contrast what is seen
33 in holocephalans.

34 **1. INTRODUCTION**

35 The restoration of homeostasis following a stress event through the action of
36 corticosteroids released *via* activation of the hypothalamus-pituitary-adrenal/interrenal
37 (HPA/HPI) axis is a feature common to all vertebrates (Denver, 2009). To initiate this process,
38 the hypophysiotropic factor, CRF (Deussing and Chen, 2018), activates corticotropic cells of the
39 anterior pituitary (Sower, 2015; Trudeau and Somoza, 2020), which in turn synthesize the
40 precursor protein, pro-opiomelanocortin (POMC; Nakanishi et al., 1979). Through the action of
41 Prohormone Convertase 1/3, the 39-amino acid hormone, adrenocorticotropic hormone (ACTH),
42 is excised from POMC in regulated secretory vesicles and released into the vascular system.
43 ACTH then binds to the melanocortin-2 receptor (Mc2r) on either adrenal cortex cells (amniote
44 tetrapods, Gallo-Payet and Battista, 2014) or interrenal cells (anamniote tetrapods, Davis et al.,
45 2013; bony fishes, Takahashi et al., 2013; cartilaginous fishes, Liang et al., 2013). An
46 understanding of the activation of Mc2r by cartilaginous fishes is the focus of the current study.

47 Mc2r is one of five G protein-coupled receptors in the melanocortin receptor gene family
48 (Cone, 2006). There are several pharmacological features that unify bony vertebrate Mc2r
49 orthologs. For these vertebrates, Mc2r requires co-expression with the accessory protein, Mrap1
50 (Metherell et al., 2005; Sebag and Hinkle, 2009, 2007) for trafficking to the plasma membrane
51 and activation following an ACTH binding event (Dores et al., 2022). In addition, bony
52 vertebrate Mc2r orthologs can only be activated by ACTH, but not by any of the melanocyte-
53 stimulating hormone-sized ligands derived from POMC (i.e., α MSH, β MSH, γ MSH; Dores and
54 Chapa, 2021). The latter observation was initially surprising given that all melanocortin-related
55 peptides (e.g., ACTH, α MSH, β MSH, γ MSH) have the HFRW “message” motif (Schwyzer,
56 1977) that is required for the activation of all melanocortin receptors (Cone, 2006). However,

57 ACTH also has the K/RKRR “address” motif (Schwyzer, 1977), which is a requirement for the
58 activation of all bony vertebrate Mc2r orthologs that have been studied (Dores et al., 2022; Dores
59 and Chapa, 2021; Shaughnessy et al., 2022). Finally, the accessory protein, Mrap2 (Chan et al.,
60 2009), the paralog of Mrap1, can facilitate the trafficking of, for example human (h) MC2R, to
61 the plasma membrane. However, this accessory protein cannot facilitate the activation of hMC2R
62 by ACTH when the receptor and accessory protein are co-expressed in mammalian cell lines
63 (Chan et al., 2009; Sebag and Hinkle, 2009; Webb and Clark, 2010).

64 Some of the pharmacological properties observed for bony vertebrate Mc2r orthologs are
65 apparent for cartilaginous fish Mc2r orthologs; however, there are some striking differences.
66 Current studies on cartilaginous fish Mc2r orthologs have investigated the pharmacological
67 properties for one species from subclass Holocephali, the elephant shark, *Callorhinchus milii*
68 (Barney et al., 2019; Reinick et al., 2012), and two species from subclass Elasmobranchii, the
69 stingray *Hemitrygon akajei* (Dores et al., 2018; Hoglin et al., 2020a, 2020b; Takahashi et al.,
70 2016), and the whale shark, *Rhincodon typus* (Hoglin et al., 2020b). All cartilaginous fish Mc2r
71 orthologs that have been studied can be activated by ACTH, but these orthologs can also be
72 activated at physiological concentrations by the non-acetylated analog of α MSH (i.e., ACTH(1-
73 13)NH₂; Dores and Chapa, 2021; Hoglin et al., 2020b). In addition, the elephant shark (es) Mc2r
74 ortholog does not require co-expression with either esMrap1 or esMrap2 to facilitate trafficking
75 to the plasma membrane. Hence, the activation of esMc2r is a Mrap-independent process
76 (Barney et al., 2019). By contrast, the two elasmobranch Mc2r orthologs are dependent on co-
77 expression with an Mrap1 ortholog for trafficking to the plasma membrane (Hoglin et al.,
78 2020b), and the trafficking of whale shark (ws) Mc2r is facilitated by either co-expression with
79 wsMrap1 or wsMrap2. Furthermore, once the elasmobranch Mc2r orthologs reach the plasma

80 membrane it does not appear that interaction with Mrap1 influences the sensitivity of the
81 receptor to stimulation by ACTH (Hoglin et al., 2023).

82 Clearly cartilaginous fish Mc2r orthologs differ from bony vertebrate Mc2r orthologs in
83 terms of ligand selectivity and the role that Mrap1 and Mrap2 play in the activation of the
84 ortholog. In addition, among the cartilaginous fishes, there are apparent differences in the role
85 that the Mraps play with respect to the interaction with Mc2r. The current studies on
86 elasmobranch Mc2r orthologs have focused on one species of stingray (*H. akajei*) from
87 Superorder Batoidea, and one species of Galean shark (*R. typus*) from Superorder Selachii. The
88 objectives of this study were to evaluate the pharmacological properties of the Mc2r ortholog
89 from a Squalomorph shark, *Squalus suckleyi*, the Pacific spiny dogfish (pd). To this end, the
90 deduced amino acid sequences of pdMc2r, pdMrap1, and pdMrap2 were obtained from a
91 transcriptome made from the interrenal gland of *S. suckleyi*. In a series of pharmacological
92 studies, *pdmc2r* cDNA was transiently expressed in Chinese hamster ovary cells and a cAMP
93 reporter gene assay was used to test whether: a) pdMc2r can be activated by ACTH in the
94 absence of a Mrap; b) pdMc2r activation by ACTH requires pdMrap1, and the receptor can be
95 activated with equal efficacy with pdMrap2; and c) pdMc2r can be activated by cartilaginous fish
96 MSH-sized ligands with efficacy equal to stimulation with ACTH. Collectively, these analyses
97 will clarify the role that the Mrap accessory proteins play in the activation of elasmobranch Mc2r
98 orthologs.

99 **2. MATERIALS AND METHODS**

100 **2.1. Ethical approval**

101 Dogfish were collected under Fisheries and Oceans Canada permit XR-139 2021. All
102 experimental procedures were approved by the Bamfield Marine Sciences Centre (BMSC)
103 animal care committee and conducted as described in animal user protocol RS-21-03.

104 2.2. Animal collection and husbandry

105 Adult male dogfish (n = 4) were captured using rod-and-reel in Barkley Sound (British
106 Columbia, Canada) during June and July 2021. Dogfish were transported to BMSC where they
107 were maintained in a 155,000 L tank. The holding tank was continuously supplied with seawater
108 (12 °C, 32 ppt) and dogfish were fed cut hake (*Merluccius merluccius*) every second day, ad
109 libitum. Prior to tissue sampling, sharks were euthanized by emersion in an overdose of tricaine
110 methanesulfonate (MS-222; > 0.2 g L-1; Syndel Labs, Vancouver, BC, Canada) followed by
111 cervical dislocation.

112 2.3. Interrenal gland reference transcriptome

113 Interrenal glands were dissected from dogfish and stored in RNAlater at -20 °C. Total
114 RNA was extracted using an Invitrogen PureLink RNA Mini Kit (Invitrogen, CA, USA) and
115 resuspended in MilliQ water. Purity of total RNA was determined using a NanoDrop One
116 (Invitrogen, CA, USA) and integrity was determined visually *via* gel electrophoresis on a 1%
117 agarose 1x TAE gel stained with ethidium bromide. Total RNA (250 ng per dogfish) was
118 submitted to the Centre d'Expertise et de Services Génome Québec for next-generation
119 sequencing on an Illumina NovaSeq 6000 (paired-end 100 base pair reads). RNA integrity
120 numbers (RIN) for all samples were 9.2 ± 0.4 (mean \pm standard deviation), where a minimum
121 acceptable RIN for sequencing is 6.5. mRNA stranded libraries were created with New England
122 Biolabs NEBNext Dual adapters. On average, $85 \text{ million} \pm 3 \text{ million}$ reads were sequenced.

123 Transcriptome assembly and annotation was conducted following Thorstensen et al.,
124 (2022). Quality control for raw reads was undertaken using FastQC version 0.11.9
125 (<https://www.bioinformatics.babraham.ac.uk/projects/fastqc/>). Raw reads were then trimmed
126 using Trimmomatic version 0.39 (Bolger et al., 2014), where reads under 36 base pairs were
127 removed, leading and trailing base pairs with Phred scores under five were removed, and
128 consecutive sets of four base pairs with mean quality scores under five were removed. The
129 quality of the trimmed reads was then checked with FastQC. Next, trimmed reads from all four
130 dogfish were assembled into a single reference transcriptome using Trinity version 2.12.0, using
131 default parameters (Grabherr et al., 2011). Completeness of the transcriptome was quantified
132 using BUSCO version 5.2.2 (Simão et al., 2015) against the vertebrate lineage
133 (vertebrata_odb10). Transcriptome annotation as undertaken following the Trinotate pipeline
134 (Bryant et al., 2017). Briefly, TransDecoder version 5.5.0 was used to detect the longest open
135 reading frames for transcripts (<https://github.com/TransDecoder/TransDecoder/wiki>). Next
136 blast+ version 2.12.0 was used to run the National Center for Biotechnology Information's
137 (NCBI) Basic Local Alignment Search Tool (BLAST) on transcripts and predicted peptides
138 (Altschul et al., 1990). HMMER version 3.2.1 was run to identify protein families from predicted
139 peptide sequences (Wheeler and Eddy, 2013). SignalP version 4.1f was run to identify signal
140 proteins (Petersen et al., 2011). TMHMM version 2.0c was run to identify transmembrane
141 helices of predicted peptides (Krogh et al., 2001). Finally, Trinotate version 3.2.2 was used to
142 compile the resultant databases into a single annotation report, reporting only transcripts with E
143 values below 0.001. The assembled and annotated interrenal gland transcriptome contained
144 485,425 unique transcripts representing 258,538 genes. The BUSCO completeness score was
145 94.6 %.

146 2.4. Mc2r, Mrap1, and Mrap2 sequences

147 Transcripts containing complete cDNA sequences for *pdmc2r*, *pdmrap1*, and *pdmrap2*
148 were located in the interrenal gland reference transcriptome. The nucleotide sequence for each
149 cDNA is presented in Supplementary Figure 1. Amino acid sequences for pdMc2r, pdMrap1, and
150 pdMrap2 were determined using the ExPASy translate tool (<https://www.expasy.org/translate/>).
151 The deduced amino acid sequences appear in Supplementary Figure 1.

152 The *pdmc2r*, *pdmrap1*, and *pdmrap2* cDNAs, and *wsmrap1* and bowfin (*Amia calva*; bf)
153 *bfrmrap1* (Shaughnessy et al., 2022) cDNAs used in the cAMP reporter gene assay were
154 synthesized by GenScript (Piscataway, NJ). Each cDNA sequence was individually inserted into
155 a pcDNA3+ expression vector. The cAMP reporter gene construct CRE-Luciferase was provided
156 by Dr. Patricia Hinkle (University of Rochester, NY).

157 2.5. Melanocortin peptides

158 For the cAMP reporter gene assays, transfected cells were either stimulated with red
159 stingray (sr) ACTH(1-24), ACTH(1-13)NH₂ (Des-acetyl α -MSH), β -MSH, γ -MSH, or δ -MSH,
160 provided by Prof. A. Takahashi (Kitasato University, Japan). The melanocortin peptides were
161 used at concentrations from 10⁻¹³ M to 10⁻⁶ M. A comparison of the deduced amino acid
162 sequences for the stingray melanocortin peptides and dogfish melanocortin peptides is presented
163 in Supplementary Figure 2.

164 2.6. cAMP reporter gene assay

165 The cAMP reporter gene assay was conducted using Chinese hamster ovary (CHO) cells
166 (ATCC, Manassas, VA) grown in Kaighn's Modification of Ham's F12K media (ATCC) and
167 supplemented with 10% fetal bovine serum, 100 U mL⁻¹ penicillin, 100 μ g mL⁻¹ streptomycin,
168 100 μ g mL⁻¹ normocin. The CHO cells were maintained in a humidified incubator with 95% air

169 and 5% CO₂ at 37°C. This cell line was selected because CHO cells do not express endogenous
170 melanocortin receptor genes (Noon et al., 2002; Sebag and Hinkle, 2007), or endogenous
171 melanocortin receptor accessory protein genes (Reinick et al., 2012).

172 For the cAMP reporter gene assay, *pdmc2r* cDNA (10 nmol transfection⁻¹) was either
173 expressed alone, or with *mrap* cDNA (30 nmol transfection⁻¹), and the *cre-luc* cDNA (83 nmol
174 transfection⁻¹; cAMP CRE-Luciferase construct; Chepurny and Holz, 2007) in 3.0 × 10⁶ CHO
175 cells as described previously (Liang et al., 2011). The transient transfections were done using the
176 Amaxa Cell Line Nucleofector II system (Lonza, Basel, Switzerland) using program U-23, and
177 the transfection solution was Solution T (Lonza, Basel, Switzerland). The transfected cells were
178 plated in a white 96-well plate (Costar 3917, Corning In., Kennebunk, ME) at a final density of
179 1.0 × 10⁵ cells well⁻¹. After 48 hours, the transfected cells were stimulated with various
180 concentrations (10⁻¹³ M to 10⁻⁶ M) of the stingray melanocortin peptides in serum-free CHO
181 media. The stimulated cells were incubated for 4 h at 37°C. Following the incubation period, the
182 stimulating media was removed, and 100 µl of luciferase substrate reagent (Bright GLO;
183 Promega, Madison, WI) was aliquoted into each well. After a 5 min incubation period at room
184 temperature, the luminescence from each well was immediately measured using a Bio-Tek
185 Synergy HT plate reader (Winooski, VT). To determine the background levels of cAMP
186 production, transfected CHO cells were stimulated with serum-free CHO media containing no
187 melanocortin peptide for the 4 h incubation period, and the average background luminescence
188 reading for each assay was subtracted from the luminescence readings of ligand-stimulated
189 assays. All assays were performed in triplicate.

190 2.7. Statistical analyses

191 Dose response curves for each assay were fitted to the Michaelis-Menton equation to
192 obtain half-maximal effective concentration (EC_{50}) and maximal response (V_{max}) values.
193 Statistical analysis of the EC_{50} and V_{max} values for the dose response curves were performed
194 using the extra-sum-of-squares F -test (Shaughnessy et al., 2022) in Prism 6 software (GraphPad
195 Inc, La Jolla, CA, USA). Significance was set at $p < 0.05$. Unless otherwise noted, all data are
196 presented as mean \pm standard error of the mean with $n = 3$. Graphs were prepared in Prism.

197 **3. RESULTS**

198 **3.1. Pacific spiny dogfish Mc2r**

199 The deduced amino acid sequence of pdMc2r was aligned with esMc2r, srMc2r, and
200 wsMc2r (Figure 1). While the N-terminal and C-terminal domains were variable in length it was
201 possible to align the transmembrane domains and intracellular and extracellular domains by
202 inserting a minimum number of gaps. The primary sequence identity for the four cartilaginous
203 fish Mc2r orthologs was 36%. When both primary sequence identity (i.e., all residues the same at
204 a given position) and primary sequence similarity (Stephenson and Freeland, 2013) were
205 evaluated the percentage was 58%. When the analysis of primary sequence identity/similarity
206 was done for just the elasmobranch Mc2r orthologs, the percentage was 63%. A comparison of
207 the primary sequence identity/similarity for the various transmembrane domains (TM),
208 intracellular domains (IC), and extracellular domains (EC) for the four cartilaginous fish Mc2r
209 orthologs is presented in Figure 1. The various domains are rather well conserved (65% primary
210 sequence identity/similarity or better) apart from EC1, EC2, and TM5 where the percent primary
211 sequence identity was 33%, 0%, and 54%, respectively. When the comparison for these domains
212 was limited to the elasmobranch sequences, the percent primary sequence identity was 50%,
213 25%, and 88%, respectively.

214 3.2. Pacific dogfish Mrap1 and Mrap2

215 The deduced amino acid sequence of pdMrap1 was aligned with the deduced amino acid
216 sequences of esMrap1 and wsMrap1 (Figure 2). The primary sequence identity/similarity of the
217 N-terminal domains of the three Mrap1 orthologs was 60%. The primary sequence
218 identity/similarity of the transmembrane domain of the three orthologs was 63%. Currently, only
219 a partial sequence of esMrap1 has been identified in the elephant shark genome; however, the
220 primary sequence identity of the C-terminal domain of the two elasmobranch Mrap1 was 47%.

221 The deduced amino acid sequences of pdMrap2, esMrap2, and wsMrap2 are also
222 presented in Figure 2. The N-terminal domains of the Mrap2 orthologs were aligned to the
223 Mrap1 orthologs by first aligning the N-linked glycosylation site in each Mrap paralog and the
224 conserved YEYY motif in each paralog, and the inserting gaps where it was appropriate. Using
225 this approach, the remainder of the Mrap2 sequences (i.e., transmembrane domain and C-
226 terminal domain) aligned with a minimum number of gaps inserted. Focusing on just the Mrap2
227 orthologs, the primary sequence identity/similarity of the N-terminal domain was 50%, whereas
228 the primary sequence identity/similarity of the transmembrane domain and the C-terminal
229 domain were 96% and 65%, respectively.

230 3.3. Pharmacological properties of pdMc2r

231 To determine whether pdMc2r is also an Mrap-independent Mc2r ortholog, pdMc2r was
232 expressed alone in CHO cells and stimulated with srACTH(1-24). As shown in Figure 3A,
233 pdMc2r was not activated at any of the concentrations of srACTH(1-24) tested. However, when
234 pdMc2r was co-expressed with either pdMrap1 or pdMrap2 activation was achieved at
235 physiologically relevant concentrations of the ligand (Figure 3A). While both dose response
236 curves reached saturation with similar V_{max} values (Figure 3A), pdMc2r was nearly two orders of
237 magnitude more sensitive to stimulation by srACTH(1-24) when co-expressed with pdMrap1 as

238 compared to when the receptor was co-expressed with pdMrap2 (Table 1). This difference in
239 ligand sensitivity (i.e., EC₅₀) was statistically significant ($p < 0.001$; Table 1).

240 To evaluate whether pdMc2r could be activated by the non-acetylated form of α MSH, the
241 receptor was co-expressed with either pdMrap1 or pdMrap2, and stimulated with srACTH(1-
242 13)NH₂. As shown in Figure 3B, pdMc2r could be activated by srACTH(1-13)NH₂ when co-
243 expressed with either Mrap paralog, and sensitivity to the ligand was enhanced nearly 10-fold
244 when the receptor was co-expressed with pdMrap1 and compared to pdMrap2 (Table 1).

245 Furthermore, co-expressing pdMc2r with pdMrap1 yielded a higher V_{max} relative to co-
246 expression with pdMrap2 (Table 1). However, pdMc2r co-expressed with pdMrap1 was nearly
247 three orders of magnitude more sensitive to stimulation by srACTH(1-24) as compared to
248 srACTH(1-13)NH₂ (Table 1), and this difference in ligand sensitivity was statistically significant
249 ($p < 0.001$).

250 Because pdMc2r could be stimulated with srACTH(1-13)NH₂, the selectivity for other
251 MSH-related peptides was evaluated. As shown in Figure 3C, pdMc2r could be activated by γ -
252 MSH, but the efficacy of this ligand was more than 10-fold lower than stimulation of the
253 receptor with srACTH(1-13)NH₂; however, V_{max} values did not differ between these ligands
254 (Table 1). The receptor only showed a weak response to β -MSH at a concentration of 10⁻⁶ M, and
255 the receptor did not respond to stimulation by δ -MSH (Figure 3C).

256 To better understand the interaction between pdMc2r and pdMrap1 (i.e., trafficking only
257 or trafficking and activation), pdMc2r was separately co-expressed with another elasmobranch
258 Mrap1 ortholog (wsMrap1), or a bony vertebrate Mrap1 ortholog (bfMrap1). Co-expression of
259 pdMc2r with pdMrap1 served as the positive control. The rationale for this experiment was that
260 because Mrap1 orthologs have high primary sequence identity in their transmembrane domain,

261 and this domain facilitates trafficking of the receptor, then if the only role for Mrap1 is
262 trafficking, the dose response curves should overlap (i.e., similar EC₅₀ values). As shown in
263 Figure 3D, the dose response curves for the receptor co-expressed with either pdMrap1 or
264 wsMrap1 had similar EC₅₀ values that were not statistically different, but with significantly
265 different V_{max} (Table 1). However, when the receptor was co-expressed with bfMrap1, there was
266 a decrease in ligand sensitivity of over two orders of magnitude, but an equivalent V_{max} (Table
267 1).

268 **4. DISCUSSION**

269 This study sought to characterize the pharmacological properties of the Mc2r ortholog of
270 the Squalomorph shark, *S. suckleyi*, and the interactions of pdMc2r with its cognate Mrap
271 paralogs, pdMrap1 and pdMrap2. With this study, representatives of all three major taxonomic
272 groups of elasmobranchs (i.e., Squalomorphii, Galeomorphii, and Batoidea), have been analyzed
273 and the pharmacological properties of elasmobranch Mc2r orthologs are strikingly similar from a
274 functional perspective (Figure 4). In the case of the Pacific spiny dogfish, activation of pdMc2r
275 expressed in CHO cells was only observed at physiologically relevant concentrations of
276 srACTH(1-24) when the receptor was co-expressed with either pdMrap1 or pdMrap2. Similar
277 results were observed for wsMc2r (Galeomorph; Hoglin et al., 2020b) and srMc2r (Batoid;
278 Dores et al., 2018), and this enhancement in activation in the presence of an Mrap paralog has
279 been attributed to increased trafficking of the Mc2r ortholog from the ER to the plasma
280 membrane (Hoglin et al., 2020b). However, it appears that sensitivity to stimulation by
281 srACTH(1-24) is enhanced nearly two orders of magnitude when pdMc2r is co-expressed with
282 pdMrap1 as compared to pdMrap2. In addition, pdMc2r can be activated by either srACTH(1-
283 24) or srACTH(1-13)NH₂ at physiologically relevant concentrations of the ligand; although,

284 pdMc2r is more sensitive to stimulation by srACTH(1-24) than srACTH(1-13)NH₂ by nearly
285 three orders of magnitude when the receptor is co-expressed with pdMrap1. Both wsMc2r and
286 srMc2r can also be active by srACTH(1-13)NH₂ and, like pdMc2r, the other elasmobranch Mc2r
287 have a higher sensitivity for ACTH than for ACTH(1-13)NH₂ (Dores et al., 2018; Hoglin et al.,
288 2020b).

289 A comparison of the pharmacological properties of the elasmobranch Mc2r orthologs
290 with the Mc2r ortholog of the holocephalon, *C. milii* reveals some similarities among
291 cartilaginous fish Mc2r orthologs, and some features unique to the elephant shark (Figure 4). For
292 example, esMc2r can be activated by either ACTH or ACTH(1-13)NH₂; however, the two
293 ligands are equipotent (Barney et al., 2019). In addition, esMc2r is Mrap independent (Reinick et
294 al., 2012) and can move to the plasma membrane in the absence of interactions with either
295 esMrap1 or esMrap2 (Barney et al., 2019). Given these observations, a closer inspection of the
296 primary sequences of esMc2r and the elasmobranch Mc2rs was warranted.

297 The level of primary sequence conservation observed among the cartilaginous fish Mc2r
298 orthologs is typical for vertebrate Mc2r orthologs (Dores, 2016; Wong and Dores, 2022), and the
299 primary sequence identity/similarity of the four cartilaginous fish Mc2r orthologs was 58%.
300 Most of the domains of the four elasmobranch Mc2r orthologs have at least 65% primary
301 sequence identity/similarity with the exception of domains EC1, EC2, and TM5. The role of
302 domain EC1 in melanocortin receptors is unclear. For example, substitution at this domain did
303 not block the activation of human MC2R (Davis et al., 2022). However, domains EC2 and TM5
304 have been implicated in the activation and trafficking of human MC2R (Chen et al., 2007; Chung
305 et al., 2008; Davis et al., 2022). Of note, the EC2 domain of cartilaginous fish Mc2r orthologs is
306 small and not conserved. It would also appear that the TM5 domain of cartilaginous fish Mc2r

307 orthologs has a rather low primary sequence identity/similarity (i.e., 54%). However, when the
308 comparison is limited to just the elasmobranch orthologs, the primary sequence
309 identity/similarity is 88%. In addition, all three elasmobranch orthologs have a F residue in TM5
310 (i.e., wsMc2r – F²⁰²; srMc2r – F²¹⁶; pdMc2r – F²⁰²) that can be aligned. A F reside in human
311 MC2R at a corresponding position in TM5 has been implicated in the trafficking of the human
312 ortholog (Davis et al., 2022). Note that esMc2r has a L residue at this position. In addition, L¹⁸⁷
313 in esMc2r is in a region of TM5 that differs substantially from the corresponding region in the
314 elasmobranch Mc2r orthologs and could account for the differences in trafficking properties
315 between esMc2r (i.e., no requirement for an interaction with an Mrap) and wsMc2r, srMc2r, and
316 pdMc2r (a requirement for an interaction with an Mrap).

317 The trafficking of vertebrate Mc2r orthologs is dependent on interaction with the
318 transmembrane domain of the Mraps (Hinkle and Sebag, 2009; Webb and Clark, 2010). The
319 cartilaginous fish Mrap paralogs that have been detected demonstrate reasonably high sequence
320 identity/similarity in the N-terminal and transmembrane domains. In addition, the
321 transmembrane domain of cartilaginous fish Mraps have high primary sequence
322 identity/similarity with the transmembrane domain of osteichthyan Mrap orthologs (Dores et al.,
323 2022), which underscores the role of this domain in trafficking. The N-terminal domain of the
324 cartilaginous Mraps has an N-linked glycosylation site and the YEYY motif, usually found in
325 osteichthyan Mrap paralogs, but lacks the δDYδ (where δ represents hydrophobic amino acids)
326 motif found in osteichthyan Mrap1 orthologs that is required for the activation of osteichthyan
327 Mc2r orthologs following an ACTH binding event (Dores and Chapa, 2021; Hinkle and Sebag,
328 2009; Webb and Clark, 2010). Not surprisingly, co-expression of osteichthyan Mc2r orthologs

329 with cartilaginous fish Mrap1 orthologs does not result in activation of the osteichthyan receptors
330 (Dores et al., 2022; Shaughnessy et al., 2022).

331 Cartilaginous fish Mrap2 orthologs also lack the δ DY δ activation motif that is absent in
332 the osteichthyan Mrap2 paralogs (Rouault et al., 2017). However, the cartilaginous fish Mrap2
333 orthologs have a remarkably high level of primary sequence conservation in their C-terminal
334 domain. Similarly, osteichthyan vertebrate Mrap2 orthologs have considerable sequence
335 identity/similarity in their C-terminal domain (Liang et al., 2011), which suggests that the C-
336 terminal domain of Mrap2 is evolutionarily and functionally significant (Rouault et al., 2017).
337 For instance, Mrap2 is hypothesized to play a role in regulating energy metabolism through its
338 interactions with the Mc4r (Rouault et al., 2017), as has been demonstrated in zebrafish (*Danio*
339 *rerio*; Sebag et al., 2013).

340 **5. CONCLUSIONS**

341 Phylogenetically ancient fishes are excellent models for studying the functional evolution
342 of the HPA/I axis (Bouyoucos et al., 2021). As current research effort begins to describe a
343 general role for Mraps in the functioning of elasmobranch Mc2r, future research effort that tests
344 the relationship between elasmobranch Mc2r/Mrap structure and function is warranted. As the
345 present study has accomplished regarding elasmobranchs, it will also be informative to more
346 fully describe the function of the Mc2r/Mrap system in holocephalans, such as the small-eyed
347 rabbitfish (*Hydrolagus affinis*), for which the appropriate genomic resources exist (Fonseca et
348 al., 2020). Pharmacological studies of vertebrate Mc2rs have now (c. 2023) described functional
349 properties of Mc2r/Mrap1 in representative gnathostomes spanning all major vertebrate taxa
350 (Dores et al., 2022), except for the lobe-finned fishes (i.e., coelacanth and lungfishes). A ‘final
351 frontier’ for understanding the functional evolution of the HPA/I axis and, specifically, the

352 evolution of Mcr/Mrap interactions will be the agnathans (i.e., hagfishes and lampreys; Haitina et
353 al., 2007).

354 **ACKNOWLEDGEMENTS**

355 The authors thank Matt Thorstensen for guidance in transcriptome assembly and
356 annotation. The Bamfield Marine Sciences Centre sits within the traditional territory of the Huu-
357 ay-aht First Nations, the University of Manitoba campuses are located on the original lands of
358 the Anishinaabeg, Cree, Oji-Cree, Dakota, and Dene peoples, and on the homeland of the Métis
359 Nation, and the University of Denver campus sits within the traditional territories and ancestral
360 homelands of the Cheyenne, Arapaho, and Ute nations.

361 **FUNDING SOURCES**

362 Support for this research was provided by the Long Endowment (University of Denver;
363 143246; R.M.D.), and a National Science Foundation Postdoctoral Fellowship (DBI-2109626;
364 C.A.S.). I.A.B. and W.G.A. were supported by an NSERC/Manitoba Hydro Industrial Research
365 Chair grant and an NSERC Discovery grant (05328) awarded to W.G.A. Additional support
366 came from a Company of Biologists Travelling Fellowship (JEBTF2210863) awarded to I.A.B.

546

547 **FIGURE CAPTIONS**

548 **Fig. 1.** Alignments of cartilaginous fish melanocortin-2 receptor (Mc2r). The deduced amino
549 acids of Pacific spiny dogfish (*Squalus suckleyi*; pd) Mc2r, whale shark (*Rhincodon typus*; ws)
550 Mc2r (accession number XP_020380838), elephant shark (*Callorhinchus milii*; es) Mc2r
551 (FAA00704), and red stingray (*Hemitrygon akajei*; sr) Mc2r (LC108747) were aligned following
552 the protocol outlined in Dores et al. (1996). The labeling of domains within the GPCRs was done
553 using the DeepTMHMM tool (<https://dtu.biolib.com/DeepTMHMM>). Sequence identity was
554 determined using the program BLOSUM
555 (<https://www.ncbi.nlm.nih.gov/Class/FieldGuide/BLOSUM62.txt>). Positions with primary
556 sequence identity are highlighted in dark blue. Positions with primary sequence similarity are
557 highlighted in gray. Positions with primary identity/similarity for only the elasmobranch
558 sequences are highlighted in light green. Regions with percent sequence identity/similarity below
559 65% are highlighted in red. Abbreviations: transmembrane domain, TM; intracellular domain,
560 IC; extracellular domain, EC.

561 **Fig. 2.** Alignments of cartilaginous fish melanocortin-2 receptor accessory proteins, Mrap1 and
562 Mrap2 orthologs. The deduced amino acid sequences Pacific spiny dogfish (*Squalus suckleyi*;
563 pd) Mrap1, Mrap2, whale shark (*Rhincodon typus*; ws) Mrap1 (XP_020375601), Mrap2
564 (XP_020377388), and elephant shark (*Callorhinchus milii*; es) Mrap1 (XM_007903550.1), and
565 Mrap2 (XP_007906624.1) were aligned following the protocol outlined in Dores et al. (1996).
566 The labeling of domains within the Mraps was done using the DeepTMHMM tool
567 (<https://dtu.biolib.com/DeepTMHMM>). The sequence identity/sequence similarity was
568 determined using the program BLOSUM
569 (<https://www.ncbi.nlm.nih.gov/Class/FieldGuide/BLOSUM62.txt>). For the Mrap1 sequences

570 positions with primary sequence identity are highlighted in dark blue. Positions with primary
571 sequence similarity are highlighted in yellow. The sequence of the C-terminal domain of
572 esMrap1 is not complete. Residues in the C-terminal of pdMrap1 and wsMrap2 that are identical
573 are highlighted in bold black.

574 **Fig. 3.** Pharmacological analysis of Pacific spiny dogfish (*Squalus suckleyi*; pd) melanocortin-2
575 receptor (Mc2r) using a cAMP reporter gene assay. A) To determine whether pdMc2r can be
576 activated without co-expression with a Mc2r accessory protein (Mrap), pdMc2r was expressed
577 alone in Chinese hamster ovary (CHO) cells and the transfected cells were stimulated with red
578 stingray (*Hemitrygon akajei*; sr) adrenocorticotrophic hormone (ACTH). In parallel, pdMc2r was
579 co-expressed with either pdMrap1 or pdMrap2 and separately stimulated with srACTH(1-24). B)
580 To determine whether pdMc2r could be activated by srACTH(1-13)NH₂, pdMc2r was either
581 expressed alone, co-expressed with pdMrap1, or co-expressed with pdMrap2 and the respective
582 transfected CHO cells were stimulated with srACTH(1-13)NH₂. C) To determine whether
583 pdMc2r could be activated by other melanocyte-stimulating hormone (MSH)-related ligands,
584 CHO cells were transfected with pdMc2r and pdMrap1 and stimulated with either srACTH(1-
585 13)NH₂, β -MSH, γ -MSH, or δ -MSH. D) To test the efficacy of activation by other Mrap1
586 orthologs, pdMc2r was either co-expressed with pdMrap1, whale shark (*Rhincodon typus*; ws)
587 Mrap1, or bowfin (*Amia calva*; bf) Mrap1, and the transfected CHO cells were stimulated with
588 srACTH(1-24).

589 **Fig. 4.** Phylogeny of cartilaginous and bony fish melanocortin-2 receptor (Mc2r) and accessory
590 protein 1 (Mrap1) function. Mc2r is portrayed in gray as a seven transmembrane domain protein.
591 Mrap1 is portrayed in red by two peptides forming a homodimer in reverse orientation. Mrap1
592 drawn in contact with Mc2r denotes a dependence on Mrap1 for trafficking Mc2r to the plasma

593 membrane. Mrap1 drawn with a blue activation motif represents Mc2r that require Mrap1 for
594 activation by ACTH. Elasmobranch pro-opiomelanocortin is drawn including color-coded
595 adrenocorticotropic hormone (ACTH) and melanocyte-stimulating hormones. Melanocortin
596 ligands that have been shown to activate Mc2r in different taxa are drawn above Mc2r and
597 Mrap1. All species of cartilaginous fish that have been tested to date (c. 2023) are shown. Note
598 that whale shark Mc2r and red stingray Mc2r have not been tested with β -, γ -, or δ -MSH; dogfish
599 Mc2r was not activated by δ -MSH. References are denoted by superscript numbers: ¹Present
600 study; ²Reinick et al. 2012; ³Takahashi et al. 2016; ⁴Dores et al. 2018; ⁵Barney et al. 2019;

602

603 **TABLES**

604 **Table 1.** Half-maximal effective concentration (EC_{50}) and maximal response (V_{max}) values (means \pm standard error of the mean) and statistical
605 comparisons for reporter gene assays of Pacific spiny dogfish (*Squalus suckleyi*) melanocortin-2 receptor (Mc2r) co-expressed with accessory
606 proteins (Mraps). Statistical comparisons were made with extra-sum-of-squares F -tests. Abbreviations: adrenocorticotrophic hormone, ACTH;
607 bowfin, bf; Mc2r accessory protein 1, Mrap1; Mc2r accessory protein 2, Mrap2; melanocyte-stimulating hormone, MSH; Pacific spiny dogfish,
608 pd; stingray, sr; whale shark, ws
